Table of Contents

Track 01: Postgrowth **15**

Xin Li & Ting Yang, Urban Planning In The Post-Growth Era: Insights From World Bank Indicators . . . 16

Karin Holmstrand, Planning Beyond Growth: A Case Study Of Wellbeing-Oriented Planning In Wales And Cornwall . . . 50

Siwei Peng & Lu Yufei Na, Research On Rural Revitalization Planning From The Perspective Of Ecological Capitalization: Taking Nuanshui Township As An Example . 69

Wei Wei, From Howard's Garden City Movement To Zero-Carbon New Towns In The Postgrowth Era: The Case Of New Town Development In The Context Of Carbon Neutrality Of Shanghai . . . 83

Jinyi Wang, Shijie Sun & Xiaoyu Cong, The Internet As A Business Game Changer: A Study On Invisible Consumption Spaces In Nanjing Old City . . . 94

Federica Fiacco, Kezala Jere & Gianni Talamini, Can Fast Urban Growth Be Low-Carbon? Sub-Saharan Cities Towards New Territorial Strategies . . . 110

Qiang Yao, Research On Strategies For Enhancing Urban Spatial Resilience In Shanghai Based On The Connotations And Characteristics Of "Resilient Cities" . . . 128

Qiang Yao, Na An & Qingji Shen, Research On Strategies For Enhancing Urban Spatial Resilience In Shanghai Based On The Connotations And Characteristics Of "Resilient Cities" . . . 151

Giulia Luciani, Nature Is (Not) Democratic. Notes For A Community-Based Approach To "Natural Resources" . . . 174

Chiara Pisano, Adriana Galderisi & Giada Limongi, What Practices To Overcome The "Cultural Remoteness" Of Inner Peripheries? A Focus On Italian Case Studies . . . 186

Dongdong Chen, Micro-Intervention As A New Approach For Urban Regeneration In Metropolises: A Case Study In Beijing . . . 203

Track 02: Markets **216**

Alberto Bortolotti, Urban Policy Financialisation In Mega-Projects. The Case Of Milano Innovation District . . . 218

Alberto Bortolotti, Large-Scale Urban Development Projects As A Dilemma Affecting The Housing Crisis. The Case Of Milano Porta Romana . . . 235

Pauline Gali, Approaching Urban Renewal Through The Lens Of Urban Rent Theory . . 249

Emanuele Garda & Marta Rodeschini, Public-Private Dialogue In The Cultural Reuse Of Historical And Architectural Heritage: The Example Of The Carmine Monastery In Italy . . . 265

Track 03: Law **278**

Guangkun Zhou, Fallacies And Revisions: Evaluation Of Economic Benefits Of Development Rights Transfer And Density Bonus –17th And 69th Neighborhoods In Shanghai Hongkou Historic Conservation Districts Regeneration As The Case . . . 280

Zhiyu Pang & Yacheng Song, A Framework For Analysing Physical Form Outcomes Of Value Capture Paths Of Regeneration Projects In Residential Historic Areas . . . 305

Sara Benkirane, Navigating Complexity: Exploring Land Planning And Management Challenges In Morocco . . . 317

Li Wang, Can Transferable Development Rights Be Applied In The Chinese Context? — — A Comparative Study Between China And The United States . . . 336

Carolina Giaimo, Principles And Rules For Spatial Planning Governance And Government In Italy . . . 353

Ines Calor, Martinho Augusto & Mateus Magarotto, Land Readjustment In Braga Municipality - Looking Into The Future, Learning From The Past . . . 365

Linlin Dai, Changwei Feng, Jian Lin & Yun Liu, Multi-Planning Integration: Construction And Progress Of China's National Territory Spatial Planning System . . . 383

Chenli Qian, Yi Huang & Xiao Wu, A Comparative Study On Zoning Guidelines For Different Planning Types In China . . . 400

Zhao Zhao, Study On The Response Of Local Legislation To Coordinate The Interests Of Multiple Subjects In Urban Renewal From The Perspective Of Property Rights . . . 411

Track 04: Borders **428**

Yifan Cai, The Evolution Of Spatial Planning In The Border Area Between Shenzhen And Hong Kong, China . . . 430

Wenbo Xu & Shengbo Zhao, Administrative Boundary Effects Of Cross-Border Migration Of Manufacturing Enterprises: A Case Study From The Pearl River Delta In China 444

Yuxiao Ma, Jianzhong Huang, Qiao Zhang & Jing Deng, Coordinated Optimisation Of Multi-Level Rail Transit Network And Regional Spatial: International Contextual Differences And The Case Of Shanghai . . . 462

Rodrigo Vielmo Moura, Analysing Local Cross-Border Cooperation In Fragile Peripheral Areas In Northern Italy . . . 479

Lin Tian & Yao Cheng, Core-Periphery Industrial Linkages Of The Metropolitan Area From The Perspective Of Enterprise Linkages: The Case Of Three Cities Adjacent To Shanghai . . . 497

Yin Dou & Yihao Zhang, Study On The Characteristics Of Regional Intergovernmental Relationships Network, Based On The Analysis Of Planning Texts . . . 515

Andrés Martínez & Pere Fuertes, «The Franco-Spanish Mediterranean Strip. An Opportunity To Turn Applied Research Into Trans-Border Planning» . . . 523

Flore Guichot, Transit-Oriented Development In Asymmetrical Context: Learning From Cross-Border Paradoxes In The Great Geneva. . . . 539

Track 05: Mobility **561**

Kaichen Zhou & Lan Wang, Deciphering The Scaling Laws And Spatial Structure In Urban Micro-Mobility: Empirical Evidence From Bike-Sharing In Shanghai . . . 563

Jia Yi Liu & Yanbin Li, Exploring The Assessment And Strategies Of Street Inclusivity In Suzhou, China . . . 576

Arne Markuske, Urban Peripheries And The 15-Minute City . . . 594

Junting Lin, Zhiwei Li, Huali Zhang & Yu Zhuang, Form Follow Mobility: A Method To Identify Potential Urbanization Area In The Over-Rail Plane Under The Orientation Of Station-City Integration And Pedestrian Priority . . . 613

Ayesha Anwar & Hong Leng, Stepping Towards A Sustainable Future With Tod: Evaluating The Potential Of The Lahore City For A Regional Policy Reform . . . 627

Yunjing Wang & Yu Zhuang, Layout Patterns And Crowd Flows Of Commercial Space In High-Speed-Rail Station Complexes . . . 650

Sota Aida, Hirokazu Abe, Noriko Otsuka, Akira Takahashi & Kensuke Yasufuku, The Evaluation On Walkability In An Aging Society: The Case Of Senri New Town, Japan671

Giovanni Fusco, Meta Berghauser Pont, Valerio Cutini & Angelika Psenner, Guiding Principles For The 15-Minute City In Peripheral Areas: The Emc2 Model. . . . 690

Cédric Wehrle, Spaces Of Automobility: Diverging Trajectories Within The Liège-Aachen Diffuse City 708

Jan Bittner, Accessibility Of Local Amenities To Reduce Car Dependency: Obsolete Concept Or Change Yet To Come? The Prague Case. 719

Yunjing Wang & Yu Zhuang, Layout Patterns And Crowd Flows Of Commercial Space In High-Speed-Rail Station Complexes – Take Three Chinese High-Speed-Rail Station Complexes As Examples 732

Arzu Erturan & Bahar Aksel, Being A Child On A Car Free Island: Exploring Independent Mobility And Children's Perception In Büyükada-Istanbul 755

Hana Elattar, Arjama Mukherjee & Jörg Rainer Noennig, Stakeholders Of Participatory Planning: A Comparisonbetween Megacities And Cities In Europe 771

Michelangelo Fusi & Michela Tiboni, The Role Of Urban Planning In Perceived Accessibility To Public Transport 788

Miruna Draghia & Valentina Stan, Exploring Transformations In Sustainable Urban Mobility: Insights From Citywalk 2.0 Project And Beyond 804

Track 06: Governance **820**

Camilo Vladimir De Lima Amaral, Antonio Di Campli, Srivastava Rishabh & Elisa Verri, Conflictual Natures: The Role Of Architectural Imagination In Building Paths For Ecological Transition In The City Of Goias – Brasil 822

Yanxia Mu, Feng Luan & Jiahui Fan, Study On Governance Model Of Multi-Subject Participation In Rural Industry Development – A Case Study Of Shanghai Rural Revitalization Model Village 850

Kaixuan Lin, Jieming Zhu & Min Zhou, A Study On The Integrated Governance Model Of Development Zone And Town: Take South Jiangsu Region Of China As An Example 856

Pan Hu, Keyi Sun, Jialu Cheng & Yu Shi, Evaluation And Spatial Governance Strategies For Old Residential Areas' Renewal And Reconstruction In Urban Downtown Districts: A Case Study Of 70 Old Residential Areas In Changzhou ,China 882

Track 07: Environment And Climate **1042**

Zhenpeng Zhang, Fang Fang, Andrew Greenlee & Jiankun Lou, Urban Heat Mitigation Effect And Affordable Housing Greenery Injustice Measured By Green View Index (Gvi): A Case Study In Washington, D.c. 1044

Zhenpeng Zhang, Fang Fang, Andrew Greenlee & Jiankun Lou, Urban Heat Mitigation Effect And Affordable Housing Greenery Injustice Measured By Green View Index (Gvi): A Case Study In Washington, D.c. 1065

Ruonan Jia & Zuobin Wu, Research On Spatial Optimization Strategies Of Rural Settlements In The Loess Plateau From The Perspective Of Disaster Prevention And Reduction—A Case Study Of Gaoxigou Village,China 1086

Sadaf Pirouzi, Fabiana Fabri & Loïc Sauvee, A Gis-Based Method For Prioritising Brownfieldstransformation Into Multifunctional Urban Greeninfrastructure: The Case Of Rouen Metropolis 1097

Luciano Agustin Pana Tronca, Climate And Transport Planning: A Messy Junction . . . 1105

Lucrezia Gelichi, Chlorophyll City: Regenerative And Restorative Urban Planning For A Sustainable Future Through Extensive And Branching Reforestation Initiatives . . . 1117

Beatriz Condessa & Rita Nicolau, Comparative Analysis Of Net Land Take In Portugal's Metropolitan Areas 1130

Jiankun Lou, Lan Wang, Jiayu Li & Yinghui Jia, How Urban Morphology Affects Wind-Heat Environment: An Example In Beijing From Ancient Cities To Modern Cities . 1140

Karina Landman, Regenerative Public Space As Game-Changing Option For Thriving Communities 1154

Christian Großhauser, „Potential Of Hydrogen Production By Wastewater Treatment Plants (Wwtps) - Technologies, Benefits, Challenges And Limitations Using The Example Of The Wastewater Treatment Plant Straubing“ 1169

Caroline Andersen & Martin Schulwitz, Asssessing Regional Potentials For Green Hydrogen Infrastructure Planning In Germany 1187

Giulio Giovannoni, Removing Cultural Barriers To Climate Change Adaptation In Tuscany1202

Roberta Pistoni, The Increasing Entry Of The Energy Subject In Spatial Planning Policies: New Visions For Energy Landscapes 1216

Apostolos Lagarias, Re-Definition(S) Of The Role Of Central Business Districts Under The Effect Of Extreme Heat Conditions And Climate Change: Evidence From The Mediterranean Context 1232

Lucila Urda Peña, Javier Julio Malo De Molina & Emilio Ontiveros, Analysis And Evaluation Of The Quality Of Open Spaces And Green Zones In Periurban Landscapes, The Greengates As Strategic Nodes Of Green Infrastructures. 1249

Krystallia Kamvasinou & Lorenzo Stefano Iannizzotto, Rethinking The Waste Of Planetary Urbanization For Urban Challenges: Potential, Strategies And Governance In Terrain Vague Projects 1269

Giulia Giacche, Anais Mohamed, Jean-Noël Consalès & Romain Melot, An Analysis Of Current Integration Of Urban Agriculture And Domestic Garden Into Urban Planning: The Case Of Île-De-France Region 1286

Evangelia Athanassiou, Planning Tools And Building Regulations Towards Greening Densely-Built Greek Cities: Scales Of 'Urban Green Grabbing' 1300

Emanuele Garda, Greening The Void: Actions For The De-Sealing And Renaturalisation Of Soils In Brownfield Regeneration Processes 1311

Margarida Calmeiro, The City Of Tomorrow Is Already With Us 1323

Ani Tola (Panariti), Paul Louis Meunier, Teuta Peshkopia & Geri Bisha, Strategies To Mitigate The Urban Heat Island Effect In Mediterranean Promenades Of France, Italy, And Albania 1334

Vidhulekha Tiwari, Ram Avtar, Santanu Bandyopadhyay & Arnab Jana, Quantifying The Effects Of Spatial Determinants Of Cooking Fuel Choices In India 1357

Alan March, Anna Hurlimann, Sareh Moosavi & Judy Bush, The Built Environment Policy And Practice Context To Facilitate Climate Change Action - The Role For Planning And Design 1371

Giovanni Ottaviano & Luciano De Bonis, The Self-Government Approach To The Planning Of The Gran Sasso Laga Park 1388

Track 08: Public Space **1398**

Ifigeneia Kokkali, The Open Orchestra Project In The Public Spaces Of Athens: An Urban Utopia With Transformative Power? 1400

Brigida Proto, On Freedom, Public Space And Women's Experiences Of Prostitution. The (In)Visible World Of The Bois De Vincennes In Paris. 1415

Yu Zhang & Qiang Sheng, Study On Spatial Distribution Of Fresh Supermarket Based On Street View Data 1429

Christine Mady, Repurposing Abandoned Transport Infrastructure Towards Social Inclusion: The Case Of Baana, Helsinkibaana, Helsinki 1442

Francesca Dal Cin, Cristiana Valente Monteiro, Nawaf Al Mushayt, Maria Ines Franco, Maria Matos Silva & Sérgio Barreiros Proença, The Public Space Between Land And Sea. Quarteira's Case 1469

Pelin Işık & Christa Reicher, Playful Urbanism In Diyarbakır: Dynamics Of Power And Play In Public Space Design 1485

Aslı Ulubaş Hamurcu & Fatih Terzi, Exploring User Preferences And Place Attachment In Urban (Public) Spaces: A Case Study Of Kadıköy Historical City Centre, Istanbul, Türkiye 1505

Yiting Jiang, How Social Media Influences Rural Spatial Practice And Place Identity: A Case Study Of Fuling Village 1523

Yan Zhou, Xinjie Shen & Hong Jiang, Continuing Community Spirit: Study On The Public Space Of "Pu-Jing" Community In The Ancient City Of Quanzhou 1537

Qianhui He, The Impact Of Online Social Activities On Public Spaces In The Digital Era - A Case Study Of Guochuang Park In Nanjing 1551

Giulio Giovannoni, Enhancing Suburban Life With Victor Gruen 1569

Ina Macaione, Alessandro Raffa & Bianca Andaloro, Design Climate-Adaptive Urban Green Regeneration: Nbs Strategies For Future-Proof Streetscapes 1578

Karla Barrantes Chaves, Nida Cruz Zúñiga & Erick Centeno Mora, Urban Parks Through People's New Lens: Opportunities Behind Covid-19 For Public Spaces' Policies In Costa Rica. 1605

Catarina Todorovic Caldeira & Ljiljana Cavic, Heterotopic Pocket Spaces Through Intermittent Occupancy 1623

Gregorio Pezzoli & Emanuele Garda, Designing The 'Right To Mobility': A Holistic Analysis To Rethink The Public City And Fighting Heat Waves In Urban Areas . . 1633

Kundani Makakavhule & Kwazi Ngcobo, In The Name Of Peace, Sanitise! 1644

May Saeedi, Tom Jefferies & Sean Cullen, Analytical Study Of Hospitality Culture And Urban Identity And Its Impact On The Future Of Marine Tourism In Red Sea Coastal Port Cities: Case Study Of Jeddah Saudi Arabia. 1659

Track 09: Inclusion **1680**

Dongyu Zhang, Hong Leng & Ziqing Yuan, Research On The Psychological Health Impacts For Children In Urban Built Environments 1682

Mengyao Zhang & Pan Hu, Study On The Comparison Of Development Efficiency Between Inner And Outer Urban Circles And The Balanced Development Strategy Of Marginal Areas: Analysis Based On The County Scale Of Chongqing 1694

Zsófi Veres, Maintain Temporal Dynamics: What Temporal Characteristic Needs To Be Preserved Within The Historic Marketplaces Of Palermo To Encourage Sustained Interactions? 1716

Xiaohe Zhang & Haixiao Pan, Equity In Essential Services Accessibility Among The Elderly: A Comparison Of Community Resilience During And After The Covid-19 Pandemic 1735

Zihao Chen & Yifan Yu, Study On Youth Friendly Urban Renewal Strategies From An Inclusive Perspective 1755

Yinghui Jia, Lan Wang & Jiankun Lou, Dispersed Urban Spatial Structure And Increased Urban Greenness Could Reduce Intra-City Health Inequalities In England 1766

Yajun Wen & Yifan Yu, Exploring Colour Planning Strategies For Children's Outdoor Playgrounds In Communities: An Analysis Of Children's Diverse Preferences In Shanghai, China 1777

Xiaojie Shen, Enhancing Social Interaction In Urban Spaces: The Role Of Vertical Greening Systems In High-Density Areas 1785

Rebecca Staats, Can Care Help Conceptualise Place Futures? Exploring The Potential Of Care As An Analytical Framework For Understanding Place Qualities 1797

Xiaojie Shen, Enhancing Social Interaction In Urban Spaces: The Role Of Vertical Greening Systems In High-Density Areas 1814

Xiaojie Shen, Enhancing Social Interaction In Urban Spaces: The Role Of Vertical Greening Systems In High-Density Areas 1826

Krity Gera, Peter Hasdell, Gerhard Bruyns & Diego Sepulveda Carmona, Exploring New Methodological Approaches To Mapping Socio-Spatial Mobilities 1838

Yun Yu & Yi Huang, How Are Youth Living In Ageing Neighbourhoods? A Case Study In The Central District Of Shanghai 1855

Angelina Grelle, Embracing Diversity: Ararat's Role In Inclusive Urban Development And Migration In Rome 1867

Carla Baldissera, All-Round Walkability Condition To Primary School In Milan 1878

Ye Zhan & Yifna Yu, Innovative Tools For Building Child-Friendly Communities: The Development And Application Of Child-Friendly Neighbourhood (Cfn) Built Environment Audit Tools, Insights From Shanghai 1890

Track 10: Education **1912**

Yujiao Wang, Xiao Wang, Chenyi Cai & Peng Tang, Deep Learning-Driven Morphological Dataset And Analysis Methods For Chinese Campuses 1913

Xueling Wang, Dynamic Visual Assessment Of Urban Streetscapes: Hengshan Street In Shanghai As A Case Study 1932

Katarzyna Rędzińska, Geospatial Virtual Reality And Planning Ar Laboratory For Education In Spatial Planning 1955

Anna Kaczorowska, Emiliya Popova, Günther H. Filz & Dorota Kamrowska-Zaluska, Building Tomorrow's Urban Futures:Reflections On The "Builddigicraft" Project And The Pursuit Of High-Quality "Baukultur" In Higher Education. 1965

Aleksandra Stupar, Ivan Simic, Vladimir Mihajlov & Aleksandar Grujicic, Embracing The Green Curricula? The New European Bauhaus As A Driver Of Environmental Change In The University Education 1984

Track 11: Housing **1997**

Miao Hu, Housing Improvement In Historic Districts Oriented Towards The People's 'Sense Of Gain' A Case Of Shanghai, China 1998

Lin Zhou & Chen Chen, Towards An Inclusive And Developmental Housing Regime In Chinese Megacities? Evidence From The Implementation Of The Affordable Rental Housing Programme In Shanghai 2007

Jiwen Han & Li Bao, Dynamics, Mechanisms, And Benefits Of Micro-Renewal In Urban Residential Areas A Case Study Of The Xiaoxihu Block In Nanjing 2027

Track 01: Postgrowth

Postgrowth - Planning for other worlds and different development models

Chairs:

- Peter Ache, Faculteit der Managementwetenschappen (RU Nijmegen)
- Christelle Morel-Journel, Université Jean Monnet Saint-Etienne
- Yahya Shaker, Politecnico di Torino

Keywords: *risks, alternative visions, dreamscapes, development model, post-growth, post-growth economy, doughnut economy, common good economy*

The current IPCC report clarifies that the window for achieving the necessary transformation and transition towards a climate-resilient development closes. At the same time, doubts about the justice, sustainability and future viability of our growth model are growing in the IPCC and the current report 'Earth for All' for the Club of Rome (September 2022).

Attempts such as the Global Agenda 2030 or the EU's Green Deal to combine ecological and social aspects aim for appropriate economic growth while decoupling economic growth and environmental destruction.

The so-called post-growth economy, the doughnut economy, the common good economy and similar concepts attempt to show alternatives to the conventional growth model that can enrich urban and spatial planning.

We need climate-resilient development to achieve social sustainability goals and sustainable urban and regional development.

We welcome theoretical, methodological, and empirical contributions that address the following questions (and more):.

- How can ideas from the post-growth debate help to understand current crises and find answers?
- Which social and economic risks areassociated with this?

For this track, we invite – academic or practice - papers reflecting on related issues, mobilising facts and figures, bringing examples to the discussion, and tracing out potential future states of things from all corners of the globe.

In addition, we invite papers that start 'dreaming' again. It is not a dream that builds castles in the clouds, a leisurely and idle exercise of compensatory nature. The educated dreaming (docta spes, Ernst Bloch) is bound to "teach desire, to desire better, to desire more, and above all to desire differently" (Thompson, 1977, p. 330).

Such a dreamscape of desires may provide the disruptive force that breaks through cultured routines and establishes other worlds and different development models.

Urban planning in the post-growth era: insights from World Bank indicators

Abstract

In the current era of IPCC reports emphasising the urgency of shifting to a climate-resilient development paradigm, there is still a theoretical gap in understanding the interplay between economic growth and economic sustainability. This study proposes a new economic growth model based on an extensive analysis of 921 indicators from the World Bank database, which identifies two main categories of growth drivers: "economic model dynamics" accounting for 73.9% of influence, and "environmental forces for development" contributing the remaining 26.1% of influence. "Urban planning plays a key role in harnessing these drivers to adapt and optimise economic growth. We advocate an integrated approach that combines rigorous data analysis with visionary planning, aiming to promote an urban renaissance of sustainable and inclusive growth.

Keywords: urban planning, post-growth era , economic growth modelling, World Bank indicators, sustainable development

1 Introduction

On 20 March 2023, the United Nations Intergovernmental Panel on Climate Change (IPCC) released the Synthesis Report of the Sixth Assessment Report: Climate Change 2023, which highlights an era of urgency for a paradigm shift towards climate-resilient development. This is despite the notable attention the topic has received in contemporary policy discourse, particularly in relation to the use of large-scale data for strategic urban planning. However, there is still a theoretical gap in understanding the interplay between economic growth, climate change, social justice and economic sustainability .

Economic growth is the most intuitive embodiment of economic dynamics, since Adam Smith(Smith, 1776) has become the core topic of economic research; but from classical economics to modern economic growth theory, the source of wealth growth is attributed to the growth of specific material factors, although the theoretical construction paradigm is intuitively simple, but in the face of the economic growth process of different development backgrounds, a serious lack of theoretical explanation occurs. Although such a theoretical paradigm is intuitive and simple, it has serious theoretical inadequacies when facing the economic growth process in different development contexts. Therefore, this study will establish a theoretical framework for the growth-driving category of economic dynamics that is more in line with the objective reality of the world's development practice on the basis of the existing economic theory research, with the help of the complexity system science theory . Based on the research goal of analysing the category of economic growth drivers from the perspective of the complexity system, this study has the following three core questions: (1) What are the categories of economic growth drivers from the perspective of the complexity system? (2) What are the role characteristics of economic growth driver categories in generating economic dynamics? (3) What is the catalytic role of urban planning in driving these forces?

The development of economic theory reflects both the stage of development of human society and the progress of human cognitive ability. Although the theoretical system of modern economics is complex, it is still possible to find the theoretical starting point based on the research lineage. Based on Solow's growth model, the growth theory model Solow(Solow, 1956), which analyses the three elements of capital, population, and technology, has gradually been formed, data as well as information has become the ultimate development element(Wu Zhiqiang et al., 2021), and the element of economic dynamics identified based on the concepts of complexity systems science is a composite element, and the factor analysis method in the field of statistics is widely used in the study of various fields of the economy.

Throughout the research history of economic power elements, so far there is no unified conclusion, and with the development of science and technology, the connotation of power elements is also constantly expanding; to Solow model based on the creation of a series of economic growth model is also a continuous iterative process, but the Solow model is limited by the logic of economic development in the era of industrialisation, has obvious theoretical shortcomings; the economic system has a number of components and there is a complex relationship between the various parts of the role. The economic system has multiple components and complex interactions between them. Therefore, system dynamics cannot be

analysed according to simple causal logic and reductionism, and it is necessary to identify the operating characteristics of system dynamics from the perspective of system evolution and development on the basis of complex simulation of the dynamical environment.

The aim of this study is to use the most comprehensive and complete set of economic statistical indicators in the World Bank database as a data base, apply the theory of complexity systems science, and build a new economic growth model for extensive analysis with the help of advanced statistical techniques. This will unravel the complex network of impacts of these indicators on economic growth, identify the main growth drivers and account for the weight of impacts of each driver; construct a model of the role of urban planning that can be developed to exploit these drivers in order to adjust and optimise economic growth; and study the complex relationship between urban planning, economic growth and sustainability.

The rest of this study is organised as follows, with Part 2 examining the theoretical lineage and related work. Part 3 discusses the theoretical framework, extraction steps, and indicators for extracting the elements of economic dynamics under the complexity perspective. Part 4 describes the data sources involved. Part 5 experiments the results of extracting economic power elements. Part 6 discusses the economic dynamics characteristics around the economic dynamics elements. Finally, in Part 7, the interactions between urban planning and economic growth, climate change, social justice and economic sustainability are derived.

2 Literature review

2.1 Significance of the study

Since the birth of modern economics, economic theory has appeared in the vein of five analytical perspectives on economic dynamics: 1) the earliest two theoretical perspectives come from the founder of classical economic theory, Adam Smith, published in 1776 in the Wealth of Nations Adam Smith proposed that there are two ways to grow the economy, namely, "increase the amount of productive labor" and "improve labor efficiency"; 2) the third theoretical perspective focuses on the growth model and the role of innovation, the core issue was first raised by Malthus in 1798, but the theoretical breakthrough until Schumpeter in 1912. "and" improve the efficiency of labor "; 2) the third theoretical analysis focus on the role of the growth model and innovation, its core issues were first raised in 1798 by Malthus, but the theoretical breakthrough until 1912 Schumpeter's theory of economic development appeared in a breakthrough in the framework of neoclassical economics, Schumpeter founded a new economic development theory. On the basis of Schumpeter's creation of the concept of "disruptive innovation"; to the end of the 20th century, after more than 200 years of continuous discussion in the economics community to form a relatively consistent view that economic growth comes from three main lines, namely, productive resource inputs, resource efficiency improvements, and disruptive innovations and progress; (3) the fourth theoretical perspective has been widely accepted Until the beginning of the 21st century, with the 2002 Nobel Prize in Economics awarded three times to behavioural economists, the psychological motivation of people as the driving force of economic development has also gradually entered the field of mainstream economics research.

The cognition of the elements of economic power has gone through the process from physical resources, to abstract resources, and then to abstract elements, reflecting the deepening of the cognition of economic theories on the laws of economic operation, as well as the differences in the laws of economic operation of human societies at different stages of development.1) The era of agrarian civilization: classical economic theories take money, labor, and land as the core; 2) The era of industrial civilization: modern growth theories take capital , population, and technology as the core; 3) the era of information civilisation: the era of information civilisation is strengthening on data resources, and data as well as information has become the ultimate development element(Wu Zhiqiang et al., 2021); 4) the era of ecological civilisation: the theoretical system with complexity system science as the core The biggest difference between the theory and the theory of the previous eras lies in the cognitive difference of the methodology of scientific research, and it is a philosophical difference about the worldview from the reductionism to the philosophical conceptual shift of holism(Zhiqiang and Xin, 2016). The basic characteristics of complex systems are that they have many components, multiple relationships or interactions between components, and interactions that produce emergent phenomena. Therefore, the elements of economic dynamics identified based on the scientific concept of complexity systems are a kind of composite elements(Sterman, 2012); it can be classified into positive and negative feedback elements according to their role on the system(Meadows and Meadows, 2007); according to the way of participation in the dynamics of the physical dimension of the economic system can be divided into the role of providing material dynamics, the role of providing energy dynamics, and the role of providing information dynamics(Andersen *et al.*, 2012).

2.2 Research Basis

2.2.1 Economic models

Modern economic growth theory is based on the Solow model, whose theoretical logic is that there is a basic growth model for economic growth, and under the framework of the basic growth model, factor inputs will directly generate the power of economic growth. The Solow growth model is built around two equations: one is the production function equation; the other is the capital accumulation equation. 1) Production function equation: the Solow model divides inputs into capital K and labour L two categories, the total output is Y and specifies the exogenous variable1 as technology A (2) Capital accumulation equation: it considers that the change in capital stock per capita $\dot{k}$ is equal to the amount of investment per capita sy minus depreciation of capital per capita in the production process $(n + g + \delta)k$ where s is the savings rate, n is the population growth rate g is the rate of technological change、δ is the rate of depreciation. The production function equation is usually expressed in Cobb-Douglas form as:

$$Y = F(K, L, A) = A \cdot K^{\alpha} \cdot L^{1-\alpha} \quad (1)$$

The usual expression for the capital accumulation equation is:

$$\dot{k} = sy - (n + g + \delta)k \quad (2)$$

[1] An exogenous variable (exogenous variable) is a variable that is influenced by external factors in an economic mechanism and is not determined by factors internal to the economic system. It only acts as an explanatory variable in the model or system and therefore only affects other variables in the model and is not affected by other variables.

2.2.2 Dynamic environment

(1) Characteristics of the dynamics of development stages. Regarding the dynamic role of capital, population and technology, by analyzing economic data(Acemoglu *et al.*, 2001; Kaldor, 1961; Maddison, 2006) , found a number of typical development facts: 1) The basic growth model underpins the efficiency of factor inputs. The poorest countries have less than 5 per cent of the per capita income of the richest countries(Summers and Heston, 1991)， This illustrates the huge difference in factor benefits of labor. 2) Factor inputs are most beneficial in the early stages of the formation of the basic growth model. The growth of the four little dragons of Asia, the newly industrialized countries, came mainly from factor growth Young(Young, 1995) (3) Factor inputs are gradually driven together at the end of the formation of the basic growth model. Empirical studies have shown a gradual convergence of the role of resource accumulation in high-income countries, which may be caused by technology transfer(Coe and Helpman, 1993).4) Simple factor inputs do not lead to changes in economic growth rates. The ratio of the contribution of labor and capital to per capita generation is approximately constant at 7 to 3(Jones and Dietrich, 2013) .

(2) Characteristics of the dynamic role of natural endowments. Natural resource endowment has a relatively limited role in the formation of economic dynamics, which is specifically manifested in two two aspects: 1) natural resource scarcity on the economic dynamics of the limit gradually reduced. In Clark's analysis of the United Kingdom found that land rent in national income from 1750 accounted for 20% to 1850 accounted for 8%, and then only 0.1% in 2010(Clark, 2010) .2) Natural resources have a greater impact on lagging economies. According to Nordhaus' calculations, per capita income growth in the U.S. declines by roughly 0.3% per year due to natural resource constraints(Nordhaus, 1969) ; while the upper limit for natural resources as a proportion of all resources used for production is about 20-25 per cent for poor countries; the lower limit for rich countries is about 5 per cent(Gylfason and Zoega, 2010; Spengler and Joseph, 1962).

(3) The dynamic role of external resources. Three distinct views on foreign trade have also developed: 1) The first view began with the classical theory that foreign trade contributes to the formation of economic dynamics. This includes Ricardo (1847), Heckscher-Ohlin (1933), Baumol (1967), Chinnery (1969), and Yujiro Speedwater (2005); 2) The second view is that foreign trade has a completely opposite effect on the formation of economic dynamics in different economies. Including Harold Dormer model, Solow model, etc., it is argued that foreign trade pushes the accumulation of resources towards higher rates of return, and due to the role of trade resources are more inclined to accumulate in areas with higher rates of return through mobility.3) The third viewpoint is put forward by the New Structural Economics, advocated by Zhang Peigang, Lin Yifu, and others. While agreeing on the importance of differences endogenous to the structure of factor endowments, they emphasise that developing countries should seek a path of industrial upgrading and economic growth that is different from that of developed countries, and that should be rooted in comparative advantages endogenously determined by the structure of their factor endowments.

2.2.3 Ternary composition

Compared to the study of information elements in the field of economics, system science provides another way of thinking. The modern idea of systems science, recognised by the scientific community, was first put forward by the Austrian biologist Bertalanffy in 1932, and was gradually and widely accepted by the scientific community in the 1950s. Based on the idea of system science, Wiener, an American applied mathematician, proposed in his epoch-making work Cybernetics, published in 1948, that matter, energy and information are the three elements that constitute the real world.(Wiener, 1961) During the same period, Qian Xuesen, in his monograph "Engineering cybernetics" published in 1954 in the United States, also explicitly proposed that, as an open complex giant system, the core elements of the physical world can be reduced to three types of elements: matter, energy and information. This idea of system theory perceives the core elements of the physical world from a higher dimension . Therefore, the elements of the economic model in economic growth theory can be more clearly identified from the perspective of system theory and can effectively resolve the debate on the relationship and role of the elements among different theoretical lines in modern economic growth theory(Zhiqiang, 2016).

2.3 Technical means

Factor analysis is a statistical method designed to reveal underlying structures and relationships in observed data, and the formal method of factor analysis was first proposed by the British statistician Karl Pearson in 1901(PEARSON, 1905). Famous mathematical statisticians such as Harold Hotelling(Hotelling, 1933b)and Steffen S. Seifert(Seifert *et al.*, 2004) have made important contributions to the mathematical theory of factor analysis. Common factor models include principal component analysis (PCA) and constant factor analysis (CFA). The American mathematical statistician Hertling extended this method to the situation group of random vectors in 1933, and Stone (stone) extracted three new variables from 17 elements of variables reflecting national income and expenditures by using Principal Component Analysis in his 1947 study on the national economy.

3 Research methodology

3.1 Research ideas

In order to address the core question of "what are the driving categories of economic growth from the perspective of complex systems", combined with the study of existing theoretical foundations, this study puts forward the "complex system dynamics hypothesis". Complex system dynamics refers to "the economic system has the characteristics of complex system, the operating mechanism of system dynamics has a high degree of complexity, and the elements of system dynamics are composed of complex dynamics factors containing complex indicators" (Figure 1). 1) System dynamics has the characteristics of complexity. According to the assumption that the economic system has multiple components and the complexity of the role of the relationship between the various parts; therefore, the system dynamics can not be analysed in accordance with simple causal logic and reductionism, and it is necessary to identify the operating characteristics of the system dynamics from the point of view of the system's evolution and development on the basis of the complexity of the dynamics of the simulation of the environment. 2) The dynamics of the elements of the complex factor composition. According to the assumption that the dynamics of the economic system should be composed of

multiple dynamics factors; and the dynamics factors also have complexity characteristics represented by multiple economic indicators.

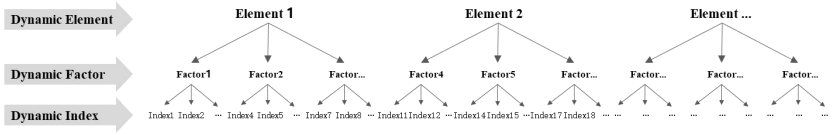

Figure 1 The way in which elements of the dynamics of the complexity economy are constituted (author's own drawing)

3.2 Data acquisition

Based on the theoretical ideas of complexity science and system dynamics, this study constructs multi-indicator constitutive factors as well as merges functional characteristic linkage factors to ultimately form the economic dynamics elements of physical dimensions that contain the characteristics of complex system dynamics. A total of 1,440 indicators in the World Bank database belong to 20 categories, including health, public sector, agriculture and rural development, urban development, infrastructure, external debt, gender, aid efficiency, education, climate change, environment, social protection and labour force, private sector, science and technology, economy and growth, energy and minerals, poverty, trade, financial sector and social development. Able to reflect the full range of socio-economic development.

3.3 Methods of analysis

Principal component analysis transforms random vectors whose components are correlated into random components whose components are uncorrelated with each other with the help of an orthogonal transformation, which geometrically manifests itself by transforming the original coordinate system into a new orthogonal coordinate system pointing in the n orthogonal directions with the widest dispersion of the sample points, and then downscaling the multidimensional variables. A few new variables with larger variance then combine the main information contained in the original multiple variables and also contain their own special meaning. The mathematical model is:

1) A coordinate transformation of the original variables gives:

$$F_1 = U_{11}X_1 + U_{12}X_2 + \cdots + U_{1n}X_n \quad (3)$$

$$F_2 = U_{21}X_1 + U_{22}X_2 + \cdots + U_{2n}X_n \quad (4)$$

$$\cdots$$

$$F_n = U_{n1}X_1 + U_{n2}X_2 + \cdots + U_{nn}X_n \quad (5)$$

2) Extract the principal components, which can be obtained:

$z_1$is called the first principal component, which satisfies the condition:

$$u_1'u_1 = 1 \quad (6)$$

$$\mathrm{var}(z_1) = \max \mathrm{var}(u'x') \quad (7)$$

$z_2$is called the second principal component, which satisfies the condition:

$$\mathrm{cov}(z_1, z_2) = 0 \quad (8)$$

$$u_2'u_2 = 1 \quad (9)$$

$$\mathrm{var}(z_2) = \max \mathrm{var}(u''x'') \quad (10)$$

The conditions satisfied by the remaining principal components are analogised one at a time.

4 Research data

4.1 Data sources

Data base construction. The steps include two processes, namely "data collection" and "data cleaning".1) Data collection. The world is regarded as a typical country in this study, and all 1440 indicators of the world in the World Bank's database and the statistical data from 1990 to 2018 are used as the data base of this study to ensure the comprehensiveness of the elements extracted.2) Data cleaning. The data were cleaned through data quality checking, and it was found that the number of indicators with valid data among the 1440 indicators was 921, that is, 519 indicators had the problem of missing data. Therefore, what was finally included in the subsequent data analysis was the 1990-2018 data of a total of 921 indicators with the world as the statistical calibre, which served as the data base for the study (Table 1).

Table 1 Classification of indicators in the World Bank database

Classification of economic indicators in the World Bank database[2]					
form	Number of indicators	Number of valid indicators	form	Number of indicators	Number of valid indicators
well-being	258	208	matrix	111	96
public sector	86	48	Social protection and the labour force	156	58
Agriculture and rural development	41	38	Private sector	161	123
urban development	18	16	science and technology	13	12
infrastructure	42	31	Economy and growth	239	132
external debt	69	18	Energy and minerals	48	42
distinguishing between the sexes	150	90	needy families	28	6
Aid effectiveness	58	52	(commercial) trade	119	110
educate	156	111	financial sector	64	35
climate change	74	65	social development	12	12

4.2 Data processing

4.2.1 Dynamic environment simulation

Steps of dynamic environment simulation through the economic development environment simulation to discover the economic dynamic environment with 871 indicators with complex system characteristics. The specific process is as follows: 1) System clustering. The data of 921 indicators with the world as the statistical calibre are subjected to "systematic

[2] World Bank database 873 indicators individually classified into a single category, 513 indicators classified into 2 or more categories, 52 indicators with no category, 2 indicators with incorrect information.

cluster analysis", forming 9 indicator clusters. 2) Cluster analysis. The first cluster group consists of 871 indicators, including economic development indicators, which constitutes the indicator system of this study to simulate the real economic dynamics environment. 3) Cluster exclusion. The 8 groups of clusters other than the first clusters mainly describe the indicators for the results of economic development, so they are not included in the power simulation environment.

From the simulation results (Fig. 2), 871 indicators related to economic development cover all 20 data categories, which fully demonstrates that: 1) the selection of indicators for simulating the environment of economic dynamics should not be limited to the 132 indicators in the category of "Economy and Growth", but should fully recognise that the formation of economic dynamics has a more complex and comprehensive mechanism; 2) the coverage of 20 data categories also indicates that this study has a more comprehensive feedback on economic dynamics based on the data, which has the basis for further research to address the Solow residual problem and endogenous growth. It should be fully recognised that the formation of economic dynamics has a more complex and comprehensive mechanism; 2) the coverage of 20 categories of data indicators also shows that this study has a more comprehensive feedback on economic dynamics on the basis of the data, and has the basis for solving the Solow residual problem and the endogenous growth problem in further research.

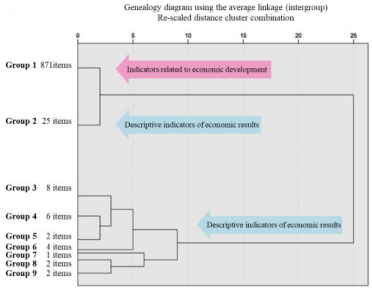

Figure 2 Tree diagram of the 921 indicators systematically clustered (author's own drawing)

4.2.2 Dynamic factor analysis

Through the economic power factor analysis, 19 economic power factors were obtained from 871 power environment simulation indicators, including 6 significant effect factors and 13 general effect factors. The steps of power factor analysis include two processes, namely "classification of effect characteristics" and "analysis of factor components". 1) Classification of effect characteristics. Bivariate correlation analysis is conducted between the 871 indicators generated by the dynamic environment simulation and the GDP, and three categories are obtained. Category 1 is "significant effect indicators", a total of 580 items, with significant positive correlation or significant inverse correlation with GDP; Category 2 is "double-edged effect indicators", a total of 265 items, which have insignificant correlation with GDP; Category 3 is unable to judge. (2) Factor component analysis. The main factors of "significant effect indicators" and "double-edged effect indicators" were extracted by the second factor analysis. From 580 items of "significant effect indicators", 6 significant effect principal factors were obtained, and according to the cumulative order of variance, F01 to F06 were used as the factor

codes (F is the first letter of the factor); from 265 items of "double-edged effect indicators", 13 double-edged effect principal factors were obtained, and according to the cumulative order of variance, F01 to F06 were used as the factor codes (F is the first letter of the factor). 13 double-edged effect main factors were obtained from the 265 "double-edged effect indicators", and C01 to C13 were used as the factor codes according to the cumulative order of variance (C is the initial letter of the common factor).

Table 2 Significant effect principal factor analysis

one-way factor analysis			quadratic factor analysis			factor nomenclature
Factor number	variance accumulation	Number of high-load indicators	Factor number	variance accumulation	Number of high-load indicators

5 Experimental results

5.1 Extraction results of dynamic elements

On the basis of 19 power factors, 9 economic power factors were found (Figure 3). The extraction of the power factors consists of two steps, namely: "factor independence calibration" and "power factor extraction".1) Factor independence calibration. Since the 19 power factors come from two groups of significant effect indicators and double-edged effect indicators, there may be correlation or covariance between the two groups of power factors, in order to test the independence of the factors, this study adopts two methods of "bivariate correlation analysis" and "multiple linear regression" to check. In order to test the independence of the factors, this study used "bivariate correlation analysis" and "multiple linear regression" to carry out calibration. It was found that there were significant correlation among 15 power factors and significant covariance among 14 power factors, so it was necessary to carry out "factor analysis" again for the 19 power factors. 2) Extraction of power factors. Nine independent dynamic factors were obtained, and the cumulative contribution rate of variance reached 84.42%. According to the cumulative order of variance, D1 to D9 were used as the codes of the factors (D is the initial letter of the dynamic element).

The naming of power factors and power elements follows three principles: 1) the principle of representativeness, i.e. the absolute value of the indicator loading coefficient representing the information contained in the main factor should be greater than 0.7, to reduce the interference of low loading indicators on the naming of the main factor. 2) the principle of comprehensiveness, i.e. a comprehensive analysis of the representative indicators selected through the principle of representativeness, and the naming based on the conclusions of theoretical basic research in the first section of this chapter. 3) the principle of directionality. That is, the naming of factors and elements seeks to highlight the direction of the role of power factors and elements in the formation of economic power, reflecting the power mechanism of power factors and elements. Through the classification of role characteristics as well as factor component analysis and naming principles, 6 significant effect factors, 13 double-edged effect factors and 9 economic power elements formed by the merger of power factors are finally identified.

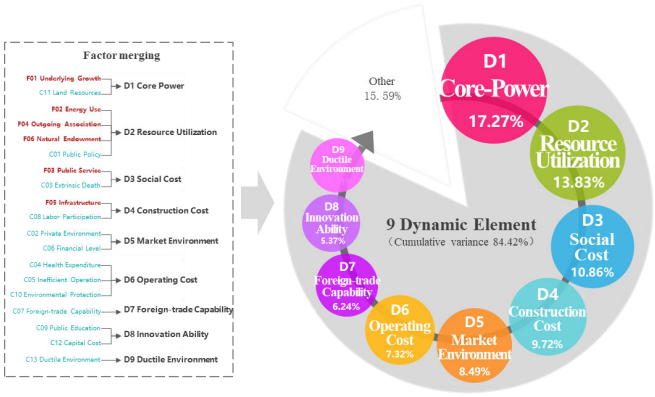

Figure 3 Compositional characteristics of the nine economic drivers (author's own drawing)

5.2 Characterisation of complex systems of dynamical elements

The nine economic drivers contain a total of 222 indicators covering 20 classifications in the World Bank database.The number of 222 indicators is very unevenly distributed among the 19 economic drivers (Figure 4). They can be broadly categorised into three levels according to the number of indicators: 1) over-indicator clustering: containing 73 indicators and only 1 factor (i.e. F01 Basic Growth); 2) more indicator clustering: containing 11 to 19 indicators and 5 factors; and 3) less indicator clustering: containing 3 to 8 indicators and 13 factors.

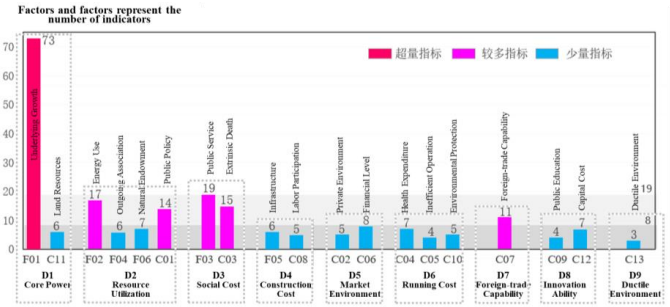

Figure 4 Complexity characteristics of the elements and factors containing indicators (authors' own drawing)

5.3 Characterisation of the economic dynamics of the power factor

(1) Factor D1: "Economic model". Reflects the dominant power model of economic growth; it consists of two power factors, F01 Basic Growth and C11 Land Resources. (1) F01 basic growth factor, as the main source of economic model contains 8 categories of economic indicators: education, population, land, labour, external resources, science and technology, health and infrastructure. (2) The "economic model" factor includes C11 land resources, which indicates that land resources are an important part of the "economic model", but its driving force plays a double-edged role.

(2) Factor D2: "Resource use". Reflects the use of various types of external resources; it consists of four driving factors: F02 energy use, F04 outward linkages, F06 natural endowments and C01 public policy. (1) Of the 17 statistical indicators represented by F02 Energy Use, 10 can be categorised as energy, including carbon dioxide emissions from electricity and heat production (as a percentage of total fuel combustion), etc.; one can be categorised as information technology, for fixed-line telephone subscriptions; one can be categorised as capital, for insurance and financial services (as a percentage of imports of business services); and five can be categorised as population, including insurance and financial services (as a percentage of imports of business services). indicators can be categorised as population, including children with HIV (0-14 years old), etc. (2) Two of the seven statistical indicators represented by the F04 outward linkages can be classified as capital, namely the unit value index of exports (2000=100) and the unit value index of imports (2000=100); three indicators can be classified as health, including domestic general government health expenditure (% of current health expenditure), etc.; and one indicator can be classified as information technology (IT). (2000=100); 1 indicator can be classified under the category of Information Technology (IT), which is Information and Communication Technology (ICT) product exports (% of total product exports); and 1 indicator can be classified under the category of Population, which is Low birth weight babies (% of births). (3) Four of the six statistical indicators represented by F06 Natural Endowments can be categorised as Energy, including Oil Rent (as a percentage of GDP), etc.; and two indicators can be categorised as Capital, Manufacturing Imports (as a percentage of Merchandise Imports) and International Tourism, Expenditures (as a percentage of Total Imports). (4) Eleven of the 14 statistical indicators represented by C01 Public Policy can be categorised as Public Policy, including the International Development Association (IDA) Resource Allocation Index (1=low, 6=high); and three can be categorised as Education, including Net Enrolment Ratio of First Year Students (as a percentage of the official school-age population), among others.

(3) Element D3: "Social costs". Reflects the maintenance costs of social development. It consists of two driving factors, F03 Public Services and C03 Accidental Deaths. (1) 19 of the 20 statistical indicators represented by F03 Public Services can be categorised as public services, including the rural population using safely managed drinking water services (% of rural population), etc.; and one indicator can be categorised as safety and health, which is the lifetime risk of maternal mortality (rates vary by country). (2) All 14 statistical indicators represented by C03 Unintentional deaths can be categorised as safety and health, including the female suicide mortality rate (per 100,000 female population).

(4) Factor D4: "Construction costs". Reflecting the costs of forming the basis for economic development, it consists of two driving factors, F05 Infrastructure and C08 Labour Participation. (1) Three of the six statistical indicators represented by F05 Infrastructure can be classified as infrastructure, including fixed broadband subscriptions), etc.; and three can be classified as safety and health, including antiretroviral treatment coverage (the proportion of people living with HIV)), etc. (2) All five statistical indicators represented by C08 Labour Participation can be classified under the Social Stability category, including Armed Forces Personnel, Total), etc.

(5) Factor D5: "Market environment". Reflects the role of marketisation level. It consists of two driving factors: C02 Private Environment and C06 Financial Level. (1) Six of the seven statistical indicators represented by C02 Private Environment can be categorised as Doing Business, including procedures for setting up warehouses (number), etc.; and one indicator can be categorised as Public Policy, with a rating of the National Policy and Institutions Assessment (CPIA) on Human Resource Development (1=low to 6=high). (2) All nine statistical indicators represented by the C06 financial level can be classified under the financial level category, including ownership of accounts in financial institutions or mobile money service providers (% of the population over 15 years of age that is female), etc.

(6) Element D6: "Running costs". Reflects the cost of normal operation of society. It consists of three driving factors: C04 Health Expenditure, C05 Inefficient Operation, and C10 Environmental Protection. (1) Of the seven statistical indicators represented by C04 Health Expenditure, six can be categorised as medical services, including the proportion of the population whose out-of-pocket medical expenditure results in the poverty line being below US$1.90 (2011 PPP) (%), etc.; and one can be categorised as education, which is the number of R&D researchers (per million people). (2) Of the 4 statistical indicators represented by C05 Inefficient Business, 2 indicators can be classified as Business Environment, including Enterprises Failing to File Full Tax Returns on Sales Revenues (% of Enterprises), etc.; 1 indicator can be classified as Health Care Services, as Causes of Death by Injury (% of total); and 1 indicator can be classified as Land, as Area of Rural Land (sq. km.). (3) One of the five statistical indicators represented by C10 Environmental protection can be categorised as environmental protection, as social contributions (% of income); one indicator can be categorised as education, as the percentage of male and female trained secondary school teachers (%); and three indicators can be categorised as land, including the area of terrestrial protected areas (% of the total area of land), etc.

(7) Factor D7: "Foreign trade capacity". Reflects the role of resources external to the economy. It consists of a power factor, C07 Foreign Trade Capacity. 10 of the 13 statistical indicators represented by C07 Foreign Trade Capacity can be categorised as International Trade, including Net Official Flows from United Nations Agencies, UNECE (in current US dollars), etc.; and 3 indicators can be categorised as Health and Safety, including Secure Internet Servers (per million people), etc.

(8) Element D8: "Innovative capacity". Reflects the conditions underlying the formation of innovation. It consists of two driving factors, C09 Public Education and C12 Capital Costs. (1) Four of the five statistical indicators represented by C09 Public Education can be categorised as education, including current expenditure on secondary education (% of total public institutional expenditure on secondary education), etc.; and one indicator can be categorised as money, which is commercial bank borrowers (per 100,000 adults). (2) All 2 statistical indicators represented by C12 cost of funds can be categorised as monetary, including interest payments (% of expenses) and interest payments (% of income).

(9) Element D9: "Resilient environment". Reflects an economy's confidence in its

development resilience. Consists of C13 Resilient Environment, a motivating factor.

One of the three statistical indicators represented by the C13 resilience environment is in the category of health services, the basic health services coverage index; two indicators can be classified as energy, including net energy imports (as a percentage of energy use)) and alternative and nuclear energy (as a percentage of total energy use), among others.

6 Analytical discussion

6.1 Validation of element extraction results

Through the extraction of economic drivers, this study obtained 19 economic drivers factors for 9 economic drivers and constituent elements. Following Owen et al. (2009) and others, the empirical model was tested using the regressions of the direct determinants of economic growth (Figure 5). The standard growth equation developed in this study is as follows:

$$GDP_i = \beta_1 \times D_1 + \cdots + \beta_i \times D_i + \varepsilon_i \quad (11)$$

where the dependent variableGDP is the gross domestic product (GDP).D_1 toD_i are the nine driving factors extracted from the factor analysis, theβ_1 toβ_i are the linear regression coefficients. The calculation results show that the regression test is superior, with a significance of 0.000, indicating that the nine economic power factors have good factor independence; the adjusted regression R-square of the model is 0.999, indicating that the model's explanatory ability is close to perfect.

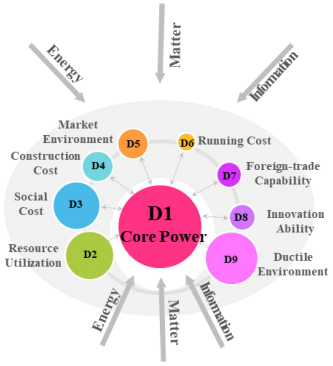

Figure 5 Theoretical modelling of the core dynamical environment hypothesis (authors' own drawing)

6.2 The dominant role of economic models in economic growth

(1) Contributing about 3/4 of world economic growth. Analysing the characteristics of the contribution of the nine power elements to economic growth, it can be found that: (1) world economic growth is mainly determined by the contribution of the economic power elements of the D1 economic model, which contributes 73.9 per cent to world economic growth, i.e., basically determines the formation of three-quarters of the world's economic growth; and (2)

the contribution of the remaining eight economic power elements to world economic growth is 26.1 per cent in the aggregate (Figure 6).

(2) Explaining about 2/5 of the economic operating mechanism. Standardised coefficients are applied to the world economic growth equation to analyse the degree of explanation of the 9 types of economic power elements to the overall model . It can be found that: 1) the D1 economic model has the highest degree of explanation of the model among the 9 economic dynamics elements, at 37.8%; 2) the degree of explanation of the model of the D1 economic model is 2.5 times to 25 times higher than that of the other 8 elements, and the range of the degree of explanation of the rest of the 8 economic dynamics elements is 1.5%-14.7%, with the total degree of explanation of the 8 elements being 62.2%.

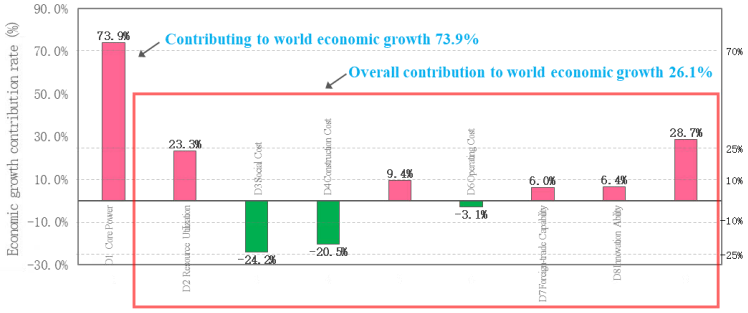

Figure 6 Contribution of the nine economic drivers to world economic growth (authors' own drawing)

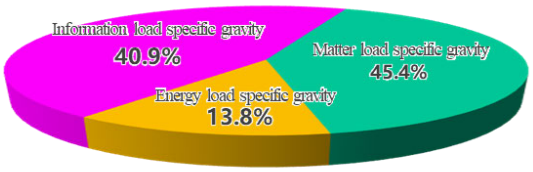
6.3 "Complexity" and "triadic character" of the economic model

The economic model element is an alternative upgrade to the Solow model. According to the world economic growth equation established in this study, the D1 economic model element contributes 73.9 per cent to economic growth and explains 37.8 per cent of the overall model; compared with the Solow model, which explains only 36.4 per cent-60.0 per cent of economic growth, the D1 economic model element has more theoretical and practical value. This is because the Solow model reduces the economic power mechanism to simple inputs of capital and labour under the total factor production constant, and this oversimplified treatment fully reflects the lack of knowledge of the complex economic growth mechanism, which is the product of a simple reductionist cognitive philosophy that lacks the concept of complexity system research.

(1) The complexity characteristics embodied in the eight types of indicators. In this section, we will analyse the driving mechanism of factor D1 from the perspective of complexity system theory, which consists of two factors, F01 basic growth and C11 land resources, and the 79 indicators belonging to it include eight new categories, namely, education, population, land, labour force, external resources, science and technology, health and sanitation, and infrastructure. The number of indicators of the eight categories is unevenly distributed, and can be classified into two levels according to the sum of the absolute values of the indicator loading coefficients. According to the absolute value of the indicator loading coefficients, the indicators

can be divided into two levels. (1) High-loading category: includes two categories, education and population, with loadings above 22 per cent; (2) Medium-loading category: includes two categories, labour force and external resources, with loadings between 10 and 20 per cent; and (3) Low-loading category: includes four categories, namely, land, science and technology, health and infrastructure, with loadings below 7 per cent.

(2) The triadic composition of matter-energy-information of the economic model. System science believes that matter, energy and information are the three elements of the physical world, which are composed of the ternary nature, and the same 79 indicators constituting the D1 elements can also be divided according to the three elements. The result of the division is that the total number of 32 indicators of information element, the absolute value of load 27.6; the total number of 36 indicators of material element, the absolute value of load 30.6; the total number of 11 indicators of energy element, the absolute value of load 9.3. By comparing the load value of material, information and energy elements, we get the proportion of the world's triad of nature, i.e., the proportion of matter: information: energy is 45.4%: 40.9%: 13.8%. From the ratio, we can get the following two conclusions: 1) matter and information are the main elements in the world's triad; 2) the weight of matter and information is close to each other, and slightly higher than that of information.



sFigure 7: Sum and proportion of world material information energy loads in years (author's own drawing)

6.4 Spatial relevance of land for economic modelling

The complementary role of land resources in the economic model. According to the composition of the D1 factor, the following correlation can be observed between the "F01 Basic growth" factor and the "C11 Land resources" factor.

(1) "F01 basic growth" is the driving core of the D1 factor. The F01 basic growth factor constituting the D1 factor consists of 73 indicators, with an absolute cumulative load factor of 91.9 per cent; while the C11 land resources factor consists of 6 indicators, with an absolute cumulative load factor of only 8.1 per cent.

(2) "C11 land resources" is a necessary component of the D1 factor. Firstly, the F01 basic growth factor and the C11 land resources factor are significantly positively correlated; secondly, the F01 basic growth factor and the C11 land resources factor are significantly covariant in the multiple linear regression; and lastly, the calculation result of the factor analysis method also combines the F01 basic growth factor and the C11 land resources factor into the D1 factor.

6.5 The "double-edged effect" of elements of the dynamic environment

The nine driving forces have a double-edged effect, and there is a wide variation in the direction of contribution of the nine driving forces to world economic growth, with six driving forces playing a positive role and three driving forces playing a negative role. Therefore, we set up economic growth equations with the nine driving forces as independent variables for each of the 84 case countries, and examine the direction of the contribution of the nine driving forces to economic growth. It can be found that there is a double-edged power effect of all nine factors.

7 Conclusion

7.1 Conclusions of the study

This study focuses on the discovery of categories of drivers of economic growth, understanding the interplay between economic growth, climate change, social justice and economic sustainability through the economic dynamics characterising the drivers, the key role of urban planning in harnessing these drivers in order to adjust and optimise the way in which economic growth occurs, quantifying the relative weights of these drivers and outlining intervention strategies.

7.2 Significance of the study

It provides ideas and research directions for the theoretical ideas of complexity science and system dynamics to study economic growth, explores the categories of economic growth drivers under big data analysis, discovers the interactive links between urban planning and the indicator system of economic growth drivers, and provides theoretical support for policy formulation and urban planning strategies.

7.3 Research limitations

The limitations of this study are as follows: (1) the limitations of data, some indicators in the World Bank database are more difficult to count, and the missing data cause 519 invalid indicators; (2) the limitations of time, although the current World Bank statistics began in 1960, the vast majority of indicators only began to be counted in 1990, which led to the time range of the data in this study from 1990 to 2018 years; (3) the complexity of the research field, as this study involves a number of fields such as urban planning, economic growth, sustainable development, etc., the study is complex and somewhat imperfect.

karin.holmstrand@vti.se

VTI, Box 55685, 102 15 Stockholm

Karin Holmstrand is a PhD student at the Swedish National Road and Transport Research Institute (VTI) and affiliated to the Department of Urban Planning and Environment at KTH. Her research concerns post-growth planning in a Swedish local and regional context.

Abstract

Although an increasing research interest in the combination of post-growth ideas and planning, questions concerning the implementation of post-growth models and initiatives in real-world planning system remain underexplored.

This study explores two post-growth initiatives, the *doughnut economics* in Cornwall and the *wellbeing economy* in Wales, by the means of a qualitative content analysis of documents related to land-use and transport planning.

The study shows that there are traces of post-growth ideas in strategic documents and plans, as well as indications that these ideas also are forming concrete policies, although some documents are still clearly growth oriented. To analyse the implications of post-growth ideas in planning practice and culture, a deeper empirical analysis is needed.

Keywords: Post-growth; case studies; wellbeing; doughnut economics; planning

1. Introduction

Planning beyond growth, or post-growth planning, has been promoted as both a response to the ongoing sustainability crises (Barry, 2019), and as an adaptation strategy to a future where growth cannot be taken for granted (Crownshaw et al., 2019). Two post-growth initiatives that have been launched are *Doughnut Economy* – a model displaying the socio-ecologically safe space in which society can operate, defined by an 'ecological ceiling' and a 'social floor' (Raworth, 2017) – and *Wellbeing Economy* – an initiative aiming to reorientate the economy towards wellbeing rather than towards growth (Fioramonti et al., 2022).

Although an increasing interest in the combination of post-growth ideas and planning, questions concerning the implementation of post-growth models in real-world planning system remain underexplored (Lange et al., 2021). To date, most of these studies apply the post-growth concept either as an entry point for criticising the mainstream (e.g. Berglund & Julier, 2020; Næss et al., 2020; Xue, 2015, 2018; Xue et al., 2017), or as a tool for imagining alternative futures (e.g. Hagbert et al., 2021; Ruiz-Alejos & Prats, 2022; Svenfelt et al., 2019). Although this focus is motivated by the low number of real-world examples of post-growth planning implemented at scale, there is a growing number of post-growth initiatives from which lessons already can be learned. This study explores places where two of these initiatives are in use, Cornwall and Wales. Cornwall adopted the Doughnut economics model in 2020. Together with the public participatory process called 'The Cornwall We Want', the localised doughnut model formed the basis of the new local plan which was published the same year. Wales became in 2015 the first country to translate the principles of the UN Sustainable Development Goals into law in the Well-being of Future Generations (Wales) Act. Furthermore, Wales joined in 2018 the Wellbeing Economy Governments, which is a network of national governments with the ambition to rethink their economy to become more wellbeing-oriented and to replace GDP as a main goal for national economics.

This study constitutes an initial step of a larger case study which aims to understand how the application of post-growth initiatives in Cornwall and Wales has influenced the strategies, processes, practices, and culture of land-use planning and transport planning at each place. The aim of this initial study is to explore the influence of post-growth ideas on documents related to land-use planning and transport planning in the two places.

The study is structured in the following way. The next chapter (Chapter 2) offers a summary of previous research on post-growth planning. Chapter 3 presents a brief description of the study design. Thereafter, the findings from the document analysis are provided (Chapter 4). The final chapters (Chapter 5 and 6) discuss the document analysis in the light of previous literature and reflect on research questions of relevance for the planned in-depth study of post-growth initiatives in Cornwall and Wales.

2. Previous research on post-growth planning

2.1 Framing 'post-growth'

As a notion, 'post-growth' refers to an alternative to the current growth-oriented paradigm (Barry, 2019; Lange et al., 2021; Savini et al., 2022). Whereas the more widely used term 'degrowth' emphasise the need to downscaling the economy, post-growth has a more agnostic aura in relation to growth – the main point of criticism being the unreflective assumptions about growth and the growth-dependence of our economies (Barry, 2019), as well as the misleading use of quantitative indicators like GDP to measure progress (Savini et al., 2022). Since these are important points in degrowth research too, it is clear that there are many overlaps between degrowth and post-growth.

Thus, post-growth is about rethinking the way land, production systems, consumption patterns, and work are organised (Lange et al., 2021). It is motivated by the failure of growth-dependent economies to sufficiently decouple economic growth from material and energy use – partly due to rebound effects – with its corresponding ecological deterioration (Hickel & Kallis, 2020). In a time of accelerating ecological crises and in a world where millions of people still do not have opportunity to meet their basic needs (United Nations Department of Economic and Social Affairs, 2023), the necessity of societal transformations towards socioecological sustainability are imperative.

Growth-critical ideas are not new per se, but they have until recently been relatively absent from the field of planning research, which, according to Lange et al. is surprising given planning's interest for issues linked to land scarcity and spatial justice. However, as Barry explains, planning has in many places become a type of institutionalised pro-growth activity, although this does not have to be the case. Instead, he suggests that:

'Hence, planning in the 21st century should be oriented around the following: how to design urban forms that produce high levels of human wellbeing and flourishing while using less energy and resources and where growth is a potential by-product, not the goal of planning.' (Barry, 2019, p.8).

Similarly, Savini et al. (2022) argue that a post-growth logic 'needs to provide a realistic but utopian vision of urban prosperity, based on the principles of post-growth urbanisation' and that it 'also needs to be backed up by a matching toolkit of planning instruments' (Savini et al., 2022, p.5).

While post-growth predominantly has a positive connotation in the literature, the term is in some studies applied synonymously to 'end of growth'. This does not refer to a deliberate transition to a planning system more apt to provide human and planetary wellbeing, but rather to an unplanned societal change provoked by the collapse of economy when the growth-era comes to its inevitable end (Crownshaw et al., 2019). It is therefore important to make clear that a post-growth future may imply substantially different things depending on whether the transitions happen in a planned manner or if it occurs beyond our control. I will here use the term 'post-growth planning' as a deliberate action to plan differently, both in terms of the planning process and the planning outcome.

2.2 Real-world studies of post-growth planning

The emerging combination of post-growth ideas and planning has given rise to a variety of case studies with different focus. In the rest of the section, I will exemplify the most prevalent themes encountered in the post-growth planning literature: post-growth as a starting point for criticising the mainstream planning; post-growth as imaginaries of alternative futures; post-

growth as experimentation with the alternative; and post-growth as specific initiatives, including doughnut economics and wellbeing economy.

2.2.1 Post-growth planning as a critique of the mainstream

Several critical urban and regional studies have motivated the need of post-growth planning by analysing the effects of eco-modernist development in cities and regions. Taking Helsinki as a case, Berglund & Julier (2020) illustrate how urban development projects, branded as 'sustainable urban development', imply commodification of public land and exploitation of valuable natural environments. In Copenhagen, another city with explicit 'green' ambitions, Xue (2015, 2018) criticises the fact that no absolute decoupling between housing growth and environmental degradation, and between economic growth and traffic growth, is achieved, as the urban development is characterised by both suburbanisation and densification. Similarly, while Copenhagen can report progresses in active travelling and public transport, road traffic has also increased (*ibid.*). Using Oslo as an example, Næss et al. (2020) problematise the rationale of urban growth by exemplifying how urban sprawl constrains accessibility and risks exploitation of agricultural land, whereas densification drives exploitation of central green areas with potential negative effects on climate adaptation, public health, and wellbeing. Turning to the national level, Xue et al. (2017) compares the opportunities for Norway to meet the Paris Agreement with either an eco-modernist agenda or a degrowth agenda, with the conclusion that an eco-modernization is unlikely to be sufficient. Fauré et al. (2016) contributes with a similar insight regarding the Swedish performance on the topic of sustainability. This study applies the doughnut model to identify the socio-ecologically safe space for Sweden as a starting point for a backcasting scenario. Since Sweden performs relatively well at the parameters of social sustainability but is far from meeting the ecological targets, the study concludes that a radical decrease in ecological impact while not jeopardising the social parameters should be of key importance.

Targeting the regional level, Rydin (2022) emphasises the importance of differentiating between post-growth planning in high-growth areas contra low-growth areas, since the prerequisites for such places look fundamentally different. While post-growth planning in high-growth areas may imply minimising resource-use, re-using the existing built stock, and favouring affordable housing, post-growth planning in low-growth areas may instead include strategies for stimulating a sufficient level of endogenous growth to maintain provision of local services. Two important factors for this purpose are land ownership and collaboration with local stakeholders (Rydin, 2022). In other non-growing areas, growth stimulating measures are not expected to have effect, and then post-growth strategies may be motivated primarily for adaptation reasons as a response to a negative population trend. Dax & Fischer (2018) describe an Austrian area with these characteristics. The case study shed light on the uneven regional development that is visible in many parts of Europe, where peripheries are generated and reinforced at different scales due to changes in migration patterns and demographics. Post-growth as a planning strategy can in this context be to prioritise how to improve well-being and local attractiveness, targeting the existing population rather than external actors and capital. Durrant et al. (2023) challenge the predominant rationale of planning based on a polycentric structure consisting of growth-nodes and peripheries, arguing that this form of planning is detrimental for communities located in the periphery. Two suggested priorities for post-growth regional planning are to promote sufficient economic activity to support local livelihood in all parts of the region, and to ensure that new

infrastructure investments replace less sustainable mobility practice rather than being an addition to it.

2.2.2 Post-growth as an imaginary of something else

Research on post-growth planning has also explored attitudes to post-growth ideas among planning professionals. Hagbert et al. (2021) investigate how planning beyond growth is perceived by various planning actors, including professional planners, other civil servants, politicians, and grassroots. The study shows that 'growth' sometimes is perceived as a prerequisite and sometimes an obstacle for sustainability. It also attests a widespread concern that a shift to post-growth policies potentially could increase social risks and revolutionary instabilities. Ruiz-Alejos & Prats (2022) address the role of local planning practices in implementing degrowth ideas, using Södertälje as a case. The study reveals that many municipal planners experienced that they do not have the mandate to integrate overarching social and environmental goals in planning and that opportunities for more visionary scenarios are lacking. Instead, these planners perceived their role as facilitating a planning process driven by private actors and developers. However, if only they had the mandate to be more proactive, the believed municipal planning to have the potential to be an enabler of change. Svenfelt et al. (2019) develop four scenarios of a future beyond GDP growth in order to initiate a discussion about post-growth futures with planners in three Swedish municipalities. All scenarios are the result of a multi-target backcasting approach based on the fulfilment of four sustainability targets, including climate, land-use, participation, and resource security. The discussions reveal a general interest to discuss various imaginaries of the future more freely, although the opinions on what a desirable future naturally diverge between the participants. Svenfelt et al. conclude that backcasting scenarios are a useful method to explore alternative development paths than what is normally predicted.

2.2.3 Post-growth planning as experimentation with alternative futures

Apart from the abovementioned exploratory approaches to post-growth imaginaries, research on post-growth planning includes case studies on places with experience of experimenting with post-growth ideas in the planning process. Crowley et al. (2021) use examples from Spain and Portugal in which citizen participation in urban planning has contributed to stopping transformations of public land into private. In this example, both the planning process, i.e. promoting a more participatory approach, and the planning outcome, i.e. avoiding commodification of public land, are in line with post-growth ideals. However, as Crowley et al. observes, this type of bottom-up governance may be less effective in considering global impacts of local planning than it is to safeguard the interests of the local community. An alliance between urban planning and post-growth advocators can arguably contribute to balancing the interests of the local contra the global. Ferreira & von Schönfeld (2020) present a manifesto for such an alliance, pointing out commodification of commons as one central discussion point for the planning actors. This is motivated by its role as fuelling economic growth, on the one hand, and driving environmental degradation and social exploitation, on the other. In this way, post-growth-inspired planning is associated with simultaneous concerns for social welfare and ecological qualities. Ferreira & von Schönfeld (2020) observe, however, that post-growth strategies are no 'silver bullet' and that its success depends on how it is designed, what the underlying motives are, and the geographical context of the place. This is illustrated by real-world experiences in which various degrees of success have been reported (Ferreira & von Schönfeld, 2020).

2.2.4 Post-growth planning as initiatives: doughnut and wellbeing

There are also case studies on places which have committed to specific post-growth initiatives, including doughnut economics and wellbeing economy. Since studies on Cornwall and Wales are of greatest relevance for this literature review, these will constitute the main part. However, some comparative studies have also been included.

Addressing the Cornwall Doughnut, Turner et al. (2020). highlights the importance of downscaling and localising the model and, when possible, linking its socioecological domains to concrete policy goals and targets This downscaling process is not without challenges (R. A. Turner & Wills, 2022). One challenge is to handle interest conflicts related to scale, time and different domains, another is to alter the growth-imperative in which local institutions typically are embedded and the path dependencies caused by vested interests. Still another question concerns whether the ecological ceiling targets should be technocratically or democratically determined (*ibid*.). The case of the Cornwall doughnut is further analysed by Honeybun et al. (2024), who argue that both statutory bodies – in particular, the Council Leadership Board – and the participation of local stakeholders have been crucial to approach sustainability issues more holistically and to gain legitimacy in the local community. Hjelmskog et al. (2023) make a similar conclusion when analysing the case of Glasgow from a doughnut economics framework. The study concludes that the model is a good tool to get a shared understanding for connections, co-benefits and trade-offs between different domains but observes that it remains unclear whether it also leads to transformative action in practice.

Khmara & Kronenberg (2023) compares four different degrowth initiatives or phenomena in order to assess their respective transformative potential, including Copenhagen as a C40 city, Totnes as a Transition Town, Amsterdam as a doughnut city, and Detroit as a shrinking city. The cases were compared with respect to urban policy, land rent, housing policy and transport, and the study concludes that the Amsterdam doughnut performed best in relation to post-growth ideals. However, Khmara & Kronenberg remark that Amsterdam adopted the doughnut model as a result of also being a C40 city and that many post-growth-oriented policies were in place before the doughnut came into place.

Several studies have taken an interest in the implementation of the Wellbeing of Future Generations (Wales) Act. Having analysed key factors for the realisation of the Wellbeing Act, Messham & Sheard (2020) conclude that the engagement of individual politicians and the political context of the time played a particularly decisive role for the Wellbeing Act to be put in place. McKinlay (2019) compares the Welsh Wellbeing Act with New Zealand's wellbeing budget, pointing out the Welsh focus on localism as one key attribute to delivering wellbeing in practice, and the presence of a 'Future Generations Commissioner', as another. The role as commissioner, whose task is to review the policymaking of all public bodies with potential implications on the wellbeing goals, does not exist in New Zealand. Howe & Nutbeam (2023) presents an interview with the first person at this position in Wales, Sophie Howe. Key learnings that Howe mentions from her time as Commissioner include the importance of legislating the wellbeing mechanism, of supporting civil servants in transforming their working methods, and of finding appropriate indicators reflecting progress towards each goal without getting obsessed by them.

Other studies have analysed the implementation of the Wellbeing Act at national and local scale. Jones (2019) reminds that every scale at which the Wellbeing Act is implemented has

implications on the degree to which wellbeing and justice can be achieved. A challenge at national level is to ensure that city problems are not prioritised at the expense of rural problems, whereas a local scale challenge is that local priorities may reinforce unequal development of the progress of specific wellbeing goals. Nesom & MacKillop (2021) explores the experiences of local actors from implementing the Wellbeing Act and observe that there is a tension between the national and the local level. Local implementation is stressed, but many local actors express a lack of clarity regarding the national government's expectations and the local government's room for action. Nesom & MacKillop argue that support, resourcing, and time for local implementation are needed, as well as trust-building between different levels of governance. On a similar note, Carter & MacKillop (2023) identify a lack of both guidance and resources as the main obstacles for local implementation. There is a clear national-local divide in attitude to the Wellbeing Act, where the local governments are less positive than the national government. Although the Wellbeing Act theoretically is based on ideas of spatial justice given its place-based approach and emphasis on participatory processes, the delivery of spatial justice in practice proves to be insufficient (Carter & MacKillop, 2023).

3. Study design

The study was carried out focusing on two places in which post-growth models or initiatives have been applied, namely Wales and Cornwall, and consisted of a qualitative content analysis of a selection of planning documents. Each document was read with three questions in mind:

- What is the prime focus and main motivation of the suggested planning approaches of the text?
- Are post-growth ideals visible in the text, and if so, in what way?
- How is urban growth and economic growth framed in the text?

For Cornwall, the local plan and the transport plan were selected for analysis. In addition to these, the annual review of the local plan was included. For Wales, the national plan, the planning policy, and the transport strategy were chosen.

The choice of documents was motivated by its relevance for reflecting the land-use planning and the transport planning at the respective places. Since the analysis aims to explore the influence of post-growth initiatives on planning documents in Cornwall and Wales, only documents published after implementation of the doughnut model and the wellbeing economy were considered. In the case of Cornwall, the annual review was also included since it offered an additional perspective on the progress of the realisation of the plan.

4. Document analysis

4.1 Cornwall

4.1.1 Cornwall Local Plan 2020-2050

Cornwall Local Plan 2020-2050 has the slogan 'Together we can' (Cornwall and Isles of Scilly Leadership Board, 2023a). This emphasis on togetherness and the positive view of

future as an opportunity for a better way of living captures well the tone in plan. The plan begins with two quotes about the long-term concerns of the environment and health, and children's right, poverty, and equal chance. Together, the initial quotes and the positive slogan underline what is considered to be central challenges of today, while pointing out the approach that the Council suggests suitable to tackle them. While emphasising the multiple challenges that society is facing, positive experiences, including community kindness and successful implementation of local solutions, are also mentioned. The need for 'a new era' is emphasised.

The local plan expresses its ambition to build a greener, cleaner, fairer, and more inclusive Cornwall. This ambition is translated into six aims: a creative net zero economy; sustainable food, land, and sea; thriving places with decent, affordable homes; equality, education, and entrepreneurship; healthy, safe, and resilient communities; and digital revolution for sustainable living. The aims are said to be based on the present conditions, on the one hand, and on citizen visions collected through the campaign 'The Cornwall we want' in 2020, on the other. In the survey of the campaign, the main themes raised by citizens concerned a greener economy less reliant on tourism; a Cornwall with more space for nature; a fairer, more inclusive, and compassionate Cornwall, and more local decision-making regarding local issues. Worth mentioning is that a resident survey from 2023 presented affordable housing as the single most important issue for Cornish citizens (Cornwall Council, 2023).

The wellbeing goals of the doughnut run like a red thread throughout the local plan. Not only is the Cornwall doughnut explicitly demonstrated, but its ideals are also implicitly present in the six aims. Both local and global ecological concerns have a prominent role: the local considerations are mainly linked to natural environment and biodiversity, whereas the global considerations are mostly represented by the net zero 2030 climate goal. Regarding social concerns, aspects of health and wellbeing, inclusion, equal chances, safety, and 'the local' are all represented in various forms throughout the aims. The focus of the plan is the needs of the present population and of the future generations to come, rather than boosting Cornwall's attractivity in terms of external skills and capital. Despite visionary formulations like 'Cornwall's creative economy is growing' (p. 27) and 'Cornwall is well positioned to develop new businesses and support existing businesses to grow' (p.28), very little is written about economic growth explicitly, and when it is addressed, it is never framed as the ultimate goal of society nor as the most central means to achieve socioecological wellbeing. In this sense, the spirit of the doughnut is clearly present in the plan: it places the social needs and the ecological limitations at its heart instead of focusing on promoting economic growth. When discussing how the plan will be delivered, the need of partnership is emphasised, since 'state institutions, however powerful, cannot achieve this vision on their own' (p.33). Partnership with the residents is pointed out as the most crucial one, although an enhanced partnership with the UK government is also mentioned.

The Cornwall Plan Annual Review 2023 displays how the proceedings of implementing the plan are going to date, based on the 22 identified socioecological areas of the Cornwall Doughnut (Cornwall and Isles of Scilly Leadership Board, 2023). In 2023, the majority of the areas were classified as off-target. The five domains that were considered to be 'significantly off-target' were the areas of air quality, biodiversity, renewables, food provision, and housing. Based on this, three short-term actions were decided as priority for the work in 2024: further actions to tackle the increased cost-of-living, e.g. supporting housing security and preventing

people's debt; encouraging organisations to do a 'pledge for nature' to promote biodiversity actions; and to make the websites related to the local plan more accessible to children and young residents. Being a prioritised area also the previous year, actions for tackling the cost-of-living have been handled in a temporary work group, which, according to the review, has now become permanent. Hence, the review offers both a snapshot of the work towards goal-fulfilment and some concrete actions and processes that are on-going (*ibid.*).

Figure 1: Social foundation of the Cornwall Doughnut (R. Turner et al., 2020).

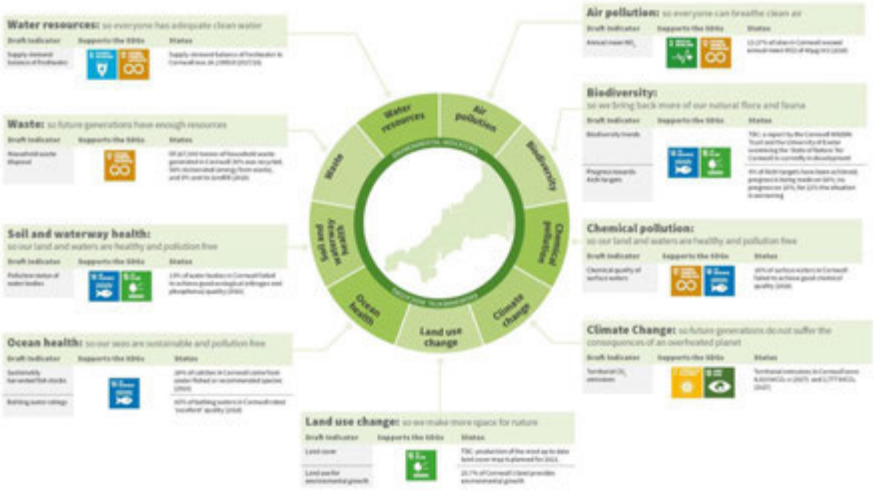

Figure 2: Ecological ceiling of the Cornwall Doughnut (R. Turner et al., 2020).

4.1.2 Cornwall Transport Plan

Turning to the Cornwall Transport Plan (Cornwall Council, 2021), the emphasis on climate change and wellbeing continues to be central. The vision declares that:

'Transport in Cornwall will be excellent and carbon neutral. Our transport system will connect people, communities, businesses and services in a way that enhances quality of life, is reliable, efficient, safe, healthy and inclusive. People will choose to travel in ways that will have low impact upon the environment and other people.' (p.2)

Key themes in the transport plan include a modal shift to more active travel and public transport, reduced speed limits for safer and more liveable streets, and replacing the predict-and-provide logic with a decide-and-provide approach. Like in the local plan, the need of 'a new era' is stressed. Furthermore, the importance of connecting the Transport Plan to other strategies and policy frameworks – locally as well as regionally and nationally – is explicitly stated.

Six transport goals are presented, including tackling climate change, supporting economic prosperity, respecting and enhancing the environment, supporting healthy active lifestyles and wellbeing, supporting community and road safety, and supporting equality of opportunity. Every goal is concretised in suggested policies and discussed in relation to the goal of carbon neutrality in 2030. In this sense, climate concerns appear to have a superior position to the other goals. There is also a red thread throughout the proposed solutions for the goals, with more active travel, reduced speeds, and less car use as examples of actions for several goals included those related to climate, health and safety. The co-benefits of more sustainable transport modes are hence emphasised. The plan also includes policies for land-use planning, as exemplified by suggestions to design for enhanced accessibility, connectivity, and inclusion, and to incorporate nature recovery in planning. For environmental reasons, the management of existing infrastructure is prioritised over construction of new roads. In order to achieve carbon neutrality in 2030, the plan highlights that travel behaviour ought to change – electrification is not sufficient. A backcasting scenario based on net zero 2030 suggests an increase in public transport travels by 50 percent and a replacement of 50 percent of the car trips to active transport modes by 2030, and a 15 percent shift to electric vehicles by 2025.

Although economic prosperity is one of the six transport goals, economic growth is not a central theme in the transport plan, which is mentioned as a difference from previous plans:

'During 2011-2019, scheme delivery focussed heavily on investment that supported economic and employment growth […] now is the right time to change course and steer investments towards road safety, locally important and green travel modes' (p.17).

Discussing economic prosperity, formulations like 'local and national transport connectivity is an important ingredient in a healthy economy' (p.12), 'lack of transport provision and poor connectivity can constrain the growth of our economy' (p. 33), and 'investment in sustainable transport connectivity is key in facilitating economic growth' (p.33) illustrate that economic growth is still considered. However, the economic concern is never discussed without emphasising the preferability of a modal shift and to sustainable freight options for climate and wellbeing related reasons. An example of this is: 'prioritising walking, cycling and public transport connectivity to and within our towns will help to support economic growth' (p.46). Other solutions to support economic prosperity are linked to improvements in connectivity,

accessibility and reliability. In this vein, economic growth is described as a potential outcome of an environment-friendly transport system rather than as the main means and end.

The transport plan is suggested to be delivered by a combination of specialised plans, working in partnerships, policy steering, bidding and lobbying. The biggest risks for failing to meet the net zero 2030 target are identified as changed national policies or local priorities, and lack of funding, of community or political support, of behaviour change and of devolved power to disincentivise car use.

4.2 Wales

4.2.1 Future Wales

Future Wales is Wales's spatial development plan which presents where long-term strategic development will be located, and which guides the planning decisions at all levels (Welsh Government, 2021a). The aim of the plan is to 'addressing key national priorities through the planning system, including sustaining and developing a vibrant economy, achieving decarbonisation and climate resilience, developing strong eco-systems and improving the health and well-being of our communities' (p. 6). The introductory chapters take their starting point in the global challenges of climate change, biodiversity loss and the recent experience of the Covid-19 pandemic and highlights how a good planning practice can offer multiple co-benefits. An example provided concerns co-locating housing, workplaces, services, and amenities, which is not only beneficial for the climate but also for social, health, economic and cultural reasons.

'Sustainable growth' is a central concept since the plan is considered to have 'an important role in driving sustainable growth and combating climate change' (p.10). Two out of eleven outcomes that the plan aims to achieve concern growth explicitly: firstly, 'a Wales where people live in distinctive regions that tackle health and socio-economic inequalities through sustainable growth' (p.54), and secondly, 'a Wales where people live and work in towns and cities which are a focus and a springboard for sustainable growth' (p.55). In the former, growth appears as a means for achieving better health and equality, whereas in the latter, growth seems to be a goal in itself. The three last outcomes concern climate and environment explicitly.

Throughout the plan, growth is depicted as something unequivocally desirable, as exemplified in formulations like 'development plans will have a forward thinking positive attitude towards enabling economic development, investment and innovation […] promoting a culture of innovation, social partnership, entrepreneurialism and skills-development' (p.55). Formulations like this give rather associations to a conventional neoliberal approach to planning than to a radically different sustainability-oriented approach.

According to the plan, cities and large towns are prioritised as areas for strategic development, since 'growing urban areas across Wales will create concentrations of jobs, services, and amenities' (p.60). The choice is motivated by the ambition to avoid sprawl, while using existing infrastructure and promoting sustainable travel modes. Furthermore, it claims that 'areas outside the urban centres will benefit directly from the strength of our large towns and cities, though improved connectivity and additional investment in new homes, jobs

and services' (p.55). While not explicitly stated, this appears to be how the plan defines 'sustainable growth': the promotion of growth nodes whose benefits are expected to 'trickle down' to the periphery. This focus on urban growth is not further problematised from a spatial justice perspective. Another aspect which is not extensively discussed is how the new modes of remote working affect the structure of labour markets and commuting patterns.

In sum, the wellbeing goals are present throughout the plan, and it is clear that urban and economic growth are not the only important aspects. Still, the whole document relies on a growth agenda, and the other aspects seem to be secondary to the growth imperative.

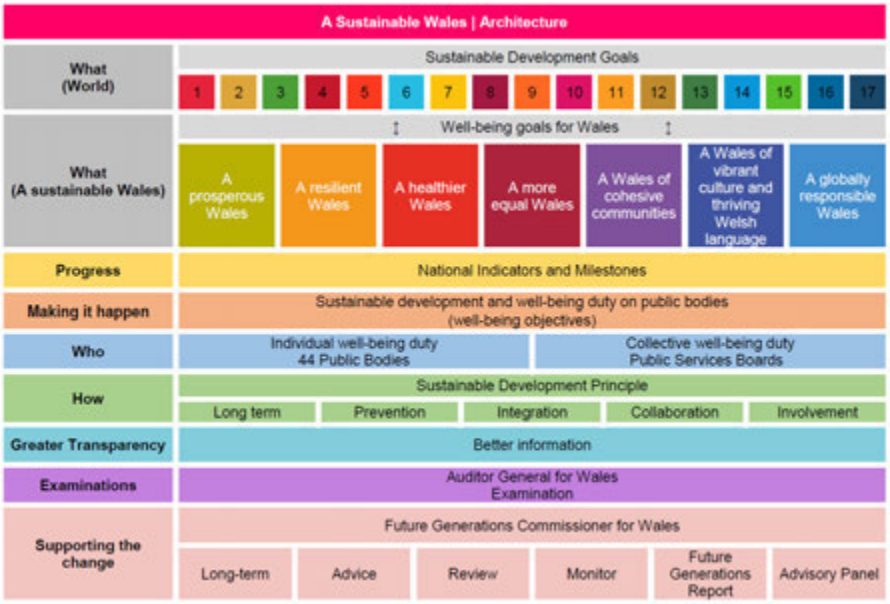

Figure 3: Wellbeing goals in Wales (Welsh Government, 2019).

4.2.2 Planning Policy Wales (PPW)

Planning Policy Wales (PPW) establishes the key principles of the planning system in Wales (Welsh Government, 2024). Although it is not part of the development plan, it is an important document in the process of planning decision-making. While pointing out 'sustainable places and wellbeing' as the goal, PPW identifies 'sustainable placemaking' as the process for goal-fulfilment. This is described as a process that involves all planning actors who need to collaborate to 'achieve sustainable economic benefits for all in line with the well-being goals' (p.17). Five outcomes of sustainable placemaking are presented with references to the social, environmental, economic and cultural wellbeing goals. The first outcome, 'growing economy in a sustainable manner', clearly reflect the idea of sustainable growth from the national plan.

In contrast to the national plan, PPW offers a definition of economic development: 'the development of land and buildings that generate sustainable long-term prosperity, jobs and

incomes.' (p. 86). Economic development is mentioned as one of the central ambitions of PPW, but the emphasis is put on increasing economic diversification and ensuring employment rather than on sole economic growth.

Many references are made to the Well-being Act and both the well-being goals and the well-being 'ways of working' – including collaboration, integration, long-term, prevention, and involvement – are present throughout PPW. However, there is no clarification on how conflicting interests linked to different well-being goals should be balanced against each other. As an example, one of the outcomes of sustainable placemaking is 'maximising environmental protection', but it is not clear how this outcome should be combined with other outcomes. Arguably, the maximal environmental protection would be to avoid exploitation overall – but since that is hardly the idea, it seems more likely that the concern for environmental protection enters the scene later in planning process, affecting the design of the plan at the margin rather than having the ability to question it more fundamentally.

4.2.3 Llwybr Newydd – The Wales Transport Strategy 2021

Llwybr Newydd, meaning 'a new path', refers to the ambition to rethink transport planning to better respond to the climate emergency and other pressing challenges of today while addressing aspects of health, poverty, inclusion, and accessibility (Welsh Government, 2021b). A three-step strategy is proposed, including bringing services to people, enabling sustainable, efficient and accessible transport, and encouraging sustainable transport choices. The strategy refers to the transport hierarchy in which the most sustainable travel modes are at the top and the most polluting are at the bottom. For infrastructure, road maintenance is prioritised over new constructions.

References to the Wellbeing Act and the wellbeing goals occur both in the aim of the strategy and in suggested priorities (Welsh Government, 2021b). The five ways of working permeate the strategy: it is long-term in that it reenforces the emphasis on the needs of future generations; it is preventive in terms of disincentivising unsustainable transport modes; it is integrative since it brings together many policy areas; it is collaborative in that it highlights the importance of partnerships for the delivery of outcomes; and it is involving in terms of encouraging increased participation of citizens and local stakeholders.

The transport strategy aims to address equality, health, climate, biodiversity, waste, economic cohesion, innovation, distribution of goods, affordability, Welsh language, art, sport, culture, and historic environment. The main economic concerns of the strategy – cohesion, innovation, distribution of goods and affordability – do not appear as superior to, or dictating the conditions of, the other goals. In this sense, the overall focus of the strategy seems to be providing a transport system that responds to the wellbeing-related needs of the residents rather than one that serves to attracting external financial or human capital.

The delivery of the strategy is suggested to occur through the National Transport Delivery Plan, mini-plans in which long-term and short-term strategies for the specific transport modes are presented, regional plans and transport commissions. Collaboration with various actors, including the UK Government, other policy areas within the Welsh Government, local authorities, regional partnerships, commercial operators, and transport users, are described as crucial for a successful implementation.

In sum, the transport strategy is clearly influenced by the ideals of wellbeing, both in its means and its ends. It is less growth-oriented than the national plan and PPW, since it appears to be less focused on sustainable growth and more on accessibility, sustainability and efficiency.

5. Discussion

The space for 'more visionary scenarios' that Ruiz-Alejos & Prats call out for (2022) undoubtedly exists in both Cornwall and Wales, which is manifested by formulations like 'a new era' and 'a new path'. None of the analysed documents define progress as measurable with GDP growth, but they differ in how growth-oriented they are. Comparing Welsh national plan and the Cornwall local plan, the former follows a logic of sustainable growth where growth seems to be both a means and an end in itself, whereas the latter discusses growth very little and never as the ultimate goal of planning. In the same vein, Cornwall transport plan depicts growth as a potential outcome rather than a means or an end. This resonates with Barry's description of growth as 'a potential by-product, not the goal of planning' (Barry, 2019). While a growth imperative to which the wellbeing goals are secondary characterises the Welsh national plan, the climate goal seems to have the superior position in the Cornwall transport plan, given how all policy areas are discussed in relation to it. Both the Cornwall doughnut and the Welsh wellbeing economy have clearly influenced the analysed planning documents – not least the two transport plans.

Despite the many references to the Welsh wellbeing goals, it is clear that the idea of sustainable growth is still prevalent in the key documents for national land-use planning in Wales. What 'sustainable growth' means is however not fully defined, nor is it clarified how conflicting interests should be weighed against each other. As both Berglund & Julier (2020) and Naess (2020) note, urban growth often implies exploitation of valuable environments – either through sprawl or though densification. How Wales will 'maximise environmental protection', which is one of the outcomes of PPW's sustainable placemaking, while promoting urban growth, is not discussed in the PPW. The Welsh transport strategy, in contrast, differ from the urban growth focus that Xue (2015: 2018) identifies in Copenhagen, in which the attention to the increase in active travelling and public transport are disguising a simultaneous rise in car travels. Welsh Government (2021b) acknowledges that growth of sustainable transport modes is not sufficient, unless they replace less sustainable transport modes. In this sense, the Welsh transport strategy is less growth-oriented than the Welsh documents for land-use planning.

Both the Welsh national plan and PPW contain traces of the post-growth planning ideas that Rydin (2022) suggests as suitable for high- and low-growth areas, in terms of using existing infrastructure in urban areas and focussing on place-based strategies to maintain provision of services in rural areas. However, the Welsh land-use documents build on a polycentric growth node-periphery structure with a conventional image of labour market and commuter patterns, which Durrant et al. (2023) describes as detrimental for communities located in the periphery. The risk is similar to what Jones (2019) and Carter & MacKillop (2023) highlight, that the urban focus of the Welsh national plan makes spatial justice difficult to achieve.

Regarding the process of post-growth planning, some observations can be made. Firstly, it is indeed difficult to fit a model or concept, like the doughnut or the wellbeing economy, into a local context, given its multiple considerations needed across both time and scale. In Wales, there is an emphasis on localism and the place-based approach – which is applauded by McKinlay (2019) – and still, several studies (Carter & MacKillop, 2023; Nesom & MacKillop, 2021) notes that there is a tension between the national and the local level in relation to the Wellbeing Act. This tension is difficult to capture only from analysing the national documents.

Secondly, there is a difference between planning documents and actual action. Although the Cornwall local plan is thoroughly influenced by the ideals of the Doughnut, the annual review shows that the majority of the sustainability targets are currently not fulfilled. However, the review also provides examples of on-going actions in the process towards the goals. In order to analyse the implications of these initiatives on planning practice – more than these glimpses that an annual review can offer – the implementation processes should be investigated separately through e.g. interviews with planning actors or analysis of policy documents and meeting minutes.

Thirdly, there are signs of a new post-growth-oriented way of planning based on backcasting in the documents. The clearest example is found in the Cornwall transport plan which explicitly refers to a shift from predict-and-provide to decide-and-provide, but a similar backcasting logic is present in the Welsh transport strategy where the net zero goal fundamentally determines the design of the strategy. Overall, the ‘safe and just space’ of the Cornwall doughnut and the Welsh wellbeing goals are examples of how the places formulate a vision which will dictate the conditions of planning.

6. Conclusions

The aim of this study was to explore the influence of post-growth ideas on documents related to land-use planning and transport planning in Cornwall and Wales. The study shows that there are traces of post-growth ideas in strategic documents and plans, as well as indications that these ideas also are forming concrete policies. The analysed documents are clearly influenced by the doughnut model and the wellbeing economy respectively, in terms of goals and ways of working. However, some documents show a more mixed picture where the growth imperative is still striking.

The post-growth ideas were generally more integrated in the transport plans than in the land-use plans. In both Cornwall and Wales, the transport plans exemplify a broader approach to planning which combines land-use and transport perspectives. In addition, both of the transport plans are characterised by a backcasting approach in which the climate goal plays a dominant role.

Given the focus on planning documents, the study was limited to concern the ‘talk’ rather than the ‘action’ of post-growth planning. To analyse the implications of post-growth ideas in planning practice and culture, a deeper empirical analysis is needed in which the specific implementation processes are followed. A suggestion for future research is to follow such a process through document analysis and interviews with planning professionals.

Research on Rural Revitalization Planning from the Perspective of Ecological Capitalization: Taking Nuanshui Township as an Example

Peng Siwei, Lu Yufei, Wang Yizhe

Email: njpsw-arch@seu.edu.cn

Abstract
Balancing environmental protection and economic growth while promoting rural revitalization and coordinated urban-rural development is a crucial issue in China. With ecological capitalization as the starting point, this research proposes a rural revitalization planning model that is led by ecological principles, supported by population, industry, and land, and complemented by culture, based on the analytical framework of "ecological resources - ecological assets - ecological capital." Taking Nuanshui Township in Inner Mongolia as a typical case, the goal is to transform it into a comprehensive national forest park in the coal mining region of western Inner Mongolia and northern Shaanxi, exhibiting Chinese-style modernization, ecological, and geological characteristics. This approach provides valuable insights for exploring the promotion of rural revitalization through ecological capitalization.

Keywords
Ecological capitalization; Rural revitalization; Nuanshui Township; Sustainable development

1. Introduction

Against the backdrop of the long-term urban-rural dual system oriented towards urban growth, the issue of rural decline has become increasingly prominent. Coordinating urban-rural relations through rural revitalization to achieve Chinese-style modernization has become an important issue in China today. China's rural revitalization strategy points out that achieving rural revitalization requires efforts in five major aspects: industrial revitalization, talent revitalization, cultural revitalization, ecological revitalization, and organizational revitalization. Based on this, ecological construction leading rural revitalization, especially using "ecological value realization" as an incentive measure for ecological protection to guide rural revitalization, is attracting increasing attention from institutions and scholars. However, research on driving rural revitalization through the realization of ecological resources' value is still in the stage of fragmented prospects and assumptions, overlooking its potential as a sustainable, universal, and proactive force for driving urban-rural integration. This study systematically elaborates the basic logic of ecological capitalization driving rural revitalization, constructs an analytical framework based on the evolutionary process of "ecological resources - ecological assets - ecological capital," and proposes planning response strategies. Using Nuanshui Township as a typical case for empirical analysis, it attempts to avoid the resource curse phenomenon and mitigate the externalities of ecological resources. The aim is to provide possible pathways for protecting the ecological environment and realizing the economic value of ecological resources, and to provide references and support for exploring the path of rural revitalization under the theory of ecological capitalization.

2. The connotation and logic of ecological capitalization

2.1 The Conceptual Connotation of Ecological Capitalization

The concept of ecological capitalization has gained certain consensus in the academic community. Relevant research believes that ecological capitalization is a way to realize the value of ecological resources, which refers to the process of transforming ecological resources with scarcity and profitability into ecological assets through ecological confirmation, and then into ecological capital through the ecological market. Its value is mainly reflected in improving the efficiency of ecological resource allocation to mitigate ecological crises caused by rough

exploitation and utilization. Among them, ecological resources not only refer to natural resources but also include corresponding social resources, which are the combination of various natural and artificial elements with ecological carrying capacity and ecological service functions. Ecological assets refer to scarce ecological resources with clear ownership that can bring benefits to the owner under certain economic and technological conditions. Ecological capital is an ecological asset that can generate future cash flows, possessing three attributes: usefulness, appreciation, and tradability.

2.2 The Inner Logic of Ecological Capitalization

Based on the above concepts, the inherent evolutionary logic of ecological capitalization can be broadly divided into two stages: the capitalization of ecological resources and the capitalization of ecological assets. In the capitalization of ecological resources stage, first, we need to understand the natural attributes of ecological resources, identify ecological production factors that can be used for production, and determine their existence value. Second, given the scarcity of ecological resources, the primary task of capitalizing ecological resources is to clarify the ownership of property rights, thereby confirming the use value of ecological resources, and converting them into ecological assets through valuation. In the capitalization of ecological assets stage, first, we need to invest in production factors such as ecological technology to transform ecological assets into active ecological capital and confirm their factor value. Then, we need to transform ecological capital into ecological services and ecological products, and realize the monetization of ecological services through market operations to demonstrate their exchange value. Finally, part of the ecological benefits will be used in various forms for ecological construction, ecological resource protection, etc., forming a circular and sustainable utilization of value-added ecological resources.

3. Construction of Rural Revitalization Planning Model from the Perspective of Ecological Capitalization

To achieve the revitalization and development of various rural areas, it is necessary to adapt to local conditions and select development paths that are in line with the characteristics of each village based on the actual development situation of different townships and villages. For example, agricultural townships should prioritize agricultural development, while industrial townships should focus on developing township industries. Therefore, rural revitalization led by ecological capitalization is obviously more suitable for townships that have rich ecological resources and are more suitable for focusing on ecological construction. Against this backdrop, planning to support the promotion of rural revitalization driven by ecological capitalization needs to focus on considering various entities for achieving rural revitalization, value-added models, and the overall framework and implementation path for planning to realize the promotion of rural revitalization driven by ecological capitalization.

3.1 Various Entities Promoting Rural Revitalization through Ecological Capitalization

The main entities driving rural revitalization through ecological capitalization can be divided into three categories. The first category is the owners of ecological resource property rights. Generally speaking, the village collective owns the ownership of ecological resources, while individual villagers enjoy the right to use, manage, and operate these resources. Only when the property rights of the collective and individuals are clearly defined and their boundaries established can the enthusiasm of property right owners be mobilized, the liquidity of ecological resources be improved, and thus the capitalization of ecological resources be promoted.

The second category of entities is market operators. Market operators can be enterprises in related industries or individuals engaged in relevant industries. These entities possess sufficient funds, channels, and mature technological systems for utilizing ecological resources. They can

effectively tap into the value of ecological resources, put them into market operations, and thereby promote the capitalization of ecological assets.

The third category of entities is the grassroots government. The grassroots government plays a crucial role in coordinating market operators and property right owners. On one hand, it can effectively reduce communication costs between the two parties. On the other hand, it is familiar with the legal and management requirements of the region, and can play a significant role in promoting the capitalization of ecological resources and ecological assets.

3.2 The planning model of promoting rural revitalization through state capitalization

To fully operationalize ecological capitalization and maximize the inherent value of ecological resources to promote rural revitalization, effective guidance must be achieved through rural revitalization planning. The rural revitalization strategy points out that achieving rural revitalization requires efforts in five major areas: industrial revitalization, talent revitalization, cultural revitalization, ecological revitalization, and organizational revitalization. Therefore, the process of guiding rural revitalization with ecology cannot be separated from industrial development, talent support, cultural support, and organizational security. Furthermore, spatial resources, as crucial resources for industrial development and rural construction, are also significant supports for rural revitalization.

Based on the above analysis, to lead with ecological capitalization and formulate rural revitalization strategies through planning to support rural revitalization, it is necessary to build a rural revitalization planning implementation framework from five dimensions: ecology, industry, land, population, and culture. As previously mentioned, rural revitalization driven by ecological capitalization should form an "ecology + N" development model led by "greening the countryside," making ecological construction and ecological dividend realization the primary task of planning to promote rural revitalization. Planning needs to take ecology as the guide, comprehensively activate ecological vitality across the entire township, and lay the foundation for achieving common prosperity. On the basis of implementing ecological construction, based on subsequent development needs, it is necessary to simultaneously promote industrial revitalization, optimize land use and population structure, and propose paths and measures for ecological industry development, land use, talent introduction, and management. Finally, by activating cultural resources, further vitality can be injected into the ecological and industrial elements of rural revitalization, enhancing its attractiveness and influence.

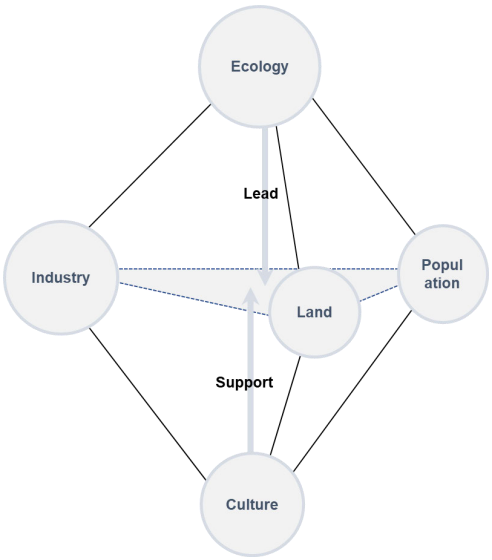

Figure 1: The "diamond" model of ecological capitalization driving rural revitalization planning

3.3 The planned action path for promoting rural revitalization through ecological capitalization

Overall, taking rural life, production, and ecological spaces as entry points, this study aims to provide guidance on the development strategies and paths for rural revitalization. Regarding the development of rural life, production, and ecological spaces, this study proposes the principles of total optimization and comprehensive planning. Total optimization involves enhancing the capacity of ecological spaces, activating the stock of production spaces, and controlling the increment of living spaces. Comprehensive planning prioritizes improving the pattern of ecological spaces, scientifically adjusting the layout of production spaces, and precisely planning the final layout of living spaces.

Specifically, for ecological spaces, continuous ecological management should be implemented to enhance their capacity, ensuring that the area of ecological spaces only increases and does not decrease, and that the types of spaces within the ecological protection red line remain unchanged. Meanwhile, four types of ecological spaces should be categorized based on actual conditions: conservation-oriented, integrated, cultivation-oriented, and restoration-oriented. Targeted measures should be formulated to increase the quantity and quality of different types of ecological spaces. For production spaces, abandoned farmland should be optimized and activated, and three agricultural production zones should be planned. Combining the results of dual evaluations, scattered and inefficient production spaces should be relocated to agricultural production zones or merged with large-scale and high-efficiency production areas through land reallocation, achieving the scale and systematization of production spaces. Scattered farmland that is not suitable for relocation can be converted to forests, while permanent basic farmland remains unchanged. For living spaces, a living space system should be precisely constructed for three types of people: those residing in the countryside, those living outside, and those returning to the countryside. Once the planning is determined, it should remain unchanged in principle. For returning villagers and tourists, characteristic stations should be planned and constructed in a scattered manner within the rural area, taking into account environmental conditions. Residents in the countryside and immigrants living outside should be concentrated

in existing settlements. Additionally, certain supporting facilities should be added based on the planned population.

In terms of ecological revitalization, corresponding governance objectives, frameworks, and implementation paths should be proposed, with a focus on implementing key ecological governance projects. For industrial revitalization, a comprehensive industrial system should be established, providing guidance on the development direction of key industries and planning for the introduction and further development of key industrial projects. In terms of land use, land use structures should be rationally regulated to ensure space for rural revitalization, and corresponding land management measures should be proposed to improve land use efficiency throughout the township. For population revitalization, predictions should be made on the size of various populations in the township, and guidance should be provided on the future development direction of different groups. In terms of cultural revitalization, strategies for the protection, inheritance, and utilization of historical and regional cultures, as well as approaches for promoting rural civilization, should be proposed. Finally, in terms of rural governance, corresponding governance strategies should be proposed for both ecological immigrants and rural residents, and innovative ideas should be put forward for the cultivation and construction of new-type collective economic organizations and social organizations.

4. Analysis of typical cases of rural revitalization from the perspective of ecological capitalization

4.1 The Development Background of Rural Revitalization in Nuanshui Township

Located in the west of Zhungeer Banner, Inner Mongolia Autonomous Region, China, and in the center of the Mengxi-Shaanbei coal mining area, which is an important coal source in China, Nuanshui Township is a typical resource-based region. Nuanshui Township belongs to severely exposed area of arsenic sandstone, a special geological structure that is one of the main factors leading to soil erosion and flood disasters in the Yellow River in China. Due to long-term coal mining and its special geological structure, Nuanshui Township has become an important area in China for promoting rural revitalization through ecological governance. Since 2009, Nuanshui Township has been designated by the Chinese government as a pilot township for the construction of an ecological natural restoration zone. By the end of 2021, the township's ecological afforestation area had reached 700,000 mu (about 46,667 hectares), with vegetation coverage exceeding 85%. However, while Nuanshui Township has achieved certain results in ecological governance, the spillover effect of ecological restoration dividends is not significant. The underdeveloped basic situation of the township has not been fundamentally changed, and some prominent issues such as the separation of people and production, as well as the separation of people and land, have not yet been resolved. How to activate the value of ecological resources to promote rural revitalization and economic development has become the main issue facing the township.

4.2 The Current Status of Rural Revitalization Development in Nuanshui Township

In 2009, the "Pilot Implementation Plan for the Promotion of Ecological Natural Restoration Area Construction in Nuanshui Township" was issued, requiring farmers who meet the conditions and are willing to relocate in the prohibited and restricted development zones of the township to do so in groups of entire communes or natural villages, adhering to a one-time planning and three-year relocation schedule, which meant withdrawing from agricultural and animal husbandry production in the same year and basically relocating the population within three years. Since the implementation of the ecological migration policy, the overall ecological condition of Nuanshui Township has improved significantly, and some ecological industries such as apricot and apple have been developed, initially realizing the transformation from lucid

waters and lush mountains to invaluable assets. In terms of ecological construction achievements, by 2010, the township had basically completed the ecological migration of the entire township, completed ecological afforestation of 208,054 mu (about 13,870 hectares), and achieved an ecological construction area of 256,300 mu (about 17,087 hectares). With the migration of villagers from various villages, comprehensive ecological improvement projects, including the treatment of arsenic sandstone, have gradually been implemented in full. By the end of 2021, the treatment of arsenic sandstone in Nuanshui Township had achieved remarkable results, with a significant increase in the vegetation coverage index (Figure 2-2-1). There were also significant improvements in agricultural product output and villager income levels, with the annual collective income of the village reaching 18,000 Yuan, per capita cultivated land area reaching 0.64 hectares per person, and the total output of economic crops reaching 7,549.9 tons. In addition to the treatment of arsenic sandstone, the township has also actively carried out ecological construction work such as soil and water conservation and returning farmland to forests, and established ecological governance platforms such as the Ordos City Soil and Water Conservation Science and Technology Demonstration Park.

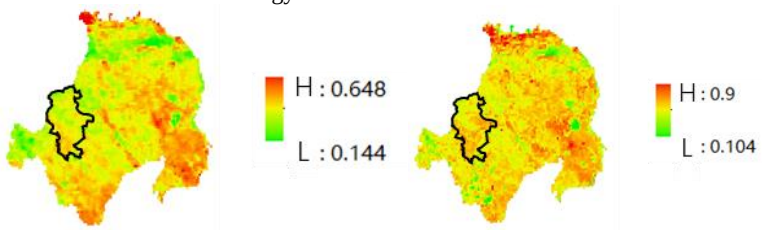

Figure 2: Vegetation Coverage Index of Nuanshui Township (Left: 2010; Right: 2021)
Data Source: Resource and Environmental Research Center of the Chinese Academy of Sciences

“Lucid waters and lush mountains are invaluable assets." The ecological construction efforts in Nuanshui Township have also generated a certain ecological dividend spillover effect, promoting rural revitalization and advancing common prosperity to a certain extent. Specifically, first, during the process of arsenic sandstone management, some arsenic sandstone resources have been fully utilized. On one hand, they have been used to develop seabuckthorn-related industries, and on the other hand, some areas have been transformed into arsenic sandstone geological parks, laying a foundation for the development of tourism in the township. Second, with the advancement of ecological restoration and returning farmland to forests, some green industries, including apricot, apple, forage, and traditional Chinese medicinal herbs, have developed effectively, providing new avenues for villagers to increase their income. Third, after the implementation of ecological migration, some homesteads and farmland have been converted into public welfare forests, and villagers can receive corresponding subsidies for public welfare forests.

However, even though the ecological construction in Nuanshui Township has promoted the pace of rural revitalization to a certain extent, there are still issues such as the monotony of tree species, small growth and yield of forest trees, and the lack of an ecological system and related industries relying on forest planting. Moreover, the ecological restoration in the township still relies primarily on natural recovery. Against this backdrop, how to improve the conversion rate of ecological construction achievements into "invaluable assets," how to promote the ecological development of Nuanshui Township from natural recovery to more proactive ecological cultivation, and further stimulate the ecological vitality and enhance the ecological value of the entire township, are the core issues that urgently need to be addressed for the future ecological revitalization of Nuanshui Township.

4.3 The Development Strategy for Rural Revitalization in Nuanshui Township

Since the implementation of the ecological migration policy, the ecological resources in Nuanshui Township have been in a state of "natural growth" without scientific and orderly management. On one hand, the township's ecological service value does not hold an advantage at the county level, and on the other hand, the value of the township's “lucid waters and lush mountains" has not been fully realized, resulting in insufficient ecological dividends. Additionally, Nuanshui Township is located at an important node for migratory birds and the Silk Road trade route, as well as the intersection of the northern and northwestern paths of sandstorms, making it an essential ecological "landing point" in the region.

To address the issues left behind by ecological migration, actively implement the "Two Mountains Theory," and fully leverage the ecological advantages of Nuanshui Township, it is necessary to actively guide and organize public participation in ecological construction. From the perspective of ecological capitalization and based on the analytical framework of "ecological resources - ecological assets - ecological capital," this plan proposes the development strategy for Nuanshui Township's Eco 2.0. This is both an inevitable choice for the current stage of development in Nuanshui Township and a necessary requirement for its development pattern.

The specific path for the Eco 2.0 construction in Nuanshui Township consists of three steps. The first step is to shape the foundation, relying on the existing ecological base to realize the capitalization of ecological resources in Nuanshui Township. Through the cultivation and construction of "three forests" - forests, fruit trees, and gardens, the basic pattern for ecological revitalization in Nuanshui Township will be formed. The second step is to release dividends, relying on Nuanshui Township's "lucid waters and lush mountains" to develop ecological industries and realize the capitalization of ecological resources, such as EOD-related industries, carbon sequestration-related industries, and others. This will transform "lucid waters and lush mountains" into "invaluable assets", allowing villagers to tangibly enjoy the dividends brought by ecological construction. The third step is proactive development, leveraging ecological dividends to attract and organize more villagers and market entities to participate in the construction of "three forests," promoting the ecological development of Nuanshui Township from natural restoration to more proactive ecological cultivation. This will further stimulate the ecological vitality of the entire township and enhance its ecological value. Ultimately, the goal is to transform Nuanshui Township into a national forest park.

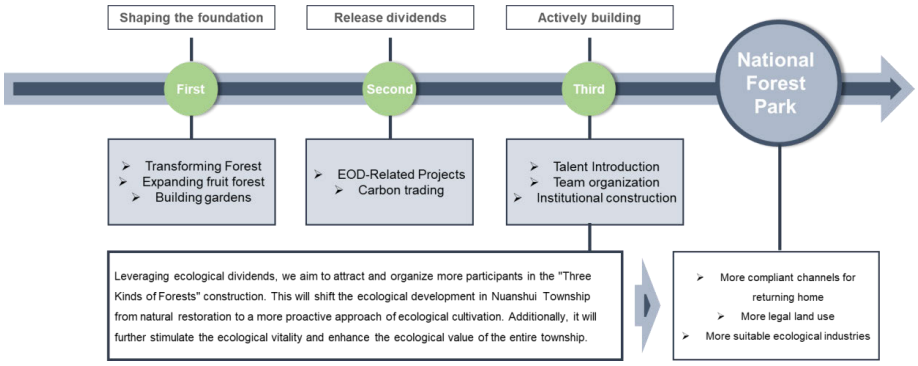

Figure 3: Action Framework

4.4 The Development Path for Rural Revitalization in Nuanshui Township

(1)Shaping the foundation

Through the cultivation and development of "forests, fruit forests, and gardens," the plan aims to enhance the integrity and biodiversity of the entire ecosystem in Nuanshui Township, thereby realizing the confirmation of ecological assets in the township and transforming them into ecological capital through valuation.

The scope of forest construction and cultivation covers the entire area of Nuanshui Township, encompassing three specific aspects. Firstly, "converting grassland to forestland" involves transforming natural grazing lands and other grasslands into arbor forests with a canopy density of no less than 0.2 through artificial afforestation. Secondly, "returning farmland to forestland" entails converting scattered and low-yield farmland into arbor forests. Thirdly, "rehabilitating mines and returning them to forestland" means planting trees in available land after mine reclamation. From the perspective of property rights, the village collectives will play a leading role in the management of this type of ecological resource, and relevant land will be collected through land transfer and other means to be consolidated and improved by the village collectives. Based on this, the plan selects six villages with relatively abundant resources in "grassland," "farmland," and "mines" - Deshengxi Village, Hanjiata Village, Kenmuken Village, Changhanbula Village, Geqiugou Village, and Shuiquangou Village - as the starting areas for artificial afforestation projects. Based on this foundation, the plan further categorizes the "forests" into three types: ecological forests, ornamental forests, and interactive forests. Ecological forests are primarily planted with arbor trees that possess water conservation and soil erosion control functions. They are located in the six administrative villages within the artificial afforestation starting areas, focusing primarily on ecological benefits and not participating in the development of the forest tourism system. In the future, they will be used primarily for the development of forest carbon sequestration. Ornamental forests are primarily planted with drought-tolerant and aesthetically pleasing ornamental arbor trees. They are primarily distributed in the four villages of Desheng Youliang, Shuiquangou, Nuanshui, and Yushuhao, often combined with fruit forests and along transit roads. These forests focus primarily on landscape benefits and have the potential to be integrated into the Nuanshui Township's forest tourism system in the future, enhancing the service value of forest tourism and ornamental aspects in Nuanshui. Interactive forests are primarily planted with tall and dense arbor trees, with some ornamental arbor trees interspersed appropriately. They are primarily distributed throughout the Nuanshui Township, combined with gardens, focusing primarily on economic benefits. In the future, they can be incorporated into the Nuanshui Township's forest tourism system, fostering a development pattern of harmonious coexistence between humans and nature.

For the unique fruit forest resources in Nuanshui Township, on one hand, the plan proposes to promote the expansion of fruit tree planting areas, specifically by increasing the planting of mixed fruits in villages other than Desheng Youliang, and to moderately develop a courtyard economy. On the other hand, the plan believes that the scenic transformation of fruit forests should be implemented appropriately, meaning to transform the more extensive, profitable, and mature fruit forests into scenic spots, opening them to the public and introducing related tourism and appreciation projects.

In terms of "gardens", the construction and cultivation scope covers the entire area of Nuanshui Township. Specifically, it involves two aspects: first, developing and building small-scale village parks with an area of no more than 20 hectares, relying on the unique resources and endowments of each village. Simultaneously, drought-tolerant shrubs will be planted in every "garden" in a manner that fills in every available space to increase the vegetation coverage and ecological service value. Once completed, the vegetation coverage within each "garden" will reach at least 90%. It is expected that by 2025, a distribution pattern of "one garden per village" will be achieved. Second, the existing park green spaces and tourist landscapes in the central town area of Nuanshui will be renovated and upgraded, and 1-2 new street green spaces will be

added. Furthermore, leisure stops can be established in conjunction with the "garden" layout to build a comprehensive leisure and recreational system throughout Nuanshui Township, enhancing the overall ecological vitality of the region.

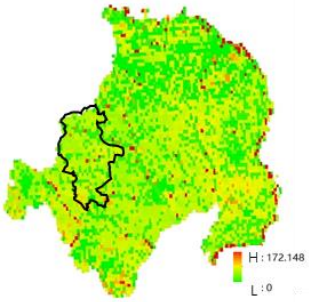
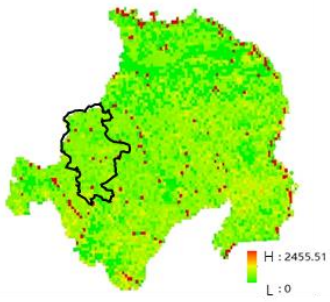
(b): Food production value



(c): Purification of environmental value



(d): Total value

Figure 4: Evaluation of the Ecological Asset Value of Nuanshui Township
Data Source: Resource and Environmental Research Center of the Chinese Academy of Sciences

(2) Release dividends

Based on laying a good foundation for the ecological environment, it is necessary to establish corresponding mechanisms to realize the capitalization of ecological assets, thus guiding the transformation of the “lucid waters and lush mountains" in Nuanshui Township into “invaluable assets". To achieve this, this plan introduces the concept of "Two Mountains Bank" and recommends the establishment of a township-level "Two Mountains Bank" in the lead, consisting of five departments: Resource Storage Center, Value Assessment Center, Asset Trading Platform, Asset Operation Center, and Financial Service Center. Through the coordinated operation of these departments, various ecological resources in Nuanshui Township will be "monetized," opening up the transformation channel from "resources to assets, to capital, to funds." In summary, the main role of "Two Mountains Bank" is to provide channels for the transformation of ecological resources into assets and funds, such as green financial services, eco-industrial projects, carbon sequestration trading projects, etc., based on the quantification of the ecological foundation.

Specifically, the first step is for the township government to establish a comprehensive information management platform for the confirmation and registration of ecological resources in the township, including the registration and confirmation of ownership, location, and area of ecological resources within the entire area of Nuanshui Township. This requires all village collectives to conduct statistics on the physical quantity accounts of forest, fruit forest, garden, and other ecological-related assets in the village, calculate the township's ecological resource

assets and their changes, and report them to the township level. The township level will then uniformly input the data into the ecological resource information management platform and form a database for each village for future use. The village databases will be managed by the village secretaries, and the township-level management platform will be managed by dedicated personnel.

Next, relying on the Resource Storage Center of the Nuanshui Township's "Two Mountains Bank," various ecological resources included in the management platform will be stored and integrated, which can be further transformed into ecological assets through capital empowerment in the future.

Based on the overall integration of the township's ecological resources, this plan recommends collaborating with relevant professional institutions to develop the "Nuanshui Township Ecological Product and Asset Accounting Methods." With the support of the Value Assessment Center, the Nuanshui Township's GEP (Gross Ecosystem Product) will be calculated according to the relevant accounting methods, giving "value tags" to the green waters and lush mountains, and achieving coordinated growth in GDP and GEP scale. It is expected that by 2025, Nuanshui Township's GEP will reach 65.6 billion Yuan, and by 2035, it will reach 133.9 billion Yuan.

After determining the asset value of Nuanshui Township's ecological resources, it is necessary to "monetize" the asset value through appropriate channels. To this end, this plan recommends utilizing the Asset Operation Center of the "Two Mountains Bank" to release ecological dividends. The Asset Operation Center primarily achieves this by introducing the EOD (Ecological-Oriented Development) model, leveraging forest, fruit forest, and garden resources based on Nuanshui Township's ecological development needs to develop EOD-related industrial projects. Among them, the plan recommends setting the EOD-related project for the forest as the construction of Nuanshui National Forest Park, the EOD-related project for the fruit forest as the Desheng Youliang Village Rural Complex Project and the Shuiquanggou "Apricot Village" Agricultural, Cultural, and Tourism Integration Development Project, and the EOD-related project for the garden as large-scale garden engineering construction projects such as the Mine Park, Pisha Rock Geological Park, and Geqiugou Botanical Garden.

In addition, this plan proposes to build the asset trading platform of “Two Mountains Bank " in Nuanshui Township into a platform primarily used for forestry and agricultural carbon sequestration trading. In the near future, carbon trading pilot projects will be carried out within the township area, and in the long run, it can be promoted to the banner, city, and even the western Inner Mongolia and northern Shaanxi regions. Based on the estimated annual emission reduction of 0.7t per mu (1 mu ≈ 667 m²) and a price of 58 Yuan per ton for afforestation projects, and the estimated annual emission reduction of 0.43t per mu and a price of 10 Yuan per ton for agricultural carbon sequestration projects, it is expected that by 2025, the annual income of forestry carbon sequestration trading in Nuanshui Township can exceed 6 million Yuan, and the annual income of agricultural carbon sequestration trading can exceed 200,000 Yuan. To achieve this, villagers and village collectives need to be guided to declare woodland as carbon sequestration forests and farmland crops as agricultural carbon sequestration trading projects. Among them, for artificial arbor forests with a continuously distributed area of 0.67 hectares or more on villagers' individual land, villagers are encouraged to apply for carbon sequestration forests individually. Otherwise, villagers are encouraged to transfer their woodland to the village collective, and the village collective will apply for carbon sequestration forests uniformly.

The financial service center of “Two Mountains Bank " in Nuanshui Township primarily relies on the aforementioned ecological projects to provide certain economic support to enterprises, cooperatives, individuals, and others within the township. It is recommended that in the near term, it mainly provides GEP (Gross Ecosystem Product) ecological value loan services and carbon account services. The GEP ecological value loan service is a lending business based on

the assessed GEP value, which can effectively activate the economic value and financial attributes of ecological products. Priority can be given to select professional cooperatives and enterprises within Nuanshui Township that urgently need loans to carry out pilot projects. Carbon account services are divided into two categories: enterprise/cooperative carbon account services and villager/village collective carbon account services. The former is mainly aimed at enterprises and cooperatives in the township that conduct carbon trading to enhance their carbon account ratings and credit lines, while the latter allows villagers participating in carbon trading to deposit their carbon reserves into personal carbon accounts, which can be cashed out after trading.

(3) Actively building

To actively implement the "Two Mountains Theory," it is necessary to promote Nuanshui Township towards more proactive ecological cultivation and construction. Therefore, the plan proposes to leverage ecological dividends to attract and organize more local, expatriate, and returning Nuanshui residents to participate in ecological cultivation efforts such as afforestation, orchard expansion, and garden construction.

First, we can use new media, offline promotion, and other methods to promote Nuanshui Township's development goals, vision, and ecological dividends to attract public participation in ecological construction. Then, we can recruit relevant personnel through four channels: forest construction, national forest construction, garden construction, and "Two Mountains Bank" experience management.

For forest construction: 1).Organized by the township government, recruit 800-1000 afforestation workers.2).Organized jointly by enterprises and the township government, recruit 150-200 forest park construction and management personnel.3).Organized jointly by enterprises and the township government, recruit 200-300 forest rangers.4)

For orchard construction: 1).Organized by village collectives, recruit 80-100 fruit farmers. 2).Organized jointly by enterprises and village collectives, recruit 50-80 personnel for rural complex construction. 3).Organized jointly by village collectives and villagers, recruit 50-80 returning residents to operate the rural complex.

For garden construction: 1).Organized by village collectives, recruit 40-60 garden construction workers. 2).Organized jointly by enterprises and village collectives, recruit 30-50 garden maintenance personnel.

For "Two Mountains Bank" operation and management: 1).Organized by the township government, recruit 30-50 offline service personnel. 2).Organized jointly by enterprises and the township government, recruit 20-30 online platform development and maintenance personnel. 3).Organized jointly by enterprises and the township government, recruit 30-50 online service personnel.

Table 1: Description of the EOD-Related Projects in Nuanshui Township

	Forests	**Fruit forests**	**Gardens**
EOD-Related Projects	Nuanshui Township National Forest Park Project	Desheng Youliang Rural Complex Project; Shuiquangou Rural-Culture-Tourism Integrated Development Project	Mining park, arsenic sandstone geological park, and other landscape engineering construction projects.
Key Participants	A listed company + township government + villagers	Social capital + township government + village collective + fruit farmers	Social capital + township government + village collective
Source of Revenue	Operating income will be generated from carbon sequestration trading, development and operation of cultural tourism projects,	Operating income from future projects will come from carbon sequestration trading, fruit tree planting and operation, as well as the development and	Operating income mainly consists of the development and operation of cultural tourism projects, as well as the

	as well as the operation of parking lots in future projects.	operation of cultural tourism projects.	operation of supporting facilities.
Ecological Construction	By conducting artificial afforestation, we can further improve the ecological indicators in Nuanshui Township, including plant coverage, forest coverage, species richness, and water source conservation capacity.	By increasing the area of fruit forests, we can enhance the transpiration of the forest, improve the forest coverage rate, and at the same time enhance the ornamental value and tourism development value of ecological resources.	By promoting the diversity of the ecosystem in Nuanshui Township, we can revitalize brownfields and underutilized park green spaces, thereby enhancing the ecological vitality of the entire region.

5. Conclusion and Discussion

This study takes the planning perspective of ecological capitalization as an entry point, integrates the dual needs of ecological protection and economic development, analyzes the basic logic of ecological capitalization driving rural revitalization, and proposes a planning model led by ecology, supported by the revitalization of population, industry, and land, and enhanced by culture. It explores the planning path for rural revitalization from the perspective of ecological capitalization. Based on this, the study uses the case of Nuanshui Township in Inner Mongolia as a typical example, constructs a three-step planning action path from shaping the foundation, releasing dividends, to active construction, based on the analytical framework of "ecological resources - ecological assets - ecological capital" and combined with the needs of various entities in rural revitalization. The study also puts forward targeted planning and guiding measures for Nuanshui Township's characteristic resources such as "forests, orchards, and gardens," as well as an EOD development model centered on the "Two Mountains Bank." It clarifies the entire development system of Nuanshui Township's rural ecological resources from confirmation of ownership rights, to ecological asset valuation, to ecological capital operation, further confirming that the capitalization of ecological resources can bring value-added benefits in terms of ecology, society, and economy. Looking forward, the study will further refine the planning framework and implementation path for rural revitalization from the perspective of ecological capitalization, providing strong support and solid guarantees for supporting rural construction and coordinated urban-rural development.

From Howard's Garden City Movement to Zero-Carbon New Towns in the postgrowth era: the case of New Town development in the context of carbon neutrality of Shanghai

Wei Wei [1]
[1]College of Architecture and Urban Planning, Tongji University, Shanghai
Ghibli.Wei@foxmail.com

Abstract: Shanghai's urban development has transitioned from traditional New Towns to the emergence of zero-carbon New Towns, driven by a commitment to carbon neutrality by 2060. This transition reflects a broader shift towards sustainability and decarbonization in urban planning. Five major New Towns around Shanghai embody this shift, focusing on renewable energy, green infrastructure, and low-carbon living. Key indicators guide their development, emphasizing mixed land use, energy-efficient buildings, sustainable transportation, waste management, and climate resilience. Effective implementation mechanisms, supported by policy, finance, and community engagement, ensure the realization of low-carbon goals. Shanghai's journey towards zero-carbon New Towns highlights a proactive approach to address climate change while creating livable, resilient urban environments.
Key words: New Town development, carbon neutrality, sustainable development, carbon reduction

1. Introduction

From Howard's garden city movement, to Taylor's concept of satellite cities, and to Saarinen's organic dispersal theory, the development of New Towns has been affected by the background of the times (Aldridge, 2017). As the largest metropolis in China, Shanghai's New Towns have developed from first-generation bedroom towns to relatively independent satellite cities, and to new regional node towns (Shen et al., 2017). Nowadays, in the postgrowth era, sustainability and de-carbonization have become the new themes of urban development. The government announced that Shanghai will achieve carbon neutrality by 2060. At the same time, Shanghai is actively establishing its carbon financial market, trying to achieve carbon neutrality by linking the financial market with carbon resources.

Under these conditions, a new generation of New Towns emerged. Five New Towns built around the main city of Shanghai, namely Jiading New Town, Qingpu New Town, Songjiang New Town, Fengxian New Town, and Nanhui New Town, will serve as the first generation of zero-carbon New Towns in Shanghai in the postgrowth era (Shen et al., 2017). These five towns, while inheriting the functions of traditional New Towns also regard sustainable development and de-carbonization as the main themes of New Town development. That is, these five New Towns will take carbon neutrality and zero carbon output as their initial construction goals.

2. The development of New Town theory

The development of urban theory concerning "New Towns" has been a significant topic within urban planning and architecture over the past century (Fishman, 1990). The concept of New Towns, which are planned urban centers created to accommodate population growth or relieve housing shortages in established cities, has evolved through various stages, influenced by social, economic, and technological changes.

The idea of planned urban spaces dates back to ancient civilizations, but in a modern context, it was Sir Ebenezer Howard in the United Kingdom who laid the foundations for contemporary New Town theory with his publication of "Garden Cities of To-morrow" in 1898 (Aldridge,

2017). Howard proposed creating self-contained communities surrounded by "greenbelts," combining urban and rural benefits to combat the squalor of Victorian cities. His ideas led to the development of the first garden cities, Letchworth and Welwyn, designed to provide healthier living environments away from overcrowded urban centers.

The concept of New Towns gained significant momentum after World War II, particularly in the United Kingdom with the New Towns Act of 1946 (Barnett, 2018). This legislation aimed to systematically relieve overcrowding in London and other bombed cities by creating over 20 New Towns designed as self-sufficient communities with their industries, residential areas, and cultural facilities. The concept also included the development of satellite towns, smaller urban bodies orbiting larger cities, to help absorb the overflow of population and functions from urban centers without the same level of self-sufficiency as New Towns.

During the same era, Nikolaus Schärer, a Swiss architect and urban planner, proposed the concept of "organic dispersal." This theory suggested that urban expansion should mimic organic growth patterns, allowing cities to expand and contract fluidly in response to environmental and demographic changes, rather than enforcing rigid, pre-planned designs (Pringle, 2023). This approach aimed to integrate more flexibility and sustainability into urban development, influencing how New Towns and satellite cities were planned to better adapt to their natural and economic environments.

In the United States, the New Town development concept was incorporated into broader urban renewal efforts during the mid-20th century (Fishman, 1990). Notable projects such as Reston, Virginia, and Columbia, Maryland, were developed, emphasizing planned approaches to residential living, economic functions, and environmental concerns. Internationally, New Town development became part of national planning strategies in many countries, including Israel, South Korea, and Singapore, each adapting the basic principles to local needs and contexts.

The late 20th and early 21st centuries have seen new dimensions added to New Town theory, emphasizing sustainability and smart technology. The focus has shifted to creating eco-cities and smart cities that incorporate advanced technology to manage urban resources efficiently and minimize environmental impact. Examples include Masdar City in Abu Dhabi and Songdo International Business District in South Korea, which integrate information technology infrastructure and eco-friendly practices at a fundamental level (Zhou, 2019).

While New Towns have been lauded for their ability to plan and manage urban growth systematically, they have also faced criticism. Challenges include creating socio-economic divides, achieving a balanced community mix, and the risk of creating isolated urban pockets that do not integrate well with surrounding regions. Planners and developers continue to address these issues by fostering more inclusive planning processes and integrating New Towns more holistically with regional economic and transportation planning.

Overall, the theory and practice of developing New Towns have evolved from simple garden city concepts to sophisticated urban ecosystems that balance human needs with technological advancements and environmental stewardship. This evolution reflects broader changes in urban planning philosophies and the continuous search for sustainable urban development strategies.

3. The history of Shanghai's New Town development

Shanghai's New Town development can be traced back to the mid-20th century when the city began experiencing rapid urbanization (Shen et al., 2017). The government initiated the

construction of New Towns to accommodate the growing population and alleviate urban congestion. Over the decades, Shanghai's New Towns have evolved in response to changing urbanization patterns, economic development, and government policies. Initially conceived as bedroom communities, these New Towns have transformed into more self-sufficient urban centers with improved infrastructure, amenities, and employment opportunities.

Spatially, New Towns in Shanghai are strategically located in the city's periphery to balance regional development and relieve pressure on the central urban area. They are typically connected to the city center through transportation networks, such as highways, railways, and metro lines. Functionally, Shanghai's New Towns serve multiple functions, including residential, commercial, industrial, and recreational purposes. They are designed with modern urban planning principles, incorporating green spaces, pedestrian-friendly streets, and mixed-use developments to create livable and sustainable communities.

Fig.1 Spatial Distribution of Shanghai's Five New Towns

Shanghai has currently formed a spatial structure consisting of one main city and five New Towns, a configuration explicitly outlined in Shanghai's 2035 Spatial Plan. These five New Towns include Jiading, Qingpu, Songjiang, Fengxian, and Nanhui. They are strategically distributed across different regions of Shanghai, providing diversity and balance to the city's development landscape (Figure1). Jiading New Town, situated in the northwest, is renowned for its unique economic and cultural ambiance; Qingpu New Town, located in the west, attracts attention with its rich historical and natural resources; Songjiang New Town, positioned in the southwest, offers modern facilities and superior living conditions; Fengxian New Town, found in the south, captivates with its charming coastal scenery and modern urban construction; Nanhui New Town, nestled in the southeast outskirts, holds a strategic geographical position and rapidly growing economic strength.

In addition, the five major New Towns in Shanghai not only play pivotal roles in Shanghai's internal development but also serve as important links connecting the city with surrounding regions. By fostering collaboration and connectivity with neighboring cities, these New Towns contribute to regional integration, economic growth, and sustainable development in the broader Shanghai metropolitan area and beyond.

In the northwest, Jiading New Town maintains close ties with neighboring cities such as Suzhou and Kunshan, acting as a bridge linking Shanghai with the dynamic economies of the Yangtze River Delta region. Its strategic location along major transportation arteries facilitates seamless connectivity and collaboration in areas such as commerce, manufacturing, and research. Nestled in the western part of Shanghai, Qingpu New Town shares borders with cities like Jiaxing and Hangzhou in Zhejiang Province. Its proximity to these regional centers enhances cultural exchange, tourism, and economic cooperation, serving as a gateway connecting Shanghai with the cultural and economic vitality of neighboring cities, promoting mutual development and prosperity. Situated in the southwest, Songjiang New Town maintains strong connections with cities such as Suzhou, Jiaxing, and Hangzhou. Its well-developed transportation infrastructure, including highways and railways, facilitates the flow of goods, people, and ideas between Shanghai and its neighboring regions. Songjiang New Town plays a pivotal role in promoting regional collaboration in areas such as education, technology, and cultural exchange. Located in the southern part of Shanghai, Fengxian New Town shares borders with cities like Ningbo and Zhoushan. Its coastal location enhances its connectivity with neighboring coastal cities and ports, facilitating trade, tourism, and maritime cooperation. Fengxian New Town serves as a key link connecting Shanghai with the vibrant economies and scenic attractions of the coastal region, promoting mutual development and prosperity. Positioned in the southeast outskirts, Nanhui New Town maintains close connections with cities such as Ningbo and Wenzhou. Its strategic location near major ports and transportation hubs fosters trade, logistics, and economic cooperation, acting as a vital node in the regional logistics network. Nanhui New Town facilitates the efficient flow of goods and services between Shanghai and neighboring cities, driving economic growth and regional integration.

Guided by the Shanghai 2035 Spatial Plan, the development of these New Towns aims to create a livable, business-friendly, and leisure-oriented urban environment. They are envisioned as crucial hubs for future economic growth and population migration, integrating modern urban infrastructure, green ecological environments, and cultural leisure facilities. By offering diverse functions and convenient transportation networks, these New Towns will attract more residents and businesses, contributing to the sustainable development of Shanghai.

4. The Zero-Carbon New Towns

Shanghai, as China's economic hub and a densely populated metropolis, has been actively addressing the challenges of climate change and environmental protection. Firstly, Shanghai's carbon peak target aims to reach the peak of carbon dioxide emissions by 2030, followed by a gradual reduction. Additionally, Shanghai has set an ambitious target to achieve carbon neutrality by 2060 (Hua et al., 2019).

In the context of Shanghai's carbon neutrality goals and the background of New Town development, the emergence of zero-carbon New Towns has become a new construction objective. With Shanghai's commitment to achieving carbon neutrality and promoting sustainable development, the direction of New Town development is evolving. Traditionally, New Town development focused on population accommodation and relieving urban functions, but in the context of carbon neutrality, zero-carbon New Towns emphasize the reduction of carbon emissions and climate friendliness during the construction process. This implies that New Town planning will increasingly consider aspects such as renewable energy utilization, energy conservation, and green transportation to achieve zero carbon emissions.

Currently, the construction status of the five major New Towns in Shanghai demonstrates a diverse and comprehensive trend. In terms of industrial structure, these New Towns are no longer solely reliant on residential areas but are gradually achieving diversified industrial development. In addition to residential areas, they also boast modern commercial districts, industrial parks, and cultural and entertainment facilities, providing residents with a richer array of lifestyle choices. Regarding infrastructure, the transportation networks of the New Towns are becoming increasingly sophisticated, including highways, railways, and metro lines, facilitating convenient connections between residents and businesses. Moreover, environmental protection receives considerable attention, with an increase in green spaces, ongoing efforts in water resource conservation, and advancements in waste management.

The low-carbon construction objectives of the five major New Towns in Shanghai primarily focus on energy utilization, transportation systems, building energy efficiency, and carbon market development. In terms of energy utilization, the New Towns will vigorously develop clean energy sources, reduce reliance on traditional fossil fuels, and encourage the adoption of energy-saving technologies by residents and businesses. Regarding transportation systems, the New Towns will optimize public transportation layouts, promote electric vehicles and other new energy transportation options, and reduce emissions from motor vehicles. In terms of building energy efficiency, the New Towns will promote green building practices and energy-efficient renovations to improve building energy performance and reduce energy consumption. Additionally, the New Towns will actively participate in carbon market development, promoting carbon trading and the growth of the carbon market to facilitate the development of a low-carbon economy and further reduce carbon emissions.

For example, Jiading New Town, located in the northwest, has been actively promoting the development of new energy vehicles and supporting industries, aiming to become a model for sustainable transportation. Qingpu New Town, known for its historical and natural resources in the west, has implemented strict environmental protection measures during its development process, preserving its ecological integrity. Songjiang New Town, with its superior living conditions in the southwest, has focused on enhancing energy efficiency in its buildings and promoting green construction practices. Fengxian New Town, situated in the south with its charming coastal scenery, has prioritized the development of renewable energy and eco-friendly tourism. Lastly, Nanhui New Town, positioned in the southeast outskirts, has been at the forefront of carbon market development, actively participating in carbon trading and promoting low-carbon industrial transformation.

5. Interpretation of high-level policies

In fact, there are a series of upper-level policies and planning guidance for the low-carbon construction of Shanghai New Town. Taking Nanhui New Town as an example, there are policies and plans at the national, Shanghai municipal and district levels to guide its low-carbon development.

As a part of Pudong New Area in Shanghai, Nanhui New Town is supported by a series of top-level policies and planning documents at the national, municipal, and district levels. These documents provide crucial guidance and support for its low-carbon development. Understanding these top-level planning policies is essential for grasping the positioning and future direction of Nanhui New Town.

In the national-level policy document, "The Fourteenth Five-Year Plan for National Economic and Social Development of Pudong New Area and the Long-Range Goals for 2035," besides

emphasizing Pudong's aspiration to become a premier destination for global investment, trade, and entrepreneurship, it also highlights the comprehensive construction of a modern economic system. This system focuses on the coordinated development of the real economy, technological innovation, modern finance, and human resources, aiming to enhance the quality and efficiency of the supply system. This implies that in future development, Pudong will strengthen support for technological innovation and green industries, promoting the structural transformation of the economy towards low-carbon and environmentally friendly sectors. Additionally, the plan emphasizes the construction of modern urban areas, including optimizing urban spatial layout, developing rail transit, and establishing ecological networks. These measures will contribute to improving urban environmental quality and advancing the city towards green and low-carbon development.

In the Shanghai-level policy document, "The Fourteenth Five-Year Plan for the Development of China (Shanghai) Pilot Free Trade Zone Lingang New Area," besides outlining the goal of establishing Lingang New Area as a special economic functional zone, it also emphasizes enhancing innovation capability. The plan underscores the promotion of international collaborative innovation and the construction of a world-class, open, and modern industrial system. This indicates that in future development, Lingang New Area will strengthen support for green technology and environmental industries, driving industries towards a low-carbon, green direction. Additionally, the plan emphasizes the goal of building the most modern, eco-friendly, convenient, vibrant, and distinctive comprehensive node coastal city. This will help promote the construction and development of low-carbon new towns.

In the Pudong New Area (district level) policy document, "The Fourteenth Five-Year Plan for the Construction of Nanhui New Town," besides setting forth the goals of building a high-level open area, an integrated reform and innovation highland, and a high-energy industry highland, it also proposes the construction of an ecological New Town and a digital New Town. The plan emphasizes increasing the area of public park green space, forest coverage, and ecological space ratio to promote the city's development towards green and low-carbon. Additionally, the plan highlights the goals of constructing a digital New Town and smart communities. This will be achieved by improving urban management through smart technologies and information, promoting the city's development towards a low-carbon and smart direction. These measures will contribute to improving the city's ecological environment and advancing towards a low-carbon development model.

6. The Zero-Carbon New Towns' indicator system

The planning of low-carbon cities in Shanghai's five major new towns is a strategic response to the global imperative of mitigating climate change and transitioning towards a sustainable future. With the commitment to achieving carbon neutrality, Shanghai has embarked on comprehensive urban planning to guide the development of its burgeoning new towns, including Nanhui, Lingang, Fengxian, Chongming, and Jiading. These cities are envisioned as models of sustainable urban development, balancing economic growth with environmental stewardship.

The initiatives for low-carbon development in Shanghai's new towns are multifaceted and comprehensive, addressing various aspects of urban planning, infrastructure development, and community engagement. Aligned with international climate goals, these initiatives aim to reduce carbon emissions, enhance energy efficiency, promote renewable energy adoption, improve air and water quality, and create resilient urban environments. Central to these efforts is the integration of sustainability principles into urban planning and design, including measures

to promote compact, mixed-use development patterns and prioritize walking, cycling, and public transit over private vehicles. In building and transportation, the new towns prioritize energy-efficient construction practices and the adoption of low-carbon transportation modes. This includes incentivizing green building construction, implementing stringent energy efficiency standards, and expanding public transportation networks. Efforts to conserve energy and resources are integral, with a focus on waste reduction, recycling, and renewable energy utilization. Additionally, resilience and adaptation are emphasized, with measures to enhance flood resilience and integrate green infrastructure solutions.

Taking Nanhui New Town as an example, a set of development indicators has been established to guide its low-carbon development journey. These indicators span various dimensions, including urban form, transportation, energy efficiency, waste management, and climate resilience. Nanhui aims to achieve a balanced mix of land uses and green spaces, with indicators focusing on mixed-use development and ecological conservation. Energy-efficient construction practices and sustainable transportation solutions are prioritized, with targets for green building construction and public transportation coverage. Efforts in resource conservation and climate resilience are also highlighted, with indicators for waste utilization and flood management. Overall, these initiatives and indicators guide Nanhui New Town's journey towards low-carbon development, fostering a sustainable, resilient, and livable urban environment. By integrating sustainability principles into urban planning and development processes, Nanhui aims to become a model of sustainable urban development, showcasing the feasibility and benefits of a low-carbon, resilient, and inclusive urban future.

Table.1 Nanhui New Town's planning indicators towards Zero-Carbon New Town

No.	Aspects	Characteristic Indicator	Indicator Value
1	Healthy and Vibrant Layout and Environment	Proportion of mixed-function blocks on construction land	0.5
2		Per capita park green area	9.5 square meters per person
3		Proportion of ecological space	0.55
4		Proportion of affordable housing and market-oriented public rental housing area in new housing	≥40%
5		Proportion of livable renovation in old neighborhoods	0.5
6	Low-carbon and Convenient Building and Transportation	Proportion of newly built two-star green buildings	1
7		Proportion of healthy buildings or ultra-low energy buildings in total building area	≥25%
8		Proportion of prefabricated or assembled buildings with a prefabrication rate of 45% or an assembly rate of not less than 65%	≥5%
9		Coverage rate of construction land rail transit stations within 600 meters/bus stops within 500 meters	80%/100%
10		Proportion of new energy buses	1
11	Efficient Energy and Resource Conservation	Number of charging piles for new energy vehicles at new construction sites with an area of over 2400 square meters	45325
12		Construction of hydrogen refueling stations (oil-hydrogen co-construction)	4 items
13		Comprehensive management and control platform for energy facilities	1 item
14		Rate of garbage resource utilization	0.75
15		Rate of non-traditional water source utilization	≥3%
16		Average reduction in carbon emissions intensity of newly built residential and public buildings	8 kgCO2/(m2·a)
17	Resilient and Safe Sponge City and	Proportion of new sponge cities in newly built urban areas	1
18		Proportion of comprehensive corridors for four types of urban engineering pipelines under all new main roads in newly built urban areas	1

19	Municipal Infrastructure	Per capita road area	≥13 m2
20		Local woody plant index	≥0.7
21		Standard compliance rate of district flood defenses	100% (defensive standard of once-in-200-year)
22	Smart and Innovative Management and Humanities	Application scenarios of "One-network Management" in new towns	Over 30 newly built application scenarios
23		Proportion of application of BIM in design and construction stages of new buildings	1
24		Construction of demonstrative digital living communities	10

7. Achievement and implementation of low-carbon goals

The implementation of urban planning schemes is crucial for the sustainable development of cities. Through effective planning implementation, cities can enhance their functionality and livability, address development issues, and achieve long-term development goals. For example, London has devised the "London Plan," which, through planning implementation, has enhanced the city's transportation efficiency and environmental quality, thus improving the residents' quality of life. Similarly, Shenzhen, China, has formulated the "Shenzhen Urban Master Plan (2010-2020)" implementation guidelines, which have propelled industrial upgrading and enhanced the city's image, making it a pivotal city in China's reform and opening-up.

To ensure the implementation of urban planning schemes, governments need to employ various methods. Firstly, governments need to provide policy and regulatory support to ensure the legality and effectiveness of the plans. For example, the Japanese government has enacted laws such as the "Urban Renewal Law" to provide legal protection for urban planning. Secondly, sufficient financial support is crucial. The Guangzhou municipal government in China, when promoting urban planning implementation, has adopted the PPP model, attracting social capital to participate in urban infrastructure construction, thereby ensuring the smooth progress of projects. Additionally, establishing effective project management and supervision mechanisms is vital. The Singaporean government, when implementing the "Singapore Concept Plan," established strict project management and supervision mechanisms to ensure the timely and quality completion of planning projects. Lastly, strengthening social participation and communication is essential. The Amsterdam municipal government in the Netherlands extensively solicited public opinions during city development planning, enhancing the legitimacy and acceptability of the plans through democratic participation.

Fig.2 implementation system of Nanhui New Town

However, the implementation of low-carbon city goals differs from traditional urban planning objectives. Low-carbon city goals emphasize reducing carbon emissions and improving energy efficiency, requiring consideration of environmental protection and sustainable development factors in urban planning and construction. For example, Copenhagen, Denmark, serves as a model for low-carbon cities, achieving significant reductions in carbon emissions through measures such as optimizing urban layout and promoting renewable energy. Therefore, it is crucial to prioritize the integration and implementation of low-carbon city goals in urban planning to steer cities towards more environmentally friendly and sustainable development.

Taking Nanhui New Town as an example, the low-carbon target implementation system covers various aspects, aiming to ensure that low-carbon planning objectives are effectively realized. Firstly, adhering to green and low-carbon development strategies, a comprehensive management framework was established during the planning phase (Figure 2). This includes innovative management mechanisms, unified management standards, and consolidated management power, providing strong organizational support for the implementation of low-carbon planning objectives.

In terms of management mechanisms, Nanhui New Town has established a leadership group dedicated to promoting green ecology and low-carbon construction. This group plays a crucial role in coordinating all relevant departments and units to ensure the effective execution of various low-carbon measures.

Regarding management systems, Nanhui New Town has strengthened the approval management of development and construction projects within the area, in line with the guidelines for the New Town. It has developed and established an energy-saving and green ecological management model that covers the entire process from project initiation, design,

construction, to operation. This model systematically implements energy-saving and ecological protection standards across the full life cycle of construction projects, from design through to operation.

Technical support measures include the involvement of third-party professional consulting firms to assist the leadership group in implementing green ecological standards throughout the construction process. This not only enhances the professionalism of project implementation but also ensures the accurate application of ecological standards.

Furthermore, promoting standardized management among participating units is key to ensuring that construction, design, construction, and supervision units strictly adhere to the green ecological content in the construction design documents, organizing construction disclosures and management accordingly. This approach effectively ensures the implementation of environmental standards during construction.

The demonstration role of government investment is also crucial in financial arrangements. Funds are strategically allocated to ensure that the necessary finances for green ecological urban planning and control mechanisms are secured by district fiscal funds. For government-funded projects, the finance department actively provides support, ensuring sufficient funding for green and low-carbon construction of projects.

Through these comprehensive measures, Nanhui New Town can effectively promote the achievement of low-carbon objectives, providing a solid foundation for the sustainable development of the city. This not only reflects the foresight in urban planning and management but also demonstrates the city's commitment and effort on the path to low-carbon development.

8. Conclusion

In conclusion, Shanghai's evolution from traditional New Towns to the emergence of zero-carbon New Towns reflects a significant shift towards sustainability and decarbonization in urban development. The commitment to carbon neutrality by 2060 has spurred the development of new urban centers that prioritize renewable energy, green infrastructure, and low-carbon lifestyles. Key indicators guide the transition, emphasizing mixed land use, energy-efficient buildings, sustainable transportation, waste management, and climate resilience. Effective implementation mechanisms, backed by policy support, financial investment, and community engagement, ensure the realization of low-carbon goals. Shanghai's journey towards zero-carbon New Towns underscores a proactive approach to address climate change while fostering livable, resilient, and inclusive urban environments.

Abstract

With the recent development of online-to-offline (O2O) industries in China, the Internet has become a game-changer, facilitating the creation of new forms of spaces. Taking Nanjing old city as a case study, this paper identifies invisible consumption spaces that are not situated on the streets or in shopping malls but are primarily located inside high-rise buildings and rely on online platforms to operate. The distribution of invisible consumption spaces presents characteristics of central agglomeration and multi-polar clustering. Based on decision tree algorithms, an analysis of a typical area indicates that spatial costs, property rights, and building management and support are the primary influencing factors. Additionally, commercial-residential buildings play a crucial role as carriers of spatial clustering. This paper argues that the emergence and development of invisible consumption spaces is a manifestation of the diversification of old city consumption spaces and a significant bottom-up regeneration strategy in the Internet era.

Keywords

Invisible consumption space, O2O, distribution characteristics, spatial clustering, space regeneration

1 Introduction

Research on consumption spaces initially began in the field of commercial geography, with studies on spatial location primarily based on Christaller's central place theory. Subsequently, as cognitive and behavioural models were proposed, the research perspective expanded to consumption behaviour (Huff, 1963). With the emergence of the information age, the Internet has become a game changer, radically altering the pathways and efficiency of communication, and profoundly transforming urban everyday life spaces. The consumption space based on online-to-offline (O2O) is precisely a new type of urban space that reflects the interplay between the explicit and the implicit.

In recent years, the O2O consumption model has developed rapidly in China. Research on O2O consumption spaces, such as takeaway restaurants, Airbnb houses (Sun, Wang and Hu, 2022), and Internet-sensation shops, has yielded relatively rich results. This research has initially established a framework for studying new types of consumption spaces under the backdrop of Internet development. However, there is an *invisible* O2O in-store consumption type that has not yet attracted much attention. These stores, as physical consumption spaces in the city, do not have storefronts opening directly to urban public spaces (on streets or in shopping malls) but are concealed within urban buildings. They operate through online platforms, focusing on experiential consumption, which mainly includes life services, entertainment, leisure, sports, and other formats. This paper refers to this type of consumption space as *invisible consumption space*. The research in this paper mainly focuses on the distribution characteristics and influencing factors of invisible consumption spaces in the context of the Internet environment. By analysing the data of invisible consumption spaces in Nanjing old city, this study explores the macro-level spatial distribution characteristics. Through case studies of typical blocks and buildings, this study aims to identify and analyse the micro-level site selection factors. The

research findings are expected to enrich and improve the types and contents of old city space regeneration under the influence of the Internet.

2 Research Overview

As information communication technology (ICT) advances, there is a notable shift in the fundamental dimensions of human cognition within the network society. The *space of flows* and *timeless time* have become the new spatial-temporal foundations (Castells, 1996). The social fabric and daily routines are reorganised by electronic communication networks, leading to time-space compression or even the end of geography. The development of ICT has brought new changes to urban space and consumption spaces (Carpio-Pinedo and Gutiérrez, 2020).

Online shopping has impacts on physical consumption spaces through substitution, enhancement, modification, and neutrality (Farag et al., 2007). Corresponding to offline physical consumption spaces, online virtual consumption spaces have emerged (Farag, Krizek and Dijst, 2006), and some traditional shopping has shifted from offline to online, which can have positive or negative impacts on physical spaces (Puel and Fernandez, 2011). Similarly, in addition to the shift from offline to online, online consumption spaces are also expanding offline. This expansion includes new retail spaces and playscapes that host offline leisure activities organised by online communities. Overall, the online-merge-offline development, known as the *bricks-and-clicks* model, is a prevalent trend in the evolution of consumption spaces (Zhen et al., 2018).

The transition of consumption spaces from *visible* to *invisible* is a common feature in numerous studies focusing on spatial distribution influenced by the Internet. Regional-scale studies focus on various industrial spatial patterns and characteristics, as well as the influencing factors among cities. The studies of urban internal scale mainly address the industrial characteristics, influencing factors, and the impact on traditional commercial space. In terms of spatial distribution, O2O consumption spaces tend to extend into back alleys and the interior of blocks horizontally, while showing a concentration trend in high-rise buildings vertically (Lu et al., 2013).

With the increasing emphasis on the cultural significance of consumption, the consumption of space also encompasses the consumption of the *third space* constructed collectively by material, spiritual, and social aspects (Soja, 1996). Consumption spaces are no longer just places for buying goods, but also offer a wider range of experiential sensations. Compared to the traditional rational-functional approach to processing information in consumption, experiential consumption focuses on the symbolic, hedonistic, and aesthetic aspects of the act (Holbrook and Hirschman, 1982). In addition to traditional retail shops, more and more studies involve cultural and recreational places (Chatterton and Hollands, 2002), as well as leisure, festival activities and spaces (Demant and Landolt, 2013; Kidder, 2012). A significant number of retail spaces in cities that cater to in-store consumers are being influenced by online shopping trends and are aiming to transition into experiential shopping destinations, possibly evolving into tourist attractions (Gilli and Ferrari, 2017). Experience is a key value in the O2O consumption

process. In general, the consumption of consumption spaces is becoming increasingly important, while the importance of location is diminishing.

Overall, research on consumption spaces in the context of the Internet is mainly concentrated in the field of urban geography, focusing on consumption behaviour and meaning, with some involving location and distribution. However, research from the perspective of space regeneration is relatively weak, especially systematic research on invisible consumption spaces, which requires further in-depth exploration.

3 Macro Distribution Characteristics of Invisible Consumption Spaces

3.1 Data Source and Processing

The study utilises Point of Interest (POI) data for the consumption spaces in Nanjing old city, which was obtained through the Gaode Open Platform (an application of Amap.com, one of the most popular digital maps in China). Each POI represents a single store (consumption space). The Gaode Open Platform provides comprehensive and complete open-source data, and it covers both offline and O2O consumption spaces, facilitating comparative research. Additionally, the data is linked to Dianping.com, a popular review platform in China similar to Yelp in Europe. This link provides information such as online reviews and average consumption per person, which aids in collecting characteristics of O2O consumption.

The data for this study was collected on 28 November, 2019, a time when the data had not yet been affected by COVID-19. The data is categorised according to the 'National Economic Industry Classification (GB/T 4754-2017)' and the POI classification codes from the Gaode Open Platform. These categories are divided into seven major groups: catering services, shopping services, educational services, life services, entertainment services, sports and leisure services, and medical services(Table 1).

Table 1. Summary of data on consumption spaces (shops) in Nanjing old city

Shop name	Name
Location	Administrative districts, latitude and longitude coordinates, and address texts
Floor levels	Extracted from address texts
Categories	Seven categories, and several subcategories
Online reviews	Ratings, and consumption per person

Data source: The floor levels are extracted according to the address text, and the other information is obtained through the Gaode Open Platform.

The article extracts POI data based on the definition of invisible consumption spaces. Consumption spaces can be categorised into two types based on their environment: street shops and internal shops. Street shops are visible consumption spaces with storefronts facing the street. In contrast, internal shops are located within buildings and are further divided into shopping mall internal shops and other internal shops. Shopping mall internal shops are considered visible consumption spaces, while other internal shops that do not have storefronts connected to public spaces and primarily operate through online platforms are considered invisible consumption

spaces. Specifically, within the POI data, places that meet the three conditions of 'not being on the first floor,' 'not located within a shopping mall,' and 'having non-empty online reviews' are identified as invisible consumption spaces.

The floor level information is derived from the address text within the POI data. When the address contains floor level information, the corresponding floor level is determined by searching, extracting, and standardising specific format key fields. If the address does not contain this information, it suggests that there is no requirement to specify the floor level in people's perception, and therefore, the default floor level is considered to be 1. Consequently, a floor level attribute label can be assigned to all POI data. The screening of internal shops in the shopping mall is completed using ArcGIS. POI data located within the shopping mall area, with a floor level less than or equal to the total number of floors of the shopping mall building, are considered shopping mall internal shops and are excluded. In addition to the store POI data, the attribute data of the buildings where invisible consumption spaces are located mainly come from relevant websites and field surveys (Table 2).

Table 2. Summary of data on buildings

Basic attribute	Name, type (office/commercial/residential/hotel, etc.), age, number of floors, standard floor area, standard floor height
Economic attribute	Sale price (10,000 yuan/m^2), rent price (yuan/m^2/day), property fee (yuan/m^2/month)
Management attribute	Owner property rights, property management, access control
Facility attribute	Independent water supply

Data source: The basic attributes, economic attributes, and property information of office/commercial/residential buildings are obtained from Diandianzu.com, Fang.com, and Anjuke.com. Additional information is collected through field surveys.

3.2 Spatial Distribution Characteristics of Invisible Consumption Spaces in Nanjing Old City

After the aforementioned data processing, it was ultimately determined that there are a total of 1,919 invisible consumption spaces in Nanjing old city (Figure 1, Table 3). It can be observed that spaces in the categories of life services, educational services, and entertainment services constitute the main components of the invisible consumption spaces. Compared to traditional stores, these spaces, although smaller in scale, are characterised by more distinctive operations and offer more customised and experiential services. This enables them to compete differently from traditional business and appeal more strongly to their target demographic, which is mainly young people.

Table 3. List of types, representative shops, and classification statistics of invisible consumption space in Nanjing old city

Types	Representative shops	Numbers	Proportion (%)
Catering services	Cat cafe, handmade dessert shop, private bakery, etc.	74	4

Shopping services	Suit customisation studio, jewelry customisation studio, etc.	56	3
Educational services	Foreign language learning, after-school tutoring, art training institutions, etc.	452	24
Life services	Hair salon, nail art studio, photo studio, massage parlour, etc.	1062	55
Entertainment services	Escape game room, private cinema, board game bar, etc.	132	7
Sports and leisure services	Fitness studio, Yoga studio, Taekwondo studio, etc.	103	5
Medical services	Postpartum recovery centre, psychological counselling centre, oral clinic, etc.	40	2
Total		1919	100

Data source: The author collated the POI data obtained by the Gaode Open Platform.

Figure 1. Spatial distribution of invisible consumption space in Nanjing old city

3.2.1 Distribution Characteristics: Central Agglomeration and Multi-Polar Clustering

This article utilises the Kernel Density Estimation (KDE) method, based on ArcGIS, to analyse the distribution of invisible consumption spaces in Nanjing old city. KDE measures the density of features around any given grid cell, describing the spatial aggregation state of geographical objects (Shi, 2010), and is a common method in spatial analysis. In this study, the Natural Breaks (Jenks) classification method is used to divide the data into six classes, which are then utilised to analyse the levels of aggregation of different poles (Figure 2). Multi-ring buffer zones are established around the city centre at 600-metre intervals to count the number of invisible consumption spaces and to construct a Lorenz curve. This curve is utilised to assess the level of aggregation centred around the city centre (Figure 3, Figure 4).

Figure 2. Natural Breaks (Jenks) classification by KDE analysis of the invisible consumption spaces in Nanjing old city

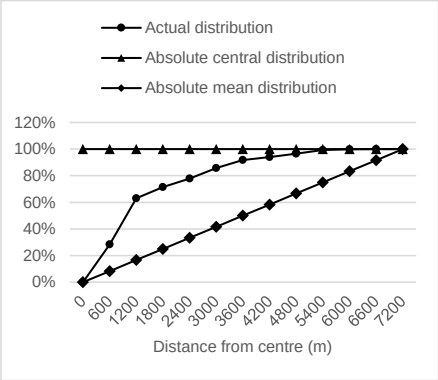

Figure 3. Lorenz curve for invisible consumption space in Nanjing old city

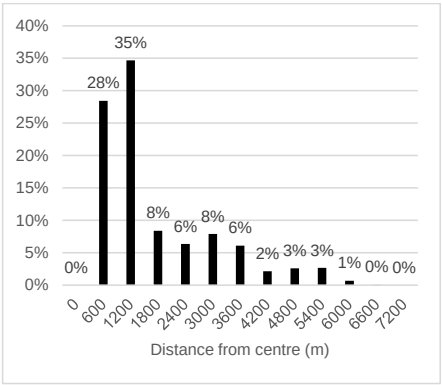

Figure 4. Statistics of invisible consumption spaces in Nanjing old city

Firstly, there is an overarching characteristic of central agglomeration. A distinct agglomeration is evident within the Xinjiekou CBD area, and the convex shape of the Lorenz curve further confirms this observation. More than 70% of the invisible consumption spaces are distributed within a 2000m radius around Xinjiekou. Additionally, secondary agglomerations can be observed in sub-centres such as Hunanlu and Daxinggong.

Secondly, on a local level, there is a characteristic of multi-polar clustering. Invisible consumption spaces are primarily located within buildings; hence, the agglomeration pattern shows a significant point aggregation. Within the Xinjiekou CBD area, they form multiple poles. The cost of operating a shop in high-rise buildings in the city centre area is much lower than that on streets and in shopping malls. As a type of microenterprise, invisible consumption

spaces are highly cost-sensitive. The multi-polar clustering formed by high-rise buildings is a result of spatial distribution driven by economic considerations.

3.2.2 Comparison of Invisible and Visible Consumption Space: Different in Proportion, Similar in Distribution

When comparing visible and invisible consumption spaces in the old city, it can be observed that there are a total of 6,561 visible consumption spaces corresponding to the categories of invisible consumption spaces, which is more than three times the number of invisible consumption spaces (Table 4). Among the visible consumption spaces, the number and proportion of shopping service spaces are much higher than those of invisible consumption spaces. These types of consumption spaces prioritise convenience and often rely on impulse buying, requiring increased visibility and accessibility. In contrast, invisible consumption spaces are mainly concentrated in experiential consumption types such as life services, entertainment, and sports and leisure.

Table 4. Numbers and Proportion of invisible and visible consumption spaces in Nanjing old city

Types	Invisible consumption spaces		Visible consumption spaces		Invisibility ratio
	Numbers	Proportion (%)	Numbers	Proportion (%)	
Catering services	74	4	789	12	0.094
Shopping services	56	3	1595	24	0.035
Educational services	452	24	713	11	0.634
Life services	1062	55	2682	41	0.396
Entertainment services	132	7	469	7	0.281
Sports and leisure services	103	5	150	2	0.687
Medical services	40	2	163	3	0.245
Total	1919	100	6561	100	0.292

Data source: The author collated the POI data obtained by the Gaode Open Platform.

Figure 5. Natural Breaks (Jenks) classification by KDE analysis of the visible consumption spaces in Nanjing old city

In terms of spatial distribution, a comparison of KDE analysis of visible and invisible spaces (Figure 2, Figure 5) shows that the overall distribution of both types of spaces is generally similar and does not exhibit significant spatial differentiation. The distribution of visible consumption spaces is relatively more extensive. In terms of density, the highest level of agglomeration for both visible and invisible consumption spaces is located in the Xinjiekou CBD area, with secondary agglomerations appearing in several sub-centres. The most apparent difference in the distribution of visible and invisible consumption spaces is observed in the Fuzimiao area. As a traditional commercial sub-centre of Nanjing, the number of invisible consumption spaces is very limited. This is mainly because the Fuzimiao area, being historical and cultural blocks, is characterised by low and multi-storey buildings, which lack the high-rise buildings required for invisible consumption spaces.

4 Micro Site Selection Influencing Factors of Invisible Consumption Spaces

4.1 Research Methods

This article selects invisible consumption spaces in the Xinjiekou and Daxinggong areas (Figure 6) to analyse the factors influencing site selection. The reasons for choosing this area are twofold. Firstly, the Xinjiekou and Daxinggong areas are the most concentrated and representative areas for the distribution of invisible consumption spaces. Secondly, as the central business area of the old city of Nanjing, it has a long history, a prosperous commercial environment, and a rich variety of spatial, functional, and economic attributes of buildings, which facilitates comparative research.

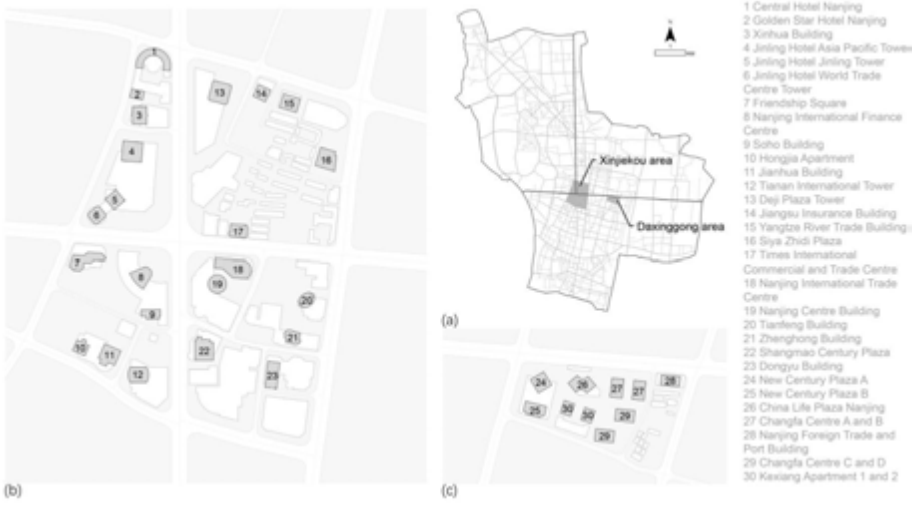

Figure 6. The research scope of Xinjiekou and Daxinggong areas
(a) Xinjiekou and Daxinggong areas in Nanjing old city
(b) Xinjiekou area and buildings
(c) Daxinggong area and buildings

The main analytical methods used in this study to research site selection factors are regression analysis and decision tree algorithms. The decision tree algorithms are inductive learning algorithms based on example data. It is commonly used to construct classification rules and form classifiers using example data. It is also used for predicting and mining unknown data and is widely applied in the fields of economic statistics and machine learning (Safavian and Landgrebe, 1991). It is also utilised in geographical space research, particularly in remote sensing information processing and urban address identification. The decision tree algorithms have the advantages of fast speed, high accuracy, easily understandable rules, and a relatively small computational load. They are suitable for both large and small sample sizes, as well as for continuous and discrete data. The basic idea is to use a hierarchical form, selecting different attribute conditions to make the most effective division of the set until significant category subsets are formed. Each path from the root to the leaf node corresponds to an extracted rule. The sample size, data characteristics, and the iterative and comprehensive relationship between the independent and dependent variables in this study fit well with the application conditions of the decision tree algorithms.

4.2 Analysis of Influencing Factors

Within the Xinjiekou and Daxinggong areas, there are 424 invisible consumption spaces spread across 30 buildings. Based on the number of stores within the building and the categories of store types (stores in a category are >= 5), buildings can be categorised into three types: first, buildings with almost no distribution of stores; second, buildings with some specific categories of stores; and third, buildings with a large number of various types of stores.

Before analysing the influencing factors, a single-factor screening is used to reduce irrelevant interference items. Based on the classification and quantification attributes of the variables, correlation, variance, chi-square, and linear regression are used to verify significance ($p <= 0.05$). The results of the single-factor screening preliminarily indicate that the site selection of invisible consumption spaces is related to building types, rental and property costs, building owner property rights, building access control, and building independent water supply, while the store floor levels, store categories, store ratings, consumption per person, and building age are irrelevant variables. Further regression analysis indicates that the clustering of invisible consumption spaces around commercial-residential buildings is the most effective factor in explaining the distribution of these spaces. In fact, in the Xinjiekou and Daxinggong areas, almost all buildings with a large number of invisible consumption spaces are commercial-residential buildings. The tendency for invisible consumption spaces to be concentrated in commercial-residential buildings is highly significant.

On this basis, the decision tree algorithms are further utilised to analyse the influencing factors through a hierarchical classification method. The dependent variable is the three situations of the buildings with invisible consumption space, with the growing method set to CRT. The results show (Figure 7) that rental and property costs, owner property rights, access control, and independent water supply have a significant impact on the site selection of invisible consumption spaces.

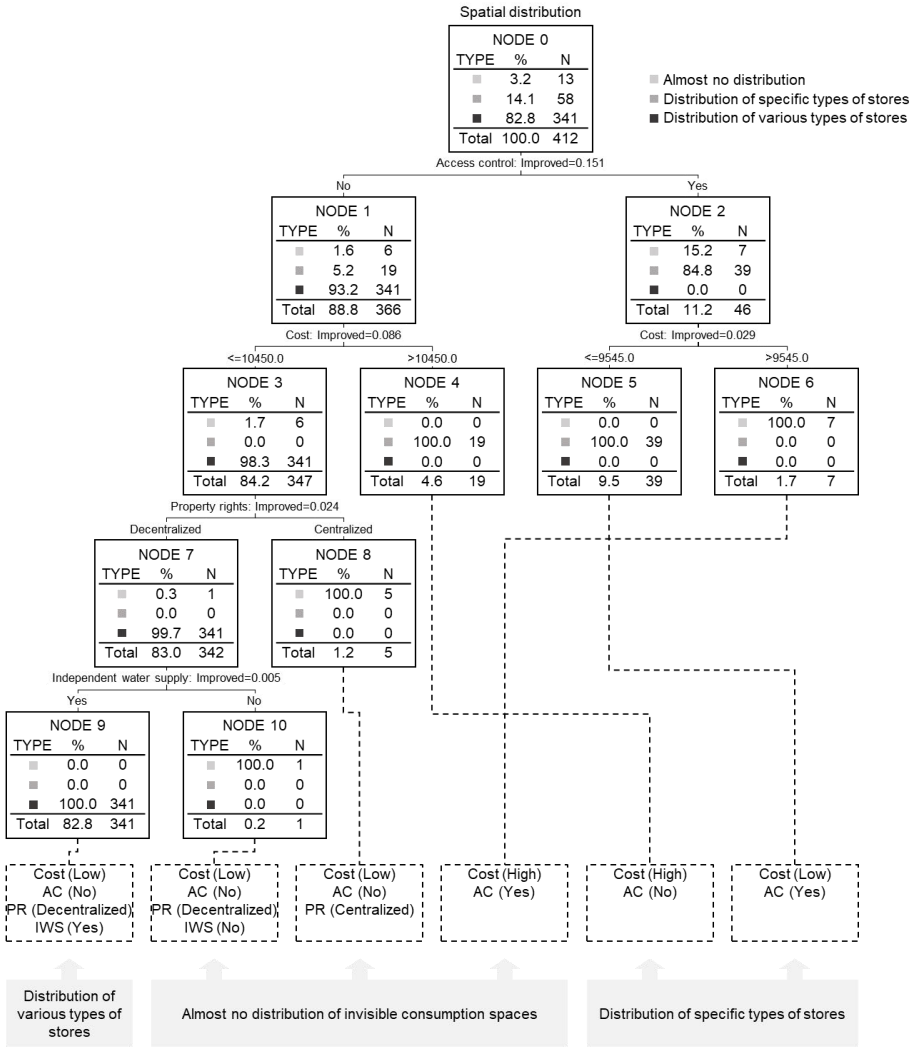

Figure 7. Process and results of decision tree algorithm

Specifically, the owner property rights, property management, and cost attributes of the buildings affect the numbers and types of invisible consumption spaces. Figure 7 shows that

the influencing factors of the three situations are different. Leaf node 1 indicates that when costs are low, owner property rights are decentralised, there is no strict access control, and there is an independent water supply, there are a large number of various types of stores present in the building. Leaf nodes 4 and 5 indicate that when costs are high or low but strict access control is in place, only specific types of stores are present in the building. Stores in buildings with strict access control are all appointment-based, membership-based life service spaces such as beauty salons and clubs. High-cost buildings only have a small number of language learning and study abroad institutions. Leaf nodes 2, 3, and 6 indicate that in cases where there is no independent water supply, property rights are consolidated, costs are high, and strict access control is enforced, there are almost no invisible consumption spaces within the building. This includes buildings with consolidated property rights that are not leased out, as well as high-end office buildings.

5 Conclusion and Discussion

5.1 Conclusion

Invisible consumption spaces, facilitated by the Internet and developed through O2O methods, represent a new form of consumption spaces in cities that has grown to a significant scale and cannot be ignored. In terms of spatial distribution, there is a macro characteristic of agglomeration towards central areas. This suggests that although invisible consumption spaces operate through the Internet, as physical consumption spaces they are still influenced by spatial elements in central areas. There is a micro characteristic of multi-polar clustering, with high-rise commercial-residential buildings serving as the main carriers for the clustering of invisible consumption spaces. This choice is based on multiple considerations, including cost, management, and support facilities.

5.1.1 The Spatial Distribution of Invisible Consumption Spaces Conforms to the Rule of General Consumption Space

As consumption spaces operate through O2O methods, traditional geographical theories still play a role in the site selection of invisible consumption spaces. The analysis in the previous text shows that the distribution of invisible consumption spaces is generally similar to that of visible consumption spaces. Firstly, on a macro level, the agglomeration centres of invisible consumption spaces are still the traditional business centres of Nanjing. Although the cognitive path of invisible consumption spaces is in cyberspace, they still need to complete the consumption in physical space. Therefore, factors such as traffic accessibility and commercial agglomeration effects, derived from geographical theories, still play an important role in their site selection. Secondly, compared with visible consumption spaces, invisible consumption spaces have a higher degree of agglomeration, showing characteristics of polar clustering in microform; that is, they are more concentrated in a particular building. Thirdly, there are significant differences in the composition and proportion of business formats between visible and invisible consumption spaces. The proportion of life services, entertainment, and sports and leisure in invisible consumption spaces is higher. This is related to the personalised and

experiential characteristics of these business formats and also reflects people's demand for diverse consumption spaces.

5.1.2 The Factor of Cost Leads to the Clustering of Invisible Consumption Spaces to Commercial-Residential Buildings in the City Centre

The commercial and service industry is cost-sensitive, and rent has a profound impact on the selection of commercial locations. This is also evident in the site selection of invisible consumption spaces. Firstly, by examining the cost factors, it is found that compared with other commercial spaces, the buildings where invisible consumption spaces are concentrated mostly have lower rent costs. Only business formats with stronger tenancy capabilities, such as foreign language training and study abroad counselling institutions, choose to locate in buildings with higher costs. Cost has become a determining factor for the types of businesses that can operate in these locations. Secondly, the analysis in the previous text revealed that invisible consumption spaces tend to favour commercial-residential buildings for their operations. Commercial-residential buildings emerged in the 1980s in some metropolises and have evolved to the present day. They are often criticised for their resource consumption, disaster prevention capabilities, environmental quality, and community atmosphere. This criticism has led to their rents being much lower than the average level in the same location. Against the backdrop of the internet era, the low rental costs of commercial-residential buildings happen to meet the needs of invisible consumption spaces, becoming a fertile ground for the development of invisible consumption spaces.

5.1.3 Management and Support Are Crucial Factors that Constrain the Distribution of Invisible Consumption Spaces

As consumption spaces within buildings, the spatial distribution of invisible consumption spaces is greatly constrained by the management and support of the buildings. Firstly, the impact of property rights on the distribution of invisible consumption spaces is mainly reflected in the differentiation between buildings with unified property rights and those with dispersed property rights in their approach to the emergence of invisible consumption spaces. High-end office buildings with integrated property rights, taking into account the overall environment and image, often carry out unified tenant recruitment, unintentionally excluding small and distinctive invisible consumption spaces. In contrast, commercial-residential buildings with dispersed property rights are controlled by different owners, and thus, under reasonable market prices and within the scope of legal use, owners typically do not impose additional requirements or restrictions on the entities that enter.

Secondly, building access control is also a factor that restricts the entry of invisible consumption spaces. The frequent movement of people in and out conflicts with strict access control measures. Therefore, under a strict access control management model, the invisible consumption spaces within are typically high-end service institutions that function based on appointments or memberships.

Thirdly, building support systems plays a crucial role in the establishment of certain types of business models, particularly independent water supply, which is essential for businesses like hair salons and catering services. Some buildings are unable to attract these types of business formats due to the lack of individual water supply systems. Thus, management and support determine the differentiation of invisible consumption spaces at the building level.

