In addition to the above commercial space block layout, the actual use of commercial space in station complexes is also affected by the more microscopic layout of entrances and exits. The node layout relationship between the commercial space of the station complex and the station entrance and exit space and urban transport space affects the origin, flow, and convergence of people travelling to and passing through the commercial space, and the "node-path" layout is reflected in the flow of people through the various entrance and exit nodes of the commercial space.

4.2.1 "Node-path" layout of commercial space in station complexes

The main users of commercial space in the station complex are leisure citizens (citizens who specially go to and use commercial space within the radius of the station), traffic passengers (passengers who pass through the commercial space in the process of entering and exiting the station by railway), and leisure passengers (passengers arriving by railway and especially go to and use commercial space), and the urban transport means to be chosen are underground, taxi, bus, and so on. The starting point of the passenger's movement is the station entrance and exit node, while the starting point of the citizen's movement is the various urban transport nodes, which are usually located between the commercial space entrance and exit

node and the station entrance and exit node. The movement of the two groups will cross and overlap, and there are commercial space entrances and exits shared by both the passengers and the citizens.

As shown in Table 1-3, the entrances and exits of the commercial space of Guangzhou East Station are mainly distributed at the end near the station, and only two ground-floor entrances and exits are set up in the city-facing area; the 16 entrances and exits of the commercial space of Chongqing Shapingba Railway Station are located at the ground floor and above; the entrances and exits of the commercial space of Shenzhen North Railway Station are set up both at the near-station end and the near-city end, of which eight entrances and exits are set up in the near-city area, and six entrances and exits are set up in the near-station area. The "node-path" layout of the commercial space of the three sample station complexes takes into account both passengers and citizens and has the potential to attract transport and leisure passengers in addition to serving as leisure shopping destinations for citizens in the vicinity.

The commercial space at Guangzhou East Railway Station can attract transport-oriented passengers transferring to the metro, and most of the entrances and exits of the commercial space are exclusively for passengers or citizens. Passengers who choose to transfer to the metro and citizens who take the metro to the commercial space are distributed in the same area, but the two movements do not interfere with each other. Passengers transferring to the metro will pass through Entrance 6/7/9 in the process, while citizens arriving by metro will enter the commercial space through Entrance 5 or Entrance 7, and Entrance 7 will be shared. People choosing buses, taxis, and walking will enter the commercial space through Entrance 2, Entrance 1/8, and Entrance 1/2/3/4/8, respectively. Leisure passengers travelling exclusively to the commercial space will mainly enter through Entrance 1/6/9. Entrance 1 will be shared by taxi-only citizens and leisure passengers, so Entrance 2/3/4/8 will be the exclusive entrance for citizens entering the commercial space, and Entrance 6 and Entrance 9 will be the exclusive entrance for passengers entering the commercial space.

The commercial space at Chongqing Shapingba Railway Station is not able to attract transport-oriented passengers entering and leaving the station, and its commercial space entrances and exits are only partially shared. People who choose the metro to go to the commercial space enter through Entrance 1/2/6/7, those who choose buses and taxis enter through Entrance 1/2, those who choose private cars enter through Entrance 4/5/12, those who choose to walk can enter through Entrance 1/2/3/6/7/8/9/10/11/12, and leisure passengers who go to the commercial space exclusively enter through Entrance 1/2/4/5, i.e. Entrance 6/7, which is directly accessible from the metro station hall on the seventh floor of the underground, and Entrance 6/7, which is directly accessible from the metro station hall on the seventh floor of the underground, as well as Entrance 6/7, which is directly accessible from the metro station hall on the seventh floor of the underground. Entrance 6/7, which is directly accessible from the MTR station hall on the seventh basement floor, and Entrance 3/6/7/8/9/10/11/12, which is accessible on foot from the city road, are the entrances and exits of the commercial space for public use.

The commercial space of Shenzhen North Railway Station attracts transport passengers entering and leaving the station on foot and the public walking to the commercial space, and their entrances and exits to the commercial space are shared by both passengers and the public.

Traffic passengers who choose to enter the station on foot and citizens who walk to the commercial space enter through Entrance 1/2/8/9/10/11/12/13/14 facing the city, while traffic passengers who choose to leave the station on foot, leisure passengers who go to the commercial space exclusively, and citizens who choose the metro, buses, and taxis enter through Entrance 3/4/5/6/7/12/13/14 adjacent to the station. There are no entrances or exits to commercial space exclusively for the public.

		On foot	E1 / E2 / E8 / E9 / E10 / E11 / E12 / E13 / E14

4.2.2 Pedestrian flow at entrances and exits of commercial space in station complexes

The pedestrian flow at the entrances and exits of commercial space in station complexes reflects the convergence effect of the "node-path" chain with different attributes. By comparing the average flow of people at the entrances and exits of the commercial space in the sample station and the flow of people at each entrance and exit, we analyse the influence of the node layout of the commercial space in the station complex on the flow of people.

As shown in Fig. 6-8, the number of entrances and exits in the commercial space of Guangzhou East Railway Station is the lowest, but the flow of people at each entrance and exit is more than 50, and there are two entrances and exits with higher than average flow of people, and the difference between the highest flow of people and the lowest flow of people reaches 164 people. Chongqing Shapingba Railway Station has six entrances and exits with higher-than-average passenger flow, and the difference in passenger flow between them is relatively small. Shenzhen North Railway Station has four entrances and exits with higher than average passenger flow, and the difference in passenger flow between the entrances and exits is in the middle.

Among the entrances and exits in the commercial space of Guangzhou East Railway Station, the ones with higher than average flow rates are Entrance 7 and Entrance 9 on the basement floor. Entrance 7 is common, and the flow rate is much higher than the other entrances and exits. It is directly opposite to the main axis of the commercial space on the basement floor, and it is the necessary entrance and exit for the traffic passengers who are transferring to the metro and for the leisure passengers who are taking the metro (Fig. 9). Entrance 9 is a special entrance for the passengers and is connected to the ground floor through the staircase facility. Entrance 9 is one of the entrances for passengers, connected to the ground floor through the staircase facility, and is close to the station access space on the ground floor, which can be used by leisure passengers and transport passengers transferring to the metro.

Among the entrances and exits of the commercial space of Chongqing Shapingba Railway Station, the ones with higher than average pedestrian flow are Entrance 1, Entrance 2, Entrance 4, Entrance 6, Entrance 7, and Entrance 11 on the ground floor. Entrance 1, Entrance 2, and Entrance 4 are shared entrances and exits, which are accessed by leisure citizens who choose to take the underground, bus, taxi, and walk, as well as by leisure passengers who travel to the commercial space exclusively (Fig. 10), and Entrance 4 is connected by a straight staircase to the station exit space and private car garage at the fourth basement floor, which is shared by leisure passengers and those who choose to travel by private car. Entrance 4 connects the station exit space on the fourth basement floor and the private car garage on the ground floor via a

straight staircase, which is shared by leisure passengers and leisure citizens who choose to travel by private car. Entrance 6, Entrance 7, and Entrance 11 are dedicated entrances for citizens, with Entrance 7 mainly carrying leisure citizens travelling on the underground, and Entrance 11 being one of the entrances for citizens to walk into the commercial space.

Among the entrances and exits of the commercial space of Shenzhen North Railway Station, the ones with higher than average pedestrian flow are Entrance 1, Entrance 3, Entrances 4+7, and Entrance 12, which are across the three floors of the commercial space. Both passengers and citizens share these five entrances and exits. Entrance 12 is close to the station space and leads to the commercial street adjacent to the station's entrance and exit space, which has the highest flow of people and is one of the shared entrances and exits for all passengers and citizens (Fig. 11). Entrance 1 is close to the city road and mainly accommodates transport passengers entering the station on foot and citizens walking to the commercial space. On the other hand, Entrance 3 and Entrances 4+7 are located in the area close to the station space and are used by transport-oriented passengers who choose to walk out of the station, leisure-oriented passengers who travel exclusively to the commercial space, as well as citizens choosing the metro, buses, and taxis.

5. Conclusions

The circle structure of centre agglomeration is usually regarded as an ideal model for the high-density development of high-speed railway station areas, while this study is based on the walking line of two types of groups, tourists and citizens, to refine the deduction of the design of the layout form of the commercial space of the high-speed railway station complex, which includes two aspects, namely, the layout of the body of the commercial space and the layout of the nodes at the entrances and exits.

Firstly, the correlation law between the block layout of the commercial space of the station complex and the total pedestrian flow. There is no positive correlation between the distance of commercial space from the station space and the use of commercial space, and the commercial space with the closest and the farthest distance from the station space shows a lower percentage of commercial space traffic, while the commercial space with the station space in a staggered layout and with the distance between the two in the middle of the commercial space, on the contrary, has a higher percentage of commercial space traffic. The reason is that the interlocking commercial space and station spaces have strong spatial connections, and the metro space is embedded between them, which attracts a large number of transport-oriented passengers to pass through the commercial space.

The proportion of long-distance passengers in the core area of China's high-speed railway stations is very large, and passengers' demand for rapid transportation is much larger than their demand for leisure consumption; therefore, the people who use the commercial space of station complexes are mainly leisure-oriented citizens in the surrounding area, and the number of leisure-oriented citizens > the number of transport-oriented passengers > the number of leisure-oriented passengers. Therefore, in the process of planning and laying out the commercial space of station complexes, attention can be paid to stations with small and medium-sized passenger scales, appropriately shorten the distance between their commercial space and station entrance and exit space, and create a staggered space for guiding traffic passengers, especially by placing

underground space between the two and stimulating the recreational potential of traffic passengers who transfer to the underground, whereas, in stations with large-scale passengers, the distance between their commercial space and station entrance and exit space needs to be maintained to provide a more comfortable and comfortable environment for the passengers. For stations with a large passenger scale, the commercial space and the station access space need to be kept at a distance for the use of the neighbouring citizens and a small number of passengers.

Second, the node layout of the commercial space of the station complex and the correlation law of the entrance and exit pedestrian flow. Firstly, the setting of entrances and exits of commercial space and the distribution of people flow are influenced by the layout of commercial space blocks. Located in the commercial space on the side of the station space, its entrances and exits are distributed in the area close to the station and facing the city, and there is a big gap between the flow of each entrance and exit. Located in the commercial space directly above the station space, its entrances and exits are distributed on the ground floor where the two are intersected, and because these entrances and exits are facing the surrounding city, the gap between the flow of each entrance and exit is relatively small. Secondly, the entrances and exits of the commercial space that are connected to the metro line usually have high pedestrian flow. Among them, the passenger-citizen shared entrances and exclusively for public use entrances and exits with a direct spatial connection with the underground line have a higher flow of people, while the entrances and exits exclusively for leisure passengers have a higher flow of people close to the station entrances and exits. Therefore, in the process of planning and laying out the commercial space nodes of the station complex, it is necessary to enhance the spatial connection between the entrances and exits of the commercial space, the metro space, and the station entry/exit space based on the block layout form of the commercial space.

Then, the layout pattern and optimisation suggestions for commercial space in the sample station complexes are:

Guangzhou East Station and Shapingba Railway Station are stations with small and medium-sized passenger scales. The commercial space of Guangzhou East Station is interlaced with the station space, with metro space embedded between the two, and the entrances and exits of the commercial space are separated for the exclusive use of passengers or citizens, especially the special entrances and exits set up for the transport-oriented passengers who change to the metro, so that the commercial space of this station complex can attract a large number of transport-oriented passengers changing to the metro while accepting citizens from the surrounding areas. The passenger scale of Shapingba Railway Station is relatively small, and its commercial space is completely superimposed with the station space, between the two there are urban transport spaces such as buses, rentals, and private garages, while the underground is located below the station exit space, and most of the entrances and exits of the commercial space are shared by citizens and passengers, and only a small number of entrances and exits are for the exclusive use of the citizens who take the underground and go to the commercial space on foot, and the commercial space of this station complex mainly serves the peripheral citizens, and only accepts a small number of leisure-type passengers. citizens, and only takes on a small number of leisure-type passengers. However, Shapingba Railway Station does not attract traffic passengers who must pass through the commercial space, and the passenger flow of the station is mainly concentrated in the ground floor entrances and exits, and the flow of people inside the

commercial space lacks traffic power, so it is possible to increase the commercial space and adjust the position of the entrances and exits of the commercial space between the station exit space and the underground to accept the traffic passengers who transfer to the underground.

Shenzhen North Railway Station is a station with a large passenger capacity. Its commercial space is completely separated from the station space, and between the two, urban transport spaces such as metro, bus, taxi, and private garage are integrated in a three-dimensional way, with entrances and exits to the commercial space shared by passengers and citizens, and a separate commercial street is set up in the area adjacent to the entrance and exit of the station, which is supplemented by the use of leisure-type passengers. Citizens choosing either mode of transport share all entrances and exits to the commercial space with leisure passengers who visit the commercial space exclusively and transport passengers who enter and exit the station on foot. Due to the large area of interchange space and station square between the station space and the surrounding urban roads, the number of transport passengers walking in and out of the station is minimal. The commercial space is far away from the station space. Even if it is close to the entrances and exits of the station space, the accessibility is low, so leisure passengers will choose to go to the commercial street, which is close to the entrance and exit of the station. The citizens who go on foot will also go to the commercial street, so the area gathers a large number of passengers and citizens. Therefore, the area gathers a large number of passengers and citizens. However, the distance between this commercial street and the two-floor commercial blocks is relatively far, so the vertical connection between the two commercial spaces can be increased appropriately so that the pedestrian flow of the commercial street can be directed to the entrances and exits of the commercial blocks below.

Finally, additional research is needed on the factors and indicators that influence the use of commercial space in station complexes. For example, the use of commercial space in station complexes is also affected by the organisational structure of various types of urban transport spaces and the urban transport sharing rate of different stations. In addition, this study focuses on analysing the layout of commercial space in station complexes from the perspective of "node-path", and abstractly expresses the use of commercial space as the total flow of people at all entrances and exits and the flow of people at all entrances and exits, which is only one aspect of measuring the effect of the use of commercial space, and can be measured by choosing more detailed indicators such as the flow of people entering stores. metrics such as inbound foot traffic to measure, and can also be supplemented with weekend foot traffic data for comparative studies with weekday usage. In addition, if the number of traffic-type passengers is increased excessively, it may affect the efficiency of passengers entering and leaving the station, and in the actual planning and design process, it is necessary to consider the balance and conversion of both traffic dispersion and commercial agglomeration.

Abstract

This study aims to discover the mobility of children in a car-free area to understand the effects of freedom of mobility on perception of space. Büyükada Island in Istanbul defines a unique alternative due to its car-free living environment and offers a significant potential in terms of creating a child-friendly environment and freedom of movement. Within this scope, "mind mapping" methodology used for exploring children's spatial perceptions and freedom of mobility through drawings and written expressions of 20 students of 10-years old, living and studying at Büyükada. This paper discusses the findings of a field study regarding active and independent mobility patterns and explores children's perception of space in a car-free settlement which can be promising for developing policies for a child-friendly urban future.