5.2 Discussion and Outlook

5.2.1 Invisible Consumption Spaces Are a Novel Form of Urban Space Regeneration in the Internet Era

With the Internet gradually becoming deeply integrated into people's everyday lives, the form of urban regeneration is also shifting from a focus on physical space renewal to a more comprehensive compound regeneration. The process of urban regeneration can be seen, to some extent, as a multi-dimensional and multi-element space production process involving entrepreneurship, employment, and business space. As a type of micro-entrepreneurial space, invisible consumption spaces have their own value. For the city, invisible consumption spaces can significantly enhance the efficiency and value of inefficient high-rise buildings, inject new vitality into a large number of vacant buildings such as commercial-residential buildings, effectively regulate the mismatch of land use and building functions, and serve as a bottom-up innovative driving force in the revitalisation of the old city. In addition, invisible consumption spaces facilitate job creation, foster innovation, diversify consumption options, support the structural reform of urban everyday life consumption, and address the increasing demand for an improved quality of life. Some invisible consumption spaces have potential cultural value because they reflect global and local dramatic unity. Through reproduction on the Internet, they have evolved into a subcultural phenomenon.

5.2.2 The Interaction between Physical Space and Cyberspace Will Generate New Forms of Urban Space

The Internet has partially replaced the functional roles of physical space, subsequently bringing about changes in everyday lifestyles and the logic of spatial distribution, enriching the forms of consumption spaces. Online and offline consumption spaces are not mutually exclusive but have interactive, complementary, and interconnected relationships. Invisible and visible consumption spaces are not in complete competition but rather promote each other through differentiated competition to meet diverse needs. With the continuous development of ICT and the advent of the Internet of Everything, new consumption spaces represented by invisible consumption spaces will face more diverse and complex changes. They have broad development potential and offer promising prospects for research.

This article presents empirical research on the old city of Nanjing, revealing the distribution characteristics and influencing factors of invisible consumption spaces to some extent. However, the study utilises POI data from a single platform, and the accuracy, comprehensiveness, and timeliness of the data still necessitate cross-verification with multiple data sources. The research

presented in this article is just a starting point, and there is a need for further exploration in areas such as the relationship between the distribution of invisible consumption spaces and urban structural elements, horizontal comparative studies between different cities, and longitudinal studies on historical evolution.

Abstract
Sub-Saharan Africa is now experiencing rapid urban growth. Considering that buildings account for most of the world's greenhouse gas emissions, guiding such an urban development towards low carbon is vital. With such an aim, this study focuses on the case of Lusaka, the capital of Zambia, which is subject to a rigid and partially outdated urban development system and lacks a deliberate policy addressing sustainable urban growth.
This study aims to demonstrate how, in the context of Lusaka, renewable technologies can contribute towards a net zero strategic territorial development. First, a systematic review of the integration of residential rooftop solar photovoltaics (RPVs) was undertaken; second, an in-depth purposive-sampled semi-structured interview with a local expert was conducted; third, the combination between renewable technologies and urban development was explored; finally, the systematic integration of RPVs based on the following four factors was proposed: (1) site coverage, (2) floor area ratio, (3) number of storeys, and (4) dwellers' density.
Results show a range of feasible hybrid solutions for addressing Lusaka's electricity needs. Furthermore, this study demonstrated that on-site energy production can influence both horizontal and vertical dimensions of buildings of energy self-sufficient energy communities: the maximum number of storeys, the maximum number of dwellers and, consequently, the floor area ratio. This study aims to pave the way towards regulated, strategic and sustainable territorial development by illustrating an easily replicable strategy.

Keywords: Fast urbanisation; Territorial strategies; On-site energy production; Sub-Saharan Africa; Lusaka

1. Background

Cities consume three-quarters of natural resources and generate equivalent greenhouse gas (GHG) emissions (Pardo Martínez et al., 2021). Today, one of the main challenges is reducing such consumption to tackle climate change. Climate resilience, energy performances of old and new buildings, and responsive urban planning—with well-defined and structured objectives—

have been identified as significant determinants of this challenge (IEA, 2022b). While spatial planning can facilitate climate actions (Hurlimann and March, 2012), 'a larger number of environmental crises take place in countries subject to high and rapid rates of urbanisation, fast urban sprawl, urban informality and weak urban governance' (Myers, 2011), often happening in developing regions of the world.

In 2020, despite hosting one-fifth of the world's population, Africa reported the lowest carbon emissions per capita (IEA, 2022b). This favoured condition, however, did not exempt the African metropolises—currently 'the epicentre of global urbanisation' (UN/ECA, 2017)—from being affected by the rampant consequences of global climate change and from facing global[ised] cities' challenges (Bini and d'Alessandro, 2017). In the period to 2050, the African continent is indeed forecasted to face the biggest floor area expansion in the world, with its building stock reaching about 50 billion square metres, doubling its current size (IEA, 2022b). The critical condition lies in the emergence of large cities despite low national income levels, leading to difficulties in providing essential services and infrastructures (Kriticos, 2019) and amplifying the already present effects of climate change, particularly in urban areas (IEA, 2022b).

1.1 . Zambia: climate change actions towards sustainable urban development.

Zambia, among other countries in the Sub-Saharan region, has been dealing with the sustainability of urban growth for a long time. In 1994, the nation embarked on a strategy of sustainable urban expansion to address the challenges of poverty, inequality, a declining economy and the government's limited capacity to provide essential public services (Makasa et al., 2010; UN-HABITAT and UNEP, 2009); during that period, the Ministry of Local Government and Housing (MLGH) developed the National Housing Policy, which called upon the private sector and local communities to engage in the planning and execution of 'sustainable human settlement projects' (UNDP, 1997). In subsequent years, the nation implemented various programmes, engaged in several initiatives, and developed new legislation to address the complexities of rapid urbanisation (Myers, 2011; UN-HABITAT and UNEP, 2009; Musonda, 2018). In 2015, the enactment of the Urban and Regional Planning Act No. 3 was expressly designed to provide additional guidance for implementing sustainable urban and rural planning and development (MNDP, 2020). In 2016, the nation amended its constitution to incorporate sustainable development as a fundamental national principle, aligning with the objectives outlined in the 2030 Agenda (MNDP, 2020). Therefore, the formulation of the National Urbanisation Policy in 2018 was driven by the need to tackle the challenges highlighted by the United Nations Sustainable Development Goal (SDG) 11: '(a) proliferation of informal settlements, (b) absence of supportive city form and functioning system of cities, (c) weak institutional and regulatory framework for urban development' (MNDP, 2020). As such, the National Housing Policy underwent revision in 2019, and an Implementation Plan was formulated to support 'sustainable, decent and affordable housing for all' (MNDP, 2020).

Notwithstanding persistent endeavours to address climate concerns via legislative measures and policy development, Zambia remained classified as a nation particularly susceptible to climate change in 2021 (COMESA, 2021). Consequently, the government presented a climate action plan to the United Nations Framework Convention on Climate Change (UNFCCC) in 2022, aiming to adapt to climate change and mitigate greenhouse gas emissions. This plan would then aim to decrease emissions resulting from future growth, as the International Energy Agency (IEA, 2022b) reported.

Even though institutional and regulatory processes are being used to introduce SDGs (MNDP, 2020), in Zambia the diversification of the energy mix should be improved in order to deal with the effects of climate change (McPherson et al., 2018; Ismail, Metcalfe, and McPherson, 2019;

MNDP, 2020; Imasiku, 2021; IEA, 2022b; Kapole, Mudenda, and Jain, 2023), such as drought and flood cycles, which show the limits of the over-reliance on hydropower (McPherson et al., 2018; Ismail, Metcalfe, and McPherson, 2019; IEA, 2022b; Kapole, Mudenda, and Jain, 2023). In 2019, the nation's reliance on hydropower accounted for 80.6 %; other energy sources were thermal (coal-powered) at 10.1 %, heavy fuel oil at 3.6 %, solar energy at 3 %, and gas, standby gas and diesel turbines at 2.8 % (MNDP, 2020). Although the country is indeed favoured by natural potentialities being abundant in hydropower and sunlight—it has the second-highest potential for solar power in the world (UNDP, 2014)—, which leads to excellent outputs both in hydroelectric and photovoltaic (IEA, 2022b), numerous hindrances to the full adoption of renewable energies were individuated: policy and regulatory barriers, as well as technical, institutional, financial and awareness-related issues (UNDP, 2014).

1.2 . Lusaka.

Materialising the dynamics mentioned above, the province of Lusaka boasts the highest urban population growth in the country (MNDP, 2020); it is considered one of the continent's fastest-growing cities (Ismail, Metcalfe, and McPherson, 2019), 'projected to at least double between 2020 and 2050' (UN-Habitat, 2022). The city's urban growth tends to follow an extensive model, expanding through new developments on the peripheries rather than within existing areas (USAID, 2018), leading to an urban sprawl which provokes overconsumption of resources (IRP, 2018), which in turn can not be guaranteed by institutions, often relying on outdated laws (Musonda, 2018). The rigid urban development system triggered several urban challenges, further amplified by the weaknesses of urban development institutions (Chigudu, 2021), showing the evident lack of a deliberate policy addressing urbanisation challenges and accompanying sustainable urban growth (Chigudu, 2021).
In line with the Zambia Vision 2030 (RoZ, 2006), Lusaka raised its policy profile on climate change adaptation and mitigation (LCC, 2016; IEA, 2022b). The effects of climate change, however, are hitting the city: low seasonal rainfall leads to load-sheddings (periods of planned energy supply disruption) lasting numerous hours per day (Jürisoo et al., 2019; Imasiku, 2021), a situation in some cases persisting more than one year (Jürisoo et al., 2019). This phenomenon triggers the users' demand for alternative and more reliable energy technologies, independent from the national grid, often fossil fuel-based (Jürisoo et al., 2019; Kapole, Mudenda, and Jain, 2023).

2. Research hypothesis and arguments

The previous section shows the efforts of local, national and international actors to face urban and climate challenges. However, the Zambian regulatory landscape does not keep pace with the evolving built environment (Chigudu, 2021), and *business-as-usual* can not cope with existing and future challenges. Climate change-aware regulations, as supported by the National Policy on Climate Change of the Republic of Zambia, must be prioritised (RoZ, 2016).

2.1 Hypothesis

Energy challenges and urban developments are strictly linked (Castán Broto and Baker, 2017; Perera, Coccolo, and Scartezzini, 2019; Bouzarovski, 2020). The paper hypothesises that the supply of energy from renewable sources can become a parameter to control Lusaka's urban morphology for a net zero territorial development.

2.2 Arguments

The urban form, the cradle of buildings' behaviours, can be a tool to face the challenge of cities' emissions. Different types of urban settlements have been demonstrated to be drivers of spatially contextualised combinations of carbon emissions (Baiocchi et al., 2015), and the study of urban-scale development strategies must be prioritised to reach net zero (Scognamiglio, Garde, and Røstvik, 2014). The physical texture of cities, once defined, is not flexible enough to allow future changes and creates long-lasting interdependencies among land use, transport, buildings, energy demand and carbon emissions (Güneralp et al., 2017); this condition calls for an urgent 're-direction of practised planning paradigms towards more sustainable spatial development' (Stoeglehner, Niemetz, and Kettl, 2011).
At present, spatial production is strictly related to the spatial dimension of energy challenges (Castán Broto and Baker, 2017), with cities across the globe significantly influenced by energy demand (Bouzarovski, 2020) and energy demand significantly influenced by cities' forms (Perera, Coccolo, and Scartezzini, 2019).
In Zambia, a country experiencing an insufficient national energy supply (fuelled by fast horizontal urban expansion and climate change effects), energy demand is expected to increase rapidly (McPherson et al., 2018; Ismail, Metcalfe, and McPherson, 2019). In such a context, integrating renewable energy technologies during urban development becomes of primary importance. In this regard, previous literature identified fundamental parameters: Salat (2010) proved that the urban form has the potential to halve the overall energy consumption and carbon emissions, while other studies reported that urban form, the density of building and population, envelopes' technology, systems' efficiency, inhabitants' behaviour and sources of energy impact energy performances (Strømann-Andersen and Sattrup, 2011; Yang et al., 2012; Stewart and Oke, 2012; Steadman, Hamilton, and Evans, 2013; Di Bernardino et al., 2015; Salvati, Coch Roura, and Cecere, 2015; Ignatius Wong, and Jusuf, 2016; Güneralp et al., 2017; Salvati et al., 2019; Hadavi and Pasdarshahri, 2020). Moreover, urban morphology parameters, such as land coverage and average building height, are found able to anticipate the urban energy performances (Salvati et al., 2019), and the urban form is found to impact the energy system in terms of cost, system autonomy and renewable energy integration (Perera, Coccolo, and Scartezzini, 2019).
Consistently, policymaking must ensure a radical reduction in greenhouse gas emissions, considering energy-related matters at the beginning of the urban planning process (Shi, Fonseca, and Schlueter, 2017). Improving the energy mix and generation from renewable sources can be the key to closing the gap in energy deficit in Lusaka (MNDP, 2020; Imasiku, 2021). In this regard, focusing on energy demand management (Grubler et al., 2012) would shift the interest from the national scale—often focusing on the supply— to the local management (Neves and Leal, 2010), following the trajectory of an energy chain already moving in the direction of decentralised and micro-scale infrastructures (Bouzarovski, 2020), levers for managing carbon emissions (McPherson et al., 2018).

2.3 Research questions

1. Is integrating residential RPVs with an urban-scale approach feasible in Lusaka?
2. How can on-site energy production be a tool to control urban expansion in both vertical and horizontal dimensions?

3. Methodology
Seeking answers to the research questions will contribute to developing a net zero strategic territorial development. In light of the observations made by previous literature, this study will: a) investigate the supply of energy from renewable sources in terms of rooftop-solar power

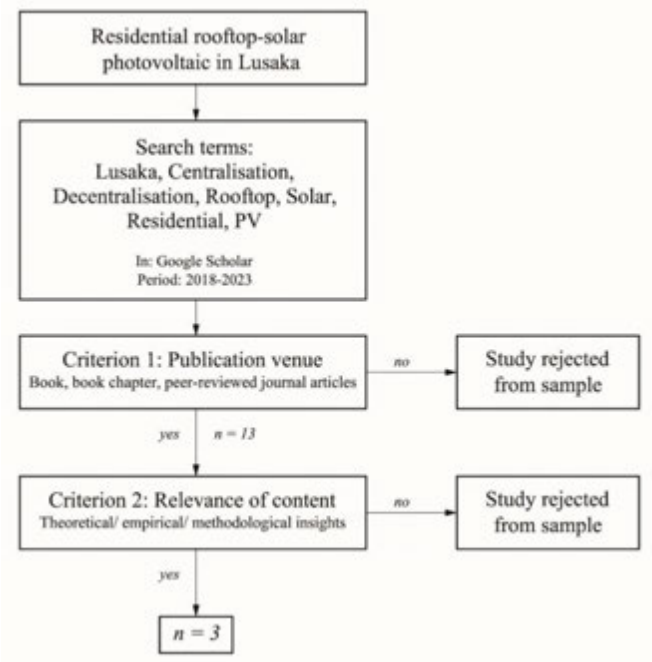
generation only; b) consider the supply of energy from renewable sources as a tool to face Lusaka's urban challenges.

This study investigates both centralised and decentralised RPV systems serving residential areas in Lusaka. Nevertheless, solar energy mini-grid systems have not been considered because of their previously verified unsustainability in the Zambian context (Stritzke and Jain, 2021; Kapole, Mudenda, and Jain, 2023). Stritzke and Jain (2021) investigated the solar mini-grids in Sinda and Mpanta, while Kapole, Mudenda, and Jain (2023) recently investigated a list of initiatives owned by both public and private institutions: Magodi mini-grid in Lundazi, Katamanda mini-grid in Chipangali, Chitandika mini-grid in Chipangali, Muhanya mini-grid in Sinda and Chibwika mini-grid in Mwinilunga. The studies observed that, although solar mini-grids are considered one of the most viable solutions to provide energy from renewables to the part of the population without access to electricity, they pose insurmountable sustainability-related limitations in the context of Zambia—in financial, environmental, and social perspectives. The public and private-owned projects were found to be financially unsustainable, especially in rural areas; in urban areas, their minimum financially sustainable residential tariff is estimated to be much above the one of the national utility ZESCO, and a lack of technical expertise hinders their implementation (Kapole, Mudenda, and Jain, 2023). The majority of the projects, however, have been defined socially—in terms of users' satisfaction and availability of electricity 24/7 (Stritzke and Jain, 2021)—and environmentally sustainable (Kapole, Mudenda, and Jain, 2023).

This premised, the study included a multiplicity of methods:

1) A systematic review (Grant and Booth, 2009) was conducted to comprehensively evaluate previous integrations of residential RPVs in Lusaka. Google Scholar was used to identify potentially relevant studies, and the terms 'Lusaka', 'PV', 'centralisation', 'decentralisation', 'rooftop', 'solar', and 'residential' were searched simultaneously. Only studies written in English from 2018 to 2023 have been selected due to the inner limitations of previous renewable technologies. The search yielded 24 works from various disciplines and venues: 12 articles, four reports, four theses, three book chapters, and one working paper. The selection was refined by including only books, book chapters and peer-reviewed journal articles, resulting in 13 pieces of work. A second refining criterion was adopted, excluding works that did not describe Lusaka's RPV strategies. Finally, the three relevant works meeting all the criteria were considered for further analysis (McPherson et al., 2018; Ismail, Metcalfe, and McPherson, 2019; Imasiku, 2021). This limited number shows an overall lack of consolidated literature on this topic.

Figure 1. Methodology adopted for the selection of articles.



2) Due to the minimal scientific work produced on the topic as of October 2023, one in-depth semi-structured interview was conducted the same month to compensate for the lack of scholarly information. The interviewee, selected by purposive sampling technique (Taherdoost, 2016) according to role and experience, was an expert in the development of renewable energy projects operating in Lusaka, holding previous experience in the development of solar projects and working for a Ministry from more than five years at the time of the interview. The interview was conducted remotely using the Google Meet tool. The respondent was requested to answer 14 open-ended questions. The interviewer encouraged free-flowing discussion; the interview lasted 1 hour and 10 minutes. Answers have been first recorded, upon explicit consent, and later transcribed. The generated transcript has been cross-checked with the recording to maintain data integrity. Finally, the RADaR technique (Watkins, 2017) was applied for qualitative data analysis.
3) Finally, the terms of combination between renewable technologies and urban development have been explored, delivering a framework for urban-integrated PV.

4. Analysis and findings

4.1 Reasons for a change

The free-flow discussion with the expert allowed the authors to gain a broad understanding. He reported that the severe load sheddings of 2014, 2015 and 2016 pushed national and international agencies not to over-rely on hydropower due to its evident limitations. Currently, the attention of the Ministry in which he operates is on the development of energy efficiency

guidelines; officials are conducting 'studies to learn how energy efficiency can be useful in urbanisation' in order to establish 'how to conserve energy at the point of use'. This understanding catalysed the authors' attention, *de facto* confirming the relevance of investigating the transitional—situated in a particular location and moment—interactions between renewable energies and urban strategies in Lusaka.

What emerged from this interview is the pivotal importance of costs and returns for the people for whom the energy systems are made: can they afford them? In this geographical and social context, future policies have to benefit everyone because 'people are part of the system as well'; in this light, activities 'to understand the social impact of grid extensions' are indeed promoted. The expert further confirmed that Lusaka is now subject to a fast increase in constructions, which follows a model of horizontal expansion moving in the direction of peri-urban areas; a higher electricity demand is consequent. Despite being 'one of the best system configurations, cost-effective', solar power generation was initially considered a non-competitive alternative due to the low tariffs of the national energy supply. 'Previously, the cost of energy was cheap, and people could afford to waste the energy. But now, as the cost of energy is slowly going up, people will be more interested in solar. We should talk about it now.' The Energy Regulation Board, in fact, lately promoted an increment of tariffs on a 5-year programme (ERB, 2023). Four incremental tariff bands are set to regulate consumption in the 'Residential' category: while the users subject to the lowest tariffs are typically not motivated to change energy sources, those subject to higher tariff bands are looking for cheaper alternatives. Accordingly, the implementation of RPVs in low-income communities would face a multiplicity of challenges—including the possibility of accessing the less expensive tariff band and the inadequacy of the building stock—; differently, middle- and high-income neighbourhoods are ideal targets for implementing RPV systems. Integrating solar power generation into users' buildings would contribute to a) demand for less energy from the national supplier and b) avoid the physical extension of the energy grid and the related challenges.

4.2 Centralisation or decentralisation in Lusaka?

Ismail, Metcalfe, and McPherson (2019) evaluated the feasibility of centralised and decentralised (both on-grid without battery-storage components and off-grid with battery-storage components) solar power generation, estimating the urban rooftop potential in Lusaka and rural Zambia, to address Zambia's electricity deficit 'attributable to climate disturbances and the nation's rapidly increasing electricity demand' (Ismail, Metcalfe, and McPherson, 2019). The study found that centralised solar generation can produce generation/cost ratios comparable with existing hydro generation ratios. In Lusaka, the study showed that a fully decentralised approach would be much more costly than the existing rate. Several hybrid generation scenarios were thus investigated, with the 70 % centralised and 30 % off-grid decentralised scenario best addressing the electricity shortages until 2030. In such a scenario, solar energy would provide affordable power and fast planning/implementation while offering autonomy to users. The study further highlighted the importance of collaboration between local and national institutions to develop long-term renewable energy legislation (Ismail, Metcalfe, and McPherson, 2019). McPherson et al. (2018) also showed that up to 50 % of total electricity demand could be met by decentralised solar photovoltaics—20 % more than what was found by Ismail, Metcalfe, and McPherson (2019)—if the energy generated is directly used. In this hybrid process, the system's low transmission expansion cost would outweigh the high storage costs (McPherson et al., 2018).

Imasiku (2021) tested the applicability of solar photovoltaic performance for grid-connected households in Lusaka (on-grid decentralised approach with battery-storage components). This hybrid model was demonstrated to alleviate the power load sheddings, meeting the demand

when hydroelectric could not, with users able to sell the excess power to the utility (configuration of a power purchase agreement). A two-bedroom house was considered for the load sizing, and the system included one residential RPV module of 1.6m^2 (China Sunergy-Nanjing CSUN285-60M), one inverter (Jiangyin HR-240P-AC/BbP)—both with low efficiency, chosen to mirror the availability on the Zambian market—and a storage battery connected to the direct current. Technical information on the model design (system design, losses, technical characteristics of photovoltaic module and inverter, system cost, etc.) is not relevant to the purpose of this study. Finally, Imasiku (2021) demonstrated that the two-bedroom household's nominal peak-hour energy consumption for middle-income earners in Zambia could be successfully met by on-site energy generation.
In summary, the feasibility of both centralised and decentralised (on-grid with/without batteries, off-grid) RPV energy generation in Lusaka was evaluated, showing that:

a) Hybrid solutions best address the need for electricity. The 70 % centralised and 30 % off-grid decentralised (with battery-storage components) scenario is the most favoured regarding costs and planning/implementation feasibility. The off-grid component was observed to be feasible up to 50 % if the solar power is directly supplied.
b) On-grid decentralised systems (with battery-storage components and commercial low-efficiency inverters and modules) have been demonstrated to meet the supply, allowing users to sell the energy surplus to the utility grid.
c) The interviewed expert confirmed that one system can not be chosen *a priori* over the other one. In the case of households using electricity only during the daytime, for example, a storage battery would not be necessary because of direct consumption. A battery would be necessary if a relevant percentage of the activities were to be operated at night. Operations to test the average loads would be thus needed before a realistic choice.

This study provided thus a range of feasible alternatives. It is important to note that the complex modelling of individual connections would have gone beyond the scope of the study, which is instead interested in understanding the feasibility of integrating residential PV with an urban scale approach.

4.3 Self-sustaining urbanisation: an approach towards net zero.

While the range of feasible renewable technology alternatives was investigated and reported in sections 4.1 and 4.2, the terms of combination with the urban development are presented below. Urban form factors have been previously recognised to have a pivotal role in urban planning and renewable energy integration and will thus be considered in this study section. The relevance of the urban form factors used in Perera, Coccolo, and Scartezzini (2019)—which investigated the influence of urban form on the grid integration of renewable energy technologies and energy systems design—has been cross-checked with other consolidated studies (Ratti, Baker, and Steemers, 2005; Salat, 2010; Strømann-Andersen and Sattrup, 2011; Yang et al., 2011; Stewart and Oke, 2012; Steadman, Hamilton, and Evans, 2013; Di Bernardino et al., 2015; Salvati, Coch Roura, and Cecere, 2015; Ignatius, Wong, and Jusuf, 2016; Güneralp et al., 2017; Salvati et al., 2019; Hadavi and Pasdarshahri, 2020; Ahmadian et al., 2021); the factors considered were: the Ground Floor Area [m^2], the number of storeys, the Treated Floor Area [m^2], the Sky View Factor (SVF), the Floor Area Ratio (FAR), the Site Coverage [%] and the Form Factor (FF). However,

a) a low-rise horizontal expansion characterises the context of Lusaka; for this reason, the authors evaluated the inclusion of the Sky View Factor as unnecessary for this study;

b) both the Treated Floor Area and the Form Factor are related to the thermal envelope (Perera, Coccolo, and Scartezzini, 2019), of which the investigation would go beyond the scope of the study;
c) in the cross-checked studies, particular importance was given to the density of people living in a given space, which is strictly related to land use and land surface; this factor has thus been considered in this study.

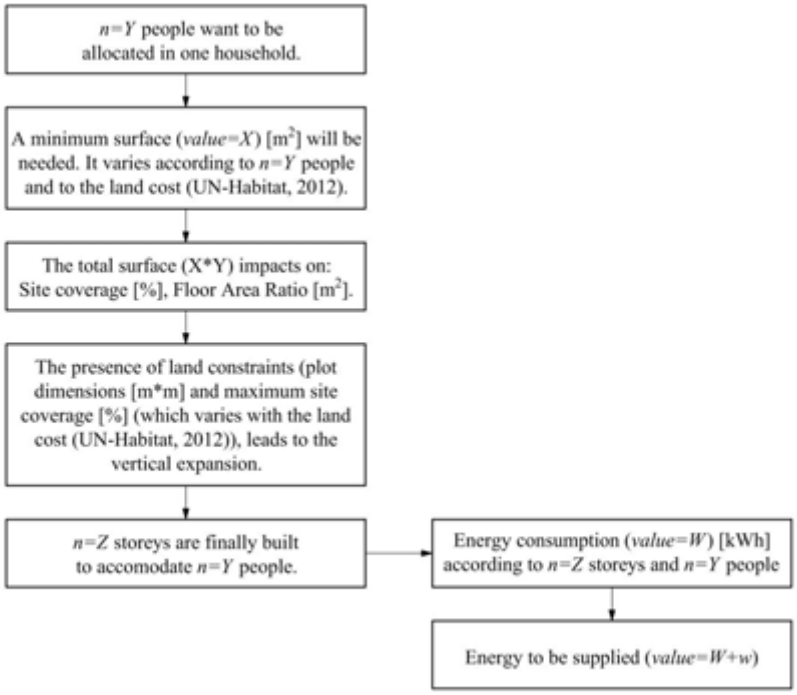
From an urban planning perspective, the following factors have been considered: Site Coverage [%], Floor Area Ratio (FAR), number of storeys, and dwellers' density. Regulations and standards related to:

i) land use and cost, plot size, site coverage, distances from boundaries and ratio area/population can be found in UN-Habitat (2012) and Chitengi (2015);
ii) the size of windows and habitable rooms can be found in the Public Health Act (GoZ, 1995);
iii) the height of buildings can be found in the Urban and Regional Planning Act, n. 3 of 2015 (GoZ, 2015);
iv) the installation of solar panels on buildings can be found in the Urban and Regional Planning Act, n. 3 of 2015 (GoZ, 2015), and on ERB website (2023).

4.4 Conceptualisation

Urban expansion, driven by housing demand, is here investigated in terms of horizontal and vertical growth, considering dimensional factors. Horizontal growth adds more ground floor space and directly relates to site coverage; vertical growth, in contrast, maintains the same ground floor space and site coverage but increases the number of storeys and the floor area ratio (Perera, Coccolo, and Scartezzini, 2019). These factors behave as variables, varying with the number of dwellers (constant) by following the minimum standards in the Public Health Act (GoZ, 1995). Finally, urban form and human behaviours lead to a specific energy consumption, which consequently suggests the amount of energy that should be supplied (Figure 2).

Figure 2. Logic representation of the process.



4.5 Upside-down perspective

This study aims to understand if on-site energy production can be a parameter to control and moderate urban expansion. The authors thus investigated the on-site energy generation as a constraint for horizontal and vertical expansion by capping the maximum energy consumption by a building to the maximum amount of energy produced. By a domino effect, this essential constraint can influence all the previously considered urban factors (Figure 3). Finally, the maximum on-site energy production could influence the maximum number of storeys, the maximum number of dwellers and, consequently, the floor area ratio. This approach shows how the number of storeys and the allowed floor area ratio increase by raising the maximum on-site energy production. The novelty of this system lies in relating often unrelated metrics towards a regulated and strategic territorial development.

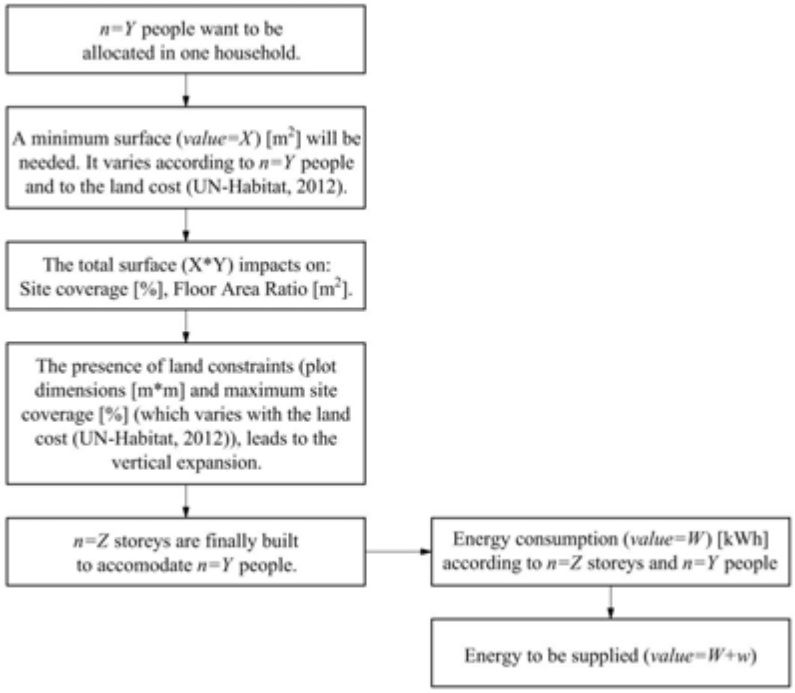


Figure 3. Theoretical prototype for urban-integrated photovoltaics.

4. Impact, significance and outputs

Can the current Zambian building regulatory landscape answer urban and climate challenges? Chigudu (2021) was critical: the rigid urban development system triggered over time several urban challenges, showing the evident lack of a deliberate policy addressing urbanisation challenges and accompanying sustainable urban growth; climate change-aware regulations, as supported by the National Policy on Climate Change of the Republic of Zambia, must be now prioritised (RoZ, 2016).

This study aimed not only at demonstrating that the implementation of renewable technologies can become a tool towards the development of urban strategies in the context of Lusaka but also at moving attention to the possibility of using the already ongoing horizontal expansion as the cradle for its own change (as explored in Fiacco and Talamini, 2021). The originally unfavoured condition was overturned: the fast horizontal expansion did not represent just an urban challenge but was exploited to ensure energetic independence for new urban developments. If applied at a large scale, this approach would address both urban and energy challenges by moderating horizontal and vertical growth through clean energy production. This urban-driven energy transition would limit the exposure to the risks deriving from fast urban development and climate change, further contributing to the development of pathways not yet investigated. The study demonstrated that the maximum on-site energy production can influence the maximum number of storeys, the maximum number of dwellers and, consequently, the floor area ratio; the on-site energy production could be linked to vertical and

horizontal growth. The novelty of this approach was indeed in the innovative relating of metrics and indicators towards a regulated and strategic territorial development.
This process can a) stimulate both private and public sector to invest in on-site energy generation, especially when in connection with residential land use, paid back by the increase in FAR, with the consequent possibility to build a higher number of units and allocate a higher number of dwellers; b) relieve the national energy utility, guaranteeing supply independence to users; c) represent a reference for a future easily-replicable self-sustaining urbanisation, avoiding a blind urban development leading to energy-hungry verticalism or horizontally hyper-extended and not well-managed spaces, which would ultimately risk becoming unlivable (Lall et al., 2021).
Urban scale strategies can only be pursued through policies that incentivise the systematic integration of renewable energy sources in new constructions, raising awareness among users and providing financial incentives and support (Ismail, Metcalfe, and McPherson, 2019). Bharwani et al. (2023) explained that locally-led and sustainable urban planning can be reached by supporting the diverse stakeholders (such as city councils and local universities) to co-create priorities, goals and knowledge around specific projects, considering the lived experience of local people alongside scientific inputs. A shift from 'government' to 'governance' (Scott, 2017) is necessary, where urban governance is meant as the 'multiple ways through which city governments, business, residents, and civil society organisations interact in managing the urban space' (Scott, 2017).

Research on Strategies for Enhancing Urban Spatial Resilience in Shanghai Based on the Connotations and Characteristics of "Resilient Cities"

Qiang YAO [1]; Na AN [1], * and Qingji SHEN [1]

Affiliation: 1. College of Architecture and Urban Planning Tongji University, Shanghai 200092, China
Email: yaoqiang@tongji.edu.cn (Y.Q.); anna2010255@tongji.edu.cn (A.N.); sqjj5688@126.com (S.Q.)

Abstract: This paper explores the enhancement strategies for urban spatial resilience in Shanghai by defining, interpreting, and identifying the characteristics of "urban spatial resilience." Firstly, it analyses the relationship between resilient cities and urban spatial resilience. Secondly, it examines the systemic composition, organisational methods, and representation of resilient cities, revealing three essential contents—hierarchical structures, resilience mechanisms, and resilience representations—and four fundamental characteristics (13 attributes): capacity, structure, mechanism, and representation. Thirdly, it reviews the urban spatial planning, spatial expansion changes, and urban compactness variations in Shanghai since 1985. Finally, the paper identifies current issues in Shanghai's urban spatial development and proposes strategies to enhance its urban spatial resilience.

Keywords: Resilient Cities, Spatial Resilience, Shanghai, Construction Principles, Enhancement Strategies

1. Introduction

Urban areas today face many crises and challenges, including global warming, increased extreme weather events, and urban flooding, which render urban systems vulnerable and susceptible to disturbances. Since the inception of the "resilient city" concept, it has emerged as a new paradigm for addressing urban risks and uncertainties, garnering sustained interest from both the academic and political realms (Sharifi, 2019). Resilience thinking posits that cities are self-regulating complex systems (Holling et al., 2002), with resilient cities serving as tools to cope with uncertainty. Constructing resilient cities or enhancing urban resilience has become crucial for cities to face various challenges and achieve long-term sustainable development (UNDRR, 2013). This understanding has gradually evolved into a global consensus. The theory of resilient cities views urban areas as open, complex mega-systems, offering significant scientific guidance for urban planning and construction practices aimed at protecting the lives and properties of residents and enhancing urban functionality.

Since 2016, Shanghai has issued a series of policy documents aimed at enhancing urban spatial resilience, such as the "RISE" Vision Goals Framework for Shanghai's Urban Development over the Next 30 Years (2016), the Shanghai City Master Plan (2017-2035) (2018), and the Shanghai Urban Operation and Safety Development Report (2019-2020) Blue Book (2021). These documents repeatedly emphasise the importance of strengthening resilient city construction and achieving compact urban development and propose that by 2035, Shanghai will be fundamentally established as a "resilient city" capable of addressing various developmental risks and swiftly recovering from them. To counter issues such as continuous urban sprawl, population concentration in central urban areas, and the slow development of new cities, Shanghai advocates for a compact metropolitan spatial pattern and a transition from extensive expansion to baseline constraint and intrinsic development (Shaobo et al., 2019). Thus, constructing resilient cities and enhancing urban spatial resilience are among the critical planning objectives for current urban development in Shanghai.

Urban spatial resilience has emerged within the development and evolution of resilience, resilient cities, and urban resilience. Therefore, it is necessary to delineate and clarify the relationships among resilience, resilient cities, urban resilience, and urban spatial resilience. This paper is based on analysing the concepts, contents, and characteristics of resilience, resilient cities, urban resilience, and urban spatial resilience. It proposes a theoretical model for urban spatial resilience and examines the development trajectory, current issues, construction principles, and urban spatial resilience enhancement strategies in Shanghai. The research conclusions presented here are intended to deepen the understanding of urban spatial resilience among city managers and researchers. This deeper understanding facilitates a more thorough grasp of the concepts, contents, and characteristics essential for building resilient cities, providing valuable insights and references for urban development strategies.

2. Definitions, Connotations, and Characteristics of Resilient Cities

2.1 The Concept and Evolution of Resilient Cities

The concept of "resilience" has been extensively applied across multiple disciplinary fields such as engineering, psychology, disaster studies, economics, management, social sciences, and environmental science. Although descriptions of "resilience" vary among disciplines, they all emphasise its characteristics related to absorption, resistance, maintenance, self-organisation, adaptation, learning, and transformation. Following the perspective of Professor Shen Qingji, this paper defines "resilience" as the capacity of a system to maintain or restore its necessary functions in the face of disturbances, adapt to changes, and swiftly transform when its adaptive capacity is constrained.

Similar to other fields, the concepts of "Urban Resilience" and "Resilient City" emerged when applied to urban systems. The term "Resilient City" was first introduced by Local Governments for Sustainability (ICLEI) during the 2002 United Nations Summit on Sustainable Development. It emphasised a systemic construction process combining material aspects such as engineering improvements and facility enhancements with social dimensions, including public participation and institutional innovation, to enhance the overall resilience of urban systems. While there is no unified definition of a resilient city within the academic community to date, there is a consensus on its connotation and value: a resilient city possesses diverse disaster adaptation capabilities. Research varies from focusing on urban stability reconfiguration under environmental impacts, highlighting the rapid adaptive system characteristics of cities, to emphasising the adaptive capacity of cities and their residents to risks, yet all converge on the core notions of "stability," "resistance," and "adaptability." By analysing the interrelations among resilience, resilient cities, urban resilience, and urban spatial resilience, this paper further explicates the definition of a resilient city as a type of advanced urban form that possesses strong adaptive and learning capacities, effectively responds to significant urban disturbances such as climate change threats, ecological issues, public health incidents within a particular spatiotemporal scope, promptly restores structural and functional stability, and continues to evolve beneficially.

This paper classifies international research on resilient cities into four stages: nascent, initial, rapid, and reflection continued development (Figure 1). From the perspective of evolutionary trends, early research on resilient cities focused on human psychological resilience and ecosystem resilience, gradually transitioning to diverse studies targeting different components and processes within urban socio-ecological systems. The scope of the inquiry has shifted from

initially addressing common natural disasters and risks to increasingly dealing with emerging urban environmental and social issues, as well as derivative problems, thereby deepening integration with the discipline of urban planning.

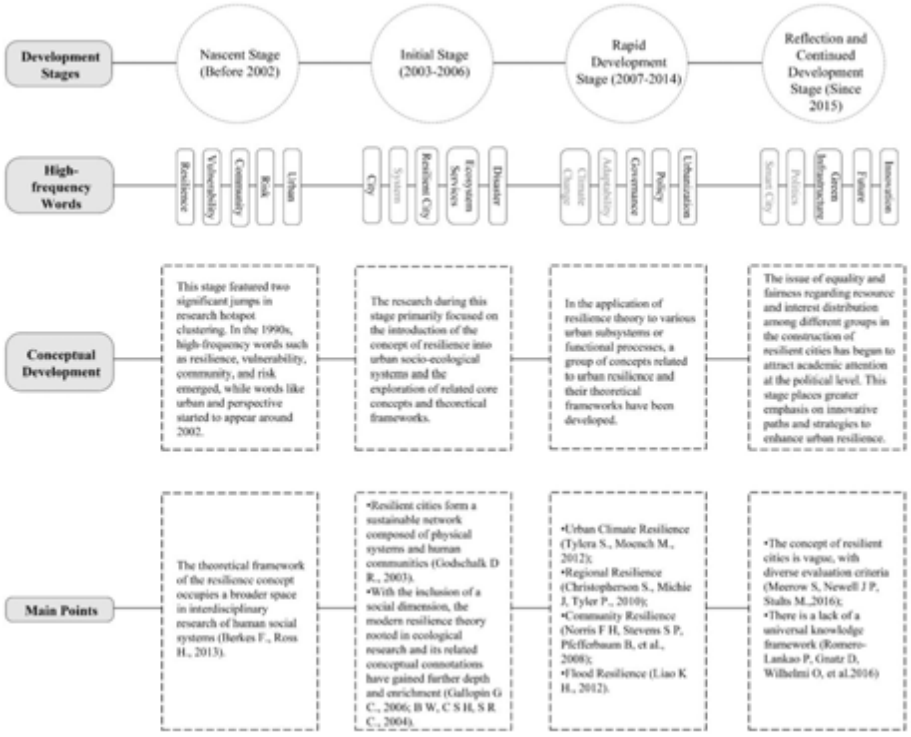

Figure 1: Evolutionary Stages of the "Resilient City" Concept

2.2 The Connotations of Resilient Cities

Based on an examination and analysis of the existing literature on "resilience," "urban resilience," and "resilient cities," this paper categorises the intrinsic connotations of resilient cities into three core components: hierarchical structures, resilience mechanisms, and resilience representations, covering the systemic composition, organisational methods, and representational forms of resilient cities (Figure 2).

Figure 2: Diagrammatic Representation of the Information Structure of Resilient Cities

(1) **Hierarchical Structure:** Refers to the stable structure formed by resilient cities' subsystems, system levels, and system elements under specific mechanisms. It represents resilient cities as complex systems.

(2) **Resilience Mechanisms:** Historical experiences indicate that urban development is long influenced and constrained by natural environments and human will, gradually evolving capabilities that maintain urban functions and structures and foster benign urban development. These capabilities are manifest in adaptive and learning abilities. The operational mechanisms of resilient cities serve as the analytical basis for examining the logical connections between their hierarchical structures and resilience representations. In integrating urban components and influencing factors, four resilience mechanisms have emerged to maintain urban structural stability—stability, sensitivity, resistance, and recovery—based on the two capability features (system organisational rules).

(3) **Resilience Representations**: From a psychological perspective, representation refers to the method by which segments of world information stored in the human mind are depicted or described, as well as how objects exist within individual psychology. Representation theory elucidates the connections between the representational information of objects and their physical or non-physical forms, linking information with people's perceptions of specific objects or events (Distin, 2005).

The representational forms of "resilient cities" are meant to express their intrinsic meanings, consisting of tangible and intangible urban characteristics. This study categorises the core connotations of "resilient cities" into four aspects based on urban components' material and non-material properties: urban spatial resilience, urban ecological resilience, urban social resilience, and urban economic resilience. These four cores are represented in different cities in varying proportions, resulting in distinctive, resilient city representations, including healthy, safe, resilient, low-carbon, ecological, and innovative resilient cities. Due to resilience

mechanisms being inherent attributes of all types of resilient cities, it is recommended to use "urban scale," "urban structure," "urban elements," and "resilience representations" as criteria for analysing city types. The classification of resilient city types should be based on assessments of their "complexity" and "connotative representations," and these criteria should be used in case studies to determine the specific type of resilient city.

(1) Based on evaluations of urban hierarchy, connectivity, and the number and types of urban elements, definitions of resilient city complexity are delineated as "ultra-high complexity (C1), high complexity (C2), medium complexity (C3), and low complexity (C4)."

(2) An evaluation system for resilient cities covering spatial resilience, ecological resilience, social resilience, and economic resilience is established. Definitions for the representational forms of resilient cities, such as health resilience, safety resilience, low-carbon resilience, ecological resilience, and intelligent resilience, are derived based on evaluation scores. In case studies, the most representative form of resilience representation can be selected as a keyword to determine the specific type of a city.

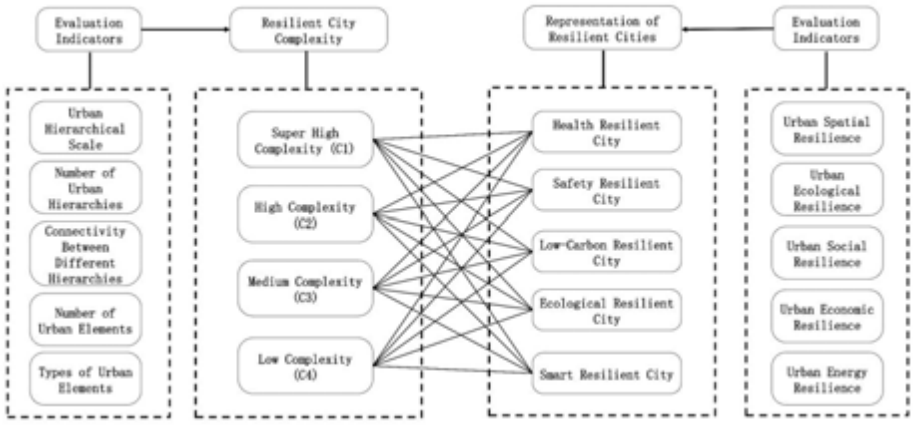

Figure 3: Classification of Resilient Cities

As shown in Figure 3, based on the results of evaluating the "complexity" and "connotative representations" of resilient cities in case studies, a combination of keywords from both categories yields 20 types of resilient cities across 4 complexity levels and 5 representational forms:

2.3 Characteristics of Resilient Cities

The characteristics of resilient cities are an extended expression of their concept and core connotations. This paper categorises the characteristics of resilient cities into four types with thirteen essential attributes (Table 1): capability characteristics, structural characteristics, mechanism characteristics, and representational characteristics.

(1) Capability Characteristics of resilient cities include adaptability and learning ability, which are the fundamental reasons behind the formation of resilience mechanisms in resilient cities.

(2) Structural and Elemental Characteristics refer to the system hierarchical structures formed under the influence of resilience mechanisms and the type and number of constituent elements of resilient cities.

(3) Mechanism Characteristics comprise stability, sensitivity, resistance, recovery, and resource redundancy. These are the system mechanisms that maintain resilient cities' functional and structural stability.

(4) Representational Characteristics include health resilience, safety resilience, low-carbon resilience, ecological resilience, and intelligent resilience. These human cognitive expressions abstract the capabilities, structures, and mechanisms of resilient cities into the most representative features.

Table 1: Classification and Analysis of Resilient City Characteristics

Characteristic Type	Characteristic Name	Characteristic Analysis
Capability Characteristics	Adaptive capacity Learning Ability	Based on historical experience, it is known that urban development is long influenced and constrained by natural environments and human will, gradually generating the ability to maintain urban functions and structures and promote benign urban development. It manifests as two capability characteristics: adaptability and learning ability.
Structural Characteristics	Hierarchical Features Elemental Features	As complex systems, cities' structural characteristics are inherent reflections of their functions and operational mechanisms. The structural features of resilient cities demonstrate the tangible or intangible urban hierarchical structures formed under the influence of resilience mechanisms, reflecting the core connotations of urban space, ecology, society, and economy and their energy and material flow characteristics.
Mechanism Characteristics	Stability Sensitivity Resistance Recovery	The operational mechanisms of resilient cities serve as the analytical basis for examining the logical connections between their hierarchical structures and resilience representations. Based on the two capability features in the integration process of urban components and influencing factors, four resilience mechanisms have emerged to maintain urban structural stability: stability, sensitivity, resistance, and recovery.
Representational Characteristics	Health Resilience	Representation theory elucidates the connections between the representational information of objects and their physical or non-physical forms, linking information with people's perceptions of specific objects or events (Distin, 2005). The representational characteristics of resilient cities are meant to express their most representative and abstracted urban features clearly.

3. Developing a Theoretical Model of Urban Spatial Resilience Based on the Connotations and Characteristics of Resilient Cities

Incorporating the definitions, connotations, and characteristics of resilience, resilient cities, urban resilience, and urban spatial resilience, this paper constructs a theoretical model for urban spatial resilience.

3.1 Urban Resilience and Urban Spatial Resilience

Urban "resilience" constitutes the core connotation of "resilient cities." Research from various countries indicates that the core information of urban "resilience" includes the constituent elements under hierarchical states, the reduction (or resistance) of disaster types, and the maintenance (or restoration) of a stable state, as well as adaptability to uncertain urban issues. Based on these core elements of urban "resilience" (Figure 4), this paper defines urban "resilience" from the perspectives of resilience capacity and system structure. Urban "resilience" is described as an inherent property of the city, manifested through a hierarchical structure organised from the bottom up by urban components. It exhibits stable characteristics that enable the city to maintain stability through rapid response capabilities, recovery capabilities in the event of sudden incidents, defence capabilities against similar events, and adaptability (or optimisation) capabilities.

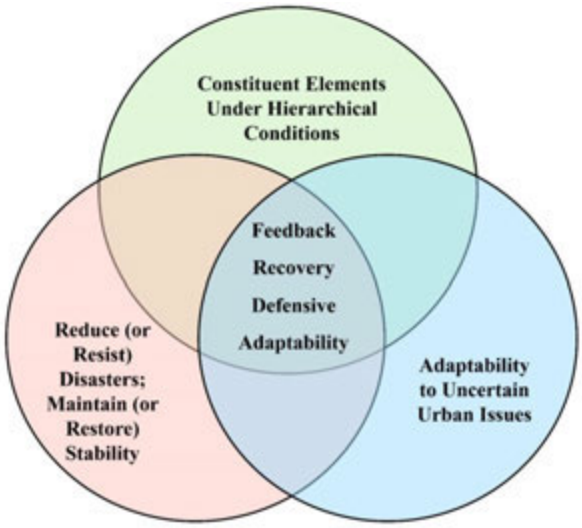

Figure 4: Core Information on Urban "Resilience"

This paper interprets urban spatial resilience as a subset of urban resilience, emphasising the state of resilience within the spatial dimension. The principal subject of the urban spatial resilience concept is urban space, with a focus on spatial attributes, representing the capacity for continuous development and operation of the urban spatial system. This capacity includes the ability to withstand disaster risks, absorb external shocks, and quickly recover essential functions. Resilient urban spaces can help maintain the integrity of urban system functionalities.

Urban spatial resilience is characterised by integrating the three elements of urban space: "scale, density, and form." Urban scale is evaluated based on ecological infrastructure and landscape safety patterns; urban density is assessed through ecological footprint and carrying capacity evaluations; urban form is measured using the "source-sink" landscape mean distance index (Xiu et al., 2018). Enhancing urban spatial resilience involves establishing redundant critical infrastructures, stable open spatial patterns, and modular, scalable spatial units across macro, meso, and micro urban scales to ensure sustainable urban development. Numerous researchers have explored urban spatial resilience from various perspectives. For instance, Liu (2014) defined "resilience planning" as the coordinated integration of rigid and flexible planning to maximise planning efficacy and defined morphological resilience as the characteristic of a spatial form that can sustain spatial development goals while fully accommodating diverse spatial usage demands (K. Liu, 2014). "Morphological resilience" planning techniques determine the material spatial elements that need rigid control according to spatial planning goals, using these rigid elements as the essential components of the spatial structure. Applying open, modular resilience planning techniques constructs an overall spatial structure closely linked with the spatial connotations of urban resilience. Famous urban models such as organic evacuation, cluster, and grid cities exemplify spatial resilience, characterised by stable, open spatial frameworks and modular, scalable spatial units. Xiu, Wei, and Wang (2018) developed a three-dimensional urban resilience research framework based on "scale—density—form" with clear spatial connotations (Xiu et al., 2018). In this framework, urban scale is evaluated based on ecological infrastructure and urban landscape safety patterns; urban density is assessed through ecological footprint and carrying capacity; urban form is evaluated using the "source-sink" landscape mean distance index. Shi (2016), using Shanghai as an example, explored the spatial requirements for enhancing resilience in mega-cities: (1) ensuring a safety baseline with life circles as the basic unit; (2) building disaster prevention systems with urban clusters as network groups; (3) coordinating the overall disaster prevention layout within the municipal area; (4) establishing regional strategic cooperation platforms (Shi, 2016).

This paper proposes that understanding urban spatial resilience should be approached from three critical perspectives:

(1) Transformation of Urban Spatial Resilience into Spatial Resilience Features: It is suggested to cognise and express "urban spatial resilience" as "spatial resilience features". It can be achieved by adopting a series of landscape indices from landscape ecology and representing the spatial resilience of different urban areas through a "Resilience Spatial Distribution Map".

(2) Relationship between Urban Spatial Resilience and Environmental Factors: Urban spatial resilience is closely linked to the natural environment, geological setting, hydrological conditions, wind environment, built environment, and spatial infrastructure factors of the city's location. Urban spatial resilience can be enhanced by expanding the spatial area under consideration.

(3) In-depth and Multi-dimensional Analysis of Urban Spatial Resilience: Efforts should be made to conduct a thorough and multifaceted analysis of urban spatial resilience. It could involve dividing urban areas into resilient and non-resilient spaces, resilient and non-resilient functions, and resilient and non-resilient structures.

3.2 Resilience" Theoretical Model

Based on the definition of "resilience," this paper establishes a "resilience" theoretical model based on its core information (Figure 5). The model specifies and describes the essential elements, operational characteristics, core information, and operational rules of the "resilience" theoretical model.

(1) Basic Elements: Includes both material entities and abstract objects.

(2) Operational Characteristics (Constraints): The "resilience" model is characterised by seven features during operation: "absorption," "resistance," "maintenance," "self-organisation," "adaptation," "learning," and "transformation."

(3) Core Information: The seven operational characteristics are simplified and categorised into four types of information, namely "recovery capability," "maintenance capability," "adaptability," and "transformation capability."

(4) Operational Rules (Also Known as Principles): These rules dictate how combinations of essential elements can form connections that represent the operational characteristics and core information of "resilience."

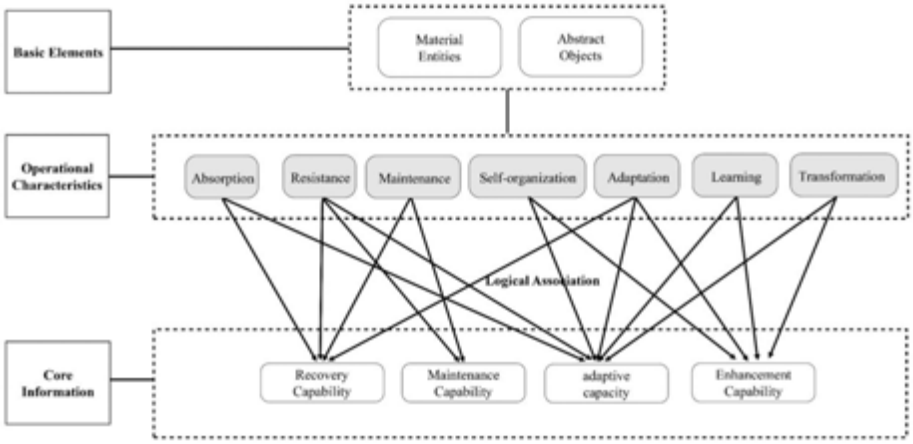

Figure 5: Theoretical Model of "Resilience"

3.3 Theoretical Model of Urban Spatial Resilience

Resilient cities are complex dynamic systems where closely interconnected subsystems create complex interactions that reflect the city’s political, economic, and social relationships. Therefore, resilient cities can be analysed through the relationships among subsystems and system elements (Yang M. et al., 2016; Zhou & Yuan, 2017). The urban spatial structure manifests the results of interactions among hierarchical structures, functions, and elements.

This study initially categorises urban spatial resilience into three systemic levels: macro, meso, and micro. Based on the physical and non-physical scale of system constituent elements, the meso and micro levels can be further subdivided, resulting in a hierarchical structure of single macro, multiple meso, and multiple micro levels (Figure 6).

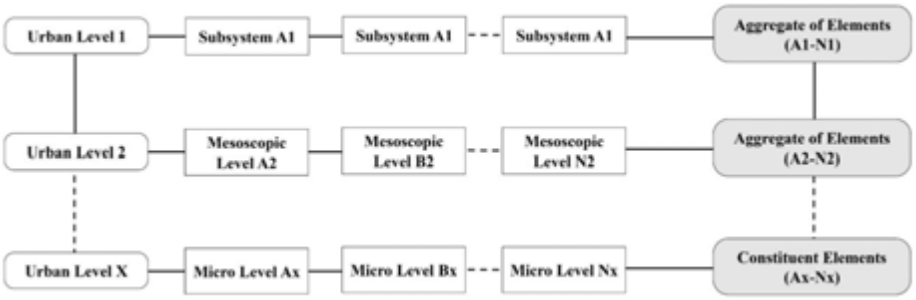

Figure 6: Schematic of Urban Spatial Hierarchical Structure

Based on the "resilience" theoretical model and the connotations and characteristics of resilient cities, this paper further proposes a theoretical model of "urban spatial resilience" (Figure 7). This model comprises operational mechanisms, influencing factors, hierarchical structures, organisational rules, intrinsic connotations and representational forms, and system capabilities.

(1) Operating Mechanisms: Adaptability and learning ability are the core operating mechanisms for urban spatial resilience. Individual cities and urban clusters optimise and reorganise their spatial resilience systems spontaneously by adapting to and learning from the impacts affecting their urban spatial resilience.

(2) Influencing Factors: These include a variety of factors such as the urban ecological environment, socio-economic factors, urban transportation, and land use. The operating mechanisms of the urban spatial resilience system are generated through adaptation to and learning from these factors affecting urban resilience spaces.

(3) Hierarchical Structure: The material and non-material essential components of cities form a stable hierarchical structure under the influence of two resilience mechanisms. From both physical and logical scales, this involves organising resilience components of urban spaces from the bottom up, forming a hierarchical structure with resilience and stability characteristics consisting of a single macro-level, multiple subsystems, multiple meso-levels, and multiple micro-levels, with individual forms varying based on specific case studies.

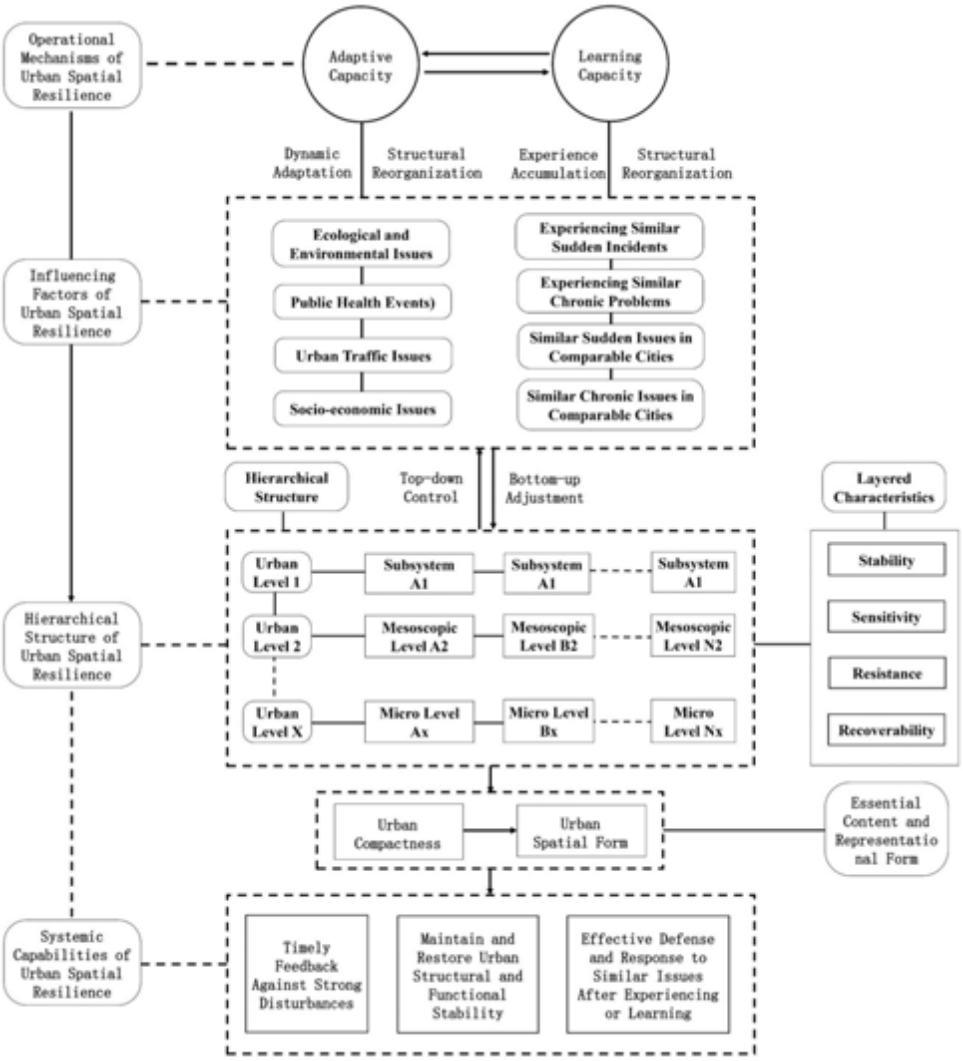

Figure 7: Theoretical Model of Urban Spatial Resilience

(4) Organisational Rules: Stability, sensitivity, resistance, and recovery serve as the organisational rules for urban spatial resilience at different hierarchical levels, forming a relatively stable structure at the system-wide level that can achieve and maintain specific functions. This stable structure can be continuously optimised through adaptation and learning concerning the types, quantities, and connections of the elements composing the different levels of urban spatial resilience.

(5) Intrinsic Connotations and Representational Forms: Urban compactness is the intrinsic connotation of urban spatial resilience, involving the economical and intensive use of land

resources, centralised layout of urban functional elements, enhanced management of urban spatial growth, promotion of high density and mixed-use of urban land, and strengthened urban planning management. The representational form of urban compactness is the urban spatial form.

(6) System Capabilities: Based on the influencing factors of urban spatial resilience, the operating mechanisms effectively organise the hierarchical structure of urban spatial resilience, fostering the generation of three system capability features of urban spatial resilience: "timely feedback against strong disturbances," "maintenance and recovery of urban structure and functional stability," and "effective defence and response to similar issues after experiencing or learning."

4. Shanghai Urban Spatial Resilience: Development Trajectory, Current Issues, and Enhancement Strategies

4.1 Urban Spatial Planning in Shanghai Since 1985

Shanghai's urban planning can be traced back to the "Greater Shanghai Plan" of 1929 (Figure 8), inspired by Ebenezer Howard's "Garden Cities of To-morrow" (1902). This plan employed a grid layout and designated a city centre in Yangpu district, encompassing government buildings, museums, and other public amenities. Although the onset of war in 1937 halted its implementation, this plan laid the foundational principles for subsequent urban planning (MacPherson, 1990). Post-war, multiple master plans were drafted, notably in 1946 and 1956, emphasising industrial development and population decentralisation to alleviate congestion in the central areas(Shanghai Local Chronicles Office, 2003). After the establishment of the People's Republic of China, Shanghai's planning ideology transitioned into the era of Soviet Planning Theory, focusing on industrial orientation and residential environment improvements (Soviet Planning Theory 1949-1958 · Shanghai: Urban Design and Planning, 2024). The 1959 plan significantly expanded Shanghai's administrative boundaries and envisioned transforming Shanghai into a leading beautiful city (Shanghai Urban Master Plan 1959 Edition, 2024). From 1984 onwards, Shanghai pivoted towards becoming a multifunctional economic hub. The 1986 plan further solidified Shanghai's status as a major international metropolis (The State Council’s Response to the Master Urban Planning Scheme for Shanghai, 1986). The plans from 1999 to 2001 established an urban spatial structure that facilitated harmonious development across various urban levels. The latest master plan (2017-2035) projects a longer-term vision, aiming to position Shanghai as a globally influential centre of technological innovation and a modernised international metropolis by 2035, introducing a spatial configuration of "one core, two axes, four wings; multiple corridors, multiple cores, multiple circles".

Figure 8 History of urban planning development in Shanghai

4.2 Urban Spatial Expansion in Shanghai Since 1985

To further analyse the urban spatial expansion of Shanghai since 1985, this study leverages data from (J. Yang & Huang, 2021), which utilises 335,709 Landsat images available on the Google Earth Engine. The methodology involves collecting training samples by combining stable samples extracted from the China Land Use/Cover Dataset (CLUD) with visual interpretation samples from satellite time series data, Google Earth, and Google Maps. The study employs multiple temporal indicators constructed from all available Landsat data, which are then input into a random forest classifier to obtain classification results, culminating in creating the China Annual Land Cover Dataset (CLCD) from 1985 onwards.

The results indicate that from 1985 to 2022, Shanghai's urban expansion predominantly exhibited a pattern of central aggregation and peripheral dispersion (Figure 9). This pattern reflects that the city's development extended beyond merely refilling old urban areas, expanding into peripheral regions and new districts. From 1985 to 1990, urban expansion was primarily concentrated in the city centre with minimal outlying growth. During this period, development focused on maximising the use of internal space and reconstructing key areas to accommodate the city's growing population and economic demands. Between 1990 and 2000, as the economy rapidly developed and urban policies adjusted, Shanghai's urban expansion began transitioning from the city centre to peripheral areas. The construction of major transport routes and new development zones catalysed swift expansion at the city's edges. After 2000, urban expansion entered a new peak period, reaching a nearly 40-year high, with the city centre area almost entirely urbanised. This trend continued until 2015. After 2015, urban growth began to slow, with expansion shifting towards suburbs and emerging satellite towns, characterised by "finger-like" growth patterns along major roadways and transit lines. By 2020, Shanghai's urban spatial expansion significantly slowed, indicating a transition into a more mature and stable development phase. The new urban development strategy emphasises ecological protection and sustainable development, aiming to improve residents' quality of life and environmental conditions while ensuring economic growth (Table 2, Table. 3).

Table 2 Changes in the area of built-up areas in Shanghai

Year	downtown area	Average annual growth	Extended strength	extension type
1985	631.45	/	/	/
1990	710.99	79.54	12.60	low speed
1995	1001.13	290.15	40.81	high speed
2000	1291.56	290.43	29.01	high speed
2005	1739.44	447.88	34.68	high speed
2010	2143.33	403.89	23.22	medium speed
2015	2355.34	212.00	9.89	low speed
2020	2489.10	133.77	5.68	low speed
2022	2537.84	48.74	1.96	low speed

Table 3 Changes in the area of downtown areas of Shanghai

Year	downtown area	Average annual growth	Extended strength	extension type
1985	358.90	/	/	
1990	416.95	58.05	16.17	low speed
1995	603.61	186.66	44.77	high speed
2000	788.56	184.95	30.64	high speed
2005	1029.50	240.94	30.55	high speed
2010	1374.12	344.62	33.47	high speed
2015	1483.85	109.74	7.99	low speed
2020	1545.64	61.79	4.16	low speed
2022	1568.33	22.69	1.47	low speed

Since 1985, Shanghai's urban area has expanded from 631.45 square kilometres to 2537.84 square kilometres in 2022, nearly quadrupling (Table 2). The pace of urban expansion has varied, generally following a 'reverse U' trend with initially slow, then rapid, and subsequently slowing growth rates. Between 1985 and 1990, urban expansion was relatively slow, focusing primarily on infilling the city centre and enhancing infrastructure. Since 1995, changes in domestic and international economic conditions and adjustments in urban policies have marked the beginning of a rapid development phase for Shanghai's urban space. During this period, large-scale developments in suburbs and new districts significantly accelerated the pace of urban expansion, with annual expansion reaching nearly 30 square kilometres. This rapid expansion continued until 2010. After that, as the availability of suitable land for development decreased and urban planning policies shifted, the pace of Shanghai's urban expansion began to slow. The focus of urban development shifted from quantity to quality, emphasising improvements in the urban living environment and economic efficiency. Since then, the rate of urban expansion has stabilised at about 10 square kilometres per year.

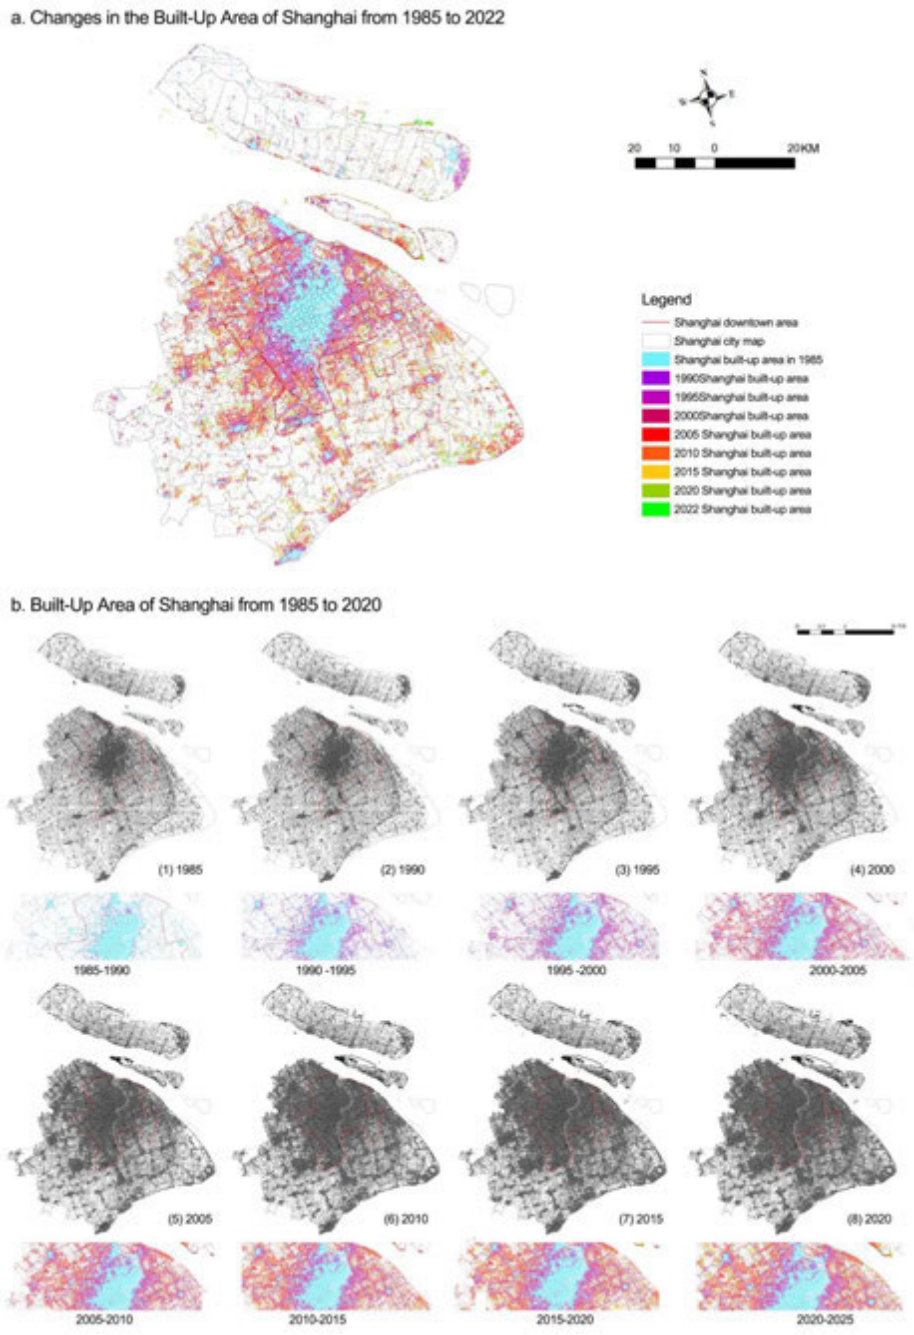

Figure 9 Changes in Shanghai's built-up area from 1985 to 2022

Since 2022, the pace of urban expansion in Shanghai has stabilised, indicating that the amount of land available for urban use in the city centre is nearing saturation. Urban development is increasingly focused on enhancing the efficiency of existing urban land use and improving the quality of urban life. The government and developers are actively seeking new urban development models, such as through urban renewal and the transformation of old districts to optimise urban spatial configuration and enhance city functions while also strengthening the construction of green infrastructure and public service facilities to support a sustainable urban future.

4.3 Current Issues in Shanghai's Urban Spatial Resilience Construction

The challenges posed by climate change and rapid urbanisation are particularly pronounced in the construction of urban spatial resilience in Shanghai. As global warming intensifies, Shanghai is increasingly subjected to extreme weather events such as floods and high temperatures. While significant progress has been made in enhancing flood defences, the measures in place to cope with high temperatures remain inadequate, especially regarding disaster monitoring and early warning systems that require further strengthening. Rapid urban expansion has exerted substantial pressure on the ecological environment, leading to a reduction in urban green spaces and wetlands and a decline in ecosystem functions. Reducing natural buffer zones and ecological barriers increases the city's vulnerability to natural disasters.

Moreover, the city's economic resilience is also being tested. Although Shanghai has become a central global commercial and financial hub, its economy is highly dependent on international markets and foreign investment, which may pose challenges during global economic instability. Additionally, Shanghai is continuously focusing on enhancing social resilience. City administrators are striving to improve public health services, the education system, and housing policies to enhance the quality of life for residents. Nevertheless, rapid urbanisation continues to cause uneven distribution of resources and social stratification. Urban planners and policymakers in Shanghai need to consider these complex factors to develop more effective strategies that promote sustainable development and strengthen urban resilience.

4.4 Analysis of the Relationship Between Urban Compactness and Urban Spatial Resilience

Urban compactness typically refers to a city's intensive and efficient spatial arrangement, encompassing high-density construction, multifunctional land use, and effective public transportation systems (Dantzig & Saaty, 1973; Lan et al., 2021). Urban spatial resilience, however, focuses on a city's ability to maintain critical functions, rapidly recover, and adapt to natural disasters, economic crises, or social changes. Both concepts are crucial topics in the field of sustainable urban development. These principles aim to enhance urban environments' liveability, sustainability, and adaptability, ensuring that cities can withstand and adapt to various challenges while continuing to thrive.

According to relevant theories of urban economics, Richardson et al. proved that the most efficient external space form of urban construction is circular. When the city is round, the compactness is 1. The larger the Richardson index, the more compact the spatial shape. This paper refers to relevant studies (Lan et al., 2021; Lv et al., 2022; Meng & Xing, 2019) and uses Richardson index to express the compactness of the block. Moreover, it is calculated as follows:

$$C = \frac{2\sqrt{\pi * A}}{P}$$

Where A is the area of the block, P is the block's perimeter.

The changes in the compactness of Shanghai city are shown in Figure 10. From 1990 to 2005, the increase in compactness was relatively stable, with an increment of approximately 0.02 every five years. It likely reflects the orderly advancement of urban planning and infrastructure development in Shanghai during this period, gradually enhancing the efficiency of urban operations and the quality of life for residents. The growth in compactness significantly accelerated between 2005 and 2010, increasing by 0.05. This change may be associated with accelerating urbanisation in Shanghai, such as hosting the 2010 Shanghai Expo. Much infrastructure construction and urban expansion likely occurred during this period. From 2010 to 2022, the growth in compactness returned to a stable state, with an increase of 0.01 every five years or two years. It indicates that urban development has entered a more mature and stable phase, where the optimisation and adjustment of urban space are more focused on details and quality, gradually enhancing urban spatial resilience.

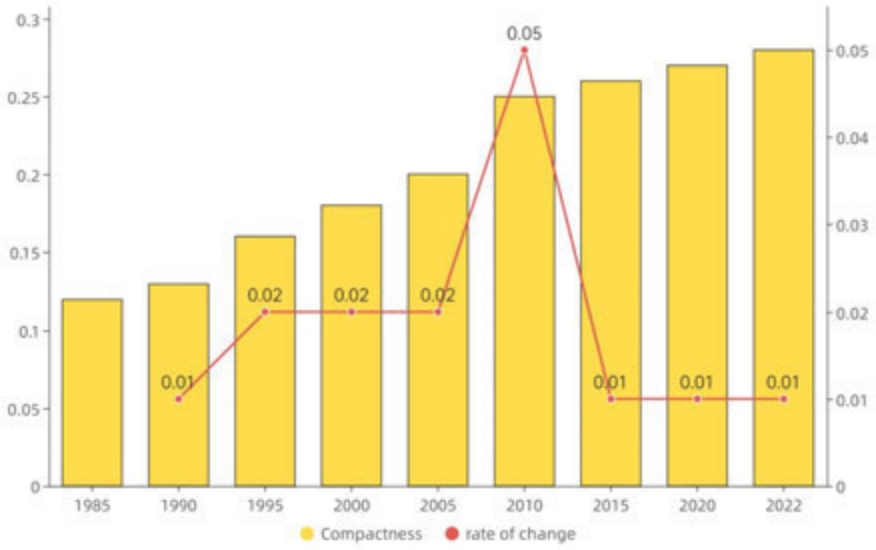

Figure 10 Changes in Shanghai's compactness from 1985 to 2022

The relationship between urban compactness and urban spatial resilience manifests in three critical aspects: ecological environment sustainability, economic vitality enhancement, and social and cultural dimensions resilience.

(1) Sustainability of the Ecological Environment: Compact cities contribute to protecting the natural environment and reducing ecological degradation by minimising land consumption and enhancing land use efficiency (Yao et al., 2022). For instance, by curbing urban sprawl and promoting the construction of high-density residential areas, more natural and semi-natural areas can be preserved, which are crucial for providing ecosystem services such as water retention, air purification, and biodiversity conservation. Furthermore, compact urban forms

help reduce commuting distances and, consequently, lower carbon emissions from transportation, thus mitigating the urban heat island effect and enhancing the overall ecological resilience of the city (Stevenson et al., 2016).

(2) Promotion of Economic Vitality: A concentrated urban layout facilitates the maximisation of resource utilisation and efficiency enhancement (B. Li, 2022). Compact cities can reduce transportation costs and time, enhance business synergies, and accelerate knowledge and technology dissemination. This environment not only attracts more businesses and talent but also fosters innovation and entrepreneurial activities, thereby strengthening the economic resilience of cities. It enables cities to recover and adapt quickly to economic fluctuations or external shocks.

(3) Resilience of Social and Cultural Dimensions: Compact urban environments promote interactions and communications among people from diverse backgrounds, enhancing cultural diversity and social inclusivity (Raman, 2010). This diversity and inclusivity are integral components of social resilience, which can reduce the risk of social fragmentation and conflict during times of change or crisis by strengthening community cohesion and mutual support.

In conclusion, the interconnectedness of urban compactness and spatial resilience spans multiple dimensions, including ecological, economic, and socio-cultural aspects. Urban planners, in their pursuit of urban compactness, should comprehensively consider its impact on the city's overall resilience to ensure more holistic and sustainable urban development.

4.5 Principles and Strategies for Building Shanghai's Urban Spatial Resilience Based on Compactness Elements

Based on the theoretical model of urban spatial resilience and the characteristics of compact urban development, this paper proposes a series of construction principles and enhancement strategies for building urban spatial resilience in Shanghai.

4.5.1 Construction Principles Proposed for Shanghai's Urban Spatial Resilience:

(1) Principle of Mixed Use: Encourage multifunctional land and space use in urban planning and construction, such as integrating commercial, residential, educational, and green spaces to form functionally integrated communities (Verdú-Vázquez et al., 2017). It reduces commuting distances and increases convenience and comfort in daily life (Gaigné et al., 2012). Developers and designers are encouraged to adopt flexible architectural designs, such as variable wall systems and multipurpose rooms, to accommodate future functional changes and diverse usage demands. It enhances the self-sufficiency of communities and provides additional support and buffering in the face of disasters or social upheavals.

(2) Ecological Priority Principle: Prioritise ecological protection and sustainable development in urban planning and expansion. Utilise natural infrastructure such as parks and wetlands to enhance the city's ecological resilience, protect biodiversity, and address urban heat island effects through microclimate regulation and flood risk reduction (Wu et al., 2020). Adopt renewable energy sources like geothermal and solar energy and promote using green building materials to reduce the environmental footprint of urban development and operations (Chel & Kaushik, 2018).

(3) Adaptive Flexibility Principle: Urban design and planning should exhibit high adaptability and flexibility, considering long-term environmental changes, social dynamics, and technological advancements (Jabareen, 2013). For example, the design of buildings and infrastructure should be adaptable to the impacts of climate change(Carter et al., 2015). Develop comprehensive strategies for natural disaster response, including constructing flood barriers, earthquake-safe building standards, and rapid-fire response systems, to effectively enhance the city’s resistance and recovery capabilities in the face of natural disasters.

4.5.2 Enhancement Strategies for Building Shanghai’s Urban Spatial Resilience:

(1) Strengthen Infrastructure Interconnectivity: Shanghai should continue to improve and strengthen its urban transportation network and public facilities to ensure rapid functional recovery after disasters (S.-C. Liu et al., 2021). Expand multimodal transportation systems, including public transit, bicycle lanes, and pedestrian paths, to reduce reliance on personal vehicles and enhance urban operational efficiency (Y. Li et al., 2024). These measures will enable the city to maintain continuity of operations and services in the face of public health emergencies or other urgent situations.

(2) Promote Green Building and Smart City Technologies: Utilise energy-efficient building materials and intelligent technologies, such as smart grids and automated management systems, to enhance the energy efficiency and operational flexibility of buildings and the city (Um-e-Habiba et al., 2024). Using energy-efficient materials, green roofs, smart grids, and automated systems reduces environmental pollution and increases the city's adaptability to various scenarios (Singh, 2024).

(3) Promote Socio-economic Diversification: Encourage industry diversification and innovation to enhance the city’s economic resilience and reduce dependence on single economic sectors. Support the development of small and medium-sized enterprises to improve the economic system’s resistance to external shocks. A diversified economic structure can help the city withstand global economic fluctuations and local economic crises(Sheng et al., 2024).

By implementing these principles and strategies, Shanghai can enhance its urban spatial resilience and ensure sustainability and high-quality living for its residents while pursuing compact urban development. These measures strengthen Shanghai’s resilience in facing future challenges, including natural disasters, economic fluctuations, and social changes.

5 Conclusion

Constructing resilient cities is one of the critical planning goals for Shanghai's urban development. Based on an interpretation of the definition, connotations, and characteristics of "resilient cities," this paper analyses current issues in Shanghai's urban spatial construction. It explores principles and strategies for enhancing urban spatial resilience in Shanghai, leading to the following six research conclusions.

(1) The Concept, Development, Connotations, and Characteristics of Resilient Cities:

A resilient city is a type of advanced urban form that possesses strong adaptive and learning capacities, effectively responds to significant urban disturbances such as climate change threats, ecological issues, and public health incidents within a particular spatiotemporal scope, promptly restores structural and functional stability, and continues to evolve beneficially. This paper

classifies international research on resilient cities into four stages: nascent, initial, rapid development and reflection of continued development. Analysing the systemic composition, organisational methods, and representational forms of resilient cities reveals that they encompass three essential connotations: urban structure, resilience mechanisms, and resilience representations. These cities also exhibit four categories (encompassing 13 specific characteristics) of essential features: capabilities, structures, mechanisms, and representations.

(2) Definition and Connotations of Urban Spatial Resilience:

Urban spatial resilience is characterised by integrating the three elements of "scale, density, and form" in urban spaces, allowing "urban spatial resilience" to be cognitively expressed as "spatial resilience features." The diversity of urban spatial resilience is evident in the variety of urban functions, choices during impact processes, socio-ecological environments, and multi-scale connections among urban components. The structural organisation of urban spatial resilience exhibits high adaptability and flexibility, manifested in the construction of hierarchical urban spatial structures at macro, meso, and micro levels and in the organisation of social functions.

(3) Theoretical Model of Urban Spatial Resilience:

Based on the connotations and characteristics of resilient cities, this paper has sequentially proposed theoretical models for "resilience" and "urban spatial resilience." The "resilience" theoretical model includes essential elements, operational characteristics, core information, and operational rules. The "urban spatial resilience" theoretical model comprises operational mechanisms, influencing factors, hierarchical structures, organisational rules, intrinsic connotations and representational forms, and system capabilities. The "urban spatial resilience" theoretical model can be applied to analyse the evolution phenomena, construction principles, and enhancement strategies of urban spatial resilience in Shanghai, realising system characteristics of urban spatial resilience that "respond timely to strong disturbances," "maintain and restore the stability of urban structure and functions," and "effectively defend against and address similar issues after experiences or learning."

(4) Evolution, Changes, and Current Issues of Urban Spatial Resilience in Shanghai since 1985:

Since 1985, urban expansion in Shanghai has predominantly displayed a pattern of central concentration with peripheral dispersion, marking a shift from mere rapid expansion to a focus on integrated quality and sustainable development. Urban spatial growth has gradually slowed, and urban compactness has progressively strengthened. Urban development has entered a more mature and stable phase, emphasising ecological protection and sustainable development, thus gradually enhancing urban spatial resilience. The city has moved from concentrated high-speed development in the city centre to more balanced development in the suburbs and new areas. During this process, Shanghai has gradually improved its urban compactness, driving the overall optimisation of transport, public services, and green infrastructure. However, as the city's scale has expanded, Shanghai faces multiple challenges, such as traffic congestion, environmental pollution, social inequality, and disaster response. Future urban planning needs to focus more on finding a new balance between developmental drive and environmental protection, strengthening community participation and technological innovation to build a more resilient and inclusive urban environment, and ensuring sustainable development strategies can effectively address upcoming social and environmental challenges.

(5) Principles and Strategies for Constructing Urban Spatial Resilience in Shanghai:

Based on the theoretical model of urban spatial resilience, the construction of Shanghai’s urban spatial resilience should adhere to the principles of multifunctional use, ecological priority and adaptive flexibility. By implementing strategies such as strengthening infrastructure connectivity, promoting green buildings and innovative city technologies, and fostering socio-economic diversification, the city’s overall resilience and capacity for sustainable development can be comprehensively enhanced. These strategies significantly improve Shanghai’s ability to respond and adapt to natural disasters, economic fluctuations, and social changes, as well as raise the overall standard of urban infrastructure and the quality of life for residents, ensuring a sense of community cohesion and security. Through these integrated measures, Shanghai can achieve a greener, more intelligent, and more humane urban development model, addressing immediate challenges while laying a solid foundation for future sustainable growth, ensuring a harmonious coexistence of urban environments and economic vitality, and thereby achieving comprehensive and enduring urban prosperity and resident well-being.

The current state of urban development across various countries indicates that traditional "safety-defense" disaster prevention concepts no longer meet the needs of contemporary urban risk management. Instead, resilience thinking, which originated in ecology, has come into focus. As an evolving concept, enhancing urban spatial resilience is an effective way to address the risks of urban climate change and follow sustainable development principles and a practical necessity to control chaotic urban sprawl and achieve compact development. The research conclusions of this paper are intended to aid urban managers and researchers in deeply understanding the concepts, connotations, and characteristics of resilient cities and urban spatial resilience. They clarify the principles for constructing urban spatial resilience, the methods for analysing it, and strategies for its enhancement, thereby enabling an appropriate response to the challenges and risks encountered in constructing resilient cities.

Abstract: This paper explores the enhancement strategies for urban spatial resilience in Shanghai by defining, interpreting, and identifying the characteristics of "urban spatial resilience." Firstly, it analyses the relationship between resilient cities and urban spatial resilience. Secondly, it examines the systemic composition, organisational methods, and representation of resilient cities, revealing three essential contents—hierarchical structures, resilience mechanisms, and resilience representations—and four fundamental characteristics (13 attributes): capacity, structure, mechanism, and representation. Thirdly, it reviews the urban spatial planning, spatial expansion changes, and urban compactness variations in Shanghai since 1985. Finally, the paper identifies current issues in Shanghai's urban spatial development and proposes strategies to enhance its urban spatial resilience.

Keywords: Resilient Cities, Spatial Resilience, Shanghai, Construction Principles, Enhancement Strategies

1. Introduction

Urban areas today face many crises and challenges, including global warming, increased extreme weather events, and urban flooding, which render urban systems vulnerable and susceptible to disturbances. Since the inception of the "resilient city" concept, it has emerged as a new paradigm for addressing urban risks and uncertainties, garnering sustained interest from both the academic and political realms (Sharifi, 2019). Resilience thinking posits that cities are self-regulating complex systems (Holling et al., 2002), with resilient cities serving as tools to cope with uncertainty. Constructing resilient cities or enhancing urban resilience has become crucial for cities to face various challenges and achieve long-term sustainable development (UNDRR, 2013). This understanding has gradually evolved into a global consensus. The theory of resilient cities views urban areas as open, complex mega-systems, offering significant scientific guidance for urban planning and construction practices aimed at protecting the lives and properties of residents and enhancing urban functionality.

Since 2016, Shanghai has issued a series of policy documents aimed at enhancing urban spatial resilience, such as the "RISE" Vision Goals Framework for Shanghai's Urban Development over the Next 30 Years (2016), the Shanghai City Master Plan (2017-2035) (2018), and the Shanghai Urban Operation and Safety Development Report (2019-2020) Blue Book (2021). These documents repeatedly emphasise the importance of strengthening resilient city construction and achieving compact urban development and propose that by 2035, Shanghai will be fundamentally established as a "resilient city" capable of addressing various developmental risks and swiftly recovering from them. To counter issues such as continuous urban sprawl, population concentration in central urban areas, and the slow development of new cities, Shanghai advocates for a compact metropolitan spatial pattern and a transition from extensive expansion to baseline constraint and intrinsic development (Shaobo et al., 2019).

Thus, constructing resilient cities and enhancing urban spatial resilience are among the critical planning objectives for current urban development in Shanghai.

Urban spatial resilience has emerged within the development and evolution of resilience, resilient cities, and urban resilience. Therefore, it is necessary to delineate and clarify the relationships among resilience, resilient cities, urban resilience, and urban spatial resilience. This paper is based on analysing the concepts, contents, and characteristics of resilience, resilient cities, urban resilience, and urban spatial resilience. It proposes a theoretical model for urban spatial resilience and examines the development trajectory, current issues, construction principles, and urban spatial resilience enhancement strategies in Shanghai. The research conclusions presented here are intended to deepen the understanding of urban spatial resilience among city managers and researchers. This deeper understanding facilitates a more thorough grasp of the concepts, contents, and characteristics essential for building resilient cities, providing valuable insights and references for urban development strategies.

2. Definitions, Connotations, and Characteristics of Resilient Cities

2.1 The Concept and Evolution of Resilient Cities

The concept of "resilience" has been extensively applied across multiple disciplinary fields such as engineering, psychology, disaster studies, economics, management, social sciences, and environmental science. Although descriptions of "resilience" vary among disciplines, they all emphasise its characteristics related to absorption, resistance, maintenance, self-organisation, adaptation, learning, and transformation. Following the perspective of Professor Shen Qingji, this paper defines "resilience" as the capacity of a system to maintain or restore its necessary functions in the face of disturbances, adapt to changes, and swiftly transform when its adaptive capacity is constrained.

Similar to other fields, the concepts of "Urban Resilience" and "Resilient City" emerged when applied to urban systems. The term "Resilient City" was first introduced by Local Governments for Sustainability (ICLEI) during the 2002 United Nations Summit on Sustainable Development. It emphasised a systemic construction process combining material aspects such as engineering improvements and facility enhancements with social dimensions, including public participation and institutional innovation, to enhance the overall resilience of urban systems. While there is no unified definition of a resilient city within the academic community to date, there is a consensus on its connotation and value: a resilient city possesses diverse disaster adaptation capabilities. Research varies from focusing on urban stability reconfiguration under environmental impacts, highlighting the rapid adaptive system characteristics of cities, to emphasising the adaptive capacity of cities and their residents to risks, yet all converge on the core notions of "stability," "resistance," and "adaptability." By analysing the interrelations among resilience, resilient cities, urban resilience, and urban spatial resilience, this paper further explicates the definition of a resilient city as a type of advanced urban form that possesses strong adaptive and learning capacities, effectively responds to significant urban disturbances such as climate change threats, ecological issues, public health incidents within a particular spatiotemporal scope, promptly restores structural and functional stability, and continues to evolve beneficially.

This paper classifies international research on resilient cities into four stages: nascent, initial, rapid, and reflection continued development (Figure 1). From the perspective of evolutionary trends, early research on resilient cities focused on human psychological resilience and

ecosystem resilience, gradually transitioning to diverse studies targeting different components and processes within urban socio-ecological systems. The scope of the inquiry has shifted from initially addressing common natural disasters and risks to increasingly dealing with emerging urban environmental and social issues, as well as derivative problems, thereby deepening integration with the discipline of urban planning.

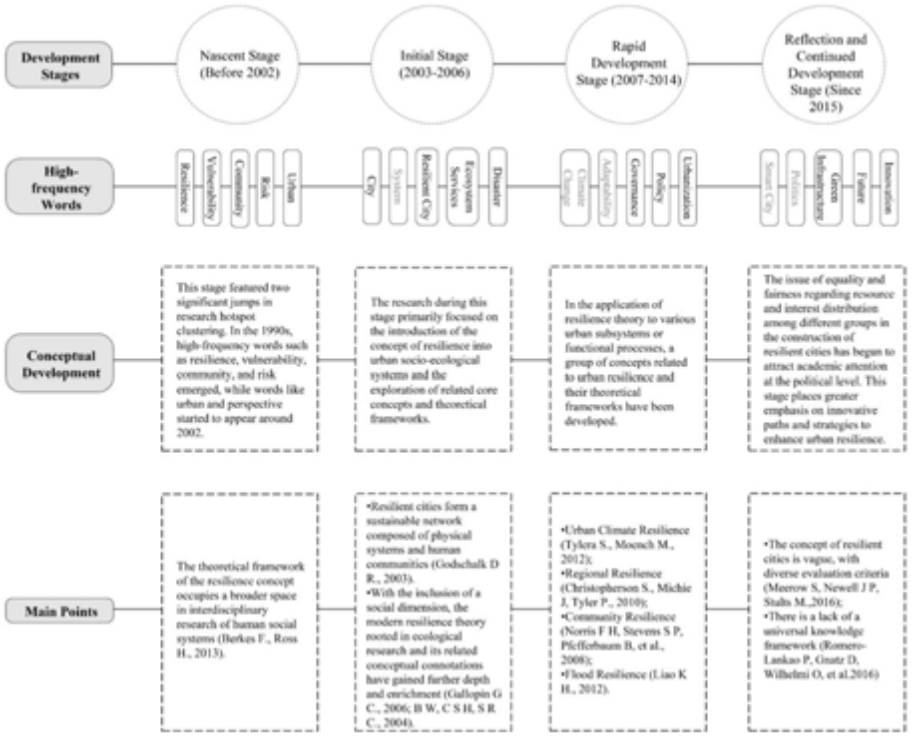

Figure 1: Evolutionary Stages of the "Resilient City" Concept

2.2 The Connotations of Resilient Cities

Based on an examination and analysis of the existing literature on "resilience," "urban resilience," and "resilient cities," this paper categorises the intrinsic connotations of resilient cities into three core components: hierarchical structures, resilience mechanisms, and resilience representations, covering the systemic composition, organisational methods, and representational forms of resilient cities (Figure 2).

Figure 2: Diagrammatic Representation of the Information Structure of Resilient Cities

(1) **Hierarchical Structure:** Refers to the stable structure formed by resilient cities' subsystems, system levels, and system elements under specific mechanisms. It represents resilient cities as complex systems.

(2) **Resilience Mechanisms:** Historical experiences indicate that urban development is long influenced and constrained by natural environments and human will, gradually evolving capabilities that maintain urban functions and structures and foster benign urban development. These capabilities are manifest in adaptive and learning abilities. The operational mechanisms of resilient cities serve as the analytical basis for examining the logical connections between their hierarchical structures and resilience representations. In integrating urban components and influencing factors, four resilience mechanisms have emerged to maintain urban structural stability—stability, sensitivity, resistance, and recovery—based on the two capability features (system organisational rules).

(3) **Resilience Representations**: From a psychological perspective, representation refers to the method by which segments of world information stored in the human mind are depicted or described, as well as how objects exist within individual psychology. Representation theory elucidates the connections between the representational information of objects and their physical or non-physical forms, linking information with people's perceptions of specific objects or events (Distin, 2005).

The representational forms of "resilient cities" are meant to express their intrinsic meanings, consisting of tangible and intangible urban characteristics. This study categorises the core connotations of "resilient cities" into four aspects based on urban components' material and non-material properties: urban spatial resilience, urban ecological resilience, urban social resilience, and urban economic resilience. These four cores are represented in different cities in varying proportions, resulting in distinctive, resilient city representations, including healthy, safe, resilient, low-carbon, ecological, and innovative resilient cities. Due to resilience

mechanisms being inherent attributes of all types of resilient cities, it is recommended to use "urban scale," "urban structure," "urban elements," and "resilience representations" as criteria for analysing city types. The classification of resilient city types should be based on assessments of their "complexity" and "connotative representations," and these criteria should be used in case studies to determine the specific type of resilient city.

(1) Based on evaluations of urban hierarchy, connectivity, and the number and types of urban elements, definitions of resilient city complexity are delineated as "ultra-high complexity (C1), high complexity (C2), medium complexity (C3), and low complexity (C4)."

(2) An evaluation system for resilient cities covering spatial resilience, ecological resilience, social resilience, and economic resilience is established. Definitions for the representational forms of resilient cities, such as health resilience, safety resilience, low-carbon resilience, ecological resilience, and intelligent resilience, are derived based on evaluation scores. In case studies, the most representative form of resilience representation can be selected as a keyword to determine the specific type of a city.

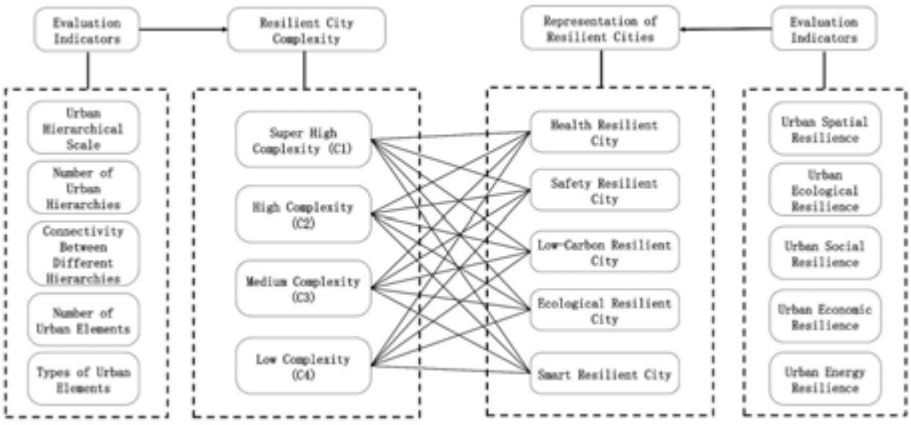

Figure 3: Classification of Resilient Cities

As shown in Figure 3, based on the results of evaluating the "complexity" and "connotative representations" of resilient cities in case studies, a combination of keywords from both categories yields 20 types of resilient cities across 4 complexity levels and 5 representational forms:

2.3 Characteristics of Resilient Cities

The characteristics of resilient cities are an extended expression of their concept and core connotations. This paper categorises the characteristics of resilient cities into four types with thirteen essential attributes (Table 1): capability characteristics, structural characteristics, mechanism characteristics, and representational characteristics.

(1) Capability Characteristics of resilient cities include adaptability and learning ability, which are the fundamental reasons behind the formation of resilience mechanisms in resilient cities.

(2) Structural and Elemental Characteristics refer to the system hierarchical structures formed under the influence of resilience mechanisms and the type and number of constituent elements of resilient cities.

(3) Mechanism Characteristics comprise stability, sensitivity, resistance, recovery, and resource redundancy. These are the system mechanisms that maintain resilient cities' functional and structural stability.

(4) Representational Characteristics include health resilience, safety resilience, low-carbon resilience, ecological resilience, and intelligent resilience. These human cognitive expressions abstract the capabilities, structures, and mechanisms of resilient cities into the most representative features.

Table 1: Classification and Analysis of Resilient City Characteristics

Characteristic Type	**Characteristic Name**	**Characteristic Analysis**
Capability Characteristics	Adaptive capacity Learning Ability	Based on historical experience, it is known that urban development is long influenced and constrained by natural environments and human will, gradually generating the ability to maintain urban functions and structures and promote benign urban development. It manifests as two capability characteristics: adaptability and learning ability.
Structural Characteristics	Hierarchical Features Elemental Features	As complex systems, cities' structural characteristics are inherent reflections of their functions and operational mechanisms. The structural features of resilient cities demonstrate the tangible or intangible urban hierarchical structures formed under the influence of resilience mechanisms, reflecting the core connotations of urban space, ecology, society, and economy and their energy and material flow characteristics.
Mechanism Characteristics	Stability Sensitivity Resistance Recovery	The operational mechanisms of resilient cities serve as the analytical basis for examining the logical connections between their hierarchical structures and resilience representations. Based on the two capability features in the integration process of urban components and influencing factors, four resilience mechanisms have emerged to maintain urban structural stability: stability, sensitivity, resistance, and recovery.
Representational Characteristics	Health Resilience	Representation theory elucidates the connections between the representational information of objects and their physical or non-physical forms, linking information with people’s perceptions of specific objects or events (Distin, 2005). The representational characteristics of resilient cities are meant to express their most representative and abstracted urban features clearly.

3. Developing a Theoretical Model of Urban Spatial Resilience Based on the Connotations and Characteristics of Resilient Cities

Incorporating the definitions, connotations, and characteristics of resilience, resilient cities, urban resilience, and urban spatial resilience, this paper constructs a theoretical model for urban spatial resilience.

3.1 Urban Resilience and Urban Spatial Resilience

Urban "resilience" constitutes the core connotation of "resilient cities." Research from various countries indicates that the core information of urban "resilience" includes the constituent elements under hierarchical states, the reduction (or resistance) of disaster types, and the maintenance (or restoration) of a stable state, as well as adaptability to uncertain urban issues. Based on these core elements of urban "resilience" (Figure 4), this paper defines urban "resilience" from the perspectives of resilience capacity and system structure. Urban "resilience" is described as an inherent property of the city, manifested through a hierarchical structure organised from the bottom up by urban components. It exhibits stable characteristics that enable the city to maintain stability through rapid response capabilities, recovery capabilities in the event of sudden incidents, defence capabilities against similar events, and adaptability (or optimisation) capabilities.

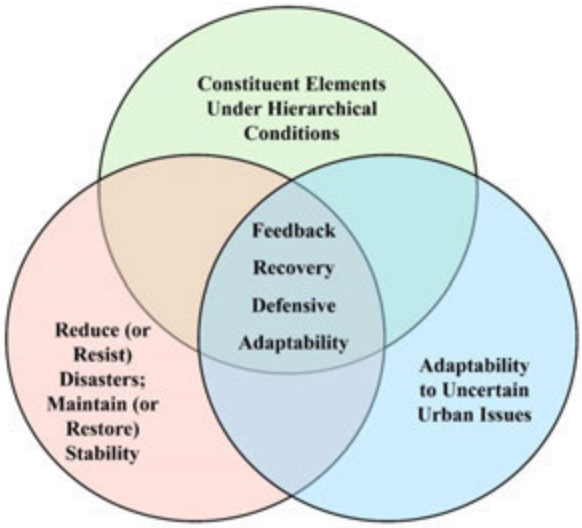

Figure 4: Core Information on Urban "Resilience"

This paper interprets urban spatial resilience as a subset of urban resilience, emphasising the state of resilience within the spatial dimension. The principal subject of the urban spatial resilience concept is urban space, with a focus on spatial attributes, representing the capacity for continuous development and operation of the urban spatial system. This capacity includes the ability to withstand disaster risks, absorb external shocks, and quickly recover essential functions. Resilient urban spaces can help maintain the integrity of urban system functionalities.

Urban spatial resilience is characterised by integrating the three elements of urban space: "scale, density, and form." Urban scale is evaluated based on ecological infrastructure and landscape safety patterns; urban density is assessed through ecological footprint and carrying capacity evaluations; urban form is measured using the "source-sink" landscape mean distance index (Xiu et al., 2018). Enhancing urban spatial resilience involves establishing redundant critical infrastructures, stable open spatial patterns, and modular, scalable spatial units across macro, meso, and micro urban scales to ensure sustainable urban development. Numerous researchers have explored urban spatial resilience from various perspectives. For instance, Liu (2014) defined "resilience planning" as the coordinated integration of rigid and flexible planning to maximise planning efficacy and defined morphological resilience as the characteristic of a spatial form that can sustain spatial development goals while fully accommodating diverse spatial usage demands (K. Liu, 2014). "Morphological resilience" planning techniques determine the material spatial elements that need rigid control according to spatial planning goals, using these rigid elements as the essential components of the spatial structure. Applying open, modular resilience planning techniques constructs an overall spatial structure closely linked with the spatial connotations of urban resilience. Famous urban models such as organic evacuation, cluster, and grid cities exemplify spatial resilience, characterised by stable, open spatial frameworks and modular, scalable spatial units. Xiu, Wei, and Wang (2018) developed a three-dimensional urban resilience research framework based on "scale—density—form" with clear spatial connotations (Xiu et al., 2018). In this framework, urban scale is evaluated based on ecological infrastructure and urban landscape safety patterns; urban density is assessed through ecological footprint and carrying capacity; urban form is evaluated using the "source-sink" landscape mean distance index. Shi (2016), using Shanghai as an example, explored the spatial requirements for enhancing resilience in mega-cities: (1) ensuring a safety baseline with life circles as the basic unit; (2) building disaster prevention systems with urban clusters as network groups; (3) coordinating the overall disaster prevention layout within the municipal area; (4) establishing regional strategic cooperation platforms (Shi, 2016).

This paper proposes that understanding urban spatial resilience should be approached from three critical perspectives:

(1) Transformation of Urban Spatial Resilience into Spatial Resilience Features: It is suggested to cognise and express "urban spatial resilience" as "spatial resilience features". It can be achieved by adopting a series of landscape indices from landscape ecology and representing the spatial resilience of different urban areas through a "Resilience Spatial Distribution Map".

(2) Relationship between Urban Spatial Resilience and Environmental Factors: Urban spatial resilience is closely linked to the natural environment, geological setting, hydrological conditions, wind environment, built environment, and spatial infrastructure factors of the city's location. Urban spatial resilience can be enhanced by expanding the spatial area under consideration.

(3) In-depth and Multi-dimensional Analysis of Urban Spatial Resilience: Efforts should be made to conduct a thorough and multifaceted analysis of urban spatial resilience. It could involve dividing urban areas into resilient and non-resilient spaces, resilient and non-resilient functions, and resilient and non-resilient structures.

3.2 Resilience" Theoretical Model

Based on the definition of "resilience," this paper establishes a "resilience" theoretical model based on its core information (Figure 5). The model specifies and describes the essential elements, operational characteristics, core information, and operational rules of the "resilience" theoretical model.

(1) Basic Elements: Includes both material entities and abstract objects.

(2) Operational Characteristics (Constraints): The "resilience" model is characterised by seven features during operation: "absorption," "resistance," "maintenance," "self-organisation," "adaptation," "learning," and "transformation."

(3) Core Information: The seven operational characteristics are simplified and categorised into four types of information, namely "recovery capability," "maintenance capability," "adaptability," and "transformation capability."

(4) Operational Rules (Also Known as Principles): These rules dictate how combinations of essential elements can form connections that represent the operational characteristics and core information of "resilience."

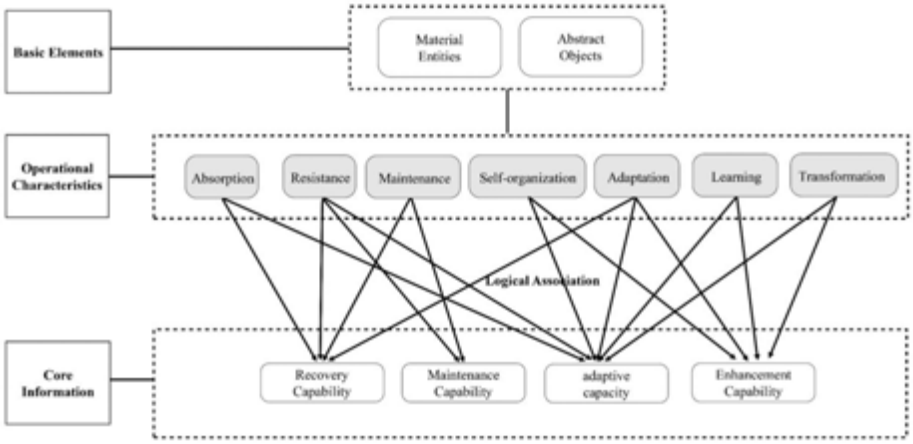

Figure 5: Theoretical Model of "Resilience"

3.3 Theoretical Model of Urban Spatial Resilience

Resilient cities are complex dynamic systems where closely interconnected subsystems create complex interactions that reflect the city’s political, economic, and social relationships. Therefore, resilient cities can be analysed through the relationships among subsystems and system elements (Yang M. et al., 2016; Zhou & Yuan, 2017). The urban spatial structure manifests the results of interactions among hierarchical structures, functions, and elements.

This study initially categorises urban spatial resilience into three systemic levels: macro, meso, and micro. Based on the physical and non-physical scale of system constituent elements, the meso and micro levels can be further subdivided, resulting in a hierarchical structure of single macro, multiple meso, and multiple micro levels (Figure 6).

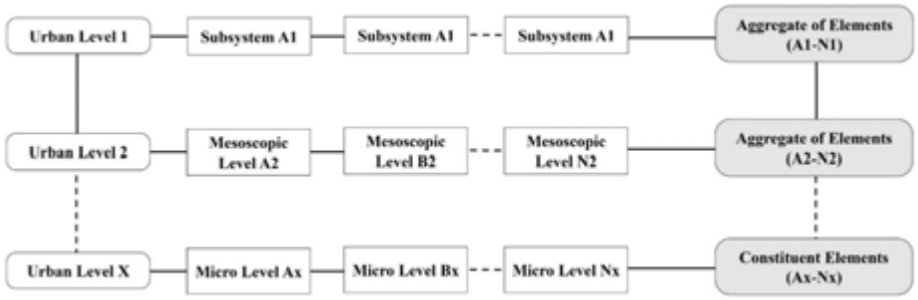

Figure 6: Schematic of Urban Spatial Hierarchical Structure

Based on the "resilience" theoretical model and the connotations and characteristics of resilient cities, this paper further proposes a theoretical model of "urban spatial resilience" (Figure 7). This model comprises operational mechanisms, influencing factors, hierarchical structures, organisational rules, intrinsic connotations and representational forms, and system capabilities.

(1) Operating Mechanisms: Adaptability and learning ability are the core operating mechanisms for urban spatial resilience. Individual cities and urban clusters optimise and reorganise their spatial resilience systems spontaneously by adapting to and learning from the impacts affecting their urban spatial resilience.

(2) Influencing Factors: These include a variety of factors such as the urban ecological environment, socio-economic factors, urban transportation, and land use. The operating mechanisms of the urban spatial resilience system are generated through adaptation to and learning from these factors affecting urban resilience spaces.

(3) Hierarchical Structure: The material and non-material essential components of cities form a stable hierarchical structure under the influence of two resilience mechanisms. From both physical and logical scales, this involves organising resilience components of urban spaces from the bottom up, forming a hierarchical structure with resilience and stability characteristics consisting of a single macro-level, multiple subsystems, multiple meso-levels, and multiple micro-levels, with individual forms varying based on specific case studies.

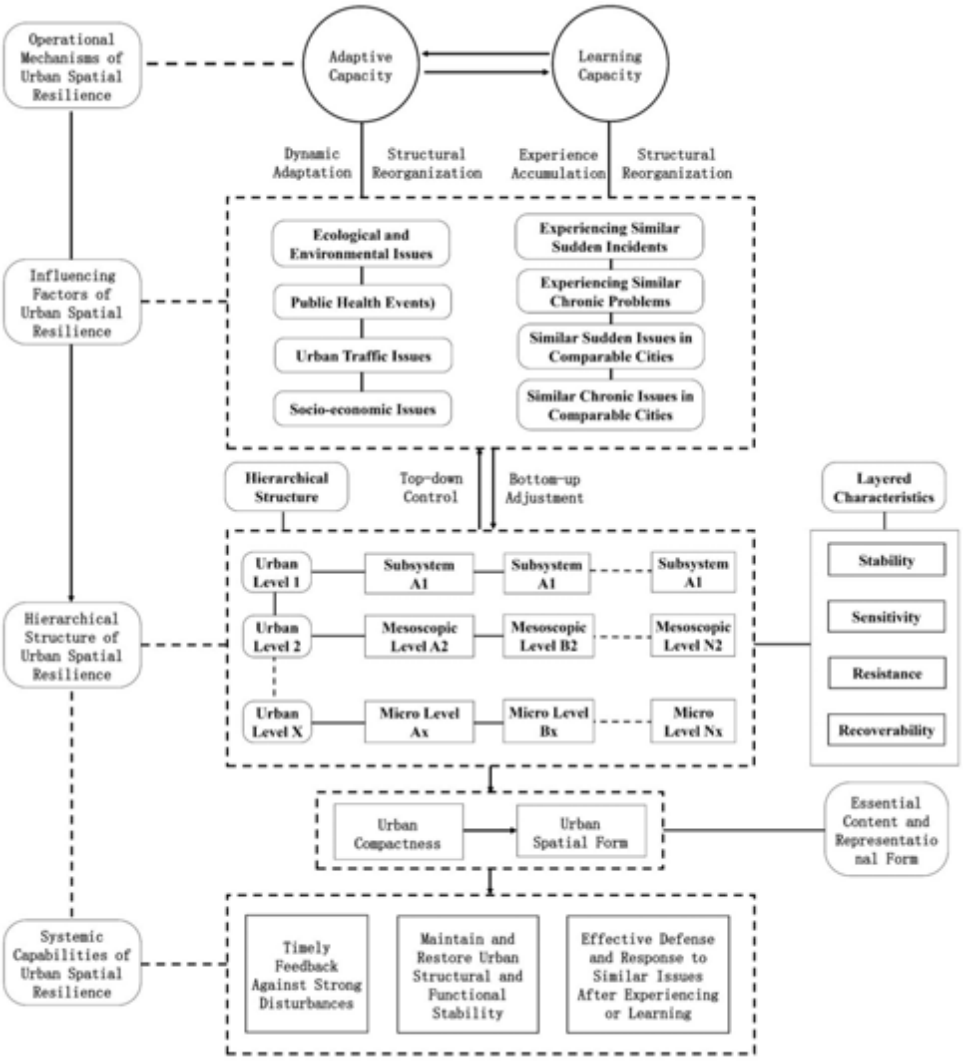

Figure 7: Theoretical Model of Urban Spatial Resilience

(4) Organisational Rules: Stability, sensitivity, resistance, and recovery serve as the organisational rules for urban spatial resilience at different hierarchical levels, forming a relatively stable structure at the system-wide level that can achieve and maintain specific functions. This stable structure can be continuously optimised through adaptation and learning concerning the types, quantities, and connections of the elements composing the different levels of urban spatial resilience.

(5) Intrinsic Connotations and Representational Forms: Urban compactness is the intrinsic connotation of urban spatial resilience, involving the economical and intensive use of land

resources, centralised layout of urban functional elements, enhanced management of urban spatial growth, promotion of high density and mixed-use of urban land, and strengthened urban planning management. The representational form of urban compactness is the urban spatial form.

(6) System Capabilities: Based on the influencing factors of urban spatial resilience, the operating mechanisms effectively organise the hierarchical structure of urban spatial resilience, fostering the generation of three system capability features of urban spatial resilience: "timely feedback against strong disturbances," "maintenance and recovery of urban structure and functional stability," and "effective defence and response to similar issues after experiencing or learning."

4. Shanghai Urban Spatial Resilience: Development Trajectory, Current Issues, and Enhancement Strategies

4.1 Urban Spatial Planning in Shanghai Since 1985

Shanghai's urban planning can be traced back to the "Greater Shanghai Plan" of 1929 (Figure 8), inspired by Ebenezer Howard's "Garden Cities of To-morrow" (1902). This plan employed a grid layout and designated a city centre in Yangpu district, encompassing government buildings, museums, and other public amenities. Although the onset of war in 1937 halted its implementation, this plan laid the foundational principles for subsequent urban planning (MacPherson, 1990). Post-war, multiple master plans were drafted, notably in 1946 and 1956, emphasising industrial development and population decentralisation to alleviate congestion in the central areas(Shanghai Local Chronicles Office, 2003). After the establishment of the People's Republic of China, Shanghai's planning ideology transitioned into the era of Soviet Planning Theory, focusing on industrial orientation and residential environment improvements (Soviet Planning Theory 1949-1958 · Shanghai: Urban Design and Planning, 2024). The 1959 plan significantly expanded Shanghai's administrative boundaries and envisioned transforming Shanghai into a leading beautiful city (Shanghai Urban Master Plan 1959 Edition, 2024). From 1984 onwards, Shanghai pivoted towards becoming a multifunctional economic hub. The 1986 plan further solidified Shanghai's status as a major international metropolis (The State Council’s Response to the Master Urban Planning Scheme for Shanghai, 1986). The plans from 1999 to 2001 established an urban spatial structure that facilitated harmonious development across various urban levels. The latest master plan (2017-2035) projects a longer-term vision, aiming to position Shanghai as a globally influential centre of technological innovation and a modernised international metropolis by 2035, introducing a spatial configuration of "one core, two axes, four wings; multiple corridors, multiple cores, multiple circles".

Figure 8 History of urban planning development in Shanghai

4.2 Urban Spatial Expansion in Shanghai Since 1985

To further analyse the urban spatial expansion of Shanghai since 1985, this study leverages data from (J. Yang & Huang, 2021), which utilises 335,709 Landsat images available on the Google Earth Engine. The methodology involves collecting training samples by combining stable samples extracted from the China Land Use/Cover Dataset (CLUD) with visual interpretation samples from satellite time series data, Google Earth, and Google Maps. The study employs multiple temporal indicators constructed from all available Landsat data, which are then input into a random forest classifier to obtain classification results, culminating in creating the China Annual Land Cover Dataset (CLCD) from 1985 onwards.

The results indicate that from 1985 to 2022, Shanghai's urban expansion predominantly exhibited a pattern of central aggregation and peripheral dispersion (Figure 9). This pattern reflects that the city's development extended beyond merely refilling old urban areas, expanding into peripheral regions and new districts. From 1985 to 1990, urban expansion was primarily concentrated in the city centre with minimal outlying growth. During this period, development focused on maximising the use of internal space and reconstructing key areas to accommodate the city's growing population and economic demands. Between 1990 and 2000, as the economy rapidly developed and urban policies adjusted, Shanghai's urban expansion began transitioning from the city centre to peripheral areas. The construction of major transport routes and new development zones catalysed swift expansion at the city's edges. After 2000, urban expansion entered a new peak period, reaching a nearly 40-year high, with the city centre area almost entirely urbanised. This trend continued until 2015. After 2015, urban growth began to slow, with expansion shifting towards suburbs and emerging satellite towns, characterised by "finger-like" growth patterns along major roadways and transit lines. By 2020, Shanghai's urban spatial expansion significantly slowed, indicating a transition into a more mature and stable development phase. The new urban development strategy emphasises ecological protection and sustainable development, aiming to improve residents' quality of life and environmental conditions while ensuring economic growth (Table 2, Table. 3).

Table 2 Changes in the area of built-up areas in Shanghai

Year	downtown area	Average annual growth	Extended strength	extension type
1985	631.45	/	/	/
1990	710.99	79.54	12.60	low speed
1995	1001.13	290.15	40.81	high speed
2000	1291.56	290.43	29.01	high speed
2005	1739.44	447.88	34.68	high speed
2010	2143.33	403.89	23.22	medium speed
2015	2355.34	212.00	9.89	low speed
2020	2489.10	133.77	5.68	low speed
2022	2537.84	48.74	1.96	low speed

Table 3 Changes in the area of downtown areas of Shanghai

Year	downtown area	Average annual growth	Extended strength	extension type
1985	358.90	/	/	
1990	416.95	58.05	16.17	low speed
1995	603.61	186.66	44.77	high speed
2000	788.56	184.95	30.64	high speed
2005	1029.50	240.94	30.55	high speed
2010	1374.12	344.62	33.47	high speed
2015	1483.85	109.74	7.99	low speed
2020	1545.64	61.79	4.16	low speed
2022	1568.33	22.69	1.47	low speed

Since 1985, Shanghai's urban area has expanded from 631.45 square kilometres to 2537.84 square kilometres in 2022, nearly quadrupling (Table 2). The pace of urban expansion has varied, generally following a 'reverse U' trend with initially slow, then rapid, and subsequently slowing growth rates. Between 1985 and 1990, urban expansion was relatively slow, focusing primarily on infilling the city centre and enhancing infrastructure. Since 1995, changes in domestic and international economic conditions and adjustments in urban policies have marked the beginning of a rapid development phase for Shanghai's urban space. During this period, large-scale developments in suburbs and new districts significantly accelerated the pace of urban expansion, with annual expansion reaching nearly 30 square kilometres. This rapid expansion continued until 2010. After that, as the availability of suitable land for development decreased and urban planning policies shifted, the pace of Shanghai's urban expansion began to slow. The focus of urban development shifted from quantity to quality, emphasising improvements in the urban living environment and economic efficiency. Since then, the rate of urban expansion has stabilised at about 10 square kilometres per year.

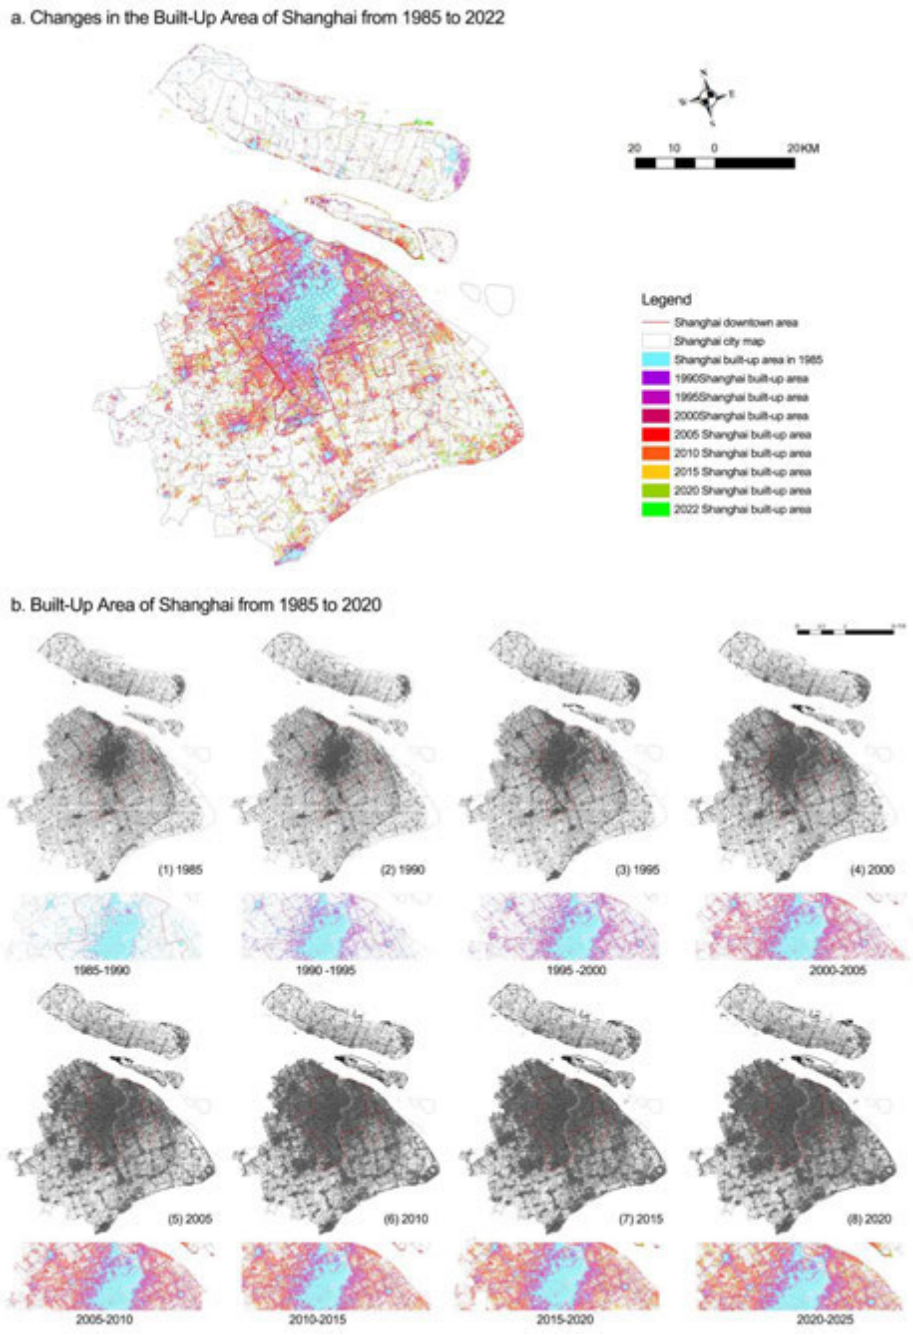

Figure 9 Changes in Shanghai's built-up area from 1985 to 2022

Since 2022, the pace of urban expansion in Shanghai has stabilised, indicating that the amount of land available for urban use in the city centre is nearing saturation. Urban development is increasingly focused on enhancing the efficiency of existing urban land use and improving the quality of urban life. The government and developers are actively seeking new urban development models, such as through urban renewal and the transformation of old districts to optimise urban spatial configuration and enhance city functions while also strengthening the construction of green infrastructure and public service facilities to support a sustainable urban future.

4.3 Current Issues in Shanghai’s Urban Spatial Resilience Construction

The challenges posed by climate change and rapid urbanisation are particularly pronounced in the construction of urban spatial resilience in Shanghai. As global warming intensifies, Shanghai is increasingly subjected to extreme weather events such as floods and high temperatures. While significant progress has been made in enhancing flood defences, the measures in place to cope with high temperatures remain inadequate, especially regarding disaster monitoring and early warning systems that require further strengthening. Rapid urban expansion has exerted substantial pressure on the ecological environment, leading to a reduction in urban green spaces and wetlands and a decline in ecosystem functions. Reducing natural buffer zones and ecological barriers increases the city's vulnerability to natural disasters.

Moreover, the city's economic resilience is also being tested. Although Shanghai has become a central global commercial and financial hub, its economy is highly dependent on international markets and foreign investment, which may pose challenges during global economic instability. Additionally, Shanghai is continuously focusing on enhancing social resilience. City administrators are striving to improve public health services, the education system, and housing policies to enhance the quality of life for residents. Nevertheless, rapid urbanisation continues to cause uneven distribution of resources and social stratification. Urban planners and policymakers in Shanghai need to consider these complex factors to develop more effective strategies that promote sustainable development and strengthen urban resilience.

4.4 Analysis of the Relationship Between Urban Compactness and Urban Spatial Resilience

Urban compactness typically refers to a city's intensive and efficient spatial arrangement, encompassing high-density construction, multifunctional land use, and effective public transportation systems (Dantzig & Saaty, 1973; Lan et al., 2021). Urban spatial resilience, however, focuses on a city's ability to maintain critical functions, rapidly recover, and adapt to natural disasters, economic crises, or social changes. Both concepts are crucial topics in the field of sustainable urban development. These principles aim to enhance urban environments' liveability, sustainability, and adaptability, ensuring that cities can withstand and adapt to various challenges while continuing to thrive.

According to relevant theories of urban economics, Richardson et al. proved that the most efficient external space form of urban construction is circular. When the city is round, the compactness is 1. The larger the Richardson index, the more compact the spatial shape. This paper refers to relevant studies (Lan et al., 2021; Lv et al., 2022; Meng & Xing, 2019) and uses Richardson index to express the compactness of the block. Moreover, it is calculated as follows:

$$C = \frac{2\sqrt{\pi * A}}{P}$$

Where A is the area of the block, P is the block's perimeter.

The changes in the compactness of Shanghai city are shown in Figure 10. From 1990 to 2005, the increase in compactness was relatively stable, with an increment of approximately 0.02 every five years. It likely reflects the orderly advancement of urban planning and infrastructure development in Shanghai during this period, gradually enhancing the efficiency of urban operations and the quality of life for residents. The growth in compactness significantly accelerated between 2005 and 2010, increasing by 0.05. This change may be associated with accelerating urbanisation in Shanghai, such as hosting the 2010 Shanghai Expo. Much infrastructure construction and urban expansion likely occurred during this period. From 2010 to 2022, the growth in compactness returned to a stable state, with an increase of 0.01 every five years or two years. It indicates that urban development has entered a more mature and stable phase, where the optimisation and adjustment of urban space are more focused on details and quality, gradually enhancing urban spatial resilience.

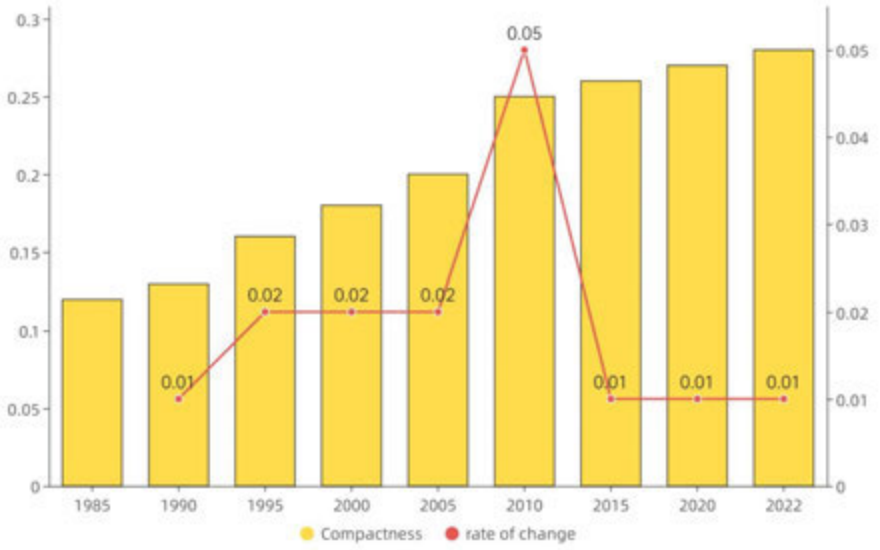

Figure 10 Changes in Shanghai's compactness from 1985 to 2022

The relationship between urban compactness and urban spatial resilience manifests in three critical aspects: ecological environment sustainability, economic vitality enhancement, and social and cultural dimensions resilience.

(1) Sustainability of the Ecological Environment: Compact cities contribute to protecting the natural environment and reducing ecological degradation by minimising land consumption and enhancing land use efficiency (Yao et al., 2022). For instance, by curbing urban sprawl and promoting the construction of high-density residential areas, more natural and semi-natural areas can be preserved, which are crucial for providing ecosystem services such as water retention, air purification, and biodiversity conservation. Furthermore, compact urban forms

help reduce commuting distances and, consequently, lower carbon emissions from transportation, thus mitigating the urban heat island effect and enhancing the overall ecological resilience of the city (Stevenson et al., 2016).

(2) Promotion of Economic Vitality: A concentrated urban layout facilitates the maximisation of resource utilisation and efficiency enhancement (B. Li, 2022). Compact cities can reduce transportation costs and time, enhance business synergies, and accelerate knowledge and technology dissemination. This environment not only attracts more businesses and talent but also fosters innovation and entrepreneurial activities, thereby strengthening the economic resilience of cities. It enables cities to recover and adapt quickly to economic fluctuations or external shocks.

(3) Resilience of Social and Cultural Dimensions: Compact urban environments promote interactions and communications among people from diverse backgrounds, enhancing cultural diversity and social inclusivity (Raman, 2010). This diversity and inclusivity are integral components of social resilience, which can reduce the risk of social fragmentation and conflict during times of change or crisis by strengthening community cohesion and mutual support.

In conclusion, the interconnectedness of urban compactness and spatial resilience spans multiple dimensions, including ecological, economic, and socio-cultural aspects. Urban planners, in their pursuit of urban compactness, should comprehensively consider its impact on the city's overall resilience to ensure more holistic and sustainable urban development.

4.5 Principles and Strategies for Building Shanghai's Urban Spatial Resilience Based on Compactness Elements

Based on the theoretical model of urban spatial resilience and the characteristics of compact urban development, this paper proposes a series of construction principles and enhancement strategies for building urban spatial resilience in Shanghai.

4.5.1 Construction Principles Proposed for Shanghai's Urban Spatial Resilience:

(1) Principle of Mixed Use: Encourage multifunctional land and space use in urban planning and construction, such as integrating commercial, residential, educational, and green spaces to form functionally integrated communities (Verdú-Vázquez et al., 2017). It reduces commuting distances and increases convenience and comfort in daily life (Gaigné et al., 2012). Developers and designers are encouraged to adopt flexible architectural designs, such as variable wall systems and multipurpose rooms, to accommodate future functional changes and diverse usage demands. It enhances the self-sufficiency of communities and provides additional support and buffering in the face of disasters or social upheavals.

(2) Ecological Priority Principle: Prioritise ecological protection and sustainable development in urban planning and expansion. Utilise natural infrastructure such as parks and wetlands to enhance the city's ecological resilience, protect biodiversity, and address urban heat island effects through microclimate regulation and flood risk reduction (Wu et al., 2020). Adopt renewable energy sources like geothermal and solar energy and promote using green building materials to reduce the environmental footprint of urban development and operations (Chel & Kaushik, 2018).

(3) Adaptive Flexibility Principle: Urban design and planning should exhibit high adaptability and flexibility, considering long-term environmental changes, social dynamics, and technological advancements (Jabareen, 2013). For example, the design of buildings and infrastructure should be adaptable to the impacts of climate change(Carter et al., 2015). Develop comprehensive strategies for natural disaster response, including constructing flood barriers, earthquake-safe building standards, and rapid-fire response systems, to effectively enhance the city's resistance and recovery capabilities in the face of natural disasters.

4.5.2 Enhancement Strategies for Building Shanghai's Urban Spatial Resilience:

(1) Strengthen Infrastructure Interconnectivity: Shanghai should continue to improve and strengthen its urban transportation network and public facilities to ensure rapid functional recovery after disasters (S.-C. Liu et al., 2021). Expand multimodal transportation systems, including public transit, bicycle lanes, and pedestrian paths, to reduce reliance on personal vehicles and enhance urban operational efficiency (Y. Li et al., 2024). These measures will enable the city to maintain continuity of operations and services in the face of public health emergencies or other urgent situations.

(2) Promote Green Building and Smart City Technologies: Utilise energy-efficient building materials and intelligent technologies, such as smart grids and automated management systems, to enhance the energy efficiency and operational flexibility of buildings and the city (Um-e-Habiba et al., 2024). Using energy-efficient materials, green roofs, smart grids, and automated systems reduces environmental pollution and increases the city's adaptability to various scenarios (Singh, 2024).

(3) Promote Socio-economic Diversification: Encourage industry diversification and innovation to enhance the city's economic resilience and reduce dependence on single economic sectors. Support the development of small and medium-sized enterprises to improve the economic system's resistance to external shocks. A diversified economic structure can help the city withstand global economic fluctuations and local economic crises(Sheng et al., 2024).

By implementing these principles and strategies, Shanghai can enhance its urban spatial resilience and ensure sustainability and high-quality living for its residents while pursuing compact urban development. These measures strengthen Shanghai's resilience in facing future challenges, including natural disasters, economic fluctuations, and social changes.

5 Conclusion

Constructing resilient cities is one of the critical planning goals for Shanghai's urban development. Based on an interpretation of the definition, connotations, and characteristics of "resilient cities," this paper analyses current issues in Shanghai's urban spatial construction. It explores principles and strategies for enhancing urban spatial resilience in Shanghai, leading to the following six research conclusions.

(1) The Concept, Development, Connotations, and Characteristics of Resilient Cities:

A resilient city is a type of advanced urban form that possesses strong adaptive and learning capacities, effectively responds to significant urban disturbances such as climate change threats, ecological issues, and public health incidents within a particular spatiotemporal scope, promptly restores structural and functional stability, and continues to evolve beneficially. This paper

classifies international research on resilient cities into four stages: nascent, initial, rapid development and reflection of continued development. Analysing the systemic composition, organisational methods, and representational forms of resilient cities reveals that they encompass three essential connotations: urban structure, resilience mechanisms, and resilience representations. These cities also exhibit four categories (encompassing 13 specific characteristics) of essential features: capabilities, structures, mechanisms, and representations.

(2) Definition and Connotations of Urban Spatial Resilience:

Urban spatial resilience is characterised by integrating the three elements of "scale, density, and form" in urban spaces, allowing "urban spatial resilience" to be cognitively expressed as "spatial resilience features." The diversity of urban spatial resilience is evident in the variety of urban functions, choices during impact processes, socio-ecological environments, and multi-scale connections among urban components. The structural organisation of urban spatial resilience exhibits high adaptability and flexibility, manifested in the construction of hierarchical urban spatial structures at macro, meso, and micro levels and in the organisation of social functions.

(3) Theoretical Model of Urban Spatial Resilience:

Based on the connotations and characteristics of resilient cities, this paper has sequentially proposed theoretical models for "resilience" and "urban spatial resilience." The "resilience" theoretical model includes essential elements, operational characteristics, core information, and operational rules. The "urban spatial resilience" theoretical model comprises operational mechanisms, influencing factors, hierarchical structures, organisational rules, intrinsic connotations and representational forms, and system capabilities. The "urban spatial resilience" theoretical model can be applied to analyse the evolution phenomena, construction principles, and enhancement strategies of urban spatial resilience in Shanghai, realising system characteristics of urban spatial resilience that "respond timely to strong disturbances," "maintain and restore the stability of urban structure and functions," and "effectively defend against and address similar issues after experiences or learning."

(4) Evolution, Changes, and Current Issues of Urban Spatial Resilience in Shanghai since 1985:

Since 1985, urban expansion in Shanghai has predominantly displayed a pattern of central concentration with peripheral dispersion, marking a shift from mere rapid expansion to a focus on integrated quality and sustainable development. Urban spatial growth has gradually slowed, and urban compactness has progressively strengthened. Urban development has entered a more mature and stable phase, emphasising ecological protection and sustainable development, thus gradually enhancing urban spatial resilience. The city has moved from concentrated high-speed development in the city centre to more balanced development in the suburbs and new areas. During this process, Shanghai has gradually improved its urban compactness, driving the overall optimisation of transport, public services, and green infrastructure. However, as the city's scale has expanded, Shanghai faces multiple challenges, such as traffic congestion, environmental pollution, social inequality, and disaster response. Future urban planning needs to focus more on finding a new balance between developmental drive and environmental protection, strengthening community participation and technological innovation to build a more resilient and inclusive urban environment, and ensuring sustainable development strategies can effectively address upcoming social and environmental challenges.

(5) Principles and Strategies for Constructing Urban Spatial Resilience in Shanghai:

Based on the theoretical model of urban spatial resilience, the construction of Shanghai’s urban spatial resilience should adhere to the principles of multifunctional use, ecological priority and adaptive flexibility. By implementing strategies such as strengthening infrastructure connectivity, promoting green buildings and innovative city technologies, and fostering socio-economic diversification, the city’s overall resilience and capacity for sustainable development can be comprehensively enhanced. These strategies significantly improve Shanghai’s ability to respond and adapt to natural disasters, economic fluctuations, and social changes, as well as raise the overall standard of urban infrastructure and the quality of life for residents, ensuring a sense of community cohesion and security. Through these integrated measures, Shanghai can achieve a greener, more intelligent, and more humane urban development model, addressing immediate challenges while laying a solid foundation for future sustainable growth, ensuring a harmonious coexistence of urban environments and economic vitality, and thereby achieving comprehensive and enduring urban prosperity and resident well-being.

The current state of urban development across various countries indicates that traditional "safety-defense" disaster prevention concepts no longer meet the needs of contemporary urban risk management. Instead, resilience thinking, which originated in ecology, has come into focus. As an evolving concept, enhancing urban spatial resilience is an effective way to address the risks of urban climate change and follow sustainable development principles and a practical necessity to control chaotic urban sprawl and achieve compact development. The research conclusions of this paper are intended to aid urban managers and researchers in deeply understanding the concepts, connotations, and characteristics of resilient cities and urban spatial resilience. They clarify the principles for constructing urban spatial resilience, the methods for analysing it, and strategies for its enhancement, thereby enabling an appropriate response to the challenges and risks encountered in constructing resilient cities.

Abstract
The paper demonstrates how different understanding of what nature is and what socio-natural assemblages it forms can lead to strikingly contrasting environmental strategies and planning approaches, and argues for a reframing of nature and natural resources governance in the context of planning practices if a truly earthcaring model is to be achieved. Considerations and reflections developed on the current mainstream environmental policies and their understanding of nature, as well as on alternative framings of nature and politics of nature, aim at outlining a frame of reference for the co-management of nature in the perspective of the urban bioregion approach, by defining the conceptual basis and identifying research and practice gaps.

Keywords
natural resources, politics, local communities, urban bioregion

1. Setting the scene: the eco-crisis we are dwelling in

Sixty-two years ago, when Rachel Carson published her book *Silent Spring* (Carson, 1962), the environment was not a matter of public and political concern, and the outbreak of environmental awareness she started at the peak of the modern economic growth narrative was fiercely opposed. Since then, one could argue, environmentalism has come a long way: the green paradigm has now become an essential requirement and often a driving force for politics and policies all over the world. Nevertheless, unprecedented ecological disruption is harming territories more seriously than ever, with limitless soil consumption, chemical pollution, alteration of hydrological cycles, annihilation of ecosystems, irreparable loss of biodiversity, and so on. It seems the strategies adopted at a global level have failed to address the problem. It might even be that relocalising the global has ultimately become a necessity precisely because this excessive acting of nature makes it impossible to grab the Earth globally (Latour, 2015). Or that the practice of thinking globally, i.e. globalism, rides contrary to the interests of "people, polity and nature" (Olwig, 2011: 401).
This paper demonstrates how different understanding of what nature is and what socio-natural assemblages it forms can lead to strikingly contrasting environmental strategies and planning approaches, and argues for a reframing of nature and natural resources governance in the context of planning practices if a truly earthcaring model is to be achieved. The topic is of extreme relevance in times of uncontested consensus over environmental issues parallel to mounting ambivalence of institutional and corporate statements over nature and environmental policies. The following sections of the text outline the argument, first, by analysing the conceptual frame of reference for the

current mainstream environmental policies and their understanding of nature, based on an apocalyptic imaginary coupled with an ecological modernisation promise of redemption. Second, alternative framings of nature and politics of nature are explored, from the new materialist tradition to post-human perspectives and more recent critical approaches. Having uncovered the de-politicising/re-politicising gestures inherent to these dominant and alternative views of nature, the argument moves to consider how they influence current planning practices, outlining an articulation of anthropocentric, ecocentric, and relational attitudes in nature management and design. The final section argues that a bioregional approach could provide an alternative promising answer to the environmental problem in planning practice. It therefore identifies research trajectories and gaps to address for the development and implementation of appropriate bioregional planning tools for the community-based management of natural resources.

2. Diving into key concepts: nature as a resource

The ecological modernization theory has emerged since the Nineties as a mainstream response to the ecological crisis. The theory's supporters argue that no system shift is necessary in the economic model, as the best way to solve the current environmental problems lies in further advancing technological progress and industrialization. Fisher and Freudenburg (2001) explain the dual argument supporting such expectations.

> "First, the theory explicitly describes environmental improvements as being *economically feasible*; indeed, entrepreneurial agents and economic/market dynamics are seen as playing leading roles in bringing about needed ecological changes. Second, in the context of the expectation for continued economic development, ecological modernization depicts political actors as building new and different coalitions to make environmental protection *politically feasible*" (*ibidem*: 702).

The roots of such a perspective can be traced back to the "sustainable development" formula introduced by the Brundtland Commission (WCED, 1987), with its belief that ongoing economic growth could be achieved by better managing technology and society within the planet's ecological limits. Sustainability therefore results from the combination of a technological and a market fix, on one side decreasing the energy and material flows required by the economic growth, while on the other accounting for nature's contribution in the current economic system. By these means, the ecological modernisation paradigm ultimately promises to fix the unbalances and disruptions brought up by the limitless growth paradigm by decoupling wealth production and the use of natural resources.

Within this system of thought the notion of nature as a resource to be properly managed has even intensified the centuries-long process of objectification and de-politicisation of nature, in particular with the introduction and mainstreaming of concepts and frameworks such as the Natural Capital and the Ecosystem Services.

Born as an attempt to bridge ecology and economics, the concept of "natural capital", which emerged in the mid-Nineties, is presented as a move from traditional economics view of nature as a resource to be used in production to nature as capital to be preserved and renewed (Fenech et al., 2003). However, the idea that placing a market

value on nature is the right strategy to preserve its intrinsic value is highly contestable, for a number of reasons. As Monbiot (2018) points out, first, the name itself is misleading, since financial capital and nature are neither comparable nor interchangeable; second, it is meaningless to price something unless it is for sale; and third, it is even counterproductive. Indeed, it suggests that an intensification of the same logic that destroys nature will be able to save it, and that the existence of a market value is more effective to stir a desire to protect nature than its intrinsic value – an idea which has already been proven wrong (Crompton, 2010). On the contrary, "markets change the meaning of the things we discuss, replacing moral obligations with commercial relationships" (Monbiot, 2018).

The concept of "ecosystem services" was first formulated in the Seventies, but became popular in the same years when the ecological modernisation and the Natural Capital were gaining consensus. It was in the following decade, with the turn of the Millenium, that institutional mainstreaming projects were initiated: the Millenium Ecosystem Assessment (MEA), the Natural Capital Project, The Economics of Ecosystem Services (TEEB). Despite growing popularity, the framework is not exempt from criticism. Among other observations, Ernstson and Sörlin (2012) interpret the Ecosystem Services approach as a technology of globalisation which, by applying a set od standardised practices and procedures, achieves objectives of abstraction, universality and comparability, virtually disconnecting the benefits bestowed by the ecosystem from the place, the social realm, and the possibility of conflict – as well as from the ecosystem itself. The result is a de-politicising gesture, to be interpreted within a wider technomanagerial turn, since "what once was political is through the [Ecosystem Services] approach translated into a scripted set of non-political acts of management" (*ibidem*, p. 282).

Overall, the concepts and frameworks proposed within the ecological modernisation paradigm operate towards a general de-politicisation by means of invisibilisation and backgrounding. For Barca (2020) what is overshadowed in the dominant environmentalist narrative is the relevance of the "forces of reproduction", those subjects that reproduce humanity by taking care of the biophysical environment and that represent potential alternatives to the current order. For Ernstson and Sörlin (2012), from the specific standpoint of the ecological modernisation frameworks and procedures, alternative ways of knowing and valuing nature are silenced and delegitimised. For Swyngedouw and Ernstson (2018), on a more general level, the invisibilised is the "intra-human exteriority" or, in other words, the heterogeneity of humanity which provides the space of the political. The resulting post-political condition, in the end, further reproduces logics of hierarchy and domination, well represented by the city-countryside power balance or more general neocolonial attitudes, which are the root of the current extractive relation with nature.

No wonder that the ecological modernisation theory has been easily integrated in the framework of the Planetary Boundaries and the Sustainable Development Goals (Barca, 2020), with an emphasis on the concept of resilience. As observed by MacGregor (2017), 'the valorisation of climate resilience over human vulnerability removes expectations of citizen resistance to the root causes of ecological crisis, thereby casting it as an inevitable and therefore non-political *fait accompli*'.

Serving to frame the emerging environmental problems and the solutions put forward by the élites as respectively unquestionable and indispensable, the dominant

environmental imaginaries and policies are in fact seen by philosopher Alain Badiou as the "contemporary form of the opium for the people" (Badiou, 2008: 139).

3. Framing the alternatives: nature, the human, and liberation

Alternative conceptualisation of nature and the nature-society nexus may help shift from domination to cooperation logics. Much of the critical thought concerning nature and the ecology is indebted to the materialist tradition.

The ecoanarchist perspective of Murray Bookchin (2017 [1982]) builds on a multifaceted ecology-freedom nexus, starting from the premise that human domination of nature derives from human domination of human by human, and is therefore necessary to liberate the latter through a deconstruction of hierarchy and domination structures in order to emancipate the former. The quest for a free ecological society model involves a reflection on an appropriate, human-sized technology and the management of natural resources by de-centralised local communities, resulting in an argument in favour of direct democracy, municipal autonomy, and community self-determination.

Despite reciprocal criticism, almost contemporary ecoanarchist and ecofeminist perspectives share the idea of a nexus between the domination of nature and the domination of human subjects, and between the achievement of a truly ecological society and a project of double emancipation. The ecofeminist thought provides refined instruments to uncover the technoscientific governing apparatus which stands as the protagonist of ecomodernist thought, since its emergence in the Eighties from the women's movements' contestation of the relationship between science, female bodies, and nature. Carolyn Merchant in *The Death of Nature* (1980) first demonstrated how modern science, degrading the natural world from a living organism to a functional machine, realised its domination on nature and women. In the same decade, from the South of the world Vandana Shiva (1989) reproposed Gandhi's critique of modern science as a form of power, which causes "*male*development" through the imposition of violence, inequalities, domination.

Starting from these premises, ecofeminist thinkers then and now have been promoting an alternative perspective on the economy, where the idea of sufficiency replaces "wellbeing" as emerging from continuous growth. This shift is meant as an act of liberation of all the values denied by the market, including self-sufficiency, cooperation, an ethics of care, and results in a renewed interpretation of politics, which re-centres everyday needs and the living world, valuing - for instance - food sovereignty and the commons, and non-hierarchical practices (Bianchi, 2012). For Salleh (2009), for example, a principle of eco-sufficiency must replace the eco-efficiency endorsed by ecomodernist theories to address the ecological crisis from the perspective of life reproduction, where nature provides for human needs rather than profit.

Such a perspective implies a reconsideration of the non-human – as well as the sub-human – focused on multispecies entanglements and aimed at cooperation and commoning. Views on this point are evolving and are definitely not homogeneous. Perspectives focused on difference and relationality are complemented by a growing body of literature drawing on posthuman views (see Haraway, 2016). Barca (2020) discusses the tension between posthuman new materialist thought and traditional materialist ecofeminism in terms of a different vision of technology.

> "A major point of tension is provided by the different visions of agency (whether this should be extended to objects) and, related to this, of technology in general. New materialism tends to see human agency as inherently incorporating technology, which cannot be separated from it, but rather should be embraced in the more-than-human understanding of subjectivity. Materialist ecofeminism, however, tends to see technology as a dangerous and often violent social *dispositif* of control over human and nonhuman life" (*ibidem*: 39).

Pellizzoni (2017, 2023) develops an analysis of the intrinsic ambivalence of posthuman thought, and critiques in particular the assumption that the suppression of dualisms should automatically have emancipatory effects. Rather, he registers "evidence of a burgeoning governmentality of science and technology which builds precisely on nondualist standpoints" (Pellizzoni, 2017: 71): the conceptualisation of the world as inherently fluid, indeed, removes any boundary to the (human or non-human) agent's action and eradicates responsibility, making space for a radical experimentalism of the kind expressed in eco-pragmatist programs such as the *Ecomodernist Manifesto* (Asafu-Adjaye et al., 2015). A fundamental point he makes is the need to aknowledge that "runaway capitalism" employs new domination patterns and techniques, taking advantage of indeterminacy and chaos as governing instruments (Pellizzoni, 2023). Drawing on his reflections, Swyngedouw and Ernstson (2018) have clearly described the new ecomodernist argument.

> "The excessiveness or supernumerary acting of 'nature' becomes enfolded within capitalism itself. To save the world and ourselves, we need not less capitalism, but a deeper, more intense and radically reflexive form of capitalism, one that revolves around reconstructing DNA and genetic material, forces gas out of shale formations so it can be 'carbon-stored' elsewhere, mobilizes the power of the nuclear to drive the economy, and works to terraform earth in a mutually benign co-constitution.
> Much of this perspective is indebted to the consolidation of non-linear ecological complexity theory that cherishes 'emergence', 'resilience', continuous experimentation, the 'indeterminacy' of nature, and radical openness, but without explicit attention to capital, culture, and politics" (*ibidem*: 13).

4. Investigating planning practices: from dualisms to relationality

In the fields of planning and management of nature, practices and policies have been described as oscillating between two opposite poles: a dominant anthropocentric dissipative attitude, updated in its green version to a "sustainable management" model, and an ecocentric conservative attitude, rooted in radical deep ecologies, which aspires to the restoration of an ideal pristine nature (Luciani, 2022; Ventura, Ribas and Saurí, 2002; Magnaghi, 2001).
As an example, in the context of river management Ventura, Ribas and Saurí (2002) identify two opposite models, anthropocentric and ecocentric, to which they refer practical and theoretical approaches. From an anthropocentric standpoint, the river is a source of natural resources, and the aim of river management is to increase the material well-being of society. From the ecocentric perspective, the goal is to reach an ecological balance, with reference to an ideal natural status of the river, before any human interference. The different disciplines involved in the two management models

represent the river, on the one hand, as a de-contextualised object of control, and on the other, as the subject to a return to an original – though hypothetical – place and time. When conflicts arise – such as disruption caused by extreme weather events – each discourse attributes the responsibility to the opposite view, and propose to radicalise their own principles as a solution. According to the authors, it is the inflexible opposition between the two that prevents the resolution of conflicts. The way out, for them, is to adopt what they call an 'environmental' model, based on a dialogue between an 'anthropic view' and a complementary 'ecosystemic view'.

On a more general level, Alberto Magnaghi (2001) has described three different attitudes towards the territory: dissipative, typical of industrial modernity, of which ecomodernism is just the most up-to-date version; conservative, mostly typical of the ecological culture; and finally, a third attitude for which development results from the enhancement of the territorial heritage, through coevolutionary interaction between environmental, territorial and urban systems, society and local cultures.

The search for a third way, an alternative to the dominant polarisation, indicates the insufficiency of both extremes in that they are still based on a centre, while a relational focus, as suggested by the ecofeminist contribution to the environmental ethics (Proctor, 1998), would allow for a more balanced approach (Table 1).

Discourse	Anthropocentric	Ecocentric	Relational
Society-nature relationship	Demand/ consumption	Preservation and restoration	Democratic care and enhancement
Aim	Increase of material wellbeing	Natural balance	Natural and human coevolutionary balance
Reference	Fluxes	Pristine nature	Human environment
Scientific discipline(s)	Water regulation (quality and quantity forecast and control)	River ecology (natural values preservation and enhancement)	Territory / landscape sciences (human and natural values enhancement)
Time	Linear progress	Retrospective	Longue durée
Space	Anonymous	A (new) previous place	Identitarian, historical, relational place
Social aspects of the river	Economic-rational	Identitarian-emotional	Relational/ dialogical
Management model	Managerial (expert-led)	Impact minimisation / contemplation (expert-led)	Integrated, cooperative (expert and local knowledge)
Origin of conflicts	Ecocentric discourse	Anthropocentric discourse	Disconnection of the two realms

Table 1: The table summarises and confronts the main characteristics of the anthropocentric and ecocentric discourses, adapted from Ventura, Ribas and Saurí (2002), and those of a third discourse, named relational and derived from the territorialist approach that Magnaghi (2001) indicates as a neither dissipative nor conservative attitude towards the territory.

The three families of approaches are ideal-typical, but examples can be found in current planning and design practices that can be traced back to one or more of these categories.

Dominant planning practices tend to adopt a resource-based, techno-centred, and even technocratic approach that results in a radicalisation of the anthropocentric and ecocentric polarities. On the anthropocentric side, under the formula of sustainable management, which embraces the institutional and globalised view of 'the Anthropocene' (Barca, 2020; Swyngedouw and Ernstson, 2018), one can find the majority of the global-level approaches to address the environmental crisis, which follow development and progress objectives and consider nature as an asset to be handled wisely with the best available technology, on which they rely to turn the tide of environmental deterioration. They make wide reference to the Natural Capital and the Ecosystem Services frameworks, and point to the need of a global expert governance to address the environmental issues. Geoengineering is one of the technological strategies envisaged to "manage" the climate, which would require large-scale international research, governance and policy frameworks (The Royal Society, 2009).
On the ecocentric side, regenerative and biophilic approaches to the built environment, alongside with a conservationist paradigm, tend to dominate in planning practices. Emerging from a shift from a mechanistic understanding of the world to an ecological worldview (Mang and Reed, 2012), regenerative approaches target self-sustaining ecological design and make extensive use of nature-based solutions, 'letting nature do the work' (Lyle, 1994), while biophilic perspectives assume nature and its processes as the main reference to design the built environment as a human biological need. Regenerative design, however, can be understood in very different terms. Biomimicry, for instance, meant as "the emulation of strategies seen in the living world as a basis for design and innovation, […] the emulation of an organism, organism behavior, or an entire ecosystem, in terms of its form, material, construction method, process strategies, or function" (Pedersen Zari and Hecht, 2020: 3), is understood by its supporters as contributing to a regenerative framework. However, the practice of mimicking nature in the built environment on the premise that "humans are an indivisible aspect of multiple interacting ecologies" (*ibidem*: 2) seems to embody the warning (see the previous paragraph) that the indeterminacy of the human and the natural subsumed in the technological can result in ambivalent approaches. Indeed, biomimicry can be seen as aiming on one side to do without nature, since its services can be provided by an artificial environment, on the other to replace nature with a cyborg ecology, whereby the natural processes become themselves dependent on technological inputs.
Alternative views, however, can be envisaged by focusing on the intricated coevolutionary relationship between diverse ecological subjects, including humans and non-human entities, without dismissing the separation, foundation of the relational - therefore political - dimension. Otherwise, post-human cyborg hybridisation could reinforce the destruction of nature by riding the simultaneity and indeterminacy of ecocentric and anthropocentric attitudes.
One of the key points of a relational attitude, which at the operational level could well employ some kinds of regenerative methodologies, is the recentring of the political in nature stewardship. Table 1 shows how both anthropocentric and ecocentric approaches, despite opposite premises and aims, tend to see the principles of their respective disciplines as normative, and therefore adopt expert-led post-political management models. The third discourse, instead, acknowledges science, technology, and even culture, as political. The management of local "natural resources", in a

cooperative coevolutionary perspective, is not driven by top-down impositions of either sustainable-exploitation, conservation-without-use or indistinct hybridisation models, but is performed by self-organised communities whereby expert and local contributions complement each other as equally relevant.
Some grassroots initiatives can be observed that seem to point to this direction. For instance, they can be identified in the everyday practices of some environmental movement groups that focus on sustainable food, renewable energy, and making to restructure the fluxes that support their basic needs on a local rather than global basis, through re-localised, self-organised and non-hierarchical networks recognised as fully immersed in the natural systems (Schlosberg and Coles, 2016). Similarly, other examples may include the permaculture movement's practices which are inspired by principles of earth care, people care, and fair share, interpreted by Centemeri (2018) as pericapitalist experiences aimed at subsistence objectives and based on "multispecies comoning".

5. Outlining research trajectories: bioregional planning

The urban bioregion approach as developed by Alberto Magnaghi (2014) translates into a territorial planning framework his definition of a third attitude, neither dissipative nor conservative, towards the territory (2001). Drawing upon the regionalist and bioregional planning tradition, the urban bioregion is, in his view,

> "the appropriate conceptual reference for a territorial project which is designed to integrate the economic (referred to the local territorial system), political (self-government of inhabited areas and work places), environmental (territorial ecosystem) and living (functional and inhabited areas of a group of cities, towns and villages) components of a socio-territorial system that pursues a coevolutionary balance between human settlement and the environment, reestablishing new forms of the long-term relationships between city and countryside that tend "towards territorial fairness" (Madec 2012)" (Magnaghi, 2020: 35).

His concept of urban bioregion describes a local territorial system whose main elements are (a) a reticular settlement system characterised by synergistic rather than centre-periphery relations, (b) hydrogeomorphological and environmental systems that coevolve with the settlement and the agro-forestry systems, and (c) forms of self-government of the living environment by the local community, aimed at assuring the self-sustainability of the territorial ecosystem and the wellbeing of the inhabitants. Such wellbeing does not derive from the extraction of resources and profit but rather from a wealth-producing enhancement of territorial heritage and a tendency to the closure of the territorial metabolic cycles.
The natural environment, described as comprising hydrogeomorphological and environmental systems, plays the role of material precondition for the very existence of the urban bioregion, and is deeply tied to the third component, the participation institutions which guarantee the local community's active involvement in the reproduction of the life-producing matrices. Such an active involvement is not limited to common forms of participation, but takes the form of social co-production, a

precondition for the reactivation of a territorialising relationality between the settled community and the natural matrices.
It is worth stressing that the bioregional project of anchoring the settlements within the ecological networks to overcome a defensive attitude that frames nature as *a priori* threatened by the urban doesn't mean that the built environment should mimic or emulate the ecosystems to merge with them - as in the indeterminacy produced by biomimicry. Rather, it implies a *care*ful study of the reproducibility rules of the natural matrices; such rules become the foundational element of the territorial project, according to relationships of mutual acknowledgement, respect, and active care.
Self-government is also necessary to collectively outline and sustain local socio-economic systems. Contrary to the widespread model of hetero-directed territories that pursue exogenous economic objectives, the self-governed urban bioregion enhances its long-lasting heritage structures – including the coevolved natural environment – to achieve endogenous forms of development.
Nature is therefore understood within the wide notion of heritage proposed by the urban bioregion frame of reference, as precondition of the settlement and long-lasting heritage to preserve and enhance for durable local development. Centemeri (2018) provides a clue to the role of intentionality and actions in transforming something into good, resource, capital, or heritage, when she specifies that "goods and resources - be they private, public or common – do not exist as mere things. It is what we do with mere things, or through mere things, that accounts for their becoming «goods» or «resources»" (*ibidem*: 3). Or again:

> "Commodification is oriented not towards creating commonwealth but towards monetary surplus through selling the commodity on the market. Capitalisation can be defined as a value practice in which the monetary return on investment is the guiding principle (Muniesa *et al.* 2017). Capitalising on something entails either considering it to be an asset, or turning it into one so as to guarantee the production of monetary economic value in the future. Commonwealth can also be considered an asset but, unlike capital, the flows it generates possess different goals" (*ibidem*: 4).

Contrary to the ecomodernist view that interprets nature as a resource or as capital, therefore implying actions involving nature are meant to produce monetary value, within the bioregional approach nature can be framed as both heritage and common good, having intrinsic and relational value. Indeed, actions involving this heritage and common good are oriented towards the reactivation of care actions, a valorisation aimed at growing durable wealth (distinct from profit) and sustaining the conditions of life reproduction. Thus, the shift of meaning from resource and capital to heritage and common good recentres the local communities' role as protagonists in the management and design of nature. Local levels of governance, at the scale of the municipality, develop coherent actions of preservation, enhancement and valorisation through agreement tools that involve a plurality of actors gathered together by the existence of a common interest in the local territorial development project.

6. To conclude: future research/action challenges

The implementation and realisation of the bioregional project still poses considerable challenges, particularly related to economic and political aspects. For what concerns the topic of nature and democracy, a constellation of exemplary grassroots initiatives can be identified, mapped, and valued (Società dei Territorialisti, n.d.). However, a necessary further step is to effectively federate a network of initiatives – the network of networks – able to represent a more powerful collective actor in the dialogue and/or conflict with the institutions and the multiple corporate and particular interest groups that aspire to grab, extract, capitalise on the territorial and natural resources to the detriment of local communities and the resource itself. Addressing such powerful interests not only requires the existence of a strong – though not hierarchical - federated network, but also points to the need to develop effective counterbalancing strategies to be incorporated in the agreement governance tools and procedures, to prevent them from turning into instruments that further reproduce de-politicising, expropriating environments that operate beyond and below the State.
At the same time, it is important to assess, articulate, and improve the convergence of bottom-up and top-down processes, accounting for the reception of such emerging bioregional, self-organised practices at the institutional level.
Tracing a pattern is a difficult job, especially in times of cultural turmoil, with a growing variety of interpretations of the environmental crisis and openings of ambivalent scenarios of meaning. Overall, the urban bioregion project provides a powerful conceptual reference and operational framework to tackle the destruction of both nature and democracy prefigured by current tendencies in hegemonic environmental policies and practices, a project which explicitly links nature stewardship and direct democracy, that values relationality without ceding to morally annihilating non-dualisms. The challenge to embrace in the present and near future action/research is to define a governance model that departs from managerial attitudes and ultimately results in a bottom-up re-politicisation of nature and environmental stewardship.

Aknowledgements

This contribution presents some of the preliminary results of the research project BioCode - Bioregional planning tools to co-design life places. Empowering local communities to manage and protect natural resources (prot. P2022NSAEJ), funded by the Italian Ministry of University and Research and the European Union – NestGenerationEU under the PRIN PNRR 2022 programme.

Abstract
The contribution focuses on the role of culture in regeneration practices in inner peripheries. The few culture-based strategies promoted so far in these areas often consist of territorial marketing operations tailored to urban tourism, which risk of trivialising and flattening local culture and identities. Instead, the promotion of a contemporary cultural production, albeit based on local heritage, memories, traditions and identities could strengthen the ongoing socio-economic development strategies and offer alternatives to the prevailing urban cultural model.
The critical review of best practices, selected from Italian and European networks that bring together culture-led regeneration practices, allows to explore whether and how current practices in inner peripheries are contributing to generate new "cultural models", tailored to the peculiarities of these areas and alternative to the urban ones.

Introduction

According to Eurostat data, in 2021 most of the EU population lived in cities (38.9 %), towns and suburbs (35.9 %). The remaining 25.2% lived in rural areas and the number of people aged 65 years or older, living in the EU's predominantly rural regions, increased on average 1.8 % each year between 2015 and 2020. In addition, almost 9 out of the 10 predominantly rural regions in Europe recorded negative rates of natural population change over the same period (EUROSTAT, 2023). Issues related declining and aging population are intertwined with those related to fewer job opportunities, weaker infrastructure, poorer access to public services, and digital divide that largely contribute to the progressive abandonment of rural areas all over Europe.
The main consequences of rural abandonment concern the loss of the relevant tangible heritage, such as historical centres, natural resources and traditional landscapes, as well as of the intangible heritage such as memories, traditional agricultural or artisanal practices, which have for long contributed to preserving local identities and ecosystem services.
These aspects are exacerbated in the so-called "inner peripheries", which represent remote rural areas characterised by low economic potential, poor accessibility to centres of economic activity and public services, as well as by the disconnection from the centers of political power (ESPON 2017, 2022).

Since the 1990s, the rebalancing of territorial disparities based on the urban-rural dualism has been addressed by EU policies on sustainable development policies in order to counteract both urban congestion and rural depopulation. The European Spatial Development Perspective (European Commission, 1999) proposed an integrated strategic vision of territorial development, recognizing rural areas as key elements for the balanced functioning of the whole territory.

In order to pursue sustainable development and improve territorial cohesion, the "Long-term Vision for the EU's rural areas" aims to make inland rural areas stronger, by strengthening services and fostering social innovation; more prosperous by diversifying economic activities and sustainable production, more connected, by improving digital networks and favouring new forms of mobility and more resilient, by improving local capacity to cope with climate, social and environmental changes (European Commission, 2022).
In Italy, this theme has been addressed since 2014, trough the National Strategy for Inner Areas (NSIA) (Barca et al. 2014), based on the classification of Italian municipalities according to their degree of peripherality. In detail, the NSIA defined "inner areas" as municipalities that are at least 20 minutes far from the first municipality offering basic services (education, healthcare, mobility). In this way, two different typologies of territorial systems are defined: poles, consisting of large, medium and small urban centres and highly specialised coastal areas, which are the centres of economic and social activities; inner areas mainly composed of rural territory and small villages, which are increasingly exposed to depopulation and impoverishment of their economic and social fabric.

According to the 2020 update of the NSIA classification (Italian Agency for Territorial Cohesion, 2022), about half of the Italian municipalities can be defined as inner areas (1929 intermediate areas, 1524 peripheral areas, 382 ultra-peripheral areas), covering about 60% of the national territory and hosting about 23% of the population. For these areas the NSIA has been addressed to improve accessibility to essential services, while promoting economic development and social cohesion through place-based approaches and active stakeholders' involvement.
Although in the Italian experience the classification of inner areas has been essentially based on the notion of peripherality, intended as distance from the places where basic services are gathered, partially reflecting the approach adopted in the Espon Project (ESPON 2017), this notion can be also more broadly considered, referring not only to the physical distance of these areas from services but also to their marginality within the economic and political networks at different geographical scales (Bock, 2016). These areas generally appear to be far from urban ways of life, from social contexts full of interactions and activities (Membretti et al. 2022).

This broader idea of "peripherality" may include cultural aspects too: nevertheless, it has been so far firstly referred to the disparities in accessing cultural activities in some areas compared to the urban hubs of culture and creativity (Florida, 2002).
According to the report "The role of culture in non-urban areas of the European Union" (Johansen et al., 2020), the primary role of culture in peripheral areas is only recently gaining attention in academic and political debate, particularly due to the need of counteracting depopulation processes by fostering culturally driven innovation. However, cultural policies in these areas are lagging behind their urban counterparts (Lygard, 2016).
The role of culture in the development strategies carried out for inner peripheries has been for long neglected or related to urban-centred cultural models and policies, scarcely respondent to the peculiarities of these areas (Cruikshank, 2018). These models have typically emphasised the "access" to cultural services and infrastructure, such as museums, archaeological sites, cultural hubs, universities, often neglecting the need of enhancing local cultural capital, especially the intangible one, as a key tool for strengthening territorial identities and the sense of belonging of local communities.

On the opposite, the Faro Convention (COE, 2005) emphasized that cultural heritage consists of all the resources inherited from the past that populations identify as an expression of their values, beliefs, knowledge, and traditions. Moreover, some authors have clearly defined

"culture" as the intangible infrastructure of a territory, shaped by its human community (Magnaghi, 2010). Thus, culture is not only a fundamental right of people living in inner peripheries but should be intended as the result of the continuous interaction over time between population and places.

Based on these premises, this contribution aims at analysing "cultural remoteness" of inner peripheries, interpreted not only as accessibility to cultural services but, above all, as the capacity of local communities to recognize and re-shape their cultural capital, developing tailored to-the-site cultural models, alternative to the urban ones.

The cultural "remoteness" of inner peripheries

Some data provided by the Italian National Statistics Institute (ISTAT) on the accessibility to culture in inner peripheries are here analyzed to quantify the persisting gap between urban centers and inner peripheries: number and distribution of museums, monuments, archaeological areas, number of visitors, number of entertainment and sports events, number of libraries, and so on.
In 2022, out of a total of 4'416 museums, monuments and archaeological sites, both public and private, about 40% are in inner areas (853 in intermediate areas, 698 in peripheral areas, 189 in ultra-peripheral areas):

- on average there are 6.2 museums or similar sites per municipality classified as pole (A) and 0.4 museums or similar sites per municipality classified as inner area (D, E, F) (Figure 1);
- all the museums in the 182 municipalities classified as pole (A) attract more than 70% of the visitors; about 44% of them has less than 5'000 visitors and about 81% of the museums or similar sites of ultra-peripheral municipalities (F) has less than 5'000 visitors and about half of them has less than 1'000 visitors;
- the average number of employees per museum is 22 in the pole municipalities (A) and 5 in the ultra-peripheral municipalities (F).

Further disparities can be observed when complementary services offered by museums (educational workshops, thematic itineraries for children, conferences and seminars, live shows and cultural entertainment initiatives, permanent or temporary exhibitions) and digital services (online ticketing, social media accounts, online virtual tours, online educational workshops, online conferences and seminars, online digital catalogues) are considered.
In detail, as regards the complementary services, the average varies according to the type of offered service between 57% (museums with live shows and cultural entertainment initiatives) and 65% (museums with conferences and seminars) in the pole municipalities, and between 31% (museums equipped for thematic itineraries for children) and 42% (museums with live shows and cultural entertainment initiatives) in the ultra-peripheral municipalities.
As regards digital services, the average varies according to the type of digital service offered between 14% (museums equipped for online educational workshops) and 76% (museums with social media accounts) in the poles, and between 4% (museums equipped for online virtual tours and online educational workshops) and 56% (museums with social media accounts) in the ultra-peripheral municipalities.

Moreover, in 2022 out of 8'131 libraries in Italy, both public and private, only 33% are in inner areas (1'373 in intermediate areas, 1'050 in peripheral areas, 277 in ultra-peripheral areas).
Looking at the percentage of film, entertainment and sporting events, in 2022, almost 87% took place in poles (A), inter-municipal poles (B) or belt municipalities (C), reaching 75% of the

audience, while less than 13% took place in intermediate (D), peripheral (E) or ultraperipheral (D) municipalities, reaching the 25% of the audience.
Finally, only 2 of the Municipalities classified as inner areas (intermediate municipalities) host universities.

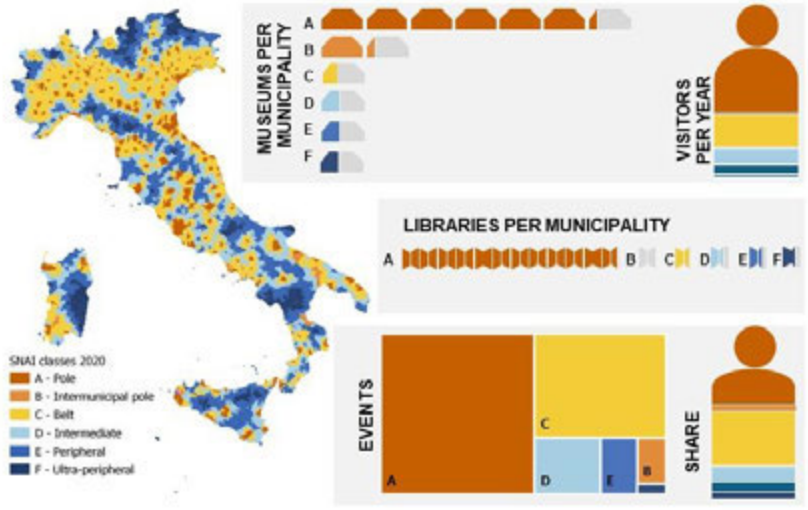

Figure 1. Distribution of museums, libraries, and events according to the SNAI classification (Source: Authors' elaboration from ISTAT data)

The concentration of museums, cultural hubs, events and universities in cities not only denies the fundamental right of inner peripheries' population to access cultural services, but also contributes to shape a concept of culture, capable of attracting a young and lively population, as a prerogative of urban areas.

Nevertheless, significant funding has been allocated on the topic "Culture and Tourism" in the inner peripheries selected as pilot areas by the first SNAI programming cycle 2014-2020, (about 16% of available funds for a total of 219 projects).
More than half of the funded projects have been addressed to relevant monuments' restoration or to promote tourism; others to the sustainable use of natural areas, promotion of festivals focused on rural traditions and creation of inter-municipal cycle and pedestrian paths (DPC, 2022).
These projects, although addressed to reduce 'cultural remoteness" of inner peripheries, due to the close link between "culture" and "tourism", may also induce negative effects, such as the museumization (Attili, 2018) of the historical villages or the loss of local identity (Sabatini, 2023): being "culture" the intangible infrastructure of a territory, shaped by its community, in fact, it is crucial to prioritize projects and initiatives capable of involving local communities in recognizing and reinterpreting legacies, practices and imaginaries to co-produce a contemporary local culture, linking ancestral and contemporary forms of knowledge, nature and technology, art and education.

According to this perspective, a kind of scouting has been carried out to identify bottom-up "culture-led" regeneration practices, capable of enhancing local resources in the field of production, maintenance, and care of places (Olcuire, 2023) in inner peripheries, starting from

the analysis of European and national networks that bring together culture-led regeneration practices, based on the peculiarities of territories, their memories, their historical landscape, local production, and new synergies between external resources and local communities (IETM, 2018).

Culture-led regeneration in the inner peripheries: from European and national networks to local practices.

To understand whether and how current practices in inner peripheries are contributing to create a new "cultural model", alternative to the urban one and tailored to the peculiarities of these areas, a methodological path based on a multiscale approach has been outlined (Figure 2).

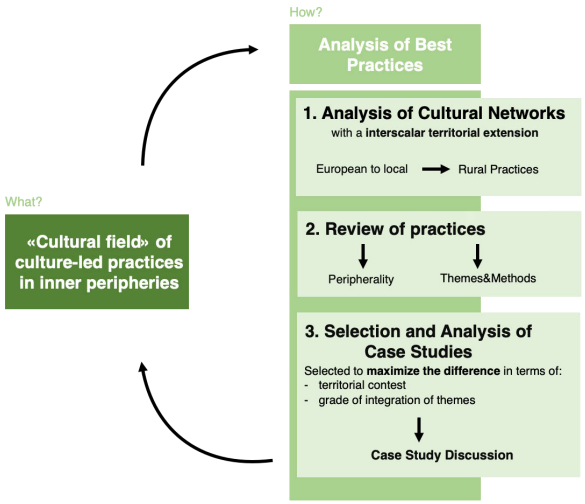

Figure 2. Methodological path for selecting of culture-led regeneration practices in inner peripheries (Source: Authors' elaboration).

This allows for a gradual focus on the local scale and the selection of practices that, being embedded in large-scale networks, benefit from the dialogue between heterogeneous actors and the possibility of exchanging knowledge and experiences developed in different contexts.
Specifically, a three-step analysis has been carried out to select culture-led regeneration practices in inner peripheries:

1. identification and selection of European networks focusing on culture-led regeneration practices developed in both urban and non-urban contexts.
2. identification and selection of national or regional networks focusing on practices carried out in non-urban and rural areas.
3. selection and analysis of culture-led regeneration practices developed at local level, and namely in inner peripheries.

The prevalence of culture-led practices carried out in urban areas compared to those developed in rural and marginal areas is evident in the first step of the analysis. Based on a systematic review of different sources, such as institutional documents (Murphy and Cameron, 2020; Arterial Network et al, 2022; Burgos et al., 2023) and institutional websites, six networks and research projects at European level that focus on urban and territorial regeneration with a

cultural and/or a community-led approach, in urban and non-urban areas have been identified (Table 1).

Table 1. European Networks

Network/Project	Description	Involved Actors
Culture Action Europe (CAE)	A European network promoting cooperation and development in the cultural sector. It advocates for the value of culture and arts in contemporary society through initiatives, advocacy, and transnational collaborations.	- Cultural organizations - Artists and cultural operators - Cultural activists - Professionals in the cultural sector
European Creative Hubs Network (ECHN)	A network bringing together creative hubs and organizations to support the creative sector in Europe. It aims to foster growth, innovation, and sustainability of creative hubs by promoting collaboration, knowledge exchange, and networking among members.	- Creative hubs - Support organizations - Professionals in the creative sector - Academic and research institutions
European Network of Cultural Centres (ENCC)	A network uniting cultural centers to promote culture and art in Europe. The ENCC aims to promote cultural diversity, access to culture for all citizens, and local and community cultural development. Through projects and initiatives, it promotes transnational cooperation and builds bridges between various European cultural communities.	- Cultural centers - Cultural organizations - Local and governmental authorities - Artists and cultural operators - Public and local community
Trans Europe Halles (TEH)	A network of independent cultural spaces promoting cultural collaboration in Europe. TEH supports cooperation among independent cultural centers and promotes cultural diversity, innovation, and the exchange of best practices in the European cultural sector.	- Independent cultural centers - Cultural organizations - Artists and cultural operators - Local and governmental authorities - Public and local community
European Land+Art Network	A network of organizations and individuals across Europe dedicated to promoting land-based art practices. It brings together artists, researchers, cultural institutions, and environmental organizations.	-Artists – researchers - cultural institutions - environmental organizations.
Ruritage	A project promoting sustainability and innovation in rural communities. Ruritage aims to enhance the cultural and natural heritage of rural areas, creating new opportunities for sustainable development through active citizen participation and engagement of various stakeholders.	- Local and regional authorities - Cultural and local development organizations - Universities and research institutions - Entrepreneurs and local businesses - Local communities

European networks play a crucial role in advocating different culture-led practices and provide a significant support to local and regional communities in developing cultural and creative practices: they act as drivers and promoters of a range of initiatives aimed at fostering cooperation, exchange and development in the European cultural field through innovative practices that address both social and environmental challenges.
Moreover, the networks/projects bring together a variety of actors engaged in different fields of cultural promotion at different scales, such as national or regional organizations, territorial cultural centers, creative centres, networks of cultural associations, foundations, NGOs, cultural enterprises, research centres (e.g. universities and research institutes).
Among these networks, only few (e.g. Ruritage) are specifically addressed to promote culture-led practices in rural areas. A number of national/regional networks that pay particular attention to local practices carried out in rural areas have been identified (Table 2).
The selected networks operate in different geographical contexts, above all in Southern and Eastern Europe, where the depopulation of rural areas appears more significant than in the rest of Europe.
These networks aim to promote cultural ecosystems, by involving a variety of local actors, such as cultural hubs, cultural associations, artists, cultural activists, researchers, entrepreneurs as well as local communities and public institutions. They aim to stimulate innovation, improve access to culture and encourage civic and community participation in the development of strategies for the social and economic growth of local communities through cooperation and exchange of resources and knowledge.

Table 2. National/regional Networks

I Level Network	II Level Network	Location	Description	Involved actors
Culture Action Europe	**Red de Espacios y Agentes de Cultura Comunitaria**	Spain	Network that promotes community culture and citizen participation in Spain, facilitating collaboration between cultural spaces and community actors to promote access to culture.	Cultural spaces, cultural associations, community organizations, public institutions, artists.
Culture Action Europe	**Clubture**	Croatia	Network that promotes independent culture in Croatia, facilitating the exchange of resources, knowledge, and best practices between independent cultural spaces and cultural operators.	Independent cultural spaces, cultural organizations, artists, cultural activists.
European Creative Hubs Network	**ARTERIA_LAB**	Portugal (Alentejo)	Network of 11 creative hubs operating in the Alentejo region of Portugal, engaging in architecture, visual arts, performing arts, design and crafts, literature, and new media.	Creative hubs, cultural organizations, artists, creative professionals, public institutions.
European Creative Hubs Network	**Matera Hub**	Italy	Innovation and culture hub located in Matera, Italy, promoting social, economic, and cultural innovation through projects, events, and collaborations.	Start-ups, entrepreneurs, artists, creative professionals, social activists.
ENCC, European Network of Cultural Centres	**Lo Stato dei Luoghi**	Italy	Platform dedicated to sustainable development and valorization of the territory, focusing on the analysis and promotion of local resources.	Local communities, local development organizations, public institutions, NGOs, research institutes.
Trans Europe Halles (TEH)	**Anténa – network for independent culture**	Slovakia	A network of cultural centres and organisations that operates in the field of independent arts and culture in Slovakia	Independent cultural spaces, cultural organizations, artists, cultural activists.

Among the selected European and national/regional networks, several culture-led practices focused on rural areas with varying degrees of peripherality have been identified (Table 3). These practices are mainly promoted by cultural organizations or associations working with artists, cultural institutions, environmental organizations, local communities, and activists. Overall, these organizations promote initiatives that bring together art, nature and local communities, to promote community development, environmental sustainability, education and enhancement of cultural heritage. The selected practices were further analyzed, focusing on both their degree of peripherality and the specific issues they address (Table 4).

The analysis of the selected practices allows some initial reflections on cultural regeneration practices in rural areas. First, most of them are bottom-up practices, linked to cultural activism organized in different legal forms, including cultural associations, social promotion associations, social enterprises, foundations; only in few cases practices are supported by public institutions. Second, all the selected practices are developed in mountain, rural, or island areas, although only some of these areas are classified as inner peripheries. Finally, these practices focus on recurring themes that can be classified into four macro-areas (Figure 3):

- sustainable local production and innovation;
- sustainable tourism;
- new ways of living and working in the territory;
- new narratives of the territory.

Table 3. Culture-led practices in rural areas

I Level Network	II Level Network	Practices	Location	Description
Culture Action Europe	Red de Espacios y Agentes de Cultura Comunitaria	**3piedras**	Spain – Ara, Alta Aragona	This organization focuses on art and ecology, promoting artistic and environmental projects.
Culture Action Europe	Clubture	**Silba Environment Art**	Croatia – Selva Island	This association focuses on environmental art and the island of Silba in Croatia, integrating art projects with the surrounding environment.
European Creative Hubs Network	Matera Hub	**Wonder Grottole**	Italiy –Grottole, Basilicata	This project involves the community of Grottole, Italy, aimed at enhancing cultural heritage and promoting local development through sustainable turism, local products and culture.
European Creative Hubs Network	ARTERIA_LAB	**Oficina do Convento**	Portogallo - Montemor-o-Novo, Alentejo	This organization acts as a multidisciplinary cultural center in Portugal, committed to promoting traditional artcraft, arts, culture, and education.
ENCC, European Network of Cultural Centres	Lo Stato dei Luoghi	**Interzona**	Italy - San Martino Valle Caudina, Campania	Interzona is an Italian cultural association, serving as a multidisciplinary center promoting culture and art through events, workshops, and projects.
ENCC, European Network of Cultural Centres	Lo Stato dei Luoghi	**Xfarm**	Italy – San Vito de Normanni, Puglia	Xfarm focuses on sustainable agriculture and art projects, integrating art with agriculture and the natural environment.
Trans Europe Halles (TEH)	Antena	**Periferne Centra**	Slovakia - Dúbravica	Perifernecentra is an organization dedicated to promoting cultural activities in peripheral rural areas related to artistic residence, ecology and art education at schools.
Trans Europe Halles (TEH)	-	**Plum Yard / Švestkový Dvůr**	Czech Republic - Malovice, South Boemia	Svestkovy Dvur is an organization focused on cultural programs and events based on theater and performing art.
Trans Europe Halles (TEH)	-	**Fundación Uxío Novoneyra**	Spagna – Lugo, Galicia	The Fundación Uxío Novoneyra is dedicated to promoting culture and the arts, particularly in Galicia, Spain.
Trans Europe Halles (TEH)	-	**Farm Cultural Park**	Italy – Favara, Sicily	Farm Cultural Park is a cultural center located in Favara, Italy, promoting contemporary art and culture through exhibitions, events, and cultural initiatives.
European Land+Art Network	-	**Arte Sella**	Italia - Borgo Valsugana, Trentino Alto Adige	Arte Sella integrates art, nature, and the environment throught outdoor art installations and environmental initiatives.
Ruritage	-	**Via Mariae**	Rumania, Harghita	Via Mariae Association supports and implements through the cooperation of the local stakeholders, the pilgrim route Via Mariae, also known as Maria's Way, that has been a connecting Western and Eastern Europe,
Ruritage	-	**Borgofuturo**	Italiy - Ripe San Ginesio, Marche	Borgofuturo promotes sustainable development and Communities-based rural regeneration in Marche region with culture-related projects and initiatives.

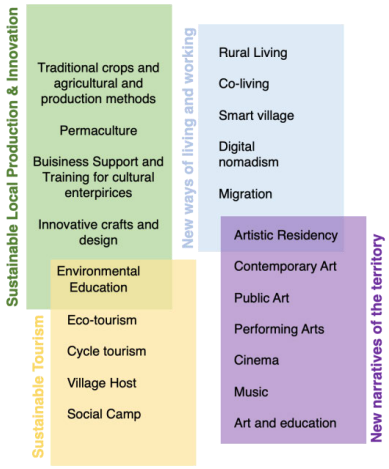

Figure 3. Thematic areas of cultural initiatives in rural areas. (Source: Authors' elaboration).

Table 4. Location and topics of the selected practices

Cataloguing Selected Pratices						
Pratices		A - Territorial Criteria			B- Thematic Criteria	
Name	Legal Form	Geographic Location	Typology of area	Inner Periphery (EPSON 2017)	Spaces	Themes of cultural initiatives
3piedras	Fundation	Spain – Ara, Alta Aragona	Mountain	yes	• Artistic Workshop • Guest House	• Environmental Education • Traditional farming and production methods • Artistic Residency, Cinema, Music • Rural Living
Silba Environment Art	Digital Platform by Fundation Kultura nova + Municipality of Zara	Croatia – Selva Island	Insular			• Enviromental Education • Artistic Residency
Wonder Grottole	Association for social promotion	Italy –Grottole, Basilicata	Rural	yes	• Guest House • Village Facilities • Territorial Paths	• Environmental Education • Village Host – Ecoturism • Traditional farming and production methods • Artistic Residency • Rural Living, Digital Nomands
Oficina do Convento	Cultural Association of Art and Communication	Portogallo - Montemor-o-Novo, Alentejo	Rural	yes	• Cultural Cente • Ceramic Workshop	• Innovative handcraft and design • Traditional production methods • Artistic Residency • Contemporary Art, Visual Art • Environmental Education
Interzona	Association for social promotion	Italy - San Martino Valle Caudina, Campania	Rural		• Cultural Center	• Contemporary Art • Artistic Residency • Rural Living
Xfarm	Project by Social Cooperative Qualcosa di diverso	Italy – San Vito de Normanni, Puglia	Rural		• Confiscated Agricultural Land	• Environmental Education • Traditional farming and production methods • Contemporary Art • Rural Living • Migration
Perifèrne Centrà	Civic Association	Slovakia - Dúbravica	Rural	yes	• Cultural Center	• Environmental Education • Traditional farming and production methods • Artistic Residency • Contemporary Art
Plum Yard / Švestkový Dvůr	Project by Theatre Group	Czech Republic - Malovice, South Boemia	Rural	yes	• Cultural Center	• Performative Arts • Artistic Residency • Art and Education
Fundación Uxío Novoneyra	Fundation	Spagna – Lugo, Galicia	Mountain	yes	• House-museum	• Artistic Residency • Rural Living
Farm Cultural Park	Cultural Association	Italy – Favara, Sicily	Rural		• Cultural Center • Guest Houses	• Artistic Residency • Contemporary Art • Public Art • Art and Education
Arte Sella	Social Enterprise	Italia - Borgo Valsugana, Trentino Alto Adige	Mountain		• Gardens • Territorial Paths	• Eco-turism • Artistic Residency • Contemporary Art • Public Art • Art and Education
Via Mariae	Cultural Association	Rumania, Harghita	Rural		• Territorial Paths • Guest House	• Eco-turism
Borgofuturo	Association for social promotion	Italy - Ripe San Ginesio, Marche	Mountain			• Social Camp • Environmental Education • Music and Festival

However, although the initiatives promoted by the selected practices may address a specific macro-area as well as individual themes, they often address a variety of themes, emphasizing interlinkages and mutual influences between both themes and areas.

A focus on Italy: examples of culture-led regeneration practices in inner peripheries

Although the selected culture-led regeneration practices are in different European countries, several factors make Italy an interesting case study.
First, about half of the selected practices are in Italy (6 out of 13). Second, Italy has been so far underrepresented in studies on cultural and creative practices (Duxbury, 2021). Third, Italian practices offer a variety of contexts, being located in rural and mountainous areas from the North to the South of the country.
Hence, three Italian practices characterized by different degrees of peripherality and starting dates and addressing different themes (Table 5).
All the selected case studies started a process aimed at generating a "new cultural model", where culture is directly shaped by local communities based on the recognition of local material and immaterial heritage. They also allow understanding how the initiatives addressing each theme, or more than one, can induce new territorial images and relevant impacts on the territory.

Table 5. The selected Italian practices

Name	Territorial Context	Foundation	Mission	Main Activities	Triggering Themes	Additional Cross-Cutting Themes	Governance and Innovation	Impacts
Wonder Grottole	Historical center of the village of Grottole, at 30km from Matera, Basilicata. Population of Grottole is 2,100 inhabitants.	Started in 2013 from the meeting of Casa Netural from Matera and a local inhabitant.	Facilitate the regeneration of the historic center through temporary living arrangements and the valorization of local resources.	Partnered with Airbnb for the Italian Sabbatical program, recovery of abandoned buildings, promotion of cultural initiatives and artist residencies.	Sustainable tourism, temporary living, architectural recovery, promotion of local territory.	Connection between local and global community, creation of training and skills growth opportunities.	Collaborations with local institutions, associations, and businesses to create collaboration networks and involve the local community.	Involvement of over 200 local community members, promotion on a national and international scale, attraction of tourists and "temporary inhabitants."
Arte Sella	Val di Sella, part of Borgo Valsugana in Bassa Valsugana, on the Trentino Alps. Population of Borgo Valsugana is 7.000 inhabitants.	Started in 1986 with an art exhibition in Villa Strobele in Val di Sella by the association «Frends of the Borgo»	Valorize the territory through artistic interventions integrated with the natural landscape.	Creation of artworks integrated into the landscape, educational projects like Arte Sella Education.	Collaboration with nature, integration of art and landscape, promotion of new models of cultural welfare.	Diversification of activities, partnerships with local and national cultural institutions.	Selection of artists with international perspective, financial and morale support from local and regional institutions.	Attraction of national and international visitors, creation of a network of cultural relations.
Interzona	San Martino Valle Caudina is an agricultural valley in the Appenine Mountains in the region of Campania. Population of 4.885 abitanti, inhabitants.	Founded in 2003 with the Interferenze festival, promoting indie and eletronic music in a rural area.	Revalorize rural territories through artistic residences and practices related to new media such as the deep listening of the territory.	Interferenze festival, artistic residences of Liminaria project, collaborations with schools and local communities.	Use of sound and new media arts, experimentation with hybrid formats, research and field studies.	Education, open hardware, international collaborations.	Weaving relationships between local and transnational levels, collaborations with urban cultural institutions.	Drafting of the Rural Futurism Manifesto, international exhibition, collaborations with urban cultural institutions.

WonderGrottole: the Italian Sabbatical

Wonder Grottole is an experimental project aimed at promoting the regeneration of the historic centre of Grottole, a village of 2,100 inhabitants located in the Basilicata region (southern Italy) and classified by the SNAI as peripheral area. The project aims at recoverying some abandoned houses and attracting of new temporary or permanent residents to encourage exchanges and relationships with the local population.

It is worth noting that in 2023 the Basilicata region, together with the Campania, has recorded the lowest negative migration balance in respect to all the Italian regions. The population trend in Basilicata shifted from -0.11% in 2002 to -0.66% in 2023. In terms of cultural statistics, Basilicata hosts less than 1% of all the registered Italian museums (or similar sites) and only 16,7% of them has more than 10,000 visitors per year.

In Grottole, the population trend moved from -0.65% in 2002 to -1.70% in 2022.

The historical center of Grottole has been characterized over the years by a progressive emigration, which has led to the gradual abandonment of the historical center where, currently, most of the buildings are abandoned. Today, the historical center hosts between 200 and 300 inhabitants, more than 70% of whom are over 70 years old.

The project started in 2013, following a walk (Netural Walk) organised by Casa Netural, a coworking space in Matera. Following this initiative, the first embryonic initiatives of the Wonder Grottole project were born from the exchange between Casa Netural and the Grottole's residents, and in particular with Silvio, the Municipal Culture Councilor.

The small village of Grottole was involved in the initiatives of the Matera Design Festival. In February 2018, the first crowdfunding campaign was promoted to launch the project and in September 2018, the social enterprise called WonderGrottole was established. The first

initiatives were related to the mapping of local resources to be involved in the project. They promoted an action for the participation of the community to map the abandoned buildings in the historical center. Using a game developed as an app, the local community mapped 629 abandoned buildings in the historic center. At the same time, a map of local knowledge, mapping and photo-storytelling of local producers was realized.
WonderGrottole focuses on sustainable slow tourism and temporary residence as a driver for the historic center’s regeneration. Specifically, the project aims at enhancing social innovation (Sacco, 2018), by favoring the exchanges between local community and temporary residents, such as tourists, researchers, artisans and artists, promoting meanwhile local resources.
A milestone of the WonderGrottole experience was the launch of the partnership with Airbnb in 2019 and the co-design of the Italian Sabbatical Programme: an international call for volunteers to host five "temporary residents" for three months, offering their skills to contribute to the revitalization of the village.
Meanwhile, the association has bought three abandoned buildings from private owners and renovated them to host WonderCasa, the association’s headquarters where guests and artists are hosted and WonderStudio, a workshop where artistic works are created. Also, Wonder Grottole launched touristic experiences in collaboration with local wine, honey and ceramic producers and promoted several cultural initiatives, such as international architectural competitions (e.g. Chiesa Diruta in collaboration with ReuseItaly), project exhibitions, the Living Culture Festival and the co-construction of the "Wonder Bee", a community apiary. The Institut Francais Nouveau Grand Tour has supported artist’ residencies, residential workshops for students and the Open School for Village Hosts hosted in Grottole.

Thus, WonderGrottole's initiatives have been aimed at promoting sustainable tourism and temporary living, with the aim of attracting energies and skills from all over the world and enhancing cultural exchange with the local community.
This is intertwined with the recovery of abandoned buildings in the historic centre, which are being transformed into accommodation and co-working spaces for the local and temporary community. The promotion of local products is also flanked by training opportunities, for both permanent and temporary inhabitants, to favor exchange and transmission of local skills. Hence, the different initiatives promoted by WonderGrottole have contributed to recovery historical heritage and promote local products and skills, renewing meanwhile the sense of belonging of inhabitants. Through collaborative projects with local institutions, associations and businesses, the project has promoted the exchange of knowledge and the empowerment of the local community that is currently more and more involved in political, social, and economic life.
Since the beginning of the project, WonderGrottole has involved more than 200 people from the local community. In 2018 and 2019, Grottole families opened their homes to students from all over Italy for the residential workshops of the Master in Relational Design of the Academy of Fine Arts of Catania, in Sicily.
The Italian Sabatic call for applications received over 280,000 applications in just one month, with over 3,000 national and international press articles on the Wonder Grottole project.
The international architectural competition for the Church of Diruta, promoted in collaboration with Reuse Italy Bcorp, collected 500 projects. The results of the competition were shown during the exhibition "La fragile bellezza" (The fragile beauty), hosted in the historical center thanks to the opening of some abandoned buildings.
In 2022, the activities of WonderGrottole brought around 2,000 tourists to the village. WonderCasa hosted 27 "temporary residents" from all over the world.

Arte Sella: the Contemporary Montain.

Arte Sella is a cultural association that plays an important role in the valorization and regeneration of the Bassa Valsugana, in the Trentino-Alto Adige region (North-eastern Italy), a vast mountainous and wooded area, characterized by a strong depopulation dynamic, especially in former industrial areas and less accessible areas. Val di Sella is located in the municipality of Borgo Valsugana with a population of about 7,000 and classified by the SNAI as an intermediate municipality.

The population trend in Trentino-Alto Adige has decreased from 1.06% in 2002 to 0.33% in 2022. In Borgo Valsugana, the population trend moved from 1.41% in 2002 to 0.82% in 2022. Looking at the statistics on culture, Trentino hosts 4% registered Italian museums (or similar sites) and 31% of them has more than 10,000 visitors per year.

Only a few dozen of people from Borgo Valsugana live in Val di Sella. For a long time, this area was an alpine pasture, and later the valley became a touristic area. Since the 1970s, Val di Sella has experienced a slow population decline, with the gradual abandonment of traditional pastoral activities and tourism.

Arte Sella was born in 1986 thanks to three inhabitants of Borgo Valsugana that organized an art exhibition in the garden of Villa Stobele, a private historic building located in the center of the Val di Sella, with the aim of combining contemporary art and nature. The exhibition was an unexpected success, attracting around 2,500 visitors. As a result, the organizers decided to repeat the experience through the creation of the Biennial Art in Nature, specialized in Land Art, where artists look to the natural landscape as an integral part of their work. This led to the creation of a four-kilometers artworks’ path called "Arte Natura": in 2002, the most famous artwork, the “Cattedrale Vegetale” by the artist Giuliano Mauri, attracted thousands of visitors and led other associations and local actors to join the project. Over the years, more than 300 artists from different parts of the world have contributed to the creation of three exhibition routes with artworks integrated into the surrounding natural landscape.

The success of the initiative led Arte Sella Association to formalize its initiative under the brand "Arte Sella. The Contemporary Mountain" and to broaden the scope of its initiatives.

The diversification of activities began in 1998, when the headquarter of ArteSella moved from Villa Strobele to another village in the valley, Malga Costa, which had lost its original rural character over time. Since 2002, Malga Costa has been enriched with numerous artworks and has become a pay-as-you-go place, hosting numerous cultural events, such as exibitions, concerts, theater performances and literary events. The original site, Villa Stobele, was reopened in 2016 to host an infopoint and educational workshops.

In 30 years of activity, the Arte Sella Association has promoted in situ artistic interventions and cultural initiatives that largely contributed to the enhancement of the territory and its natural heritage.

Today Arte Sella promotes different but complementary initiatives: in addition to artistic events and biennials, initiatives have been carried out to integrate landscape and sports activities or to promote innovative and ecological learning paths for students, teachers, and educators, training programs for social workers and teachers, focused on themes related to nature, art and care, placing viability, biodiversity, environment and quality of life at the center, have been carried out.

Furthermore, Arte Sella is now a permanent fixture in the area: a pole of cultural well-being, with a growing number of visitors: from around 15,000 in 2006 to around 80,000 in 2022. Today, the association counts not only on the close collaboration with the municipal and provincial authorities, which is essential to support Arte Sella's activities over time, on the numerous partnerships with other cultural institutions and regional museums, but also on a dense network of national and international relationships.

Interzona: Sound, arts and technoculture in rural areas.

The cultural association Interzona - APS is concerned with the revitalization of some rural and inner areas in Southern Italy through artistic practices related to the use of new media in sound art and technocultures, that are based on the relationship between art, culture and technology.
The association headquarter is in San Martino Valle Caudina, a mountain village of 4,885 inhabitants, in the Campania region. It has been classified by the SNAI as an intermediate municipality. Campania region is experiencing a significant decline in population: from 0.42% in 2002 to -0.26% in 2022. In San Martino Valle Caudina the population trend shifted from -0.40% in 2002 to -0.62% in 2022.
Interzona was founded in 2003 on the idea of Leandro Pisano, a researcher from San Martino Valle Caudina. He launched the first edition of the Interferenze festival, which included live events, performances, software art installations and digital experimentation in the rural area of Valle Caudina. Compared to other digital art festivals, Interferenze was the only one organized in a rural area, and it became a laboratory for experimentation and research in such territories. The 2005 edition of the festival took place in the historical center of San Martino Valle Caudina, which was transformed into a hybrid zone of meeting between locals, artists and tourists. The path of Interferenze continued until 2010, spreading to other rural areas of the Campania region. The last edition of the festival was held in Bisaccia, a village of the rural area of Irpinia, on the border between Campania and Basilicata regions. Then, a review process of the project and its sustainability, going beyond the Festival and its prevailing entertainment nature, was started. Hence, in 2014, Interzona launched Liminaria, a research project aimed at creating networks of cultural, social and economic actors from local communities and abroad.
The Liminaria project deployed different actions aimed at relating spaces, landscapes and inhabitants. In detail, it was addressed to re-launch marginal territories as privileged areas to promote cultural actions based on sound and new media.
The Project was tested over the years in several inner areas of southern Italy (Puglia, Molise, and Sicily), with hybrid formats in between of temporary residencies, laboratories, workshops and action-research projects. These actions converged in a research platform inspired by the concept of (neo)rurality, based on the exploration of the territory through a process of deep and immersive listening between artists and communities.
In 2019, Leandro Pisano, together with Beatrice Ferrara, drafted the Manifesto of Rural Futurism, a document in which the threads of the research carried out on the field during the first five years were pulled together, point by point, to share Liminaria's approach with other rural territories, both in Italy and at international level.
The Liminaria project was presented in exhibitions in Australia and New Zealand and, in 2022, landed in Japan with an exhibition of art related to sound and new media, as a conclusion of a three-year transnational cooperation project between Italy and Japan "Energies in the Rural", co-produced by Interzona and the public Aomori Contemporary Art Center (ACAC).

Hence, over the years the Interzona's field of action has extended from cultural and performance events, including a sound art residency program for international artists, to collaborative pathways with schools. The Interzona association has been involved in educational projects focused on land, communities and new technologies, developing open hardware projects with schools, cooperating with different village communities and weaving relationships between local and transnational levels, between exogenous and endogenous realities and actors.

Conclusions

The purpose of this contribution is to explore the “cultural remoteness” of the inner peripheries, interpreted not only as lack of access to cultural services but, above all, as the lack of bottom-up initiatives aimed at creating tailored to-the-site cultural models, based on the recognition and

reinterpretation of local cultural heritage and alternative to the dominant urban cultural models (Duxbury and Campbell, 2011).
To this aim, a set of culture-led regeneration practices carried out in peripheral areas have been selected within some European networks/projects focused on culture-led regeneration in both urban and non-urban areas.

Most of the examined practices highlight the importance of actively involving the local communities and developing networks of relationships going far beyond the local boundaries, while preserving their place-based identity. Most of the practices have been carried out thanks to partnerships between different actors, in the public-private and third sectors, and have dealt with different themes, trying to connect natural and cultural heritage, different artistic languages, new technologies and local traditions, innovative agricultural practices and local productions, permanent and temporary residents, environmental education and sustainable tourism.

In particular, the three Italian practices are based on the enhancement of tangible and intangible cultural assets through hybridisation, overlapping and encounters with external resources, where cultural initiatives are never exclusively aimed at entertainment and the consumption of cultural products coming from outside the territory, but are always closely linked to the local natural and cultural environment.

This is evident in the case of WonderGrottole, where the attraction of temporary residents allows the exchange of knowledge and skills creates mutually beneficial relationships between permanent and temporary residents, facilitating the communication between people with different cultural backgrounds through expressive storytelling, visual arts or physical interaction with inhabitants and places.
The Arte Sella initiatives, in Bassa Valsugana, have contributed significantly to the development of the Val di Sella, thanks to the symbiosis between art and nature, where one contributes to the definition of the other (Sechi, 2022). Here the artistic process is the result of the link established between nature and art, creating unique and non-reproducible products. Artistic practices favour the emergence of new territorial imaginaries and generate new forms of culture, strictly rooted in the local context. (Lowe, 2000)
The projects carried out by Interzona, such as the Liminaria project, directly engage with local communities through the artistic practice of deep listening, to create new perceptions of places and environmental resources. The aim is to create imaginaries that nourish the possibility of looking at their own places of living with different eyes (or, in the case of Liminaria, listening with 'different' ears), with particular reference to the natural resources of these territories (Pioselli and Pisano, 2020).

Moreover, in the investigated practices, culture seems to emerge as a key tool for opening up new spaces of participation, valorisation of resources, sharing between local and external actors, as well as for creating large-scale networks of collaboration and exchange networks, capable of amplifying and extending the impacts of individual practices well beyond the local context.
Finally, using both artistic and non-artistic forms, often integrated, these practices, although so far, they did not produce an impact in terms of population growth, have surely favoured the regeneration of local relational and cultural capital, nourished by exchange and hybridisation with external resources, which might represent a more fertile ground for attracting young and lively population.
They have contributed to activate dynamic development processes that, framed in wider relational networks, guarantee the continuity of the local initiatives, and provide relevant

examples of overcoming the cultural remoteness of inner peripheries through culture, social/creative innovation and collaborative governance (Ansell and Gash, 2008).

Micro-Intervention as a New Approach for Urban Regeneration in Metropolises: A Case Study in Beijing

Dongdong Chen
Affiliation: Beijing Municipal Institute of City Planning and Design
Email: camchen-bicp@foxmail.com

Abstract

This study examines urban regeneration in Beijing through the lens of micro-intervention strategies, in alignment with the city's 2016-2035 Master Plan. As Beijing confronts challenges of its vast population and rapid urban growth, it has adopted a sustainable development model characterised by a growth cap and a strategic emphasis on minimalistic interventions. This paper examines three exemplary cases—No. 17 Guangminglou Residence, Wangjing Walk Business District, and Langyuan Vintage Factory—to illustrate how Beijing manages growth constraints while enhancing the quality of urban life. The micro-intervention projects are analysed to demonstrate their role in promoting cultural vitality and maintaining architectural integrity without the extensive construction typically associated with urban redevelopment. This research draws upon a longitudinal collaboration with the Beijing municipal government, incorporating insights from over 200 case studies since 2021. It reflects on the adaptability and effectiveness of Beijing's urban strategies. The findings suggest that Beijing's approach could serve as a model for sustainable urban transformation that other global cities facing similar developmental pressures might consider. This investigation offers a comprehensive insight into the potential of targeted, small-scale interventions to drive significant enhancements in urban sustainability and liveability.

Keywords

Urban regeneration, micro-intervention, sustainable development, Beijing urban planning

Introduction

Since the 1950s, the phenomenon of rapid urban expansion has prompted discussions on the effective management of urban development boundaries and the utilisation of city resources in a more efficient manner. The concepts of "smart growth" and "post-growth" have emerged as a means of achieving a balance between economic development and sustainable outcomes (Hess, 2010; Jackson, 2011). One method for reutilising urban resources is redevelopment, which has evolved from mere physical space reconstruction and beautification to focusing on sustained improvements to social environments and regeneration (Wu, Xu and Gar-On Yeh, 2007; Roberts, 2000). In the present era, this approach has become the dominant strategy employed by numerous cities in their pursuit of improvement and adaptive reuse.

Furthermore, China has increasingly prioritised sustainable development over purely economic gains since 2020. For instance, President Xi Jinping asserted that the ecological environment itself is the economy, thereby underscoring a shift towards environmental consideration in economic planning (Xinhua, 2020). The Ministry of Natural Resources has integrated urban development boundaries into national spatial planning, thereby providing guidance for this new direction (Government of China, 2019). The 2017 master plan for Beijing establishes a framework for the city's future growth, incorporating measures such as industrial permits, prohibited lists, and differentiated urban density controls (Beijing Municipal Bureau of Natural Resources and Planning, 2017). A notable aspect of this plan is the adoption of "micro-intervention" regeneration strategies, which replace large-scale demolitions with small-scale, gradual improvements. The approach to micro-intervention regeneration has already generated

a number of practices, which have in turn shaped a distinct model for the city's urban regeneration.

This paper examines three specific case studies that have been implemented under Beijing's micro-intervention strategy. The case studies include No. 17 Guangminglou Residence, Wangjing Walk Business District, and Langyuan Vintage Factory. This paper examines the operational principles of these initiatives, summarising their distinctive models and interpreting how such urban regeneration contributes to the sustainable development of metropolises. The following sections of this article are structured as follows: the next section reviews global literature on urban regeneration, followed by a methodology section. The fourth through sixth sections provide detailed accounts of each case study, while the final section discusses the significance of micro-intervention strategies for sustainable development.

Urban Regeneration: Global Perspectives and China's Strategic Approaches

In the mid-20th century, cities across the globe were confronted with the challenges posed by uncontrolled urban expansion. In response, various nations adopted sophisticated urban management policies with the objective of addressing inefficient land use, excessive dependence on automobiles, and environmental degradation. In the United States, the adoption of the "smart growth" philosophy facilitated the implementation of strategies such as "Urban Growth Boundaries" and "Transit-Oriented Developments" to effectively manage urban sprawl (Daniels, 2001). Similarly, the United Kingdom's "Green Belt" policy was instrumental in curtailing the unplanned expansion of urban areas (Hall, 2002). Japan concentrated on enhancing its public transportation systems to reduce reliance on personal vehicles (Hayashi et al., 2004). Singapore maintained urban order and efficient land utilisation through intensive spatial planning and stringent land development policies (Kempton et al., 2022). These initiatives were of great significance in controlling urban expansion, enhancing environmental protection, and promoting sustainable development.

As the 21st century commenced, particularly in the aftermath of the 2008 global financial crisis, there was a paradigm shift from a sole focus on GDP growth to an acknowledgement of the importance of ecological sustainability, social equity, and quality of life (Harris, 2010; Schneider et al., 2010). This shift gave rise to the "post-growth" theory, which advocates for economic activities to be harmonised with ecological capacities and societal well-being (Fritz and Koch, 2014; Kadekodi, 1992). Cities such as Amsterdam have implemented this theory by supporting circular economies and enhancing public transportation systems, thereby reducing reliance on conventional growth models (Flint and Danner, 2001).

In China, the rapid urbanisation that occurred between the late 20th and early 21st centuries initially prioritised economic growth and speed. However, as environmental concerns and resource pressures mounted, the Chinese government, during the second decade of the 21st century, redirected its urban planning strategies towards prioritising ecological protection and sustainable development. This strategic pivot involved the integration of the "Three Land Management Red Lines" into national spatial planning, which effectively balanced urban and rural growth (Liu et al., 2019). These red lines included ecological protection redlines, permanent basic farmland, and urban development boundaries. In response to the challenges posed by urbanisation, major cities such as Beijing and Shanghai developed urban master plans that regulated development space and population growth. These plans ensured the implementation of high-quality, sustainable urban development (Merics, 2021).

Following the enactment of the "14th Five-Year Plan" in 2020, China has actively promoted urban regeneration with the objective of transitioning towards high-quality development. The plan emphasises the implementation of intensive, green, and low-carbon development models, advocating a balanced "reserve-renovate-rebuild" strategy that prioritises the preservation and enhancement of existing structures (United Nations Development Programme, 2021). Furthermore, the State Council issued directives to avoid large-scale demolitions and constructions, promoting small-scale, incremental regeneration to ensure sustainability. (Asian Development Bank, 2021). The Beijing government developed the "Beijing Urban Regeneration Action Plan" (Beijing Municipal Government, 2021), which sets out specific objectives, tasks, and measures for urban regeneration during the "14th Five-Year" period. This plan provides a robust framework of policy and institutional support for these initiatives.

The urban regeneration strategy of Beijing has transitioned from a property-led approach of demolition and redevelopment to a more comprehensive strategy that prioritises functional transformation, quality enhancement, and cultural preservation. Notable projects include the renovation of Shougang Industrial Park (Wang, Duan and Zheng, 2023), the conservation project for Nanluoguxiang (Zhang, Kang and Koo, 2019; Min and Aili, 2015), and the revitalisation of Wangfujing pedestrian street (Zhou, 2012), which illustrate Beijing's strategic shift in urban regeneration. These initiatives not only preserve the city's historical heritage, but also improve the quality of life for residents, and stimulate economic growth through business upgrading. The projects illustrate the efficacy of applying urban regeneration principles to diverse local contexts.

Methodology

The methodology adopted in this study utilises a qualitative case approach, designed to provide an in-depth analysis of urban regeneration projects implemented in Beijing from 2020 to 2022. The research involved continuous investigation of over 200 urban regeneration initiatives during this three-year period.

The sources of these projects varied. Some of the projects were initiated by enterprises or local authorities seeking upgrades of their own properties. While others were initiated by district governments to enhance safety and environmental conditions within their jurisdictions. In collaboration with municipal and district governments, the research specifically targeted projects that were representative of broader trends or that demonstrated innovative practices within the sphere of urban regeneration. This selection process, conducted jointly by municipal and district governments along with researchers, ensured that each chosen project significantly aligned with the overarching goals of urban policy and practice.

Figure 1. The distribution of Beijing's urban regeneration projects from 2020-2022 (Source: author)

Primary data collection was conducted through organised interviews with a diverse array of stakeholders, including project developers, urban planners, architects, researchers, and government officials who were involved in the planning and reviewing phases of the projects. These interviews aimed to gather comprehensive insights into the project implementation process, the challenges faced, the strategies deployed, and the outcomes achieved. This methodology allowed for a multi-dimensional analysis of the projects, covering both the technical aspects of planning and design as well as the administrative and execution phases.

For projects identified as particularly significant, the research methodology included field visits. During these visits, interviews were conducted with a wide range of individuals, including local residents, visitors, sub-district and neighbourhood-level workers, and other local workers such as delivery riders. This method facilitated the collection of a broad spectrum of perspectives and experiences, providing a deep understanding of the community's interactions with and responses to the urban regeneration projects.

This study focuses on three key cases: No. 17 Guangminglou Residence, Wangjing Walk Business District, and Langyuan Vintage Factory. Each represents a distinctive approach to the micro-intervention regeneration of old residential buildings, commercial areas, and industrial facilities, respectively. The research involved comprehensive tracking of these projects from initiation and design through approval and operation. Extensive longitudinal monitoring and multiple site visits were conducted to ensure the accuracy and completeness of the data. This comprehensive examination provides critical insights into the challenges and innovations associated with micro-intervention strategies in urban regeneration.

No. 17 Guangminglou Residence

No. 17 Guangminglou Residence is a residential building located in Longtan Subdistrict, Dongcheng District, Beijing. Constructed in the 1960s, the three-storey building covers an area of 335.7 square metres with a floor area of 1007.1 square metres. Over time, the building has undergone significant deterioration, exhibiting a number of structural deficiencies, including partial cracking, which presents a significant risk to the safety of its occupants. The building's design and facilities are outdated and lack basic living conveniences, particularly the arrangement where every five households share a kitchen and bathroom, which severely compromises the quality of life and privacy of the residents and is in urgent need of improvement.

Figure 2. Before and after regeneration of No. 17 Guangminglou Residence
(Source: https://baijiahao.baidu.com/s?id=1751087758495236894&wfr=spider&for=pc)

Feature 1: Minimal increase for enhanced urban aesthetics and living conditions

In contrast to traditional large-scale demolition and rebuilding projects, the regeneration of No. 17 Guangminglou Residence employs a micro-intervention strategy. The objective of this approach is to preserve as much of the original architectural character and urban fabric as possible, while implementing necessary functional enhancements. The project entailed the addition of a single storey to the existing three-storey structure, resulting in a total height of 12.7 metres and an increase in floor area of 420.9 square metres. This approach, which could be described as prudent and incremental, was designed to ensure harmony with historical architecture and the adjacent older residential districts, thereby maintaining continuity of the urban facade and overall aesthetic coherence.

The renovation has provided each household with independent kitchen and bathroom facilities, thus transitioning from the previous non-self-contained units to fully equipped dwellings. This significant upgrade has enhanced the convenience and comfort of residents. Furthermore, the expanded living area has alleviated the previously cramped conditions, increasing the residential area from 35 to 46 square metres per household. This not only enhances the quality of life of residents but also significantly increases the private living space available to them.

Figure 4. Floor plan after regeneration of No. 17 Guangminglou Residence
(Source: Beijing Tsinghua Tongheng Urban Planning & Design Institute)

Feature 2: New Financial Framework for Collaborative Urban Regeneration

The No. 17 Guangminglou Residence, which was previously owned by the Dongcheng District government and designated as public housing, was occupied by tenants rather than homeowners. The regeneration project introduces an innovative funding model that involves residents, the property owner (Dongcheng District government), and both municipal and district governments in a collaborative financing arrangement. This model represents a departure from traditional funding models that are typically financed solely by the government or developers. It introduces a more diversified and sustainable funding source. The direct participation of residents not only alleviate the financial pressure on the government but also allows residents to engage actively in the regeneration process.

The total project cost is approximately 20 million RMB. The total government subsidies amount to approximately 5.8 million RMB, comprising municipal subsidies of 2630 RMB per square metre and district subsidies of 3156 RMB per square metre. The residents contributed approximately 4.2 million RMB, which represents a substantial level of involvement, accounting for 21% of the total cost. Meanwhile, the property owner, Dongcheng District government, invested approximately 10 million RMB, covering half of the total expenses. This financial structure ensures a balanced economic burden among all stakeholders, thereby reducing the dependence on a single financial source.

The residents primarily benefit from the considerable appreciation in housing value that occurs as a result of the regeneration process. The cost to residents was calculated using the original

housing area of 35 square metres at a renovation cost price of 1560 RMB per square metre, while the additional 11 square metres were calculated at a reconstruction cost price of 6564 RMB per square metre. Consequently, the average contribution cost for residents was calculated as (35 * 1560 + 11 * 6564) / 46, which equates to approximately 2800 RMB per square metre. This figure is considerably lower than the prevailing secondary market price of 100,000 RMB per square metre. By participating in the regeneration process, residents were able to transition from tenants to homeowners. This resulted in a notable increase in the value of their asset, with each household gaining an expansion in living space from 35 square metres to 46 square metres. This improvement in both living quality and financial feasibility represents a significant enhancement in the standard of living for the residents. This co-financing model offers a financially viable and socially responsible approach to urban regeneration, representing a sustainable method that benefits the entire community.

In conclusion, the regeneration of No. 17 Guangminlou Residence exemplifies a successful model for the regeneration of Beijing's aged residential buildings. The project demonstrated an effective balance between architectural preservation and the implementation of enhancements to living conditions. This was achieved through the adoption of a minimalistic design approach that aligns with the existing urban fabric. Moreover, the innovative financial model, which involved a collaborative investment strategy among residents, the property owner, and government agencies, demonstrated a sustainable and propagable approach to urban regeneration. This project not only enhanced the safety and functionality of the housing but also facilitated a significant shift in the residents' status from tenants to homeowners, thereby enhancing both their quality of life and financial stability. Therefore, No. 17 Guangminglou Residence represents a pivotal development in urban regeneration strategies, offering valuable insights for future projects in similar urban settings.

Wangjing Walk Business District

The Wangjing Walk Business District is situated in the Wangjing area of Beijing's Chaoyang District. It was previously a derelict zone characterised by a 380-metre road lined with commercial buildings, the majority of which were owned by Vanke and Fangheng. The district's regeneration was initiated with the objective of addressing a range of issues, including outdated environments, suboptimal business operations, and significant traffic congestion. The project aimed to enhance the commercial appeal and public spaces quality of the district, thereby improving inclusivity and accessibility to better serve the community's predominantly international demographics. The revitalisation has not only improved services but also significantly boosted urban vitality, transforming Wangjing Walk into a vibrant and dynamic business district.

The regeneration project of Wangjing Walk Business District represents a significant departure from traditional commercial complex renovations, which are typically developer-led and focus primarily on enhancing the commercial property itself through expansions, façade beautification, and interior refurbishment in order to attract more consumers. In these conventional models, the transformation of external public spaces is often relegated to a secondary role, usually addressed last in the renovation process with minimal investment.

In stark contrast, the Wangjing Walk Business District project commenced its transformation with a focus on the enhancement of public spaces, with a particular emphasis on the improvement of the central roadway environment within the commercial district. This initial step, spearheaded by the government and financially supported by them, demonstrated a strong

commitment to the revitalisation of regional development. The government's initial investment not only upgraded the infrastructure but also successfully encouraged private capital to participate in the renovation of adjacent commercial entities. This approach effectively mobilised resources and strengths from both the public and private sectors, collectively advancing the comprehensive regeneration of the area.

Furthermore, the Wangjing Walk Business District regeneration did not result in an increase in the scale of the buildings, thereby minimizing disruptions to the surrounding urban environment. Instead, the project substantially enhanced the area's aesthetic quality and functionality by upgrading environmental conditions and augmenting public services. This strategy, which places a core emphasis on the renovation of public spaces, not only improves the commercial viability of the area but also strengthens community cohesion and resident satisfaction. The Wangjing Walk Business District project offers a novel perspective and a practical example for sustainable development in urban commercial districts. It demonstrates how public space-focused regeneration can profoundly impact both economic vitality and social integration in urban settings.

Figure 5. Before and after regeneration of Wangjing Walk Business District

Feature 1: Government-Led, Corporate-Participated Regeneration Model

In the Wangjing Walk Business District regeneration project, the government, Vanke, and Fangheng played distinct financial roles and collaborated to drive the project's success. Both Vanke and Fangheng are prominent real estate developers in China, with substantial fixed assets on either side of Wangjing Walk.

At the outset, the government made an initial investment of 13 million RMB, which was focused on essential infrastructural renovations such as road repairs and lighting system upgrades. This funding constituted the initial stage of the broader district transformation.

Subsequently, Vanke, as a principal corporate entity, made a further investment of 35 million RMB. This expenditure was not only allocated to the development of recreational, artistic, and support facilities along the district, such as new commercial spaces, public art installations, and green projects, but also included substantial internal renovations and business model enhancements for Vanke-owned commercial buildings and offices along Wangjing Walk. The initiatives were designed to enhance the district's commercial appeal and public aesthetics, thereby improving the experience for residents and visitors and optimising Vanke's own asset value and operational efficiency.

Fangheng also provided financial support, albeit on a smaller scale, with a contribution of 5 million RMB. The investment was directed towards further enriching the district's recreational and artistic facilities, including the addition of art exhibitions and temporary event spaces, as well as other beautification projects. These enhancements served to enhance the overall cultural atmosphere and functionality of the district.

The layered financial contributions and their sequence ensured that the project's diverse needs were met, while also reflecting the spirit of collaboration and shared responsibility between the government and enterprises in urban regeneration efforts. This cooperative model effectively leveraged the strengths of each party, optimised resource allocation, and facilitated the transformation of Wangjing Walk from a traditional commercial street into a modern, international business and cultural district.

Feature 2: Strategic Business Alignment through Community Insights

In the preliminary phase of the Wangjing Walk Business District regeneration project, the project team conducted extensive and detailed market research and resident opinion collection to ensure that the regeneration plan comprehensively and accurately reflected the specific needs of the area. The research activities, which spanned several months, included roundtable discussions, questionnaire surveys, and door-to-door interviews. These covered 11,400 effective tax-paying enterprises out of 26,700 legal entities in the district, including 1,113 foreign-related enterprises. The substantial tax contributions from these foreign-related enterprises, accounting for 59.6% of the district's revenue, served to highlight Wangjing Walk's international business stature and its broad international consumer demand.

The resident surveys and interviews employed a multi-level and multi-dimensional approach, addressing satisfaction with the current living environment, expectations for the regeneration, and specific demands for new facilities. The residents expressed a strong need for improvements in infrastructure, including transportation and public spaces, as well as a desire for more recreational and cultural activities within the district. These insights enabled the project team to define the project's commercial positioning. This was to create a multifunctional commercial and cultural district that meets international standards, incorporating more outdoor recreational facilities and a diverse range of commercial and cultural amenities.

The preliminary research and opinion gathering conducted for this project were comprehensive and designed to align the modifications with the actual needs and expectations of the residents. This foundational work facilitated the development of a district that not only meets international standards but also addresses the specific requirements of the local community. The methodical approach to data collection and analysis was of great importance in guiding the regeneration and enhancement of the district's commercial and cultural environment. This approach reflecting a careful consideration of both broader objectives and detailed resident feedback.

The regeneration of Wangjing Walk Business District has significantly enhanced the area's commercial vitality and community environment, as evidenced by substantial increases in foot traffic and fiscal revenue following the regeneration. In particular, the average daily foot traffic increased from 4,784 on weekdays and 4,428 on weekends to 15,436 and 20,844, respectively. This increase not only demonstrated a significant boost in the district's appeal but also reflected an uptick in commercial activities.

In terms of economic impact, annual sales increased from approximately 800 million RMB prior to the regeneration to 1.2 billion RMB, representing a 50% increase. Moreover, fiscal tax revenue saw a significant rise, amounting to approximately 56 million RMB annually. This revenue growth not only provided the local government with increased fiscal income but also demonstrated the positive impact of enhanced public services and infrastructure investments on the prosperity of commercial activities.

In conclusion, the Wangjing Walk Business District regeneration project was implemented in a manner that avoided merely expanding the building area, thereby minimising disruptions to the surrounding community during construction. The investments made by each participating party were kept within reasonable bounds, ensuring a balanced contribution to the project. The project's outcomes were notably significant, yielding substantial economic benefits and enhancing social impact. This regeneration has established a new paradigm for the revitalisation of ageing urban commercial districts, demonstrating the efficacy of government-led improvements in public spaces. This approach effectively encourages local businesses and property owners to voluntarily participate in the upgrading of their properties on a voluntary basis. The project's collaborative funding model has been instrumental in fostering regional revitalisation, with subsequent economic growth and increased land values enriching the community. Ultimately, this has resulted in a mutually beneficial scenario for all stakeholders involved, thus establishing a replicable model for urban development.

Langyuan Vintage Factory

Langyuan Vintage represents a seminal example of industrial heritage micro-intervention. Strategically situated in the core of Beijing's Central Business District (CBD), the factory originally served as the Wan Dong medical equipment factory. As the CBD continues to evolve and urbanisation progresses, traditional industrial facilities are becoming increasingly incompatible with the modern urban landscape. In 2009, the Beijing Capital Group acquired the development rights to this site, launching a city regeneration project centred around cultural and creative industries. The project retained the industrial character of the area while introducing new cultural and public service functions to meet the diverse development needs of the city.

Figure 6. After regeneration of Langyuan Vintage Factory
(Source: https://www.xiaohongshu.com/explore/63073aaf000000001b02418c; https://175586960.b2b.11467.com/news/2885968.asp)

Feature 1: Preservation of Industrial Ambience and Provision of Diverse Spaces

The regeneration of Langyuan Vintage is characterised by a profound respect for the site's historical value. In contrast to the conventional demolition and reconstruction practices typically employed in such cases, the Beijing Capital Group opted to maintain the low-density characteristics of the industrial park and its industrial architectural appearance. This resulted in the transformation of the area into a "back garden" within the CBD. Although this strategy resulted in higher renovation and maintenance costs, the continued spatial quality and historical value it brought has endowed the area with a unique cultural atmosphere.

The project adhered to the principle of "repairing the old as old," thereby ensuring that the original structures and features of the factory were retained to the greatest extent possible. For instance, the site's original red brick walls and large industrial windows were meticulously restored and preserved. The spaces were redesigned with a variety of functions in mind, including bookstores, zen spaces, cafes, and co-working spaces catering to the culture and entertainment industries. This has made it the preferred relaxation destination for CBD employees after work.

In particular, some spacious industrial areas were transformed into venues suitable for theatre, art exhibitions, and other cultural events, such as the Lanjing Art Centre and Yu She Performance Space. This has enhanced Langyuan’s cultural atmosphere and provided unique interactive platforms for artists and audiences.

Feature 2: Cultivation of Culture and Community

Langyuan Vintage plays an instrumental role in enhancing the quality and scope of community public services by integrating a multitude of cultural activities and facilities. For example, the Liang Yue City Bookroom, which is accessible 24 hours a day, provides a shared space where reading and learning can be enjoyed, thereby enriching the cultural lives of the residents. Furthermore, the annual Langyuan Book Fair has become a significant event, attracting book enthusiasts and creative industry professionals alike, and fostering community cultural exchanges and the development of the creative industries.

The cultural facilities and activities not only enrich the residents' cultural lives but also gradually shape an attractive cultural community, enhancing the cohesiveness of the community.

In the process of regenerating Langyuan Vintage, the developer eschewed the profit-driven model typical of real estate developments, instead prioritising the enhancement of the spatial quality of the area and the continuous implantation and cultivation of a cultural atmosphere with the objective of creating a lasting impact. This strategy has demonstrably enhanced the value of the entire park. The protective transformation of the old industrial architecture and the careful planning of cultural content have enabled Langyuan Vintage to not only preserve valuable urban historical memories but also to foster new social value and business opportunities. The project exemplifies the profound potential of culture and creativity in regenerating urban spaces, offering new avenues for sustainable urban development and providing valuable insights and lessons for the regeneration of other industrial heritage sites in Beijing.

Conclusion

This paper examines the transformation of urban regeneration strategies in Beijing, providing a detailed analysis of three exemplary cases. This analysis reveals the core features of micro-intervention urban regeneration strategies. These strategies adhere to a minimalist approach to urban intervention, eschewing the mere expansion of building scales in favour of a focus on enhancing architectural quality, improving public spaces, addressing the needs of local residents and workers, and fostering high-quality cultural content. This regeneration approach offers a more sustainable path of development for metropolises in the global south, particularly those that have reached developmental limits and require refined management of urban construction.

The study is significantly supported by the Beijing municipal government, whose conception of a project repository in the Beijing Urban Regeneration Action Plan has provided a wealth of empirical data. Since 2020, the Beijing government has consistently updated its urban regeneration project repository, with over 80% of the 200-plus projects tracked from 2020 to 2022 employing micro-intervention strategies. This substantial corpus of data provides a robust foundation for the prominence of micro-intervention strategies in Beijing's urban regeneration efforts since 2020. In the future, Beijing will continue to pursue this strategy, with a focus on managing overall urban construction volumes and enhancing spatial quality, cultural significance, community care, and collaborative construction. This approach will be employed in order to gradually address the issues that have accumulated during periods of rapid urban expansion. As a representative megacity in the global south, Beijing's experiences and practices in urban regeneration could provide insights for other cities at similar stages of development.

It is important to note that this study is subject to certain methodological limitations. In the case of Wangjing Walk, the data on residents and businesses was obtain from the project constructors, rather than directly from the residents themselves. This approach may limit the comprehensive understanding of residents' negative feedback. In order to enhance the accuracy and depth of future research, this paper will, in subsequent studies, collect first-hand data through direct interviews with residents. This will further refine the research methodology in order to perfect the study's conclusions.

Track 02: Markets

Markets - Planning for property markets, Financialization, and Private Actors

Chairs:

- Matthieu Gimat, Université Paris 1 Panthéon-Sorbonne
- Tuna Tasan Kok, University of Amsterdam
- Petra Samaha, Sciences Po Paris

Keywords: *Financialisation, financial actors, adaptive planning strategies, property-led planning, property developers and investors, property-led urban development coalitions*

In the context of rising housing prices during the last decades, public actors found new ways to use planning to regulate property markets, for instance, by imposing affordable housing in new residential developments through inclusionary housing programs. At the same time, planning has been seen as a way to promote growth in property markets, notably by encouraging projects amenable to international capital or secure real estate values in increasingly volatile markets. With the growing interest of financial actors (such as sovereign wealth funds, pension funds, insurers, and investment trusts) for real estate, the regulatory capacity of planning is particularly under scrutiny as these actors' strategies have been linked to increasing rents, evictions, and rapid social change. The growing size of their portfolios also makes these actors central for implementing rehabilitation and urban renewal policies, which are essential to bringing carbon emissions to net zero. This track seeks to explore the intersections of planning, governance, and property studies, with a specific emphasis on critical perspectives that examine how planning systems, including regulations, grapple with the challenges posed by financialisation in contemporary urban environments. However, within planning scholarship, there is untapped potential for further exploration of property actors, their strategies, and their relative positions in relation to regulations. We welcome theoretical, methodological, and empirical contributions that address the following key themes.

Public Planning Mechanisms and Financialisation: Papers in this category should investigate how public planning mechanisms and institutions respond to cities' financialisation. We encourage critical examinations of regulatory frameworks, policy responses, and their implications for urban development.

Emerging Adaptive Planning Strategies: This theme seeks to explore the innovative and adaptive planning strategies that are emerging in response to the challenges posed by property-led planning and financialisation. Contributions should illuminate novel approaches, tools, and practices that planners employ.

Relational Dynamics among Public, Private, and Community Actors: While our primary goal is to shed light on lesser-known actors, such as property developers and investors, and their relational positions within urban planning coalitions, we also invite abstracts that delve into the

complex relationships among public sector actors, private developers, and local communities in the context of property-led urban developments. This theme encourages in-depth analyses of power dynamics, collaborative efforts, and conflicts among these key stakeholders.

Gender Balances in Property Coalitions: Specifically, we are interested in studies that investigate gender dynamics within property-led urban development coalitions. How do gender imbalances influence decision-making processes and outcomes in urban development projects?

Global Perspectives: We encourage submissions that offer insights from low and middle-income countries, exploring how they experience similar financialisation trends in urban development. Comparative studies and cross-cultural perspectives are particularly welcome.

Urban policy financialisation in mega-projects. The case of Milano Innovation District

Alberto Bortolotti
Affiliation: Department of Architecture and Urban Studies, Politecnico di Milano

ORCID: 0000-0002-1457-4262

Abstract
Urban mega-projects are key policy instruments for connecting financial and real estate markets through the financialisation of strategic lands and the 'deterritorialisation' of actors, decisions, and strategies. Milano is currently characterised by multiple large-scale operations pursued by global developers and investors. This article problematises one of such projects, the Milano Innovation District, by reconstructing its spatial development through interviews, field observations and desk analysis, showing how financialised planning and policy measures generate deterritorialisation, and building on the financialisation literature intertwining real estate and spatial planning fields. Finally, this article discusses the role of state planning in underpinning spatial development, arguing that financialisation depowered the capacity of planning to recapture land value and rebalance urban rent. In essence, the financialisation techniques for collecting capital and delivering urban mega-projects have deterritorialised the governance of urban transformations, compromising the spatial government led by local, regional and central governments.

Keywords
deterritorialisation, financialisation, urban policies, urban mega-projects, Milano Innovation District

1. Introduction

Over the last decades, the financialisation of the economy (Epstein, 2005) has guided the change from a system of economies of scale spread over the territories to an increasingly globalised single economic system which clusters a significant part of the financial capital in the major cities. This change assumes the name of financialisation and, specifically in the sector of real estate, coincides with the transformation of real estate assets into tradable goods (Gotham, 2009) with the tendency to treat the built environment and landed areas as products exchanged on the financial market (Harvey, 2005; Savini and Aalbers, 2016; Van Loon and Aalbers, 2017).

Following this discourse, urban mega-projects (Fainstein, 2008; Flyvbjerg, 2014), represent the tipping point of such shift towards unpredicted financing methods, as ‘levers’ capable of welding the objectives of the financial market to the real estate industry and markets, particularly by (de)territorializing the land-value capital and converting it into financial capital following the logics of business plans tailored by property developers and their investors. In other words, urban mega-projects act as urban policies. The financialisation of such urban mega-projects implies ‘deterritorialism’ perspectives, reflected in deterritorialised urban policy measures which enable ‘world governance visions’ in financial schemes linked to property urban development (Medeiros et al., 2021: 965).

Through the category of ‘deterritorialisation’, I refer to the practice of progressively abstracting and dematerialising the essence of (urban) public policies, although these continue to affect territories, land and built environment, within a reshaping process of deterritorialisation & reterritorialisation (Cocco, 2007). Such category is intertwined with the concept of ‘territorial

deterritorialism' which «is an approach under which bounded spaces – territories – are the objects of policymaking and planning» (Faludi, 2018, p. 73). Even though several authors (Agnew, 1994; Capello et al., 2018) argued that 'deterritorialism governance' would represent a «concrete policy action to reduce the negative effects posed by the presence of national boundaries» (Medeiros et al., 2021, p. 965), this article suggests that the deterritorialisation (through financialisation) of urban mega-projects depowers the government's capacity to shape the same projects through strategic planning. Nonetheless, this process interacts with David Harvey's 'uneven geographic development' theory which lighted a crucial contradiction between territorial and financial logics of power in capital accumulation regimes (Harvey, 2005, p. 107).

Thus, deterritorialisation shifts the governance of urban mega-projects from a local public-led perspective to a global private-led one and requires a step-by-step process to prevent governance 'traps' (Medeiros et al., 2021). To some extent, the privatisation of leading actors, which occurs through deterritorialisation in large-scale operations, could potentially be predicted and interpreted before its massive expansion through conceiving urban mega-projects as exemplary cases of financialised 'collective apparatus' (Foucault, 1984), in other words as territorialities alienated by public collective power which historically guided apparatus (Foucault, 1984). Thus, such projects are what Harvey's theory defined as «innumerable points for the extraction of value and surplus value» (Harvey, 2005, p. 97). In this sense, financialisation interacts with spatial planning, urban policies, and strategic projects especially due to its role in shifting the societal spatialisation from political to economic – and financial – power (Foucault, 1982).

The financialisation of urban policies and projects is caused by the financialisation of real estate, which deterritorialise and treat properties as commodities within a shift from a traditionally non-financial sector to a financial one (Mosciaro, 2021; Aalbers et al., 2017). The shift towards the financialisation of urban policy architectures occurs in all the geographic spaces in which urban land and built environment are treated as financial assets/products/commodities (Aalbers, 2017; Van Loon et al., 2018). Within this global context, local financialised major projects, specifically in Milan, «are seen as both tools to revitalise real estate markets and key arenas in which political and economic actors bargain» (Conte and Anselmi, 2022, p. 2); in fact, according to Aalbers (2017, p. 3) financialisation may be defined as «the increasing dominance of financial actors, markets, practices, measurements and narrative», encompassing both an economic and political dimension.

Milano is an emergent 'middle-range' metropolis massively characterised by high-speed globalising and financialised tendencies that are forged by the site development of multiple urban mega-projects delivered by several global developers. Among the majors, the Australian property developer Lendlease is currently managing two of the three largest Milanese brownfields: the Milano Innovation District (MIND), over 1.000.000 m^2 located along the north-western axis and laying in the former EXPO 2015 site and Santa Giulia large-scale development project, 1.200.000 m^2 located on the cross-border district between Milano and San Donato Milanese municipalities along with the south-eastern railway line. This article aims to problematise the MIND case study by analysing how this exemplary urban mega-project financialised spatial planning and policies, (de)territorializing investments and enabling

financial instruments for bridging financial and property markets. In other words, the present article answers the following two research questions: How does financialisation interact with the real estate development of urban mega-projects? What financial and planning techniques govern the deterritorialisation of such projects? Thus, this contribution places the deterritorialisation of real estate assets and markets because of financialisation, presenting MIND as a case study for generalising a shift towards abstract models of large-scale spatial planning and project financing.

The argument for the deterritorialisation of urban policy financialisation will be built along with the following five paragraphs. Firstly, I will discuss the methodology and materials employed in this article. Secondly, I will frame the urban policy financialisation by examining its techniques linked to the deterritorialisation of property assets. Thirdly, I will introduce and problematise the Milanese planning system in the challenge of urban renewal. Fourthly, I will present and case of Milano Innovation Districting, considering case research as relevant in this field of analysis since, according to Harvey (2005, p.120), «case study work should internalise theorising practices in uneven geographical development».

2. Method and Materials

This case research is based on the study of one single urban mega-project, which is exemplary of financial and planning techniques linking the Milanese planning system to the financialisation of property techniques shaping such large-scale operation, as the article is revealing. Thus, the discussion proposed in this article comes from an empirical study of the Milano Innovation District (MIND) urban development project. In this sense, I argue that such a case is not a deviant or an extreme one; on the contrary, the in-depth analysis of the MIND mega-project demonstrates its similarity in terms of formulation, implementation and results of other European large-scale developments underpinned by a valorisation of public lands and assets. In fact, even though Italy overall, is a country with a limited level of real estate financialisation (Mosciaro, 2021), Milano represents an exemption since particularly its economic system is closer to other major European cities rather than other large Italian urban nodes.

This case analysis lights the de-territorialisation of urban development and policies through financialised real estate mechanisms affecting urban mega-projects, which I conceive as urban policies themselves following the urban policy theory of Dente, Bobbio, Fareri and Morisi (1990), even though there is no unique definition of urban policy (Briata and Raco, 2022). I decided to frame the result of built environment financialisation as ‘deterritorialisation’ instead of ‘decontextualisation’ since the evident majority of recent urban development projects are decontextualised in architecture and urban design terms, but only some of them are activated and managed through deterritorialised techniques delivered by financial (abstract) rationalities.

Regarding the case selection, MIND was chosen due to its relevant position in the context of large-scale development projects currently under development in the city of Milano. This case is underpinned by a structured public-private partnership in one of the largest strategic areas, as pointed out above. Its (semi)public nature maximises the availability and utility of information deciphered mainly from press articles, academic essays, official documents and semi-structured interviews that were essentials for validating these contents. In particular, the case selection of

MIND has taken into account its relevancy and exemplarity in planning traditions, cultures and motives, which are similar to other European experiences, a variety of territorial governance arrangements, institutional settings and planning techniques present in the site development, and a significant range of representations of planning intentions pursued by Lendlease as the main property developer.

3. The urban policy financialisation driving MIND's deterritorialisation

The processes of formulation and implementation of urban mega-projects are based on the principle of multiplying their land value in the financial market, thus exploiting financial leverage techniques on bonds issued by 'vehicle companies' named Special-Purpose Vehicles (SPVs), which are controlled by single property developers, joint ventures among them and investors or public-private-partnerships (Guironnet et al., 2016). Nowadays, vehicle companies constitute the main method for the financialisation of urban mega-projects through the so-called financial technique named 'securitisation' by which the (local) real estate assets are transformed into tradable bonds emitted by the SPV on the (global) financial market.

The realisation of urban mega-projects through SPVs is intertwined to the use of special planning devices (e.g., Key Opportunity Areas, Zone d'Aménagement Concerté, Programmi Integrati di Intervento, Accordi di Programma etc.), which combine aspects of land alienation with the planning flexibility that underpins complex phases of formulation, implementation and especially negotiation in public-private partnerships, which tend to be underpinned by public goods. It is relevant to notice that, in parallel with the introduction of such planning devices, local governments of major world countries have established legal & financial devices to deliver and leverage an increasing number of financialised urban mega-projects, such as Tax Incremented Financings (TIFs) in the United States, or CEPACs in Brazil, or the Dipiaio in China (Mosciaro, 2021).

In this sense, planning mechanisms delivered within the framework of public-private negotiations generally do not guarantee adequate transparency, so the profitability of urban mega-project operations underpins opacity in decision-making which often underlines forms of 'empathy' of local governments towards investors and developers (Raco et al., 2018, p. 13). The circumstances led to an 'enabling attitude' (Tasan-Kok and Ozogul, 2021) which massively increased the capacity of urban mega-projects to extract land value capture and trade it among national and international investors through the exchange financial products, especially to intuitional funds and trusts. At the same time, issues related to 'bureaucratic slowness' are assumed by investors and developers as a 'calculated risk' in pro-growth urban contexts in which local governments attempt to favour property development and, in general, the real estate industry (Raco et al., 2018: 13).

This recent phase of property financialisation has maximised the capacity to mobilize real estate assets as securities, bonds, shares, and equity in the financial market, hence the shift from the extensive use of financial grants (Fainstein and Gray, 1996, p. 31) to flexible spatial planning aimed at supporting financial allocations. In these unprecedented circumstances, the real estate industry is able to generate urban mega-projects such as MIND, which entails a more sophisticated set of socio-legal and socio-technical rules, policies, values, and frameworks

defined by the corporate ownership structure of vehicles (as dedicated funds) led by the property developer (Adisson, 2018, p. 374).

In essence, the financialisation of the MIND urban mega-project enables not only the decontextualisation of the area from the built environment, as it happened in other Milanese key opportunity areas – Grandi Funzioni Urbane (GFU) – recognised by the structural plan – Piano di Governo del Territorio (PGT) – but also the deterritorialisation of planning and policy techniques which are alienated from local real estate market cycles since the business plan logics relay only on long-term investing schedules managing times, operations and narratives. As mentioned, such deterritorialisation is already conceptualised by the Program Agreement – Accordo di Programma (AdP) – which anticipated the MIND Integrated Action Plan – Programma Integrato di Intervento (PII) – framing program agreements both as strategic strategies and planning tools. Particularly, PII is a planning tool established in the 1990s to develop large-scale urban projects, according to a project-led mindset which, since that period, has been guiding the Milanese urban policy *per project*, reflecting the finance-led dynamics of the business plan following 'diversification' logics.

Finally, flagship urban mega-projects encompass local development, regional cohesion and national/international promotion making such type of urban development, as the MIND case, political projects and urban policy themselves (Albrechts et al., 2003; Altshuler and Luberoff, 2003); I argue that the increasing financialisation of real estate assets which is affecting property development is maximised in financialised urban mega-projects in which planning techniques and urban policies are progressively dependent by deterritorialisation according to financial investment schemes which tend to be tailored and abstracted from legal and planning systems.

4. The financialisation of the Milanese planning system

The Milanese urban policy has undergone a series of structural shifts towards financialised spatial planning underpinned by a project-led mindset. As pointed out above, financialisation affects the methods by which local governments deliver strategic spatial planning and urban policies according to structural plans. Particularly, the municipal government of private and public funding to pursue large-scale development projects is increasingly relying on financial investments provided by the property industry, so several authors argue that financialisation is nowadays institutionally intrinsic in framing public-private partnerships which underpin urban mega-projects (Fainstein, 2016; Aalbers, 2020; Van Loon et al., 2018; Savini and Aalbers, 2016), seeing finance shaping planning systems and their urban policies. In this sense, despite the case of Milano is not encompassed by debt-issuing practices to receive banking loans for financing urban mega-projects (as in the TIFs), according to several interviews, I argue that its planning system appears to be financialised in cultural, political, and organisational terms.

The result of such a financialisation is a Milanese planning system highly characterised by project-led logics which are guiding the major urban mega-projects as the cases of Porta Nuova (Anselmi and Vicari, 2020), Bicocca (Kaika and Ruggiero, 2016) and Sesto (Savini & Aalbers, 2016) show.

Thus, based on the Milanese experience, which is similar to the ones of other European cities, it could be argued that urban mega-projects formally conceived as state strategies are increasingly framed as financialised policy devices. According to Lake (2015), urban policies (e.g., urban mega-projects) are becoming financial devices following the securitisation of

property bonds through Real Estate Investment Funds (REIFs) or marketisation of property shares through Real Estate Investment Trusts (REITs) – in which equity (i.e., REIT's shares) may be traded also in order to acquire property assets – and such processes have been progressively specialised in several Western cities, among Europe and America. Thus, this process is not unique, and it is always characterised by a determinant role of the state in fostering financialised strategies (Tasan-Kok, 2010).

Although the Milanese planning system does not prescribe any specific financial measure to invest in key opportunity areas selected by its structural plan, such areas are normally developed through public-private partnerships between public and private companies or joint ventures among private operators in which financial viability is roughly checked by the local government. So, the Milanese planning system appeared to be relevantly financialised, particularly in routing global investments into local government plans (Anselmi and Vicari, 2020) and governing such operations through public procurement techniques and legal contracts which enhance new codes of capital and market dependence (Raco and Brill, 2022). To some extent, the socio-spatial effects of such a 'financial attracting regime' establish a potential equation between the expansion in the financialisation of real estate assets and the gentrification of peripheral districts affected by renewal projects since urbanisation drives accumulation through the financialisation of such real estate products.

5. The financialised urban mega-project of MIND towards deterritorialisation

The Milano Innovation District (MIND) is one of the major Italian urban mega-projects. Located in the former EXPO 2015 area, MIND occupies a total gross floor area of 1,044,102.00 m^2 to be developed according to a building index of 0.52 m^2/m^2 (Comune di Milano, Arexpo & Lendlease, 2020). It is an urban mega-project pursued through sised financialisation techniques, aiming to become the pivot for driving the Milanese northwest quadrant urbanisation by intertwining this large-scale project with the greenfield operation of Cascina Merlata, and the Rho Fair complex. In this sense, the renewal project of such a large-scale public area in the post-EXPO years represents not only the urban regeneration of a key opportunity area for Milano, Lombardy, and Italy but also an attempt to establish a solid public-private partnership between the (landlord) national public company Arexpo and the (tenant/leasing) international property development company Lendlease.

The urban context in which the redevelopment project is located appears as a peri-urban enclave surrounded by railway and motorway infrastructures. Thus, the MIND urban mega-project links the renewed district to the layout of a new Milanese urban growth within a political environment in favour of fast changes during the last decade (Di Vita and Morandi, 2018). Following this perspective, the MIND area, over 1 million m^2 belonging to Arexpo, is becoming a strategic district for attracting science, knowledge, and innovation with the aim of creating an open incubator, enabling territorial excellence through the enhancement of investments already placed and the legacy of Expo 2015 (Comune di Milano, Arexpo and Lendlease, 2020). This urban concept reminds the 'TechnoCity' delivered by the Pirelli family for the Bicocca renewal project, the first Milanese large-scale operations in which land was mobilised as a financial asset, thus financialising such brownfield (Kaika and Ruggiero, 2016).

However, the MIND urban mega-project holds a long history that started in 2002 when the Fiera Milano Foundation acquired 520.000 m2 (more than half part of the entire greenfield) from the Milanese-based property development companies Bastogi & Brioschi Sviluppo

Immobiliare, owned by the Cabassi family. Consequently, the area remained 'frozen' until 2006, when Fiera Milano Foundation and Cabassi's groups presented a masterplan designed by the architecture office 5+1AA to call for an Integrated Action Plan – Programma Integrato di Intervento (PII). Almost parallelly, in 2007, the Municipality of Milano submitted its candidature to host the World Expo 2015, selecting that area to cluster the international pavilions. Although the City of Milano won the competition for hosting the mega-event already in 2008 and albeit the approval of the Program Agreement – Accordo di Programma (AdP) – was fast, the following implementation phases remained suspended until 2011 when the Municipality of Milano and Lombardy Region (the two major investors together with Municipality of Rho, former Province of Milano and Fiera Milano Foundation), acquired the entire area assigning its ownership and management to the new public-controlled company Arexpo Spa (2011-active). Consequently, the election of the centre-leftist Mayor, Giuliano Pisapia, in 2011, contributed to unlocking such political stalemate (Gaeta and Di Vita, 2021: 4). Within this municipal leadership, there was a restart of the implementation phase (2011-2015), which has seen the execution of the new masterplan called 'Planetary Garden' proposed by the Architectural Advisory Board for EXPO 2015 (Jacques Herzog, Stefano Boeri, Ricky Burdett, and William McDonough), and the government tender for management and construction.

At the end of the mega-event, after more than a year of inactivity, a period which can be interpreted as a planning disaster (Gaeta and Di Vita, 2021: 4), the Expo 2015 site was relaunched through two national government actions: the proposal of the Human Technopole research centre as a driver for capturing global financial and knowledge capitals, and the acquiring of 39,28% of Arexpo Spa shares by the Ministry of Economics and Finance (MEF) (Arexpo, 2016). Within this operation, the new governance of the public company is composed of 39,28% owned by MEF, 21,05% by Lombardy Region, 21,05% by Municipality of Milano, 16,80% by Fiera Milano Foundation, 1,21% by the Metropolitan City of Milano, and 0,61% by Municipality of Rho. In this management framework, important decisions are guaranteed only whether is reached a quorum of 71% of share capital (Arexpo, 2016). Meanwhile, the other two main shareholders Municipality of Milano and Lombardy Region, pushed San Donato Group and the University of Milano to move into the Expo site, respectively, the new IRCCS Galeazzi Hospital and a new Campus for Scientific Sciences.

It is necessary to remark that before this governance reconstruction of Arexpo Spa, there was an auction for selling the area, which failed since any bid was submitted. Thus, such government action catalysed unpredicted financial interests through the selection of public functions (e.g., 'public anchors'), which worked as drivers (Gaeta and Di Vita, 2021: 5) for attracting global capital since it guaranteed potential public-private partnerships. Between 2017 and 2019, there was the formulation phase of the urban mega-project, in which the global Australian property developer Lendlease successfully won the competition to manage the redevelopment of the former EXPO area within a Leasing Agreement - 'Concessione', in Italian legal terms – of 99 years through an initial investment and signing a Framework Contract with Arexpo, Lombardy Region, Municipality of Milano and other institutional actors, delivering the Integrated Action Plan – Programma Integrato di Intervento (PII) – for the area latterly. This new urban mega-project has been called Milano Innovation District (MIND). Particularly, in 2018, Lendlease and Carlo Ratti Associates (CRA), in cooperation with Arexpo, Systematica and Land (see Fig. 1), submitted a masterplan, for providing such PII, and, subsequently, since 2020, the construction phases of Human Technopole, University of Milano campus and Galeazzi Hospital have been started.

The MIND masterplan follows the 'pro-growth approach' launched with EXPO 2015, seeing its site development as a gateway for enhancing the competitiveness of Milano in the global city network and capturing growth potentialities (Bolocan Goldstein, 2015). In fact, such an approach, as in other major European cities, is intrinsically intertwined with urban mega-projects, which are fundamental for underpinning financialised urban narratives (Raco and Brill, 2022). In this sense, the development of the EXPO 2015 mega-event and the redevelopment of the MIND mega-project are two connected episodes within a longer-term process of the city's transformation and repositioning (Gaeta and Di Vita, 2021: 13). Also, EXPO 2015 and MIND can be seen as two «Siamese twin projects, which are inseparably tied together span over alternate periods of crisis and recovery, stagnation and acceleration, disorientation and confidence» (Gaeta and Di Vita, 2021: 3).

Such masterplan keeps the previous longitudinal division marked by two orthogonal axes called *cardus* and *decumanus* which are referred to the ancient Roman Empire practice of measuring agricultural land. Nevertheless, the masterplan presented by Lendlease and Carlo Ratti Associates (CRA) modifies the axes' meaning (Gaeta and Di Vita, 2021: 9) in a scheme north-south instead of east-west since all of the three 'public anchors' – IRCCS Galeazzi Hospital, the Human Technopole, University of Milano Campus, for a total 316.000 m^2 of gross floor area – are located on the northern side, while the private settlements directly managed by Lendlease will be built in the southern side. Moreover, each catalyst function is linked to a specific sub-district (deploying three sub-masterplans): West Gate & Galeazzi Hospital, Green Heart and Human Technopole, and Knowledge Hub & University Campus (see Fig. 2). Subsequently, the general planning of the area had two relevant changes with the design of two new masterplans, one designed by the London-based planning office Allies & Morrison, which shaped MIND as an 'American city' linked to concentrate urbanisation (see Fig. 3), while the following one designed by the Bologna-based firm Mario Cucinella displayed, especially for 'West Gate', an architectural morphology linked the Milanese pattern of avenues and courtyard buildings (see Fig. 4). Concerning the planning practice of the implementation phases, it could be argued that the financialised attitude pursued by Lendlease in driving the decisional process following organised planning and financially-driven advanced governance of the mega-project, in terms of business plans, functional programs and urban design solutions, despite the lack of public transportation and access to the private side of site development.

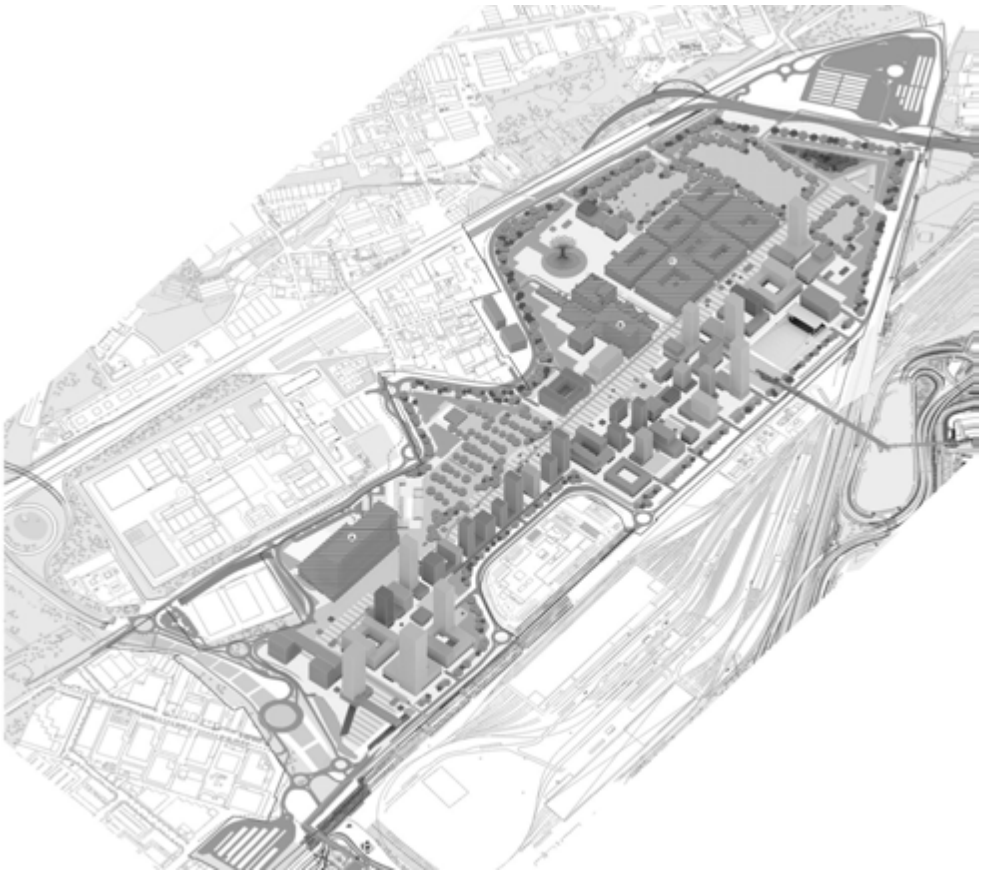

Fig. 1 MIND PII (Lendlease, Arexpo, Carlo Ratti Associati, Municipality of Milano, 2020)

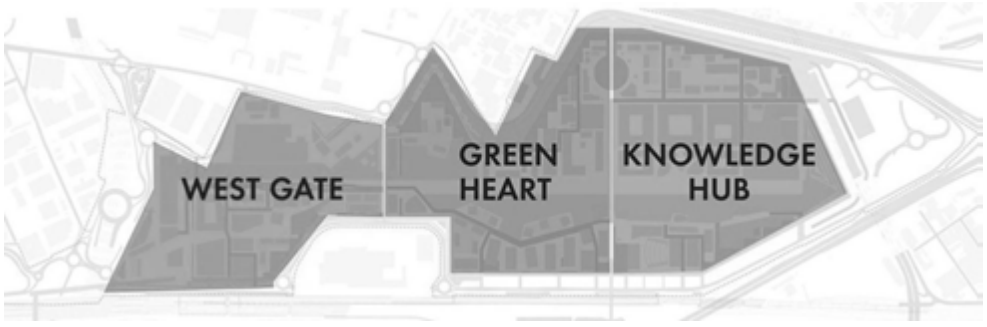

Fig. 2 Subdistricts (Lendlease, 2020)

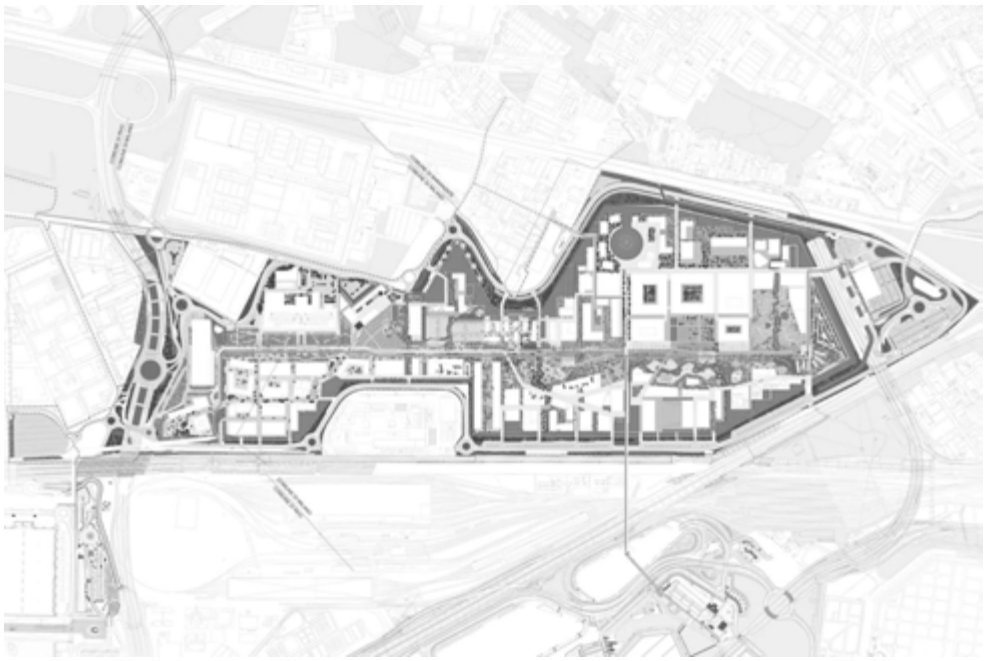

Fig. 3 Allies & Morrison MIND Masterplan (A&M, 2021)

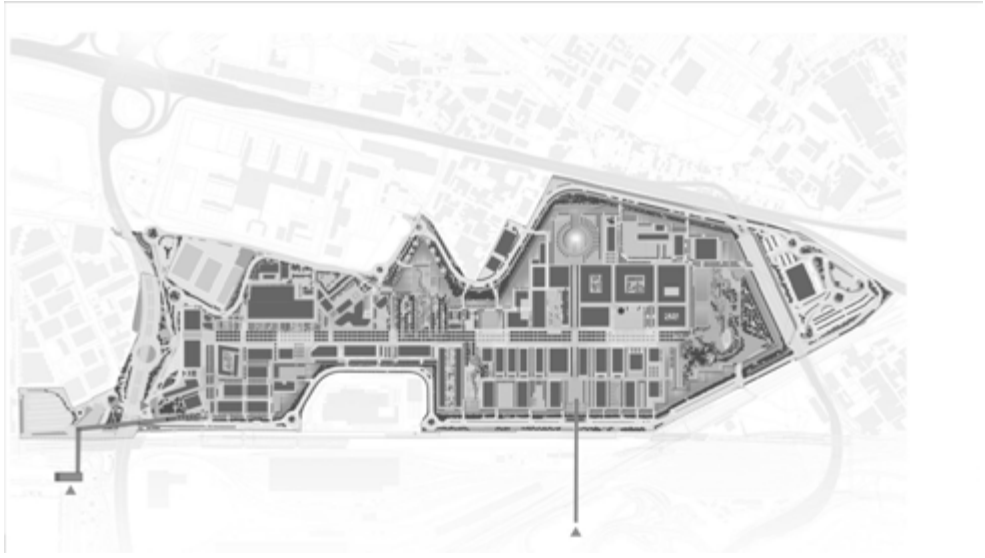

Fig. 4 Mario Cucinella MIND Masterplan (MCA, 2022)

In addition to the three 'public anchors' that MIND is hosting, in compliance with the PII, new accommodation, leisure, and free time functions will be directly developed by Lendlease following environmental and sustainable values of living and working (317,000 m^2 of gross floor area, 103,000 m^2 of services such as commercial and neighbourhoods businesses, 90,000 m^2 residential units, 30,000 m^2 of production activities such as laboratories, 305,000 m^2 of offices), for hosting approximately 70.000 people in total. Moreover, Lendlease established a joint venture with Ream Sgr Spa (a Turin-based property developer and manager) to provide about 30,000 m^2 of social housing residences and office units used by the university campus through the multi-division alternative REIF named 'Cervino'.

The site development of MIND is intrinsically linked both to the new real estate financing techniques and to active real estate management in the specialisation of the business plan that Lendlease is applying to the property valorisation of the area. Using Lendlease Global Commercial Italy Fund, the beginning phase of the investment program was confirmed in 2021, framing a long-term spatial plan which combines a joint venture with an institutional investor in the 'West Gate' district and the public-private partnership with the University of Milano in the 'Knowledge Hub' district. Subsequently, it has been established the alternative investment fund 'Lendlease Renaissance I' as an SPV managed by Lendlease for underpinning the joint venture with the Canada Pension Plan (CPP) investment board for a value of about 400 million euros of equity acting in the 'West Gate' district with a predicted ending value of about 800 million euros. Such investment is affecting only the 'West Gate' district, 11 plots 'Stralci Funzionali' for different destinations of use (office, retail, hotels, residential and ancillary spaces) and a total of 164.000 m^2. However, according to press declarations by Arexpo Spa officials, the estimation of the entire MIND redevelopment project is roughly 4,5 billion euros (Gervasoni et al., 2024).

In this sense, the active real estate management approach pursued by Lendlease as a specialised property developer combining high expertise in both corporate and project management marked a shift in the Italian real estate sector beyond the 2007 subprime mortgage financial crisis. Such a shift has occurred, not only due to an internationalisation of the professional figure of the property developer but also due to the transformation of the technical-financial instruments suitable for the urban development of large public areas, which historically was strongly linked to real estate cycles, therefore with constrained choices to profit maximisation in the short run. In fact, the management of the area for 99 years implies, for the property developer, the strategic programming of a long-term business plan capable of contemplating a return value shaped over time. In other words, this temporal dimension configures multiple and integrated design choices, generating repercussions of spatial order, for example, inherent in the use of high-performance, sustainable, and replaceable materials, or construction technologies that allow the re-functionalisation and transformation of individual properties for adaptation to the required property market demand.

Overall, the financialisation of the MIND urban mega-project deploys several financial interventions, planning instruments and policy tools, which are tailored and fragmented among the 24 'functional excerpts' (sub-lands) – 'Stralci Funzionali' – and in consideration of the articulated and complex levels of risk regarding each property asset class which is connected indeed to such function (e.g., commercial and housing real estate assets hold a lower investment risk rather than large multifunctional assets). Each 'function excerpt' clusters an independent settlement since the financialisation of the real estate assets lying on a specific sub-land need

to be specialised and managed based on diversified investors' demand. Thus, in such excerpts, financialisation affects spatial planning, urban design and architectural design implications addressed by the investors' (tenants) business plan (e.g., retail, timeline, arrangements etc.) in reshaping the built environment over time. The consequence of such fragmentation in sub-lands (through financialisation) is the deterritorialisation of funding and spatial devices treating built constructions and objects, and this process affects the entire MIND masterplan. In other words, from an urban design angle, the masterplan appears unitarian, while from the financialisation angle, it can change according to the spatial planning flexibility defined by the PII.

6. Discussion

The nexus between property financialisation and cities' urbanisation has massively increased capital accumulation in urban mega-projects, clearly demonstrating how urban policies underpinning such projects have often become policy & financial instruments to pursue financialisation (Salet, 2008; Haila, 2008). As Lake (2015) pointed out, such a process has been delivered by the silent predominance of economic policy to social and urban policies (and partially spatial planning), which have been treated as subordinate, and thus financialised over the last decade. Following this discourse, urban policy financialisation seems to be reflected in flagship (political) projects both in financial and cultural terms (Briata and Raco, 2022).

To some extent, notable similarities with Milano in financial and spatial techniques used for delivering large-scale projects over other major European cities such as London (Raco and Brill, 2022), Amsterdam (Tasan-kok and Ozogul, 2021) & Paris (Guironnet et al., 2016), let me argue that the planning systems delivering urban policies have been increasingly and systematically reshaped towards financialisation, through enabling financialised property development (Salet, 2008). In fact, as in such cases, Milano uses «transnational capital and large-scale regeneration projects to promote its international reputation» (Conte and Anselmi, 2022), conceiving urban mega-projects as 'catalysts of urban and political change' (Swyngedouw et al, 2002, p. 546) for empowering local real estate markets and political arenas in global power configurations.

As I showed in the MIND case, particularly urban policy tools and (partially) spatial planning techniques are increasingly affected by financialisation through the standardisation of (global) real estate parameters enabling local project financing and underpinning the negotiating conditions of urban mega-projects, implying unprecedented uses of financial indicators linked to property investment, profitability and building permits (Raco and Brill, 2022; Edwards, 2020). Indeed, such financialised techniques used by global investors for delivering urban mega-projects are reflected in the local market-led orientation of planning systems in which specialised property developers are currently key players, representing such investors' interests and delivering a deterritorialisation of real estate narratives, motives, and techniques (Haila, 2021; Cocco, 2007). Finance has always been there, but such financialisation practices and instruments have multiplied its importance, making real estate one of the leading global asset classes.

Moreover, urban policy financialisation exercises increasing 'pressure' on land interests, dampening the thrust of radical reforms on land value recapture in European countries (Edwards, 2020). Thus, the urban policy program of large-scale projects set by the Milanese local government, and often affected by regional and central governments on some key opportunity areas, as in the MIND case, tend to prepare suitable sites for enabling public-private

partnerships, joint ventures and planning agreements, facilitating viability-based arrangements (Colenutt et al., 2015) which follow deterritorialisation criteria. This shift towards viability-based planning, conceived as an extension of financialisation into (state) strategic spatial planning, which I argue coincides with the deterritorialisation of urban policies (e.g., urban mega-projects) and a loss of solid planning principles, is practically traduced as a bundle of financialised metrics and reasoning used into spaces and situations (Briata and Raco, 2022; Chiapello, 2015) addressed to embed financial capital into real estate operations.

Also, the MIND case demonstrates that, due to the financialisation of property development, urban-mega projects and, in general, large-scale operations are increasingly shaped by the knowledge and know-how held by property developers, and investors who manage large datasets and operate with corporate structures capable of spatializing financial techniques underpinning the deterritorialisation of urban policies (and projects). This configuration has, paradoxically, made central, regional and especially local governments increasingly dependent on the information provided by property developers and investors, making the latter able to move easily between building regulations and planning permissions (Raco et al., 2018). Consequently, today a 'heavy' vision of statutory plans and masterplans diverges from the site development managing structures of urban mega-projects, which, on the contrary, as in the case of MIND, are based on a principle of long-term planning flexibility. Such a 'flexible attitude' addressed by planning systems has been spread over Europe (World Bank, 2020), and it represents another relevant effect of the urban policy deterritorialisation since the constant reshaping of strategic areas disjunct their planning from statutory plans. Nonetheless, the urban policy financialisation has promoted the affirmation of new foreign social leading groups and the attraction of capital in selected incumbent major European cities together with gentrification effects.

The direct consequence of such planning flexibility is the 'project-led mindset' (Secchi, 1986) enabled by *ad hoc* instruments, as the PIIs in Milano, which guides the concept of a deterritorialised and financialised city (Tasan-Kok and Ozogul, 2021). Thus, the governance of the planning system is re-centred to what has been called 'devolved localism' (Briata and Raco, 2022) by which local governments, property developers and investors select suitable sites for financialised large-scale operations determining the such project-led layout of the city, thus a viability-based planning (Colenutt et al., 2015; Chiapello, 2015). Within this scenario, urban mega-projects address a 'stimulus' condition' for financially leverage local property markets, projecting land rent as essential drivers (Haila, 2021) to foster Milan in the global investment arena.

6. Conclusions

Financialisation has an ever-stronger impact on determining what needs to be planned (Halbert and Attuyer, 2016) and in which phases, following unpredicted deterritorialised methods. Thus, the constitutive conditions driving the financialisation of urban mega-projects have seen an overall alienation of the methods of activation, implementation, and management as they decrease the state planning power to deliver such projects.

According to this scenario, property investors and developers are taking a leading role due to their capacity to impress financial calculations over investment allocations, disassociating (e.g.,

deterritorialising) them from their impacts on local economies and actors and, instead, following the fluctuation regimes of capital (Briata and Raco, 2022; Chiodelli, 2012).

In conclusion, the viability-based and financialised urban policies reversed the *raison d'être* of (state) strategic spatial planning, which in the past addressed urban mega-projects based on planning & political principles, along with a trend which sees a massive rise of trans-scalar 'policy territorial integration approaches' (Medeiros et al., 2020), combined with multi-level and multi-actor governance (Faludi, 2018).

Thus, financialisation is deterritorialising planning practices and motives in parallel with the increasing complexity of land investment strategies and the rise of market-led property operations, inverting the ethos of the planning system (Briata and Raco, 2022). In other words, although spatial planning continues to keep a fundamental role in land use policy, the deterritorialisation of planning aims affects their endeavour towards recapturing land value, depowering the major lever for rebalancing urban rent. Nonetheless, I argue that strategic planning is still the key to counterbalancing the effects of urban policy financialisation, and the State should not abdicate its leading role in arranging spatial configurations.

Acknowledgements

I hereby thank my doctoral supervisor, Professor Gabriele Pasqui, for his relevant advice in researching financialisation and spatial planning implications on urban mega-projects and for his support in writing this article.

Large-scale urban development projects as a dilemma affecting the housing crisis. The case of Milano Porta Romana

Abstract
This paper explores the linkages between housing studies and large-scale urban development projects through the lens of financialisation. Especially over the last three decades, global real estate finance massively hit local real estate markets, thus generating segregation, exclusion, and densification by commodifying housing as a financial asset class. Particularly, property financialisation has routed major projects into catalysts to extract capital gains from land value rather than levers to foster the right to housing and plan a 'just city'. Through the case of Milano Porta Romana, this paper shows how financialised schemes which are shaping such a large-scale urban regeneration project represent a dilemma for scholars, practitioners and politicians since, on the one hand, they produce home provision but, on the other hand, they rise up the housing costs without really tackling the housing unaffordability issue and these conditions affect the 'right to the city' for students, middle-class workers, and migrants.

Keywords
financialisation, large-scale urban development projects, housing crisis; densification; Milano Porta Romana

1. Introduction

This paper investigates the linkages among property financialisation, grand planning operations and urban policy from the housing crisis angle. In this contribution, I argue that the financialisation of large-scale urban development projects (Salet, 2008) massively hit the 'right to housing' for students, middle-class workers, and migrants (Arbaci, 2019), along with global investment trends intertwined with housing commodification and marketisation. Particularly, through the generalisation of the Milano Porta Romana case, I frame the financialisation practices and techniques affecting plan-making by showing the interactions between the real estate markets, in which the assets are developed and managed, and the financial market, in which the same assets are treated and traded as financial products (securities, bonds, shares, equities, loans etcetera).

This process generated significant insights on how private equity, but especially institutional investors (Holm et al., 2023), as occurred in the Porta Romana case, established joint ventures and public-private partnerships for 'financialising' large-scale projects (Savini & Aalbers, 2016; Aalbers & Christophers, 2014). Such dynamics affected the policy- and plan-making of local governments and massively decreased the housing affordability for middle- and low-income classes (Adisson et al., 2022; Aalbers et al., 2020; Aalbers, 2019; Van Loon & Aalbers, 2017). In other words, the nexus between property financialisation, which globally enabled real estate as one of the major asset classes, and the austerity reforms which locally reduced the state capital transfers, severely harmed the 'right to housing' in both Global North and South countries (Mazzuccato & Farha, 2023; Waldron, 2018; Aalbers, 2016; Sassen, 2015).

I organised this paper as follows: in the first section, I illustrated the housing unaffordability of Milano; in the second section, I introduced the project-led attitudes affecting the city-making; in the third section I explained the financialisation of Milano Porta Romana as an exemplary case of the interactions between finance and planning in delivering urban regeneration pursued by relevant property developers and institutional investors; in the fourth section, I discuss the case findings in relation to the planning and policy measures introduced by the Milanese local government to reframe major projects (Fareri, 2009) over the last decades, explaining why the financialisation of such projects represents a dilemma affecting the housing crisis. In conclusion, I tackle the impact of property financialisation on Milano's planning and affordable housing system by delivering a few policy recommendations on potential ways to revamp the social and public housing provision.

This paper's methodology encompasses a literature review of the main academic contributions related to urban development and housing financialisation; a desk analysis of the Milanese planning and policy frames and regulations; the use of semi-structured interviews of several key actors; the case study analysis of Porta Romana railyard; and field observations of the plan-making collected during meetings, interviews, readings, conferences.

Finally, the case of Porta Romana shows that the bundle of financialised practices and instruments mobilised by institutional investors and their development partners generated a collapse of publicly driven plan-making towards privatisation, alienation, decontextualisation and deterritorialisation of large-scale urban development projects, which tend to marginalise the 'right to housing'. The dilemma between valorising the provision of affordable housing or enabling the packaging of property investments over the major projects challenges the role of (state) spatial planning in shaping the housing demand.

2. Framing the Milanese housing unaffordability

Milano is a middle-range metropolis with nearly 1.4 million residents nestled within a metropolitan area of 3.2 million people, garners recognition as one of Europe's leading unaffordable cities. This reputation stems from escalating homelessness, a prevalence of low-wage jobs, and limited public and social housing offerings (Bricocoli and Peverini, 2024; Holm et al., 2023).

Following the Expo 2015 mega-event, Milano firmly established itself among the world's major cities (Pasqui, 2018). Evolving from a traditional regional hub to a middle-range metropolis (Bassetti et al., 2005), Milano has adeptly navigated global interdependencies and investments (Bolocan Goldstein, 2017), diversifying major projects to meet financial demands. Prior indications of this 'city globalisation' were highlighted by Taylor & Derudder (2004) for connectivity and by Dente et al. (1990) for administrative capabilities. This trend is exemplified by Milano's participation in the 'C40 Cities' network and its 'Reinventing Cities' program, aimed at urban renewal in key locations like Piazzale Loreto, the Ex Macello, and Scalo Lambrate. Additionally, global developers Lendlease and Hines are spearheading three major urban transformations: the Milano Innovation District in the Expo area, Milano Santa Giulia, and Milano Sesto (ex-Falck's industries areas).

Like many Southern European capitals, Milano currently operates with a limited welfare model (Allen et al., 2004), resulting in scant state housing provisions, particularly in affordable rentals. This situation contrasts sharply with the expansive homeownership facilitated by the post-war 'Fanfani Plan' (Coppola, 2012), leaving approximately 70% of Milanese citizens as landlords (Holm et al., 2023). However, Milano stands out from other Italian cities with its substantial public housing developments dating back to the 1950s through the 1980s, which now accommodate 10% of the city's population (Comune di Milano, 2023).

Over the past decade, Milano's real estate market has experienced significant growth, with a 41% increase in property values and a 22% rise in rental prices (OCA Report 2023; Assolombarda, 2021). This market is predominantly driven by equity investments via non-listed Real Estate Investment Funds (REIFs), particularly 'Fondi Chiusi', which saw a nearly €1 billion market capitalisation in 2022 (Holm et al., 2023).

Among these financial instruments, the Fondo Investimenti Abitare (FIA), managed by Cassa Depositi e Prestiti (CDP) Real Asset and supported by institutional investors like Generali life-insurances and Cariplo Foundation, focuses on affordable housing. Meanwhile, the Municipality of Milano has privatised a significant portion of social housing/quasi-market dwellings owned by the municipal-controlled company MM (Nomisma, 2022; Comune di Milano, 2023).

This privatisation coincided with state neoliberalisation and financialisation efforts (Lake, 2015), leading to the dismantling of public property assets through actions such as establishing the 'Agenzia del Demanio' and introducing legislation on REIMFs and Special-Purpose Vehicles (Caudo, 2004).

In terms of policy regulation, real estate actors in Milano, akin to counterparts globally, have pursued urban regeneration by aligning financial business plans with flexible masterplans. This approach was facilitated by liberalised planning authorisation, exemplified by initiatives like the 'Segnalazione Certificata Inizio Attività' (SCIA) and the repeal of fair rental fees (Legislative Decree 222/2016; Law 431/1998), as well as specific qualifications for REIFs and related Special-Purpose Vehicles (SPVs), often managed by Savings Management Companies (SGR) (Legislative Decree 228/1999).

3. A project-led scenario

In parallel with the legislative engines enacted to fuel the State property financialisation, which alienated numerous public residences, the Lombardy Region and the City of Milano implemented significant planning adjustments through Regional Law 9/1999 and Regional Law 12/2005. This led to the inception of Integrated Action Plans, known as Piani Integrati di Intervento (PII), and the revision of structural plans via Piani di Governo del Territorio (PGT), facilitating a range of large-scale transformative projects alongside the restructuring of major state enterprises and the hosting of Expo 2015 mega-event. Notable among these projects were Porta Nuova-Garibaldi and CityLife, designed as catalysts for urban renewal to attract financial investments (Anselmi and Vicari, 2020; Conte and Anselmi, 2022).

The latest structural plan, PGT 'Milano 2030', ratified in 2019, redefined major regeneration initiatives as 'Grandi Urbane Funzioni' (GFUs), aiming to integrate these projects into the

surrounding urban fabric. However, this attempt to guide large-scale project planning coincided with urban densification (Salet, 2008), resulting in substantial increases in building volumes within the GFUs, subway stations, railway stations, and main thoroughfares (up to 1 m^2/m^2 building index) (Comune di Milano, 2019), maximising returns for investors and developers, particularly in semi-central districts.

In essence, akin to trends observed in other globalised cities (Swyngedouw et al., 2002; Salet, 2008), since the late 1990s (Bolocan Goldstein and Bonfantini, 2007), successive administrations in Milano pursued urban policies intertwining real estate financialisation with regeneration efforts, facilitating the extraction of urban rents to be exchanged as financial products, *project by project*.

In Milano, significant public lands have undergone financialisation over recent decades through sales, leases, or sale & lease-back arrangements, including projects such as 'Ex Macello' near Argonne Avenue, 'Green Between – Tessiture Urbane' initiative in Crescenzago, the ex-railyards regeneration of Scalo Greco' and decommissioned military barracks in the western part of the city. Within these processes, social housing has been utilised for the first time as a catalyst for urban development and capital accumulation, involving state, state-controlled, or state-funded entities such as the national railways authority and company (Ferrovie dello Stato FS, Rete Ferroviaria Italiana RFI), the Ministry of Defense, and InvestiRE/Redo Sgr (Holm et al., 2023).

Various scholars (Ponzini and Vani, 2012; Gastaldi and Baiocco, 2013; Gastaldi and Camerin, 2015; Artioli, 2016) argue that the financialisation of public assets (such as ex-barracks and yards) stems from shifts in strategic and logistical frameworks within these sectors, compounded by a lack of state capacity in planning large brownfield sites. The austerity measures governing the provision of public assets by local governments, particularly in land renovation projects, have been exacerbated by complex reforms and legislation, leading to fragmented institutional settings. This has prompted local governments to primarily pursue land sales through financialisation and alienation techniques (Artioli, 2016), despite the considerable value of Italian public real estate assets, estimated at approximately 450 billion euros (Gastaldi and Camerin, 2015).

In summary, it can be argued that the urban policies implemented by past PGTs, as well as the mentioned operations of land alienation and financialisation (Kaika and Ruggiero, 2016), have exacerbated spatial and socioeconomic disparities, particularly in peripheral neighbourhoods while fueling property speculation and densification in residential settlements and delivering plan-making within a project-led perspective.

4. The case of Milano Porta Romana between urban densification and housing provision

The redevelopment of the decommissioned Porta Romana ex-railyard, known as the Milano Porta Romana large-scale project, highlights emerging trends in the affordable housing crisis due to property financialisation's impact on Milanese urban planning. These large-scale projects exemplify how the State, particularly the Milanese local government, facilitated significant property developments to stimulate Milano's real estate market.

The history of Port Romana regeneration is intertwined with the negotiations among the Municipality of Milano, Lombardy Region and Ferrovie dello Stato (FS) in 2007-2016 aimed at redeveloping all the seven decommissioned former Milanese railyards, in total covering approximately 1.290.384 m^2 (see Fig. 2; Fig. 4). This negotiation process led to the adoption of an Area Development Plan (AdP) integrated into the city's structural plan (Piano di Governo del Territorio PGT). The AdP is a planning instrument which was conceived to orchestrate further yard densification and approved in 2016 after initial setbacks in 2015. The approved AdP (Comune di Milano, 2016) outlined parameters such as a building index of 0.65 m^2/m^2, with a 65% allocation for green spaces and 35% for built-up areas, along with provisions for affordable social housing in each yard (see Fig. 1; Fig. 3).

The initial AdP draft was established by the Municipality of Milano, Lombardy Region, FS and the latter's property company - Sistemi Urbani - during Letizia Moratti's right-wing local government (2006-2011). Within the following centre-leftist mayor Giuliano Pisapia the AdP was subsequently endorsed in 2012, affirming the previous decisions made by Moratti's administration. Pisapia's administration sought to validate the AdP by fostering a participatory process, culminating in a strategic document in 2013 outlining guidelines for the master planning of the seven sites. However, the scope of this participatory process was limited, primarily focused on consensus-building objectives. In 2015, an initial version of the AdP failed to gain approval from the city council but was eventually approved in 2016 with slight revisions (Pasqui, 2018). Shortly thereafter, Savills, a relevant REIT and institutional investor associated with the Milanese property developer Coima, acquired a portion of the Farini ex-railyard, one of the seven sites, from Sistemi Urbani, thereby entering the de facto governance sphere previously dominated by state and state-controlled entities.

In its final iteration, the AdP was controversially negotiated by the City of Milano, the Lombardy Region (due to its involvement in the Circle Line mobility project), FS, and two other FS-controlled companies (FS Sistemi Urbani, focusing on real estate, and RFI, focusing on the rail network), along with Savills. Within the AdP's approval, FS Sistemi Urbani initiated a master plan design competition in 2017 to allocate development rights, with participation from five international architecture firms. Later, in 2021, the Municipality of Milano and FS Sistemi Urbani commenced a new participatory process aimed at 'enhancing citizen involvement' although the fundamental aspects of the master plans had already been established (Pasqui, 2018).

Throughout the entire process, various conflicts arose, leading to four separate lawsuits filed by residents, environmental associations, and FS itself against the city regarding the failed approval of the AdP in 2015. Key controversies included the recognition of FS as the rightful landowner and recipient of development rights, which had been granted in the early 20th century for railyard services without building rights; the legitimacy of using the AdP, originally intended for state actors, to organise what essentially amounted to a public-private partnership; the determination of development fees owed by FS to the city and the applicability of national legislation on 'extraordinary development rights'; and the proportion of green areas in the overall functional mix. However, the lawsuits ultimately favoured FS and the city, with the one initiated by FS being resolved upon the approval of the new AdP (Holm et al., 2023; Montedoro, 2018).

Following the procedures set by the AdP, in November 2020, the 'Porta Romana Fund' – a close-end REIF promoted and managed by Coima Sgr and subscribed by Covivio, Prada Holding and the 'COIMA ESG City Impact fund' (CECIF), the largest Italian REIF with an

investment capacity of 500 million euros – purchased the Scalo di Porta Romana, one of the 7 former railyards, for 180 million euros. Coima Sgr is the richest Milanese property development company (Coima, 2023), and it is owned by the entrepreneur Manfredi Catella, who established a joint venture with Hines Italy before the Expo 2015 for developing the Porta Nuova Garibaldi large-scale project.

After winning the auction, the three main actors managing Porta Romana Fund signed a 'value chart' for splitting the plots according to specific asset classes defined per 'functional areas' that they will directly develop and manage, within a total area of roughly 200.000 m^2 (see Fig. 5). The agreement assigned all the housing provisions to CECIF (thus Coima) and most of the office and retail units to Covivio to avoid internal competition among the operators which undesigned the Porta Romana REIF. The Municipality of Milano agreed to obtain development fees for roughly 50 million euros plus a range of planning gains, including social housing provision (Holm et al., 2023).

Coima, as the site owner and under AdP's provisions, directly organised and oversaw a design competition for the masterplan, won by the American firm Diller Scofidio+Refro. As per the PGT, the area later gained recognition as a 'special zone' (Zona Speciale Scalo Romana) through a PII approved by the Municipality in May 2022 (Comune di Milano, 2023) (see Fig. 2). The comprehensive plan allocates 112,150 sqm for urban purposes (retail, productive, hospitality, private non-residential services), 53,575 sqm for residences (market rate, social and public housing), and 95,397 sqm of green spaces. In total, 68% of the development is earmarked for housing, with 44% designated for residential social housing, including 11% for public housing and 22% for moderate rent (see figure below).

Following Milano & Cortina's successful bid for the 2026 Winter Olympics, the project gained renewed significance as Porta Romana was designated as the site for the Olympic Village. Currently, Coima is developing it with a project by Skidmore, Owings & Merril, the runners-up in the masterplanning competition (see Fig. 2).

Three functional areas were delineated based on the referenced 'value chart', each corresponding to distinct development stakeholders: the western quadrant encompasses a mixed-use area housing the Olympic Village developed by Coima, with Covivio developing the eastern part; the central section forms a network of connections expanding the existing Prada Foundation managed by Prada (see Fig. 5). Coima SGR will oversee the development of both market-rate and social housing, including the Olympic Village, which will be repurposed into student housing with 1,000 beds post-Olympics. In March 2023, Coima entered into an agreement with Consorzio Cooperative Lavoratori CLL – a consortium of housing cooperatives primarily involved in quasi-market/social housing production alongside other public and private entities. Coima hailed the new partnership as "a groundbreaking development in the Italian landscape (…)" introducing a novel model for social and subsidised housing development, a sector historically dominated by the public sector (…) 'COIMA Housing' aims to address up to 25% of Milano's current social housing demand, equating to approximately 40,000 residences (Coima, 2023).

The ultimate goal is to establish a national investment platform for social housing initiatives with a multiplier effect." Additionally, Coima established the 'COIMA Housing' Fund (COIMA Housing), a closed-end real estate fund focusing on various types of social housing development, targeting a size exceeding 400 million euros, with an initial closing planned for about 300 million euros. The principal investor and sponsor of 'The COIMA Housing Fund' is

the ‘COIMA ESG City Impact Fund’ (CECIF). With an investment leverage of 800 million euros and capacity of 500 million euros, CECIF stands as Italy's largest closed-end alternative fund, with Porta Romana being its flagship project, supported by a consortium of institutional investors, including professional social security organisations, funds, banks, and banking foundations (ENPAM Foundation, Cassa Forense, Cassa Dottori Commercialisti, Inarcassa, BCC Credito Cooperativo, Foundation CARIPARO, Compagnia di San Paolo, and Coima) (Coima, 2023).

Intesa Sanpaolo is also joining ‘COIMA Housing’ as part of "its commitment to fostering the development of 8,000 social housing units for youth and seniors". ‘COIMA Housing Fund’ participated in the inaugural call of a newly established fund promoted by CDP, the ‘Fondo Nazionale Abitare Sostenibile’ (National Fund for Sustainable Housing), aimed at financing new projects for senior, student, and social housing.

However, despite the relevant provision of social and student housing in the Porta Romana redevelopment project, which is developed in a moment of deep need for the ‘right to housing’ for students, middle-class workers, and migrants in the city of Milano (Bricocoli and Peverini, 2024), several rumours already reported the high rental fees for those settlements (Maggioni, 2024). In that sense, the financialisation of this large-scale project with forward-looking ESG targets and housing affordability does not allow the achievement of equal benefits for the working class housing demand nor a recapture of land surplus value extracted through such property operation.

Overall, the Porta Romana large-scale redevelopment project reflects a complex interplay of public and private actors, urban planning strategies, and socioeconomic dynamics, emphasising the evolving nature of the Milanese property densification towards financialization.

5. Discussion. Porta Romana densification and ‘all-you-can-eat urbanism’

In the chapters above, I explained the interactions between housing financialisation and planning-enabling attitudes in Milano. Second, I unpacked the urban development financialisation of the Porta Romana ex-railyard, which clearly demonstrates the nexus between finance and planning and, especially, how property financialisation is harming the right to housing.

Moreover, the implementation process faced challenges, including legal disputes and conflicts over property ownership and governance tools' use. Despite these challenges, the project progressed, attracting investments from entities like Savills and the establishment of the 'Porta Romana Fund' by Coima Sgr and partners in 2020.

Coima plays a pivotal role in both formulating and executing large-scale development endeavors, acting as facilitators and managers of financial aspects. Their ascent in Milano's property development scene is supported by political and financial ties with national and international funds like Cassa Depositi e Prestiti and Qatar Investment Authority, notably seen in the Porta Nuova project.

Coima's involvement extended to the development of the former Scalo di Porta Romana, allocating housing provisions to ‘COIMA ESG City Impact Fund’ (CECIF) and other assets to Covivio Spa. Additionally, Coima initiated partnerships for social housing development,

emphasising a shift towards professionalised property developers supported by institutional capital.

Thus, the Porta Romana initiative signifies a further progression, where mainstream financial actors engage in social housing within governance agreements alongside state entities overseeing spatial planning. ‘COIMA Housing Fund's launch and agreement with CCL cooperatives demonstrate an intent to enter the social residential housing market, enhancing capital and expertise directly and through partnerships. This shift marks a significant change in Milano's social housing governance, potentially embraced by city elites, warranting further examination.

Amidst promoting urban regeneration and real estate investment, Milano pursues public objectives through planning gains like green spaces, cycling lanes, and rail projects. Social housing provision gains prominence, reflecting the looming housing crisis, yet predominantly caters to middle-class demographics, sidelining traditional public housing. Despite this, low development fees persist, attracting institutional capital aligned with ESG targets, crucial for urban regeneration projects involving major investors, mirroring trends in Europe and the USA.

While the 2026 Olympics saw less central government involvement compared to Expo 2015, state-supported mechanisms like CDP remain prominent (Muller, 2011; Raco, 2013; Raco et al., 2018). Developers like Coima now spearhead state-backed projects with institutional investors' backing, reshaping affordable housing financialisation norms.

Thus, Porta Romana exemplifies the convergence of large-scale projects driving property financialisation (Anselmi & Vicari, 2020; Conte & Anselmi, 2022), the packaging of long-term investments from institutional backers (Van Loon et al., 2017), and a state-enabling attitude facilitating land value extraction (Tasan-Kok & Ozogul, 2021; Fainstein, 2012; Tasan-Kok, 2010), densification and alienation through spatial planning. Milano's recent structural plans facilitate a flexible built environment where developers and investors manoeuvre capital, fostering real estate market financialisation amidst a global trend of housing rights dismantlement (Mazzuccato & Farha, 2023). In other words, the bundle of policy, planning and financial measures reflected in the recent PGTs, AdPs, and PIIs, frame a sort of ‘all-you-can-eat urbanism’ able to satisfy every ‘investing-risk appetite’ and each property developer/investor’s demand by easily transform and circulate financial and land capital over Milano.

6. Conclusions

The exacerbation of financialisation on real estate, spatial planning, and urban policies, alongside the expansion of neoliberal politics (Lake, 2015), led to a failure to introduce countermeasures for rebalancing inequalities in several 'globalised cities' (Swyngedouw et al., 2002). As highlighted by Raco & Tasan-Kok (2023), spatial planning scarcely negotiates planning gains, even when large-scale projects yield substantial financial profits for property investors and developers.

The financialisation of urban policies (Lake, 2015) caused strategic planning to nearly vanish in the practices of many Western cities, depriving redistributive principles of urban rent,

especially in large-scale densification processes. Consequently, this significantly contributed to the housing crisis through expulsion, eviction, and gentrification phenomena.

The Municipality of Milano initially facilitated the financialisation of large-scale projects and brownfield densification, only recently partially recognizing their associated issues. Urban development financialisation poses a dilemma for planning decisions between urban regeneration and profit redistribution linked to inequalities, particularly for the current and previous centre-leftist local governments under Giuseppe Sala and Giuliano Pisapia.

In conclusion, while the Milanese planning policy framework demonstrated an unexpected ability to handle multiple large-scale projects simultaneously, it struggled to recapture land value surplus (Fainstein, 2012) through planning and financial tools, which could prevent market distortions and socio-spatial polarisation between 'city of the rich' and 'city of the poor' towards project-led mindsets (Secchi, 2013). Instead, recent urban politics and planning instruments fostered an 'all-you-can-eat urbanism' mindset, in which the planning & policy frames fit all types of densification projects, enabling the extraction and marketisation of urban rent while harming the housing rights of students, middle-class workers, and migrants.

Abstract

A major urban renewal policy has been implemented in France since the 2000s, bringing about extensive urban and social changes in vast social housing complexes built during the post-war period of massive construction. Drawing on an urban political economy framework, this paper analyses two French urban renewal projects as a commodification and a privatization of neighbourhoods that have been characterized for decades by a public or quasi-public land ownership and by non-market-oriented forms of management. I argue that under certain conditions, urban renewal may produce different types of urban rents, which are mostly appropriated by private stakeholders. This paper investigates the role of state and local governments in these processes to underline the existence of public strategies favouring the profitability of private housing development and the production of urban rents in these areas.

Keywords : Rents, Urban Renewal, Social Housing, Commodification, France

1 Introduction: Land Rents, Urban Renewal, and Public Action

Since the early 2000s, in France, many social housing neighbourhoods, mostly built between the 1950s and the 1970s, have been the target of a substantial urban renewal policy, led by a state agency. While the spatial and social effects of this urban renewal program have been studied by many authors (Gilbert 2014; Kipfer 2016; Lelévrier 2023), as well as its political consequences at a macro-level (Beal, Epstein, and Pinson 2018; Epstein 2013), the way it changes the urban production mode of these social housing neighbourhoods deserves further explorations, in the field of urban political economy. This presentation, based on ongoing PhD research, will offer an approach of urban renewal in France through the lens of urban rent theory. This paper argue that French urban renewal projects can be considered as a commodification and privatization process of social housing neighbourhoods and can lead to the formation of different urban rents, depending on the dynamics of each local property market. It also insists on the role of public action in the very concrete processes which realize the commodification of land and enable the formation of urban rents.

Since a seminal article by Neil Smith (1979), the *rent gap* question has been addressed by an abundant literature. The rent gap hypothesis can be considered not only as an explanation for social changes, such as gentrification, but also as an interpretation, through the prism of markets and urban rents, of certain types of spatial transformations and built environment changes, within the perspective of uneven development (Smith 1982). The starting point of the rent gap hypothesis can be found in the multidimensional devalorisation processes experienced by some private housing neighbourhoods, leading to a gap between the rent captured under the current use of land and the rent which could be extracted from higher and better uses of the land, if the area was redeveloped (López-Morales et al. 2019). Smith's first formulations of the rent gap theory were quite silent about the role of the State in such processes (Boulay 2022).

Nevertheless, numerous authors since then have emphasized the part played by the state, both by national and local governments, in the rent gap formation (Badcock 1989): public infrastructure investment, as well as the adaptation of construction guidelines and urban renewal legislation have a strong effect on the potential rents which can be created through a redevelopment project and appropriated by private developers (Lan and Lee 2021; López-Morales et al. 2019). Neil Smith himself (1996) has afterwards studied the role of a quasi-public organization, the Redevelopment Authority, in the urban renewal of Society Hill in Philadelphia.

Focusing on the processes of devalorisation and revalorisation of the capital invested in some urban areas as driving urban renewal, Rachel Weber (2002) highlights the participation of the state in the "creative destruction of the built environment". She pays a particular attention to the way in which urban redevelopment operations are justified and organized by federal and local governments. The local and federal states are involved in the selective devaluation process that occurs in some neighbourhoods, which get stigmatized by local governments through a "discourse of blight" and depicted as obsolescent. Processes of devalorisation and revalorisation cannot be considered as "purely market-determined" (Weber 2002), as the state also contributes to the redevelopment of these urban areas, by authorising and even sometimes leading demolitions, and more broadly, by setting all the conditions for private capital to be safely and successfully invested and able to extract value from redevelopment sectors.

Approaching French urban renewal policy as neoliberal redevelopment and rent extraction strategies implies a comprehension of how land rents are produced within the urban space. This problem was tackled by the French Marxist urban sociology, and particularly by Christian Topalov, whose work provides a useful insight into the mechanisms of urban rents' formation. Christian Topalov analyses urban changes as the product of a "spatial competition of land uses", resulting in the elimination of "inferior", from a capitalist point of view, land uses by "superior" ones, that is which generate more profit, partly appropriated by landowners (Topalov 1984). Urban development leads to the formation of rents, understood as the "fixation and transformation of localized surpluses generated by the development of capital for a given activity and a given place" (*ibid.*: 13). The state can intervene at various levels in this process. On the one hand, public land ownership can hinder the development of capitalist land uses. First, it forms "land easements of obsolete large public facilities" or "land reserves" and there is no guarantee that they will be exploited "to produce maximum land rent" (Topalov 1984:47–48). As a consequence, public land or infrastructure may embody some of the barriers which hamper the continuous geographical expansion of capital (Harvey 1982) and further accumulation within the built environment. Second, some of these properties are subject to "social" management by the state or local authorities, leading to "distract land from more profitable private uses and to allocate it to public operations of social housing or social facilities" (Topalov 1984:47–48). However, on the other hand, the state can support the development of the most profitable capitalist land uses and promote the formation of urban rents and their appropriation, as part of the urban development process, by capitalist actors, notably by developers. Selling public land can constitute a "direct aid to the accumulation of real estate capital" through sales "at cost price" rather than market price (*ibid.*). Furthermore, infrastructure and development costs are often borne by the local and national governments, especially in "urban restructuring operations" (*ibid*: 101). Through these means, the state attempts to influence a crucial element in the formation of urban rents, namely the production of use values. Stemming from social processes and agglomeration effects, use values are vital

for the development of capital within the urban space, however private capital is never able to control these processes and to create use values on his own. Conversely, according to Christian Topalov, the state plays an important role in the production of use values in the urban space and can mobilize this political and economic resource for the benefit of urban rents. Yet, public authorities are only partly in control of the emergence of use values. Hence the pursuit of "greater security in creating localized conditions of private surplus profit" is not always successful (*ibid*: 31-32). The French urban renewal policy can provide concrete case studies to explore the conditions in which urban rents can be produced and to analyse the effective role of the state in these processes.

2 The Urban Renewal Policy in France since the early 2000s: Privatization and Commodification of Devalued Social Housing Neighbourhoods

Since the early 2000s, the French state has launched a vast urban renewal policy, targeting over 600 high-rise social housing estates inherited from a post-war period of massive construction. This legacy of the Fordist period experienced a difficult transition towards a flexible accumulation regime and new urban production modes (Bidou-Zachariasen 1995). Large social housing complexes known as "*grands ensembles*" have undergone profound transformations in their spatial organization and population dynamics in the post-Fordist era. Concentrations of poor and racialized inhabitants progressively emerged in these peripheral social housing estates, because of socio-economic and urban mutations, but also under the influence of public policies and management by social landlords. Starting from the 1980s, these social housing complexes began to be considered as a national public problem (Tissot 2007) and targeted with specific policies (Bonneville 2005), because of their urban decay and of their social and racial composition, in relation to the increasing political demand for mix-tenure urban development, in France (Blanc 2010) like in other European countries (Kleinhans 2004).

The National Urban Renewal Program (PNRU) is launched in 2003 in this political and social context. It is implemented by local authorities and social landlords at local scale. They benefit from special funding that they obtain by signing urban renewal contracts with a state Agency, the National Agency for Urban Renewal (ANRU), which was established on purpose in 2004. The ANRU defines a national doctrine of urban renewal, following the cardinal objective of creating tenure mix in large social housing estates (Epstein 2013). Operationally speaking, the aim of changing the population of these poor neighbourhoods is supposed to be achieved by significant demolition and rebuilding, exemplifying the domination of a "strong 'physicist' approach" in the current urban policies (Moulaert, Swyngedouw, and Rodriguez 2001). Targeting mostly social housing estates, demolition first aims to disperse, through relocation, concentrations of poor and racialized populations (Lelévrier 2010). This urban intervention should then enable wealthier households to come and live in these areas, by the means of property development, in place of demolished social housing buildings. I will focus on this dimension of the French urban renewal policy: the state-initiated *rénovation urbaine* is not only a form of social engineering (Desage, Morel Journel, and Sala Pala 2014) but can also be interpreted as a process of commodification and privatization of large social housing estates (Lelévrier 2023). Within an urban political economy framework, the objective of incorporating private housing, mostly dedicated to future homeowners, in these neighbourhoods can be understood to integrate new urban areas into property markets and to open them to real estate development and private capital (Dormois, Pinson, and Reignier 2005).

French *grands ensembles* were mainly built between 1953 and 1973, thanks to public and quasi-public capital (Préteceille 1973), resulting in the creation of a mass social housing supply, with an administrative rent-setting system, instead of a market-oriented management (Topalov 1987; Kemeny 1995). The ANRU breaks a form of path dependency which followed from a mostly public or quasi-public land ownership and from the inclusion of these neighbourhoods in financing circuits based on long-term semi-public loans (45 years). Therefore, for the most part, large social housing estates have not undergone significant changes since their construction, neither in land ownership nor in their housing supply structure. They thus embody the barrier that public ownership and "social management" of land can represent for the development of capitalist land uses (Topalov 1984): large social housing neighbourhoods were not land to buy, available for property development, nor urban areas which could be transformed depending on the only initiative of private capital. Urban renewal programs can be seen as a state action aiming at removing land barriers that blocked private capital's access to social housing complexes, which get integrated into land and real estate valorisation processes that play out in other parts of the city, and sometimes at their borders, at least in some urban contexts. Considered as "fossilized[1]" by this public monopoly on land, residential social housing neighbourhoods produced, for social landlords, a limited land rent, as they could not extract a high rental income from mature dwellings with low and regulated rents (Kemeny 1995). Furthermore, in some large social housing complexes, high vacancy rates and a difficult management of decayed buildings, for both technical and social reasons, also contributed to reduce the land rent perceived by social landlords. Therefore, within certain urban contexts, these devalued and deprived neighbourhoods were far from being an optimal land use from a capitalist perspective, in comparison with the potential land rent that could have been capitalized under another land use. Exhibiting all the characteristics of an "inferior" land use, large social housing estates can thus constitute a specific situation of rent gap. Although it would be an application of the rent gap hypothesis to public housing estates rather than to private homeownership neighbourhoods, the situation of the *grands ensembles* seems to fulfil most of the criteria that G. Boulay (2022) suggests controlling to test the rent gap hypothesis. Thus, through the ANRU and an urban renewal doctrine promoting housing diversification, the state enables and organizes the filling of rent gaps and the replacement of a low land rent based on degraded and mature social housing dwellings by “superior” residential or economic land uses.

In addition, urban renewal policies have to be understood in a broader context of neoliberalization of housing markets and especially of the social housing sector, which is increasingly dominated by the “residual model” depicted by M. Harloe (1995). Dynamics of privatization (Aalbers and Holm 2008; Bernt, Colini, and Förste 2017), commodification (Forrest and Murie 1995) and even financialization (Aalbers, Loon, and Fernandez 2017; Byrne and Norris 2022) of social housing supply have been evidenced in many European countries, partly in relation to urban renewal projects.

3 Issues and Research Method

This paper explores how housing diversification is implemented and how private housing is incorporated in two large social housing estates located in property markets with contrasting dynamics. On the one hand, the Chantereine district is situated in the city of Alfortville, in the inner suburbs of Paris. The municipality of Alfortville has been, since its creation in the 19th century, a working-class area, under a socialist local government since 1945. In recent times, it

[1] Interview with a member of the ANRU staff, in charge of the Alfortville project, June 2021.

has been experiencing an increasing pressure on land and real estate prices, like many working-class municipalities of the core of the Paris region. On the other hand, the Southeastern Districts of Saint-Etienne, in the South-East of France, are situated in a former mining and industrial town, which has gone through a strong demographic decline and a situation which can be considered as urban shrinkage. Saint-Etienne's property market is characterized by high vacancy rates and low housing sell and rental prices.

This paper aims at analysing the concrete conditions in which unfolds the state-initiated process of privatization and commodification of land in social housing estates targeted by the French urban renewal program. It raises the tangible question of the production of urban rents in former devalued and poor urban areas, within two different property market contexts. This paper suggests that the French urban renewal program is an active commodification and marketization policy, led by national and local governments, on public land which was formerly assigned to non-market-oriented forms of management. Even in a slack housing market context, public authorities endeavour to stimulate private property investment and to create urban rents through urban renewal projects.

The argument is based on provisional results from my PhD work and on material collected since my master's thesis. I will draw on semi-structured interviews (8 for Alfortville, 20 for Saint-Etienne) conducted between April 2021 and March 2024 with people involved in the design and implementation of urban renewal projects in the two areas under study. I principally met local government officers of different municipality departments, civil servants of the national state and of the urban renewal state agency, members of social landlords' staff and elective representants. As I sought to understand how urban redevelopment projects had been designed and developed starting from the late 1990s, I interviewed both people in activity and retired persons. Since I study processes which date back to more than 20 years ago, it was necessary to contrast the output of the interviews with written documents, which I collected in part during the interviews and mostly through an archive research. I gathered a vast range of documents, among which planning documents, project design studies, internal administrative memos, and meeting reports.

4 Alfortville and the Strength of the Market: Housing Diversification of a Social Housing Complex and Production of Urban Rents in the Near Suburbs of Paris

Located around ten kilometres from Paris, Alfortville is connected to the mass transit system and easily reachable from the city centre. The Chantereine district is located at the southern end of the municipality (Figure 1), in a working-class residential area. Chantereine consists of a complex of seven tower blocks[2] containing 1,250 housing units built between 1970 and 1973. This social housing estate was constructed on municipally owned land, provided to the local social landlord through a long-term lease. This area has experienced a process of deterioration and devaluation leading it to be perceived as the "stigmatised district of Alfortville[3]", characterized by very low rents and hosting a disadvantaged population. Since 2009, Chantereine has been undergoing urban renewal initiatives, as part of the National Programme of Urban Renewal (PNRU) and the New National Programme of Urban Renewal (NPNRU) since 2014. Following the national guidelines of urban renewal, the municipality of Alfortville and the other local stakeholders have opted for a massive urban change, as the project involves

[2] There were more exactly six tower blocks and one "*barre*", that is a long horizontal building.
[3] Interview with an ex-local government officer of the municipality of Alfortville, June 2021.

extensive demolitions: at the end of the two urban renewal programmes, upon completion of the NPNRU, 72 percent of the neighbourhood's initial housing units will have been demolished. On the plots freed up by demolition, a new housing supply is constructed, providing different residential tenures. New social housing units (271 homes under the PNRU) built by the local social landlord contribute to renew and diversify the social housing supply in the neighbourhood. In compliance with the ANRU principles of housing diversification, private housing is also incorporated in the area: as part of the first program, 174 market-rate housing units sold mostly to homebuyers have been delivered in 2016 and 2017 by private developers that operate at national scale. In addition, 31 "affordable" housing units[4] have been produced by the local social landlord and sold below market rates. This housing construction programme has been elaborated by the municipality, which is designated as the project leader within the ANRU doctrine, and by a quasi-public development corporation, named Grand Paris Aménagement, which has been chosen by the municipality to oversee urban renewal operations. Even though urban renewal projects aim at fostering private development in social housing complexes, the intervention of real estate companies often unfold under a strong public and quasi-public control (Dormois et al. 2005).

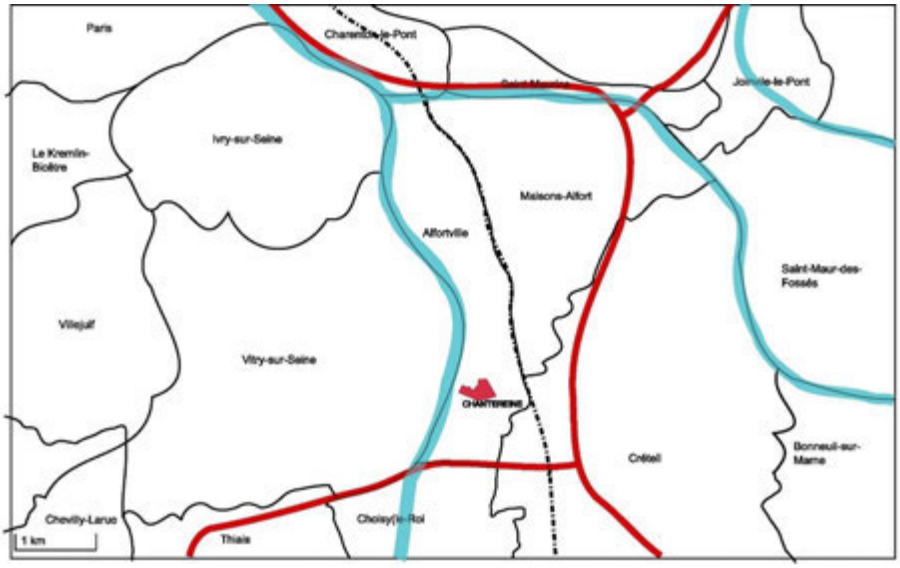

Figure 1. Location map of Chantereine in Alfortville (Pauline Gali, 2023)

Contrary to what has been observed in other urban renewal projects characterized with a lack of private initiative and a weak attractiveness (Bonneville 2005; Saint-Macary 2011), attracting private operators in Chantereine seems to have been less difficult than in many vast social housing estates. Due to the increasing tightness of the local real estate market, the municipality, assisted by the quasi-public development corporation, Grand Paris Aménagement, "had more to select developers than to seek after them[5]". The attractiveness of Alfortville and Chantereine

[4] I refer to housing units in programmes of "*accession sociale à la propriété*" developed by a social landlord.
[5] Interview with an ex-local government officer of the municipality of Alfortville, June 2021.

for real estate development put the municipality in a relative position of strength: an ex-member of the municipal staff considers that the municipal authority, in its relationship to property developers, was like an "oil magnate[6]". On the one hand, this favourable position enabled the municipality and Grand Paris Aménagement to control developers' operations and to impose them many demands on the characteristics of the new constructions. On the other hand, the construction of private housing in Chantereine is far from being the result of a spontaneous influx of private capital into the neighbourhood: it is the fruit of a national policy, funded by the ANRU, and of strategies implemented by a local government to secure developers' operations and "promote private capital investment by creating conditions for its profitability" (Faudry-Brenac and Moreau 1973). The existence of public investment and strategies aimed at attracting and securing private development, expected to come over a second phase of the project, has been highlighted in many urban renewal areas, and more broadly within redevelopment operations, in France (Arab and Miot 2021) and in other countries characterized by some forms of neoliberalization of urban development (Weber 2002; Bernt et al. 2017; Robinson and Attuyer 2021).

From the case of urban renewal in France, I propose to understand the public policies aiming at guaranteeing the profitability of private development operations as practices that organize the production of urban rents. Urban renewal integrates to property market neighbourhoods which were not part of valorisation processes and in which land had no exchange value. By the progressive construction of exchanges values through the different steps of commodification implied by the urban renewal process, several waves of urban rents can be produced. Public action is likely to influence indeed the possibility of urban rents' formation, but also their level and their repartition among the urban renewal projects' stakeholders. A concept of the French Marxist urban sociologist Jean Lojkine can be used to describe and analyse this process: Jean Lojkine created the idea of "*rentes en cascade*" (1971), that is "successive rents", to describe the urbanisation of lands during the post-war massive construction period and the building of the *grands ensembles.* On the basis of the Chantereine project, it is possible to establish that urban renewal produces "successive rents" through different processes of valorisation of capital.

Firstly, demolition encouraged by the ANRU and executed by local stakeholders removes the obstacle to the geographical expansion of capital that constituted high-rise social housing residential areas. These public and quasi-public owned land generated, for the reasons described above, a degraded rental income, which was appropriated by a local social landlord (stage 1, Figure 2). Some of the land freed up by demolition is dedicated to the construction of a new market-rate housing supply for homeownership. At this step of the process, the plot of land gets both commodified and privatized, and thus integrated in market exchanges and circulations (stage 2). The municipality or the public development corporation, which acquires the land from social landlords at a price set by the ANRU (30 euros/sqm)[7], sells the land to a private property developer. This sell of former publicly owned land is likely to generate a land rent appropriable by the municipality. The level of this rent depends on the strategies implemented by the local government, which is led to reflect both on the future value the land should have (Weber 2021) and on the room for manoeuvre it should keep to control the housing supply's characteristics and the future population to whom the homes will be sold. The municipality may choose to give a high price to its land and to set a value close to market rates, so as to receive a higher rent. In

[6] *Ibid.*

[7] Or for free, in the case of Alfortville, as the land belonged to the municipality and was provided to the social landlord by an emphyteutic lease.

Alfortville, the municipality, assisted by Grand Paris Aménagement, set a quite high price for the plots sold to private developers for an urban renewal project: 560 euro per square meter of completed floor area, which is 30 percent higher than the price planned at the beginning of the project in 2011 (430 euro per square meter)[8]. However, the municipality chose not to set the land price at the highest market rates, in order to give itself more negotiating leverage with developers and to impose more easily its requirements on the private housing future features, price and inhabitants.

The third stage of the process of commodification of land freed up by demolition lies in the sale of housing units by the developer through which it realizes and appropriates a portion of the land rent created by the production of the housing units. The requirements defended by the municipality regarding the selling prices and characteristics of the housing units tend to lower the rent captured by developers, by limiting the profits from the sale of housing units and potentially increasing their production costs. The housing estates built in Chantereine were sold at prices on average 30 percent lower than those observed for new housing units in the rest of the municipality[9], which goes well beyond the expected effect of a reduced VAT rate (5.5% instead of the normal 20%[10]) applied, at a national scale, to housing units built in urban renewal projects. Furthermore, the municipality of Alfortville imposed quality criteria for every housing unit and favoured the production of family apartments by asking operators to include more two and three-bedroom units in their programs. Implemented thanks to diverse planning documents, more informal instruments and direct negotiation with developers, this public control on developers aimed to guarantee an adaptation of the new private housing supply to the population the municipality is willing to attract in Chantereine through the urban renewal project.

Other dimensions of local and national public action rather favour and tend to increase the urban rent appropriated by developers. First, the subsidization of demolitions and development costs by the ANRU allows developers to acquire plots on which they can operate without incurring additional expenses. Second, the Alfortville municipality has granted several adaptations of the urban project to limit the risks borne by private capitals. In anticipations of the developers' preferences, the local government, and Grand Paris Aménagement reorganized the overall plan of the project, relocating the plots dedicated to private housing to the area that benefited first from urban interventions. The construction of new social housing and the creation of a vast public space were intended for forming a "new screen[11]" to facilitate the arrival of private operators, which often only intervene in the later stages of urban renewal projects. At developers' request, the municipality also allowed a higher construction density: market-rate housing residences (as some social housing ones) reach significant heights (up to eight floors). This high density contributes to the profitability of private housing programmes, which have already benefited, as seen before, from land selling prices that were not totally set at market rates.

[9] 3700 € per square meter on average for the two market-rate property development programmes of Chantereine, instead of 5200 €/sq on average in 2016-2017 in Alfortville.

[10] Created by a law in 2006, this tax benefit applies to most of housing units built in urban renewal districts, bought for homeownership and under certain income conditions.

[11] Interview with an ex-local government officer of the municipality of Alfortville, June 2021.

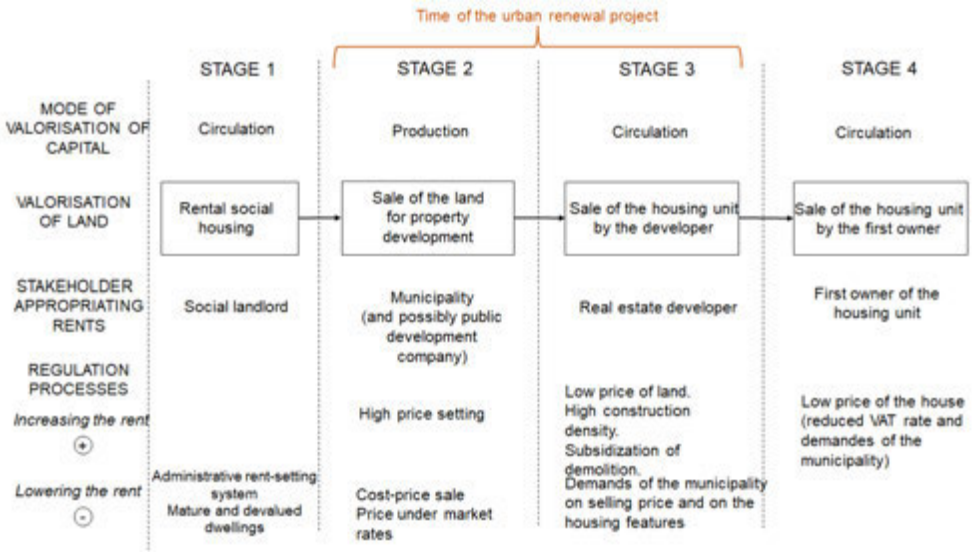

Figure 2.The "successive rents" model based on the urban renewal project of Alfortville (Pauline Gali, 2024).

Finally, the resale of the housing unit by the first buyer appears as the fourth moment in the formation of an urban rent. In the case of Alfortville, thanks to the local government strategies to produce "affordable" housing and to the state subsidization of urban renewal, the first purchaser of the apartment bought it at a low initial price, quite inferior at market rates. If the first buyer, in the second-hand housing market, adjusts the selling price of his home to market rates, the difference between the "affordable" initial price and the market value corresponds to a rent appropriated by the first owner of the apartment. As a consequence, public action in favour of the production of affordable housing in urban renewal projects results in the privatization of a rent by a few households. In Alfortville, it is noted that for housing units built by developers, resale prices are on average 33 percent higher than the purchase price.

Urban renewal therefore organizes the production of "successive rents" through the valorisation of an urban space which was not integrated to market-led urban development dynamics. Public action, by the state and by local governments, influences not only the conditions that enable the formation of rent but also the extent of the urban rent and how it is distributed. These rents are mostly appropriated by private actors, notably by the developers and the first buyer, although the municipality may also benefit from part of the land rent for its fiscal resources. This pattern (Figure 2), based on the Alfortville's case, is likely to apply to metropolitan tight and highly valued markets. Nevertheless, in the words of Christian Topalov, the State enables and promotes urban rents but does not create them directly (Topalov 1984:199; Périlleux 2023:67). It raises the question of the effectiveness of public action in terms of rent production within large public housing estates undergoing urban renewal located in slack and less valued market contexts.

5 The Southeastern Districts (*Quartiers Sud-Est*) of Saint-Etienne, the Commodification without the Rent? Privatization of a Social Housing Complex within a Weak Property Market

The Southeastern Districts of Saint-Etienne embody the reality of an urban renewal project conducted in a context of a weak property market, in a city that has undergone urban shrinkage for many years (Cunningham-Sabot and Roth 2013). Local actors describe a city where "there is no market[12]" for new private housing and where "land rent is negative[13]". Attracting developers to Saint-Etienne is no easy task, even in some central neighbourhoods of the city, some of which are included in the PNRU and NPNRU. In the peripheral social housing estates, such as the Southeastern Districts, according to local public actors, the task is even more challenging due to the lack of residential attractiveness, both for inhabitants and developers. In terms of land uses, these areas remain specialized in accommodating modest households within vast social housing complexes, partly renewed as part of the urban renewal programmes. Although social mixing was a principle promoted by the ANRU, it has never been the central focus of the urban renewal project in the Southeastern Districts. Housing diversification was considered as a way to enable some of the neighbourhood's inhabitants to become property owners where they already lived. In that respect, the aim was also to build a new housing supply adapted to families with children who tend to leave the city centre for its suburban outskirts, an objective also promoted across Saint-Etienne as a whole (Morel Journel and Sala Pala 2011; Miot 2012). Finally, housing diversification was also intended to contribute to urban change in vast social housing complexes that have been largely demolished, in a logic of reducing the social housing stock subject to high vacancy rates and de-densifying the neighbourhood.

Composed of five sectors built successively between 1953 and 1970, the Southeast Districts initially included over 4,500 housing units, of which 689 were demolished between 1989 and 2000 and approximately 700 as part of the PNRU. In the initial urban project, established in the mid-2000s, 226 new housing units were to be built, including 65 market-rate housing units that have never been constructed[14]. Among this ambitious construction programme, only operation of housing diversification has been concretely planned: the local social landlord, with the support of the municipality, attempted between 2009 and 2012 to develop affordable housing for sale, by the means of an operation of 25 units as part of a mixed-tenure estate[15]. After two failed attempts to launch the operation, because of a lack of potential clients, the "Sisley" residence was eventually entirely developed as social housing by the local social landlord. Local actors first attribute this commercial failure to the narrowness of the local housing market, which makes very delicate to complete an operation of 25 apartments led with quasi-public capital and to find households interested to buy flats sold at 1940 euro per square meter[16], in a neighbourhood considered though as not attractive (figure 3). The local social landlord has taken a risk and the responsibility for the initiative of a first housing diversification operation in the neighbourhood and has been confronted with the difficulties of Saint-Etienne's housing market, in which the production of urban rents is not so easy to engage. The municipality and the social landlord learnt lessons from this failed experience, which encouraged them to pay a particular attention to the selling price of the homes, to their architectural form, which cannot be as dense as the "Sisley" building was, and at the timing in which the operation is implemented: the "Sisley" programme has been planned at a relatively early stage of the urban

project, even before the demolition of a large high-rise block nearby. Nevertheless, the municipality experienced another setback on a piece of land also located in the central part of the urban renewal project and of the neighbourhood: on this plot, it planned to develop a mixed-use project including shops and housing. After having failed to convince a developer to build a housing programme on this site, the municipality eventually accepted the construction of a small shopping area, without residential units on the upper floors.

Figure 3: Sales brochure for the "Sisley" Programme of the local social landlord, attached to a letter addressed by the Director of the social landlord to the Mayor of Saint-Etienne, December 2010 (Municipal Archive of Saint-Etienne (6985 W 6).

Despite the injunction for housing diversification promoted by the ANRU and all the efforts of local government to establish favourable conditions for private residential investment, there is no guarantee to realize the construction of market-rate housing and thus to set off the production of urban rents. If private initiative does not follow public investment strategies and does not take over from them, the formation of rents, although theoretically enabled by urban renewal,

remains a potentiality. In Saint-Étienne, this is even a very uncertain prospect: in a context of overall devaluation of the local housing market, characterized by significant vacancy rates and an overabundant supply of older housing units, it is not certain that there is a rent gap to fill between the peripheral social housing neighbourhoods and the rest of the urban space. At the scale of Saint-Étienne, property market does not lead to valuation differentials significant enough for a large social housing neighbourhood to offer private developers prospects for creating and appropriating any land rent.

Nonetheless, the municipality of Saint-Etienne attempts, by leveraging small publicly owned land plots on the outskirts of the neighbourhood, to inject a market dynamic into it by adopting a role of "market leader[17]." Following a call for projects, the municipality sold a 5,300 m² parcel where a former school was located to a local architect, Julien Rivat, for 150,000 euros[18]. This sale allowed for the construction of 13 houses, benefiting from the Passivhaus environmental label. These homes, each around 100 square meters, have been sold within two months for around 1,950 euro per square meter excluding taxes, a price set in consultation with the municipality. Another disused school, also on the outskirts of the urban renewal perimeter, was sold in 2022 for 600,000 euros to a local developer to create a student residence with 201 studios sold separately[19]. A call for proposals had been organized to attract private real estate operators' attention after an initial failed attempt to implement a building programme with a property developer in 2012.

Despite the setbacks encountered on the most central parcels of the urban renewal project, the municipality manages, on the outskirts rather than in heart of the Southeastern Districts, to anchor the neighbourhood to housing markets and to property-led development by betting on specific real estate products. Despite the weakness of the housing market in Saint-Etienne, the municipality tries to arouse private initiatives by privatizing publicly owned land. Furthermore, in the Southeastern Districts, the choice of the municipality to develop economic activities on some pieces of land freed up by demolitions deploy commodification logics even where housing diversification was deemed impossible or not desirable. Thus, even when market context makes uncertain or difficult the prospect of “successive rents” within the field of property development, the aim of normalising, from all points of view, large social housing estates keeps driving publicly led processes of privatization and commodification of land in these neighbourhoods. Urban renewal projects are consequently part of the geographical extension of the capital and of market-oriented land uses, with the support of local and national governments.

6 Conclusion

This paper offered an analysis of French urban renewal projects drawing on an urban political economy framework. It focused on the formation of land rents in the field of property development in large social housing estates. Urban renewal appears as a policy paving the way to produce urban rents by promoting "higher" land uses in social housing complexes which were characterized by a public or quasi-public land ownership and by a non-market-oriented management. Public authorities, whether the central state through an Agency or local governments, play a major role in creating the conditions for the formation of such rents by seeking to ensure the profitability of real estate development operations and minimizing associated risks. However, the comparison drawn between the urban renewal projects of

Alfortville and Saint-Etienne underlines that public action on its own cannot directly trigger the formation of urban rents: as C. Topalov wrote, "the State does not create rent, it is construction that will enable the effective realization of the rents potentially inscribed in the urban plan" (Topalov 1984:199).

Public-private dialogue in the cultural reuse of historical and architectural heritage: the example of the Carmine Monastery in Italy

Emanuele Garda
Affiliation: University of Bergamo
Email: emanuele.garda@unibg.it

Marta Rodeschini
Affiliation: University of Bergamo
Email: marta.rodeschini@unibg.it

Abstract

The paper analyses the restoration process of the former Monastero del Carmine, a complex structure of historical value located in the city of Bergamo (Italy). Built after the 14th century, the Monastery experienced a long period of abandonment from the 18th century until the second half of the 20th century when the property was transferred to the Municipality. In the gradual recovery, the theatre company Teatro Tascabile di Bergamo (TTB) played a significant role. Important for the reuse process was the Special Public Private Partnership activated between the TTB and the Municipality, thanks to which a complex process of material and immaterial regeneration began. The paper presents a public heritage regeneration process highlighting the role of the actors involved and the technical-administrative tool adopted.

Introduction

The unused building heritage, whether privately or publicly owned, represents a significant presence in the Italian territory (Garda, 2018). To define appropriate strategies and actions for reuse, it is necessary to consider both its quantitative conditions and the different approaches.
In Italy, private buildings are divided into: 50% second homes/vacation homes, 10% dwellings occupied by non-residents or rented on the "informal market," and approximately 40% of homes are completely unused (Gentili and Hoekstra, 2018). Abandoned private buildings, which make up 30% of the total heritage, amount to 10 million properties (Istat, 2019). Various approaches can be recognized concerning reuse methods: (i) coercive by the public authority; (ii) enabling to promote the reuse of properties; (iii) incentivizing, particularly at the economic level (Moroni, 2020).
Conversely, public buildings in Italy amount to more than one million two hundred thousand units (MEF, 2021). About 70% (over 800 thousand buildings) are owned by local administrations (municipalities), corresponding to 82% of the total surface area. The rest is owned by central state administrations or other central public entities. A significant percentage, around 7%, of these public buildings is currently unused. The value of unused public buildings is estimated to be 13 billion euros (MEF, 2021)[1].

[1] The value of unused public assets directly managed by administrations is estimated at approximately 66 billion euros, divided as follows: 14 billion euros for “institutional” properties

There are three ways through which a public building can be recovered: (i) through sale by the owning institution; (ii) by transformation and direct use for new public needs; (iii) by transferring only the management to other entities for public or collective interest purposes (Moroni, 2020). For these reasons, the enhancement of public real estate assets has been a significant issue in the policies of central and local administrations for years (Mangialardo, 2017).
To the public-private dichotomy, Nobel Prize-winning economist Elinor Ostrom adds the "third way": common goods made by communities. That is, a place that continues to exist and function because there is a community that takes care of it and, in this sense, regenerates if supported by the self-organized community, allowing collective benefits and fostering cooperation (Ostrom, 1990).
In the early 1990s, within the context of feminist studies, American philosopher Joan Tronto and activist Berenice Fisher developed the "care theory", defining it as:

> "a species activity that includes everything we do to maintain, continue, and repair our 'world' so that we can live in it as well as possible. That world includes our bodies, ourselves, and our environment, all of which we seek to interweave in a complex, life-sustaining web" (Tronto, Fisher, 1990, p. 40)[2].

This essay aims to delve into a specific process of reusing an architectural complex of public ownership located in an Italian city (Bergamo), where the municipal authority has entrusted the management of this "common good" to a local association dedicated to promoting cultural functions. The contribution, in particular, not only presents the complex history of the site (Monastero del Carmine) and the community of managers/users (Teatro Tascabile di Bergamo) but also outlines the initial results of an ongoing research project on the technical and managerial tools used in the progressive regeneration process of this significant entity.

The urban context

The paper addresses the case of the Monastero del Carmine located in the Municipality of Bergamo, a medium-sized city in the Lombardy Region[3] with more than 120,000 inhabitants and the capital of the province of the same name, which has more than 1.1 million residents.
Bergamo is situated and developed on a small isolated hill system (up to 590 meters above sea level) at the foothills of the valleys and overlooking the plain. From its origins, the city of Bergamo has been connected to the flatlands through natural corridors that mediate the transit

leased to private individuals for a fee; 7.6 billion euros for "residential and commercial" properties – excluding "social residential" – leased to private individuals for a fee; 13 billion euros for "unused" properties; 5.4 billion euros for "institutional" properties given to private individuals free of charge and 1.2 billion euros for "residential and commercial" properties; 22.5 billion euros for "residential and commercial" properties leased to private individuals for social purposes.

[2] From this perspective, the theory of care assumes a political and moral significance related to the public sphere. In Tronto's interpretation, care is articulated into four analytically distinct but interconnected phases: (i) caring about; (ii) taking care of; (iii) caregiving; (iv) care receiving (Tronto, 1993).

[3] Region Lombardy is the most populous Italian region, with nearly 10 million inhabitants. The region is divided into 1504 municipalities grouped into 12 provinces with Milan as the capital. It is located in the center of northern Italy, at the foot of the Alps and in the middle of the Po Valley, and is situated on the main routes connecting the Mediterranean area and central Europe. Its surface area covers 23,860 square kilometers and is divided almost equally between the plains (accounting for about 47 percent of the territory) and the mountainous areas (accounting for 41 percent). The remaining 12 percent of the region is hilly.

between the mountain and the plain, along which historical settlements have progressively developed. It is precisely in close dependence on its morphological and conformational peculiarities that the city developed its spatial structure; it guided its expansion by distributing into distinct parts and planes: the main city in an elevated position on the mountain, and the hamlets, stretched outward, some of which are larger than the city itself (Pagani, 2000). The territory and the city of Bergamo have progressively shaped themselves over centuries, leaving multiple marks on its current urban structure.

Therefore, the territorial system of Bergamo shows a tension between urbanization and residual rural spaces, in line with urban changes recognizable on a regional scale in Lombardy and within the broader Po Valley. The Municipality of Bergamo today consists of 25 neighborhoods of varying sizes and functions. The neighborhood recognized as the core with high historical, cultural, and tourist value is Città Alta.

The "*Map of the City and Outer Hamlets of Bergamo"* drawn by Giuseppe Manzini in 1816 constitutes a fundamental milestone in the history of Bergamo cartography, being among the first to result from a territorial survey, and clearly shows the palm-like structure of the city.

Fig. 1. "Map of the City and Outer Hamlets of Bergamo" by Giuseppe Manzini, 1816, consulted at the Angelo Mai Civic Library in Bergamo. The map is particularly significant as it shows the central role of Città Alta in territorial development.

In fact, the original residential nucleus of Città Alta gradually expanded, reaching the plain below as early as the Roman period. This expansion did not occur in a radial manner but along well-defined paths, outlining a city with a palm-shaped layout, where the palm is formed by the dense core of the city on the hill, and the finger-like extensions of the hamlets descend to the plain, marking the directions towards nearby centers. Over time, there was a progressive consolidation of the Città Bassa, where the "character of the place as a space of different sociality, based on the ephemeral, but also on impromptu presences of services as peripheral as they are complementary to the domestic life of the ancient city" becomes evident (Pizzigoni, 2021).

The twentieth century marks the era of modern urban planning, focusing primarily on urban expansion, the construction of the "new city" on the plain, and the "modernization" of the pre-existing urban layout (Bonfantini, 2008). Specifically, in Città Alta, three plans were implemented: (i) the Rehabilitation Plan (1926-1935) to meet hygiene, building, and road requirements necessary for the modern life of the early twentieth century; (ii) the Conservation Rehabilitation Plan (1975-1980) aimed at the conscious preservation and transmission of the historical heritage; (iii) the Recovery Plan (2005-2015), interpreting the historic center as a realm of multiple interactions and a place meant to play an active and driving role within a complex territorial system.

Today, Città Alta faces issues common to many Italian historic centers:

- It is subjected to massive daily tourism that often does not fully appreciate its cultural richness.
- Most available financial resources seem directed towards mere tourist enhancement rather than cultural-tourist development.
- It risks losing the diverse social strata that constituted its vitality until the 1970s due to tensions between residents and external populations (tourists).
- It exhibits low cultural activism among its citizens.

However, within this territorial context, a diverse network of social, educational, and cultural activities emerges, provided by significant public institutions that coexist and operate by promoting quality and valuable initiatives. In Città Alta, there are: 7 museums, 4 libraries, a botanical garden, numerous schools (including kindergartens, primary, secondary, and a Classical High School), and two campuses of the University of Bergamo.

Also noteworthy is the presence of the Association for Città Alta and the Hills of Bergamo, formed by neighborhood residents, who are committed to promoting an idea of sustainable and active citizenship, responsible tourism that integrates rather than impoverishes the social composition of Città Alta, and ensures the protection of local shops and the availability of permanent cultural services.

Case Study Presentation

The *Monastero del Carmine* (Monastery of Carmine) is located in the heart of the historic center of Bergamo, in the northern part of Città Alta. This architectural complex is deeply involved in the urban development of the city and incorporates a series of architectural elements that have existed for centuries into a unified building.

The earliest records of the Monastero del Carmine date back to the 12th century when the "Humiliated Monks" established a textile workshop there. The Carmelites later took over, giving the complex its name. The monastery saw its peak activity between the late 1400s and early 1500s with the construction of most of the cloister, the refectory, the monks' quarters, and

concluded in the second half of the 1600s with the creation of the stables, the Chapter Hall, and the new library.
It was suppressed in 1797 during the Napoleonic era, followed by a period of decline and degradation. The premises were used as residences and craft workshops.
In 1956, the "parish benefice" of Sant'Agata donated the complex to the Municipality of Bergamo, and a twenty-year period of structural consolidation work began. Although these efforts remedied serious structural issues, often through emergency interventions involving the demolition of vaults and the reconstruction of floors and roofs, they led to the loss of some original architectural features.
During those years, numerous reflections and proposals were made for a new use of the Carmine complex, such as a Museum of Arts and Popular Traditions, a boarding school, or socio-cultural activities. In 1982, part of the complex was occupied by the Mycological Group and the Speleological Group of the “Nottole” (AA.VV., 1982).
Despite numerous proposals, the building remained largely unused for several decades until 1996, when it began to host the Teatro Tascabile of Bergamo. This gave it the identity it has today, enhancing its significant relationships with the life of Città Alta and its social and cultural role.

Fig. 2. The image identifies the former Carmine Monastery complex (white rectangle) within the historic city (source: Google Earth)

History of the TTB
The *Teatro Tascabile of Bergamo* (TTB), founded in 1973 by Renzo Vescovi, has historically been one of the main actors in Bergamo's cultural life and is an internationally recognized theater company. It has operated from the former Monastero del Carmine since 1996, through successive precarious municipal concessions, the latest of which was signed in February 2016.
The presence of the TTB in the former Monastero del Carmine and the prestigious cultural activities it carries out there have not only provided continuous regular maintenance of the property but also ensured its accessibility and public use. This has initiated a process of valorization, creating a vibrant place where significant cultural activities of general interest are carried out. It can be defined as a "cultural asset" not only for its architectural value but also for

the richness of the activities it hosts, implementing actions and strategies to prevent abandonment and loss of its value (SPPP, 2018, p. 3).
In 2012, the Ministry for Cultural Heritage and Activities (Regional Directorate for Cultural and Landscape Heritage of Lombardy), the State Property Agency (Lombardy Branch), and the Municipality of Bergamo signed an Enhancement Agreement (pursuant to art. 112, paragraph 4 of Legislative Decree 22 January 2004, no. 42 and subsequent amendments) for Bergamo - "Compendium of the Former Monastero del Carmine and Former Sant'Agata Prison,"[4] aimed at defining common strategies and objectives for the protection and enhancement of the Carmine/Sant'Agata compendium.
In 2015, the Municipality published a call for the selection of suitable candidates for the enhancement and management of the aforementioned real estate complex. The public procedure did not yield any suitable proposals, despite the TTB already being present at the Monastero del Carmine.
Therefore, the Municipality decided to pursue a different path, shared with all parties involved, by separating the destinies of the two complexes: the former Sant'Agata prison and the former Monastero del Carmine. This was done to create a mix of functions capable of promoting a high-quality project, primarily focused on public/cultural uses and ensuring greater economic sustainability for the entire operation in 2017.

Special Public-Private Partnership

To support this regeneration process, the Municipality of Bergamo promoted the signing of a Memorandum of Understanding aimed at defining the forms of collaboration for the enhancement of the Carmine complex.In it, the importance of the Monastero del Carmine as a place for artistic sharing, for research, training, theatrical production and for the development of various projects and initiatives (seminars, meetings, residency, performances and open rehearsals with national and international groups) is reaffirmed.
In 2016, a national law was passed (Legislative Decree No. 50/2016), which in Article 151, paragraph 3 provided the possibility for the Mibact (Ministry of Cultural Heritage and Activities and Tourism) and local authorities to activate "special forms of partnership with public bodies and entities and with private entities, aimed at enabling the recovery, restoration, programmed maintenance, management, opening to public enjoyment and enhancement of immovable cultural assets, through simplified procedures for identifying the private partner." This article, which is relevant to this regeneration experience, establishes new forms of public-private partnership-named Special Public Private Partnership (SPPP) - that, with greater operational flexibility, aim to enhance the cultural heritage spread across the country.
In 2018, after the discovery of this administrative innovation, the Teatro Tascabile and the Municipality of Bergamo, with the advice of Fondazione Fitzcarraldo, decided to adopt the PSPP for the first time in Italy, putting in place a new model of relationship between public entities, cultural bodies and private entities for the recovery and management of historic properties through specific activities. With the approval of the Special Public-Private Partnership the TTB was given the opportunity to use the Carmine complex for 20 years, renewable for an equal period (SPPP, 2018, p. 33).

[4] Monastery and Carmine are part of the same historic block. St. Agatha's Prison originated from walls dating back to 908. It was then used as a prison in 1802 . The church was divided internally to house the women's wing and offices. The prison function was maintained until 1978. Located in the northwestern part of Bergamo's Upper City, the Former Prison of Sant'Agata consists of three bodies of different widths arranged in a C-shape around the courtyard. It turns out to be articulated in several levels, on which large common spaces or very small, intimate and private rooms are distributed.

The governing, co-designing, and safeguarding body of the Partnership is the Technical Table in which a contact person from the Teatro Tascabile, a contact person from the city administration (manager of Heritage), and a contact person from MIBACT (delegate of the Superintendent of Fine Arts) participate. These are joined by experts and collaborators in relation to the topics of discussion. More generally, the technical table is the forum where choices and direct and indirect results arising from collaboration and opportunities generated in cultural heritage enhancement processes are evaluated.
Although TTB can operate administratively as a private entity, it was decided to adopt an approach comparable to that of a public administration (for example, in the selection of companies involved in construction work).
In June 2019, the firm Artedil spa was selected, and in September 2019 on the occasion of the European Heritage Days promoted in collaboration with the City Administration of Bergamo, the TTB inaugurated the works on the first and second lots (theater hall and chapter hall) and presented the plan for the realization of the third lot, which includes the creation of an "artist guesthouse" also open for hosting tourists.
The overall program (SPPP, 2018, p. 44) envisions the rehabilitation of the Monastero del Carmine in 4 phases linked to as many cultural actions: (i) Renzo Vescovi Theater; (ii) Chapter Hall; (iii) Atelier (artist guesthouse); (iv) Cloister.
The Renzo Vescovi Theater, dedicated to the founder who died in 2005, is the former refectory of the Carmelites: a large room with a rectangular floor plan, on the walls of which, painted in fresco, are twelve roundels depicting the Blessed Virgin of Carmel with Child and the most significant figures of the Carmelite Order. Since 1996 the refectory has been used by TTB for rehearsals, performances and hospitality.
The Foyer-Library, originally the kitchen serving the Monastery refectory, has been used as a space for actors' dressing rooms since 1996. In today's overall reorganization of the space, it has been transformed into the foyer-library: on the one hand the place where spectators wait before entering the auditorium for the performance, and on the other hand, on a special mezzanine, the place for consulting texts belonging to the Eurasian Theatre Library. In fact, all theater-laboratories, like the Teatro Tascabile, build a library fund within their premises, which for TTB is represented by the Eurasian Theatre Library. The Library is now owned by the University and is included in the National Library Service[5].

Materials and Methods

From a methodological point of view, the work is based (i) on an extensive literature review, (ii) on official reports, documents, and national and international press review of project and history of Monastero del Carmine, (iii) on the analysis of the legislative instrument of Special Public-Private Partnership, (iv) on interviews with significant stakeholders.
The first part of the research included the study and analysis of the case from a historical, social and cultural point of view through bibliographic research, consultation of the press review and administrative documents prepared over the years and the numerous experiences involving the monastery. The process of tangible and intangible regeneration was also examined through the projects presented when the SPPP was approved.

[5] The BTE was born from an initial nucleus of volumes that belonged to the leader and founder of the Pocket Theater Renzo Vescovi, to which was added in 2019 the Nicola Savarese fund, a great scholar of performing arts, and in particular of the relationship between Eastern and Western theater. It is currently possible to consult its approximately 4,000 volumes in a mezzanine area of the foyer on which 6 reading stations are set up, suitable for Italian and foreign students and scholars. It is a growing project: in fact, two more important funds are planned to be acquired: the personal library of Eugenio Barba, director of Odin Teatret (DK), and that of Ferdinando Taviani, perhaps the most important theater scholar of his generation.

After taking a detailed picture of the situation, we focused on mapping the stakeholders involved in the regeneration process to conduct semi-structured interviews with them.
Series of semi-structured interviews were conducted with the stakeholders. They were representatives of the institutions and the main actors involved in the practices. The interviews lasted between 30 and 90 min, and focused on the main open themes: the origin of the project and the reason of their involvement, the project timeline, the role the interviewee play in the process of regeneration, the stakeholders with whom the interviewee cooperated, the management of the event, and the results on the territory and on community everyday life.
In order to focus the analysis on the governing instrument of the process - the SPPP - the interview was structured by asking the interviewees what their role was within the life of the Monastero del Carmine before the drafting of the SPPP, during and in the period immediately following and after the first five years of the instrument's implementation.
Also of key importance was the phase of site visits to learn about the Monastery, its spaces and uses.
The stakeholders interviewed were identified by recognizing the responsibilities and expertise they brought to the SPPP project and therefore can be divided based on the role they played in the process. Seven people were interviewed who were crucial to the success of the project and represented the different thematic and technical components.
First of all, TTB members were identified who have been using the Monastery since 1996 and expressed the need to transform it into a welcoming place capable of meeting the needs of a cultural association and supporting the processes of expanding their offerings. In this regard, Alessandro Rigoletti, a TTB member, was interviewed.
As anticipated earlier, from the need to find an agreement between the ownership of the building, the Municipality of Bergamo, and the beneficiaries of it, the TTB, a fruitful relationship of discussion and advice was born with the Municipality Manager Erminia Renata Carbone; with the lawyer Franco Milella, an expert in common goods and consultant to the Fitzcarraldo Foundation, and the TTB.
The foresight and vision of these stakeholders made it possible to find in the special public-private partnership a valuable tool to enable an equal relationship between the owners and usufructuaries of the building that would give the possibility of finding useful funding for a regeneration project. architect Gloria Gusmaroli, who has been working at TTB since 2020 and is in charge of promoting the project and its technical implementation, was then interviewed.
A key role in the development of the project is given by the involvement of the community, not only from an intangible point of view, but also through the possibility of offering economic funding. This is because the design of TTB confronts the issue of the relationship between entrepreneurship and cultural associations. The Special Public-Private Partnership is the means by which to promote the sharing of choices and the simplification of procedures according to a different vision in the management of public assets and resource raising. To sustain the project vision, the municipal administration had to involve its relational capital by activating private entities toward the economic support of planned activities.
The resources on which the project rests come from different forms and sources of funding (fundraising mix). Among the most important are the Art Bonus (in 2014 a tax credit was introduced for liberal cash disbursements in support of culture and entertainment as a support of patronage in favor of cultural heritage) with which TTB activated two funding lines, one related to building interventions and one to cultural activities[6].

[6] The narrative of the first fundraising campaign with Art Bonus, along with the digital and on-site giving back, received the “Special 1st Place Award for Social Campaign” in the “Art Bonus 2021 Competition”

Since 2020 there is an increasingly strong link between the promotional communication strategy and the expected results about the involvement of funders and the economic return of the action taken, generating a sense of place that becomes the glue for a lasting relationship between TTB, economic operators and local associations. Representatives of the latter were considered in the interviews.

Discussion

The analysis conducted on the various sources presented in the previous section, allowed some key themes to emerge regarding: (i) The nature of the instrument adopted (SPPP); (ii) The role given to the temporal dimension; (iii) The characteristics of the place and its architecture; and (iv) The learning/empowerment process by the actors involved.

The first core of reflections includes the type of innovative instrument adopted by the various actors (TTB, Bergamo City Council and Superintendence) to promote the process of recovery and re-functionalization of the spaces of the Monastero del Carmine.

The SPPP turns out to be a flexible tool, which in the concept of "Special" introduced by the national legislation, hides a strong vagueness that should not necessarily be considered as a negative condition. This "ambiguous" nature of it, as claimed by some interviewees, allows its application to different types of objective contexts/conditions that differ in:

1) the architecture of the places of possible application, as the absence of explicit identification by national standards, allows for the possibility of regenerating both spaces with historical value and buildings of more recent construction;the only condition to be met the condition of public property;

2) the "community" of subjects called upon to manage the public good and ensure the maintenance physical structures and at the same time the provision of functions of public and collective interest;

3) The type of activities and functions delivered by the subjects entrusted in the management that may cover different aspects of collective interest are going to decline in a timely manner the broad concept of "culture".

The PSPP tool in the experience of Bergamo and the Monastery del Carmine has been configured as a "stage" capable of stimulating dialogue between subjects very different from each other in terms of objectives, technical-organizational skills and responsibilities towards the regeneration process activated. This open, equal, symmetrical dialogue between a public subject (Municipality of Bergamo) and an associative reality with a strong identity and history (The TTB) , took on a role of exchange and mutual learning. The diversity of the actors involved in the path was gradually accepted, until it became an opportunity for strengthening in the program of objectives and interventions.

The one presented was the first case in Italy of application of the Special Public Private-Partnership, which, for the first time, was able to create a space for reflection and sharing of ideas and planning of a shared project. The drafting of the project document allowed for the sharing of objectives and proposals, as well as the confrontation and discussion of critical and controversial issues (e.g., the management of financial aspects or the need to submit to very binding protection regulations). The SPPP has empowered a private actor to care for a public good of general interest for the entire community, legitimizing an alliance and, most importantly, increasing the credibility of a private entity of a cultural nature vis-à-vis public and funding institutions. This also succeeded in giving value to the entire regeneration process in order to receive funding and expand collaborations with other public and private actors. The instrument therefore, in its flexibility, granted more opportunities, compared to other more traditional instruments, to adapt commitments and projects.

The second aspect repeatedly considered by the interviewees and official documents, which assumed, and was debated at length when the SPPP was drafted, is the temporal aspect. Before

the SPPP, the municipality granted the Monastery space to the TTB with short-term concessions. This condition reduced the ability to plan a program of tangible (e.g., rehabilitation of some spaces) and intangible interventions. The provision of a longer management time makes it possible to think about long-term planning and imagine other related activities.
Adopting a time frame of 20 years, as a result of mediation between TTB, the consultants and the municipality, has made it possible to be able to plan complex actions and at the same time to activate other relevant initiatives: the raising of funding, to participation in calls for funding bodies, to investment on people and so on.
Time is associated, particularly when dealing with cultural associations and public funding, with the theme of uncertainty.
This story of regeneration cannot be separated from the place where it took place. The historical, cultural, and architectural richness of the Monastery allowed for this process, which took advantage of the beauty of this place and changed with the story of the Teatro Tascabile. The typical architectural structure of a Monastery has been adapted to the needs of TTB's theatrical and cultural activities. The constraints of a historic building, in addition to the difficulties, have also offered the possibility, for example by activating specific projects, to experiment with new forms of inhabiting the historic space, generating a vital osmosis between the community that manages it and the functions provided, between the monastery complex and TTB.

Conclusions

The subject of abandoned public heritage is of considerable relevance and great impact in the urban dynamics of Italian cities. On the one hand there are the problems arising from its abandonment and the costs involved in its regeneration; on the other hand having public buildings of inestimable historical and architectural value represents an opportunity for local communities.
The regeneration of public heritage can take place through its disposal, its renovation for other public activities or through a partnership with a private entity that commits itself to its management.
The experience of the Monastero del Carmine in Bergamo was the first Italian case in which the Special Public Private Partnership was adopted, i.e. the municipality and a private association become partners in the management of the property by developing an agreement.
Prior to the introduction of the SPPP in Italy, legislation favoured the use of public assets by incentivising economic and capital profitability and not by increasing cultural and social valorisation. This approach characterised the Italian legislation of the 30 years prior to 2016 and was sometimes unsuccessful. The SPPP changes the idea that a public asset must necessarily be made profitable and invests in co-responsibility between the public and private sectors, fostering a process of contamination and mutual improvement that implies the desire and the need to go beyond one's own competences and to constantly learn new disciplinary and other skills.
For the Teatro tascabile di Bergamo, a private organisation involved in the management of the Monastero del Carmine, doing theatrical work means not only staging performances and activities related to theatrical culture, but also implies engaging in cultural and building development through the care of a place and, together with it, of the community to which it belongs. Thanks to the SPPP, the Monastero del Carmine has taken on a central role in Bergamo's urban context, becoming a point of reference not only for the municipal administration, but for the entire community in terms of cultural and social initiatives.

Track 03: Law

LAW - Planning and legal procedures for land-use and transport policies

Chairs:

- Rachelle Alterman, Technion University, Israel
- Florence Lerique, Université Bordeaux Montaigne
- Tristan Claus, KU Leuven

Keywords: *Spatial planning law, land use; land policy, property rights, housing regulations, development control, participation in planning procedures; governance of spatial planning; land-value capture; frugal use of land resources*

When grounded in laws and regulations, spatial planning intervenes in the allocation and distribution of land and development. It thereby intervenes to a lesser or greater extent in private property rights or market expectations, from regulating what may or may not be built on specific parcels of land down to outright expropriation. Research questions range from procedural-administrative processes, through substantive planning goals and their expression in land use regulation, and all the way into the global environmental arena. Can the laws and institutions that govern planning meet the challenges posed by climate change, sustainability, demographic changes and increasing economic and political uncertainties?

This track aims to provide a platform for sharing research on any topic that connects planning and law with property rights. Examples of topic areas:

Statutory (regulatory) planning systems and instruments: What are the challenges within a given country, or comparatively.

Governance structures and procedures: How does planning law structure the relationships between central governmental control, local government, markets, and non-governmental organisations?

Legitimacy of planning interventions: How does the law frame public participation, stakeholder involvement, lobbyism, and dispute resolution;

Regulatory instruments of spatial planning: How well do instruments work, such as local statutory plans, land use plans, building permits, expropriation, compensation,

regulation of agricultural land, open space and natural resources, heritage-building regulation,

Land value capture through agreements with developers, developer obligations, land readjustment, taxation of land values (betterment tax, etc.), transfer of development rights, expropriation, compensation,

Theory of property rights: How to deal with tensions between public and private rights and responsibilities (i.e. with land for public services, customary collective or private rights).

How can planning law contribute to the environment and climate change challenges: Sobriety (frugal use of land) for the compact city, permeability of the soil, cleaning of contaminated land, etc.?

Contributions may look at the general theory of planning and law or investigate particular issues, focusing either on a particular country or cross-nationally. Since legal and planning systems vary greatly from country to country, authors should make the terms they use as transparent as possible.

Abstract: Development rights transfer and density bonus (TDR&DB)are often vaguely and implicitly used as a financial compensation tool in historic conservation districts regeneration in Shanghai to compensate to achieve a comprehensive cost-benefit balance. However, this is a misinterpretation and deviation of the effect of TDR&DB. This paper takes the 17th and 69th neighborhoods in Hongkou District as an example, explains the constraints on the cost-benefit of the regeneration, analyzes the market mechanism of TDR&DB, and evaluates the economic benefits of TDR&DB in detail with the help of land value allocation rate method and revenue reduction method. The study concludes that: 1) local governments often have the false illusion of FAR when using TDR&DB, they should restrain their urge to increase FAR and restore the basic attributes of public interest orientation of TDR&DB. They should explore the shift from the land expropriation model to the rights conversion model to reduce the cost of urban regeneration; 2) the idea of cost-benefit balance has obscured the essence and value of TDR, the essence of the TDR is to realize the efficient utilization of overall spatial resources through the dynamic adjustment of development rights. This provides a new way for the introduction of this system into our country; 3) market players can obtain more economic benefits by using TDR&DB, and they should make more "special public contributions" for the regional development. It is suggested to introduce the concepts of "incentive coefficient" and "incentive amount" to accurately evaluate the "special public contributions"; 4) The TDR&DB should take into account their external effects on the surrounding areas, and further research should be conducted to quantify and evaluate the external effects of the receiving lots, so as to promote the practical application of TDR&DB. The above conclusions can provide useful references for constructing a sustainable urban regeneration mechanism in China.

Key Words： Development rights transfer and density bonus (TDR&DB)，Evaluation of Economic Benefits, Economic calculations, historic conservation districts, Market mechanism, Urban regeneration

Introduction

Shanghai's "Historical Conservation Block" refers to historical block with distinctive historical architectural features outside designated historical preservation zones. These areas possess a significant number of historically valuable buildings or exhibit unique spatial layouts and streetscapes that merit preservation (Chen, 2018) . In Shanghai, there are a total of 250 Historical Conservation Block, covering over 17 square kilometers. Compared to traditional designated historical preservation zones, these blocks may not individually boast prominent historical buildings or architectural significance. However, collectively, they form the foundational fabric of Shanghai's urban landscape. These neighborhoods play a vital role in Shanghai's historical preservation framework and contribute significantly to maintaining the city's distinctive character (Chen et al.,2021). Many of the neighborhood conservation areas are located within the scope of old renovation district in the central urban areas. Within these neighborhoods, residents often face poor building safety, sanitation, and living conditions. There is a strong desire among residents for urban regeneration and improvement of public facilities. However, the regeneration of these neighborhoods faces increasing challenges, such as balancing land acquisition funds, addressing prominent conflicts between residents' needs and heritage conservation. These issues have gradually become tough "nuts to crack" in the urban regeneration process.

In the regeneration of Shanghai's Historical Conservation Block, an innovative approach is adopted, known as "pairing and combining," to integrate the conservation areas with other plots for development. For instance, in the combined development of Blocks 17 and 69, Block 17 is designated as a Historical Conservation Block, whereas Block 69 is situated within a specific urban policy zone.[①]In the regeneration process, there is often a vaguely and dimly application of TDR&DB to obtain more development rights, aiming to achieve a balanced cost-benefit ratio. Currently, this practice typically treats TDR&DB as economic compensation tools, lacking theoretical analysis of their market mechanisms, economic benefits, and calculation methods. This approach easily leads to misinterpretation and deviation regarding the role and effectiveness of TDR&DB.

1. Constraints and Bottlenecks in Shanghai's Historical Conservation Block

1.1 Conservation-oriented regeneration breaks the previous cost-benefit balance

Cost-benefit equilibrium in regeneration refers to the scenario where the capital investment in a regeneration project is either less than or equal to the income generated by the project. Unlike typical renovations of old districts, Historical Conservation Block focus on retaining or protecting rather than wholesale demolition which is characteristic of traditional regeneration. The "primarily retention-based" approach to Historical Conservation Block regeneration disrupts the existing balance between input and output of the redevelopment sites, thereby increasing the complexity of regeneration efforts.

Currently, many of the remaining redevelopment sites in Shanghai's central urban areas involve heritage conservation. Although these sites are often well-located, the need for heritage conservation typically results in lower FAR after regeneration compared to sites developed under normal circumstances. As a result, the land value of these sites cannot be fully realized. Meanwhile, as property prices rise year by year, the demolition costs for original residents also gradually increase. The profits obtained from land redevelopment are increasingly unable to cover the costs of resettling residents and the initial development expenses. This situation has led to a significant imbalance between costs and benefits in the regeneration of Historical Conservation Block (Zhu & Gao, 2018) [1].

1.2 The previous land use control system makes it difficult to readjust the spatial benefits

Currently, China's existing land use control system is a product of the incremental era. The logic of " rent-investing " under this system often leads it to become a fiscal tool rather than adhering to its original policy intentions when addressing issues related to existing urban regeneration (Zhou, 2022) .In fact, while the current land use control

system can prevent the occurrence of negative externalities, it fails to establish a market price for externalities. As a result, it cannot ensure the Pareto optimality in urban regeneration (Wolfram, 1981).

Moreover, it can lead to original residents or developers exploiting "rent gap" through land use changes, exacerbating issues of rent-seeking, gentrification, and the paradox of anti-commons, thus creating social fairness and efficiency imbalances. Original residents and developers can gain significant profits in primary land markets by claiming substantial compensation for land acquisition without bearing the costs of public services. As operational expenses for public services increase post-regeneration, the government's fiscal deficit will further worsen (Zhao and Song, 2021). Simultaneously, the post-regeneration increase in land and housing rents inevitably attracts higher-income individuals, displacing the original low-income residents and leading to urban gentrification.

1.3 The previous policies of TDR&DB cannot make up for the huge cost gap

Currently, the policies governing the regeneration of Shanghai's Historical Conservation Block primarily include the "Shanghai Urban Regeneration Regulations" (2021 version), the "Shanghai Urban Regeneration Planning Land Implementation Regulations" (2017 version), the "Opinions on Deepening Urban Organic Regeneration to Promote Historical Heritage Conservation" (2017 version), the "Implementation Regulations on Planning Land Management to Implement the Opinions on Deepening Urban Organic Regeneration to Promote Historical Heritage Conservation" (2021 version), as well as other relevant preferential policies related to urban redevelopment. These existing policies have to some extent stimulated developers' enthusiasm to participate in urban regeneration. However, their measures for TDR&DB still cannot fully bridge the substantial cost gap in the regeneration of Historical Conservation Block from the government's financial perspective. The currently available transferable and bonus FAR is too small, and the scenarios where TDR&DB can be applied are too limited, making it difficult to address the significant funding shortfall arising from the complex regeneration process.

2. Analysis of Market Mechanisms for Development Rights Transfer and Density Bonus

Transferable Development Rights (TDR) refers to the process of selling or transferring the unused development rights from a "sending plot" to a "receiving plot" through market transactions or government intervention. Typically, the unused development rights transfer among multiple plots in an "equal quantities " manner. Unused development rights refer to the difference between the maximum planned FAR and the actual utilized FAR of a plot.

Density Bonus (DB), on the other hand, involve converting public spaces or facilities into FAR as a reward to market developers. It is a form of compensation from the government to market developers for providing public services. DB are usually provided in the form of "equivalent conversion," where new development rights are rewarded to one or multiple sites (Deng, et al., 2020; Zhan, 2019).

So, how do TDR&DB contribute to the overall social benefits? This paper constructs a marginal benefit function for TDR&DB based on relevant principles of economics, and conducts an in-depth analysis of their market mechanisms. For the sake of convenience in the study, the following basic conditions are set: 1) Assume there are two plots of land with planned FAR of 6.0; 2) Assume the two plots of land have equal areas, and there are no transaction costs; 3) The current FAR of each plot of land have already reached the planned FAR.