Keywords: child friendly cities, child perception, independent mobility, mind mapping.

Introduction

In today's cities, transportation is developing with the motor vehicle-oriented approach, and traffic problems and their effects are addressed as an important field of study by different disciplines. The problem of the pressure that fossil fuel-using motor vehicle traffic puts on the environment and citizens becomes even more important when it comes to children, preventing their safe and free movement and weakening their relationship with the city. Cities where motor vehicles and highways are dense and dominant are increasing, and the areas where children can walk safely, play, and experience the city freely are decreasing day by day. However, it is noteworthy that within the scope of urban transportation policies and plans, there are few studies on children's access and rights to sustainable transportation, which gives priority to sustainable transportation modes such as pedestrian, bicycle and public transportation (Gilbert et al., 2018). Whereas settlements that children can move safely and freely are important for the healthy development of children who will be adult urban residents of the future.

Studies in the literature show that increased motor vehicle traffic reduces children's physical activities and games (Mindell & Karlsen, 2012), reduces their access to parks and playgrounds (Veitch, Salmon and Ball, 2007), and restricts their free mobility (Collins and Kearns, 2001; Haikkola et al., 2007; Tranter and Doyle, 1996) and weakens the perception of space (Appleyard, 2022; Mitchell, Kearns and Collins, 2007; Rissotto and Tonucci, 2002). As children's opportunities for active movement such as walking and cycling decrease, their free mobility also decreases, and this negatively affects both their physical, mental, and social development (Villanueva et al., 2014). Studies show that parents also restrict their children's independent mobility due to concerns about traffic safety (Björklid and Nordström, 2007; Chandwania and Natu, 2022; Tranter and Doyle, 1996; Villanueva et al., 2014; Wales, Martensson and Jansson, 2021), prefer motor vehicular instead of active transportation for home-school journeys (Appleyard, 2022; Collins and Kearns, 2001; Mitchell, Kearns and Collins, 2007), or cause children to be accompanied by an adult (Collins and Kearns, 2001; Kyttä, 2004).

The Child Friendly Cities (UNICEF, 2024a) approach, based on the Convention on the Rights of the Child (UNICEF, 2024b) declared by UNICEF in 1989, is defined as 'cities and communities where children feel safe, have their voices heard and can benefit from social services'. Based on this definition, one of the main goals is to create urban environments where children feel safe, where there is no traffic safety or pressure, and where children can move safely and alone on the streets (Riggio, 2002). At this point, supporting the active and independent mobility of children in their daily lives, making cities car-free, reducing and slowing down traffic in cities, and expanding sustainable and active transportation types are considered to be one of the important steps in creating child-friendly environments (Gilbert et al., 2018; Jansson et al., 2022; Karsten and van Vliet, 2006; Tranter and Doyle, 1996). As Chawla stated, walking and cycling, which are sustainable and active modes of transportation, are also child-friendly modes of transportation (Chawla, 2002). Walking and cycling are also the most basic and independent forms of mobility that children can do on their own. On the other hand, while car-dominated transportation systems contradict the Convention on the Rights of the Child because they restrict the mobility of children, active transportation types such as pedestrian transportation and bicycle transportation support the child rights-based transportation system (Gilbert et al., 2018).

Children's independent mobility, or freedom of mobility, is one of the most important components of child-friendly cities. (Freeman and Tranter, 2011; Global Designing Cities Initiative, 2022; Haider, 2007; Kyttä, 2004). This concept is defined as the ability of children to move and play freely and on their own in the environment they live in, without being accompanied or observed by any adult (Hillman, Adams and Whitelegg, 1990; Tranter and Whitelegg, 1994; Wales, Martensson and Jansson, 2021). In their independent mobility, the activities that children perform with their peers or friends are also considered in the independent category (Mikkelsen and Christensen, 2009). Children's independent mobility and therefore their physical-social health are closely related to the environment in which they grow up (Björklid and Nordström, 2007), and are shaped by the existence of environmental opportunities and their ability to access these opportunities independently (Broberg, Kyttä and Fagerholm, 2013; Kyttä, 2003, 2004). Research shows that the independent mobility of children is decreasing all over the world (Johansson et al., 2020; Wales, Martensson and Jansson, 2021), in this context, it is accepted that vehicle-dense cities are one of the important problems in terms of the independent mobility of children.

There are physical and social benefits of increasing children's active mobility in cities (Carver et al., 2013; Fagerholm and Broberg, 2011; Kyttä, 2004; Maiss and Handy, 2011; Villanueva et al., 2014; Wales, Martensson and Jansson, 2021). Active and independent mobility of children can be supported by reducing traffic and increasing walkability (Bourke, 2017; Carroll et al., 2015; Kaplan, Nielsen and Prato, 2016; Prezza, 2007; Villanueva et al., 2014). Independent mobility can contribute to children's development (Mikkelsen and Christensen, 2009), may decrease health problems such as obesity (Mackett et al., 2007), and improve environmental perceptions (Appleyard, 2022; Björklid and Nordström, 2007; Carroll et al., 2015; Mitchell, Kearns and Collins, 2007). There are also studies showing that the sense of social belonging and social bonds may increase (Bourke, 2017; Carver et al., 2013) and social relations may improve (Pacilli et al., 2013). In addition, by reducing vehicle traffic, speed and density, it becomes possible for children to travel with active modes of transportation (Kaplan, Nielsen and Prato, 2016) and thus a child-friendly environment can be created (Gilbert et al., 2018; Tranter and Doyle, 1996), free mobility may increase (Carroll et al., 2015; Whitzman, Worthington and Mizrachi, 2009), and the opportunity to play games in car-free areas may increase (Njeru, 2022). These studies reveal the benefits of car-free settlements in terms of both the physical and mental development and health of children. Considering all these benefits, it is very important to investigate the opportunities that enable/restrict children to freely explore the environments and neighbourhoods in which they live and to act independently (Veitch, Salmon and Ball, 2007) and to produce policies and plans that give priority to children (Carroll et al., 2015).

Considering that urbanized areas are increasing in the world and motor vehicles dominate urban transportation, it is important to explore the opportunities car-free settlements. Studying the mobility and space perception of children living in a non-motorized environment, which the studies in the literature are idealizing, would provide important clues. Within this scope, the purpose of the study is to discover the mobility of children in a car-free area and to understand the effects of freedom of mobility on perception of space. For this purpose, a car-free island from Istanbul, Büyükada Island, has been chosen for the case study. It is aimed to reveal through which spaces children living in Büyükada perceive and give meaning to their living spaces by producing mind maps through a workshop to be held with children. Thus, by identifying children's routes in Büyükada and the areas they use, it will enable questioning the relationships between space

perception and mobility. As part of the case study, spatial components of children's perception about the place they live in and the relation with their mobility types were determined by mind maps with 20 students of 9–10-years old residents of Büyükada Island.

Methodology

As the methodology, "mind mapping" used for exploring children's free mobility experience through drawings and written expressions. Field work was carried out with 20 students of 9–10-years-, living on the Island and studying at Büyükada Primary School. According to Piaget, a child in this period can think logically and process information in his/her mind schematically depending on his/her senses, movements, and intuitions. During this period, children can draw what they perceive about the environment in an abstract way and transfer the routes they know (Appleyard, 2017). Since children's physical and mental development reaches the level where they can perceive the city and act independently at this age, working with children of this age group will ensure that their contributions are at the highest level.

On the other hand, in the curriculum determined by the Ministry of National Education of Türkiye, environmental literacy, perception of change and continuity, map literacy, location analysis and spatial perception, which are among the basic skills that the Social Studies course aims to provide, are included in the 4th grade curriculum. In the 4th grade curriculum, the Learning Area "People, Places and Environments" aims to give students an awareness of human-environment interaction, to establish the cause-and-effect relationships of interaction and to gain an individual or social perspective for the future. It is aimed to provide students with the skills of research, environmental literacy, perception of change and continuity, observation, map literacy and spatial perception with an approach that opens from simple to complex, from near to far and from the location to the environment.

As a beginning of the study, observations were made on the school street while students leave the building after class hours to better understand the mobility behaviours of the children. The individual and group behaviours of the children were noted by observing the streets and routes that the students mostly used after school. Observations supported by shadowing method (Gehl and Svarre, 2013) for identifying the behaviour patterns during their journeys.

For the first phase of the in-class study, individual mind maps were prepared by children to explore the individual perception of space. Children were asked individually to draw and write the island they experienced on a blank sheet of paper. Then in the second phase, collective maps were produced in groups of 2-3 people to determine the general perception about the Büyükada. Children were asked to make markings on a ready-made map, and their verbal transmissions were recorded at the same time. University students studying in the City and Regional Planning Department of Mimar Sinan Fine Arts University accompanied the groups to avoid problems in map reading and prevent this from being an obstacle for the study.

The maps prepared with the children reveal the spaces through children's experience and perception about the Büyükada. The details of the drawings and verbal expressions with the identification of the activity areas related to mobility patterns helped to determine the level of

children's perception about the environment they live in. The prevalence of spaces used by children on the island reveals children's emotional, spatial, or functional related motivations for using and limiting space in a settlement without motorized vehicles pressure.

Büyükada: A car-free district of Istanbul

With its 16 million residents, Istanbul is the most crowded city of Turkiye (TÜİK, 2023). The metropolitan area is shaped by a variety of urban typologies from different historical periods, diverse lifestyles, and heavy traffic load of transportation. Experiencing the Istanbul metropolitan area as a child has difficulties, such as lack of accessibility to amenities, dependency on vehicle urban mobility, large scale physical environment challenging for cognitive mapping. On the contrary, the Büyükada Island in the Sea of Marmara defines a unique alternative due to its low-density urbanization, accessible services, strong urban identity, and car-free transportation. As the largest island district of Istanbul Metropolitan area, the Büyükada, which have managed to preserve the culture of car-free living, and offers a great potential for children and adults, in terms of creating a child-friendly environment and freedom of movement. Since the 19th century, transportation has been provided by horse-drawn carriages and phaetons. Motorized vehicles are only used for public services such as fire brigades, ambulances, and garbage collection. The increase in the number of individual electric vehicles over the last 10 years has brought a different dynamism to on-island mobility. In 2022 the municipality banned horse-drawn carriages, since public transportation was provided by electric shuttles and electric cards. As a result of this heritage residents and even visitors of the islands have this non-motorized and pedestrian dominant awareness as mind setting.

In contrast to the increasing motorized vehicle-oriented development of the Istanbul metropolis since the 1980s, the Princes' Islands are only car-free areas in Turkiye. Büyükada, the largest of the islands, is a settlement where private motor vehicle ownership doesn't exist, transportation is provided by pedestrians, bicycles, electric bicycles, and electric shuttles. The winter population is higher than on the other 3 islands, and offers functional diversity at different levels in terms of education, health, culture, etc. Therefore, Büyükada has significant advantages over Istanbul in terms of creating a child and youth friendly environment and freedom of movement. The Büyükada is a small settlement with a population of 8586 according to 2022 statistics (Adalar Municipality, 2023). According to the 2020 household survey results, 19% of the population living in the Büyükada have battery-powered vehicles or electric bicycles, 17% have bicycles and 52% do not own any vehicle (IBB IPA Statistics Office, 2020). According to the same study, the majority of trips to the islands are made by active transportation modes such as walking and cycling. Children make their school journeys in the Büyükada without a vehicle, and for home-school journeys within the island or to the mainland, pedestrian and ferry options are the highest with 35.7% each, while private vehicles account for 0.9% (IBB İPA Statistics Office, 2020). Therefore, the Büyükada, where there are no private cars, active transportation modes are common, and children go to school on foot, was selected as the study area.

Exploring Children's Island Perceptions, Mobility Behaviours and Activity Spaces

To explore children's perception of the Island and mobility patterns, a field study was conducted with 20 children. The study group consisted of 10 female and 10 male students residing in the Büyükada. While 12 of the children live in the centre of the Island where commercial facilities and services concentrated among dense urban patterns, 8 of them live on the periphery with lower building density and a more dominant natural environment. The primary school is located in the centre of the settlement and within walking distance of the pier, the market area and most of the residential areas.

Figure 1: Mind Mapping study and drawings of children

Figure 2: Walking routes and activity spaces of children from mind maps and collective maps.

The in-class activity conducted with the students within the research's scope is a two-stage mapping exercise. In the first phase, mind mapping, children were asked to draw and describe the Büyükada on a blank paper. As a hint, they were told to describe their favourite places, streets, home, or school surroundings of the Büyükada to someone who did not know the island. At this stage, it was aimed to determine children's perceptions of location, spatial relations, scale, and spatial details. In the second phase students worked on collective maps, and asked to mark their favourite, least favourite and most frequently visited places on a map showing the current state of the settlement, and to draw the routes of the places they visited. Finding from the mapping exercises with children provided insights about **the general set up and perception of space, mobility patterns and spaces, functions and activities, spaces for play and relationships with the natural environment.**

In terms of **general set up and perception of the space,** the areas where children live, play and use are spread over various parts of the island, and therefore their perception of space covers a wide area. 15 out of 20 children referred to their own home and its close surroundings when defining their living environment on individual mind maps. They defined other spaces by associating them with their location in relation to the house and axes of connection. 3 students chose to draw a single favourite spot (the restaurant in Dilburnu (Dil cape) and its flowery entrance; an old mansion and its garden, which she found peaceful) or a situation (a family picture among their favourite buildings). In each case, the drawings contain spatial references and details.

17 children who preferred to describe their living environment by drawing a map used their own house (89%), the school (65%), the hospital adjacent to the school (53%), and other houses (70%) as main references while describing their physical environment. While the rate of drawing the houses of classmates, neighbours or relatives was 53% in individual mind maps, in all collective island maps, the houses of relatives and friends were marked in addition to their own houses.

In the collective mapping study, students marked the locations by reading on the existing map. Since they were novices in map reading, 90% of the students used the ferry pier as the starting point for finding directions and marked the school by following the road from there. Ferries are the main vehicles to connect the islands to Istanbul mainland. Therefore, pier is also a real starting point when stepping onto the island. The fact that children start from the pier, which is the entry point to the island, by simulating real life while searching for a place on the map and find the house and school by following the path they walk shows the high level of children's spatial cognitive perceptions.

In terms of **mobility,** walking emerges as the primary mode of transportation. Children's school journeys are mostly made by walking as individuals or accompanied by their siblings / friends, rather than by their families. Children living in the periphery mostly use vehicles for commuting. Electric motorcycles are the most common ones, another way is the public shuttles. In mind maps 2 students draw the route of the shuttles, and 4 picture the electric vehicles.