2.1 Analysis of the market mechanism of TDR

Assuming plot G is an old community already planned for high-rise residential use, with a planned FAR of 6.0. However, during the development process, it is discovered that there are buildings of historical heritage value that need to be preserved. Therefore, the planned floor area ratio remains unchanged at the current 1.5FAR. In other words, plot G has "unused development rights" corresponding to a FAR of 4.5. Plot H, on the other hand, is for the regeneration of commercial office use in the central urban area, and it has already reached its planned FAR 6.0. Since the utility of historical heritage does not increase with the FAR, the marginal benefit curve of plot G is steeper compared to plot H. This is illustrated in Fig 1.

Now, considering the scenario of TDR, denoting the marginal benefit of plot G as R_G and the marginal benefit of plot H as R_H. When the values of their marginal benefits are

balanced at R_G', R_H', the development rights transfer is completed. At this point, plot G transfers from R_G (1.5 FAR) to R_H' (3.5 FAR), and plot H transfers from R_H (6.0 FAR) to R_H' (8.5 FAR). This leads to an increase in overall social benefits, reaching the optimal maximum value. However, for the purpose of historical heritage preservation, there is a need to limit the development of plot G, maintaining its FAR at 1.5 (as shown by positions R_G and R_G' in the Fig.1). This restriction prevents the transfer of development rights between F_G' and F_H', meaning that the land value income corresponding to $R_G'R_H'N_G'$ cannot be captured, resulting in a "deadweight loss" of social benefits, represented by the black shaded area in Fig 1. Due to the existence of this "deadweight loss," overall social benefits cannot be maximized.

It is important to note that this scenario of TDR may bring about significant negative externalities for the receiving plots. For example, there could be increased pressure on infrastructure in central areas and damage to urban landscape.

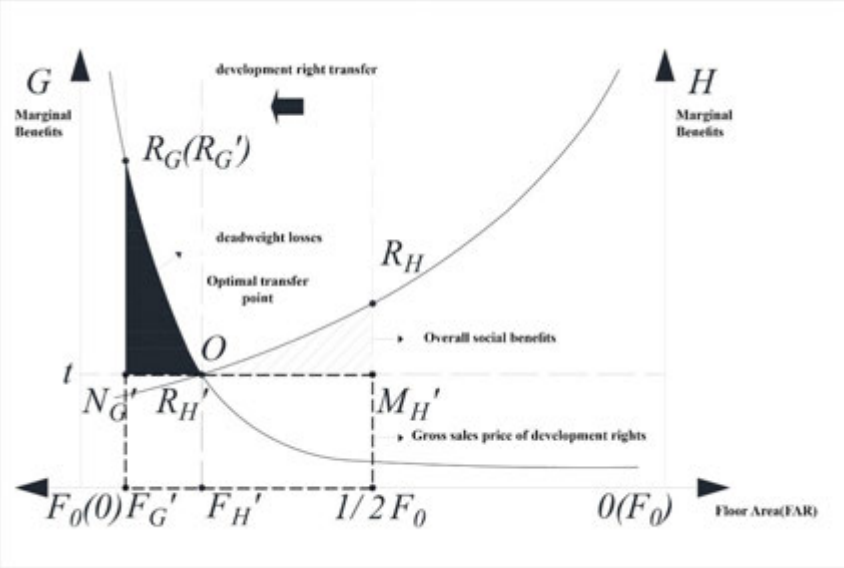

Fig 1 Analysis of the market mechanism of TDR
(Source: by the author)

2.2 Analysis of market mechanisms for DB

Consider a different scenario where plot I is designated for the preservation of historical buildings, with a planned FAR equal to the current FAR (1.5), and plot J is for

commercial office use in the central urban area, having already reached its planned FAR (6.0). Unlike the previous scenario, plot I cannot be developed due to preservation restrictions and thus does not have any "unused development rights." Plot J has already reached its planned FAR, so there is no TDR in this sense.

However, to maintain the historical buildings on plot I, plot J can increase its FAR through DB, thereby obtaining land value income corresponding to "$R_HR_H'F_H'1/2F_0$" in the shaded area of Fig 2. The process of DB not only realizes the public interest within plot I but also enhances the land value income of plot J itself. It is important to note that in reality, the value of DB cannot be infinitely increased considering the impact of development on transportation and municipal infrastructure capacity.

In this scenario, the land value income obtained by plot J through DB should be equal to the cost required for maintaining the historical buildings on plot I. The analysis of this scenario also applies to DB between restricted plots and developable plots, such as those designated for green space protection, ecological conservation, farmland protection. Additionally, DB bring about numerous positive and negative spatial externalities, which require more deeper research.

For instance, protected plots contribute to the enhancement of regional historical value and tourism attractiveness, leading to positive externalities. Conversely, receiving plots experiencing high-intensity development may cause negative externalities such as reduced sunlight exposure for neighboring high-rise buildings, excessive burden on infrastructure, and damage to urban landscape.

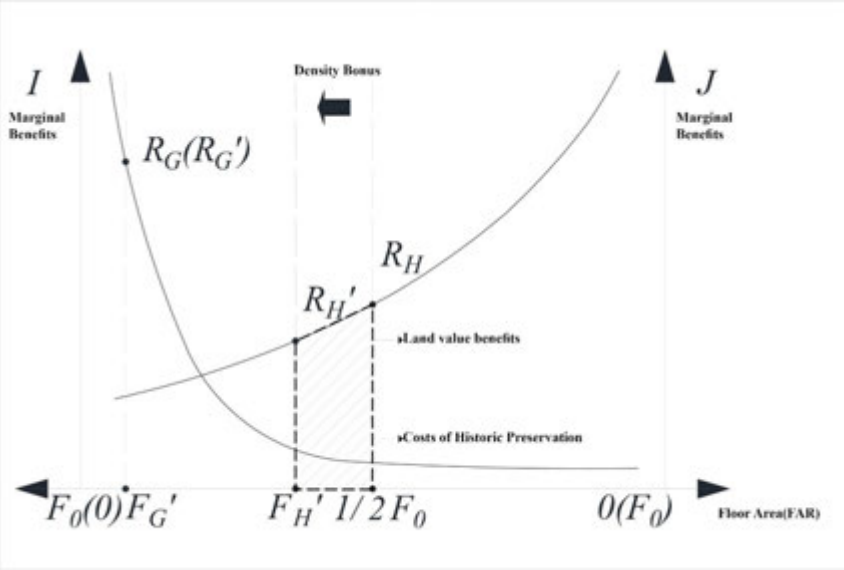

Fig 2 Analysis of market mechanism for DB
(Source: by the author)

This paper argues that relying solely on TDR cannot achieve the maximization of overall social benefits due to the presence of "deadweight loss." Therefore, it is necessary to utilize DB to balance the construction costs of heritage preservation in receiving plots. By enhancing the spatial quality of sending plots and "saving" development costs, DB contributes to the improvement of overall social benefits.

3. Economic Valuation Method for Development Rights Transfer and Density Bonus

3.1 Economic Valuation Method for TDR

The economic value of a piece of land (the sending plot) refers to the spatial value corresponding to the development rights on that land. Therefore, the economic value of development rights reflects the factors contributing to the value of the land. However, if this development rights is used on another piece of land (the receiving plot), its economic value can only represent the spatial value on the receiving plot. It is disconnected from the sending plot, reflecting the value of the receiving plot. In other

words, the price of transferring development rights involve both the price of the sending plot and the price of the receiving plot (Nihata, 2003, p. 128-130).

This paper employs the method of land value distribution rate to conduct economic valuation for transferring development rights. The prerequisite of this method is that the value of land can be determined based on the sum of products allocated according to its most efficient land use. Previous studies have shown that the coefficient of determination for FAR as an explanatory variable is 0.808, which is statistically significant (Yamashita, 2004). Therefore, FAR can be considered as a product for land value distribution. This method assumes that the sending plot and the receiving plot are traded by developers in a free market, while the government possesses complete information and has defined clear and optimal development rights, maximizing the total social output within the plots and their surrounding areas. Consequently, both the sending plot and the receiving plot can be utilized most effectively before and after the TDR&DB. Then, land prices are allocated volumetrically based on FAR, and the price of transferring development rights is determined according to the change in FAR.

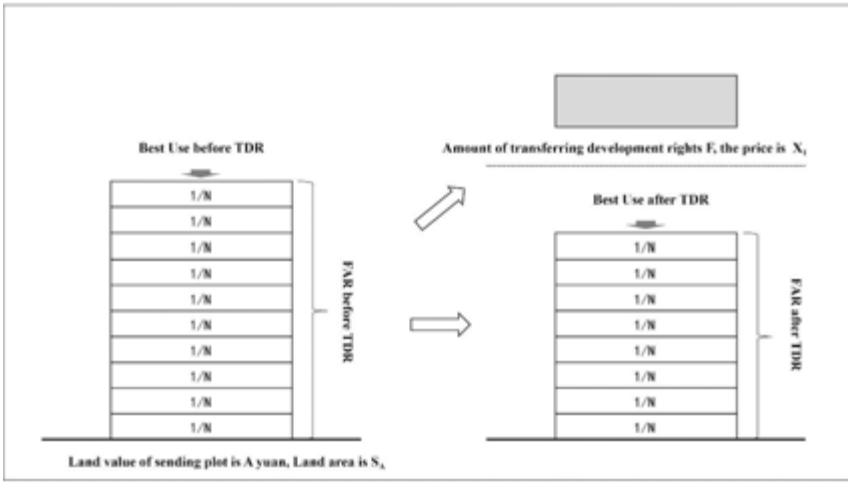

Fig 3: Transfer of development rights of sending land

(Source: TDR of architectural space and its utilization, Yasuo Hibata Nezu)

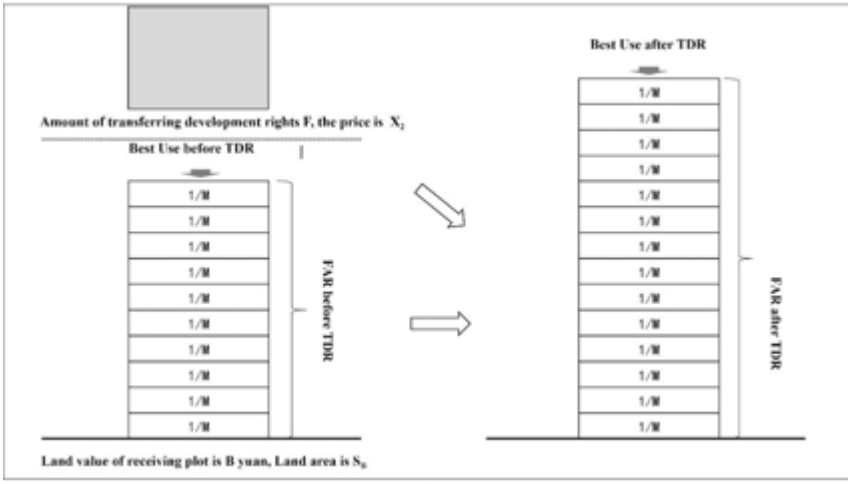

Fig 4: Transfer of development rights of the land parcel

(Source: TDR of architectural space and its utilization, Yasuo Hibata Nezu)

As shown in Fig 3 and 4, the study assumes that the land value of the sending plot is A million yuan, with a land area of S_A and a FAR of N. Correspondingly, the land value of the receiving plot is B million yuan, with a land area of S_B and a FAR of M. Now, a portion of the development rights (F) is transferred from the sending plot to the receiving plot. Therefore, before the TDR, the price of this development rights (X_1) can be calculated using formula (1), while after the TDR, the price of this development rights (X2) can be calculated using formula (2).

The price of TDR in sending plot $\mathbf{X_1}$= land value of sending plot A × (FAR before TDR - FAR after TDR)/ FAR before TDR (1)

α = **(FAR before TDR - FAR after TDR)/ FAR before TDR**

The price of TDR in receiving plot $\mathbf{X_2}$= land value of receiving plot B × (FAR after TDR - FAR before TDR)/ FAR before TDR (2)

β = **(FAR after TDR - FAR before TDR)/ FAR before TDR**

The latter parts of the two formulas are respectively defined as the allocation coefficient **α** for transferring development rights from the sending plot and the allocation coefficient **β** for transferring development rights to the receiving plot. Then, the difference in transferring development rights between the sending plot and the receiving plot is proportionally allocated, resulting in the actual transaction price of transferring development rights. The overall process can be calculated according to Table 1.

Table 1 Valuation Method for Development Rights Transfer

The Price of TDR		
a	b	c = a－b
Sending plot	Receiving plot	Difference
α·A	β·B	α·A－β·B
Distribution of the difference		The Price of TDR
d = a /（a+b）	e = c×d	f = a－e
Distribution rate	Distribution amount	The Price of TDR
$\frac{\alpha \cdot A}{\alpha \cdot A + \beta \cdot B}$	$\frac{\alpha \cdot A(\alpha \cdot A - \beta \cdot B)}{\alpha \cdot A + \beta \cdot B}$	$\alpha \cdot A - \frac{\alpha \cdot A(\alpha \cdot A - \beta \cdot B)}{\alpha \cdot A + \beta \cdot B}$

(Source: Source: TDR of architectural space and its utilization, Yasuo Hibata Nezu)

In the calculation process, it is necessary to specify the exact quantity of transferring development rights. According to the requirements of the "Implementation Rules for Strengthening Floor Area Ratio Management and Promoting High-Quality Utilization of Land Resources (2020 Edition)"(Shanghai Municipal Bureau of Planning and Natural Resources, 2020), In the central urban area of Shanghai, the maximum FAR for newly built residential lands is 2.5, while for newly built commercial and office lands, the maximum FAR is 4.0. Therefore, transferring development rights refers to the difference between the planned maximum FAR and the current FAR. For example, if the current FAR of the sending plot is 1.0 and it is planned for residential use (with a planned FAR of 2.5), then the 1.5 FAR development rights can be transferred.

Through the above calculation, we can further clarify the profit and loss of the sending and receiving plots. The sending plot needs to ensure a positive income for the development rights transfer to be tradable in the market. The profit and loss of the receiving plot can be calculated under the condition of setting a certain proportion of

leasing and selling floor space.

3.2 Economic Valuation Method for DB

the land value income obtained by the receiving plot through DB should be consistent with the construction cost required for historical preservation within the sending plot. This paper adopts the income approach method for economic calculation of DB. Assuming that the construction cost of historical preservation includes the reconstruction cost of historical buildings and sites, this cost can be obtained using the following formula (3). Here, C_A represents the unit construction cost of the sending plot, and F_A is the planned construction area of the sending plot.

Historic Preservation Costs =
Unit Area Cost in Sending Plot ×Planned Floor Area in Sending Plot

$$= C_A \times F_A \quad (3)$$

The awarded development rights is equal to the construction cost of historical preservation divided by the net present value (NPV) of income per unit area of the receiving plot. The NPV of income per unit area of the receiving plot can be calculated using formula (4). Here, $\mathbf{NPV_R}$ is the NPV of income per unit area of the receiving plot. $\mathbf{E_t}$ represents the total net income per unit area of the project in the $\mathbf{t^{nd}}$ year of the receiving plot (in yuan/m²). **i** is the rate of return. $\mathbf{C_B}$ is the construction cost per unit area of the receiving plot (in yuan/m²). If there is a certain proportion of leasing and selling, it is necessary to calculate the net present value **V** of rental income. Assuming equal annual net rental income for a finite number of years in the future, denoted as **A**, the NPV of finite-year rental income can be calculated according to the following formula. The bonus FAR is the ratio of awarded development rights to the area of the receiving plot. The economic calculation approach for DB is illustrated in Fig 5.

Awarded Development Rights =Historic Preservation Costs ÷ NPV of Receiving Plot

NPV of Receiving Plot： $NPV_{承} = \sum_{t=1}^{n} \frac{E_t}{(1+i)^t} - C_B$

Present value of net rental income for a finite number of years:

$$V = \frac{A}{i}\ （1 - \frac{1}{（1+i）^n}）$$

Bonus FAR = Awarded Development Rights ÷ Area of Receiving Plot

$$= \frac{C_A}{NPV_{承}} \times \frac{F_A}{S_B} \quad (4)$$

Through the formula for calculating the bonus FAR, it can be seen that the ratio of the unit construction cost of public contribution per unit area of the sending plot to the NPV of income per unit area of the receiving plot is the **DB Coefficient**. This coefficient depending on the nature of the public contribution and the income situation of the receiving plot. The **DB Volume** is determined by the ratio of the building area formed by the public contribution of the sending plot to the base area of the receiving plot. The greater the contribution to the public interest, the larger the volume of the DB.

4. 17th and 69th Neighborhoods as the Case

4.1 Implementation background

The 17th block in Hongkou District stretches from Jiangxibei Road in the east to Haining Road in the south, from Henan North Road in the west to Wujin Road in the north. It covers an area of approximately 39,630 square meters and involves 3,010 households. The area to be acquired for demolition is approximately 62,000 square meters, and a total of 735 households to be relocated, as shown in Fig 6.

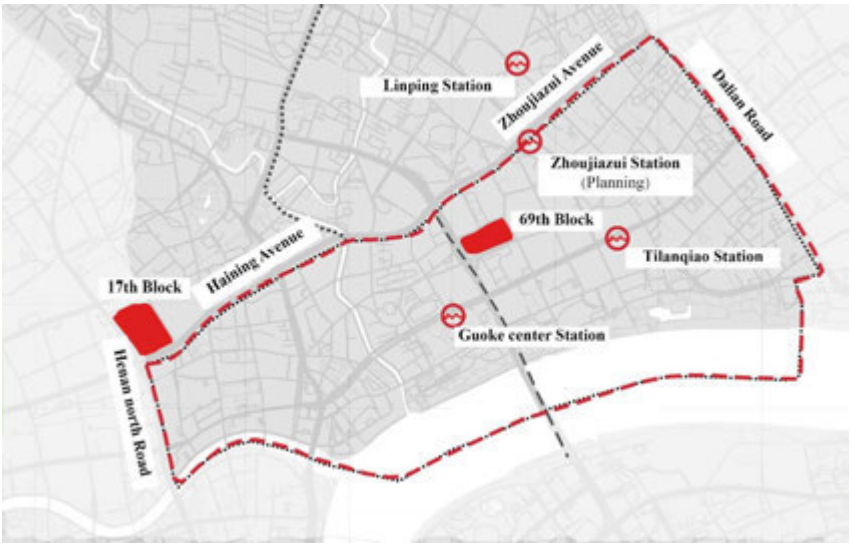

Fig 6: Hongkou District 17 and 69 block locations
(source：https://www.sohu.com/a/441881828_260616)

The houses in the 17th block of Hongkou District have a long history and were designated as the second batch of “Historical Conservation Block” in 2017. The renovation of the area must meet the requirements for historical preservation. In September 2020, the redevelopment site of the 17th block was successfully completed and handed over. At the same time, the urban planning adjustment scheme and approval documents for the 17th block were officially announced (Shanghai Municipal Planning Bureau Document No. [2020] 266). According to the planning scheme, the main land

use type in the 17th block is Class I residential land, with a FAR of 1.1 and a building height of 10 meters.

Located in the core area of North Bund in Hongkou District, Shanghai, Block 69 is designated as land parcel hk300-02 according to the latest approved "Control Detailed Planning for North Bund Area" (Shanghai Municipal Document No. [2020] 39). The planned area of the block is 20,691 square meters, with a land use designation for commercial, office, restaurant, and hotel purposes, without involving historical preservation. The plot FAR is 10.0. According to the urban design of the North Bund in Hongkou, a 300-meter-high landmark building will be constructed here in the future, aiming to create a headquarters base with global influence and benchmark leadership along with surrounding plots.

On December 31, 2020, the land auction announcement was issued (Land Parcel Announcement No.: 202028201). Blocks 17 and 69 in Hongkou District were jointly put up for auction, with a total land area of 58,025.2 square meters. The winning bid was 11.14 billion yuan, and the land use was designated for residential and commercial, restaurant, and hotel purposes.

4.2 Economic calculation

Block 17 has 1.4 FAR transferable development rights, while Block 69 can accept this transferable development rights based on a planned FAR of 4.0.

Based on the land auction and transaction data released by the Shanghai land market, the following assumptions are made: For Block 17, the construction cost per square meter for the preservation buildings is estimated to be 15,000 yuan/m^2, and the selling price is estimated to be 200,000 yuan/m^2.

For Block 69, the construction cost per square meter for commercial office buildings is estimated to be 12,000 yuan/m^2, and the selling price is estimated to be 80,000 yuan/m^2. The annual rental income per square meter is estimated to be 31,000 yuan/m^2/year, with an average vacancy rate of 15%, an operating expense rate of 25%, and a return rate of 5.7%. The evaluation period for commercial office buildings is set at 50 years.

The floor price is determined comprehensively based on the market comparison method and the benchmark land price correction method. The floor price for residential land in Block 17 is 120,000 yuan/m^2, and for commercial land in Block 69, it is 30,000 yuan/m^2. Excluding the underground part.

table 2 Calculation of the overall economic benefits of TDR&DB for 17th and 69th block

Overall economic returns (fully rented)		**(billion yuan)**
a Overall returns of Sending plot	b Overall returns of Receiving plot	c Overall returns
-1.12	-1.59	**-2.71**
Overall economic returns (fully sale)		**(billion yuan)**
a Overall returns of Sending plot	b Overall returns of Receiving plot	c Overall returns
-1.12	+4.83	**+3.71**

(Source: by the author)

(Source: by the author)

4.3 Discussion of results

Through economic calculation, it is evident that although the selling price of villas in the Hongkou District of Shanghai is relatively high (200,000 yuan/m^2), the sending plot still incurs a loss of -1,121,839,000 yuan during the TDR. In a more general scenario, if only the development rights of historical areas are transferred without maintenance and repair, the selling/leasing price of the sending plot will not significantly increase. TDR may even result in greater losses for the sending plot, making it impossible for market transactions. The "deadweight loss" mentioned earlier is the main reason for the losses incurred by the sending plot. This also empirically explains that relying solely on TDR in the renovation of historical areas cannot effectively enhance overall social benefits within the market mechanism. Furthermore, the receiving plot will experience different profit and loss situations depending on the ratio of rent/sales floor area. If all units are leased, there will be significant economic losses (-2,201,214,000 yuan), whereas if all units are sold, there will be significant economic gains (+4,212,787,000 yuan).

The DB can to some extent compensate for the shortcomings of TDR. Not only can it balance the construction costs of historical areas, but it can also enhance the spatial quality and selling price of buildings and environments within the historical areas. This leads to an overall increase in social benefits, reaching up to 3,710,023,000 yuan (while a loss of -2,708,013,000 yuan occurs if all units are leased). Additionally, through calculation, it can be observed that the operational mode of the building has a significant impact on the return rate. Considering the future fluctuations in the usage of office buildings, a cautious approach should still be adopted in handling the DB.

The planned FAR for the receiving plot after the TDR&DB should ideally be around 7.0-8.0. However, the actual planned FAR is 10.0. The main reason for the residual FAR of 2.0-3.0 is that the local government is strongly motivated to increase the FAR to obtain more land fees to offset the costs of demolition and relocation. Another reason is that the planned FAR for the receiving plot is pre-set according to the urban design rather than based on the results of the assessment of TDR&DB.

5. Further Revision and Suggestions

5.1 Revision 1: Back to Public Interest Orientation of TDR&DB

In comparison to local governments, developers are more likely to accept the economic valuation results of TDR&DB. This is because the reduction in FAR reduces the cost of purchasing land, and developers do not need to excessively pursue development rights. They only need to ensure sufficient rent/sale income in the later stages of development. However, from the perspective of local governments, this may not meet their funding gap for demolition and relocation. Unlike Western countries, China cannot increase revenue through property taxes. This exacerbates the difficulty of completing demolition and relocation at the government level. Many local governments resort to seek higher FAR through the TDR&DB in order to obtain "profits" or "income" for government finance. However, this creates an false illusion of FAR. According to Professor Zhao Yanjing's viewpoint, the "cash flow" brought about by increasing FAR cannot be counted as "income" but rather as "financing." Increasing financing levels without synchronously improving the quality of public services will damage the net assets of all original shareholders (homeowners in the city) (Zhao, 2023) . It is this false illusion of FAR that prompts local governments to misinterpret the planning policy tool of TDR&DB, turning it into an economic compensation tool to offset land acquisition costs.

The article argues that TDR&DB are oriented towards achieving public interests, aiming to address spatial interest imbalances in specific regeneration scenarios (Zhu et al., 2022). On one hand, there should be restraint the impulse to increase FAR, making TDR&DB back to public interest orientation. For instance, in the regeneration of 17th and 69th blocks, TDR&DB can not only balance the construction costs of preserving historical charm but also enhance the spatial quality and sale price of buildings within the preserved areas. Additionally, they can generate cash-flow income in receiving plots, thereby enhancing overall societal benefits. On the other hand, local governments should explore a shift from the traditional demolition model to rights adjustment model. This involves reorganizing and adjusting the spatial rights before and after regeneration while preserving the spatial rights of original residents, significantly reducing the costs of demolition.

5.2 Revision 2：A New Way For Introducing TDR In China

From the perspective of international experience, the TDR system is designed to optimize spatial resources by coordinating the "unused development rights" from a comprehensive development perspective. However, under China's collective land management system, the concept of “unused development rights” can be considered nonexistent. In contrast, in countries with private land management system in the West, although unused development rights belong to the land holders as legitimate rights, their use still requires authorization from local governments (Chen&Qi, 2023).

This means the utilization of development rights needs to be approved and regulated by local governments through planning, permitting, and project approval processes. From this perspective, whether unused development rights exist or not, dynamic adjustments of development rights can still drive urban regeneration. Therefore, the introduction of TDR system in China is not about simply copying or imitating Western systems, but rather about understanding its fundamental role and adapting it to the local context.

Urban regeneration involves the reconfiguration of overall spatial resources, aiming to optimize the functional layout of the city and enhance the value of lands. The entire process of urban regeneration is essentially a process of reconfiguring, readjusting, and realizing development rights (Zhou & Zhuo, 2023).

Therefore, urban regeneration requires continuous, frequent, and dynamic adjustments of development rights. There are three main pathways for dynamically adjusting development rights in urban regeneration:

1) **spatial growth model:** By increasing development rights (FAR), the urban spatial layout can be optimized, achieving compact and intensive urban development and maximizing effective land use.
2) **spatial optimization model:** In situations where development rights (FAR) remain largely unchanged, this approach promotes the efficient use of low-efficiency land and upgrades its functions. It helps alleviate pressure on transportation, municipal services, and infrastructure in central urban areas, reducing negative impacts caused by urban land layout.
3) **spatial protection model:** Under strict limitations or even reductions in development rights (FAR), this approach focuses on protecting and maintaining

public resources such as historical buildings, natural resources, green spaces, and parks in the city. It aims to enhance the cultural and natural environmental characteristics of the city.

Following this three patterns of dynamically adjusting development rights should be a new and reasonable approach to introducing the TDR system in China.

5.3 Revision 3：More Refined Valuation Method for DB

It is evident that market developers can gain significantly higher economic benefits through DB. The total income without TDR&DB (calculated based on ordinary residential properties at 100,000 yuan/m^2) can reach up to 344.982 million yuan at most, while the total income with TDR&DB can reach up to 3,710.023 million yuan at most, nearly 10 times higher. Therefore, market developers should make more special public contributions to the future development of the area. The basic and mandatory public facilities that cannot cover all needs. Local governments can specify and clarify the special public contributions of market developers in the planning regulation.

One misconception in China's DB system is n the oversight of the policy context of "special public contributions," wrongly including some basic and mandatory public facilities in the DB system. This has led to the "misuse" of DB system. Special public contributions can include elderly/child-friendly facilities, walkable neighborhood facilities, low carbon environmental facilities, resilient safety facilities, improvement of central urban area spaces, enhancement of central urban area functions (facilities required for future public welfare development), landscape enhancement, historical preservation (especially in non-historical districts), etc.

To accurately account for "special public contributions," the core principle is that the economic benefits obtained through DB should be consistent with the construction costs required for that specific public contribution. It is recommended to introduce the concepts of "DB Coefficient" and "DB Volume", and conduct economic valuation for each type of "special public contribution." Additionally, establishing technical standards can help avoid waste of urban resources and prevent ineffective construction (Zhuo & Zhou, 2023).

5.4 Revision 4：Reconsidering the External Effects of TDR&DB

It's also essential to consider external effects of TDR&DB on surrounding areas (Costonis, 1973) . Typically, TDR&DB involve transferring all "unused development rights" to the receiving plots, allowing which to significantly exceed the original FAR. This sometimes even doubling the FAR, leading to significant negative external effects on transportation facilities, public amenities, infrastructure, landscape, and the housing market. It's necessary to accurately calculate the external effects on the receiving plot based on economic theory when implementing TDR&DB. Currently, due to a lack of quantitative research on these negative external effects, TDR&DB often face criticism for potentially leading to excessive development.

Additionally, the location selecting of receiving plots can help mitigate the impact of negative external effects. For example, in the 17th and 69th blocks, the receiving plot is situated in the North Bund area, which serves as the core carrier of global urban functions in Hongkou District. This area falls under specific policy regulations, effectively reducing the occurrence of the negative external effects. At times, multiple receiving plots can be designated to balance the cost and benefits of special public contributions.

Note ①: Shanghai's specific policy areas include the Central Activity Zone (CAZ), public central areas, innovative function clusters, strategic reserved areas, etc.
Note ②: Volume refers to the total floor area of land for development, and is also an important indicator to measure the amount of development rights.

A Framework for Analysing Physical Form Outcomes of Value Capture Paths of Regeneration Projects in Residential Historic Areas

PANG Zhiyu
Affiliation: School of Architecture, Southeast University, PhD Candidate.
Email: apchpzy@163.com, His main research interest is on the implementation paths of regeneration projects in residential historic areas.

Keywords

Value Capture, Physical Form, Residential Historic Area, Regeneration Project

Abstract

This study develops a framework to analyse the impact of value capture paths on physical form outcomes in residential historic area regeneration projects. The framework, using four independent variables: adjusting property rights, changing use, increasing intensity, and improving quality, and five dependent variables: plot form, building type, number of building floors, building density, and setback distance, is applied to the XIAOXIHU historic area in Nanjing, China. The findings reveal that the same planning control conditions can yield different spatial form outcomes, largely explained by value capture paths. The framework is informative for both planning and policy design.

1. Introduction

1.1 Regeneration Projects in Residential Historic Areas

The regeneration mode of residential historic areas can be broadly categorized into overall redevelopment and progressive regeneration (Ministry of Housing and Urban-Rural Development, 2021). The former is usually led by the government or developers, moving out all or most of the residents by means of expropriation, and carrying out shock-style overall demolition and construction; while the latter is implemented by a diversity of stakeholders, with property rights as the unit and the willing of the residents as the basis, and carrying out gradual regeneration. In recent years, with the increasing awareness of cultural conservation and property rights, "small-scale, progressive" has gradually become a positive guide for the regeneration of historic areas (WANG et al, 2023).

1.2 Regeneration Project as Systematic Social Practice

The conservation and regeneration of historic areas is a systematic social practice that involves regeneration policies, resource allocation, planning and design, construction, operation and maintenance, and community governance, etc (TANG, 2020). The "small-scale and progressive" regeneration model involves multiple interests and complex property relations. Literatures on this topic are scattered in the fields of planning, architecture, historic conservation, municipal government, economy, society, policy management and other disciplines, forming relatively independent knowledge accumulation from different perspectives. However, the working mechanism of spatial regeneration practice is not a simple combination of disciplinary knowledge, but rather a multi-sectoral, multi-actor game and collaborative behavior under the intervention of regulations and policies.

1.3 The Gap in Existing Literature

Most of the existing relevant results exist in the form of knowledge in various disciplines, explaining the mechanism of the interaction between non-physical factors and the physical environment from different academic perspectives. However, it is difficult to utilize the mechanism theory in the planning and designing practice of physical space by only revealing "the inner working mode of each element as well as the operation rules and principles of interconnection and interaction under certain conditions" (Tennekes et al, 2015). It has been pointed out that the role of complex social practices on space is centered on the issue of value capture paths. Therefore, it is necessary to follow the organizational path of practical work, integrate theoretical methods scattered in various disciplines, and establish the correlation between value capture paths and changes in the physical form.

1.4 Objective of This Study

This study intends to build a framework to analyze how the value capture path of residential historic area regeneration projects affects the physical This study intends to build a framework to analyze how the value capture path of residential historic area regeneration projects affects the physical form outcomes. Firstly, through the literature review, the analytical framework of Value Capture Paths and Physical Form of Regeneration Projects is established, and the hypothesis of correlation analysis is put forward; secondly, the research hypotheses are verified one by one through the study of 32 Regeneration Projects in the XIAOXIHU Block, Nanjing, the research hypotheses are verified one by one; thirdly, the roles of adjusting property rights, changing use, increasing intensity, and improving quality on the physical space are discussed; finally, the Implications for planning are discussed. Third, the role of adjusting property rights, changing use, increasing intensity, and improving quality on physical space are discussed; and finally, Implications for planning regulation and supporting policies are discussed.

2. Literature Review and Synthesis

2.1 Value Capture Paths of Regeneration Projects

Game theory, rent gap theory, and other theories have been trying to elucidate the financial equilibrium behind regeneration projects, and Zhao (2021) simplifies this financial equilibrium by summarising the value capture paths of urban regeneration into four categories: adjusting property rights, changing use, increasing intensity, and improving quality. (1) Adjusting property rights. For historical reasons, property in China is divided into two types: "property rights", which can be traded freely, and "limited property rights", which can only be used but cannot be traded freely. "Changing from "small property rights" to "large property rights" will bring additional premium. (2) Changing use, different uses of land bring different revenues and are priced differently in the market, and if the conversion is realised through planning, the corresponding progressive value can be derived from it; (3) Increasing intensity, through the increase in floor area ratio, from the additional floor area ratio to obtain the financing required for urban regeneration; (4) Enhancing quality, old properties often no longer reflect the appreciation of the land, if the quality is upgraded, the missing land value can be captured through property appreciation.

In reality, specific urban regeneration projects can be combinations of the above four paths. Planning and design is to maximise the difference in value of the assets before and after the

regeneration by choosing different combinations of schemes according to the specific conditions of the project, so as to create conditions for achieving financial balance of the regeneration project. Different choices will lead to completely different results after the regeneration.

2.2 Physical Form of Regeneration Projects

The classical urban morphology theory divides physical space into three hierarchies: streets, plots, and buildings (Conzen, 1960). Considering that the unit of this study is a regeneration project, the elements of the street level are not considered.

Indicators at the plot level are mainly referred to the study of Bobkova (2021). who suggest that plot form can be understood through three indicators: plot area, street frontage ratio, and compactness, of which the most crucial indicator is plot area. The geometric measure that captures the potential to host diverse strategies is simply plot area. Plots provide an essential link between the spatial and non-spatial parameters of cities, such as land-uses and property.

The indicators of the building hierarchy are mainly based on the study of Dong (2022). who, after analysing the building types in the XIAOXIHU Block over time, found five basic building types. Type A: courtyard houses from the Ming and Qing Dynasties (before 1912), Type B1: single-family house from the Republic of China era (1912-1949), Type B2: townhouses from the Republic of China era (1912-1949), Type C1: courtyard houses built in the 1950s-1960s (traditional layout), Type C2: courtyard houses built in the 1950s-1960s (modified layout).

In addition, three commonly used planning control indicators, namely number of floors, building density, and setback distance, are introduced in this study for the sake of interface with planning and design practice.

2.3 The Causal Relationship between Value Capture Paths and Physical Form Outcomes

According to above referenced studies, this study proposes a causal hypnosis between value capture paths and physical form outcomes. The hypnosis of association between independent and dependent variables is shown in Figure 1.

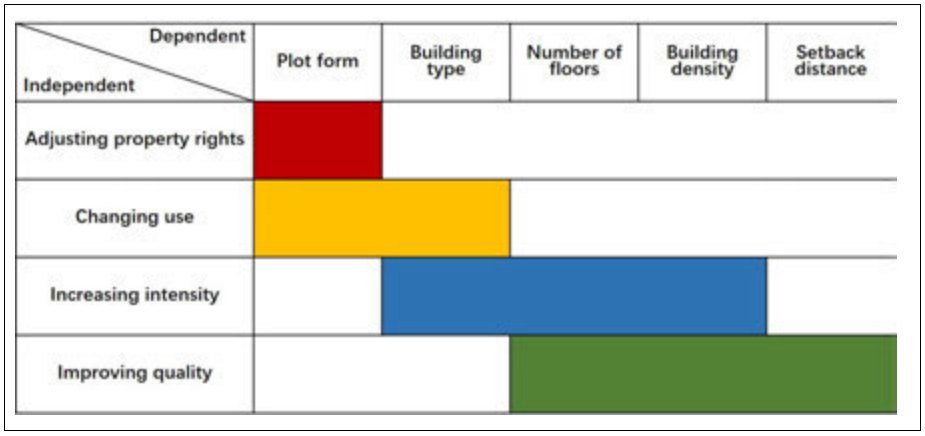

Figure 1. The Framework for Analysing Physical Form Outcomes of Value Capture Paths

3. Case Study Location and Data

3.1 Case Study Location and Overview

The XIAOXIHU Block (DAYUFANG Lane Historic Area) is located in the southern historic district of Nanjing (Figure 1). In 2015, the Nanjing Municipal Bureau of Planning and Natural Resources, as the main body of planning and management, explored the conservation and regeneration strategy of the XIAOXIHU Block as a pilot project. In 2016, the People's Government of QINHUAI District designated the district state-owned enterprise Nanjing Historic District Preservation and Construction Group Limited Liability Company (the "Historic Preservation Company") as the implementation body. In the same year, we undertook the planning and design work. The progressive regeneration changes in the XIAOXIHU Block are shown in Figures 3 and 4.

Figure 2. The XIAOXIHU Block in the southern historic district of Nanjing

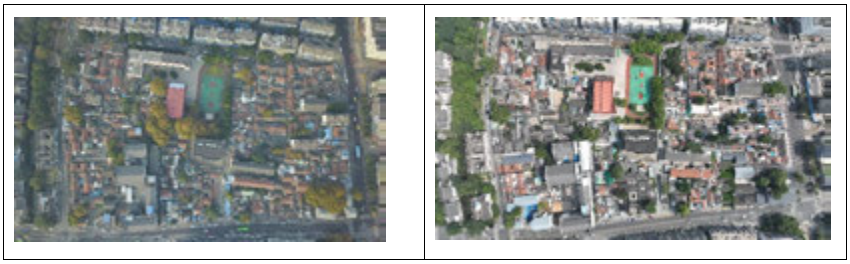

Figure 3. The XIAOXIHU Block before Regeneration
Figure 4. The XIAOXIHU Block after Regeneration

The Detailed Construction Planning for Micro-Regeneration of XIAOXIHU Block (DAYUFANG Lane Historic Area), QINHUAI District, Nanjing (hereinafter referred to as the Micro-Regeneration Plans) is the main planning basis for the progressive regeneration of the XIAOXIHU Block, and it has set up a two-level planning and control system for the different conservation and regeneration challenges of the streets, alleys, plots and buildings (Figure 5): the higher level is the 15 "Planning Control Units" surrounded by the red lines of the streets and alleys, specifying the basic control requirements; the lower level is the 127 "Micro-Regeneration Implementation Units" based on property plots, integrating the historic texture, property rights, and willingness to relocate., and the boundaries of the units and some of the control requirements can be dynamically adjusted during the process of implementation (Figure 6).

Figure 5. Two-level control unit
Figure 6. Micro-regeneration guidelines

The spatial distribution of the 32 regeneration projects in the XIAOXIHU Block is shown in Figure 7. By 2021, the first set of construction projects (P1-P17 in Figure 7) have been completed and put into use, and the main implementation contents include the regeneration of historic streets and infrastructure, the regeneration of courtyard buildings voluntarily vacated by the subject of property rights, and the regeneration of buildings to which the subject of property rights has moved back to their original locations. From 2021 to the present, led by the demonstration of the first phase of the regeneration, the subsequent projects (P18-P32 in Figure 7) will continue to be carried out.

The implementation of the regeneration projects follows the principle of "who finances, who benefits". The management agent coordinates the whole regeneration process, and according to the assessment of dangerous buildings, provides different proportions of subsidies to the owner of the property right who renews the building independently; the implementation agent acquires the building or participates in investing in part of the regeneration independently, provides public services, and obtains different degrees of balance through the sale and lease of space; the owner of the property right contributes to the regeneration of the real estate held by the owner and pays the land premium in accordance with the regulations, and obtains the benefits from the change of land price, the regeneration of the house, and the increase of the capacity of the building. capacity increase, etc.

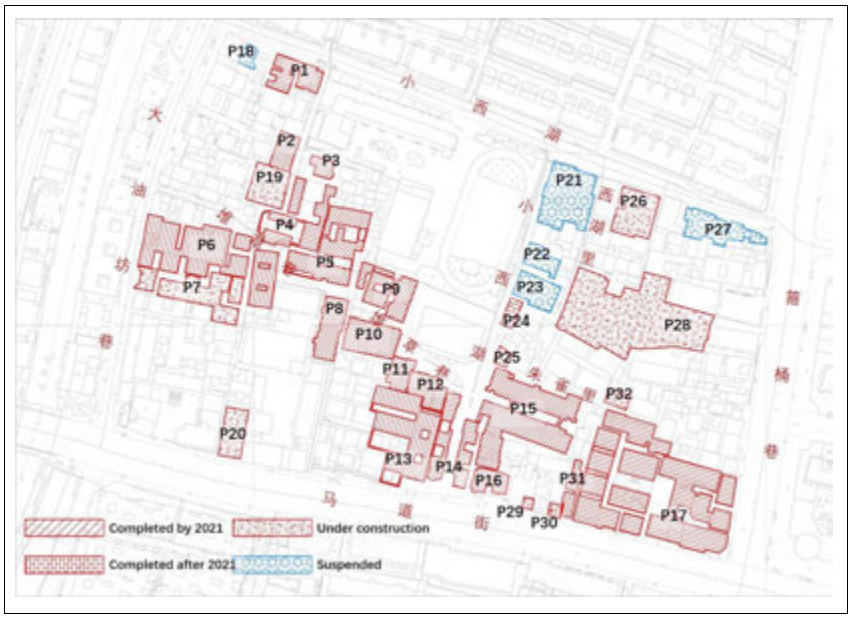

Figure 7. The 32 construction projects in the XIAOXIHU Block

3.2 Case Study Data

Through the interviews with the stakeholders and the analysis of the construction project drawings, the value capture paths and physical space changes of the 32 regeneration projects were obtained as shown in Table 1.

4. Results

4.1 How Adjusting Property Rights Affect Physical Form Outcomes

The impact of adjusting property rights on the physical space is mainly reflected in a significant increase in plot area. There are deeper reasons behind this phenomenon:

One is the loss of the rules and order of traditional urban tissues, which is strongly adjusted by planning control. As shown in Figure 8, the XIAOXIHU Block had 117 plots in 1936, and after the founding of the People's Republic of China (PRC), as the speed of urban housing construction could not meet the needs of the surging population, an original plot or even a building was sub-leased to a few to a dozen households. By 2016, 216 plots existed in The XIAOXIHU Block (Figure 9). Planning control (Figure 5) delineated 15 planning control units and 127 micro-regeneration implementation units, which directly led to an increase in plot area.

Figure 8. The 117 plots in the XIAOXIHU Block in 1936
Figure 9. The 216 plots in the XIAOXIHU Block in 2016

This trend is also exacerbated by the acquisition of houses by implemention agent with a background in state-owned enterprises, which are then converted and reused as a whole. A large number of projects in the XIAOXIHU Block have been undertaken by state-owned enterprises that acquire residential housing and lease it out for rent after overall regeneration. The need for market operation leads to the fact that the scattered and fragmented plots cannot be directly used by hotels, restaurants and other businesses, so the increase in plot area is an inevitable result of this implementation path. Typical projects such as P17, which originally had a number of plots (Figure 10), were later acquired and built as a hotel (Figure 11).

Figure 10. The several plots before regeneration
Figure 11. The HUAJIANTANG hotel after regeneration

4.2 How Changing Use Affect Physical Form Outcomes

Changing Use within the XIAOXIHU Block is mainly reflected in the change of residential use to commercial use or public use, and apart from the increase in plot area mentioned in section 4.1, another notable result in terms of physical form is the increase in the building setback distance. This result occurs in P01, P07, P14, P16, and P31, and the reasons behind it are equally twofold:

One lies in the fact that change of use projects is mainly implemented by state-owned enterprise, which are subject to stricter government regulation. With a dense residential population and high building density within the historic area, buildings are often connected to each other or have very little space between them, and as traditional buildings are mostly wooden structures, it is easy for fires to spread in patches in the event of a fire. For the XIAOXIHU Lot, which is over 300 meters wide in the east-west direction and about 200 meters wide in the north-south direction, the twisting and narrow internal alleyways must assume the function of fire escapes. These projects implemented by state-owned enterprise therefore need to give priority to setting back a sufficient distance to meet firefighting needs.

The second lies in the need for larger outdoor spaces for change of use for commercial purposes. These outdoor spaces are uniformly designed as green spaces (e.g., Project P11, Figure 12), shop fronts (e.g., Project P14, Figure 13), etc. to increase the popularity of retail and catering, thus indirectly bringing about an increase in the setback distance.

Figure 12. Green space outside the shops of the P14 in the XIAOXIHU Block
Figure 13. Seating outside the shops of the P11 project in the XIAOXIHU Block

4.3 How Increasing Intensity Affect Physical Form Outcomes

The morphological outcome of increased intensity is either increased height or increased density, but these two outcomes occur in two separate implementation scenarios.

Most of the projects with relatively simple property rights relationship and not affecting the sunlight conditions of other residents have adopted the way of increasing building height. Among P08, P18, P19, P20, P27, P28 and P31, the P27 is most typical. The project is adjacent to the street on the north side, which will not have any impact on the sunlight, ventilation and other conditions of the rear side, and therefore the way of increasing the height of the storey has been adopted directly. In addition, the ownership of the site is relatively simple, and there is no problem of not being able to increase the height due to divergent views of residents within the same plot.

On the other hand, projects with complex property rights, or with sensitive sunlight conditions in the surrounding plots, tend to adopt the approach of increasing density. Typical projects such as P20, the south brick house in the east-west courtyard is partly owned by government, in the north, an originally timber-framed three-bay old house housing three separate families (Figure 14). The original construction plan was to increase the capacity by adding more floors, but later, due to the objection of the residents on the north side of the site, the only way to increase the capacity was to slightly raise the ridge height and add mezzanine floors (Figure 15).

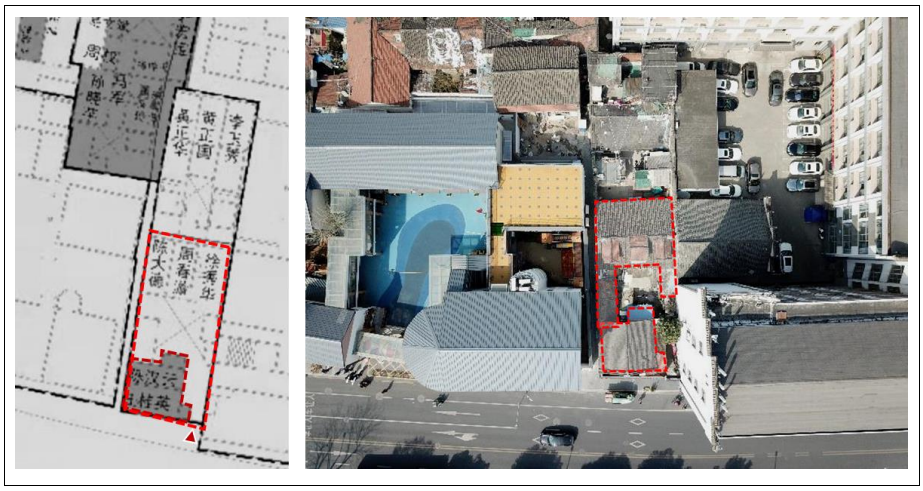

Figure 14. The several plots before regeneration

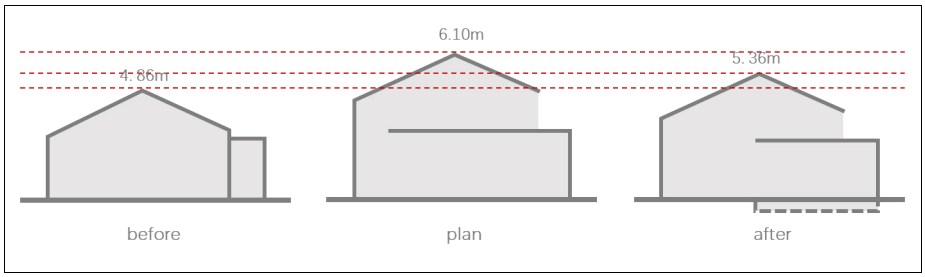

Figure 15. The HUAJIANTANG hotel after regeneration

4.4 How Improving Quality Affect Physical Form Outcomes

The effect of improving quality on the physical form is relatively indirect, with two outcomes: increased setback distances and reduced building density. Typical projects such as P21, P22, and P23, where state-owned enterprises plan to obtain funds through loans and vacate the property rights subject to be converted into high-end housing for sale, have a high demand for the quality of living environment. The project has changed from a mix of multi-family residents (Figure 16) to a mix of commercial and residential upscale housing (Figure 17), which is still in progress, and the setback spacing and building density of the upscale housing is significantly lower than before the update.

Figure 16. Mixed multi-family living before regeneration
Figure 17. Mixed commercial/residential high-end residences after regeneration (rendering)

5. Discussion and Conclusion

Despite the fact that the physical form of residential historic areas is strongly controlled by planning, significant effects of spatial value-added pathways on material forms can still be seen. Specifically, adjusting property rights will lead to an increase in the plot area, the change of use will lead to an increase in plot area and setback distance, increasing intensity will lead to an increase in the number of floors or building density, and increasing quality will lead to an increase in the setback distance and a decrease in the building density.

The value capture path does not determine the final physical form, but it does lead to certain morphological outcomes being more likely than others, which sheds new light on planning and design efforts and the design of regeneration policies. For planning design, it is important to carefully evaluate the morphological outcomes of planning control conditions (height, density, and floor area ratio) in order to protect the historic value of the historic area; for policy design, it is important to interact positively with planning design, which on the one hand enables the planning design objectives to be realized, and on the other hand avoids excessive policy dividends that lead to the upheaval of the historic form.

The value capture path - physical form outcome study in this research complements the single causal explanation of planning control - built form, which does not fully explain the particular direction of variation in physical form. This paper complements the institutional literature in planning and urban studies as it does not only focus on the interaction between stakeholders, but also examines the link between this interaction with physical form.

Abstract

This paper investigates the complexities of land management in Morocco, highlighting the shortcomings of its land tenure system and the challenges stemming from planning techniques. It examines the legal, institutional, and operational frameworks, revealing how limited consideration of land characteristics in planning processes leads to significant implementation constraints. The analysis addresses governance issues, land programming across multiple levels—national sectoral, strategic territorial, and urban—and the financial and legislative obstacles to land mobilisation. Additionally, this paper assesses the current urban policy to underscore the gaps in land resource optimisation. Finally, it identifies sustainable land use practices and proposes strategies for revitalising land management in Morocco, grounded in international standards and best practices.

Key words: Land governance, planning processes, urban policy.

1. Introduction

Land tenure is defined as “the set of relationships between people concerning access to and control over land and natural resources” (Lavigne Delville and Le Meur, 2016, p.84). Shaped by history, it has evolved through customary laws and unique local practices specific to each country. It also represents a social dynamic, mirroring the governance and cultural management of the society. Land governance defines property rights and how they are administered by stakeholders. Additionally, it intersects with several public policies across different scales of territorial development (Land and Development technical committee, 2009).

In Africa, land tenure sits at the crossroads of various imperatives for territorial sustainability, including food supply and natural resource protection (Gueringer, Perrin and Barthes, 2017). Land serves a crucial social function as a source of attachment and identity, and as a means of maintaining ties among managing communities (Mansion and Broutin, 2014). The continent is experiencing a rapid demographic growth, with projections indicating that the population will reach 2.8 billion by 2060 (Canning, Jobanputra, and Yazbeck, 2016). This growth is accompanied by swift urbanisation, which increases the pressure on urban and rural lands.

Mansion and Broutin (2014) highlight the complexity of African land tenure legislation, characterised by the coexistence of customary practices and modern regimes. Land structures exhibit a notable duality, with state-managed public lands on one side and traditional customs, which sometimes lead to social conflicts, on the other. Modern practices, established during colonisation, were based on the privatisation of property and initially favoured colonists and elites (Lavigne Delville and Le Meur, 2016).

Historically, colonisation established a legal basis for property, introducing the concept of the state domain, whereby the state became the owner of unregistered lands while preserving certain customary rights for land use and exploitation (Comby, 2007). This system has resulted in a complex legal framework that, despite independence, has not led to significant structural reforms in many African countries. Colonial regulations were maintained, allowing governments to retain control and redistribute land power (Chouquer, 2009).

The diversity of rules implies that local stakeholders have greater governance flexibility, which encourages competition among regulatory bodies (Lavigne Delville and Le Meur, 2016). This situation leads to arbitrary management practices that disproportionately harm disadvantaged populations. As a result, African land tenure systems remain characterised by legal complexity and high institutional risks, stemming from diverse and often contradictory regulatory frameworks. This context underscores an urgent need for reforms to improve land management and mitigate the risks associated with these systems (Mansion and Broutin, 2014).

In Morocco, land is a strategic priority for economic growth and reducing socio-spatial inequalities (Economic, Social, and Environmental Council, 2019). Gradually, several actions have been undertaken to amend the Kingdom's land policy. In December 2015, reflective discussions were initiated at the National Land Tenure Conference, held under the high patronage of His Majesty King Mohammed VI. The Royal Letter addressed to participants called on the government to design and implement a National Land Strategy, which is currently under development. Additionally, the legal framework is being progressively reformed to align with new socioeconomic requirements (Economic, Social, and Environmental Council, 2018).

The Moroccan land tenure system is characterised by a dual regime of registered and unregistered properties, with a diversity of legal statuses, each governed by its own institutional and regulatory framework. Land issues involve numerous stakeholders and decision-making commissions, and the rules for property transfer are varied and often complex (El Ouagari, 2021).

Furthermore, national sectoral plans are designed without a strategic orientation framework, leading to difficulties in intersectoral convergence (Economic, Social, and Environmental Council, 2019). Their lack of coherence, particularly regarding land issues, hampers operationalisation. Similarly, territorial planning documents are created without adequately addressing land issues. Major projects are often planned on parcels without an understanding of their legal and physical constraints, which hinders realisation. This also affects urban planning documents, as they are frequently developed using outdated land maps or without proper land surveying (Valyans Consulting and AESA Europe, 2022).

Consequently, the lack of control over land data during the planning process leads to discrepancies between projections and actual outcomes. Securing land plots poses a substantial obstacle to deploying national strategies and territorial documents. This difficulty stems from multidimensional dysfunctions, including operational, legislative, financial, and governance issues (Guezzar, 2019).

Therefore, this paper aims to explore the shortcomings in land planning and identify ways to improve land optimisation. Its objective is to examine the land tenure system in Morocco and pinpoint the factors contributing to challenges in land management stemming from planning techniques. The organisation of this paper is as follows: Section 2 highlights the legal framework, stakeholders, characteristics, and mobilisation processes for each legal status,

exposing the complexity of the land tenure system and its regulatory and governance shortcomings. Section 3 analyses land programming at three levels of planning: national sectoral, strategic territorial, and urban. This section demonstrates the limited consideration given to land characteristics during the planning process, leading to constraints in implementing planning documents. Section 4 examines factors contributing to land management challenges within the urban planning system, presenting financial, legislative, and governance issues affecting land mobilisation. It also details the current urban policy, highlighting gaps in land resource optimisation. Finally, the conclusion summarises key findings and outlines approaches to addressing land issues on an international scale. The aim is to identify sustainable land use planning and management practices to instil a new dynamic in Morocco.

This paper relies on a literature review of land tenure issues in Africa and Morocco, drawing on a diverse range of published sources. It is grounded in a detailed documentary analysis of legislative and regulatory frameworks pertaining to land management and planning in Morocco. Additionally, it builds on an examination of national, territorial, and urban planning documents, such as the National Strategy for the Development of Logistic Competitiveness 2010-2030, the Casablanca-Settat Regional Spatial Planning Scheme, the Casablanca-Settat Regional Development Programme 2016-2021, and the 2012 Settat Development Plan.

2. Complexity of Morocco's land tenure system

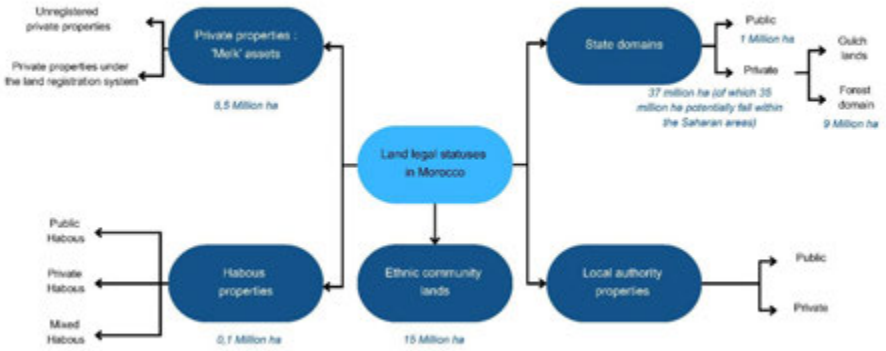
Morocco's land tenure system combines traditional Muslim law with the modern land registration law established in 1913, creating a dual legal framework for registered and unregistered property (M'Hasni, Feljy, and Khalali, 2003). A range of legal statuses, each governed by specific laws, processes, and stakeholders, further characterises the land structure. This section explores the distinctive features of each status, addressing the limitations within the legal framework and constraints on land mobilisation. In addition, it examines limitations in land governance.

2.1 Specific features of land tenure legal statuses

Morocco's history has significantly shaped land access and property rights. In the pre-Islamic era, land was collectively held by tribes, with no concept of private property. The introduction of Islam in the seventh century created a distinction between land owned by the Muslim community and land managed by beneficiary tribes (Rhomri Mounir, 2019). During the protectorate period, further changes occurred, separating land managed by the administration from privately owned land. The land registration system, implemented in 1913, officially recognised individual ownership (Economic, Social, and Environmental Council, 2019).

Today, the registration process identifies assets and specifies the associated rights. However, it remains optional, resulting in a dual land tenure system that combines Muslim and modern laws. This duality creates insecurity in real estate transactions, as unregistered property lacks publicised rights and faces restrictions on access to financing. Consequently, limited land registration undermines land management and weakens the security of property ownership. Rhomri Mounir (2019) notes that this widespread lack of registration negatively impacts the overall security of property exchanges. Furthermore, the legal landscape is complex, with numerous statuses to consider (Figure 1) and an extensive legislative and regulatory framework. However, this system has limitations, including intricate rules, varied mobilisation methods, and outdated regulations (El Ouagari, 2021).

Figure 1: Legal statuses of the land tenure system in Morocco



Note: Figure 1 illustrates the various legal statuses of land in Morocco, as detailed in Section 2.1, and specifies their extent in hectares, based on data from the Economic, Social, and Environmental Council (2018).

Private properties, referred to as "Melk" assets, are typically characterised by their alienability, prescriptibility (excluding registered properties), and seizability. These assets may be registered or unregistered and are subject to expropriation for public use. The expropriation process can range from voluntary ownership transfers to forced transfers by the state, such as confiscation or pre-emption. While private investments can facilitate rapid ownership transfers with minimal stakeholder involvement, expropriation for public use is common. However, the management of these properties, especially in rural areas, is often complicated by joint ownership and fragmentation. Additionally, the slow pace of expropriation procedures often stems from compensation assessments by authorities, which frequently fall below market value, leading to legal disputes and delays in final compensation payments to the expropriated party (Millennium Challenge Account Morocco, 2020).

According to El Ouagari (2021), the State's public domain includes properties, such as roads and buildings, that are not privately owned and are deemed inalienable, unseizable, and imprescriptible. These assets may be used for up to 10 or 20 years under certain conditions and can be transferred to the State's private domain if they are no longer needed for public use. However, the laws governing this process date back to 1914 and 1918, rendering the procedure complicated and time-consuming.

The State's private domain (SPD) includes assets that belong to the state but are not part of its public domain. These assets can be registered, expropriated, and mobilised through various means, including amicable agreements or expropriation involving pre-emption, confiscation, declassification, exchange, or donation. To encourage agricultural investments, public-private partnerships may involve leasing or selling land. However, the SPD faces challenges such as low registration rates, insufficient project monitoring, and a lengthy

expropriation process. Moreover, there is no mechanism to replenish the state land reserve, posing a significant issue due to its depletion (Millennium Challenge Account Morocco, 2020).

As stated by Rhomri Mounir (2019), Guich lands are a component of the SPD and were allocated to the military prior to 1912 as a form of compensation, exempt from taxation. These lands are inalienable, prescriptible, and seizable, and can be registered and expropriated in the public interest. However, challenges such as low registration rates and the absence of specific regulations governing their management make it difficult to mobilise these lands for investment purposes (Millennium Challenge Account Morocco, 2020).

The forest domain, a component of the SPD, includes state-owned woodlands, maritime and terrestrial dunes, and sandy dunes. This estate also comprises woodlands managed by local authorities and private individuals, with the state entrusted with management. These assets are inalienable except for cases of public utility and may be expropriated. The process for utilising these assets varies by project, with distraction applied for public utility projects, and temporary occupation or real estate exchange used for other purposes. For large infrastructure projects, expropriation for public utility may be required to transfer assets from the forest estate to the SPD. These processes involve numerous stakeholders (Millennium Challenge Account Morocco, 2020).

Local authority properties are divided into two categories: public and private. The public domain includes spaces such as streets, squares, and parks and is non-transferable, immutable, and cannot be leased for more than 10-20 years. Conversely, private property refers to assets outside the public domain that can be managed through leases, sales, transfers, or exchanges, often by tender or informal means. However, managing these properties is complicated by illegal occupation, compounded by outdated regulations, slow registration processes, and complex procedures. Despite efforts to modernise legislation for communes with Organic Law 113-14 in 2015, the legal framework remains outdated (Millennium Challenge Account Morocco, 2020).

Ethnic community lands, commonly used for farming or grazing and governed by traditional practices, possess unique characteristics, such as being imprescriptible and unseizable, yet subject to expropriation (Decroux, 1977). These lands can be mobilised through either melkisation or alienation, which involves transferring ownership from undivided community ownership to individual private ownership via rights of claim or direct agreements (e.g., partnerships, exchanges). However, despite the modernisation of the legal framework in 2019, mobilising these lands remains challenging due to slow asset clearance and a high volume of court disputes (Millennium Challenge Account Morocco, 2020).

Habous properties are assets held for pious or charitable purposes and are divided into three categories: public, private, and mixed. Public properties are used for general purposes, private ones benefit the settlor's family for up to three generations, and mixed properties combine both purposes (Idllalène, 2013). These assets are inalienable, imprescriptible, and unseizable, but they can be registered, exchanged, or expropriated with the agreement of the Ministry of Habous and Islamic Affairs. They can be mobilised in various ways, such as through donations, exchanges, auctions, tendered leases, and public-private partnerships. However, their management is often hindered by slow registration and numerous disputes, making mobilisation procedures lengthy, restrictive, and subject to the required approval of the supervisory administration (Ministry of Habous and Islamic Affairs, 2010).

2.2 Institutional framework and land governance

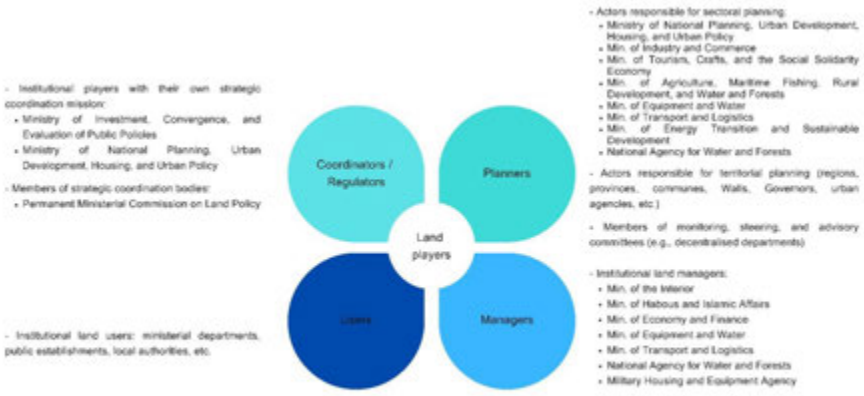
In Morocco, the dual nature of the land regime and the multitude of legal statuses result in numerous stakeholders operating under the jurisdiction of various ministerial departments (Millennium Challenge Account Morocco, 2020; El Ouagari, 2021). Table 1 lists the primary actors for each land status.

Land status	Stakeholders
Melk properties	Individuals or legal entities under private law, along with all entities empowered to expropriate.
State public domain	Ministry of Public Works and Water, Provincial Public Works Departments, Unified Regional Investment Commissions (URIC), and designated public institutions.
State private domain	Ministry of Economy and Finance via the State Domains Directorate, Regional Directorates of State Domains, URIC.
Guich lands	State Domains Directorate, State, Usufructuary Tribes.
Forest domain	Departments, Regional Directorates, and Provincial Services of Water and Forests, URIC.
Habous properties	His Majesty King Mohammed VI, Ministry of Habous and Islamic Affairs, Supreme Council for the Control of Finances of Habous, Constituents, Beneficiaries.
Ethnic community land	Supervised by the Ministry of the Interior (Directorate of Rural Affairs), Ethnic Communities, Beneficiaries, Naibs, Central and Provincial Trusteeship Councils.
Local authority properties	Local Authorities (Regions, Prefectures, Provinces, Municipalities) supervised by the Ministry of the Interior.

Table 1: Main land stakeholders in Morocco.

According to Valyans Consulting and AESA Europe (2022), land actors are divided into four categories: regulators, planners, managers, and users (Figure 2). Regulatory bodies play a key role in coordinating strategies to ensure the highest level of governance. They establish land strategies and oversee their implementation. Planners represent institutional planning bodies, including sectoral, territorial, and urban planners, who program land use and occupation. Managers are landowners, such as ministries and agencies responsible for land administration. Finally, users require access to and acquisition of land plots to fulfil their prerogatives.

Figure 2: Key actors in the land sector, categorised by field of action.



Note: Figure 2 illustrates the key stakeholders involved in land issues, categorised by their field of action. The main actors within each category are listed, compiled based on data from Valyans Consulting and AESA Europe (2022).

There are four levels of governance in Morocco: strategic coordination, sectoral and territorial planning, mobilisation, and monitoring and evaluation. Strategic coordination involves developing public policies that address land issues and align them with one another. However, at this level, coordination and communication between regulatory bodies occasionally lack synergy, resulting in limited convergence of public policies. Sectoral planning is conducted by central departments, often without fully considering local territorial features, which can hinder implementation. The absence of a comprehensive strategy and reference framework sometimes leads to land being programmed individually by each party involved, without cohesive oversight of other departments' actions. Monitoring and evaluation are characterised by systems that require strengthening at all levels of governance. Nevertheless, significant improvements are underway, including the development of the National Land Strategy and its implementation mechanisms, following Royal High Directions (Valyans Consulting and AESA Europe, 2022).

3. Sectoral and territorial planning at odds with actual land use

In Morocco, three distinct levels of planning directly impact land use across different territorial scales. At the national level, ministries conduct sectoral planning to develop cross-cutting and sector-specific strategies, which are subsequently implemented at the territorial level on designated support lands. At the regional level, strategic territorial planning involves formulating development strategies for local authorities, with the spatialisation of these documents significantly affecting land use. At the local level, urban agencies conduct urban planning, creating documents that serve as the primary instruments for land programming (Valyans Consulting and AESA Europe, 2022). This section aims to provide a comprehensive understanding of these three planning levels, highlight their associated shortcomings, and explore the factors influencing land planning and management.

3.1 Current state of sectoral planning

Since 2000, Morocco has implemented national sectoral strategies, recognising land as a “strategic resource” essential to achieving the country’s development objectives across various industries (Economic, Social, and Environmental Council, 2019). However, these national strategies have consistently fallen short of their initial objectives, with notable discrepancies between their ambitions and actual outcomes (Economic, Social, and Environmental Council, 2014a).

For example, the National Strategy for the Development of Logistic Competitiveness 2010-2030 was designed to improve the national economy’s competitiveness by establishing an integrated network of “Multi-Flow Logistic Zones”. Yet, by 2019, the implementation rate was only 14 percent, due in part to the weak institutional positioning of the Moroccan Agency for Logistic Development and the absence of relevant legislative and regulatory texts (Moroccan Court of Accounts, 2020). The successful realisation of this strategy requires the mobilisation of 3,300 hectares of land (Ministry of Equipment and Transportation, 2010). To date, the only developed area is the logistics platform at Zenata, overseen by the National Society of Transport and Logistics and facilitated by land ownership. Securing appropriate land for logistics platforms remains a crucial issue, and logistics operators with access to such land play an essential role in effective planning (Debrie and Mareï, 2019).

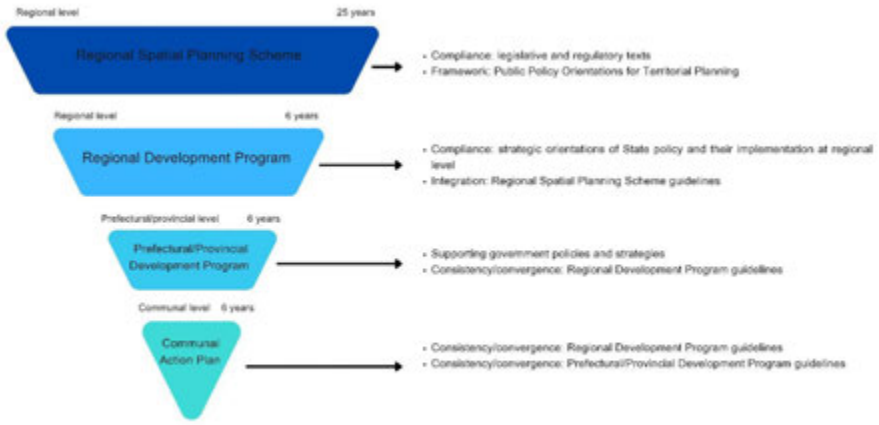
Sectoral planning at central and regional levels faces several challenges. At the central level, various ministerial departments and public agencies design national strategies intended for territorial application at the regional and local levels by decentralised ministerial departments. However, land management presents a significant barrier to effective implementation. The lack of coordination between sectors often restricts land mobilisation, weakening the territorial deployment of strategies (Valyans Consulting and AESA Europe, 2022).

According to the Special Commission on the Development Model (2021), there is a notable lack of cross-sectoral coordination and consultation between national and local levels, resulting in a top-down approach that inadequately incorporates regional and local stakeholders. This disconnect leads to strategies misaligned with on-the-ground realities, creating operational constraints. Additionally, regional strategies remain largely dependent on consultations with central headquarters due to delays in administrative devolution and limited regional delegation of power. Furthermore, the absence of detailed land maps and inadequate land information sources contribute to planning challenges, with stakeholders having limited control over land specifics. This often leads to mobilisation constraints, including legal and physical clearance issues and illegal occupancy (Valyans Consulting and AESA Europe, 2022).

3.2 Strategic territorial planning challenges

Strategic territorial planning encompasses the development of strategies by local authorities and other planners, such as urban agencies and steering committees. The Regional Spatial Planning Scheme (RSPS) guides the long-term development of regions by setting strategic directions for 25 years. Moreover, each council (regional, provincial, communal) is required to create a plan every six years, detailing upcoming projects and actions. These documents are crafted through participatory methods and overseen by a chairman to ensure effective implementation and evaluation. The Regional Development Program (RDP) focuses on sustainable regional growth, the Prefectural/Provincial Development Program (PDP) promotes social development, and the Communal Action Plan (CAP) enhances local services at the municipal level. These documents are characterised by a hierarchical structure (Figure 3).

Figure 3: Hierarchy of strategic territorial planning documents



Note: Figure 3 illustrates the hierarchy of the different territorial planning documents. The RSPS is developed in accordance with current legislative texts. The RDP must align with RSPS guidelines, the PDP must incorporate RDP directives, and the CAP must comply with the guidelines of both the RDP and PDP. This hierarchy is based on information from organic laws 111-14, 112-14, and 113-14.

According to Valyans Consulting and AESA Europe (2022), organic laws require that the RDP, PDP, and CAP be completed within the first year of council mandates. This necessitates the simultaneous development of these tools, complicating efforts to achieve legislative coherence and convergence. Each document must follow specific protocols, involving numerous committees and the same actors within set timelines. Shortcomings in human resources across planning bodies contribute to procedural inefficiencies and redundancies. Additionally, regional stakeholders' heavy reliance on the national level further hampers swift local decision-making and the timely execution of territorial documents.

These plans are not enforceable unless incorporated into urban planning documents, which are slow to design and update (El Idrissi, Omar, 2019). The absence of a comprehensive land information system exacerbates these issues, as commissioned consultancies face difficulties in obtaining accurate land data (El Ouagari, 2021). Outdated databases result in suboptimal project planning that fails to account for specific land characteristics. These systemic challenges cause significant delays and obstacles in project implementation. For instance, in the Casablanca-Settat RDP 2016-2021, over half of the planned projects failed to materialise due to inadequate land mobilisation strategies, despite the planned development of 1,500 hectares of business parks (Boston Consulting Group, 2022).

3.3 Urban planning out of step with on-the-ground realities

According to Law 12-90 on urban planning and the Dahir of 25 June 1960 on rural agglomerations, the primary urban planning documents are the Urban Development Master Plan (UDMP), the Development Plan (DP), and the Development Plan for Rural Agglomerations (DPRA). These documents are essential for guiding the urban development of territories: the UDMP outlines the general organisation and orientations for urban development, enforceable against the administration. The DP converts these orientations into legal prescriptions enforceable against third parties, while the DPRA focuses on managing rural

agglomerations through compulsory building and subdivision permits. The DP and DPRA define land use with precise regulations, imposing restrictive urban planning servitudes and making them the main tools for land programming.

However, these plans have several limitations. According to Valyans Consulting and AESA Europe (2022), a lack of coordination between documents is observed at all planning levels. This stems from the absence of national land use planning guidelines, insufficient convergence among stakeholders, and varying timeframes for drafting and publishing documents. These discrepancies significantly impact the coherence of the territorial development framework, particularly concerning land issues. Additionally, under Article 11 of Law 12-90, all documents must comply with the provisions of the UDMP. In practice, however, numerous instances of zoning and equipment nonconformity between these plans have been noted (Moroccan Court of Accounts, 2018).

Urban planning documents face multiple methodological constraints during their development (Guezzar, 2019). The initial design stage, the territorial diagnosis, often relies on a quantitative rather than a qualitative approach due to standard specifications. These specifications lack rigor and tend to produce generic and summary diagnoses, primarily based on demographic projections (Debbi, 2008). As a result, this approach frequently overlooks critical aspects, such as land-related issues. Engineering firms typically do not conduct detailed inventories on land ownership status or existing land issues (El Idrissi, Abdelwahed, 2019). The absence of an accessible land information system and effective regulations for data sharing exacerbates this problem, leading to the drafting of urban planning documents without adequate control over land use. This situation is further compounded by the difficulties urban agencies and their service providers face in collecting accurate land data (El Ouagari, 2021).

4. Impacts of urban planning on land management

This section explores the multifaceted challenges of urban planning in Morocco by examining the financial, legislative, and governance issues that affect land management within the planning system. It delves into the specifics of urban policy and its implications for land resource optimisation. By highlighting the impacts of planning documents and processes on land use, it underscores the consequences for urbanisation and investment.

4.1 Urban planning challenges

In Section 2.3, the methodological shortcomings of urban planning documents were highlighted, particularly their lack of in-depth studies during the preliminary diagnostic phases. This leads to discrepancies between projections and actual conditions, hindering the effective implementation of planning documents. These issues are further exacerbated by the absence of multidimensional programming in terms of space, time, and costs. As a result, without a clear action plan, these documents function merely as a “spatialisation of consultations with various stakeholders” (Guezzar, 2019, p.27) and “instruments for programming facilities” (Chouiki, 2019a, p.18).

Funding deficiencies are a major barrier to acquiring the land needed for infrastructure, with municipalities heavily reliant on state financial support (El Idrissi, Abdelwahed, 2019). The lack of resources undermines the effectiveness of the decentralisation policy, preventing it from addressing urbanisation challenges or supporting effective land management. This situation is further compounded by a lack of consensus among stakeholders regarding

budgeting mechanisms. The World Bank (2017) estimated that urban infrastructure would require investments of 320 billion dirhams between 2017 and 2027, with municipalities expected to contribute nearly 70 percent of this amount. However, local budgets and taxes fall short of enabling the execution of urban planning provisions or covering development costs.

Urban planning documents lack the flexibility required to adapt to socio-economic and urban changes and are characterised by their "inability to integrate the unpredictable needs of residents and investors" (Economic, Social, and Environmental Council, 2014b, p.11/12). Their preparation is marked by long lead times for publication, rendering them outdated by the time they address dysfunctions identified in the diagnostic phase (Guezzar, 2019). This inefficiency stems from an outdated and rigid legal and regulatory framework that does not accommodate local specificities or the challenges of modernisation (World Bank, 2018).

Furthermore, urban governance involves a multitude of overlapping responsibilities. The centralised state continues to initiate and approve planning documents, sidelining local communes and delaying administrative devolution. This leads to ineffective stakeholder involvement and a lack of continuity in planning processes, often due to limited resources and frequent changes in representatives (Valyans Consulting and AESA Europe, 2022).

In addition, the lack of regional delegation of authority slows decision-making. Despite the involvement of local authorities, it is often difficult to honour commitments to constructing planned facilities. The complex interplay of diverse stakeholders, each with different interests, makes achieving consensus on land use challenging and intensifies the "power play in the production of space" (El Idrissi, Omar, 2019, p.89).

Since the Protectorate, there has been a separation between development and monitoring (Chouiki, 2019a). Once approved, planning documents lack mandatory implementation monitoring and are primarily managed through the examination of building permits by urban management departments. Nevertheless, several evaluation actions have been undertaken by the Studies departments of Urban Agencies. For instance, the mid-term assessment of the 2012 Settat Development Plan revealed a 10 percent equipment completion rate, highlighting the plan's limited operationalisation between 2012 and 2017. Consequently, a new urban planning document was drafted and formally approved in 2018, with the aim of addressing these constraints (Settat Urban Agency, 2018).

4.2 Urban policy and the limited rationalisation of land use

Cities are currently experiencing rapid urbanisation, characterised by significant expansion of urban areas, the development of metropolitan regions, and widespread peri-urbanisation. This ongoing urban sprawl, a legacy of the protectorate era, has led to the overconsumption of agriculturally productive land, which is vital for both economic and ecological functions. As a result, the annual demand for urban land is estimated at approximately 7,000 hectares, requiring a budget of 1.8 billion dirhams (World Bank, 2018).

Urban planning documents play a pivotal role in shaping this dynamic, often responding to land pressure by designating new urbanisation zones. However, these documents impose regulations that promote low-rise, space-intensive development patterns. This contributes to significant environmental issues, socio-spatial fragmentation, and the intensification of unregulated habitats (Adidi, 2019).

The urbanisation process faces multiple challenges in land mobilisation, hindered by the "state's disengagement from the land market" (Chouiki, 2019a, p.17). During the Protectorate period, the government actively created strategic land reserves through expropriation for public utility. However, post-independence state intervention has become sporadic and limited to

arbitrating land issues (Guezzar, 2019). The near exhaustion of public land reserves and the absence of mechanisms for replenishment raise concerns regarding the effective implementation of urban planning documents.

The depletion of public reserves means that facilities of general interest are often planned on private property. Decentralised services frequently overestimate their land requirements, leading to locations being reserved without sufficient funding for acquisition. These plots remain frozen for up to 10 years and are returned to the owners if not utilised. Due to limited resources, these services rarely proceed with land acquisition, leaving the parcels unusable for other purposes. Additionally, departments face challenges in securing available and suitable land for new facilities. This has contributed to the low national implementation rate of urban planning documents, with no urban agencies reporting implementation rates exceeding 20 percent since 2000 (Chouiki, 2019b).

The rigidity of urban planning documents has fostered a land market outside the formal system, characterised by derogation and informal urbanisation. Introduced in 1999, the derogation procedure relaxed authorisation processes to encourage private investment, supporting the completion of significant socio-economic projects by both public and private entities (Economic, Social, and Environmental Council, 2014b, p.11/12). However, evaluations revealed mixed outcomes: although many projects have generated wealth and jobs, 24 percent of derogations were requested in territories not covered by planning documents. This has led to the degradation of agricultural land, disruption of environmental resources, and exacerbation of socio-spatial disparities. It has also contributed to the spread of unregulated urban development in certain areas (Moroccan Court of Accounts, 2018).

4.3 Land issues hindering economic development

Land mobilisation is a critical factor for economic and territorial development, with land availability and accessibility being essential for business competitiveness and attracting investments. However, Morocco's New Development Model identifies land as one of the main obstacles to entrepreneurial dynamism (Special Commission on the Development Model, 2021). Despite significant investment promotion reforms, land-related issues continue to hinder the completion of investment projects. This is supported by the National Business Environment Committee's 2021-2025 roadmap (2021, p.21), which states that "32 percent of Moroccan companies view access to land as a significant hurdle to their development". This issue is compounded by several factors, including legal, urban planning, speculation, and taxation challenges.

As stated by the Casablanca Urban Agency (2015), legal factors impede investment, including slow registration processes and a traditional regime that fosters information opacity, insecurity in real estate transactions, and limited access to financing. Incomplete clarification of the legal status of state-owned land further slows socio-economic development projects. Additionally, complex and slow land acquisition procedures create challenges in legally clearing plots. The slowness and complexity of administrative processes for urban planning documents also delay investment, leading to land retention and speculation. The lengthy procedures for drafting and approving these documents are misaligned with the short time-frame of investment, and once approved, they often fail to address the challenges of economic development and rapid change (Casablanca Urban Agency, 2015).

Urban centres today face immense land pressure, as demand for land continues to rise and market forces intensify. However, easily mobilisable land for investment is limited due to two main factors: the depletion of public land reserves and the retention of urbanisable land by speculators (Valyans Consulting and AESA Europe, 2022). Unutilised land potential exists in

areas such as industrial and economic zones, which are subject to significant speculation. This hinders the mobilisation of land for productive investment and drives up land prices in urban areas, thereby limiting the profitability of investment projects (Economic, Social, and Environmental Council, 2019).

Casablanca has encountered a persistent land crisis, with post-independence reserves quickly depleted and no public land remaining within the urban perimeter. Intense speculation has immobilised productive land for rental opportunities, causing disruption in the land market and creating a significant shortage (Kaioua, 1998). The scarcity of land in the centre of the metropolitan area has exacerbated territorial imbalances, making mobilisation challenging. Speculation drove the price of industrial land up by 40 to 80 percent between 2009 and 2015. Consequently, access to land has been identified as a major barrier to urban and economic development in Casablanca, discouraging investment and reducing the metropolis's attractiveness (Urban Sciences and Development, 2022).

According to the Casablanca Urban Agency (2015), Morocco's taxation system encompasses various fees related to land transactions, including acquisition, sale, division, construction, as well as mortgages and inheritance rights. Numerous tax exemptions and incentives are available to stimulate investment, particularly in productive sectors such as industry. However, public authorities have limited involvement in land market development, resulting in a lack of regulation to control speculation. Essential tools such as expropriation and the right to preemption exist but are insufficient (Valyans Consulting and AESA Europe, 2022). The current fiscal regime lacks mechanisms to discourage land retention and freezing, thereby exacerbating speculation and illegal practices. The absence of an appropriate fiscal tool for tax adjustments following urban zoning changes further compounds this issue (Economic, Social, and Environmental Council, 2019). The tax on unbuilt land is the only instrument available, but it faces collection challenges nationwide, weakening municipal taxation due to inadequate monitoring and control (Moroccan Court of Accounts, 2018).

5. Conclusion: Towards a paradigm shift in land planning and management in Morocco

The complexity of Morocco's land system stems from its dual regulatory structure and limited land registration, resulting in less secure property rights and challenging governance (Rhomri Mounir, 2019). The diversity of legal statuses further complicates decision-making, exacerbated by minimal stakeholder engagement and weak strategic coordination. An outdated legislative framework and complex land mobilisation procedures add to these challenges (Millennium Challenge Account Morocco, 2020).

All planning levels face a lack of reliable land data and rely on top-down approaches that fail to incorporate local insights or consider territorial constraints. Consequently, planning documents often overlook practical land use capacities, leading to significant implementation challenges (Valyans Consulting and AESA Europe, 2022). Key issues include the absence of a comprehensive database accessible to all stakeholders, which would facilitate the rationalisation of land mobilisation. These obstacles arise from gaps in land knowledge methods—such as the lack of land observatories, Geographic Information Systems (GIS), and consistent land monitoring—as well as deficiencies in the tools and sources used for land information (El Ouagari, 2021).

Urban planning has been criticised for prioritising procedural processes over proactive strategies, resulting in speculative urbanism (Chouiki, 2019b). Driven by demographic growth, urban sprawl consumes extensive land resources and adversely impacts rural areas through habitat dispersion and increased infrastructure costs (Adidi, 2019). The inadequacy of modern

financing mechanisms and continued reliance on outdated legal frameworks hinder the efficient development of urban areas (Casablanca Urban Agency, 2015). Given these challenges, there is a pressing need to rethink land management strategies to align with sustainable development goals and to address the shortcomings in land use policies that contribute to environmental degradation and inefficient land utilisation.

According to the Organisation for Economic Co-operation and Development (2017), international land use planning systems are characterised by decentralised governance and hierarchical planning documents. At the national level, general policies are established through guidelines and laws, while regions focus on economic development. Local authorities, particularly municipalities, play a crucial role, as they directly manage planning and land use decisions. These planning documents typically have a short lifespan of 10 years or less and are frequently revised to accommodate the evolving needs of urban development. Community interests are safeguarded either through neighbourhood forums or public referenda, which approve plans, ensure engagement, and address local needs.

Moreover, legislative and regulatory systems for land use are continuously updated to address modern concerns such as sustainability and efficient land utilisation. Planning structures achieve alignment through two primary modes of convergence: vertical and horizontal. Vertical convergence ensures that planning at higher levels is legally binding on lower levels, as seen in countries like South Korea, Turkey, and Switzerland. Horizontal convergence is facilitated through committees that promote coordination and consultation among various stakeholders (Organisation for Economic Co-operation and Development, 2017).

In France, a significant shift in land planning policy has prioritised land sobriety to protect natural resources, biodiversity, and agricultural land. The goal is to counteract urban sprawl and prevent the fragmentation of natural spaces. Urban and strategic planning documents emphasise efficient land use, promote stronger central areas, and control urban growth. A robust legislative and regulatory framework supports these aims by setting clear targets for reducing land consumption and soil artificialisation. These planning documents include specific, measurable objectives and are regularly reviewed through environmental impact assessments to ensure alignment with environmental commitments. Additionally, these policies foster improved land management and encourage regional planners to deepen their understanding of local land dynamics (National Federation of Urban Planning Agencies, 2021; National Federation of Territorial Coherence Schemes, 2022).

To reshape land management in Morocco, a comprehensive reform of planning and administrative methods is essential. A key priority is revising institutional, governance, and coordination frameworks. This includes accelerating decentralisation, empowering municipalities and local communities by enhancing their resources, and establishing a system in which higher-level planning documents are legally binding on lower-level ones.

Additionally, strengthening horizontal coordination through the creation or activation of coordination committees and broadening stakeholder consultation is necessary. Developing a regulatory framework for the exchange and sharing of land information is also crucial, particularly in the context of implementing the National Land Strategy. This framework should enforce coordination among stakeholders, especially when public policies are modified, and

incorporate local land specificities by involving regional actors in national strategy development.

Furthermore, amendments to planning legislation and regulations are needed to integrate sustainability, ecological transition, and land sobriety. The urban strategy requires modernisation to transition from continuous sprawl to a more rational use of land. This includes creating flexible planning documents with regularly updated timelines that respond to socioeconomic development needs. These documents should encourage vertical development and promote denser, more resource-efficient areas. Optimising public facility programming and introducing mechanisms to reactivate unproductive lots are also essential.

Lastly, improving transparency in land information access for both public administrations and private investors is crucial. Measures to regulate the land market—such as implementing fiscal deterrents against land speculation and strengthening taxation mechanisms—are necessary. This includes developing a digital tool to facilitate tax collection, ultimately increasing municipalities' fiscal potential. These proposals aim to encourage sustainable growth, maximise efficient land use, and enhance governance and transparency in Morocco's land management sector.

Abstract: Transferable development right (TDR) is an innovative land management tool created under zoning system in the United States and widely applied in the preservation of historical buildings and natural resources. Chinese scholars have introduced it and conducted extensive research, advocating for the establishment of a trading market for land development rights. However, there are significant misunderstandings that need clarification. Firstly, In China's property rights system, "development rights" is implicitly included within the "land use rights" specified in the Civil Code. Secondly, China's quotas-trading between governments differs from the TDR system in the United States, where land development rights are traded among private landowners. Additionally, the transfer of floor area ratio (FAR) between land users does not hold practical significance in the Chinese context.

Keywords: TDR, FAR, land use control, property rights

1. Introduction

Development rights transfer (referred to as TDR) is an innovative land use management tool created under the zoning system in the United States. New York pioneered this mechanism as part of an effort to preserve historic landmarks in the face of a long postwar building boom that increasingly threatened their viability[Erreur ! Source du renvoi introuvable.]. The "landmark transfers" provision, which allowed unused development rights on designated landmarks to be transferred to adjacent plots, was added to zoning resolution in 1968. This mechanism provided economic relief to owners of landmarked properties, thereby furthering the purpose of the landmark preservation law and provided the city a measure of legal protection from a takings challenge[Erreur ! Source du renvoi introuvable.].

The case of Penn Central Transportation Co. v. New York City was a milestone in the legalization of TDR. In 1960s, although the Grand Central Terminal, owned by Penn Central Transportation Company had been designated as a landmark by Landmarks Preservation Commission, Penn Central still entered into a renewable 50-year lease and sublease agreement with UGP Properties, Inc. UGP was to build office towers above the terminal; however, the commission denied the application on the ground of landmark preservation. Penn Central and UGP sued the city council, claiming that LPC's decision constituted a government “taking” of its property no less than if the government had condemned a plot of Penn Central’s land**Erreur ! Source du renvoi introuvable.**. The case wended its way to the US Supreme Court. In 1978, the Court upheld the Landmarks Preservation Law, and gave the TDR concept some legitimacy by adding that if a taking had occurred, the TDRs "undoubtedly mitigate whatever financial burdens the law has imposed on appellants, and, for that reason, are to be taken into account in considering the impact of the regulation"[1] .

In the United States, a majority of TDR programs are used either for environmental protection or farmland preservation. In addition, there are a few programs that use TDRs to protect rural character, to preserve historic sites, and to implement urban design and revitalization goals[1].

Chinese scholars have been attempting to introduce TDR to address issues such as urban-rural disparities, unfair distribution of land value increment, inadequate consideration of farmers' rights, and insufficient motivation for urban renewal in the Chinese context. The main focuses are as follows:

One type of TDR is referred to as land-use quotas-based TDR. Specifically, Researchers propose endowing rural areas with development rights in the form of quotas and transferring them to urban areas. This enables rural areas to obtain monetary compensation through quotas transactions, which will benefit farmland and environmental preservation goals. While this approach bears similarities to the American practice, the dual urban-rural land system and land quota system in China make its essence different from that of the United States.

Another type of TDR is referred to as floor area ratio(FAR)-based TDR. Relevant research suggests that in the case of urban renewal or historic preservation, permitting unused development rights to be transferred to other plots in the form of FAR can attract market entities to preserve historic buildings. This approach may seem similar to New York's landmark preservation, yet its essence differs significantly.

Based on the aforementioned background, this study conducts a comparative analysis of two sets of cases to examine the inherent differences in TDR under different land ownership systems in China and the United States. Through this research, a deeper understanding of the applicability of the TDR mechanism in China can be achieved.

Meanwhile, China’s experiences to promote land resource protection to be presented in this paper, which will be of great significance to other countries.

2. Comparative cases: The Practices of TDR in China and the United States

2.1 Land Management Systems in China and the United States

2.1.1 Chinese Land Management System

The Chinese government has implemented a dual urban-rural land ownership system, whereby urban land is state-owned, while land in rural and suburban areas is collectively owned. The Land Administration Law of the People's Republic of China stipulates that ownership of all state-owned land is exercised by the State Council on behalf of the state. Acting as agents of the central government, local governments are specifically responsible for land utilization and protection, and they are delegated the authority, in the interest of the public, to expropriate or requisition collectively owned land.

Since the start of reform and opening up in 1978, China's economy has developed rapidly, with a significant influx of foreign capital. This is partly attributed to local governments' strategy of attracting businesses at the expense of land resources. However, several issues have arisen, such as land use inefficiency, significant loss of arable land, and inadequacy in protecting farmers' rights during land requisition. During the 1986-1996 period, China's arable land decreased at an alarming rate of 280,000 hectares per year[2]. To curb this trend and strengthen land management, the central government issued an important document in 1997 titled "Notice on Further Strengthening Land Management and Effectively Protecting Arable Land", which directly led to the revision of the "Land Administration Law".

The "Land Administration Law" promulgated in 1998 reaffirmed that "treasuring and reasonably utilizing land, and effectively protecting arable land, are the basic national policies of our country". It proposed to establish a stringent land use control system, thereby strengthening the central government's authority over land use and protection. It introduced a mechanism—balancing the occupation and reclamation of arable land—to achieve the goal of maintaining the quantity of arable land. Under this system, construction land quotas are distributed hierarchically by higher-level governments through the land use master plan and the annual land use plan. The Master Plan sets long-term regulations on both the quantity and spatial distribution of agricultural land in a locality that is allowed to be converted construction land, while the Annual Land Use Plan breaks down these long-term objectives for each year[3]. Overall, the Chinese government adopted a "dual management" approach to protect arable land and promote efficiency in land utilization. At the same time, a land

inspection system was established to ensure the regulations made in the plan are executed properly.

In 2004, the central government proposed "the increase in urban construction land should be linked to the decrease in rural construction land." It clarified the corresponding implementation plan: several rural construction land parcels intended for reclamation as arable land (i.e., demolished parcels) and parcels intended for urban construction (i.e., newly built parcels) together constitute a "new construction and demolition project area" (hereinafter referred to as the project area). By combining construction and demolition, along with arable land reclamation, the goal is for the total amount of construction land in the project area not to increase and for that of arable land not to decrease. In other words, aiming to transfer the development rights of rural areas to urban districts by eliminating the development rights of rural areas, this sets the institutional background and basic form of TDR in China.

2.1.2 American Land Management System

The land ownership in the United States, where most of the land is privately owned, differs from that in China. According to statistics, sixty percent (1.4 billion acres) of the 2.3 billion acres of land surface is privately owned, 29 percent is owned by the Federal Government, 9 percent by state and local governments, and 2 percent is in Indian reservations[4]. The state-owned land is managed by U.S. Department of the Interior in the form of national parks, national wildlife refuges and the like, While privately owned lands are regulated by the local government through covenants, zoning and other legal devices[5].

In 1916, New York City adopted the nation's first comprehensive zoning, Building Zone Resolution, to regulate private property rights for the benefit of public health, safety, comfort, convenience and general welfare. The Resolution divided the five boroughs into three different kinds of use districts, five different height districts, and five different area districts[6]. In 1922, the Department of Commerce issued the Standard State Zoning Enabling Act, a model law, delegating local governments to enact zoning law through the authority of state police powers.

The conventional zoning (also referred to as Euclid zoning due to village of Euclid v. Ambler Realty Company) divides the municipalities into several districts to separate incompatible uses[6]. In recent decades, many innovative tools have been created by local governments to fulfill certain goals. Nevertheless, the zoning law sets restrictions on property owners' development rights. However, within the ownership system, the development rights by law belong to individuals, and the TDR trading typically occurs between rights holders, usually in a market environment.

2.2 Land-use quotas-based TDR： Practices of Zhejiang Province in China Comparing with that of Boulder County in the United States

2.2.1 The Practice of TDRs in Zhejiang Province, China

Situated in the Yangtze River Delta, Zhejiang has been one of the most economically dynamic provinces since the economic reforms[3], which has led to significant challenges for its land resources. Based on statistics, from 1995 to 2009, Zhejiang's GDP increased from 355.755 billion yuan to 2,299.035 billion yuan, and the per capita GDP nearly quintupled. Zhejiang Province adopted the approach of attracting investment with low-priced land like many other cities in China. As a result, rapid economic development led to a dramatic expansion of construction land, encroaching significantly on arable land. Statistics also showed that its arable land decreased by 138,700 hectares, and per capita arable land dropped from 0.048 hectares to 0.037 hectares during the period from 1997 to 2009, while construction land increased by 405,800 hectares compared to 1997.

The Land Use Master Plan for Zhejiang Province (1997-2010) was approved by the State Council in 1999 and stipulated that 66,667ha of agricultural land could be converted for construction purposes[3]. To meet the central government's request for "the amount of arable land cultivated equals that of depleted" Zhejiang had to reclaim an equivalent quantity of arable land that was to be converted to construction land.

In terms of the distribution of construction land quotas, Zhejiang provincial government allocated them nearly proportionally to cities based on their GDP performance[3]. This was a relatively fair approach, as each municipality has a desire for more quotas. However, cities or counties with strong development potential tended to have a shortage of construction land quotas, while economically backward areas had more than they needed.

To tackle this dilemma, the provincial government initiated a mechanism allowing for the transfer of construction land and farmland quotas between urban and rural areas as well as between regions, which many scholars also referred to as China’s TDR.

the TDRs between urban and rural areas can be achieved through "land consolidation," which entails cultivating abandoned parcels into arable land, and "rural construction land reclamation," which involves demolishing rural residential or industrial buildings and converting the land into arable land. In the case of land consolidation, municipalities would be rewarded with construction land quotas equivalent to as much as 72 percent of the newly cultivated arable land. By employing the latter type of TDR, local governments could acquire an equal amount of additional construction land quotas if a certain amount of non-agricultural land within their

jurisdictions was reclaimed as farmland[3].

Additionally, TDRs across localities could be realized through a two-step process. Firstly, municipalities with less demand for construction could sell their unused quotas, which were typically earned through "rural construction land reclamation" or "land consolidation," to cities or counties in need of extra quotas. However, in terms of trade-in areas, locating these purchased quotas would inevitably encroach upon prime farmland, as 85 percent of arable land had been designated as prime farmland in the Land Use Master Plan. Therefore, the prime farmland preservation accountability needed to be transferred to other municipalities capable of bearing extra burdens.

Let's assume there are one developed city, City A, and one underdeveloped city, City B in Zhejiang Province (Fig. 1). Both City A and City B will be distributed with construction land quotas through the Land Use Master Plan (LUMP) and Annual Land Use Plan (ALUP). However, due to strong development momentum, City A requires more construction land quotas. Construction land quotas obtained through land consolidation and rural construction land reclamation within its jurisdiction are intended to facilitate urban expansion. In addition, in cases where additional quotas are needed for further economic development, City A can purchase them from City B, typically acquired through similar means. Meanwhile, to locate these quotas and maintain the amount of prime farmland, City A can make a payment to City B for assuming this accountability on its behalf.

In this process, City A fully realizes its economic potential through sufficient development land, while City B, lacking development opportunities, finds that the marginal benefits from land development are lower than those from quota trading. Therefore, City B is eager to generate revenues by selling quotas. As for Zhejiang Province, it fulfills the development and protection responsibilities imposed by the central government. This can be described as a win-win transaction for all parties involved.

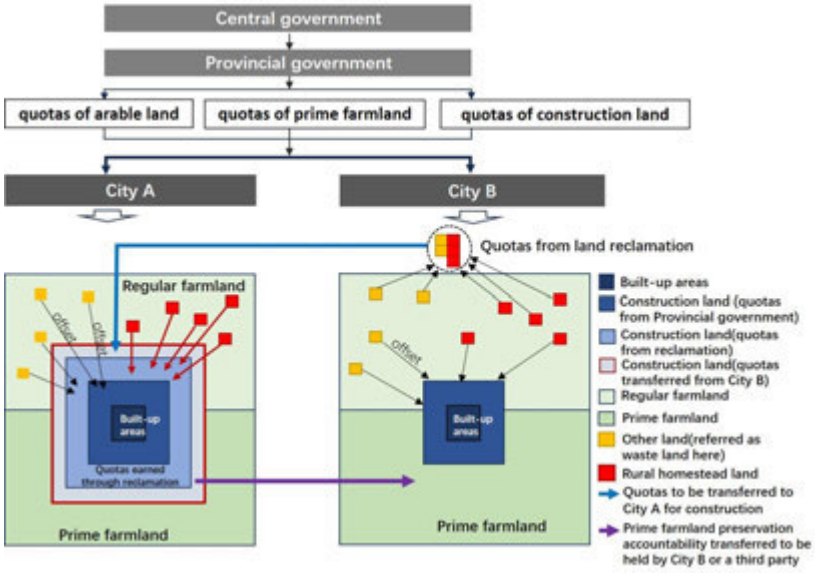

Fig. 1 The ideal type of TDRs between rural and urban areas and between localities

However, this innovative instrument, which had breached central government regulations, raised several concerns. It was reported that some local governments rushed to convert fish ponds, riverbanks, and hilltops into prime farmland to meet quotas, prioritizing quantity over quality[3]. Additionally, local governments could undermine farmers' benefits by forcibly relocating them to cities. Consequently, the central government halted further implementation of Zhejiang's practices in 2004.

2.2.2 The Practice of TDRs in Boulder County, America

Boulder County, Colorado, spans 1,946 square kilometers and has a population of approximately 330,000 people as of 2022. Boulder, the most populous municipality in the county, is the county seat (Fig. 3).

Fig. 3 Location and layout of the Boulder County
Source: google

The study by Nelson, A. C., Pruetz, R., & Woodruff, D. (2013) showed how the TDR program was operated in Boulder County. In 1981, Boulder County adopted a clustering technique known as a non-urban planned unit development (referred to as NUPUD), granting a density bonus in case that 75 percent of the parcel are permanently preserved. The base density could be doubled, from one unit per 35 acres to two units per 35 acres. This clustering technique significantly contributed to resources

preservation and growth management.

In 1989, the county upgraded this mechanism to allow the density bonus to be transferred to a noncontiguous parcel, which was referred to as non-contiguous non-urban planned unit development (referred to as NCNUPUD). The NCNUPUD includes two or more noncontiguous parcels, between which development rights can be transferred. In this situation, receiving sites can achieve up to three times the density permitted under the NUPUD process. For example, one unit allowed to be developed on a 35-acre site by right, two units through NUPUD, and six units with NCNUPUD[7].

The NCNUPUD could be utilized within the jurisdiction of Boulder County, as well as being employed between Boulder County and a city in case that an intergovernmental agreement (IGA) had been reached. For example, in 1996, Boulder County and the city of Longmont entered into a TDR IGA. The Planning Area of Longmont, which was outside its city limits and intended for future development, was designated as receiving sites (Fig. 4). When property owners chose to preserve sending sites, the conservation easements were granted to Boulder County and the city jointly. If all the owners in the sending areas were willing to sell their development rights, a greenbelt, with valuable agricultural and environmental resources, was going to be created[7].

2.3 FAR-based TDR: A Case of Shenzhen in China Comparing with that of New York City in the United States

2.3.1 A Case of TDRs in Shenzhen, China

Shenzhen, located in Guangdong province, spans a total area of 1,997 square kilometers, comparable to that of Boulder County. However, by the end of 2023, Shenzhen's population had surged to 17.79 million people, with a GDP of 34,606.40 billion yuan. Remarkably, just 35 years ago, Shenzhen was nothing more than a small fishing village. In 1978, the Chinese government decided to implement nationwide

reforms and opening-up policies. The State Council granted Shenzhen the status of an economic special zone, positioning it as a pioneer in China's economic reform. Over the past three decades, Shenzhen has effectively utilized policies, the domestic market, and its proximity to Hong Kong to rapidly evolve into a first-tier city.

Like many other cities in China, Shenzhen's rapid economic development has consumed a significant amount of land. By 2005, the spatial capacity was estimated to be insufficient to support further development, leading to the decision, in 2009, to implement urban renewal to facilitate economic development by demolishing underutilized parcels[8].

Shenzhen has devised an urban renewal plan, through which a few urban renewal units were designated. Each unit typically involves multiple property owners and other stakeholders. Developers are authorized to create the plans, determining land use categories and their intensity. As widely acknowledged, residential and commercial utilization, combined with a higher Floor Area Ratio (FAR), can yield significant revenue for developers. However, this comes at a cost: developers are responsible for demolishing existing structures on behalf of the government, relocating native residents, and transferring a portion of the land, free of charge, to the government for public facilities. Additionally, developers are required to pay for the land use rights (usually below market prices). These expenditures prompt developers to negotiate with the government, seeking higher profits by increasing intensity.

Due to Shenzhen's high population density and significant shortage of infrastructure and public facilities, in the event that additional plots are transferred to the government for public benefit, the floor area on those plots can be transferred to other lots for the developers' benefit (Fig. 5). This approach is somewhat similar to "bonus density" adopted by New York city.

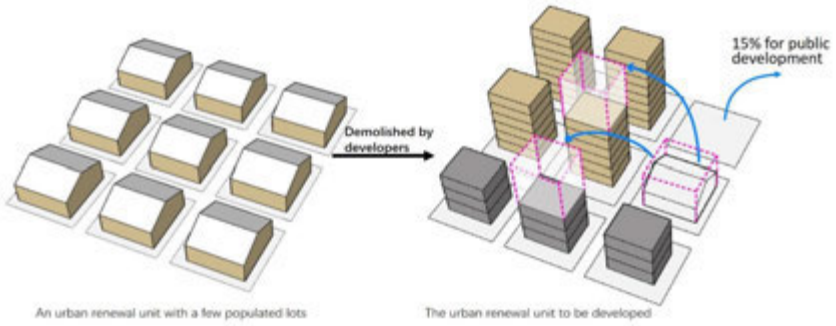

Fig. 5 FAR-based TDRs in an urban renewal unit

The urban renewal unit of Baolong Street, Longgang District, Shenzhen City can serve as an example(Fig.6,Fig.7). According to the plan, the area will be redeveloped

for industrial and residential use. In order to implement this vision, developers need to demolish the buildings on 104.5 hectares of land, among which 38.2 hectares will be transferred to the government for public facilities. Additionally, the developer, on behalf of the government, had to demolish the properties outside the urban renewal unit with an area of 8930 square meters. As an incentive, the development rights on this parcel will be transferred to a certain plot within the renewal unit at a specified ratio.

2.3.2 A Case of TDRs in New York City, America

The case of the Theater Subdistrict can illustrate how the FAR was transferred in New York City(Fig.8). The Theater Subdistrict is part of the Special Midtown District, one of the special purpose districts in New York's zoning resolution. The establishment of this subdistrict aims to protect the entertainment industry of Broadway from being encroached by abutting residential and office development. Many of the theaters in the area were built in the nineteenth century. In the 1970s, some significantly historic buildings were demolished, with only a few theaters designated as landmarks being preserved. By the 1980s, promoted by the "Save the Theaters" movement, New York City founded the Theater Advisory Council, and the area was designated as the Theater Subdistrict. Meanwhile, within the Special Midtown District, a special provision was created allowing property owners of listed theaters to sell their unused development rights, but the scope of the transfers was strictly limited.

In response to pressure imposed by stakeholders and the expansion of Times Square, New York City reformed the TDR rules in 1998. The amendment greatly widened TDR receiving areas by allowing listed theaters to transfer floor area anywhere within the Theater Subdistrict, expanded the Subdistrict to include the 8th Avenue Corridor up to 56th Street, reduced the procedural requirement to streamline the process[Erreur ! Source du renvoi introuvable.]. Through this tool The TDR trading in the Theater Subdistrict has become one of the most active programs in New York City. This initiative has enabled the preservation and of Broadway's entertainment industry and cultural brands.

3. The Difference Between TDRs in China and that in America and its Applicability in China

Two sets of comparative cases have been presented above, from which we can conclude that there are significant differences between TDRs in China and those in America.

Firstly, the goals of TDR vary. Through quota trading, Zhejiang Province and municipalities sought to fulfill the central government's objectives of farmland protection, while also addressing the scarcity of construction land quotas in developed municipalities. Conversely, Boulder County utilized TDRs for growth management, aiming to prevent urban sprawl and preserve agricultural and environmental resources. Similarly, regarding Shenzhen and New York City, the former aimed to incentivize developers to undertake governmental responsibilities, such as demolishing dilapidated

buildings and constructing public facilities, resembling more of a density bonus rather than a straightforward FAR transfer. The latter focused on the protection of historic buildings, facilitating the transfer of development rights between preservation sites and development parcels.

Secondly, the entities involved in the transaction are different. In the Zhejiang case, it was the local governments who promoted the transfers, since the quotas of prime farmland and construction land are strictly controlled by the central government. In the Boulder and New York City cases, local governments only establish rules and supervise implementation, while the transfers were still carried out by property owners. In the case of Shenzhen, developers traded with the government for additional floor areas.

The aforementioned distinctions between the two fundamentally lie in the difference in land ownership. In China, land ownership belongs to the government, which not only formulates land use regulations but also eagerly obtains revenue through selling land use rights. In the United States, since land is privately owned, the government intervenes in the amounts of development rights and the transaction process through planning, yet it does not directly engage in TDR trading.

Therefore, in the context of China, it is necessary to reexamine the essence of the TDR mechanism. Quotas-based TDR is one type used merely within a limited scope under the control of the central government, including the transfer of construction land quotas between urban and rural areas and that across regions limitedly. FAR-based TDR is essentially a density bonus, where developers take on public obligations on behalf of the government in exchange for additional floor area.

4. Conclusions

Given that Chinese scholars are advocating for the adoption of the TDR mechanism from the United States to address issues in China, such as the dual urban-rural land ownership system, government monopoly on land revenue, and lack of protection for farmers' rights, this article raises the question: Can Transferable Development Rights be Applied in the Chinese Context? It first introduces the backgrounds of land management in China and the United States respectively, and then compares the differences and similarities between the two countries' TDR systems from two perspectives: quotas-based TDR and FAR-based TDR, using two sets of case studies—Zhejiang Province and Boulder County, Shenzhen and New York City. The study finds that in both sets of cases, both the goals and the trading entities of TDR are different, which fundamentally stems from the different land systems in the two countries. As a result, the roles of the government differ. In China, with urban land being owned by the government, it has a strong incentive to acquire larger construction quotas to generate more fiscal revenue through TDR, while at the same time passing on accountability that the government fails to hold to developers.

In conclusion, the essence and connotations of TDR in the Chinese context differ significantly from those in the United States, and their implementation should fully consider China's institutional framework. Additionally, this article introduces China's experiences, thereby filling the gap in TDR research within the context of developing countries.

Principles and rules for spatial planning governance and government in Italy

Carolina Giaimo
DIST- Interuniversity Department of Regional and Urban Studies and Planning, Politecnico di Torino
carolina.giaimo@polito.it:

Abstract
The paper argues that a law reforming the planning system as a spatial government activity is needed in Italy: it is necessary that regional laws descend from new principles and rules to allow for more effective operations in the respective local municipal systems and the vast metropolitan and regional area. It relaunches planning through a plan that can dictate rules not only for the performance of private initiative but also for public policy and concrete actions of the institution responsible for that plan. There are outlined the main contents of the INU proposal, starting from the necessary to move from a plan that exercises public authority (often only formal) to a plan that includes public-private and public-public negotiation transparently and helpfully for the general interest.

Keywords
spatial planning, governance, government

1. Territory and its government and governance

Following the reform of Title V of the Italian Constitution in 2001, among the various functions and activities performed by the public authorities, that of "territorial governance and government", has become increasingly important. This expression can be taken to mean a "broad complex set of interacting functions, with a strongly polysemic meaning that calls into question all the constituent institutions of the Republic that are responsible for and competent in the relative fundamental activities, including the function and method of territorial planning" (Barbieri 2023, p. 162). This is a decidedly more articulated conception than the one that, at the beginning of the 1990s of the last century, was still considered the most accredited and which saw in the government of the territory the "complex of institutions that preside over the regulation, control, and management of land use" (Morbidelli 1994, p. 755). Today, this concept covers the regulation of land use; it extends to the environment and landscape, referring to the complex sustainability of use and not only to the legitimacy concerning the rules of use itself.
However, the difficulties connected to the perimeter of this concept also reside in a rather heterogeneous legislation stratified over time, whose 'regulatory heart' is still, inexorably, represented by the national Spatial Planning Law n. 1150/1942, albeit amended and supplemented several times in eighty years of the Republic. It is flanked not only by national laws, which regulate, in competition with the town planning regulations and with each other, specific spatial areas of territory or sectors (laws such as those on the protection of natural beauty or the protection of things of artistic and historical interest, or parks, protected areas, hydrographical basins, or laws on areas destined for economic and social housing, artisan and industrial production facilities, large commercial businesses, etc.), but also regional spatial planning laws, which regulate the development of the territory of the Italian Republic(since the entry in force of Presidential Decree n. 616/1977) and sectoral laws.
If we consider that this very dense set of laws is accompanied by the respective instruments (plans), it could be useful to try to understand why the territory appears to be governed (and planned) in a hypertrophic manner.

1.1 Background. A hierarchical planning system

Consistent with what was instituted by Law n. 1150/1942, planning has long been commonly defined and described, according to an authoritative and strictly legal approach, as a "procedural facts" of acts of public power connected in cascade, each with the function of better specifying what had already been disposed of by the preceding one, according to relations of supra- and sub-ordination, or according to relations from the general to the particular. In this way, "the concept of planning is identified in the legislative regulation of an activity which, while resolving itself in a multitude of measures, intends to maintain the organic coordination of them and proceeds through a series of acts which gradually condition themselves from the most general to the most particular, that is, from the Territorial Coordination Plan to the measure by which the execution of the single construction is permitted" (Stella Richter 1984, p. 7). As has been observed in this regard, (*ibidem*, p. 8), accepting such an approach implies that in order for a given territory to be considered correctly and fully planned, it must be affected by a multiplicity of overlapping territorial and town-planning instruments; the content of the various acts linked together must necessarily be homogeneous; plans of a broader territorial scope are of greater importance than those of a more circumscribed scope, whose function is substantially executive of the more general one.
This type of conception has been the most widespread, particularly in the legal-administrative culture of town planning (and can be found in most juridical town planning manuals), until the debate on the relationship between the various institutional levels (and therefore between their

acts) was significantly reopened, concomitant with the approval of Law n. 142/1990 reforming the local self-government system, which above all was to give definitive implementation to the principle of political and administrative pluralism contained in the text of the Constitution. Having quickly fallen into oblivion, a new impetus to the discussion only came with the entry in force of Law n. 56/2014, which provided provisions for metropolitan cities, provinces, unions and mergers of municipalities and which, in the original intentions of the legislator, should have subsequently led to the abolition of the provinces.

The aforementioned is a conception that takes for granted the identity of the function of all possible types of plans, which are distinguished solely according to the greater or lesser territorial extension of their object, and that implies, therefore, that more significant extension corresponds to more generic forecasts and vice versa. It is, moreover, well known that such a conception does not correspond to the actual reality of things, nor even to the normative reality: the abstract aspiration to the systemic order of this conception only determines a flattening of the relevance of the urban planning instruments provided for by the legal system, attributing to them an identity of function that they certainly do not have and that it is probably not correct that they should have.

Other arguments supporting the criticism of the so-called cascade planning can be found concerning the fact that some planning instruments, among those foreseen by law, may only be prepared with this conditioning of the existing ones. That is, it is possible that planning may still take place regardless of the existence of plans of a more general content and a broader territorial scope: in fact, it has commonly occurred in Italy that territorial plans have either not been prepared or have been prepared after many of those destined, according to the above conception, to a conformative and executive function. This circumstance highlights the erroneousness and the futility of the reference to the 'procedural case' in explaining the planning system at various levels.

Moreover, according to the cascade conception of planning, one is led to think that the authority competent to adopt the highest-ranking plan is first and foremost entitled to plan; therefore, originally first and foremost to the State (which should have dictated the general guidelines for the development of the national territory) but above all to the region, particularly after the entry into force of Presidential Decree 616/1977, to which is attributed the task of adopting the regional territorial plan; then to a metropolitan or provincial 'intermediate body', to which is entrusted the drafting of a specific plan for its territory and, only at the end, to the municipality, whose powers of the urban plan (however named in the various regions) cannot exceed the boundaries of the administered territory.

It is well known that post-war town planning events have shown (Campos Venuti and Oliva, 1993) that the central role of planning was assumed neither by the State nor then entirely by the regions, but precisely and above all by the municipality, considered, by the same legislative regulations, as the actual holder of the power of territorial planning to which the responsibility for the conformation of the territory and the individual properties that make it up should undoubtedly be attributed since it is the municipal level where the use of land is defined, obligatorily and with the plan.

2. A new planning season

There are many good reasons to believe that the basic principles of planning must be reconsidered and new ones sought: the current stage of society requires the activation of a new process of governance of planning, capable of involving the entire institutional system in a policy of territorial government closely anchored to subsidiarity, institutional cooperation, co-planning of structural choices, coherence and operational effectiveness of the contents of the plans.

The increasing complexity of the development processes that have characterised the last few decades calls for a change in the instruments of government and governance and their management methods. This reality requires a clear shift towards the processual and integrated nature of planning, which goes beyond the current system of hierarchically ordered 'cascade' plans aimed at controlling and regulating land use and sectoral plans drawn up by different and substantially separate institutional subjects.
What is needed is an appropriate style of government based on shared knowledge, subsidiarity (Giaimo 2022: 5), methods and procedures of cooperation and co-planning between territorial authorities, consultation and participation of public and private stakeholders. The government of the territory should, therefore, be conceived as a process capable of placing itself at the centre of a new institutional, administrative and physical-organisational model of the many territories, knowing how to renounce hierarchical and dirigiste forms and proposing itself as the product of a collaborative, participated and shared construction with the territories and their respective institutions, placing itself within a broader chessboard of challenges and opportunities.

2.1 More than thirty years of subsidiarity

Reconnecting the threads of the discourse around the principle of subsidiarity is a valuable exercise that finds a valid pretext in the thirtieth anniversary of the Maastricht European Treaty (1992).
Suppose it appears, in fact, of dramatic evidence and urgency to update a reflection on the issues of the common foreign and security policy established by the Treaty in order to safeguard common values, fundamental interests and the independence of the Union. In that case, it is equally important to observe, with reference to territorial governance, the consequences that its use has had on the process of European integration concerning the character of legislation and the exercise of competing competencies but also, in general, with respect to the distribution of competences between the Union and the Member States (De Pasquale 2021). We should not forget that Maastricht did not celebrate the 'birth' of the principle but 're-employed' its original meaning and role (the roots of which go back much further than 1992), in the conviction that with its 'codification' subsidiarity could be used as a 'brake' to limit the indefinite expansion of Union law, which would otherwise be inevitable given the primacy the latter enjoys. In this way, it could be enshrined that, in areas that are not within its exclusive competence, the Union intervenes where individual states action is insufficient to achieve the objective. Symmetrically, this principle is found within a country in the relationship between state and local institutions. In essence, the conceptual core of subsidiarity lies in the principle that a higher-level entity should not act in situations where the lower-level entity (down to the citizen) can act on its own and, in addition, that the intervention of the higher-level entity should be temporary and aimed at restoring the autonomy of action to the lower-level entity. On this aspect, we should not forget that in Italy, the historical roots of subsidiary thinking inspired the Camaldoli Code (a programmatic document of the Italian Catholic forces drafted in 1943) and the Italian Constitution of 1948 itself, even though its formal entry into the constitutional dictate only occurred with Law n. 3/2001.
For this reason, interest in the principle of subsidiarity is not limited to considerations of its relevance, given a better organisation of levels of government. However, it extends to the contribution it can provide to support a broad and conscious participation in the democratic life of a country (especially at the local level), constituting 'the tool to introduce new forms of opening of the state to civil society' (Di Giacomo Russo 2015: 139). It is particularly evident if we take into account "the cultural contributions historically underpinning subsidiarity, namely social doctrine, liberal and federalist thought" (cit.: 38). In this sense, the principle of

subsidiarity also enshrines the recognition of the right to action of individuals and social groups pursuing together the goal of the common good.
Over time, subsidiarity has thus taken two prevailing directions.
In this regard, we speak of vertical subsidiarity, which indicates a completed distribution of competencies between the various levels of a state's positive order, and of horizontal subsidiarity, which indicates the *subsidatio* role played by the public subject in support and aid of private individuals.
Reasoning along the vertical direction of the territorial governance and government, the convinced assumption of the principle of subsidiarity for the innovation of spatial planning action (and of the processual and integrated nature of planning) appears more necessary than ever to overcome the historical 'system of plans' descending from Law n. 1150/1942, which was hierarchically ordered and aimed at controlling and regulating land use transformation.
A second good reason to practise the principle of subsidiarity with conviction concerns its possible declination along the ideal-typical horizontal direction that empowers citizens (individuals and associations) to carry out activities of general interest such as the care, regeneration and shared management of common goods. From this perspective, the principle of subsidiarity sanctions the recognition of the right to action of the individual and of social groups that jointly pursue the objective of the collective interest, taking on the profile of a 'philosophy of human action' that is open to solidarity and realised in the achievement of the common good.
Within the perspective of actions of care and social welfare (welfare), subsidiarity is, therefore, an enabling condition for enhancing the system of relations that involves organisations, individuals, and institutions and intervenes in defining collective choices on functions and uses of urban space, especially that deputed to the provision of services.

3. Principles and aims for contemporary spatial planning. The INU's proposal

In concurrent legislation of the territorial governance and government, the State maintains an ostentatious disinterest concerning the dutiful formulation of a catalogue of principles adequate to the agenda of emerging themes. However, contemporary urban planning law is by no means in a weak phase: thanks to regional activism, the horizontal syncretism between the most advanced planning practices, and the interventions of the jurisprudential formant, it appears to be in the midst of a generative phase, destined to affect the planning function profoundly (Boscolo 2024, p. 9). Such adaptability does not, however, overshadow the limitations of a model with regional traction, arising first and foremost from the need for more basic ordering coordinates. It is sufficient to observe the differences between the two most recent regional spatial planning laws (Marche regional law n.19/2023 and Abruzzo regional law n. 58/2023) to grasp the effects of the lack of a common legislative-regulatory frame of reference.
Within this framework, the Italian National Institute of Urbanism (INU) proposed an articulated text (*Law of Fundamental Principles and General Rules for the Government of the territory and planning*) for a law's proposal (INU 2024). The text enunciates the fundamental principles of the subject, in line with the constitutional scheme and with the function of the orientation of regional legislative production assigned to the state law, but also indicates, as an immediate corollary that actualises those same principles, the goals to which the government of the territory and planning must aim at in the crisis (climatic-environmental and socio-settlement) and formulates a series of general rules that, although structurally distinct from the principles, should also contribute to guarantee a common basis for regional legislation. Not only the article express the regulatory criteria of future delegated legislation on the crucial issues of urban taxation and public promotional intervention in urban regeneration and dictates specific rules on the issue - debated for decades and back in the news with the revival of the debate on

differentiated regionalism - of the regulation of territorial endowments (spaces for general use, supply platforms, but also ecological spaces and equipment: to guarantee green and blue networks) and the minimum levels of services (Art. 117, II paragraph, lett. m., Constitution.) to be guaranteed in every part of the country. This contribution focuses on Art. 2 of the proposal, poignantly entitled 'fundamental principles and purposes'.

The fundamental principles of the subject matter are normative enunciations with a general content, characterised by value and deontic surplus. In this, they differ from the specific provisions found at the subordinate levels of a regulatory system. Principles constitute the immanent and stable element of a regulatory system, but (far from any fixity) they guide its constant updating due to their open structure, which allows for adherence to the underlying value dynamics of the system. Principles (in the plural) constitute the backbone of a system as they compose a combinatory palimpsest within which they balance each other and from which they cannot be isolated.

INU's proposal focuses on a catalogue of principles, recognised and already in operation, capable of providing a guideline to the accelerated mutation of the discipline and of constituting a reliable reference for the interpretation and integration of a system that evolves as a result of the incorporation of new values or instances (this is the case of the soil theme, the recognition of the essentiality of ecosystem services or the introduction of measures for adaptation to climate change). The result is a photograph of contemporary urbanism rendered comprehensible in its structural order.

In the list suggested by Art. 2 of the proposal, the only legacies of the 1942 town planning law have their place, which can be identified in the principle of integral planning of the territory and in the principle of due process as the place of balancing the various interests with the territory as the terminal. Two principles whose immanence has not prevented the redesigning and actualisation of the figure of the plan (even if there are increasingly frequent 'escapes' from the plan: not only the location of public works and plants for the production of energy from renewable sources but also the reduction to the rank of building of urban regeneration in the National Building Code, Decree n. 380/2001) and the introduction of devices aimed at favouring the broadest participation, anticipated, informed and incidental within deliberative arenas.

The proposal, therefore, recalls principles deduced in regional legislation and others to which the most advanced planning experiences are informed. The consolidation of the principle of sustainability (the background to the function of 'custodial' protection of terrestrial environmental matrices assumed by the territorial governance and government) has resulted in recognition of the essentiality of ecosystem services, in ecological continuities but also urban ecosystems; in parallel, the awareness has matured that urban fabrics guarantee urbanity services because of their capacity to guarantee quality, efficiency and inclusiveness to urban users: generative environmental systems and efficient urban systems must therefore be preserved given intergenerational transmission (in a suitably extensive rereading of the renewed Art. 9 of the Constitution.).

The reference to inclusivity recalls how the urban is the place of satisfaction (or frustration) of social rights: the principle of territorial equality moves from the consideration that large cohorts risk suffering an unjust condition of marginality due to the denial of access to rights that are infrastructurally but for some also territorially conditioned. Hence, not only the radical rethinking of the issue of standards, going beyond parametric logics and favouring proximity-oriented localisations (as better articulated by Art. 16 of the proposal that prefigures the overcoming of Ministerial Decree 1444/1968), but in broader terms also an emphasis on the need to return to active policies for the many different suburbs or internal areas, in order to guarantee equal opportunities in terms of capacity and cohesion to subjects that suffer unacceptable territorial injustices.

The principle of an adequate cognitive foundation and the correlative consistency of planning solutions recognises the centrality of the cognitive apparatus, which is also implemented as a result of participation and guarantees objective cognitive frameworks, from which a rigorous constraint on the consistency of urban planning decisions derives. A constraint that becomes stringent about the invariants that are the subject of substantially constrained ascertainment and, in any case, reduces the traditional rate of discretionality of urban planning decisions (with a consequent increase in the margins of justiciability).
The principles of equalisation and compensation reaffirm the unavoidability of overcoming the intrinsic discriminatory nature produced by the solutions of resetting areas connoted by homologous statutory characteristics and reconnect the effectiveness of actions for the public city to the overcoming of recourse to expropriation. The proposal thus allows a glimpse of an innovative principle aimed at imposing, as a legitimising factor of every transformation generating diffusive externalities, the prior compensation of impacts and pressures, with the consequent internalisation of environmental costs in the hands of the promoter (a principle that is also at the basis of redistributive devices of territorial equalisation and compensation affirmed and practised, for example, by the Metropolitan Territorial Plan of Milan and Bologna).
Concerted systems represent the alternative to the 'cascade' planning model hinged on Co-planning Conferences aimed at favouring (starting from shared cognitive frameworks) inter-institutional understandings and agreements. In such a scenario, the prospect of the principle of extrinsic coherence (no longer conformity) between the various planning levels is decisive, by which the local level instrument can contextualise and better define the solutions congruent with the effective pursuit of the objective prefigured by the supra-local plan (so-called result constraint). In not dissimilar terms, a principle of intrinsic coherence also operates between the functions and components of the plan (strategic-structural, regulatory and operational), guaranteeing flexibility and overcoming the need for continuous variants in the passage from the prefigurative level to the operational-planning level, also in this case in the pursuit of intransigible planning objectives. This is the space carved out (on the push of case law) for the negotiability of profiles that the plan (characterised by graded regulatory hardness for the consolidated city and for the tissues to be redesigned and regenerated) regulates in 'non-conclusive' terms precisely to favour (also through recourse to concurrency in the case of allocation of scarce resources), the emergence of concretely feasible solutions that can be deduced in operational agreements (referable to the genus of Art. 11 of Law n. 241/1990), not inseparable from an adequate recovery of public value.
Article 2 keeps separate from the fundamental principles the list of the aims of the territorial governance and government and its fundamental planning activity, expressed in concrete statements (semantically different from the principles), in which the echoes of the challenges posed by the crisis affecting the territories resonate clearly. The requirements of climate neutrality, energy efficiency, etc., stand out on this side, but - taking up the diptych between environmental continuity and urban fabrics and the parallelism between ecosystem services and urbanity services (which would lead one to reflect on the status of environmental and urban common goods) - the regeneration and limitation of soil consumption find articulated discipline above all. Regeneration (urban and territorial) understood in its broadest meaning, as a tool for raising the quality of settlement but also social and environmental as an expression of the recovery function of degraded contexts; the subject-soil to be framed not only in quantitative terms but - as suggested by the most up-to-date European indications that push towards an authentic cultural reframing - with attention to qualitative profiles and biodiversity and, more generally, to ecological dimensions and - again - in function of the recovery of resilience through safety programmes, as indicated by the Nature Restoration Law approved by the European Parliament in July 2023.

3.1 Focusing on urban standard

In the Italian technical and disciplinary field, it is a shared opinion (Giaimo 2019; Laboratorio standard 2021; De Leo 2021) the need to update the discipline of urban standard introduced in Italy by Decree n. 1444 in 1968, especially within the framework of law of principles on the concurrent subject of territorial government and governace (Barbieri 2023), in implementation of the reform of Title V of the Constitution (Law n. 3/2001). Today, Italy is divided into 21 territories between regions and provinces with ordinary and autonomous statutes that regulate public utilities (urban standard) in a manner that is also significantly differentiated, both in terms of definitions, approaches, and technicalities. It is also fundamental not to lose sight of the fact that in addition to the legitimate specificities on a regional legislative basis (in the application of Presidential Decree n. 616/1977), there are different levels of objective achievement of urban standards in the various regional realities, both in quantitative and qualitative terms.

More so on this occasion, the operation aimed at (trying to) clear the field of possible misunderstandings through the exercise of definitions proves to be of fundamental importance. The expression ‘urban and territorial endowments’ refers to the set of areas, buildings and public or private equipment for public use, aimed at the realisation and provision of services of public utility and collective interest, at favouring suitable settlement conditions and quality of life, of relations, of social cohesion, as well as at improving universal accessibility, quality and usability of public space. The set above of areas, buildings, and equipment may also be used for temporary uses, provided they fall within the scope of services of public utility and collective interest.

Considering the enduring criticality of the contemporary condition regarding welfare policies and citizens' wellbeing, we must acknowledge that writing the law of principles on the territorial governance and government is a good and proper opportunity to guarantee the pursuit of certain fundamental rights. Therefore, the expression 'minimum and mandatory urban and territorial endowments' should be referred to the essential level of services (ELS) concerning civil and social rights, which the State must guarantee throughout the national territory under Article 117, paragraph 2, letter m) of the Constitution.

Another issue is alluded to through the term ‘services,’ by which we mean the actions and/or works that provide something and/or perform functions to satisfy the needs of the community. The notion of ‘service’ has mistakenly led some to interpret the need for greater attention to settlement quality by assimilating Ecosystem Services (SE) to urban standards (i.e. ‘minimum and mandatory urban and territorial endowments’).

It is due to the change in the cognitive perspective of knowledge related to the ecological functions of soils, particularly in the meaning developed by Ispra (2018) based on EU Directive 231/2006. Such an approach recovers, albeit in an anthropocentric interpretation, the value of environmental resources (Full World, Daly 2005) and transforms the meaning of ‘functions’ into ‘services’, where these services respond to a direct or indirect demand for ecological services performed free of charge by Natural Capital and recognisable quantitatively from a biophysical and economic point of view.

According to the most established definitions in the literature, Ecosystem Services are ‘the multiple benefits provided by ecosystems to human race’ (MEA 2005) and ‘the contributions that ecosystems make to human wellbeing’ (CICES 2013): it is emphasised that for both definitions, the ecosystem component provided (good or function) is understood as the outcome of an ‘end product’ of ecological systems. The change of perspective introduced by ES lies in the connection between human wellbeing and ecosystem functionality, which is made evident by assuming the perspective of the beneficiaries or recipients of the services/benefits (Cortinovis, Zardo and Geneletti 2016).

The ecosystem approach, as defined by the COP 5 Working paper (UNEP/CBD/COP/5/23, 103-109, 2000), therefore, aims at quantifying the functions that natural capital performs in a more 'anthropocentric' vision, seeking to remove barriers between the human economy, social aspirations and the natural environment. The developed actions integrate ecological, social and economic information and highlight the (direct or indirect) 'benefits' that nature generates for humans to achieve a socially and scientifically acceptable balance between the priorities of nature conservation, resource use and benefit sharing.

Within this perspective, the term 'ecological and environmental endowments' is to be understood as the areas of public and private property, natural or semi-natural, that contribute to the achievement of the goals of environmental sustainability about the protection of the environment, biodiversity and ecosystems, as envisaged with the amendment of the Constitution in 2022 in Art. 9, i.e. precisely where (Arts. 1 to 12 - Part I) the fundamental principles are enunciated.

This is all the more evident when one considers that the EU Parliament approved the Nature Restoration Law on 12 July 2023. A measure proposed by the European Commission (partly contested by farmers) makes nature protection and the restoration of European habitats a legal obligation. Therefore, striving to support the ES mthodological integration in planning is even more necessary.

It has been argued (Salata 2021) that regulatory ES are best suited to support urban planning and the identification of operational priorities related to urban 'quality' and collective wellbeing about their close dependence on planned land use treatment. A public urban garden with an excellent tree-arbustive endowment can absorb much more atmospheric particulate matter than the mere lawn of a private garden. At the same time, a tree row planted in a private garden could retain much more agricultural nutrients than a small urban forest if that garden were in a run-off corridor dependent on diffuse nutrient sources.

The spatial analysis of ES can prove decisive in the structural and operational design of urban and spatial regeneration (on both public and private land), directly affecting urban quality and public health.

It is evident, therefore, that the ES are not superimposable not only to the urban standards of 1968 but also not even to an actualised conceptualisation in terms of endowment: attempting to superimpose the 'ecosystem service' to the 'urban and territorial endowment' can, especially in such a delicate moment of construction of methodologies in support of the protection of biodiversity through the integration of the ES in planning, generate great misunderstandings.

It is also intuitive that specific endowments can contribute to improving ecosystem capacities in different urban contexts (and also extra-urban contexts, mainly agricultural), as well as the fact that it is possible to characterise ecosystemically the (public and private) green spaces of cities by understanding what initiatives to adopt to make them more performing under different profiles, but it is not true that all urban and territorial endowments can generate ecosystem services.

More appropriately, it is believed that, in the formation of new urban planning tools and the revision of existing ones, municipalities should carry out, based on appropriate operational indications, a reconnaissance and quanti-qualitative verification of the actual state of areas, buildings and public or private equipment for public use aimed at the realisation and provision of services, services rendered and related performances, including those provided under agreements. It needs to be updated to reflect the resident population, the population actually present, the fluctuating population, the demographic structure, and the social composition.

All these materials must become an integral part of the documents that contribute to forming the cognitive framework of the urban and territorial planning tools for the sustainable government of the territory aimed at urban and territorial regeneration.

4. Conclusions

The law proposal put forward by the INU is a 'multifunctional' regulatory model capable of flanking the formulation of the fundamental principles and general rules of territorial government and governance with the regulation of several matters of exclusive State legislation. It also identifies those matters in which this law provides for a delegation to issue the necessary legislative decrees within the principles and timeframes defined therein. The INU's proposal regulates the scope and concept of territorial government and governance; the fundamental principles and purposes of territorial government; the tasks and functions of the State, regions and local territorial authorities; the instruments of planning and co-planning.
The law text drafted by INU presents two particularly innovative aspects: the shift from a predominantly parametric approach in the sizing of urban standards to the use of new qualitative-quantitative criteria, ensuring that the prefiguration of new urban allocations proceeds hand in hand with the introduction of the ELS (Essential Levels of Services);
the proposal of a plan form that tends to replace the principle of conformity with that of consistency progressively.
As a result of this transition, the urban planning discipline should seek substantial agreement between each new planning instrument and the objectives and addresses set by the superordinate plans.
This will achieve two effects: favouring the flexibility of urban planning instruments and reducing the recourse to urban planning variants.
These are contents and innovations to be introduced with the aim of making urban planning, at all levels, more in tune with the new challenges that the territorial government and governance must face: from the needs of ecological transition to adaptation to climate change, from the prevention of hydrogeological risk to the progressive zeroing of soil consumption.

Abstract
Land readjustment, a promising yet often underestimated approach, encounters numerous hurdles in Portugal. Like many urban centres, Braga confronts the pressing need to accommodate a growing population and economic expansion, while safeguarding urban quality.
The analysis delves into three case studies of land readjustment implemented through Execution Units, an operational planning tool. These cases underscore the challenges in balancing public objectives with private stakeholders' interests, steering legal frameworks, and achieving equitable outcomes. Despite successful collaborations and infrastructure developments in some instances, challenges persist in securing agreements, implementing comprehensive urban solutions, and fostering community engagement.
The findings emphasize the importance of adaptive policy frameworks, collaborative governance structures, and strategic planning to overcome these challenges and realize sustainable urban development goals in Braga Municipality.
Keywords: Master Plan; Braga Municipality; Execution Unit; Spatial planning

Introduction

The land readjustment process is an urban planning practice aimed at redistributing and reorganising land use in specific urban areas (Lombard and Rakodi, 2016; European Commission, 2020; Briata and Fioretti, 2023). In countries such as Spain, France, Germany, United States, and China, land readjustment is a common practice and is used for various purposes, such as infrastructure improvements, revitalisation of brownfields, creation of green spaces, promotion of affordable housing, and development of other real estate projects with public interest. “In dynamic and diverse urban contexts such as those found in Europe, effective collaboration among stakeholders is crucial for the success of land readjustment projects”, as highlighted by (European Commission, 2020). With urban areas across the country facing issues related to urbanisation and land use management, innovative urban planning strategies, such as land readjustment, are being explored as proactive tools for sustainable urban development.
Urban areas in Portugal are facing challenges akin to those observed in other European cities, encompassing land use conflicts, infrastructure provision, and environmental degradation (Freilich and Shultz, 2018; Briata and Fioretti, 2023). Within this framework, novel approaches in urban planning are imperative to navigate the intricate interplay between urban expansion and the pursuit of sustainable urban spaces (Magarotto and Costa, 2021; Schmid et al., 2024). Emerging urban planning instruments, such as land readjustment processes, endeavour to address the imperative of reorganising specific areas within urban agglomerations (Muñoz Gielen and Mualam, 2019; Schmid et al., 2024).
Land readjustment aims to redistribute and reorganize land use as a valuable tool in development areas and addressing the complex challenges of urban territory, including infrastructure needs and real estate pressure (Freilich and Shultz, 2018; Muñoz Gielen and Mualam, 2019; Schmid et al., 2024; Güngör and Polat, 2017; Samora-Arvela et al., 2017; Magarotto and Costa, 2021). In this regard, land readjustment emerges as a proactive response

to rapid urbanization and the need for more equitable and quality urban development, leading to the effectiveness of land readjustment in creating more efficient and inclusive urban spaces, promoting a better quality of life for residents (Xi et al., 2014; Fernandes and Seixas, 2018; Salvati et al., 2018; Zhang et al., 2022).

Moreover, academic research highlights the significance of land readjustment as an effective tool for fostering sustainable urban development and social equity. This perspective highlights the relevance of land readjustment not only as an urban planning tool but also as a mean to achieve broader social and economic development goals in cities.

The challenges associated with land readjustment in Braga resonate with broader global trends in urban development. The rapid development worldwide has led to increased pressure on land resources, exacerbating issues related to land use conflicts, infrastructure provision, and environmental degradation (Fernandes and Seixas, 2018; Salvati et al., 2018; Schmid et al., 2024). This states the urgent need for solutions to address the complex interplay between urban growth and sustainability.

While the theoretical benefits of land readjustment are widely recognised, its practical implementation often encounters challenges stemming from institutional, legal, and financial constraints. The success of land readjustment is contingent upon effective coordination among multiple stakeholders, including government agencies, landowners, developers, and local communities (Muñoz Gielen and Mualam, 2019). Moreover, the complex legal frameworks governing land tenure and property rights can complicate negotiations and delay project timelines on land readjustment. This legal complexity is also evident in European contexts (Muñoz Gielen and Mualam, 2019; Schmid et al., 2024). These outcomes underscore the importance of addressing institutional barriers and streamlining regulatory processes to facilitate the effective implementation of land readjustment initiatives in Braga.

In addition to addressing institutional and legal challenges, successful land readjustment in Braga must also consider the social and environmental dimensions of urban development. As emphasised by Bravo-Rodríguez and Rivas-Navarro (2021) in Spain, Condessa et al., (2015) in Portugal, Gueydan (2021) in France and Louw (2008) in Netherlands, community engagement and participatory decision-making are essential for ensuring the equitable distribution of benefits and mitigating potential social conflicts arising from land readjustment. Furthermore, proactive measures to protect natural ecosystems and enhance green infrastructure can contribute to the resilience and sustainability of urban landscapes.

Incorporating these principles into the planning and implementation of land readjustment initiatives can help Braga navigate the complexities of urbanisation while fostering inclusive and environmentally sustainable development. The aim of this study is to discuss the challenges encountered in the land readjustment process in Braga Municipality, evaluate the effectiveness of Braga's Master Plan in addressing these challenges, and propose improvements to optimise land readjustment initiatives in the future master plan. Additionally, the study seeks to explore innovative territorial planning strategies and compare them with international experiences, with the goal of providing specific recommendations to promote sustainable urban development in Braga.

Methodology
Study area

The study area encompasses the Municipality of Braga, located in the northern region of Portugal. The city of Braga is renowned for its rich history, vibrant culture, and impressive landscape, being included in the UNESCO Heritage List for its landscape value since 2019. It is situated approximately 50 kilometres northeast of Porto and about 25 kilometres east of the Atlantic coast. The city is set amidst a mountainous landscape, with fertile valleys and winding rivers, providing a unique natural environment for urban development.

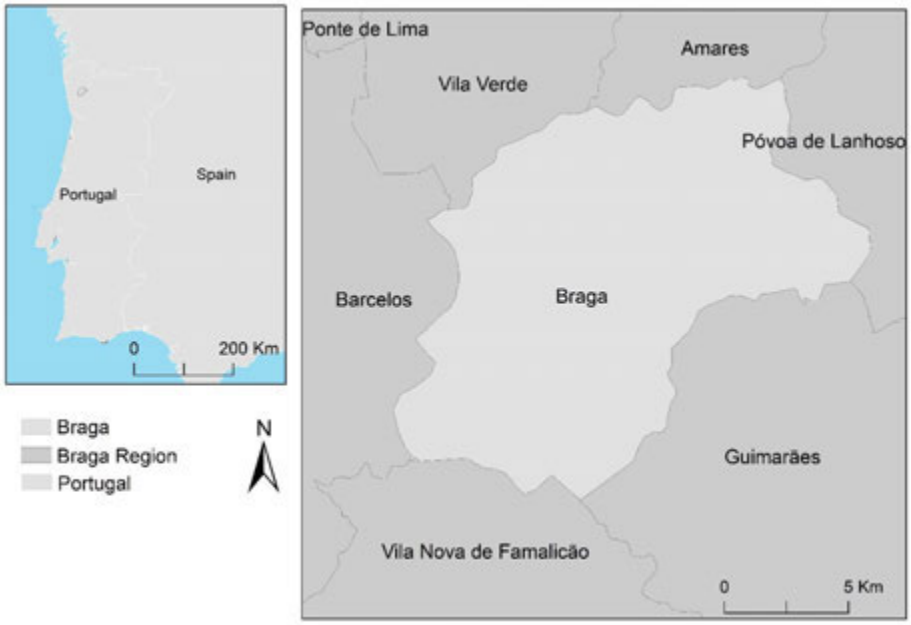

Figure 1 – Braga Municipality. Source: Own elaboration

Being one of the few municipalities in Portugal with population growth between 1991 and 2021 (6%), the increase in housing prices in Braga has emerged as a pressing challenge for residents and the city's economic industrial cluster. In tandem with this scenario, a significant reform of the Portuguese planning system has taken place, particularly focusing on the implementation of territorial management instruments. This reform has spurred the development of enforcement tools aimed at ensuring a coherent spatial planning framework. This transition is exemplified by Decree-Law no. 380/99, dated September 22, which introduced a new implementation entity alongside the traditional “loteamentos”, known as “unidades de execução”.

After decades of stagnant prices, juxtaposed with the expansive urban land traditionally delineated within the ambit of initial planning generations, this trend has recently sparked concerns regarding housing affordability. Many families now grapple with the challenge of securing suitable accommodation at reasonable prices. Additionally, the escalating land prices for economic activities in Braga present a significant challenge for both existing businesses and prospective investors. The economic expansion in Braga in the last decade increased demand

for industrial land, driving up prices due to heightened competition among businesses. As a result, it is crucial for local authorities and stakeholders in the real estate sector to proactively address this issue, seeking solutions that promote equity and fair access to land.
To explore the challenges and potential of land readjustment in Braga Municipality, we focused our study on three specific cases. Among the few cases already decided by the city council, we chose this set of cases for their significance and relevance to land readjustment scenarios. By examining these cases, we aim to gain valuable insights into the processes, obstacles, and results of land readjustment, aligning with the objectives of our study.

Data Collection

The data collection process involved analysing relevant literature and documentation concerning land readjustment cases in Europe, Portugal and the Municipality of Braga. Initially, an extensive review of existing literature on land readjustment, urban planning, and sustainable development was conducted. This literature review focused on practices and experiences related to land readjustment cases, in countries with wider experience and contexts somehow related to the Portuguese framework. Through this analysis we identified trends, challenges, and best practices associated with land readjustment, providing a robust theoretical foundation for the study.
In addition to the literature review, official government documents, land readjustment project reports, and other pertinent materials pertaining to specific land readjustment cases were examined. These documents included urban development plans, zoning regulations, and project reports, all of which are publicly available.
Analysing these documents yielded insights into the objectives, strategies, implementation processes, and outcomes of land readjustment cases in Braga.
The combination of these data collection methods facilitated a comprehensive understanding of land readjustment cases, complementing the ones in the Municipality of Braga, and laying a solid foundation for the analysis and interpretation of study results.
However, it is important to acknowledge the limitations of this study. One limitation is the restricted availability of land readjustment cases in Braga, which may have influenced the depth of the analysis and the comprehensive understanding of each case's specific contexts. Additionally, given the predominantly qualitative nature of the approach used, there is a potential for bias in interpreting the results, as the conclusions are based on subjective interpretations of the collected data. These limitations emphasise the need for caution when generalising the findings and underscore the importance of future research to further investigate specific aspects of land readjustment in Braga.

Land Readjustment in the European Context

Despite the inception of the modern concept of land readjustment in the first half of the 20th century in Europe the tangible outcomes of land readjustment processes have only begun to materialise recently within the planning framework (Condessa et al., 2015). This delay is primarily attributed to reforms associated with decentralisation and the simplification of the planning process (ESPON, 2018). In land readjustment, the generated public value typically manifests as green spaces, infrastructure, social housing, and facilities. These outcomes are realised through instruments that vary significantly among countries (van der Krabben and Needham, 2008; Hartmann and Spit, 2015; Muñoz Gielen, Maguregui Salas and Burón Cuadrado, 2017).
For a brief overview of the European landscape, we explore the land readjustment tools in France and Spain, both of which have experience in applying such mechanisms and have

notably influenced the Portuguese system (Condessa et al., 2015). This influence stems from the administrative heritage of the two countries, particularly the Napoleonic tradition (Newman and Thornley, 1996; Pollitt, Thiel and Homburg, 2007).

These countries are known for their rigid planning structures, which are mainly hierarchical and involve significant state interference in all planning processes (Organization for Economic Cooperation and Development, 2017).

France stands out due to its long tradition in this field, dating back to 1803 when landowners were encouraged to collaborate for spatial planning actions (Gueydan, 2021). This historical context offers unique insights into the evolution and implementation of land readjustment practices compared to other countries. However, it was only in 1967 that the association foncières urbains became a legal tool, established by the Code de l'Urbanisme (Law 67/1253 of Decembre 30th, 1967). This tool, still in force today, coexists with traditional forms of urban management like licensing. The creation of association foncières urbains (where land parcelling is deliberated) allows for the subsequent development of a zone d'aménagement concerté.

Typically, these tools involve land parcelling and subsequent urban design (Vacher, 2014; Hartmann and Spit, 2015), underpinned by a complex legal framework aimed at providing clarity and facilitating interaction between public and private landowners (van der Krabben and Needham, 2008). The initiation of the land readjustment process commonly relies on both cadastre and urban design, a consistent practice observed across the identified cases. These characteristics are also associated with active involvement from planning authorities (Hartmann and Spit, 2015; Muñoz Gielen, Maguregui Salas and Burón Cuadrado, 2017) and operational urbanism, which became more prominent in the planning landscape with the integration of neoliberal ideals. In this paradigm, the State delegates competences to the private sector and lower levels of administration to pursue their interests and address bureaucratic hurdles that impede public action (Alonso, Clifton and Díaz-Fuentes, 2015; Gray and Kallin, 2023).

While significant, it's noteworthy that land readjustment isn't the prevailing approach to development management in these countries. Instead, licensing, and isolated actions of rehabilitation and building tend to take precedence. This dynamic exists within a legal framework where the rights of private ownership are constitutionally established (Condessa et al., 2015).

Despite extensive literature on land readjustment, specific cases are not deeply-described in scientific literature (Condessa et al., 2015) and are challenging to compare (Louw, 2008). Nonetheless, we address five significant cases in France and Spain that either contributed to the discussion or suggested improvements to the case studies of Braga.

In Spain, the expansion of the AVE (*Alta Velocidad Española)* network and the development of Murcia's airport contribute to enhancing the metropolitan area, which faces challenges in establishing its position within the territorial hierarchy. Land readjustment processes have been reported as crucial in securing land reserves and achieving the primary objectives of the municipal plan, which has been in place since 1985. In Murcia, urban development primarily relies on local plans or detailed studies, with detailed studies being predominant: out of 550 planning processes, 486 were conducted through detailed studies, while only 117 were through execution units (Moncada-García, 2022).

Another notable case in Spain concerns Granada, where at the beginning of the plan implementation, the municipality adopted a strategy of collaborating with the private sector by abdicating the allocation of land reserves for public use. Since the beginning of the century, the approach has shifted, and planning authorities have guaranteed land provision to ensure social cohesion, as by the establishment of two sports pavilions reported by Bravo-Rodríguez and Rivas-Navarro (2021).

In France, the Les Charmes du Petit Bois case initiated a land readjustment process to facilitate the provision of social housing. Landowners were to sell their land to the agence foncière urbaine if they lacked interest in participating in the development process. Forty percent of them opted to sell their parcels, thereby enhancing the attractiveness of the urban development project. Public investment was implemented in stages (Vacher, 2014).

Similarly, in the case of ÉcoQuartier La Baudière, land readjustment aimed to mitigate undesirable urban density in a rural setting and establish facilities to alleviate the impacts of low density. The revision of higher-level plans facilitated the construction of green spaces, and public investment followed a phased approach (Vacher, 2014).

The third French case, Marne Europe, aimed to anticipate externalities generated by a metro station to consolidate urban space, illustrating the versatility of land readjustment in addressing different scales and purposes. The objective was to remediate a brownfield as part of the Grand Paris Express Projet (Mouton, Guelton and Poinsot, 2024).

The objective of this paper is not to offer an in-depth analysis of these cases and as, such, additional details are summarized in Table 1. It is noteworthy that these cases have some

common grounds. First, there is a strong subjacent public aim. These processes have been instrumental in securing land reserves, facilitating social housing provision, mitigating undesirable urban density, and anticipating externalities generated by infrastructure projects. Also, municipalities play a pivotal role in all cases, either by facilitating the execution of planned initiatives or by creating the necessary fiscal, legal, and expertise conditions for private landowners to pursue their intentions.
Overall, all these cases underscore the importance of context-specific planning approaches, the need for innovative solutions to urban challenges, and the role of collaborative efforts between public and private stakeholders in achieving sustainable urban development.

Land Readjustment in Portugal

While urban planning is constitutionally designated as a public responsibility, private developers have largely dominated its implementation in recent decades in Portugal, with recognised constraints for adequate urban development. In response to this prevalent practice, the principle of equity was introduced by a wide legislation reform in 1999 (by Decree-Law no. 380/99 of 1999 - Legal Framework of Planning Instruments – RJIGT). This piece of law mandated that municipal plans incorporate compensation procedures to ensure a fair redistribution of benefits and costs among property owners and between them and the local government. Municipal Master Plans are therefore required to delineate general criteria.
Land adjustment implementation occurs within specific territorial units known as Execution Units. According to RJIGT, "the Municipality promotes the coordinated and scheduled execution of territorial planning, with the collaboration of public and private entities, carrying out infrastructures and equipment according to the public interest, objectives, and priorities established in intermunicipal and municipal plans, using the means provided for by law" (cf. Article 146).
This process entails identifying the physical boundaries of the area intended for urban development and identifying all property owners. These boundaries are delimited by the municipality on its own initiative or at the request of interested owners (cf. Article 147 of RJIGT) and are subject to a period of public discussion on terms analogous to those foreseen for Detailed Plans or Urbanization Plan.
Each Execution Unit must specify the extent of municipal administration involvement in the process. To uphold the principle of equitable redistribution of benefits and costs, three distinct execution systems are outlined: compensation, imposition, and cooperation (Condessa et al., 2015).
In the compensation system, private stakeholders, such as landowners and developers, take the initiative to develop the urban layout, provide necessary infrastructure, and determine the distribution of costs and benefits among all involved parties, including the municipality. Moreover, they are obligated to compensate the municipality, often through the allocation of land parcels for public use or payment of taxes, in accordance with municipal regulations. The municipality retains the authority to approve, modify, or reject the proposal based on legal provisions outlined in municipal plans and regulations.
In cases where the local government spearheads Execution Unit projects, landowners' participation is typically compulsory, although full consent may not always be legally required. Under the imposition system, the municipality undertakes urban execution directly or by setting agreements with private developers.
Conversely, in the cooperation system, the municipality initiates the process and collaborates with private stakeholders voluntarily or at the municipality's instigation.
In both cooperation and compensation systems, the definition of specific mechanisms to ensure equity among all parties involved and support compensation, whether in the form of cession of

land or currency, is crucial. This stage is where the principles of equity, transparency, and fairness are conceptualized.
Nevertheless, local authorities and private stakeholders retain the legitimacy to define additional mechanisms, provided they adhere to the principle of equity.
The rights and obligations of the parties are defined by an urbanization contract as defined in, specifically aiming at (a) establishing the rights and obligations of the parties involved in the execution unit; (b) specifying the obligations of the parties involved regarding the execution of urbanization works, the responsibilities they are subject to, and the deadline for compliance; (c) outlining the formalization of the transfer to the Municipality of the areas to be relocated by private parties for infrastructure purposes (Articles 148 and 150 of RJIGT).
Land readjustment in Portugal has indeed faced numerous challenges, resulting in few successful cases being delivered. Despite its potential, there is a scarcity of literature on the subject, indicating a lack of comprehensive understanding and documentation of land readjustment initiatives in the country. Additionally, municipalities grapple with the implementation and effectiveness of execution units, which are intended to facilitate urban development projects. This struggle underscores the complexity and obstacles inherent in land readjustment processes, highlighting the need for further research, effective governance, and innovative strategies to overcome existing challenges and promote sustainable urban development.

Braga Municipality cases

Land readjustment processes in Braga Municipality are relatively recent, having been incorporated since the 2015 version of the Master Plan (Notice No. 11741/2015 of October 14). It represents the third iteration of Master Plans in Braga, following versions from 1994 and 2001.
The current zoning of Braga Master Plans includes 40 Unidades Operativas de Planeamento e Gestão (UOPG), where Execution Units delimitation is mandatory unless specific requirements outlined in Article 99 of the Master Plan regulation are met. These requirements stipulate that a development project must be proven to be the most appropriate solution, not harm the environment or significantly compromise any possible integrated solutions with adjacent land, not compromise the potential application of land readjustment mechanisms to adjacent plots and have the necessary infrastructure provisions such as access to public roads, water supply, and sewage systems, within a specified distance from road.
The UOPG cover a total area of 3371 hectares, representing 16% of the municipality's territory. They vary in size, with the largest covering 807 hectares and the smallest 7 hectares, with an average size of 33.84 hectares. Execution Units may encompass sub-areas within these larger UOPG, with specific limits to be decided and approved by the city council.
As of April 2024, the Braga City Hall Council had approved five Execution Units under the provision of the Master Plan, while three others were awaiting final decisions after the public participation period. All these units were initiated under private initiative, and none required the distribution of charges and benefits. This lack of requirement stemmed from either having a single owner or alternative agreements in cases where there were multiple owners.
More recently, the Braga Municipality has undertaken additional land readjustment initiatives under the *Plano de Urbanização das Sete Fontes*. This plan, published in 2022, encompasses 26 execution units and includes detailed urban design and land readjustment procedures. It aims to create a large park surrounding the historic water supply system to Braga City, dating back to the 18th century, covering 30 hectares, and featuring various amenities.

While the land readjustment within the Sete Fontes Plan presents interesting dynamics, its highly specific context sets it apart from land readjustment cases governed by the Master Plan. Consequently, the Sete Fontes Plan will not be examined within the scope of this paper.
The paper conducts an analysis of three land readjustment cases within Braga Municipality outlined by the Master Plan. These cases were selected based on their representativeness and complementary nature, allowing for an elucidation of primary challenges, stakeholder perspectives, and resultant outcomes. Despite not necessarily being considered successful from the authors' standpoint, these cases are viewed as initial efforts aimed at transcending prevailing development approaches and addressing challenges in integrated planning practices.

Lomar Unit

The Lomar Unit project began in 2017 as the first of its kind in Braga. It was initiated to support the expansion of Bosch, the municipality's main industry, which employs around 5,000 people and generates two billion euros in revenue annually. Bosch has invested in land acquisition and proceeded with the construction of a new building for production infrastructure and offices, a new cafeteria, and a new parking lot, reinforcing human resources with the creation of 1,000 full-time positions, totalling an investment exceeding 36 million euros (CM-Braga, 2017).
The Execution unit is part of the UOPG 25 – Parque Oeste e envolvente – Ferreiros, a major UOPG located in the South-West part of the city of Braga. Its main objectives include enhancing the Este River by creating a park along its banks, structuring the road network to facilitate the expansion of industrial zones and the organization of economic activities, providing the area with general infrastructure, notably the South Wastewater Treatment Plant, and ensuring adequate coordination with existing urban clusters (Article 110 of Master Plan regulation). According to the same document, this Execution Unit should be ensured through a system of cooperation. The Municipality of Braga considered there to be an unquestionable public interest in the execution of urbanization works (such as road, parking spaces and sidewalks) that can ensure appropriate use for economic activities, as well as recognised the interest in supporting and promoting investment projects that are pivotal for the municipality's economic development.
The preliminary proposal for the execution unit limits approved in June 2017 was enlarged, after the participation of three neighbouring landowners during the public hearing period. The final proposal required cooperation from the municipality and the seven landowners, who held property of the 15 parcels of land within the Execution Unit limits. After adjustments, it was approved in November 2017.
The urbanization agreement among the stakeholders took place in September 2019 and aimed to regulate the relations between the parties involved and establish the terms and conditions of their participation, through a cooperation system, in the partial execution of UOPG 25.

Figure - 2: Lomar Unit final proposal. Source: Braga Municipality website (CM-Braga, 2024)

The agreement foresees three stages of implementation. First phase comprehended a construction of the road and Bosh buildings. Phase two regarded another stretch of road and building the parking area. Both these phases are concluded and in use, as shown in aerial photographs (Figure 3). Third phase foresees the construction of a local access to a local (to be built) park in the west limit of the Execution Unit and is not yet complete.

Despite being an interesting and successful example, we can point out that the only executed infrastructure was dependent on a single company, with high interest in the development. The remaining part, subject to investment of other private owners and the municipality has not yet been undertaken, revealing difficulties in implementing upon the need to conciliate different landowners.

Figure - 3: Current situation of Lomar area. Source: Aerial view of 2021 (DGT, 2021)

Quinta da Mata Unit

The Quinta Mata Unit was established in response to the Municipality's urgent need to construct the South Wastewater Treatment Plant. This facility is essential for augmenting the city centre's sewage treatment capacity, which has been strained by recent urban growth. Consequently, there is a significant public interest in defining the boundaries of the Execution Unit and ensuring prompt land allocation. The initiative has been spearheaded by the Municipality in collaboration with AGERE, the local company responsible for water and sewage management. The proposed urban project entails the construction of industrial pavilions, in accordance with the zoning regulations outlined in the Master Plan. Meeting the maximum index is imperative as it guarantees the allocation of land required for the sewage treatment station. Additionally, the urban design necessitates the construction of a new road in the southern part of the unit to facilitate connectivity with the local road network. Despite extensive negotiations with the landowner, consensus on the allotment design has not yet been achieved.

It is noteworthy that, under Portuguese law, the approval of execution unit delineation does not hinge on the acceptance of landowners. However, as seen in the Lomar case, a public hearing is conducted, allowing citizens to participate. If any landowner within an execution unit opts out of the land readjustment process, the municipality is obligated to initiate expropriation proceedings and assume their duties and rights. Nonetheless, the provision of land for infrastructure, equipment, and green areas can only be realized upon reaching a land adjustment agreement, typically through replotting or joint allotment, followed by land registration.

In this case, although expropriation is a viable option, the municipality has refrained from initiating procedures in anticipation of reaching an agreement. Given that expropriation processes tend to be protracted, the municipality risks missing funding deadlines if an agreement is not reached in time. In Braga, as in Portugal generally, expropriation is considered a last resort due to various structural challenges. These include the inefficiency of the legal

system, the absence of a standard method for evaluating land value (leading to potentially high payments by public authorities), and the complexity of legal procedures. This aligns with Condessa's observation that a lack of a reliable land valuation mechanism integrated into the planning process is a major pitfall of land readjustment initiatives (Condessa et al., 2015). Consequently, in Braga municipality, expropriations are infrequent, and efforts are made to secure agreements whenever possible.

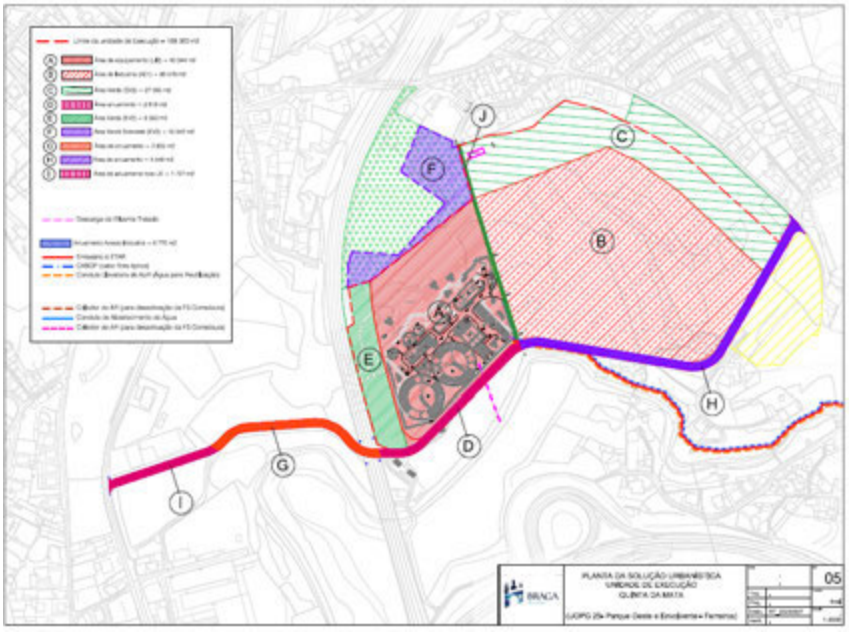

Figure - 4: Quinta da Mata final proposal; Source: Braga Municipality website (CM-Braga, 2024)

Alto da Vela Unit

The Alto da Vela Unit had its preliminary version approved on November 2023 and the final limit on March 2024. The project includes the provision for 24 detached housing units, supported by a winding road adapted to the hilly location. Initially, it encompassed two landowners, but the owner of the major parcel acquired the smaller one to avoid negotiating. This is a recurrent situation. In fact, five out of the eight execution units in Braga Municipality today have a single owner, despite including several parcels. This may be explained by a reluctance to deal with partners in development projects but also denotes a high acquisitive capacity from local companies.

Figure - 5: Alto da Vela final proposal. Source: Braga Municipality website (CM-Braga, 2024)

The urban infrastructure for Alto da Vela is, from our perspective, not entirely satisfactory. The new road is a continuation of an existing one (which supports the construction of seven detached houses) but fails to ensure a connection with the existing local road further north. A new execution unit is expected to fill that gap. However, there is no guarantee on the timing of that development, leaving the Braga territory with yet another dead-end road.

The lack of road terminations is a highly common outcome from the past years' policy of development in Braga Municipality, often limited by the cadastre, enhanced by the new roads indicated in the Master Plan, and the lack of proper land management. The Master Plan design has contributed to this situation by "drawing" many new roads on the zoning plans. As developers frequently report that reaching agreements with neighbours is not possible, the municipal management has allowed bits of roads to be started without the guarantee of connections (see examples in Figure 5).

The Alto da Vela Execution Unit was successful in assuring two pieces of land to be joined, but it does not provide what we believe is one of its main objectives – to provide a comprehensive road structure and connections to the local network. Despite having gone through all the formal procedures of an execution unit, in our opinion, it fails to deliver an adequate urban solution. This proves yet again the municipality's fragile capacity for negotiation and its ability to be firm on objectives. Despite its pitfalls, this is an example has representativeness among current practice.

Figure - 6: Example of dead-ends in Braga, highlighted in yellow.

The lack of road terminations is a highly common outcome from the past years' policy of development in Braga Municipality, often limited by the cadastre, enhanced by the new roads indicated in the Master Plan, and the lack of proper land management. The Master Plan design has contributed to this situation by "drawing" many new roads on the zoning plans. As developers frequently report that reaching agreements with neighbours is not possible, the municipal management has allowed bits of roads to be started without the guarantee of connections (see examples in Figure 5).
The Alto da Vela Execution Unit was successful in assuring two pieces of land to be joined, but it does not provide what we believe is one of its main objectives – to provide a comprehensive road structure and connections to the local network. Despite having gone through all the formal procedures of an execution unit, in our opinion, it fails to deliver an adequate urban solution. This proves yet again the municipality's fragile capacity for negotiation and its ability to be firm on objectives. Despite its pitfalls, this is an example has representativeness among current practice.

Discussion & Conclusions

The analysis of three distinct cases of land readjustment within Braga Municipality provides valuable insights into the complexities and challenges inherent in urban development initiatives. These cases offer a comprehensive view of the varied dynamics and outcomes associated with such projects as we also verified with the European examples.
The cases in Braga do not present significant indications of community involvement, despite the mandatory public hearing periods stipulated by law. Similar challenges are observed in the European examples. On one hand, there is recurrent situation of a single landowner in land readjustment process and on the other hand processes that involve several landowners have difficulties in meeting their end (as in the Lomar case). This is an aspect, the outcome could benefit from improved communication, (as well as fiscal, juridical, and policy changes) to

attract private landowners to collaborate more closely with the planning authorities. However, this scenario differs significantly from European cases where most of the processes progress independently of the number of owners. We believe this is primarily due to the strategic and public objectives associated with these operational tools in spatial planning instruments. This process implies a high level of information, and the cases suggest that Portuguese landowners may not yet have the skills to understand and recognize the benefits for themselves, others, and the collective. This aspect is considerably relevant due to the recent introduction of land readjustment tools into the daily planning practice. The longevity of land readjustment in the national context seems to have a significant impact and Portugal is quite a youthful player in this matter, namely compared to other European counties.

The examination of the case studies also highlights a tendency of the municipality to prioritize procedural fulfilment over the pursuit of urban solutions of sufficient quality. Land readjustment is frequently approached as a mere obligation rather than an opportunity to guarantee optimal urban solutions.

Across all cases, the tension between public interest objectives and the interests of private stakeholders is evident. While projects like the Lomar Unit demonstrate successful collaboration between the municipality and major industry players, challenges arise in reconciling diverse interests and ensuring equitable outcomes for all stakeholders. The municipality's need to address pressing infrastructure requirements, such as the South Wastewater Treatment Plant in the Quinta da Mata Unit, underscores the imperative of balancing public utility needs with private property rights.

Negotiating agreements among multiple landowners and coordinating diverse stakeholder interests emerge as significant challenges in all the cases under study. The delays and obstacles encountered in reaching consensus on infrastructure provision and land allotment design highlight the complexities of navigating legal frameworks and competing priorities. Despite legal provisions for land readjustment processes being met, as seen in the Alto da Vela Unit and in European examples, challenges persist in securing agreements and ensuring timely project implementation.

Another common thread across the cases is the inadequacy of infrastructure planning and implementation, particularly regarding road connectivity and comprehensive urban solutions. While certain infrastructure components, such as road construction and building developments, have been realized in the Lomar and Quinta da Mata Units, challenges remain in achieving seamless integration with existing urban networks. The fragmented road network and lack of connectivity, exemplified in the Alto da Vela Unit, reflect broader issues in municipal negotiation capacity and urban planning effectiveness. The European cases appear to concur that the urban project must be interdependent with the surroundings.

Conclusions point out that while land readjustment holds immense potential for transforming urban landscapes and fostering sustainable development in Portugal, overcoming these challenges is paramount. Addressing fragmented land ownership, streamlining regulatory processes, securing funding, and fostering community support are essential steps towards successful land readjustment projects in the country. In addition, strengthening the legal bases governing land readjustment is imperative to promote investor and community confidence.

The cases underscore the importance of collaborative governance structures and strategic planning in navigating the complexities of urban development. Effective coordination among stakeholders, transparent negotiation processes, and proactive engagement with the community are essential for addressing diverse interests and achieving sustainable outcomes. The success of projects like the Lomar Unit highlights the potential for fruitful collaboration between the municipality and private sector entities in driving economic growth and infrastructure development.

Addressing the challenges identified requires adaptive policy and legal frameworks that facilitate streamlined decision-making, expedite project approvals, and ensure equitable outcomes for all stakeholders. Proactive measures to streamline land readjustment processes, clarify legal requirements, and provide support for negotiation and dispute resolution can enhance the efficiency and effectiveness of urban development initiatives.

Investing in integrated planning approaches and prioritizing infrastructure development are critical for addressing the evolving needs of growing urban areas. Comprehensive strategies that emphasize connectivity, sustainability, and community engagement can help mitigate infrastructure shortcomings and foster inclusive and resilient urban environments.

The analysis of land readjustment initiatives within the Municipality of Braga provides valuable insights into the complexities of urban governance and the challenges of translating intentions into tangible outcomes. By acknowledging the importance of community engagement, skills development, and policy adaptation, the Municipality of Braga can design the next Master Plan with more suitable tools. Consequently, these cases serve as significant milestones in the municipality's journey towards transcending traditional development approaches and realising its vision for a prosperous and inclusive urban future.

Abstract: Spatial planning entails the adept control and scientific management of national territorial space a task crucial for achieving a balance between development and conservation.

In 2019, China initiated a spatial planning framework. This reform stands as a milestone, showcasing significant innovation in planning concepts, technical methodologies, and management systems in China over recent decades. This paper first reviews the pre-reform landscape, including the diverse planning types, prevalent issues, and experimental endeavors. Subsequently, it delineates the principal measures undertaken in China's national territorial spatial planning, encompassing aspects such as institutional management, systematic composition, compilation content, and technical methods. Lastly, it discusses the consequential shifts in objectives and goals within the realm of national territorial spatial planning objects and goals. China's spatial planning reform offers valuable insights for nations and regions grappling with the challenges of global climate change and aspiring for sustainable development.

Keywords: Spatial planning; National territory spatial planning; Planning reform; China.

1. Introduction

Spatial planning originated within the context of European integration. In the 1960s, strategic spatial planning was elevated as the conventional approach for urban and regional planning in Europe (Liu and Zhou, 2021, p.1). The European Spatial Development Perspective (ESDP), issued in 1999, was a quantum leap in the practical application of spatial planning (Rivolin and Faludi, 2005, p.196). The European Commission (1999) concluded that regional development was propagated through coordinated spatial policies, enhancing economic, social, and environmental harmony. Subsequently, governments and their planning communities across European Union countries began implementing spatial planning in practice (Yu, Cheng and Jiang, 2020, p.16). Spatial planning is considered a vital public policy for rational land resource allocation and orderly spatial structure layout in most countries globally (Medeiros, 2019, p.172; Trkulja, Tosic and Zivanovic, 2012, p.1729). It has become a fundamental institutional framework for addressing the challenges of spatial development and governance, especially in an era of economic globalisation (Zhang, Man and Zhang, 2023, p.1). The specific content, organisational methods, hierarchical systems, and other aspects of spatial planning vary among countries by being tailored to their socioeconomic development and national characteristics. However, they typically exhibit strong systematic and continuous features, ensuring comprehensive planning and management coverage of their territories. Spatial planning plays a significant role in the comprehensive coordination of national or regional political, economic, social, and ecological elements.

During the early 21st century, as China evolved, it progressively formulated methods in spatial planning, including urban-rural planning, land-use planning, main functional zone planning, etc. The implementation of these plans has propelled the rapid urbanisation process. However, in recent years, China has faced challenges such as global climate change, slowing urbanisation rates (Niu et al., 2024, p.24), negative population growth (Cheng and Guo, 2023, p.102), and environmental pollution (Yang, Xing and Jones, 2019, p1; Cai, Wang and Li, 2023, p.76). Due to limited resources and environmental carrying capacity, the government must utilise inventory resources and attain sustainable development. The previous approach to incremental development, predominant during China's rapid urbanisation, and managed by

various departments, is no longer suitable for the current national situation (Song et al., 2024, p.10). Against this backdrop, in March 2018, part of the institutional reforms in China was establishing the Ministry of Natural Resources (MNR). This ministry was tasked with establishing a spatial planning system while overseeing its implementation, marking the most significant spatial planning reform in China's history. "The Opinions on the Establishment and Supervision of the Implementation of the National Territory Spatial Planning System" (hereinafter referred to as the "Opinions") released in May 2019, proposed the establishment of a "top-level design" for the National Territory Spatial Planning (NTSP) system and its supervision (the Central Committee of the Communist Party of China and the State Council, 2019). This launched the comprehensive implementation of spatial planning reform nationwide. In 2022, the first national-level comprehensive implementation of "multi-planning integration" for overall plans was executed. The plans of 31 provincial-level regions in mainland China were submitted to the State Council, with 14 consented to. The authorizing bodies have received over 90 percent of the 350 municipal-level overall plans and 2,220 county-level overall plans nationwide, with the majority having completed the review process. Some municipalities and counties are receiving approval gradually. Overall, a unified and scientifically efficient NTSP system was formed nationwide. In an era of ecological civilisation, this newly established NTSP system is a plan that induces high-quality development and coordinates the protection and development of space. It also follows the requirements of strategic guidance and rigid control, achieves integrated urban-rural development, and coordinates the allocation of comprehensive territorial elements. It aims to address issues such as overlapping scopes and conflicting content among various previous plans, strictly adhere to the bottom line of food security, ecological security, and national security, and achieve high-quality development and life in urban and rural areas. It realises the organic integration of various spatial planning such as economic and social development, urban and rural construction, land use, ecological environment protection, forestry, water conservancy, transportation, and marine affairs.

Recently, NTSP has been a focal point of Chinese societal attention and a hot topic of discussion in the domestic planning academic community. However, due to being in a continuous process of reform exploration, there has been relatively little research on it internationally. After nearly six years of practice, the reform of China's NTSP has yielded phased achievements. In this context, this study systematically reviews the progress of China's NTSP reform and summarises its practices and characteristics. The aim is to provide a reference for countries or regions facing global climate change challenges and needing sustainable development.

2. The Origin of China's NTSP Reform

2.1 China's Spatial Planning Types Before the Reform

Most developed countries coordinate and guide spatial development through integrated spatial planning systems. Dissimilar to this, this is determined by China's institutional characteristics and basic national conditions. Before the NSTP reform, there were multiple plans instead of a strictly unified national spatial planning system. According to incomplete

data, over 80 types of plans, which the traditional spatial planning system incorporates, have a legal basis (Li et al., 2020, p.63). Each plan serves a different purpose. Amongst various types of plans, strategic, land and resources, ecological and environmental, urban and rural construction, and infrastructure (Figure 1), may serve the purpose of strategic guidance, resource protection and utilisation, construction, and development. The content is diverse but not well-structured.

Per laws, regulations, and national government documents, spatial planning with clarity and extensive influence include urban-rural planning, land-use planning, main functional zone planning, and eco-environmental protection planning. They are managed by the Ministry of Housing and Urban-Rural Development, the former Ministry of Land and Resources, the National Development and Reform Commission, and the former Ministry of Environmental Protection respectively. Based on China's administrative division system, spatial planning is split into national, provincial, municipal, county, and township administrative levels, Conclusively, due to a lack of consolidation and disorderly nature, the coexistence of multiple plans with "each doing its own thing" has led to prominent issues.

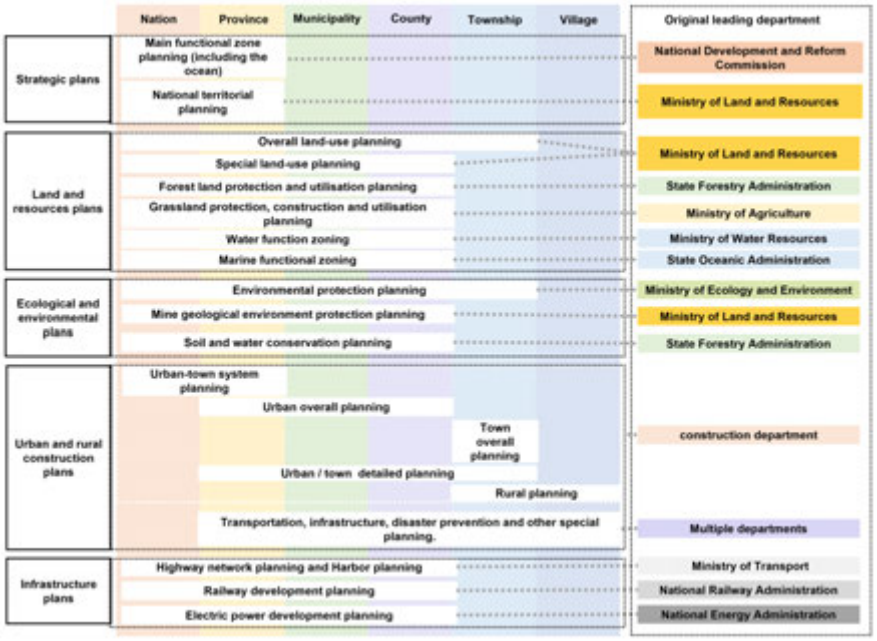

Figure 1: Traditional spatial planning system in China

2.2 China's Spatial Planning Issues Before the Reform

Before the NSTP reform, many spatial planning types with overlapping and conflicting content existed. Over 80 different types of plans corresponded to various administrative levels. They were managed by different departments, had different preparation and approval authorities, and were based on different laws and regulations. They also held different legal

statuses, and used different technical standards, making coordination and alignment challenging. Additionally, there were often significant disparities in objectives, content, and outcomes due to the diverse values and focal points. Prominent issues of functional overlap and content discord ensued among different plans.

The approval processes for various plans were complex, lacking overall coordination among management departments. Due to the leadership of several administrative departments, institutional and structural obstacles existed operationally in spatial planning at all levels. During the administrative review, different approval authorities, procedures, and focus areas led to a more prolonged coordination process. Furthermore, by statute and administrative documents, administrative powers to allocate land development rights were granted to different planning departments, thus creating independent approval authorities between departments and a lack of coordination.

Disorderly growth caused by the absence of long-term effective guidance in Urban development stems from the frequent changes in local plans caused by the lack of a planning authority. The "priority of superior power" feature of China's governance system, ensures that higher-level governments possess more authority. Higher-level plans serve as a basis for lower-level plans, with higher-level departments authorizing approval and supervising the implementation of lower-level plans. Higher-level plans often lack strategic and policy guidance. Thus, when lower-level plans try to imitate them, they lack operational and adaptive strength. At the same time, there is a phenomenon where lower-level plans tend to prioritise their interests, magnify the scale of development incrementally, and adjust layouts accordingly to the detriment of the higher-level plans' frameworks.

The foundational data for various plans lack uniformity (Liu, Zhan and Liu, 2019, p.51), with discrepancies in geographic coordinate systems, making it difficult for plans to connect. Cities like Guangzhou, early adopters of the "multi-planning Integration" approach, objectively face this challenge. Consequently, it is crucial to establish a unified coordinate conversion platform and a unified data infrastructure platform to achieve the conversion of different geographic coordinate systems and unify the spatial basic parameters of multiple plans. This would facilitate the subsequent planning and implementation of the "multi-planning Integration."

2.3 China's Exploration of " Multi-Planning Integration " Before the Reform

In the 1990s, prior to the NTSP reform, local cities like Shanghai conducted voluntary exploratory experiments, integrating different tiers of plans independently. In 2014, this evolved into pilot projects executed in 28 cities and counties selected by the National Development and Reform Commission, the Ministry of Environmental Protection, the Ministry of Land and Resources, and the Ministry of Housing and Urban-Rural Development. This initiated research on the "multi-planning Integration" scheme for economic and social development planning, urban-rural planning, land-use planning, and eco-environment protection planning. For the duration, a plan served as the core with other plans complementing it. It comprised three schemes dominated by economic and social development planning, urban-rural planning, and land-use planning, respectively.

In 2017, predicated by the city and county pilot projects and led by the General Office of the Communist Party of China Central Committee and the General Office of the State Council, nine provincial-level administrative units were selected. These units, inclusive of Hainan and

Ningxia, were chosen to conduct provincial-level spatial planning pilots and formulate unified provincial-level overall planning. It was mandatory to adopt a "top and down linkage, collaborative promotion" approach, synchronously advancing provincial, municipal, and county-level NTSP pilot projects. This ensured the interconnectivity and hierarchical management of spatial planning. Due to institutional reforms, this pilot project was discontinued. Overall, the phases of evolution in "multi-planning integration" from local voluntary experiments to departmental deployment and nationally coordinated pilots are replete with accomplishment and experience aiding NTSP reform. However, challenges as departments overly emphasise their functions persist, leading to insufficient integration of multiple plans.