> *Zeynep Ö.: "When my mom takes care of my brother, she can't pick me up from school, so I go down to the market and take the bus."*
>
> *Pamir: "my parents bring me to school on an electric motorcycle, but I like walking more because I can observe"*
>
> *Zeynep B.: "My sister brings me to school by electric car, our house is close to the museum"*
>
> *Hazal: "we live close to school, so I walk with my brother, and sometimes my mom brings us with the electric motorcycle"*

Depending on the weather conditions, students walk to school or are given a ride by their parents via electric bicycles. It has been observed that children walk in groups after school as well as accompanied by an adult. In some cases, adults provide access to neighbourhood children with their electric vehicles, in the sense of a division of labour. Most of the children participating in the study own a bicycle. However, they reported that they used bicycles for recreational purposes around the home and usually walked to school or were chauffeured by their parents with electric bicycles.

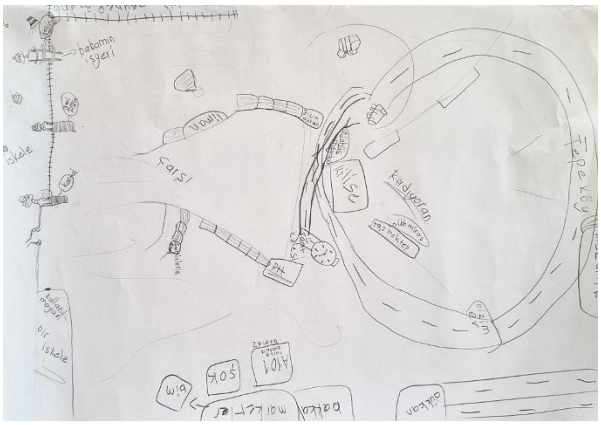

Figure 3: Mind map drawing of a child that shows transportation hubs and routes.

Regarding urban mobility, the main elements reflected in children's mind maps about transportation are the ferry pier and the electrical public shuttles' station. Ferries provide the main connection with Istanbul and other islands. Therefore, the pier is the entrance gate to the island; it constitutes the centre of the settlement functionally and semantically. The shuttle station takes places in part of a square surrounded by shops and cafes in the market area. The square is not only a transportation hub, but an important node / junction for the centre. Children mark these two areas as landmarks, gathering points for daily activities as well as the centres for transportation.

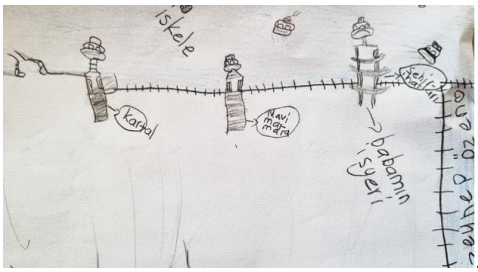

Figure 4: Detailed landmarks of the Island such as ferry pier

Another prominent element on the maps is the market area where urban **functions and activities** concentrate. Shops and commercial areas included in 59% of the individual maps, were marked in all the collective maps in detail, with the names of the chain markets, local shopkeepers, cafes, and the workplaces of acquaintances. Children mention that they can meet on their own in the market area in their free time, while those living in the centre play on the street. The market area is one of the activity areas of the Büyükada children with its commercial vividness.

Asya: "I like to spend time at the coast because we can sit there with our friends. There are cafes and parks."

When it comes to **the natural environment,** it has been observed that children establish a close relationship with nature and draw in detail the elements that shape the environment they live in. Children know the types of trees, write their names in drawings and visualize them in different ways. All the children said they liked the forest areas at the back of the island. Dil cape, beaches, the big tour route, forests and Aya Yorgi hill are mentioned equally with the uses in the centre. However, this area is more secluded due to the sparseness of the settlement pattern, families do not allow children to go alone for safety reasons. Instead, these areas are visited for family activities such as visiting relatives, nature walks, cycling or swimming in summer. Therefore, the limited use of forested areas by children is not due to accessibility, but to parental concerns about safety and strangers' danger.

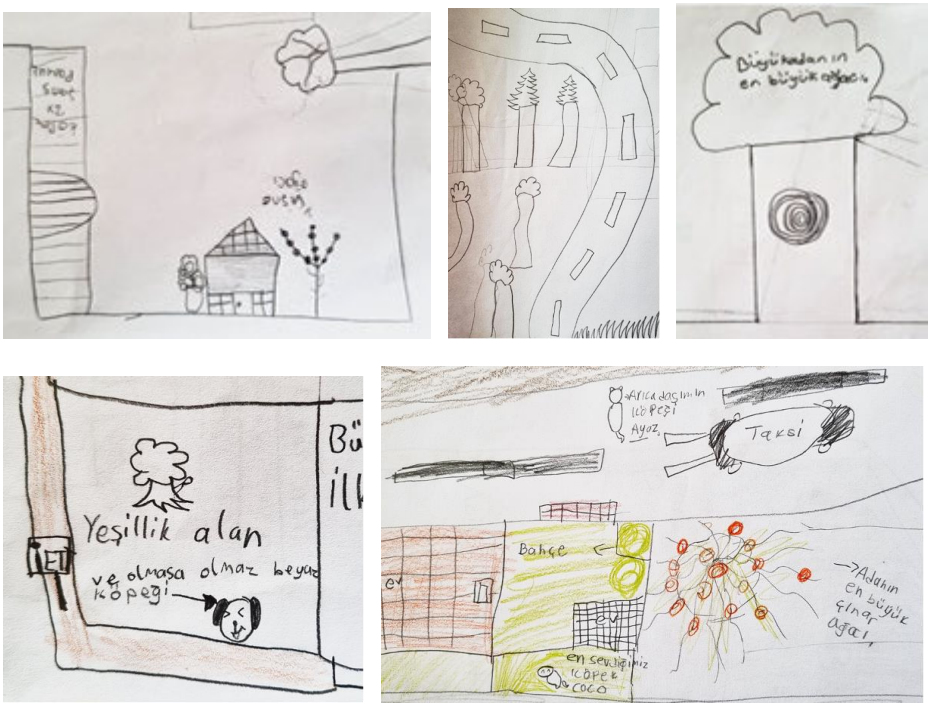

Figure 5: Details of natural element such as trees, gardens, animals in children's mind maps drawings

In terms of play, children drew several places where they played, such as the school garden, the streets where they lived, the island's square and the football field. In their out-of-school activities, most of the children can perform independent activities such as playing on the street / in the park, going to sports, or wandering around the city centre, alone or with groups of friends. The school

garden is one of the most important gatherings and after school play areas since it also offers children out-of-school alternatives with courses and activities. While all boys marked the football field as an important gathering place on the collective map, girls predominantly marked Atatürk Square. Çınar square, located at the intersection of the market and the residential area in the centre, is also expressed by both boys and girls as a play street. Another important finding is that walking backwards on a slope, running and pacing, the movement itself can turn into a game. These findings suggest that active mobility in car-free settings can support play function and turn independent mobility into fun.

Regarding the **interactions between children's independent mobility and their perception** of space, it has been seen that there is a close and strong relationship between active and independent mobility and strong spatial perception. The most important finding of the mapping research is that children who are taken to school by their caregivers cannot identify the routes they use on a map, cannot define spatial references or identical structures. Although they can draw their immediate surroundings around home and micro-scale spatial relations in individual mind maps, their perception of the whole is poor compared to children who commute on foot.

Walking speed makes it possible to notice details and develop a strong perception of space. On the other hand, walking together after school, even if it is for the purpose of going home, provides shared free time on the street. In this way, individual awareness of the environment can be shared, that enables peer education. Naming the animals on the route together, talking about tree and plant species, eating and shopping together in the market reinforces the experience of both life and space. Since children walk with their siblings or friends, they know each other's homes and even their parents' workplaces which enhances the sense of security in the neighbourhood. 75% of children were aware of the names of neighbourhoods, streets or special functions and mentioned them when describing the settlement.

Conclusion

This paper discusses the findings of the field study that shows children living on a car-free island have developed perception of space which allows them to describe the details of space and the ability to find their way independently. In addition, their spatial perceptions vary in terms of their mobility patterns and durations, location of their homes, distances to the centre, and differentiate according to the variety of urban elements they encounter every day.

In the mind maps produced as part of the study, children describe the environment they walk and perceive through four basic components (Zhu and Lee, 2008) as pedestrian facilities, housing density, land use mix and street connectivity. *Residential density* is expressed in terms of rows of houses defining streets or a description of specific houses. Among the activity patterns, children's favourite places to go alone or with their caregivers were the market area, pier, and the coast where the commercial and services take place with the highest level of *land use mix*. Büyükada offers a variety of functions such as Adalar Museum, libraries, football fields, tennis courts, woodlands,

seashores, and beaches. All these uses are marked in the mind maps and collective maps in addition to the mix use zones. *Pedestrian facilities* are at a high level as the entire island is a pedestrian priority area. This issue is reflected on the mind maps through open public spaces and the promenade on the coastline of the centre. The promenade starts from the small port, continues with cafes, restaurants, municipality building, ferry piers and supermarket, ends at the Atatürk Square. Atatürk Square is an important gathering point of the island's public pedestrian system. In collective maps children defined the square as a most important meeting and playing point by also mentioning the monument on the square as climbing wall or slide statue. Modern style monument on the square became a playing point for Büyükada children with its form that enables them to climb, slide and sit on top of it. In the means of *street connectivity*, the permeable car-free street pattern ensures a high level of connectivity in the centre. In children's mind maps, the streets of Büyükada appear as the main area of activity and the connectors of urban uses and movement areas.

The study showed, in addition to functional diversity, richness and elements that lead to sensory diversity strengthen the relationship between children and space. The variety of natural elements provides significant potential in this regard. Children referred to noisy and crowded areas, silent and peaceful spots, different materials and textures that create surfaces in the urban environment. The elements that attract different senses are recognized in their cognitive mappings.

Findings of the mutual analyses on mind maps and the voice recordings showed that the children's perception of the built environment in Büyükada, is parallel to the natural environment. Büyükada has a very strong natural identity as well as its identical architectural environment. As a result of the study, it was determined that children perceive the built environment together with natural environment references. The sea shore, hills, sloping streets and stairs, which are the result of the rugged topography, play an important role in the perception of space. The viewpoints defined by the hills, combined with the presence of monumental buildings such as the Greek Orphanage and the church of Aya Yorgi, strengthen the emphasis on landmarks. Clock tower, Splendid Palace Hotel, Taşmektep (renovated museum), Anadolu Club, Church and Hamidiye Mosque are landmarks in the centre.

Figure 6: Details of landmarks of Büyükada such as Greek Orphanage, Clock Tower, Hamidiye Mosque and Dilburnu (Dil cape) in children's mind maps.

In most of the studies that use mind mapping method on children's neighbourhood walkability, children marked traffic points, zebra crossings, parking cars as well as the sidewalks and traffic

lanes as a part of their spatial perception. Whereas in Büyükada, children draw streets and roads as connections of spaces and functions, without mentioning any traffic information. It is concluded that when traffic pressure is removed, children can see roads in their most basic urban function. They may not be perceived as traffic or problem areas that limit movement. Roads connect and unite different parts of the city, forming the whole and providing circulation.

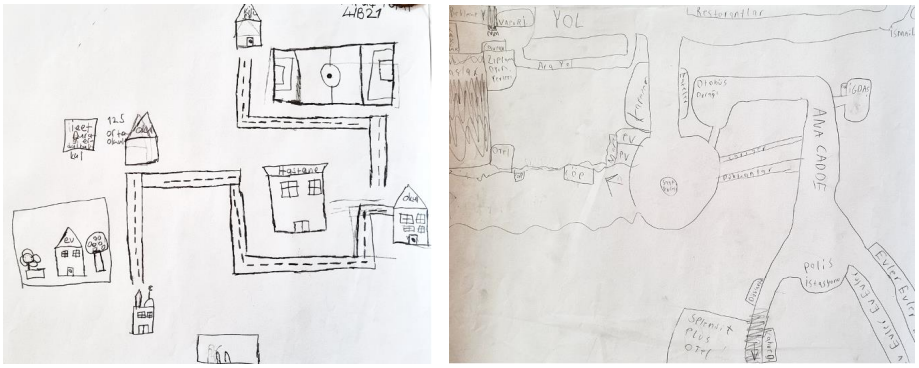

Figure 7: Details of street connectivity and connected activity spaces in children's mind maps.

Another finding of the study was about parental concerns and its' relationship with children's independent movements. It has been determined despite living in an environment without motorized vehicle traffic, the parental concerns persist, and parents continue to chauffeur their children the presence of electric vehicles, the inability to get up early in the morning, or weather conditions. This situation shows that even in car-free environments, parental concerns do not completely disappear and can be limiting on children's independent movements as in other studies in the literature (Collins & Kearns, 2001; Kyttä, 2004).

As a result, children's independent mobility allowed them to establish more connections with nature, to perceive landmarks in the urban space they live in, and to spend time and play in diverse urban areas such as the market centre on the island or in natural areas such as the seaside and forests. It is concluded that what is attractive for children in the Büyükada settlement is not attractive playgrounds, well-designed facilities, or smart schoolyards, but a realistic and coherent diversity of the whole environment at a perceptible and walkable scale. This is a real-life experience for children, and in Büyükada, removal of the vehicle pressure makes this experience possible for children. These findings from a car-free settlement can be promising for strengthening the policies for building a child-friendly urban future.

Abstract

Participatory planning is regarded as an accelerator of sustainable development. However, it comes with its own set of challenges. In this paper, we study the challenges that are explicit in the case of Megacities. As they are more prominent in our current years, megacities form a large portion of their countries' population, not to mention they constitute an issue when combatting climate change. In the context of megacities, the analysis of the participation process requires a breakdown of the one factor which constitutes the biggest difference between its application in cities and megacities: the stakeholders and their extrapolation. Following this method, a solution for its implementation in megacities is proposed highlighting the use of digital tools and following the learnings from the city of "Vinnytsia" and applying them to the case of the megacity of "London".