2.4 A New Era of China's Spatial Planning Reform

In 2019, the "Opinions" officially proposed establishing a "multi-planning integration" NTSP system. This consolidates the previous separate spatial planning (main functional zone planning, land-use planning, urban-rural planning, etc.) previously managed by different departments, into a unified NTSP system. It shall be regulated by the Ministry of Natural Resources (MNR).

This unified system represents the inheritance and development of main functional zone planning, land-use planning, and urban-rural planning. It is a comprehensive, systematic, and innovative construction of the spatial system. Its purpose is to make overall arrangements for the all-region, all-element, and all-process development and protection of terrestrial and marine, urban and rural, above-ground and underground "mountains, rivers, forests, farmlands, lakes, grasslands, sands, glaciers," and other national territorial spaces. Its terminus a quo includes responding to the requirements of China's new era of ecological civilisation construction, changing the previous emphasis on development and neglect of resource protection, and guiding the sustainable development of national territorial space. Synchronically, the government has clarified the legal status of NTSP reform from the legislative perspective, amending the "Land Administration Law" to stipulate the requirements and legal effectiveness of NTSP. It represents a systemic and reconstructive planning reform in aspects such as planning systems, management institutions, technical methods, and interdisciplinary fields, for China in recent decades.

3. Major Measures of China's NTSP (Reform

3.1 Unified Management Functions of Spatial Planning

China being vast in territory and population, possesses a complex national administration. Over time, numerous spatial planning and management mechanisms have been developed lacking a unified top-level design and institutional framework. This has resulted in conflicts between different management departments, driven by departmental interests and the struggle for "discourse power," leading to conflict between different spatial planning.

The core measure of the NTSP reform is to centralise the responsibility of NTSP under one department, while "strengthening the guiding and restraining the role of NTSP on various special plans." The previous issue of "multi-planning conflicts" precipitated by institutional mechanisms will be explored.

To bolster the management of NTSP, China established the MNR in 2018. It integrated

previous responsibilities for the formulation and approval of all spatial planning. This consolidation comprises the management of national territorial planning and land-use planning from the former Ministry of Land and Resources, main functional zone planning from the National Development and Reform Commission, and urban-rural planning from the Ministry of Housing and Urban-Rural Development. It also includes resource investigation and demarcation registration management responsibilities related to natural resources from the Ministry of Water Resources, the Ministry of Agriculture, the State Forestry Administration, the State Oceanic Administration, and the National Bureau of Surveying, Mapping, and Geoinformation. A high degree of accord in spatial planning rights has been achieved through institutional reforms. This initiated the reconstruction of the NTSP system, ending the history of "Nine Dragons Water Control" of planning formulation and management by multiple departments. All spatial planning formulations are to be uniformly managed by the MNR.

The MNR is tasked with establishing the spatial planning system and supervising its implementation, promoting the strategy and system of main functional zones. It oversees the formulation, approval, and implementation of overall, detailed and special planning by governments at all levels and relevant competent departments (Table 1). The MNR issued guidelines for formulating plans and has convened national video conferences to promote the formulation of NTSP. The aim is to standardise the development of NTSP across the country according to the requirements of a "unified map, unified standards, unified planning, and unified platform."

Table1: Institutions responsible for formulating and approving NTSP (NTSP Bureau of the MNR, 2021, p.11)

Corresponding planning			**Formulation department**	**Approval department**
overall planning	national-level NTSP		The Ministry of Natural Resources and relevant departments	the Central Committee of the Communist Party of China and the State Council.
	provincial-level NTSP		provincial-level Government	After deliberation by the local People's Congress Standing Committee, it shall be submitted to the State Council
	municipal, county and township level NTSP	the municipal-level NTSP approved by the State Council	municipal-level Government	After deliberation by the local People's Congress Standing Committee, the provincial-level government shall report to the State Council

	other municipal, county and township level NTSP	same-level Government	Provincial governments clarify the requirements for the compilation and approval of content and procedures
detailed planning	Within the boundaries of urban-town development	natural resources department of the municipal or county government	Municipal and county level government
	Village areas beyond the boundaries of urban-town development	township government	Municipal and county level government
special planning	special planning for coastal zones, nature reserves, and trans-administrative or basin NTSP.	local or higher-level natural resources department	same-level Government
	Special planning for specific fields involving spatial utilisation,	relevant authorities	Approved according to relevant regulations

3.2 Composition of the NTSP System

The "multi-planning integration" NTSP system framework includes "five levels, three types, and four systems" (Figure 2). The "five levels" are the administrative levels of the national, provincial, municipal, county, and township in China's management system. The "three types" of planning include national territorial spatial overall planning, detailed planning, and special planning. The "four systems" are the formulation and approval system, implementation and supervision system, legal and policy system, and technical standards system of NTSP.

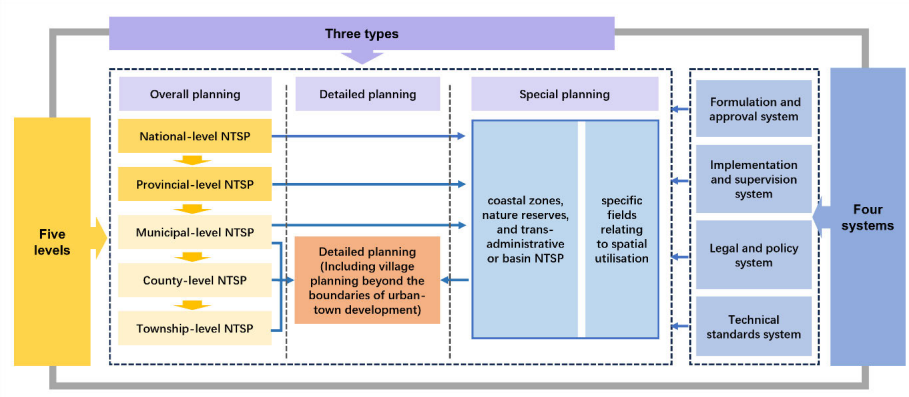

Figure 2: "five levels, three types, and four systems" of NTSP system

3.2.1 Overall Planning of NTSP

The national-level overall planning is a comprehensive arrangement that outlines the policies and principles for protecting, developing, utilizing, and restoring national land space, while focusing on strategic considerations. It is formulated by the MNR and other relevant departments, authorised by the Central Committee of the Communist Party of China and the State Council. The Provincial-level overall planning which implements the national-level overall planning, guides the formulation of overall planning at the municipal and county levels, and emphasises coordination, is organised by provincial governments. Post-review by the local People's Congress Standing Committee, it is submitted to the State Council for approval. Municipal-level, county-level, and township-level overall planning refine the requirements of higher-level overall planning and provide specific arrangements for development and protection within their administrative regions, centred on implementation. Municipal governments organise several municipal-level overall planning, approved by the State Council, reviewed by the local People's Congress Standing Committee, submitted to the provincial government, and transferred back to the State Council. The framework for planning content and procedures is enshrined in the overall planning for municipal-level, county-level, and township-level, based on local conditions by provincial governments. The township-level overall planning may be compiled based on several townships as units or consolidated with municipal-level overall planning, all contingent on local circumstances by local authorities.

3.2.2 Detailed Planning of NTSP

The detailed planning provides practical arrangements for land use, development intensity, and construction in specific areas. It serves as the legal framework for land development and protection activities, land use control, issuance of urban and rural construction project planning permits, and various construction activities. There are two types of detailed planning; within urban-town development boundaries and beyond urban-town development boundaries. The former is organised by the natural resources department of the municipal or county government and submitted for approval by the same-level government. The latter are in rural areas with one

or several administrative villages, used as a unit. Detailed planning is prepared by the township government as a practical village plan and submitted for approval by the higher-level government.

3.2.3 Special Planning of NTSP

Special planning rare specialised arrangements created for specific regions (basins) or fields indicating specific functions and requirements for spatial development, protection, and utilisation. It includes; (1) Special planning for coastal zones, nature reserves, and trans-administrative or basin NTSP. This is organised by the local or higher-level natural resources department and submitted for approval by the same-level government. (2) Special planning for specific fields involving spatial utilisation, such as transportation, energy, water conservancy, agriculture, information, municipal infrastructure, public service facilities, military facilities, ecological and cultural heritage protection, forestry, and grassland planning, organised by relevant authorities.

3.3 Core Contents of NTSP Compilation

The current NTSP invokes the implementation of national strategies, clarification of spatial development goals, and optimisation of urbanisation patterns, agricultural production patterns, and ecological protection patterns. It dictates the determination of spatial development strategies, the transformation of territory spatial development and protection methods, and the enhancement of the quality and efficiency of territory spatial development and protection. On this basis, preliminary work as unified base map data, clear classification and zoning standards for land and sea use, double evaluation, and double assessment in the compilation of NTSP has been executed by various regions. The structural optimisation of territory spatial layout and the protection and utilisation of various natural resource elements have been executed. Delineating the "three zones and three lines" is the principal objective of establishing the entire NTSP (Figure 3). Coordinated planning and this delineation are at the core of unified control of various spatial planning purposes.

The "three lines" refer to the permanent basic farmland red line, ecological protection red line, and urban-town development boundary. The permanent basic farmland red line indicates the cultivated land under permanent special protection. This ensures national food security and the supply of important agricultural products. It is necessary to strictly demarcate according to relevant national regulations while implementing the permanent basic farmland protection tasks, disintegrated and assigned by superior plans. The ecological protection red line is a rigid control line within the ecological space. It indicates areas with special and important ecological functions within the ecological space that must be safeguarded, ensuring national ecological security. This is inclusive of forests, grasslands, wetlands, and water bodies. It also comprises urban and rural areas, mining land, and aquaculture areas that should be gradually and orderly phased out. The urban-town development boundary is the territorial spatial boundary where urban development and concentrated construction can be executed within a certain period. It includes cities, towns, and various development zones. It is a policy line for urban spatial control, emphasizing conservation, intensification, and green development. Each province controls the scope of urban development boundaries, not exceeding 1.3 times the total scale of

urban construction land in 2020, while having the autonomy to guide cities and counties in delineating urban development boundaries.

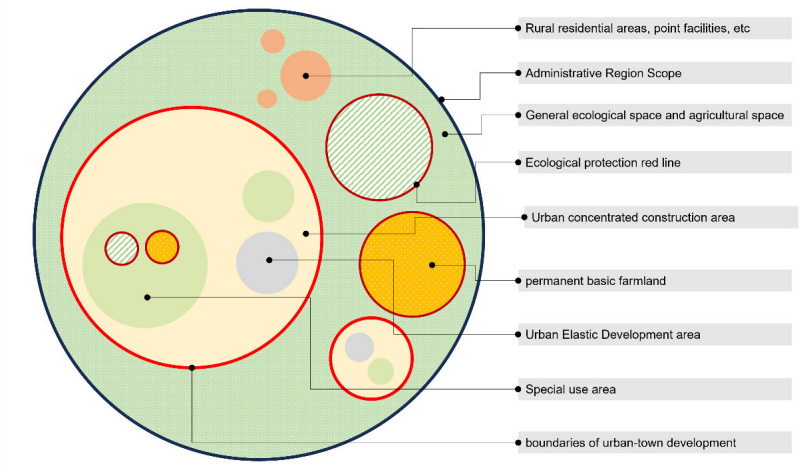

Figure 3: The division of the "three zones and three lines"

These considerations must be adhered to in delineating the "three lines": (1) The "three lines" must be perceived as the red line with non-navigable boundaries for adjusting economic structure, planning industrial development, and promoting urbanisation. Protection targets of 18.65 billion mu of arable land and 1.546 billion mu of permanent basic farmland must be set by the state by 2020 (NTSP Bureau of the MNR, 2023, p.79). (2) Demarcation per the priority order of arable land and permanent basic farmland red line, ecological protection red line, and urban-town development boundary. This ensures the three control lines do not intersect, overlap, or conflict. (3) An incorporation of the results of this delineation of "three lines" into "one map" of NTSP, achieving integration of "numbers, lines, and maps". Synchronously, it improves the functionality of the national territory spatial basic information platform, ensuring that targets such as arable land, permanent basic farmland red line, and ecological protection red line be implemented, assessed, and held accountable.

The national results of this delineation reveal that more than 30 percent of the land territory and 150,000 square kilometers of sea area are designated as ecological protection red lines, leading the world in implementing the ecological protection red line system (People's Daily, 2023).. Policies like comprehensive land consolidation, redevelopment of inefficient urban land, the nexus of urban and rural construction land increase and decrease, and entry of collectively operated construction land into the market should be introduced. These policy measures should be consolidated with the overall planning and detailed planning implementation management mechanism to form a platform and institutional design. This optimises the territory spatial pattern after delineating the "three zones and three lines", which is both principled and flexible, shifting focus from "how to delineate" to "how to manage".

3.4 Digital Technology Application of the NTSP System

The NTSP system emphasises the use of digital technology to establish a unified national

digital NTSP "one map" system (Figure 4). This aims to lead the transformation of territory spatial governance through "digitalisation" and advance government management and service efficiency.

The "one map" system of NTSP is characterised by; (1) Basic data possessing authenticity, systematicity, and standardisation. Based on "the third national land survey and annual change survey", high-resolution remote sensing images and three-dimensional surveying and mapping data, integrating various spatial data like meteorology, hydrology, geology, and population, the system adopts unified standards for data inclusion. This unified base map accurately indicates the national territory spatial data. (2) Management implementation which features interconnectedness, efficiency, and authority. Data is relayed through the system to various departments and regions.

Using the basic information platform, the NTSP "one map" implementation supervision information system is constructed, integrating the results of the national "three zones and three lines" delineation and the "five levels, three types" of NTSP. This encapsulates the entire domain, effectively updates, and is authoritative and unified. This serves as a framework for cross-departmental, cross-level, and cross-process planning management. The digital and intelligent management of the entire process of the NTSP is a noteworthy accomplishment.

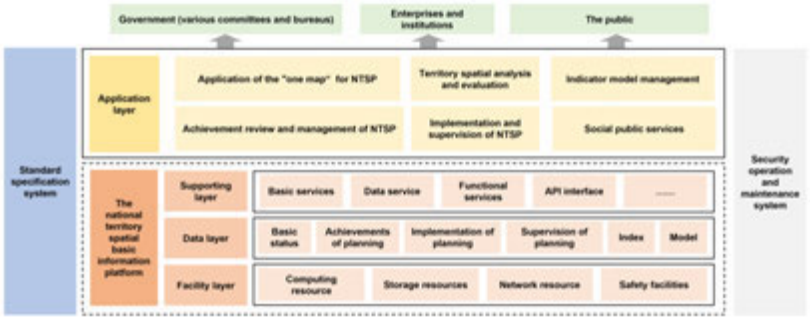

Figure 4: Construction framework of NTSP "One Map" (NTSP Bureau of the MNR, 2023, p.190)

4. Discussion

4.1 From Urban-Oriented Planning to Entire Land and Sea Area-Oriented NTSP

An important change in the reform of NTSP is the expansion of planning scope from urban areas with concentrated populations, facilities, and industries to encompassing the entire territory. This covers marine and terrestrial areas, including elements like urban and rural construction land, transportation, and water conservancy. It consists of other construction areas and non-construction land (arable land, forests, and water). This change is closely linked to the concept that "mountains, rivers, forests, farmlands, lakes, and grasses form a community of life" which is emphasised by Chinese President Xi Jinping. In preparation for NTSP at all levels and based on this idea of coordinated governance, coordination of all types

of natural resource elements across the entire territory is perceived as an important goal.

To cope with this change, corresponding changes have been made in the technical methods used in planning preparation, including making the types of basic land use and spatial zoning more complex. In this process, the MNR issued the "Classification Guidelines for Land and Sea Use in Territorial Spatial Survey, Planning, and Utilisation Control." It unified the investigation, statistics, and planning classification standards for all NTSP involved, including 24 primary classes, 113 secondary classes, and 140 tertiary classes. It is worth noting that this classification absorbs and connects the original classifications of land-use planning and urban-rural planning. It incorporates concepts related to marine functional zoning, which was not previously addressed by land-use planning and urban-rural planning.

Due to the significant changes in the objects and scope controlled by planning guidance, there has been a huge impact on the development of the planning industry in mainland China. In planning preparation, the composition of planning teams has become unprecedentedly diverse. In addition to urban planning professionals, many professionals in geographic information technology, land planning, geography, marine science, ecology, and mineral resources have joined, forming comprehensive planning teams with multidisciplinary backgrounds. Previously, most of China's urban master plans were prepared by urban planning institutions such as the China Academy of Urban Planning & Design. The units responsible for preparing the overall planning of NTSP have become a tripartite situation of urban planning institutions, land planning institutions, and surveying, mapping, and information institutions. Completion of a plan often requires the collaborative efforts of these three types of institutions, sometimes supplemented by local urban design institutions. They form a consolidated vessel to complete the planning together, dissimilar to the traditional planning projects that can be completed by a single design unit or team. In the specific work of planning preparation, because the teams involved belong to different units, and sometimes work locations are not in the same city, there are also significant differences in work habits. During the several years of preparation, the entire project is often segmented into several sub-projects for operation. This means that it is in a fragmented state, and each team completes its section according to its work habits and expertise, resulting in a mosaic-like outcome. This type of planning preparation consortium is not in line with the requirement of "multi-planning Integration" advocated which undermines the systematic nature of planning and leads to significant fragmentation.

4.2 From Blueprint Planning to Bottom-Line Planning

Another important change in the reform of NTSP is that the planning objectives are more comprehensive than before. This shifts from a previous focus solely on maximizing the spatial expansion of local economic growth to effectively addressing ecological, environmental, and social-cultural issues while continuing economic growth, emphasizing ecological priority, green development, and sustainable development. This reflects a change in the value of planning, emphasizing tight constraints on resources and the environment, and increasing the level of resource conservation and intensive use.

This change is precipitated byo the requirements of China's ecological civilisation system reform. To achieve the goal of sustainable development, it is necessary to scientifically constrain urban-town spatial development and strictly protect the bottom line of food security

and core ecological space. Therefore, delineating of the "three lines" has become one of the core contents of NTSP. Among them, the permanent basic farmland red line and ecological protection red line determine the bottom line of national land resource protection. This aims to ensure agricultural production and ecological security; the urban-town development boundary determines the upper limit of land development, ensuring high-quality development.

This bottom-line thinking of planning is different from that in Western developed countries. The pressure of population and cities on the environment and farmland in Western countries has not been so great as to affect national security and survival. There has been no systematic planning theory based on the premise of protecting farmland. In countries where the relationship between people and land, especially land resources, is not tense, the focus and approach of spatial planning control may differ. Although there is also an emphasis on controlling urban sprawl, the urban space in Western countries typically exhibits large areas of ecological leisure and agricultural space, extensive low-density suburban residential areas, and small-scale high-density central cities. After more than 40 years of rapid urbanisation in China, issues such as food security and ecological security have emerged. This has not been seen in Western developed countries, and it affects the public's survival and quality of life. By delineating the "three lines", China's reform of NTSP aims to ensure ecological security, food security, and national security.

The NTSP must plan the development of urban individuals under the premise of meeting national food and ecological security. Subsequently, the "three lines" become a prerequisite for urban-town spatial planning. In the specific process of planning preparation, the delineation of the "three lines" is carried out uniformly at the national level, and the MNR has formulated rules for delineation. Protection tasks are determined from the national level to the township level, including scale, quantity, and layout, with an accuracy reaching the scale of patches and then delineated in a coordinated manner from the bottom up on a unified base map. In this process, three rounds of trials of "top-down" and "bottom-up" have been experienced, forming a unified national "three lines" result, which is incorporated into NTSP at all levels. As can be seen, the "three lines" as a bottom-line constraint, in the five-level NTSP system, the requirement is for strict implementation from top to bottom and gradual transmission. The results of delineating the "three lines", to become one of the independent outcomes of NTSP, have been officially used before planning is approved. Between September 28, 2022, to April 11, 2023, the MNR approved the delineation results of the "three lines" for all provinces nationwide. Thus, the first comprehensive delineation of the "three lines", that is the most basic and important control outcome in the NTSP system, has been completed. It serves as the foundation for land use control in territorial spatial planning. In the process of approving construction land, various regions must strictly implement control measures under the "third line". After delineating the "three lines", how to use the results specifically and formulate corresponding management rules is one of the key areas currently being researched by the MNR.

It is worth noting that delineating the "three lines" is an attempt at reform, representing an innovative endeavor that inherits various historical regulatory policies, technical standards, and relevant planning initiatives. Due to factors such as data limitations, temporal constraints, and experiential gaps, certain controversies surrounding the practical application of the outcomes within society are inherent. A perspective suggests that the outcome lacks precision

and may pose certain hindrances to regional economic development, advocating for potential adjustments in the future. The feasibility and modalities of such adjustments constitute a widely debated topic among the academic and professional planning communities.

5. Conclusion

In addressing the historical issue of inconsistency in multiple planning systems, China has undertaken a nationwide reform of its NTSP in recent years. This reform not only reflects changes in the governance approach of the country but has also sparked intense academic discourse. Since 2018, over 2000 Chinese-language papers have been published on the subject. Scholars and industry professionals in China have engaged in vigorous discussions regarding the reform, spanning various disciplines such as urban planning, geography, land resource management, ecology, resource science, environmental science, and marine science. In the practical realm of planning, these academic discussions have aided the government continuously, particularly the MNR. This is done by formulating technical guidelines and showcasing a collective effort between academia, government, and industry to actively explore solutions at the nexus of technology- theory- institutional frameworks.

At the institutional level, this reform has completed the top-level design of the NTSP system, establishing the foundational and statutory status of NTSP within the national spatial governance system, thereby forming the "Chinese solution" to spatial governance. At the operational level, under the leadership of the MNR, significant progress has been made in the formulation of NTSP. This includes the establishment of the "three lines" nationwide, which serve as non-negotiable boundaries for sustainable development. Furthermore, the overall planning at the national, provincial, municipal, county, and township levels has almost been completed, approved, or in the process of approval. Additionally, a unified digital territorial spatial planning "one map" system has been established nationwide. These efforts have laid the groundwork for China's sustainable development. It will serve as the basis for development activities until 2035, serving as the primary public policy tool for spatial and resource allocation.

While China's NTSP reform has achieved breakthroughs in multi-planning Integration, several unresolved contradictions and issues persist. First, legislative reforms are imperative.. Although the revised "land management law" of 2019 clarifies the legal status of NTSP, detailed provisions regarding its formulation, approval, implementation, and oversight are lacking. Consequently, NTSP is currently in a transitional state deficient of comprehensive legal support, undermining the gravity and authority of the planning process. There is a need to strengthen legislative efforts to specify the entire process and critical junctures of planning formulation, approval, implementation, modification, and supervision. This must ensure alignment with existing laws and enhance the role of the rule of law in guiding, regulating, and safeguarding the " multi-planning Integration " reform. Second, interdepartmental coordination still requires strengthening. Despite achieving integration among the main functional zone planning, land-use planning, and urban-rural planning, NTSP cannot replace special planning, and other departments still need to formulate corresponding special planning. These industry regulatory authorities often prioritise their development needs, paying less attention to conflicts between development and protection, and the tight

constraints between demand and resources. This often results in special planning lacking precise alignment with the content of overall planning and insufficient guidance for detailed planning formulation, thus limiting the effectiveness of coordinated guidance. It is imperative to promptly establish a special planning management system, break down barriers between different departments, and coordinate spatial conflicts on the "one map" of NTSP. There should be a strengthening of the implementation of special planning derived from overall planning and better promotion of socio-economic development.

Spatial planning, as a form of public policy, exerts significant influence on the development of a country or region. Despite substantial political, economic, and socio-cultural disparities between China and other countries, China has incorporated experiences from developed nations such as the Netherlands and Japan in formulating its spatial planning reform. Over the past few years, China has accumulated its own experiences and lessons, which could serve as a reference for countries or regions in similar development stages, grappling with global climate change challenges, and striving for sustainable development to enhance their spatial planning systems.

Abstract

Zoning guidelines are technical methods commonly employed in various types of urban planning, including comprehensive urban design, landscape planning, regulatory detailed planning, and architectural features and styles planning. These guidelines aim to protect and define urban character, controlling spatial forms in specific districts. Often, when different zoning types are compiled without clear distinctions, redundancy and contradictions can arise, leading to inefficient management.

This article, in conjunction with relevant zoning guideline examples, distinguishes between the zoning guidelines corresponding to the four types of planning by comparing their coverage, control objectives, content, and methods. It defines the roles, functions, and interrelationships of these guidelines at different scales. This approach aims to systematically control urban landscapes through a layered and cumulative process, effectively addressing different levels.

Keywords

Zoning guidelines, comprehensive urban design, landscape planning, regulatory detailed planning, architectural features and styles planning

1 Introduction

Zoning guidelines, as a technical approach, are commonly employed across various planning types such as comprehensive urban design, landscape planning, regulatory detailed planning, and architectural features and styles planning. The objective of these guidelines is to protect and shape the distinctive urban character by controlling and guiding the spatial form of specific urban sectors.

Presently, there is no strict and uniform definition of "cityscape zoning" in China, and different types of planning compilations have varied connotations and requirements. For instance, in cityscape planning, cityscape zoning refers to areas within a city that share similar development traits (Dai and Liu, 2013); in urban landscape planning, it indicates regions that require special control within urban planning management or landscape character protection and construction (Bai, 2015); in architectural features and styles planning, it pertains to areas with similar architectural cultural and structural characteristics (Zhao, 2017). Correspondingly, the different types of zoning guidelines also vary in their control levels and focus tasks.

However, the current domestic compilation of various zoning guidelines often leads to confusion, resulting in poor linkage with higher-level plans, and insufficient conveyance of key contents from superior plans. Moreover, as the importance of planning management increases, zoning guidelines are expected to directly guide planning management. However, there exists a disconnect between control and implementation, making the practical application of zoning

guidelines inadequate (Wang et al., 2019). Therefore, it is essential to distinguish between different types of zoning guidelines to avoid duplication, misalignment, or even contradictions, thereby enhancing the efficiency of planning management.

This article incorporates case studies from the Comprehensive Urban Design Guidelines of Jurong City, the Cityscape Guidelines for Landscape Planning of Fujian Province, the Statutory Maps for Regulatory Detailed Planning of the Futian District in Shenzhen, and the Cityscape Guidelines for Architectural Features and Styles Planning of Fuzhou City. By differentiating the coverage, control objectives, content, and methods of various types of zoning guidelines, the study aims to define the roles, functions, and interrelationships of these guidelines at different scales. This approach seeks to systematically control urban landscapes in a layered and cumulative manner, addressing different levels systematically.

2 Comparative Analysis of Zoning Guideline Types

Different types of planning have distinct roles and functions within the entire planning system, and thus, their corresponding zoning guidelines differ in coverage due to their inherent nature of guidance and control (Figure 1).

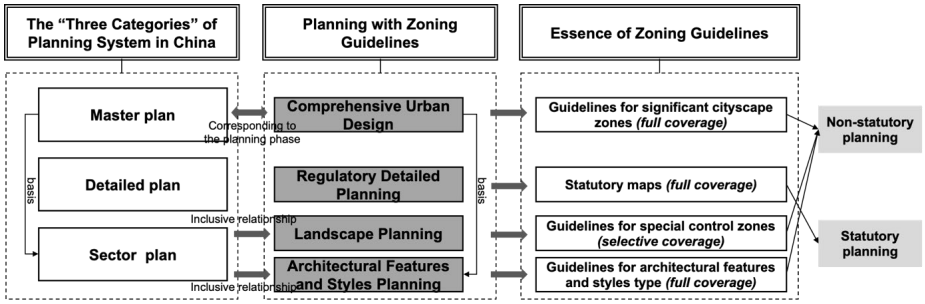

Figure 1. Relationships Among the Four Types of Zoning Guidelines

2.1 Zoning Guidelines in Comprehensive Urban Design

Comprehensive urban design, as a non-statutory planning corresponding to the stage of master plan, can guide and control the large-scale urban form from a macro perspective, emphasizing urban characteristics. The cityscape zoning guidelines at the meso-level are a crucial intermediary in the comprehensive urban design process, bridging the overall structure and macro guidance system, and guiding the urban design of lower-level areas. Although cityscape zoning in comprehensive urban design is extensive, not all urban spaces are distinctively characterized or resource-rich. Therefore, it is unnecessary to impose control requirements on the entire area. Instead, through the assessment and grading of cityscape zones, extremely important and moderately important cityscape zones are selected for focused "cityscape zoning control" (Wu et al., 2021).

For example, in the Comprehensive Urban Design Guidelines of Jurong City, the central urban area of Jurong can be divided into 11 cityscape zones. Through sensitivity grading and landscape sensitivity analysis, these zones are categorized into three levels. The extremely important cityscape zones include the Old City Cultural Cityscape Zone, the South High-Speed Rail Hub Cityscape Zone, and the North Evergrande Cultural and Tourism Cityscape Zone. Moderately important cityscape zones include the Golden River Science and Education Cityscape Zone, the Main Urban Comprehensive Cityscape Zone, and the East Urban

Comprehensive Cityscape Zone, along with five general cityscape zones. Direct control is applied specifically to the extremely and moderately important cityscape zones (Figure 2).

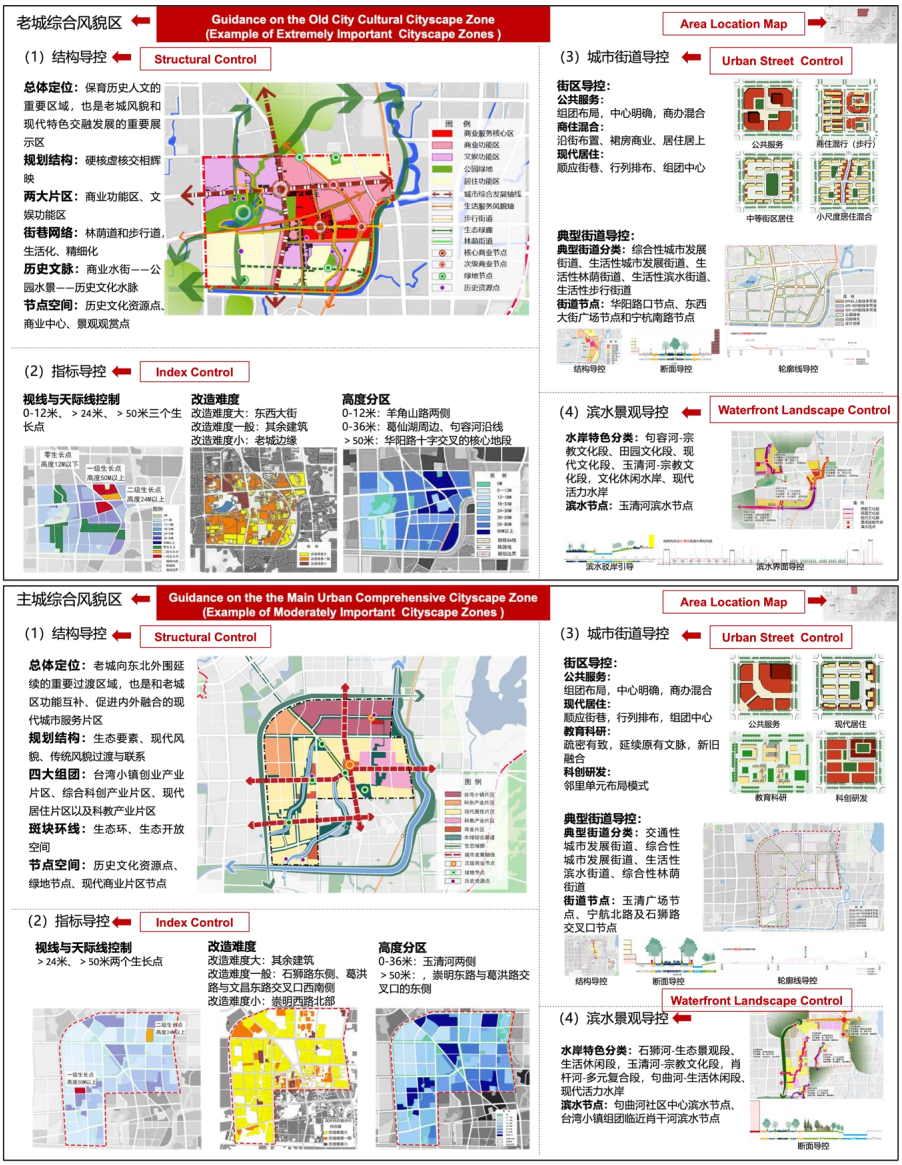

Figure 2. Example of Zoning Guidelines in Comprehensive Urban Design
Source: Urban Planning& Design Institute CO., LED of Southeast University. (2020) Comprehensive Urban Design Guidelines of Jurong City. Nanjing: Southeast University Press.

2.2 Zoning Guidelines in Landscape Planning

Landscape planning, also a non-statutory planning, is not compulsory for all cities. However, it shares many similarities with comprehensive urban design in terms of objective setting, theoretical references, focus areas, and design methods. The main differences lie in "tendency of dissemination, visual dominance, and technical flexibility" (Li and Zhu, 2009). It is a refinement of the urban design section of master plan and can serve as the superior plan for individual urban designs (Fujian Provincial Department of Housing and Urban-Rural Development, 2013). The zoning guidelines in landscape planning typically refer to special control zone guidelines, which are essential for urban planning management or landscape character protection and construction, providing specific planning control guidelines. These zones have characteristic dominance and unified control, differing from the comprehensive cityscape zoning in comprehensive urban design. Outside of special control zones, general control zones are guided by standard requirements.

Taking the Cityscape Guidelines for Landscape Planning of Fujian Province as an example, areas requiring special control include historical cultural heritage cityscape zones, natural ecological protection cityscape zones, urban core areas, and key urban node areas. For instance, a well-preserved ancient town district within a town is designated as a special control area, necessitating the development of corresponding street pattern control guidelines and architectural features and styles control guidelines (Figure 3).

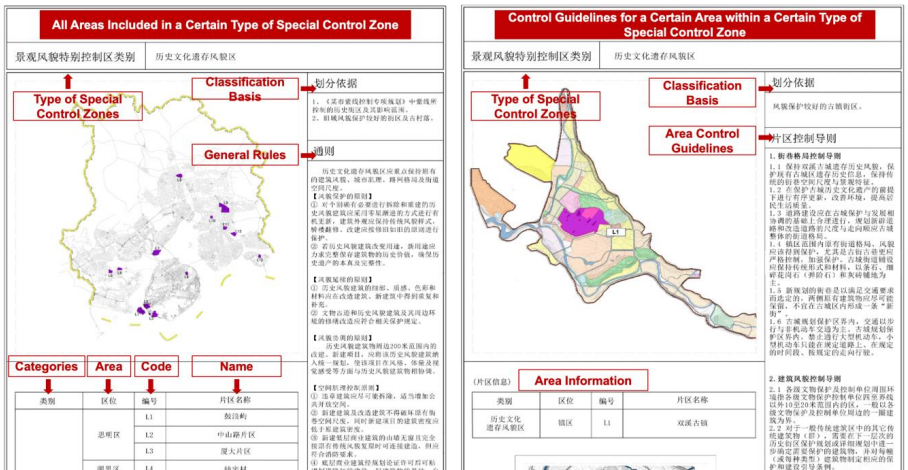

Figure 3. Example of Zoning Guidelines in Landscape Planning

Available at: https://zjt.fujian.gov.cn/xxgk/zfxxgkzl/xxgkml/dfxfgzfgzhgfxwj/qt_3796/201311/t20131104_2870981.htm (Accessed: 30 May 2024).

2.3 Zoning Guidelines in Regulatory Detailed Planning

Regulatory detailed planning, as a core component of China's statutory urban planning system, not only deepens the implementation of master plan but also serves as the direct basis for setting land lease conditions and guiding lower-level planning designs. The zoning guidelines in regulatory detailed planning are statutory maps that need to be prepared for all management units within the control plan's scope. Thus, unlike landscape planning, its planning scope is comprehensive and legally binding.

For example, the Statutory Maps for Regulatory Detailed Planning of the Futian District in Shenzhen divides the entire Futian District based on land use, urban spatial structure, municipal facilities, and natural environmental conditions into 29 management units, including areas like Huaqiang North, the Central District, and Meilin. Full-coverage maps are prepared for each management unit from the block to the plot level, specifying control indices (Figure 4).

2.4 Zoning Guidelines in Architectural Features and Styles Planning

Architectural features and styles planning, as a specialized plan focused on architectural character, builds on master and detailed planning with thorough, specific, and targeted content (He, 2010). The zoning guidelines in architectural features and styles planning essentially belong to a category of architectural features and styles type zoning guidelines, classifying architectural character based on the building's function, height, and location within the urban spatial structure, and providing corresponding control requirements. The planning scope of architectural features and styles type zoning guidelines is comprehensive, covering all types of buildings, including residential areas, mixed-use areas, public buildings, elementary and secondary schools, kindergartens and community public buildings, parks and squares, green buffer zones, and logistics parks.

Taking the Cityscape Guidelines for Architectural Features and Styles Planning of Fuzhou City as an example, the entire city of Fuzhou is designated into controlled areas, which include historical sections, key urban functional areas, significant urban civic activity centers and their surrounding areas, and important urban corridors. Each category is further subdivided into types; for instance, the key urban functional area consists of 13 commercial and business districts, 5 cultural and sports center districts, and 5 transportation hub areas and their surroundings. The guidelines provide directives on architectural height, facade design, facade width, discount rate, permeability, height-to-width ratio, levels of building height, facades, roofs, landscaping, and the materials and colors used (Figure 5).

3 Control Differences in Zoning Guidelines

Different levels and types of zoning guidelines have distinct guiding control targets, degrees, and methods, and they vary in their control objectives, content, and methods (Table 1).

Table 1. Comparison of Control Measures Among Zoning Guidelines

Types of Zoning Guidelines	Control Objectives	Control Content	Control Methods
Zoning Guidelines in Comprehensive Urban Design	Inherit and convey the overall characteristic spatial structure, guiding the preparation of lower-level plans.	It requires the control and guidance of subsystems such as characteristic patterns, urban form, open spaces, and landscape features by cityscape zoning. It also needs to provide more refined control points and basis for the street patterns, urban streets, and waterfront landscapes of the zone.	Consider both macro and micro levels
Zoning Guidelines in Landscape Planning	Provide a basis for planning management of special control zones, connected with the regulatory detailed planning.	Mainly control and guide aspects such as functional positioning, overall intention, landscape corridors, architectural styles, and skyline (with emphasis based on zone characteristics).	Targeted guidance, general rules or guidelines
Zoning Guidelines in Regulatory Detailed Planning	Provide a basis for land transfer, detailed construction planning, and architectural design.	Control land use (boundaries of different types of land, building types within various types of land), environmental capacity (building height, building density, plot ratio, green space ratio, etc.), construction control (building volume, form, color, etc.), activity control (location of plot entrances and exits, parking spaces, bus station land boundaries and station locations, pedestrian traffic and other transportation facilities, etc.), and facility matching control (location of municipal pipelines, boundaries of engineering facility lands, etc.).	Integrate into regulatory management unit maps
Zoning Guidelines in Architectural Features and Styles Planning	Provide a basis for urban design, architectural design, and construction management.	Mainly includes building form, volume, color, material, ancillary facilities, environmental elements, etc.	Targeted guidelines

3.1 Control Objectives

In comprehensive urban design, meso-level cityscape zoning guidelines serve as a critical medium connecting the objectives of comprehensive urban design with the next level of planning and design. They can propagate the overall characteristic spatial structure, guiding and controlling regulatory detailed planning, cityscape planning, or district urban design.

In landscape planning, these guidelines provide a basis for the planning management of special control areas, facilitating the implementation of overall planning objectives on specific subdivided plots to enhance the operability of specialized landscape planning.

In regulatory detailed planning, the statutory maps directly guide constructive detailed planning, providing the basis for land lease conditions and architectural design.

In architectural features and styles planning, the zoning guidelines, through guiding and controlling the character of buildings and streets, provide a basis for urban design, architectural design, and building management, thus protecting the city's diverse and cohesive traditional character.

3.2 Control Content

In comprehensive urban design, cityscape zoning guidelines should reinforce macro goals and characteristic structures at the zoning level, meaning control of subsystems like characteristic patterns, urban form, open spaces, and landscape character needs to be conveyed through cityscape zoning. Additionally, indicators for views and skylines, transformation difficulty, height zoning, etc., need to be controlled, providing more detailed guidance for the district's block patterns, urban streets, waterfront landscapes, and architectural character (Wu et al., 2021).

In landscape planning, special control zones include historical cultural heritage areas, natural ecological protection areas, urban central nodes, civic activity nodes, transportation hub nodes, and other special areas. These guidelines focus on functional positioning, overall intentions, landscape corridors, architectural character, and skylines, proposing protection and coordination principles for character preservation, ecological utilization, and more, with particular attention to "three edges" (next to mountains, waters, roads) and "three nodes" (urban centers, civic activities, transportation hubs) (Fujian Provincial Department of Housing and Urban-Rural Development, 2013).

In regulatory detailed planning, the statutory map control system encompasses multiple aspects: land use control, which includes boundaries for different land uses and building types within each category; environmental capacity control, covering building height, density, floor area ratio, and green space ratio; building construction control, addressing building volume, color, and materials; activity control, specifying locations for plot entrances, parking spots, public transport areas, and other traffic facilities; and infrastructure control, defining positions of municipal pipelines and boundaries of engineering facilities.

In architectural features and styles planning, the control elements of zoning guidelines include architectural style, building volume (plan and height), architectural form (facade, roof, walls, and base), color (roof, walls, doors, and windows), building materials (roof, walls, doors, and windows), ancillary facilities, and environmental factors. The focus is more on the detailed and micro-level aspects of individual building elements.

3.3 Control Methods

In comprehensive urban design, these guidelines usually consider both meso and micro perspectives, corresponding to the sections and control content, comprising "structural control + index control + form control". Each content section may include one or more forms within "master plans + general rules + specific rules + detailed rules," primarily emphasizing guiding control. The index control section, as a quantitative guide, provides clear and crucial evidence for local development management (Qian, 2021).

In landscape planning, these guidelines typically include “general rules + district guidelines”, setting design guidance according to the landscape characteristics and planning management requirements of special control areas. They also emphasize alignment with control regulations to incorporate landscape control requirements into the respective units or plot regulations.

In regulatory detailed planning, on one hand, statutory maps are strategically compiled in layers and levels to define control points for each spatial dimension, organized by street unit, community unit, and plot unit. On the other hand, these statutory maps are integrated with urban design guidelines to enhance the control and guidance over urban spatial quality (Huang, Sun, and Zhang, 2019).

In architectural features and styles planning, zoning guidelines target different building types, specifically controlling them from mandatory, advisory, and suggestive perspectives.

4 Conclusion

This paper conducts a comparative study of zoning guidelines within comprehensive urban design, landscape planning, regulatory detailed planning, and architectural features and styles planning. It distinguishes these guidelines by their inherent nature of control, coverage, control objectives, content, and methods, clarifying the roles and functions that zoning guidelines should fulfill at different scales and their interconnections, thereby achieving the effect of urban character control in a layered and incremental manner.

However, zoning guidelines, as a technical tool, are commonly found in various types of planning throughout China, and are not limited to just the four types mentioned above. Yet, some zoning guidelines, such as charming urban and rural landscape zoning guidelines (Wu et al., 2022), have not been widely implemented. Currently, the drafting process and content of most zoning guidelines in China are not clearly defined. There are overlaps in control content among some guidelines, and their control directions may even be contradictory, which is highly detrimental to the execution of planning management work. Moreover, since most zoning guidelines are non-statutory and not all cities prepare them, different types of cities in China—such as scenic cities with distinctive landscapes or smaller cities with less internal variation—have different requirements for cityscape control. Which types of zoning guidelines should be drafted for these different types of cities still needs further study. This suggests that a more standardized approach and clearer guidelines are necessary to ensure effective urban planning and management.

Study on the Response of Local Legislation to Coordinate the Interests of Multiple Subjects in Urban Renewal from the Perspective of Property Rights

Author: ZHAO ZHAO

Current affiliation: Beijing Municipal institute of City Planning & Design

Position: Engineer

Postal addresses: No.60 Nanlishi Road, Xicheng District, Beijing, China, 100054

Master's degree: Peking University, Urban and Regional Planning(2017-2020)

Bachelor's degree: Sun Yat-sen University(2013-2017)

Main research interests: urban renewal, revitalisation and utilisation of industrial land, and multi-dimensional co-management

Abstract: This article analyses the challenges of coordinating the interests of multiple parties in urban renewal and the institutional response through the development of local legislation on urban renewal in Beijing, using the policy mechanisms and practices of urban renewal projects in Beijing as an example. The article is divided into three sections: (1) defining the characteristics of property rights in urban renewal, and clarifying the key points of the legislation; (2) constructing an analytical framework of 'subject identification-interest expression-interest coordination' for the pluralistic subjects; and (3) analysing the responses of local legislation, including the concept and responsibilities of each type of subject, and the establishment of conflict negotiation and mediation mechanisms. Overall, the legislative design effectively responds to the property rights dilemma in practice. This principled legal framework clarifies the responsibilities of different government departments and facilitates the next step of developing specific policy tools to guide project practice.

Key words: Urban renewal; property rights; co-ordination of interests; multiple subjects; local legislation

1 Introduction

Urban renewal is currently a significant development strategy in China. The new period of urbanisation in China is faced with the need to promote the optimisation of urban structure, functional improvement and quality enhancement, and has put forward new requirements for the transformation of urban development methods. It has become a consensus among Chinese cities to safeguard urban renewal activities through laws. Since 2020, Shenzhen, Shanghai, Liaoning and Guangzhou have enacted or disseminated local regulations, while Chongqing, Xi'an, Zhuhai and Chengdu have introduced local regulatory documents.

Urban renewal is a complex process that involves a multitude of legal and regulatory issues, including land management law, urban planning and construction law. Currently, China has not yet enacted specific legislation on urban renewal at the national level. The coordination of the interest related to property rights must adhere to the framework of laws and regulations in order to ensure the legality and fairness of the renewal process. Consequently, property rights has become a pivotal concern in the examination of local legislation on urban renewal. This plays a pivotal role in guiding and constraining the resolution of property rights issues in practice. The reasonable resolution of property rights issues can facilitate the smooth progression of urban renewal and the realisation of sustainable urban development.

Nevertheless, the current policy framework for property rights remains inadequate, and a comprehensive analysis of the property rights relationship in urban renewal is required. The ladder theory of public participation, as proposed by Arnstein & Sherry (1969), identifies three levels of participation: no participation, symbolic participation, and civic power. However, public participation in China's current urban governance remains limited and the autonomous participation is weak(Hu Juan, 2013). This paper takes the policy mechanism and project practice of urban renewal in Beijing as an example and analyses the characteristics of the property rights in urban renewal, the key points of concern in renewal legislation. An analytical framework for the property rights of multiple subjects is built to analyse the challenges of coordinating the interests of multiple subjects. Lastly, the institutional response in urban renewal in light of the practice of local legislation in urban renewal in Beijing is discussed.

2 Defining the connotation of property rights in urban renewal and identifying the key points of legislation

As urban renewal is not just a matter of "wiping the slate clean" for the original property rights holders, the various types of renewal involve a wide range of stakeholders. Urban renewal is characterised by many objects, many types of relationships and complex property rights relationships. This paper starts from an analysis of the characteristics and problems of property rights relationships and further identifies the key points that should be considered in the legislation.

Urban renewal is not simply a "wiping the table" type of process for the original property owner. There are many stakeholders involved in different types of renewal, and the renewal period will occur during the replacement, reorganisation or buyout of property rights. This will result in changes to the original property rights relationships. Urban renewal is characterised by many objects, many types of relationships and complex property rights relationships. This paper analyses the characteristics and problems of property rights relationships and identifies the core points that should be addressed in legislation.

2.1 Characteristics and Problems of Current Property Rights Relationships

2.1.1 Diversified and complex property rights relationships for stock assets

2.1.1.1 Unclear management rights and responsibilities

As an example, Beijing has a significant number of old residential communities, with a total floor area of approximately 160 million square metres of urban residential districts constructed before 2000, representing over 25 per cent of the city's urban housing. In the context of restructuring, bankruptcy and reorganisation of the original ownership units of the districts and the implementation of the housing system reform, the property rights of the old districts exhibit characteristics of diversification and fragmentation. In particular, the special type of "public housing" in old residential areas, namely non-commercial housing, is typically constructed by the government or enterprises and then leased to lessees. The management of this type of public housing is even more dispersed, with property rights, asset management of the housing (which may be in the hands of the government), and the actual property management unit being inconsistent. The inconsistency between the actual occupants and the property rights unit, as well as the property management unit has led to unclear management responsibilities and low levels of property management.

2.1.1.2 Obstacles to reaching Willingness for Renewal

For commercial buildings, it is also challenging to reach a unified willingness to renew. Currently, commercial buildings are frequently sold in a decentralised manner, with fragmented property rights. This results in inconsistent renewal needs among owners, which in turn makes it challenging to reach a willingness to renew. The associated negotiation costs are high, which often leads to a prolonged project cycle due to a lengthy negotiation process. This, in turn, further increases the investment cost of the project.

2.1.2 Unequal rights and obligations of property rights holders of stock assets

2.1.2.1 Low utilisation efficiency of land and housing of state-owned enterprises (SOEs)

The stock of land and housing resources of Beijing's state-owned enterprises (SOEs) is considerable in scale, yet the current utilisation efficiency is low. In Beijing, the majority of SOEs acquire land at a lower cost. While a considerable proportion of land has a low plot ratio, with approximately 60% of SOEs' land having a plot ratio of less than 0.5 (Chen Xiangling et al., 2015). However, there is currently no evaluation mechanism or assessment requirements for the efficiency of land use by SOEs. Furthermore, the cost of holding land and housing assets by SOEs is low, and renewal often brings high economic costs, arising from the demolition and reconstruction of buildings or changes in the function of the land. Consequently, SOEs lack incentives to renew.

2.1.2.2 Residents' low willingness to contribute to renewal and reconstruction

At present, the old residential communities has not yet established a mature property management and property fee payment mechanism. Residents lack responsibility for the maintenance of community public space and the collection rate of the property charge is low. On the one hand, residents anticipate the advantages of enhanced asset value and improved living quality resulting from renewal. However, they are reluctant to shoulder the associated economic costs, such as renovation fees. On the other hand, residents exhibit a lack of awareness regarding the quality of their old residential communities. The majority of elderly residents are content with the current state of property management, which is based on cost-saving measures. Consequently, they are unwilling to pay a high level of property fees to obtain a higher quality living environment.

2.1.3 Difficulty in reorganising rights and interests

The renewal of stock space assets frequently entails changes in ownership and use rights, as well as fluctuations in asset values before and after renewal. Current methods of reorganising interests and benefits of the assets are limited. In particular, the revitalisation and utilisation of historic buildings is chanlleging. Due to their high historical conservation value, the form of renovation is based on conservation and repair, and the original function of the buildings is mainly residential(Figure 1). Following renovation, they are mostly used as offices, flats, retail and other integrated business operations. The majority of these historic buildings are in the form of public housing property rights. Therefore, they are unable to obtain ownership of the buildings while only be granted the right to operate the building. This leads to difficulties in balancing the costs of the project with the long-term operating revenues, as well as difficulties in obtaining bank loans through the mortgage of the buildings.

Figure.1 No.23 House of Shijia Hutong, originally used for residential purpose, now converted into Shijia Hutong Museum

2.2 Identifying the key elements of the legislation

Property rights in urban regeneration include not only the ownership of assets, but also the right to use and the right to operate. In addition to residential and commercial buildings with clear property rights, attention should also be paid to tenants of public housing, management units of public spaces and facilities, and transformation and operation companies involved in the adaptive use of historic buildings, etc. Therefore, the definition and interpretation of property rights are the core legislative points of urban renewal. The interests of different subjects change before and after urban renewal, and the reorganisation of these rights and interests depends on the change of ownership and use rights, so the key to optimising the allocation of urban resources through urban renewal is to reduce the institutional costs of reorganising the above property rights. By analysing the main features and problems of property rights in current urban renewal, it can be concluded that the core of the coordination of interests in urban renewal legislation is to reduce the system costs, which can be divided into four aspects: defining the boundaries of property rights, emphasising the reciprocity of rights and responsibilities, restructuring the flexible rights and interests, and improving the dispute resolution mechanism.

Firstly, the boundaries of property rights for different renewal objects should be classified and defined. This should be accompanied by a clarification of the rights and responsibilities of various property owners according to the characteristics of their rights and interests. In addition, the corresponding asset management rights should be refined. Secondly, there should be an emphasis on the equivalence of rights and responsibilities. This should be accompanied by the establishment of a system of full life-cycle responsibility for property owners. Furthermore, the right to renewal should be equated with the obligation to renew. For instance, in the case of older residential areas and other privately owned properties, it is essential to clarify that the owners of

these properties are responsible for maintaining them and for funding any necessary renewal or reconstruction. In accordance with the Land Management Law and other pertinent legal requirements, state-owned land use right holders are responsible for the use of land and all buildings within the designated land use period. This responsibility encompasses the obligation to ensure that the land is used efficiently for industrial purposes in alignment with urban development requirements. Concurrently, the mechanism for reorganising rights and interests should be flexible. In the event that a property rights holder lacks the capacity to renew, a third party may be engaged to facilitate renewal through a range of methods, including transfer and collaboration. Finally, the dispute resolution mechanism should be enhanced to provide institutionalised channels for the expression of demands and consultation for multiple subjects.

3 constructing a framework for analysing the interests of multiple parties in urban renewal

In general, the subjects involved in urban renewal projects can be divided into three main categories: management subjects, implementation subjects and property rights subjects. The renewal and transformation of physical space inevitably brings about changes in the interests of different subjects, which leads to a large difference in the demands. The lack of effective negotiation and distribution mechanisms results in a large number of renewal projects gives rise to contradictions and disputes (Wang Shujing & Guo Fei, 2021). Consequently, it is imperative that different subjects are guided to effectively express their core demands and facilitate the formation of consensus among them. The topic divides the analysis of property rights issues in urban renewal into three stages: subject identification, interest expression, and interest coordination, with the aim of elucidating the roles and responsibilities of different subjects in the city and the key points of policy support needed at different stages of the urban renewal process.

3.1 Subject identification Stage

3.1.1 Property Rights Holders

3.1.1.1 Types of Property Right Holders

As the concept of property owner is vague and lacks clear explanations in various regulations and policies, this paper uses the concept of "property right holders" in the *Beijing Urban Renewal Regulations* to analyse property rights issues in urban renewal. The assets involved in urban renewal can be divided into three categories: private assets, state-owned assets, and public property rights, including public space and public facilities. Each category of asset corresponds to a distinct type of property rights holder. Among these, private assets include land and housing assets owned by individuals and private enterprises. State-owned assets comprise land and housing assets owned by SOEs and government agencies, which are often subject to stricter supervision due to their special nature. Finally, space assets such as roads, parks, metro stations, and other social common use assets are included.

It is necessary to determine the corresponding responsible subjects according to the different types of characteristics. For those with clear property rights, such as old commercial housing, commercial buildings, and public buildings with clear property rights (such as schools, hospitals, and administrative organisations), the owners shall be the right holders of the renewal and reconstruction. In the case of property rights

relationships that are more complex, such as those pertaining to publicly owned housing, it is necessary to identify and designate specific types of property rights units. These may include, for example, enterprise-owned dormitory flats, guaranteed housing built by the government in the early days, and so forth. These units shall serve as the right holders for renewal and reconstruction. In the case of public assets, such as roads, squares, green spaces, waterfront spaces and other public spaces, the relevant authorities shall be the right holders for renewal and reconstruction.

3.1.1.2 Concept of property right holders and their rights and obligations

The majority of the relevant provisions pertaining to the rights and obligations of property rights holders are derived from the Property Management Ordinance, which delineates the rights and obligations of property rights holders. For instance, the ordinance explicitly states that property rights holders in Shenzhen can declare the urban renewal programme, demolition and reconstruction type of renewal. Furthermore, the ordinance allows property rights holders to express their will to renew. In particular, with regard to the renewal of commercial buildings, commercial housing and other housing, the concept of 'owners' as defined in the Civil Code is analogous to that of property right holders. Consequently, property right holders are entitled to exercise rights and assume obligations with regard to the exclusive part of the building, as well as the common part, including the right to make decisions, to undertake repairs and maintenance, and to assume obligations in this regard.

3.1.2 Implementing entities

3.1.2.1 Concept and Responsibilities of the Implementing Body

The implementation entity is typically a government-commissioned organisation or a market-oriented enterprise, which is specifically responsible for project declaration, scheme design, identification of construction units, management of the construction process, acceptance of project completion and completion of delivery, and is also responsible for property management, etc. It is the executor of urban renewal.

However, there is no uniform and clear definition of the concept and responsibilities of the implementation entity in Beijing. Consequently, different projects are easily confused with the concepts of property rights and construction units. In addition, for comprehensive regional renewal projects, including commercial building renovation and old residential area renovation, there are often multiple implementation entities, and it is challenging to establish cross-project collaboration between different implementation bodies. Therefore, it is essential to clarify the selection of the implementation entities and the specific content of the work.

Chinese cities such as Shanghai and Shenzhen have elucidated that urban renewal projects can be implemented by property rights holders, market players, or led by the government. However, the definition and responsibilities of the implementing entities vary from place to place (e.g. Table 1). From the perspective of urban renewal implementers, these can be broadly classified into four categories: property rights holders' independent implementation mode, market players' individual implementation mode, government-led implementation mode (including local state-owned enterprises), and co-operation implementation mode.

Table.1: Comparison of Different Cities on Implementing and Coordinating Subjects

municipalities	The main body of implementation	Responsibilities of the implementing entity

Shanghai	**Implementing entities:** property right holders implement on their own or in cooperation with market players Coordinating body: market players	The main body of renewal coordination is responsible for promoting the willingness to achieve regional renewal, integrating market resources, investigating the current situation, conducting thematic studies, preparing regional renewal programs, and coordinating and promoting the implementation of renewal projects, etc.
Shenzhen	**Implementing entities:** by the property rights holders, enterprises with real estate development qualifications (hereinafter referred to as market players) or municipal or district people's governments	Preparation of urban renewal unit plans, fulfillment of the obligation to hand over public land, urban infrastructure and public service facilities, innovative industrial housing, public housing, etc., without compensation, and establishment of fund supervision accounts or other supervisory measures, etc., in accordance with the plans.
Chongqing	**Implementing entities:** Government, property rights holders, relevant entities	Signing of performance monitoring agreements, advice on area planning programs, etc.

(Source: mapping based on comparisons of local documents)

3.1.2.1 Selection of implementation organisations

The manner in which different cities select the implementation body varies. For instance, the city of Shenzhen stipulates that an urban renewal project that adheres to the stipulated regulations may be implemented by property rights holders, market entities, or through a joint effort between municipal and district governments. In addition, Shenzhen differentiates between the roles of the reporting body and the main body in implementing renewal projects. The scope of the reporting body's responsibilities varies depending on the specific renewal project. For instance, the reporting body may be tasked with reporting on the original property rights or those held by a market entity. In such cases, the reporting body may be required to coordinate with multiple property rights holders. Alternatively, the reporting body may be commissioned by a single property rights holder or market entity to oversee the project.

Concurrently, in instances where multiple property rights holders fall within the scope of renewal, various jurisdictions permit urban renewal projects to adopt a collaborative implementation mode. For instance, the city of Shanghai has put forth the concept of a coordinating body for renewal, which is tasked with facilitating the achievement of regional consensus on renewal, integrating market resources, and preparing regional renewal programmes. Additionally, the proposal suggests that market entities (non-property rights holders) may serve as both the implementing body and the coordinating body.

3.1.3 Neighbouring rights holders

In current practice, there is a problem of difficultly in dealing with the conflict of neighbouring relationships. For example, the vertical pipeline reconstruction within the building itself of the old district faces the problem of whether the property right holders with neighbouring relationships agree or not. This can result in the implementation of the project being affected. In urban renewal activities, neighbouring property rights holders are expected to provide the necessary facilities, help to achieve an improved quality of the living environment, eliminate housing safety hazards and pursue other public interests. Nevertheless, the majority of cities currently lack the requisite framework to accommodate the concept, rights, and obligations of neighbouring rights holders.

3.2 Expression of Interest Stage

3.2.1 Status and Problems

It is evident that public participation represents an important avenue for the expression of interest. This paper primarily analyses the form of interest expression that involves the participation of property rights holders as a central element. Currently, Beijing has established a process of public participation in urban renewal, and has accumulated some practical experience. For instance, in the context of installing lifts in

older districts, local government officials and community self-governance organisations convene residents to engage in deliberations and communication with the objective of resolving conflicts and disputes. This is typically conducted through a structured forum known as a "discussion meeting." In the renewal of commercial districts, business associations, as industry organisations, act as intermediaries in the upgrading and management of commercial districts, inviting commercial tenants in the districts to participate in the renewal activities.

However, most urban renewal projects still suffer from a lack of resident participation, as evidenced by the absence of a mechanism for coordinating the interests of all parties involved in the transformation of old neighbourhoods, the lack of interaction between multiple actors, insufficient publicity of policies, and imperfect information and feedback mechanisms.

The grass-roots governments of street offices and communities are frequently responsible for coordinating the interests of all parties in a project and guiding bottom-up demands for renewal. However, the current limited number of grass-roots government (street offices and communities) staff, as well as the lack of operational paths to promote co-operation among all parties, make it challenging to negotiate and discuss the actual work of the project.

3.2.2 relevant experience

Successful cases of urban regeneration usually have used consultation throughout the process. The Roppongi project in Tokyo, Japan, explored the "everyone does it, everyone benefits" model. The implementing body and the original owners set up "agreement meeting" to widely gather the opinions of the residents. And through the rights exchange, the value of the rights of the land owners, legal building owners, other rights holders or implementers before the renewal, and the proportion of the funds provided, are used to allocate the due rights of the buildings and their land after the renewal. Through the rights exchange, the complex land ownership problems are solved by allocating the due rights of the renewed buildings and their land in proportion to the value of the rights and the funds provided by the former land owners, other rights holders or implementers.

Shanghai has established the 'One Map, Three Meetings' system, which facilitates communication and consultation between community units and residents on matters of immediate interest and community development. This system also allows for the collection of opinions and suggestions from residents through the establishment of a system of programme design maps, hearings, co-ordination meetings and appraisal committees. This integration of pluralistic main bodies throughout the planning and consultation, construction and implementation, and operation and management processes is designed to stimulate the long-term motivation for self-renewal of the aboriginal people. Integrate multiple subjects throughout the entire process of planning, consultation, construction, implementation, and operation management, thereby fostering long-term motivation for self-renewal of the residents.

3.3 Coordination of Interests Phase

3.3.1 Present situation and problems

Urban regeneration itself is a process of reconciling existing interests, and an effective mechanism for coordinating interests is crucial to the implementation of regeneration. From a practical point of view, the most difficult problem in the consultation process is the 'resolution of disputes', and this is also an issue that has received a great deal of attention in legislation.

Nevertheless, the coordination mechanism of interests in the current renewal practice in Beijing is still in its infancy, as evidenced by the following four aspects: (1) It is challenging to ascertain who benefits and who pays in the financing of renewal projects. Furthermore, in the transformation of old neighbourhoods, residents desire to enjoy the benefits of improved living quality, yet the awareness of contributing to the payment of fees has not yet been established. (2) The current urban renewal projects are challenging to achieve consensus on the willingness to renew. For instance, some of the current safety, energy saving and environmental protection aspects of the buildings do not meet the standards. Furthermore, there is a lack of cooperation from small owners in the renewal and transformation process, which has resulted in difficulties in implementing the project. (3) There is a dearth of efficacious conflict mediation mechanisms, and the majority of communities have yet to implement an effective democratic deliberation workflow. (4) It is challenging to establish an effective communication mechanism with property owners for projects with complex ownership structures.

3.3.2 relevant experience

In order to protect the interests of the "majority", Hong Kong, Taiwan and Japan have introduced compulsory sale systems. In Hong Kong, the Land (Compulsory Sale for Redevelopment) Ordinance stipulates that a person in possession of more than 80 per cent of the freehold interest may, in the event of unsuccessful attempts to purchase the minority freehold interest, apply to the court for a compulsory sale order to auction the minority freehold interest on the basis of a valuation report on the value of the freehold interest. The sale is to be conducted by way of public auction in order to ensure that the interests of the minority freeholders are not prejudiced. In order to ensure that the interests of minority shareholders are not prejudiced, the sale must be conducted in the form of a public market auction.

In Japan, the right to request for sale was created, whereby the purchaser designee has the right to request the owner who does not agree to the redevelopment, or his/her successor, to sell his/her right to zone ownership and the right to utilise the base at the market price. Furthermore, if the aforementioned subject experiences significant difficulties in his/her life after the right to request for sale has been exercised and his/her continued residence will not have a significant impact on the implementation of the

resolution on redevelopment, he/she may apply to the court to request for the postponement of the period of the transfer. Taiwan has established a rights conversion system, which facilitates the conversion of rights such as building ownership, lease contracts, and mortgages. To illustrate, in the case of building ownership, negotiations are held in principle, and in the event of a failure to reach an agreement, a rights conversion plan is implemented to assess the value of each right, with the land and buildings subsequently allocated in proportion to the value.

4 Response of local regulations to the issue of coordination of interests

Finally, this paper analyses the main aspects of urban renewal, including the implementation process, negotiation of interests, and dispute resolution procedures outlined in the ***Beijing Urban Renewal Regulations***[1]***(hereinafter referred to as The Regulations)***, which is implemented in 2023. The aim is to demonstrate how local legislation responds to the needs of disputing and coordinating interests in reality. ***The Regulations*** address the solutions in several areas, including the rights and obligations of the property rights holders, implementing entities, and neighbouring rights holders, as well as the rules and procedures of the consultation mechanism and the disposal of objections.

4.1 Clarify the concept and rights and obligations of property right holders

4.1.1 Concept, rights and obligations

The Regulations clarify the legal relationship of urban renewal, make it clear that property right holders are responsible for the renewal of the properties they hold, enjoy corresponding rights and assume corresponding obligations, and encourage property right holders to play the role of the main body in urban renewal, effectively responding to the problem of residents' unwillingness to bear the costs of renovation, and safeguarding the right to propose and vote on the renewal programme.

Article 18 proposes that the rights of property rights holders include the right to propose proposals for renewal needs, independent or cooperative renewal with market entities, independent selection of the implementation of the main body, joint implementation of the renewal of the renewal and other renewal methods and paths, and the right to enjoy the right to operate and the right to income according to the law, the right to be informed of the implementation of urban renewal, the right to supervise and the right to make suggestions, etc.

Article 19 puts forward, the property rights holder shall bear the obligations including cooperate with the investigation, provide materials, cooperate with the illegal construction management, construction, etc., and actively perform the decision of the owners, etc., and clearly participate in the update meeting, carry out common consultation is the property rights holder common part to manage, execute the

[1] Beijing Urban Renewal Regulations

implementation of the implementation of the programme by the law after the vote, review and adoption of the obligations in the aspects of the project involving hidden safety hazards of the people's livelihood, the property rights holders have the obligation to To carry out or co-operate with the renewal.

4.1.2 Special property right holders: state-owned enterprises

State-owned enterprises occupy a unique position in relation to property rights. On the one hand, they are property right holders, which entails the right and obligation to renew and reconstruct their own assets. On the other hand, they are the users and possessors of state-owned assets, which entails the responsibility of preserving and increasing the value of state-owned assets. Consequently, the "Regulations" for state-owned enterprises to update the responsibility and task for special provisions are necessary in order to resolve the aforementioned low efficiency of state-owned enterprises in land use. The assessment mechanism is not yet mature enough to address this issue.

Article 7 proposes that state-owned enterprises and institutions, as property right holders, should take the initiative to carry out renewal.

Article 56 proposes that the state-owned assets supervision and management agency should establish and improve an assessment mechanism that is appropriate to the participation of state-owned enterprises in urban renewal activities.

4.2 Implementing entities and Their Responsibilities

4.2.1 Connotation and Determination of the Implementing entities

The Regulation specifies the connotation, duties and selection method of the implementation subject, which effectively responds to the current unclear meaning of the implementation subject, and the unclear concept of the property right subject and the construction unit.

Article 20 proposes that for different tenure relationships, differentiated ways of determining the main body of implementation should be designed. The urban renewal project involves a single property right holder, who is responsible for determining the implementation of the main body. In the case of a property right holder with more than one property, the implementation of the main body is jointly commissioned after consensus. In the event that consensus cannot be reached, the property right holder is required to vote in accordance with the law to determine the implementation of the main body. However, in the case of urban renewal projects with complex tenure relationships, the aforementioned rules cannot be applied to determine the implementation of the main body. Instead, the laws and regulations pertaining to public interest, public safety, and other relevant considerations must be taken into account. In the event that the necessity for renewal is absolute, the people's government of the district is empowered to adopt the bidding process and other means of determining the implementation body in

accordance with the law.

Concurrently, the Shanghai mechanism for coordinating the main body, as set forth in Article 22, explicitly permits the designation of regional (district) renewal projects or multiple urban renewal projects as urban renewal implementation units. This designation allows for unified planning, coordinated implementation, and the balancing of funds for regional renewal through the packaging of multiple projects. For urban renewal projects implemented as an implementation unit, a unit co-ordination subject system is established, authorising the district people's government to determine the subject that is compatible with the urban renewal activities within the scope of the implementation unit to be the coordinating subject of the implementation unit.

4.2.2 Duties and rights of the implementing entity

Article 23 delineates the qualifications of the implementation body and its specific work responsibilities, which serves to enhance the enthusiasm of relevant enterprises to participate in urban renewal, protects the rights and interests of the implementation body, and also provides guidance to the implementation body on the implementation of the project. In addition, the implementing body is responsible for conducting an assessment of the current situation within the project, an assessment of the performance of housing buildings, an assessment of fire safety, a solicitation of renewal needs, and the preparation of an implementation plan. In light of the actual situation, the district government may empower the implementation unit coordinator to undertake functions such as integrating market resources. Given the multifaceted nature of the implementation body's responsibilities, it is advisable to select a body with the requisite expertise to fulfil the aforementioned roles. This could include entities with the capacity to plan and design, renovate and construct, manage properties and operate at a later stage.

4.3 Rights and obligations of neighbouring rights holders

In accordance with the Civil Code, neighbouring rights holders are obliged to provide the necessary facilities in a manner consistent with the principles of favourable production, convenient living, solidarity and mutual assistance, fairness and reasonableness. Article 28 stipulates that neighbouring rights holders must provide the necessary facilities for urban renewal activities, including cooperation (e.g. surveying, etc.), granting the necessary access areas and construction workplaces, and providing the necessary water and drainage facilities for the implementation of renewal and reconstruction. Concurrently, in the event that losses are incurred by the neighbouring rights holders as a consequence of the aforementioned provision of facilities, they shall be compensated or indemnified in accordance with the relevant legislation.

4.4 The establishment of a consultative platform

With regard to the establishment of a consultation platform, the Regulations provide for institutional design at three levels: public participation, consultation and voting, and democratic deliberation mechanisms.

Article 8 sets forth the overarching principles of public participation, which must align with the tenets of transparency, impartiality, and fairness. These principles are intended to enhance the involvement of property rights holders and interested parties in the formulation of urban renewal plans, the creation of policy, and the conduct of democratic decision-making in accordance with the law. Moreover, they are designed to empower owners' self-governing organizations, thereby safeguarding the public's right to know, participate, and supervise in urban renewal projects.

Article 24 delineates the stipulations pertaining to consultative voting on the implementation programme. In instances where multiple property rights holders are involved, the owners are required to vote on the implementation programme of the common parts in accordance with the law.

Article 25 proposes the establishment of a democratic deliberation system for urban renewal projects. This system would facilitate multi-dimensional consultation on project generation, implementation and evaluation, and would provide a platform for the expression of opinions and suggestions from a range of stakeholders. This could be achieved through the use of community forums and other forms of engagement, in conjunction with the specific needs of the project.

4.5 Procedures for handling objections

The Regulations stipulate a corresponding mechanism for the disposal of objections in the event of refusal to implement the implementation plan or in the event that a small number of people are unable to reach a consensus, thus forming an effective programme for the protection of public interests and public security.

In the event that an individual property rights holder declines to implement the implementation programme adopted by vote, other property rights holders, owners' associations or owners' committees are entitled to file lawsuits to the People's Court in accordance with the law. And the use of the People's Mediation System to help parties reach voluntary mediation agreements is encouraged. In the event that the implementation of the project entails considerations of public safety as stipulated by laws and regulations, the district urban renewal authority may make a renewal decision with reference to the relevant provisions on major administrative decisions. Should the property right holder be dissatisfied with the decision, they may apply for administrative reconsideration or file an administrative lawsuit in accordance with the relevant legislation.

5 Conclusion

The article commences with an examination of the definition of property rights, followed by an analysis of the connotations of property rights. This is then extended to encompass the connotations of property rights in urban renewal. The characteristics of the current situation are then constructed, a framework for analysing the interests of multiple subjects is constructed, and finally, the response of Beijing's urban renewal legislation to the current property rights issues is analysed. The article presents a research framework comprising the identification of subjects, expression of interests

and coordination of interests. It then analyses the problems and experiences of the current situation. The primary strategies of the legislation are evaluated in the context of Beijing's legislative practice, including the clarification of the types of property rights and the corresponding objects of property rights, the clarification of the concept of property rights subjects and their rights and obligations, and the clarification of the implementation subjects and their responsibilities in the process of defining the rights and obligations of neighbouring rights. In general, the legislative system has been designed to address the issues related to property rights in Beijing. On the one hand, the legislation has established a system of duties for the property right holder (Table 2), which facilitates the delineation of rights and responsibilities and thus contributes to the protection of rights and interests in practice. Concurrently, the legislation should also facilitate the rights and responsibilities of neighbouring right holders, which would also assist the public in distinguishing ownership and facilitate the smooth implementation of urban renewal projects involving the public interest.

In essence, the majority of the institutional framework within the legislation is guided by principles. While the policies in principle cannot be directly supported in project practice, they offer numerous advantages and provide flexibility in the implementation of the law. This encompasses the specification of the details of support policies in terms of funding, planning and land to be issued by different sectoral authorities. Additionally, it empowers district-level governments to consider regional characteristics and realities when formulating support policies conducive to the implementation of the project, such as guidelines on the specific implementation process.

In the subsequent stages of legislation and law implementation, it is recommended that the operational guidelines be refined in the future, taking into account the successful experience of specific projects. For instance, in the domains of interest consultation and conflict resolution, it is proposed that the workbook on consultation and shared governance be further refined in the subsequent phase, with due consideration of the experience of practical projects. This will enable grassroots staff and residents to participate in proposing topics and putting forward their needs for the urban renewl.

Table 2: Comparison of Property Rights Dilemmas and Institutional Responses

Property Rights Dilemma	**Stage**	**Practical challenges**	**Response of Local Legislation**
Ambiguity in property rights boundaries	Subject identification	The responsible entities for different updating objects are not clearly defined	Clarify the concept and rights and obligations of property right holders
			Clarify the responsibilities and tasks of SOEs
The difficulty of property rights restructuring		Lack of clarity in the responsibilities of the implementing entities	Clarify the process of determining the implementing entities and its responsibilities

		and failure to protect their rights and interests	
Ambiguity in property rights boundaries		Lack of definition of neighborhood relations, difficult to achieve public interest and public security	Clarify the rights and obligations of neighboring rights holder
The difficulty of property rights restructuring	Expression of Interest	Lack of interaction between different parties	Define the rules of the democratic consultation mechanism
The rights and responsibilities of property rights holders are not equivalent		Lack of feedback mechanism	
	Coordination of Interests	Lack of awareness of funding	Clarify the concept and rights and obligations of property right holders
		Conflict of interest affects public safety and public interest	Define the procedures for handling objections

There are still limitations and shortcomings in this paper, as it only analyses the conflicts of interest and adjustments associated with the change in ownership of the asset, but does not analyse the corresponding changes in interests associated with the increase in plot ratio, the change in land use and the increase in housing value. In the future, all types of interest changes in urban renewal should be analysed more systematically, as well as the impacts and problems they bring.

Track 04: Borders

BORDERS - Transboundary planning for sustainability and cohesion

Chairs:

- Alois Humer, University of Vienna
- Thomas Perrin, Research centre TVES-Lille
- Simin Yan, Universität Heidelberg, Geographisches Institut

Keywords: *planning systems, regional planning, city regions, soft spaces, planning cultures, EU Cohesion Policy, cross-border cooperation, comparative planning studies, transnational planning, actors, scales, institutional change, policy transition*

Current transformation processes towards sustainability and equity that planning seeks to frame require a transboundary perspective on problems and policy responses. While local, regional or national authorities are typically endowed with the mandate for regulatory spatial planning, the existence and importance of planning across administrative borders of jurisdictions is evident. Cross-border regions and large-scale macro-regions are often associated with European spatial planning, but transboundary planning processes also exist within countries at various scales, visible, for example, in the emergence of soft spaces such as city-regions. These transboundary planning processes are especially interesting regarding their governance arrangements, their relationship with statutory planning systems and practices, and their mechanisms for democratic control and participation. Moreover, new planning scales might challenge existing administrative divisions and practices, causing or solving challenges related to policy integration.

This track discusses new planning spaces, formal and informal planning arrangements and comparative perspectives on planning systems, cultures, and practices in Europe and beyond across various scales and borders. We are interested in exploring not only the spatial but also the institutional and practice implications of such new and, at times, ‘transitional’ planning spaces. Comparative research, including the local, city-regional, regional, national and supra-national levels, is most welcome. Research on planning systems and planning cultures can provide essential insights into ideas, policies and practices – and the role actors play in shaping these – especially when transcending national perspectives and exploring local and regional specificities. Comparative perspectives within and between different country contexts can also reveal processes of policy transfer and policy diffusion and illustrate how planning ideas travel across borders.

We welcome theoretical perspectives, empirical, analytical work, and policy-centred discussions alike. For example, contributions to the Track BORDERS might address the following issues:

- Comparative perspectives on planning systems and planning cultures
- The changing nature and role of borders in spatial planning

- Visions and strategies at the macro-regional or continental level
- Planning across internal and external EU borders
- Drivers for cross-border cooperation and EU integration
- Wicked problems such as climate change as transboundary challenges for planning
- Maritime spatial planning and its linkages and interactions with planning on land
- Processes of international policy transfer and policy diffusion
- Spatial planning in functional regions and soft spaces
- Democratic mechanisms and citizen involvement in non-statutory planning processes
- Instances of rescaling and the resulting processes of institutional change
- Planning beyond territorialism
- Planning practices that cross administrative divisions and sectoral siloes
- The role of city-regions in the sustainability debate and the just and green transition

THE EVOLUTION OF SPATIAL PLANNING IN THE BORDER AREA BETWEEN SHENZHEN AND HONG KONG, CHINA

Yifan Cai
AECOM Asia Company Limited
461838630@qq.com

Abstract
Spatial planning in border areas is a complex undertaking, particularly due to diverse governmental systems. This complexity is further highlighted by the unique "One Nation Two Systems" principle in China, which governs the distinct governance structures of Hong Kong and Shenzhen. The Guangdong-Hong Kong-Macao Greater Bay Area (GBA) Development Outline has triggered significant changes in spatial planning within the border area between Shenzhen and Hong Kong. This study aims to examine the evolution of spatial planning in this border region, identifying various stages of planning development, key outcomes, influential factors, and coordination mechanisms. Ultimately, the study seeks to propose a more democratic and efficient coordination mechanism for border area planning, drawing on insights from the case study.

keywords: spatial planning, cross-border cooperation, policy transfer

1. Introduction

Spatial planning in border areas presents a unique set of challenges that require careful coordination and collaboration across various jurisdictions and stakeholders. The presence of different governmental systems, divergent objectives, cultural disparities, and uneven socio-economic development further complicate the planning process in these border regions. This is particularly evident in the case of the border area between Hong Kong, a Special Administrative Region (SAR) of China, and Shenzhen, a mainland Chinese city adjacent to Hong Kong.

Under the "One Country, Two Systems" principle, Hong Kong maintains a high degree of autonomy and operates under its own independent governmental system, distinct from the mainland Chinese system. This has historically led to a prolonged development segregation between Hong Kong and Shenzhen, despite their geographical proximity. However, the promulgation of the Guangdong-Hong Kong-Macao Greater Bay Area (GBA) Development Outline in 2019 and the enactment of the Hong Kong national security law in 2020 have positioned Hong Kong and Shenzhen as the core twin cities of the GBA, with Hong Kong being urged to integrate further into mainland China's national development strategy. Instead of being organised by transregional planning, Shenzhen and Hong Kong have their own urban planning system while continuously influencing and developing border areas under mutual government coordination and democratic feedback. This has led to a series of changes in the urban planning and social development in the Shenzhen-Hong Kong border area, driven by political dynamics and policy transfer.

This study explores the evolution of spatial planning in the border area between Shenzhen and Hong Kong, examining how both sides have worded towards unified development goals and consensus on win-win situations in spatial planning through multiple driving forces. Through the case study, the study aims to identify more democratic and effective coordination mechanisms and promotion methods for spatial planning in the border area, ensuring that planning can be effectively implemented and utilized in practical operations beyond the realm of technical feasibility.

2. Research Overview

Scholars have engaged in extensive debates on regional planning as a form of policy transfer and a complex system that necessitates looking beyond borders. Despite this theoretical discourse, practical planning activities, politics, and governance often confine regions within territorial political units. This juxtaposition has been labelled the "planning paradox" by Paasi, A. and Zimmerbauer, K. (2015), emphasizing the importance of acknowledging open and porous borders in strategic planning, even in the presence of delineated territorial political units.

Existing empirical studies on urban planning in border areas primarily focus on conducting factual surveys and offering planning guidance. However, these studies frequently overlook the long-term and dynamic nature of border area planning, shaped by technical considerations, socio-cultural elements, and the political landscape. Scholars like Sykes, O., Shaw, D., and Webb, B. (2023) have explored cross-border planning initiatives in various global regions such as the EU, ASEAN, and China's Belt and Road Initiatives, providing a comprehensive perspective on this form of planning. Researchers have also delved into specific cases in diverse regions with unique characteristics. For example, Song, Z. and Zhu, Q. (2020) analysed the spatio-temporal patterns of urbanization in 134 border counties in China, investigating the driving forces behind urbanization in these areas. Additionally, S P Mulya et al (2021) examined land use changes in the border area of Bogor Regency and City from 2010 to 2020, viewing border planning as a direct outcome or framework for decision-making while overlooking its long-term dynamic and adaptable nature. Wen, X., Lyu, Z. & Liu, T. (2023) studied port areas at China's borders, outlining the features of the cross-border flow network, including infrastructure, ecological networks, industrial networks, and cross-border communities, while proposing optimization measures for spatial considerations. Innovative approaches for developing cross-border functional areas have been explored, as evidenced in the work of Jakubowski, A. et al. (2022) who introduced the concept of the Cross-border Functional Area (CBFA) in the Lithuanian-Polish borderland. Their case study illustrates that establishing a flexible destination management structure can enhance cooperation among key stakeholders across borders, facilitate cross-border projects, and promote tourist products effectively.

Planning is not just a blueprint and a result, but a constantly coordinated dynamic process. Planning in border areas takes place amidst complex political and socio-economic environments. This paper aims to comprehend the evolution of border area planning through long-term policy changes and planning advancements, to gain a more comprehensive understanding of the influences of factors such as policies, socio-cultural environments, and various stakeholders on the development of border planning.

3. Methodology

To comprehensively investigate the evolution and dynamics of spatial planning in the border area between Hong Kong and Shenzhen, this study delves into the policies and initiatives of border area planning in Shenzhen and Hong Kong in the past decades. This period is characterised by significant political transformations and notable progress in the border area, making it a crucial focus for analysing the impact of social change and policy transfer on spatial planning and development in the border area.

The methodology involves analysing various policies and planning maps to select pertinent content and create diagrams illustrating the changes in the scope of the Shenzhen-Hong Kong

development area over different periods. These diagrams aim to identify the key outcomes and changes of various development stages, both physical and non-physical.

Furthermore, the study considers public opinions, social affairs, and key economic issues to identify the driving factors influencing planning and decision-making processes. Coordination among government-specific departments is deemed essential for facilitating discussions at both high-level and technical levels. Once strategic consensus is reached, multiple stakeholders, including the Shenzhen district bureau, Hong Kong NGOs, Members of the Hong Kong Legislative Council, urban planning consultants, headquarters, and companies, are involved in the spatial planning formation and decision-making process. Analysing the roles and involvement of these diverse parties is crucial for understanding the coordination and development mechanisms in the planning process.

4. Planning and Policy Development in the Border Area

4.1 Identification of the Planning Stages in the Border Areas

Spatial planning has been developed rapidly in Hong Kong and Shenzhen in the past decades, especially in their border area which hold significant potential for collaborative development. Despite Shenzhen and Hong Kong having distinct development phases and planning systems, they have reached a consensus under the regional strategic policies. Four main planning stages in the border of Shenzhen and Hong Kong are identified: the independent and self-interested stage, the Shenzhen one-side promoting stage, the regional strategic coordinating stage, and the Hong Kong-Shenzhen two-side cooperating stage.

(1) Stage 1: Self-interested Stage

Initially, both Shenzhen and Hong Kong focused on their development and interests regardless of coordination with the other. For example, Hong Kong initiated plans to develop two new towns near the border, primarily aimed at meeting the needs of residents and creating job opportunities, without taking into account coordination or cooperation with Shenzhen. Additionally, Hong Kong used to plan its NIMBY facilities, such as tombs at the border area, directing facing the city centre of Hong Kong in the border area. The presence of NIMBY facilities in the border area of Hong Kong faced consistent opposition from the citizens in Shenzhen. During this stage, spatial conflicts arose, and the border areas were not fully utilized as valuable space.

(2) Stage 2: Shenzhen One-side Promoting Stage

Due to the topographical constraints, Shenzhen had extensively developed much of its border area, with development activities suspended. During the past decades, Shenzhen expressed a keen interest in establishing collaborative relationships with Hong Kong to attract Hong Kong high-level enterprises, advanced academic institutions, and international experience. Two Shenzhen-Hong Kong cooperation zones, including the Qianhai Development Zone and the Houhai Development Zone, were planned in the border area of Shenzhen to develop the financial industry and headquarters with Hong Kong by 2018 at the initiative of Shenzhen.

(3) Stage 3: the Regional Strategic Coordinating Stage

The release of the regional policy GBA Development Outline in 2019 marked the initiation of a strategic vision and development objectives for GBA cities where the development of Qianhai and Houhai Development Zone was emphasised and proposed to get more political support. After the GBA Development Outline was released in 2019, integrating Hong Kong into the national development framework was a key issue, leading to enhanced planning and

mutual interaction in the border area. The companies and institutions from both cities were joined together and formed a new industrial cooperation.

Following the release of the GBA Development Outline, Shenzhen unveiled Shenzhen Territorial Planning and each administrative district formulated its respective five-year plan for 2020-2025. Each district in Shenzhen urged to plan its Shenzhen-Hong Kong development zone to achieve more resources and benefit from regional cooperation. Three main development zones were proposed, including the Futian Free Trade Zone, Luohu Economy Belt, and Sha Tou Kok development area. Hong Kong enterprises and academic institutions have been involved in these development areas, while Hong Kong did not have a plan to establish its own cooperation zone within its territory.

(4) Stage 4: Hong kong-Shenzhen Two-side Cooperating Stage

To increase land supply and foster greater cooperation with Shenzhen, the Hong Kong government unveiled ambitious plans to develop the Northern Metropolis in the border area in 2021. This strategic initiative aims to increase land supply and foster greater cooperation with the neighbouring city of Shenzhen. Subsequently, both cities started cooperating on the border area planning.

In 2022, the Luohu District of Shenzhen, which has the closest relationship and the most bordering areas with Hong Kong, was positioned by the Shenzhen government as the Shenzhen-Hong Kong Modern Commerce and Trade Upgrade Development Zone, aligning its development with Hong Kong. Luohu District not only issued the Shenzhen-Hong Kong Industrial Development White Paper and a spatial integration framework but also established a Shenzhen-Hong Kong Development Department under its original Luohu Development Bureau, to comprehensively integrate with Hong Kong for planning and development and manage affairs related to Hong Kong. As a result, Shenzhen has transitioned from a strategy of individual development zone integration to a regional Shenzhen-Hong Kong coordinated development strategy, achieving breakthroughs in terms of development scale and strategic vision.

Further on, Hong Kong developed an Action Guideline for the Northern Metropolitan in 2023, focusing on expanding the areas and refining the infrastructure within the region. This Action Guideline further specified the scale and building design plans of the development area, while also establishing a detailed timetable to expedite the planning and construction of the Northern Metropolitan.

Released time	Properties	Policies/Plannings	Main content
2019.2	Regional policy (GBA)	Guangdong-Hong Kong-Macao Great Bay Area Development Outline	The goal is to build the GBA into a world-class Bay Area and a world-class city cluster.
2019.8	Territorial Policy (Shenzhen)	Opinions on Supporting Shenzhen to Build a Pioneering Demonstration Zone of Socialism	Shenzhen plans to take the lead in establishing a modern economic system and play a key role in the construction of an international technology and innovation centre in the GBA.

Released time	Properties	Policies/Plannings	Main content
		with Chinese Characteristics	
2019.12	Territorial Policy (Shenzhen)	Luohu Port Economic Belt Development Plan	Launch five major initiatives to create a sustainable development pilot demonstration zone.
2021.6	Territorial Planning (Shenzhen)	Territorial Spatial Master Planning of Shenzhen (2020-2035), and Shenzhen 14th Five Year Plan and the Long-Range Objectives through 2035	In 2030, Shenzhen plans to be an important global city as an innovation centre, financial centre, business centre and cultural centre. The plan clarifies urban vision, urban development pattern, ecological pattern, people's livelihood, innovation development, etc.
2021.9	Territorial Policy (Shenzhen)	Comprehensively Deepen the Reform and Opening up Plan of the Qianhai Shenzhen-Hong Kong Modern Service Industry Cooperation Zone	The total area of the Qianhai Cooperation Zone has expanded from 14.92 km^2 to 120.56 km^2.
2021.10	Territorial Policy (Hong Kong)	The Chief Executive of Hong Kong's 2021 Policy Address, and Development Strategies for Northern Metropolitan Areas	The construction of a 300 km^2 metropolitan area in the north of Hong Kong, in conjunction with the ports and transportation infrastructure of Shenzhen and Hong Kong, to form a strategic layout of "twin cities, three circles" between Shenzhen and Hong Kong.
2022.9	Territorial Policy (Shenzhen)	Luohu Shenzhen-Hong Kong Deeply Integrated Development White Paper	Luohu whole district is positioned as Luohu Shenzhen-Hong Kong Deeply Integrated Development Area with a total area of 95km^2.
2023.10	Territorial Policy (Hong Kong)	Action Guideline for Northern Metropolitan Areas	The construction of a 300 km^2 metropolitan area in the north of Hong Kong, in conjunction with the ports and transportation infrastructure of Shenzhen and Hong Kong, to form a strategic layout of "twin cities, three circles" between Shenzhen and Hong Kong.

4.2 Identification of the Influenced Outcomes and Changes

These stages have been shaped not only by multi-level economic and social policies but also by input from citizens and non-governmental organisations. This influence has resulted in the expansion of developing areas, relocation of NIMBY(Not In My Backyard) facilities, alignment of industries and functions, enhancement of cross-border infrastructure connections, and transformation of boundary control points in the border area.

(1) Extension of Developing Areas

Expansion of Development Areas Within the overarching trend of promoting border region development, a significant shift has occurred in the expansion of development areas. Both Shenzhen and Hong Kong have progressively increased the number of development zones and the scale of land occupation to capitalise on the regional value in the border area and foster collaborative opportunities.

After undergoing shifts in planning and policies, Shenzhen and Hong Kong have significantly expanded their development areas in the border region, albeit at varying paces. With the release of the Greater Bay Area (GBA) Development Outline, Shenzhen delineated specific industrial objectives for the Shenzhen-Hong Kong cooperation zones and meticulously planned infrastructure, such as metro lines, to improve connectivity in the border area. Embracing the concept of establishing a Port Economic Belt in the border region, multiple development zones have been proposed. Subsequently, Hong Kong proposed the Northern Metropolis in the border area, envisioning extensive land development for local housing, industrial purposes and collaboration with Shenzhen in technology and innovation. This strategic shift signifies a move towards a more integrated and interconnected approach to development, emphasizing cross-border cooperation and synergy in technology and innovation.

Before 2019

Regional strategic planning in 2019

Shenzhen formulated its 5-year plan in 2020-2021

Hong Kong envisioned the Northern Metropolis in 2022

Luohu, Shenzhen was positioned as a main district to coordinate with Hong Kong in 2022

Hong Kong made an Action Guideline for Northern Metropolis in 2023

Diagram 2: Expanding development areas of Shenzhen and Hong Kong in the border area
Source: Provided by the author

(2) NIMBY Facilities and Space Conflict

In the context of border planning considerations between the two regions, NIMBY facilities that previously posed challenges to each other have garnered attention. These facilities have been highlighted in government policies and neighbouring public opinions as requiring relocation to address spatial conflicts in the border area.

Prior to 2019, Hong Kong had planned to construct a tomb at the border between Hong Kong and Shenzhen, directly facing the residential area of Shenzhen. This decision sparked extensive protests among the citizens of Shenzhen due to certain Chinese cultural beliefs. However, following the announcement in 2019 by the Hong Kong government to halt the construction of the tomb, taking into account the well-being of the Shenzhen citizens, plans were made to relocate the tomb as part of the Hong Kong Northern Metropolis Development Strategy in 2021 to accommodate new industrial development.

(3) Alignment of Cooperative Industries and Functions

With the expansion of the development areas, the scope of industries for cooperation broadened from finance, technology and innovation, and modern services to include logistics, the food industry, modern consumption, modern commerce, and more. To leverage Hong Kong's advanced international status and receive special policy preferences, several special development areas are planned within the Shenzhen border area, subject to some Hong Kong standards or laws, referred to as "Within the domestic boundary, but outside the national border" or "Domestic but extraterritorial."

In addition to industrial cooperation, Shenzhen and Hong Kong have collaborated to establish several Sino-foreign cooperative universities in the border area, leveraging Hong Kong's internationalized education resources. These cooperative programs in the border area include The Chinese University of Hong Kong (Shenzhen) and the City University of Hong Kong (Shenzhen), among others.

(4) Cross-border Infrastructure Connectivity

Shenzhen has put forth plans to enhance the public transportation infrastructure in the border area, focusing on improving connectivity through the introduction of several metro lines linking to the cross-border ports. In alignment with this initiative, Hong Kong included the development of the Wenjindu Station near the Wenjindu Port in its Northern Metropolis Development Strategy 2021. Subsequently, Shenzhen unveiled its updated metro expansion plans in 2021, which included extending Metro Line 25 to the Wenjindu Port to enhance accessibility.

In response to these developments, Hong Kong made slight adjustments in its Northern Metropolis Action Guideline 2023, modifying the railway line type and relocating the Metro Station closer to the boundary control points. This strategic shift aims to streamline cross-border travel and improve connectivity between the two regions. Ongoing discussions between Shenzhen and Hong Kong focus on establishing a transfer station at the port to facilitate seamless cross-border transportation for residents on both sides. Efforts are also underway to explore the feasibility of a metro line directly connecting to the basement of the Wenjindu Entry Inspection Building, further enhancing transportation convenience and efficiency in the border area.

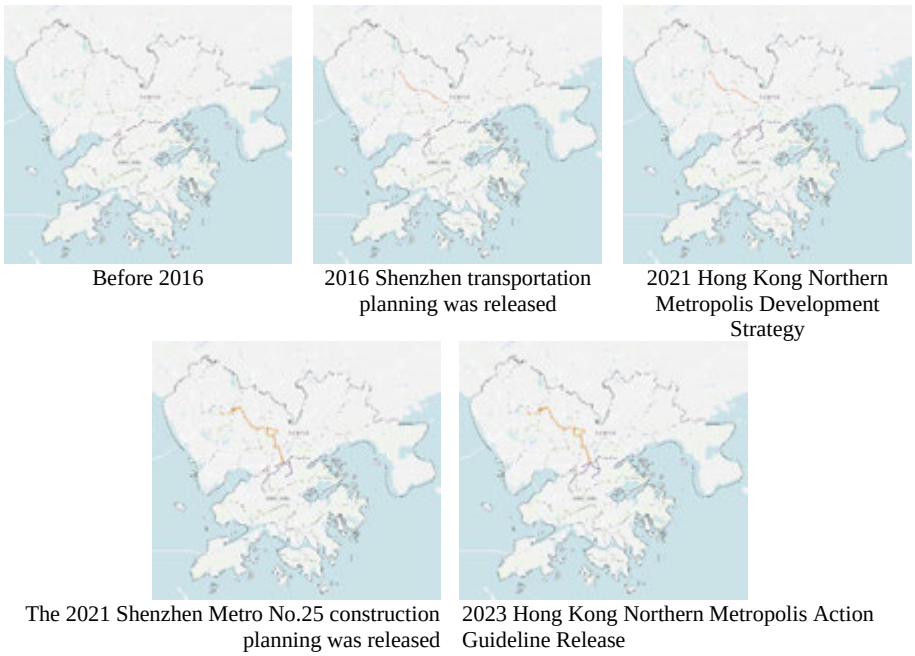

Diagram 3: Transporation planning in the border area between Shenzhen and Hong Kong
Source: Provided by the author

(5) Transformation of Boundary Control Points

The functional positioning of the seven Shenzhen-Hong Kong land ports is experiencing notable transformations in response to policy adjustments. Notably, since 2019, both the Shenzhen Bay Port and Huanggang Port have undergone significant upgrades, with Huanggang Port pioneering an innovative one-stop customs clearance model aimed at improving efficiency and service quality. Looking ahead, the strategic planning for the seven ports will involve repositioning them based on functionality, with freight ports situated on the periphery and passenger ports centralized within the city. These strategic changes are expected to introduce fresh opportunities and challenges to the development of the Shenzhen-Hong Kong ports, impacting trade flows, passenger traffic, and overall port operations in the border area.

(6) Planning and Construction Process

Historically, Hong Kong's intricate public consultation and approval procedures have often led to delays in urban planning and construction projects. Nevertheless, through ongoing communication and collaboration with Shenzhen, Hong Kong has expedited the planning and implementation of the Northern Metropolis. The 2023 Hong Kong Northern Metropolis Action Guideline outlines a defined construction schedule to complete the project within a two-decade timeframe.

5. Influencing Factors and Coordinating Mechanism

5.1 Factors Influencing Planning and Decision-making

The analysis of factors influencing planning in the border area involves multiple levels of consideration. The strategic coordination between Hong Kong and Shenzhen is shaped by a combination of political, market, technical, and public opinion factors.

(1) Political Context

Reflecting on history, the year 2019 marked a critical political transformation point, where national policies directed the cities in the GBA towards a new development trajectory. The coordinated development of Shenzhen and Hong Kong has become a national strategy. Since then, Hong Kong and Shenzhen have been dedicated to deepening cross-border cooperation continuously, promoting the coordinated development of the two places in areas such as innovation, industry, talent, and urban planning, and jointly constructing a more competitive city cluster in the Greater Bay Area.

(2) Market Demand

In the past, Hong Kong held a more advanced and developed position compared to Shenzhen, particularly in terms of the economy. However, in recent years, Shenzhen has significantly bolstered its capabilities in business, trade activities, manufacturing, and modern services. This has resulted in increased tourism and family visits from Hong Kong to Shenzhen and more business trips between the two cities than before. Statistics from the Hong Kong Customs and Excise Department show that from 2010 to 2019, the average annual growth rate of land-based cross-border passenger flow between Shenzhen and Hong Kong was approximately 2.80%. This indicates that the economic and social ties between the two places have grown closer, and cross-border exchanges have been continuously strengthened. The heightened market activity and cooperation across the border have led to a steady rise in land prices in these border regions. Therefore, utilizing the border area to facilitate twin-cities development is a logical response to this market demand.

(3) Technically Comprehensive Feasibility

The evaluation and approval of spatial planning proposals rely on various technical considerations, including factors such as land carrying capacity, transportation feasibility, environmental impact, etc. These aspects require in-depth analysis and expert judgment from planning consultants or institutions, as well as thorough review and assessment by relevant government departments. Before the Hong Kong government formally proposed the development of the Northern Metropolis, a comprehensive land survey and analysis were conducted to gather basic data on developable land to support the border development initiative. Similarly, Shenzhen also conducted a comprehensive analysis of areas available for development and urban renewal in the built border regions, based on which development zones that can be coordinated with Hong Kong were proposed.

(4) Public Opinion

The active engagement of residents, businesses, and various stakeholders in the planning processes of Hong Kong and Shenzhen has become increasingly significant. Their concerns and perspectives play a pivotal role in shaping the planning decisions and strategies, influencing the direction of development in the region. Stakeholders such as local residents, cross-border enterprises, and academic institutions specializing in regional development provide valuable insights that directly impact the planning process. In Hong Kong, non-governmental organizations (NGOs) and members of the Legislative Council play a crucial role in representing the interests of the public and specific stakeholder groups. These entities advocate for community interests and provide input on spatial planning initiatives to the Hong

Kong government, significantly influencing the planning and decision-making processes. For example, Dr. Zhang, representing an academic institution in Hong Kong, has presented research findings on border development, proposing development areas, targeted industries, and strategic orientations to inform planning efforts. Additionally, Legislative Council members from Daguling village in Hong Kong have persistently advocated for the preservation of the village's environment and opposed the establishment of 'Not In My Backyard' (NIMBY) facilities during border area development. Their steadfast advocacy has been integral in shaping the planning discussions and decision-making processes in both Hong Kong and Shenzhen, contributing to the formulation of more balanced and practical development plans.

5.2 Cross-border Coordinating Mechanisms and Role Casting in the Planning Process

Given the different planning and regulatory systems between Hong Kong and Shenzhen, it is challenging to easily align their spatial planning efforts. Therefore, coordination mechanisms are particularly important in cross-border planning. Key components of the coordination mechanism in the case of Shenzhen and Hong Kong include the involvement of government coordination departments, related government bureaus/departments, planning advisory institutions, the Legislative Council and public participation. These stakeholders play integral roles in addressing the complexities arising from the differing planning and regulatory systems of Hong Kong and Shenzhen. By fostering collaboration among these entities, the coordination mechanisms serve to bridge the gap between Shenzhen and Hong Kong and facilitate the harmonization of their cross-border planning endeavours.

(1) Government Coordination Departments

Hong Kong has established the Northern Metropolis Office as a key coordinating body for the region, while Shenzhen's former Development and Reform Bureau functions as the central hub for the Shenzhen-Hong Kong Modern Service Industry Cooperation Zone, facilitating cross-border communication and collaboration between the two cities. These governmental coordination departments act as vital bridges for fostering dialogue and cooperation between Shenzhen and Hong Kong, particularly in border areas. These entities are tasked with overseeing all aspects of coordination between the two regions, organizing technical discussions, facilitating official visits between both sides and more. By facilitating regular communication and engagement through various initiatives, these coordination departments play a crucial role in enhancing mutual understanding and promoting collaboration between Shenzhen and Hong Kong.

(2) Related Government Bureaus/Departments

The key government bureaus/departments involved in the planning and policymaking process mainly include the Hong Kong Development Bureau, Hong Kong Security Bureau, Shenzhen Development and Reform Commission, Shenzhen Planning Bureau, and Shenzhen Port Office. Each of these departments focuses on their respective areas of expertise to contribute to the planning and policy formulation process. Their expertise and insights are essential in providing valuable input and guidance in shaping policies and strategies that align with the goals and priorities of both Shenzhen and Hong Kong. By leveraging the collective knowledge and experience of these government officials, the planning process can be more comprehensive and effective in addressing the needs and challenges of the region.

(3) Specialized Groups

Shenzhen and Hong Kong have collaboratively established 19 Shenzhen-Hong Kong Specialized Groups, each focusing on different technical domains to facilitate cross-border cooperation and development. These specialized groups cover a wide range of areas, including the Connecting Northern Metropolis Development Strategy, Qianhai Construction, Hetao Construction, Technology and Innovation, Port Construction, Financial Services, Cross-border Transportation, Cross-border Railway Infrastructure, Special Services, Commercial and Trade, Hong Kong Teenager Entrepreneurship and Employment, Social Welfare, Medicine, Education, Public Service, Culture and Sports Tourism, Law, Environment Protection, and Talent. The members of Specialized Groups consist of both experts and officers of these government bureaus or departments from Shenzhen and Hong Kong.

To promote border area development and enhance coordination, regular meetings are convened in either Shenzhen or Hong Kong, where specific topics are discussed in a roundtable format, enabling each Specialized Group from both sides to delve into their respective fields in detail, exchange insights, and collaboratively devise solutions that benefit both regions. By fostering open dialogue and strategic planning through these specialized groups, Shenzhen and Hong Kong can effectively address shared challenges, leverage each other's strengths, and drive sustainable development and growth in the border region.

(4) Planning Advisory Institutions

Given the varying levels of information accessibility in Shenzhen and Hong Kong, advisory bodies serve as vital intermediaries in bridging the information gap and fostering effective communication between Shenzhen and Hong Kong. These advisory bodies play a critical role in ensuring that both sides are well informed about each other's policies, plans, and initiatives, thereby facilitating a more seamless and coordinated planning process. Urban planning consultants are instrumental in this endeavour, leveraging their expertise in urban development to facilitate communication and collaboration among stakeholders from both sides of the border. These consultants possess a deep understanding of the complexities of urban planning and can effectively convey insights and recommendations to relevant parties. In addition to their role in coordinating the spatial planning for both sides, urban planning consultants also play a crucial role in engaging with potential enterprises and companies that may be impacted by or involved in the planning process. By involving these stakeholders early on and soliciting their input, consultants can ensure that urban development plans are more sustainable, inclusive, and responsive to the needs of all parties involved. This collaborative approach not only enhances the quality of planning outcomes but also fosters a sense of shared ownership and commitment to the development of the region.

(5) Legislative Council and Public Opinions

The Legislative Council of Hong Kong plays a pivotal role in approving planning and development projects in the region. Both Hong Kong and Shenzhen prioritise public consultation stages in their planning processes, allowing the public to review proposals and offer input for optimization. The Legislative Council and public opinion influence decision-making, ensuring projects are legally sound and aligned with community needs. Active involvement of these entities guarantees that planning outcomes reflect the preferences of the communities they serve.

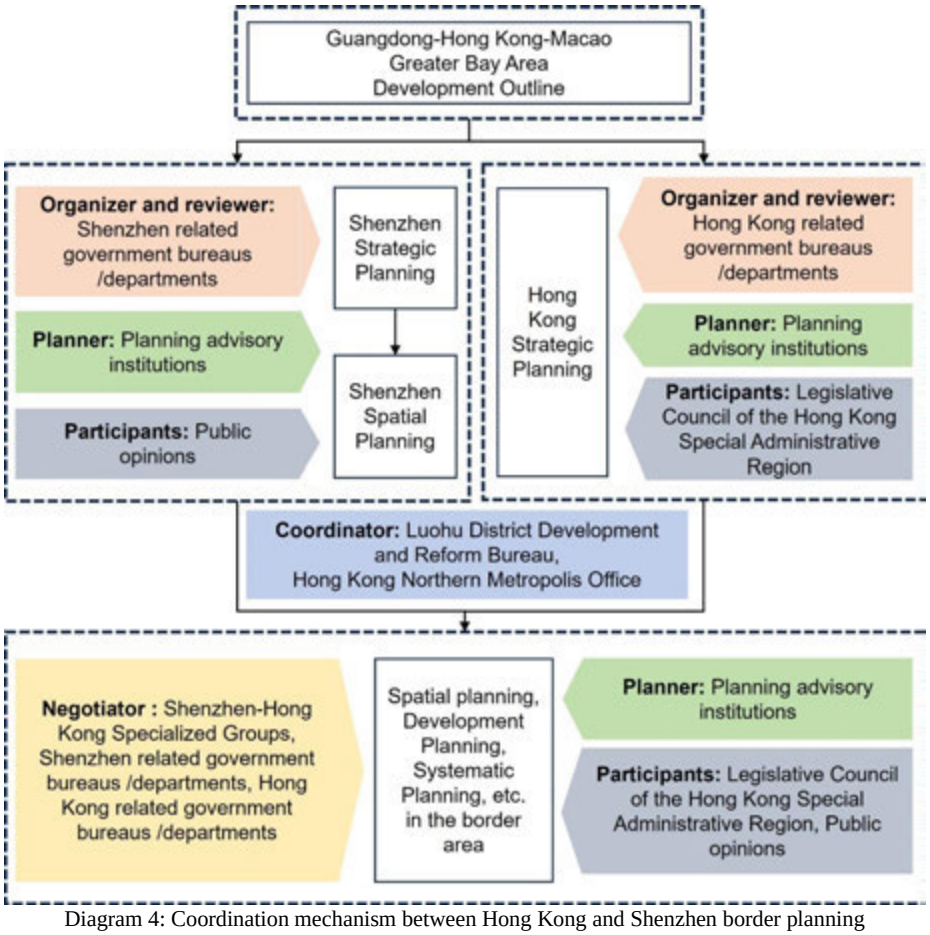

Diagram 4: Coordination mechanism between Hong Kong and Shenzhen border planning

6. Conclusion

By employing a multi-faceted approach that integrates policy analysis, mapping techniques, stakeholder engagement, and decision-making processes, this study provides a comprehensive understanding of the complexities and dynamics of border area planning in the Shenzhen-Hong Kong border region. The cross-border regional strategy plays a pivotal role in shaping development ideas of border areas, determining the establishment of common goals and development ideas between the two sides. Consistent macro development strategies, driven by market demand and technological conditions, can accelerate the planning and development of border areas. In the context of different political systems and socio-cultural conditions, building a communication bridge for border area planning becomes a shared responsibility for both sides.

In the case of border area planning between Shenzhen and Hong Kong, a cross-border coordination mechanism has been successfully established through collaborative efforts, enabling continuous optimization and adjustment of planning on both sides to achieve

mutually beneficial outcomes. Drawing insights from this case study, several suggestions are proposed to enhance the democratic and effective coordination mechanism for border area planning implementation.

Firstly, it is advisable to organize specialized workshops for the relevant specialized groups for more frequent and informal discussion. In the coordination mechanism, intentions and proposals are often expressed in a relatively indirect manner, making it difficult to receive immediate and precise responses during official coordination meetings. For instance, when Hong Kong presents its plans for Wenjindu port construction in such meetings, they may clash with the planning on the Shenzhen side. As a result, refining and reaching consensus on optimized proposals often require a significant amount of time for feedback. The specialized workshops would provide a platform for each side to fully articulate their technical details and primary concerns. By involving consulting firms experienced in both regions to manage spatial resource allocation and plan regional industrial development, the workshop can significantly expedite the scheme-making process on behalf of both parties. This approach aims to facilitate cross-border construction by implementing innovative mechanisms and unified standards. Secondly, an information-sharing mechanism shall be established to timely disseminate information on border area planning, policies, and development dynamics, promoting interaction and cooperation between both parties. During the planning formulation process, planning adversaries could be the key bridges to understanding the planning and intentions of the other party. In most border planning cases, planning adversaries are often cross-national companies with a better understanding and information about foreign planning. Finally, establishing a bilateral supervision and evaluation mechanism could enhance democracy and public engagement in border areas, incorporating public opinions and input from legislators from both sides. Regularly evaluate the progress and effectiveness of border area planning, and make timely adjustments and optimizations to planning schemes, ensuring the achievement of win-win goals for both parties.

Border areas planning serve not only to resolve spatial conflicts but also to promote mutual benefits. Therefore, the planning of border areas necessitates the establishment of tailored, effective, and rational coordination mechanisms, information-sharing mechanisms, as well as evaluation and supervision mechanisms. Although the focus of this case study is on the border area between the Special Administrative Region and mainland China, the coordination mechanism utilized during the planning process holds significant relevance and applicability to cross-border planning endeavours that involve different systems.

Email: shengbo2016@seu.edu.cn

Abstract
This study examines the migration trajectories of 468 representative leading manufacturing enterprises in the Pearl River Delta (PRD) region, aiming to analyze the impact of various administrative boundaries on the relocation and site selection decisions of these enterprises. The analysis focuses on the cross-boundary migration behavior of enterprises at both the inter-prefecture-level city and intra-prefecture-level city levels. The key findings are: (1) Despite the highly contiguous urban development in the PRD region, few enterprises choose to migrate across prefecture-level cities. (2) Driven by cost considerations and the local industrial network, urban boundary areas have become a significant target for enterprise relocation. (3) County/district and street boundaries within cities do not impose constraints on enterprise migration. Instead, intra-prefecture-level city migration is relatively frequent.

Keywords
Administrative boundary, Manufacturing enterprises, Cross-boundary migration, Dynamic mechanism, Pearl River Delta

1 Introduction

Manufacturing industry is a crucial driving force for urban development, and the aggregation and diffusion of manufacturing spaces often play a pivotal role in the evolution of urban and regional spatial patterns. The headquarters of manufacturing enterprises are particularly significant as they exercise critical control and influence over regional industrial chains. Observing the location selection and relocation activities of manufacturing enterprises provides an important perspective for studying the evolution of regional industrial spatial structures. As early as the 1940s, the cross-regional relocation of enterprises in the United States driven by labor costs and competition among enterprises attracted the attention of academics (McLaughlin and Robock, 1949). Evolutionary economic geography pays more attention to the study of industrial clusters and enterprise dynamics (Cooke and Morgan, 1998), focusing on analyzing the historical evolution of the spatial distribution of economic activities, especially emphasizing the "dynamic", "historical inheritance", and "synergy" of this process (He et al., 2014). Neoclassical economic theory argues that enterprises seek to locate in areas that maximize expected profits, which is the primary driver of relocation (Nakosteen and Zimmer,

1987). It is often observed in research that the advantages of headquarters agglomeration drive enterprises to relocate their headquarters to a few central cities (Holloway and Wheeler, 1991), which further strengthens the agglomeration advantages of enterprise headquarters (Klier, 2006; Wu and Ning, 2010).

For different types of enterprises, academics have explored various perspectives on their relocation patterns. For cross-border manufacturing enterprises, clustering factors, innovation factors, and enterprise heterogeneity characteristics are key factors influencing their location choices (Ye et al., 2019). For Chinese state-owned enterprises, institutional factors still play a dominant role (Wang et al., 2021), and tend to be strengthened. Institutional embeddedness can significantly promote enterprise relocation (Long et al., 2020). High-tech enterprises tend to relocate nearby and prefer to move into existing technology parks or headquarters agglomeration areas (Zhang and Zhang, 2022). Case studies of Japanese and Taiwanese enterprises in China show that cultural factors are also important in influencing enterprise location choices (Chang et al., 2010). Additionally, regional ecological benefits and government regulations on environmental protection are also among the important factors affecting enterprise relocation (Chen et al., 2019). It is evident that for different types of enterprises in different regions, the factors influencing their relocation are often complex and diverse.

On one hand, with the rapid development of information technology, the theory of regional network spatial structure represented by "space of flows" (Castells M, 1989) (Sassen, 1998; Hall, 1999) is increasingly being applied to analyze the emerging phenomenon of "Mega-City Regions." It is generally believed that within mega-city regions, as infrastructure continues to iterate and cross-border infrastructure (highways, subways, high-speed railways) is continuously constructed, the hindrance effect of administrative boundaries begins to dissipate. This allows for effective flows of population, industry, and capital between regions, leading to the formation of various functional agglomeration spaces during the process of these flows (Yuan et al., 2023). Existing research has observed a high frequency of flows of various factors within the Guangdong-Hong Kong-Macao Greater Bay Area. It is believed that boundary effects will significantly decrease, promoting rapid growth in cross-city border areas and forming a high-density industrial functional network (Li et al., 2018). In the "highly integrated and mobile" functional network of the Greater Bay Area (Fang et al., 2022), enterprise relocation is undoubtedly an important way for the agglomeration and diffusion of industrial functional elements. On one hand, the functional connections of spatial organizations between subsidiaries and headquarters within enterprises significantly promote the network density of the PRD, enhancing the overall functional polycentricity of the metropolitan area and simultaneously greatly increasing the agglomeration function intensity of cross-city enterprises. On the other hand, the distribution of enterprise headquarters exhibits a certain degree of heterogeneity, not entirely concentrated in the main urban areas of Guangzhou and Shenzhen. The agglomeration function intensity of headquarters in the Guangzhou-Shenzhen corridor, especially in areas near Shenzhen such as Longgang and Bao'an, has significantly increased (Zhao et al., 2021).

On the other hand, the significant impact of administrative divisions and administrative boundaries on regional economic development, enterprise location selection, and relocation has been verified in numerous studies. Although administrative boundaries are non-physical, they

can cause discontinuities between regions through boundary effects, leading to regional inequality (Zheng, 2023). In Chinese geographical and planning research, "administrative region economy" is believed to have originated from the central government delegating economic development authority to local governments since the reform and opening up, greatly enhancing the enthusiasm of local governments to develop local economies (Sun et al., 2020), and forming a distinctive "local corporatism" (Jiang et al., 1996). The "institutional distance" between administrative regions is believed to deeply affect regional economic integration, indicating that local governments compete more for capital elements than for labor, establishing obvious institutional spatial boundaries and administrative barriers (Wang et al., 2023). The special environment of China's economic transformation has created substantial differences in political resources possessed by governments at different regions and levels. Private enterprises have to consider the location decision of their headquarters under the guidance of strategic thinking in pursuing political resources (Wan, 2009). For resource-based enterprises, among the four factors that influence enterprise relocation - policy, economy, strategy, and sentiment - government policy factors have the most significant impact on the relocation of resource-based enterprises (Li, 2015).

Based on this, the following hypotheses are proposed in this study: Under the conditions of highly contiguous development of physical space and high-frequency flow of industrial factors in the Guangdong-Hong Kong-Macao Greater Bay Area, the administrative boundaries, in general, would not have a significant impact on the migration of enterprises' partial functions, such as the cross-prefecture-level city layout of subsidiaries and branches. However, does it still have a certain effect on the relocation of corporate headquarters? If the administrative boundary has no impact on the relocation of corporate headquarters, what kind of spatial pattern should the relocation of corporate headquarters in the Greater Bay Area exhibit? If there is a certain impact, what is the mechanism of this administrative boundary's effect, and how does it occur?

2 Data and Methodology

2.1 Study area and data

The research area of this study comprises nine cities at or above the prefecture-level in the PRD region, specifically including Shenzhen, Dongguan, Huizhou, Guangzhou, Foshan, Zhaoqing, Zhuhai, Zhongshan, and Jiangmen. The spatial identification precision of corporate headquarters locations is at the level of subdistrict/township, with a total of 604 spatial units. The research focuses on the 468 enterprises listed in the "Top 500 Guangdong Manufacturing Enterprises 2022" jointly released by Guangdong Enterprise Confederation and Guangdong Entrepreneurs Association, which are located within the aforementioned research scope. Through the use of business registration change information data from websites such as *Tianyancha* and *Qichacha*, the author retrieved the address change information of the enterprises since their establishment, excluded duplicate change data in terms of actual geographical location, and recorded the spatial migration of these enterprises. Additionally, information such as the city of operation, establishment time, and industry type of these enterprises was also collected.

Due to the significant time span of the sample enterprises' establishment, ranging from the

1980s to 2016 (131 enterprises were established before 2000, 249 between 2000 and 2010, and 88 after 2010), it is difficult to conduct standardized analysis of each enterprise based on a unified time frame. To reflect the overall trend characteristics, the study focuses on the migration trajectories of enterprises since 2000 (for enterprises established after 2000, the sub-district address where they were located at the time of establishment is selected). This time span of over 20 years can stably reflect the development status and spatial migration demands of the enterprises, considering that the average lifespan of manufacturing enterprises is only about 10 years, and the probability of demise significantly decreases for enterprises that have survived for more than 20 years (Xie, 2018).

2.2 Methodology

Social network analysis is a crucial research method in new economic sociology, focusing on studying social phenomena and structures from the perspective of "relationships." In recent years, it has also been widely used to measure economic and industrial relationships between spatial locations (Hou et al., 2009; Huang et al., 2023). This paper primarily employs social network analysis methodology and the network analysis functions of UCINET to measure and analyze the migration network of manufacturing corporate headquarters in the PRD region.

In the study, the addresses of the enterprises are standardized to the centroid of the respective sub-districts to facilitate a better analysis of the spatial connections between sub-district units. Based on the frequency of enterprise migrations between sub-district spatial units, a corporate migration network is established for the 604 sub-district spatial units in the PRD to study the degree of connection and network structural characteristics between different spatial regions. In the social network, enterprise migrations between spatial units are considered as a type of connection, and Gephi is used to visualize the network map and identify the strength of connections between various subgroups.

3 Multiscale characteristics of cross-border migration of enterprises

3.1The distribution of enterprise migration samples

Based on the statistical analysis of the migration trajectories of the 468 sample enterprises in this study since 2000, the data reveals the following patterns: (1) Only one enterprise underwent cross-provincial migration, specifically from Zhejiang Province to Guangdong Province. (2) There were only three enterprises that migrated across different prefecture-level cities. (3) Eighty-four enterprises migrated across different urban districts within the same city. (4) Eighty-six enterprises migrated across different sub-districts within the same urban district. (5) One hundred and twenty-one enterprises migrated within the same sub-district. (6) One hundred and seventy-three enterprises never underwent any migration.

The data suggests that most migrations occur within the same city or urban district, indicating a relatively localized pattern of corporate relocation in the PRD region. Cross-provincial and cross-city migrations are relatively rare, reflecting the concentration of economic activities and the attractiveness of the local environment for manufacturing enterprises.

Tab.1 Types and quantities of enterprise migration

Types	Number of enterprises	Proportion (%)
Inter provincial migration	1	0.2
Migration across prefecture level cities	3	0.6
Inter district migration within the city	84	17.9
Same district relocation within the city (excluding sub-district relocation)	86	18.4
Internal relocation within sub-district	121	25.9
No migration	173	37.0
Total	468	100

In this study, non-relocated enterprises and enterprises that only migrated in a sub-district are regarded as spatially stable manufacturing factors, and then we can observe which areas are more conducive to the long-term stability of manufacturing enterprises. By sorting out the distribution of 293 qualified enterprises, it can be seen that the stable manufacturing area in the PRD region mainly includes 7 sectors: Shenzhen Nanshan-Guangming sector, Zhuhai Jinwan-Doumen sector, Zhuhai-Zhongshan boundary sector, Dongguan east sector, West of Dongguan City-Guangzhou Nansha sector, Foshan Shunde sector, Foshan Nanhai-Sanshui sector.

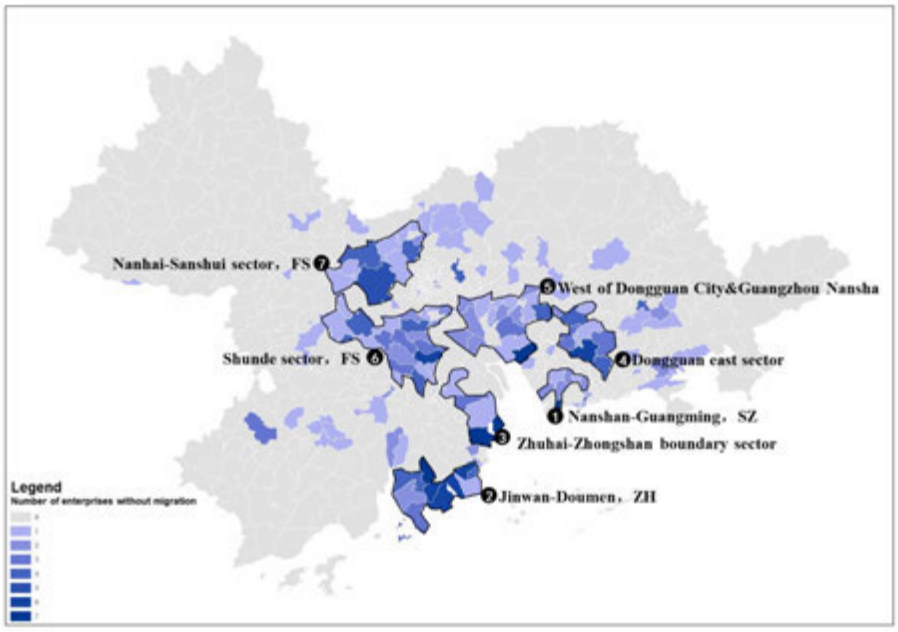

Fig.1 Distribution map of enterprises without migration and migrated over short distances

As above, by analyzing the places where 174 cross-sub-district migration enterprises have moved in and out, it is possible to analyze which regions are losing manufacturing and which

are strengthening. The analysis shows that most of the headquarters of manufacturing enterprises moved out of the central areas of cities, such as Futian District, Shenzhen, Xiangzhou District, Zhuhai City, and Chancheng District, Foshan City. The places where enterprises move in are relatively scattered. On the one hand, the suburbs of cities are an important direction for the proliferation of manufacturing headquarters. The concentrated areas include Doumen District of Zhuhai City, Guangming District of Shenzhen City, and Sanshui District of Foshan City. On the other hand, in Shenzhen, there is also a tendency for the headquarters of manufacturing enterprises to further gather in the central area of the city, such as Yuehai sub-district in Nanshan District and Xin'an sub-district in Baoan District.

Overall, the migration frequency of leading enterprises in the PRD region is relatively low, failing to form a dense and complex migration network within the region. Instead, they have maintained overall stability. The scope of enterprise migration is primarily confined to within the administrative jurisdictions of prefecture-level cities, rarely breaching administrative boundaries. Among these, Shenzhen, Zhuhai, and Foshan are key cities with relatively active enterprise migration. While the networks between these cities exhibit geographical proximity, they lack correlation.

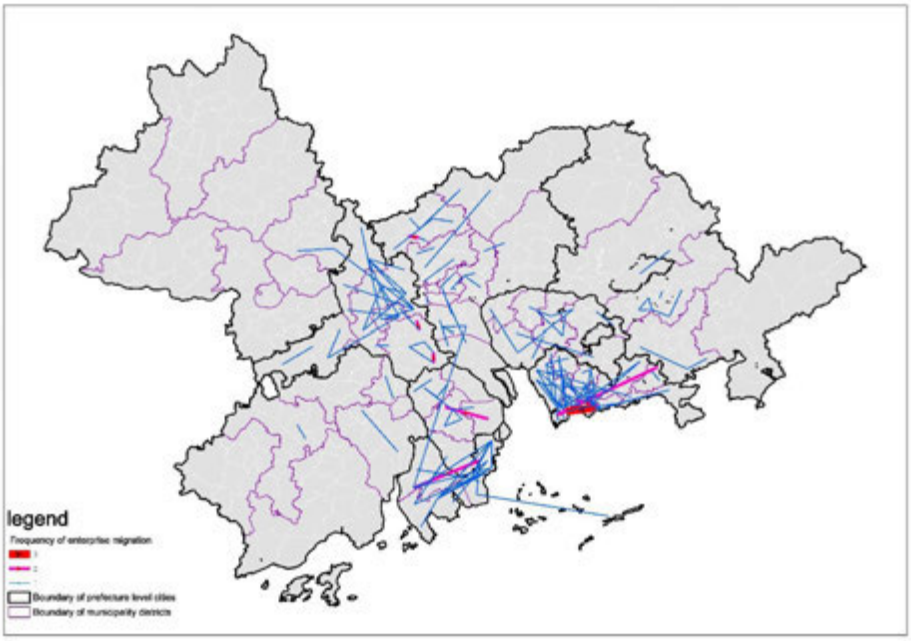

Fig.2 The migration trajectory of enterprises and the administrative boundaries of prefecture level cities and municipal districts

3.1Migration network of enterprises across prefecture level cities

As mentioned above, the spatial migration network of corporate headquarters in the PRD region exhibits a high degree of "unitization." Specifically, enterprises tend to exhibit high-frequency

migration within the administrative jurisdictions of prefecture-level cities, while cross-city networks have not formed, demonstrating a significant administrative boundary effect. Applying social network analysis to observe the spatial migration networks of enterprises in each city, it can be found that the enterprise migration networks in the PRD region can be broadly classified into the following types:

(1) High-frequency - Networked: This category includes Shenzhen and Zhuhai. It is characterized by frequent migrations of enterprises within the city, exhibiting relatively complex spatial network features. Notably, some sub-districts have formed significant clusters of enterprises, and these sub-districts serve as the core of the city's enterprise migration network. For example, Yuehai Sub-district, Nanshan Sub-district, and Xixiang Sub-district in Shenzhen, and Nanping Sub-district, Hongqi Sub-district, and Tangjiawan Sub-district in Zhuhai.

(2) High-frequency - Discrete: This group comprises Guangzhou, Foshan, Dongguan, and Zhongshan. These cities exhibit a certain level of activity in enterprise migrations within their respective domains, but they have not formed spatial networks. From the perspective of spatial connections, there are numerous subgroups of spatial units that form migration relationships, but they are disconnected from each other, failing to form highly concentrated enterprise clusters within sub-districts as seen in Shenzhen.

(3) Low-frequency - Discrete: This category includes Huizhou, Jiangmen, and Zhaoqing. These cities have a low level of activity in enterprise migrations within their administrative boundaries, with only a small number of migrations, let alone the formation of dense spatial networks. One of the objective reasons for this is that their economic development base is relatively weak, resulting in a lower number of enterprises within their domains.

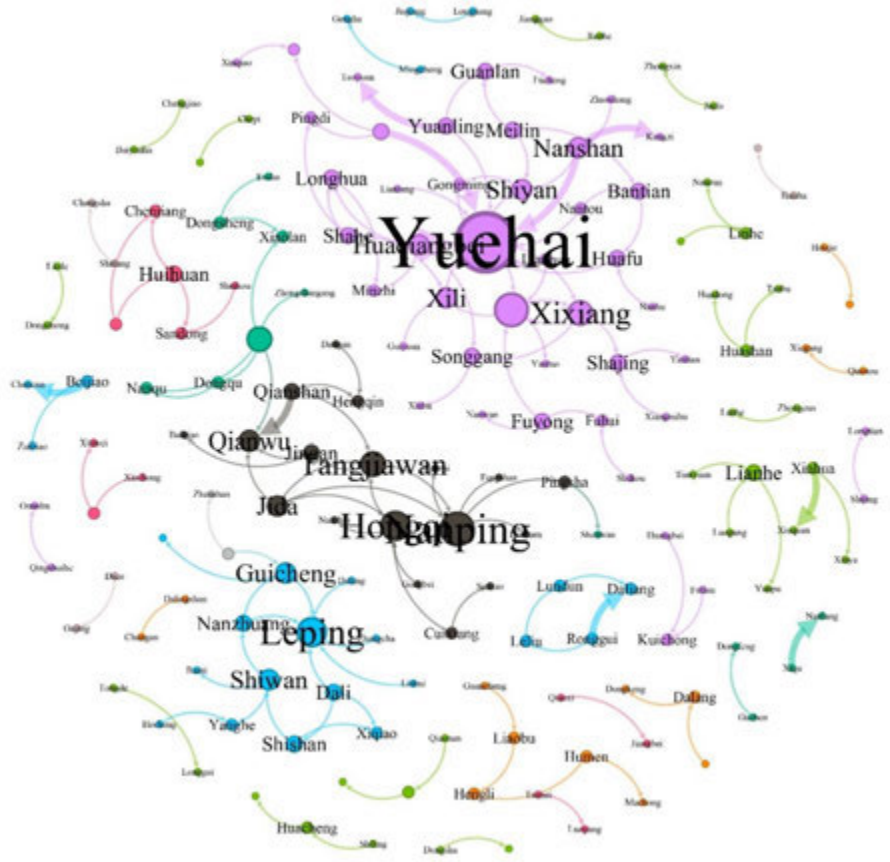

Fig.3 Spatial Network of Enterprise Migration in 9 Cities of the PRD

3.2 Internal enterprise migration network within prefecture level cities

Due to the high degree of typicality of Shenzhen's enterprise migration network within the PRD region, Shenzhen serves as an exemplary case to analyze whether the administrative boundaries of municipalities and sub-districts can play a role in enterprise migration. To investigate this issue, this study utilizes social network analysis to cluster the spatial migration relationships of enterprises within Shenzhen. It is found that sub-district boundaries and municipal district boundaries have a significant limiting effect on enterprise migration in Shenzhen. From the perspective of overall spatial relationships, enterprises in various municipal districts have high-frequency migration relationships, making it difficult to form distinct spatial subgroups based on municipal districts in the network structure. This phenomenon is significantly different from the network relationships across prefecture-level cities. Among sub-districts, enterprise migration seems to be more of a norm, with a high frequency of migrations between enterprises located in Nanshan, Yuehai, Xili, Huaqiangbei, Shatou, and other districts belonging to different

municipal districts.

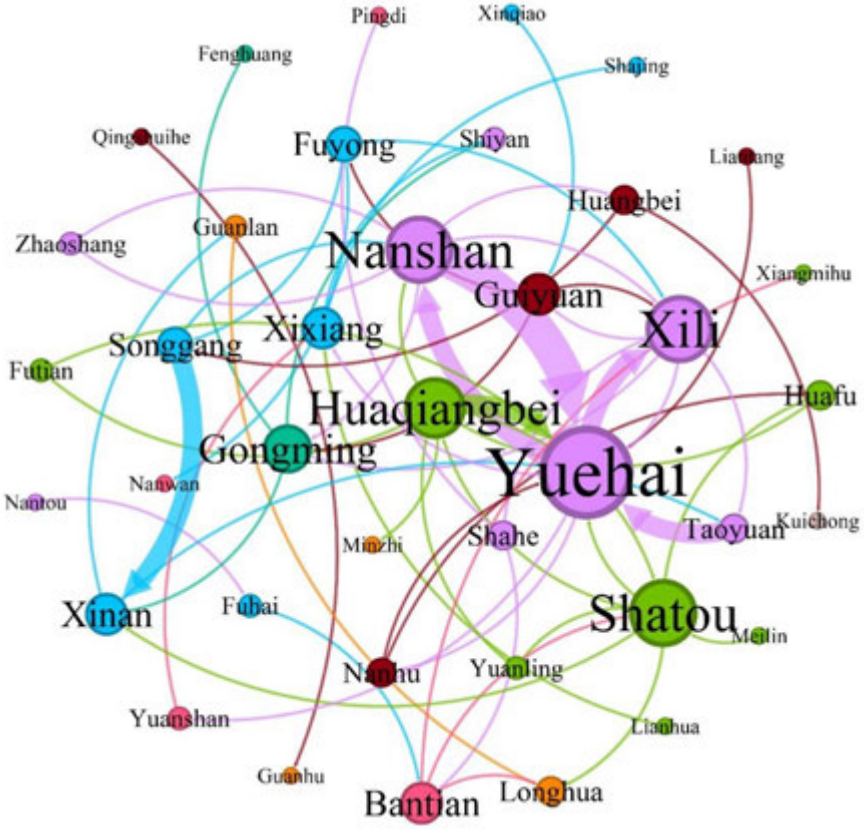

Fig. 4 Spatial Network of Enterprise Migration in Shenzhen City

4 The spatial agglomeration of enterprises in typical border areas

4.1 Characteristics of Enterprise Headquarters Agglomeration in Border Areas

In general, there is a clear trend of manufacturing enterprise headquarters relocating from central urban areas to outer suburban areas. Except for a few areas such as Yuehai Sub-district in Shenzhen, manufacturing enterprise headquarters in the central urban areas of Shenzhen, Guangzhou, Zhuhai, and other cities have experienced significant losses. Correspondingly, the outer suburbs, or urban fringe areas, have become the primary destination for manufacturing enterprise relocations.

This study also employed the standard deviational ellipse (SDE) tool to analyze whether there is a clear directionality in the overall migration patterns of manufacturing enterprise headquarters in various cities. The analysis results reveal significant differences in the distribution of manufacturing enterprise headquarters across cities.

(1) In the Shenzhen-Dongguan-Huizhou region, Shenzhen's manufacturing enterprises exhibit a clear trend of spatial diffusion and northward movement. The dispersion of enterprises in Dongguan remains stable but there is an overall southward movement. Meanwhile, enterprises in Huizhou tend to move closer to Dongguan and Shenzhen. Overall, there is a clear trend of manufacturing enterprise headquarters relocating from the central areas of their respective cities to cluster in the boundary regions of Shenzhen, Dongguan, and Huizhou.

(2) In the Guangzhou-Foshan-Zhaoqing region, the distribution of enterprises in Guangzhou remains generally stable. In Foshan, enterprises have relocated from towns and sub-districts near the Guangzhou-Foshan boundary to more distant areas, resulting in increased dispersion. While the sample size of enterprises in Zhaoqing is small, there is also a tendency for them to migrate to more peripheral areas.

(3) In the Zhuhai-Zhongshan-Jiangmen region, enterprises in Zhuhai tend to migrate from central districts such as Gongbei and Xiangzhou to peripheral areas near ports like Doumen and Jinwan, with an increased concentration of enterprises. In Zhongshan, there is a clear trend of diffusion in the enterprise distribution, with a noticeable concentration towards areas adjacent to Zhuhai. The sample size of enterprises in Jiangmen is small, and the overall change in distribution characteristics is not significant.

(4) Overall, there is a significant clustering of enterprise headquarters along the Shenzhen-Dongguan, Shenzhen-Huizhou, and Zhuhai-Zhongshan boundaries. Although enterprises are relocating from central urban areas to outer suburban areas, they are not crossing administrative boundaries, completing address changes within their respective administrative jurisdictions.

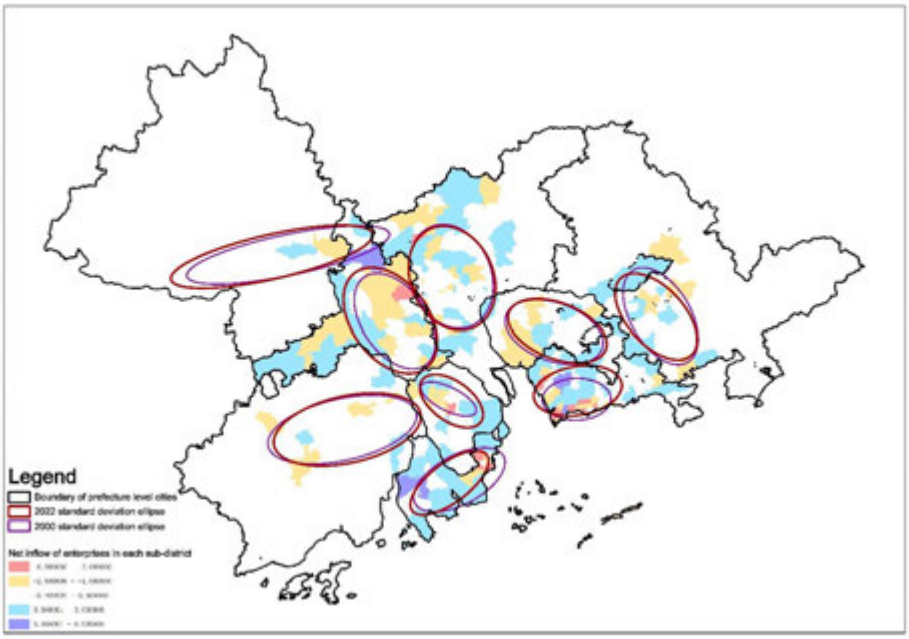

Fig.5 Elliptical Analysis of the Distribution Standard Deviation of Manufacturing Enterprises in Various Cities of the PRD

Tab.2 Standard deviation ellipse analysis of the distribution pattern evolution of manufacturing enterprises in various cities

region	Distribution of enterprise start-up			Distribution of mature enterprises		
	XStdDist	YStdDist	Rotation	XStdDist	YStdDist	Rotation
Shenzhen	0.170	0.104	88.784	0.221	0.121	80.314
Dongguan	0.252	0.143	109.204	0.257	0.137	110.83
Huizhou	0.148	0.264	149.107	0.142	0.258	137.466
Guangzhou	0.200	0.265	158.766	0.205	0.267	156.156
Foshan	0.161	0.265	144.918	0.190	0.294	143.150
Zhaoqing	0.514	0.102	78.125	0.513	0.110	77.252
Zhuhai	0.249	0.122	61.613	0.231	0.098	53.066
Zhongshan	0.151	0.059	116.348	0.179	0.099	125.589
Jiangmen	0.377	0.154	77.311	0.372	0.166	77.580

4.2 Case analysis of typical border areas

4.2.1 Shenzhen-Huizhou Border: Unilateral Agglomeration Driven by Shenzhen Enterprise Spillovers

Shenzhen, with its robust industrial innovation foundation, boasts the largest number and highest quality of manufacturing enterprise headquarters in the PRD region. In recent years, due to the continuously rising costs of land and other factors in the central urban area, relocating to lower-cost suburbs has become an important choice for manufacturing enterprises to maintain their competitiveness. Among these destinations, the border areas of Shenzhen, Dongguan, and Huizhou are significant migration hubs. However, it is noteworthy that most of the manufacturing enterprises relocating to this border area originate from the central urban area of Shenzhen, while there is a limited influx of enterprises from Huizhou and Dongguan.

To promote coordinated development among the three cities, around 2010, the idea of constructing an industrial cooperation demonstration zone in the border area was proposed. This initiative aimed to leverage the respective advantages of the three cities and jointly develop competitive industrial park platforms. However, since the concept remained at the level of overall planning without establishing a cross-regional development mechanism for benefit sharing and balancing, the progress of the cross-administrative cooperation platform was sluggish.

Huizhou hopes to rely on the growth poles of Shenzhen and Dongguan to drive its manufacturing development and maximize its land resource advantages. However, it also

worries about losing control over land use. Similarly, Dongguan has concerns about its dominant role in developing this area and the associated land interests, leading to a lack of proactive cooperation. Ultimately, the "Pingxinqing" cooperation zone was shelved due to difficulties in balancing the interests of the three parties, difficulties in coordination, and the inability to break through institutional barriers. Shenzhen had to build an industrial park called "Shenzhen International Low-Carbon City" within its own jurisdiction. This kind of cross-boundary conflict over interest coordination undoubtedly plays a significant role in Shenzhen's unilateral transfer of industries to border areas.

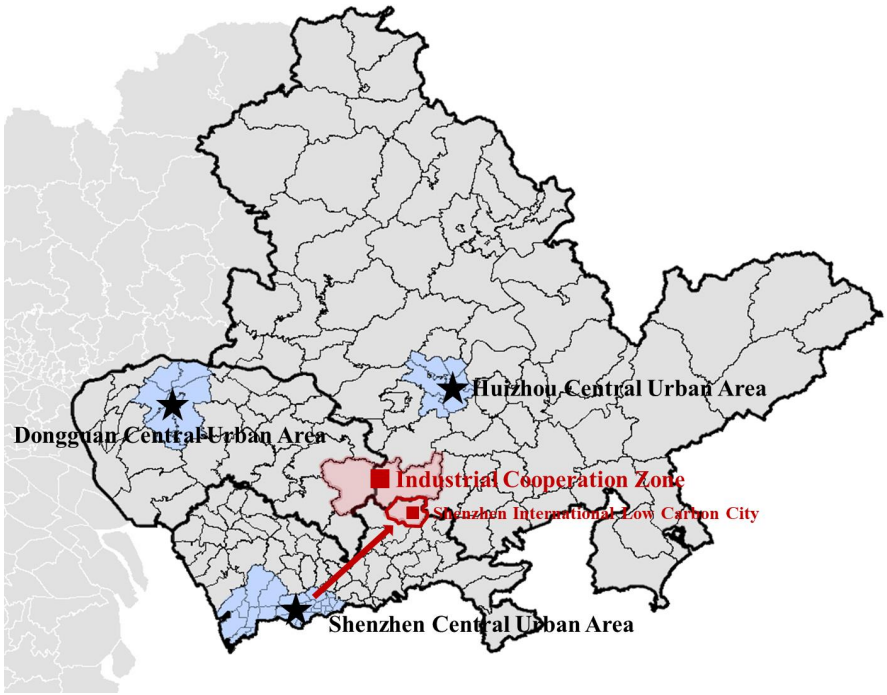

Fig.6 Distribution of industrial platforms in the cross-border areas of Shenzhen, Dongguan, and Huizhou

4.2.2 Zhuhai Zhongshan Border: Enterprise Agglomeration Driven by High Level Platforms

Compared to the difficulties encountered by Shenzhen, Dongguan, and Huizhou in coordinating development in their border areas, the border region between Zhuhai and Zhongshan has developed a significantly different spatial pattern. In Zhuhai, some enterprises have spontaneously relocated from the land-saturated central urban area to the Zhuhai High-tech Industrial Development Zone. Similarly, in Zhongshan, numerous enterprises have shifted from the central urban area and other towns to the coastal Cuiheng New Area in the east. Under the joint promotion of these two forces, a contiguous emerging industrial cluster has taken shape

in the border area between Zhuhai and Zhongshan. While the two cities have not formulated significant planning schemes or joint agreements for the border region, this emerging industrial hub is still accelerating its formation.

The key factors behind this difference lie in the geographical conditions and economic development levels of the region compared to the Shenzhen-Dongguan-Huizhou border. Firstly, Zhuhai and Zhongshan have smaller municipal areas, and their border areas are closer to the central urban districts, making it more convenient for enterprises to change their business locations. Secondly, although the governments of the two cities have not jointly formulated plans or issued relevant policies, they have reached a consensus on the key direction of regional development under the guidance of higher-level planning. Both cities have identified the Pearl River Estuary region as a potential area for future development and have established high-level industrial development support platforms, which has facilitated the concentration of enterprises in this region.

This example also demonstrates that the industrial park platforms established by local governments are significant driving factors for promoting industrial transfer and the relocation of enterprises. These platforms offer enterprises numerous preferential conditions in terms of land, tax policies, infrastructure, public services, and talent attraction, making them attractive destinations for relocation.

Fig.7 Distribution of Industrial Platforms in Zhuhai Zhongshan Cross border Area

5 Mechanism of Administrative Boundary Effect

This study aims to apply the "Thrust-Traction" model from the field of urbanization research to explain the typical phenomenon of enterprises relocating from central urban areas to outer suburbs without crossing prefecture-level city administrative boundaries, from the perspective of comprehensive cost-benefit analysis.

(1) Under the model of local government corporatism, retaining tax-generating enterprises is crucial for promoting local economic growth. Local governments often adopt various measures to retain enterprises. Governments can offer incentives such as land supply, tax concessions, and infrastructure support to encourage enterprises to develop locally in the long term.

(2) As enterprises develop locally, they form close social network ties with the local production network. These ties include not only explicit connections in the industrial and supply chains, but also localized demands for education, healthcare, and other services for the company's employees. This stable embedded relationship is a significant reason for deterring enterprises from migrating across prefecture-level cities.

(3) Cross-city migration of enterprises may involve significant uncertainty, especially when there are significant differences in the business environment between different cities, which can lead to significant adaptation costs for enterprises in new cities.

For enterprises located in regional central cities, staying local requires paying higher land costs and higher operating costs in terms of energy, labor, and logistics. However, the benefits are also evident: staying in regional central cities ensures continued government support, avoiding the need to re-establish relationships with neighboring city governments, and minimizing disruption to existing business networks. Additionally, there is a risk of losing skilled employees who may not be willing to relocate.

For enterprises in peripheral cities, relocating to regional central cities during the upgrading process to access higher-level business resources and research and development capabilities is a viable option. However, the high operating costs in regional central cities may adversely affect business operations. Furthermore, complete relocation often requires re-establishing government-enterprise relations, and there is significant uncertainty about whether they will receive the same level of support as in their original location. Therefore, relocating to border areas adjacent to regional central cities offers the advantage of more convenient access to information, services, and research and development, while maintaining local cost advantages and "government-enterprise relations" advantages.

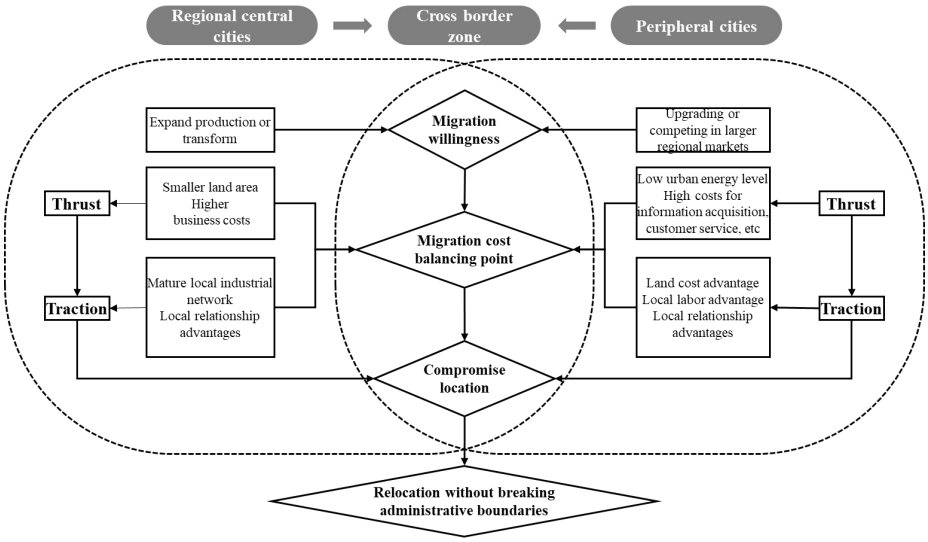

Fig.8 Analysis framework for enterprise migration decisions based on the " Thrust-Traction " model

6 Conclusions and Discussion

The research has shown that while the PRD region has achieved a high level of concentrated development in terms of physical space and the complexity of human, logistics, and information flow networks among cities, there still exists a certain degree of "administrative division barriers" in the relocation of manufacturing enterprise headquarters at the prefecture-level city level. Within prefecture-level cities, however, enterprises exhibit frequent cross-regional migration and mobility without being affected by administrative divisions at the municipal district or sub-district level. This indicates that the phenomenon of "administrative district economy" is primarily manifested at the level of prefecture-level city governments in China, which is consistent with existing research on local corporatism.

From the perspective of the mechanisms of enterprise relocation and site selection, two primary "push-pull" forces determine the migration decisions of enterprises: optimization of operating costs and maintenance of localized networks. From the cost perspective, as the population and functions of central urban areas continue to grow, land prices, energy, transportation, and other operating costs for enterprises inevitably increase, making it difficult to meet the new spatial demands of enterprise transformation and expansion. Therefore, relocation to urban suburban areas with relatively lower costs is a common phenomenon in the development of manufacturing enterprises. Under the sole influence of cost factors, it is a reasonable assumption for enterprises to cross administrative boundaries and relocate to adjacent cities with lower comprehensive costs.

However, enterprise operations are extremely complex systems, and the ability to integrate into the local industrial ecological network is a crucial factor. In China, the government often plays

an important supporting role in local industrial development, including but not limited to the supply of industrial land, the formulation of industrial assistance policies, preferential policies for talent recruitment, support for scientific and technological research and development activities, the provision of public service facilities, and urban infrastructure construction. Once an enterprise leaves its original city and relocates to a new location, it will lose its stable government-business relationship that has been cultivated for many years and incur significant costs in adapting to the new environment. Correspondingly, local governments are also reluctant to let local enterprises leave their jurisdictions due to considerations such as tax revenue and employment.

It is important to note that the enterprise relocations discussed in this study are based solely on the registered location of enterprises obtained from the business administration departments. Although this address can generally be considered as the location of the enterprise headquarters, it does not fully reflect the spatial and temporal characteristics of the economic activities of the enterprise. Modern enterprises often have complex organizational structures and operate in multiple locations, often establishing different types of branches or subsidiaries in multiple cities or flexibly leasing office space to meet production needs. A comprehensive review of the spatial distribution and migration characteristics of various functions within enterprises and a re-examination of the comprehensive effects of administrative boundaries will be an important direction for future improvements in this research.

Abstract:

As the urbanisation rate in China continues to rise, there is an urgent need to enhance the rail transit system to facilitate the growth of major cities and regions. This study examines the contrasts and interconnections between China's rail transit system concepts and those of other countries, as well as the discrepancies in the histories of construction and operational approaches. Based on a clear understanding of these differences, the study employs multiple data sources to analyse the rail transit network in Shanghai. It finds that the network is well-developed, particularly in high-speed railways and metros. However, it lacks an intermediate level. To address this issue, the study proposes a multi-level rail transit network and spatially coordinated optimisation strategy tailored to urban demands. This strategy encompasses rail transit networks at three spatial scales, with specific strategies determined by the availability of urban resources. In conclusion, the study proposes a multi-level rail transit network and spatially coordinated optimisation strategy tailored to urban demands. This strategy encompasses rail transit networks at three spatial scales, with specific strategies determined by urban resources. The study emphasises the significance of recognising contextual variations and tailoring solutions to local requirements.

Keywords: Regional integration; Rail transit network; Metropolitan areas; Cross-cultural comparison; Shanghai

1. Introduction

Currently, China's urbanisation rate has exceeded 60%. As the functions of large cities expand, their spheres of influence expand accordingly, and this expansion has led to the blurring of the boundaries between cities and their neighbourhoods. Against this background, the Chinese government has made coordinated regional development an important national strategy. China's major cities, including Shanghai, emphasise development strategies from a 'city-region' perspective (Shanghai Municipality People's Government, 2018). As a vital transportation network for supporting the growth of large cities and regions, the planning and construction of rail transit systems must be expanded to align with the transportation and development needs of the city and its surrounding areas.

Rail transit plays a pivotal role in public transportation and serves as a crucial infrastructure for supporting the spatial development of cities and regions. Existing research indicates a

[1] Supported by the National Key R&D Program of China (Project No. 2022YFC3800204) ; Supported by Shanghai Tongji Urban Planning & Design Institute Co., Ltd. & China Intelligent Urbanization Co-creation Center for High Density Region (KY-2023-PT-A04).

significant influence relationship between rail transit and urban space (Urena, Menerault, and Garmendia, 2009; Cao,2023). Consequently, the rail transit system should be adjusted following changes in urban development orientation. China's megacities, including Shanghai, are attempting to plan and build rational rail transit systems in their urban areas to support efficient inter-city connectivity through rail transit systems and effectively promote regional development.

It should be noted that urban rail transit is a term that encompasses various types of local rail systems that provide passenger service within and around urban or suburban areas. In China's national standard, "Nouns and Terms Commonly Used in Urban Public Transport," urban rail transit is defined as "a general term for fast and high-capacity public transport that is usually powered by electric energy and operates on wheeled rails." The scope of this study is defined as the Shanghai metropolitan area, Shanghai city area and central Shanghai, with reference to official data. Given the different spatial scales that can be effectively served by different rail transport types, the study focuses on four rail transport types: national high-speed railway, inter-city railway, suburban railway and metro. Due to the differences in spatial scale and administrative authority, there are differences between Chinese and foreign cities in terms of rail transit concepts and service situations. For example, the understanding and construction of the four types of rail transit described in the previous section are not the same in China and abroad.

Furthermore, the construction and operation entities and existing problems are also different. Furthermore, research has indicated that the functional structure of the Shanghai metropolitan area is not a 'centre-periphery' commuting circle structure, in contrast to other metropolitan areas that exhibit a concentrated and significant centripetal commuting flow. Therefore, in the Chinese context, the scale and structure of the metropolitan area differ from that of foreign countries (Niu, Yue and Li,2020). Understanding these differences is a crucial prerequisite for comparing other countries' cases and discussing the Chinese scenario.

The objective of this study is to examine the similarities and differences between China and other countries in terms of concepts related to rail transit systems. Additionally, the study will compare the differences in the construction history and operation of rail transit in different countries. Based on elucidating the discrepancies, the pivotal concerns confronting the construction of Shanghai's rail transit system are analysed through multi-source data. It is necessary to summarise the influential relationship and basic laws between rail transit networks and spatial development, proposing reasonable solutions as well.

The subsequent analysis presents the current development status of rail transit in Shanghai, focusing on the contextual differences between international and local conditions. This analysis also proposes a strategy for optimising a multi-level rail transit line network within the context of the Shanghai metropolitan area. The initial section of the study examines the international contextual differences of rail transit systems, considering similarities and differences in spatial scales, development history, and the relationship between rail transit networks and urban development. Additionally, case comparisons are made. In the second part, an assessment is made of the service capacity of Shanghai's rail transit system, the current problems of the rail transit system are analysed, and the focus of future optimisation is deduced, all based on multi-source data. In the third part, a problem-oriented approach is taken, and an attempt is made to propose a solution consisting of goals and layout strategies for rail transit at different spatial levels.

2. International Contextual Differences and Case Comparison of Rail Transit Systems

The modern metropolitan area represents a novel interpretation of the 'city region' concept in the context of globalisation and information technology. The concept of the metropolitan area or metropolitan region is multifaceted and ambiguous, encompassing a variety of administrative, functional and spatial entities, as well as other connotations (Zhang Wang and Hu, 2022). China's rail transport planning and construction are similarly closely related to administration, function, and space. Therefore, the scope of the study was determined based on official information, including the extent of the Shanghai metropolitan area as defined in the Spatial Cooperation Plan of Greater Shanghai Metropolitan Area (Shanghai Municipality People's Government, Jiangsu Province People's Government, Zhejiang Province People's Government, 2022) , as well as the extent of Shanghai city and central Shanghai area as defined in Shanghai 2035 (Shanghai Master Plan 2017-2035)(Shanghai Municipality People's Government, 2018) (Figure 1). High-speed railways and inter-city railways primarily serve the Shanghai metropolitan area and beyond. Suburban railways primarily serve the Shanghai city area, while the metro primarily serves the central Shanghai city.

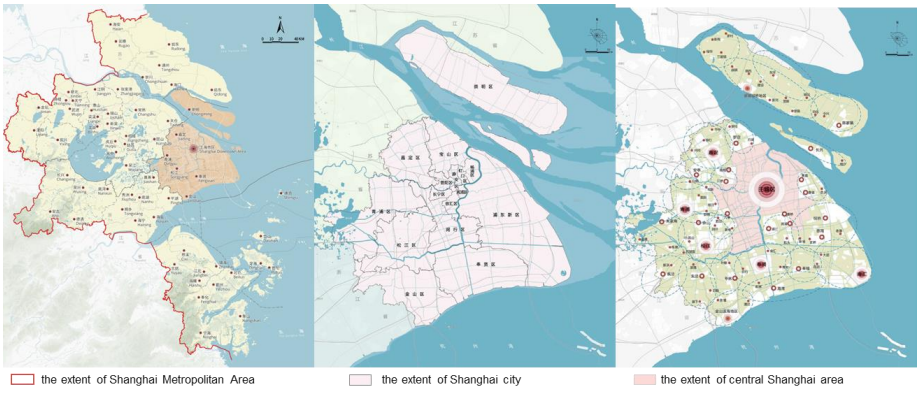

Figure 1. Scope of the study.

Tokyo (Cao,2023) , Paris (Sun, 2024), and London (Chen, Shi and Liu, 2010) have constructed multi-level rail network systems across various rail transport levels within the scope of integrated regional development. These systems serve different travelling scopes with clear functional planning and achieve regional connectivity through line layouts and hub construction. They serve as appropriate reference cases. The selection and construction of the Shanghai Metro at the early stage involved the participation of departments or companies from Japan, France, Germany, and other countries (Yu, 2023). A comparison of the differences between Shanghai and other developed cities in terms of spatial scale, development history, rail transit network structure and suburban railway construction will assist in understanding the development of Shanghai's rail transit. It will serve as the basis for subsequent research.

2.1 Spatial Scale

The discussion of the spatial scale constitutes the foundation of the case study. Analysing administrative units and populations covered by similar spatial layers through analogies helps eliminate comprehension biases arising from international contextual differences, aiding in

scientifically determining the scope of comparison and reference

Using a radius of 30 km for comparison, this circle can cover the main urban area of Shanghai, the Tokyo metropolitan area and surrounding areas, the Greater Paris area (The Metropolis of Greater Paris) and surrounding regions, as well as the Greater London area (The Metropolis of Greater London) and surrounding regions, covering approximately 14.47 million people, 20 million people, 8 million people, and 10 million people, respectively. Using a radius of 50 km for comparison, this circle can cover most of the Shanghai metropolitan area, most of the Tokyo metropolitan area, most of the Île-de-France region, and most of the London metropolitan area covering approximately 25 million people, 30 million people, 12 million people, and 14 million people, respectively.Regarding spatial scale and population coverage, the central Shanghai area is comparable to the metropolitan areas of the other case cities. Similarly, the Shanghai city area is analogous to the metropolitan area boundaries of the other case cities. In China, rail transport is typically approved and projected by the central government and constructed and operated by state-owned enterprises. The national railway system, which includes high-speed railways, general-purpose railways and comprehensive transport hubs, is planned in the Medium- and Long-Term Railway Network Planning. The urban rail transit system in various population densities reflects the overall distribution of the urban population, which is related to the demand for rail transit service capacity.

The overall population density within different spatial circles in Shanghai is higher than that of Tokyo, Paris and London, particularly in the core and central urban areas. Job density indicates the segregation of employment opportunities within a city, which may result in a greater distance between workplaces and residential areas, placing additional pressure on the rail system during peak commuting hours. From the perspective of job density, Shanghai has an overall job density lower than Tokyo but higher than Paris and London, with the difference in job density particularly pronounced in the core urban areas compared to Tokyo. This reflects a more significant polarisation in the population distribution centre in Shanghai (Figure 2), while the job distribution centre in Tokyo is even more pronounced (Figure 3).

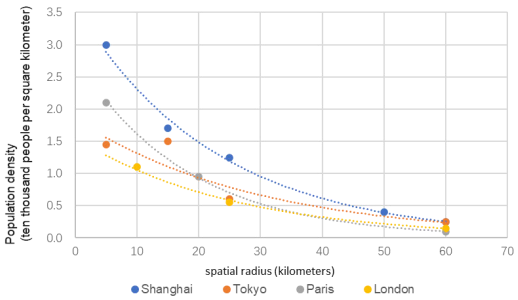

Figure 2. The spatial distribution of population density.

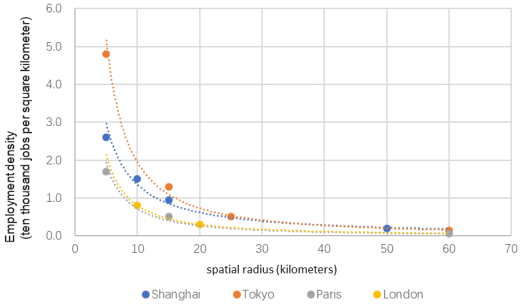

Figure 3. The spatial distribution of job density

The study concludes that the scope of the Shanghai city is comparable to that of other metropolitan areas, based on an analogy between spatial scales. Consequently, the efficiency of the rail system in Shanghai should be at least as high as that of other global metropolitan areas in the future. Additionally, the rail transit system should have a competitive advantage over car trips. It must be mindful of the potential increase in post densities and commuter trips, which could lead to pressure.

2.2 Development History

A review of the development history of rail transport systems can assist in understanding the process of planning and construction of existing rail transport systems, as well as in evaluating the priorities for future rail transport in the context of the city's development stage.

In China, the government is typically responsible for approving and projecting rail transport projects, with state-owned enterprises assuming the role of construction and operational responsibility. China's national railway, which is comprised of a comprehensive national network deployed in a unified manner, with resource property rights belonging to the state and the objective of connecting China's major cities through extensive new infrastructure development, represents a significant national strategy for China. It is now at a first-class level in terms of scale and service capacity (Perl and Geotz, 2015). The metro network of each city is a public service, and the responsibility for this lies with the local government. The city's level of development and the locality's financial capacity are, therefore, critical factors in determining the extent of the metro network. Over the past two decades, the metro service capacity of major Chinese cities, including Shanghai, Beijing, Guangzhou, and others, has undergone a significant expansion, reaching a high level of development. However, the scale of suburban railways built and operated in China is tiny, influenced by factors such as urbanisation, government priorities, and the difficulty of cross-regional intergovernmental collaboration.

To illustrate, the city of Shanghai initiated the preliminary programme of metro planning in 1956, established the Shanghai Metro Company in 1985, and commenced trial operations for the inaugural metro line in 1993. Since then, the construction and operational mileage of the Shanghai metro has increased rapidly, especially with the opportunity presented by the 2010 Shanghai World Expo. The Shanghai government identified rail transit development as a critical strategy to address urban transportation issues. Plans were made to complete more than 400 kilometres of metro lines before the Shanghai World Expo, marking the beginning of Shanghai Metro's transition from a single line to the formation of a network. By 2022, the total length of

the Shanghai metro network will have reached 831 kilometres(Yu, 2023) (Figure 4). Similarly, the construction of high-speed railways related to Shanghai is of a considerable scale and has a robust service capacity. In contrast, the construction of the suburban railway in Shanghai commenced relatively late, and its long-term sustainability has been questioned due to concerns about the potential for development uncertainty. This is attributed to the separation of power and responsibility, the mismatch between the time distribution of the remaining capacity and the demand, the financial risk associated with the general efficiency of the passenger flow, and the poor integration of the track with the city's spatial layout (Li, 2022).

Figure 4. Statistics on operating mileage and passenger volume of Shanghai rail transit lines

A comparison of the population and rail transport development of the Shanghai suburban railway, the Tokyo metropolitan area and the Île-de-France region reveals that the urbanisation process in Tokyo and Paris has seen the construction of railways at an earlier stage and the formation of a larger scale of municipal rail systems. It can be assumed that suburban railways have supported the development of the metropolitan area to a certain extent. In contrast, Shanghai initiated the construction of its rail transit system only after its population reached 10 million on a smaller scale. This requires that the operational service of the Shanghai suburban railway, compared to private cars, should have a particular competitive advantage in terms of convenience and timeliness (Figure 5).

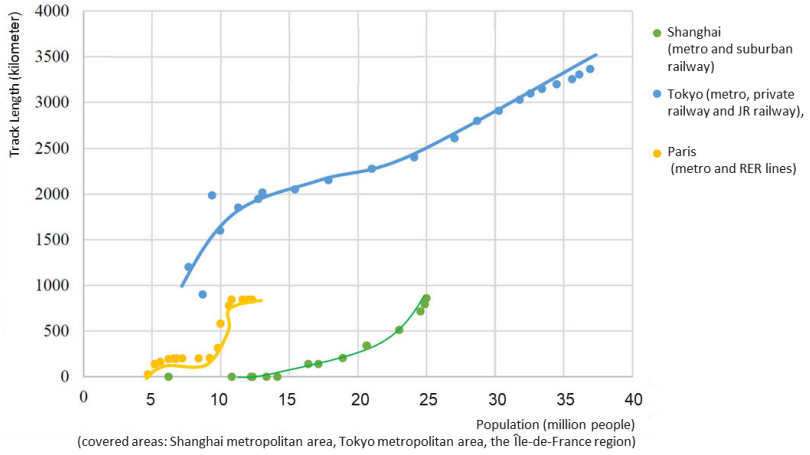

Figure 5. Relationship between track length of rail transit construction and population growth

2.3 Relationship between Rail Transport Network and Urban Development

There is a close relationship between urbanisation and the development of the rail transit system, which is reflected in the discussion on the development history and generally recognised by the existing research (Gu and Kou,2017; Hu et al., 2023). Understanding the role of the rail transit network in the spatial structure of the city will assist in clarifying the functional positioning and mode of Shanghai's regional rail, thereby further enhancing the scientific nature of Shanghai's rail transit planning and construction programme.

In terms of rail transit types, subways typically provide high-density homogeneous services to the core areas within a 5km radius, radiating to the central city within a 15km radius. Shanghai's subway construction has reached this level. Suburban railways usually radiate outward, connecting suburban centres and new urban nodes along different development corridors. This requirement aligns with Shanghai's goal of elevating the development level of new cities. This section analyses and refers to the multi-level rail transit networks in Tokyo and Paris as case studies. This is in line with the goal of the Shanghai Municipality of simultaneously upgrading the development level of the new towns. Consequently, this section employs Japan and Paris case studies as a point of reference for analysing their multi-layered rail networks. At this spatial level, the rail transit in Paris consists of the RER (RéseauExpressRégional) line and the Transilien line. The RER, as a regional rapid railway, is a hybrid commuter rail and rapid transit system serving Paris and its suburbs. Its purpose is to alleviate the city's population concentration and achieve urbanisation of its suburbs. It is planned to serve Paris and its suburbs at the same time as the RER line. In terms of online network structure, the RER line penetrates deep into and through the centre of Paris, connecting with the metro network through the core hubs. This is due to the better engineering conditions in Paris, which allowed the RER line to be built under the metro in the centre of the city, forming a two-tiered network of municipal rail and metro.At first, rail transport serving the Tokyo metropolitan area comprised national railway lines, private railway（私鉄 Shitetsu） lines, and underground lines. However, the National Railway was split and privatised due to poor management, resulting in the formation of the Japan Railway Group, from which the JR lines were derived. Initially, the private railway lines had no access to the city centre. They could only connect to central Tokyo via the National Railway Yamanote Line (now JR Yamanote Line), which led to a sharp rise in passenger pressure on the private railway and Yamanote Loop. This was later attempted to be resolved through the operation of a suburban private railway and a city underground running directly through the city (Cao, 2023). Nevertheless, the Yamanote Line continues to experience significant passenger pressure in terms of city rail service. The Yamanote Line is connected to 15 radial lines of JR railways and private railways, which are situated within 30-50 km and 50-80 km circles around the periphery of the Tokyo metropolitan area. These radial lines connect the system of centres in the Tokyo metropolitan area to form a de facto ring-shaped central belt. The periphery of the Tokyo metropolitan area generates a significant centripetal commuter flow within the Tokyo metropolitan area. The cross-section of the city line into the centre of the metropolis reaches its maximum in the vicinity of the Yamanote Loop (5 km radius circle)(Zhang et al., 2023),

Analogous to the rail transit networks of Shanghai, Paris, and Tokyo, the study concludes that there are significant differences between the rail transit systems constructed in Shanghai and those in cities such as Paris and Japan. These differences are primarily related to the construction of municipal railways. Consequently, it is imperative to exercise greater caution when considering the construction of municipal railways and their relationship with other

railways. At the same time, the construction of railways must be viewed as a policy tool for urban resource allocation, particularly in the context of the urbanisation rate of Shanghai. Given that the city's urbanisation rate has already exceeded 89%, the construction of municipal railways in the city can be considered to have the potential to influence the spatial resources of the city and demographic changes to a greater extent. In light of this, it is crucial that the municipal railways effectively connect the city centre, suburban centres and new town areas.

2.4 Construction and Operation of Suburban Railway

Based on the preceding analysis, it can be concluded that the construction focus of Shanghai's future rail transport will be the city-area rail. Consequently, the discussion will be specifically centred on the city-area transport. Firstly, to facilitate comparison, the Tokyo metropolitan area, which has a larger total population and a more developed rail transit system at the same level, is chosen as a case for comparison. This enables the analysis and discussion of possible situations that may arise in the future development of Shanghai's municipal rail transit. Secondly, to provide a reference for the construction and operation of Shanghai's municipal rail transit, the rail transit service capacity and management and operation mode of Tokyo, Paris and other cities are compared.

With regard to the spatial structure reflected by the travel flow, it can be observed that both the central city of Shanghai and the periphery of the Tokyo Metropolitan Area Department are distributed with more central nodes. However, the nodes in the periphery of Shanghai have a lower energy level, and the number of trips flowing into the central city is also smaller. Compared to the million-strong populations of Yokohama, Saitama, and Chiba on the periphery of the Tokyo Metropolitan Area Department, the new towns around the Shanghai central city are all less than 500,000 people, representing a smaller scale. Furthermore, the daily trips from the new towns into the central city of Shanghai are approximately 100,000-300,000, considerably smaller than those into the Tokyo Metropolitan Area Department. The reasons for this phenomenon are numerous, and the related factors interact in complex ways. On the one hand, the failure of Shanghai's new towns to reach their expected scale is related to poor transport timeliness. On the other hand, Shanghai hopes that the new towns will become independent and integrated node cities directly connecting to other cities in the region rather than relying on the nodes in the central city of Shanghai. This necessitates the enhancement of rail transport efficiency and the implementation of effective support mechanisms for Shanghai's new towns while concurrently avoiding the creation of high-intensity commuter traffic. The imbalance in the job-to-population ratio has resulted in large-scale long-distance commuting and high-intensity rail traffic in Tokyo. Shanghai has a more balanced job-to-life ratio than Tokyo, with smaller differences in job-to-life ratios across the city. Therefore, the impact of rail on the job-to-life balance should be carefully considered in the process of developing the city region.

Using Tokyo, Paris, London, and New York as examples, discuss the service capacity of suburban railways, emphasizing the need for timeliness and sustainability in the construction of Shanghai's suburban railway system (Table 1). Therefore, the construction of a city-region railway in Shanghai should also be undertaken with the aim of ensuring timeliness and sustainability. In order to ensure timeliness, the travelling speed of the city-region railway should be significantly increased compared to the metro (30km/h), up to about 50km/h. This will alleviate the connectivity obstacles caused by spatial distance and ensure a high frequency of train departures. From the perspective of the stage of development and the interval between train departures, it is necessary to avoid opening too many urban lines when the new city's level

of competence is insufficient to ensure the sustainability of the urban railway setup. There is a certain contradiction between the insufficient capacity of the new city and the sustainability of the urban railway setup. On the one hand, the construction of a large number of new lines may result in the inefficient utilisation of resources in the context of a limited volume of the new city. Conversely, if the number of urban railway trips is insufficient, it will be unable to support the development of the new city. This contradiction should be considered from the perspective of the more significant regional level, i.e., through the inter-city railway connecting the new city and other cities, to support the development of the new city in line with the development of the new city into a new city. This is also consistent with the objective of developing the new city into an individual and integrated node city.

Table 1. Comparison of suburban railway service capacity

City	Paris	Tokyo	London	New York
travel speed	40—50 km/h	45—60 km/h	—	45—70 km/h
peak hour departure frequency	3—5 min	2—5 min	4—8min	8—20min
off-peak departure frequency	—	—	20—30min	30—60min

In terms of management and operation, two points require clarification: the sustainability of construction and operation and the manner in which management and operation are coordinated. With regard to the construction and operation of rail transit networks in metropolitan areas, there is considerable variation between different cases in terms of the public and private sectors involved. However, there is a consistent reliance on financial support and development along passenger routes in order to ensure the sustainability of rail transit development. In China, rail transport is typically approved and projected by the central government, with state-owned enterprises assuming responsibility for construction and operation. The national railway system, comprising high-speed railways, ordinary-speed railways and comprehensive transport hubs, is planned in the Medium- and Long-Term Railway Network Plan. The urban rail transit system is organised and formulated based on urban master plans and urban transport development plans. Consequently, there are specific challenges in the cross-area and cross-line operation of rail transport between the national railway system and the urban rail transport system, which serves the metropolitan area and the metropolitan region.

3. Current Situation of Megacities in China: A Case Study of Shanghai

Shanghai is the largest economic centre in China and an emerging global city. It is also the core city of the Yangtze River Delta city cluster. In the Shanghai Urban Master Plan, also known as 'SHANGHAI 2035,' formulated by the Shanghai government, the goal vision of 'Striving for the Excellent Global City' is proposed. As a significant component of the public transport system, the rail transport plan must consider Shanghai's development strategy and address the challenges in the planning and construction of the existing rail network. Furthermore, it also helps to summarise a model suitable for Chinese cities.

A review of the historical development of Shanghai's rail transport reveals that it can be divided into three periods, each characterised by a distinct relationship between the rail system and the spatial development of the city. The period between 1993 and 2010 represents the initial integration phase between Shanghai's rail network and urban space. This involved the

construction of comprehensive metro corridors with the objective of enhancing connectivity in critical areas of the central city. Additionally, the metro was designed to address deficiencies in public transport services in these areas. From 2011 to 2020 is the second stage, which is characterised by the enhancement of the metro network. During this period, the metro network underwent continuous encryption in order to accommodate the rising demand for rail travel in central Shanghai. This resulted in a gradual shift in the proportion of rail travel compared to ground bus travel. Shanghai is in the third stage of rail transit and urban spatial development. This stage is characterised by a shift in the rail transit system from lagging behind spatial development to optimising and guiding spatial development. It can be observed that the Shanghai government has identified the optimisation of the rail transit network as a significant undertaking. This period presents an opportune moment for adjusting the rail transit network in Shanghai. During this period, it is crucial to analyse the current situation in accordance with the development goals and to consider the synergistic relationship between rail transit and space.

3.1 International Perspective: China's Interface with International Markets

'Dual circulation' is a national economic strategy proposed by the Chinese government. The Economist summarised the strategy as 'keeping China open to the world (the "great international circulation") while reinforcing its own market (the "great domestic circulation")'. As China's largest economic centre and an important node supporting the 'dual circulation' policy, Shanghai should efficiently connect domestic and foreign markets.

From the perspective of hubs, the analysis of the connection between Shanghai's main hubs and regions suggests that Shanghai's major external hubs face significant pressure and exhibit low passenger flow decomposition efficiency. The external hubs analysed here include Shanghai Pudong International Airport and Shanghai Hongqiao Integrated Transportation Hub. Nevertheless, the introduction of rail transit lines still requires discussion, and the main corridors are predominantly westward, with inadequate connections to the north and south.

Shanghai Pudong International Airport, the largest international airport in the Yangtze River Delta region, serves as one of the most critical international gateways in the area. Situated in the eastern coastal area of Shanghai, it is yet to be linked by high-speed rail. Connecting to other cities in the Yangtze River Delta and Hongqiao Station requires traversing through the main urban area of Shanghai, resulting in inefficiency and adding to the city's traffic burden. Currently, Shanghai is constructing the Dongfang Transportation Hub, aiming to effectively alleviate passenger flow by introducing high-speed rail and urban rail transit.

The Shanghai Hongqiao Integrated Transport Hub encompasses the airport, railway station (Hongqiao Station), metro stations, and long-distance bus stations. It serves as the primary transport hub connecting domestic destinations in Shanghai. Currently, it is facing challenges due to the presence of multiple overlapping passenger flows and difficulty in expanding capacity. All high-speed rail lines operating in Shanghai, including the Beijing-Shanghai High-Speed Railway and the Shanghai-Hangzhou-Ningbo High-Speed Railway, terminate at Hongqiao Station. In terms of passenger flow, Hongqiao Station handles nearly 60% of Shanghai's railway passenger transportation demand, with daily passenger throughput approaching 90% of its design capacity (430,000 passengers per day). The annual passenger throughput at Hongqiao Station is two to five times that of Shanghai's other two railway stations, with passenger flows exceeding ten million, namely Shanghai Station and Shanghai South Station (Figure 6). The passage resources at Hongqiao Hub are extremely limited, making it challenging to meet the increasing connectivity demands. This also reflects the inability of

Shanghai's other railway hubs to fulfil a synergistic role.

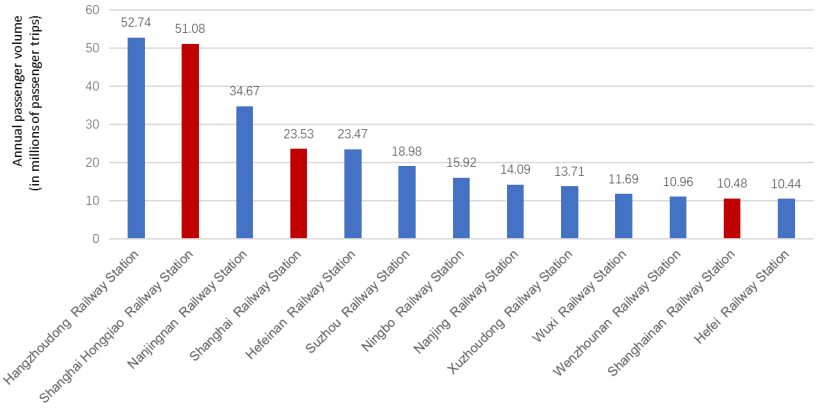

Figure 6. Annual passenger flow statistics of major railway stations in the Yangtze River Delta Urban Agglomeration (2021)

3.2 Regional Perspectives: Capacity to Lead Regional Development

As the core city of the Yangtze River Delta urban agglomeration, Shanghai should effectively lead regional development. Therefore, from a regional perspective, an evaluation is made of the connectivity of rail transit with major cities in the region and its impact on the urban spatial system.

Firstly, there are few intercity and suburban railways, making it difficult to meet the demand for direct connections between major cities in the Yangtze River Delta urban agglomeration. At the metropolitan level, the construction of major national high-speed railways has basically met the connectivity demand of core cities. The proportion of rail transit trips between Shanghai and cities such as Suzhou, Wuxi, and Changzhou in the Yangtze River Delta urban agglomeration has reached 20.7%, 29%, and 41.1%, respectively. However, it is currently unable to effectively connect various levels of nodes through rail transit. The proportion of current rail transit hubs entering node centres is only one-third. Studies suggest that travel efficiency should correspondingly increase with the development of urban agglomerations and the increase in urbanisation rates. The single high-speed rail model of metropolitan areas should evolve towards a multi-network direct connection approach, i.e., transitioning from interconnection between high-level cities and connecting high-level cities to the next-level nodes through various types of rail transit. This poses requirements for intercity and suburban railways in metropolitan areas (Chen Zhou and Qiao, 2017). There is still a significant gap between the Shanghai metropolitan area and the Tokyo metropolitan area (Figure 7).

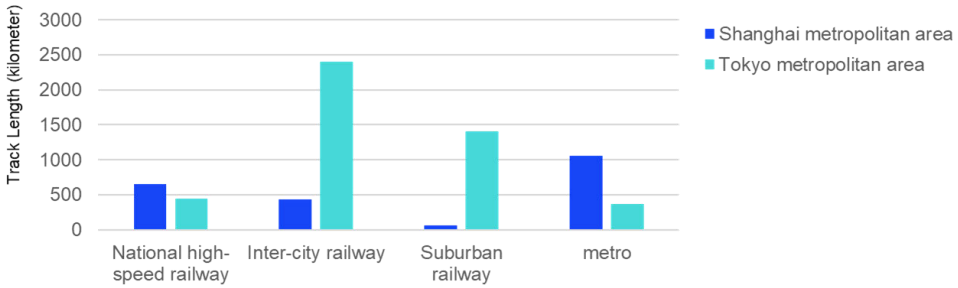

Figure 7. A comparison of the operational development of rail transit in the Shanghai metropolitan area and Tokyo metropolitan area

Secondly, under the background of regional integration, rail transit still cannot support the construction of new cities to become independent nodal cities, and there is a risk of marginalisation for new cities in Shanghai. As mentioned earlier, Shanghai hopes that new cities can become independent, comprehensive nodal cities, which requires good internal and external connectivity to enhance the radiation capacity of new cities. On one hand, the timeliness of the connection between new cities and the central area of Shanghai is poor. Compared with other cities near Shanghai, new cities lack competitiveness, and the travel time from each new city to the main railway stations of Shanghai exceeds several times that of cities near Shanghai. Rail transit travel is less competitive than car travel in new cities. The rail transit connecting new cities is all subways. For example, in the central, vibrant area of Shanghai, People's Square, driving or taking rail transit from new cities to strategic nodes of the city takes nearly an hour, exceeding the time taken by driving from new cities (Figure 8). On the other hand, new cities lack high-level hubs and have insufficient external radiation capacity. External transportation in new cities mainly relies on expressway networks and lacks high-level railways to meet multifunctional demands. Compared with cities of similar population size, new cities lack transportation hubs that match the city's scale and level to support external connections.