Keywords: *Participatory Planning – Megacities – City Development – Planning Stakeholders*

Introduction:

As urban areas are rapidly growing, with more than 4 billion people, representing more than 50% of the world's population currently living in urban areas (Ritchie et al., 2018), handling each type of urban space individually is necessary for sustainable planning. This is to allow the shaping of processes tailor-made to fit the type of communities living in it and most importantly to keep up with its rate of expansion. An extraordinary phenomenon of urbanization is the formation of Megacities. Megacities are defined by their population size, which crosses the threshold of 10 million inhabitants (World Urbanization Prospects The 2018 Revision, 2018). Other than their defining aspect, the unique characteristics of megacities include their expansive size, intricate infrastructure, rapid growth, and socio-economic diversity ((Wenzel et al., 2007) and (Buehler, 2003.)). These necessitate a re-evaluation of traditional planning methods including participatory planning approaches. As megacities form a complex eco-system, their development elements are usually differentiated between one another during the planning process. This is already true in other types of cities and leads to the shift of power structures between the different stakeholders depending on the objective of the development. This division of elements shows, nevertheless, a higher level of disconnect in megacities due to their high level of complexity, which results in most cases in a top-down approach in decision making. Megacities are furthermore characterised by two attributes: their high population density and the speed in which they expand. Currently, there are 33 megacities worldwide, a number expected to rise to 44 in the next 10 years, as projected by the United Nations Department of Economics and Social Affairs (United Nations, 2018). A megacity forms a complex organism where the race between sustainability and growth is fierce. With high speed expansion, pollution becomes just as fast on the rise. This is then worsened by the difficulty of controlling

and maintaining sustainable development with the high number of stakeholders involved. A common trend to overcome this obstacle in recent years, has been to regard megacities as agglomeration of neighbourhoods. Planners breakdown the megacity into neighbourhood islands, where development could be controlled and to an extent monitored. This method has proven however ineffective in recent studies, as the case in the research conducted in a selection of Eastern megacities such as Hong Kong (Edermann et al., 2023). Such methods tackle the centres of neighbourhoods and fail at their border. In their attempts to remedy such failures, the authorities create new masterplans with overarching policies. These in turn suffer under the magnitude of the challenge and resolve into one of two faults: failing to account for the individuality of established communities in each neighbourhood or expanding the city more to cater for the residents' needs, an endless loop as the megacity becomes even more difficult to contain and manage. On the other side of the spectrum, small cities have mastered the art of maintaining an identity whilst creating their overarching masterplans. As planning methods were created with cities of medium and small scale in mind, their application proves more effective. Adaptations are in any case needed to match with socio-economic and administrative contexts, nevertheless, the tools themselves do not need to be altered. A good witness is reflected in the use of participatory planning as a sustainable development method.

In this research, we discuss the use of small cities as a blueprint for the translation of urban planning processes into megacities. The focus point in this method is to tackle the division and boiling-down of stakeholders in small cities and allocating their counterparts in a megacity as a whole. As part of the SURPRISE project[1] we will investigate the research question at hand by dissecting the processes taking place in the Ukrainian city of Vinnytsia and translating the learnings into the European Megacity of London.

To tackle this challenge, we will start by understanding participatory planning and the stakeholders that are involved. We will then move on to studying the two cities in question, mapping out their stakeholders and comparing them to one another. At the end, we will be deriving conclusions, highlighting what solutions megacities could adopt and what could be enhanced in small cities' planning.

2. Participatory Planning:

2.1 – Its definition and principles

Participatory planning signifies the involvement of all stakeholders and end-users of an area in its development plan. This method has been commonly used since the 1960s and has been referred to as a tool for sustainable development. In itself, participatory planning was the result of the shift from urban planning to strategic planning development. The main pillar of this method is the inclusion of different stakeholders in the decision-making process while urban planners play the role of mediators between the different stakeholders (Steinberg, 2005).

Researchers such as Jane Jacobs (Jacobs, 1961) and Sillak et al (Sillak et al., 2021) have studied how the involvement of citizens is related to the durability of the development. Jacobs has discussed this topic from the perspective of ownership. She explains in her book how citizens who are involved in the planning phase tend to protect said developments, e.g. against vandalizers in the case of small developments, and maintain the developments as a community. Sillak et al, amongst other researchers, have perceived the question of sustainability from a knowledge perspective. They have investigated participatory planning in topics such as energy

[1] The Sustainable Urban Planning and Resilient Reconstruction In Ukraine with Spatial Data Science (SURPRISE) project is conducted by HafenCity University in Hamburg, Germany. It focuses on creating a pathway for sustainable planning in Ukrainian cities.

planning and perceived the citizens as holders of first-hand experience on the place, and therefore, having communicated to them any missing knowledge and through working with the experts, they are guaranteed to communicate a development masterplan that will correspond to the needs of the place. This helps prevent the repetition of work through the modification and readaptation of development plans during the operational phase.

2.2. - Obstacles in participatory planning:

Whether in megacities or small towns, participatory planning forms consistently a challenge for modern-day planners. From the start of the process, the challenge rises in managing and engaging stakeholders into the conversation (Cohen et al., 2015). The risk is this challenge resulting in only having a small sample of the society joining the decision-making process. More often than not, if this issue is not resolved, the sample in itself is then over-dominated by city officials and authoritative figures (Innes and Booher, 2004).
The second challenge is apparent when discussing more technical sectors related to planning, such as energy topics, governance, and economic issues among others. In this scenario, it is the case that there is a gap between the knowledge required for an effective debate, and that which the general public possesses. In energy topics for example, this problem is caused due to the discrete nature of the field. From complicated energy bills, lack of available open-data on the topic, to the complex theories behind its planning process, many energy topics present a black box for the normal citizen (Crippa et al., 2021). This is to say that such lack of knowledge is not the citizen's fault. Therefore, the role of the mediator (i.e. urban planner) in the participatory process is to ensure a levelling of all involved stakeholders in terms of knowledge. This solution adds in turn to the timespan of the planning process as a whole. The latter issue of time, with its different scales is one of the challenges in every planning process as they are viewed by experts as lengthy add-ons to the development process. To tackle this issue, developers resolve to the inclusion of citizens in the last phase which is the reviewing of the resulting plan, leading to frustration from the citizens and lack of enthusiasm in joining the conversation for future projects. The cycle continues leading to disinterested citizens and an inactive citizenry. The last common challenge of participatory planning is the translation of plans made by citizens into effective plans that could be used on site. This issue related and adds to two of the previously mentioned challenges: the lengthening of the process due to reformation of the plans, and the overruling of some of the citizens additions resulting once again in their frustration.

2.3- Breakdown of participatory planning stakeholders in megacities vs cities:

Finding the solution to the first obstacle of the subsection above, starts with understanding the stakeholders necessary for participatory planning. In its essence and as presented by Jacobs in her book (Jacobs, 1961), participatory planning is only effective if all samples of the community take part, arguing that minorities are often overlooked although they bring a unique perspective to issues at hand. Other researchers, such as Siliak et al (Sillak et al., 2021) and Voorberg (Voorberg et al., 2015) have expanded on the need for experts to join the conversation in the technical development areas such as energy and traffic. Since our research is discussing the overarching concept of city developments, we have also taken into the work of researchers tackling large-scale issues of development, such as the work of Arlati et al in discussing the CLEVER Corridor project in Hamburg, Germany (Arlati et al., 2021). From merging the literature, we can divide the stakeholders into 4 different categories: Experts, planners, stakeholders with economic interest, Authorities.

- Experts:

Needed especially in complex technical issues, such as sustainability, water management, energy, traffic, among others. This category of holds deeper knowledge on the topic in question. Their presence helps with asking and answering case-specific questions which then bridges the gap between the resulting masterplan and what can be realized on site.

- Planners:
  Planners are first and foremost mediators of the conversation. Equipped with the right tools, they guide the different stakeholders to reach the wanted results. They are sometimes hired by the city directly or are part of development consultancy and planning offices that are responsible for the project.
- Authorities:
  Comprised of government representatives and city offices, the level of authoritative figures involved on a project depends to its scale and its implication on local politics
- Economic-Interest Stakeholders:
  This last category is for private entities including, among others, funding agencies, energy companies and real estate developers. Despite them not being present in all types of projects, their involvement provides a challenge as the ideals they are reflecting has economic interest in their centres instead of general-interest questions such as sustainable development. Their contribution, however, provides a good inside on the feasibility of suggested plans.

The citizens, despite being at the centre of the process, constitute several intersections with each of the 4 mentioned categories, as they are workers, experts, city officers as well as citizens. They are therefore encompassing all the categories, as shown in Figure 1 below.

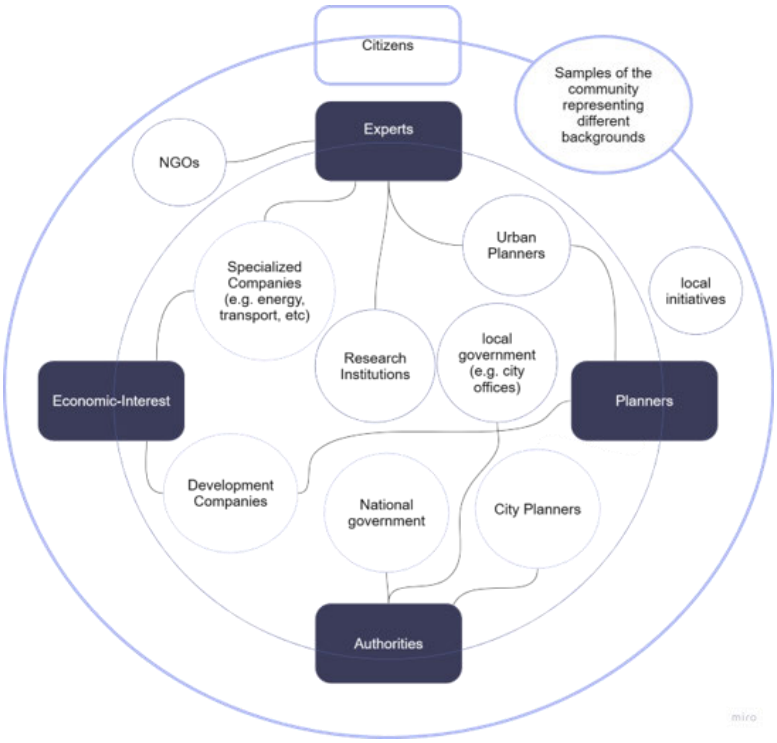

Figure 1: Categories of stakeholders in participatory planning

3 – Stakeholders distinction between cities and megacities

This stakeholder's breakdown, has been made in studying participatory planning in cities. The question rising here, is whether this categorization could be applicable to megacities in their large-scale development processes. In this section, we will study the 2 examples of Vinnytsia, Ukraine, and London, England to view what the above-mentioned categories translate into in the small city and how such learnings can be applied into the megacity.

3.1- Vinnytsia, Ukraine as a city example:

The first city of our study, is the city of Vinnytsia located in west-centre Ukraine. As Ukrainian administrative boundaries follow the hierarchy adopted from the traditional Soviet planning, the name Vinnytsia is given to both the Oblast and the Hromada as shown in Figure 2. With a population of over 350000 in the Hromada and 1.5M in the Oblast, the general population density of Vinnytsia amounts to 56.98/km² (City Population, 2022). As is the case in most post-Soviet cities, Vinnytsia currently faces a shift in identity where the current population is inclined to a more European image and development trends. A change is also obvious in its economy, where traditional industries are fading and their sources of income are shifting. Previously known as "Small Kyiv", the actors in Vinnytsia are conducting big movements to

reassign the city's urban identity. It is currently regarded as a power-player in its local region and in Ukraine (Melnychuk and Gnatiuk, 2019)

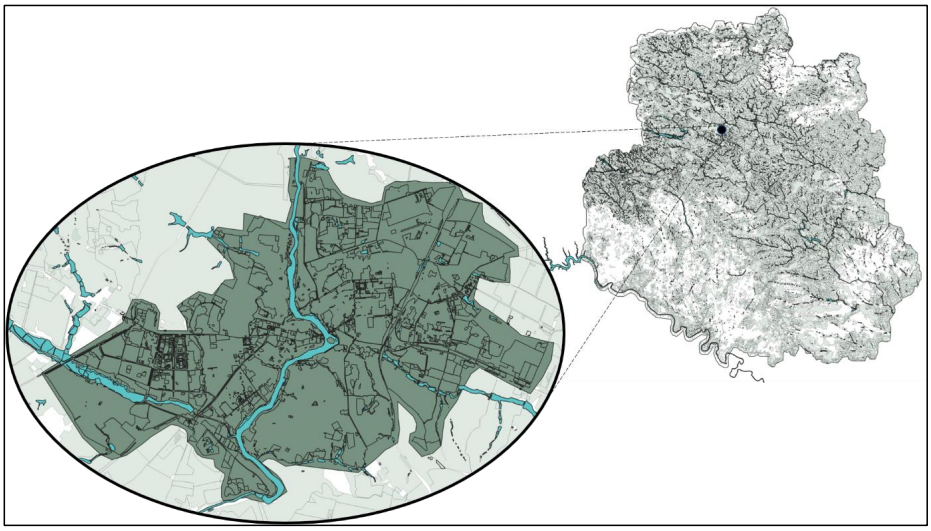

Figure 2 Map showing the position of the Hromada Vinnytsia in the Oblast of Vinnytsia using OpenStreetMap data

3.2 – Stakeholders in Vinnytsia, Ukraine

Currently in a wake of development, the Ukrainian city is following a plan to derive a more sustainable development path for its citizens. One of the pillars of which is the planned increased involvement of citizens in decision-making. To carry this task, and in the frame of work of the SURPRISE project, the degree of involvement of different stakeholders has been identified through conversations held with the local representatives. As explained in Figure 3 below, some stakeholders in Ukraine contribute only at the Oblast level. Translated into Western European planning definition, an Oblast could signify a municipality while the Hromada is the city. In the context of Vinnytsia, it could be regarded as an Oblast encompassing a town, prompting two different layers of intervention depending on the project. One main learning from this division, is the stakeholders' categories themselves do not differ based on the development scale, but rather stakeholders themselves are distributed throughout the different scales. For example, authorities are needed at both scales, however the level of jurisdiction needed is the variable.

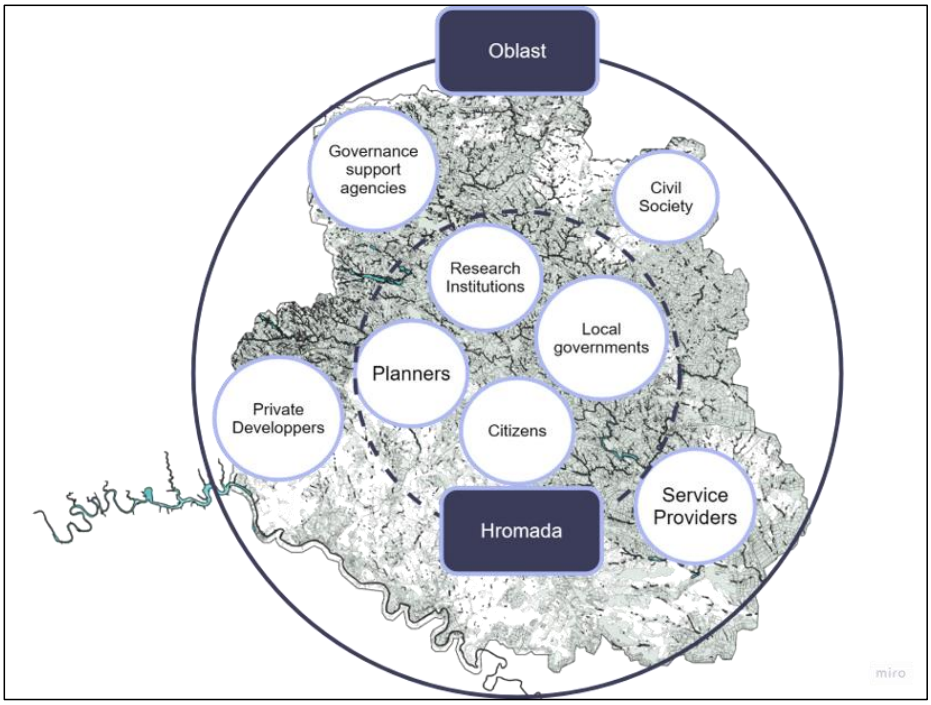

Figure 3 Distribution of participatory planning stakeholders between the Oblast and the Hromadas based on conversations with local actors in the frame of the SURPRISE Project

3.3- The Greater London area as an example of Megacity:

England's London is one of the two megacities of Western Europe, the other one being Paris, France. In 2024, London is house to a population of 9.7 million. The megacity encompasses the greater London area which has the city of London at its centre, forming only 2.9 sq.KM out of the 1569 sq.Km of the Greater London Area. London (referring to the greater London area in this research) has a population density of 5596 residents per sq.Km. (World Population Review, 2024). It encompasses an exceedingly diverse population, with 41% of its population formed by immigrants. With a very rich history, London is currently a global economic hub. As a megacity, London faces challenges such as traffic congestion, housing affordability, air pollution, and income inequality (Wenzel et al., 2007). Urban planning and sustainability initiatives are being implemented to address these issues. Although London is technically not a coastal city, it is often studied as a coastal megacity thanks to the Thames river crossing the city, connecting it to the North Sea, and its very close proximity to the coast.

3.4 – Comparison between stakeholders of Vinnytsia and London:

To understand the development of megacities, researchers have distinguished between the megacities in the western and eastern parts of the world. The development of the megacity of London has been studied as shown in Figure 4 (Li et al., 2019). A trend that has been spotted amongst them, is the tackling of problems through construction of satellite cities to fulfil the needs of the residents. The question we are investigating however is focused on a process encompassing the megacity as a whole.
Following the blueprint of the city of Vinnytsia, the inclusion of all stakeholders' categories remains a defying aspect to achieving effective participatory planning. To understand the difference between the two different city types, we resolve to extracting the stakeholder examples from Vinnytsia and assigning their counterparts in London as seen in Table 1.

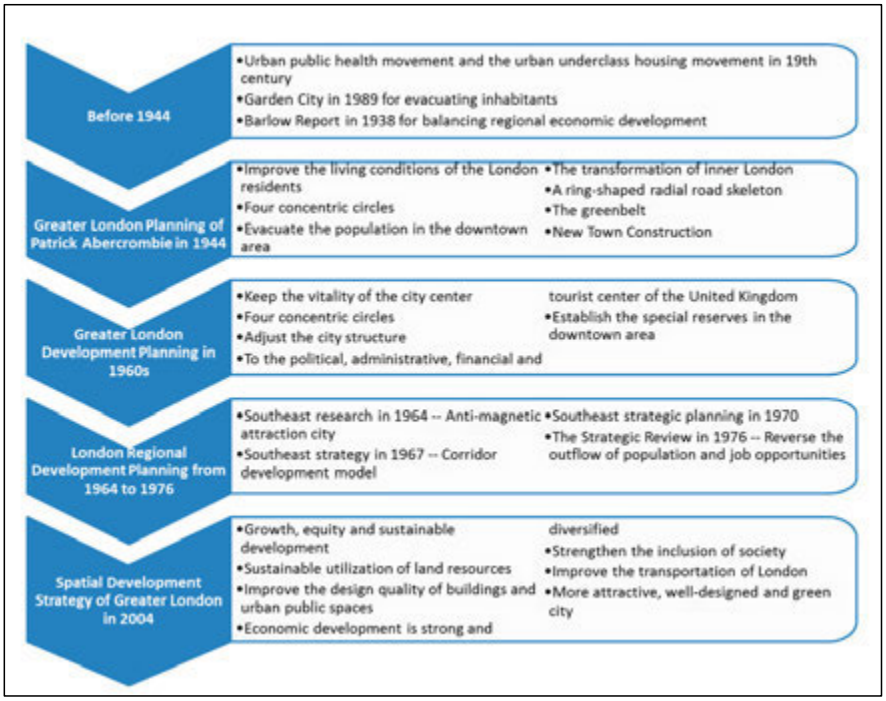

Figure 4 Development history of the Greater London area - Extract from Li et al (2019)

One stakeholder category that stands out as differing greatly between the megacity London and the city of Vinnytsia, is the "Authorities" category. In the example of Vinnytsia, Ukraine, the authorities are divided into local authorities and central government (Vinnytsia City Council, 2024). Their bodies are divided such as:

- Local authorities:
  - Mayor's office
  - City Council: includes several deputy mayors responsible for the different sectors, such as the deputy mayor of urban mobility and transport.
  - Executive bodies of the city council: working under control of the city council

- Central government:

The central government in Ukraine is divided into several ministries that are involved to different degrees in urban planning development. Some ministries such as Ministry of Restoration and the Ministry of Infrastructure, are conducting more fast-paced work in the domain of sustainable development. The involvement of ministries in participatory planning can only happen at the oblast level.

In the city of London, and as the case in metropoles and large cities, the city is divided into several boroughs, signifying the different neighbourhoods with their different uses. The division of authorities and their inclusion in planning processes in London are as follow (London Councils, 2022):

- The boroughs: they manage the neighbourhoods, and are in charge of planning applications, maintain the roads and deliver environmental and leisure services. They can be regarded as a union of the different neighbourhoods.
- The city of London: works on a smaller scale than the boroughs but is responsible for the communication of the image of London to the outside world.
- Greater London Authority: includes the mayor and is the authority responsible for the overall development vision of the megacity. We can understand from there their indispensability in the participatory planning process.
- Local government association: representing the council on the national level. As it deals with issues concerning England as a whole, its presence in the development process can be referred to at the later phases.

3.5 – Process differences between cities and megacities:

Taking the case of Vinnytsia as an example, we can see how the Hromada involved less stakeholders in its process than the Oblast. This is however justified by the character of these two different spatial contexts, where each Hromada comprises one centre, specific communal characteristics, and specific challenges. This scenario is different when breaking a megacity like London into boroughs. Despite the different boroughs facing different sets of challenges, their impacts on one another are inevitable. The points elaborated upon provide examples of the aspects that result in the difference of the processes between the cities and megacities.

(a) Financial centres:

A city centre is easily allocated on the map of a small city. In the case of Vinnytsia, tackling issues regarding the centre of the city can be done individually by each Hromada, meaning the participatory process can be divided by Hromada, with a bigger set of contributions to tackle the Oblast as a whole. The city of London, however, not estranged to other megacities around the world, comprises of several financial centres (Roberts, 2008). Such centres are visited daily by inter-city commuters. These are residents of the city of London, who live in a residential borough but work in one of the many financial centres. The further development of London's industrial district for example cannot be carried without the inclusion of neighbouring citizens that are not part of this specific district but are influenced by its impact on pollution and on the traffic condition among others.

(b) Environmental issues:

Environmental sustainability is a subject controlled first and foremost by local developments. In the megacity, the degree of contributions of different neighbourhoods to the issue at hand

varies. As explained in previous sections, such issues are mostly tackled by further development of the megacity with minimum contributions to existing constructions.

Stakeholder	**Vinnytsia (Hromada)**	**London**
Governments	- City offices - Local governments for Oblast - Central government ministries	- Wards - The boroughs - The city of London - Greater London Authority - Local government association - Transport for London
Private Entities	- Private businesses	- Private businesses
Research Institutes	- Research Institutes in the Hromada - Research Institutes in the Oblast - International Partners - Institute of development studies as a main player	- Research Institutes and university all over the Megacity act independent of their location - International experts
City Planners	- Government assigned planners (Oblast) - Private planning offices	- The mayor's planning consultants (London.gov.uk) - Private planning offices
NGOs	- Working together with research institutes on development topics - Shift in focus into post-war and post-soviet developments - International NGOs with presence Vinnytsia	- A big focus of NGOs is the raising of the voice of minorities - A focus on human rights issues on the local and international level

(c) Energy issues:

In Europe, and with the provided legislations for energy communities, small cities residents have proven to have more ownership over the energy discourse in their cities. Energy communities, defined as stakeholders of energy in the urban setting, are more prominent in cities where ownerships of houses are more common than apartment buildings. This provides cities with the characteristic of having residents with more knowledge and involvement in such a technical topic than a megacity. This solves, to a certain degree, the knowledge issue prominent in participatory planning.

(d) Community engagement:

The sense of community in the megacity is far from non-existent. It is however more obvious on small scales, such as a sense of community in the neighbourhoods themselves. Small city communities possess feelings of ownership over the city as a whole. This makes the inclusion of citizens an easier task.

Table 1: assigning the stakeholders to the contexts of Vinnytsia and London

4 - Proposed Stakeholders involvement strategy in megacities

The challenge at hand is understanding how megacities can conduct an effective participation process on its large scale. Studying the two examples at hand, it can be seen how the involvement of all stakeholders' categories is easier to be achieved in smaller cities than in megacities. To achieve the up-scaling of the process without losing its integrity, a proposed solution can be the division of the process through the timeline rather than spatially as shown in the figure 5 below. This solution is proposed to tackled the obstacles elaborated upon in section 3.

As opposed to the usual spatial division of stakeholders, the timeline division attempts the inclusion of all categories of stakeholders concerned with the megacity. It solves the issue of the enlarged scale by dividing the process into 2 phases. In the first phase, directly-impacted stakeholders are included to have a first-hand discussion of the needs and problems of the development location. The first phase would include the definition of the problem at hand, the co-creation of a solution through collaborative work with the stakeholders, and the reduction of the knowledge gap on the topic which is easier to achieve with the smaller group.

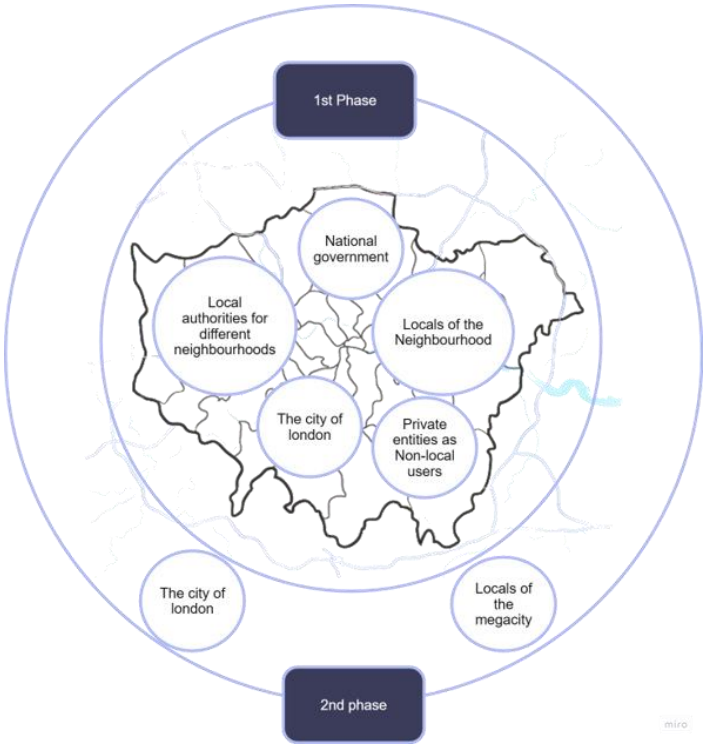

Figure 5 Proposed division of stakeholders through the development timeline of the megacity of London

Whereas the second phase involves larger contributors to the decision-making. It assures the acknowledgement of the impact of the development on a larger scale, be it a larger radius of neighbourhoods or the megacity as a whole. The involvement of larger-scale authorities in the second phase ensures the feasibility assessment of the development and prevents the overshadowing of the voices of local communities that are more involved during the first phase.

5 - Digital tools as a future solution

Smart cities have been an expanding concept in cities regardless of their scale. They are regarded as a solution to a big part of the sustainability question. One of the areas in which this is achieved is the introduction of digital tools for sustainable planning, including digital tools for participatory planning. Democracies around the world are facing increasing demands from citizens to be included in decision-making processes, thus, many political systems have responded by opening up to the public by incorporation more participatory elements. In the context of the deliberative democracy becoming a focal point in political science, a communicative turn in planning has emerged that emphasises more intensive and widespread citizen participation (Friedman 1987; Healey 1992; Healey 1997; Peric´ and Miljuš 2017 in Timotijevic, et al. 2024). The application of technical tools has to be analysed in the context of the different participatory procedures and the respective institutional contexts (Silva, Carlos Nunes, Herbert Kubicek, 2010).

5.1 – Implications of digital participation technologies in urban planning

Digital participation technologies have the potential to reshape urban planning and development practice, especially in enabling constructive participation in early pre-design phases thus allowing for changes on a feasible basis (Münster et al., 2017). Some implications of introducing digital participation technologies in urban planning include the possibility to utilise a wider knowledge base through crowdsourcing knowledge compared to conventional design practices and to tap into the creativity and experience of citizen expertise. In addition, design sentiment analysis, interactive and communication-oriented planning process allowing direct exchange between stakeholders and agile processes are all advantages of integration of digital participation technologies (Münster et al., 2017).

5.2 – Challenges of digital participation technologies in urban planning

Some key challenges were identified by Münster et al., 2017 for the introduction of digital participation technologies in urban planning. These challenges, as illustrated in Fig. 6, consist of:

- Few users – It is often a challenge to find a sufficient number of users due to lack of information on the process, barriers in culture or accessibility of issues.
- Wrong users – Due to self-selection biases, participants choosing to take part in an urban planning process may rarely represent a majority of inhabitants

- Communication issues – Prior thoughts, beliefs and feelings may influence participants, including framing effects such as presentation formats, techniques or media channels and the level of presented problem and objectives
- Process deficits – The lack of transparency, inclusion and fairness could result in disagreement as a result of the process leading to poor decisions

Initiatives have been carried out in both of our study cities to accelerate their development into smart cities and their use of digital tools to ensure better inclusion of the public in participatory planning. In this regard, the movement towards such tools depends greatly on the political and economic contexts and needs to consider the challenges of integrating digital participatory tools in planning processes. Nevertheless, the methods to conduct this shift can be learned from set examples.