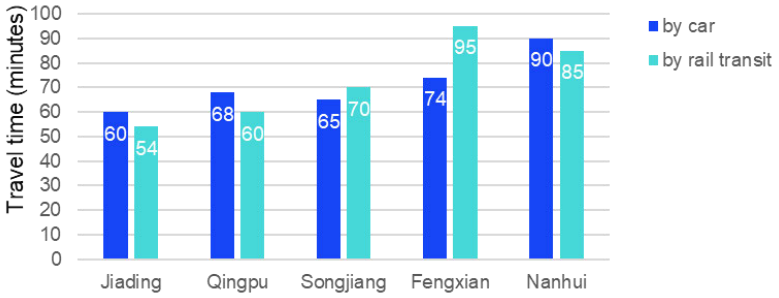

Figure 8. Comparison of travel time from the new city to the central urban area of Shanghai using different modes of transportation

3.3 Urban Perspective: Railway Network Efficiency

As a megacity, Shanghai is subject to considerable pressure in terms of transportation. The capacity of public transportation, particularly high-capacity rail transit services, is crucial. This is closely related to the city's operational efficiency, livability, and sustainability. Consequently, it is of paramount importance to evaluate the efficiency of the rail transit network and to analyse its service capacity.

As a megacity, Shanghai is subject to considerable pressure in terms of transportation. The capacity of public transportation, particularly high-capacity rail transit services, is of crucial importance. This is closely related to the city's operational efficiency, livability, and sustainability. Consequently, it is of paramount importance to evaluate the efficiency of the rail transit network and to analyse its service capacity.

On the one hand, there is a considerable demand for long-distance commuting within the central city of Shanghai. The existing metro network is unable to adequately support the development of new urban strategic spaces. Due to operational speed and station stops, the metro network's efficient service range to urban agglomeration spaces is limited to a radius of less than 20km. As a consequence of the expansion of Shanghai's strategic space in the suburban areas, there has been a notable increase in long-distance commuting, resulting in a situation where a considerable number of long-distance commuters occupy the capacity of stations along the lines. By calculating the cumulative congestion contribution of each sub-district, it was found that the density of the metro network in the central ring area of Shanghai had significantly decreased, which was closely related to road congestion. Conversely, there is a considerable volume of travel between Shanghai and its surrounding areas, yet there is a dearth of rapid rail transit modes for rapid connections. Currently, the fastest mode of travel between Shanghai's sub-centres and new cities and areas near Shanghai, as well as between new cities and areas near Shanghai, is by road, which is a lengthy process.

4. A Viable Approach: Multi-level Rail Transit Network and Spatial Co-optimisation Strategies

4.1 Relationship Discussion

Complex mutual influences exist between rail transit networks and urban spaces, influenced by node levels and functions, reflecting requirements on time elements. When urban and regional development needs are reflected in rail transit networks, these demands are manifested not only in spatial connections but also in requirements for connection time and intensity. From a practical perspective, reflecting this relationship can be achieved by discussing the composition of multi-level rail transit networks from a spatiotemporal perspective.

Research suggests that the rail transit system of a megacity should consist of at least three levels corresponding to three spatiotemporal scales, each level containing different types of rail transit and serving different functions. These levels should contain various rail transit types and serve different functions, with the levels interconnected through hubs. Firstly, the central level consists of dense rail transit networks formed by metro and suburban lines. These lines are primarily used for daily life and commuting trips, with service capacity reaching specific locations within an hour. Secondly, the metropolitan level, which should not be divided by administrative boundaries and also includes adjacent metropolitan areas, consists of a well-structured rail transit network composed of suburban and intercity lines, supplemented by metro lines. This network mainly serves longer-distance daily life and commuting trips, connecting

central cities, new cities, and peripheral cities. It also connects urban nodes within 1 hour. Thirdly, the regional level, which encompasses metropolitan areas and beyond, is characterised by the linking of major city nodes through intercity or high-speed rail lines, the construction of transportation corridors, and the provision of services primarily for business travel, with service capacity reaching urban transportation hubs within one hour.

4.2 Possible Key Points and Methods for Synergistic Optimisation

Based on the analysis of case studies and the discussion on the relationship between rail transit networks and urban spaces, a multi-level rail transit network and spatial synergistic optimisation strategy for megacities is proposed, including five possible critical areas of focus.

Before detailing the specific areas of focus, it is essential to emphasise that while the mutual influence between rail transit networks and urban spaces is established, the construction of rail transit should be based on the development goals and layout strategies of cities and regions, taking into account the specific development situation, financial resources, and construction capabilities of the city. A study on Spain suggests that Spain's ambitious layout and construction of high-speed rail systems have led to inefficient route construction and high costs (Perl and Goetz, 2014). Conversely, Shanghai and its surrounding area have a well-developed infrastructure, extensive transportation networks, a stable economic environment, and an appropriate institutional framework, which provides an ideal context for a comprehensive discussion on rail transit systems.

(1) Regional Corridors and Urban Strategies

The construction and optimisation of regional corridors are inextricably linked to urban vision and development goals. As a case in point, the city of Shanghai has set forth objectives about regional leadership, economic development, ecology, and culture. Consequently, it is essential to consider the provision of adequate and rational support for external gateways, the establishment of corridors of an appropriate type that align with the pattern of regional industries, ecology, and culture elements, and the prioritisation of corridor development based on urban functions and travel demands.

(2) Multi-level Networks and Urban-Town Systems

Based on spatial circle layers, it is necessary to consider urban-town systems, propose requirements for connection time and intensity for rail transit networks, and reflect these in rail transit types and operating modes in order to ensure efficient connections between different nodes. It is recommended that rail transit channels be constructed according to the varying connectivity characteristics of metropolitan areas, with a particular focus on strengthening channel connections for key development areas.

(3) Hub Systems and Element Allocation

Rail transit is connected to urban spaces through stations, and hub systems of rail transit with different functions and levels are more efficient compared to single large hubs and can more effectively influence urban resource allocation. Possible hub types include regional comprehensive hubs, linking international, national, and regional travel; regional essential hubs, linking major cities in the region; regional new city hubs, serving as essential nodes for new cities to integrate into the region; urban multifunctional hubs, linking suburban railways and

subways; urban subway hubs, connecting multiple subway lines.

(4) Improvement of Rail Network Efficiency in Central Areas

With urban development, the construction of metro networks often becomes an essential means to alleviate urban transportation pressure in central areas. Therefore, most megacities have well-developed metro networks in central areas, with limited space underground. Analysing urban travel demands, coordinating with urban central systems, and focusing on improving travel efficiency in strategic functional areas of cities are important directions for rail transit optimisation. In addition, the construction of suburban railways is also an effective way to improve the efficiency of rail networks in central areas.

(5) Development, Construction and Operation Mode

The delineation of clear development, construction, and operation methods is crucial for the sustainability of rail transit construction. In the context of China, the delineation of administrative powers is of particular importance, requiring clarity on the responsibilities between central and local governments, as well as among local governments. Furthermore, the establishment of coordinated organisations and methods, along with the determination of lead departments to coordinate multiple management and operation entities, are essential. Third, in the coordination process, it is essential to clarify technical solutions, dispatch responsibilities, and service standards in order to guarantee the reliability of coordination. Fourth, in addition to providing essential financial support, it is necessary to implement a reasonable development strategy along the line in order to ensure the sustainability of rail transit development.

5. Conclusion

The comparison reveals differences in the concept of spatial scale, administrative authority and understanding of rail transport types between megacities in China and other countries. With regard to spatial scale, the city limits of Chinese megacities are comparable to the metropolitan area limits of cities such as Tokyo, Paris and London. Furthermore, the population distribution is more concentrated.

The differences in regional administration and development styles are reflected in the development history of rail transport, which in turn affects the different sequences of spatial development and rail transport system construction in different cities. In the case of Shanghai, the critical difference lies in the fact that the high-speed railway and metro are very well-developed in the rail transit network. However, there is a lack of intermediate level, i.e., the urban rail within a service radius of 50 km. This affects the construction of the hub system accordingly, and ultimately, the service efficiency of Shanghai's rail transit system fails to reach the level of other urban metropolitan areas.

The study proposes an optimisation idea, namely a strategy of multi-level rail transit network and spatial co-optimisation. The rationale behind this strategy is that there is a complex interrelationship between the rail transit network and urban space. This is reflected in the impact of the rail transit system on the spatial and temporal characteristics of the region, as well as the requirements of the regional cities and the development needs of the region in terms of the linkage of the rail transit network. The strategy comprises a three-tier rail network construction model corresponding to the three spatial and temporal scales. It also includes specific synergistic optimisation points and methods. Specific optimisation points relate to the

construction objectives and layout strategies of cities and regions. For example, in Shanghai, these include (1) regional corridors related to urban development strategies, (2) multi-layer rail transit networks related to the urban system, (3) rail transit hub systems related to urban resource allocation, (4) rail transit network efficiency, and (5) development, construction and operation modes.

The study highlights that Chinese megacities such as Shanghai have a favourable foundation for development, a dense transport network, a relatively stable economic climate and an appropriate institutional framework. Consequently, it is possible to discuss a strategy for optimising the rail transport system in an idealistic manner that is as comprehensive as possible. The logic of multi-level rail transit networks with spatial co-optimisation is appropriate for other regions. However, caution is needed in terms of the way it is achieved and the specific strategy.

Analysing Local Cross-border Cooperation in Fragile Peripheral Areas in Northern Italy

Rodrigo Vielmo Moura
Department of Architecture and Urban Studies, Politecnico di Milano, Milan, Italy
rodrigo.vielmo@polimi.it

Abstract
The Italian National Strategy for Inner Areas created a legal and innovative territorial arrangement requiring municipal collaboration for policy and decision-making. This paper aims to verify the strategies, approaches, and projects associated with local cross-border cooperation, discuss the implications and effects, and generate reflections on the defined and unexploited opportunities to interact with municipalities within and outside the inner area's boundaries. The findings indicate that cross-border strategies are linked to healthcare, education, and mobility services. However, all the examined documents fail to make explicit indications that one municipality must cooperate with another to activate such an asset or system. The new local strategy must take advantage of the proximity of the nearby inner areas to boost integrated regional development and better exploit the territorial capital.

Keywords: Local cross-border cooperation, Integrated territorial development, territorial cohesion, National strategy for inner areas, socio-economic development

1. Introduction

Planning systems, territorial policies, models of governance and administrative structures usually change over the years as they need to be updated and coherent to respond to complex and uncertain challenges within the urban, peripheral and rural environment. In this process, a range of concepts and approaches are constantly created, adapted, revised, and implemented. For instance, 'from government to governance', the mix of top-down and bottom-up initiatives, multi-level governance, social and territorial cohesion, integrated regional development, and participatory processes. In the European Union (EU) context, there is the pursuit of a more balanced, integrated and assertive territorial development through democratic processes that respect a sustainable energy transition and innovative strategies that take advantage of the territorial potential (EC, 2022).

Over the years, the EU Regional Policy, also known as the Cohesion Policy, has been adapted, including and raising attention to the territorial cohesion dimension (Faludi, 2018). Policy instruments such as the European Structural and Investment Funds (ESIF) are means of counterattacking the socioeconomic and territorial disparities of member states' regions. The quest for multidimensional cohesion demonstrates the commitment to achieving spatial justice and delivering citizens' rights, especially in fragile and peripheral territories. Another key element within the EU sphere is the devotion to transnational planning and cross-border cooperation for more than 30 years. It is worth pointing out that the EU internal border regions cover about forty per cent (40%) of the EU territory and host about 150 million people (European Parliament, 2022). Research, innovation, conceptual frameworks, priorities, objectives, axes, instruments, mechanisms, tools and funds are all (interconnected) elements that make positive changes possible and feasible in this type of context.

In the sense of European cross-border cooperation, Interreg A assists, encourages, and finances the collaboration between EU regions (NUTS III). Basically, '[i]t aims to tackle common challenges identified jointly in the border regions and to exploit the untapped growth potential

in border areas' (Autonomous Province of Bolzano, 2023, p. 5). Studies such as overcoming obstacles in border regions (EC, 2016) underline, on the one hand, common issues in this type of border (legal, administrative, and language barriers, economic disparity, physical access, sociocultural differences, lack of interest from public authorities working together) and by the other, reasons for crossing borders (leisure, to buy goods and/or services, to visit friends and/or family, employment, business, education and so forth). Nevertheless, despite the relevance and the extensive research and interest in this type of cooperation (EU member states), this paper pays attention to the local (or domestic) cross-border cooperation taking place in Italy due to a relatively new policy requirement.

Linked to EU partnership agreements and programming periods (2014-2020 and 2021-2027) and conceptually and methodologically influenced by multi-level governance, local development projects, and the place-based approach, the Italian government launched the National Strategy for Inner Areas, or *Strategia Nazionale per le Aree Interne* (SNAI) (Barca et al., 2009; Barca et al., 2014). In sum, the SNAI seeks to reverse demographic trends, foster socioeconomic development, unlock the territorial capital, and deliver better essential public services such as healthcare, mobility, and education, especially to fragile peripheral areas – known as Inner Areas in the Italian context. Barca et al. (2014) state that the Italian territory is covered by about sixty per cent of inner areas and around one-quarter of Italy's population.

Despite the significance of the national goals, what is also relevant about this policy (or programme) and a subject of analysis is the creation of new areas (or boundaries) that comprise numerous municipalities and involve all Italian regions. It requires local, provincial, and regional collaboration. Also, it is important to note that depending on the country or state legislation (law, codes and other formal agreements), this type of municipal cooperation and territorial arrangement is restricted and unfeasible. Legal obstacles and the absence of financial resources (possibly from the regional or central government) discourage and limit this relationship. In this national case, the inner areas, on the one hand, demonstrate a possibility to boost the integrated territorial development and reverse the existing fragility condition (since the central level encourages, creates and facilitates the requirement of funds and demands local cross-border cooperation) and, by the other hand, may create new challenges to the local authorities due to the new attributions linked to the strategy design, time-management, participatory process, definition of goals and projects, monitoring and evaluation.

This national policy has established more than one hundred new areas across Italy in the last decade (Dipartimento per le politiche di coesione, 2023), and several questions emerge due to the possible implications and effects of this type of territorial arrangement which links with spatial planning, governance, regional policies, and socioeconomic and territorial cohesion dimensions.

As related above, this paper is interested in the municipal cross-border aspect. Thus, this contribution aims to answer the following questions: (i) How do the national and local strategies address the aspect of cross-border cooperation? (ii) What are (if so) the indications, approaches, strategies, and projects to bolster integrated development and take advantage of the endogenous and exogenous potential growth that neighbouring and inner area municipalities can offer? (iii) What are the possible implications and effects of this new territorial arrangement at the local level?

In order to address the previous questions, one specific inner area has been selected: the Inner Area of Alto Lago di Como e Valli del Lario in Northern Italy. Currently, this new arrangement

covers 41 municipalities, is home to more than 50 thousand inhabitants (Comitato Nazionale Aree Interne, 2022), is located in two provinces, Como and Lecco, embraces Lake Como and the mountains, and borders Switzerland.

Therefore, this paper aims (i) to verify what are the intentions, vision, goals, strategies, approaches and projects that can be associated with the cross-border cooperation matter and (ii) generate a critical reflection grounded on the defined but also the unexploited or neglected opportunities to interacting with municipalities within and outside the inner area boundaries in order to address local needs, enhance territorial cohesion, socioeconomic development, and endogenous and exogenous growth.

The qualitative research method, which includes textual analysis and follows methodological studies such as Weck and Kamuf (2020) and Borén and Schmitt (2022), examines four official documents. The first two represent approved strategies from the national to the local level, 'Strategia Nazionale per le Aree Interne' (Barca et al., 2014) and Strategia d'Area – Alto Lago di Como e Valli del Lario (Comune di Taceno, 2018). The others, 'Un'Agenda strategica per l'Alto Lago di Como e Valli del Lario' (DAStU, 2023a) and 'Il ritratto territorial dell'Alto Lago di Como e Valli del Lario' (DAStU, 2023b) have been selected because of their complementary aspect and the time span they have been published. They are documents developed from two workshops and a partnership between the scientific and political environment (Department of Architecture and Urban Studies, Politecnico di Milano and Regione Lombardia). Still, the latter is the basis for constructing the new Area's Strategy as part of the 2021-2027 PP.

The first section introduces the research topic, questions, aims, and methodology to address such a theme. The second section localises the inner area of Alto Lago di Como e Valli del Lario geographically and details the area's characteristics and existing fragility (issues, barriers and challenges). The third section examines and presents findings related to local cross-border cooperation. The fourth section discusses the possible effects of local cross-border cooperation and the strategies. It approaches the socioeconomic development aspect and the inner area's strategies to interact within and outside the boundaries. The fifth section concludes the paper and points out future research.

2. The Geography of Alto Lago di Como e Valli del Lario: Characteristics of the Territory and Recent Dynamics

The Inner Area of Alto Lago di Como e Valli del Lario currently covers 41 municipalities (2021-2027 PP) and is home to 50,082 inhabitants (Comitato Nazionale Aree Interne, 2022). This new territorial arrangement is located in two provinces (Como and Lecco) in Northern Italy, and both are within the Lombardy Region limits. Ten municipalities from the Province of Lecco have been added to the current PP.

Lake Como is the main natural resource, but there are also the mountains, where several municipalities are located. The economic and productive structure of the area is directly linked with the manufacturing sector (steel processing, engineering and machinery components and textiles) (DAStU, 2023a).

Figure 1 shows the municipalities involved and the new boundaries created due to the SNAI effect. Through this map, it is possible to recognise that Lake Como divides the provinces[1] and

[1] The municipalities of Lecco and Como have a different classification, being considered hubs that offer basic services to the residents of the surrounding municipalities.

municipalities (discussed later), and the capitals of provinces are not part of the inner area. This specific inner area brings an important feature that helps to explain local daily problems, challenges and barriers: the altimetric difference.

The altimetric difference is not in itself a problem. However, one must recognise the existence of global cases in which this factor creates difficulties and obstacles, especially in attracting people, managing and delivering essential services to the population, as well as the interaction and physical connection with other settlements, towns and cities. In fact, the problems are maximised by the existing agreements, arrangements, infrastructure and governance. Low population density combined with altimetric barriers can trigger problems for socio-economic development. Scholars argue that the accumulation of skilled and educated people working together (human capital and agglomeration factor) is usually considered vital to socio-economic growth and explains the city's success worldwide (Glaeser, 2011).

Concerning the inner study area, in addition to low density (more pronounced in the mountain communes), the most common problems are associated with ageing, lack of prospects and opportunities, strengthening the desire to leave the communes or having to travel daily for work, leisure or education, lack of services, infrastructure and accessibility related to local public transport, which enhances, favours and maintains the concept of car-dependency.

Furthermore, there is a lack of educational and health services that cannot cater to an ageing population that demands frequent services and assistance. In the case of this inner area, the geomorphological configuration, a factor responsible for the natural beauty and landscape, is also one of the causes of the lack of connection and the difficulty in implementing better services due to the existing difference in altitude.

In numbers, it is possible to go from 200 to 1,500 metres in a few kilometres. Population density, also among the challenges, is very low, with an average of 87.28 inhabitants per km2. More specifically, of the 32 municipal administrations, 68% have a population of fewer than 1,000 inhabitants, and 29% have fewer than 300 inhabitants in the mountain area (Comune di Taceno, 2018). On the other hand, Alto Lago di Como e Valli del Lario is rich in natural resources, landscape views, gastronomy, architecture, and heritage (Comune di Taceno, 2018). Lake Como, for instance, is an internationally recognised natural resource with natural ecosystems and touristic activities that enhance the quality of life of the inner area's municipalities.

Thus, this section presented central characteristics to understand the study area to address later the strategies, approaches and projects linked to the cross-border matter.

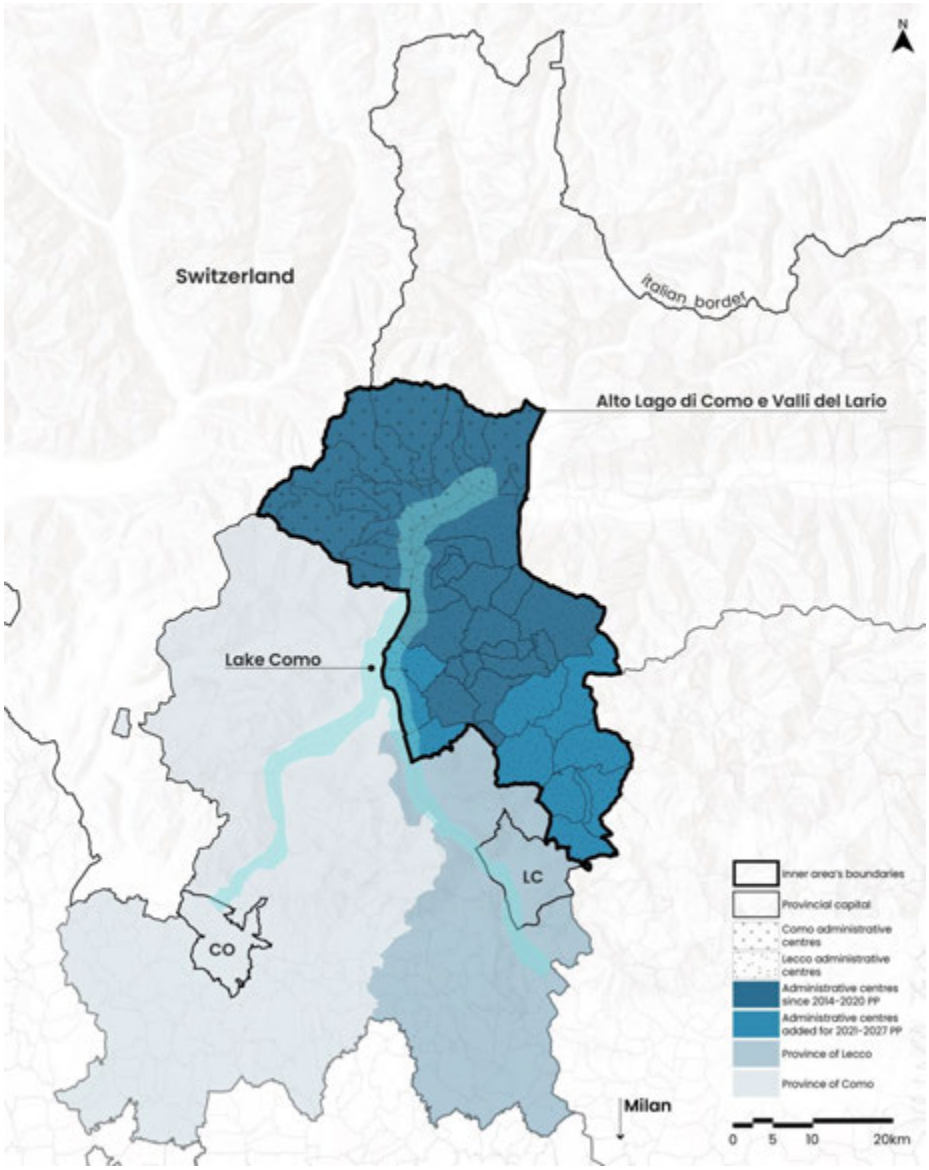

Figure 1. Inner Area of Alto Lago di Como e Valli del Lario. Source: Author's own elaboration.

3. Reviewing the strategies and projects of Alto Lago di Como e Valli del Lario

This section examines four official documents with the aim of verifying the intentions, vision, strategies, approaches and projects linked to cross-border cooperation in the context of the Inner Area of Alto Lago di Como e Valli del Lario strategies and plans. The methodology is based on textual analysis and studies by Weck and Kamuf (2020) and Borén and Schmitt (2022). Although with a more general aspect (due to the nature of a national strategy or plan), the SNAI

will be reviewed to ascertain what guidelines and recommendations exist regarding cross-border possibilities in the context of inner areas. After that, the focus falls strictly on the inner area of study. Thus, three documents strongly connected with the inner area's municipalities (2014-2020 PP) are analysed. It is important to note that the 2021-2027 PP strategy is being developed. However, two workshops have already been held with the local community and actors representing public authorities, the private sector, academics, and experts. The meetings resulted in two interesting documents (DAStU, 2023a, 2023b) that provide updates and original analyses of Alto Lago di Como e Valli del Lario. These documents will serve to find out what is currently being discussed and what has been new since the national strategy was published in 2014 and the local one in 2018.

The findings are organised and presented by level of government (from national to local) and follow the publication timeline. Given the challenge in transferring the local needs, aims and desired scenarios into projects and interventions for various reasons, the content below depicts not only the defined projects but also (where applicable) the vision, statements, intentions, guidelines, suggestions and recommendations. In other words, the results are not just looking for explicit statements but for everything that can be related to the subject of cross-border cooperation. Although cross-border cooperation intensely links to EU member states and external borders, this paper is also interested in how the group of municipalities (which make up an inner area) are using this innovative territorial arrangement to rationally and intelligently exploit the territorial capital and European and national funds to create a mechanism of cooperation to help reduce disparities and tackle common challenges across their domestic borders (EC, 2024).

3.1. The National Strategy for Inner Areas

The national strategy initially states that the policy created is a work in progress with strict agreement with the regions. It recognises the importance of effective dialogue between the central and regional levels with the municipalities and provinces. In fact, the SNAI place the municipalities as the main actors in the creation of the local strategy. 'The municipalities involved in each project area will create appropriate forms of service partnership (or, where appropriate, associations) that will help to boost the long-term sustainability of the strategy' (Barca et al., 2014, p. 9). In addition, the policy-makers emphasise that the growth of the inner areas in the coming years depends on external factors (exogenous development).

In order to identify internal and external dynamics, it is suggested that the inner areas, through the various local bodies and subsystems, propose realistic scenarios that can be realised by defining tangible objectives and projects that can be implemented. In this scenario, it is possible to recognise the transfer of responsibility through bottom-up initiatives. 'Local communities alone can interpret the variety and complexity of the local society and territorial capital that characterise them, and turn them into projects' (Barca et al., 2014, p. 18).

For the inner area's 'success', the national policy again focuses on the importance of endogenous and exogenous factors. They assume that the endogenous factor may trigger innovation, maintenance and preservation of local identity and internal knowledge about territorial activities. Hence, it would empower the inhabitants, boost the local economy, and attract other people to consume inner services and products.

With respect to (domestic or international) cross-border integration and cooperation, the inner areas, through funding and local development projects, need to become evolving territorial

systems that connect with the other areas of the Italian territory 'in terms of space, relations, economy - and culture (Barca et al., 2014, p. 16). Policy-makers see the inner areas as an issue that influences not only the national level but also the European and global levels.

Although the inner areas themselves are responsible for developing projects (according to local characteristics and future objectives), there are some sectors that SNAI obliges – in an attempt to strengthen and provide basic citizenship rights. Besides combating demographic trends such as depopulation, SNAI focuses on providing essential public services as a crucial means of reducing existing disparities and fragility. Mobility, healthcare, education and virtual connectivity are the basis of this national policy. Municipal cross-border cooperation may be seen in the demand for new forms of governance that require 'new associated management models for municipal activities' (Barca et al., 2014, p. 42).

The central level of government recognises its role in providing essential services to the inhabitants of Italian territory, regardless of geographical position. As a way of improving these services in inner areas, they state that there needs to be a reorganisation of educational facilities as well as health centres (hospitals and smaller units) in order to concentrate (where possible) and guarantee specialised and emergency services for citizens. For these actions to be feasible, mobility projects, especially accessibility, are expressed. Better coordination of transport planning that analyses transport demand and encourages modal shifts towards collective transport (Barca et al., 2014). These issues are vital for adequate flows into and out of the inner area to utilise essential services.

This section has presented possible links and indications of cooperation between municipalities. The national strategy serves as a guide for constructing all local strategies. In the following sections, the documents present findings on cross-border cooperation in the North Lake Como area.

3.2. Strategia d'Area Alto Lago di Como e Valli del Lario

The local strategy, officially named *Strategia d'Area Alto Lago di Como e Valli del Lario*, rather than the national one, naturally indicate and points out municipalities. The links with the theme of cross-border cooperation align with intentions, goals, and projects aimed at maximising basic public services such as education, healthcare and mobility. In addition, it details the topics of governance, tourism and entrepreneurship initiatives.

The document begins by reiterating that due to its proximity to influential universities and research centres and its history in specific production sectors (see section 2), the inner area's population has cognitive and social capital and an orientation towards 'doing business'. Alto Lago di Como e Valli del Lario is located in two provinces, which naturally increases the number of public bodies, facilities, institutions, and authorities, which, in this case (but not exclusively), implies governance challenges.
As for municipal cross-border governance, the inner area shows concrete actions in the legal sphere. There have been several mergers and unions of municipalities and administrative centres in the last decade. For example, the merger between Bellano and Vendrogno, the merger of other municipal centres that gave rise to the Comune di Gravedona and Uniti and, more recently, the Comune di Valvarrone, which was formed through the merger of Introzzo, Tremenico and Vendrogno. The above examples demonstrate the wish to improve the management of services and personal capacity and reduce operating financial costs. It is important to emphasise that these occurrences are related to both provinces, Lecco and Como.

Although there is 'local' centralisation on the part of the two mountain communities in the management of civil protection functions and other social services, technical issues such as the type of interface, the use of different digital systems (software) and also the deficit of administrative and institutional capacity building are points that explain the reduction or limitation of cross-border cooperation in this area. Moreover, the inner area has two different health agencies (ATS), one for each province. On the other hand, local public transport is managed by a single agency – 'Agenzia del Bacino di Varese-Como-Lecco'. The management of navigation on Lake Como competes with 'Gestione Navegazione Laghi', which runs Lake Maggiore and Lake Garda.

In the view of improving the management of local services and consequently local governance, the municipalities defined the subsequent topic of intervention topic and two related projects: 'rationalising functions in associated form, increasing the level of associationism between local authorities' (Comune di Taceno, 2018, p. 23). Shortly, the projects aim to improve the following types of services: civil protection, land register, and seismic regulations. They also aim to implement capacity-building actions in the administrative sector as well as for officials and other professionals linked to local strategy development. In this process, the aim is not only to train local bodies but also to have an integrated organisational model. Together with the above actions, the projects linked to local administrations seek to implement information, awareness-raising and empowerment dynamics for the local community (active citizenship).

With regard to educational projects, the local strategy recognises the difficulty in providing such a service due to financial and organisational issues, geographical position and (low) population density. Thus, the centralisation of services and especially facilities mentioned by the local strategy follows the guidelines of the central level (SNAI). In this sense, essential public services such as education and healthcare are somewhat closely linked to and dependent on mobility, accessibility and virtual connectivity as factors in achieving better performance.

In terms of education, the topic is 'strengthening the educational offer to favour the territorial anchoring of settled populations (and new populations)' (Comune di Taceno, 2018, p. 23). The projects revolve around teaching English language, integrated subjects, and new technologies, as well as having such facilities as hubs for reconciling work and family time by better aligning pre-school and after-school timetables. Offering extracurricular activities for children, parents and residents of the inner area who work outside the inner area or whose schedules make it difficult to manage the situation. In short, the school and primary and secondary centres are planned as meeting points to address and increase knowledge about local, cultural and innovation issues for different people with different needs.
Moreover, in the educational and training sphere, some projects aim to bring students together through exchanges with entrepreneurs and companies from the local area and beyond, as well as educational hubs and research centres. Innovation, mechanics, mechatronics, energy efficiency, and the development of entrepreneurial profiles are at the forefront of these projects.

As regards healthcare, the main topic of intervention is 'increasing services aimed at taking care of people with chronic and frail conditions by the social and health care system and improving conditions for social inclusion' (Comune di Taceno, 2018, p. 25). Local development projects align with the improvement and application of the Territorial Social and Health Centre, or 'Presidio Socio-Sanitario Territoriale' (PreSST) model. In the province of Lecco, the PreSST model will operate in Bellano, serving the municipalities closest to the lake, and in Introbio, serving those in the mountains or valleys. The dynamics for the Province of Como are in line

with services at a hospital located in Gravedona ed Uniti. There are actions to construct an integrated network with telecare and telemedicine services.

The local strategy understands that in order to provide education and health services in person and build a more connected inner area that can develop socio-economically, it is crucial to have good mobility conditions, especially accessibility between municipalities – regardless of geographical location. To this end, the main goal is 'increasing the level of accessibility of the area in relation to the specific geographies defined by the local public transport system and territorial nodes' (Comune di Taceno, 2018, p. 24). In this context, the projects seek to strengthen local public transport (LPT) services along the main routes but at the same time on secondary routes – improving accessibility to the main routes through better management and encouraging people to opt for LPT rather than private individual vehicles (usually cars). In addition, the connection and navigation services on Lake Como should be expanded to minimise the existing natural barrier aspect.

Conclusively, the local level believes that a new multidisciplinary arrangement made up of companies in the tourism field is essential for connecting the territory. The lack and the need for a logic of networking and making growth in local partnerships are competencies of a managerial and entrepreneurial nature. To this end, the expected outcome is to 'increase the tourist offer's integration level for an integrated and distinctive communication of the area and a systemic organisation of reception services and accommodation proposals' (Comune di Taceno, 2018, p. 28).Thus, tourism appears as a way of connecting the mountains to the lake, bringing more people from within the inner area and tourists with the assumption of developing the socio-economic and cultural environment of the inner area.

With regard to international cross-border cooperation, the local strategy only mentions the existence of projects between Italy and Switzerland (Interreg Italia-Svizzera). There is no project in this PP that strengthens this link or opens up new windows of cooperation.

3.3. Un'Agenda Strategica per l'Alto Lago di Como e Valli del Lario

Considering the need and objective of reversing demographic trends, the strategic agenda raises noteworthy points about this factor and makes direct links with essential public services. The absence of educational and health personnel is notable and severe, especially in the sparsely populated communes located in the mountains. In this sense, it is stated that even with the implementation of incentive policies (free rent and salary increases), this event is not being reversed. A few points help explain this situation: the attractiveness in terms of quality of life, services and financial remuneration found in Switzerland and some nearby towns. In addition, the inefficiency of public transport, difficulties due to high prices, lack of options or the poor state of repair of flats and houses reinforce this situation. As a result, the level of education is compromised and often interrupted. It leads to differences in learning between students from other locations - reinforcing the fragility of the inner area.

The existing fragmentation in terms of governance is once again exposed. In fact, these problems are related to basic public services. However, this time, they include the cultural sphere, which reduces the supply or even deprives citizens of services and activities linked to cinema, theatres and bookshops, for example. On the other hand, governance has been upgraded according to the strategic agenda. DAStU (2023a) points out that the communes, despite challenges and barriers, are moving towards greater cooperation. They use the case of the Riserva Naturale Pian di Spagna e Lago di Mezzola, where 11 communes, the two provinces

(Lecco and Como), the two mountain communities and the Lombardy Region are involved. However, the authors mention that the processes of associationism and the merging of the communes have not made as much progress.

As mentioned in the previous sections, mobility is undoubtedly a key dimension in the progress or decline of these communes. In this sense, although some improvements have been made in recent years in matters of soft (active) mobility and public transport connections, the document argues that the lack of integration, infrastructure and quality of access between the two shores of Lago di Como diminishes endogenous development and reinforces the employment and service dependence of the residents of the inner area on the external poles (Lecco, Menaggio and Morbegno).

After presenting some existing issues that partly explain the fragility of the inner area of Alto Lago di Como e Valli del Lario, some strategic lines of action that will most likely guide the definition of local development projects will be presented. They have been constructed based on the results of meetings with various local actors and following stakeholder processes. Basically, they are organised into three points that are segmented according to the nature, detail or need of the intervention area.

'Abitare l'Alto Lago' raises the issue of housing in terms of favourable conditions and housing options and in terms of keeping or attracting people to increase the number of inhabitants in the inner area. To this end, it is proposed that disused or vacant public buildings be redeveloped and reused. These intended buildings are generally found in the historic centres of the communes bordering the lake and the side valleys. Redeveloping these buildings is an option to offer more affordable (and fair) rents to health, education and public administration professionals, as well as single elderly and disabled people. Still, within this axis of intervention, there is the idea of requalifying private property as a means of directing these spaces towards recreational and tourist purposes. Lastly, bearing in mind that the municipalities bordering the lake, those on the mid-coast and in the mountains are at strategic points for accessing natural parks and trekking and cycling routes, for example, there is a third action that aims to improve people's enjoyment of the communes by strengthening the small centralities that exist in the mountains where a variety of services and activities need to be improved for both residents and visitors (bars, agro-tourism, coworking spaces, cycle workshops, tourist information offices, appointment centres for health services, among others).

The second strategic line is called 'Muoversi in Alto Lago'. The agenda begins by recognising the 2014-2020 PP projects but also mentions that more is needed through a different vision. It proposes the development of a Mobility Plan for the area that involves the various actors, institutions and organisations responsible for mobility in Alto Lago di Como e Valli del Lario at different stages of production. In this sense, the authors suggest that the plan could define an integrated mobility system that complements the current offer, which is considered precarious at different points. In short, the problems remain the same as those identified in the previous PP, but with more detail. The idea is to put a MaaS platform into practice, connecting the two shores of the lake to the side valleys via R-Link and train. There should be more connection points that encourage intermodality (i.e. taking the bike on the ferry), secondary LPT networks and cycle-pedestrian routes. Communication between existing public transport services and private services that mainly serve the tourist sector is also suggested. In addition, Bus Alpin, a system applied in Switzerland, is pointed out as a reference to follow.

'Dal Lago alla Montagna' is the third strategic axis. This line emphasises a problematic area sector: the poor connection between the lake and the mountains. Although the difference in altitude naturally imposes some barriers to access, the inner area has a concentrated territorial capital that must be unlocked and exploited sustainably, impacting the socio-economic, cultural and tourist sectors. To this end, the strategic agenda proposes that the lake should have a unitary system for tourist enjoyment and promotion that can, over the next few years, deseasonalise tourism. While most tourist accommodation is concentrated in the municipalities close to the lake, the mountains have a weak and limited infrastructure. In addition, the role of the forest and parks needs to be rethought regarding governance and accessibility.

Currently, the forests and other areas in a strategic position linking the lake to the mountains are privately owned with numerous parcels of land, making it difficult to manage them towards the common good. Finally, the historic trails must be better managed and integrated into routes. The following section looks at this issue of routes and tracks in detail and shows how various itineraries cross different municipalities, provinces, and international borders.

3.4. Il Ritratto Territoriale dell'Alto Lago di Como e Valli del Lario

The current object of analysis is the result of two workshops and contact with various local actors, following the same conceptual and organisational structure as the strategic agenda (section 3.3.). Many issues linked to cross-border cooperation are repeated in this document. Hence, this section aims to bring new analyses, such as the commuting flow analysis that shows the reasons for travelling/commuting as well as the internal and external flows touching Alto Lago di Como e Valli del Lario.

The different flows were analysed, taking into account all the municipalities belonging to Alto Lago di Como e Valli del Lario (2021-2027 PP). In this regard, it was noted that the largest internal flows (those with origin and destination within the inner area) are quite high for occasional reasons. Regarding inward movements (with origin outside the area and destination in the inner area), the data indicate very high flows for occasional reasons and quite high flows for work reasons. Outflows (with origin within the inner area and destination outside the inner area) indicate high numbers for study and work reasons, with work being the main reason for outflows. The scarcity of educational centres (primary and secondary) and the lack of dynamism in the job offer are pointed out as the leading causes for outflows.

However, when analysing the distribution of movements, the rates show that internal and inward flows are greater than outward flows. The authors understand this data in the following way: the municipalities have an internal polarisation in that the population belonging to the inner area, as well as some people from neighbouring municipalities, move to the so-called hubs in the inner area that can offer higher quality services. These centres are the municipalities that border the lake. Colico is the municipality with the highest internal flow rate and high inflow rates. Cortenova registers the highest number of arrivals. On the west side of the lake, Gravedona and Uniti have the highest outflows due to essential services. Regarding dependence on other communes for work, services and education, the most popular centres outside the inner area are Lecco, Menaggio and Morbegno.

Navigation under Lake Como was also analysed. Despite being a vital natural resource (and decisive for the socio-economic development of the southern part), Lake Como is currently seen as a barrier. In short, there is an imbalance in navigation on both shores. The Lecco shore has a discreet offer mainly in the low season months (May-October) with only five daily

weekend departures and eight destinations during the six high season months. Como's shore is far superior in this respect. There are 33 daily weekend departures, and 29 destinations (or options) are offered all year round. Data about the pre-pandemic boarding numbers (tickets bought annually) validates the shore imbalances. There were 20 thousand tickets boarded for Lecco compared to 610 thousand for Como.

Finally, the Area Strategy mentions the importance of upgrading and activating historic routes and itineraries that cross the inner area of Alto Lago di Como e Valli del Lario. In addition to encouraging tourism and soft mobility, the aim is to enhance cultural, historical, and natural heritage. North Lake Como is a tourism association that helps promote socio-cultural events that encourage internal and external tourism. The association also partners in a European project, *Le Vie del Viandante – trekking senza confini*, co-funded by Interreg Italia-Switzerland. Two important itineraries cross the inner area, Sentiero del Viandante (9) and Via dei Monti Lariani (11). In total, they are 60.5 and 144.8 kilometres long, respectively. They also serve as links to other routes to the south and north. Figure 2 demonstrates the number of existing itineraries that allow one to explore and move around the inner area, other provinces and Switzerland.

4. Discussion

In this section, the preceding results and findings are discussed in order to answer the research questions related to the Inner Area of Alto Lago di Como e Valli del Lario, Northern Italy. The content follows the same order pointed out in the introduction.

[2] https://www.leviedelviandante.eu/wp-content/uploads/2021/09/Viandante_mappa_4.pdf

The four public documents examined do not explicitly state local or international cross-border cooperation, indicating that, for instance, such a municipality or administrative centre needs to work with a particular one to strengthen and improve such service or sector. A more in-depth interpretation and reflection was required. Therefore, the previous sections presented issues, problems, and situations to contextualise and elucidate the intentions, desired scenarios, goals, and local development projects.

Firstly, cross-border relations are mostly linked to essential services and governance, although tourism and entrepreneurship are also approached. Yet, it is important to state that as the municipalities in the study area have a low population rate and a shortage of services (mainly in the mountain territory), they naturally depend on others. Thus, there is already an inward and outward flow in near essential service hubs (inside and outside the inner area boundaries) due to the concentration of specific services and for work and leisure reasons. This relationship or necessity applies even before the SNAI was launched in 2014 or the local strategy was approved and signed in 2020.

Most local interventions have been defined to increase the quality of mobility, healthcare and education services and systems. The discourses and projects about interaction and cooperation between the inner area's municipalities follow the same path, that is, focused on improving the LPT infrastructure and services to provide suitable levels of accessibility in order to make use of the hospitals and other healthcare facilities, as well as educational centres. Furthermore, given the fragmented local governance, which is maximised by the inner area comprising two provinces with different interfaces and software for the administrative management of public services, the new administrative capacity-building strategies converge to more municipal cross-border cooperation. The present projects aim to train personnel of different divisions and departments to increase the quality of services and interaction and cooperation between municipalities. Additionally, the recent unions and mergers of administrative centres (found in the two provinces) increase the responsibilities and the demand for a high administrative capacity and municipal cross-border contact.

The health and education strategies and projects that foresee the improvement and centralisation of activities and services in large units prove to be adequate because, on the one hand, there is a lack of workers for the functions and the requirement of financial resources to build new facilities and maintenance and, by the other, there are many municipalities with a low population where the cost-benefit of operations is compromised. Although the SNAI mentions telemedicine and assistance projects, the local strategy has not yet stipulated concrete projects. As a result, for the centralisation of services and activities to have an excellent cross-border effect, mobility and accessibility projects need to result, essentially LPT and creative interventions to attend mountain municipalities more frequently.

The findings show that the central level did not indicate or encourage any strategy or action for collaboration between the inner area's municipalities or from the outside. Although decentralisation of government and tasks is an essential factor that enables autonomy in terms of policy- and decision-making, for example, having guidelines and recommendations from the national and regional level within the context of the inner areas would be ideal not only for the country to have coherence and assertiveness in pursuit of common goals, but also to increase exogenous development, a subject raised and emphasised during the national strategy.
In the context of the 'Strategia d'Area' (in effect), the nearby hubs of essential services (Lecco, Como and Menaggio) were rarely considered for projects linked to the inner area. Lecco was cited a few times because its educational centres naturally attract residents and students from

inside and outside Alto Lago di Como e Valli del Lario. Also, the local strategy did not make direct links with Varenna, Bellagio and Menaggio, cities with a strong tourism sector, in order to activate the northern part of the lake or at least have a synergy and regular contact to improve the navigation of Lake Como and the extension of itineraries and routes that facilitate mobility and accessibility for residents on both shores of the lake.

Clearly, the strategy needs to develop and focuses on its municipalities. Nonetheless, exogenous development is just as crucial as endogenous, considering the proximity to municipalities with better levels of socio-economic development, tourism and basic services. Varenna, for example, has been added to the Inner Area of Alto Lago di Como e Valli del Lario for the 2021-2027 PP. Yet, all the new documents so far fail to point to municipalities that could be catalysts for this 'second new development opportunity'.

Another striking issue is that at no point did the three local documents mention the existence of another inner area neighbouring to reinforce the area's socio-economic growth. When the first strategy was built, there was the 'Inner Area of Valchiavenna' (a pilot project), and nowadays, there is the 'Inner area of Lario Intelvese' and the 'Inner Area of Valli Lario Ceresio'. Both inner areas border the study area. In this sense, the commuting flow analysis showed high internal and incoming flows in Alto Lago di Como e Valli de Lario to the extent that it is quite probable that the residents of the inner areas of northern Italy and Lombardy cross the boundaries and depend (even minimally) on the municipalities belonging to each inner area. Expanding the analysis and gathering evidence on needs and activities from other inner areas seems fundamental for structuring new projects to strengthen activities, services and systems towards integrated regional development and social and territorial cohesion.

The EU instruments, such as Integrated Territorial Investment and Community-led Local Development, could be applied first because the central level (SNAI) recommended them and second, to take advantage of the financial resources and the mix of possibilities arising from the combination of more than one fund and priority axe, for example, to connect the lake to the mountain better.

The last two documents contain additional points that can be used to discuss cross-border cooperation matters. Although these contents are not projects, the statements and proposals are more coherent and are closely linked to the current problems of the study context. 'Abitare Alto Lago' is an approach that encourages and attracts people to these areas, particularly people in the health and education sectors. In those days where climate change issues are gradually critical, and quality of life has become a relevant factor in choosing where to live (leveraged by the possibility of online meetings and remote working), the natural ecosystems and the landscape of Alto Lago di Como e Valli del Lario combined with numerous outdoor activities both on the lake and in the mountains, and the relative proximity to Milan and airports may attract new residents and trigger the socio-economic development.

The navigation of Lake Como has undoubtedly received greater attention in recent workshops, resulting in new analyses, data, proposals and potential approaches. The last document points out imbalances to the extent that the western shore (Como) is much more heavily used than the eastern one (Lecco), where LPT is more widely used due to better connections and infrastructure with major urban centres (Lecco and Milan). Moreover, the agency's timetables demonstrate different combinations and destinations for crossing the lake. Hence, innovative projects are expected to advance the number of crossings that allow intermodality (bicycles and other micromobility devices) and stations with services and infrastructure for automobiles to

continue their journey. The lake must be considered the main element for the development and union of the two provinces and municipalities involved. Lakes Project brings interesting standpoints to reconsider this natural resource as a catalyst (ESPON, 2021).

The various itineraries have been treated and considered as relevant elements for cross-border cooperation and socio-economic, cultural, and local identity development purposes. Figure 2 revealed various routes, tracks, and paths for different types of activities that can be linked to tourism, preferably sustainable tourism that does not lead to reducing residents' quality of life due to the high use of local infrastructures and systems. More regular collaboration with the North Lake Como association and existing international projects seems crucial to exploit the inner area territorial capital.

Regarding the possible local cross-border effects and implications at the local level, one can argue that the production of the Area's Strategy and the accumulation of multilevel actors have undoubtedly brought more work and challenges mainly to municipal administrations to cope. It forced them to think more, be prepared and trained, and be in contact with experts, stakeholders, the local community, and companies that may share common interests but also conflicts of interest. Above all, it demanded managing and allocating funds and making critical decisions. The various funds open up opportunities, but the absence of 'Local Action Groups' (LAG) may weaken the desired scenarios (DAStU, 2023a). A suitable and responsive strategy requires technical and community expertise, regular debate, and time to identify local problems and opportunities and avoid political, public or private conflicts.

Contrarily, all these complex activities unlocked new windows of opportunity for the following years. The inner areas represent a new territorial arrangement that combines European, national, regional and municipal funds and allows dialogue and the possibility of taking advantage of the territorial capital and potential of other municipalities legally towards a territorial and social cohesion change.

5. Conclusion

The review of four official documents put into evidence the cross-border strategies, approaches, and projects currently impacting the Inner Area of Alto Lago di Como e Valli del Lario in Northern Italy.

The conclusions of this paper indicate that cross-border strategies are intensely linked to the provision of (better) essential services (healthcare, education and mobility) and projects to maximise the municipal administrative capacity, tourism and entrepreneurship weaknesses. However, this association had to be inferred because all the documents fail to make explicit indications that one municipality must work or cooperate with another (even on the same lake shore or province) to activate such an asset or system.
Independently of the level of government, the documents could be more emphatic about the theme of integrated territorial development to the extent that neighbouring inner areas could work together. Alto Lago di Como e Valli del Lario borders two inner areas, and another is quite close. The analysis made it clear that although the goals are mostly consistent with local needs and opportunities when transferred to the project sphere, it is possible to notice how difficult it is to take advantage of the inner area's territorial potential.

In conclusion, there is much to review and consider regarding the potential of each municipality and the Swiss border, where there are already European projects (Interreg). The new local

strategy for the 2021-2027 PP must take advantage of the proximity of the nearby inner areas to boost integrated regional development and better exploit the territorial capital as a way to enhance endogenous and exogenous growth and territorial cohesion.

Core-periphery Industrial Linkages of the Metropolitan Area from the Perspective of Enterprise Linkages: The Case of Three Cities Adjacent to Shanghai

Author's Name: Lin Tian[1*], Yao Cheng[1]
Affiliation: College of Architecture and Urban Planning, Tongji University, Shanghai, China
Email: 2210293@tongji.edu.cn

Abstract

To explore how cross-border industrial linkages are constructed between the centre and peripheral cities of the metropolitan area, this study takes the perspective of enterprise linkages and selects three county-level cities which are adjacent to Shanghai, as cases. First, city networks in the Shanghai metropolitan area are built using enterprise headquarter-branch linkage data; then, the descriptive statistical analysis is conducted based on enterprise questionnaires. The results show that from 2001 to 2018, enterprise linkages between Shanghai and its surrounding county-level cities increased significantly. The market forces in the industrial linkages between the three cities and Shanghai have somewhat transcended administrative barriers, which is the result of enterprises' 'voting with their feet'. The key reason why enterprises are located in these three cities is that they are close to Shanghai for access to productive services, technology, labour, information and other resources while enjoying the lower rent and preferential policies of the local industrial parks.

Keywords:

City Network, Metropolitan Area, Peripheral Cities, Cross-border, Industrial Linkage

1. Introduction

Modern urban regions' development has seen a new stage marked by the deepening and restructuring of the spatial division of labor. Specifically, design, R&D, marketing, and other functions at the two ends of the value chain have become more concentrated in high-level cities, while manufacturing has been gradually dispersed and relocated to surrounding small(medium)-sized cities, which, in turn, will influence the central cities after the formation of new agglomerations on the periphery. Yet this is not necessarily

a spatial gradient of dispersion, as periphery-core linkages across geographical and administrative boundaries may be formed. This economic geography phenomenon can be explained by the 'urban network externalities' theory - the agglomeration externality from the central city extends beyond its geographical boundary, while some peripheral cities 'borrow size' from it, jointly generating externalities through the city network (Capello, 2000; Hesse, 2016). The emergence of growth poles of regional economic development in an agglomerate form of metropolises has also led to the passive and active integration of their peripheral areas. Small or medium-sized cities (towns) on the periphery of megacities face enormous opportunities and challenges, not only as carriers of their economic activities but also in their important positions in the industrial networks of the larger region.

Since China's reform and opening up in 1978 and its membership of the World Trade Organization since 2001, its economy has developed rapidly and has become increasingly integrated into the global production network, driving the evolution of the spatial organisation of local industries. This is manifested in the gradual specialisation of the division of labour among industries in the geographical space, and the frequent flow of people, logistics, capital and information among cities. As a result, large-scale urban spatial organisations such as city clusters and metropolitan areas have been formed and developed, and have become important spatial carriers for the optimisation and reorganisation of industrial chains and participation in global competition (Shen *et al*, 2023). Smaller cities around developed central cities have shown a tendency to build economic linkages across borders. The latter have also begun to actively take 'integration into metropolitan areas' as an essential strategic choice in order to enhance their position in the regional production network. For example, the practice of cross-boundary industrial co-operation in some pioneering regions, such as the Guangdong-Hong Kong-Macao Greater Bay Area and the Yangtze River Delta Region, has given rise to the mode of enclave economy, and even forms like 'reverse/two-way enclaves' have emerged (Cao and Zeng, 2022; Luo *et al*, 2023).

To verify the above phenomenon, this study takes the perspective of enterprises and uses three county-level cities, Kunshan, Taicang and Jiashan, which are adjacent to Shanghai, as examples. From a macro perspective, using the data on the headquarter-branch of enterprises at three time points, this study constructs city networks in the Shanghai metropolitan area and takes a longitudinal view of the evolution of industrial linkages. From a micro perspective, based on 144 enterprise questionnaires distributed in the three cities, the study explores the detailed expressions of their industrial linkages with Shanghai by descriptive statistical analysis, and qualitatively explains the causes. Finally, planning implications are discussed concerning the findings, i.e. how peripheral-core industrial linkages across borders should be built.

2. Literature Review

The earliest studies on the spatial organisation of industries were mainly based on the Industrial Cluster Theory (Marshall, 1890). After comparative advantages gave rise to the regional division of labour, regional industrial organizations were formed through enterprises' linkages between regions (Massey, 1984). Although the openness and outward linkages of industrial clusters have been gradually emphasised in later periods (Maskell, 2001), they are still based mainly on geographical proximity over local space. Evolutionary economic geography challenges the authoritative explanation by Marshallian externalities for the emergence and development of clusters (He, 2018). It incorporates temporal and spatial elements to reveal the mechanisms of progressive evolution in the spatial distribution of economic activities (Frenken and Boschma, 2007; He, 2018). In this regard, scholars mostly start from the entry, growth, decline and exit of enterprises and their locational behaviour to explore the synergistic evolution of enterprises, industries, networks and regions (He, 2018).

With the deepening of economic globalisation and the international division of labour, the era of global production networks has arrived (Hess and Yeung, 2006). The spatial unit used to study economic evolution has shifted from local industrial agglomerations to inter-city (region) industrial networks. Frobel (1980) was the first to introduce the concept of the new international division of labour into the study of regions, arguing that it led to a global restructuring of national or regional production structures, resulting in the formation of a metropolitan area in which the peripheral areas are closely linked to the central city. The spatial organisation of industries in the metropolitan area is differentiated under the law of market economy in accordance with the principle of optimal production efficiency, and the relationship between cities is gradually transformed from one of mutual competition and independent development to one of central city-driven hinterland and inter-city co-operation.

Scott (1982) believed that as firms grew, their production and management functions were hierarchically restructured, and a process of concentration of management and control functions in the central city and decentralisation of production functions occurred within urban areas. Not all firms within an industrial cluster are connected to each other (Giuliani and Bell, 2005), but similar location, knowledge, norms, organisations, and social ties help heterogeneous actors to form partners or engage in knowledge exchange and collective learning, and these similarities are referred to as geographic proximity, cognitive proximity, institutional proximity, organisational proximity and social proximity, respectively (Boschma, 2005). The last four do not necessarily rely on geographic proximity and can be connected beyond boundaries; in other words, these proximities depend on agglomeration in certain kinds of networks (Capello, 2000). Proximity can explain why intra-cluster networks are not homogeneous and why some firms can have more linkages with firms outside the cluster (Taylor, 2001).

Enterprises choose their location freely on the basis of the profit-maximising principle, so that their linkages are essentially more reflective of the laws of the market economy. According to the doctrine of 'transaction costs', when it is more cost-effective to carry out all types of activities within the same enterprise, a vertically integrated structure is formed within the enterprise, which is spatially reflected in the fact that the enterprise's headquarters set up branches in different places to conduct all types of activities more efficiently; when outsourcing a certain type of activities (inter-firm transactions) is less costly, it will result in the formation of inter-firm horizontal integration, which is reflected in the process of specialisation of enterprises (Liu and Ren, 2006). Thus, the self-organising power of enterprises - as 'actors' - profoundly affects the regional economic configuration and the position of cities and towns in the economic network (Liu and Ren, 2006). Influenced by Castells' (1996) theory of the 'space of flow', studies of city networks based on enterprise linkages have begun to emerge. Network analysis methods mainly include Taylor's (2002) connection network modelling method, and Alderson's corporate headquarters-branching method (Alderson and Beckfield, 2004). This type of methods has also begun to be used by some Chinese scholars in meso-level studies of city clusters and metropolitan regions (Cheng and LeGates, 2018).

To sum up, previous research on the regional industrial spatial organisation based on cross-city linkages is insufficient in the following aspects: most of the analyses use enterprise linkage data to build city networks, focusing mainly on the characteristics of regional industrial spatial structure at the macro level, but lacking in-depth discussions on the mechanisms of linkage construction and factor flows caused by enterprise behaviours at the micro level. Research on the 'centre-periphery' of metropolitan areas tends to take the central city as the study object. However, what distinguishes peripheral cities from ordinary small and medium-sized cities (towns) is that they are an important component of the regional industrial division of labour and the production chain, and they have taken on industrial functions far beyond their own. But few studies have taken peripheral cities as the entry point, making it difficult to comprehensively observe the 'centre-periphery' relationship. On the other hand, studies of city industry tend to view cities as independent systems, ignoring the fact that their industrial functions are greatly influenced by the outside world, especially by nearby metropolises.

3. Method and Data

3.1. Study Area

Three county-level cities bordering Shanghai are selected for this study (Figure 1), of which Taicang and Kunshan are administered by the Suzhou prefecture-level city in Jiangsu Province, and Jiashan is under the Jiaxing prefecture-level city in Zhejiang Province. The three cities have well-developed economies, with GDPs of 173.494 billion yuan, 514.060 billion yuan, and 90.811 billion yuan in 2023, respectively, and

a high proportion of secondary and tertiary industries; they have high rates of urbanisation (all exceeding 70% in 2023), with permanent populations of 848,000, 2,148,500 and 664,000, respectively. All three cities are within 30 minutes of Shanghai by high-speed railway and belong to the core of the Shanghai metropolitan area, with close connections with Shanghai. They have long had the key goal of connecting to Shanghai in terms of local industrial development, and have been selected in many studies as typical research cases of small and medium-sized cities in the surroundings of large cities for comparison. The Shanghai metropolitan area, located at the heart of China's eastern seaboard and the Yangtze River Delta region, is not only an important national economic growth pole, but is also growing into a city region with global influence. In recent years, with the deepening of the regional industrial spatial division of labour, Shanghai has upgraded its industrial structure and driven the economic development of its hinterland. Therefore, the industrial spatial organisation of small and medium-sized cities around Shanghai is undergoing deep changes and needs to be re-recognised from the perspective of external influences.

Figure 1. Study area: location of Taicang, Kunshan and Jiashan around Shanghai

3.2. Research Design

Firms or enterprises are the key ‘actors’ in the regional production chain. Driven by the market, guided by the government, and influenced by other actors, their behaviours and decisions (e.g. re-location, branching, transactions, cooperation, investment, etc.) build

inter-city industrial linkages; conversely, industrial linkages can be manifested through the internal and external connections, and forward and backward linkages of firms.

On this basis, the empirical study of this article takes enterprises as the perspective and is divided into two parts. The first part is a macroscopic city network study, which aims to take a longitudinal view of the overall picture of the evolution of industrial linkages in the Shanghai metropolitan area. The study area is extended to the Shanghai metropolitan area (but this is much smaller than the government-planned 'Greater Shanghai metropolitan area'). County-level zones ('municipal districts', 'counties', or 'county-level cities', which are below prefecture-level cities) are used as the analysis units, with a total of 16 units. A number of municipal districts in the Shanghai central city are merged into a single unit, while six units in the suburbs of Shanghai are retained; outside of Shanghai, in addition to the three case study cities, the other six county-level units are included in this part of the analysis for comparison.

For enterprise linkages, we obtained data from the 2001 and 2008 China Economic Census, and data from the 2018 registration by the Bureau of Industry and Commerce of enterprises[1]. This study focuses on only two categories of enterprises, manufacturing and productive services. Then, referring to Cheng's (2018) approach, we applied SQL to identify the headquarters (head office, group, etc.) and branches (branch office, sub-factory, sub-division, etc.) based on the matching of the enterprise names and thus processed them as enterprise headquarters-branch linkage pairs[2]. Next, we summarised the headquarters and branches of each link based on the units in which they are located, and then translated them into a directed matrix of 'city dyads.' Then, the city networks of the Shanghai metropolitan area were constructed by taking the analysed units as nodes and the number of 'city dyads' as the weights of the edges. Finally, these city networks were visualised in the ArcGIS platform to describe the evolution of the industrial linkages between the three cities and Shanghai.

The second part is a microscopic questionnaire data analysis, in order to explore more in-depth characteristics and causes. We distributed enterprise questionnaires in the three cities between September to November 2018, with questions on basic information about the enterprise, distribution of their upstream and downstream linkage enterprises in the industry chain, their service and technology linkages, inter-city commuting of their employees, and their choice of cities for future investment, etc. A total of 144 valid

[1] These datasets provide statistical information on all enterprises in the nation in various industries in the current year, including enterprise name, establishment time, address, city, industry category, number of employees, etc. There are differences between the two types of datasets, but due to the large sample size and comprehensive enterprise lists and information, comparative analyses are possible.

[2] Within the enterprise linkage, the headquarters implements managerial decisions and issues directives, while the branches carry out the orders, and the headquarters have a controlling role over their branches, and it can be assumed that the city in which the headquarters is located is more in control. Thus the enterprise headquarter-branch linkage is directional.

questionnaires were eventually collected (73 from Taicang, 37 from Kunshan, and 34 from Jiashan). We then applied descriptive statistical analysis method to explore the specific performance of the industrial linkages between these three cities and Shanghai. At the same time, combined with interviews with enterprise managers and other materials, we qualitatively explained the causes of the phenomenon.

4. Results

4.1. Macro Perspective: Evolutionary Characteristics of Industrial Linkages

Figure 2 illustrates the changes in city networks based on enterprise linkages in the study area from 2001 to 2018. Overall, both productive services and manufacturing networks have been increasing in density, but have diverged in terms of spatial organisation. Manufacturing enterprises have been spreading to the periphery step by step - from 2001 to 2008, the direction of linkages were mainly from Shanghai to the periphery, indicating that manufacturing headquarters remained in Shanghai and branches spread to the periphery; by 2018, however, linkages from the periphery pointing to Shanghai were even stronger, suggesting that the headquarters of some enterprises have also relocated out of the Shanghai central city or that enterprises from peripheral areas have set up branches in Shanghai. In stark contrast, although the production service industry has seen near-domain diffusion in the suburbs of Shanghai, it tends to be polarised at the metropolitan area scale, i.e., the headquarters are highly concentrated in Shanghai, and the direction of the headquarter-branch linkages mainly points to the peripheral cities from the Shanghai central city, which suggests that the Shanghai metropolitan area has formed a hierarchical network structure. To some extent, this result confirms Scott's (2001) view that highly modular manufacturing industries spread over a wider spatial area without being restricted by location, while high value-added and high-grade industries represented by productive services have a higher sensitivity to location and are more likely to form agglomerations. Embedded in the whole production chain, the productive service industry is difficult to fully divide labour, the services they offer are often intangible, and there is a need for the transmission of intentional information between enterprises and between enterprises and their customers. In order to face markets with great uncertainty, productive services enterprises choose to concentrate in central cities to reduce costs and are closely linked to each other to form flexible network systems.

Regarding the number of ‘city dyads’ between peripheral county-level cities and Shanghai, Kunshan ranks the highest, followed by Zhangjiagang, Jiangyin, Taicang, and Changshu, and even equals (or surpasses) their own prefecture-level cities or provincial capitals. It can be seen that in the regional division of labour, certain cities are gradually demonstrating their important position by taking advantage of their specialization.

In recent years, Kunshan has seized the opportunity of the accelerated inflow of international capital into the Yangtze River Delta region, actively developed export processing trade and attracted investments, and taken the initiative to share part of Shanghai's modern service functions, attracting a large number of enterprises to move in, and successfully realising the externally oriented economy and dislocation development. As early as the 2002 version of the city's comprehensive plan, Kunshan considered the development of connecting with Shanghai; in 2016, its 'Thirteenth Five-Year Plan for National Economic and Social Development' further clarified the strategic goal of 'integrating into Shanghai, complementing Shanghai and serving Shanghai', proposing to fully connect with Shanghai's functions as a centre of economy, finance, trade, shipping, and R&D. Similarly, Taicang in 2003 for the first time defined 'connecting to Shanghai' development strategy, and then in its 'thirteenth five-year plan' put forward to focus on the promotion of concepts, planning, industry, elements, platforms, transport, social services and other aspects of the integration into Shanghai in depth. On the contrary, Jiashan and Pinghu, which also border Shanghai, have far fewer linkages with Shanghai than Kunshan and Taicang, or even Zhangjiagang and Changshu, which do not border Shanghai. Although Jiashan has also been emphasising the strategy of connecting to Shanghai from the early days to the present, it has not replicated the success of Kunshan due to its development land constraints, the distance between its main urban area and Shanghai, and its failure to keep up with investment attraction.

To sum up, with the deepening of the division of labour and the upgrading of the overall economic level of the Shanghai metropolitan area, the spatial polarization of productive service enterprises has been further enhanced, while manufacturing enterprises are gradually spreading to the periphery, and the overall spatial pattern of the industry tends to be networked, and the cross-regional organization of enterprises has promoted the frequent flow of factors of production within a wider range.

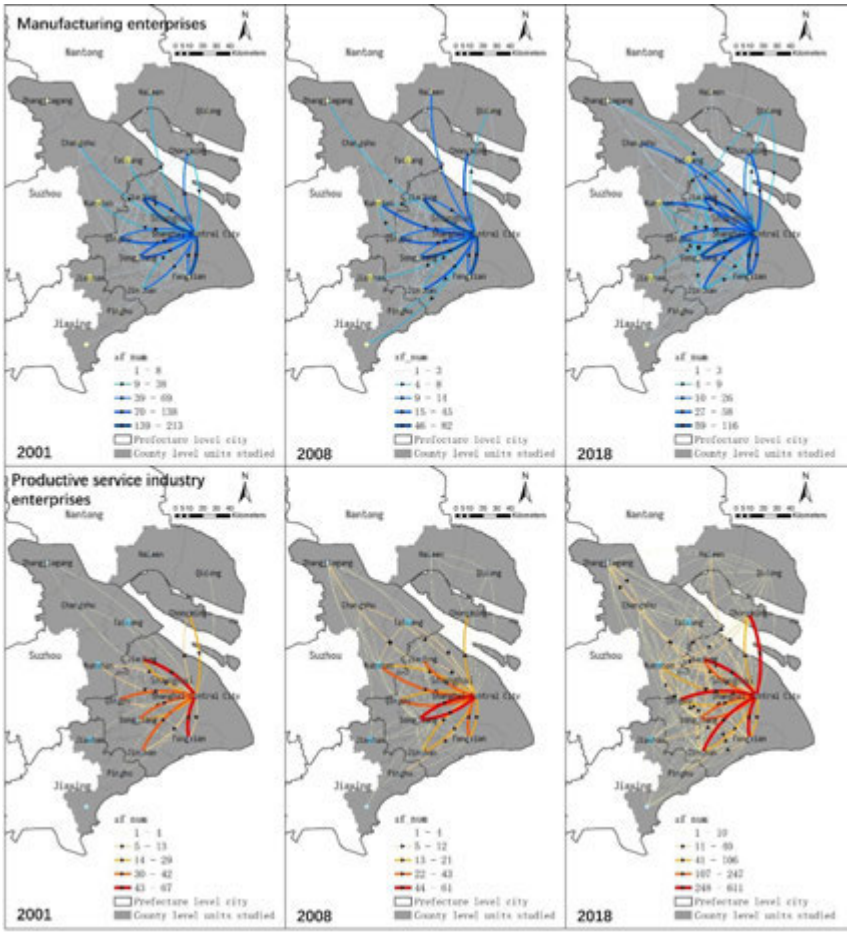

Figure 2. Headquarter-branch linkage networks of manufacturing and productive services enterprises, 2001, 2008 and 2018 (In this figure, the thicker and darker the connecting lines, the greater the number of links; the direction of the arrows represents the direction from the headquarters to the branches.)

4.2. Micro Perspective: Mechanistic Explanation of Linkage Formation

As it is difficult to contact and get permission from numerous enterprises, there are very few studies on the spatial organisation of industries using enterprise questionnaire data. This study attempts to explore more details and reasons for this through questionnaires for individual enterprises after mapping the macro data.

Firstly, we look into the basic information of the interviewed enterprises. The industry types of the interviewed enterprises in the three cities are different, but they are all

mainly in the electronic information, machinery manufacturing, new energy and new material industries. In regard to the types of enterprises, they all contain a certain proportion of foreign investment components, including foreign or Hong Kong/Macao/Taiwan investment, Chinese-foreign joint ventures or co-operative operations, etc. Kunshan has the highest proportion of foreign (or Hong Kong/Macao/Taiwan) invested enterprises, while Jiashan has a lot of Taiwan-invested enterprises due to historical factors, and Taicang has the highest proportion of privately owned and state-owned enterprises. In terms of enterprise size, they are concentrated at both ends of the spectrum - large (annual output value of 100 million to 500 million yuan) and micro (annual output value of less than 10 million yuan), with Taicang having a significantly higher proportion of small and micro enterprises, and Kunshan having a higher proportion of large and super-large enterprises. Divided by the number of employees, small and micro enterprises with less than 300 employees accounted for the highest proportion, with Taicang having the highest proportion of enterprises with less than 50 employees.

The reasons why interviewed enterprises chose to locate in the three cities are very consistent (Figure 3), with ‘proximity to Shanghai’ and ‘favourable investment incentives of industrial parks’ ranking in the top two, followed by ‘convenient transportation’, ‘proximity to upstream and downstream enterprises’, and ‘good cultural atmosphere of the city’. As to which city the interviewed enterprises are currently invested in and which city they would like to invest in in the future (Figure 4), the largest number is the provinces in which the enterprises are located, which is to be expected. But it is worth noting that the next most common city is Shanghai. Similarly, as shown in Figure 5, Shanghai is second only to their respective provinces, in terms of the location of upstream and downstream supporting enterprises (e.g., raw material suppliers, component manufacturers, sales agents, etc.), the source of productive service providers (including advertising, tax, consulting, lawyer, etc.), and technological consulting collaborators (for enterprises that do not have their own R&D centres) for these interviewed enterprises. This means that market forces have to some extent surpassed administrative barriers in the construction of industrial links between the three cities and Shanghai.

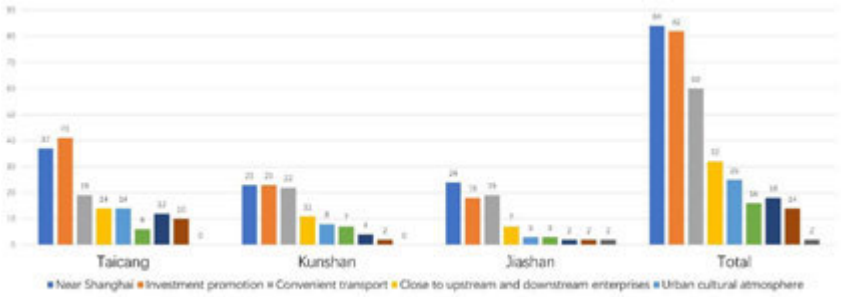

Figure 3. Reasons for locations selected by enterprises interviewed in the three county-level cities[3]

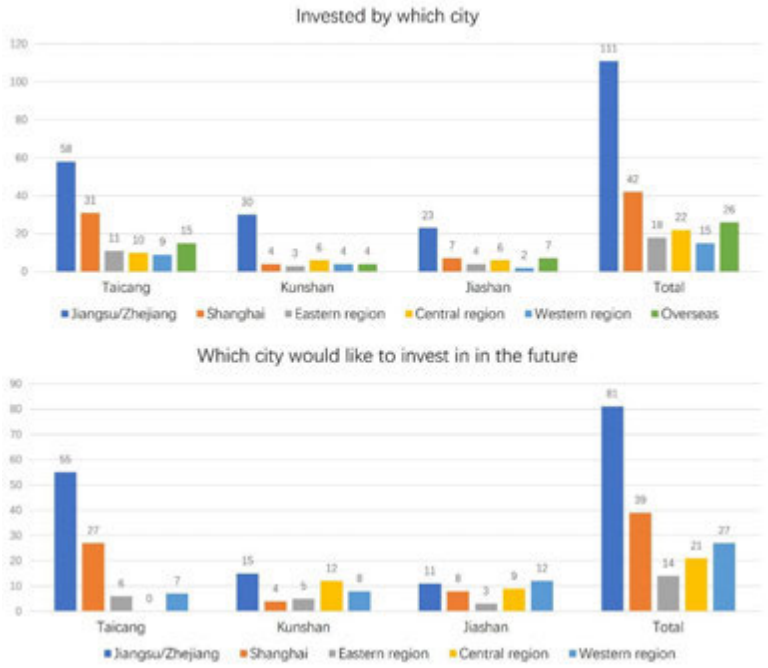

Figure 4. Main origins and future directions of investment of interviewed enterprises

[3] The reason that the total number is greater than the number of surveyed firms 144 is because this question is a multiple-choice question, and the same reason is also true for the following figures that show the same situation.

Figure 5. Locations of upstream and downstream supporting enterprises, service providers and technical consulting partners of the interviewed enterprises

With regard to the employee profile of the interviewed enterprises (Figure 6), although the vast majority of the labour force originates from and resides in the local area due to constraints on the recruitment costs of the enterprises and the cost of employee commuting, a portion of the employees still reside in Shanghai (15.3% of the total). According to Figure 7, 28% of enterprises have employees with frequent commutes to and from Shanghai, most of whom are top managers and senior technicians. This is because this group of people has settled their entire family in Shanghai in order to enjoy a high level of public services and living environment, and they also have enough financial capacity to afford the cost of extra-long-distance commuting (they usually

drive a car or take a high-speed train between their home and their workplace). Their commuting frequency concentrates on daily round trips, followed by weekly round trips on weekdays at the company and weekends back to Shanghai. This supports the existence of frequent industrial linkages and factor mobility relationships between the three case cities and Shanghai, as people flows are the concrete spatial manifestation of abstract linkages.

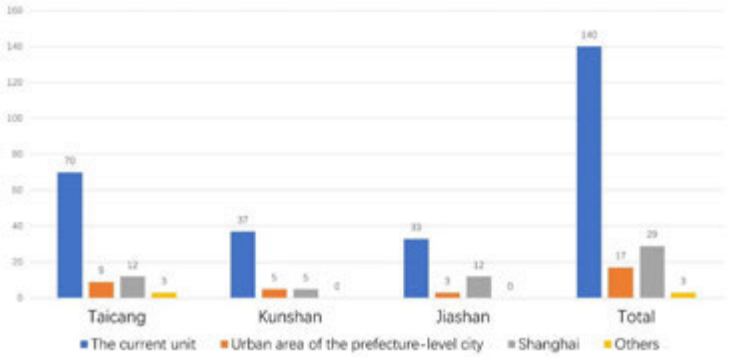

Figure 6. Location of employees' residence in the interviewed enterprises

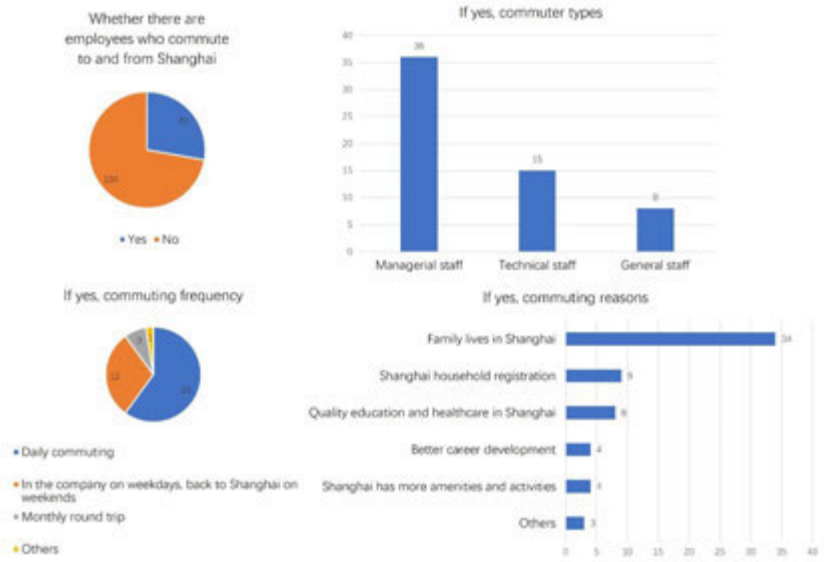

Figure 7. Employees of the interviewed enterprises commute to and from Shanghai

With regard to the satisfaction of the interviewed enterprises with various aspects of the industrial parks in which they are located, they are more satisfied with the parts on geographic location, infrastructure, social security conditions, investment and financing environment, and the efficiency and flexibility of government services, while the most dissatisfied parts concentrate on human resource supply as well as the cost of land, labour, and facilities. This suggests that the location of these enterprises is mainly based on better location and investment and production environment, and also reveals that the industrial policies of the three cities in terms of tax incentives, financial subsidies and talent attraction are still insufficient or have not met the expectations of most of the enterprises, even though these factors have been postponed by them.

The above results suggest that cross-border industrial linkages are formed as a result of independent 'voting with feet' by enterprises, and are also influenced by local government policies. The key reason why firms choose to locate in these three cities is the proximity to Shanghai for access to productive services, technology, talents, labour, information and other resources while enjoying relatively lower land rents and preferential policies in local industrial parks. Taking all factors into account, these are the options that maximise their benefits.

5. Discussion and Conclusion

5.1. Discussion

Urban competition in the era of globalisation has been transformed into city-region competition between metropolises and their surrounding areas. As engines of regional economic growth and 'fronts' for regional economic integration, metropolitan areas are no longer a collection of isolated economies, but rather a series of small and medium-sized cities with close economic ties to the central city to allocate resources together. As any node city in the network, the all-industry development model is unsustainable. The main feature of the metropolitan area economy is the centre-periphery linkage, i.e., integrated resource allocation and vertical division of labour in industries (Shen *et al*, 2023). Therefore, small and medium-sized cities in the periphery of the metropolitan area should not continue the traditional independent and self-sufficient mode, but seek to cooperate with the central city and other cities, and transform into the metropolitan area economy mode.

This paper draws the following planning implications: firstly, as shown in our city network analysis, Shanghai's economy is closely dependent on the cities in its hinterland. More precisely, the rise of Shanghai as a metropolis with international influence is behind the rise of the Shanghai metropolitan area as a whole, which relies on the joint interaction between the centre and its hinterland, and on the establishment of a close division of labour and collaboration system between cities of different levels. To develop into a global city region, the Shanghai metropolitan area needs to further

promote the optimisation and upgrading of its economic and industrial structure and segmentation of its industries, promote the concentration and heightened development of its core functions, and guide the transfer of other functions outward in an orderly manner. Cities around Shanghai should seize the opportunity of the metropolitan area's industrial spatial organisation evolution and function overflow, take into account their own comparative advantages in their development positioning, and accurately undertake the specific functions overflowed from Shanghai, so as to enhance their position in the city network.

Secondly, the regional specialised division of labour is premised on close and rational functional links between cities, so it is important to reshape the overall architecture of regional governance to guide the spatial reconfiguration of industrial organisation and the development of specialised nodes in the metropolitan area. In addition to the Shanghai metropolitan area, this also applies to other metropolitan areas regions in China. The market segmentation caused by the ‘’administrative economy‘’ model needs to be broken up, and a sound regional coordination mechanism should be established to promote the free flow of factors of production, so as to realise the overall benefit of ‘’1+1>2‘’. The governments should build a cooperation platform between cities without breaking through the administrative boundaries, coordinate the development positioning, urban planning, policy support and other issues in regional cooperation, and then guide enterprises and the society to enrich the content of cooperation through market-oriented means, and enterprises should provide timely feedback to the government for the problems existing in the cooperation to make up for the market failure and governmental failure.

Finally, returning to the perspective of small cities on the periphery of the metropolitan area, although the three case cities have attracted more and more transferring industries by their proximity to Shanghai, the results of the enterprise questionnaire analysis indicate that the survival environment of the interviewed enterprises still shows some deficiencies. In order for these small and medium-sized cities to sustainably attract high-quality enterprises to settle in, and thus truly achieve ‘integration into Shanghai’, the following two points should be considered: first, they should flexibly and purposefully optimize the preferential policies for investment incentives and the talent introduction, to optimize the soft environment for economic development through policy innovation; second, they should provide housing and a higher level of public services for the imported talents and labour.

5.2. Conclusion

The study reaches the following base conclusions: a. Comparing the changes in city networks in 2001, 2008 and 2018, the links between Shanghai and its neighboring county-level cities have increased significantly. Among them, Kunshan and Taicang have seen the most significant growth, with their links to Shanghai even equaling (or surpassing) those of the prefecture-level cities and provincial capitals to which they

belong; Jiashan, however, is a little less impressive. b. The top reason for location choice of the interviewed enterprises is 'proximity to Shanghai', followed by ' investment promotion policies of industrial parks', meaning that the formation of cross-city industrial linkages is the result of enterprises voting with their feet actively. c. Shanghai is second only to the cities in the provinces to which the three cities belong in terms of the cities in which they invested in the interviewed enterprises, the cities where upstream and downstream specialized enterprises are located, and the cities where they provide productive services, which means that the market forces in the links between the three cities and Shanghai somewhat surpass the geographic proximity and barriers of administrative factors. d. 25% of the interviewed enterprises have frequent (daily or weekly) commuters between their workplace and Shanghai (residential place), which also indicates the frequent factor flows between these three cities and Shanghai.

To summarize, although these three cities are relatively small in scale and low in rank, they have all successfully 'captured' the flowing resources in the production chain of the Shanghai metropolitan area, developed industrial interactions with Shanghai across the provincial administrative boundaries, and realized their own elevated status in the regional economic network.

The main contributions of this study are twofold: first, to provide reference for the integration planning of the metropolitan areas - to explore the industrial spatial planning and cross-city industrial cooperation paths between the center and the periphery cities in order to achieve the goal of complementarity and win-win situation. Second, to guide the industrial planning of small and medium-sized cities on the periphery of megacities - to seek connection and cooperation with the central city and to optimize their industrial space, so that they can adapt to the development direction of regional industrial linkages and transition to a metropolitan-area economy.

Abstract
Many studies have been carried out to measure the complex inter-city networks by using multi-source data. However, few studies have considered the networks of concern that local governments have with each other. In this paper, we use text analysis and social network analysis to mine the texts of government plans of 41 cities in the Yangtze River Delta to construct a network of attention among cities. It is found that the network is characterised by overall polarisation and local flattening, and that the degree of attention to each city is not perfectly correlated with its economic and population size. The study concludes with recommendations for a regional planning platform that removes administrative and institutional barriers.
Keywords: regional planning, intergovernmental relations, text analysis, social network analysis, Yangtze River Delta (YRD)

1 Introduction

With the development of the region's integration, urban economic and social development is more affected by urban network. Many scholars have conducted research on the urban network in the Yangtze River Delta (YRD) and found that the network has become much closer in recent years. Existing researches mostly focus on the civilian connections between cities by using data such as people migration, investment or traffic flow, which reveals the laws in civilian connections. However, the cooperation and competence between local municipal governments has become more intense, too, there is still a lack of research from a governmental perspective, which hinders the knowledge of local governments' demands and limits the horizon of policy research. Using linkages extracted from planning texts of 41 cities in YRD as research data and social network analysis as research method, this paper aims to find out the pattern and characteristics of intergovernmental network and the elements that influence this situation, and puts forward planning suggestions for the development of regional integration.

2 Literature review

2.1 Evolution of the regional urban network in YRD

The YRD megapolitan cluster is a region in China with a high level of economic and social development and a well-developed urban system, comprising three provinces (Jiangsu, Zhejiang and Anhui) and one municipality (Shanghai), with 41 cities, an area of more than 350,000 km², a resident population of more than 230 million, and a total economic volume of 30 trillion yuan (Figure 1). The planning and practical research on the joint development of the YRD can be traced back to the proposal of the Shanghai Economic Zone in 1982, while since then progress has been made in joint cooperation meetings, the establishment of communication mechanisms, and the making of regional plans, etc. The integrated development of the YRD was upgraded to a national strategy in 2018, and the spatial scope was expanded from Shanghai and its neighbouring cities initially to three provinces and one municipality at present, and the release of the new policies in Pudong and Hongqiao in 2021 marked the entry into the new development stage. Overall, the collaborative planning of the YRD has roughly gone through

several stages, including Shanghai leading the neighbouring cities, collaboration at the provincial level, national strategy leading, and opening up of key areas leading.

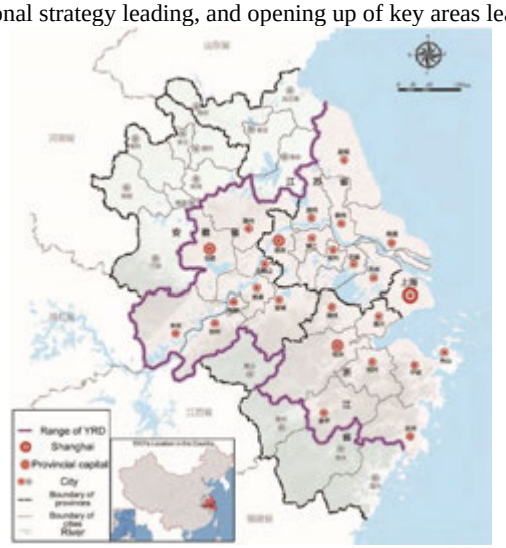

Figure 1 The scope the Yangtze River Delta megapolitan cluster

This process was initially driven by economic factors. With the implementation of fiscal reform policies in the 1990s, the subjectivity of cities in their own development has greatly increased. In terms of controlling and competing for resources, achieving economic stability and growth, and expanding the scale of benefits, local governments have indeed become special 'quasi-market entities' (Cen, 2006; Su et al., 2022; Qin et al., 2023), and therefore tend to be more specific and perceptive in the making of planning that involves their own interests, which may show a certain pattern of linkage among the collection of many individual cities. In recent years, inter-city cooperation has further expanded to ecological protection, science and technology, and social governance. Some scholars summarise it as the four stages of 'preliminary proposal-spontaneous cooperation-integration system construction-national strategy' (Cui, 2018), and some scholars point out that the two core demands and motivations for the integrated development of the YRD are national strategy and local development (Liu, Wang and Chen, 2020). Therefore, the development of the YRD city cluster is subject to both bottom-up and top-down forces.

In order to measure the development of urban networks in the YRD, many scholars have tried to analyse data from different sources, such as enterprise headquarters-branch data (Yang et al., 2021), intercity investment data (Li et al.,2024), Internet search index data (Li and Xiao, 2022), high-speed rail accessibility (Gao et al., 2019), location-based services (LBS) data (Cui et al., 2020), logistics data (Wang et al., 2018), patent cooperation data (Song and Kim, 2022), and so on. The above studies have used citizens, enterprises, vehicles, and other economically active individuals as research objects, suggesting that the civilian linkages of the YRD megapolitan cluster have formed a more complex multi-layered linkage network. Significant urban network externalities exist between Chinese cities and can influence urban economic growth (Huang, Hong and Ma, 2020; Zhang et al., 2020).

However, not many network studies have been carried out from the perspective of city governments, as data for quantitative studies are difficult to obtain. Compared to micro-actors and macro-regional planning, local governments at the meso-level represent local development aspirations and are more future-oriented, forward-looking and holistic. Local governments practice regional inter-city linkages and collaborative governance in a variety of ways, and this type of interaction among governments is called intergovernmental relationship. Competition and cooperation between local governments will influence the economic development of their cities, and these development intentions will be reflected in planning texts or policy documents that will guide the direction of development for a certain period in the future. It is therefore of value for in-depth research.

2.2 Research based on planning textual analysis

Textual analysis refers to the process of going from the surface of a text to the deeper layers of it in order to discover the deeper meanings that cannot be grasped through ordinary reading. Indeed, a number of studies have used textual analysis of planning texts, for example to assess the quality of planning texts (Brody, 2003; Song, 2015) and to make comparisons between different plans (Du, Lu and Zhang, 2019).

The Five-Year Plan is a policy plan prepared every five years by all levels of government in China, now in its fourteenth five years, for the period 2021-2025, and is comparable in that all cities in China are required to prepare it and the text is similar in length. A city's Five-Year Plan is an important overarching plan that sets out a vision for the city's development over a period of time. A study of the planning texts of several cities reveals a pattern of linkages between the cities' wills. An important part of the five-year plan is the city's strategy for integration into regional development, including the establishment of cooperative links with other cities, making it a good source of data for the study.

3 Research methodology and results

3.1 Research data and methods

This paper uses the 14th Five-Year Plan texts of 41 cities in the YRD as research data, and the source is the government website of each city. The inter-city link data is extracted from the texts using Python. The research methods used are word frequency analysis and social network analysis (SNA). Word frequency statistics refers to counting the number of times a particular word or symbol appears in text or speech data, which is used to discover the regular features of the text content; social network analysis (SNA) is a method to further reveal the social relationships by analysing the network structure of individuals, social organisations and even social events. Specifically, if city B is mentioned N times in the planning text of city A, it is counted as N links from A to B in the link matrix. Thus, the constructed link matrix is directed. Indegree represents the degree to which cities receive attention and outdegree represents the degree to which cities pay attention to other cities. Cities with a high indegree receive more attention, and cities with a high outdegree are more willing to pay attention to other cities.

1,750 links between 41 cities in the YRD are extracted from the texts of their 14th five-year plans (Figure 2). The above link matrix was entered into Gephi to compute linkage network metrics and modularity analysis, and visualised using a geo-layout.

Figure 2 The Connection Network among Cities in YRD Based on the Text of the 14th Five-Year Plan

3.2 Whole network analysis

The modularity algorithm in Gephi, which is one of the methods for calculating network topology parameters, is used to divide the nodes into a module with approximate degrees. The results are shown in the figure, where different colours represent different modules, node size represents the degree of frequency of occurrence, and connecting arrows represent the direction of contact (Figure 3). The visualisation results show that core cities are more attractive, with Shanghai, Hefei, Nanjing and Hangzhou having the highest indegrees, all above 100, and the sum of the four cities' indegrees accounting for 65% of all cities, suggesting that even at the local government level, attention to other cities remains polarised. In terms of outdegree, the situation is flat, with the maximum value of 119 for Ma'anshan. Ranking the difference between indegree and outdegree in descending order, as shown in the figure, the cities that are not negative include Shanghai, Hefei, Nanjing, Hangzhou, Ningbo, Lianyungang, Suzhou (JS), Xuzhou, Zhoushan and Wenzhou (Figure 4), indicating that these cities in the Yangtze River Delta do not receive less attention than outward attention, indicating that their development has the characteristics of attracting other cities. It is worth noting that Lianyungang and Zhoushan are not the most prominent cities in terms of economic volume or political status, but after reviewing the planning text, it is found that the main reason for their attention is the harbour, suggesting that their access to the outside world is valued by other cities.

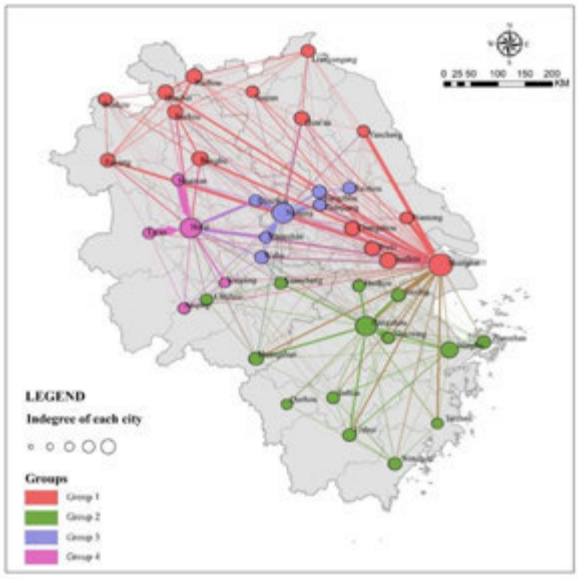

Figure 3 The 4 Groups Found by SNA

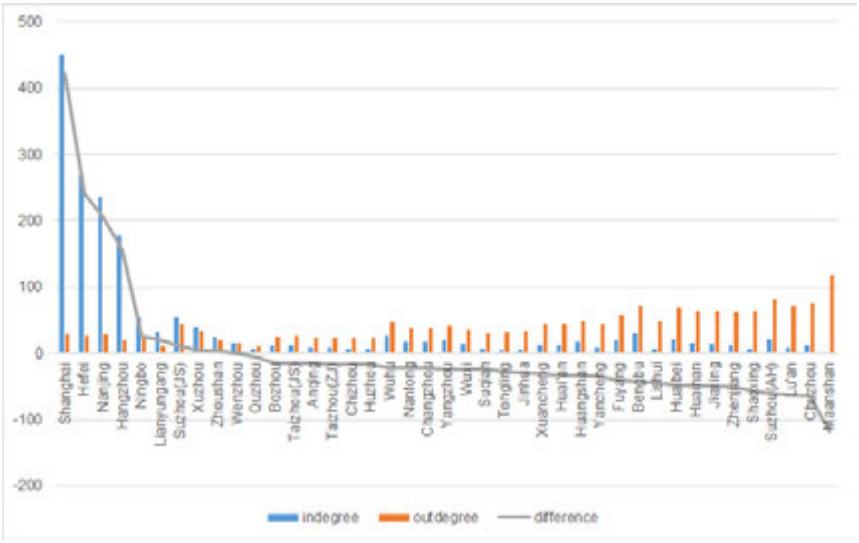

Figure 4 Difference Between Indegree and Outdegree

The results of the modularity algorithm analysis show that the 41 cities are divided into 4 modules: 15 cities led by Shanghai, 7 cities led by Nanjing, 5 cities led by Hefei and 14 cities led by Hangzhou. It can be seen that Shanghai is the core city of the YRD metropolitan cluster, and all the cities mention Shanghai in their plans; Shanghai's sphere of influence covers southern and northern Jiangsu and northern Anhui; Hefei and Nanjing's sphere of influence

mainly focuses on their neighbouring cities; and Hangzhou's sphere of influence covers most of the cities in Zhejiang Province.

3.3 Comparison analysis

To explore the relationship between the attention given to cities in the intergovernmental network and their own attributes (population and economic size), the share of attention for each city is compared with the share of population and the share of GDP in 2022, as shown in the figure.

The ranking of the difference between indegree and GDP share in descending order shows the cities that have a higher position in the network of intergovernmental relations than in the total economic volume (Figure 5). The highest ranked city is Hefei, the provincial capital of Anhui Province, due to the capital priority strategy and high-tech industry, which makes it attract more attention from cities within Anhui. There are also cities such as Bengbu, Zhoushan, Huaibei, Huangshan and Lianyungang, due to their more central role in the hinterland and their external transport links such as harbours. In contrast, cities such as Suzhou, Wuxi, Nantong, Changzhou and Ningbo in Jiangsu Province, which have high GDPs and are also generally regarded as developed among the cities in the YRD, receive less attention, suggesting a lack of features in their development that would attract other cities.

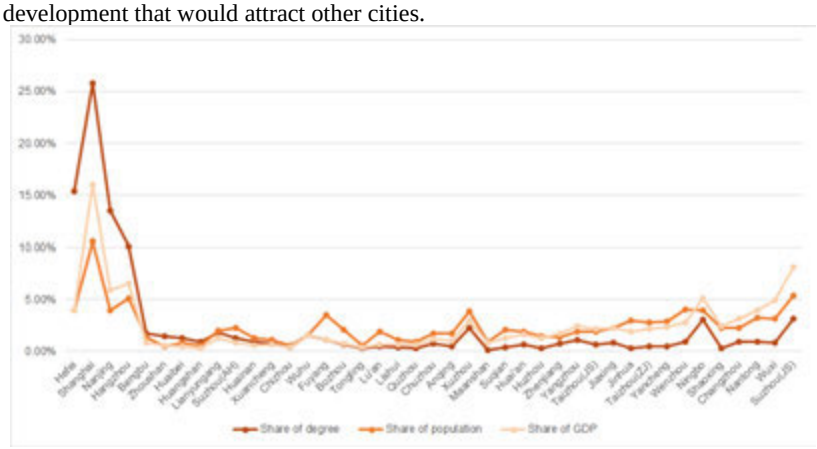

Figure 5 Comparison of the Share of Indegree, Population and GDP

4 Conclusion and outlook

4.1 Conclusions

The study found that the linkage network is characterised by the coexistence of overall polarisation and local flattening. With the convenience of transport and communication, some remote ordinary cities are also willing to directly contact high-level cities such as Shanghai, instead of only contacting high-level cities in their province. However, this flattening is only reflected in the unidirectional connection of low-level cities with high-level cities, and high-level cities hardly take the initiative to connect low-level cities. In terms of outdegree and indegree, it is largely consistent with the reality that economically underdeveloped cities have a high outdegree and economically developed cities have a high indegree, which reflects the characteristics of the outgoing nodes and the relationship between the demands of the incoming nodes on them, and also reflects the characteristics of the development of the two types of cities:

the incoming cities are rich in resources and development advantages in terms of science and technology, trade and commerce, high education, transportation, medical care and so on, and the outgoing cities actively dock with them. In the case of incoming cities, the content of docking mainly includes industrial investment, infrastructure, public services and so on.

The innovation of this study lies in the fact that the use of planning texts from local governments in the region to some extent fills the gap in the visualisation of intergovernmental relations, and facilitates the consideration of the willingness of local governments to develop in the formulation of regional planning. The study also explores the factors that influence the formation of the network of linkages, and finds that economic volume is not the only reason for linkages with other cities, providing suggestions for the integrated development of cities in the region.

It is therefore recommended that city governments should be guided by the concept of openness in removing administrative and institutional barriers. The analysis of the planning text concluded that the relationship between cities is a meso-level perspective and that it is necessary to take into account the characteristics of specific cities and think about how they can undertake and integrate macro-strategic arrangements and how to improve synergies in the development of different places, such as the possibility of forming a multi-level regional planning platform based on the linkage of intercity development.

4.2 Outlooks

However, this study has its limitations. First, urban planning is usually only one aspect of urban development, and the cooperative and competitive relationships between cities are influenced by many factors, such as geographical location, level of economic development and political environment. Therefore, it is difficult to reflect the comprehensive relationship between cities simply by extracting linkages from urban planning texts. Second, extracting linkages through urban planning is also not comprehensive, because cooperative relationships between cities are also carried out through other forms of cooperation agreements, meetings, and so on. Some scholars have also used web crawlers to obtain data, and this study provides a comparable data source and method. In order to analyse the relationships between cities more comprehensively, the introduction of other data and methods for a comprehensive study can be considered in the future, leading to more valuable conclusions.

Paper submitted to:

«Game Changer: Planning for Just and Sustainable Urban Regions»

Congress of the Association for European Schools of Planning (AESOP)
Sciences Po, Paris, july 2024

on its track n°4: «Borders. Transboundary planning for sustainability and cohesion»

Abstract

This paper deals with an ongoing procedure to establish a transboundary partnership between two institutions at both sides of the Mediterranean Franco-Spanish border, between Région Occitanie (in France) and Catalonia (in Spain). It presents, on one hand, a range of methodological issues that try to link teaching, practice, and research, in order to produce applied architecture and planning according to research standards. On the other, it proposes a series of specific actions to be made, both at an institution level (such as the creation of double degrees) and from a thematic approach (such as the exploration of mid-density urban patterns). These could, by responding to the specific problems of this bi-national territory, serve as design and methodological guidelines for wider actions, such as transboundary planning.

Trans-boundary, Pyrénnées-Mediterranée, Applied Research, Architecture, Planning

1. Introduction

Is it feasible to establish common planning strategies, with the aim of preserving the identity and evolution of a common territory, between two different countries in a trans-border situation? In this text, we will try to respond to this issue through the particular example of the region assembling the Mediterranean shores of South-East France (in the Région Occitanie), and those of North-East Spain (in Catalonia).

After describing the geographical particularities of this bi-national region, summarizing its main problems and potentialities, we will propose a particular methodology of work that assembles research, teaching, and practice, and that will lead to the completion of pilot-projects; these will allow, further on, a planning initiative at a larger scale. We will, as well, illustrate the whole picture with the partial results of our ongoing scientific and pedagogic activity, developped in this context.

2. Geographical definition

If it where a geographical tentative of definition, the territory we aim to treat can be described through four different types of limits. Two of them would be physically equivalent, and correspond to the deltas of the two main rivers that drain the Alps, in France (the Rhône) and

Figure 1: definition of the Eurorégion Pyrénnées-Méditerranée (Midi-Pyrénnées and Languedoc-Roussillon formed together later on, in 2015, the Région Occitanie) (source: Eurorégion Pyrénnées-Méditerranée)

the Pyrenees, on its Spanish southern slope (the Ebro). Dividing this 600 km. long coast line, the Pyrennees (that would be our third internal boundary) come to meet the sea in Port Bou, as an imposing perpendicular barrier with the last spurs of the Sierra de Les Alberes; they establish as well, and at its watershed, the administrative border between both countries. The fourth limit of this coastal strip becomes more diffuse, but could be assimilated, inland, to a shore plain of irregular size, always backed up by a secondary mountain range running parallel to the sea; at some points raising very close to the water (like the double Cordillera Pre-Litoral and Litoral in Catalonia), and, at some other moments a bit further away (like La Montagne Noire, or Les Cévennes, in Occitanie).

Most of the coastline in the French sector is occupied by large lagoons (around Sète, Narbonne, or Perpignan) which are less frequent in the Spanish side (deltas of Ebro and Llobregat, and at the Empordà, close to the border), that in all appears to be more abrupt and rocky. Concerning urban areas, we will find two different sizes of cities. On the one hand, and at the Northern and Southern limits, the metropolitan areas of Montpellier and Barcelona, that, although very far from being equal in size and character, contain similar problems and situations… They will thus be considered as equivalent fields of experimentation for us, since, as well, they are the cities that host both our research institutions.

On the other hand, there exist a series of small size province cities, such as (listed from North to South) Béziers, Narbonne, Perpignan, Girona, and Tarragona, which, as the biggest cities,

have an adequate balance of similarities and differences between them, able to be used in comparative exercises. Regarding the climate, although there exist slight variations due to latitude, we can consider its range to respond, at both sides of the Pyrenees, to a similar pattern, that would depend basically on the position regarding the cross section of the territory: with a high influence of the sea when close to the shore (in temperature and humidity), and a progressive more continental behaviour when approaching the backline mountain ranges. In

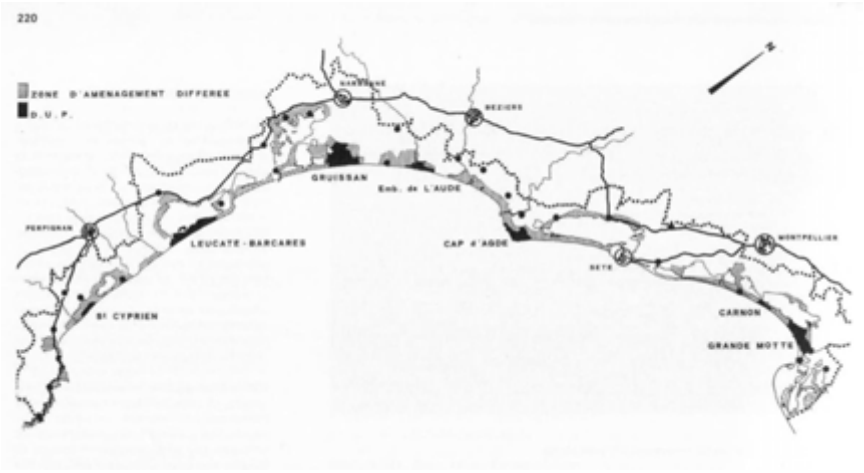

Figure 2: The mediterranean arch of the Région Occitanie, as drawn by the authors of the 'Mission Racine' (source : archives départementales de l'Hérault)

many senses, our territory can be assimilated to what Alberto MAGNAGHI has called a «bio-region» (MAGNAGHI, 2014), with quite homogeneous geographical, economical, and social issues, that transcend administrative cutting of the nations, and even the regions, that it is formed with.

3. Problems and opportunities of the trans-border region

This context has been recognized by the European Union with the creation of the EGTC (European Grouping of Territorial Cooperation) called «Eurorégion Pyrénnées-Méditerranée». Although this administrative structure has allowed a number of opportunities (such as described in VICENTE, 2021), its border, nowadays, still lacks of porosity and relations. Especially if compared with northern European cases, like those, for example, separating Germany from France (in Strasbourg) or Switzerland (in Basel), or Belgium from France (in Lille).

This resistance to a further integration can be explained by a range of different reasons. These would go from the mostly agricultural and natural character of the lands close to the border (as opposed to the cases just mentioned) to the distance between the main cities; and, probably and as pointed by certain authors (De KEMMETER, 2024), a certain distrust of the Région Occitanie towards the much more dynamic Catalonia. But the main difficulty nowadays still has to do with infrastructure; although the french A9 and the Spanish AP7 can be considered, together, as a very efficient main axis of the European highway network, a critical funnel

persists in the rail lines between Perpignan and Montpellier. This sector is nowadays the only

Figure 3: several of our activities over the last years have been centered in explaining at the other side of the border the issues of the euro-region, as with this image of Port-Leucate for a conference in Barcelona (source: the authors)

portion of a cross-european corridor, sparing from Seville to Hamburg where trains cannot run with high speed standards, and the accomplishment of the LNMP (*«Ligne Nouvelle Montpellier-Perpignan»*) is not planned to be finished before 2035, as earliest.

Concerning teaching and research, bi-national regional movement is almost non-existent, with the exception of some punctual collaborations in the fields of medicine, agronomy, or law. No visible cooperation appears, neither, on planning nor urbanism at a certain scale, except those cases linked with very practical issues close to the border line. However, common problematics arise in all the fields, that we think would be easier, and more logical, to treat and solve in cooperation.

3. Disciplinary issues

As architects and planners, we believe that many of our current challenges cannot be furthermore addressed in a classical way. This affects both methodology we use for working (that tends to be more collaborative, and further anchored to research), and the subjects we treat: these have now the necessity to be linked with major crucial issues, such as the impact of climate change in our territories. This is why we consider this trans-boundary context, with its high quality but also extremely fragile landscapes, and with its range of cities showing all of today's problematics, to be an opportunity full of potential for experiencing new protocols for acting as designers.

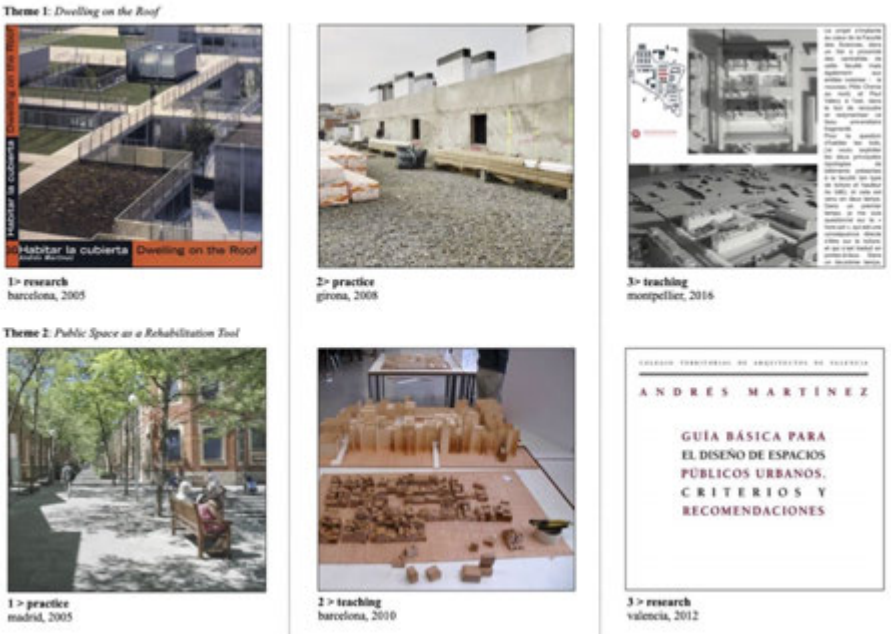

Figure 4: different orders tested for the place of teaching in the «Applied Research Triangle», as presented in Westminster in 2019 (source: the authors)

We propose to update, at this occasion, the theories of «Research by Design» (established mostly by the english school of though around applied arts) to nourish our practice from research and teaching activities. According to RUST (2007, 48),

«(...) the history of another field [of knowledge] is instructive. Medical research in the modern era began with the study of pathology in the 19th century. However that effort offered few if any 'cures' and it was only in the 1940's that a century of scientific effort began to be translated into practical progress for doctoring. At that point a new discipline of clinical research arose to provide the tools for innovation in medicine but it was a severe challenge to the medical schools of the day, and posed new ethical and intellectual questions that took decades to answer. We are so used to today's culture of clinical research that it is hard to remember that, in the lifetime of some of us, that tradition was tentative and not understood by the great majority of doctors of their teachers».

Although RUST adds that *«(...) we should recognize (...) that a research culture cannot mature overnight, and new methods cannot be expected work reliably without a period of experiment and reflection»*, we think that time has come to get into proper realizations to what, in architecture and planning, has basically been a theoretical debate. Applied to architecture, the authors that, in our opinion, came closer to what proposes RUST and what we aim to our experiment were VIGANÒ and SECCHI, and especially their analysis of the Veneto lo link the physical support, and particularly its ecological issues, to contemporary ways of living, in what

Figure 5: cartography drawn by Saverio MURATORI for the region of Grassano, Italy (source: Archivo Muratori, Biblioteca Poletti, Modena)

Franceso INDOVINA called the *«citta diffusa»* (INDOVINA, 2009), and with a methodology, according to Bernardo SECCHI, of a *«practice charged with theory»* (SECCHI, 1995).

Apart from these main references, we are also interested in our work in two other complementary approaches. On one hand, one that would consider the graphic analysis techniques developed by Saverio MURATORI to establish a complete cartography of Italian regions, that we intend to use as an inspiration for our cartographical approach to this territory. On the other hand, and with a direct application to our region, we are interested in the way the team of architects involved in the «Mission Racine» worked to plan and build, between 1960 and 1980, a series of holiday towns in the windy and sandy shores of the Languedoc-Roussillon; first, with the thorough diagnosis they made of the problems and potential of the territory and its particular sites, and later on with the capacity they had to use it for a multi-scale regional plan, sensitive simultaneously to landscape, urban, infrastructural, social, and even (if understood with the mentality of those years) ecological issues (see DELORME, 2022).

4. Structure of the trans-border partnership

Although wishing to establish basically a scientific approach, and searching for its applied results, this franco-spanish partnership aims to have an implication, in a progressive way over the years, in different formats of collaboration. We consider ourselves now capable to answer two questions we asked back in 2019 in two different scientific forums, about the role of

teaching in the creation of knowledge preceding applied research: in Westminster University,

Figure 6: the *«citta diffusa»* in the Veneto, as drawn by VIGANÒ-SECCHI (source: VIGANÒ, 2010)

we asked ourselves what came first in what, at that time, we were calling an «Applied Research Triangle» (MARTÍNEZ, 2019); in another proposal for Antwerp University, we defended the capacity of a method of teaching architectural studios that we called «horizontal», to «launch research themes» (MARTÍNEZ *et alt.*, 2019).

Five years later, we wish now to establish a permanent structure able to work in the way we proposed in those papers written back in 2019. First action in this sense, and following that «launching role» accorded to teaching, we are now able to start, in September 2024, a double degree in architecture between our two institutions: on the French side, the École Nationale Supérieure d'Architecture de Montpellier (ENSAM), and, on the Spanish side, the Escola Tècnica Superior d'Arquitectura del Vallès (ETSAV, in Barcelona).

Both schools depend on public universities, both are of similar (and reduced) size, and both have a clear experimental and metropolitan character. The aim is to deliver, together and simultaneously, two European architectural degrees, with an organization based on two main criteria: on one side, a back and forth mobility, on a semestrial basis, of the students of both nationalities, that will work always together, between the sites of Montpellier and Barcelona;

and, on the other, the existence of a binomial teaching in studio, always counting

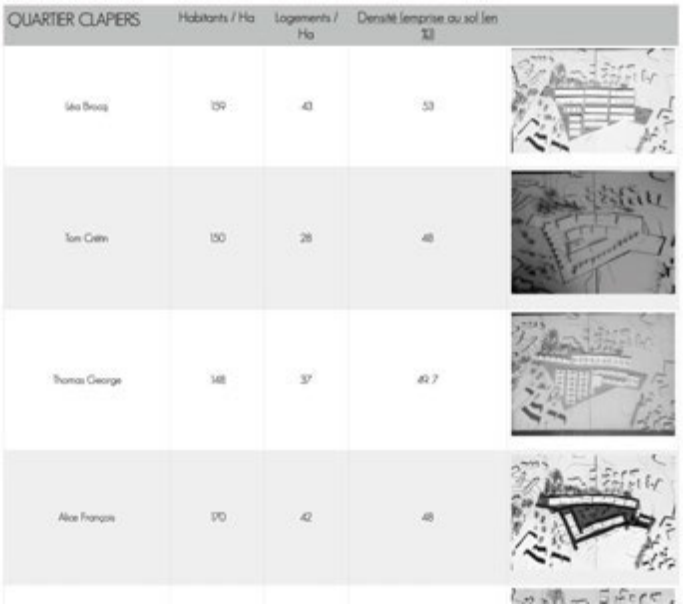

Figure 7: a «capacity test» on a mid-density neighborhood : graphic comparison of a quantitative approach measuring different parameters of density, and its consequences in urban form (source: students of S4 at ENSAM, 2020)

simultaneously with a faculty from each nationality.

We wish to insert this initiative in the roots of two declared intentions of the European Union. First, the establishment of a common European teaching and scientific space, for which the main issue, according to recent European officials declarations (NAVARRO, 2024), is the creation of common trans-national degrees; we want this double delivery of french and Spanish degrees to be considered as a first step towards that eventual European unique degree in architecture. Second, we think the importance given by Europe, for several decades now, to trans-border regions, is still very relevant nowadays. In our context, this concerns both funding (with specific programs, like the INTERREG or SUDOE), and the creation of particular administrative structures, such as the Eurorégion Pyrénnées-Méditerranée (EPM) mentioned above, that through its Eurocampus offers two different initiatives that suit well our interests: the creation of higher education partnerships (in particular the establishment of double-degrees, like the one already started in the field of Law between the universities of Toulouse and Barcelona), and the interest for common study and transformation in Environment, Climate, and Energy.

For the launching of this double-degree, we count already with the support of national french authorities, such as the Ministère de la Culture through its aid to international initiatives of

architectural schools, and the explicit support of the French foreign authorities in Spain, both through the consulate in Barcelona, and the embassy in Madrid. At the same time, we are still seeking for co-funding of regional and local authorities that would help collaborate for student and faculty mobility, such as the Région Occitanie, the Generalitat de Catalunya, and the Métropole de Montpellier.

In the structure being mounted, the teaching collaboration would only be a first step to a wider partnership involving scientific activities in our research laboratories, the «*Laboratoire Innovation Architectures et Milieux*» (LIFAM, Montpellier), and the «*Centre de Recerca i Serveis per l'Administració Local*» (CRAL, in Barcelona). On its financial side, we intend to

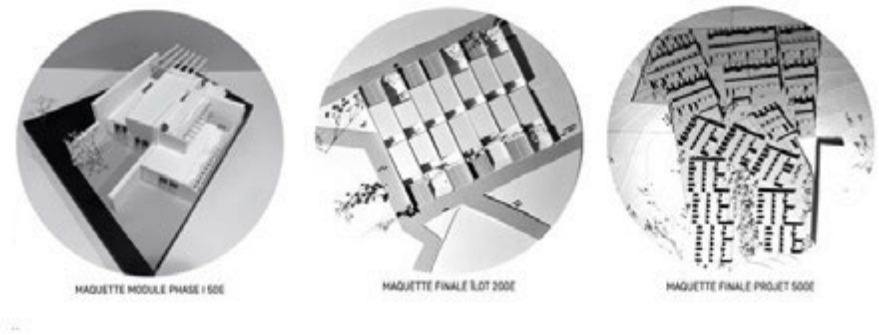

Figure 8: the three steps of the definition of a mid-density pattern: the unity, the lot, and the neighborhood (source: Théophile LEROY, student S4 at ENSAM, 2021)

respond together to a specific call for the creation of international research networks proposed by the French «*Agence Nationale de la Recherche*» (ANR), named «*Montage de Réseaux Scientifiques Européens ou Internationaux*» (MRSEI), on its call due in September 2024. We will need to be associated (as demanded by the call) with a third research institution, probably in North-West Italy, to complete geographically the western Mediterranean arch. On the institutional side, a research chair «*Pour une esthétique du changement*», is planned to start working soon. It is currently on process of being labelled by the French authorities of the Ministère de la Culture,and it will allow the entrance of private co-funding in our research activities[1].

However, the final funding aim of this partnership is to apply together to high range European programs, like the Next Generation program (and in particular its chapters dealing with renewable energies and self-sufficient communities), and those proposed by the European Research Council (ERC).

4. Specific thematic proposals

[1] translated to english: «Creation of European and International Research Networks» (for MRSEI), and «In Search of an Aesthetic of Transformation» (for «une esthétique»…)

While progressively mounting this structure, we plan to work at least in two levels of definition. The first one intends to establish an operational cartography of the bi-national territory, to be done mostly through our teaching activities. This cartographic production should be able to go further than a simple technique of analysis or diagnosis, to allow an observation of reality which

Figure 9: some of our previous publications treated the potential of the agricultural metropolitan parks as a new form of public space and heritage (in the image, Parc Agrari del Baix Llobregat, in Barcelona) (source: the authors)

is able to highlight relevant issues, by representing them through different layers to be crossed in different combinations. This could be done taking profit of the architectural drawing skills of our students students, and taking as a graphic model the experiments of MURATORI, mentioned above.

At a second level, and to be developed in the scientific axis, we intend to establish a comparative applied research by the design, and construction, of selected pilot-projects at both sides of the border, with the will to transfer the results obtained as design recommendations, first addressed to public authorities in charge of housing and planning, and further on to private developers through the form of «Market Replication Models» (MRM).

One of the research themes we propose is the creation of mid-density residential patterns (in the way these are defined by authors such as, for example, KROPF, 2013). These new forms of neighborhoods can, through the establishment of self-sufficient energetic communities, respond at the same time to problems such as the integration of renewable sources in urban tissues, the changes provoked by electric mobility, or the restoration of a balance with natural resources, considering these as a new form of public space, in the metropolitan environment.

Our intentions on this particular axis concern mostly housing and urban structure issues… but not only. We consider these questions cannot, nowadays, be treated apart from concepts such as «urban habitability» (as defined by BLANC, 2009), access to services, quality of public

space, or anything contributing to the community realm, the sense of «urbanity», and, of course, the consideration for re-use and transformation of existing patterns. This, alltogether, should allow us to properly respond, first with a local and particular approach, and further on with

Figure 9: our proposal (see MARTíNEZ, 2023) for the site of the first mid-density pilot project to be designed. In the border between an existing metropolitan urban pattern (el Prat del Llobregat, Barcelona), and the Parc Agrari del Baix Llobregat, with all its pre-existing elements. Currently planned as a high density new neighborhood, to be, ideally, modified (source: Institut Cartographic de Catalunya)

more general applications, to the challenges caused in certain European regions (like this western mediterranean basin) by climate change, the impact of renewal energies in landscape, or deep social transformations currently ongoing.

It is important for us to point out that this whole experiment is linked, and updates, a number of historic threads on housing and urban production in European history. Some of these focus on the links between building typology and urban morphology, represented mostly by the Italian school (i.e. CANNIGIA and MAFFEI, 1984); some others insist on what they call «landscapes of energy», that is all the urban fabric created, in one way or another, around production and energy (MANGIN, PANNERAI, 1999); lastly, we are also interested in those that treat the importance of housing and urban tissues built for specific communities, mostly working populations, but not only (KIRSCHENMANN and MUSCHALEN, 1980). For us, these new types of metropolitan communities could, at the same time, be considered some sort of «specific population», linked by «energetic issues», and their patterns created, in part, according to typo-morphological laws. Two other more recent questions, should, however, be considered: the one of the metropolitan landscape used as public space, that of the re-use of the existing built environment.

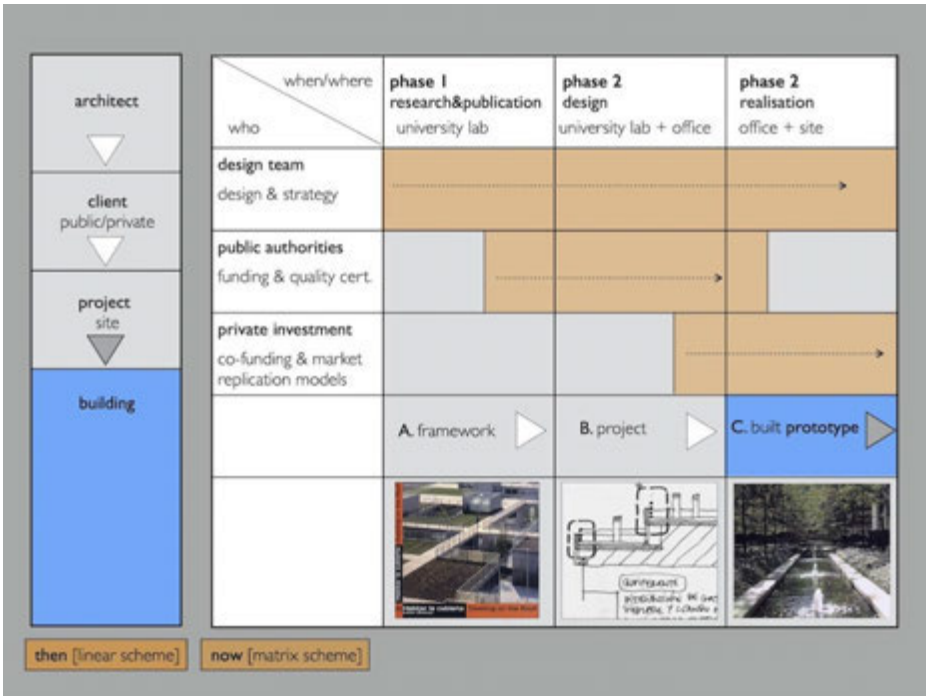

Figure 11: matrix for the organization of an applied architectural research procedure, from publication, to pilot-project, to completion in site, as presented in a congress in Stuttgart in 2009 (source: the authors)

Apart from this main theme, we keep on our backminds some other thematic proposals, that we will just name here briefly. One, for example, would have to do with the rehabilitation of social housing of the 60s formed by towers and bars, through interventions that would be both functional and spatial, rather than only technical and energetical. On the other hand, a very particular issue for this territory, that is the potential of reconversion of the architecture of mass tourism, prevalent in the shore of both countries and basically out of date in several ways. With some sectors like the one mentioned of the Mission Racine, considered among the most valuable modernist production in housing in the sencond part of the century.

5. The drift from applied research into planning

We believe this bottom-up approach (that starts on applied architecture and urban design with comparative research methods) can lead, later on, to the definition of efficient trans-border planning practices and policies, suitable across administrative bi-national divisions.

As already pointed out, there is a specific will of knowledge transfer of the results of these procedure, both to the public authorities and the market actors through MRMs. In fact, some of

the ETSAV's post-degree actions (like the Master MArq) already point in this direction, by

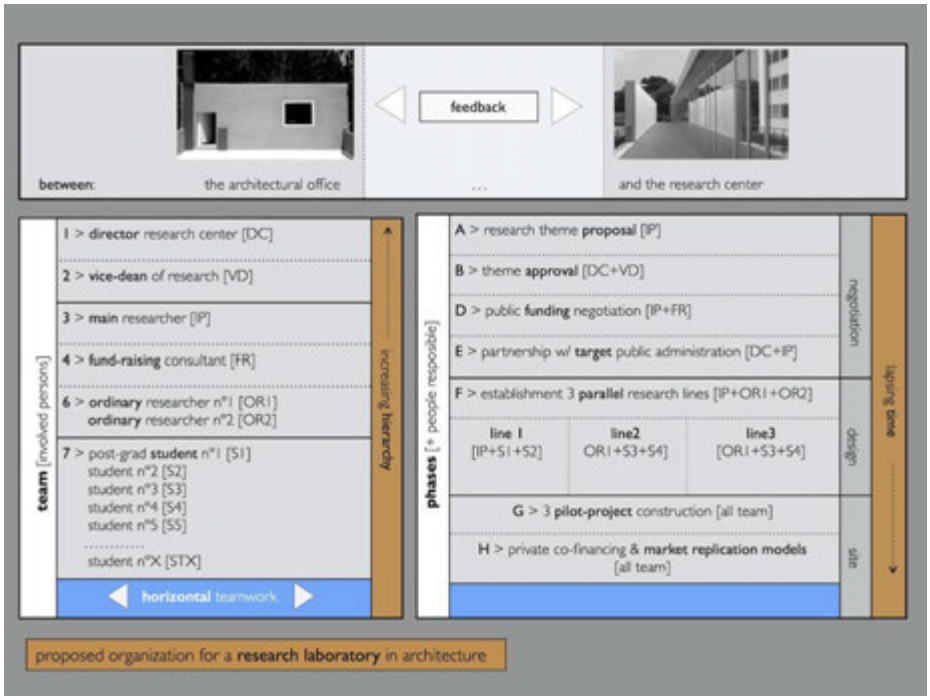

Figure 12: possible scheme of the organization of a university laboratory in applied research (source: the authors)

treating specific issues after requests of the local metropolitan authorities, and normally involving several scales of intervention, from housing formats to large landscapes.

Our contribution to this congress wishes to present this cooperation, currently under construction, to a wider audience outside our institutions or universities. In order to get, simultaneously, proper feedback before its implementation, and to contribute to the debate of turning planning into a game-changer for more just, and sustainable, regions, as proposed by the organization.

Transit-oriented Development in asymmetrical context: Learning from cross-border paradoxes in the Great Geneva.

Flore Guichot
Early-stage researcher TOD-IS-RUR / Phd EPFL
EPFL, Lab-U-HRC
flore.guichot@epfl.ch

Abstract

Transit-oriented Development (TOD) is hailed as a solution to sustainable urban growth; yet research often overlooks its impact in asymmetrical contexts like cross-border metropolises. This study challenges this gap, examining public transport and urbanisation projects in Great Geneva. The region, nestled between Switzerland and France, faces significant socio-economic and institutional asymmetry. While the Agglomeration Project aims for cohesion, local conflicts abound. Through critical analysis, three paradoxes emerge: the metropolitan, radio-centric, and development paradoxes. These paradoxes question TOD's agency in an asymmetrical context. Understanding these paradoxes is necessary to inform future planning in such regions beyond rhetorical discourses.

keywords: TOD, cross-border metropolis, asymmetry, planning, conflicts

Introduction

Transit-oriented Development (TOD) is pictured as a pivotal strategy to accommodate growth while ending car dependency in metropolitan areas. However, prevailing TOD research is often embedded in normative and progressive assumptions, failing to address the complexity of the model's impact in asymmetrical context such as cross-border metropolis. Meanwhile, border studies which focus on such context tend to view cross-border cooperation project, specially concerning public transport network, as a manifestation of cross-border functional and institutional integration but fail to question their impact in asymmetrical metropolitan context. This contribution challenges these gaps in sustainable development discourse by adopting a critical perspective on public transport infrastructure and urbanisation development in the asymmetrical cross-border contexts of the Great Geneva.

Nestled between Switzerland and France, the case study of the Great Geneva Agglomeration is characterised by its strong functional integration, supported by a strong socio-economic asymmetry across-the border. Since 2006, the agglomeration's institutional integration is manifesting through the definition of a cross-border territorial vision, which is nevertheless impacted by institutional asymmetry across the border. Setting a radio-centric model of coordination of new transport axes and urban development at the centre of its cross-border cooperation vision, the *Projet d'Agglomération* (PA) intention is to foster territorial cohesion in the cross-border metropolis. Nevertheless, in the last 10 years, conflicts and contestations around the implementation of this vision multiply.

Critically analyzing conflicting cases, alongside socio-spatial and economic dynamics, financing tools and legal frameworks, the study highlights three paradoxes in the current implementation of TOD model as a support to territorial cohesion—the metropolitan paradox, the radio-centric paradox, and the development paradoxe.

1- TOD in cross-border context

1.1 TOD

TOD, understood here as coordinated planning of public transport infrastructure and densification projects around station nodes, is actively promoted in international reports (OECD, UN-habitat, EEA), as a pivotal strategy reach sustainable metropolitan development (Newman and Kenworthy, 2015). Through the combination of transit infrastructure, promoting regional accessibility to employment hubs, and a mixed-use, compact, and pedestrian-friendly station environment, it intends to mitigate car dependency in suburban contexts, while stemming sprawl and reduce arable land consumption. Hence, the model actively supports metropolitan functioning while mitigating its externalities.

From this standpoint, several research studies from the American school of thought have focused on demonstrating TOD's benefits (Cervero, 2007; Renne, 2013), and assessing its performances (Renne, 2009; Bertolini, 1999). More recently, a dense body of literature has focused on "making TOD happen" (Curtis et al., 2009) though the identification of challenges and good practices of land-use and transport integration (Lierop et al., 2016). However, these contributions are marked by intrinsic normative and progressive assumptions around the implementation of the TOD model (Angelo et Wachsmuth, 2015).

Despite the wide acceptance of the benefit of the model, another branch of research stresses the singularities of both implementation processes and the impact of the TOD model in different contexts (Staricco et Vital Brovarone, 2018; Thomas et al., 2016). As some authors point out, the model generalisation went along with the development of site-specific tools and policies at both state, regional, metropolitan, and local levels, which, generated different applications and outcomes (Gallez et al., 2013). This line of research has, therefore, dived into the social-spatial, economic, and political conditions in which the model is being designed and implemented (Grillet-Aubert, 2015; Gallez et al., 2015). Such research participated to interrogate the model's role in the promotion of spatial (in)justices (Mollé et al., 2019; Derakhti et al., 2020) and showing some of the contradictions embedded in TOD discourse (Roy-Baillargeon, 2017). These input challenge TOD's ready-made normative assumptions, bringing transport and land development projects back into political spheres. To this intent, critical scholars, particularly Fillion and Keil (2016), engage and look at conflicts that emerge from this development to understand the « shortcomings of the current age».

1.2 Border Studies

As « in-between » territories (Grosjean, 2019), cross-border metropolis are particular cases, to observe TOD's agency in metropolitan construction. In Border Studies the notion of integration has been dominant to frame cross-border metropolis analysis (Van Houtum, 2000). Sohn et Walther (2009) propose a grid to articulate the institution and functional dimensions of metropolitan cross-border integration. Defining both notion as such 'functional integration then relates to the form and intensity of socio-economic interactions observed on either side of a border, through the extension of the metropolitan area, while institutional integration concerns the form and intensity of interactions between political actors possibly willing to collaborate' [1]. In their paper, imbalance between functional and institutional integration are critically reflected upon as an enabler of metropolisation process.

In the field of Border Studies, public transport lines crossing the border epitomise the institutional integration of functional integration, as their realisation demand strong cooperation from the different

[1] Authors' translation

territorial actors while aiming at facilitating functional relation between the two regions (Medeiros, 2019). As a result, a lot of contributions reflect on the obstacles to overcome and opportunities to increase these developments (Medeiros et al, 2021). However, less contributions reflect on the condition of implementation of such project and their impact. As a matter of fact, transport infrastructure is even broadly assumed to entail territorial cohesion (Lopez et al, 2008), understood in EU terms, as policies aiming to rebalance socio, economical and environment inequalities (Durán Laguna, 2024). However, asymmetries inherent to cross-border context, though often underlined (Decoville et al, 2011) are little problematised with regards to transport provision, despite empirical evidence that they support rebordering movement at the local level (Herzog et Sohn, 2014).

This contribution aims to analyze conflicts arising from the implementation of cross-border transport and urbanisation projects in the Grand Geneva metropolis. The first part examines the asymmetrical nature of functional and institutional integration in the region. The second part focuses on analyzing conflicts surrounding the implementation of the TOD model. Rather than viewing conflicts in isolation, they are contextualised within a relational perspective to transcend a narrow interpretation of these disputes. The definition of paradoxes draws on a hybrid methodology, combining quantitative and cartographic data analysis, examination of planning documents and alternative proposals, and semi-structured interviews with various stakeholders, including public and private actors and citizen associations.

2- Framing cross-border cooperation in socio-economic and institutional asymmetry

2.1 Functional integration and socio-economic asymmetry

The Grand Geneva agglomeration stands as one of the most dynamic regions in Europe in terms of the labor market. Daily, the number of workers crossing the border to work in the Canton de Genève exceeds 100,000, which represents one-quarter of Geneva's work force. In addition, according to the Frontier Observatory, the number of cross-border workers could nearly double within the next decade. This functional integration is inseparable from the cross-border socio-economical differential, which is one of the highest in Europe. As in most cross-border cases, cross-border flows are generated by enterprises and individuals utilizing the differentials across the border to maximise socio-economic opportunities.

Due to both Swiss and local conditions, including taxation mechanisms, the Geneva Canton is significantly more attractive to enterprises than the French part of the agglomeration. From an individual perspective, Swiss-based salaries are much higher than French ones for the same position, and accordingly, Swiss living costs are significantly higher than French ones. Land value and housing prices also vary significantly across the border. Geneva has one of the most expensive housing markets in Switzerland. Despite a recent rebound in housing construction, buildable land scarcity due to cantonal and federal protection laws and the accumulation of delays in housing generated a long-standing housing crisis. On the French side of the agglomeration, the entire Haute-Savoie department and the Pays de Gex have some of France's most expensive housing market. Nevertheless, the rupture at the border in terms of housing cost is clearly readable. Hence, the French neighboring region remains significantly more affordable in terms of housing than the Swiss part of the agglomeration. Finally, a much more recent and much more volatile aspect heightened each of these phonemenons in recent years. In 2015, the Swiss National Bank abolished the minimum exchange rate that pegged the Swiss franc at 1.2 to 1 euro. Consequently, the parity between the franc and the euro, in favor of the franc, had a direct impact on widening the cross-border differential between the two parts of the metropolis, as well as within French territories, between the population working within the national territory and the border population.

These asymmetrical socio-economic conditions support a metropolitan functional integration by specialisation. As demonstrated by Decoville et al. (2013), this dynamic « leads to a process of cross-border suburbanisation, involves a process of functional specialisation of space, with the centre concentrating economic activity and jobs while the periphery, which is attractive in residential terms, is relegated to the role of a dormitory area. ». As the authors point out, in such a configuration, exceptionally competitive in economic terms, functional integration feeds and is fed by cross-border socio-economical differential and, therefore, does not lead to territorial 'convergence' but digs the differential between territories (Decoville et al, 2013).

2.2 Cross-border cooperation …

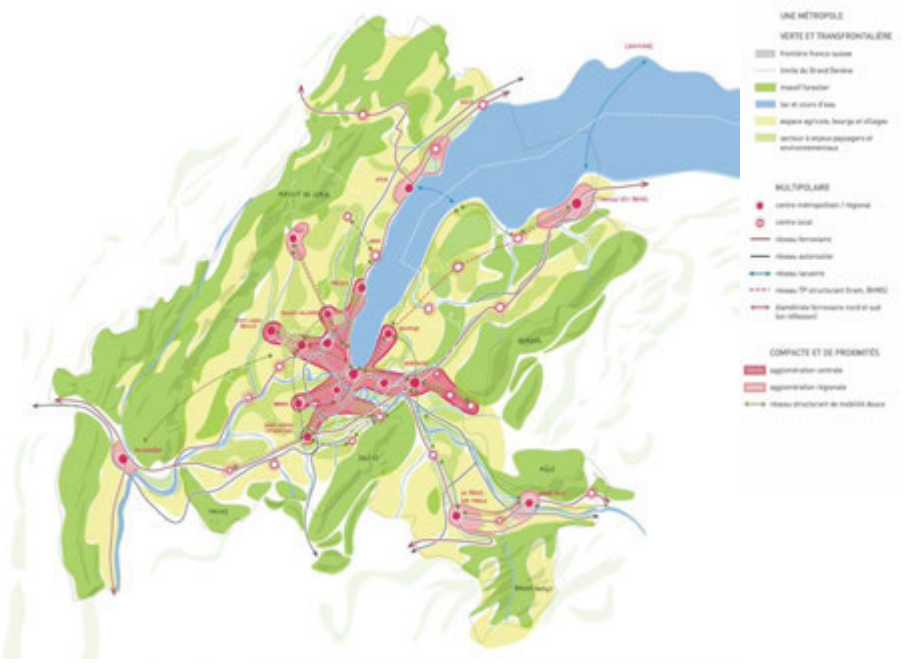

Figure 1. Vision d'ensemble de l'Agglomération, 2021. Source : Plan d'Agglomération Grand Genève (PA4), 2021.

Since 2006, cross-border cooperation in the Great Geneva metropolis took a new turn with the development of the *Projet d'Agglomeration* (PA). The PA is a Swiss planning devices developed at the agglomeration level by member entities. This tool was accompanied by the creation of the program in favor of agglomeration traffic (PTA), which allows the agglomeration, including cross-border ones, to benefit from federal funding of up to 45% to support transport projects. However, this financing is subordinated to the compliance to the federal spatial planning law (LAT) and to the coherent coordination of transport and urbanisation. Constituted into a GLCT (G*roupement Local de Cooperation Transfrontalière*) in 2012, the Grand Genève is the autonomous entity responsible for the development of these plans. The four generations of PA aim to produce a coherent vision coordinating transport, urbanisation, and environment on both side of the border. Since the very first PA, the sated goal is to promote territorial cohesion. Formally, all the plans promote the development of radio-centric transport axes from Geneva, organizing the urban development in corridors and hierarchal poles (Figure 1). Thus, model of cross-border cooperation and the modality of territorial

cross-border cohesion, understood as the rebalancing of territorial inequalities, is materialised through the radio-centric TOD model. The rise of metropolitan planning in the form of TOD, in recent years is therefore closely intertwined with the evolution of cross-border cooperation modes and mechanisms. These modes of metropolitan cross-border governance are designed and implemented by actors with diverse interests and capacities to assert them, which inevitably affects power dynamics among the various territorial. Therefore, beyond socio-economic asymmetries, understanding the current development projects necessitates an examination of cross-border institutional relationships.

2.3 …and institutional asymmetry

The PA encompasses numerous territorial entities, both intra- and supra-metropolitan. The emergence of the PA and the establishment of the GLCT contributed to the diminishing role of both national states in favor of local entities. However, the substantial proportion of funding that the Swiss Confederation allocates to the PA, coupled with a compliance examination of these plans with the Federal policies and development objectives, bestows upon the Swiss state a passive yet dominant role in the directions taken by territorial development.

At the regional level, the two primary entities are the Geneva Canton and the *Pôle Métropolitain du Genevois Français*. Despite their balanced voting capacity in the GLCT, these entities have a fundamentally unbalanced relationship depending on their legitimacy, material, and immaterial capital. The Canton of Geneva stands as an anomaly within Switzerland. As a Canton-city it has a leading role in planning, marginalizing the autonomy of municipalities. The Canton of Geneva is thus an extremely integrated and autonomous entity regarding spatial planning. In addition to the financial capital, the Canton's long planning history give it significant symbolic and knowledge capital. Lastly, the Canton possesses substantial human resources in numbers, abilities, qualifications, and experiences dedicated to its spatial development. Thus, the Canton of Geneva combines financial, symbolic, and human capital with substantial autonomy and legitimacy in planning matters.

On the French side of the agglomeration the strength and competencies of the different territorial entities are much more fragmented. The *Pôle Métropolitain* is a relatively recent entity that emerged from the *Assemblé Générale de Coopération* (ARC) in 2018. Its explicit goal is to 'elevate' the French part of the territory to the metropolitan scale to assert the French region's interests within the agglomeration.[2] However, this entity has a limited budgetary capacity as it is financed mainly by intercommunal contribution, in addition to INTERREG financial support. Hence, as a young structure with relatively low financial capacity, it still lacks sufficient expertise and human resources. The *Pôle Métropolitan* is the assemblage of eight EPCI (*Etablissement Public de Coopération Intercommunale*), each with planning competencies within their respective territories. The collaboration within the *Pôle Métropolitan* and the delegation of competencies are thus voluntary. According to French law, the designation *Pôle Métropolitain* is given to entities 'unable to become metropolises'[3], therefore, showcasing the French state's inability to recognise the existence of the cross-border metropolis, contrary to Switzerland. Furthermore, the legitimacy of the *Pôle* is far from established. As such, it competes with the departments and the region competencies, as well as their desire to be the primary interlocutor for cross-border interactions. Hence, despite the *Pôle Métropolitan* federating the fragmented French part of the agglomeration to constitute a stronger interlocutor with Geneva, its fragile assembly and challenging position in the region contributes to its marginalisation and weakening and to the asymmetry in the relationship with the Canton de Genève. Finally, the *Compensation Financière Genevoise* agreed upon in 1973, and which set a financial

[2] Statuts du Pole Métropolitain, Comité syndical, 2018. Available at. https://www.genevoisfrancais.org/wp-content/uploads/statuts-pole-metropolitain-genevois-francais-2018-1.pdf

[3] LOI n° 2010-1563 du 16 décembre 2010 de réforme des collectivités territoriales, République Francaise, 2010.

retrocession from the Canton of Geneva to French department and communes, determined by the number of cross-border workers, remains an essential agent in the subordination of French departments and municipalities to the Canton of Geneva.

Hence, the territorial project emerging from the cross-border cooperation cannot be separated from the power (im)balance and hierarchisation that characterises the metropolis. The question raised by this contribution is the agency of the current TOD project in this dynamic and its impacts.

4- Local conflicts for regional paradoxes

4.1 Metropolitan paradox: between accessibility and specialisation.

The first paradox explored pertains to the mechanism of metropolitan development in the cross-border context. The map (Figure 2) illustrates the gap between resident workforce and job provision per commune in the metropolis, more pronounced in France than in Switzerland, but reflecting the typical centre-periphery However, this gap has notably widened over the past 20 years, with job-resident ratios doubling or more in most communes of the Canton of Geneva while stagnating or decreasing on the French side of the agglomeration. Over 35% of the population in many French communes are now cross-border workers, a figure that has notably risen in those farthest from Geneva over the past eight years. Thus, the mechanism of functional specialisation remains prevalent, with job positions concentrated in the centre and the French periphery evolving into dormitory communities, despite the stated political desire to rebalance the employment-resident ratio since the first PA in 2007. As a result, there is a perpetual increase in cross-border flows in overall volume and the distances traveled by cross-border workers.

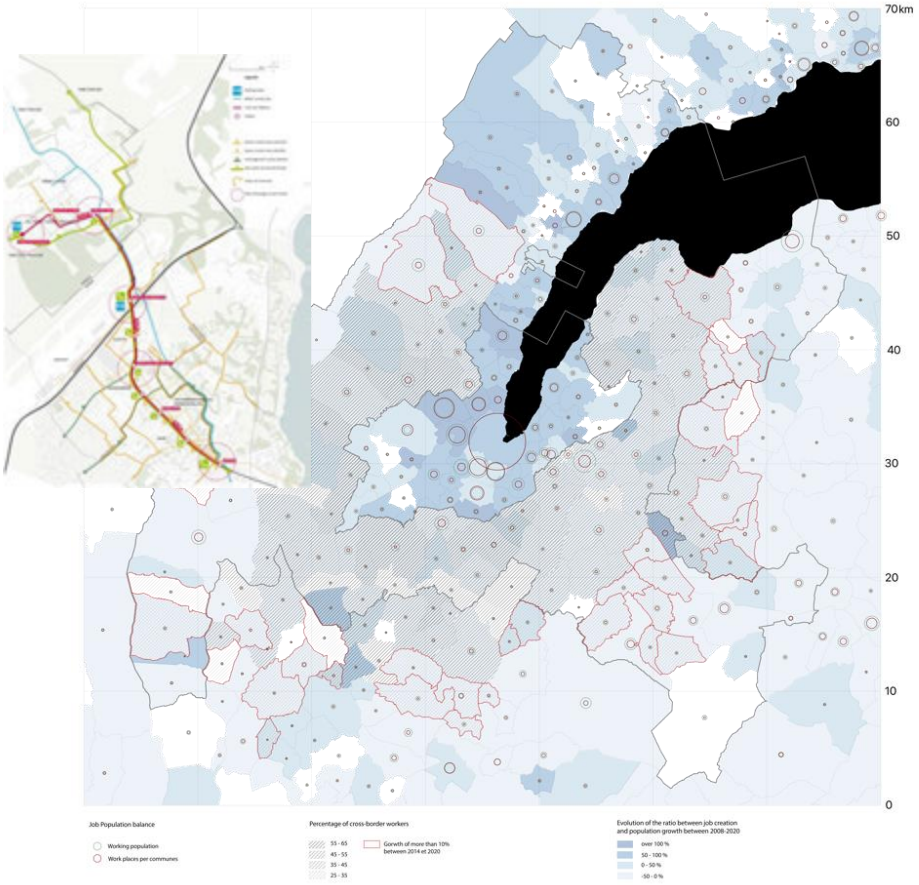

Figure 2. A specialised metropolis, author's production, 2024. Sources: INSEE-OST-ge.ch

An essential notion of the TOD model is the development of functionally diverse zones around transit nodes to foster pedestrian-friendly local community life (Ogra et Ndebele, 2014). However, diversity within the TOD framework lacks a clear spatial definition, particularly in scale and relation to the local context. Mixed land use is a challenging concept in a metropolis such as the Great Geneva where functional integration is done through specialisation.

Hence, this is where the paradox emerges when using the TOD model in the asymmetric metropolis of Great Geneva. Whiteout the capacity to rebalance the territory, the establishment of transport axes intending to alleviate the externalities associated with cross-border worker flow, reinforces, and increases the functional specialisation of each side of the metropolis and therefore transport need. This paradox will be illustrated through the cross-border development of the tram des Nations.

4.1.1 Tram des Nations : a cross-border infrastructure

Since the first PA, a structuring transport axe was imagined connecting the centre of Geneva to the municipality of Ferney-Voltaire and Gex. This project was materialised through a tramline toward Ferney (Figure 3, in red) and a BRT connecting Geneva to Gex (Figure 3, in bleu), both passing through Grand-Saconnex in Switzerland. The project's total budget is 40 million euros, with 35% funded by the Swiss Confederation and 11% by the French state. On the Swiss side, the remaining

54% on the Swiss side are covered by the canton and municipality. While no formal urban densification is tied to the Swiss project, Confederation financing requires a coherent development of transport and urbanisation. On the French side, the tram project is bundled to the development of a ZAC (*Zone d'Aménagement Concerté*), in Ferney-Voltaire. To finance and manage this coordinated development, the inter-communality of Pays de Gex established), a private law structure, *Société Publique Locale* (SPL), owned 60% by Pays de Gex Agglomeration and 40% by the Ain Department and local municipalities. Thus, Ferney-Voltaire, where the new development is located, holds a mere 5% representation in the SPL. This structure oversees the tram project and Ferney Innovation ZAC, with competencies in urban planning, property management, and socio-economic development.

Figure 3. Tram des Nation, author's production, 2021. Sources: Participer.ge.ch

Figure 4. Posters, 2022. Sources: Association Poterie Ripost

4.1.2 La ZAC de Ferney-Voltaire: Specialisation against sustainability

The municipally of Ferney-Voltaire, located next to the Franco-Swiss border, has nearly 11,000 residents. Like many in the Pays de Gex, its population has doubled in the past 25 years, with almost half its workforce commuting to Geneva. The ZAC Ferney innovation project, launched in 2012 and managed by *SPL Terrinov* since 2016, is located on the last agricultural land in the commune. Combine with the tramline expansion, it includes a mixed-use development on a 64-hectare plot, featuring 195,000 square meters of economic activity space, 63,000 square meters of leisure and cultural amenities, and 2,500 housing units (Figure 5).

Opposition to the project emerged after Ferney-Voltaire's Municipality issued the building permit in 2020. The *Poterie Riposte* association, formed by residents, mobilized against the commercial zone development within the ZAC, known as the Poterie zone. They initiated legal action, organised community protests, and raised awareness campaigns. Collaborating with local and Geneva-based architects, they also proposed an alternative project. Currently, the Poterie commercial centre project is on hold following the withdrawal of the *Altarea Cogedim group*, tasked with the development, leaving the ZAC's future uncertain. Poterie Riposte represents one of the first instances of citizen mobilisation against current urban development policies in the region, viewing the commercial centre as emblematic of an unsustainable development model geared toward Geneva. While the contestations' focus is on the commercial centre for legal reasons, the association opposes the entire ZAC project, challenging its form, function, and impact on the city's existing structure.

Opposition to the project centres on several concerns. Firstly, residents are alarmed by the planned new commercial zone adjacent to the border, designed with direct access to the customs office, expected to cause a significant increase in traffic and pollution between Ferney and Geneva, as evidenced by the planned 1,600 parking spaces. The association points out the incoherence of developing this new car-oriented specialised zone with the simultaneous significant investment in public transport. Secondly, they fear the competition this facility will pose to local activities in the city centre and the already fragile local social and economic fabric in the cross-border context,

encapsulated in the slogan ‘city-centre or commercial centre.’ (Figure 4). Additionally, discontent arises from the design of the new tramline, which diverges after the border, prioritizing access to future residential zones over Ferney’s city centre. Finally, the *international city of knowledge*, encompassing approximately 130,000 square meters of office and tertiary activity development, intended to promote employment on the French side, is seen as the project's adjustable variable according to SPL *Terrinov* and will be realised last.

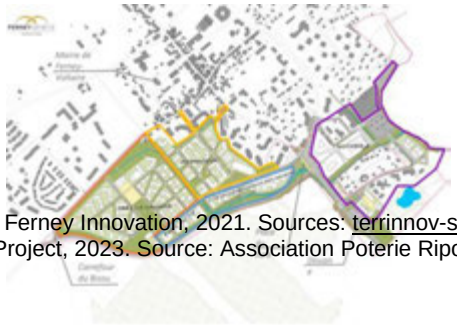

Figure 6. Left (a): ZAC Ferney Innovation, 2021. Sources: terrinnov-spl.fr, Right (b,c): Counter-Project, 2023. Source: Association Poterie Riposte

Figure 5. ZAC Ferney Innovation, 2021. Sources: terrinnov-spl.fr

For the inhabitants of Ferney, this comfort the idea of the creation of a « Ville-dortoir » aimed solely at hosting Geneva's workforce (Figure 4). The current design reinforces the perception of the project autarkic mixed zone, composed of « mono-functional fragments directed towards and for Geneva. », disconnected from Ferney's existing fabric and sacrificing local quality of life for metropolitan functionality. The association's counter project aims to reduce total square footage and prioritise space for local economic activities and workshops, alongside enhancing connectivity to the existing city centre (Figure 6.b.c). While its feasibility is questioned, the proposal underscores the importance of considering site-specific functional complementarity and diversity in the asymmetric cross-border

context.

4.1.3 Grand-Saconnex : metropolitan infrastructure vs local implications

On the Canton de Genève side, the tramline development has stirred tensions among the local population. Following the Municipality of Grand-Saconnex's approval of the project, a committee of residents, along with other local and cantonal associations, gathered enough signatures to organise a referendum opposing the tramline extension. Put to communal popular vote in 2022, the construction was narrowly approved by the Grand-Saconnex population, with 51.54% of the votes.

Figure 7. Left (a): traffic map, 2022. Right (b) : Poster, 2022. Source : enjeux.sauvegarde-geneve.ch

The referendum committee presented several arguments against the tram's implementation. Firstly, they raised concerns about the loss of municipal lands covered with a tree canopy for tram infrastructure construction. Secondly, they highlighted the transformation of the mobility scheme required for the tram's implementation and the resulting nuisances in the municipality. The tram's implantation and express cycle lanes necessitate the closure of a part of the main axis leading to Geneva, with the Tunnel des Nations constructed to redirect car traffic. However, with 22,000 vehicles crossing the municipality daily and a projected modal shift ranging from 1,300 to 6,000 vehicles per day, and the tunnel capacity of 20,000 vehicle per day, there are concerns about infrastructure saturation leading to parallel routes through neighborhoods (Figure 7b). Additionally, the opponents to the project perceives the cycle path design prioritizing major axes as detrimental to the local network. Finally, the refusal of tram development is also attributed to its perceived 'Gigantism' or the metropolitan scale of the infrastructure, reaching up to 35 meters in width. Furthermore, although not legally linked, the Confederation's financing of the tram project implies an implicit commitment from municipalities to densify around the infrastructure, which the inhabitants fear (Figure 7a). In this context, despite acknowledging the municipality's status as a 'transit city,' residents feel sacrificed to the metropolitan scale and to the preservation of the city-centre's quality.

The conflicts surrounding the development of the Nations tram highlight the paradoxes inherent in implementing a TOD-like project in an asymmetrical metropolis characterised by functional integration through specialisation. The specialisation paradox leads to escalating flows and the overflow of new infrastructure capacities, creating conflicting rationales between metropolitan and local scales. While the tram project aims to enhance local accessibility through decarbonised modes, it is perceived by both Swiss and French populations as sacrificing local quality of life in the periphery for the benefit of the centre. Consequently, the current project exacerbates divides between local and regional areas and between centre and periphery, with significant disparities on each side of the border.

4.2 Radio-centric paradox: between interdependency and autonomy.

The second paradox concerns the border relationship, formal development of the model, and functional interplay between territories, balancing interdependence, and autonomy. In Greater Geneva, the TOD model has historically taken a radio-centric form, characterised by radial connections from Geneva to residential centres in France, following major flows between employment and residential poles.

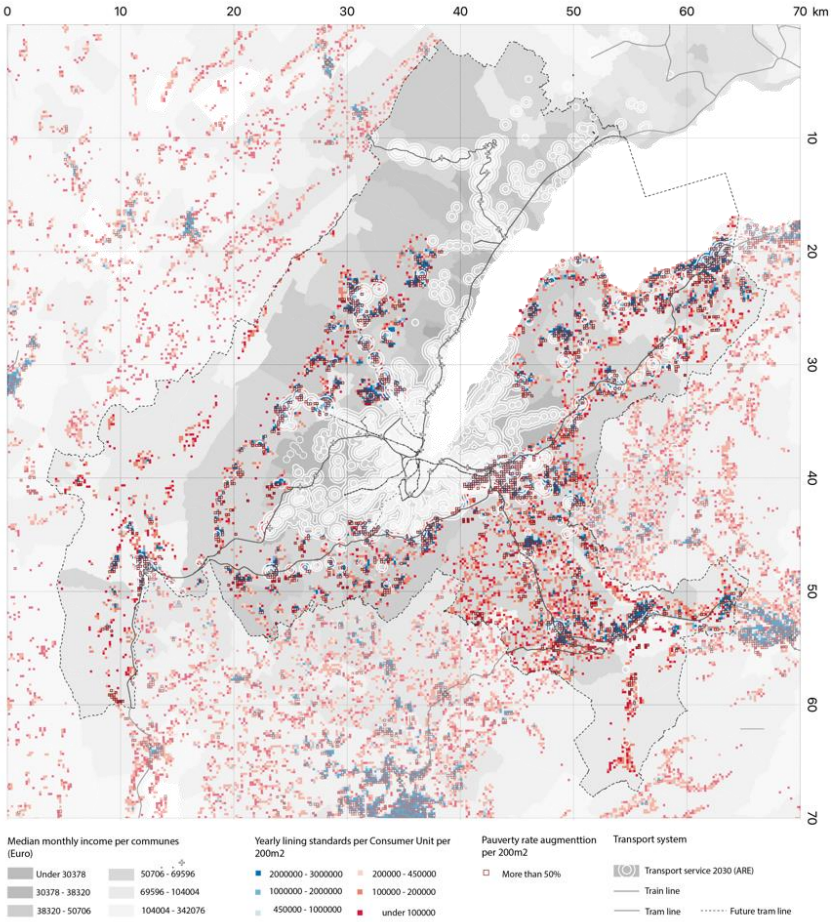
The map (Figure 8) illustrates the projected public transport service quality by the *Office fédéral de l'aménagement du territoire (LAT)* for 2030, based on planned transport axes. Implementing the radio-centric model is expected to provide good service to 54.6% of the agglomeration's population, leaving 45.4% unaffected. As the model radiates from the centre, service diminishes towards the French periphery, with only 13.7% expected to have good service and 22.3% with average service. Consequently, 77.7% of the French population will have poor or no public transport service. Logically, the bordering communes, with a high proportion of cross-border workers, are both the wealthiest and best served. However, there is significant disparity in living standards within the French part of the agglomeration. Core cities and villages, well-served areas, also have the highest living standards but are experiencing the fastest increase in poverty due to rising costs driven by cross-border worker concentration. This exacerbates the gap between French-based salaries and local living standards, correlating selective public transport connectivity with wealth disparity and poverty. Consequently, there's a structural inequality between connected and unconnected areas while at the same time increasing socio-spatial differentiation within the connected poles.

The TOD model, as advocated by Bertolini (1999), prioritises regional accessibility to employment hubs, which is perceived as inherently beneficial for supporting regional functional integration between poles. However, in the asymmetrical context of Greater Geneva, the disparity between Swiss and French salaries creates a polarisation of employment attractiveness towards Geneva. This reinforces the integration of territories and the dependence of French areas on Geneva. Consequently,

Figure 8. Living standards and connectivity. Author's production, 2024. Sources: INSEE-OST-ge.ch

French municipalities struggle to fill public service positions, leading to a decline in residents' quality of life. Moreover, the proximity to Geneva and cross-border purchasing power have led to increased living costs and rents, widening the social gap between Swiss and French employees.

Therefore, a paradox arises from the TOD model's selective nature and its formal implementation in a mono-oriented, radio-centric fashion, and the pursuit of territorial cohesion. In Greater Geneva, this



implementation, focused on connectivity via sustainable modes, results in the centre's saturation while deepening dependency and vulnerability in neighboring French territories. To illustrate this paradox, two conflicting projects will be discussed: the Autoroute du Chablais and the Mobility pricing project around Geneva. Although they are independent national projects, they underscore the two facets of the same paradox in the centre-periphery relationship within an asymmetrical metropolitan context.

4.2.1 The Chablais Highway: French Territories Seeking Autonomy.

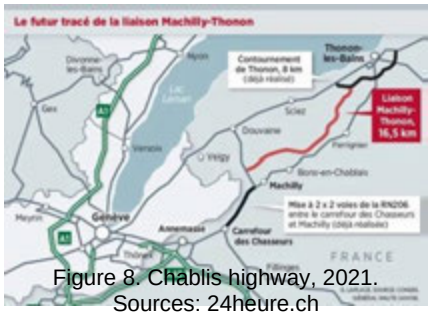


Figure 8. Chablis highway, 2021. Sources: 24heure.ch

The first project under discussion is the proposed highway connection from Thonon-les-Bains to Machilly in the French Chablais region. This highway segment aims to link existing road networks, providing an eastern bypass around Geneva (Figure 8). Initially conceived as part of the *Désenclavement du Chablais* policies since 1999, the project encountered various hurdles before being revived as an independent highway concession in 2010. In 2019, the French government declared the highway as a public utility. However, this decision sparked opposition from the cities of Geneva and Carouge, along with the French Green Party (EELV), leading to appeals filed with the French *Conseil d'Etat*.

Despite the rejection of these appeals in 2021, local authorities, favoring the project, viewed them as Swiss interference in French national territory. This conflict between Geneva and Carouge and French municipalities has escalated, resulting in the exclusion of the highway project from the 2021 PA4 plan, despite being closer to realisation than ever before.

Beyond the institutional dispute, the proposed highway project from Thonon-les-Bains to Machilly has spurred involvement from citizen associations, creating a complex debate. On one side, the association *OUI au désenclavement du Chablais* advocates for the highway's construction, while groups like *Action abandon autoroute* (3AC) oppose it. Despite appeals and demonstrations against the project, the French Constitutional Council approved it in July 2023.

The project's opponents denounce the infrastructure for its local impact, including the downgrading of agricultural land and the destruction of ecologically valuable environments. They also point out the increase in traffic resulting from the creation of this infrastructure, labeled as a 'car vacuum', and its impact on both health and climate. Conversely, residents see the highway as a solution to redirect heavy goods traffic, going towards the Arve Valley, away from village centres, benefiting community health and quality of life. On the regional scale, organisations opposing the project, as well as the Geneva Canton's authorities, argue that this new infrastructure competes with the recent connection of Thonon-les-Bains, Perrignier and Machilly to Geneva as part of the *Léman Express* network. However, these two projects do not address the same demand. For the French municipalities and local associations, supporting the project is a means to reconnect to their national territory and reduce the unique influence towards Geneva, which they hold responsible for rent increases, labor shortages, and dormitory towns development. The *OUI au désenclavement du Chablais* association supports the highway as well as all multimodal projects to develop new orientations for the region and beak away from Geneva's mono-attraction. Similar discourses reflect the municipalities' desire to create a more sustainable local economy by emancipating themselves from Geneva. However, regarding the highway associations opposing the project argue that, as a private concession despite significant public participation, the highway will support a financially selective opening of the region (Figure 9).

Figure 9: Le Chablais libéré sous caution, 2023. Sources: Le Faucigny

Thus, beyond the respective perspectives and divisions generated by this infrastructure, the project highlights functional and symbolic issues for the French regions that still need to be addressed and may even be intensified by the current radio-centric development project.

4.2.3 Urban toll: protecting the city from the metropolis.

The second project discussed here involves the Canton of Geneva's urban toll initiative, initially conceived as a response to a Swiss Confederation pilot project call in 2014. Selected for federal co-financing and legal exemptions, the project evolved into a mobility pricing strategy. The significant difference lies in the intention to reduce mobility, which no longer applies solely to individual motorised modes but to all forms of mobility during peak hours. This involves combining an entry fee for cars, applicable at all hours but higher during off-peak hours, with a discounted pricing scheme for public transport during off-peak hours. The latest studies published by the Canton de Genève

demonstrating the viability and progress of the project's deliberation. However, the future of this project remains uncertain due to recent federal political changes.

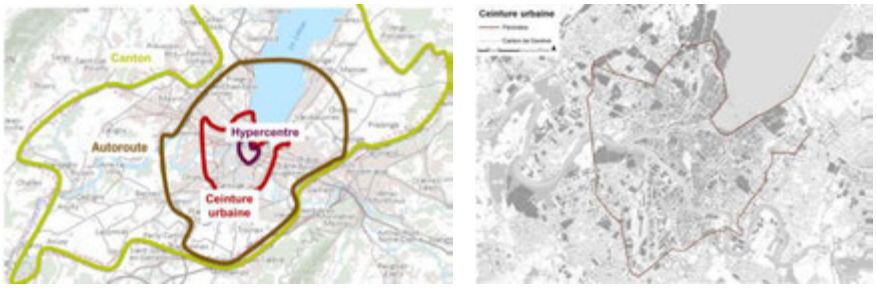

Figure 10. Left(a) four possible petimetres of the urban toll,2023 Source : Grand conseil de la République et du canton de Genève. Right : Urban toll cordon, 2022. Source : Tribune de Genève

The project entails a cordoned toll system, with fees linked to both entry and exit from the urban core. Four perimeter options were considered, with the chosen option being at the Geneva urban belt level, selected for technical reasons (Figure 10 a.b). Nevertheless, as emphasised by Geneva's Transport Office, the aim is not to restrict the entry of workers essential for Geneva's economy but to limit non-constrained mobility. The report on the matter even specifies that this scheme should not affect the economic attractiveness of the urban core[4]. Hence, the project seeks to alleviate road congestion and public transportation strain without compromising economic attractiveness. By incentivizing temporal shifting of travel demand, it addresses the centre's infrastructure saturation. At the same time, it is clearly targeted at addressing residents growing discontent with network congestion and associated nuisances. This is demonstrated by the intention to provide a discount for toll use exclusively to residents rather than frequent users as initially proposed.

The Geneva branch of the Swiss populist party (UDC) vehemently opposes the project, labeling it as discriminatory against the periphery and an infringement on the right to access the city centre. They argue that this device will contribute to the deterioration of living quality in the periphery and its construction[5]. Regarding public opinion, consultations indicate that the population is slightly favorable to the project. However, the study was conducted within a panel of French public transport user much higher than the current percentage of those with have access to public transportation[6].

This project signifies a re-enclosure of the city centre, admittedly oriented towards car mobility, but indicative of a re-division of metropolitan issues between the periphery and the centre. By implementing the urban toll and radio-centric TOD model, the centre would be able to insulate itself from metropolitan externalities while sustaining economic growth. However, in the cross-border context, such a toll system will affect Swiss-based and French-based populations differently, particularly since public transport discounts have little chance to extend to the French side. These risks exacerbating social-spatial selectivity between metropolitan populations earning Swiss and French base salaries, while further delineating the division between those well-connected by public transport and the rest of the agglomeration.

[4] Rapport du Conseil d État au Grand Conseil sur la tarification de la mobilité, Grand conseil de la République et du canton de Genève, Febuary 2023
[5] NON au péage urbain qui veut mettre Genève sous cloche!, UDC Genève, December 2022. Available at: https://www.udc-ge.ch/publication/non-au-peage-urbain-qui-veut-mettre-geneve-sous-cloche/
[6] Péage urbain à Genève: enquête auprès de la population, OCT, 2017

The debates sparked by these two projects illustrate the paradox of implementing the TOD model in a radio-centric manner. While new connections are being established from the center to the periphery, they create spatial differentiation and increase dependencies, leading to a desire for autonomy in the periphery and fortification of the center. Whether aimed at preserving areas from metropolitan externalities while maximizing economic opportunities, or mitigating socio-spatial inequities, these movements contribute to weakening territorial cohesion.

4.3 Development paradox. Between preservation and growth.

The final paradox emerges from the differing capacities for implementing the TOD model on each side of the border, shaped by distinct democratic and legal systems. These differences directly influence the development strategies of each national territory. To grasp the present context, it's crucial to dive into the historical morphological evolution of the metropolitan area. The development of the Geneva metropolitan area followed a typical process of "rurbanisation," with unique consequences due to the border and early land protection policies by the Canton of Geneva and the Confederation. As early as the 1950s, the Canton enacted laws to safeguard its rural landscape, reinforced by LAT in 1979 and the first sectoral plan for agricultural land use (SDA). With this plan, the Swiss Confederation defined a minimum area of quality agricultural land, which each Canton must preserve. These measures limited urban expansion within Geneva, leading to the export of growth to French territories. Meanwhile, French municipalities, autonomous in urban planning, were encouraged to host a growing number of cross-border populations by financial compensation. The current metropolitan structure is thus that of a core city surrounded by a rural green belt and a periphery with a predominantly rural imaginary, along with a French periphery more distant from the city centre but more assertive in its urban imagery. Today, a key aim of the Greater Geneva project is to address this growth imbalance and its associated externalities.

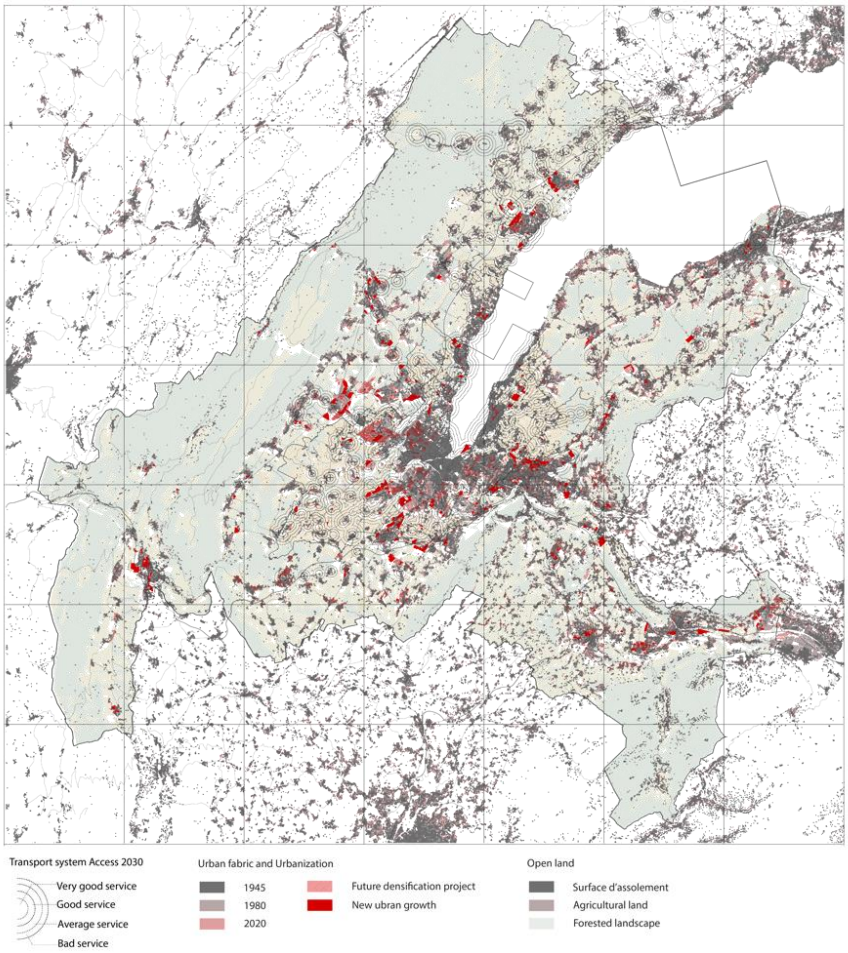

Figure 11. Development and preservation. Author's production, 2024. Sources: SITG

The map illustrates the evolution of built-up areas on both sides of the border from 1945 to 2020, incorporating future development zones outlined in the PA4. The map clearly illustrates the significant role played by densification in the French periphery since the 1950s, mainly around village nodes, forming multiple poles with little hierarchy. The cross-border vision clearly aims to evenly distribute new population growth between the Swiss and French sides, with developments oriented towards future public transport-serviced areas. However, most projects are on existing built-up areas in Switzerland and open spaces in France.

TOD model is an organisational framework of urban growth towards the periphery. Combine with green development, its effectiveness relies on developing compact urbanisation around key transport nodes along structuring axes (Cervero et Sullivan, 2011). This approach fosters new development over existing urban fabric. However, the idea that urbanisation should adapt to transportation is increasingly challenging to uphold in a context where ecological, normative, or ideological awareness tends to make ex-nihilo urbanisation less acceptable.

The limitations of this development model are exacerbated in a border context, where territories differ in their capacity to develop or preserve open spaces. The paradox lies in implementing a model centred on organizing new transport axes to redirect urbanisation, aiming for territorial rebalancing within an asymmetrical morphological, legal, and institutional framework, ultimately reinforcing development disparities on both sides of the border.

Bernex- Transport without urbanity?

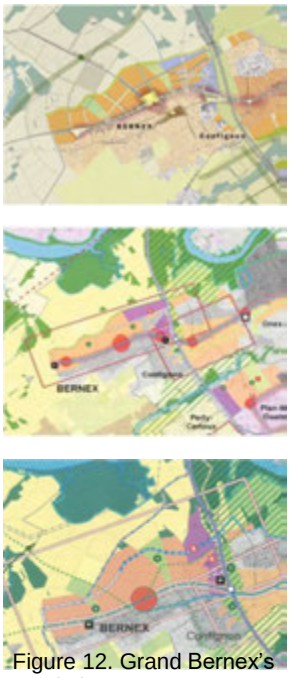

Figure 12. Grand Bernex's evolution, 2015. Source : Le Grand projet de Bernex Nord et Est, Les Verts Genève.

Bernex is a municipality of the Geneva Canton, located west of the city centre, with approximately 10,000 inhabitants. The concept of connecting the municipality of Bernex to Geneva via a tramline was initially introduced in the Canton of Geneva's master plan of 2001. The urban development initiative for Bernex emerged in the Plan Guide of 2010, subsequently confirmed as a priority project. in *Plan Directeur* of 2013 with a significantly wider footprint (Figure 12). The project aimed to establish a nearly continuous corridor of urban expansion along the tramline from Geneva's centre to the outskirts of Bernex. This entailed developing the northern part of the municipality, primarily consisting of agricultural land. The Canton envisioned the new development with intermediate to high density. Named *Grand Bernex*, the plan encompassed 150 hectares divided into two zones: Bernex-Nord and Bernex-Est. The proposed development aimed to accommodate 12,000 new residents and create 5,000 jobs by 2030, doubling the municipality's current population. Concurrently, the tramway extension, co-financed by the Confederation, commenced with the initial extension to the municipality's entrance, completed in 2011 and reached the end of the commune ten years later. As early as 2013, certain municipalities, the Green Party of Geneva, and the ASBEC (Association Qualité de vie à Bernex et Confignon) initiated opposition against the project.

The opponent of the Green Party expresses the inconsistency of attempting to transform this end-of-line municipality into a 'regional centre', envisioned to lead to suburbanisation [7]. Despite the acknowledging the need to house new populations in the Canton, the association formally opposes the excessive reclassification of agricultural land, highlighting the inherent tension between preserving open spaces and increasing density. Additionally, they criticise the municipality's car-centric development plan, particularly the construction of a new 2x2 lane road to Geneva despite the availability of direct tram access to new neighborhoods.

The approval of Geneva's *Plan Directeur* by the Swiss Confederation in 2015 came with reservations, requiring the canton to reduce the projected impact on agricultural

[7] LE GRAND PROJET DE BERNEX NORD / EST, La transformation des territoires bernésiens entre ville et campagne. Vision et orientation d aménagement. Les Vert Genève, February 2015.

land. Consequently, the footprint of planned developments, including the *Grand Bernex* project, had to be diminished. This led to a reduction in the project's size and a postponement of the Bernex-Nord development. While the reduction in parcel size occurred, the population objectives remained the same, necessitating increased density. Current plans involve the construction of 2,800 new housing units and 2,550 jobs in the Bernex-Est and Vailly sectors, with the municipality committed to completing an initial phase of 1,600 housing units and 1,600 jobs by 2030. The remaining densification is expected to be pursued after 2030 without a specific timeline. Ultimately, Bernex-Nord is still projected to accommodate 5,700 housing units and 5,700 jobs, although no timeframe has been set for this densification due to current feasibility issues.

Figure 13. First development phase, 2024.
Source: ge.ch

For the first development phase (Figure 13), every parcel for which the commune publishes a localised neighborhood plan, local associations oppose through referendums. The oppositions highlight concerns about transforming agricultural or natural land into urban development zones, objections to perceived excessive density, and criticisms of the quality of new neighborhoods. The last referendum initiated by the Association Communale Bernésienne (ACB) opposes the development of Bernex-Vailly, characterizing it as a 'hyper-urban' project in a peri-urban context. Central to the criticism are the proposed density and building height, with the suggested limit of 29 meters seen as 'destroying the villages quality'. This opposition underscores the clash between the entrenched village imagery within the municipality and the proposed urban development, despite an acknowledgment of the commune's peri-urban nature.

The current situation in Bernex illustrates a challenge where a cul-de-sac tram infrastructure intended to stimulate urbanisation faces obstacles due to the imperative to preserve agricultural land. Contribute to housing construction delays in the Canton of Geneva, this problematic emphasises the imbalanced development between both sides of the agglomeration. The case highlights the complexity of steering urbanisation through large-scale projects in the Swiss context.

Saint-Genis-Pouilly - Urbanity without transport

Saint-Genis-Pouilly is a municipality of the Pays de Gex located on the French side of the agglomeration bordering Switzerland. Since the institution of the first PA, this town, with a population of 12,000 and the triangle it forms with the municipalities of Thoiry (6,000 inhabitants) and Sergy (2,500 inhabitants), was identified as a regional centre earmarked for the development of a structuring public transportation axe toward Geneva. In 2012, with the second PA2, the GLCT reduced the project by abandoning Thoiry and a new terminus in Saint-Genis (Figure 14). Concurrently, already deferred to a horizon of 2050 in PA2, the line's rehabilitation intended to connect the municipalities of Pays de Gex disappears in the third PA. Co-funded by the Swiss Confederation, the Swiss portion of the tramway line connecting the Geneva train station to CERN

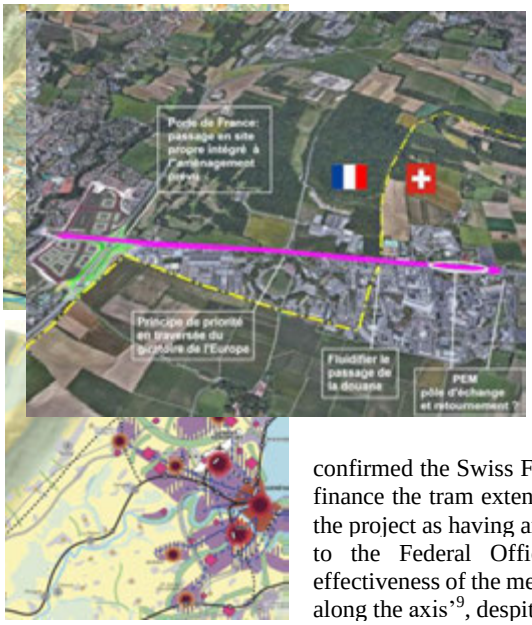

Figure 14. Top(a): PA1 extract, 2007. Bottom(b): PA2 (extract), 2021. Source : GrandGenève.org

via the Swiss municipality of Meyrin was inaugurated in sections between 2007 and 2011. As of today, the line terminates at CERN, the European research hub located 300m from the border.

In 2015, during discussions on co-financing agglomeration measures, the Swiss Confederation downgraded the tram section intended to connect CERN to the centre of Saint-Genis-Pouilly to a non-priority project. As a result, the Pays de Gex intermunicipality removed the project from its spatial development plan. Furthermore, the agreements regarding the third-generation urban development project confirmed the Swiss Federal Council's definitive decision not to co-finance the tram extension. This decision was justified by assessing the project as having an 'insufficient degree of maturity'[8]. According to the Federal Office for Spatial Development (ARE), 'the effectiveness of the measure is low due to insufficient current density along the axis'[9], despite this corridor being subject to a *contrat d'axe* since 2012. Whit the *contrat d'axe*, in exchange of the financing of the infrastructure by the Ain Department, the inter-communality of the Pays de Gex and the municipality of St-Genis-Pouilly commit to focus urban growth within a radius of 500 meters around tram stops. Hence, in addition to densification projects in the urban core, an operation involving the construction of 1,400 housing units and associated public facilities just after the customs checkpoint is currently under construction (Figure 15).

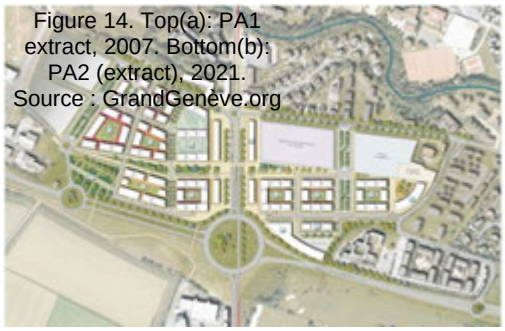

Figure 15. urban extension around the tramway, 2012. Source : RR&A

In 2015, a citizen petition led by the Franco-Swiss cross-border association, the *Groupement transfrontalier Européen*, in collaboration with the municipality of Saint-Genis-Pouilly, garnered over 3,500 signatures to contest the abandonment of the tramway project and advocate for its necessity to improve the quality of life for the city's residents. In response to this mobilisation, the Conseil Departmental de l'Ain, along with the municipalities, committed to financing the 2.1-kilometer extension of the tramline between CERN and the centre of Saint-Genis-Pouilly. However, Geneva was left responsible for completing the missing 300 meters on the Swiss side. After being repeatedly postponed due to political discord, lack of funding, and Geneva Canton's prioritisation of

[8] Accord sur les prestations entre la confédération suisse, le canton de Genève et le Canton de Vaud concernant le projet d'agglomération Grand Genève, 2e génération 2011-2012, 2012. (Authors' translation)

[9] *Ibidem*

projects on the other side of Pays de Gex, which were co-financed by the Confederation, the project was eventually scaled down. In 2019, France and Swiss representatives signed a new partnership, in which the Ain Department along with the Pays de Gex inter-communality committed to constructing a BRT connecting the border to the centre of Saint-Genis (Figure 16). Its completion is scheduled for 2026. The primary reason for this decision is budgetary since the implementation of the BRT is approximately 2.8 times less costly than the tram. Moreover, the former can be implemented with or without the Swiss connection, which was not the case with the tram. However, the Geneva Canton has committed to creating dedicated bus lanes on its side of the border. Therefore, a BRT will be delayed compared to the ongoing development, resulting in a transit rupture between Geneva and Saint-Genis.

Figure 16. BRT project, 2023. Source : Pays de Gex Agglo

The rejection of the tramway extension toward France in favor of prioritizing Switzerland's national territory and international connectivity symbolises a clear reluctance to meet cross-border metropolis needs, both from the Confederation and the Canton of Geneva, while still benefiting from its international advantages.

These examples reveal how transport and urbanisation strategies differ across the border. Cross-border cooperation fails to eliminate inequalities of treatment between national territories, with urbanisation subordinated to transportation on the Swiss side, and transportation subordinated to development on the French side. This disparity is further reinforced by disparities in citizen's capacity and institutional differences. However, in both cases the growth-oriented corridor vision, which neglects historical, morphological, and perspective contexts, shows it limits with the growing awareness toward land preservation.

Conclusion

The implementation of the current radio-centric TOD regional vision in Great Geneva reveals paradoxes that outline internal tensions within the asymmetrical cross-border metropolis between territorial cohesion discourse and metropolisation processes.