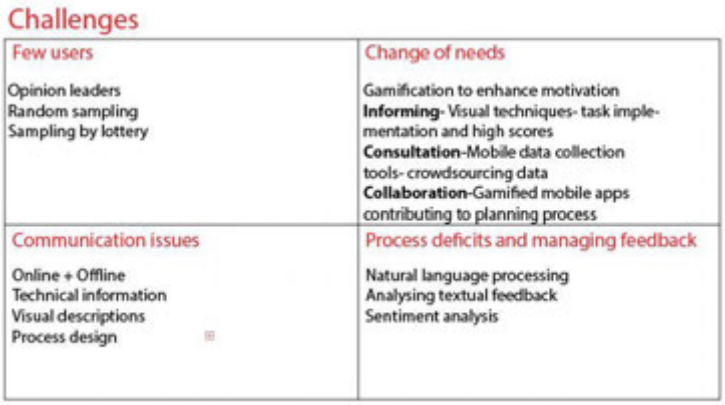

Figure 6 Key challenges and promising approaches adapted from Münster et al.

5 - Conclusion:

This paper has revisited the planning method that is participatory planning from the perspective of megacities, by studying the European city of Vinnytsia and the megacity of London. Through the analysis, differences were extracted between the two cities in respect first and foremost to stakeholders, but also with regard to the general challenges faced by the two cases when it comes to sustainable development. It is important to note that some factors were not considered in this analysis, as is the case that, despite the inclusion of the city governance structures in both scenarios, some political constraints still do exist that could limit the participation of some of the mentioned stakeholders. A number of political and socio-economic differences also exist between the two cities, that affect highly the public perception of such exercises. The goal of the study remains to showcase the possibility to derive learnings from cities and to adapt them into the cases of megacities instead of regarding megacities as islands in urban planning learnings.

In the case of Vinnytsia, it was concluded that the inclusion of stakeholders, namely authoritative figures, is dependent on the scale of the development. This was then explained as a symptom of the scale of the city (mentioned as a Hromada) and its individuality in the municipality (or the Oblast). This individuality is shared by all small cities, and result in the lack of justification for the inclusion of residents and stakeholders from outside the city itself if the development is of small scale. Different actors are then called upon for Oblast development projects. These can share similar categories as those included for Hromada development but are of different specialities and interests.

While studying the city of London, it was noted how the development of satellite cities followed the trend set by western megacities. It also corresponds to the pattern of megacities to fulfil their residents needs through further development. We addressed therefore the challenge of attempting to regard the megacity as a unified entity during the participatory planning process. The blueprint derived from Ukraine was therefore altered to a different concept which is the distribution of stakeholders through the phases of the project, to allow for a more inclusive process. Such alterations allow the carrying of successful processes and their exchange between different cities.

This to say, that although cities cannot copy each other’s processes, there is some learning available despite differences in the scale. Understanding the history of city developments and the reasoning behind the methods used in conducting urban planning are a mandatory step to their re-adaptation. This could however only be achieved when transparency exists in the planning process, which allows for a more in-depth look on the conditions in which planning decisions were made.

Lastly, more research needs to be carried out to study the tools used for conducting participatory processes. The introduction of digital tools for participatory planning, which provide a remarkable solution for large-scale citizens inclusion as is the case for megacities. It provided a way to conduct the process in a time-efficient manner and while despite the different circumstances. Digital citizen involvement however should be studied more to overcome its shortcomings, and especially to assure the process being conducted fairly and democratically.

Acknowledgment:

This research was conducted as part of the work of the research project “Sustainable Urban Planning and Resilient Reconstruction in Ukraine with Spatial Data Science” funded by the Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ). Abstract
The integration of urban and transport planning is strongly supported in the literature, and the transit stop is an element common to both fields. Stops provide accessibility, which can be measured objectively (section 1) or evaluated from the user's perspective (section 2). This paper reads the topic by exploring the factors that influence perceived accessibility in the literature (section 3), with particular attention to the elements included in the domain of urban planning, like places of residence and urban design (section 4). Results (section 5) show some inconsistencies about the role of spatial factors in shaping accessibility perceptions, as well as a lack of relevance of the issue of transit stops. Therefore, some new approaches are suggested to fill the gaps in future research.

Keywords: Urban planning, transport planning, perceived accessibility, public transport, transit stop

1. Accessibility as a common theme for urban and transport planning
The integration of urban and transport planning is a concept that has been well-documented in academic literature (Bertolini, le Clercq and Kapoen, 2005). This integration lays the foundations for sustainable city planning (Barbarossa and La Greca, 2014) by providing viable alternatives to car transport (Nigro, Bertolini and Moccia, 2019). Such an approach can take different forms, from micro-scale actions such as community involvement in traffic calming measures (Boglietti and Tiboni, 2022) to transit-oriented development (TOD) (for a review see Taki *et al.*, 2017). The term TOD was first coined by Peter Calthorpe (1993) to describe a "mixed-use community that encourages people to live near transit services and to decrease their dependence on driving." However, citizens can use these services only in presence of an element of interchange between the place of activities and the service itself. This element is the transit stop, which varies according to the mode of transport (e.g. bus stop, metro station, train station). In the context of a transport network that resemble a mesh of arcs and nodes, stations serve as nodes. The transit stop plays a crucial role both in urban and transport planning realms. Its positioning and design considerations encompass transport aspects (e.g., supply and demand) and urban planning elements (e.g., land use) (Tira, 2011). Consequently, the stop serves as a critical interface between these two domains, facilitating access not only to public transport (PT) systems but also to nearby activities. Accessibility emerges as a key conceptual

focus for this integration, bridging transport attributes (e.g., speed and travel costs) with the land use system (e.g., density and functional mix) (Straatemeier and Bertolini, 2020).

1.1 Accessibility: definitions

The term “accessibility” may encompass various interpretations. A wide variety of definitions of accessibility can be found in the literature, but there are also many commonalities. One widely cited definition defines accessibility as “the extent to which land use and transportation systems allow activities or destinations to be reached through combination of transportation modes” (Geurs and Ritsema Van Eck, 2001). This sentence recalls the interaction models between land use and mobility (Wegener and Fuerst, 1999) and between accessibility and land use (Hansen, 1959). According to the latter, accessibility is the ease with which places (or activities) can be reached in relation to one or more starting points in a given space. A definition that focuses on mobility sees accessibility as “the extent to which the land-use and transport systems enable individuals to reach activities by a (combination of) transport mode(s)” (Geurs and Van Wee, 2004 p. 2). However, Handy (2002) emphasised that accessibility is the measure of interaction potential, distinguishing that term from “mobility”, which is instead the ability to move or to be moved. In summary, accessibility can be defined as the ease of reaching a destination (Litman, 2011). Some common points emerge from this overview, which were established by Geurs and Van Wee (2004) as the four theoretical components of accessibility: transport network (supply), land use (supply, demand), temporal factors (demand), and individual characteristics (demand). Given the importance played by transport and mobility networks, PT can thus have a fundamental role in ensuring sustainable accessibility. Referring to accessibility and PT, can be interpreted as access to the PT system itself, or as access to the destination reached by the systems, or both (Olsson, Friman and Lättman, 2021). Accessibility to PT is becoming increasingly important in the design and evaluation of transport systems (Saif, Zefreh and Torok, 2018).

1.2 Accessibility: measures

Given the importance of accessibility, it is clear that the measurement of this concept is a fundamental issue. The traditional assessment methods are based on mathematical models and tools known as accessibility instruments (a collection of which can be found in Hull, Silva and Bertolini (2012)), which, however, encounter some limitations in the literature. Firstly, despite their usefulness, low use is detected, due to several barriers, namely political (focus on mobility instead of accessibility), organisational (lack of integration between transport and mobility planning), and institutional (lack of institutional framework) (Silva *et al.*, 2017). Secondly, these tools make aggregate measurements, seeing people as homogeneous, without considering individual capabilities (Pereira *et al.*, 2017). In fact, they evaluate objective measures such as (average) travel time and distance, not capturing the perceived accessibility of certain individuals or groups of people (Lättman, Friman and Olsson, 2016). Indeed, if travel time does not accurately reflect lived reality, spatial accessibility measures can hide access inequalities (Curl, 2018). Notably, such limit can also be considered as a limit to the concept of the "city of x minutes", as the actual travel times to reach a specific service can vary depending on the individual. These considerations have led to a growing interest in the user's point of view, and in the concept of "perceived accessibility". Given the importance that PT stops play in providing accessibility, both in urban and transport planning, the current paper reviews how the issue has been treated in research about perceived accessibility, with particular attention to the elements that can be included in the domain of urban planning.

2. Perceived accessibility: accessibility by the citizen's perspective

Citizen's perspective is not a brand-new subject. A paradigm shift has been called for by Handy and Niemeier (1997), who emphasised how accessibility must be based on how individuals perceive their surroundings and evaluate the aspects that are most important to them. Although various definitions of accessibility centre on transportation (see section 1), people-focused definitions do not lack. For instance, Kwan (1998) defined accessibility as "a property of people revealing how easily an individual can reach activity locations" (p. 192), while Bertolini (1999), describing "accessible areas", referred to places in which many people arrive and can perform different activities. Burgio and Maritano (2012) defined accessibility as "the capacity to access goods and services by a person" (p. 2), while Curl, Nelson and Anable (2015) referred to "the ability for people to reach destinations" (p. 87). These definitions, together, focus on people's ability to satisfy their needs (Huisman, 2005). Such concept has been expressed in various way in literature. Jehle *et al.*, (2022) identified four: "Experienced Accessibility" (Chorus and De Jong, 2011); "Self-Reported Accessibility" (Curl, Nelson and Anable, 2015; Ryan and Pereira, 2021); "Subjective Accessibility" (Damurski, Pluta and Zipser, 2020), "Perceived Accessibility". As the latter is the most used term (i.e. Lättman, Friman and Olsson, 2016; Ryan et al, 2016; Pot, Van Wee and Tillema, 2021), it will be used in this paper via the abbreviation PA. If centred on PT, PA can be referred as "how easy it is to live a satisfactory life using the transport system" (Lättman, Friman and Olsson, 2016, p. 36); while a broader definition can be "how individuals or groups of individuals understand or experience their own accessibility" (Jamei *et al.*, 2022, p. 4).

2.1 Perceived accessibility: implicit references

Although, as seen, the topic has been considered relevant for at least fifteen years, 85% of the research was carried out only in the last 10 years (ibidem). Research investigating PA can address the topic implicitly or explicitly. For instance, Delbosc and Currie (2011), investigated "transport disadvantage (…) measured using subjective, self-reported measurements" (p. 557). That is, how people report (and therefore perceive) the transport supply (and thus, the accessibility provided by it) of their area of residence in comparison with other regions. Additional implicit mentions are in research about the propensity to use specific transport modes (Roy and Basu, 2020; Raghuram Kadali, 2021), given that the intention of use PT is in fact directly linked to the accessibility of the system itself (Guglielmetti Mugion *et al.*, 2018). A greater propensity to use PT may imply a greater propensity to walk to the PT stop, thus further implicit references to PA may be found in research which compare the standard catchment areas of PT stops versus the ones perceived by the users (El-Geneidy, Grimsud and Wasfi, 2014). Broadening the concept of PA to the act of walking, implicit mentions of PA can be also traced back in the topic of perceived walkability (for a review, see De Vos *et al.*, 2023).

2.2 Perceived accessibility: explicit references

Given that PA research aims to address how accessibility is perceived by the users, explicit research on PA often focused on specific categories of citizens, namely weak users, including the elderly (i.e. Hess, 2012; Vitman-Schorr, Ryan and Pereira, 2021); women (Al-Rashid et al., 2021), disabled people (Sze and Christensen, 2017), reduced mobility people (Andrade et al., 2024) and minority (Chen, Wang and Wu, 2022). Another line of research aims to recognize the gaps between measured accessibility and perceived accessibility, having found the existence of such a gap (i.e. Curl, Nelson and Anable, 2015;). However, even research focused on PA

attempts in some way to describe the phenomenon by measuring it, loyal to Peter Drucke's the statement that "only what gets measured, gets managed" (Klaus, 2015, p.81). For such purpose, the most used measurement units are perceived travel time (i.e. Börjesson, 2012; Tiznado-Aitken *et al.*, 2020; Ryan and Pereira, 2021) and abstract indexes of PA such as the PAC (Perceived Accessibility Scale) developed by Lättman, Olsson and Friman (2016). However, it is possible to find additional methods in literature. For instance, some research describe PA through proxies like perceived distance (Hess, 2012) perceived utility (Coppola and Silvestri, 2018); probability to face a certain barrier (Sundling *et al.*, 2013); perceived Level of Service (LOS) (Campisi *et al.*, 2022). Such approaches to study PA are quantitative, but some exceptions emerge. In Andrade et al. (2024), the material collected from the interviews was analysed obtaining first-level categories and then organized by making a narrative description. Tiznado-Aitken *et al.*, (2020) applied a convergent mixed approach: a quantitative analysis, which resulted in accessibility maps based on origin/destination matrices, was accompanied by focus groups, the results of which were analysed with word clouds. Curl (2013) chose a qualitative approach, with extensive use of interviews and cognitive maps drawn by the interviewees.

2.3 Perceived accessibility and public transport

Since the strong relationship between accessibility and transportation (see section 1), unsurprisingly PT play a significant role in research about PA, both in PA *through* the PT or *towards* the PT. For instance, Lättman, Friman and Olsson (2016) asked to their surveyee their satisfaction degreed in reaching daily activities with PT, while Jehle *et al.* (2022) asked information about how train users reach train stations. Otherwise, if the PT is not the focus of the study, transportation in broader term play a role in research. Friman, Lättman and Olsson (2020) looked over PA to carpooling, while in Lättman, Friman and Olsson (2020), car use restriction effects on PA has been investigated. Vreeswijk *et al (*2014) explored route selections linked to the role of environment demonstrating that people choose their routes based on subjective considerations, like preferring linear or already known routes, even if longer.

3. Elements that influence perceived accessibility to public transport

Factors which influence PA can be clustered into four typologies: sociodemographic, transport related, personal, spatial. Research conducted so far demonstrate a clear correlation between PA and perceived safety and security of PT (i.e. Jones and Lucas, 2012; Lättman, Olsson and Friman, 2018; M. Friman, Lättman and Olsson, 2020), as well as between PA and perceived quality of PT (i.e. Lättman, Friman and Olsson, 2016; M. Friman, Lättman and Olsson, 2020; Lukina *et al.*, 2023). A positive correlation has also been demonstrated with personal aspects such as: attitude towards PT (van der Vlugt, Curl and Wittowsky, 2019; Pot, Van Wee and Tillema, 2021; van der Vlugt, Curl and Scheiner, 2022); the social narrative towards the different PT systems (Tiznado-Aitken *et al.*, 2020); emotions and memories (Curl, 2013); environmental consciousness (Cheng and Chen, 2015).