The projects discussed here illustrate discrepancies between political discourse, cross-border cooperation intentions, national priorities, and local reception. They underscore how technical and economic rationales behind the regional vision tends to overlook the bi-national and local realities, leading to the re-emergence of divides between rural and urban imaginaries, centre and periphery, and national territories, in the interplay between classic metropolitan divisions and transborder asymmetry.

These projects and their contestations demonstrate the entanglement of scales and the complex relationship between involved actors. Beyond institutional and socioeconomic asymmetry, national policies and regulatory systems significantly impact metropolitan development. Moreover, differences in democratic structures and planning expertise question the cohesive implementation of the model. Hence, conflicting political interests manifest in the metropolis in addition to different capacities among actors, leading to differences in treatment.

But more fundamentally, the paradoxes that emerge between connectivity and specialisation, autonomy and interdependence, and preservation and growth reflect conflicting ideals about the metropolis' future. They challenge the implicit hierarchical relationships and roles assigned to different metropolitan entities by the current development model. While TOD offers regional accessibility, intended to connect the different part of the agglomeration though sustainable modes of transport, its implementation supports classical metropolisation processes, growth through functional

specialization, spatial differentiation through selectivity and hierarchization. Hence, the paradoxes illustrate the role of the current radio-centric TOD model in perpetuating and even enforcing socio-spatial inequalities, rather than striving for territorial cohesion. Overcoming these paradoxes, therefore not only demand to homogenize development modalities and policies, but to address current development lack of attention to contextual dimensions and divides that are being reproduced by it.

Keywords: *changes, transport modes, mobility policies, urban models, actors, South, gender, critical studies*

Our societies are currently undergoing a series of transitions: ecological, energetic and digital. This context calls for changes in mobility behaviours as well as in transport and urban planning policies. The aim of this track is to question these changes. What changes have already occurred? What changes are coming? This track welcomes contributions on ways of conceptualising, theorising, and empirically examining these changes in different geographical contexts.

Topics to be addressed include, for example:

- Changes in transport modes: what changes in car ownership and use (young people's relationship with cars, peak-car, post-car world, the future of electrification and autonomous vehicles, etc.)? Has the cycling revolution happened (where, how, for whom, etc.)? Will the pedestrian revolution happen (where, how, for whom, etc.)? What is the future of shared mobility?
- Changes in transport and urban planning policies: in recent years, new urban models have been proposed to promote sustainable mobility (Superblocks, the low traffic neighbourhood, 15-minute city, Car-free city, tactical urbanism, etc.). What did that change? What are their limits?
- Changes in mobility policies' design and implementation: new players have emerged in the mobility sector (Uber, Lime, etc.). What changes did they introduce to sustainable mobility management? Are sustainable mobility policies still designed, produced and managed in a top-down fashion? What role for bottom-up actors (diverse social actors, groups and movements) play in shaping sustainable mobility policies?
- Changes in theoretical and methodological approaches: new theoretical approaches have been developed, namely gender studies, global south studies, postcolonial studies, etc. What does it change when we study sustainable mobility from a gender perspective? From a Southern perspective? What are the benefits and limitations of

critical transport studies? What new methodological approaches are implemented to study mobilities?

Deciphering the Scaling Laws and Spatial Structure in Urban Micro-mobility: Empirical Evidence from Bike-Sharing in Shanghai

Abstract
Micro-mobility, including bicycles and other low-speed vehicles, significantly enhances urban mobility and provides a sustainable alternative to traditional transport modes. Despite extensive research on the universal laws in urban mobility and its impacts on urban growth, the empirical distribution and allometric scaling phenomenon of micro-mobility like bike-sharing remain poorly understood. This study delves into the scaling laws and spatial dynamics specific to micro-mobility using bike-sharing data from Shanghai. The number of cycling visitation to any location in the city is inversely related to the square of the cycling distance multiplied by the frequency. This scaling relationship is controlled by a parameter that describes the attractiveness of different locations in the city for cycling. It is noteworthy that the size distribution of the spatial clusters, as determined by spatial clustering analysis of the attractiveness, conforms to Ziff's law. This implies that the spatial structure underlying the cycling is a highly ordered, hierarchical system, which coincides with the central place theory. This study provides a framework that can effectively predict the distribution of micro-mobility within a city, which can help to understand and utilize the dynamics of complex urban systems in order to promote more sustainable urban mobility solutions.

Introduction

The burgeoning field of micro-mobility has emerged as a critical component in addressing the complexities of urban transportation and sustainability (Reck et al., 2022, Abduljabbar et al., 2021, Madapur et al., 2020). As cities grapple with escalating traffic congestion and environmental concerns, micro-mobility offers an innovative solution by promoting bicycles and other lightweight, low-speed vehicles as viable alternatives to traditional motorized transport (Abduljabbar et al., 2021, Steinacker et al., 2022, Diao et al., 2021). This shift not only promises to enhance urban mobility but also aligns with broader sustainability goals by reducing carbon emissions and improving public health (Diao et al., 2021, Zhang and Mi, 2018, Abduljabbar et al., 2021). During the outbreak of the COVID-19 pandemic at the end of 2019, bike-sharing systems were responsible for more than half of urban transportation during the lockdown period (Zhu et al., 2022, Shaer et al., 2021, Hu et al., 2021, Teixeira and Lopes, 2020).

Extensive research on urban mobility has explored the scaling laws that describe how the empirical distributions of urban mobility change with various factors (Dong et al., 2022, Schlapfer et al., 2021, Song et al., 2010, Yan et al., 2013, Wang et al., 2014). For instance, it has been shown that the taxis visitation in various locations in city follows a power-law distribution (Zheng and Zhou, 2017). Studies have found that this power-law distribution is influenced by factors such as travel distance (Schlapfer et al., 2021, Zheng and Zhou, 2017, Wang et al., 2023). Similarly, research into how population density and urban form affect mobility patterns reveals that larger cities exhibit non-linear increases in travel times and transportation costs due to congestion (Louf and Barthelemy, 2014). These studies highlight the complex interdependencies between urban growth, mobility, and infrastructure. However, most existing research has focused predominantly on conventional modes of transportation, such as cars and public transit, with less attention given to micro-mobility programme like bike-sharing. Although micro-mobility offers potential sustainability benefits by reducing reliance on motorized transport, its dynamics within the urban systems remain underexplored. Furthermore, studies have investigated the relationship between the built environment and cycling activities, emphasizing how urban design factors influences cycling frequency and distance (Cervero and Duncan, 2003, Moudon et al., 2005, Cervero et al., 2009, Buehler and Dill, 2015, Xu et al., 2019). Despite the contribution of these studies, they tend to remain descriptive and static, failing to fully take into account the underlying phenomenon of allometric scaling in urban mobility (Alessandretti et al., 2020, Batty, 2013, Bettencourt, 2013). This gap highlights the need for more dynamic studies that can better explain the allometric scaling phenomenon of micro-mobility systems and their impact on urban dynamics.

This study seeks to address the gaps in understanding the specific scaling laws and spatial dynamics of urban micro-mobility, using extensive bike-sharing data from Shanghai. By analyzing cycling trajectories and usage patterns, this study confirms that cycling visitations are strongly influenced by cycling distance and frequency, exhibiting a power-law distribution, which is modulated by a parameter reflecting the attractiveness of various city locations for cycling. Notably, the size distribution of these attractiveness clusters, as determined by spatial clustering analysis, adheres to Zipf's law. This finding suggests that the spatial structure of cycling mobility in the city is highly ordered and hierarchical, aligning well with central place theory. The results underscore the importance of integrating these insights into urban planning and transportation strategies, emphasizing how micro-mobility can play a pivotal role in shaping sustainable urban growth. Ultimately, this paper advances the discourse on the universal laws of micro-mobility and contributes a novel framework for enhancing urban planning through the lens of bike-sharing data.

Results

The scaling laws of Micro-mobility in Shanghai

We fitted the relationship between the number of bike visitations and the travel distance or the frequency of cyclists visiting the same location by bike in a week separately (Fig. 1a, 1b), revealing that the number of visitations N decreased proportionally with the increasing travel distance r when only considering distance. When considering the travel frequency f over a continuous week, N also decreased proportionally with increasing f for each cyclist. Similarly, when treating distance r and frequency f as a combined variable rf, the relationship between rf and N followed a power-law distribution with a fixed exponent between 2.4-2.8 (Fig. 1c, 1d). This implies that the number of bike visitations to any location in the city depends solely on the travel distance and frequency. Therefore, the relationship between the bike visitations to any location i in the city and the distance-frequency can be described as a power function (Equation 1).

$$N_i = \frac{\mu_i}{(rf)^{-\eta}} \qquad (1)$$

Since the power-law exponent η is a fixed value, the constant term μ_i determines the magnitude of bike trip attractivity at any location in the city, which can be considered as the " attractiveness" for micro-mobility. We conducted power-law fits for the top 30 grid cells with the highest bike trip attractiveness in Shanghai, and found that the power-law relationship was significant with a fitting R^2 of around 0.99 (Fig. 1e). Moreover, this scaling law of bike was not influenced by the specific spatial position of the analyzed unit, indicating its universality (Fig. 1f).

Attractiveness of Micro-mobility visitations and its spatial structure

As previously described, this study has derived a power-law function that indicates the bike visitation of any location in the city only depends on the constant term μ_i when the product of travel distance and frequency is constant. Therefore, the constant term μ_i in the power-law function can be considered as the attractiveness of a location for bike visitations, which

characterizes the spatial interaction of urban internal space based on bike-sharing flows (Fig. 2a).

By observing the spatial distribution characteristics of μ_i, a significant phenomenon can be observed, that is, grids with higher attractiveness tend to exhibit an agglomeration distribution, forming some larger central clusters, such as Jing'an Temple and People's Square, Shanghai. Grids with lower attractiveness tend to be clustered around these central clusters. Meanwhile, outside a certain spatial range, some smaller sub-central clusters with a larger number of grid units can be found. This spatial structure shows a strong correspondence with the central hierarchy structure in the central place theory. According to previous research on the spectrum of human flow based on mobile phone signaling data, this center-like distribution system, which is similar to a hierarchical scale, originates from the agglomeration effect of commercial and public service facilities in the city (Schlapfer et al., 2021).

To further verify the hierarchical nature of the spatial distribution of bike attractiveness, the City Clustering Algorithm (CCA) was employed to identify spatial clusters with different levels of attractiveness (Fig. 2b). The CCA involves setting a threshold for the attractiveness parameter μ and setting all values below the threshold to zero. Then, contiguous spatial locations with non-zero values are recursively merged into spatial clusters until all non-zero grid cells have been merged. Through the CCA, spatial clusters with significant differences in attractiveness can be effectively identified.

Subsequently, the size of each spatial cluster was fitted to a power-law relationship, known as Zipf's law, which is commonly used to describe the basic principle of urban size growth (Fig. 2c). The fitted results showed that the size distribution of the spatial clusters emerging from the bike flow conformed to Zipf's law, and the size-rank relationship was approximated by a power-law relationship with an exponent of 1.08. This indicates that there is a highly ordered hierarchical structure in the spatial locations towards which the bike flow is directed.

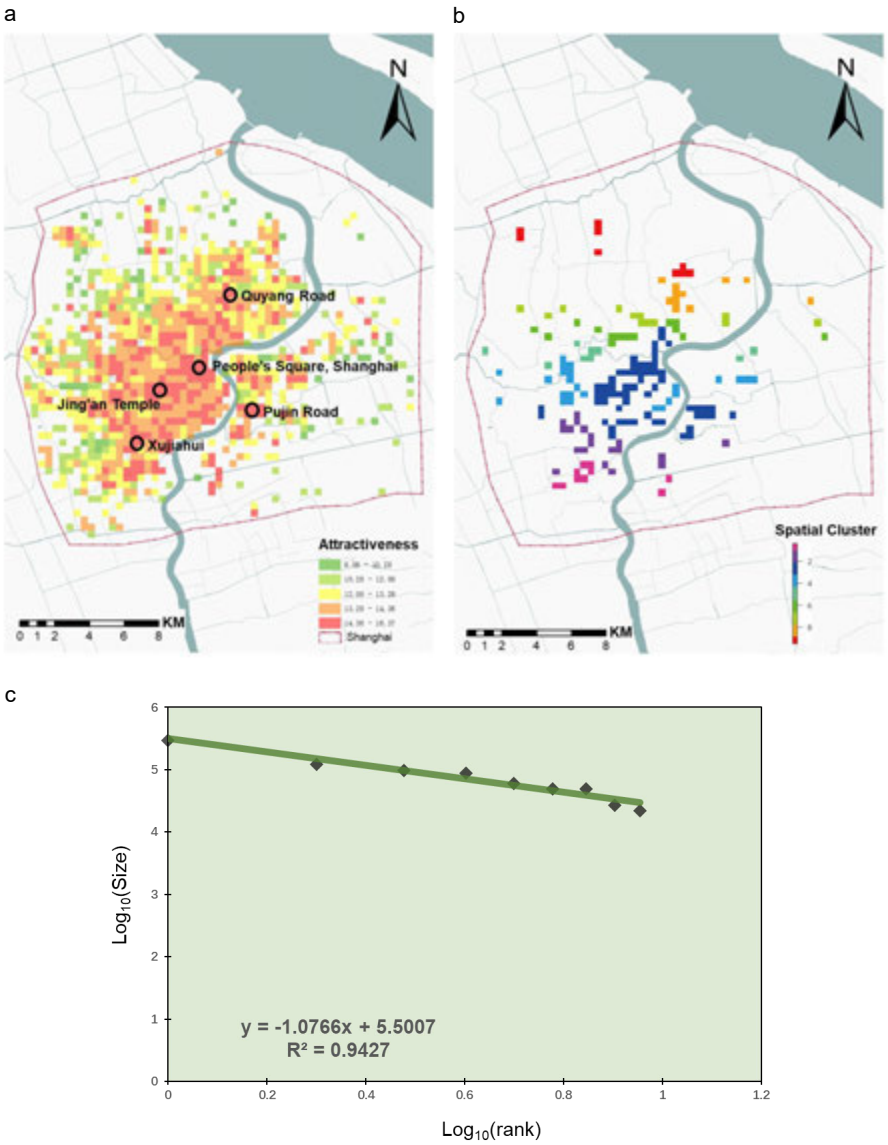

Fig.2| Spatial structure of micro-mobility attractiveness. a, Spatial distribution of the attractiveness μ_i. **b**, Spatial clusters based on City Clustering Algorithm. **c**, Rank–size distribution of the attractiveness of spatial clusters.

Discussion

The results reveal a empirical power-law distribution in the relationship between bike visitations and travel distance and frequency across varying locations in Shanghai. This finding

corroborates the existence of scaling laws in urban micro-mobility, which have been observed in other modes of transport across different urban settings (Bettencourt, 2013, Schläpfer et al., 2014, Dong et al., 2022, Schlapfer et al., 2021). Our results innovatively confirm the presence of allometric scaling phenomenon within short-distance, high-frequency micro-mobility patterns. This suggests that in urban settings, cycling activities are highly concentrated, with most cycling activities occurring over shorter, more frequent trips, while longer trips are relatively rare. The cycling power exponent discovered in this study is greater than 2, higher than the exponents for car travel found in existing studies, aligning with our understanding that micro-mobility is more sensitive to distance and frequency (Schlapfer et al., 2021). Moreover, this finding provides deep insights into the growth mechanisms of cycling networks. The presence of a power-law distribution suggests that preferential attachment and rich-get-richer effects exist within the cycling network (Fabiano L. Ribeiro, 2021). New or casual cyclists are more likely to choose cycling locations that are frequently visited, leading to disproportionate growth in activity at certain locations due to their accessible location, well-maintained facilities, or good connectivity. Over time, these areas will further consolidate their status as major cycling hubs, attracting even more cyclists. Urban planners need to consider existing cycling patterns and network effects when designing cycling infrastructure, by planning multiple attractive nodes or enhancing the interconnectivity of the entire network. Urban transport networks are dynamically evolving and require continuous monitoring and adjustment. Understanding and applying the principles of preferential attachment and rich-get-richer can assist urban planners in timely strategy adjustments to meet the changing needs of urban development and resident behavior patterns.

Furthermore, our findings indicate that the scaling phenomenon in micro-mobility is controlled by a parameter that describes the attractiveness of different locations in the city for cycling. It is noteworthy that the size distribution of the attractiveness clusters conforms to Zipf's law. This implies that the spatial structure underlying cycling mobility is a highly ordered, hierarchical system, which coincides with the central place theory. This orderliness likely stems from the varying influence of urban services and facilities provided at different sites (Schlapfer et al., 2021). At the micro-scale, typically where micro-mobility occurs, there are still multiple attractive nodes within the city that play central roles in driving mobility. These nodes may correspond to cultural facilities, commercial areas, parks, and other public spaces (M Batty, 1989, Tian et al., 2015). This pattern indicates that even at micro scales, the city structure exhibits fractal characteristics; that is, every part of the city, regardless of size, may reflect the structural features of the entire city. Such ordered spatial distribution suggests that the form and function of the city maintain consistency and continuity across different scales, with each community or neighborhood acting as a microcosm of the city structure. These findings not only enrich our understanding of the spatial structure at the micro-scale within cities but also provide valuable theoretical and empirical support for urban planning and sustainable transportation development. This insight emphasizes that even at the local scale, the design and planning of urban spaces must consider their complexity and inherent orderliness.

In conclusion, this study presents novel evidence regarding the empirical distribution and allometric growth of intra-urban micro-mobility. It is demonstrated that this short-distance, low-speed sustainable mode of transportation is subject to scaling laws, in a manner analogous to other forms of mobility. Furthermore, the study reveals the underlying spatial structure that governs the scaling law of micro-mobility. This structure is characterized by a highly ordered and hierarchical spatial configuration, influenced by factors such as "preferential attachment" and the "rich get richer" effect. This study provides urban planners and policy makers with a robust analytical framework that can effectively predict the distribution of micro-mobility

within a city. This framework can be used to understand and utilize the dynamics of complex urban systems in order to promote more sustainable, efficient, and convenient urban mobility solutions. For future research, it is essential to conduct longitudinal studies to assess the temporal stability of these scaling patterns and delve into the causative mechanisms behind the observed power-law distributions and spatial clustering. Such studies will enrich our understanding of how urban micro-mobility systems evolve over time, offering insights that could refine current urban planning and policy strategies.

This study acknowledges several limitations. First, the temporal scope of the bike-sharing data used is confined to a single week. This short duration may not adequately represent the distance-frequency distribution of cycling trips over a more extended period, potentially limiting the generalizability of the cycling visit patterns observed. Second, while this study introduces an attractiveness parameter, its mathematical and practical significance, along with its correlation with the characteristics of the built environment, requires further exploration to fully understand its implications. Lastly, as the analysis focuses solely on central city of Shanghai, the applicability of the findings to other urban settings, both within China and globally, may require additional validation.

Data

This study utilizes large-scale bike-sharing data to explore the universal laws of cycling visits across various districts within Shanghai. The focus is specifically on the city center, defined as the area within the Outer Ring Road. This region, spanning approximately 660 square kilometers, includes the historically established urban districts of Huangpu, Xuhui, Changning, Yangpu, Hongkou, Putuo, and Jing'an, as well as the Inner Outer Ring Road areas of the Pudong New Area (Fig. 3a). Shanghai's location at the eastern edge of the Yangtze River Delta provides relatively flat terrain and a climate favorable for cycling. As one of the pioneering cities in adopting bike-sharing systems, Shanghai boasts a fleet of over 1.3 million bicycles, facilitating frequent usage among a relatively stable user base.

The data utilized in this study is the Shanghai shared bike order dataset provided by Meituan. This dataset encompasses over 4.6 million shared bike orders from over one million anonymous users over the course of a single week (June 17th, 2019 to June 23rd, 2019). The data includes order number, user number, bike number, start time, start location latitude and longitude, end time, end location latitude and longitude, and other pertinent information.

The preprocessing of the bike-sharing dataset in this paper is comprised of three distinct steps (Fig. 3b). In the initial stage of the study, the area under investigation is divided into a regular grid comprising square cells of uniform dimensions, with a side length of 500 meters. A total of 2,551 grid cells were obtained within the central city of Shanghai. Subsequently, the bike-sharing trip data with spatial and temporal location information were intersected with the regular grid in ArcGIS, and the bike-sharing data with obvious anomalies were excluded. In the second step, the set of individuals who have accessed the cycling network in each grid cell is identified. For each grid cell, this paper calculates the weekly frequency of cycling visits to the grid cell within a consecutive week's time span. Concurrently, the distance traveled by cyclists is calculated based on the starting point of their journey. In the third step, the riding visits are obtained by calculating the riding distance and riding frequency, respectively. The initial distance for the riding distance grouping is set at 800 metres, with the riding visits within each distance group calculated sequentially with an equal distance bin of 300 metres.

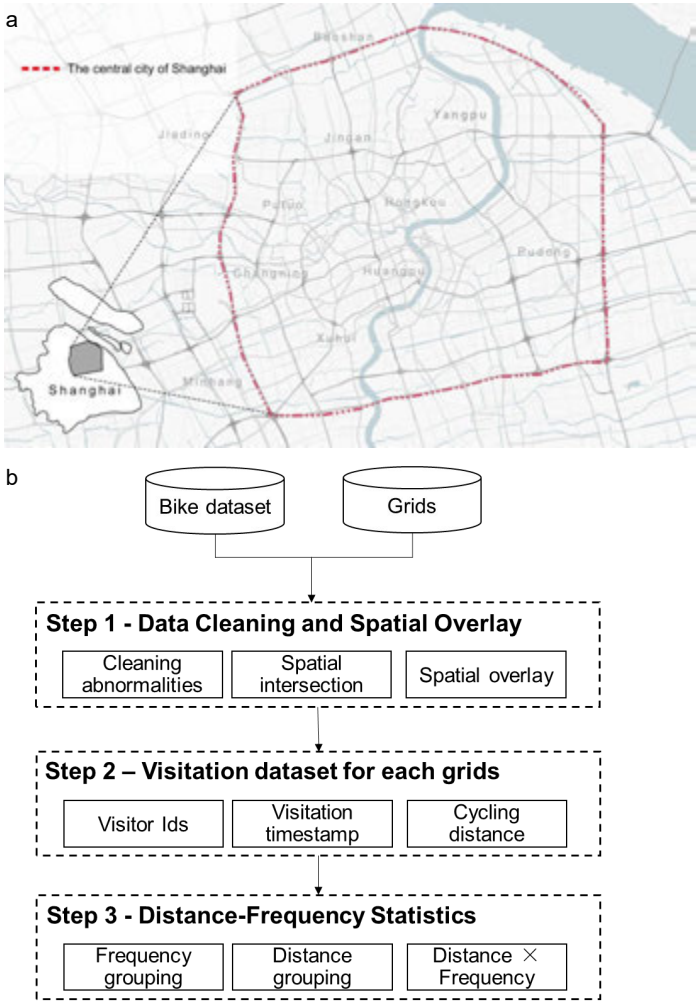

Fig.3| Data. a, Study area. **b**, Data pre-processing.

Methods

Scaling laws are known to exhibit power law distributions, which can reflect self-similar features in the process of urban scale growth or scaling of human travel behavior. This phenomenon has been observed in various studies, including those by Batty (2019), Schläpfer et al. (2021), Gong et al. (2021), Batty et al. (1989), Rybski et al. (2019), and Longley et al. (1989). In this paper, we employ the power function form of the scaling law to fit the relationship between cycling and distance and frequency. This reflects the quantitative scaling relationship between cycling visits and cycling distance and frequency. The functional form is as follows (Equation 2).

$$N = Y_0 X^{\eta} \qquad \text{(Equation 2)}$$

Where, the number of bike visitations to any location in the city, denoted by N, is a function of the travel distance, frequency, and the product of distance and frequency, which is represented by N. The parameters of the power function, denoted by Y_0 and η, influence the scaling factor, which is typically fixed (Batty, 2015, Batty et al., 2008). The coefficient, Y_0, influences the power-law relationship. The simultaneous application of logarithms to both sides of Equation 2 yield the linear functional form (Equation 3).

$$LogN = \eta LogX + logY_0 \qquad \text{(Equation 3)}$$

Where, the slope of the fitted straight line for a linear function represents the power exponent of the power function, denoted by η. Consequently, the logarithmic approach to fitting was employed in this study (Equation 3).

Exploring the Assessment and Strategies of Street Inclusivity in Suzhou, China

Liu Jiayi Li Yanbin

ABSTRACT

Nowadays, the concept and significant value of inclusive development are widely recognized globally, making it a fundamental principle in urban planning. Simultaneously, urban spatial development has transitioned from incremental expansion to stock renewal. From strict separation between market blocks to integrated, there is a trend of diversity and inclusion in the spatial form and functionality of streets. Guided by this principle, street design aims to accommodate people of different genders and age groups, thereby promoting more profound face-to-face communication and social activities. In the context of advocating for a fair, diverse, and inclusive urban spatial renewal, it is essential to exploring how to better accommodate various social activities, functional layouts, and the experiences of stakeholder. Creating a friendly and integrated street environment is crucial to further enhance urban inclusivity and social openness. This effort holds significant practical importance.

As one of Chinese pilot cities for urban renewal, the city of Suzhou boasts a rich array of distinctive characteristics and historical streets. This paper selected four representative types of streets in Suzhou, using multiple sources of data such as street scenes,Point of Interest(POI) and Location-Based Services (LBS). A street inclusiveness assessment system was constructed to interpret street factors from three dimensions: spatial comfort, functional convenience, and human activities.This study analyzed the correlation between indicators, and uses the Analytic Hierarchy Process (AHP) to determine indicator weights and standardized values. The assessment of inclusive scores for the four streets were calculated. For the measurement of certain indicators, the study adopted the GSAM (Grounded Segment Anything Model) to segment and recognize objects. This model has the capability to automatically segment objects in images or videos, generate high-quality labels, and produce measurement results for the factors with a single click. The total score for inclusivity assessment of the four streets is ultimately determined through a combination weighting method.

The results of street inclusive assessment indicated that: (1) "Historical Character Streets" presented good performance across various indicators.This marked them suitable for creating highly inclusive and vibrant gathering spaces. (2) The high street penetration rate and density of store facilities demonstrated the potential for inclusive vitality of "Lifestyle and Culture Streets". (3) "Modern Distinctive Streets" performed better in terms of sky openness and pedestrian friendliness,but have a lower greenery ratio. (4) "Lifestyle Landscape Streets" had a higher quality of greenery and accessibility to other parks, but they showed lower inclusion attributes towards functional formats and human activities. Correlation analysis founded that as street building enclosure increases, the proportion of cultural facilities distribution also increases accordingly, providing a wider range of cultural activities. The indicators of accessibility to park and greenery spaces revealed a positive correlation with the proportion of business facilities, indicating a preference for environmentally superior areas among commercial establishments. In terms of inclusion assessment scores, "Historical Character Streets" and "Lifestyle and Culture Streets" received higher evaluation scores , while "Modern Distinctive Streets" and "Lifestyle Landscape Streets" exhibited lower values in this regard. Accordingly, based on the specific presentation of

indicators for these four types of streets, the study proposed corresponding renewal strategies, aiming to assist the relevant authorities in improving the inclusion and vitality of streets. It will enhance the quality and happiness of community residents.

KEYWORDS: Street Inclusion ; urban space; Streets classification; Assessment of Inclusivity; scenario strategies

1. Introduction

Currently, urban development in China has shifted its focus from expanding the quantity of cities to updating existing areas[1]. Streets, as a crucial component of urban space, play an indispensable role in city renewal and have garnered widespread attention. The transformation from strictly separated market districts to integrated street life reflects a diverse and inclusive trend in the form and function of street spaces. Enhancing inclusivity from all aspects has gradually become a focal point for evaluating streets' ability to better meet various social activities, functional formats, and people's experiences while creating a friendly and harmonious environment. This is also one of the critical directions for street renewal work. However, during recent years' urban renewal processes, there has been homogenization in street space design with insufficient consideration for inclusivity resulting in inadequate attractiveness of streets. Based on this issue, this paper establishes an inclusive evaluation system for streets and selects four distinctive streets in Suzhou City as empirical case studies to explore ways to enhance vitality and inclusivity during urban street renewal work.

The concept and value of inclusive development are widely recognized globally at present[2]. The inclusiveness of urban streets is reflected in their capacity to accommodate buildings and facilities on both sides, as well as in their design concepts that promote equilibrium in areas such as economy and culture[3]. Guided by this principle, street design aims to cater to individuals of diverse genders and age groups, thereby fostering more profound and varied face-to-face communication and activities[4]. In the field of urban planning, streets refer to roads within urban areas primarily utilized for daily life services and social activities for residents, encompassing elements such as ground-level shops, open spaces, and service facilities connected to the streets; all these elements can impact street inclusiveness[5]. Simultaneously, inclusive development necessitates comprehensive consideration of the needs of vulnerable groups while seeking consensus through negotiation to resolve potential conflicts between different group demands and avoid excessive polarization. Currently advocating for harmonious livable modern cities entails not only meeting basic functional requirements in urban street facilities but also adhering to a "people-oriented" value perspective[6].

In theoretical terms, the concepts of 'inclusive design' and 'universal design' were proposed in the 1990s[7]. By studying the changes in elderly people's perception of outdoor environments, the book 'Inclusive Urban Design - Living Streets' puts forward six design principles and provides detailed discussions[8]. At the level of urban public space design, starting with inclusive design for families with children, creative transformations are made to public spaces such as streets to meet

different population characteristics and regional requirements[9]. Inclusive design for older people needs to adhere to principles of hierarchy, accessibility, safety, and psychological well-being[10]. Additionally, vibrant spaces can better integrate multiple functions, purposes, and choices[11].

In terms of quantitative analysis, previous studies have primarily focused on examining the impact of inclusive pedestrian facilities and proposed a novel model (PLOS) for evaluating and enhancing the influence of street infrastructure on pedestrian service levels[12]. In order to realize an all-encompassing vision for streets, a comprehensive questionnaire survey and logistic regression analysis were conducted in Singapore to assess six dimensions of urban street design: accessibility, connectivity, streetscape, safety, vibrancy, and greenery[13]. The evaluation of sociality in commercial streets revealed that spatial accessibility significantly influences user participation in street activities[14]; mixed-use formats and favorable pedestrian experiences positively contribute to the creation of inclusive social spaces[15]. Furthermore, it was found that the urban street vitality and inclusivity is closely intertwined with their external representation as well as constituent elements.

The external representation primarily encompass crowd gathering intensity and commercial activity frequency. For instance, mobile signaling data is utilized to investigate the spatiotemporal distribution of crowds, aiming to explore the correlation between waterfront spaces and vitality[16]. Simultaneously, it delves into the deficiency of vitality in commercial pedestrian areas to comprehend users' evaluations of nodal spaces, buildings, and crowd activities[17]. In terms of constituent elements, diverse research methods are employed including establishing a vitality system for historical block public spaces based on dimensions such as spatial accessibility, spatial quality, and attributes[18]. Factors like sidewalk width and ground floor interface transparency exert influence on staying behavior within commercial pedestrian areas[19]. The examination of factors like social functional density and functional mix enables an exploration of the relationship between environment and citizen activities while enhancing street space quality. Furthermore, the study highlights that ground-level commercial facilities impact attractiveness while transportation convenience relies on spatial structure accessibility[20].

Currently, research on the assessment of street inclusivity primarily focuses on theoretical foundations, design strategies, and evaluations of vitality composition. However, there is a lack of analysis that combines urban street vitality and inclusivity assessment with quantitative indicators. Existing studies on specific types of streets are still too general and require more detailed classification to reflect their characteristics and diversity. In this study, we conducted feature analysis on pedestrian-oriented streets in Suzhou City and identified outstanding historical value, strong sense of life, and distinctive architectural styles from different eras as the basis for classifying these streets. The streets under investigation are categorized as follows: firstly, "Historical Comprehensive Streets" (Pingjiang Road) which possess significant historical and cultural heritage, serve as tourist attractions with intellectual property functions, offer comprehensive commercial services, and attract a substantial number of tourists; secondly, "Historical Life Service Streets" (Fengmen Hengjie) primarily focusing on life service functions while exhibiting a strong local atmosphere influenced by market trading activities; thirdly, "Modern Comprehensive Streets" (Huaihai Street) characterized by high commercial density and closely arranged shops with a modern style and distinctive ambiance; fourthly, "Modern Life Service Streets" (Xietang Old Street) featuring beautiful landscape environments while predominantly serving life service functions. By assessing the inclusiveness level of these four

types of urban streets, our aim is to effectively harness their inherent potential in order to enhance residents' quality of life.

2. Study area and Methodology

2.1 Research scope

As one of the pilot cities for urban regeneration, Suzhou has diverse historical and cultural districts with distinctive characteristics, forming streets that exhibit diverse historical and modern styles. This study primarily relies on high-frequency street vocabulary from social platforms such as Xiaohongshu and Dianping, along with popular check-in streets from hotlists, for the purpose of identifying 44 frequently mentioned "internet-famous" streets in the urban area of Suzhou. Based on their main features, these streets were manually reviewed and classified into four types: "Historical Comprehensive Streets", "Modern Comprehensive Streets", "Historical Life Service Streets", and "Modern Life Service Streets" (refer to Table 1). Among these, "Historical Comprehensive Streets" encompass historically significant cultural streets in Suzhou, characterized by high cultural value, diverse functions, and strong tourist attraction. "Modern Comprehensive Streets" are distinguished by high levels of commercial development, spaciousness , and well-equipped facilities. "Historical Life Service Streets" are often influenced by market trading hours and emanate a strong local atmosphere of bustling life. "Modern Life Service Streets" boast beautiful landscapes and a serene atmosphere, with unique street styles. Based on the results of classification, our study ultimately selected Pingjiang Road, Huaihai Street, Fengmen Heng Street, and Xietang Old Street as four representative examples of streets (as shown in Figure 1), and evaluated their inclusiveness from specified perspectives and data indicators

Table 1 The classification and screening of Suzhou city streets

Classification	Street
Historical Comprehensive Street	Pingjiang Road, Shantang Street, Wusha Road, Taohuawu Street,etc
Modern Comprehensive Street	Huaihai Street, Gongyuan Road, Zhongjie Road, Jinfan Road, etc
Historical Life Service Street	Fengmen Heng Street, Daoqian Street, Pishi Street, Dongzhong Market, etc
Modern Life Service Street	Xietang Old Street, Dashitou Alley, Ximei Alley, Yangyu Alley, etc

Figure 1 Street location map of this study

Pingjiang Road, recognized as one of the first historical and cultural streets in Suzhou, spans approximately 1606 meters. It exhibits a delicate texture and a street pattern resembling fish bones. Adorned with grey tiles and the style of a water town, Pingjiang Road displays its unique charm and rich cultural heritages. While the natural landscape along the street is commendable. It serves as an important tourist attraction and a prominent symbol of Suzhou. Huaihai Street, known for its Japanese-style charm, is designated as a "national-level famous and characteristic commercial street." The present architectural texture is relatively orderly, with clean street interfaces and spacious pedestrian areas. However, it suffers from a lack of greenery and a sense of hierarchy.

Fengmen Heng Street, with its quaint and humanistic appeal, attracts many visitors with its traditional style and local market culture. The present architectural texture of Fengmen Heng Street exhibits relative fragmentation. It is essential to improve street cleanliness as well as greenery. Xietang Old Street creates a kind of antique leisurely life atmosphere, and the good natural environment provides a good place for local people to walk and relax.

Figure 2 Investigation on plane texture and present statuses of four streets

2.2 Construction of an inclusive assessment

This study involved manual selection of objects and on-site inspections, utilizing handheld cameras to capture street view images aligned with the line of sight, along with points of interest (POI) data and LBS data etc, for analysis and review. The study examined streets from three dimensions: spatial inclusivity, functional inclusivity, and social inclusivity. Sixteen indicators were selected.

Spatial inclusivity primarily reflects the pursuit of high standards of comfort. The space permeability reflects the street's capacity and friendliness. Street greenery emphasizes the perceived environmental quality. Sky openness contributes to improving urban microclimates and alleviating the pressure of individual living and working. Enclosure indicates the degree to which buildings, walls, and other structures enclose public spaces. A good enclosure degree provides a comfortable and shaded feeling. Street width-to-building height ratio and building width-to- street width ratio have significant effects on spatial behavioral cognition, especially when the street width-to-building height ratio is less than 1[21]. In narrow spaces, the sense of enclosure is strong, leading to feelings of oppression and affecting the walking experience.

In the dimension of social inclusivity., our study concentrates on the diversity of street businesses, considering living and public service facilities (such as telecommunication services and public toilets), catering facilities (such as restaurants and tea houses), and cultural facilities (such as art galleries and museums) within the street space. These functional venues not only meet people's basic needs but also stimulate consumer behaviors, thereby positively impacting the inclusiveness of the street. Commercial density reflects the intensity of urban development and the convenience of daily life. A higher degree of street business aggregation indicates a higher level of mixed-use, which is beneficial for shortening distances to destinations.

In terms of social inclusivity, the study indicators cover the accessibility of green spaces, public transit, pedestrian-friendliness, and the average density of crowds on weekdays and holidays. Accessibility to green spaces is related to the well-being of residents around the street, as these green areas serve as primary recreational spaces for daily activities, thereby attracting more foot traffic to nearby streets. The accessibility of public transit reflects the friendliness of people reaching the street, with well-developed public transportation providing more efficient and convenient commuting options for street stakeholders. Pedestrian-friendliness reflects the connectivity of the pedestrian traffic network, which can promote commercial and social activities. Crowd density reflects the real-time concentration of people and their activities on the street.The assessment of inclusive street is shown in Table 2.

Target Layer	Criterion Layer	Factor Layer	Data Collection
Assessment of Street Inclusivity	Spatial Inclusivity	Space permeability	$I_{sp}=\frac{S_{\text{ground window}}+S_{\text{ground door}}}{S_{\text{all}}}$ [22]
		Street greenery	$I_{green}=\frac{S_{green}}{S_{\text{all}}}$
		Sky openness	$I_{sky}=\frac{S_{\text{sky}}}{S_{\text{all}}}$
		Enclosure	$I_{en}=\frac{S_{\text{building}}+S_{\text{wall}}+S_{\text{fence}}+S_{\text{pole}}}{S_{\text{all}}}$
		Street width-to-building height ratio	$A_r=\frac{Sw}{Bh}$
		Building width-to- street width ratio	$A_r=\frac{Bw}{Sw}$
	Functional Inclusivity	Degree of business aggregation	$H=-\sum_{i=1}^{S}(P_i \ln P_i)$
		Proportions of living and public services	
		Proportion of catering facilities	$f_n(x)=\frac{1}{n\pi h^2}\sum_{n=1}^{n} K\left(1-\frac{(x-x_i)^2-(y-y_i)^2}{h^2}\right)$
		Proportion of cultural facilities	

	Commercial density	$D_{poi} = \frac{N_p}{L_r}$
Social Inclusivity	**Green space accessibility**	$D_{green} = \min d_{\text{green}}$
	Public transit accessibility	$D_{pt} = \min d_{\text{pt}}$
	Pedestrian friendliness	$I_{pf} = \frac{S_{\text{sidewalk}}}{S_{\text{all}}}$
	Average Crowded density on weekdays	$Density = \frac{1}{(radius)^2}\sum_{i=1}^{n}\left[\frac{3}{\pi}\cdot opp_i\left(1-\left(\frac{dist_i}{radius}\right)^2\right)^2\right]$, For dist_i <radius [23]
	Average Crowded density on holidays	

Table 2 The assessment of inclusive streets

2.3Methods

After specifying the research objects, this paper utilizes the deep learning technique: Fully Convolutional Network (FCN) model along with relevant methods to perform semantic segmentation recognition on the street image data in scenery surveys[24]. It extracts relevant elements and calculates the area proportions of each element in images. Simultaneously, the Grounded Segment Anything Model (GSAM) is employed to detect and extract target elements required for calculating the space permeability on the street[25]. This model can automatically segment object types in images or videos, generate high-quality labels, and derive element calculation results. The model employs street images of our study for calculation and analysis to ensure accurary and quality of data sources. In additional, the research quantifies relevant indicators through the Argis analysis and represents the crowd density level with heatmaps illustrating the population distribution.

In the process of weighting statistical indicators, this study initially employs the Analytic Hierarchy Process (AHP) to allow professionals to score the relative importance of indicators and calculate subjective weights through consistency tests.[26] Subsequently, the entropy weight method is utilized to determine objective weights by assessing indicators' relative degree of change in order to establish their weights within the overall system. Indicators with a greater degree of relative change are given greater weights to accurately reflect their importance in the overall system. Finally, a combination weighting method based on game theory is employed to calculate optimal weights for comprehensive subjective and objective indicators, thereby obtaining an inclusiveness score for the street. Due to data sources encompass multiple dimensions such as street view images, LBS and POI data with inherent differences in nature and measurement units, standardized processing of data becomes necessary. Additionally, descriptive analysis and correlation matrices are conducted on these indicators while revising and optimizing detection methods to enhance the efficiency and accuracy of results. This facilitates the credibility and correction of problems.

3. Assessment Result of Street Inclusivity

3.1 The determination of weight value

According to the evaluation system framework, this paper first employs the Analytic Hierarchy Process (AHP) to categorize the elements associated with evaluation decision-making into three levels: target, criteria, and factor layer. This includes one target layer, three criteria layers, and sixteen factor layers. Qualitative and quantitative analysis are conducted based on this framework. In this process, our study invited nine experts in architecture and urban planning as well as eleven relevant professionals to score the relative importance of indicators and calculate the results of subjective AHP weight values (Table 3), confirming that the judgment matrix meets consistency requirements.

On the other hand, the entropy weight method is an objective weighting approach used for determining indicator weights by evaluating their relative degree of change[27]. Sixteen factor-layers (X_1~X_{16}) are standardized, and within each indicator category, we calculate the proportion of each standardized value to all standardized values for that specific indicator (p_{ij}).

$$p_{ij} = \frac{X_{ij}^*}{\sum_{j=1}^{n} X_{ij}^*} \quad (1)$$

Subsequently, the entropy value(e_i) for each indicator is calculated.

$$e_i = -\ln(n)^{-1} \sum_{j=1}^{n} p_{ij} * lnp_{ij} \ \ (\text{if} \ \ p_{ij} = 0 \ , \ \ e_i = 0 \ ) \quad (2)$$

Finally, based on the entropy value(e_i) , the study determined the weights w_i(Table 3). for each indicator using a formula.(w_i)

$$w_i = \frac{d_i}{\sum_{i=1}^{17} d_i} \ (d_i = 1 - e_i) \quad (3)$$

The combination weighting model based on game theory aims to minimize the discrepancy between the optimal weight and the various weights of each indicator, ultimately obtaining the optimal evaluation weights for both. Thus, following the calculation of the subjective weight (AHP) value and objective weight (Entropy) value, a more reasonable weight value is obtained through the game theory combination weighting method. The specific calculation steps are outlined as follows[28]:

The basic weight vector, denoted as w_k, represents the set of weights determined by the weight calculation method. $w_k = \{w_{k1}, w_{k2}, \dots, w_{km}\}$ k=1，2...L. Here, m represent the number of indicators. Since this study selects 2 weighting methods and 16 indicators, we have L=2 and m=16.

If $a = \{a_1, a_2\}$ is considered as the linear combination coefficient, then any linear combination of two vectors determines the comprehensive weight vector w for assessment:

$$w = \sum_{k=1}^{L} a_k \cdot w_k^T \ \ (a_k>0) \quad (4)$$

The weight vector a_k was optimized according to the minimization of the range between w and w_k, resulting in the optimal weight value w^*. The optimization objective function is as follows:

$$\min_{a_k>0} \left\| \sum_{k=1}^{2} a_k \cdot w_k^T - w_k \right\|_2 \tag{5}$$

In this formula: K=1 or 2.

The corresponding linear equations are derived from the differential properties of the matrix.

$$\begin{bmatrix} w_1 \cdot w_1^T & w_1 \cdot w_2^T \\ w_2 \cdot w_1^T & w_2 \cdot w_2^T \end{bmatrix} \begin{bmatrix} a_1 \\ a_2 \end{bmatrix} = \begin{bmatrix} w_1 \cdot w_1^T \\ w_2 \cdot w_2^T \end{bmatrix} \tag{6}$$

Finally, the values of the combination coefficient a_1, a_2 can be determined through mathematical calculation of the determinant. Standardization processing is necessary in order to ensure that sum of weights equals 1. After standardization, the final combination weight based on game theory can be calculated using the following formula.

$$w = a_1^* w_1^T + a_2^* w_2^T \tag{7}$$

Table 3 The weighted value of three methods

Target Layer	Criterion Layer	Factor Layer	AHP Weighted value	Entropy weight method	Final Combination weight
Urban Street Inclusivity	**Spatial Inclusivity**(0.382)	Space permeability	0.038	0.037	0.037
		Street greenery	0.062	0.069	0.065
		Sky openness	0.078	0.074	0.077
		Enclosure	0.054	0.039	0.048
		Street width to building height ratio	0.085	0.040	0.069
		Building width to street width ratio	0.112	0.038	0.086
	Functional Inclusivity(0.234)	Degree of business aggregation	0.010	0.036	0.019
		Proportions of living and public services	0.033	0.082	0.050
		Proportion of catering facilities	0.040	0.083	0.055
		Proportion of cultural facilities	0.037	0.055	0.043

	Commercial density	0.046	0.106	0.067
Social Inclusivity(0.384)	Green space accessibility	0.075	0.103	0.086
	Public transit accessibility	0.139	0.046	0.107
	Pedestrian friendliness	0.081	0.067	0.076
	Average Crowd density on weekdays	0.019	0.051	0.030
	Average Crowd density on holidays	0.091	0.075	0.085

From the perspective of the criterion layer, social inclusivity, representing the street's service target intuitively, carries the most prominent weight, while spatial inclusivity is considered a fundamental micro-perception of the street, significantly affecting its inclusiveness. The impact of functional inclusivity is relatively insignificant. From the perspective of factor layer, effective public transit ensures the arrival of diverse social groups to the street, making accessibility of public transit occupy a dominant position in terms of weight. The accessibility of green spaces, with significant weight proportion, is measured by the average distance from the center of the street to the surrounding parks and green spaces. As the primary venues for residents' daily recreational activities, green spaces attract more residents and other stakeholders, fulfilling their basic living needs. The average crowded density on holidays also carries significant weight, as bustling streets often attract more people, reflecting diverse inclusiveness.

Regarding spatial inclusivity, the building width to street width ratio significantly has a greater impact on people's visual perception of the street and holds the highest weight in terms of comfortable inclusiveness in public space. Additionally, sky openness, street greenery, and the street width to building height ratio also carry relatively high weights. Open skies and green views have a soothing effect on pedestrians. In contrast, the degree of business aggregation, concerning functional inclusivity, is deemed to have a relatively low impact on inclusiveness among factors. Predominantly, various customer groups on the street prioritize catering, residential, and cultural facilities, relegating other functions to a lesser role in enhancing inclusiveness.

3.2Descriptive statistics of indicators

The calculation results of indicator data in the study reveals significant differences in spatial, functional, and social inclusivity among four representative types of streets: Pingjiang Road performs excellently in all three dimensions. Fengmen Heng Street, representing grassroots cultural streets, excels in functional inclusivity. Huaihai Street, in its endeavor to establish a model of modern-style streets, exhibits relatively weak consideration for social inclusivity. Xietang Old Street, a newly constructed commercial street with a New Chinese style in recent years, requires further development in terms of social inclusivity.

In the dimension of spatial inclusivity, Fengmen Heng Street performs the best in space permeability owing to its open ground floor storefronts. Xietang Old Street has a much higher

street greenery compared to the other three streets, indicating effective landscaping and greening efforts. Given that the greenery of streets in ancient cities is constrained by narrow layouts, often limited to decorative interstitial spaces between buildings, this constraint may contribute to the lower street greenery observed on Pingjiang Road and Fengmen Heng Street. Meanwhile, Huaihai Street, a modern commercial street frequently employs billboards and neon lights on store facades to attract merchants and customers, potentially impacting street greenery. Pingjiang Road, Fengmen Heng Street, and Xietang Old Street demonstrate comparable levels of sky openness, suggesting similar degrees of openness in their vistas. In terms of the building width to street width ratio and street width to building height ratio, Pingjiang Road performs satisfactorily in both aspects, not only ensuring visual aesthetics but also efficiently utilizing limited space to accommodate more commercial stores, cultural venues, and community service facilities. Simultaneously the building width to street width ratio of Huaihai Street provides a comfortable spatial scale, contributing to the attraction of pedestrian flow. Pingjiang Road and Xietang Old Street feature relatively low enclosure, promoting a sense of spaciousness and enhancing positive psychological experiences.

In terms of functional inclusivity, the higher Commercial density in Fengmen Heng Street reflects the frequent commercial activities in the area, affirming its potential for future development. Higher degrees of business aggregation lead to greater convenience for citizens. The relatively low degree of business aggregation on Huaihai Street indicates a weaker diversity of functions and a lower degree of service concentration in the area. The remaining three streets display similar degrees of business aggregation. The proportions of living and public services, catering facilities, and cultural facilities reflects the quantity of services provided in a particular function within the street. A higher proportion indicates greater service opportunities for diverse people. Pingjiang Road, representing historical streets, features a relatively high proportions of living and public services, as well as catering facilities, reflecting a coexistence of lively and commercial atmosphere. On the other hand, the higher proportion of cultural facilities in Fengmen Heng Street reflects its unique vibrant grassroots cultural atmosphere.

Regarding social inclusivity, Baidu's heat map provides real-time information on crowd gathering and street space utilization, displaying the spatiotemporal intensity of different locations. This study collected heat map data for October 2nd, 3rd, 6th, and 14th, as well as October 7th, 10th, 11th, and 13th, 2023, calculating the average heat value representing the average crowd density during holidays and workdays respectively. The results show that regardless of whether it is workdays or holidays, Pingjiang Road exhibits a high density of crowd distribution, reflecting its high tourism value and attractiveness to people. Conversely, Xietang Old Street ranks at the bottom of the four streets in terms of average crowd density on both holidays and workdays, indicating its limited appeal to crowds and its current state of relative inactivity. In terms of pedestrian friendliness, Huaihai Street provides great convenience for pedestrians and non-motorized vehicles owing to its systematic, rational, and spacious road layout, creating a pedestrian-friendly environment conducive to promoting activities and enhancing social inclusiveness. Pingjiang Road is surrounded by abundant ancient city parks and verdant areas. Moreover, its central location enables it to offer high levels of accessibility to green spaces and public transit, thereby attracting a diverse range of customers.

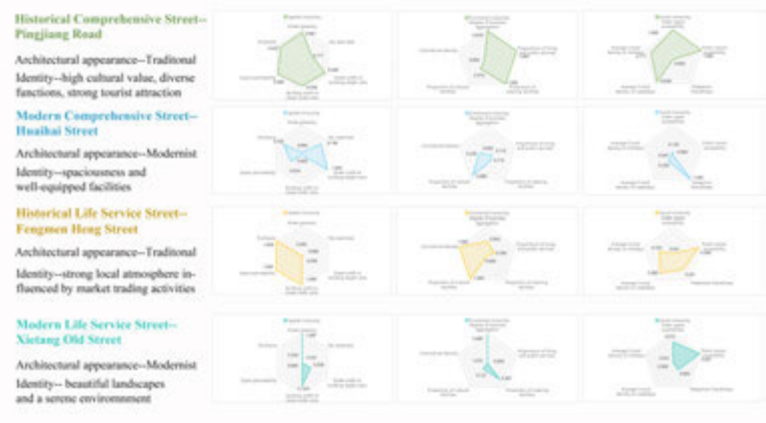

Figure 4 Four representative street inclusion indicators radar map

3.3Total assessment score of street inclusivity

The standardized numerical values obtained from the statistics of each indicator in the assessment are multiplied by their respective final combination weights. The inclusivity assessment scores for the four representative streets can be obtained by adding and summing these values for each item. The resulting scores (table 4) are as follows：

Table 4 Total assessment score of street inclusivity

Representative	Pingjiang Road	Huaihai Street	Fengmen Heng Street	Xietang Old Street
Assessment score	0.581	0.343	0.394	0.243

Pingjiang Road, representing the "Historical Comprehensive Streets", clearly outperforms in the inclusivity assessment. This is evident from high-weight indicators such as street greenery, average crowd density, public transit accessibility, and green space accessibility, aligning with its expected role as a significant protected street in Suzhou's cultural district and ancient city area. Fengmen Heng Street, representing the "Historical Life Services Streets", and Huaihai Street, representing the "Modern Comprehensive Streets", closely follow. These streets exhibit excellent indicators in space permeability, enclosure, and commercial density, indicating potential to achieve higher inclusivity quality. In comparison, Xietang Old Street, representing the "Modern Life Services Streets", displays a lower level of inclusiveness compared to the other representative streets. Thus, it is essential to update and optimize strategies to enhance its spatial, functional, and social inclusiveness

Based on a comprehensive analysis of various indicators, Pingjiang Road, as a representative old street in Suzhou, demonstrates diverse functionality and bustling popularity. Its assessment values in all dimensions are relatively high, and it attains the highest level of overall inclusiveness. Therefore, when updating its design, it requires only minor optimization without excessive

interference. However, in recent years, despite meeting contemporary demands in terms of architectural scale and accessibility, the newly renovated Huaihai Street and Xietang Old Street have lower indicator values for public transit accessibility, average crowd density, and the proportions of living and public services. As a result, their attractiveness to people is limited, leading to lower overall inclusiveness

4. Renaissance strategies

After considering the inclusivity assessment results of the four types of streets, it is evident that Pingjiang Road emerges as the most inclusive street. However, it still encounters challenges such as a low proportion of cultural facilities and pedestrian-friendliness. In order to address these issues without compromising the existing comfortable street greenery, it is recommended to appropriately increase the commercial density, enhance the proportion of cultural facilities, and enrich cultural experiences and historical heritage functions. For instance, establishing a Water Town Cultural Academy can effectively stimulate pedestrian flow and elevate inclusiveness quality on this street.

For the remaining three streets with low inclusivity assessment scores, namely Fengmen Hengjie representing traditional local culture, Huaihai Street showcasing modern fashion, and Xietang Old Street reflecting contemporary urban life, based on the data results of the evaluation system, corresponding update strategy suggestions are provided from the perspectives of specific population groups, functions, and spatial inclusivity dimensions. These strategies aim to be applied to streets with similar attributes in order to achieve inclusive and diverse characteristics.

The revitalization of Fengmen Hengjie, a representative market culture street, should address the evolving daily life needs of its inhabitants and overcome the current limitations resulting from an exclusive focus on catering to a single customer group. (1) In terms of social inclusivity, enhancements can be made to pedestrian walkways to improve their user-friendliness and facilitate access to surrounding park greenery, thereby addressing the issue of inadequate pedestrian amenities. Moreover, regular hosting of diverse events and festive temple fairs can attract visitors from various backgrounds and interests by showcasing historical intangible cultural heritage, culinary delights, shopping opportunities, etc. (2) With regards to spatial inclusivity, careful attention should be given to building layout and space design in order to ensure ample lighting conditions and incorporate natural landscapes. Given the limited street greenery, ecological challenges, and compact nature of the street's space constraints; garden-style designs could be implemented within microspaces at street corners or intersections. (3) In terms of functional inclusivity, it is imperative to enhance the proportion of living and public services and catering facilities in order to diversify people's options on the streets. By augmenting the street greenery, we can also elevate the design aesthetics of ground floors, thereby attracting a greater number of businesses to establish themselves and meeting diverse consumer needs through differentiated distribution of functions, thus fostering Fumen's inclusivity.

The preservation and promotion of distinct cultural features and unique architectural styles should be prioritized in the renovation of modern streets like Huaihai Street, aiming to create an appealing place that is both inclusive and compatible with individuality for residents and tourists. (1) In terms of social inclusivity, artistic interactive devices could be installed on specific sections

of walls along the street to provide visitors with opportunities for interaction while showcasing its history. These artistic interactive devices can take various forms such as photo spots, as well as projection games or musical performances, attracting a more diverse clientele while addressing concerns regarding lower crowd density. (2) In terms of spatial inclusivity, Huaihai Street exhibits a high degree of sky openness and relatively tall building enclosure; however, the street greenery is low. During the renovation process, it is necessary to adjust the building width-to- street width ratio while transforming monotonous and dull walls into refreshing and comfortable vertical greenery. Considering sustainable development, diversity and hierarchy can be enhanced through combinations of different materials and colors in storefront designs. (3) In terms of functional inclusivity, based on the issues identified in the inclusivity assessment, it is necessary to further diversify the types of businesses on Huaihai Street. This can be achieved by adding more daily retail stores and organizing regular market activities to meet residents' purchasing needs for daily necessities. Enhancing openness in building facades will not only increase attractiveness but also infuse vitality into modern-style streets, creating a street space with rich experiential qualities.

The revitalization of modern urban streets, exemplified by Xietang Old Street, should prioritize enhancing and refining the functional layout while introducing a greater array of cultural amenities to infuse more vitality into the area. (1) In terms of functional inclusivity, Xietang's long-established street with its chessboard arrangement of streets and lanes is characterized by densely intertwined open courtyards and interlacing pathways. Building upon the issues identified in the comprehensive evaluation, efforts can be made to address relatively low commercial density, distribution ratio of living and public facilities, and proportion of cultural facilities in Xietang. For future development, support can be extended to small businesses and entrepreneurs to encourage them in opening new storefronts thereby increasing shop density and attracting more creative and small-scale retail enterprises. Simultaneously, methods such as hosting large-scale cultural themed festivals can also be employed to augment the distribution ratio of cultural facilities providing residents and tourists with an expanded range of choices. （2）In terms of spatial inclusivity, Xietang Old Street exhibits a notable disparity in street permeability compared to other streets. This discrepancy primarily stems from the prevalence of tea houses and small shops, resulting in a lower population density. To address this concern, it is imperative to adjust the street width-to-building height ratio and augment the incorporation of residential and cultural amenities while enhancing the diversity and hierarchical nature of storefront design. However, Xietang Old Street claims the top spot among the four streets in terms of Street greenery, signifying its immense potential for development.

4.5. Conclusion

The contemporary urban street research is gradually shifting its focus towards "diversity and inclusivity" and being more "people-oriented", while also emphasizing objectivity and precision. Drawing on multi-source data, this article constructs a comprehensive street inclusivity assessment system comprising 16 indicator factors such as street greenery and sky openness. Four typical streets, namely Pingjiang Road, Huaihai Street, Fengmen Hengjie, and Xietang Old Street are selected for inclusivity assessment. The evaluation results reveal the following: (1) Pingjiang Road excels in various indicators and is well-suited for creating a highly inclusive vitality gathering place. (2) Huaihai Street performs admirably in terms of sky openness and pedestrian friendliness but has a lower street greenery. (3) Fengmen Hengjie exhibits great potential for

inclusive development due to its high street permeability and commercial density. (4) Xietang Old Street retains its old-fashioned style with alley layout but falls slightly short in terms of commercial density, proportion of living and public facilities, cultural facilities, etc. In the correlation analysis of indicator factors, it was observed that higher enclosure degrees of street buildings corresponded to an increased proportion of cultural facilities distribution, thereby offering a more diverse range of cultural activities. In design, the street greenery is often compromised to accommodate commercial and cultural facility requirements. Regarding inclusivity assessment scores, Pingjiang Road representing "historical style streets" exhibits the highest inclusivity, while Huaihai Street representing "modern style streets" and Fengmen Hengjie representing "community culture streets" demonstrate lower levels of inclusivity. Xietang Old Street representing "modern life streets" ranks last in this regard. Consequently, corresponding strategies for inclusive updates are proposed for each category. For future urban street updates, it is crucial to comprehend the key elements influencing street inclusivity and consider them comprehensively from dimensions such as spatial layout, functionality, and user groups on the street.

In the process of quantifying relevant indicators, this paper introduces the GSAM model for calculating street permeability index. Compared to previous methods, the GSAM model is more efficient and convenient, capable of rapidly processing a large number of image elements. However, when applying it to calculate indicators, there are interferences that can affect measurement accuracy such as complex clipping of multi-story buildings, pedestrians on streets, distances between buildings, and window patterns. These interferences need to be eliminated in order to enhance result accuracy. Additionally, further explanation is needed regarding the integration and entry points of quantified research on street inclusivity and traditional street vitality. The construction of an inclusivity evaluation system lacks indicator innovation and requires breakthroughs in subsequent research to explore more quantitative assessments of micro-level inclusive qualities.

Urban Peripheries and the 15-Minute City: A comparative study on proximity-based strategies for the transformation of suburban and periurban areas

Arne Markuske
Affiliation: Technical University of Munich | Chair for Sustainable Urbanism
Email: arne.markuske@tum.de

Abstract
Urban areas are responsible for more than 60 percent of greenhouse gas emissions. As the global urban population increases, future growth will happen primarily in urban peripheries. This raises the question if proximity-based approaches such as the 15-minute city (FMC) can be applied for the sustainable transformation of urban peripheries. Therefore, this study comparing the long-term strategic vision of Melbourne, Portland and Vancouver investigates if these visions address strategies for transformatinng of urban peripheries and if those strategies align with the FMC concept. The study reveals, that the visions, although relying on important points of the FMC, deviate from the original concept regarding the allocation of workspaces: While the urban function of working isn't necessarily a part of complete or 20-minute neighbourhoods, it is one of the essential functions named in the original FMC concept. This is due to challenges which occur when applying proximity-based approaches such as the FMC to urban peripheries which cannot provide the building and population density needed in order to make the provision most daily essentials viable inside a 15-minute walking distance. This poses a dilemma as promoting walking as the main mode of transit is of utter importance for the FMC concept.

Keywords: urban peripheries, 15-minute city, complete neighbourhoods, Zwischenstadt, proximity, mobility

1. Introduction

Since its introduction in 2016, the 15-minute city (FMC) (Moreno 2020; Moreno et al., 2021) has become a popular model for urban planning and urban design (Pozoukidoi and Chatziyiannaki, 2021, p. 3). This is mainly due to global challenges such as climate change and the Covid-19 pandemic as the FMC concept is aimed at reducing greenhouse gas (GHG) emissions and improving city dwellers' quality of life by providing all daily essential within a 15-minute walk from home (Allem et al., 2022, p. 2). There is an urgent need for transformational urban models as well as strategies and policies for their implementation as 55 percent of the global population already live in urban environments (UN Habitat, 2020) and urban areas are responsible for more than 60 percent of global GHG emissions (United Nations, 2020). In their second white book (livre blanc) Moreno and his team at Chaire ETI list several cities such as Ottawa, Melbourne, Portland, Barcelona, Milano, Nantes and Mulhouse which are considered pioneers in implementing the FMC as the basis for their urban planning- and urban design strategies (Chair ETI, 2020, pp. 20-45). As the share of the global population living in urban areas is expected to grow up to 68 percent by 2050 (UN Habitat, 2020) it is worth mentioning that "urbanization in the twenty-first century is increasingly occurring in the peripheral areas outside the city" (Wu and Keil, 2022, p. 11). Regarding the previously mentioned list of cities, it is striking that the majority of these so-called pioneer cities are

metropolises of national or even international importance which already profit from dense and mixed-use urban structure: Siedentop and Gerten (2023, p. 2) estimate that the majority of people living in the central and middle parts of large cities already profit from living in a FMC. However, as Bremer (2022, p. 33) points out the majority of people in western industrialised countries does not live in compact urban centres, but in disperse, low-density settlement-structures for which Thomas Sieverts (2013) coined the term *Zwischenstadt*. Bremer estimates, that up to 75 percent of the German population live in Zwischenstadt-like areas according to their mobility patterns (Bremer, 2022, p. 33). As Sieverts Zwischenstadt (2013) is a collective term which can be referred to as a fuzzy concept, one can argue about the exact definition and delimitation of the settlement structures it includes. Regardless of the exact delimitation and proportion of people living in Zwischenstadt-like environments it is needless to say that developing guiding principles for the transformation of these Zwischenstadt-like areas in order to reduce GHG emissions, improve social cohesion and increase it climate resilience can play an important role for the sustainable transformation of the built environment (Sieverts, 2005, p. 29). As a response to these needs Carlos Moreno suggests to extend the FMC concept to semi- or less dense areas. This adaptation of the FMC will be called 30-minute territory (*territoire de la démi heure*) and could provide a new territorial framework for urban planning and design, according to Moreno (2020, pp. 127f.).

2. Methods

The aforementioned subjects in section 1 raise two general questions: If and how are transformational urban strategies which are based on proximity and active mobility such as the FMC or 30-minute territory applied on Zwischenstadt-like urban peripheries? Second, what is the image of the FMC or 30-minute territory in terms of urban form, typologies and urban design, especially in Zwischenstadt-like urban peripheries?

For this reason, in this study the long-term strategic visions of Melbourne (Plan Melbourne 2017-2050), Portland (2035 Comprehensive Plan) and Vancouver (Vancouver Plan 2050) will be compared regarding the following questions: First, are urban peripheries addressed at all and which significance is given to them? Second, which strategies for the transformation of urban peripheries have been developed and how do these correlate with the thematic pillars of the FMC. And third, which significance is given to work as a social function and the allocation of workplaces?

2.1 Spatial framework

Sieverts' Zwischenstadt is a fuzzy concept which does not provide an exact definition and delimitation of the settlement structures included. It acts as a collective term subsuming areas which can be described as ruralised cities or urbanised countryside at the same time and, therefore, can't be clearly categorised into town or countryside (Sieverts, 2013, p. 14). It comprises large infrastructure facilities, suburbia as well as commercial- and industrial zones which are typically found in the peripheries of cities, but also later phenomena which occur in larger agglomeration areas, such as post-suburbia, exurbia, edge-cities and technoburbs. As this study compares three metropolises and their agglomeration areas it will focus on the transformation of low-density suburbs as well as commercial and industrial areas in the peripheries of these cities. For this reason and, as the German term Zwischenstadt is hard to translate into English and could interrupt the flow of reading, in the following sections I will refer to those urban structures which are subject to the investigation as *urban peripheries*.

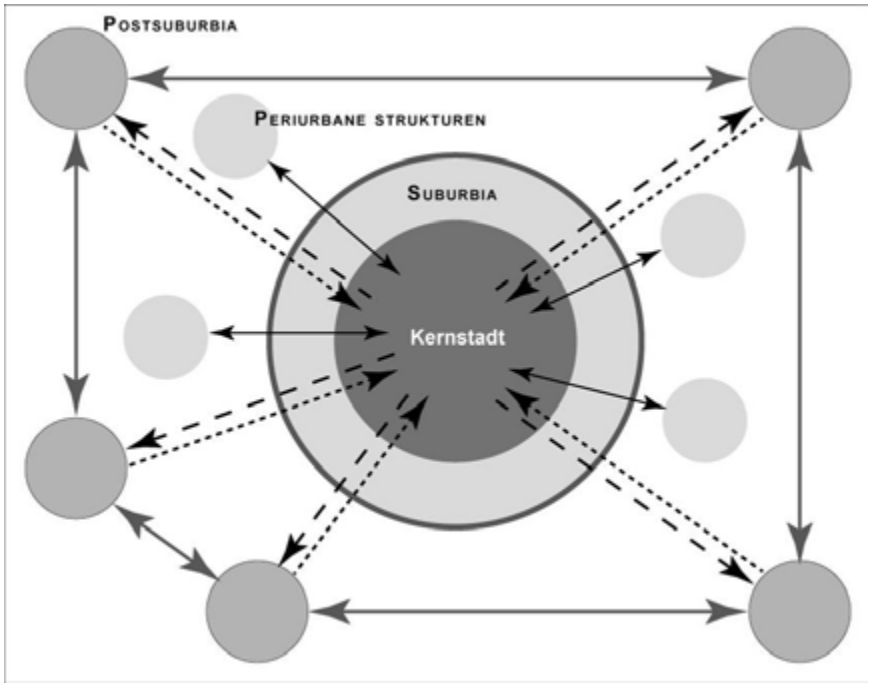

Fig. 1: Different phenomena as part of Zwischenstadt and their relations

2.2 Sample

The cities of Melbourne and Portland have been chosen, because they have repeatedly been mentioned in the writings of Carlos Moreno and Chaire ETI as pioneer cities of the FMC (Chaire ETI, 2020, pp. 20-45; Moreno, 2020, pp. 118f.). Additionally, Vancouver made its dedication towards the FMC concept clear on several occasions (City of Vancouver, n.d.). Furthermore the cities have provided one document coherently presenting their long-term strategic vision which makes a comparison possible without carrying out a meta-analysis of a variety of strategic planning documents. Finally, as they are all cities which consist to a large extent of suburbs, their urban structure is fairly comparable among each other and it is more likely to identify strategies pursuing the transformation of urban peripheries.

2.3 Analytical framework

Moreno's FMC concept is based on proximity and active mobility (Abbiasov et al., 2024, p. 445) and integrates several previous urban models, such as the neighbourhood unit, urban villages and transit-oriented design (Pozoukidou and Chatziyiannaki, 2021, p. 2) as well as the compact city, the walkable city and the green city (Allam et al., 2022, p. 2;) Therefore it suggests a number of goals and strategies in order to transform our built environment into FMCs such as prioritisation of active mobility (Moreno, 2020, p. 51), the redesign of streets (Moreno, 2020, p. 70) and placemaking (*topophilie*) (Moreno, 2020, pp. 116f.) together with the idea of a continuous, defragmented urban fabric with a minimum density and mixture of urban functions (Moreno, 2020, p. 51) in order to provide the needed proximity to the essential six urban functions which are living, working, education, supply, health and green (Moreno, 2020, p. 120). These strategies can be summarised under the following four thematic pillars on which the FMC concept is build: *Urban form, mobility, placemaking* and *climate resilience*.

3. Comparison of long-term strategic visions

This comparative study will identify for each sample if and how urban peripheries are being addressed and which strategies are being pursued for their sustainable transformation. The strategies will be summarised and compared following the thematic pillars of the FMC: *urban form, mobility and placemaking*. Climate resilience will be no part of the comparison as this study is focussed on the built environment and the allocation of urban functions in urban peripheries. Later these findings will be summarised and compared to the original FMC concept.

3.1 Plan Melbourne 2017-2050

Melbourne is one of the cities which have adapted their official planning policies to the concept of the 15-Minute city (Moreno, 2020, p. 118f.). Plan Melbourne 2017-2050 is the central strategy in order to „manage growth in the city and suburbs to the year 2050“ (DELWP, 2017, p. 3). In this subsection Plan Melbourne 2017-2050 will be analysed.

3.1.1 Structure and main goals of Plan Melbourne 2017-2050

Melbourne's main challenge is to manage population growth over the coming years without further sprawling (DELWP, 2017, p. 6). For this reason it is bases on "9 principles that underpin a long-term vision for Melbourne“ and structured around „7 outcomes to drive Melbourne as a competitive, liveable and sustainable city, 32 directions setting out how these outcomes can be achieved [and] 90 policies outlining how each outcome will be approached, delivered and achieved“ (DELWP, 2017, p. 3). These principles include the creation of 20-minute neighbourhoods and a network of centres (DELWP, 2017, p. 10).

3.1.2 Strategies related to urban peripheries

Plan Melbourne does not directly address urban peripheries with Zwischenstadt-like features, but it identifies several zones with shared morphological features such as the Central Business District (CBD) as well as inner, middle and outer suburbs (DELWP, 2017, p. 36) which are repeatedly addressed in different policies and directions. There is no map or list provided to make clear which parts of the city are categorised as inner, middle or outer suburbs. Compared to the phases of Melbourne's urban development (*Fig. 2*) these zones can be partly assigned to different development phases as the CBD and those suburbs which have evolved before the rise in private car ownership have a more compact structure and are therefore more walkable. There are several inner and middle suburbs which already fulfil the criteria of a 20-minute neighbourhood and middle and outer suburbs which don't (DELWP, 2017, p. 47). This means that urban peripheries are most likely to be found in these middle and outer suburbs. Therefore, the following analysis will outline strategies aiming at transforming those structures into complete and walkable 20-minute neighbourhoods.

3.1.3 Strategic approaches to transforming urban peripheries

Urban form. Melbourne is a city of suburbs (DELWP, 2017, p. 5). Therefore the authors of Plan Melbourne intend to manage future population growth by urban planning and urban design in order to avoid sprawl and transform these suburbs into compact, walkable 20-minute neighbourhoods. Those are supported by a network of centres which has different levels of hierarchy: „Metropolitan activity centres are supported by a network of major and neighbourhood activity centres of varying size, role and function." (DELWP, 2017, p. 47). It is intended that Melbourne's growth is focussed around these existing functional cores and nodes which means introducing middle- and high-density housing, especially in middle-ring suburbs which are already well served with jobs and services (DELWP, 2017, p. 47). In other locations the value of existing infrastructures shall be optimised by increasing population density (DELWP, 2017, p. 49). For growth areas the authors seek to avoid to „[…] recreate the 'dormitory' suburbs of the post-war boom" (DELWP, 2017, p. 45). Therefore, "the guidelines support planning for local jobs, local town centres rather than car-based shopping centres, better access by walking and bikes, and a healthy environment." (DELWP, 2017, p.49). As the following quote reveals, inner and middle suburbs which already are compact and walkable neighbourhoods act as a role model for Melbourne's 20-minute neighbourhoods: „Planning will be undertaken to ensure that the best parts of Melbourne are maintained and the benefits experienced in established inner and middle suburbs of Melbourne from compact, walkable neighbourhoods can also be realised in middle and outer areas" (DELWP, 2017, p. 47). This also includes Transit-Oriented-Development (TOD) as well as offering mixed-use developments with density and greater housing diversity close to employment and transport which will create opportunity and choice for medium- and low-income households (DELWP, 2017, p. 47). One strategy which is also worth mentioning is densification of middle and outer suburbs by greyfield development which means replacing detached single-family homes on large lots with mixed-use multi-family buildings after they have reached their designated lifespan (DELWP, 2017, p. 51).

Mobility. One recurring strategy which repeatedly appears in different chapters of Plan Melbourne is reducing car-dependency (DELWP, 2017, p. 123) not only by transforming the urban structure, but also by improving infrastructure for walking, cycling and public transport (DELWP, 2017, p. 100).

Placemaking. The authors of Plan Melbourne do not solely address the promotion of walking and cycling on the level of infrastructure but also emphasise that „Streets are both places to pass through and destinations" (DELWP, 2017, p. 81) and thus, placemaking practices need to be integrated in road design practices (DELWP, 2017, p. 81). According to the authors, making walking and cycling more enjoyable by attaching importance to placemaking practices and the design quality of the built environment can improve social cohesion the local economy (DELWP, 2017, p. 99).

The concept of the 20-minute neighbourhood integrates these different strategies aiming at improving the inhabitants' quality of life and at reducing greenhouse gas emission: „The 20-minute neighbourhood is all about 'living locally'—giving people the ability to meet most of their everyday needs within a 20-minute walk, cycle or local public transport trip of their home. If 20-minute neighbourhoods existed across Melbourne, it could reduce travel by nine million passenger kilometres and cut Melbourne's daily greenhouse gas emissions by more than 370,000 tonnes." (DELWP, 2017, p. 98).

3.1.4 Alignment with the 15-minute city concept

Plan Melbourne includes several strategies which are part of the FMC concept: First, Plan Melbourne suggests the transformation of existing middle and outer suburbs into compact, walkable 20-minute neighbourhoods where most of the residents' daily needs can be met within 20 minutes of walking, cycling or public transport. This is a strong reference to the concept of hyper-proximity in the 15-minute city, although 20-minute neighbourhoods rather pursues a accessibility-based approach than a proximity-based approach. Second, Plan Melbourne intends to reduce car-dependency and make walking, cycling and riding public transport more enjoyable and safer by investing in the needed infrastructure. Promoting active mobility is likewise an important part of the FMC concept (Moreno, 2020, pp. 33, 70). Third, the authors of Plan Melbourne address placemaking and the design qualities of the built environment in order to improve social cohesion. This strategy aligns with a concept which Moreno calls „topophilie" (Moreno, 2020, pp. 116f., 123) which can be translated into *love for your city*.

It is worth mentioning that Plan Melbourne's 20-minute neighbourhood deviates from the 15-minute city concept in several respects: In Moreno's description of the FMC working is one of the six social urban functions which need to be accessible in 15 minutes by walking or cycling from where one lives (Moreno, 2020, p. 120). The authors of Plan Melbourne, on the other hand, make it very clear that „[due] to the specialised and diverse nature of many people's work, access to employment will often be outside the 20-minute neighbourhood." (DELWP, 2017, p. 99). They clearly point out that „[the] distribution of jobs across Melbourne is uneven" (DELWP, 2017, p. 36). Despite generally intending to provide more jobs closer to where people live (DELWP, 2017, p. 37) the strategy to resolve the uneven distribution of jobs across Melbourne is the decentral centralisation of jobs in so-called Metropolitan Activity Centres (DELWP, 2017, p. 14). This approach aligns with the strategy of creating a network of centres (DELWP, 2017, p. 10) and Transit-Oriented-Development (DELWP, 2017, p. 100). It is noteworthy that, concerning urban peripheries in the middle and outer suburbs, Plan Melbourne does not pursue a strategy of transforming urban peripheries into a continuous mixed-use urban fabric, but to create a network of centres whose mesh size is defined by a 20-minute isochrone. Future development and densification will primarily take place around existing centres and in established neighbourhoods (DELWP, 2017, p. 47). On the one hand, this can be an adequate strategy to avoid sprawl. On the other hand, focussing on existing centres and established neighbourhoods will not improve access to jobs and services in neighbourhoods which already are underserved. However, the plan identifies several hallmarks for 20-minute neighbourhoods: One of them is „A 20-minute neighbourhood must […] deliver housing/population at densities that make local services and transport viable" (DELWP, 2017, p. 98). This is interesting regarding urban peripheries, because the statement implies that there is minimum population density threshold under which providing local services and public transport is no longer viable. This means that, according to Plan Melbourne, transforming underserved neighbourhoods in urban peripheries into 20-minute neighbourhoods means increasing density until it exceeds the minimum density to make local services and public transport viable.

3.2 Portland 2035 Comprehensive Plan

In their second whitebook Moreno and his Team at Chaire ETI list several cities which are pioneers in implementing the 15-minute city concept. Portland is one of them (Chaire ETI, 2020, p. 29-31). Portland has started to implement the FMC concept in its urban planning policies by adopting the 2015 Climate Action Plan aiming at significantly reducing greenhouse gas emissions by transforming its urban form, promoting active mobility and creating vibrant 20-minute neighbourhoods (Chaire ETI, 2020, p. 29). Since then the city has updated the 2035 Comprehensive Plan (BPS, 2023a) and complemented it with an Urban

Design Direction (BPS, 2023b). In this subsection the 2035 Comprehensive Plan will be analysed.

3.2.1 Structure and main goals of Portland's 2035 Comprehensive Plan

The 2035 Comprehensive Plan is Portland's central planning strategy to manage growth by guiding land use development and public facility investment (BPS, 2023a, p. 41). It is based on five guiding principles (BPS, 2023a, p. 7) and divided in ten thematic chapters which include, among others, urban form, housing and transportation (BPS, 2023a, p. 5). Its main goal is to manage the expected growth in order to avoid sprawl and to „expand access to employment and great neighborhoods" (BPS, 2023a, p. 8). Another important goal of the plan is that by 2035, 80% of Portland's inhabitants live in so-called complete neighbourhoods (BPS, 2023a, p. 90). The Comprehensive Plan defines a complete neighbourhood as follows: „A neighborhood where people have safe and convenient access to the goods and services needed in daily life, which include a variety of housing options, grocery stores and other commercial services, high-quality public schools, and parks. Complete neighborhoods are also easily accessible by foot, wheelchair, bike, and transit for people of all ages and abilities." (BPS, 2023a, p. 296). As a tool to achieve that goal Portland's Bureau of Planning and Sustainability (BPS) has „developed the 20-minute neighborhood index to measure access to community amenities, products and services." (BPS, 2023a, p. 36). The strategies aimed at transforming Portland's neighbourhoods into complete 20-minute neighbourhoods are spread across the 10 chapters of the Comprehensive Plan.

3.2.2 Strategies related to urban peripheries

Portland's 2035 Comprehensive Plan does not directly address urban peripheries, but it defines five distinctive pattern areas including Rivers, Central City, Inner Neighbourhoods, Western Neighbourhoods and Eastern Neighbourhoods (BPS, 2023a, p. 110). Additionally, the authors point out that the urban structures inside the Inner Neighbourhoods Pattern Area already have the desired qualities of complete neighbourhoods (BPS, 2023a, p. 114). The Western neighbourhoods are largely shaped by the mountainous terrain (BPS, 2023a, pp. 115f.) whereas the Eastern Neighbourhoods are characterised as mainly suburban, a low building density, wide street corridors and gaps in the network of pedestrian and bicycle paths (BPS, 2023a, p. 115). For these reasons it can be assumed that the Eastern Neighbourhoods Pattern Area matches most with the characteristics of urban peripheries and this analysis will focus on strategies aiming at transforming the Eastern Neighbourhoods into complete neighbourhoods.

3.2.3 Strategic approaches to transforming urban peripheries

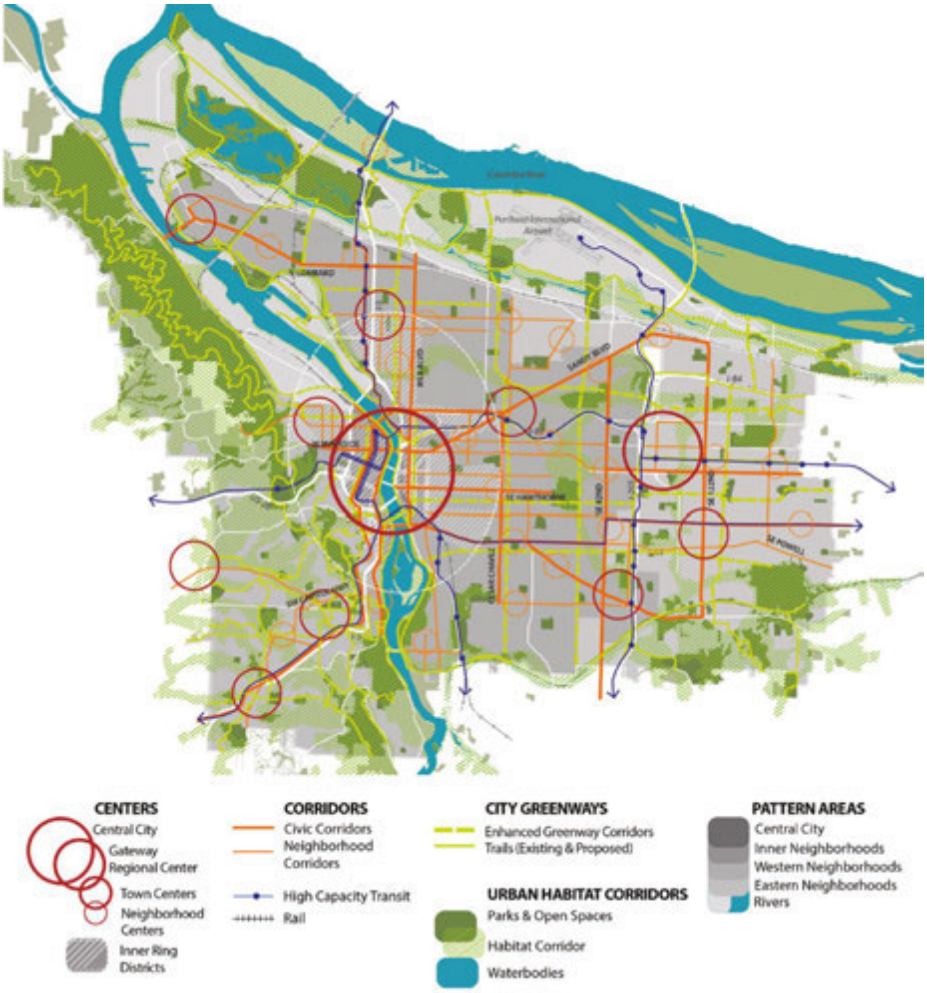

Fig. 3: Portland's urban development strategy depicting center, corridors and pattern areas

Urban form. The authors of the Comprehensive Plan assume that „[how] people live and get around is partly determined by the location of services and other destinations and the arrangement and design of buildings and connections provided by streets, trails, and other public spaces." (BPS, 2023a, p. 90). That is why a whole chapter of the document is dedicated to the topic of urban form. One superordinate strategy for all pattern areas is to create a network of centres on different hierarchical levels connected by corridors. Centres and corridors act as anchors for complete neighbourhoods (BPS, 2023a, p. 90).In general centres are described as „compact and pedestrian-oriented urban places [which] are connected to public transit and active transportation networks" (BPS, 2023a, p. 98). There are four types of centres which are Central City, Regional Center, Town Center and Neighbourhood Center (BPS, 2023a, p. 99). Regarding the transformation of the Eastern Neighbourhoods, mainly town centres and

neighbourhood centres are of increased interest. Additionally the Gateway Regional Center which shall act as a „an employment and community service hub within the area and region“ (BPS, 2023a, p. 295) in order to reduce pressure on the central city is located in the Eastern Neighbourhoods. High density housing and public places which enable vibrant public life shall be added here (BPS, 2023a, p. 101).

As the names imply, neighbourhood centres mainly serve the surrounding neighbourhood. They are characterised by multi-level, mixed-use buildings with up to four floors (BPS, 2023a, p. 102). Neighbourhood centres also act as local transportation hubs, but aren't necessarily connected to rapid transit (BPS, 2023a, p. 233). Town centres have a larger catchment area and „provide a full range of commercial and community services, high-density housing, mid-rise commercial and mid-rise mixed-use buildings (typically up to five to seven stories in height), are served by high-capacity transit connections, and have a substantial employment component“ (BPS, 2023a, p. 295). This means that town centres play an important role for decentralising work location and creating work locations closer to where people live. Neighbourhoods are connected among each other and to other parts of the city and central city by corridors. There are larger civic corridors and smaller neighbourhood corridors. The authors of the comprehensive plan intend to redevelop corridors order to cater to their surrounding neighbourhoods by providing public transit, stores, housing and office spaces (BPS, 2023a, p. 104). As linear centres they play an important role in covering peripheral areas without 20-minute access to a town- or neighbourhood centres with service and work locations. Therefore, they need to offer a minimum building and population density which makes public transport and services viable (BPS, 2023a, p. 104). A look on the map indicating the results of Portland's 20-minute neighbourhood index or completeness score reveal that the areas with the lowest score are primarily located in the western and eastern neighbourhoods which do not have a regular network of neighbourhood centres compared to the inner neighbourhoods. This is another indicator for the important role which corridors could play especially for transforming urban peripheries into complete neighbourhoods.

Mobility. The central idea of complete neighbourhoods is to reduce car dependency and the need for mobility in general by providing services and facility within a distance of a 20-minute walk. Furthermore, the authors clearly pursue a strategy of prioritising active mobility (BPS, 2023a, p. 234). This strategy also includes the redesign of streets and to „[encourage] walking as the most attractive mode of transportation for most short trips, within neighborhoods and to centers, corridors, and major destinations, and as a means for accessing transit.“ (BPS, 2023a, p. 237).

Placemaking. The authors of the Comprehensive Plan point out that streets are part of the transport infrastructure, but also places for social interactions and should, therefore, integrate both functions (BPS, 2023a, p. 236). Therefore, civic corridors shall be enhanced as distinctive place which offer an attractive pedestrian environment (BPS, 2023a, p. 105). In general, the comprehensive plan pursues a strategy of integrating strategies and measure related to the topics of active mobility, street design and placemaking in order to enhance the pedestrian experience (BPS, 2023a, p. 132). At the same time, it is questionable if the strategy of enhancing public life around civic and neighbourhood corridors which basically are major streets can be successful. Without a substantial reduction of car traffic the attractiveness of these places will be limited by noise and air pollution.

3.2.4 Alignment with the 15-minute city concept

Portland's 2035 Comprehensive Plan includes several strategies which are also part of the FMC concept: First, the authors of the Comprehensive Plan suggest to transform Portland's existing neighbourhoods into complete, walkable 20-minute neighbourhoods. Complete neighbourhoods or 20-minute neighbourhoods rely on accessibility to daily needs which is an important part of the FMC concept. Second, the Comprehensive Plan pursues the goal of reducing car-dependency and to promote walking as the most important mode of transport together with a prioritisation of active mobility including the redesign of streets and placemaking practices. The prioritisation of active mobility and especially walking as the main mode of transport is an important part of the FMC concept. Third, in the Comprehensive Plan strategies and measures related to the topics of mobility and placemaking heavily integrated. This can be seen as an interpretation of the term *topophilie* as part of the FMC concept.

However, there is a striking difference between complete neighbourhoods and the 15-minute city concept: Working which is one of the six essential functions which are part of the FMC is not necessarily a part of complete neighbourhoods. Although the plan pursues a strategy of decentralising work locations it does so by promoting decentral centralisation of work locations as new commercial spaces are concentrated in regional- and town centres. Based on the strategy of creating a network of centres and corridors in combination with transit-oriented development, densification and diversification around these corridors could be helpful to create jobs closer to where people live. The Comprehensive Plan does not suggest to create a continuous mixes-use urban fabric, but a network of centres and corridors. Future growth is concentrated around centres, corridors and transit stations.

3.3 Vancouver Plan 2050

The Vancouver City Council has approved the Vancouver Plan 2050 in 2022 as their „visionary long-range land use plan to guide growth and change over the next 30 years" (City of Vancouver, 2022, p. 7). One important goal of the Vancouver Plan is to develop complete, connected neighbourhoods „using the '15-minute city' principle" (City of Vancouver, n.d.). In this subsection the Vancouver Plan 2050 will be analysed.

3.3.1 Structure and main goals of the Vancouver Plan 2050

The Vancouver Plan outlines the long-range strategic vision for Vancouver's urban development for the next 30 years (City of Vancouver, 2022, p. 7). It is based on a vision and three foundational principles as well as three big ideas. Additionally, the plan presents vision statements for several policy areas, such as housing, transportation and public space, together with policy directions and policies to achieve the desired states for each policy area (City of Vancouver, 2022, p. 27). Another important part of the Vancouver Plan is the land-use strategy which show how the policy directions and policies of the plan can be realised in a spatial dimension (City of Vancouver, 2022, p. 27). Complete neighbourhoods are part of the vision and the three big ideas (City of Vancouver, 2022, pp. 22, 40) which makes them a core concept of the Vancouver Plan. The authors of the plan pick up on Vancouver's strategy to embrace „compact urban forms, walkable neighbourhoods, and sustainable transportation modes as critical solutions to combat climate change and maximize liveability" (City of Vancouver, 2022, p. 15). Further important topics which are addressed in the plan is the spatial mismatch between jobs and housing and the underutilisation of residential neighbourhoods with low building and population densities: More than half of Vancouver's jobs are located only on 10 percent of the land, but at the same time more than half of Vancouver's area is used for only 15 percent of its homes (City of Vancouver, 2022, p. 9).

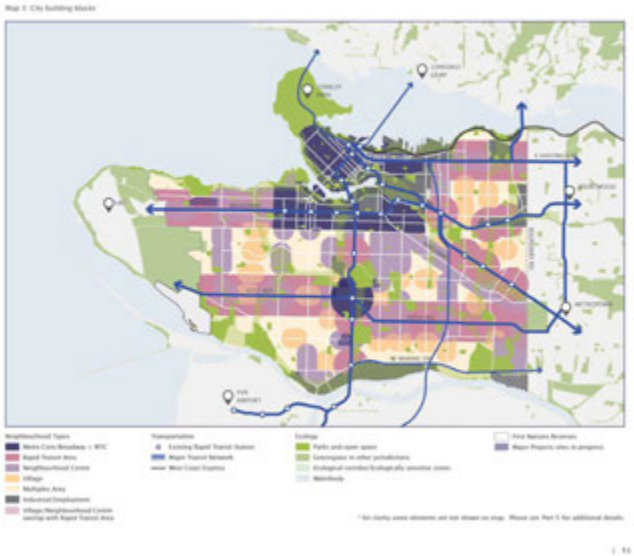

Fig. 4: Urban development strategy for Vancouver depicting different neighbourhood types

3.3.2 Strategies related to urban peripheries

The authors of the Vancouver Plan 2050 do not directly address the transformation of urban peripheries, but they point out several problems related to urban peripheries: „[more] than one-third of residential neighbourhoods do not have enough people living in them to support local businesses. Over half of Vancouver residents live in neighbourhoods without walkable access to daily needs such as food and services“ (City of Vancouver, 2022, p. 9).SEP Additionally, the plan lists different types of neighbourhoods such as rapid transit areas, neighbourhood centres and villages for which different strategies and policies apply. Although the term village might be misleading, because it is widely associated with rural life, the term refers to low-density neighbourhoods with a lack of public transport and services (City of Vancouver, 2022, p. 50). Therefore, this analysis will focus on strategies to transform these low-density neighbourhoods into complete neighbourhoods. For low-density neighbourhoods, the plan suggests a strategy of densification and diversification of housing choice.

3.3.3 Strategic approaches to transforming urban peripheries

Urban form. The main goal of the Vancouver Plan is to become a city of complete neighbourhoods. Therefore, the authors pursue a strategy to create a network of centres, each catering to a complete neighbourhood (City of Vancouver, 2022, p. 54). To achieve that goal, existing centres shall be strengthened by providing more opportunities for people to live close by. In underserved areas new neighbourhood centres shall be created by locating shops, amenities and public transport close together (City of Vancouver, 2022, p. 54). For that reason rapid-transit areas play an important role for creating new neighbourhood centres and „vibrant, mixed-use neighbourhoods providing more opportunities for purpose-built rental and social housing, childcare, community infrastructure, and arts and culture uses“ (City of Vancouver, 2022, p. 60).

The authors point out that a minimum building density is needed to provide for rental and social housing (City of Vancouver, 2022, p. 62). Therefore, the plan suggests to add so-called middle-housing around neighbourhood centres, rapid-transit areas and low-density neighbourhoods. Middle housing comprises ground oriented solutions such as multiplexes and townhouses as well as low-rise apartment buildings and mixed-use low-rise buildings (City of Vancouver, 2022, p. 60). The plan recommends multiplexes as a „new type of ground-oriented housing as a similar but more affordable and sustainable option to single-detached homes“ (City of Vancouver, 2022, p. 60). These are an effective measure to increase and diversify housing choice, but also to include small-scale mixed-use buildings to provide more job space, and local serving shops and services especially in low-density neighbourhoods labelled as villages in the land-use strategy (City of Vancouver, 2022, p. 62).

As already mentioned the authors of the plan also address the spatial mismatch between housing and jobs. Therefore the plan suggests to decentralise work locations by providing office space in neighbourhood centres (City of Vancouver, 2022, p. 54). Additionally and noteworthy, is the strategy to implement compatible light-industrial uses in rapid-transit areas and neighbourhood centres (City of Vancouver, 2022, p. 62). Examples for compatible light-industrial uses can be artist studios and maker spaces (City of Vancouver, 2022, p. 97). Furthermore the plan suggests to explore compatible uses to be added such as commercial and cultural facilities to industrial areas (City of Vancouver, 2022, p. 96).

Mobility. One core feature of Vancouver's complete neighbourhood is that they are walkable (City of Vancouver, 2022, p. 40). City-wide high-quality networks for walking, cycling and public transport are „the backbone of complete neighbourhoods“ (City of Vancouver, 2022, p. 47). Therefore, the Vancouver Plan suggests to „[create] people-first streets that are safe, attractive, and support people walking, rolling, biking, and taking transit“ (City of Vancouver, 2022, p. 45).

Placemaking. The authors of the Vancouver Plan emphasise that complete neighbourhoods „provide more opportunities for social interaction as people meet and connect on the street, at their favourite coffee shop, local playground, and during everyday activities like walking to get groceries“ (City of Vancouver, 2022, p. 52). For that reason the plan pursues a strategy of providing attractive public spaces to enhance public life as „[public] space is fundamental to participation in public life“ (City of Vancouver, 2022, p. 132).

3.3.4 Alignment with the 15-minute city concept

The Vancouver Plan 2050 includes several strategies which are also part of the FMC concept: First, at the core of the plan is a strategy to transform low-density residential suburbs into walkable complete neighbourhoods. The plan identifies several areas across the city which can be transformed into so-called multiplex areas. It is noteworthy that Vancouver's definition of a complete neighbourhood also includes „flexible work spaces“ (City of Vancouver, 2022, p. 154). This strategy relates to the concept of *hyper-proximity*, which is an important part of the FMC concept. Second, for the authors of the Vancouver Plan also pursue complete neighbourhoods to reduce car-dependency, and to prioritise active mobility in order to enhance public life and social cohesion as well as the health of its residents (City of Vancouver, 2022, p. 52). Third, the Vancouver Plan integrates topics related to mobility and placemaking as the authors emphasise the importance of walking, local services and public spaces in general for social interaction. This strategy relates to the term *topophilie* and

Moreno's emphasis on the meaning of public space for social interaction and urban culture (Moreno, 2020, p. 70).

The Vancouver Plan promotes a strategy of creating a city of complete neighbourhoods which are anchored to a network of centres which are connected by a high quality network for pedestrians, cyclists and public transport. It does not necessarily suggest to create a continuous mixed-use urban fabric, but the authors lay great emphasis on decentralising work. They pursue that goal not only with a strategy of decentral centralisation of work locations in town- or neighbourhood centres but suggest to add flexible work spaces and compatible light-industry to neighbourhoods and also to add compatible uses in industrial and commercial areas. Furthermore the authors developed an alternative typology to the now dominant single-family detached house: The multiplex which still offers ground-oriented housing, but at higher building and population densities that support local shops and services.

4. Discussion

The comparative analysis of the long-term strategic vision of Melbourne, Portland and Vancouver reveals that each city developed strategies which are to a great extent based on the 15-minute city concept developed by Carlos Moreno and his Team at Chaire ETI. The analysis further reveals that each city developed an own interpretation of the FMC concept based on its distinctive conditions. This also means that planners in Melbourne, Portland and Vancouver do not necessarily mean exactly the same when referring to the term *complete neighbourhoods* or *20-minute neighbourhoods*.

In section 2.3 three thematic pillars have been named as the analytical framework for the comparative study: *Urban form, mobility and placemaking*. *Fig. 5* shows strategies mentioned in the writings of Moreno and his team related to the four pillars or central topics as well as for the three cases.

Thematic Pillars and Strategies	FMC	Melbourne	Portland	Vancouver
Urban Form				
- spatial continuity and defragmentation	x			
- decentralisation of densities	x			
- avoid sprawl		x	x	x
- create a network of centres		x	x	x
- densification (housing + mixed-use) in and around existing functional cores and nodes		x		
- densification of low-density neighbourhoods				x
- transit-oriented development		x		
- decentralisation of work locations		x		
- create jobs closer to where people live	x	x		x
- add further functions to industrial and commercial zones				x
- add small scale commercial spaces in neighbourhoods				x
Mobility				
- reduce the need for mobility by providing everything needed in walking distance	x	x	x	x

- walking as the main mode of transport for short trips	x	x	x	x
- prioritisation of active mobility	x	x	x	x
- redesign of streets / reallocation of street space	x	x	x	x
- reduce car-dependency	x	x	x	x
Placemaking				
- enhance public life	x	x	x	x
- provide attractive public spaces and high design quality of the built environment in general	x	x	x	x
Climate Resilience				
- provide green spaces across the city	x	x	x	x

Fig. 5: Comparison of transformational strategies included in the FMC concept and the three samples

The table shows that there are some strategies with a great degree of agreement among the original FMC concept and its adaptations such as strategies concerning a mobility turn, placemaking and increasing climate resilience by providing green spaces across the city. Concerning urban form, the concept of complete- or 20-minute neighbourhoods differs from the original FMC concept: First, working is one of the six social urban functions of the FMC, but not necessarily of complete- or 20-minute neighbourhoods.

Second, in *Droit de cite* Moreno (2020, p. 51) relates to a continuous mixed-use urban fabric. The analysed examples, however, have a very different background and urban structure with extensive low-density residential suburbs. Therefore, their planners suggest to fight sprawl and create complete neighbourhoods by creating a network of centres and to strengthen existing centres with densification, and connections between those centres. In Portland these connections, referred to as corridors, play a more important role as in Melbourne and Vancouver. The Vancouver Plan lays more emphasis on the decentralisation of work as flexible work locations and small commercial spaces shall be provided in compact neighbourhoods. It is worth mentioning that in another paper, Moreno and his team refer to “different urban nodes [that] could be accessed within 15-minute walk or via cycling” (Allam et al., 2022, p. 2) which is closer to the network-of-centres-strategy than a continuous mixed-use fabric. It appears as if the promoters of the FMC haven’t agreed on the urban form for the 15-minute city, yet.

Third, another important difference between the three cases is that in Melbourne and Portland, planners suggest to create complete neighbourhoods by densification around existing centres and in order to profit from existing infrastructure. The Vancouver Plan, however suggests the comprehensive densification and functional diversification of low-density neighbourhoods by introducing a new typology called to multiplex. According to the Vancouver Plan, low-density urban peripheries shall be transformed into multiplex areas.

In all three cases the authors assumed that a minimum population density is needed to make local shops, public transport and services viable. This points in the direction that promoting an incremental redevelopment of urban peripheries by increasing building density, housing choice and introducing small, mixed-use buildings could be an efficient strategy for their sustainable transformation.

Furthermore, the case study reveals that not all long-term strategic visions which claim to build on the FMC, really implement all aspects of the FMC concept. Concerning the urban form of complete neighbourhoods and the allocation of workplaces there are significant deviations from the original concept. These strategies of Melbourne and Portland deviate from the original FMC concept to an extend which raises the question if their strategies truly are an application of the FMC concept or just established concepts and strategies such as the compact, walkable city and transit-oriented development assembled under a new label.

5. Conclusions

The 15-minute city has become a popular urban model and extensively discussed among planners and scholars. It is based on proximity and active mobility (Abbiasov, 2024, p. 445) while pursuing the goal of providing convenient access to the goods and services needed in daily life in a walkable distance (Moreno, 2021, p. 101) But in contrast to previous urban models based on the concept of accessibility by public transport, such as transit-oriented development or settlement axes, the FMC promotes an approach of physical proximity (Siedentop and Gerten, 2023, p. 2). This aligns with the assessment of Pozoukidou and Chatziyiannaki (2021, p. 3) that „the main difference in relation to other neighborhood centered approaches is that FMCs intend to bring activities to the neighborhoods and not people to the activities, restoring the urban planning concept of proximity“. Additionally, they emphasise the importance of the allocation of workplaces „[as] the trip from home to work comprises the main and most inelastic everyday trip, localizing workplaces appropriately is imperative“ (Pozoukidou and Chatziyiannaki, 2021, p. 4).

Despite the fact that Vancouver's vision is more elaborated when it comes to strategies for decentralising work places, Melbourne and Portland do not include working into the urban functions which should be accessible within a 20-minute walking distance, at all. In another comparative study of *Plan Melbourne*, *Portland's 2035 Comprehensive Plan* and *Paris en Commun*, Pozoukidou and Chatziyiannaki (2021, p. 21) came to the conclusion that they adopt a mentality that is closer to the notion of accessibility rather than proximity which can be confirmed by this comparative study. The comparative study further reveals that operationalising the FMC concept into planning strategies, especially for the transformation of urban peripheries comes with certain difficulties: Pozoukidou and Chatziyiannaki (2021, p. 13) question if the required market range and threshold populations can be reached for all facilities included in the six social urban functions included in the FMC. According to them, these threshold populations and market ranges rather lead to a hierarchical system of centres with different centralities (Pozoukidou and Chatziyiannaki, 2021, p. 4). These findings align with a study of EIT Urban Mobility (2022) which identified several challenges that come with redesigning cities according to the FMC concept (Olivari et al., 2023, p. 3): Especially in suburban contexts the FMC concept faces morphological challenges as their density might be too low to make local shops as well as public transport and services viable (EIT Urban Mobility, 2022, pp. 21f.). Siedentop and Gerten (2023, p. 2) conclude that for disperse and low-density settlement-structures outside of established centres the promise of a *local lifestyle* will be hard to realise. The long-term strategic visions of Melbourne, Portland and Vancouver confirm this assessment.

6. Outlook

The success of the term *15-minute city* shows that catchy terms can increase public interest in strategies for sustainable urban planning and design. Providing proximity or accessibility to most everyday needs and promoting attractive environments for walking and cycling together with attractive public places are promising transformation goals for urban peripheries: Thomas Sieverts who initially promoted the term *Zwischenstadt* pointed out that walkability plays a key role in transforming urban peripheries (Sieverts, 2013, p. 39). A study investigating the correlation between the "accessibility of amenities within a 15-minute walk from home and the usage of these amenities" (Abbiasov et al., 2024, p. 451) found out that there is a strong positive correlation. This means that walking can only be the primary mode of transport if there are destinations to reach within a convenient timespan. Unfortunately, this goal is especially hard to achieve for urban peripheries with large monofunctional low-density residential neighbourhoods which poses a dilemma. For the sustainable transformation of urban peripheries this could lead towards two different conclusion: First, if urban peripheries cannot provide the population density needed to make most daily essentials viable inside the area of a 15-minute walk, proximity-based approaches such as the FMC should be let aside in favor of accessibility-based approaches aiming at making these amenities reachable by the use of different modes of transport in a certain timespan. Second, if the central quality of the FMC is not the physical proximity of most daily essential but merely the sufficient condition for walking and social cohesion, especially for urban peripheries new strategies to promote walking and improve social cohesion in low-density environments should be explored.

Further research on the 15-minute city and the 30-minute territory and the transformation of urban peripheries should therefore investigate: First, which existing settlement structures in urban peripheries already meet the criteria of the 15-minute city or 30-minute territory and by which morphological features the structures are characterised? Second, how public life and public space correlate with meeting the criteria and perhaps distinctive morphological features? Third, if and how European cities apply the FMC concept on urban peripheries. And fourth, which typologies can provide the building and population density needed to make local shops, public transport and service viable based on their different catchment area and population threshold?

Form Follow Mobility: A Method to Identify Potential Urbanization Area in the Over-Rail Plane under the Orientation of Station-city Integration and Pedestrian Priority

Junting Lin，Zhiwei Li, Huali Zhang, Yu Zhuang
College of Architecture and Urban Planning, Tongji University
1115800986@qq.com

Abstract
Under the people-centred approach, some areas have begun to abandon the network configuration that prioritises vehicles over walking, and create many pedestrian priority zones. In recent years, a new kind of pedestrian priority areas called over-rail plane has emerged with the concept of station-city integration. However, real examples show that not all developments with over-rail plane have been successful, and there is a need to make full use of pedestrian mobility and efficiently layout urban functions. This paper explores a methodology that can help to judge the functional potential within over-rail plane before formal design, and provides a reference for formal design: firstly, the wool algorithm is modified to generate paths with the shortest detours according to the requirements of over-rail plane; and then SDNA tool is applied to identify its flow potential and divide different potential zones for urban function. Taking Chongqing Shapingba Station as an example, this article evaluates the potential of implanting urban functional within over-rail plane and verifies the effectiveness of the method by comparing it with the real design; taking Shenzhen North Station as an example, the article identifies the high-potential areas in the current over-rail plane that can be embedded with additional functions.

Keywords: Over-rail Plane; Pedestrian-Priority Area; Identify Potential Urbanization Area; Wool Algorithm; SDNA tool

1 Introduction

1.1 Background

Under the people-centred approach, some areas have begun to abandon the network thought that prioritises vehicles over walking, and create many pedestrian priority zones when necessary. In recent years, a new kind of pedestrian priority areas has emerged in railway station areas with the introduction of the concept of station-city integration: Some railway stations add *covers above and around the railway yards which is called over-rail plane* (Fig. 1) and implant urban functions in this new substrate to fix the fragmentation between the railway station and the city. Shapingba Station has applied the strategy and achieved good development efficiency. However, not all railway stations with over-rail plane are successful. Some of them are oversize and lack of urban function to support people's staying and relaxing, therefore lack of vitality, such as Shenzhen North Railway Station and Guangzhou East Railway Station (Fig. 2). Therefore, for these railway stations which adopt the strategy of adding over-rail plane, *it is crucial to efficiently and rationally implant urban functions after determining the broad scope of over-rail plane*. On the other hand, over-rail plane development is an extremely complex design process. Therefore, *how to judge the potential of various areas for implanting urban*

functions within over-rail plane before the formal design, especially the high-potential area, becomes a problem worth exploring.

1.2 Literature Review

Existing studies on mobility can be classified into three categories according to the transport modes involved: the first is to assess the ability of citizens to travel at large or medium scales based on rapid modes of transport such as cars, rail, buses and so on, the second is to assess the ability and priority of slow transport at small and medium scales based on walking, and the third is to assess the efficiency of the connectivity between different modes of transport. The second one is related to this research. Related studies mainly focus on the pedestrian network attached to carriageway roads (Jin R, 2023). Only a few studies focus on pedestrian mobility within pedestrian priority zones. Table 1 compiles a number of studies related to pedestrian priority: Allan Andrew (2010) proposes a number of benefits brought about by advocating pedestrian priority; GwangYa Han (2011) points out that pedestrian mobility and node organisation influences the outcome of the piazza as a pedestrian priority zone using the example of Roman squares, and he further proposes a system of urban design elements to improve the quality of pedestrian-oriented suqares in Rome; Bilgehan (2018) constructs an evaluation index system for urban squares based on pedestrian mobility. In addition to these studies, there is another kind of studies related to pedestrian priority zone in the table. They use the term “Pedestrian Priority” as well (Han Sangjin, 2013, 2021; Pahk So-Hyang, 2021; Jeon Woo Hoon, 2022). But these studies are looking for zones with higher pedestrian priority in the pedestrian network attached to the vehicular traffic, which is still essentially vehicular priority.

Overall, the above studies mainly focus on pedestrian priority zones such as at-grade pedestrian walkways and plazas, failing to pay attention to an emerging category of pedestrian priority zones in recent years – over-rail plane. This paper explores a methods for pedestrian network organisation and urban function arrangement in this area under the orientations of station-city integration and pedestrian priority, which is expected to fill the gap of existing studies on this area.

2 Methodology

2.1 Research Object and its Character

The research object of this paper is over-rail plane, which can be classified into two kinds: with urban functions already implanted(Fig. 3), and to be implanted (Fig. 4).

For the first kind of research objects, the article applies the relevant methods to divide the functional potential areas in the over-rail plane, and compares the results with the actual design results to check the reasonableness of this method. This article selects the over-rail plane of Chongqing Shapingba Station as an example of this type of object (Fig. 3).

For the second kind, the paper applies the method to predict the high-potential areas in which urban functions can be implanted in the over-rail plane of the station. In this paper, the over-rail area of Shenzhen North Station is selected as an example of this type of object (Fig. 4).

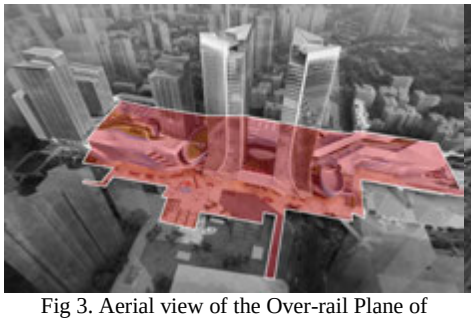

Fig 3. Aerial view of the Over-rail Plane of Congqing Shapingba Station
Source: Drawn by Author

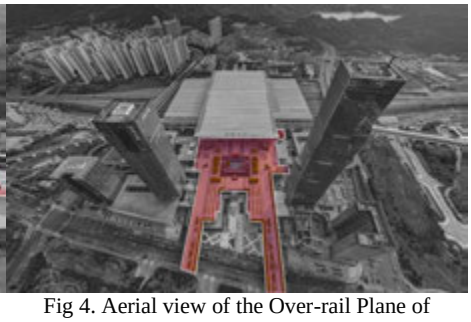

Fig 4. Aerial view of the Over-rail Plane of Shenzhen North Station
Source: Drawn by Author

There are several requirements in over-rail plane, in decreasing order of priority:

The first requirement is the priority of the railway yards and station buildings. Railway is development driver of the railway station area. The arrangement of the railway station building precedes other urban functions in the two selected cases and the arrangement of the railway station building is a constraint for subsequent decisions.

The second requirement is the priority of walking. Apart from little logistical transport, walking is the only mode of transport within the over-rail plane, and walking should be encouraged and prioritised in this area. What's more, railway station is a area for large pedestrian gather and leaving, which requires efficient pedestrian circulation as well.

The third requirement is station-city integration. Stations bring in a large number of people, and fully utilising the potential of pedestrian mobility in over-rail plane is conducive to improving functional performance and increasing functional output.

These requirements will be combined with specific method in following text.

2.2 Methods

The potential for implanting urban functions in the over-rail plane is mainly determined by the structure of the external connections. The location of the external pedestrain sources determines the possible walking paths within the over-rail plane as well as the flow potential of the corresponding paths, which will cut out several zones, and the potential of the paths adjoining these zones will determine the potential for implanting urban functions in this area, determining whether they are vibrant nodes suitable for commercial development, or or whether they will be used as logistical spaces, equipment spaces and other large-scale auxiliary spaces. According to the above understanding, two main methods should be selected and used in this paper: *method one is used to generate potential internal paths under external pedestrian flow conditions, and method two is mainly used to evaluate the pedestrian potential of these paths.*

2.2.1 Path Generation: Wool Algorithm

The methods and theories about path generation were first explored by Frei Otto in 1990s (Chenyuan Li,2021). He gave three different forms for pedestrian paths: 1. direct path network (Fig 5-a), 2. shortest path network (Fig. 5-b), and 3. shortest detour network (Fig. 5-c). The direct path network, where all destinations are directly connected, is the most direct and simplest path, however this network is not the shortest. Therefore he studied the second shortest path network. Soap bubbles will form a morphology with the smallest surface area in a stable environment, whereby Frey-Otto obtained the shortest path network with the total length of the paths being the only minimum fixed value, and the result of the morphology taking on a dendritic shape. However, the above two algorithms are more extreme and have their own advantages and disadvantages in terms of total path length and degree of detour, so he investigated a third shortest detour network. This network was obtained by the wool experiment(Fig 5-d): dry wool connecting various destination points adsorbed together after wetting because of water tension, and some of the paths aggregated into a new path. This method, called the wool algorithm, reduces the total length of the paths at each destination point while keeping the winding factor in a relatively low range. The wool algorithm is also used in the Kartal Pendik masterplan: the designer treats the roads on the periphery of the design area as emergent points of pedestrian flow, connects the emergent points to the opposite emergent points (Fig. 6-a), and performs morphology simulation operations through the wool algorithm

(Fig. 6-b) to get the initial road network of the urban design (Fig. 6-c); ultimately, a number of curves can be extracted from it to optimise the network (Fig. 6-d).

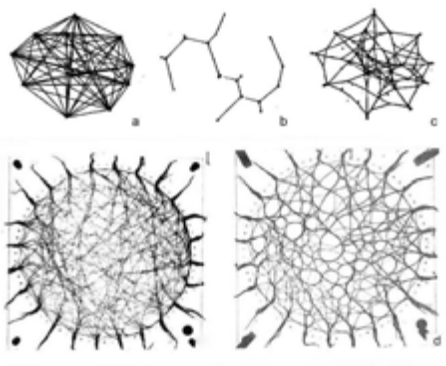

Fig 5. Frei Otto's Three Pedestrian Paths Source: Ninglin, liu and Peng Tang (2018) Research on the Path Generation Method of Composite Functional Spatial Paths of Cities and Buildings Based on Minimum Detour Networks (Conference paper), 2018 Chinese Academic Symposium on Teaching and Research on Architectural Digital Technology in Architectural Faculties.

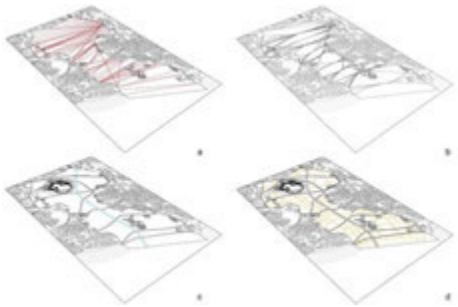

Fig 6. Use of wool algorithm in Kartal Pendik masterplanning (Source: Chengyuan, LI (2021) *Research on the application method of parametric shaping in architectural design*(Master thesis), Tianjin, Tianjin University.)

Ninglin Liu (2018) has compared the three path generation methods given by Frei Otto, pointing out that relative to the direct path network, the shortest path network makes the total length shrink by about 70%, and the third minimum detour network is 25%-35%; the minimum path network makes the number of paths between any two points drop to 1, and the minimum detour network controls its shrinkage by 30%-60%; the minimum path network makes the number of spaces is reduced by more than 70 per cent, and the minimum diversions network reduces it by about 25 per cent. Accordingly, she believes that the second network is suitable for the situation of obtaining the only shortest path, but the accessibility between any points in the site is poor, the reference value of spatial delineation is low, and the adjustment parameter is less flexible; whereas, the third network is more suitable for architects and urban designers to generate path prototypes on a daily basis. Considering the research object of this paper – over-rail plane, the construction of paths need to consider whether to meet the following needs: reasonable reduction of the total length of the path, to ensure convenient accessibility to any location within the site and the organic organisation of the path division space. On this basis, further combined with Liu 's research, the shortest detour network is suitable as the path generation method in this paper, and its specific generation algorithm is the wool algorithm.

However, the classical wool algorithm has several shortcomings in practical use that limit its application. The first one is that the classical wool algorithm cannot adapt to non-convex spatial contours (Fig. 7). Its generation results often go beyond that type of contour. The second one is that the generation results of the classical wool algorithm cannot avoid internal obstacle regions (Fig. 8). The two specific cases covered in this paper happen to involve these two conditions, so this paper will provide ideas for improved application of the classical wool algorithm, which is one innovation of this paper.

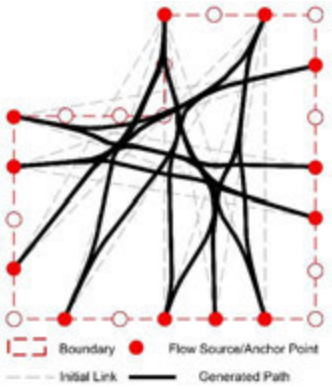

Fig 7. Result of Wool Algorithm Overflow the Non-convex Boundary
Source: Drawn by Author

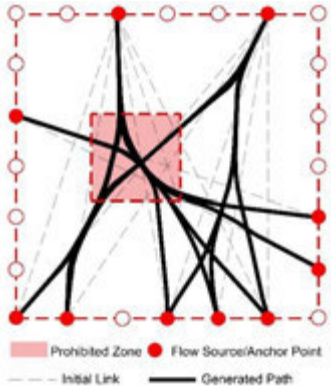

Fig 8. Result of Wool Algorithm Fail to Avoid Internal Obstacle
Source: Drawn by Author

2.2.2 Path Analysis and Zoning：Spatial Design Network Analysis Tool（SDNA）

Regarding the existing path analysis methods, there are Depthmap and SDNA (Spatial Design Network Analysis Tool) which is mature. Among them, Depthmap is mainly used for evaluating the planar network, which is not perfect in analysing the three-dimensional network, while SDNA is a tool developed specifically for three-dimensional network analysis. Since the relationship between the over-rail plane in this paper is three-dimensional, SDNA is chosen for the analysis. The specific tutorial on the use of SDNA can be found in its manual (https://sdna-plus.readthedocs.io/en/latest/). Regarding the selection of specific analysis indexes, this part is elaborated in conjunction with specific cases since different cases have different situations.

2.2.3 Integration of Methods

In this research, the modified wool algorithm is used to generate the initial pedestrian network, and the SDNA analysis tool is used to evaluate the potential of pedestrian flow and the path hierarchy. On this basis, the potential of different areas for implanting urban functions is judged. The specific steps are as follows:

(1) On-site research to determine the sources of pedestrian inside and outside the site;

(2) Establishing direct paths between sources of pedestrian;

(3) Simulate the process of the wool experiment to generate a pedestrian network pattern with minimal meandering;

(4) Converting the generated paths into segment according to analysis requirement and modelling the peripheral and underground pedestrian network;

(5) Evaluate the pedestrian potential of different paths using the SDNA analysis tool and classify the paths accordingly;

(6) Determining different potential areas of the over-rail plane that can be used for arranging urban functions according to the hierarchy of paths.

Among them, step 1, step 2, and step 3 are completed in GRASSHOPPER, and the full diagram of the program is as follows (Fig. 9); step 4 is completed in RHINO; and step 5 and step 6 are completed in ARCMAP.

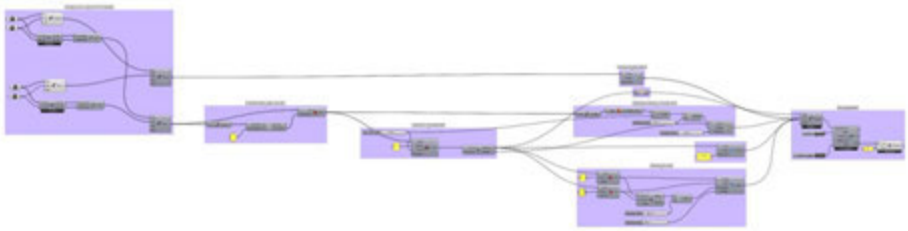

Fig 9. Wool Algorithm Programme Based on the Grasshopper Platform
Source: Drawn by Author

3 Application

3.1 The Over-rail Plane of Chongqing Shapingba Station

3.1.1 Determining Primary Source of People

Through on-site research, there are mainly three kinds of source of people in the over-rail plane area of Chongqing Shapingba Station:

(1) Entrance to the railway station building, as shown at point 1 in Figure 10, where a large number of train passengers enter or leave the covered area.

(2) Footbridge entrances and exits connecting to the neighbourhood, e.g. Points 2 - 12 in Figure 10, from which people from the neighbourhood enter or leave the over-rail plane.

(3) Major vertical transport facilities such as those leading to the metro station, e.g. Points 13 - 16 in Figure 10, from which citizens or travellers may enter or leave the covered area.

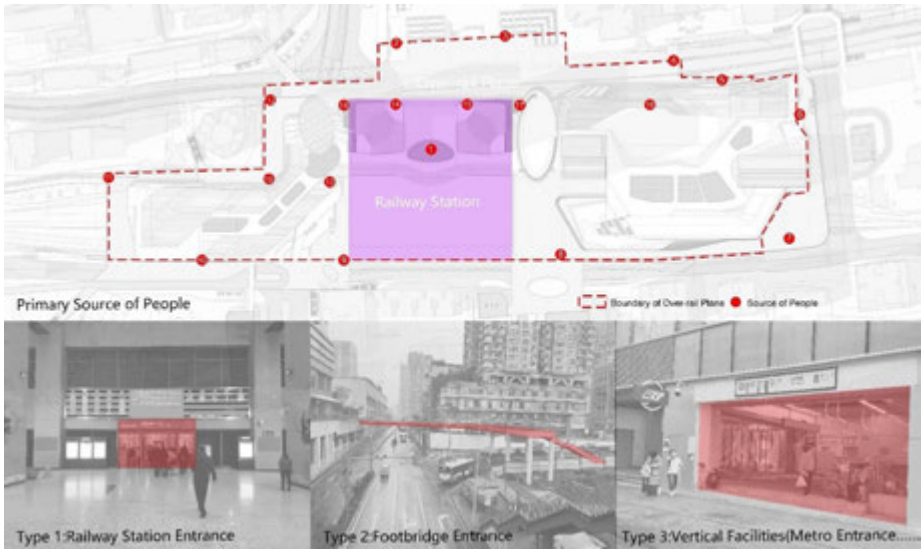

Fig 10. Primary Source of People and its Typical Types in the Over-rail Plane of Shapingba Station, Chongqing, China (Source: Drawn by Author)

It is also important to note that the railway station building has a higher priority than the pedestrian in the over-rail plane, and the generation result of the point placement as described above will show a result that pedestrian flows go through the railway station building. However, this area requires ticket checking and has security requirements in reality, and does not allow the public to freely enter and exit without a ticket. In order to avoid this situation, the wool algorithm needs to be improved. Since the railway station building is not free to pass through, citizens who originally planned to pass through this area will instead go around the outer contour of the railway station building, making the corner space of the railway station building a meeting point for pedestrian flow (Fig. 11). Therefore, this research set two pedestrian intersections at the corners of the railway station house (point 17 and point 18 in Fig. 10) when the wool algorithm was used to generate the walking network, and this modification could avoid the generation of paths that cross the railway station house as an obstacle area. Similarly, the irregular shape of the upper cover plate leads to a similar phenomenon (Fig. 12), and the intersection points of foot traffic are set at the corners of the contours (point 19 of Fig. 10).

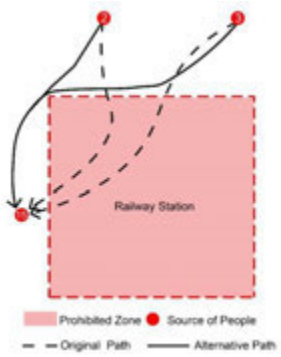

Fig 11. Changes in Path Affected by Railway Station
Source: Drawn by Author

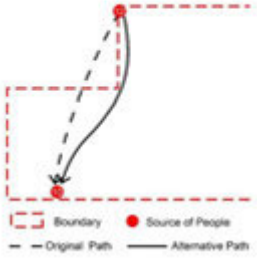

Fig 12. Changes in Path Affected by Concave Corners
Source: Drawn by Author

3.1.2 Generation and Evaluation

After completing the selection of pedestrian sources, the link between them is added according to reality and the wool algorithm is initiated aggregate the paths to obtain the shortest meandering walking path (Fig. 13). The resulting network is simplified to a segment model according to the analysis requirements of SDNA tool, and the peripheral and underground pedestrian network is built to obtain a complete pedestrian network model (Fig. 14). In Figure 14, red is the ground pedestrian network along the carriageway, grey is the next level of red one, blue is the over-rail pedestrian network to be assessed for its potential, and the other colours such as green and brown are the underground pedestrian network that supports the over-rail network. The above networks are imported into Arcmap and the analysis is carried out following the steps of the SDNA tool.

In this case, BtH (Hybrid Betweenness) is selected as the index for path evaluation. It is a measure of intermediation/penetration is an indicator of pedestrian potential, equivalent to Choice index in spatial syntax. The larger the value means the higher the potential for pedestrian flow. BthX indicates that the flow potential is calculated considering X meters as the distance, and Bth500/Bthn is generally chosen according to the needs. In the evaluation results of this case, there is some correlation among the three indicators of Bth500, Bth750, and Bthn, and Bth750 has the most outstanding effect for visualisation, so Bth750 is chosen to visualise the analysis result. Figure 15 shows the global visualisation results. Since this is a three-dimensional model, resulting in a serious superposition of above and below ground in the plan view which seriously affect the judgement. So the visualisation results related to the over-rail plane are extracted separately (Fig.16).

On the basis of Fig.16, we can determine the level of each path: the green and blue paths in Fig. 16 are classified as ordinary paths, these paths have low potential for pedestrian flow and are indicated by thin lines in Fig.17, which can be adjusted according to the needs of the subsequent design; the paths in other colours in Fig. 16 are classified as high-potential paths for pedestrian flow, these paths have high potential for pedestrian flow and are indicated by bold lines in Fig.17. With the help of the high-potential paths and little low-potential paths, we divided a number of zones (Fig.17): the zones adjacent to two high-potential paths are judged to be areas with high potential for implanting urban functions and are shown in red; the zones adjacent to

one high-potential paths are judged to have medium potential for implanting urban functions and are indicated in yellow; and the zones away from the high-potential paths are judged to have low potential for the implantation of urban functions and are showed in blue. The red zone is suitable for implanting functions that require high pedestrian flow, such as commerce. And the blue areas are prioritised for layout of equipment space, logistic space, large anchor shops, etc.

3.1.3 Overlay Comparison with Existing Design Results

In order to verify whether the above results are sufficiently effective in guiding subsequent design practice, the article compares the results with the design outcomes. Considering that the Chongqing Shapingba Railway Station Complex has produced some modifications during the implementation process due to management and other factors, the author chooses the first

version of the complete text of the programme, which has a text marking time of June 2018, to compare with this case. The analysis was carried out by means of a stacked comparison, in which Figure 17 and the layout plan for the over-rail plane were superimposed to obtain Figure 18.

The following phenomena can be observed from Figure 18:

1. the shapes of the functional areas are regularised considering the efficiency of plane utilisation, indicating that the path generated by the wool algorithm is still flawed. It only considers the performance and potential of the paths and ignores the regularity of the regions formed by the path cuts, which is a direction that can be further optimised in the future.

2. The types of functions and the potential of the area show some consistency: in the red area, there are a large number of small and medium-sized shops that bring vitality, with only a small amount of back-office space; in the yellow area, the number of medium-sized shops is beginning to increase, with a certain amount of back-office space and traffic space; in the blue area, there are mainly large warehousing spaces (the supermarket) and vertical traffic space.

This demonstrates the effectiveness of the methodology to a certain extent, but there is potential for further optimisation.

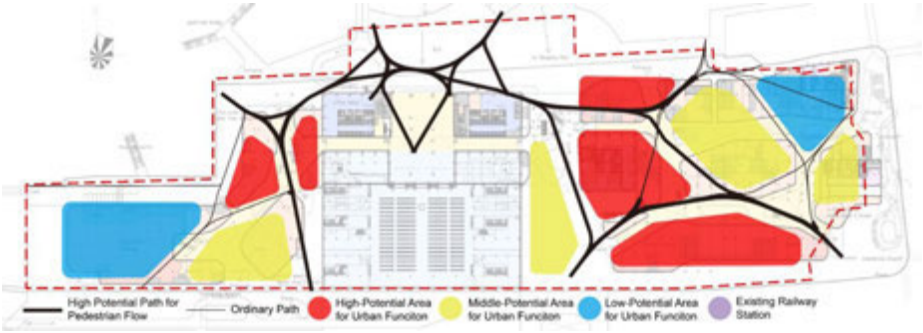

Fig 18. Overlay of Analyses and Actual Design Results
Source: Drawn by Author

3.2 The Over-rail Plane of Shenzhen North Station

3.2.1 Determining Primary Source of People

In the over-rail plane of Shenzhen North Railway Station, the following types of entrances and exits become the source of pedestrian (Fig. 19):

(1) Entrance to the railway station building, as shown at Point 1-3 in Figure 19, where a large number of train passengers enter or leave the covered area.

(2) Footbridge entrances and exits connecting to the neighbourhood, e.g. Points 4-5 in Figure 19, from which people from the neighbourhood enter or leave the over-rail plane.

(3) Major vertical traffic such as escalators to the MTR station, e.g. Point 12-15 in Figure 19, citizens or travellers are likely to enter or leave the covered area from this portion.

(4) Office buildings, commercial buildings, and transport facilities located at the edge of the over-rail plane, such as Points 6 - 11 in Figure 19, where points 6 and 9 are entrances and exits of commercial buildings, points 8 and 11 are entrances of office buildings, point 7 goes to the taxi stand, and point 10 goes to the bus stop.

In addition, since some of the points are too close to each other, it is considered to combine these neighbouring points to reduce the amount of computation, e.g. Point 3 is actually a collection of railway station entrances and two adjacent vertical facilities leading to the metro.

What's more, the current situation in the over-rail plane needs to be considered. Since the existing sunken courtyard is not freely accessible, people who had planned to pass through this area will instead follow the outer contour in a roundabout way, making it a pedestrian intersection. Therefore the research sets four pedestrian intersections at the corners (point 16-point 19 of Fig. 19) in order to avoid generating paths through the courtyard. This is similar to the way dealt with previously (Fig. 10).

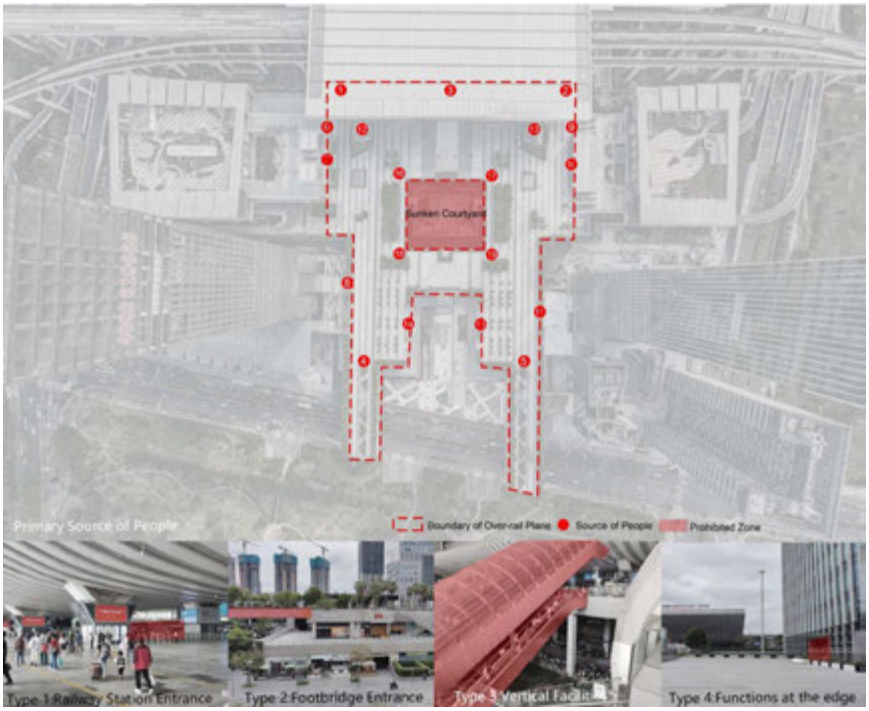

Fig 19. Primary Source of People and its Typical Types in the Over-rail Plane of Shenzhen North Station, Guangdong, China (Source: Drawn by Author)

3.2.2 Generation and Evaluation

The analytical application process for this case is essentially the same as the previous case, where differences are highlighted in italics:

In this case, the wool algorithm is also used to obtain the shortest meandering walking paths (Fig. 20), and the resulting network is simplified to a segment model in accordance with SDNA

analysis requirements. After supplementing with the peripheral and subterranean walking network, the SDNA tool is used to analyse as well.

In this case, Bth (Hybrid Betweenness) is also selected as the indicator for path evaluation. *During the path evaluation process of this case, three indicators, Bth500, Bth750 and Bthn, are used to be visualised, but the effect was not outstanding, indicating that the* over-rail plane *of Shenzhen North Station is not closely connected with the surrounding area, and its centrality of the station area is not strong. Therefore Bth300, which reflects centrality in smaller scale, is used for the visualisation.* Figure 21 shows the global visualisation results. Similarly, the visualisation results related to the over-rail plane are extracted separately (Fig. 22).

On the basis of Figure 22, the article determines the hierarchy of paths (Fig. 23, with exactly the same criteria and methodology as in the previous case). With the help of high potential path for pedestrain flow, *we selected a number of high potential areas (Fig. 23) according to two criteria: firstly, they are adjacent to three or more high potential paths, and secondly, they have a regular shape, which will facilitate a more efficient use of the planes in the case of smaller planes.*

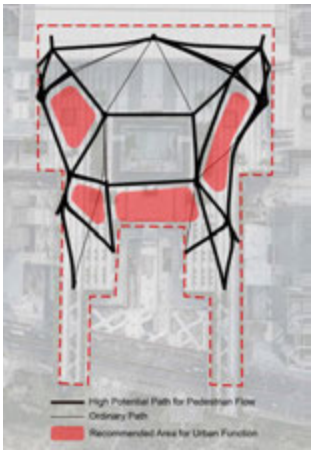

Fig 23. Identification of the Potential of Path and Regions (Source: Drawn by Author)

4 Discussion and Summary

This paper combines the wool algorithm and the SDNA analysis tool to explore a method to generate paths and divide potential functional zones in the over-rail area, and its innovations are mainly as follows:

(1) This paper improves the classical wool algorithm: firstly, it can be adapted to the existence of non-convex space after improvement; secondly, its generation results can avoid the internal obstacle zones, which expands the application possibilities of this classical algorithm.

(2) Focusing on an emerging kind of pedestrian priority areas – over-rail plane, we summarise the points inside and outside this class of areas that may become sources of pedestrian flow, and provide a method to organise its pedestrian system based on the sources of pedestrian flow and delineate the functional potential areas.

At the same time, we also found that the method has some shortcoming that deserve further enhancement:

(1) The wool algorithm can not be directly used to generate pedestrian networks, but only provides reference for path generation. Because it only considers the performance of paths and ignores whether the sites generated by path cutting are suitable for the embedding of urban functions. In the future, the regularity of the shape generated by cutting can be further taken into consideration to make it closer to the final design ;

(2) The research on the effectiveness of the current method is a qualitative comparison of the stacked maps, and more quantitative studies are to be conducted by introducing elements such as poi (point of interest).

Dr. Ayesha is a PhD scholar at the School of Architecture and Design, Harbin Institute of Technology, China. She specializes in sustainable urban development, with a focus on TOD in South Asian cities. She is also an assistant professor at the Department of Architecture, FADFA, University of Gujrat, Pakistan, where she teaches various subjects regarding Architecture and Urban Design.

Hong Leng, Ph.D., is a professor in the School of Architecture and Design, Harbin Institute of Technology, and director of the Key Laboratory of National Territory Spatial Planning and Ecological Restoration in Cold Regions, Ministry of Natural Resources. Her research focuses on theory of livable urban planning in cold regions.

Abstract

This study investigates the potential of Transit-Oriented Development (TOD) in Lahore, Pakistan, a developing city in South Asia, to address its pressing transport and environmental challenges. Recognized as the world's most polluted city in 2022, Lahore confronts urgent issues exacerbated by urban sprawl and automobile dependency. Despite the introduction of a mass transit system, the city lacks robust urban planning strategies to effectively utilize these services. Our research seeks to bridge this gap by evaluating the TOD potential at 95 transit stations across four transit lines, using Geographic Information Systems (GIS) and Spatial Multicriteria Analysis (SMCA). The findings contribute to a sustainable urban planning framework, aiming to assist planners in making informed decisions for the development, funding, and implementation of TOD strategies, as outlined in the Master Plan for Lahore Division (MPLD-2050). This comprehensive approach will act as game changer, rejuvenating Lahore's urban center and promoting sustainable urban growth in emerging economies.

Keywords: Developing City, Game Changer, Sustainable Urban Planning, South Asia Transit-Oriented Development (TOD)

1. Background

According to the United Nations (UN, 2018), 55 percent (55%) of the global population currently resides in urban areas, a figure expected to double by 2050. This urban expansion is driven by population growth and migration to cities. Urban centers, as economic powerhouses, generate over 80 percent (80%) of the world's Gross Domestic Product (GDP), as reported by the World bank (2020). However, cities also consume approximately 70 percent (70%) of the world's resources, positioning them as major consumers of energy and significant contributors to greenhouse gas (GHG) emissions. The trends of urban sprawl and increased reliance on automobiles exacerbate these issues. Consequently, there is a growing advocacy for investment in public transport as a means to counteract low density development and rejuvenate urban environments. Such investments promote sustainability by enhancing convenience, encouraging active travel, improving air quality, reducing congestion, and mitigating climate shifts.

In this context, cities in developing countries encounter significant difficulties in maximizing prospects foe eco-friendly urban planning. These challenges stem from immediate transportation needs, disjointed organizational structures, problems with interdepartmental coordination, and stringent administrative environments. Many major cities in Asia are currently making significant investments in public transport networks, oscillating between transit-oriented models and auto-centric, traffic-congested urban forms. Moreover, transforming city structures and strengthening teamwork within the transportation sector consistently pose considerable challenges. This is particularly evident in Lahore, the cultural capital of Pakistan, which has recently initiated a mass transit system as a step towards sustainability. However, there is an urgent need for effective planning approaches to utilize these services effectively as tools for urban revitalization.

Transit-Oriented Development (TOD) has garnered increasing recognition among scholars and professionals for integrating transportation with urban development, spatial planning, and design to provide comprehensive solutions to contemporary urban challenges globally. TOD encourages walking, cycling, and the use of public transit over cars by fostering the development of multi-

functional communities near transport nodes, characterized by average to high density levels and walker-friendly zones. While much of the research demonstrating TOD's practical implementation comes from developed countries (Singh *et al.*, 2017; Hamid and Saadi, 2018; Li *et al.*, 2019; Teklemariam and Shen, 2020), there remains a notable gap in its applicability and evidence for developing nations, which compel the formulation of bespoke action plans.

This research seeks to bridge existing gap by conducting focused research on the potential for TOD in Lahore, Pakistan—a developing city in South Asia facing significant challenges related to its transportation sector and associated environmental and urban issues. Lahore, often in the global spotlight as the 'World's most polluted city,' has endured years of severe smog conditions(IQAir, 2022). Moreover, the new Master Plan for Lahore Division (MPLD-2050) proposes TOD principles for major transit corridors, but falls short on proactive implementation steps. This research aims to evaluate the TOD's potential in Lahore as a sustainable strategy that could revolutionize its comprehensive issues, thus marking a progressive step towards a sustainable future. Additionally, it seeks to develop a framework for sustainable urban planning that enhances emerging economies through the effective utilization of transit services like BRT and LRT.

2. Literature Review

Achieving sustainable urban growth is a primary goal of transportation-linked urban strategies, despite their inherent contradictions. Throughout the 20th century, as cities expanded, transportation systems both supported urban development and posed challenges to economic, social, and environmental sustainability (Banister, 2005). Sustainability is commonly interpreted through the concept of sustainable development, defined by the World Commission on Environment and Development (WCED, 1987) as meeting the needs of the present without compromising the ability of future generations to meet their own. Understanding 'sustainable urban development' is critical when exploring the interplay between cities and sustainability (Dizdaroglu and Yigitcanlar, 2016). This involves a continuous alignment of resource use, investment, technological progress, and institutional change with the needs of both present and future populations.

This narrative is especially pertinent in Asia, where bustling cities and robust economic growth are marred by significant sustainability challenges. According to the Asian Development Bank (ADB, 2017), 80 percent (80%) of new economic growth in Asia will stem from urban areas, leading to urban sprawl and an increased reliance on vehicles (Jenks, Kozak and Takkanon, 2008). These dynamics contribute to traffic congestion, environmental pollution, and unequal access to services, exacerbated by inadequate urban planning and limited transportation alternatives. To address these issues, many Asian cities have escalated their investment in mass rapid transit systems. From 2001 to 2010, the majority of these systems were constructed in Asia, with half being built in China alone. This trend is expected to continue, with approximately 30 cities in China, including Beijing and Shanghai, and nearly 20 in India, such as Delhi and Mumbai, alongside several in Southeast Asia like Bangkok and Jakarta, actively expanding their transit infrastructures. According to ADB projections (2017), emerging Asia will require $26 trillion in infrastructure investments from 2016 to 2030 to sustain growth and address climate change, with $8.4 trillion earmarked for the transport sector (Abiad, Farrin and Hale, 2019).

In South Asia, however, the trajectory of urban transport development has diverged significantly from other regions. Major cities here have followed a delayed development path compared to global cities such as Tokyo, Paris, and London, which had established extensive rapid transit networks before the advent of mass motorization (Barter, 2018). South Asian countries initially prioritized increasing road capacity to alleviate traffic congestion, fostering auto-oriented urban planning standards. Consequently, air quality in South Asia remains critically poor, with countries like Bangladesh, Pakistan, and India featuring among the top five most polluted nations as per the 2019 World Air Quality Report by IQAir (IQAir, 2019). Furthermore, a study of 114 countries worldwide indicates that economic and population growth have been significant drivers of increasing global CO2 emissions over recent decades, with urban centers at the heart of this trend (Pani and Mukhopadhyay, 2010).

Dense urban planning is essential for managing energy consumption and reducing carbon emissions, achievable through strategies like TOD and mixed land-use. Research indicates a strong correlation between urban development density and CO2 emissions: areas with low-density expansion tend to have higher emissions compared to those with compact urban growth (Glaeser and Kahn, 2010). Moreover, implementing TOD strategies can significantly lessen Vehicle Miles Traveled (VMT) and related greenhouse gas (GHG) emissions (Haas and Miknaitis, 2010). Additionally, mixed-use designs can lower carbon emissions by minimizing travel distances and reducing reliance on automobiles (Fong *et al.*, 2008).

(Calthorpe, 1993) outlined best practices for smart city planning through eight design principles, including enhancing walkability and bicycle systems, developing dense networks of streets and pathways, promoting mass transit, zoning for mixed land-use, aligning density with transit capacity, fostering compact regions with short travel distances, and optimizing mobility by managing parking and road space. These principles align well with the features of TOD, emphasizing compact growth, pedestrian and bicycle friendliness, and the integration of public spaces around transit stations, which are designed as community hubs (Thomas *et al.*, 2018). TOD's success in promoting urban and transportation sustainability is notable. Originating in the 1980s to address urban issues in U.S. cities, the approach has gained global recognition, particularly in developing countries grappling with rapid urbanization and increasing traffic congestion. This concept resonates with the challenges described in South Asia, where there is a critical need for sustainable infrastructure to accommodate burgeoning urban populations and mitigate environmental impacts.

Since the 1990s, TOD has become a key term among urban planning circles worldwide. It has gained recognition from scholars and professionals for its approach to integrating the transport sector with urban development, spatial planning, and design to address contemporary urban challenges comprehensively. Although TOD initiatives have been implemented globally, it has become apparent that their outcomes can vary significantly. This variability underscores that the results of any given plan depend on a complex array of factors, methods, and interactions. Consequently, after practical applications, global literature has offered various critiques of TODs, particularly from American, European, and Australian contexts. These critiques often highlight how many projects have evolved into Transit Adjacent Developments (TAD) without the necessary supportive conditions.

Integrating TOD planning across various levels is essential to effectively address transportation challenges. The TOD approach can be viewed from two perspectives: one at the station level, involving prescriptive guidelines for development, and another at the regional level, which allows for a more flexible approach to urban growth (Hrelja *et al.*, 2020). First, TOD requires high-quality rail transit services that connect municipalities and must be planned, managed, and financed at the metropolitan or regional level. Second, station areas along transit lines can differ significantly in their current development status and potential for growth, as well as their balance between being a node and a place. Regional planning is crucial in evaluating the specific role each station plays within a broader territorial framework, thereby guiding local decision-making to align with larger-scale objectives.

A substantial body of literature on TOD assessment incorporates both quantitative and qualitative analyses. Various scholars have proposed numerous indicators to establish empirical or theoretical foundations within specific contexts. Calthorpe (1993) introduced the '3D' approach to TOD, encompassing Density—with a high concentration of housing, population, workplaces, and recreational sites; Diversity—featuring mixed land uses; and Design—promoting compact urban forms and pedestrian-friendly environments. Building on this foundation, Cervero and Kockelman (1997); Ewing and Cervero (2010) and Renne (2016) expanded the definition by adding three additional dimensions: Distance to transit stations, Terminus Accessibility, and Demand Management of urban car traffic. Furthermore, Knowles (Knowles, 2012; D. Knowles and Ferbrache, 2016) identified High-frequency transit service as another critical requirement for successful TOD.

Researchers have employed various methodologies to analyze transit station areas, utilizing spatial analysis, spatial statistics, and simulation techniques. Notably, Evans and Pratt (2007) and Singh *et al.* (2014) developed a TOD index to quantify existing levels at transit stations. Higgins and Kanaroglou (2016) used the latent class method to classify 372 stations in Toronto into distinct TOD typologies, while Shirke *et al.* (2017) applied a discrete choice model to assess the impacts of TOD along Mumbai's Metro Line-1. Further advancing TOD assessment, Mirzahossein *et al.* (2022) utilized the Analytic Hierarchy Process (AHP) to devise an interactive transit system in and Iranian city. The integration of both qualitative and quantitative methods has been prevalent, enhancing TOD evaluation(Nagari, Suryan and Pratiwi, 2020; Millard-Ball, 2021; Mohamad, Fahmy-Abdullah and Masrom, 2021; Liu *et al.*, 2022; Maheshwari, Grigolon and Brussel, 2022). The evaluation of a TOD involves integrating factors related to Transportation, Orientation and Urban Growth, which may differ in scope and can be spatial or non-spatial, often demanding Multiple Criteria Analysis (MCA) for an inclusive valuation. Spatial Multi Criteria Analysis (SMCA) is particularly favored for identifying priority interference areas, thus deepening insights into regional TOD levels. In a recent example, Ibrahim *et al.* (2023) used SMCA to evaluate TOD potential in Alexandria, Egypt . This interconnected approach highlights the evolving complexity and precision in TOD research, emphasizing the importance of multifaceted assessment techniques to inform urban planning and development strategies.

Although the aforementioned studies have made significant contributions to evaluating TOD in various contexts, most TOD research and implementation examples are derived from developed countries. This has resulted in a noticeable gap in knowledge and practical application for developing cities. Consequently, we have chosen to employ the 3D criteria to assess the extent to which TOD supportive characteristics exist in Lahore and identify areas that require improvement

to steer the city towards sustainable growth. The selection of criteria and relevant indicators is grounded in a thorough review of pertinent literature and the availability of data within the context of developing countries. This approach ensures that our methodology is both informed and adaptable to the specific challenges and resources of these regions.

3. Research Approach and Case Study Background

3.1 Research Approach

We worked on 3Ds criteria established by Cervero and Kockelman (1997) which includes density, diversity and design. Higher density around stations promotes public transit usage, while greater diversity attracts visitors to use BRT/LRT services and explore the area on foot. Pedestrian-friendly designs further encourage walking near these transit stations. The selection of indicators for each criterion is guided by specific reasons and the availability of data. The detailed methodology is illustrated in the Figure.1, and the Table.1 outlines the final selected variables, providing descriptions and the data sources utilized for this study.

Before evaluating TOD, it is crucial to delineate the "TOD area" around each transit node, usually defined by a walking distance of 400m to 800m. In Lahore, the typical walking distance to access public transport is around 600m(JICA, 2012). Stations along transit lines are strategically placed about 1km apart, supporting an optimal walking distance of 500-600m. For this study, we have considered a 500m radius (equivalent to a 5-minute walk) as the basis for measuring indicators within the areas surrounding the four transit lines (Figure 2).

Population density is calculated as the ratio of population to land area, as shown in Equation (1). For this analysis, the WorldPop open population repository (WOPR) provided population data set for Pakistan in 2020, with a resolution of 100 meters. This dataset, in Geotiff format, was processed more using ArcGIS to compute the population density within each demarcated zone.

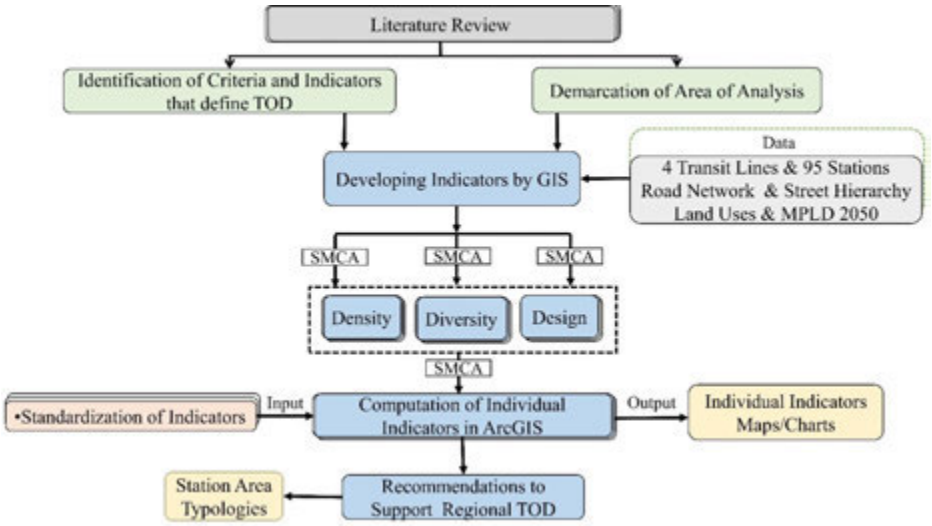

Figure 1. Research Framework

Table 1 Criteria and indicators

Criteria	Indicators	Description	Data Source
Density	Population Density	Number of people/sqkm	WorldPop
Diversity	Land use Diversity	Entropy index	Computed with ArcGIS
Design	Open Space Ratio	Area of open spaces and parks	Computed with ArcGIS
	Landuse Mixedness	Ratio of residential land use with non-residential land uses	Computed with ArcGIS
	Intersection Density	Number of intersections per km2	Computed with ArcGIS
	Walkable/Cyclable paths	Aggregate length in meters of walkable and cyclable routes	Computed with ArcGIS

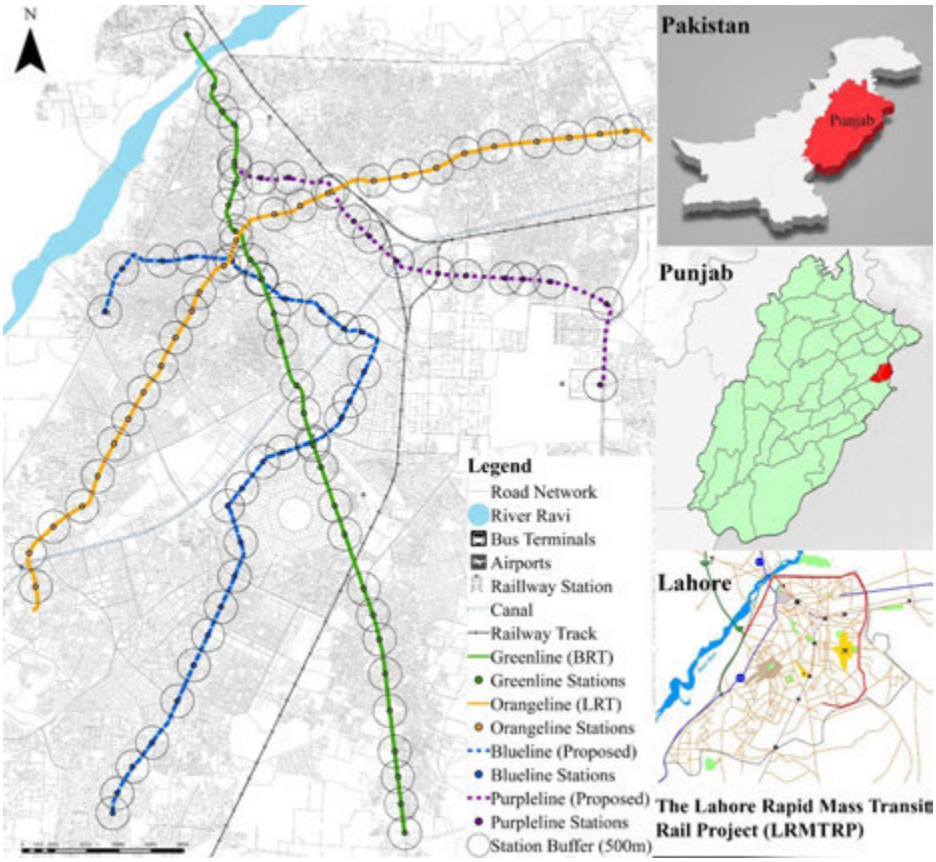

Figure 2. Transit lines in LRMTRP with demarcated TOD Area

$$Population\ Density = \frac{\text{No. of People}}{\text{Buffer Area}} \quad (1)$$

Building on the analysis of population density, the study also examined land use diversity, which evaluates the spatial variety of various land use categories in accessible proximity. This diversity in land usage addresses various needs of residents, thereby encouraging the use of transportation services during off-peak times and on holidays. Among several methods considered, the entropy method was chosen to quantify land use diversity. The specific formula employed is detailed below.

$$Entropy\ Index = \frac{-\sum_i Q_{lu_t} \times \ln(Q_{lu_t})}{\ln(n)} \quad (2)$$

where

$lu_t = land\ use\ class\ (1,2,\ldots\ldots,n)\ within\ analysis\ area\ t$

Q_{lu_t} = Propotion of particular land use within area of analysis t

S_{lu_t} = Overall spatial extent of the designaed landuse in area t

S_t = Total area of analysis t

Design plays a crucial role in creating accessible environments that promote walking, an essential component for TOD. Moreover, design is not merely linked to travel choices; it also forms a vital connection in the spatial layout between residents and stations, facilitating the development of high-quality open spaces. Under this criterion, indicators such as land use mixedness, walkable and cyclable pathways, intersection density, and the ratio of open spaces have been selected.

The objective of assessing land use mixedness is to determine how well-suited an area is for walking and cycling. This concept is distinct from diversity index as it explicitly measures the integration of residential areas with other land uses. A good blend of residential and other land uses supports a higher number of non-work-related trips that can be made by walking or cycling, as indicated by various studies (Jacobs, 1961; Evans and Pratt, 2007). Therefore, we calculated mixedness using a formula developed by Zhang and Guindon (2006):

$$\text{Land use Mixedness} = \frac{\sum_{nt} S_c}{\sum_{nt}(S_c+S_r)}\ \forall t \text{ a} \qquad (3)$$

S_c = Aggregate area of non − residential urban land uses

S_r = Total area of residential landuse within (t)

The length of walkable and cyclable paths is computed in meters. Data related to roads network is employed in ArcGIS (version 10.8) to compute intersection density, depicted as the number of intersections per square kilometer within each station buffer area. Furthermore, this study utilizes the open space ratio as an indicator of walkability. Research by McCormack et al. (2010) demonstrated that high-quality green spaces and parks encourage walking within neighborhoods. Koohsari et al. (2013) also found that the size and quality of these areas positively influence pedestrian activity. Further supporting this, studies by Zhang et al. (2020) and Zlot and Schmid (2005) indicated that neighborhoods with abundant parks are generally more walkable. In this study, we employ the following formula to calculate the open space ratio.

$$Open\ Space\ Ratio = \frac{Area\ of\ open\ spaces\ and\ parks\ (sqm)}{Total\ catchment\ area\ of\ a\ station\ (sqm)} \qquad (4)$$

After developing individual indicators in ArcGIS, further step is spatial multi-criteria analysis (SMCA). It involves standardizing values reflecting indicators to compare and aggregate. This standardization is crucial due to the diverse units of measurement used in computing these indicators. In this study, among the various methods available, we employ the "maximum" method. Under this approach, the highest attained indicator value is assigned a value of "1". All other values are then proportionally assigned a value between 0 and 1, based on their ratio to this maximum value.

3.2 The Case Study Background

Lahore, Pakistan's cultural capital and one of the top thirty most populated cities globally, is a key center for economic, political, transportation, entertainment, and education. According to the 2017 census, its population stands at 11 million with an annual growth rate of 4.07 percent (4.07%) since 1998 (PBS, 2018). Contributing 13.2 percent (13.2%) to Pakistan's GDP, Lahore ranks 122nd worldwide in economic output (Ali et al., 2020).With a history that spans over two millennia, the city is celebrated for its significant architectural heritage and vibrant cultural scene.

Once governed by the Mughal Empire and later under British colonial rule, Lahore became the Islamic Republic of Pakistan following its freedom in 1947. Known for its historical architecture, including mosques, temples, churches, tombs, and parks, Lahore is a vibrant destination for tourists. Its urban landscape is characterized by a densely populated walled city and more expansive urban and outlying regions to the south and southeast (NESPAK, 2004). As a major metropolitan center, Lahore offers a variety of commercial and trade opportunities and is becoming a key player in the technology sector. Historically referred to as the "Mughal city of gardens" (Naz and Anjum, 2007)and the "Paris of the East," the region has seen significant transformations over the past few years through urban rejuvenation, heritage conservation, renovation initiatives, and extensive infrastructure improvements. Transitioning from the "City of Gardens" to the "City of Concrete," Lahore faces ongoing challenges such as urban decay, escalating land prices, and infrastructural concerns (Abubakar, 2016).

A significant undertaking is the Lahore Rapid Mass Transit Rail Project (LRMTRP), encompassing 97 kilometers of rail lines to deliver sustainable transport in Lahore. The project is divided into two stages: Phase I features the Greenline (MBS), operational since 10 February, 2013, and the Orangeline, operational since October 2020. Phase II proposes two additional lines: the blue and purple lines. However, a noted issue with these infrastructure projects is their isolated development, often disregarding the city's character(Rana, Bhatti and e Saqib, 2017).A research on Greenline by Anwar et al. (2020) also noted that transport infrastructure dominance alters the city's overall character. Further confirmation was found regarding the neglect of social considerations during the design and construction phases. Attention was exclusively directed towards physical infrastructure, neglecting softer elements such as community development, socio-cultural values, and people-centric design (Anwar, Leng and Ahmad, 2024).

Numerous urban green spaces in Lahore have been converted into pavement for infrastructure projects such as flyovers, underpasses, and road expansions, often at the expense of the city's green belts. Furthermore, the construction of the Greenline and Orange Line has negatively impacted the city's environment and cultural identity. While Lahore has made significant strides in infrastructure, it continues to face numerous challenges. Many of these major projects are executed in isolation, without an integrated plan or strategic framework (Alam, 2015).

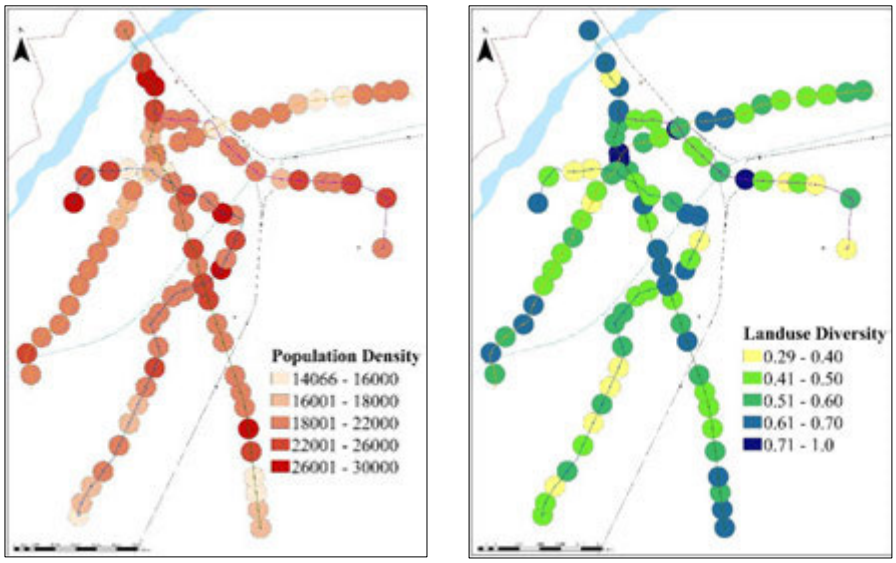
Despite these issues, Lahore has taken a step towards sustainability by implementing a mass transit system. However, the city still struggles to find effective planning approaches that can transform these services into tools for urban renewal. Once known as a garden city, Lahore is now in a phase of urban transformation, and is eagerly awaiting sustainable initiatives to bridge these developmental gaps.

4. Results and Discussion

Utilizing population density as a benchmark is pivotal for assessing transit areas, as regions around transit stations with high population densities typically see increased public transit ridership and spur urban development. Thus, areas of high-density development not only suggest substantial travel demand but also indicate a strong alignment with TOD principles. Figure 3a visually represents the population density within specific zones around each transit station. Notably, the highest population densities occur near Azaadi Chowk Station and Timber Market Station, due to the tightly packed and densely populated residential parcels. In contrast, the areas near Canal and Liberty Station exhibit higher densities due to multistory building structures. This variation underscores the influence of residential patterns and architectural styles on the population density surrounding transit stations.

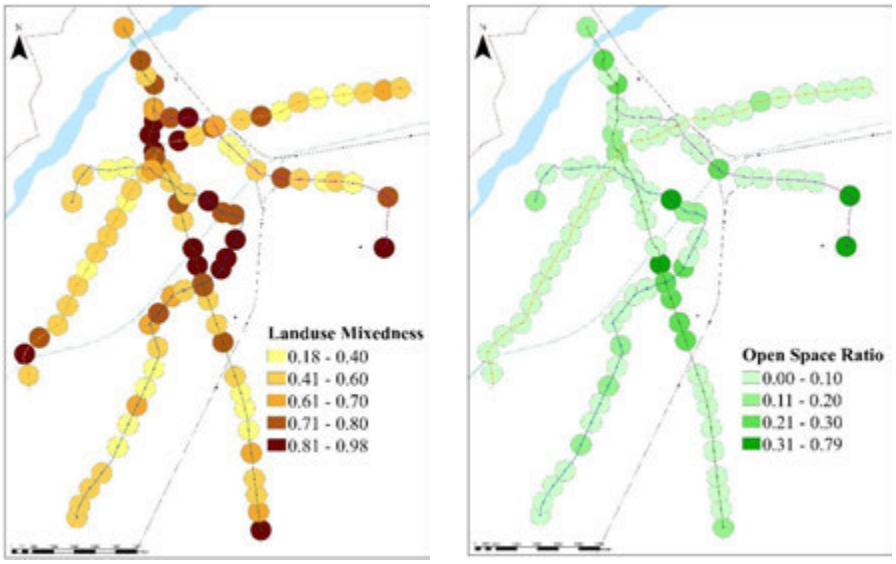
The entropy method was adopted to evaluate land use diversity, and parcel-level land use data was compiled in vector format using ArcGIS 10.8. This dataset includes a 500-meter radius around each station and incorporates data from surveys, Google Earth, OpenStreetMap, and extensive field trips. The analysis covered diverse types of land uses including commercial, educational, healthcare, institutional, industrial, religious, parks and green spaces, leisure zones, graveyards, underutilized or vacant plots, residential areas, utilities, and transportation facilities. Figure 3b illustrates the land use diversity surrounding each node. The calculated measure ranges between 0 and 1, with higher values indicating increased land use diversity and improved TOD effectiveness. Notably, the highest levels of land use diversity are observed near Railway Station, Dharampura Station, Lake Road, MAO College Station, and Shama Station. These locations serve as central hubs for a variety of businesses that cater to the entire city. Conversely, the lowest diversity values are found at Samanabad Station, Shamnagar Station, NFC Society Station, Askari IX Station, and Airport Station, predominantly due to the prevalence of residential neighborhoods. This comprehensive approach underscores the complex nature of urban development and its potential to support TOD.

In the same context, figure 4a displays the land use mixedness for all 95 stations in the area. This mixedness also spans from 0 to 1, where 0 indicates no residential usage and 1 denotes exclusively residential areas. A mixedness value of 0.5 represents a balanced mix of residential and other land usage, suggesting a harmonious blend. Subsequently, the open space ratio is calculated and presented in Figure 4b.



(a) (b)

Figure 3. (a) Population density (b) Land use diversity



(a) (b)

Figure 4. (a) Landuse Mixedness (b) Open Space Ratio

Intersections significantly enhance walkability and cyclability by reducing travel distances. A higher density of intersections provides more route options for pedestrians and cyclists, effectively shortening their travel paths. This phenomenon is demonstrated across 95 stations of the LRMTRP, as illustrated in Figure 5. The highest intersection density is observed around Bhaati Chowk Station, Janazgah Station, Lakshmi Chowk Station, Samanabad, and Ichra Station. These areas benefit from old, organic development in the city core, characterized by small land parcels. In contrast, the lowest densities are observed around Liberty Chowk Station, Canal Station, and Gulberg College Station—areas of newer planned development—as well as Airport Station and NFC Society Station, which are characterized by vacant land parcels.

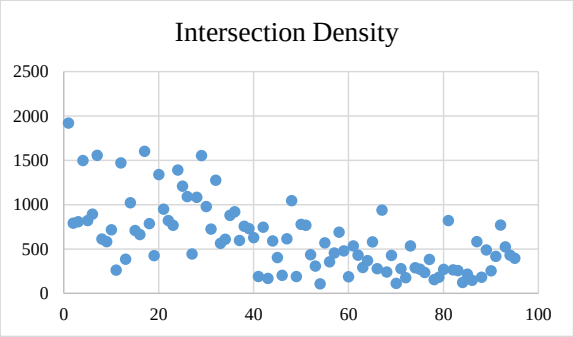


Figure 5. Intersection density around 95 stations of LRMTRP

Similarly, the total length of pathways, measured in meters using ArcGIS, varies significantly, as depicted in Figure 6. Pathway lengths range from 0 to 36,573 meters. Stations such as Samanabad, Bhaati Chowk, Timber Market, Lakshmi Chowk, and Chungi Amra Sidhu report the highest measurements, corresponding to their locations in the dense, inner core of the city. Conversely, stations like Liberty Chowk, NFC Society, Marrian Stop, and Gulberg College, situated in newly developed areas, report the shortest pathways. Additionally, Boharwala Chowk Station exhibits lower values due to its proximity to railway infrastructure. This distribution highlights how urban planning influences pedestrian and cyclist accessibility.

After computing all indicators, their results are standardized for spatial multi-criteria analysis (SMCA). The standardized results for all indicators around the 95 stations of the LRMTRP are displayed in Table 2. Using these values, stations can be compared to identify which criteria require improvements based on the context and location of each station within the region. For instance, a standardized value of 1 for intersection density at Bhaati Station shows that this area has the highest intersection density among all stations. There is a necessity to focus on individual stations by enhancing their low-scoring criteria to contribute to TOD for a sustainable future. Radar charts

have been created for three sample stations located in varied city zones—urban, suburban, and greenfield—to highlight areas for improvement based on their standardized values (Figure7).

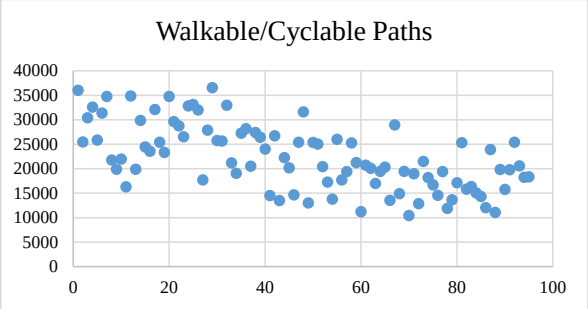

Figure 6. Walkable/cyclable paths

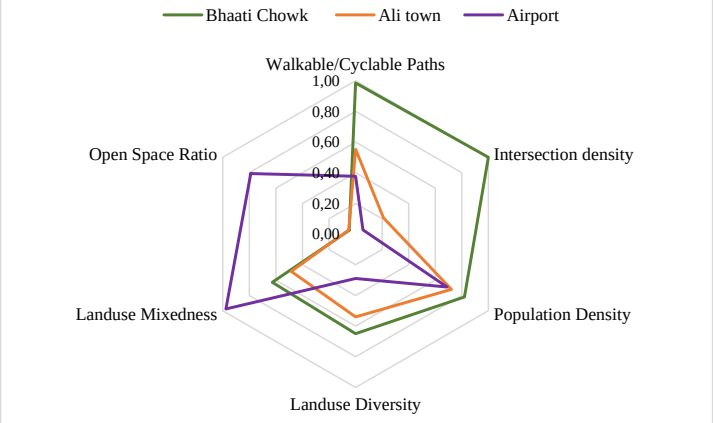

Figure 7. Radar Charts for 3 Sample Stations

5. Conclusion and Recommendations

Research on practical TOD implementation has traditionally been conducted in developed countries, leaving a gap in evidence and experience regarding its applicability in developing cities. To address this gap, this study focuses on TOD application in Pakistan, specifically examining planning parameters critical for implementing TOD as a sustainable transport strategy in mega cities. The case study of Lahore is particularly highlighted to provide context-specific insights.

The results indicate that TOD is feasible in Lahore. It suggests that each node, whether existing or proposed, must be tailored stemming from its unique features and difficulties to effectively implement TOD. The recent master plan for the Lahore Division (MPLD 2050) recommends densification along the existing public transport corridors of the orange and green lines, as well as along major structural plan roads (Figure 8).

These lines currently operate at nearly 40% below their projected capacity, surrounded by low-density areas near major stations. To combat this, a 500-meter radius around each station has been designated for regeneration and densification. This approach aims to enhance accessibility and walkability, fostering an urban environment conducive to TOD. The typical building height in these areas is currently 2 to 3 floors. There is a proposal to increase the permitted building height between 8 and 12 stories within this 500-meter radius around the main transit stations, which is expected to increase the population density to approximately 350 to 400 persons per hectare. This adjustment highlights Lahore's potential to adopt TOD as a sustainable strategy.

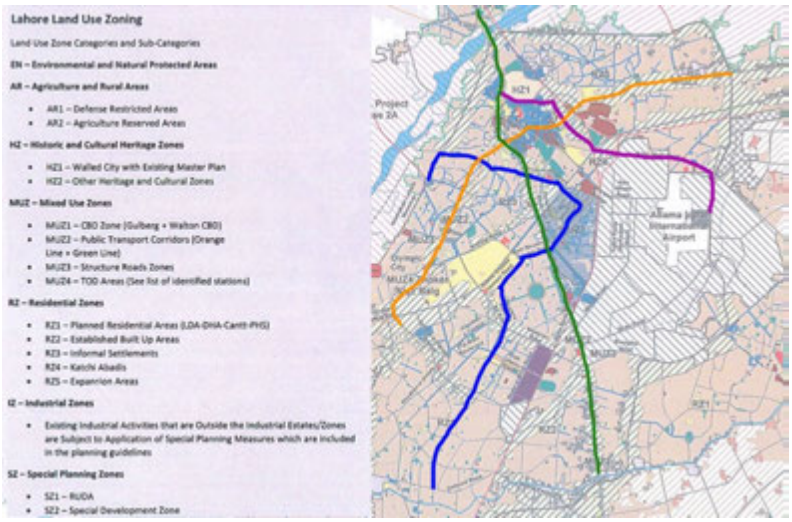

Figure 8. Transit lines of Lahore in Master Plan of Lahore Division (MPLD-2050)

This study assessed the existing characteristics of Lahore's urban landscape around transit nodes to evaluate the potential for adopting TOD. Our findings reveal that variations in different indicators across various transit nodes are due to their distinct contexts within the region. A significant issue in implementing TOD is the application of uniform Floor Space Index (FSI) or Floor Area Ratio (FAR) across the city, which overlooks local nuances such as existing infrastructure. The cornerstone of effective TOD is context-specific design, which considers factors like transit capabilities, lot dimensions, street sizes, and infrastructure capabilities.

To pave the way for urban redevelopment, a gradual and necessary process through democratic means is essential. Instead of granting higher FSI universally, it should be market-responsive, awarded selectively to those contributing to urban development. This approach prevents "Transit Adjacent Development" (TAD), which merely accumulates floor space near transit stations without necessarily increasing public transit ridership. Moreover, challenges such as lengthy timelines for

urban development, uncertain demographic shifts, and difficulties in achieving a jobs-housing balance pose substantial obstacles.

As Lahore continues on its urban development path, addressing these challenges and opportunities will be vital in shaping a sustainable and inclusive urban future. Based on the results from various indicators, all 95 stations across four mass transit lines have been categorized into three types, reflecting their development context as illustrated in Figure 9. Additionally, associated possibilities, challenges, and representative stations have been compiled in Table 3. These outcomes offer a valuable diagnostic tool for planners, policymakers, and governmental authorities, enabling them to assess and compare the efficacy of TOD attributes in both existing and proposed neighborhoods. Moreover, incorporating TOD principles into urban planning frameworks, such as the MPLD 2050, can guide future transit projects and promote sustainable urban growth in Lahore, other cities in Pakistan, and other emerging nations aspiring to implement public transport networks. This comprehensive approach will act as game changer, rejuvenating Lahore's urban center and promoting sustainable urban growth in emerging economies.

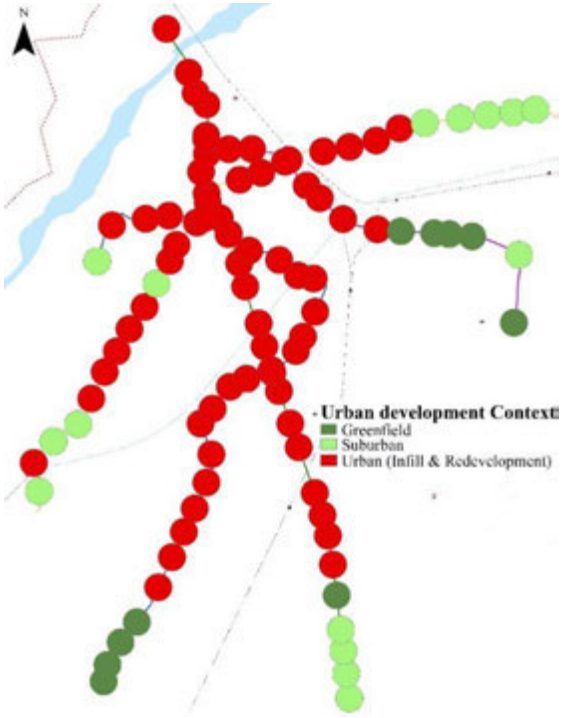

Figure 9. Development Context of all Stations

Table 3. Urban Development Context of all Stations of LRMTS

Urban Development Context	Opportunities	Challenges	Representative Case
Greenfield	Abundance of government lands New communities can be master planned around transit Lower land costs Increased financial resources available Construction of higher capacity infrastructure is feasible Strong political backing Minimal regulatory barriers Road safety is emphasized through systematic concepts	Long timeline for city development. Uncertain population composition. Challenges in achieving jobs-housing balance initially. Weak public transport connectivity promotes sprawl. Developers may lack risk appetite.	Askari IX, Zarrar Shaheed, Jora Pull, Saddat Chowk, Valencia Town, Engineers Society, NFC Society, Military Accounts Society, Atari Saroba, Airport
Suburban	More spots are at hand for transformation. Chance to enhance transit access in low-density areas. Lower land costs.	Sprawled lower density growth pattern. Singular land uses. Poor mobility connections, prioritizing automobiles over pedestrians, public transport, and non-motorized options like walking and cycling.	Ali Town, Canal View, Hanjarwal, Dulu Khurd, Gajjumata, Guldasht colony, Dera Gujran, Islam Park, Babu Sabu, Bund Road
Urban	Proximity to major transit routes and business hubs. Greater utilization of active travel modes, especially in low and middle-income areas. Potential for enhancing transit accessibility. Chances for redevelopment of aging buildings.	Multiple ownership complicates land assembly. Varying property dimensions and layouts. Current land uses are often not transit-friendly. Large block sizes hinder accessibility. Inadequate and risky pedestrian and bicycle infrastructure. Narrow or limited pathways. Layout Patterns and Crowd Flows of Commercial Space in High-Speed-Rail Station Complexes

-- Take three Chinese high-speed-rail station complexes as examples

Yunjing Wang is a PhD student at the Department of Architecture, College of Architecture and Urban Planning, Tongji University, focusing on the direction of station-city integration, commercial complexes, and urban renewal, and has published three articles in Chinese domestic journals as the first author or corresponding author.

Professor Zhuang is the deputy director of the Urban Design Branch of the China Society of Urban Planning, head of the Urban Design Team of the Department of Architecture, College of Architecture and Urban Planning, Tongji University, and a PhD supervisor.

Abstract

The commercial space in the high-speed railway station area is a key factor in stimulating the vitality of the crowd in the station area, and the station complex can maximally convert the transport value of the station area into comprehensive functional value. In the era of ordinary railways, the high-speed railway station was only regarded as a passenger transport hub. The commercial space was only used as a supporting facility to serve the transport interchange activities, which failed to attract the crowd to stay for long. Still, with the gradual increase in the proportion of short-distance and commuter passengers, however, as the proportion of short-distance and commuter passengers grows gradually, the commercial space in station complexes that have appeared in recent years has also failed to take into account the needs of both passengers and citizens. In this paper, based on the block layout relationship between commercial space, station access space, and urban transport space, we construct a "node-path" network of commercial space entrances and exits with high-speed rail station entrances and exits as well as urban traffic entrances and exits, analyse the correspondence between the commercial space layout pattern of the station complexes and the flow of crowds, and explore how different commercial space layout patterns influence the flow of crowds. It also discusses how different commercial space layout patterns affect the behavioural activities of the crowd. Finally, it concludes that: 1. Appropriately narrowing the distance between the commercial space and the station space of small and medium-sized passenger stations, especially placing underground space between the two, can stimulate the consumption potential of transport-oriented passengers who transfer to the underground. 2. The entrance and exit settings of the commercial space and the distribution of the flow of people are affected by the layout of the commercial space. 3. The commercial space entrances and exits related to the movement lines of underground passengers are also affected by the layout of commercial space blocks. 4. The entrances and exits of commercial spaces related to the moving lines usually have higher pedestrian flow. This study can provide new perspectives and methods for analysing the layout patterns of commercial space in station areas and offer design suggestions for improving the use of commercial space in station complexes.

Station-city Integration; Station Complex; Commercial Space; Crowd Flow; Layout Design

1. Introduction

The high-speed railway station is an important transport intersection in the overall layout of the region, gathering a large amount of internal and external traffic in the city. However, the urban station hub area is not only a mobility node in the transport network but also an aggregation place in the city, and it is a waste of the value embedded in the circulation to use it only as a transport hub for the collection and distribution of human flow. Relying on the traffic advantage of the high-speed railway station to create urban functions such as commerce, business, exhibition, leisure, and so on in the surrounding area and organically integrating the traffic function (switching to articulation) with the urban function (commerce, office, leisure,

etc.) (Peng Qiyuan *et al.,* 2017), in addition, it can make full use of the transport value of high-speed rail stations, explore the urban place attributes of high-speed rail stations, and promote the linked development of high-speed rail stations and cities.

The commercial function is one of the main functions of utilising the overflow effect of station traffic effectively, and commercial space has rich spatial forms and types of business, that can meet the consumption needs of different groups of users. In China's high-density cities, where urbanisation is accelerating and land resources are relatively scarce, the joint development of station hubs and commercial facilities can realise the spatial connection between the two sides of the station and the city and promote the integrated development of the station and the city in the traffic hub area. For example, New York's Grand Central Station, London Bridge Station, and Tokyo's Shibuya Station have become important urban business and commercial centres.

As a comprehensive transport hub, the high-speed railway station in the high-density city centre has strong transport value and a functional development basis. It can closely connect with and interact with the neighbouring urban space, so it can rely on the transport advantage to enhance the comprehensive urban functional value of the station area, especially the commercial function that drives the area's economic growth. It is necessary to introduce commercial functions reasonably and appropriately, taking into account the needs of consumption activities of station passengers and neighbouring citizens, and to establish a close connection with other spatial elements in the station area to create a synergistic effect between the station and the city.

However, in the current practice of construction of commercial space in the high-speed railway station area, it is obvious that there is insufficient consideration of the user groups and their needs, especially since the resources of people flowing from both the station and the city are not fully utilised at the same time. In the era of ordinary railways, the commercial space of high-speed railway station complexes in China was mainly a supporting facility serving fast-passing passengers. With the gradual growth of the proportion of short-distance and commuter passengers, the user groups in the station area not only demand the station's internal and external traffic functions but also pursue higher-quality consumption and leisure functions. However, the commercial space of station complexes that have appeared in recent years, despite emphasising the integration of commercial space with the station and the city in terms of spatial form, still presents the result of mainly serving the use of part of the group, producing a large number of unused and inefficient commercial spaces. The practical exploration of creating station-city integrated commercial space is still in its infancy and lacks effective supporting theories and assessment methods.

The station complex mentioned in this study refers to a complex system that contains station space, urban transport space, and commercial space and has great potential to develop into a regional public centre. Compared with the single passenger transport function of a traditional station, a station complex contains more comprehensive urban functions that are closely linked to the station space, and the urban transport space is placed between the station space and the urban functional space, playing a transitional role in linking the station and the city, while the urban functional space crosses the red line of the station site and is laid out close to the station space (Fig. 1). Due to the high degree of integration of various functional spaces,

clear and convenient spatial organisation and flow guidance are required to ensure basic passenger distribution and transfer functions while avoiding mutual interference and influence between functional spaces.

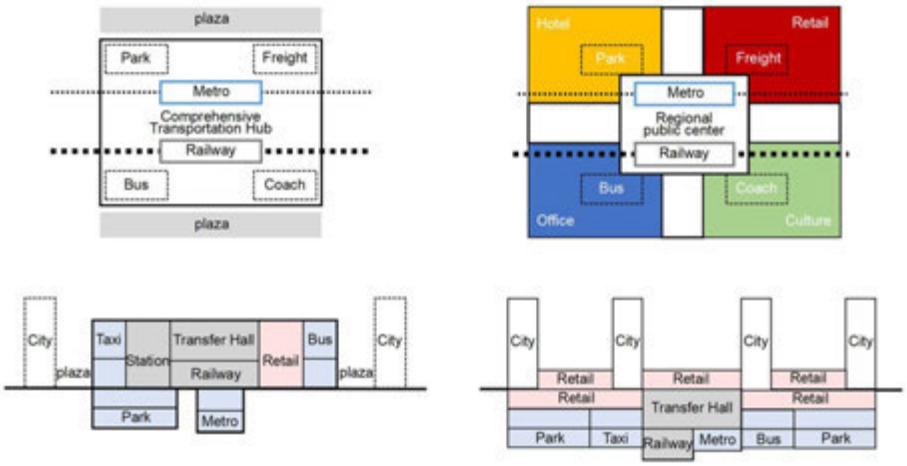

Fig. 1: Spatial pattern diagram of traditional stations and station complexes

Established studies have focused on the general organisation of station areas (Qi Guangping and LU Guanyu, 2019; Dai Yizheng *et al.*, 2018). Some studies have analysed the coupling relationship between commercial space and other spatial elements of traffic interchange activities (Gui Wangyang *et al.*, 2023; Yu Baofei and Ren Jun, 2021; Chen Binbin *et al.*, 2021). Few studies have focused on the fine-grained design of commercial space in high-speed rail station complexes from the perspective of passenger-citizen behavioural activity characteristics. On the one hand, existing studies have paid insufficient attention to the specific morphological design of commercial space in station complexes, lacked effective morphological analysis methods for commercial space layout, and have not yet answered the question of how the commercial space in station complexes should be linked to the station and the city, respectively. How should the commercial space of the station complex link the station and the city, respectively, and what role will other urban transport elements play? On the other hand, the existing studies have not deeply explored the influence of the layout of commercial space in station complexes on the flow of people, such as what kind of spatial use results will be brought about by different layout patterns.

This study selected Guangzhou East Railway Station, Chongqing Shapingba Railway Station, and Shenzhen North Railway Station, located in the centre of high-density cities in China, as the research samples. The commercial spaces of the three sample stations are similar in terms of industry composition but completely different in layout pattern. Among them, the layout pattern of the commercial space of the high-speed railway station complexes is broken down into two levels: block layout and node layout, and the crowd flow characteristics are mainly based on the data of pedestrian flow at the entrances and exits of the commercial space.

This study focuses on the layout of commercial space in high-speed railway station complexes. It builds a "node-path" network of commercial space entrances and exits with high-speed railway station entrances and exits and urban traffic entrances and exits based on the block layout. In addition, this study will classify the passengers and citizens in the commercial space of the station complex according to the purpose of travel and different types of urban transport, graphically present the behavioural activity chains of different groups, and explore the correlation between the behavioural activity characteristics of different groups in the station complex and the layout pattern of the commercial space.

The subsequent chapters are arranged as follows: Section 4 demonstrates the correspondence between the layout patterns of the commercial space of the sample station complexes and their crowd flow characteristics, Section 4.1 summarises the relationship between the commercial space of the sample stations and the block layout of the station space and urban transport spaces, corresponds the block layout characteristics of the commercial space of the sample station complexes to the total flow of people at all entrances and exits and analyses the impacts of different commercial space on the proportion of commercial space use. The impact of different commercial space layout patterns on the percentage of commercial space use is analysed. Section 4.2 abstracts the three types of functional blocks into multiple functional nodes, draws the behavioural activity chain of passengers and citizens going to the commercial space, respectively, constructs the relationship between commercial space entrances and exits with station entrances and exits as well as other urban traffic entrances and exits, corresponds the characteristics of the node layout of the commercial space of the sample station complexes with the flow of people at all entrances and exits, and analyses the effect of different node layouts of commercial space on the convergence of pedestrian flow at all entrances and exits. The influence of different commercial space node layout patterns on the gathering effect of pedestrian flow at each entrance and exit is analysed. Section 5 summarises the layout patterns of the commercial space of the sample station complexes, puts forward optimisation suggestions for different patterns, and proposes the commercial space layout suggestions of the high-speed rail station complex based on the characteristics of passenger-citizen behaviours and activities.

2. Literature Review

2.1 Study on the layout of commercial space in station areas

Theories related to functional space layout in station areas. TOD theory focuses on developing and constructing functional spaces that are closely linked to transport nodes. (Calthorpe Peter, 1993) Based on the study of high-speed railway station areas in Germany, France, Japan, and other countries, Schutz et al. were the first to put forward the circle structure model of the station area, i.e., with the increase of the distance from the station, the correlation between each functional space and the station gradually decreases and eventually forms a functional circle centred on the station. station-centred functional circles (Schütz Elmar, 1998). This theory initially explores the layout pattern of functional spaces in station areas. The commercial space of the station complex concerned in this study is located in the first circle,

which can take advantage of the traffic spillover effect of the railway station. The node-place model proposed by Bertolini is an analytical model for evaluating transport nodes from the perspective of public transport and land use based on the theory of the transport-land use feedback loop (Bertolini Luca, 1999; Bertolini Luca, 1996). The node-place model is an analytical model based on the theory of traffic-land use a feedback loop to evaluate transport nodes from the perspectives of public transport and land use (Bertolini Luca, 1996, 1999), in which the value of place is reflected in the development progress and development of the area around the high-speed railway station, and the use of commercial space is one of the indicators to measure the value of place in the station area, and the model can partly reflect the characteristics of the layout of the functional space and the effect of the use of station area.

Research and methodological tools for commercial space layout in station areas. Scholars have already classified commercial space in station areas into three categories: station commercial, station peripheral commercial, and peripheral area commercial, of which station commercial is commercial space developed integrally with station stations and transport facilities (Li Chuancheng *et al.*, 2016), which is consistent with the scope of commercial space that this study focuses on. Some scholars have also categorised commercial space as profitable building space and have analysed the coupling relationship between commercial space and elements of transport space and public space, proposing the layout patterns of tandem, adjacent, interspersed, composite, and cascading (Qi Guangping and LU Guanyu, 2019). In addition to conventional graphical analyses and qualitative descriptive methods, studies have been conducted to quantify the spatial organisation of station areas using urban spatial analysis tools such as Depth Map, such as exploring the correlation between the spatial integration degree of station peripheral areas and the functional layout of land (Du Qianyu and Zhang Fan, 2019). For example, to analyse the integration, connectivity, and comprehensibility of the underground interchange space of high-speed rail stations (Gui Wangyang et al., 2023), some studies abstract the complex urban spatial structure into graphical relationships based on urban morphology and building typology (Wang Zhendong & Wang Yindong, 2011). (Wang Zhendong and Wang Yinpu, 2015). The spatial structure of the station area is more complex, and it is difficult to determine a unified spatial reference point, but the connecting relationship between spaces can be expressed in diagrammatic form.

The distribution of crowd flow in the station area directly affects the use of commercial space. Still, few studies have analysed the connection between commercial space and other spatial elements in the station area from the perspective of crowd flow. Based on the above relevant theories, existing studies, and methods, this study will analyse the layout pattern of commercial space in station complexes from the two spatial floors of blocks and nodes by mapping the crowd flow in commercial space and summarising the layout pattern and expected usage effect of commercial space in station complexes.

2.2 Study on the crowd activity in station areas

Types of people who use the functional space in the station area. Studies have classified station users into two categories, namely "traffic transfer users" and "destination users" (Zhuo Weide *et al.*, 2022). For example, the destination segment is divided into four categories:

business, commuting, visiting relatives, and shopping (Wang Shaojian *et al.,* 2021). Other studies have analysed the functional space needs of different groups, such as short- and medium-distance passengers who are highly time-sensitive and have higher requirements for the accessibility of commercial space, long-distance passengers who are more likely to be price-sensitive and concerned about the type of commercial space, and citizens from the urban end of the city, who are more likely to have higher requirements for the quality and accessibility of commercial spaces (Wang Li, 2015).

Research and methodological tools for crowd activities in commercial space in station areas. Studies have used pedestrian simulation software to obtain complete data on crowd activities in station areas that cannot be collected in short-term studies, such as using AnyLogic software to simulate peak passenger flows in the distant future (Chen Binbin et al., 2021). For example, AnyLogic software is used to simulate the transfer situation of passengers leaving the station and to analyse the problems of the transfer space in the station based on the two indicators of transfer time and regional passenger density (Yu Baofei and Ren Jun, 2021). The problems of station transfer space are analysed based on two indicators: transfer time and regional passenger density. A large number of studies have also focused on the use of commercial office space in railway station areas, using field research, observation point counting, and other methods to obtain data such as the average number of people entering the shop per hour and the path flow of people to comprehensively evaluate the performance of the use of commercial space in the area of the railway station (Zhang Lingzhu *et al.,* 2019; Zhuang Yu and Yao Yiqian, 2016). This study mainly analyses the impact of the layout pattern of commercial space in station areas on crowd use, i.e., treating multi-floor commercial space blocks as a whole and ignoring the differences in the number of people entering the shop within the commercial space so that the use of the commercial space can be simplified to the flow of people converging to the entrances and exits of the commercial space.

Existing studies have mainly focused on transport interchange activities in station areas. Still, few studies have analysed the distribution among activities of different groups, or separately transport interchange activities and destination leisure activities, and the interweaving and transformation phenomenon of the dynamic lines of the two types of activities. In this study, according to the basis of traffic transfer and destination leisure groups and taking into account the different starting points of activities of tourists and citizens, the population using commercial space is classified into three categories: leisure citizens, traffic tourists, and leisure tourists, and the commercial space of the station complex is taken as the core to analyse the origin, flow, and process of the three categories of people converging to the entrances and exits of the commercial space in the station area.

3. Methods

3.1 Sample Selection

Since the urban location of the station affects the use of commercial space, this study selects high-speed rail stations located in the centre of high-density cities in China (Fig. 2) as samples among the station complexes that have been built and operated for many years and

have well-functioning commercial space: Guangzhou East Railway Station, Chongqing Shapingba Railway Station, and Shenzhen North Railway Station, which are located no more than 10km away from the city centre and represent different commercial space layout patterns of the station complexes. The scope of the study is the station access space, the multi-floor commercial space, and the urban transport space between them. Among them, urban traffic space which is far away from commercial space and does not have a spatial connection is not considered. The entrances and exits of the commercial space are set as the junction between the space of each floor and the external space. The vertical connection within the commercial space is not taken into account, i.e., multiple entrances and exits located at the same position in the commercial space of each floor are all connected with the external space of the ground floor through the vertical connection. Only the entrances and exits on the ground floor of the position are taken into account.

Fig. 2: Urban location of the sample stations

3.2 Layout analysis of commercial space in station complexes

First, the overall layout of the commercial space of the station complex is analysed. Through field research on the layout relationship between commercial space, station access space, and urban transport space, the "space-block" relationship of the three types of functional space is extracted. The second is to analyse the layout of the entrances and exits of the commercial space. Abstract the three types of functional spaces into corresponding functional nodes, take the entrances and exits of commercial space as the core, draw the footpaths of passengers and citizens who may pass by commercial space and whose destinations are commercial space, and construct a "node-path" network. In terms of the spatial object of the research, only the floors of commercial space that have a close spatial connection with the station entry and exit spaces are selected.

3.3 Pedestrian flow analysis of commercial space in station complex

The first is to compare the pedestrian flow in the station space and commercial space, and the proportion of the pedestrian flow in the commercial space to the total pedestrian flow in the station core area. The footfall in the station space is the total footfall entering and exiting the station; the footfall in the commercial space includes all the footfall passing through the

commercial space and the footfall destined for the commercial space; and the total footfall in the station core area is the footfall entering all the functional spaces. The second is to compare the pedestrian flow of each entrance and exit of the commercial space of the station complex. The research time is selected on weekdays, and taking into account that shops basically start the business at 10:00 a.m., the two time periods of lunch peak and evening peak are selected, and each time the people flow statistics lasts for 5 minutes.

4. Results

4.1 Layout and use of blocks of commercial space in station complexes

In the planning and design stage of a station complex, the number of passengers in the station influences the layout patterns of the functional space (Suo Chao and Zhang Hao, 2015). Considering the impact of the rapid in-and-out passenger flow of the station on the commercial space, the commercial space of the high-speed railway station complex will be appropriately far away from the in-and-out space of the station, and after the station complex is put into use, the location of the body layout of the commercial space usually significantly affects the overall use of the commercial space (Li Chuancheng et al., 2016).

4.1.1 "Space-block" layout of commercial space in station complexes

The commercial space of the station complex is usually chosen to face the external urban space, taking into account the accessibility of the public to the commercial space and the potential for passengers to pass through the commercial space on their way, including the urban transport space of the metro and motor vehicle loading and unloading points, which is usually laid out between the commercial space and the entrance and exit space of the railway station, i.e., forming a horizontal layout structure of external urban space, commercial space, urban traffic space, and station entrance and exit space. The passenger scale of Shenzhen North Station, Guangzhou East Station, and Chongqing Shapingba Railway Station decreases in turn, so the potential for integrating the commercial space of the station complex with the station space increases in turn. The average daily arrivals and departures of Shenzhen North Station are more than 0.2 million; the average daily arrivals and departures of Guangzhou East Station are about 0.05 million; and the average daily arrivals and departures of Chongqing Shapingba Railway Station are less than 0.01 million. The "space-block" layout characteristics of the commercial space of the three sampled station complexes are: far away from each other, overlapping, and overlapping, respectively (Fig. 3).

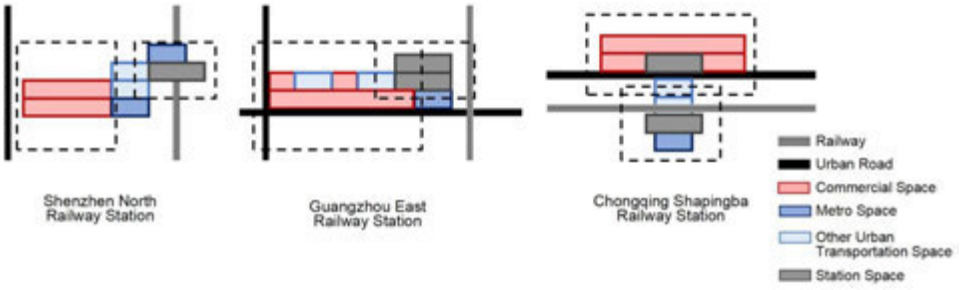

Fig. 3: Schematic layout of commercial space with station space and urban transport space

The commercial space of Shenzhen North Railway Station is completely separated from the station entrance and exit space, and between the two is an urban transport space integrating metro, buses, and taxis. The commercial space of this station complex consists of two floors with no vertical dislocation; the plan form is a U-shape facing south; and the concave space on the south side is a continuous outdoor promenade. The commercial space on the ground floor is connected to the metro station hall, and the commercial space on the second floor is connected to the transfer hall for buses and taxis. The city-facing area of the commercial space is adjacent to only one city road, with city roads farther away in the other two directions (Fig. 4). The shop formats are mainly catering, retail, and lifestyle services.

The commercial space of Guangzhou East Railway Station is intertwined with the station access space, and the urban transport space is embedded between the two. The commercial space of this station complex has four floors, and this study only considers the ground floor and the first underground floor, which are closely connected with the station space and the urban transport space. These two layers of commercial space are in the shape of a ladder; the ground-floor commercial space is located on the south side of the station space; between the two is the motor vehicle lane and drop-off area; the ground-floor commercial space is deep below the station space; and the underground station hall is below the station space. The city-facing area of the commercial space is adjacent to three city streets with plenty of pavements and overpasses (Fig. 4). The shop formats are mainly catering, retail, and life service, with the ground floor mainly for fast food, the first basement floor mainly for retail business, supplemented by a small number of catering businesses, and life service businesses and hypermarkets located in the second and third basement spaces.

The commercial space of Chongqing Shapingba Railway Station is completely superimposed with the station access space and urban transport space, and all kinds of urban transport space are spaced out from the station access space, and the commercial space is located above the two, adjacent to the station access space. The main part of the commercial space of this sample station complex is five floors, and the local part is seven floors, only the ground floor and the first floor, which are closely connected with the station space and urban transport space, are considered in this study. These two floors of commercial space are located entirely on the ground, and the plan form is a dumbbell shape distributed on both sides of the

station building, and the east and west sides are connected through the aerial connecting corridor that spans above the station space with the commercial space on the ground floor. The commercial space is close to several urban roads and overpasses (Fig. 4). The shop formats are equally dominated by catering, retail, and lifestyle services.

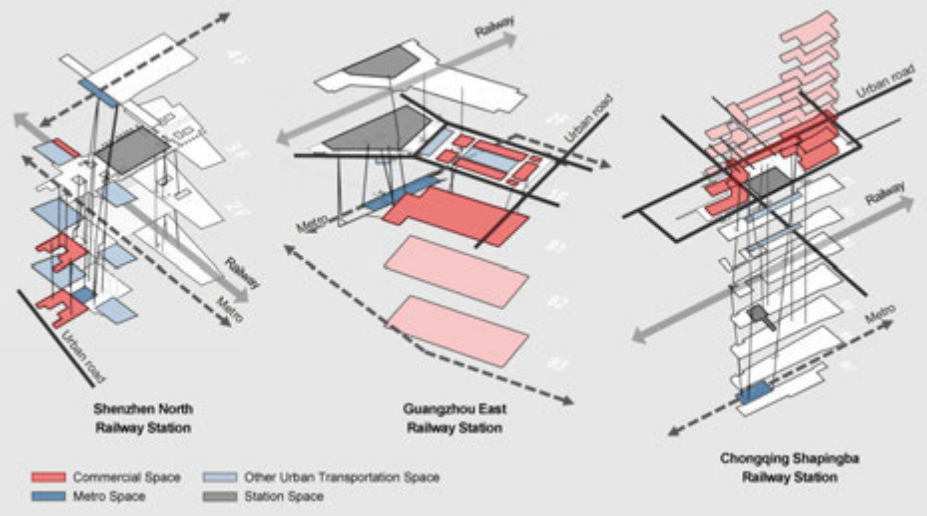

Fig. 4: General layout of commercial space in the sample station complexes

4.1.2 Total footfall of commercial space in station complexes

The pedestrian flow in the station space is usually proportional to the size of the station passenger flow, while the pedestrian flow in the commercial space is jointly influenced by the size of the passengers and the layout location of the commercial space. Based on the passenger scale of the station, the influence of the layout location of the commercial space of the station complex on the flow of people is analysed by comparing the relative size of the commercial space flow of the sample station to the station space flow of people and the proportion of the commercial space flow of people to the total flow of people.

As shown in Fig. 5, the percentage of commercial space use in Guangzhou East Station, Chongqing Shapingba Railway Station, and Shenzhen North Railway Station decreases in turn. Guangzhou East Station has a higher commercial space footfall than its station space; Chongqing Shapingba Railway Station and Shenzhen North Railway Station both have a lower commercial space footfall than station space footfall; and Chongqing Shapingba Railway Station has a relatively small gap between commercial space footfall and station space footfall. Among them, Guangzhou East Station, which has a medium passenger size, has the highest pedestrian flow of commercial space in its staggered layout, while Chongqing Shapingba Railway Station, which has a smaller passenger size, does not have a pedestrian flow of commercial space in its overlapping layout that exceeds that of Guangzhou East Station. In addition, although the pedestrian flow in the commercial space of Chongqing Shapingba Railway Station is lower than that of Shenzhen North Railway Station, the total pedestrian flow

of the former is much smaller than that of the latter, and thus the commercial space usage ratio of Chongqing Shapingba Railway Station is still higher than that of Shenzhen North Railway Station, which also shows that the calculation of the respective commercial space usage ratios of the sample stations can be used to make effective comparisons between the stations.

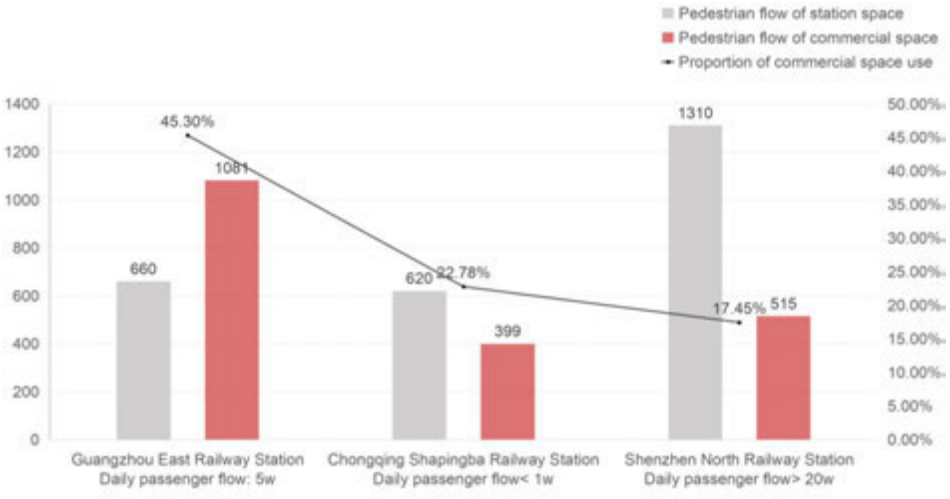

Fig. 5: Total footfall in commercial space of the sample station complexes

4.2 Nodal layout and use of commercial space in station complexes

In addition to the above commercial space block layout, the actual use of commercial space in station complexes is also affected by the more microscopic layout of entrances and exits. The node layout relationship between the commercial space of the station complex and the station entrance and exit space and urban transport space affects the origin, flow, and convergence of people travelling to and passing through the commercial space, and the "node-path" layout is reflected in the flow of people through the various entrance and exit nodes of the commercial space.

4.2.1 "Node-path" layout of commercial space in station complexes

The main users of commercial space in the station complex are leisure citizens (citizens who specially go to and use commercial space within the radius of the station), traffic passengers (passengers who pass through the commercial space in the process of entering and exiting the station by railway), and leisure passengers (passengers arriving by railway and especially go to and use commercial space), and the urban transport means to be chosen are underground, taxi, bus, and so on. The starting point of the passenger's movement is the station entrance and exit node, while the starting point of the citizen's movement is the various urban transport nodes, which are usually located between the commercial space entrance and exit

node and the station entrance and exit node. The movement of the two groups will cross and overlap, and there are commercial space entrances and exits shared by both the passengers and the citizens.

As shown in Table 1-3, the entrances and exits of the commercial space of Guangzhou East Station are mainly distributed at the end near the station, and only two ground-floor entrances and exits are set up in the city-facing area; the 16 entrances and exits of the commercial space of Chongqing Shapingba Railway Station are located at the ground floor and above; the entrances and exits of the commercial space of Shenzhen North Railway Station are set up both at the near-station end and the near-city end, of which eight entrances and exits are set up in the near-city area, and six entrances and exits are set up in the near-station area. The "node-path" layout of the commercial space of the three sample station complexes takes into account both passengers and citizens and has the potential to attract transport and leisure passengers in addition to serving as leisure shopping destinations for citizens in the vicinity.

The commercial space at Guangzhou East Railway Station can attract transport-oriented passengers transferring to the metro, and most of the entrances and exits of the commercial space are exclusively for passengers or citizens. Passengers who choose to transfer to the metro and citizens who take the metro to the commercial space are distributed in the same area, but the two movements do not interfere with each other. Passengers transferring to the metro will pass through Entrance 6/7/9 in the process, while citizens arriving by metro will enter the commercial space through Entrance 5 or Entrance 7, and Entrance 7 will be shared. People choosing buses, taxis, and walking will enter the commercial space through Entrance 2, Entrance 1/8, and Entrance 1/2/3/4/8, respectively. Leisure passengers travelling exclusively to the commercial space will mainly enter through Entrance 1/6/9. Entrance 1 will be shared by taxi-only citizens and leisure passengers, so Entrance 2/3/4/8 will be the exclusive entrance for citizens entering the commercial space, and Entrance 6 and Entrance 9 will be the exclusive entrance for passengers entering the commercial space.

The commercial space at Chongqing Shapingba Railway Station is not able to attract transport-oriented passengers entering and leaving the station, and its commercial space entrances and exits are only partially shared. People who choose the metro to go to the commercial space enter through Entrance 1/2/6/7, those who choose buses and taxis enter through Entrance 1/2, those who choose private cars enter through Entrance 4/5/12, those who choose to walk can enter through Entrance 1/2/3/6/7/8/9/10/11/12, and leisure passengers who go to the commercial space exclusively enter through Entrance 1/2/4/5, i.e. Entrance 6/7, which is directly accessible from the metro station hall on the seventh floor of the underground, and Entrance 6/7, which is directly accessible from the metro station hall on the seventh floor of the underground, as well as Entrance 6/7, which is directly accessible from the metro station hall on the seventh floor of the underground. Entrance 6/7, which is directly accessible from the MTR station hall on the seventh basement floor, and Entrance 3/6/7/8/9/10/11/12, which is accessible on foot from the city road, are the entrances and exits of the commercial space for public use.

The commercial space of Shenzhen North Railway Station attracts transport passengers entering and leaving the station on foot and the public walking to the commercial space, and their entrances and exits to the commercial space are shared by both passengers and the public.

Traffic passengers who choose to enter the station on foot and citizens who walk to the commercial space enter through Entrance 1/2/8/9/10/11/12/13/14 facing the city, while traffic passengers who choose to leave the station on foot, leisure passengers who go to the commercial space exclusively, and citizens who choose the metro, buses, and taxis enter through Entrance 3/4/5/6/7/12/13/14 adjacent to the station. There are no entrances or exits to commercial space exclusively for the public.

4.2.2 Pedestrian flow at entrances and exits of commercial space in station complexes

The pedestrian flow at the entrances and exits of commercial space in station complexes reflects the convergence effect of the "node-path" chain with different attributes. By comparing the average flow of people at the entrances and exits of the commercial space in the sample station and the flow of people at each entrance and exit, we analyse the influence of the node layout of the commercial space in the station complex on the flow of people.

As shown in Fig. 6-8, the number of entrances and exits in the commercial space of Guangzhou East Railway Station is the lowest, but the flow of people at each entrance and exit is more than 50, and there are two entrances and exits with higher than average flow of people, and the difference between the highest flow of people and the lowest flow of people reaches 164 people. Chongqing Shapingba Railway Station has six entrances and exits with higher-than-average passenger flow, and the difference in passenger flow between them is relatively small. Shenzhen North Railway Station has four entrances and exits with higher than average passenger flow, and the difference in passenger flow between the entrances and exits is in the middle.

Among the entrances and exits in the commercial space of Guangzhou East Railway Station, the ones with higher than average flow rates are Entrance 7 and Entrance 9 on the basement floor. Entrance 7 is common, and the flow rate is much higher than the other entrances and exits. It is directly opposite to the main axis of the commercial space on the basement floor, and it is the necessary entrance and exit for the traffic passengers who are transferring to the metro and for the leisure passengers who are taking the metro (Fig. 9). Entrance 9 is a special entrance for the passengers and is connected to the ground floor through the staircase facility. Entrance 9 is one of the entrances for passengers, connected to the ground floor through the staircase facility, and is close to the station access space on the ground floor, which can be used by leisure passengers and transport passengers transferring to the metro.

Among the entrances and exits of the commercial space of Chongqing Shapingba Railway Station, the ones with higher than average pedestrian flow are Entrance 1, Entrance 2, Entrance 4, Entrance 6, Entrance 7, and Entrance 11 on the ground floor. Entrance 1, Entrance 2, and Entrance 4 are shared entrances and exits, which are accessed by leisure citizens who choose to take the underground, bus, taxi, and walk, as well as by leisure passengers who travel to the commercial space exclusively (Fig. 10), and Entrance 4 is connected by a straight staircase to the station exit space and private car garage at the fourth basement floor, which is shared by leisure passengers and those who choose to travel by private car. Entrance 4 connects the station exit space on the fourth basement floor and the private car garage on the ground floor via a

straight staircase, which is shared by leisure passengers and leisure citizens who choose to travel by private car. Entrance 6, Entrance 7, and Entrance 11 are dedicated entrances for citizens, with Entrance 7 mainly carrying leisure citizens travelling on the underground, and Entrance 11 being one of the entrances for citizens to walk into the commercial space.

Among the entrances and exits of the commercial space of Shenzhen North Railway Station, the ones with higher than average pedestrian flow are Entrance 1, Entrance 3, Entrances 4+7, and Entrance 12, which are across the three floors of the commercial space. Both passengers and citizens share these five entrances and exits. Entrance 12 is close to the station space and leads to the commercial street adjacent to the station's entrance and exit space, which has the highest flow of people and is one of the shared entrances and exits for all passengers and citizens (Fig. 11). Entrance 1 is close to the city road and mainly accommodates transport passengers entering the station on foot and citizens walking to the commercial space. On the other hand, Entrance 3 and Entrances 4+7 are located in the area close to the station space and are used by transport-oriented passengers who choose to walk out of the station, leisure-oriented passengers who travel exclusively to the commercial space, as well as citizens choosing the metro, buses, and taxis.

5. Conclusions

The circle structure of centre agglomeration is usually regarded as an ideal model for the high-density development of high-speed railway station areas, while this study is based on the walking line of two types of groups, tourists and citizens, to refine the deduction of the design of the layout form of the commercial space of the high-speed railway station complex, which includes two aspects, namely, the layout of the body of the commercial space and the layout of the nodes at the entrances and exits.

Firstly, the correlation law between the block layout of the commercial space of the station complex and the total pedestrian flow. There is no positive correlation between the distance of commercial space from the station space and the use of commercial space, and the commercial space with the closest and the farthest distance from the station space shows a lower percentage of commercial space traffic, while the commercial space with the station space in a staggered layout and with the distance between the two in the middle of the commercial space, on the contrary, has a higher percentage of commercial space traffic. The reason is that the interlocking commercial space and station spaces have strong spatial connections, and the metro space is embedded between them, which attracts a large number of transport-oriented passengers to pass through the commercial space.

The proportion of long-distance passengers in the core area of China's high-speed railway stations is very large, and passengers' demand for rapid transportation is much larger than their demand for leisure consumption; therefore, the people who use the commercial space of station complexes are mainly leisure-oriented citizens in the surrounding area, and the number of leisure-oriented citizens > the number of transport-oriented passengers > the number of leisure-oriented passengers. Therefore, in the process of planning and laying out the commercial space of station complexes, attention can be paid to stations with small and medium-sized passenger scales, appropriately shorten the distance between their commercial space and station entrance and exit space, and create a staggered space for guiding traffic passengers, especially by placing

underground space between the two and stimulating the recreational potential of traffic passengers who transfer to the underground, whereas, in stations with large-scale passengers, the distance between their commercial space and station entrance and exit space needs to be maintained to provide a more comfortable and comfortable environment for the passengers. For stations with a large passenger scale, the commercial space and the station access space need to be kept at a distance for the use of the neighbouring citizens and a small number of passengers.

Second, the node layout of the commercial space of the station complex and the correlation law of the entrance and exit pedestrian flow. Firstly, the setting of entrances and exits of commercial space and the distribution of people flow are influenced by the layout of commercial space blocks. Located in the commercial space on the side of the station space, its entrances and exits are distributed in the area close to the station and facing the city, and there is a big gap between the flow of each entrance and exit. Located in the commercial space directly above the station space, its entrances and exits are distributed on the ground floor where the two are intersected, and because these entrances and exits are facing the surrounding city, the gap between the flow of each entrance and exit is relatively small. Secondly, the entrances and exits of the commercial space that are connected to the metro line usually have high pedestrian flow. Among them, the passenger-citizen shared entrances and exclusively for public use entrances and exits with a direct spatial connection with the underground line have a higher flow of people, while the entrances and exits exclusively for leisure passengers have a higher flow of people close to the station entrances and exits. Therefore, in the process of planning and laying out the commercial space nodes of the station complex, it is necessary to enhance the spatial connection between the entrances and exits of the commercial space, the metro space, and the station entry/exit space based on the block layout form of the commercial space.

Then, the layout pattern and optimisation suggestions for commercial space in the sample station complexes are:

Guangzhou East Station and Shapingba Railway Station are stations with small and medium-sized passenger scales. The commercial space of Guangzhou East Station is interlaced with the station space, with metro space embedded between the two, and the entrances and exits of the commercial space are separated for the exclusive use of passengers or citizens, especially the special entrances and exits set up for the transport-oriented passengers who change to the metro, so that the commercial space of this station complex can attract a large number of transport-oriented passengers changing to the metro while accepting citizens from the surrounding areas. The passenger scale of Shapingba Railway Station is relatively small, and its commercial space is completely superimposed with the station space, between the two there are urban transport spaces such as buses, rentals, and private garages, while the underground is located below the station exit space, and most of the entrances and exits of the commercial space are shared by citizens and passengers, and only a small number of entrances and exits are for the exclusive use of the citizens who take the underground and go to the commercial space on foot, and the commercial space of this station complex mainly serves the peripheral citizens, and only accepts a small number of leisure-type passengers. citizens, and only takes on a small number of leisure-type passengers. However, Shapingba Railway Station does not attract traffic passengers who must pass through the commercial space, and the passenger flow of the station is mainly concentrated in the ground floor entrances and exits, and the flow of people inside the

commercial space lacks traffic power, so it is possible to increase the commercial space and adjust the position of the entrances and exits of the commercial space between the station exit space and the underground to accept the traffic passengers who transfer to the underground.

Shenzhen North Railway Station is a station with a large passenger capacity. Its commercial space is completely separated from the station space, and between the two, urban transport spaces such as metro, bus, taxi, and private garage are integrated in a three-dimensional way, with entrances and exits to the commercial space shared by passengers and citizens, and a separate commercial street is set up in the area adjacent to the entrance and exit of the station, which is supplemented by the use of leisure-type passengers. Citizens choosing either mode of transport share all entrances and exits to the commercial space with leisure passengers who visit the commercial space exclusively and transport passengers who enter and exit the station on foot. Due to the large area of interchange space and station square between the station space and the surrounding urban roads, the number of transport passengers walking in and out of the station is minimal. The commercial space is far away from the station space. Even if it is close to the entrances and exits of the station space, the accessibility is low, so leisure passengers will choose to go to the commercial street, which is close to the entrance and exit of the station. The citizens who go on foot will also go to the commercial street, so the area gathers a large number of passengers and citizens. Therefore, the area gathers a large number of passengers and citizens. However, the distance between this commercial street and the two-floor commercial blocks is relatively far, so the vertical connection between the two commercial spaces can be increased appropriately so that the pedestrian flow of the commercial street can be directed to the entrances and exits of the commercial blocks below.

Finally, additional research is needed on the factors and indicators that influence the use of commercial space in station complexes. For example, the use of commercial space in station complexes is also affected by the organisational structure of various types of urban transport spaces and the urban transport sharing rate of different stations. In addition, this study focuses on analysing the layout of commercial space in station complexes from the perspective of "node-path", and abstractly expresses the use of commercial space as the total flow of people at all entrances and exits and the flow of people at all entrances and exits, which is only one aspect of measuring the effect of the use of commercial space, and can be measured by choosing more detailed indicators such as the flow of people entering stores. metrics such as inbound foot traffic to measure, and can also be supplemented with weekend foot traffic data for comparative studies with weekday usage. In addition, if the number of traffic-type passengers is increased excessively, it may affect the efficiency of passengers entering and leaving the station, and in the actual planning and design process, it is necessary to consider the balance and conversion of both traffic dispersion and commercial agglomeration.

Abstract. This study aimed to enhance urban environments for the elderly by assessing walkability in the Takanodai area of Senri New Town, Japan. Seven indicators for walkability were selected through a literature review, and a quantitative evaluation using the seven indicators was conducted. The results are presented in a heat map of walkability, and shows that pedestrian-only paths scored lower than roadways in detached house residential areas. This suggests that slopes and stairs of pedestrian-only paths were not considered obstacles at the time of construction of the new town, and have remained unchanged over time. It is possibly due to a low level of awareness on addressing barrier-free issues by whom? in the past. In contrast, pedestrianized street in public housing zone scored higher than others. The reason for this may be that the public housing zone was designed with better green space and sidewalks. The study's findings could inform improvement areas for future urban development for creating walkable cities accessible to all citizens.

Keywords: walkability, elderly, slopes and stairs, Newtown, urban development

1.Introduction

In recent years, Japan has experienced a rapid aging of society with a declining birthrate, and there has been growing interest in the concept of compact cities, where urban functions are concentrated, and in the development of cities where people can reach daily amenities on foot. Against this social background, there is a need to develop urban environments that focus on the lifestyles and health promotion of the elderly. In Japan, however, there are still few studies on developing walkability index focusing on the elderly, and only a few of them focus on the evaluation of regional characteristics and real estate values, or on health promotion (Hanibuchi, 2011).

In Japan, the Ministry of Land, Infrastructure, Transport, and Tourism (MLIT) has begun to pursue the applications for "Walkability Promotion Cities" to encourage the development of

cities where people can walk to their daily needs from 2019. The program encourages a shift from the car-centered society of recent years to the creation of a walkable city. This initiative is expected not only to create a rich, people-centered living space, but also to increase local consumption and investment, increase tourism, extend healthy life expectancy, prevent loneliness and isolation, and solve various local problems and create a new value for healthy living. The number of walkable cities is increasing every year, and by April 2024, 372 cities nationwide will be designated as walkable cities (The Ministry of Land, Infrastructure, Transport and Tourism, 2024).

The purpose of this study is to obtain key factors that will contribute to the development of urban environments for the elderly in preparation for an aging population in the future. As the first step, walkability indices in previous studies are reviewed, and an index for evaluating walkability for the elderly is developed for this study. Next, using the selected indicators, we evaluate walkability in the Takanodai area of Senri New Town, which has one of the most aged populations in Japan.

---

2. Literature review of previous studies

2.1 Recent Previous Studies

In this chapter, we conduct a literature review based on recent previous studies and create a simple and objective walkability index for the elderly. In order to develop the walkability index for the elderly, five recent studies were selected and the indices used in each study are summarized. We have selected these five studies because these studies introduced the walkability indices related to factors such as slopes and stairs influencing on the walkability of the elderly. Four of the five papers are published by Japanese authors and it was useful for us to look into previous work which addressed specific Japanese contexts and pointed out the issue of applying walkability indices developed in western countries for Japanese built environment.

Alves et al. (2020) aimed to create a walkability index for the elderly, focusing on "slope" and "stairs". The authors divided the three major categories for qualifying factors of public space into urban tissue (e.g. pedestrian surface quality, sidewalks existence and width, etc.), urban scene (e.g. existence of trees, vegetation, urban furniture), and safety (e.g. street lighting quality, diversity of information signs), and assigned appropriate weights and scores to each of these axes. They also focused on “slope” and “stairs” as factors that affect the ease of walking for the elderly. In order to evaluate the walkability of each street, a set of positive evaluation factors that increases walkability and negative evaluation factors that decreases walkability have been established. The three positive evaluation factors are related to urban tissue, urban scene, and

safety, while the two negative evaluation factors are slope and stairs.

The three positive evaluation factors were selected based on a literature review of previous studies identified by Alves et al. (2020). The weighting of the three indicators is also determined based on their work: 60% of the total walkability index is allocated for urban organization, 24% for urban landscape, and 16% for safety. For the two negative indicators, slope and stairs are identified as factors that hinder walking activities for the elderly, and the criteria for the angle of the street slope are classified into three patterns: less than 5%, between 5% and 8%, and more than 8% (e.g. 10% is expressed as a rise of 1 meter after advancing 10 meters). The authors also developed a corresponding index for stairs, which was incorporated into the slope criteria rather than being considered separately from slope.

Morioka et al. (2021) pointed out in their study that walking behavior is classified into three categories based on previous research: 1) "necessary activity" that occurs due to necessity in public areas, 2) "voluntary activity" that occurs based on the individual's positive intention, and 3) "social activity" that occurs when others intervene in necessary or voluntary behavior. The "voluntary activities" are studied in this paper. Unlike "necessary activities," "voluntary activities," require an environment that is not only "easy to walk", but also "makes people want to walk" as a factor that induces walking behavior. The authors have identified "density," "facility density," "street form," "human scale," "landscape," and "public transportation" as urban indicators related to walking behavior based on a literature review of previous studies, and used the five indicators, while "public transportation," was excluded in their study. Of the five indicators, "density," "facility quality," and "street form" are used as environmental indicators that makes it “easy to walk”, while "human scale" and "landscape" are used as promoting factors to walk.

Kato and Kanki (2017) proposed a shift to "smart shrinking," in which residents themselves maintain an independent living environment by promoting community development that makes their own neighborhoods more attractive. As the first step to realize a smart shrinking, the concept of walkability has been developed mainly in the field of public health and used to create a regional evaluation index. From the index, they adopted the four elements of "household density," "convenience of local facilities," "road connectivity," and "local safety," which can be easily obtained by geographic information systems, from among the indicators used in previous studies. In their study, all of the indicators used to calculate walkability are on the scale of the city block, which can be easily processed by a geographic information system.

Shimizu (2020) aimed to develop a walkability index for the Japanese context. The Walkability Index developed by Shimizu (2020) is a 100-point scale that measures the

concentration of urban amenities within walking distance of a given point. Urban amenities include convenience stores and drugstores, restaurants and cafes, and bookstores and cultural facilities. This study is similar to the Walk Score®, a well-known index developed in the U.S (Walk Score, 2024). The Walk Score® is a weighted score of neighborhood facilities based on their necessity and distance from a certain point, and is used to measure the neighborhood environment from the viewpoint of walkability. Walk Score® is widely used as an objective index to measure the neighborhood environment in terms of walkability. They have identified "property search," "community development," "real estate strategy," and "survey research" as scenarios for utilizing this index, and has succeeded in creating an intuitive and easy-to-understand index by displaying a heat map of the Walkability Index.

Itoh et al. (2021) classify the elements of walkability into three stages. The first stage is the urban environment and structure, the attributes of individuals (e.g. presence of sidewalks, crosswalk, etc.) and their purposes for walking, the second stage is the effects of the contents of the first stage on the quality of walking and the promotion of walking, and the third stage is the effects of the second stage on the city and individuals. Furthermore, when applying the Walkability Index developed by Frank et al. (2005) in the Japanese context, it is necessary to consider the relationship between the urban environment and structure and the quality of walking. The paper then identified three key indicators of walkability quality: "accessibility," "comfort," and "safety," and examines their relationship to the urban environment and urban structure, respectively.

Based on the above walkability indices used in these previous, we selected several appropriate ones for the elderly and adopted them as the walkability indices in this study.

2.2 Results of Indicator Selection

The following table is a summary of the indices used in the above previous studies (Table 1). We have identified four categories (Street conditions, Land utilization, Landscape, and Safety) which are drawn upon most frequently used indicators from the five studies we reviewed. Then, one or more indicators were adopted from each category Presence of sidewalks, pavement condition, stairs, slopes, and street lighting can hinder the elderly from walking. In contrast, park space and green space can have positive effects for the elderly, as they are encouraging them to walk.

In this study, the following seven items are decided to form a walkability index (Table 2) in order to create an objective and simple walkability index and to evaluate the walkability of each street.

Table 1. Results of the literature review and indexes used in this study

	Street conditions							Land utilization					Landscape		Safety			
	presence of sidewalks	pavement condition	width of a street	stairs	distance to public transportation	Intersection density/road accessibility	slopes	population density/household density	medical and welfare facilities	educational facilities	commercial facilities	park space	green space	percentage of water surface	urban furniture	street lightning	information sign	crime and accident rate	amount of traffic
Alves et al. (2020) Walkability Index for Elderly Health	○	○	○	○		○	○						○		○	○	○		
Morioka et al. (2021) A Study on Walkability grasped from Environment both of "Easy to Walk" and "Encouragement to Walk" that supports Walking			○						○	○	○	○	○	○					
Kato and Kanki(2017) Development and Verification of Indicator about Regional Evaluation based on walkability in Residential Area			○					○	○	○	○	○						○	
Shimizu(2020) Development of Walkability Index					○				○	○	○	○							
Itoh et.al. (2021) A Study on the Conceptual Framework of Walkability and Issues for its Application in Japan						○													○
Indices adopted in this study	○	○		○			○					○	○			○			

Furthermore, the following walkability index and its criteria are defined and applied in one case study area in Senri New Town. The walkability index developed for this study is defined as the average of the scores of all seven items: presence of sidewalks, pavement condition, stairs, slopes, park space, green space, and street lighting. Each item is rated from 1 to 3 points according to conditions identified in Table 2. For example, different scores are given to the presence of sidewalk: 1 for “no sidewalk on both sides of road”, 2 for “only on side walk” and 3 for “sidewalks exist on both sides of the road or street is pedestrianized”. All streets were surveyed using Google Street View. For streets not supported by Google Street

View, the survey was conducted on site by Aida. It is therefore noted that the research is based on a subjective view of the researcher.

Table 2. Indices and Walkability Score

Indices		Criterion	Score
Street conditions	presence of sidewalks	no sidewalk on both sides	1
		on one side only	2
		exists on both sides / pedestrians only	3
	pavement condition	bad coditions	1
		some steps or obstacles	2
		good conditions	3
	stairs	some stairs exist	1
		no stairs exist	3
	slopes	less than 5%	1
		more than 5% and less than 8%	2
		more than 8%	3
Land utilization	park space	Parks are available for rest while walking	1
		no parks to rest while walking	3
landscape	green space	less than 20%	1
		more than 20% and less than 25%	2
		more than 25%	3
safety	street lighting	no lighing on both sides	1
		on one side only	2
		exists on both sides	3

For the selection of the reference value for “slopes,” in the previous study by Alves et al. (2020) was used. The selection of the reference value for “green space” was based on the results of a social experiment conducted by the Ministry of Land, Infrastructure, Transport and Tourism (2005) and the evaluation criteria used at the Voluntary Simplified Assessment Site (2014). According to these studies, more than 25% green space of the total area space of

a city is sufficient to be considered to have an attractive urban environment, while less than 20% is considered as insufficient.

3. Application of walkability index in the Takanodai area

3.1 Site Selection

In this study, Takanodai 2-chome, a neighborhood of within Senri New Town the Suita City, is selected as the site for the field survey.

Senri New Town was the first large-scale new town in Japan, which was planned to cope with the housing shortage caused by population growth in the postwar 1950s. To prevent urban sprawl caused by housing shortages and to provide inexpensive, high-quality housing to the public, Osaka Prefecture began development of Senri New Town in 1960 in the Senri Hills in the northern part of the prefecture. The planned site was 1,160 hectares, which spanned the current cities of Toyonaka and Suita, and had a planned population of 150,000 people. A major feature of the project was the emphasis placed on creating a favorable living environment. The entire new town is surrounded by green areas, and parks and schools are systematically located based on the neighborhood residential area theory systematized by Clarence Arthur Perry (Discover Senri, 2022) in the 1920's. The coverage of green area of the new town is more than 20% of the total area space.

In addition, the walking environment for residents was comprehensively developed. In the early stage of the development, the separation of pedestrians and cars was achieved by arranging cul-de-sacs according to the Radburn method (Discover Senri, 2022), and in the late stage of the development, the separation of pedestrians and cars was achieved by using pedestrian bridges following the idea of Buchanan report (Buchanan, 1963). To contain traffic and segregate cars from pedestrians, the planning of the new town took advantage of the undulating topography of the Hokusetsu area where the main part of the new town was planned.
In the Takanodai area, the current challenges are to cope with the aging of housing and to provide a variety of housing styles. Furthermore, the proportion of elderly residents is particularly high in Senri New Town, with 14.4% of the residents are aged between 65 and 75and 24.5% are older people aged 75 and over, for a total of 38.9% in the 2020 survey. The Takanodai area consists of the highest proportion of elderly residents among all 12 residential districts in the new town. This ratio is much higher than the average of all 12 residential districts in Senri New Town, where 11.7% of the residents are aged between 65 and 75 and 18.1% are older people aged 75 and over, for a combined ratio of 29.8%. Among them, 2-Chome (a small district within a neighborhood) maintains a diversity of urban amenities with a moderate

number of schools and detached houses, and is not limited to residential function of public housing. For these reasons, the area was considered to be as mixed-used area and an appropriate case for applying the walkability index.

Fig.1 shows a street map of Takanodai 2-Chome area. The area can be divided in two zones according to housing styles: A zone shows the public housing zone (predominantly medium and high-rise apartment blocks), and B zone shows the detached housing zone.
In order to conduct the survey systematically, we have decided to assign a point number to the intersection of streets in Takanodai 2-Chome. The streets connecting the two numbered points are given names. (e.g. The street connecting points “m” and “n” is named "Rm,n".). ‘R’ indicates roads.

Figure 1. Street Map of Takanodai 2-chome (Source: Aida, 2024)

3.2 Walking Environment in the Takanodai Area

The Takanodai area was one of the first residential areas developed in Senri New Town, and was planned to be separated from pedestrians and vehicles by a cul-de-sac and a pedestrian footpath. A cul-de-sac is a type of street design to prevent through traffic. The cul-de-sac was extensively used in the early development areas of Senri New Town to separate vehicles from pedestrians. The Takanodai area is one of typical applications of the cul-de-sac design.

Figure 2 below shows a street planned as a pedestrian footpath called *Suita-Takanodai private line*. These footpaths were constructed in March 1984, so approximately 40 years have passed from the start of their use. The streets that include these exclusive footpaths are R3,5, R6,9, R6,15, R7,9, R7,10, R10,11, R10,14, R14,21, R16,17, R17,37, R21,23, R21,24, R51,52, R53,54, and 14 street connecting points in total.

In addition, there are streets in the public housing zone (Zone A) that are pedestrianized streets because vehicles cannot enter, and these are shown in Figure 3. These streets include R18,27, R19,26, R26,27, R26,31, R30,36, R31,32, R31,35, R32,36, R32,44, R35,39, R36,42, R37,38, R39,45, R40,43, R41,42, R42,44, R47,50. The 17 streets are applicable.

4. Results and Discussion

This chapter discusses analysis results from the walkability index applied in selected streets within the Takanodai 2-Chome.

4.1 Results

The following figure shows a heat-map display of the overall Walkability Score. There are different types of streets within the studied areas and ‘short pedestrian streets’ and ‘streets with driveways’ are found in the public housing zone. In contrast, two-lane large streets and streets pedestrian lanes are typical examples in the detaching housing zone (Figure 3).

Figure 4. the overall Walkability Score

Figure 4 shows that the streets with high walkability are footpaths in the public housing zone (R18,27, R26,31, R30,36, R35,39), streets with sidewalks in the public housing zone (R34,38), two-lane large streets with sidewalks in the detached housing zone (R1,2, R2,4, R14,22, R20,24,

R24,28, R28,43), footpaths in the detached housing zone (R6,9, R14,21, R17,37).
Figure 5 - Figure 11 below shows a heat map of all 73 streets in respect of each of the seven stems in the walkability index.

Figure 6. pavement condition

Figure 7. stairs

Figure 8. slopes

Figure 9. park space

Figure 10. green space

Figure 11. street lighting

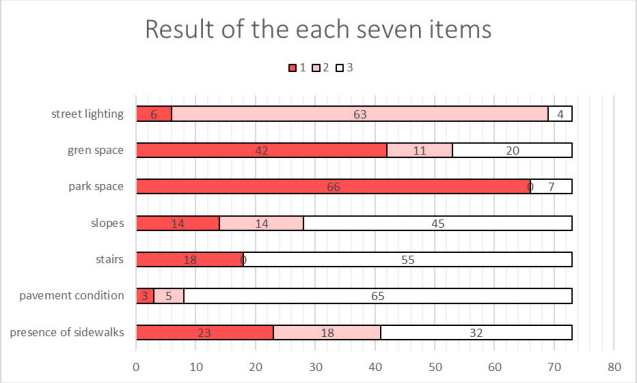

Figure 12. Total results from each of the seven items

The above figures show in terms of green space and park space, the majority of streets studied scores at the lowest (42 streets and 66 streets out of 73 studied). For slopes, stairs and pavement condition, the majority of streets scored with a higher point. Therefore, in Takanodai 2-Chome, there is an urgent need to increase green space and to prepare parks along the streets.

4.2 Discussions

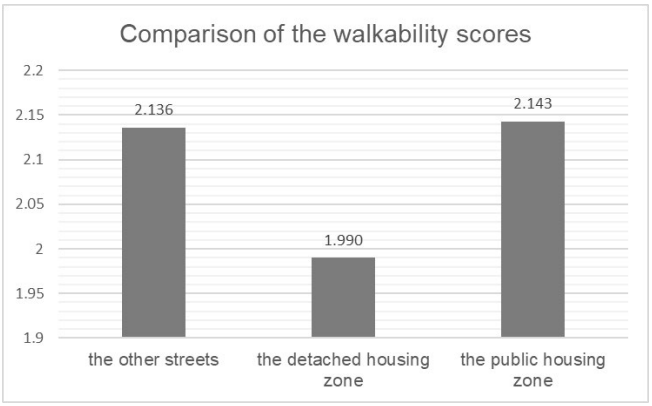

Figure 13. Comparison of Walkability Scores by different study areas

Figure 13 shows that the walkability scores of pedestrian footpaths in the Suita-Takanodai detached housing zone are lower than the other streets which are not footpaths, but streets shared by vehicles and pedestrians (see Figure 2).
On the other hand, average walkability for pedestrianized streets in the public housing zone tended to be slightly higher than the overall.

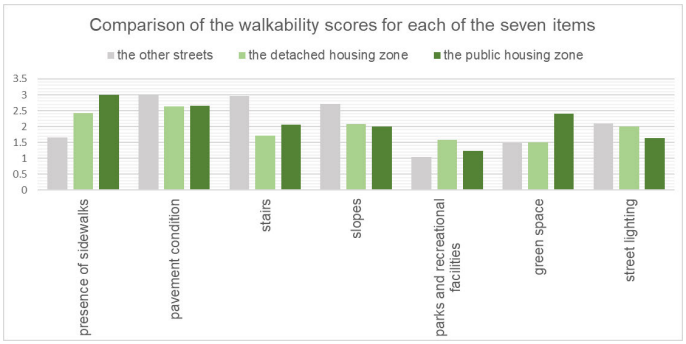

Figure 14. Comparison of scores for seven items by street characteristics

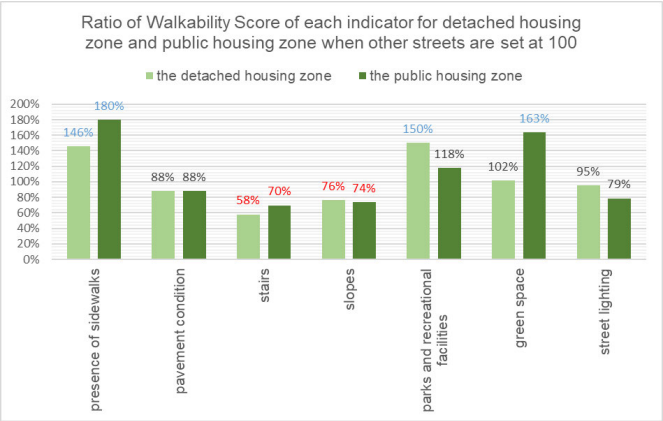

Figure 15. Ratio of Walkability Score of each item for detached housing zone and public housing zone when other streets are set at 100

Figure 14 shows the Comparison of scores for seven items by different study areas, and Figure 15 shows the Ratio of Walkability Score of each indicator for detached housing zone and public housing zone when other streets are set at 100. From these results, two possible factors for the low scores of walkability index in the detached housing zone are the presence of stairs and the slopes. Also, two possible factors for the high scores of walkability index in the public housing zone are the presence of sidewalks and the green space.

Figure 15 shows that stairs and the slopes are the main causes of reduced walkability scored in the detached house zone. Therefore, the walkability score was recalculated using the five indicators excluding the stairs and the slopes, and the result is shown in Figure 16 below.

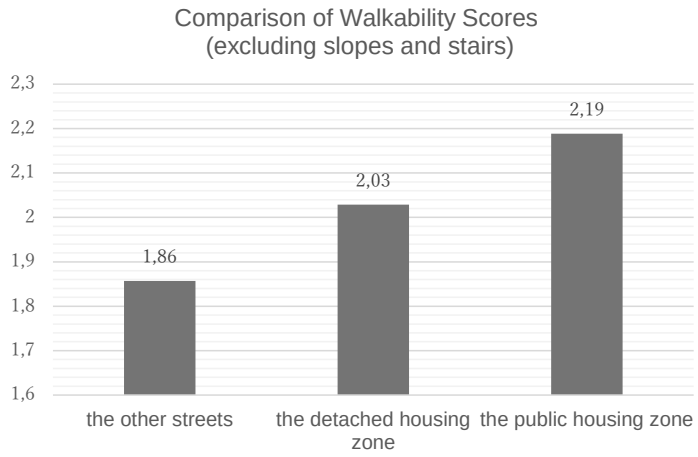

Figure 16. Walkability Score Comparison (excluding stairs and the slopes)

From Figure 16, when walkability scores were calculated for the indicators excluding stairs and the slopes, the results were as follows: pedestrianized streets in the public housing zone scored higher than the other streets. This indicates that all indicators except stairs and the slopes have high scores in the both public housing and detached housing zone compared to those in the other streets.

This suggests that the *Suita-Takanodai private line*, which was developed approximately 40 years ago as a footpath based on the idea of separating vehicles and pedestrians, may have a slightly lower walkability score than the other streets today. This may be related to the age group of residents who moved in at the time of the development of Senri New Town. In the 1970s, when Senri New Town was first developed, many residents were families with small children, and the aging rate in Senri New Town was low compared to the national average. This was due to the fact that the majority of residents were relatively physically healthy in terms of walking at that time. However, the rapid aging of the population in Senri New Town has made streets problematic for the elderly in terms of walking activities, which resulted in low walkability scores in this study. On the other hand, in the public housing zone, apartments surrounded by green spaces, and the entire zone is covered with greenery. Therefore, the amount of green space is considered to be high and the landscape is considered to be well kept.

More than 60 years have passed since the opening of New Town, and there are still problems such as aging public housing and lack of facilities for the elderly. At the time of the opening of the town, there was a shortage of elementary schools due to the large number of people

with children moving in at the same time, and after the children became independent and moved out from home, the demand for senior citizen facilities rose dramatically due to the aging of the remaining residents. In 2007, the population of Senri New Town dropped from 129,860 to a minimum of 89,212. The Senri New Town Revitalization Liaison Council was established consisting of the six organizations (Osaka Prefecture, Toyonaka City, Suita City, Urban Renaissance Agency, Osaka Prefectural Housing Supply Corporation, and Osaka Prefectural Urban Development Promotion Center) in order to revitalize Senri New Town for the future. The six organizations have formulated the “Senri New Town Revitalization Guidelines 2018 (Osaka prefecture, 2018),” to maintain and develop the vitality of the town.

In particular, the seventh of the sixteen revitalization policies for New Town, as shown in the Senri New Town Revitalization Guidelines 2018 (Osaka prefecture, 2018), is to "enhance the transportation environment to create a town where people can live comfortably on foot". In particular, the seventh point in the policy is to "enhance the transportation environment to create a walkable town." As explicitly mentioned, ‘walkability’ in the policy document, it describes the development of safe and comfortable walking spaces from the viewpoint of barrier-free access and signage for wayfinding in order to create a town where residents can live with peace of mind.

As described above, in Senri New Town, several municipalities and organizations are collaborating in various efforts to improve New Town under the initiative to revitalize the town in response to the recent declining birthrate and aging population.

However, the results of this survey showed that the pedestrian footpaths in the detached housing zone, which should have been rated higher, were rated low, and the other streets in the district were rated higher. This suggests that when Senri New Town was developed in 1970, people were not as conscious of barrier-free access as they are today and regulations on barrier-free were not introduced by public authorities. Therefore, it is possible that the slopes and the slopes were not considered to be an obstacle to walking, especially for younger residents, which may have remained unchanged and unimproved up to today. Otherwise, the score of walkability of footpaths in the public housing zone should have been rated higher. This is because public housing zone have a well-developed green environment and a thorough separation of vehicles and pedestrians. However, the both zones have low scores for slopes and stairs, and it will be a challenge for the Takanodai area to improve these obstacles in the future, given the hilly topographic condition.

5. Conclusion and Future Prospects

When evaluating the walkability of an area, the characteristics of its residents and the process of street structure and design can be taken into account. By calculating walkability scores for individual streets that are used only by pedestrian-only or shared with vehicles, it is possible to appropriately identify certain streets that require some development. In addition, the walkability evaluation can visualize the walkability of each street by displaying the numerical values on a heat map, making it possible to create intuitive and easy-to-understand maps. These maps can serve as evidence in discussing improvement areas.

A walkable city for the elderly is also a walkable city for people of other ages. Therefore, walkability evaluation index developed for the elderly can be used as an indicator for the creation of walkable neighborhoods for everyone. We believe that the application of any walkability indices, including this study, is a useful method that will help create walkable cities for all citizens in the future.
As a prospect for future research, we believe that a more multifaceted walkability evaluation can be conducted by combining this research with studies focusing on the relationship of walking time and walking routes. This is especially an important point to be considered in the walkability of older people since their walking speed would reduce by ageing.

Abstract
The 15-minute City (15mC) is a novel urban planning approach aiming at affordable and sustainable mobility while enhancing urban life. Implementing this concept in car-dependent outskirts and suburbs poses significant challenges due to their lacking essential morphological features. Cities, especially in metropolitan areas, function as interconnected networks rather than standalone walkable neighbourhoods, complicating the implementation further. The Evolutive Meshed Compact City (emc2) offers a networked pedestrian-based 15mC model suitable for many European peripheries. The model relies on a set of guiding principles and detailed specifications, which are interrelated across different scales. To evaluate its potential in European metropolitan peripheries, a research design is proposed, focusing on its ability to facilitate a successful transition to a 15mC. Additionally, the paper compares the emc2 model with other proposed 15mC solutions.

15-minute City, Suburbs, Networked Densification, Pedestrian-Friendly Urban Form

1. Introduction: challenges for the 15-minute City in metropolitan peripheries

Developing a 15-minute City (15mC) represents a novel planning strategy aimed at fostering affordable and sustainable mobility. However, its objectives extend beyond mere transportation goals, encompassing the enhancement of overall city life and the prioritisation of human needs in urban planning. Indeed, the concept of the 15mC aligns closely with the Sustainable Development research agenda, which seeks to enhance quality of life while facilitating the energy and ecological transition of 21st-century cities. By promoting pedestrian-based proximity, the 15mC aims to enable inhabitants and city users to access destinations that fulfil most of their daily needs within a short walking distance (Moreno et al., 2021; EIT Urban Mobility, 2022). This shift is expected to reduce reliance on motorised traffic and render retail and services viable at a local scale.

Pedestrian-based proximity should not be narrowly interpreted solely in terms of short distances that are easily traversed on foot. Two additional considerations must be integrated into the framework. Firstly, the 15mC must recognize the multi-scalar nature of urban life by accommodating both short- and long-distance movement patterns. Secondly, it must ensure that pedestrian and non-pedestrian movement respects the well-being of pedestrians, both while walking and when stationary. This entails that the 15mC should harmonise functional considerations regarding pedestrian accessibility to destinations across different scales with the

broader affordances of public space to address a variety of human needs that arise from its usage.

Compact European cities have already implemented 15mC solutions with notable success, as evidenced by Paris and Barcelona. However, the transition to a 15mC is considerably more challenging in post-war car-dependent outskirts and suburbs due to stringent prerequisites concerning urban form and spatial organisation, aspects often overlooked in much of the European literature on the subject. In contrast, North American cities exhibit greater attention to retrofitting suburbia, as highlighted by the work of Duhnam-Jones and Williamson (2011). For instance, the city of Portland has tailored its 15mC policy to suit its diverse urban forms, including the retrofitting of suburbs with small retailers through accessory commercial units. We contend that European cities possess significant untapped potential to intervene in the physical form of their outskirts and suburbs and to implement ambitious 15mC policies.

In both Europe and North America, car-dependent outskirts and suburbs often lack several key morphological prerequisites for the 15mC: centrality, density, proximity to services and public transport, mixed land use, quality walking and cycling infrastructure, and attractive public spaces. These prerequisites significantly influence people's behaviours through intermediate concepts such as walkability, sense of place, ease of access, and vibrancy (Gehl, 2011; Dovey et al., 2017). We believe that interventions solely focused on improving pedestrian accessibility, without addressing these underlying morphological challenges, will struggle to successfully implement the 15mC in peripheral areas. What is required is a new coherent framework to guide interventions across the various facets of the 15mC.

Moreover, to successfully implement the 15mC concept in outskirts and suburbs, it's crucial to acknowledge that cities operate as open networks rather than as collections of self-sufficient "walkable neighbourhoods" or "urban villages." This is especially true in a metropolitan context, where multiple centres at different scales interact through infrastructural networks. These networks profoundly influence the localization of retail and services, which are only viable where human flows concentrate within a movement economy (Hillier, 1996).

The Evolutive Meshed Compact City (emc2) is being developed to offer a workable urban model capable of ensuring the necessary coherence of a 15mC strategy in urban peripheries. The model suggests distributing compact urban form as corridor development along pre-existing main roads connected to wider-range mobility options, thereby forming a meshed structure across the metropolitan area. This necessitates smart densification along these streets, which are further redesigned for pedestrians to transform into lively main streets. Presently, the emc2 model is the subject of a coordinated research effort by the authors and will be the focus of this paper.

The paper is structured as follows: Section 2 will delineate the emc2 model through its five overarching guiding principles. Section 3 will outline a research design aimed at evaluating the potential of the emc2 model in European metropolitan peripheries and identifying its strengths and weaknesses. This analysis aims to discern where the model is most effective in facilitating a successful transition to a 15mC in peripheral areas. Finally, Section 4 will conclude by examining the emc2 model in relation to other overlapping or sometimes competing models for organising urban space.

2. The emc2 model through its five guiding principles

The emc2 model is a model of a networked pedestrian-based 15mC well adapted to the prevailing conditions of many peripheries and suburbs in European metropolitan areas. The model can be specified through the implications of a few guiding principles. Each principle, it

its turn, will allow us to identify more detailed specifications. Principles and detailed specifications imply each other, across scales and within a given scale. This systemic view of the organisation of urban space could eventually give rise to an even more detailed pattern language (Alexander et al. 1977; Mehaffy et al. 2020) for the 15mC in European metropolitan peripheries, which could serve as guidelines for decision makers, planners and urban designers.

Principle 1. A meshed foreground network of main streets is the backbone of an uninterrupted system of pedestrian public space, enhanced by multimodality.

The main components of the emc2 model are main streets, i.e. streets concentrating urban activity and pedestrian public life (Gehl, 2011). They correspond to what are normally identified as high streets in the UK, where they remain a central element even in a suburban context (Vaughan, 2015). This concept of main street should not be confused here with the one used in traffic engineering, corresponding to an arterial road, with high traffic capacity and long-range significance. At the same time, it is only by applying all the founding principles of the emc2 model that the concept of the main street can be understood. Every principle will add a new facet to it. Within this first principle, main streets will be barely defined as important elements of the street network and of the urban mobility system, characterised by a high potential of pedestrian flow.

Specification 1.1. Foreground mesh of main streets. The foreground network within an urban street system is the set of the streets with the highest levels of configurational centrality across various scales (Hillier, 1996). As such, it is characterised by the configurational properties imparted to each street by the overall topology of the street network, regardless of the functions they serve. As noted by Hillier, streets with the highest configurational centrality are directly interconnected, forming a fully connected network. Typically, in large urban areas, a system of hubs and spokes emerges, where accessibility extends not only to the central hubs but also to the spokes, which channel ‘through movement'

However, to maintain consistency with the principles of the 15-minute walking city, the foreground network within the emc2 model will intentionally exclude motorways and similar roads that prohibit pedestrian access and building entrances. Although these roads often possess high configurational centrality values at the metropolitan scale, they lack the frequent connections necessary to increase configurational centrality at smaller scales (Berghauser Pont et al. 2019). Research in space syntax and other configurational approaches indicates that defining a foreground network in this manner provides valuable insights into the distribution and intensity of pedestrian flows (Lerman et al. 2014; Berghauser Pont et al. 2019), which, in turn, correlates with the level of activity in adjacent buildings, particularly for retail and service establishments benefiting from increased pedestrian traffic.

The spatial structure of the foreground network is of paramount importance in the emc2 model. Firstly, to ensure continuity in pedestrian movement and in the distribution of pedestrian-based activities, the foreground network must be completely connected even when motorways are excluded from it; otherwise, car-based mobility becomes a necessity even for connecting relatively close places. Secondly, the network should be as meshed as possible, avoiding long tree-like structures, to create redundancy of connections and minimise spaces where pedestrians are too far away from a main street. Main streets in traditional central urban areas create meshes of around 400 metres in length (Mehaffy et al., 2010). This could serve as an objective for the most densely populated peripheral areas covered by the emc2 model. More realistically, in suburban and peri-urban peripheries, the sides of the meshed structure could be up to 1000-1500 metres long, while still keeping most of the inner area within a 10-minute walk from

several main streets. The foundational idea of the emc2 model for the peripheral 15mC is to place inhabitants and city users, wherever they are, at close walking distance from main streets.

Specification 1.2. Uninterrupted public space system with pervasive pedestrian multimodality. The interconnected and meshed foreground network could not serve as the backbone of the 15mC if it were not integrated within a wider system of public spaces for pedestrians. Uninterrupted public space is necessary throughout the urban area: all main streets should be walkable, along with the ordinary and capillary streets that feed into them, as well as the plazas, squares, and parks connected to them. Multimodality, especially transit and cycling, must be considered as options to enhance pedestrian accessibility beyond the 15-minute threshold and should not presuppose car use to access their networks. The ease of using cycling and transit for longer trips will reduce suburban areas' dependence on cars for integration into the metropolitan area (Newman and Kenworthy, 1999).

Pedestrian-based multimodality recognizes the necessity of long-distance travel within the contemporary city. However, whenever possible, both short- and long-distance patterns of movement within the city are supported by the same foreground street network. Transit options compatible with the main streets (such as streetcars and buses) can be integrated within them, as well as bicycle paths and some residual car traffic. The goal is to reinforce the centrality of main streets with transit routes without sacrificing pedestrian space within them. Over the last forty years, many European cities have used streetcar projects as means for the requalification of public space (MVG, 2008). While some of the most central axes have become completely pedestrianised (except for the presence of streetcar tracks), more peripheral streets have been able to accommodate requalified sidewalks, cycle paths, as well as residual space for car traffic. From this perspective, European projects differ from many North American counterparts, where light railway transit has been preferred to streetcars: the distance between stops is normally greater, speeds are higher, and, as a consequence, tracks are often physically protected from pedestrian crossing, thereby becoming, along with much more generous space for car traffic, a major obstacle to the pedestrian functioning of the street.

Principle 2. The network of main streets develops synergies with ecological networks and with far-range mobility corridors and keeps its structure over time.

The contemporary metropolis is, as a networked space, in need of a network urbanism (Dupuy, 2008). Following this premise, we see the network of main streets as one of the many networks of contemporary urbanisation, albeit the most important of them. As such, it should develop synergies (and avoid conflicts) with ecological networks (namely blue and green networks) and with far-range mobility corridors (highways, railways). From this principle, the network of main streets also gets the role of main intermediary structure between different networks of the contemporary metropolitan area.

Specification 2.1. Green and blue ecological networks are interconnected corridors of undeveloped land of ecological significance, as well as water bodies near them. Urban green spaces have the potential to provide crucial ecosystem services that lower health risks, increase the resilience and ecological integrity of cities, improve the health of residents, and create more equitable living spaces across the socioeconomic spectrum. Enough nearby green space benefit the physical and mental health of residents and can strengthen communal cohesion and belonging via a myriad of pathways (Hartig et al., 2014; WHO, 2016; Braubach et al., 2017; Dizdaroglu, 2021).

However, for such positive effects to occur, both the quantity and the qualities of such space must be sufficient. It is recognised that the ecological quality is also a function of the multiple

connections existing among the different green and blue areas. Accordingly, the attention is presently more on the creation of networked corridors of rich natural life than on the sheer size of urban parks. Indeed, green and blue corridors can count on specific topographic features structuring their continuity (a talweg, a ridge, the coast of a large waterbody). Renaturalization actions are sometimes needed to ensure continuity. More attention is also given to further connecting other green areas (public and private gardens, playgrounds, etc.) to the main ecological corridors, even if in a lighter way (through street trees and hedges, road crossing devices for small animals, etc.). Indeed, isolation of ecological patches seems to be more hampering than loss of contiguity: fragmentation per se could even have moderate positive effects (Fahrig, 2019) when ecological patches are not completely isolated.

Availability of connected green and blue areas in the suburbs doesn't imply accessibility to them. Synergies are created when easy connections are made for pedestrians to access these ecological corridors with pathways leading to the main streets, which remain the most accessible elements for inhabitants and city-users alike. Crossings and overlays are also possible but taking care of not disrupting neither the ecological functions of green space nor the human usage of public space.

Specification 2.2. Mobility corridors are necessary to ensure long-distance connections within a metropolitan area and beyond it, with further destinations. These corridors are made of motorways and railways serving the main centres of the metropolitan area. As such, they are a main concern of national and regional planning policies. Necessary as they are, they are made of infrastructural elements which are hardly compatible with pedestrian-friendly public space. There is ample research on the barrier effects of far-range transport infrastructure for pedestrian-based local street networks (for a review see Van Eldijk et al. 2022). The main point is the inter-scalar nature of mobility systems. Car and railway infrastructure aim at decreasing the impedance (travel time) to access destinations on the national and regional scales. But this infrastructure often does so by introducing physical barriers in mobility systems on a more local scale, increasing impedance for walking and cycling, to access destinations within neighbourhoods or among neighbourhoods. The emc2 model aims at minimising these disruptions, above all when they concern the most essential elements of the human-centred city: main streets. Whenever the latter enter in conflict with transportation infrastructure, overpasses and tunnels should be foreseen for these extra-urban elements, leaving the ground floor always for pedestrian main streets. The positioning of main streets and transportation infrastructure also need attention: parallel positioning in close proximity is problematic as it severs the main street from its pedestrian shed. Similar conflicts arise between ecological and mobility corridors, necessitating appropriate solutions, but with less compelling requirements (tunnels and overpasses can sometimes be acceptable for ecological continuity, as well as parallel positioning in proximity if the necessary connections are foreseen).

Mobility corridors and main streets can also develop synergies. By creating multimodal synapses with city streets (railway stations, park & ride facilities, multimodal hubs) in a pedestrian-friendly environment, mobility corridors can feed the pedestrian flows on main streets and the use of their embedded transit and cycling systems. As a result, their movement economy is enhanced beyond the flows linked to their configurational potential within the street network. Specific design patterns are needed to ensure pedestrian-friendly connections between multimodal synapsis and main streets.

Specification 2.3. Structure preserving development. All networks evolve over time: the network of main streets, green and blue networks, mobility corridor networks and even the network of ordinary streets serving new urban developments. Based on simple considerations of resource parsimony or on more theoretical considerations of system wholeness, complexity

and resilience (Gunderson and Holling, 2002; Alexander, 2003; Salingaros, 2005; Mehaffy and Salingaros, 2013), these developments have to be structure-preserving, adding new elements incrementally to old ones as much as possible. Research in urban morphology has already pointed out that urban development always combines permanence and change (Hanson, 1989; Panerai, 2013; Romice et al., 2020, Fusco et al., 2024): the street network and the plot system are the main morphological infrastructure, changing relatively slowly over the decades and even the centuries. Supported by this infrastructure, faster cycles of building construction and reconstruction can take place without losing the apparent continuity of a given settlement. Within this overarching consideration, the permanence of high streets is considered as an even more compelling principle. Not only the layout of main streets is rarely modified, but when new main streets add to the old ones, they do so by intensifying or widening the spatial extent of the foreground network and without degrading the status of the old main streets. Of course, despite this general rule, urban history presents cases of demoted main streets, sometimes happening when a new parallel street absorbs its functions (Caniggia and Maffei, 2017). In the fragile suburban contexts, the emc2 model recommends extreme caution when allowing such shifts in centrality, suggesting taking stock of all the potential of established main streets.

Principle 3. Locally, the main street acts as an accessible, dense, and diverse centre for a neighbouring area.

One of the most notable aspects of the emc2 model is its vision of main streets as central elements within suburban and peri-urban peripheries. This approach shifts the focus away from a collection of suburban villages acting as central points for their immediate surroundings and instead emphasises the interconnection of central axes across different villages to create a more distributed and linear centrality in metropolitan peripheries. This concept, described by Hillier (1996) as pervasive centrality, firmly establishes main streets as key components of the socioeconomic functioning of the suburbs.

Specification 3.1. Main Street as an accessible linear centre. We have already established that main streets are integral components of the foreground network at a broader scale, yet they are also easily accessible locally. This dual accessibility implies that main streets possess high configurational centrality, facilitating movement both at a mesoscale (beyond the 15-minute walking distance, through their connections with other elements of the foreground network) and at a more local scale (within the 15-minute walking distance, through their connections to ordinary streets and other local public spaces). This multi-scalar network centrality is crucial for generating business opportunities across various activities within the movement economy (see below).

The central role of main streets within a pedestrian shed is analysed by Mehaffy et al. (2010) in their examination of traditional urbanisation, and it is envisioned as a significant pattern in their new pattern language (Mehaffy et al., 2020). As a matter of fact, several post-war developments in European cities have struggled to maintain the vitality of their main streets and squares due to inadequate accessibility and multi-scale centrality within their layout and the larger urban area where they are situated. For a main street to function effectively as a local node within a broader centrality network spanning the entire metropolitan area, it must also serve as a bridging tie within the conurbation system, facilitating connections between neighbourhoods. This capacity, derived from their configurational properties, positions main streets as pivotal locations within the grid, acting as bottlenecks for most movement flows and thus suitable for catalysing the coalescence of local densification processes.

Specification 3.2. Main street as a dense and diverse linear centre. The favourable pedestrian accessibility of main streets, coupled with the presence of easily accessible

transportation connections, positions them as focal points for both spontaneous market-driven and planned selective densification. Main streets typically exhibit higher built-up densities than their surroundings and host a diverse range of activities and services. Public-receiving activities such as retail, public and private services, etc., are primarily situated along the main street or on plazas and squares connected to it. These activities on and around main streets benefit from the movement economy (Hillier, 1996; Berghauser Pont et al., 2019; Bobkova et al., 2019; Araldi, 2020; Froy, 2023): flows, concentrated on the main axes by the configuration of the street network, create opportunities for socioeconomic interaction and are a primary driver for the presence of retail and market-driven activities. The presence of these activities, in turn, enhances the utilisation of public spaces on main streets, fostering opportunities for additional services. Consequently, activities on main streets form a dense network (Salingaros, 2005; Mehaffy et al., 2020), with close spacing between them (multiple activities per 100 metres) and good intervisibility, well-suited to the fluidity of pedestrian movement within the walkable space.

In suburban areas, where car dependency undermines the pedestrian flow potential of main streets, locating public facilities such as administrations and schools on main streets within a pedestrian-friendly environment can enhance pedestrian flows and stimulate activities within the movement economy. However, in these suburban contexts, some degree of car access to these activities may still be necessary to maintain their local concentrations on main streets. Addressing car access raises concerns about mitigating the negative impact of car flows on main streets and identifying parking options that are compatible with pedestrian spaces on main streets.

Principle 4. The main street is pedestrian-friendly and enhances public life.

This principle ensures that main streets remain human-centred environments, fostering social interaction and well-being. Pedestrian-friendliness of main streets encompasses both ease of pedestrian movement (walkability) and opportunities for pedestrian stay, interaction, and a strong sense of place. Guidelines for designing street public spaces with a focus on human-centeredness exist (Ståhle et al., 2022; ADEME, 2023), along with experiments proposing innovative temporary solutions through tactical urbanism (Bertolini, 2020; Lydon and Garcia, 2015). In what follows, we will emphasise what we perceive as the most compelling specifications, recognizing that extensive fine-tuning will be necessary to address local specificities and needs.

Specification 4.1. Active built-up frontage on the main street. Build-up frontages along main streets guide pedestrian movement, visually define perceived space, and provide opportunities for locating activities on the ground floor. The significance of visually defining the channel of movement in urban spaces has been underscored since the pioneering works of Cullen (1961) and Lynch (1959), extending further back to the contributions of Sitte (1889). Lynch (1959) posits that paths and edges are fundamental linear features that structure human perception and cognition of urban space; the former is experienced physically through walking, while the latter is primarily perceived visually. When the edge of a built-up frontage aligns with the path of a street, the imageability of the urban structure is notably reinforced, precisely the objective in the case of a main street. It is unsurprising that authors advocating for recommended urban patterns emphasise the importance of certain visual requirements. Firstly, buildings, whether adjacent or detached, align to create an urban frontage, fostering a street corridor effect (Alexander et al., 1977; Gehl, 2010). Secondly, setbacks are either minimal or absent to ensure a strong connection between the street and buildings. Lastly, terminated vistas can be employed to prevent the impression of endless peripheral axes (Mehaffy et al., 2020). To further enhance

the connection to outdoor spaces and provide pedestrians with a sheltered interface, arcades can be developed along the building frontage (Alexander et al., 1977; Mehaffy et al., 2020).

The build-up frontage also results in higher building density, offering opportunities for both living and working along main streets. A functional requirement for buildings along main streets is to accommodate activities, particularly on the ground floor. The challenges of having ground-floor residential units along busy main streets could be addressed by a simple prescription: ground floors are designated for activities. Regarding residential opportunities, an urban frontage on main streets consisting of mid-rise buildings (2 to 5-6 floors) could provide housing options often lacking in suburban areas, such as small to mid-sized flats. These options could complement the larger units found in suburban housing developments and social housing complexes. This housing shortage is well-documented in the North American context (Parolek, 2020) and is a structural barrier to achieving social and generational diversity in many European suburbs. As for high-rise buildings, they pose challenges on peripheral and suburban main streets. Outside the compact fabric of central city perimeter blocks, high-rises tend to be freestanding constructions, weakly connected to the public space of the main street and disrupting the urban frontage. Specific retrofitting strategies may be necessary to integrate existing high-rise buildings into the active urban frontage of peripheral and suburban main streets.

Specification 4.2. Main Street as a walkable environment. The focus here is on the layout and organisation of public space. Main streets should provide ample pedestrian space to accommodate groups of people walking comfortably. This entails prioritising pedestrian space, ensuring frequent ground-level pedestrian crossings that cater to all users, including children, the elderly, and the physically impaired, and incorporating street trees to offer shade and thermal comfort (Jacobs, 1993). There are compositional differences among three types of main streets:

- Large urban boulevards, wider than 30-40 metres, can feature spacious sidewalks (5 metres and more), accommodate multiple modes of transportation, and include several rows of trees. However, efforts should be made to mitigate the separation between opposing sidewalks.
- Urban avenues (20-30 metres wide) may need to compromise on multimodality and vegetation presence to ensure ample pedestrian space but are generally easier for pedestrians to cross.
- Unplanned main streets (typically less than 15-20 metres wide and irregular) often stem from the development of faubourgs or linear villages along what Caniggia and Maffei (2017) term a matrix route. These streets may consider pedestrianisation or shared spaces as options and should minimise on-street parking.

Shared spaces with clear pedestrian priority can serve as an alternative to expansive sidewalks, even on larger main streets, as demonstrated by Mariahilfer Straße in Vienna. However, in suburban contexts, car parking may be deemed necessary, necessitating compromises. To prioritise pedestrian use, a limited amount of short-term surface parking could be allocated on side streets or behind retail premises.

Specification 4.3. Main street as a hub for social interaction with soft interfaces. As discussed in Principle 3, the intensity of public life is strongly influenced by the role of the street within the broader street network. Bolin et al. (2021) demonstrated in a comprehensive European study that more central streets—those with higher levels of network centrality—in dense neighbourhoods experience greater movement and co-presence. However, the social and economic objective of main streets extends beyond facilitating pedestrian flow; it aims to encourage as much of this movement as possible to transition into social interaction and lingering.

Analysis of traditional urban forms provides invaluable insights into features that go beyond mere presence of built-up frontages. Active interfaces between buildings and streets are essential for urban vitality and natural surveillance. The vitality of street life is enriched by spatial relationships between private and public spaces (Gehl, 2010; Jacobs, 1961), facilitated by the adjacency and permeability of buildings directly accessible from the street. This relationship is elucidated in the interface maps drawn by Hillier and Hanson (1984) to explore the relationship of building entrances and public space in terms of movement and potential encounter. Co-presence and interaction are favoured in traditional streets (Shu, 2000), where the density of entrances and shallow topological depth between private and public spaces foster street vitality, safety, and social control.

Many recommendations can be gleaned from the preceding discussion:

- Facades along main streets should always be "soft" and active, engaging pedestrians with opportunities for interaction such as doors to enter, windows to look at, and recesses allowing for sitting (Gehl, 2010; Dovey and Wood, 2015; Fusco et al., 2024). Blank walls and opaque fences should be avoided.
- Urban furniture, both public and private, should encourage lingering and interaction, while pockets of activity should be developed in recesses of the urban frontage (such as setbacks within private lots or extensions of public space), away from pedestrian movement and car parking (Alexander et al., 1977).
- Layered spaces at building edges add depth to public/private interfaces (Shu, 2000; Gehl, 2010; Mehaffy et al., 2020): setbacks used for public activities and open verandas of bars, shops, and restaurants provide additional opportunities for social interaction and leisure.
- "Eyes on the street" are fostered by buildings facing the street, featuring balconies and windows above the ground floor (Jacobs, 1961), thereby enhancing the safety of public space usage.

All these features have been observed by the aforementioned authors in urban environments that are particularly successful in terms of utilisation and liveliness of public space, what Gehl (2010) defines as intensity of public life. The goal of the emc2 model is simply to ensure that these morphological elements supporting main street public life in peripheral and suburban areas, albeit combined differently to accommodate local specificities, are maximally present.

Specification 4.4. Main street as a beacon for shared urban values. Main streets serve as the embodiment of urbanity within each sector of the metropolitan area. Hosting key functions and frequented public spaces, and bordered by significant buildings, they are imbued with human meaning, anchoring community values for inhabitants and city users across a wider area. They represent the enduring presence of the community over historical time (Griffiths, 2015) and serve as an implicit agreement regarding expectations for any urban intervention in the physical layout and functioning of urban space (Gourdon, 2001).

These fundamental considerations can have far-reaching implications for design preferences and necessitate community engagement in any proposed transformation of the streetscape or public space layout of main streets. Therefore, greater attention may be warranted to use materials, proportions, and details that resonate with the local context and cultural preferences along main streets. The historical origins of main streets, whether they evolved spontaneously as faubourgs or were planned as avenues, can significantly contribute to the sense of place, complementing the design and functional considerations highlighted in Specification 3.2. Main streets will also serve as natural venues for ephemeral events, such as local markets, cultural or sporting events, and community or political gatherings. Organising these events to reclaim street space for pedestrians (Bertolini, 2020; Lyndon and Garcia, 2015) could be one of the

initial actions to implement to catalyse the transition of present-day peripheral main streets to the desired levels of urbanity outlined in the emc2 model.

Ensuring equal attention to all users of the main street, regardless of age and ability, through the provision of appropriate urban furniture and the removal of architectural barriers, not only enhances the quality of public space but also reflects important shared values. This stands in contrast to the current imbalance in the use of peripheral arterial roads, which often prioritise car drivers at the expense of neglected pedestrians.

Principle 5. The inside of the mesh is well connected to the main streets and accommodates functions outside of the movement economy.

This last principle addresses the areas within the mesh of main streets and how to establish walkable connections to incorporate them into the pedestrian shed surrounding the main streets, thereby expanding the potential clientele for their activities. In broad terms, urban functions that do not primarily serve the needs of the movement economy are situated within the mesh. These may include residential developments, urban parks, as well as industrial and agricultural areas.

Specification 5.1. Meshed Network of Local Streets. Local streets should be as meshed as possible, facilitating the efficient distribution of both pedestrian and motorised traffic while delineating blocks. Suburban and peri-urban areas in Europe often fall short in this regard, with numerous local streets branching off from main axes without effectively delineating small-sized blocks (100-150 metres maximum). Local loops can be implemented to discourage through-traffic, a strategy recently employed even in the regular urban grid of Barcelona's city centre to foster more pedestrian-friendly environments on local streets. The interconnectedness of local streets can also facilitate future development of new main streets, enhancing the density of the foreground network. This is particularly evident when a former suburban area transitions into a more central and densely populated settlement: establishing a new main street is often more feasible by catalysing densification and mixed-use development on an existing local street within a meshed network, rather than creating a new right-of-way through costly expropriation procedures. The redundancy of the meshedness of main and local streets enhances the morphological resilience of the model (refer to Specification 2.3): the foreground network of main streets can grow organically, enabling the city to function as a complex adaptive system.

Specification 5.2. Interconnected Capillary Pathways. Pathways that serve a few buildings or a housing subdivision, or traverse parks and playgrounds, are interconnected (though not necessarily meshed) for pedestrians and, whenever feasible, for cyclists. They may explicitly prohibit larger vehicles to create tranquil pedestrian sanctuaries. These pedestrian interconnections offer shortcuts across areas delimited by main streets, facilitating easier pedestrian access to the latter. However, it's important to note that the spatial configuration of the background network of alleys and pathways is the most culture-specific aspect of the street network (Habraken, 1998; Hillier, 2012), balancing privacy and publicness in residential areas. According to Hillier, the interstitial part of the background network serves a conservative function in urban space, aimed at maintaining and reinforcing existing social structures, in contrast to the generative role and serendipity of the foreground network of main streets. While its morphology generally allows for more control, its configuration is highly contingent upon the cultural context it seeks to uphold: the embedded rules governing patterns of movement and interaction are heavily influenced by existing cultural systems.

Specification 5.3. Distributed Parcs in the core of the mesh. Neighbourhood parks and community gardens, not directly involved in the movement economy, can thrive within a semi-

pedestrian environment at the core of the mesh of main streets. The concept of situating a park at the heart of a neighbourhood originated in previous urban models, namely the Garden City (Howard, 1902), and the Neighbourhood Unit (Perry, 1929), and resonates in contemporary works on pattern languages (Mehaffy et al., 2020). However, in the Garden City paradigm, we are dealing more with a large central park for a mid-sized city of 32,000 inhabitants than with distributed parks within neighbourhoods. The central parkway of Welwyn, UK, is a good example of the implementation of this Garden City guideline. Distributed local parks provide an additional amenity within a short walking distance for inhabitants and city users, complementing the 15-minute city offer. Of course, larger green spaces in the periphery remain crucial to support multi-scalar interactions between local parks inside the mesh and larger green areas and rural land. This calls for effective connections of the local parks to the green and blue networks (Specification 2.1).

Specification 5.4. Integration of Activity Areas into the Urban Fabric. When the interior of the mesh includes an activity area (industry, logistics, or intensive urban farming zone), it should be treated as an integral part of the urban space, with interconnected local streets facilitating pedestrian and bicycle access to the main streets. Specific access routes may be designated for heavy truck traffic, linking directly to nearby motorways without traversing the main streets. Examining the case of the Greater Manchester Area, Froy (2023) illustrates how logistical and industrial activities can leverage direct access to regional and national infrastructure, albeit at the expense of the multi-scale balance of the urban street network configuration. Therefore, it's crucial to ensure comfortable pedestrian and bicycle access to encourage employees to walk or cycle to local main streets and partake in the activities offered there, be it after work or during breaks. In contrast, large retailers should maintain a direct, pedestrian-friendly interface on the main street and contribute to its allure, even if their premises extend further into the mesh. While this specification draws less directly from empirical observations of best practices, it logically follows from the guiding principles of the emc2 model.

To wrap up this section, let's refine the concept of the main street within the emc2 model: it stands as a pivotal element of the street network, primarily catering to pedestrian movement while accommodating various modes of transportation to varying degrees. It serves as a catalyst for a diverse array of retail and service offerings, fostering vibrant public life within its vicinity. Moreover, it functions as an attractive focal point for a broader area, presenting opportunities for further urban densification given its inherently higher density compared to its immediate surroundings. By integrating its five guiding principles, the emc2 model proposes a meshed network of main streets as the foundational organising principle of the 15mC. This approach ensures pervasive centrality, even in peripheral and suburban areas, while capitalising on potential synergies with ecological and transportation networks.

3. An empirical research design to assess the potential of the emc2 model

Planning normally intervenes in the existing city, and contemporary urban peripheries in Europe are more or less prone to the requirements of the emc2 model. We will thus present a framework to assess the potential of contemporary urban peripheries to develop the emc2 model. Indeed, many European urban outskirts already possess incipient networks of main streets, which could serve as the backbone of the peripheral 15mC, as foreseen by the emc2 model. Beyond the model specification presented in the previous section, our research design consists of the following five steps.

The first step aims at assessing the potential of the emc2 model at the scale of whole metropolitan areas. The usual way of assessing 15mC potential in metropolitan areas is

relatively functional (Moreno et al. 2021, EIT Urban Mobility 2022): analysts look for possible local centres based on concentrations of urban functions (possibly divided in several categories to assess the presence of all of them) and define 15mC potential based on pedestrian sheds calculated around these centres. Within the emc2 model, functional concentrations are not a guarantee of the proximity-based 15mC, but rather a result of other requirements. What we want to assess is the potential for a given street to be a main street and of the resulting network of main streets to be as meshed as possible. Activities integrated along pedestrian-friendly main streets seem much more apt to induce pedestrian-based movement and public life than those randomly agglomerated within a given spatial extent. Researchers will thus first assess the pedestrian foreground street network, using the multi-scale configurational approach by Berghauser Pont et al. (2019): we calculate street centrality at different scales and identify both city streets (making up the pedestrian foreground network within and beyond the 15m radius) and main neighbourhood streets (complementing the foreground network within the 15 radius). We further assess the built-up streetscape of these main streets to ensure the presence of an urban frontage, of a sufficient built-up density and of setbacks and street cross-sections compatible with a pedestrian-friendly environment. After having checked these morphological pre-conditions, we assess the functional requirements: concentration of proximity-based activities (retail and services) and enough population in pedestrian sheds around the main streets. Clearly, part of the foreground network in peripheral and suburban areas lack many of the other morphological and functional features of the main streets, suggesting possible planning strategies to further connect the existing network of main streets by taking advantage of the already present configurational potential. In other instances, the foreground network could not be meshed enough, suggesting the presence of weak ties and possible strategies to reinforce them. These metropolitan-wide assessments will be carried out on six European metropolitan areas: the French Riviera, Lille-Roubaix-Tourcoing, Vienna, the Versilia conurbation, Florence and Gothenburg.

A second step of the analysis aims at understanding the historical genesis of the observable networks of main streets, inherited from planning or from spontaneous growth, including pre-existing rural settlements and faubourgs. The identification of the persistence of peripheral and suburban main streets over more than a century of urban history will be a main goal of the analysis. Within selected test areas, the historical formation of the observable forms and functions will be assessed through the study of old cadastral documents, above all in Vienna, where old cadastral documents include usage data. From the understanding of the underlying long-term and short-term dynamics, and considering the present situation of the test areas, possible implications for the implementation of the emc2 model can be identified, as well as the evolutive potential of the model over time. These analyses will also reveal insights into different spatial qualities in existing linear settlements, which will inform further phases of the research.

The third step of the research design studies the relations of the network of main streets of the emc2 model with other fundamental networks, mainly the multi-modal mobility network and the green/blue ecological network. The goal is to understand synergies and conflicts related to the different networks. The interaction of pedestrian movement and use of public space with car flows, as well as with bicycle and transit options will be assessed through the development of an agent-based model on a test area of the French Riviera. The synergies with the green and blue ecological networks and the implications on the ecosystem services effectively produced for inhabitants and city-users will be particularly assessed in Gothenburg, Sweden. These applications should also identify the implications for the functioning of the 15mC in the metropolitan peripheries and produce more detailed specifications for the emc2 model.

The fourth research step will zoom on peripheral test areas, which will have been previously selected because they are already organised around more or less well functioning main streets. Their fine-grained assessment will include their present form and human usage, and their possible transformations, through fieldwork, morpho-functional analysis, 3D-models and interaction with local authorities. Researchers will assess details of public space layout, organisation and usage, building façades, use of building ground-floors and of their pertaining open areas, etc. At this scale, the concentration of activities can be assessed through their capacity to create a pedestrian-based web characterised by small distances, intervisibility and ease of pedestrian reach. As the test areas are particularly favourable to emc2 solutions, this phase of the research aims at understanding the observable advantages and drawbacks of these almost-emc2 examples, quantifying their contribution to the objectives of the 15-minute city, and identifying possible improvement for a full emc2 implementation.

In a last research step, researchers will look for generalisation, to pass from what is learned on a given case study to what could be applied to all case studies and, beyond, to all European cities wishing to implement the emc2 model. The assessment of the theoretical model in the light of the obtained results is an essential aspect of generalisation of findings. A second objective of this final phase is to produce assessment and intervention guidelines for the use of urban practitioners. To include all the scales of the analysis (metropolitan, sector-wide and local) and to respect the coherence of the overall model, guidelines could be produced in the form of a pattern language (Alexander et al. 1977, Mehaffy et al. 2020).

4. Discussion: the emc2 and other models to organise the 15-mitute city

The emc2 model distinguishes itself from other seemingly related models designed to structure proximity-based cities or offer alternatives to car-dependent urban sprawl.

Transit-oriented development (TOD, as exposed by Cervero et al. 2004) is an urban planning and design approach that revolves around creating mixed-use, pedestrian-friendly communities centred on public transportation hubs, such as train stations, subway stops, or bus terminals. TOD emphasises the strategic placement of residential, commercial, and recreational spaces within walking distance of public transportation facilities, aiming to incentivize residents to use transit instead of relying on private vehicles. A foundational principle of TOD is densification and the mix of uses around transit nodes. This mix of uses not only facilitates residents in meeting their daily needs without long-distance travel but also aligns with the ethos of the pedestrian-based 15mC.

Densification is pivotal for the very viability of TOD. Increased residential and commercial densities around transit nodes justify (and pay for) the significant capital costs of new high-performance transit infrastructure and provide an alternative to urban sprawl. This density is intended to foster vibrant street life and economic vitality. Design of public space is identified as an important aspect among the different Ds of the TOD model (Cervero and Cockelman 1997, Ogra and Ndebele 2014). However, design quality alone overlooks the configurational aspects that contribute to the success of pedestrian environments, particularly concerning natural movement flows within the street network topology. The extra-flows produced by the transit hub, regardless of pedestrian configurational potential, are deemed sufficient to ensure the viability of retail and service within the TOD scheme.

Despite its well-intentioned elements, the TOD model appears to clash with the networked fabric of the pedestrian-centred 15mC. Human scale considerations are primarily concentrated around the relatively distant hubs, relying on high-capacity transit to bridge the gaps between them. This approach disrupts the continuity of pedestrian flow and restricts opportunities for

the development of retail and services to specific nodal points. In comparison to the emc2 model, TOD seems more suited to structuring metropolitan growth when demographic demand justifies it and financial resources are available to establish new high-performance transit lines. In Europe, the ambitious Grand Paris Express project and the concurrent development of dense urban hubs around its stations stand out as exemplary instances of coherent TOD (Bove and Cornut, 2024).

TOD presents itself as a capital-intensive alternative to suburban sprawl, while emc2 is more akin to a low-cost retrofitting strategy for suburbs. Its aim is to provide suburbanites with a 15mC environment through limited densification around requalified main streets. However, there is potential for profitable hybridization between the TOD and emc2 models. Both envision the presence of a network of rapid transit, but for emc2, the distinction between streetcar and railway lines is crucial. Streetcars can seamlessly integrate with the pedestrian multimodality of main streets, whereas railways are more efficient in connecting a large metropolitan area. However, they must be integrated within a pervasive network of pedestrian-based main streets and cannot be solely relied upon to create a pedestrian-friendly environment.

The Neighbourhood Unit (NU), introduced by C. Perry (1929), holds a significant position in urban planning history and can be viewed as an initial response of pedestrian-based cities to the disruptive influence of automobile systems. This model underscores the establishment of self-contained residential neighbourhoods equipped with various amenities and services within walking distance. Consequently, it remains a relevant option for addressing the challenges posed by the contemporary 15mC. The classical Neighbourhood Unit is designed to be compact and pedestrian-friendly, with a distinct boundary that delineates it from surrounding areas. This setup aims to promote pedestrian mobility within the neighbourhood while reducing the necessity for long-distance travel. Unlike the emc2 model, the NU model relinquishes the traditional centrality role of main streets, allowing them to serve as arterial roads encircling the neighbourhood. Organised around a hierarchical street network, the NU model features major arterial roads on the periphery and interconnected smaller streets within. This design aligns with the principles of traffic engineering, which were emerging in the 1920s, facilitating regulated traffic flow and fostering a sense of enclosure and safety within the neighbourhood.

Each neighbourhood unit encompasses a centrally located public space, such as a park, square, or playground, serving as a focal point for community activities and gatherings. Surrounding this space are vital civic services for the community, including schools, libraries, churches, and healthcare facilities. Interestingly, Perry's original model recognized that retail and commercial services required the through-flows facilitated by cars and thus situated them along the surrounding arterial roads, complete with necessary parking facilities. However, post-war European implementations of the NU model, often seen in social housing projects, deviated from Perry's approach by placing retail and commercial services within the core of the neighbourhood and its civic centre. Consequently, these market-based activities, heavily reliant on the movement economy, encountered challenges due to the low configurational potential of their locations within the mesh, away from the main axes. Additionally, they suffered from the gradual impoverishment of the housing projects.

What appears most problematic with the NU model is its pursuit of a self-contained settlement within a broader metropolitan context. This vision, later revived by the urban village ideal, contradicts the networked nature of cities and overlooks the intricate overlap and intertwining of catchment areas for various urban services, as noted early on by Alexander (1965) and later elucidated by network-based theories (Hillier 1996, Salingaros 2005, Mehaffy et al. 2010). NU implementations in European outskirts have consequently experienced a continual erosion of

their proximity-based offerings and have become increasingly reliant on car-based mobility, which could better integrate the networked nature of cities.

Finally, the emc2 model shares intriguing similarities with Alexander's pattern language (Alexander et al. 1977), particularly concerning the detailed specifications of Principle 4. However, when examining the urban model that emerges from this pattern language at larger scales, it appears to align more closely with the NU model. Alexander designates local transport areas approximately one-mile wide as zones for pedestrian and bicycle movement (pattern #11). Like the NU model, these areas are delineated by ring roads for car traffic (pattern #17), while maintaining one side open to connect with the surrounding countryside forming a broad ecological network.

At the heart of these local transport areas lies a pedestrian promenade (pattern #31), which, interestingly, is not the primary commercial axis but rather a pedestrian-friendly public space linking short shopping streets (pattern #32). These streets, in turn, create a dispersed network of shopping nodes (pattern #19). Two main distinctions emerge when comparing this approach to the emc2 model. Firstly, akin to the NU model, Alexander's model envisions pedestrian-friendly zones for short distances as distinct modules, relying on automobiles (and transit, as in pattern #16) to connect them within a broader urban framework. Secondly, it overlooks the observable pattern of ribbon development seen in retail and service sectors, which is heavily influenced by the movement economy and was already well-documented by contemporary urban geographers (Berry 1967). Instead, it proposes a more dispersed form of retail, lacking support from the configurational properties of the network.

In response to these general shortcomings of the NU and of Alexander's model, the emc2 model seeks to reconnect with more traditional patterns of street centrality. It aligns with a broader movement evident in European cities (and beyond) aimed at reclaiming existing streets for the public realm, following decades of prioritising motorised traffic management (Bertolini, 2020; Norton, 2015). However, this doesn't imply that the emc2 model is always the optimal solution for European metropolitan areas. Unique historical heritage and topographical constraints have given rise to distinct patterns of agglomerated villages, often situated on hilltops, ridges, or along hill-flanks. Even on flat terrain, agglomerated villages that once punctuated rural spaces have subsequently been integrated into wider peri-urban contexts, creating local pedestrian-friendly areas, alongside more linear settlements and faubourgs. In all these scenarios, there's potential for hybridization between the emc2 model and urban village concepts. This could involve revitalising main roads that connect villages, fostering a more pervasive centrality across the region.

We emphasise that the geographic scope of the proposed emc2 model primarily encompasses the suburban and peri-urban peripheries within European metropolitan areas. While the guiding principles and some detailed specifications are broadly applicable, others may be more context-specific to European urbanisation. This reflects the primary domain of expertise of the authors.

Spaces of automobility: diverging trajectories within the Liège-Aachen diffuse city

Cédric Wehrle
Affiliation: University of Liège
E-mail: cedric.wehrle@uliege.be

Abstract
The Liège-Aachen metropolitan axis sets itself apart from neighbouring cases of diffuse city by lying both at the centre of the continent and at the edge of two countries, languages, and planning cultures. The socio-technical system of automobility constitutes a defining catalyst not only for accentuating already present dispersed settlement structures, but also for producing, within a very short time span, characteristic urban forms linked to the car. This contribution aims to interrogate this very type of transborder diffuse city through the lens of automobility and a future post-car discourse. Specifically, it proposes, in the light of both Belgian and German past planning practices, to compare the spatial impact of current policy objectives and government plans in both regions to reduce future car use.

Keywords: diffuse city, urban morphology, automobility, post-car policies, transborder

Context: automobility and the European diffuse city

Emissions from the transportation sector have been recognized not only as a significant contributing factor to global climate change, but also one of the sectors on which the most ambitious CO_2 emissions reduction targets are set by the members of the European Union (2021). Indeed, one can assume that the goal of reducing emissions by around 35% by 2030 and achieving net zero emissions by 2050 (ibid.) might not be met without a significant shift in how today's mobility practices which today contribute to shaping contemporary urban settlements.

To understand this relationship between mobility practices and production of space, the term 'automobility' has been used to describe the socio-technical system in which the generalised dependency towards the use of a single mode of transportation – the car – enables (Dupuy 1995), conditions (Urry 2004), or even dictates (Böhm et al. 2006) social practices. This 'system of automobility' has subsequently been used to describe various topics related to the challenges facing the contemporary urban condition, such as social marginalisation (Walks 2015), healthcare issues (Solnit 2001), spatial fragmentation (Graham & Marvin 2001), waste of spatial resources (Berger 2006), loss of economic productivity (Rigal 2020), etc.

The rapid expansion of the system of automobility, especially in the three decades following the Second World War (Ross 1998), has also served as a catalyst for a shift in how urban settlements are spatially distributed. Indeed, automobility has allowed to funnel the rapid economic and demographic growth away from the traditional pattern of concentric expansion of the historic urban core towards the one of the 'diffuse city'. This condition has been defined by featuring extensive land use, absence of an overarching spatial hierarchy, dispersion of the built fabric, as well as high degree infrastructural connectivity (Grosjean 2010). The term 'diffuse city' originally was applied to northern Italy (Indovina 1990) but has since been related to many other geographic contexts around the world (Barcelloni Corte & Viganò 2022), each sporting their own regional characteristics. For the purpose of this article, one can name the

German *Zwischenstadt* (Sieverts 2001), the Dutch *tapijtmetropool* (Neutelings 1991), the French *rurbanisation* (Bauer & Roux 1976), and the Belgian *banlieue radieuse* (Smets 1968). For most of these cases studies, patterns of urban diffusion predate the advent of the system of automobility. Yet, the latter, especially through the building of new road infrastructure (e.g., Van Acker 2014) constitutes a defining catalyst not only for accentuating already present dispersed settlement structures, but also for producing characteristic new urban forms (e.g., Buchanan 1963, Pope 2015), within a very short time span.

Recognizing the tight relationship between mobility practices and urban morphology which plays out within the system of automobility, a growing number of research is being conducted on exploring the spatial consequences of a radical shift towards a world "beyond mobility" (Cervero et al. 2017), "after the car" (Dennis & Urry 2010), or "post-car" (Cogato Lanza et al. 2021), in which a potential diminishing of the automobile can lead to new territorial configurations. Indeed, considering what is already there as a potentially formidable resource of grey energy, it would not only reallocate the way road space is shared, but the car's ancillary spaces would also find a new purpose within a post-carbon diffuse city.

Hypothesis: automobility fuelling diverging trajectories

The goal of this paper is to show how the lens of automobility can offer explanations on how diffuse cities can acquire a variety of formal urban characteristics, and how, in turn, a post-car discourse could produce original urban forms. First, it proposes, in the light of the scientific work describing urban planning practices during the 20th century, to compare a hybrid diffuse city context through the means of cartographic visualisation. Secondly, it will feature an overview of government plans being having been drafted in the last decade to dramatically reduce the modal share of the car. This overview will finally be followed by opening a discussion about the potential spatial impact of these policy objectives.

As mentioned above, despite western Europe having undergone as a whole a comparable process of intense urban production, relying on the car as a formidable emancipating power – car adoption rates being similar between countries (Mees 2010) – the multitude of iterations of diffuse city which are still being described around the continent attest to the many ways this process has in effect taken form. Indeed, despite sharing common technical systems, unique characteristics arise through specific geographic and socio-political factors.

Similarly, European countries, bound by common agreements, have been drafting documents aimed at describing how to honour the quantitative targets the transition away from fossil fuels entails. This paper hypothesises that, as different planning cultures produced different spaces of automobility despite sharing comparable metrics, similar targets in CO_2 reduction can possibly result in distinct spatial answers. While the project of the Transition is far from clearly formulated, this paper will use as evidence the transition which is already under way, in the form of official planning documents.

Common ground: automobility in the Liège–Aachen diffuse city

To address this hypothesis, the case study of the Liège-Aachen diffuse city can be of particular interest. This territory, which lies on the border between Belgium and Germany, on the northern Ardennes foothills, features a high degree of almost continuous urban sprawl (EEA 2016), hosts a great variety of interlocking land uses (residential, agricultural, industrial, natural), as well as is irrigated by major transcontinental road and rail infrastructure. It also features a long and shared history of urban diffusion: First, soil composition led to a dispersed agrarian settlement

pattern from the Middle Ages onward (Lefèvre 1926). Later, the position of coal deposits has also served as the prime rationality for directing urban expansion in both countries (Kranz 1998, Wiesenmann 1998). Finally, with the advent of the Industrial Revolution, both nations have sought to disperse the rapidly rising population throughout their territory to curb rural exodus (Prince & Rowntree 1910, Blotevogel 2018).

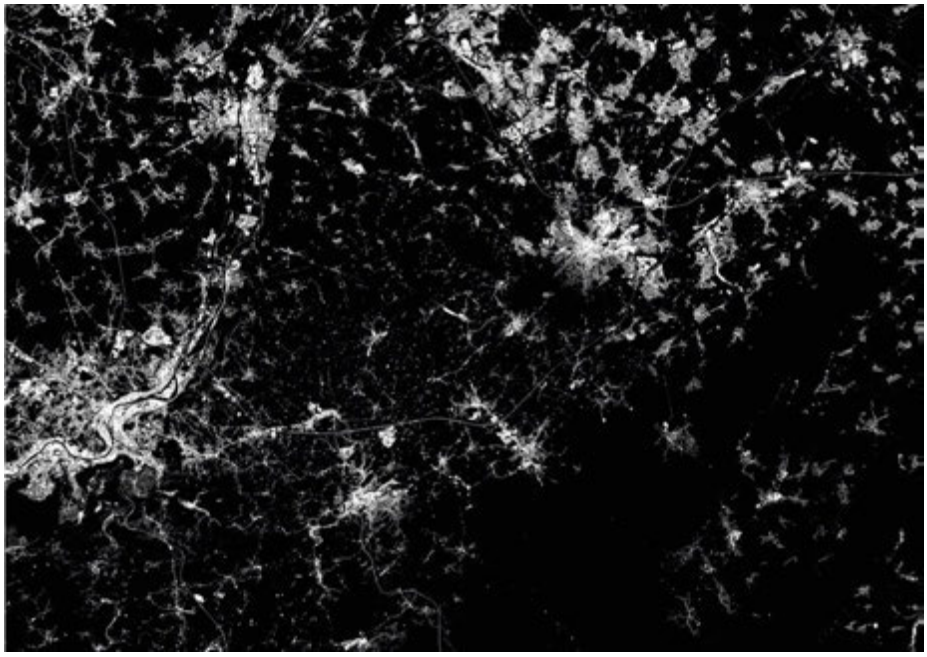

Figure 1. Impermeable areas of the transborder Liège-Aachen diffuse city. Source: elaborated by the author, data from Copernicus 2018.

As detailed above, the Liège-Aachen metropolitan axis fits on many aspects within the definition of the diffuse city (Grosjean 2010) but sets itself apart from neighbouring western European examples in several ways. Firstly, it lies both at the centre of Europe and at the edge of two countries, languages, and planning cultures. Secondly, it crucially lacks a hegemonic urban centre of which this case study can be seen as the hinterland. Lastly, despite being part of the oldest recognized European cross-border collaboration – the Euregio Meuse-Rhine (Geelen 2007) – it lacks a common territorial project.

Drifting borders: the rise of automobility in the Liège–Aachen diffuse city

Being located at the border of two countries, not to mention two major linguistic areas, the large waves of urbanisation hitting the Liège–Aachen diffuse city were throughout history approached in a different way. The period between the end of the Second World War to the mid 1970s offers a particularly clear glimpse into how the opportunities for building a territory adapted to the car were seized with different planning methodologies in mind, and thus morphologically diverging results. Indeed, these three decades see responses to the rapid spread of car use in western Europe, coupled with an increase in centralised planning by the state (Ryckewaert 2011), which lay the groundwork for subsequent zoning and building laws.

The table below aim to compare how, in Belgium and in Germany, a variety of tools of urban planning were harnessed to arrive to the spatial zoning plan, the cartographic document which would cement the urban morphology of the automobile diffuse city. These documents (the Belgian *Plan de secteur* and the German *Flächennutzungsplan*, respectively) indeed lie within a wider cultural genealogy. This genealogy starts at the beginning of the 20th century and is divided into general urban planning principles (territorial equilibrium, de-urbanisation, decentralised concentration, *auflockerung*/loosening up), archetypical spatial models which can incarnate the above principles (garden city, linear city, central place system), spatial plans drafted at different scales, as well as legislative tools aimed at steering urban growth.

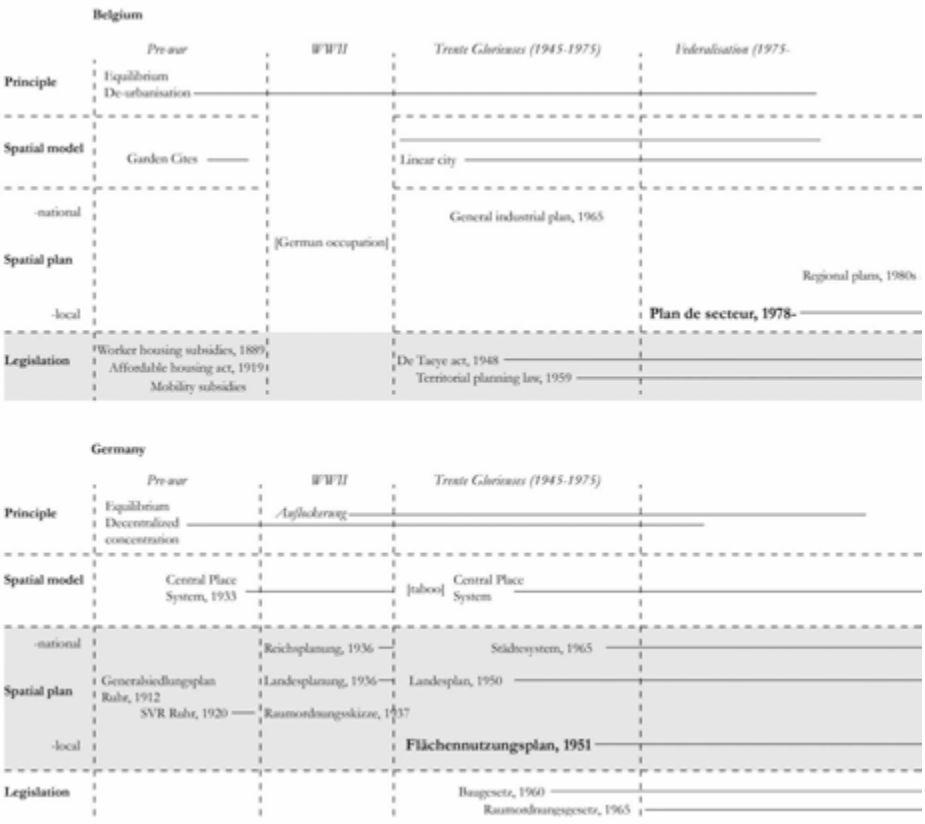

Figure 2. Comparative genealogy of Belgian and German planning instruments during the early to middle of the 20th century. Source: elaborated by the author.

Theses chronologic tables above highlight two urban planning typologies, the German one relying on an integrated spatial approach, while the Belgian chose a primarily legislative one (Nadin & Stead 2008, Dühr 2011). The Aachen region, located close to the heavily planned Ruhr basin, became a laboratory for Christaller's (1933) central space theory. The necessity to organise a vast industrial apparatus, and later the war effort, led to Christaller's theory to enjoy a wide influence (Kegler 2015). After the war, following a brief fall from grace, the central place theory was enshrined as an official planning instrument to hierarchically classify

settlements. The Land Nordrhein-Westfalen arrived at a drawn zoning plan as soon as 1951, the rest of the country following suit in the next decade and-a-half (Blotevogel 2004, 2018). In Belgium, however, the more fragmented land ownership structure (Healey 2006) was first developed using mostly legislative tools, facilitating housing production and commuting along a fine mesh of mobility infrastructure (De Block 2014). This accentuated what was later called the *banlieue radieuse* ideal (Smets 1968, De Meulder et al. 1999), in which access to private property outside city centres was encouraged. One thus refrained for drawing corseted buildable areas before the mid 1970s (Coppens et al. 2020), while more integrated spatial planning – in the form of linear bands following freeways, rivers, and railways (Ryckewaert 2011) – remained the prerogative of the industrial sector[1].

Comparing urban morphologies

In order to accommodate the automobile, new spatial typologies had to be devised by which to transform the territory. Such projects, such as the *autogerechte Stadt* in Germany (Reichow 1959), or imported models from the Anglo-American world, notably Hilberseimer's *New City* (1944), principles from Buchanan's *Traffic in Towns* (1963) or Gibberd's *Town Design* (1959), each propose new typologies of infrastructural space, as well as – to a certain degree – guidelines to transform the existing. Among those, one can mention the 'bypassing network', which allows for fast travel without interacting with the previous urban fabric, as well as the cul-de-sac, arranged in a 'ladder' (Pope 2015) structure, designed to strongly steer vehicular flow, thereby redefining the articulation between the private and the public space (Grosjean 2010).

Despite planners having access to a common canon of references, the divergence in planning methods between Belgium and Germany at this critical period resulted in very different settlement patterns between two regions, despite them sharing similar metrics of population growth, economic fortunes, and car adoption rates. The following couple of maps intends to illustrate this effect within the case study area. In the figure below, showing the sealed surfaces on a fragment of the Belgian-German border, one can appreciate the striking difference in urban morphology, despite the two areas displaying comparable built density and functional typologies.

[1] One should not interpret the here highlighted dichotomy as too rigid. For example, Christaller's influence has been evident on several official urban plans for the Liège region (L'équerre 1963, Nols & Parent 1972, Grulois 2011). However, the recommendations stemming from these documents failed to be implemented in a coherent way across the whole territory (Wahle 1977).

Figure 3. Impermeable surfaces in the Liège–Aachen diffuse city (fragment). Source: elaborated by the author, data from Copernicus, 2018.

Figure 4. Road network typology in the Liège–Aachen diffuse city (fragment). Source: elaborated by the author.

In figure 4, the red lines, representing roads built since 1945 in the same fragment, highlight how this morphological divergence between the constitutive parts of the Liège-Aachen metropolitan axis has been exacerbated with the rise of automobility. One can observe that the new urbanisation in Belgium occurred mostly along a dense network of pre-existing roads (in black), with the notable exception of the transcontinental – and industrially essential – E40 freeway. Indeed, by looking solely at the map of roads, the urban transformation which has occurred since the middle of the 20th century is almost imperceptible. In Germany, however, the increased population sprawl across the territory was harnessed to shape existing settlements as a system of interconnected discrete small centres. This was achieved through the implementation of a ladder-like new road network serving residential and selected industrial areas, as well as a carefully articulated (partially implemented) fast network bypassing the settled clusters.

Futures of automobility in the Liège–Aachen diffuse city

One has been able in the previous paragraph to observe how adapting a territory to a new socio-technical system can lead to significantly varied spatial results. The following section is dedicated to comparing current plans issued by the government to reduce future car use and honour European climate targets. The table below offers an overview of the two countries' planning system destined to address the first 2030 deadline.

	Belgium	**Germany**
Federal level	Vision de la Mobilité en Belgique, 2017	Leitbilder der Raumentwicklung, 2016
Regional level	*Schéma de développement du territoire, in preparation* Vision FAST 2030, 2019 ↳ Schéma régional de mobilité, 2019	Landesentwicklungsplan, 2022
Agglomeration level	Plan urbain de mobilité (Liège agglomeration), 2019	Regionalplan Bezirk Köln, 2022
Communal level	*Schéma de développement territorial (Liège), in preparation* Plan communal de mobilité (Liège), 2021	Aachen*2030 Masterplan, 2018 ↳ Mobilitätsstrategie 2030, 2020

Figure 5. Comparison of contemporary Belgian and German planning instruments. Source: elaborated by the author.

Both countries being today federal systems, mobility planning is the most articulate at the regional level (Wallonia and Nordrhein-Westfalen, respectively). These main regional strategies are the *vision FAST 2030* (2019) and its operational *Schéma regional de mobilité* (2019) in Wallonia, as well as the chapter on mobility of the integrated *Landesentwicklungsplan* Nordrhein-Westfalen (2022)[2]. Both plans are informed by national guidelines, such as the *Vision de la mobilité en Belgique de l'Autorité fédérale* (2017) and the *Leitbilder der Raumentwicklung* (2016). At the Belgian local level, one can mention the *Plan urbain de mobilité* on the Liège agglomeration (2019), as well numerous communal plans. Here again, these plans have been formulated while the corresponding integrated urban planning document had not been published. Finally, at the German communal level, the Aachener

2 In Wallonia, the equivalent document, the *Schéma de développement du territoire* (2023), is still at the drafting stage at the time of writing, the previous iteration, the *Schéma de développement de l'espace regional*, having been approved already in 1999.

Mobilitätsstrategie 2030 (2020) serves as a companion piece of the overarching *Aachen*2030 Masterplan* (2018).

In the light of the historic planning cultures displayed by each country, such a systemic difference in architecture can be partly explained by a reliance on integrated spatial and mobility planning in Germany, under the umbrella of urban planning at a regional level. Indeed, in the *Landesentwicklungsplan* (2022), "integration of urban- and mobility planning" serves as an overarching title to the chapter (Ibid.:119). Planning for mobility can improve accessibility, yet also bring nuisances and consume precious land resources. Businesses should be able to implement themselves more flexibly than before (ibid., 9), with the appropriate infrastructure to be supplied if necessary. In the equivalent Wallonian *Schéma directeur de territoire* (2023), however, if many of the proposed measures overlap, the wording is opposite: the space occupied by mobility is considered as an entity in itself, as one should "structure the territory in order to support flexible, durable and carbon-free mobility" (ibid.:74), nudging citizens towards a more sustainable use of the existing infrastructure.

Conclusion and further discussion

This paper has proposed to consider the specific influence of the system of automobility on the morphology of the European diffuse city. In particular, looking at the case study of the transborder Liège–Aachen metropolitan axis has highlighted how regions with comparable economic and social metrics (Geelen 2007) as well as geographic similitudes have, during an intensely directive period of urban planning, developed following divergent paths. Shifting gaze on contemporary practices, a survey of the official documents discussing plans for a rapid modal shift – a way to perhaps signal an end to the hegemonic rule of automobility – has again shown varied approaches to the problem. While the spatial effect of such policies is still to be determined, accentuating these planning culture discrepancies could not only reveal and bolster territorial specificities, but might as well weaken potential leavers for activating synergies between neighbours dealing with common socio-ecological threats.

In 2021, violent floods in both Germany and Belgium (European State of the Climate 2021) highlighted how geographically inherent territorial solidarities are ever more a crucial factor for understanding our territories in a way that is meaningful to tackle the challenges of the transition. However, as there is not only one single way towards success, different approaches to spatialise the same metrics linked to automobility and its possible decline can be found. For new solidarities between territories sharing common ecological threats to emerge, the implication of such diverging paths cannot be ignored.

Accessibility of local amenities to reduce car dependency: Obsolete concept or change yet to come? The Prague case.

Author's Name: Jan Bittner

Abstract
This paper aims to present a novel interdisciplinary framework investigating the phenomenon of urban transport based on behavioural aspects of mobility interaction with the built environment in the Czech-specific context. The central research question lies in testing the influence of the accessibility of local amenities on car dependency within the suburbs of Prague. The work utilises an activity-based modelling technique, quantifying individual travel behaviour using geolocated travel diaries. The method is based on two regression models, measuring (i) PKT (person kilometres travelled) and (ii) the number of regular car / PT users. Local amenities accessibility constitutes independent variables, whereas personal socio-economic background plus built environment characteristics control variables. The sample comprises suburban residents who are parents of at least one child aged 0-15 and state their home geolocation.

Keywords
Built Environment, Travel Behaviour, Suburbs, Amenities, Education

Introduction

The sudden transition from central planning to a free market in Eastern Bloc countries caused uncoordinated and deregulated growth followed by sheer car ownership. Extensive suburban areas heavily dependent on cars exploded around larger cities (Stanilov and Sýkora 2014). Nowadays, ongoing climate changes, technological revolution, and planned energetic transition bring entirely new challenges to urban transport planning (Shakibamanesh et al. 2020). Such challenges also draw attention to the question of car dependency in the Czech planning practice. In response, Czech local plans started working with various planning practices to reduce car dependency in suburban areas. One of the most widespread practices constitutes retrofitting local amenities in suburban residential areas. Since such practice is part of various well-established global urban concepts (New Urbanism, low-traffic neighbourhoods, TOD, 15-minute city, etc.), the relationship between amenities and transport has been well-researched for decades in the USA and Western Europe (Ewing and Cervero 2010; Næss 2022). Whereas solid evidence from various backgrounds supports Western urban transport planning, Czech planning remains hovering "in the dark" without empirical findings concerning specific central European contexts. This paper brings the first insights into measuring amenities' influence on travel behaviour.

Most of the contemporary planning concepts mentioned above work with amenities accessibility; however, there are plenty of lapses and issues in applying such an attitude to real practice. As stated by (Næss, 2006), "the dog is buried" in the matter of personal choice. People do not go to the nearest cinema because of its proximity. Nor do university students go to the nearest university. On the other hand, things may work differently on a more local level. Parents may choose the closest kindergarten or primary school due to walking time. The same could work for recreational facilities (going to the closest gym) or primary health care (visiting the closest GP), etc. However, also local amenity selection by proximity works with vague assumptions which are not always met. Such assumptions are that there are no competing facilities (e.g. two schools within a similar distance), facilities do not vary in quality (one school is significantly better) or other hidden motivations (school proximity to parent's workplace).

Nevertheless, the distinction between higher and local facilities in the previous paragraph merely captures the real-world complexity – often influenced by various personal socioeconomic backgrounds (Ortúzar et al., 2011). On top of that, people have different motivations and preferences, often socially bound, limited by institutions, etc. (Neutens et al., 2007). This makes travel behaviour a complex discipline in its gritty attempts to predict individual choices. To take at least some of this complexity into account, three decisions were made when designing this research: (i) only local amenities accessibility is considered, (ii) facilities must not significantly vary in their quality, and (iii) socio-economical aspects must be included in the model. Considering the first and second points, local educational facilities were found to fit the criteria best. Firstly, Czech lower educational facilities are considered even, mostly run by local municipalities. Secondly, in the suburbs, primary educational facilities are often distributed individually (one school per municipality). Thirdly, lower education is governed by municipal governments, including planning and spatial distribution of new ones. On top of that, accessible educational amenities are considered to spread wider benefits (e.g. in matters of social cohesion) (Hickman et al., 2017), so their positive influence on residential travel behaviour may join to "the club" of benefits.

Method and Data

Travel behaviour modelling is a sub-group of activity-based modelling (ABM) (Hensher, 2008; Ortúzar et al., 2011). To gain a disaggregated form of person-trip data, travel survey diaries are

mostly employed. The surveys include the socio-economic characteristics of every respondent and his/her travel behaviour, including the number of vehicles owned, frequency of car/PT usage, etc. Based on respondent address (self-geolocated), built environment characteristics such as residential density, urban centres and facility accessibility are derived by GIS analysis. In the case of this research, suburban zones and their centre's definition were adopted by the work of (Ouředníček, 2018).

In the case of this paper, questionaries were collected by the Prague Technical Road Administration Authority (TSK) by November 2021 and focused on residents of Prague's inner city (N = 1000) and the wider metropolitan area (N = 1000). The final population sample was filtered from the TSK data by the following parameters: adults (age 15+), suburban residents (zone 1-4) (Ouředníček, 2018), having at least one child in their household (age 0-14), and not being a student. The final sample size (N = 151) is spatially spread across the region (see Figure 1 below).

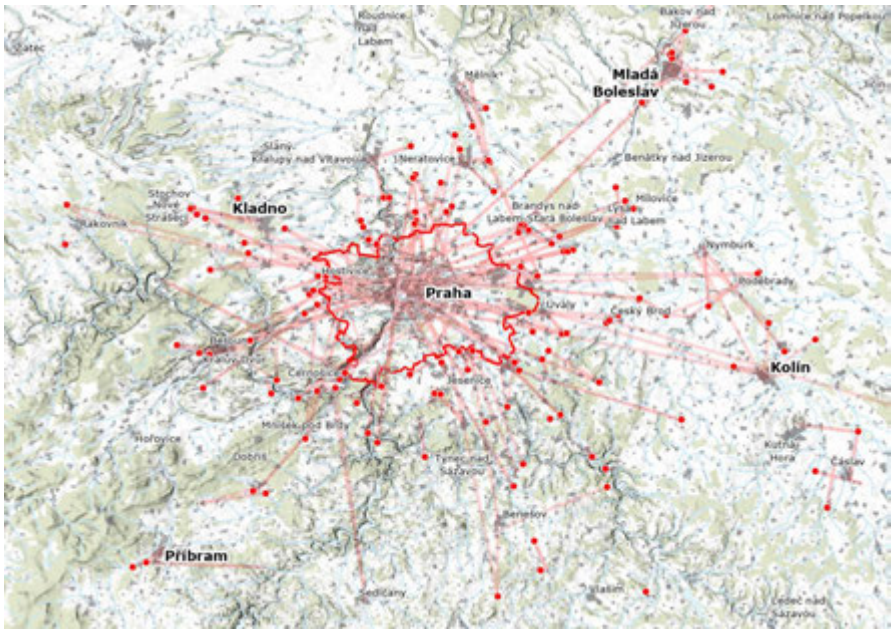

Figure 1 Respondent's home and their trips within one day

Socio-economic characteristics

The sample comprises parents mostly around in their 30s, roughly balanced between women and men (F 77, M74). The most frequent households contain three or four members. Both variables (age and household occupation) meet similar group characteristics to the Czech National Census 2021 (Ryšavý and Fiedor, 2023).

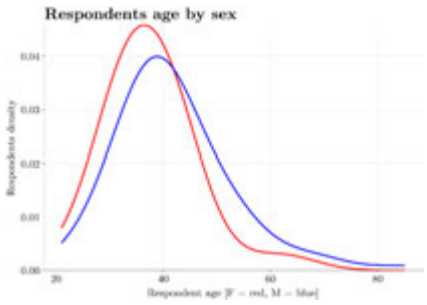

Figure 2 Respondents age by sex

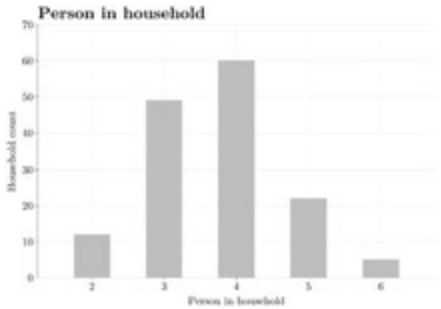

Figure 3 Persons in houshold

The primary survey data contains two children sub-categories: pre-school (age 0-5) and school (age 6-14). As shown in the charts below, the most common are households with one or two children and two adults. Comparing children sub-categories, one preschool and one school child is the most common, however, other combinations are also evenly spread across.

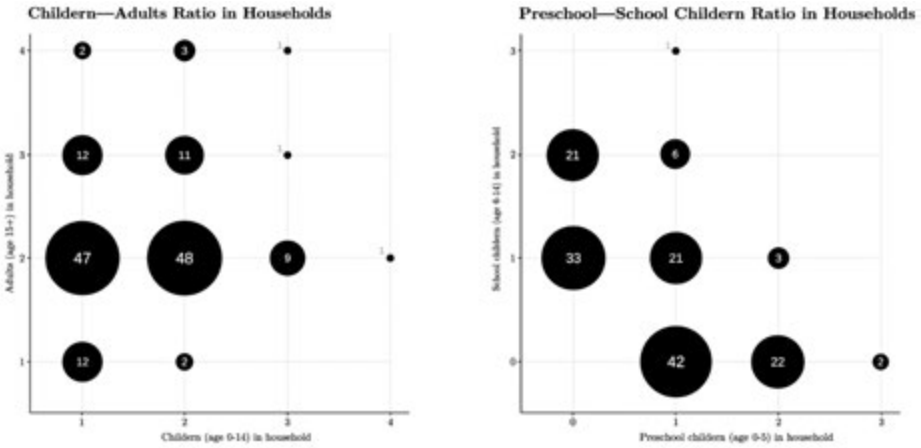

Figure 4 Adults-children and children sub-groups proportion

Other followed socio-economical characterstics are household income (normalised per adult person) and respondent education. The respondent's household income seems to be quite low (survey median CZK 22k compared to nationwide median CZK 34k (ČSÚ, 2022). However, distortion is assumed by the fact that most households with children (age 0-5) have one member on maternity/parental leave. On top of that, some other adults (age 15+) in the household may not be economically active (students). Unlike income discussed above, education distribution seems to follow common suburban patterns of an educated population, mostly diploma (secondary) and masters.

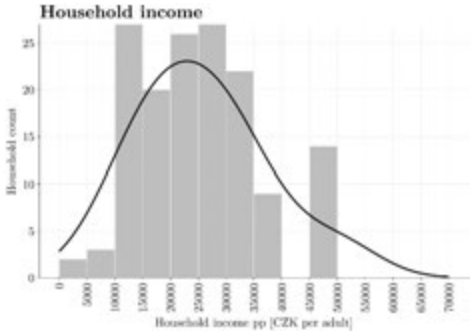

Figure 6 Household income pp

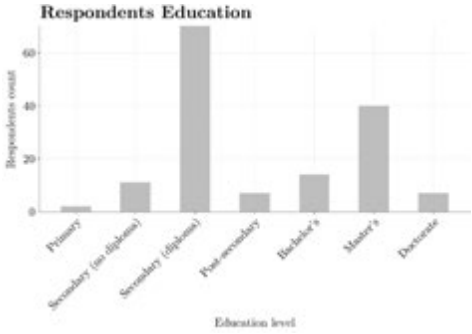

Figure 5 Respondents education

Travel Behaviour

The second group of data collected in the survey covers the travel behaviour of each respondent. The travel behaviour survey may be divided into two sections: general knowledge and trip-specific knowledge.

The first section, general knowledge, describes personal travel characteristics and habits, such as the number of vehicles in the household, PT ticket subscription or travel mode use frequency for an "ordinary weekday". Travel mode use frequency is depicted below (see Figure 7), comparing car and PT use within uneven time periods. The most obvious pattern is that respondents, unsurprisingly, tend to use cars much more frequently than PT. Over one hundred respondents use the car more than three times per week, whereas the most common frequency of PT use is less than once per month. Putting frequencies of both categories together, the car use frequency dominates across all PT use frequency categories. Thus, the sample meets the assumption of car-dependent suburban residents.

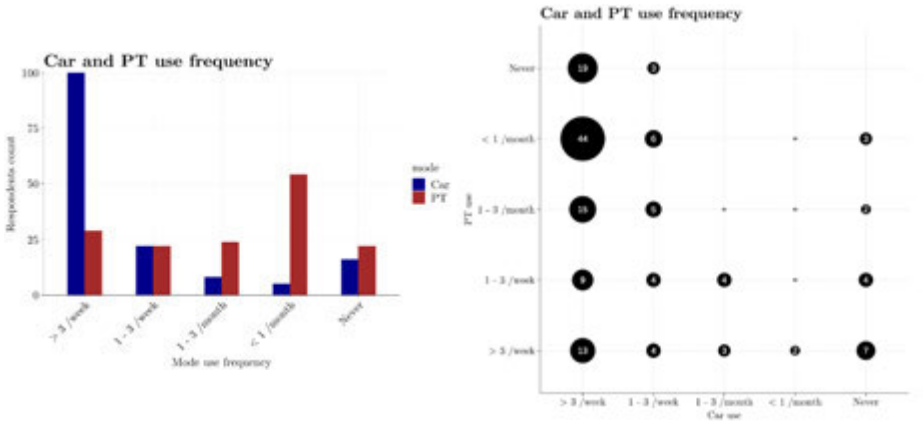

Figure 7 Car and PT frequency

The second section, trip-specific knowledge, utilises data from the personal trip inventory. Mostly, home and work locations are gained, and VTM distances are summed up. The researched sample shows sharply skewed distributions to the first interval (especially in the case of distance travelled by other transport means than a car). This may show the proportion of respondents working from home (the survey was collected between Corona epidemic waves,

however, well apart from previous lockdowns). Secondly, the distribution may show a trend in combining more transport modes, especially car and PT or walking. The specific data distribution is reflected in generalised linear regression models (GLM) in the following chapter, where negative quasi-Poisson distribution is utilised.

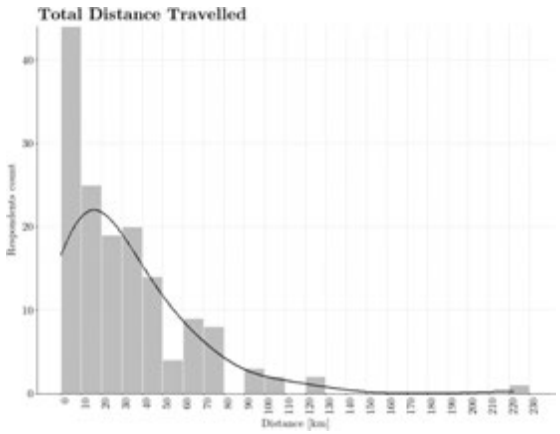

Figure 8 Distance travelled distribution

Built environment

Unlike the first and second groups, data in this third group are entirely created by secondary GIS analysis, mostly focused on home location and municipality. There is a "standard protocol" of which variables to use in order to control built environment influence – 5Ds (Ewing and Cervero, 2010). The bold lines below indicate the variable used in regression models presented later.

Density	**Household/population density**
	Job density
Diversity	Land use mix
	Job-housing balance
Design	**Intersection/street density**
	% 4-way intersection
Destination accessibility	Job accessibility by car
	Job accessibility by PT
	Distance to downtown
Distance to transit	**Distance to the nearest transit stop**

Table 1 Built environment controls – 5Ds (Ewing and Cervero, 2010)

The residential density constitutes a "traditional" challenge in terms of its definition; which places are considered to be residential and which are not? How to find out where these places are inhabited? And what to do with mixed-use? (Mees, 2010) Considering the poor quality of Czech geospatial data, built-up areas in all researched municipalities (over 100) were created by manual editing of digital zoning plans. Industrial and other obvious non-residential functions were filtered out (see Figure 9 – left). In the case of extensive recreational neighbourhoods,

where some houses are residential and some are not, only locations with a majority of objects with postal addresses were included (see Figure 9 – right: the east bank of the river is considered a residential area, whereas the west bank remains recreational, thus blank).

Figure 9 Built-up residential area – definition

The output residential density shows a shallow distribution between 10 and 30 inhabitants per ha, with a spike between 12.5 and 15. These numbers correspond to the general residential density of the Czech suburbs. Job-residents balance gained from The Czech Ministry of Treasury (MF, 2020) unsurprisingly, it indicates that most suburbs offer 0.1 to 0.3 jobs per inhabitant. This finding also meets prior assumptions.

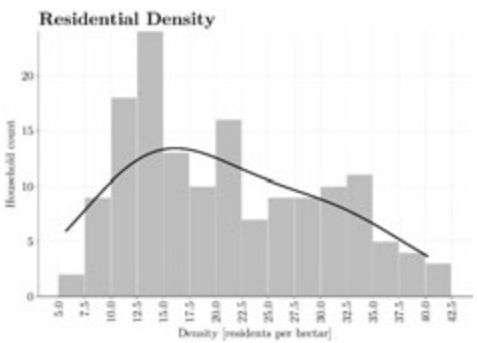

Figure 10 Residential density

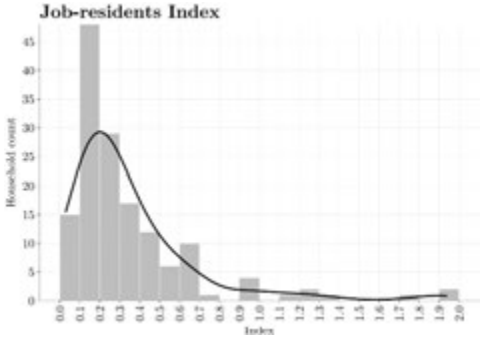

Figure 11 Job-residents index

Destination accessibility also shows unsurprising results for suburban locations – good, stable accessibility of urban centres by car and largely differing accessibility by PT across municipalities (see Figure 12 – left). Whereas car accessibility median time is 21 minutes with 8.9 minutes SD, PT accessibility offers a median of 57 minutes with 24.6 minutes SD! The ratio between car and PT accessibility is later used to determine municipality accessibility by PT compared to a car (see Figure 12 – right). On average, sample suburbs are 2.5 times better accessible by car than PT.

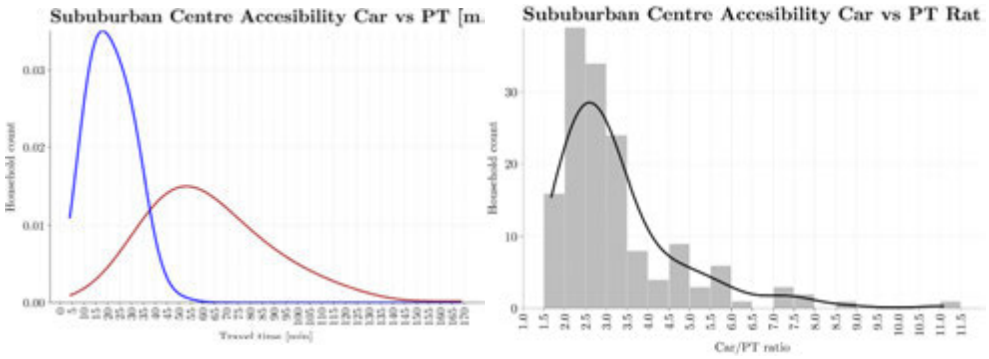

Figure 12 Urban centre accessibility car vs PT (blue: car, red: PT)

Last but the most important variable from the built environment group is accessibility to the educational facilities. Since the survey distinguishes between preschool and school children, accessibility to both kindergarten and primary school was measured (red and blue lines in Figure 13 – left). However, for parents of preschool children, only kindergarten accessibility is relevant and vice versa. Thus, a new variable, "Accessibility to the relevant ed. facility", was created, taking into account only relevant facilities (see Figure 13 – right). In the case of parents of both children groups (pre- and school), the average school and kindergarten accessibility was counted.

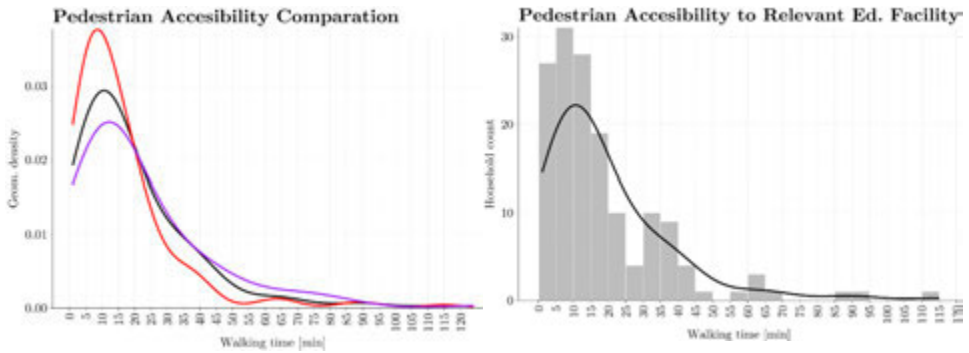

Figure 13 Pedestrian accessibility to educational amenities (red: kindergarten, violet: school, black: relevant education facility)

In summary, most input data individually behave as expected. Most distributions show Gaussian patterns, although in many cases skewed. In the case of the mentioned specifics and anomalies, findings were reflected in regression models presented in the next chapter.

Results

Data presented in the previous chapter includes: (i) personal kilometres travelled (PKT) and (ii) frequency of car and PT use. Those two variables are used as dependent (predicted) in two presented regression model sets to denote individual travel behaviour. In both sets, the researched independent variable is pedestrian accessibility to relevant educational facilities. Other variables, such as socioeconomic and built environment, are considered as controls.
Before commencing the description of the results, it is necessary to declare that certain built environment variables exhibit a strong correlation. Typically, residential density, municipal size, street density, household size and household type. The listed variables, mostly representing the built environment, also correlate to the researched independent variable – pedestrian accessibility to the relevant education facility. On the one hand, this indicates that more populous and dense suburbs are already fitted with educational amenities. On top of that, the correlation may signal a stronger connection between education and other amenities, typically concentrated together.

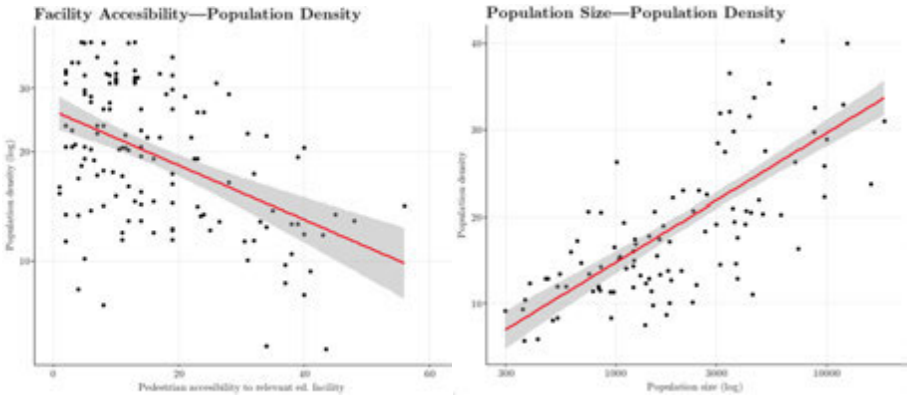

Figure 14 Variables correlation

Set one: personal kilometres travelled (PKT)
The first set of models consists of three GMLs predicting (i) total PKT travelled by the respondent, (ii) car-only PKT travelled by respondent, and (iii) PKT by other means than a car (PT, biking, walking, etc.) – see table 2.

variable	estimate			std.error			statistic			p.value		
PKT (N = 150)	total	car-only	no-car	total	car-only	no-car	total	car-only	no-car	total	car-only	no-car
(Intercept)	2.556	*insig.*	*insig.*	0.334	*insig.*	*insig.*	7.517	*insig.*	*insig.*	<0.001***	*insig.*	*insig.*
Living in detached house	0.464	*insig.*	*insig.*	0.225	*insig.*	*insig.*	2.066	*insig.*	*insig.*	<0.05*	*insig.*	*insig.*
Respondent economically active	0.543	*insig.*	1.320	0.216	*insig.*	0.580	2.515	*insig.*	2.269	<0.05*	*insig.*	<0.05*
Ed Facility < 20 min walking	0.437	*insig.*	0.871	0.190	*insig.*	0.443	2.300	*insig.*	1.963	<0.05*	*insig.*	<0.1 .

Table 2 Set one: GLM quasi-Poisson: PKT estimates – only PKT total significant variables selected

variable	odds ratios		CI		p.value	
N = 150	model 1	model 2	model 1	model 2	model 1	model 2
(Intercept)	*insig.*	0.08	*insig.*	0.00 – 1.11	insig.	<0.1 .
Respondent economically active	3.82	3.64	1.56 – 9.97	1.49 – 9.50	<0.01 **	<0.01 **
Cars in household	2.01	2.23	1.30 – 3.31	1.42 – 3.73	<0.01 **	<0.01 **
Respondent sex	0.28	0.29	0.13 – 0.60	0.13 – 0.63	<0.01 **	<0.01 **
Car/PT urban centre accessibility ratio	1.91	1.96	1.37 – 2.84	1.42 – 2.86	<0.001***	<0.001***
Residential density	0.96	–	0.92 – 1.00	–	<0.05 *	–
Ed Facility Accessible < 20 min walking	–	0.37	–	0.16 – 0.83	–	<0.05 *

Table 3 Set two: GLM binomial: Probability of regular car use (more than 3 times a week)

The initial finding shows that the car-only PKT vastly varies. Thus, none of the predictors of car-only PKT did not show significance. On the other hand, total PKT and no-car PKT work better. Perhaps the most surprising result lies in the increment of total PKT when the educational facility is accessible by walking (< 20 min). This may be caused by the fact that total PKT comprises car-only and no-car PKT, including activities like walking with children to school. To support this claim, unlike total PTK and no car PKT, car PKT indignancy may overall indicate that car use is far more complex and influenced by various hidden factors. Due to the high correlation with other built environment variables, especially residential density, only accessibility to education facilities was used (the accessibility variable also indicated the best statistical performance).
Due to the small sample (N = 150), the estimated magnitude of variables may not be accurate. However, their significance clearly declares trends. To improve overall model reliability, the sample shall be extended, and more continuous variables like dwelling size, household income, and persons in the household should be included.

Set two: car and PT use frequency
Regarding the focus of this research and the limited size of the sample (N = 150), categorical variables of car and PT use frequency were combined into dummy variables. To create the dummy variable, original survey intervals (see Figure 7) were binomially split by thresholds: using a car more than three times a week is considered regular usage, and vice versa; less than three times a week is irregular. In the case of PT, the threshold was set to at least once a week due to the broader distribution of counts in categories (see Figure 7). Created groups of "regular" and "irregular" users of car and PT are visualised below in the context of residential density. The distribution between regular PT users / irregular car users and irregular PT users / regular car users share very similar patterns. This may show that most commuters using a car regularly do not go by PT, and conversely, regular PT users don't drive. The spike in regular PT users / irregular car users, around 30 inhabitants/ha, shows better PT accessibility in more populated and, thus, bigger municipalities (see Figure 14). On the other hand, regular car users are spread across residential densities, starting at 12 (1st quantile) along to 22 (3rd quantile). Overall, all groups of users significantly differ in the context of residential density (ANOVA test).

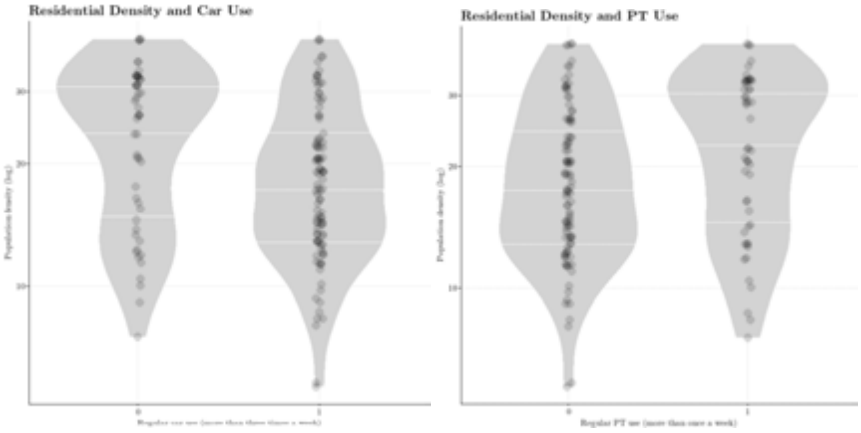

Figure 15: car and PT regular users distribution according to residential density

The GLM binomial regression is made on two models – the first using residential density (model 1) and the second replacing the density with educational facility accessibility (model 2). The reason for the isolation of these two variables is to avoid strong multicollinearity due to high mutual correlation. Due to unbalanced group sizes (regular cars are approximately two times bigger), irregular car users were weighted by two.
The model results (see Table 3) show that being economically active increases the probability of frequent car use. The same works for the number of cars owned. The other variable increasing car use probability is the ratio of car/PT urban centre accessibility – weaker PT accessibility, higher probability of regular car use. All three findings listed above are unsurprising and may confirm assumed trends. A bit surprising is the fact that being a woman strongly decreases the chance of regular car use (by 72%). This may show that women use PT instead of cars or stay home. Now, to the model's merit: residential density and educational facilities accessibility. Both variables in the corresponding model show expected trends – the increment of each person per hectare reduces the chance of regular car use by 4% in model one, and the educational facility accessible within 20 minutes reduces the chance of regular car use by 63%. Although educational facility accessibility may be connected with other close amenities, such as shops, sports centres, etc., the trend indicates a general connection between amenities accessibility and respondents' regular modal choices.
To conclude, both binomial regression models showed robust and significant results of educational facility accessibility (or residential density) influence on regular car use. Although the influence in the case of educational facilities may be indirect (correlation, not causation), the trend shows a positive tendency to be further scrutinised by employing a bigger sample and collecting geolocations of other facilities.

Discussion and Conclusion

To address the conference mobility track theme, this paper tried to shed the first rays of light onto the issue of car dependency – an issue resonating especially in the age of ecological and energetic transitions. Although the global academic discourse recognises suburban car dependency as a serious problem with ecological, social, or health consequences, Czech (and other Eastern European) research focuses only on transport supply – mostly transport systems effectivity. This paper provided a pioneering insight into the travel behaviour of Prague suburban residents and its connection to the built environment. The final focus was set on local educational facilities and their influence on residential travel behaviour. Compared to similar global research papers, this paper worked with a rather small sample of 150 respondents, sometimes methodically hitting limits – especially in the case of predicting distance travelled by respondents (PKT). The models in the first section predict PKT only by a few dummy variables that turned out to be significant. In this case, expectations were initially higher. On the other hand, the second set of models – probability prediction of regular car use – turned out to be fruitful, indicating strong results, including respondents' socio-economic characteristics. Although there is no way to prove causality between educational facilities accessibility and travel behaviour by a single set of travel dairies, the ultimate goal of this paper – to prove a connection between – was achieved. To move such research forward, further modelling is required, especially with a bigger sample and including a wider spectrum of amenities such as sport and recreation, culture, social care, healthcare, or public transport. Overall, the presented results show clear trends, thus worthy to continue working on.

Layout Patterns and Crowd Flows of Commercial Space in High-Speed-Rail Station Complexes

-- Take three Chinese high-speed-rail station complexes as examples

Yunjing Wang is a PhD student at the Department of Architecture, College of Architecture and Urban Planning, Tongji University, focusing on the direction of station-city integration, commercial complexes, and urban renewal, and has published three articles in Chinese domestic journals as the first author or corresponding author.

Professor Zhuang is the deputy director of the Urban Design Branch of the China Society of Urban Planning, head of the Urban Design Team of the Department of Architecture, College of Architecture and Urban Planning, Tongji University, and a PhD supervisor.

Abstract

The commercial space in the high-speed railway station area is a key factor in stimulating the vitality of the crowd in the station area, and the station complex can maximally convert the transport value of the station area into comprehensive functional value. In the era of ordinary railways, the high-speed railway station was only regarded as a passenger transport hub. The commercial space was only used as a supporting facility to serve the transport interchange activities, which failed to attract the crowd to stay for long. Still, with the gradual increase in the proportion of short-distance and commuter passengers, however, as the proportion of short-distance and commuter passengers grows gradually, the commercial space in station complexes that have appeared in recent years has also failed to take into account the needs of both passengers and citizens. In this paper, based on the block layout relationship between commercial space, station access space, and urban transport space, we construct a "node-path" network of commercial space entrances and exits with high-speed rail station entrances and exits as well as urban traffic entrances and exits, analyse the correspondence between the commercial space layout pattern of the station complexes and the flow of crowds, and explore how different commercial space layout patterns influence the flow of crowds. It also discusses how different commercial space layout patterns affect the behavioural activities of the crowd. Finally, it concludes that: 1. Appropriately narrowing the distance between the commercial space and the station space of small and medium-sized passenger stations, especially placing underground space between the two, can stimulate the consumption potential of transport-oriented passengers who transfer to the underground. 2. The entrance and exit settings of the commercial space and the distribution of the flow of people are affected by the layout of the commercial space. 3. The commercial space entrances and exits related to the movement lines of underground passengers are also affected by the layout of commercial space blocks. 4. The entrances and exits of commercial spaces related to the moving lines usually have higher pedestrian flow. This study can provide new perspectives and methods for analysing the layout patterns of commercial space in station areas and offer design suggestions for improving the use of commercial space in station complexes.

Station-city Integration; Station Complex; Commercial Space; Crowd Flow; Layout Design

1. Introduction

The high-speed railway station is an important transport intersection in the overall layout of the region, gathering a large amount of internal and external traffic in the city. However, the urban station hub area is not only a mobility node in the transport network but also an aggregation place in the city, and it is a waste of the value embedded in the circulation to use it only as a transport hub for the collection and distribution of human flow. Relying on the traffic advantage of the high-speed railway station to create urban functions such as commerce, business, exhibition, leisure, and so on in the surrounding area and organically integrating the traffic function (switching to articulation) with the urban function (commerce, office, leisure,

etc.) (Peng Qiyuan *et al.,* 2017), in addition, it can make full use of the transport value of high-speed rail stations, explore the urban place attributes of high-speed rail stations, and promote the linked development of high-speed rail stations and cities.

The commercial function is one of the main functions of utilising the overflow effect of station traffic effectively, and commercial space has rich spatial forms and types of business, that can meet the consumption needs of different groups of users. In China's high-density cities, where urbanisation is accelerating and land resources are relatively scarce, the joint development of station hubs and commercial facilities can realise the spatial connection between the two sides of the station and the city and promote the integrated development of the station and the city in the traffic hub area. For example, New York's Grand Central Station, London Bridge Station, and Tokyo's Shibuya Station have become important urban business and commercial centres.

As a comprehensive transport hub, the high-speed railway station in the high-density city centre has strong transport value and a functional development basis. It can closely connect with and interact with the neighbouring urban space, so it can rely on the transport advantage to enhance the comprehensive urban functional value of the station area, especially the commercial function that drives the area's economic growth. It is necessary to introduce commercial functions reasonably and appropriately, taking into account the needs of consumption activities of station passengers and neighbouring citizens, and to establish a close connection with other spatial elements in the station area to create a synergistic effect between the station and the city.

However, in the current practice of construction of commercial space in the high-speed railway station area, it is obvious that there is insufficient consideration of the user groups and their needs, especially since the resources of people flowing from both the station and the city are not fully utilised at the same time. In the era of ordinary railways, the commercial space of high-speed railway station complexes in China was mainly a supporting facility serving fast-passing passengers. With the gradual growth of the proportion of short-distance and commuter passengers, the user groups in the station area not only demand the station's internal and external traffic functions but also pursue higher-quality consumption and leisure functions. However, the commercial space of station complexes that have appeared in recent years, despite emphasising the integration of commercial space with the station and the city in terms of spatial form, still presents the result of mainly serving the use of part of the group, producing a large number of unused and inefficient commercial spaces. The practical exploration of creating station-city integrated commercial space is still in its infancy and lacks effective supporting theories and assessment methods.

The station complex mentioned in this study refers to a complex system that contains station space, urban transport space, and commercial space and has great potential to develop into a regional public centre. Compared with the single passenger transport function of a traditional station, a station complex contains more comprehensive urban functions that are closely linked to the station space, and the urban transport space is placed between the station space and the urban functional space, playing a transitional role in linking the station and the city, while the urban functional space crosses the red line of the station site and is laid out close to the station space (Fig. 1). Due to the high degree of integration of various functional spaces,

clear and convenient spatial organisation and flow guidance are required to ensure basic passenger distribution and transfer functions while avoiding mutual interference and influence between functional spaces.

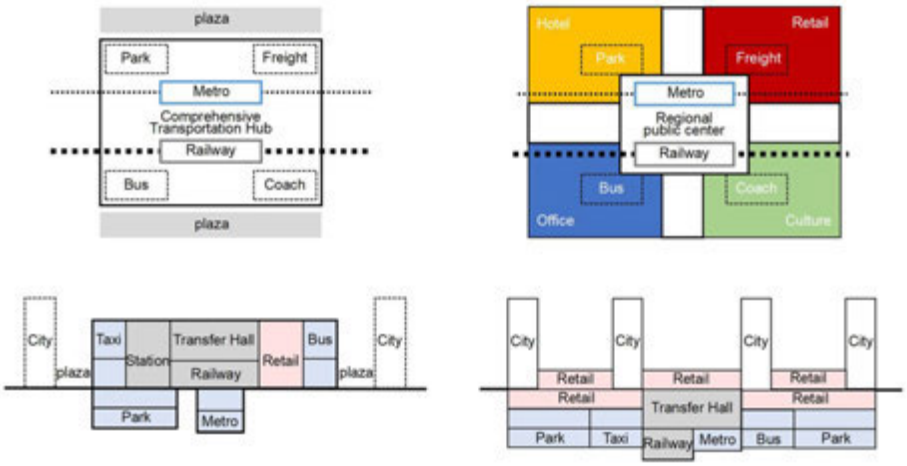

Fig. 1: Spatial pattern diagram of traditional stations and station complexes

Established studies have focused on the general organisation of station areas (Qi Guangping and LU Guanyu, 2019; Dai Yizheng *et al.*, 2018). Some studies have analysed the coupling relationship between commercial space and other spatial elements of traffic interchange activities (Gui Wangyang *et al.*, 2023; Yu Baofei and Ren Jun, 2021; Chen Binbin *et al.*, 2021). Few studies have focused on the fine-grained design of commercial space in high-speed rail station complexes from the perspective of passenger-citizen behavioural activity characteristics. On the one hand, existing studies have paid insufficient attention to the specific morphological design of commercial space in station complexes, lacked effective morphological analysis methods for commercial space layout, and have not yet answered the question of how the commercial space in station complexes should be linked to the station and the city, respectively. How should the commercial space of the station complex link the station and the city, respectively, and what role will other urban transport elements play? On the other hand, the existing studies have not deeply explored the influence of the layout of commercial space in station complexes on the flow of people, such as what kind of spatial use results will be brought about by different layout patterns.

This study selected Guangzhou East Railway Station, Chongqing Shapingba Railway Station, and Shenzhen North Railway Station, located in the centre of high-density cities in China, as the research samples. The commercial spaces of the three sample stations are similar in terms of industry composition but completely different in layout pattern. Among them, the layout pattern of the commercial space of the high-speed railway station complexes is broken down into two levels: block layout and node layout, and the crowd flow characteristics are mainly based on the data of pedestrian flow at the entrances and exits of the commercial space.

This study focuses on the layout of commercial space in high-speed railway station complexes. It builds a "node-path" network of commercial space entrances and exits with high-speed railway station entrances and exits and urban traffic entrances and exits based on the block layout. In addition, this study will classify the passengers and citizens in the commercial space of the station complex according to the purpose of travel and different types of urban transport, graphically present the behavioural activity chains of different groups, and explore the correlation between the behavioural activity characteristics of different groups in the station complex and the layout pattern of the commercial space.

The subsequent chapters are arranged as follows: Section 4 demonstrates the correspondence between the layout patterns of the commercial space of the sample station complexes and their crowd flow characteristics, Section 4.1 summarises the relationship between the commercial space of the sample stations and the block layout of the station space and urban transport spaces, corresponds the block layout characteristics of the commercial space of the sample station complexes to the total flow of people at all entrances and exits and analyses the impacts of different commercial space on the proportion of commercial space use. The impact of different commercial space layout patterns on the percentage of commercial space use is analysed. Section 4.2 abstracts the three types of functional blocks into multiple functional nodes, draws the behavioural activity chain of passengers and citizens going to the commercial space, respectively, constructs the relationship between commercial space entrances and exits with station entrances and exits as well as other urban traffic entrances and exits, corresponds the characteristics of the node layout of the commercial space of the sample station complexes with the flow of people at all entrances and exits, and analyses the effect of different node layouts of commercial space on the convergence of pedestrian flow at all entrances and exits. The influence of different commercial space node layout patterns on the gathering effect of pedestrian flow at each entrance and exit is analysed. Section 5 summarises the layout patterns of the commercial space of the sample station complexes, puts forward optimisation suggestions for different patterns, and proposes the commercial space layout suggestions of the high-speed rail station complex based on the characteristics of passenger-citizen behaviours and activities.

2. Literature Review

2.1 Study on the layout of commercial space in station areas

Theories related to functional space layout in station areas. TOD theory focuses on developing and constructing functional spaces that are closely linked to transport nodes. (Calthorpe Peter, 1993) Based on the study of high-speed railway station areas in Germany, France, Japan, and other countries, Schutz et al. were the first to put forward the circle structure model of the station area, i.e., with the increase of the distance from the station, the correlation between each functional space and the station gradually decreases and eventually forms a functional circle centred on the station. station-centred functional circles (Schütz Elmar, 1998). This theory initially explores the layout pattern of functional spaces in station areas. The commercial space of the station complex concerned in this study is located in the first circle,

which can take advantage of the traffic spillover effect of the railway station. The node-place model proposed by Bertolini is an analytical model for evaluating transport nodes from the perspective of public transport and land use based on the theory of the transport-land use feedback loop (Bertolini Luca, 1999; Bertolini Luca, 1996). The node-place model is an analytical model based on the theory of traffic-land use a feedback loop to evaluate transport nodes from the perspectives of public transport and land use (Bertolini Luca, 1996, 1999), in which the value of place is reflected in the development progress and development of the area around the high-speed railway station, and the use of commercial space is one of the indicators to measure the value of place in the station area, and the model can partly reflect the characteristics of the layout of the functional space and the effect of the use of station area.

Research and methodological tools for commercial space layout in station areas. Scholars have already classified commercial space in station areas into three categories: station commercial, station peripheral commercial, and peripheral area commercial, of which station commercial is commercial space developed integrally with station stations and transport facilities (Li Chuancheng *et al.*, 2016), which is consistent with the scope of commercial space that this study focuses on. Some scholars have also categorised commercial space as profitable building space and have analysed the coupling relationship between commercial space and elements of transport space and public space, proposing the layout patterns of tandem, adjacent, interspersed, composite, and cascading (Qi Guangping and LU Guanyu, 2019). In addition to conventional graphical analyses and qualitative descriptive methods, studies have been conducted to quantify the spatial organisation of station areas using urban spatial analysis tools such as Depth Map, such as exploring the correlation between the spatial integration degree of station peripheral areas and the functional layout of land (Du Qianyu and Zhang Fan, 2019). For example, to analyse the integration, connectivity, and comprehensibility of the underground interchange space of high-speed rail stations (Gui Wangyang et al., 2023), some studies abstract the complex urban spatial structure into graphical relationships based on urban morphology and building typology (Wang Zhendong & Wang Yindong, 2011). (Wang Zhendong and Wang Yinpu, 2015). The spatial structure of the station area is more complex, and it is difficult to determine a unified spatial reference point, but the connecting relationship between spaces can be expressed in diagrammatic form.

The distribution of crowd flow in the station area directly affects the use of commercial space. Still, few studies have analysed the connection between commercial space and other spatial elements in the station area from the perspective of crowd flow. Based on the above relevant theories, existing studies, and methods, this study will analyse the layout pattern of commercial space in station complexes from the two spatial floors of blocks and nodes by mapping the crowd flow in commercial space and summarising the layout pattern and expected usage effect of commercial space in station complexes.

2.2 Study on the crowd activity in station areas

Types of people who use the functional space in the station area. Studies have classified station users into two categories, namely "traffic transfer users" and "destination users" (Zhuo Weide *et al.*, 2022). For example, the destination segment is divided into four categories:

business, commuting, visiting relatives, and shopping (Wang Shaojian *et al.,* 2021). Other studies have analysed the functional space needs of different groups, such as short- and medium-distance passengers who are highly time-sensitive and have higher requirements for the accessibility of commercial space, long-distance passengers who are more likely to be price-sensitive and concerned about the type of commercial space, and citizens from the urban end of the city, who are more likely to have higher requirements for the quality and accessibility of commercial spaces (Wang Li, 2015).

Research and methodological tools for crowd activities in commercial space in station areas. Studies have used pedestrian simulation software to obtain complete data on crowd activities in station areas that cannot be collected in short-term studies, such as using AnyLogic software to simulate peak passenger flows in the distant future (Chen Binbin et al., 2021). For example, AnyLogic software is used to simulate the transfer situation of passengers leaving the station and to analyse the problems of the transfer space in the station based on the two indicators of transfer time and regional passenger density (Yu Baofei and Ren Jun, 2021). The problems of station transfer space are analysed based on two indicators: transfer time and regional passenger density. A large number of studies have also focused on the use of commercial office space in railway station areas, using field research, observation point counting, and other methods to obtain data such as the average number of people entering the shop per hour and the path flow of people to comprehensively evaluate the performance of the use of commercial space in the area of the railway station (Zhang Lingzhu *et al.,* 2019; Zhuang Yu and Yao Yiqian, 2016). This study mainly analyses the impact of the layout pattern of commercial space in station areas on crowd use, i.e., treating multi-floor commercial space blocks as a whole and ignoring the differences in the number of people entering the shop within the commercial space so that the use of the commercial space can be simplified to the flow of people converging to the entrances and exits of the commercial space.

Existing studies have mainly focused on transport interchange activities in station areas. Still, few studies have analysed the distribution among activities of different groups, or separately transport interchange activities and destination leisure activities, and the interweaving and transformation phenomenon of the dynamic lines of the two types of activities. In this study, according to the basis of traffic transfer and destination leisure groups and taking into account the different starting points of activities of tourists and citizens, the population using commercial space is classified into three categories: leisure citizens, traffic tourists, and leisure tourists, and the commercial space of the station complex is taken as the core to analyse the origin, flow, and process of the three categories of people converging to the entrances and exits of the commercial space in the station area.

3. Methods

3.1 Sample Selection

Since the urban location of the station affects the use of commercial space, this study selects high-speed rail stations located in the centre of high-density cities in China (Fig. 2) as samples among the station complexes that have been built and operated for many years and

have well-functioning commercial space: Guangzhou East Railway Station, Chongqing Shapingba Railway Station, and Shenzhen North Railway Station, which are located no more than 10km away from the city centre and represent different commercial space layout patterns of the station complexes. The scope of the study is the station access space, the multi-floor commercial space, and the urban transport space between them. Among them, urban traffic space which is far away from commercial space and does not have a spatial connection is not considered. The entrances and exits of the commercial space are set as the junction between the space of each floor and the external space. The vertical connection within the commercial space is not taken into account, i.e., multiple entrances and exits located at the same position in the commercial space of each floor are all connected with the external space of the ground floor through the vertical connection. Only the entrances and exits on the ground floor of the position are taken into account.

Fig. 2: Urban location of the sample stations

3.2 Layout analysis of commercial space in station complexes

First, the overall layout of the commercial space of the station complex is analysed. Through field research on the layout relationship between commercial space, station access space, and urban transport space, the "space-block" relationship of the three types of functional space is extracted. The second is to analyse the layout of the entrances and exits of the commercial space. Abstract the three types of functional spaces into corresponding functional nodes, take the entrances and exits of commercial space as the core, draw the footpaths of passengers and citizens who may pass by commercial space and whose destinations are commercial space, and construct a "node-path" network. In terms of the spatial object of the research, only the floors of commercial space that have a close spatial connection with the station entry and exit spaces are selected.

3.3 Pedestrian flow analysis of commercial space in station complex

The first is to compare the pedestrian flow in the station space and commercial space, and the proportion of the pedestrian flow in the commercial space to the total pedestrian flow in the station core area. The footfall in the station space is the total footfall entering and exiting the station; the footfall in the commercial space includes all the footfall passing through the

commercial space and the footfall destined for the commercial space; and the total footfall in the station core area is the footfall entering all the functional spaces. The second is to compare the pedestrian flow of each entrance and exit of the commercial space of the station complex. The research time is selected on weekdays, and taking into account that shops basically start the business at 10:00 a.m., the two time periods of lunch peak and evening peak are selected, and each time the people flow statistics lasts for 5 minutes.

4. Results

4.1 Layout and use of blocks of commercial space in station complexes

In the planning and design stage of a station complex, the number of passengers in the station influences the layout patterns of the functional space (Suo Chao and Zhang Hao, 2015). Considering the impact of the rapid in-and-out passenger flow of the station on the commercial space, the commercial space of the high-speed railway station complex will be appropriately far away from the in-and-out space of the station, and after the station complex is put into use, the location of the body layout of the commercial space usually significantly affects the overall use of the commercial space (Li Chuancheng et al., 2016).

4.1.1 "Space-block" layout of commercial space in station complexes

The commercial space of the station complex is usually chosen to face the external urban space, taking into account the accessibility of the public to the commercial space and the potential for passengers to pass through the commercial space on their way, including the urban transport space of the metro and motor vehicle loading and unloading points, which is usually laid out between the commercial space and the entrance and exit space of the railway station, i.e., forming a horizontal layout structure of external urban space, commercial space, urban traffic space, and station entrance and exit space. The passenger scale of Shenzhen North Station, Guangzhou East Station, and Chongqing Shapingba Railway Station decreases in turn, so the potential for integrating the commercial space of the station complex with the station space increases in turn. The average daily arrivals and departures of Shenzhen North Station are more than 0.2 million; the average daily arrivals and departures of Guangzhou East Station are about 0.05 million; and the average daily arrivals and departures of Chongqing Shapingba Railway Station are less than 0.01 million. The "space-block" layout characteristics of the commercial space of the three sampled station complexes are: far away from each other, overlapping, and overlapping, respectively (Fig. 3).

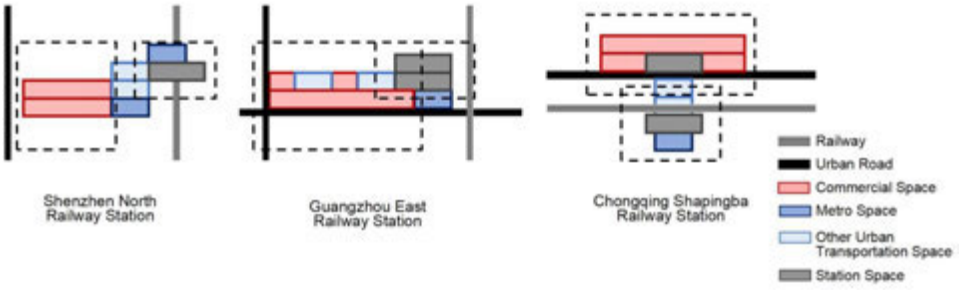

Fig. 3: Schematic layout of commercial space with station space and urban transport space

The commercial space of Shenzhen North Railway Station is completely separated from the station entrance and exit space, and between the two is an urban transport space integrating metro, buses, and taxis. The commercial space of this station complex consists of two floors with no vertical dislocation; the plan form is a U-shape facing south; and the concave space on the south side is a continuous outdoor promenade. The commercial space on the ground floor is connected to the metro station hall, and the commercial space on the second floor is connected to the transfer hall for buses and taxis. The city-facing area of the commercial space is adjacent to only one city road, with city roads farther away in the other two directions (Fig. 4). The shop formats are mainly catering, retail, and lifestyle services.

The commercial space of Guangzhou East Railway Station is intertwined with the station access space, and the urban transport space is embedded between the two. The commercial space of this station complex has four floors, and this study only considers the ground floor and the first underground floor, which are closely connected with the station space and the urban transport space. These two layers of commercial space are in the shape of a ladder; the ground-floor commercial space is located on the south side of the station space; between the two is the motor vehicle lane and drop-off area; the ground-floor commercial space is deep below the station space; and the underground station hall is below the station space. The city-facing area of the commercial space is adjacent to three city streets with plenty of pavements and overpasses (Fig. 4). The shop formats are mainly catering, retail, and life service, with the ground floor mainly for fast food, the first basement floor mainly for retail business, supplemented by a small number of catering businesses, and life service businesses and hypermarkets located in the second and third basement spaces.

The commercial space of Chongqing Shapingba Railway Station is completely superimposed with the station access space and urban transport space, and all kinds of urban transport space are spaced out from the station access space, and the commercial space is located above the two, adjacent to the station access space. The main part of the commercial space of this sample station complex is five floors, and the local part is seven floors, only the ground floor and the first floor, which are closely connected with the station space and urban transport space, are considered in this study. These two floors of commercial space are located entirely on the ground, and the plan form is a dumbbell shape distributed on both sides of the

station building, and the east and west sides are connected through the aerial connecting corridor that spans above the station space with the commercial space on the ground floor. The commercial space is close to several urban roads and overpasses (Fig. 4). The shop formats are equally dominated by catering, retail, and lifestyle services.

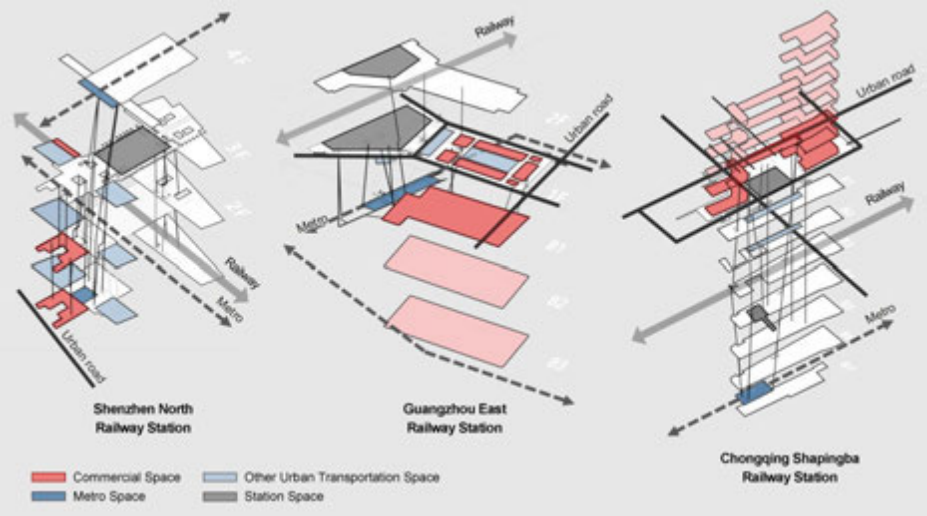

Fig. 4: General layout of commercial space in the sample station complexes

4.1.2 Total footfall of commercial space in station complexes

The pedestrian flow in the station space is usually proportional to the size of the station passenger flow, while the pedestrian flow in the commercial space is jointly influenced by the size of the passengers and the layout location of the commercial space. Based on the passenger scale of the station, the influence of the layout location of the commercial space of the station complex on the flow of people is analysed by comparing the relative size of the commercial space flow of the sample station to the station space flow of people and the proportion of the commercial space flow of people to the total flow of people.

As shown in Fig. 5, the percentage of commercial space use in Guangzhou East Station, Chongqing Shapingba Railway Station, and Shenzhen North Railway Station decreases in turn. Guangzhou East Station has a higher commercial space footfall than its station space; Chongqing Shapingba Railway Station and Shenzhen North Railway Station both have a lower commercial space footfall than station space footfall; and Chongqing Shapingba Railway Station has a relatively small gap between commercial space footfall and station space footfall. Among them, Guangzhou East Station, which has a medium passenger size, has the highest pedestrian flow of commercial space in its staggered layout, while Chongqing Shapingba Railway Station, which has a smaller passenger size, does not have a pedestrian flow of commercial space in its overlapping layout that exceeds that of Guangzhou East Station. In addition, although the pedestrian flow in the commercial space of Chongqing Shapingba Railway Station is lower than that of Shenzhen North Railway Station, the total pedestrian flow

of the former is much smaller than that of the latter, and thus the commercial space usage ratio of Chongqing Shapingba Railway Station is still higher than that of Shenzhen North Railway Station, which also shows that the calculation of the respective commercial space usage ratios of the sample stations can be used to make effective comparisons between the stations.

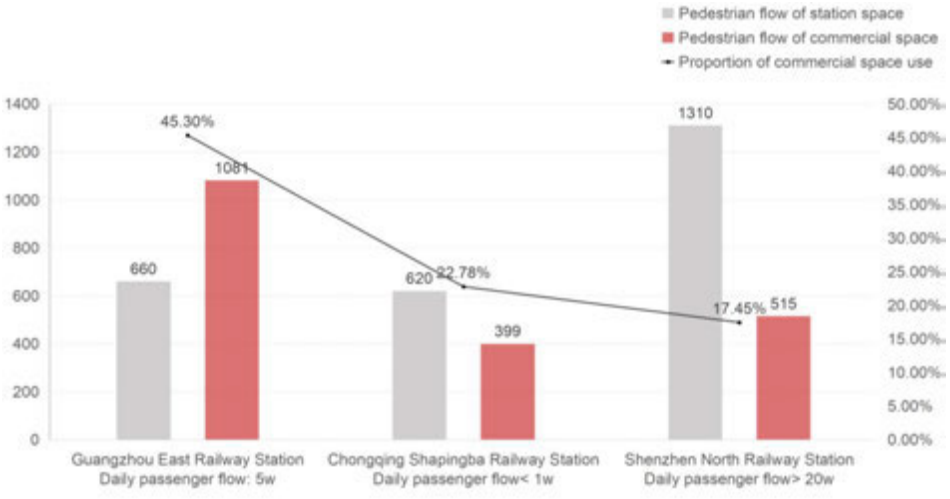

Fig. 5: Total footfall in commercial space of the sample station complexes

4.2 Nodal layout and use of commercial space in station complexes