3.1 Sociodemographic factors

Some sociodemographic conditions have shown a certain correlation to PA, like the existence of disability conditions (i.e. Curl, 2018; Márquez, Poveda and Vega, 2019; Campisi *et al.*, 2022). Other factors, instead, show contrasting results. For example, some studies demonstrate that an advanced age is associated with a worsening of PA (i.e. Ryan *et al.*, 2016; Lättman *et al.*, 2019; Liu *et al.*, 2021). This result is not surprising, especially in studies where PA is

measured in perceived time and perceived distance (like in Curl, 2018 and Tiznado-Aitken *et al.*, 2020), as older people walk slower than youth. Yet, in some studies (i.e. Cheng and Chen, 2015; Lättman, Friman and Olsson, 2016; Campisi *et al.*, 2022) even young people perceive worse PA, while other studies do not see a correlation between PA and age (i.e. Ryan *et al.*, 2016; Lättman, Olsson and Friman, 2018; van der Vlugt, Curl and Wittowsky, 2019).

3.2 Spatial factors

People are guided by their perceptions, and perceptions of the environment shape mobility decisions representing the "lived reality" of accessibility (Van der Gluct ey al., 2022, p.1). Therefore, it could be expected that spatial context plays a fundamental role on PA. When referring to PA to PT, some research investigate the context through the concept of "barriers" (i.e. Sundling *et al.*, 2013). By "barriers to PT" are generally meant all those elements that impact accessibility to PT (Olsson, Friman and Lättman, 2021). They can be material (geographical location, location of stops, weather conditions) and immaterial (insecurity) (Tiznado-Aitken *et al.*, 2020). Van der Gluct et al., (2019) also stated that perceptions are influenced by aspects such as safety, atmosphere, a barrier-free environment. Since this review focuses on the spatial variables, a more comprehensive explanation is provided in the next section.

4. Spatial factors and their influence on perceived accessibility

Effects of spatial variables on PA can been clustered into three categories: perceived distance as a proxy of PA; place of residence; urban design. The first group include all the studies that focused on the concept of perceived distance, which in section 2 was described as one of the proxies for measuring PA. In fact, if perceived distances are shorter than actual ones, travellers can be encouraged to take trips towards destination, meaning that the destination is perceived as more accessible. In addition, even if studies often do not explicitly focus on PA, the approaches they use provide key findings regarding the influence of spatial variables on PA. The second group includes studies that have focused on differences between geographical areas (parts of cities, different cities, different types of settlements) while the third group contains research on the role of urban design elements such as sidewalks, furniture and lighting.

4.1 Perceived distance as proxy of perceived accessibility

Some research does not explicitly mention PA but investigates the gap between real distances and perceived distances. This approach can be particularly useful for determining the effective catchment area of PT stops. The conventional used radii (e.g. 400 m. for bus, 800 m. for metro) may in fact not correctly reflect the distances that people are willing to travel to reach a station. Therefore, a perceived catchment area larger than a traditional one may in fact indicate greater perceived accessibility to PT stops itself. Such approach has been carried out by El-Geneidy, Grimsud and Wasfi (2014), developing a methodology taking into account transportation, socio-demographic and neighbourhood variables. About the last category, they found that network density (e.g. number of nodes in the road graph) increased the service area, while density and vicinity to downtown decreased it. Other studies have been carried out by O'Sullivan and Morrall (1996) and by Sarker, Mailer and Sikder (2019), both demonstrating that stops in urban areas have a shorter range of action than those in extra-urban areas. Hess (2012) also investigated walking distance to PT stop, demonstrating that characteristics of built environment like density and network intersections have a strong impact in encouraging people

to walk further to reach the transit stop. Krizek, Horning and El-Geneidy, (2012) linked perceived distance to place of residence, showing that urban residents underestimate distances, while suburban residents underestimate them.

4.2 Place of residence

Interactions between spatial factors and PA has been, indeed, investigated through the urban/extraurban dichotomy. Such approach has been used by Curl, Nelson and Anable (2015): aiming at comparing objective and subjective measures of accessibility in the UK, they performed a GIS-based research using national census areas as study areas. The result showed that in urban areas, PA is higher than measured accessibility, while in rural areas the opposite situation occurs. Such result is consistent with Olsson, Friman and Lättman (2021) findings, who demonstrate that who live in urban areas perceive double accessibility than those who live outside. However, Vitman-Schorr, Ayalon and Khalaila (2019) obtained opposite results. They explored the direct and indirect effects of settlement type on PA, comparing urban and rural (kibbutzim) locations in Israel. They found a higher PA in rural areas due to higher security perception and more social participation, in turn due to a greater "sense of place" among the inhabitants. This suggests that the sense of belonging of particular communities such as Israeli kibbutzim may be a powerful determinant of perceptions of accessibility. Centre/periphery is another dichotomy that has been explored, for instance, by Lukina *et al.* (2021), who conducted a survey aimed to investigate possible links between PA and place of residence in Moscow, Russia. As reference study area, they used the 12 districts into which the Russian capital is divided. The results show that, contrary to what was expected, PA was not higher in the city centre district. Similar results were found by Chen, Wang and Wu (2022), who investigated role of built environment in perception among three disadvantage population (minority, poverty, elderly) in South Carolina, USA. Their analysis indicated that high and low values of PA can be found in both central and rural areas. However, the results change if the mode of transport is differentiated. Ceccato *et al*. (2020) compared perceived and measured accessibility in Turin, Italy, comparing cars and PT and visualizing data on a map. They pointed out that PA by car is greater in the periphery, while public transport PA is greater in the centre and along the metro corridors. The result confirms the strong role of the PT supply. Studies specifically focused on studying differences between neighbourhoods have not highlighted significant findings, as stated by Lättman, Olsson and Friman (2018): they compared PA between different residential areas of Malmö, Sweden, without finding significant differences between areas. Liu *et al.* (2021) conducted a survey in Kumning, China, investigating the relationship between the ease of using smartphone-based services, perceived accessibility, and perceived transport equity during COVID-19. Sociodemographic variables like age and car ownership showed a significant correlation, while place of residence no. These outcomes may be the result of a residential sorting mechanism, in which people tend to choose, as a place of residence, environments in which they can meet their preferences, as proposed by Pot, Koster and Tillema (2023). In fact, in their research focused on Dutch rural areas, they found that, across different regions, PA is five times less variable than measured accessibility. On the other hand, significant effects with place of residence were found by Tiznado-Aitken, Muñoz and Hurtubia (2021). The results of their survey in Santiago de Chile showed that distribution of opportunities is positively correlated to PA to PT. In fact, residents of areas with fewer opportunities experience lower levels of accessibility, having to make longer and less comfortable journeys. Other significant results can be found in Tiznado-Aitken *et al.* (2020). Their survey, always in Santiago de Chile demonstrates the a big impact of isolation: those who live in isolated areas

prefer to use the car or a combination of car and metro, rather than walking. Areas with few services or little traffic are in fact perceived as dangerous to cross. They also argue that a safe, friendly and attractive environment can therefore encourage PA. This argument leads to the next topic covered in the paper, that of urban design.

4.3 Urban design

Numerous studies highlight how urban design elements influence perceived accessibility. Security of built space has been investigated by Börjesson (2012) who, in order to assess the elements that contribute to security, focused on how secure people felt in urban environments when walking. Findings show that security is a significant component to PA to PT, particularly for women. This result is consistent with Lotfi and Koohsari (2009), who analysed PA to neighbourhood activities in two different districts of Teheran, finding that fear and crime have strong impacts to PA. Another element that has a positive impact on PA is directness, i.e. how direct a path from A to B is. Vreeswijk *et al.* (2014) demonstrated that the perception of travel time depends on road hierarchy and route directivity, as the most direct routes and those higher in the hierarchy were perceived as relatively fast. Curl (2013) identified some factors which links environment and the sphere of emotions and sensations, such as pleasantness and beautifulness, finding positive correlation with PA. On the other hand, complexity of urban space has a negative influence, as due to a more complex landscape, travellers remember more elements of their route, leading them to perceive longer distances (Krizek, Horning and El-Geneidy, 2012). Notably, according to Jehle *et al.* (2022), a "stimulating" surroundings has no effect in encouraging people to walk. However, an important role is played by the quality of pavements and pedestrian paths,

Reference	**Spatial factor**	**Correlation with PA**
El-Geneidy, Grimsud and Wasfi, 2014; Hess, 2012 O'Sullivan and Morrall, 1996; Sarker, Mailer and Sikder 2019	Perceived distance from PT stops (urban areas)	Negative

Table 1. Spatial factors affecting PA to PT

(i.e. Cheng and Chen 2015; Andrade et al. 2024), thus linking the theme of PA to that of walkability. Campisi et al. (2022) focused on factors that affect perceived level of service (LOS) of sidewalks in Thessaloniki, Greece, finding that a smooth walking environment has a positive correlation with PA. Curl and Mason (2019) examined the role of walking as a mediator between older people's mental wellbeing and their perceptions of their built and social environment in deprived urban areas. They found a relationship between neighbourhood perception and wellbeing. De Vos et al. (2023) conducted a systematic literature review on perceived walkability, finding that characteristics related to the built environment, such as neighbourhood aesthetics and paving's quality, have effects on perceived walkability. Jehle et al. (2022) explored the topic of pedestrian accessibility, which can be defined as "the ease with which certain destinations can be reached by walking" (p. 1). They conducted a survey with the specific aim to investigate PA by walk to six train stations in six German cities. Results shows that aspects related to the built environment such as the directness of the path to the station, walking comfort (e.g. wide and continuous footpaths), traffic safety and street security have strong impacts. In addition, they observed significant differences between cities according to their size: in smaller cities people are more likely to walk to reach the train station.

5. Final reflections: findings and gaps

The studies presented in this review have focused on correlations between PA and different variables, mostly through quantitative methods. In this way, significant links were identified between PA and the quality of PT, as well as between PA and perceived safety. However, correlations with spatial factors are less clear: this result is quite unexpected, given the emphasis that accessibility models give to land use (see section 1). Starting specifically from these models, some authors deduct a very strong role of land use and environment of PA: for instance, conceptualising PA as a "function of perceptions on the distribution and characteristics of

activities, transport and temporal feasibility of seizing these opportunities through the transport system" (Pot, Koster and Tillema, 2023, p. 3).

5.1 Contradictions about distance from city centre

Contradictions emerge by comparing the results of research that focus on perceived distance and studies that investigate the role of residence through the urban/extraurban dichotomy. The first group of studies highlights how, in areas further away from the city centre, the real service area of PT stops increases, while the second group highlights how, in urban areas, the PA is greater than in extra-urban areas. If perceived distance is considered as a proxy for PA, then the first group of studies seems to associate a negative correlation between urbanity and PA, while the second group of studies identifies a positive correlation. However, two aspects need to be considered. Firstly, in central areas, the PT coverage is typically more extensive, thereby reducing the necessity for individuals to walk in order to reach the stops. Secondly, the perceived distances are a function of the time it takes to travel them. Consequently, in less dense (and less congested) areas, it is possible to travel a greater distance in the same amount of time, which leads to an underestimation of perceived distances and an increase in the actual catchment areas. Consequently, the use of perceived distance as a measure of perceived accessibility may not be the most accurate approach.

5.2 Inconclusive results about place of residence

Research that focuses on differences between places of residence does not highlight significant associations with PA. However, the study areas considered in such research are very large, and therefore presumably very heterogeneous within them, like the districts of Moscow (Lukina *et al.*, 2021), the Dutch municipalities (Pot, Koster and Tillema, 2023), the counties of South Carolina (Cheng and Chen, 2015). Consequentially, it is suggested that future research on this topic should be conducted in smaller study areas, selected through qualitative criteria and not using administrative subdivisions. Furthermore, future research could consider not only the place of residence (origin), but also the place of destination, focusing the surveys among subjects such as workers of specific firms, as well as school students, shop customers, and other frequenters of activities located in a defined area. Similar approach can be found in Damurski, Pluta and Zipser (2020), where the study areas were selected through an inventory process and where the survey concerned not only residents but also users of public spaces.

Figure 1. Location of the reviewed case studies

Figure 2. Location of the reviewed case studies, focus on Northern Europe

5.3 Emerging spatial factors

It has been observed that the role of spatial factors emerges under two conditions. The first condition is that PA is measured through perceived time as in Börjesson (2012), Vreeswijk *et al.* (2014), Ceccato *et al.* (2020), Tiznado-Aitken, Muñoz and Hurtubia (2021), Jehle *et al.* (2022), rather than through indexes that contain a high level of abstraction within. The second condition is the use of mixed - qualitative and quantitative - approaches, as exemplified by Curl (2013) and Tiznado-Aitken *et al.* (2020), in order to more effectively capture users' perceptions of the built environment. Indeed, the representation of the environment carried out through quantitative and numerical terms (such as density), or through dichotomies does not always demonstrate to be sufficient. It is also important to consider that the majority of the studies were conducted in Northern European cities, which are characterised by a high presence of transit-oriented development (TOD) such as Stockholm and Copenhagen (Papa and Bertolini, 2015). It is noteworthy that the role of the place of residence clearly emerges in the research conducted in Santiago de Chile, a city characterised by pronounced spatial inequalities. Future research conducted outside Northern Europe could lead to consolidate these findings. A comparison of PA between TOD and not TOD neighbourhood could lead to significant results, Additionally, a comparison between case studies in different areas of the world, perhaps including cultural characteristics of residents (as also highlighted by Lukina *et al* 2021), could be beneficial.

5.4 Lack of emphasis on public transport stop

Finally, a significant gap in the literature is the relative lack of relevance, outside of studies focused on catchment areas, of PT stop. Although numerous studies have focused on PT, or consider PT as a key element, the stop is often considered a mere element of the transport network, and not the object of the investigation (notable exceptions are Ryan *et al.*, 2016; Jehle *et al.*, 2022). This discrepancy is in contrast with the fundamental role that the stop play in the context of accessibility (see section 1), and future research could consider the PT stop as an element of urban space (and thus as a spatial element) rather than a mere transportation node (as suggested by Vitale Brovarone, 2021).

5.5 Final conclusions

The research conducted to date has highlighted a gap between measured accessibility and perceived accessibility (PA). Moreover, there is substantial evidence indicating a strong

correlation between PA and the perception of PT and perceived safety, as well as with certain sociodemographic factors (e.g., disability) and attitudinal conditions. However, the role of the spatial factors remains less clear, with some research suggesting an influence and others finding no significant correlations. It is therefore proposed that, future research should focus on the following aspects, in order to address the aforementioned gap:

- describing PA through time perceived by people rather than through perceived distance or abstract PA indexes;
- analysing study areas described with qualitative rather than quantitative terms;
- collecting data and information with mixed quantitative-qualitative methods;
- focusing not only on the place of residence but also on the destination;
- isolating the PT stop as an element in its own right, also considering its role as spatial element;
- extending the research beyond the geographical areas explored so far.

Such research could assist in elucidating the manner in which urban planning decisions can guide the perceived accessibility of PT, thereby identifying potential new ways of dialogue between urban and transport planning disciplines.

Abstract (up to 125 words)
In response to societal shifts towards green and digital transitions, urban mobility emerges as a pivotal arena for change, influencing behaviour, transportation modes, as well as urban planning policies. This paper investigates the role of CityWalk 2.0 project in promoting energy-efficient urban mobility and shifting urban transport systems from car-centric to active mobility modes. Firstly, a literature review is conducted to define a framework for categorising different practices that promote active mobility. Secondly, a comparative analysis was conducted between three CityWalk 2.0 pilot cities. Despite the distinct local contexts, the results showcase the evident impact of 'soft' and 'hard' actions across various dimensions. Common walkability issues related to regulation and street design, as well as the elevation of pedestrians and cyclists to the apex of the "traffic pyramid" are highlighted in the cities' approaches to sustainable urban mobility. In conclusion, the paper provides essential guidelines for reshaping the discourse on urban mobility transformations in the 21st century.

Keywords: urban transportation, street redesign, travel behaviour, urban mobility policies

1. Introduction

In the context of the twin green and digital transition, urban mobility emerges as a driving domain for transformation (Schipper et al, 2020). A new paradigm raises around the concept of sustainable urban mobility, leveraging technological advancements and societal changes. This shift significantly impacts not only behavioural patterns and transportation modes but also shapes urban planning policies (Van Acker et al, 2016).

Urban mobility plays a pivotal role in shaping the sustainability and liveability of cities worldwide. In accordance with the European transport legislation, concerted efforts are directed towards achieving a competitive and resource-efficient transport infrastructure to align with the ambitious objectives outlined in the 2030 climate and energy framework, namely the reduction of greenhouse gas emissions by at least 40% compared to 1990 levels, the increase of energy efficiency by at least 32.5% and the increase of energy from renewables by at least 32% (EC, 2011; EC, 2013). Considering the significant proportion of European citizens residing in urban areas and the projected exponential growth of the urban population globally, estimated to surpass two-thirds of the world's population by 2050, urbanisation challenges need to be urgently addressed (UN, 2019). The exponential rise in urban population necessitates a heightened emphasis on sustainable urban mobility, as current transportation systems heavily dependent on cars causes harmful environmental effects, health risks, and a deficiency of quality public spaces in the urban context (Schipper, 2002).

Firstly, the dominance of conventional modes of urban transport, notably car-centric mobility, exacerbates these challenges, posing significant obstacles to environmental, social and economic sustainability. European cities are progressively adopting Sustainable Urban Mobility Plans (SUMP), which advocate for walking, cycling, public transportation and shared mobility services as substitutes for private car usage (Maltese et al, 2021). Generally, SUMPs tackle issues stemming from excessive car traffic, including congestion, air pollution, noise, CO2 emissions, compromised road safety and decreased physical activity levels among residents (Hudoklin et al, 2021).

Secondly, the well-being of residents is highly impacted by car traffic dominance, leading to congestion and safety hazards. Moreover, current transportation systems, heavily reliant on automobiles, contribute to adverse environmental effects, health concerns and a lack of high-quality public spaces, greenery and public amenities within urban areas (Schipper, 2002). In this context, active urban mobility emerges as a compelling solution to mitigate the adverse impacts of car-dependent transportation systems. Active forms of mobility, such as walking, cycling, and micro-mobility offer a promising pathway towards achieving sustainable urban transportation. These modes of travel not only reduce reliance on fossil fuels, but also promote public health, enhance urban liveability and foster community cohesion. Through empirical research and data-driven analysis, cities can unlock the full potential of street experiments as powerful tools for fostering sustainable urban mobility (Bertolini, 2020).

Upon this background, the CItyWalk 2.0 project emerges as a beacon of innovation and collaboration, building upon the legacy of its predecessor, CityWalk (2016-2019), to pioneer new pathways towards energy-efficient urban transport. At its core, CityWalk 2.0 seeks to catalyse a paradigm shift in urban mobility, steering cities away from the entrenched reliance on energy-intensive automobile-centric systems towards a more sustainable and resilient future. The project aims to become a catalyst for transformative change in urban mobility in 10 pilot cities located in the Danube Region, particularly in the Central and Eastern part of Europe. By advocating for specific policy changes at both local and transnational levels, CityWalk 2.0 aims not only to reduce the energy footprint of urban transport, but also to foster a global network of decision-makers committed to sustainable mobility.

Literature shows that addressing the root causes of car dependency requires a multifaceted approach that extends beyond the realm of physical infrastructure and encompasses not only technological innovations, but also behavioural change interventions (García-Garcés et al, 2016). Therefore, key elements of CityWalk 2.0 include redesigning streets to encourage active mobility and discourage car use, changing the travel behaviour of citizens and strengthening the political will and commitment to implement the transformation.

Central to fostering sustainable urban mobility is the imperative to prioritise pedestrians' needs and create inclusive environments. Achieving this demands a delicate balance, ensuring equitable distribution of urban space, while enhancing conditions for walking and active transportation. By adopting a holistic approach and leveraging universal design principles, cities can cultivate socially inclusive, pedestrian-friendly spaces. Simultaneously, evaluating city street experiments and integrating ‘soft’ and ‘hard’ measures unlocks synergistic effects, propelling sustainable mobility initiatives forward and shaping resilient urban ecosystems capable of meeting diverse community needs (Anciaes and Jones, 2020; Bertolini, 2020; García-Garcés et al, 2016).

2. Methodology

The present research is conducted within the framework of the CITYWALK 2.0 project, funded under the Interreg Danube program. The project entitled "Together for Energy-efficient Urban Mobility: Decreasing Carbon Intensity of Urban Transport by supporting Shift to Active Urban Mobility through rethinking street design and changing travel behaviour" started in January 2024, building upon the foundation laid by its predecessor, CITYWALK project.

The main objective of this paper is to investigate the impact of CITYWALK 2.0 project in promoting energy-efficient urban mobility and shifting urban transport systems from car-centric to active mobility modes. Specifically, the paper highlights measures to effectively reduce carbon emissions, based on the interventions tested by three pilot cities: Nyiregyhaza (Hungary), Ptuj (Slovenia), and Valjevo (Republic of Serbia). Given the diverse geographical and cultural landscape of Central and Eastern Europe, it is crucial to acknowledge the prevailing mentality and rigidity towards change. Moreover, cultural factors also play a significant role in shaping attitudes towards change in Eastern European cities. Deep-seated cultural values, such as a preference for private car ownership as a symbol of status and independence, can pose challenges in promoting alternative and more sustainable transportation systems.

Data collection and analysis for this research were conducted through a multifaceted approach. Firstly, an extensive literature review was undertaken to synthesise existing knowledge and identify gaps in understanding the existing body of knowledge related to sustainable urban mobility practices. Based on the findings, this paper proposes a categorisation framework of different practices that fall under two main categories: street redesign (‘hard’ interventions) and travel behaviour change (‘soft’ intervention). Additionally, qualitative methods such as case studies were conducted to gather insights into the methods and pilot actions employed to stimulate a transition towards active mobility in the three Central and Eastern European cities (Nyiregyhaza, Ptuj and Valjevo). Finally, the paper suggests a list of policy recommendations for cities which pursue the objective of decreasing carbon intensity of urban transportation systems. Overall, this methodological approach enabled a robust exploration of the role of street experiments as potential triggers of systemic change in urban mobility, with a focus on moving away from motorised traffic dominance towards non-motorized travel.

3. Literature review

Based on the existing literature, this paper provides a conceptual framework for categorising transformations in sustainable urban mobility, based on current theories, concepts and practices. Urban mobility is not merely a transportation issue, it is also intricately linked to broader societal and environmental challenges. Planning for sustainable mobility typically involves fostering efficient transportation options that enhance competitiveness while simultaneously mitigating air and noise pollution, including the reduction of greenhouse gas emissions.

Existing literature highlights a notable increase in research dedicated to active mobility, coupled with the development of conceptual frameworks aimed at guiding interventions (Koszowski et al, 2019). The concept of active mobility, also known as active transportation, encompasses modes of transportation reliant on human power, notably including walking and cycling, utilised for various travel purposes (Kong et al, 2024). They advocate for the integration of active mobility into daily routines, insisting that cities should prioritise the development of infrastructure conducive to walking and

cycling. This approach embodies an urban planning ethos centred on prioritising the needs of people over specific modes of transportation. The most efficient and cheapest way is to shift from extremely energy-intensive (and inefficient) car-based mobility to active forms of mobility (walking, cycling), with micro-mobility and public transport as the primary means of transportation. Generally, strategies for facilitating a modal shift towards active transport focus on reallocating road space and creating pedestrian and cyclist-friendly environments, such as safe and extensive networks of bike lanes, pedestrian paths and accessible public spaces (Ferretto et al, 2021; Kong et al, 2024).

The literature also emphasises the positive impacts of active mobility on various aspects including health, safety, life quality, economy, environment and air quality (Koszowski et al, 2019; Ferretto et al, 2021; Pisoni et al, 2022; Kong et al, 2024). However, there are several factors which determine the adoption of active mobility, such as the built environment, infrastructure development, user perceptions and individual health (Rojas López and Wong, 2017; Ferretto et al, 2021). Psychological and neighbourhood variables play a significant role in influencing individuals' mobility behaviour, highlighting the need for comprehensive urban design tools to create healthier urban environments (Götschi et al, 2017; Said et al, 2021).

Various transportation policy measures have proven beneficial in encouraging a shift from car use to public transportation or environmentally friendly modes such as walking or cycling (García-Garcés et al, 2016). Concretely, these measures vary from reallocating road space to accommodate pedestrian and cyclist-friendly urban settings (Ferretto et al, 2021) to Travel Behaviour Change Programmes. These initiatives are designed to incentivize individuals to reduce their reliance on cars, particularly for single-occupancy trips. Numerous societal and individual benefits have been demonstrated when walking or cycling replaces car use. Such programs encompass personal travel planning, travel awareness, campaigns, workplace or educational institution travel plans and strategies like car-sharing.

There is a wide range of concepts and theories that address the issue of active mobility, always placed into two basic categories, commonly referred to as ‘hard’ and ‘soft’ interventions (Anciaes and Jones, 2022; Bertolini, 2020; García-Garcés et al, 2016). The first category of ‘hard’ interventions refers to street redesign, involving tangible alterations to the physical infrastructure. The second category of ‘soft’ interventions refers to travel behaviour change, which targets individual habits and choices. These interventions offer distinct yet synergistic avenues towards achieving safer, more efficient and equitable urban transportation systems.

3.1 ‘Hard’ interventions - Street redesign

Street redesign refers to a process of altering the physical layout, infrastructure and amenities of roads and streets within urban or suburban areas. This approach aims to improve various aspects of street function, such as safety, accessibility and efficiency. Street redesign projects often involve modifications to road geometry, traffic flow patterns, signage and markings, pedestrian infrastructure, cycling facilities, landscaping and street furniture (Lahart et al, 2013; Anciaes and Jones, 2022).

In numerous urban centres, a sustained trend is emerging towards allocating increased space for pedestrians, reflecting a novel paradigm in transportation and urban governance centred on promoting health, well-being and urban liveability (Anciaes and Jones, 2020). The reconfiguration of streets to prioritise pedestrian access yields

various advantages, encompassing enhancements in local economic communities and environmental sustainability (Bertolini, 2020).

Street redesign has the potential to achieve greater cost-efficiency by addressing driver behaviour, thereby effectively managing traffic speeds. Enhanced public spaces not only instil a sense of civic pride, but also attract private investment, thus stimulating employment opportunities and enhancing commercial and retail activity. Promoting pedestrian and cyclist-friendly environments, accessible to individuals of diverse ages and physical abilities, fosters street vitality and social interaction (Tmou and Rodi, 2023). Moreover, prioritising improved street redesign contributes to enhanced value for investment towards social inclusivity (Lahart et al, 2013).

Several subcategories of possible interventions fall under the street redesign measures, each serving distinct purposes within the urban planning and transportation policies (Figure 1).

(1) *Pedestrian-only streets*, designated exclusively for pedestrian traffic, not only encourage walking and active transportation, but also contribute to community cohesion and economic vitality when used as public spaces which accommodate certain activities (Lahart et al, 2013; Bertolini, 2020). (2) *Shared space streets* eliminate barriers hindering movement between transportation modes, cultivating vibrant urban environments with outdoor activities for children and pleasant spaces for walking and cycling (Lahart et al, 2013; Peters, 2017). Another requirement for streets to become shared spaces in residential areas is to host less than 100 vehicles per hour during the afternoon peak (Hamilton-Baillie, 2008). (3) The transformation of boulevards from main roads focuses on revitalising *avenues* to prioritise aesthetics, pedestrian-friendly infrastructure and versatile utility, serving their initial scope (Jacobs et al, 2002). (4) *Promenades* serve as expansive avenues, blending leisure walking with recreational activities, offering lively environments for public activities (Miaux and Garneau, 2016). (5) *Low-speed streets and slow zones* aim to reduce injuries and enhance safety and comfort for non-motorized users by reducing vehicle speed limit up to 30 km/h and prioritising pedestrians and cyclists (Neki et al, 2021). Moreover, traffic calming interventions include adjustments to road geometry, such as horizontal and vertical modifications, as well as lane narrowing and insertion of slow zones near sensitive land uses like schools or parks. (6) *Parklets* repurpose on-street parking spaces into (semi-)public areas for alternative uses, promoting walking, cycling, social interaction and economic activity (Speck, 2018; Bertolini, 2020). Parking-space installations gather basic structures that provide amenities such as seating, bike racks, public art or exercise equipment. (7) *Cycling infrastructure* optimises the use of limited public space, mitigates climate change, and improves accessibility, emphasising systemic interventions to cultivate sustainable transportation environments (Hofmeister and Stibe, 2017; Tosics et al, 2022). (8) *Urban signage* embodies various codes and elements such as architectural, compositional, graphical, colour, to guide movement and facilitate a user-friendly navigation within cities (Sokolova, 2018). (9) *Urban furniture/ amenities* encompass aesthetic and comfort-oriented elements that contribute to city liveability, comfortable and secure environment, urban identity and guide movement through elements such as public art, lighting, seating and bicycle parking amenities (Lahart et al, 2013; Bolkaner et al, 2019).

Street redesign		
Sub-category	**Definition**	**Source**
Pedestrian-only streets	Pedestrian-only streets, designated exclusively for pedestrian traffic, not only encourage walking and active transportation, but also contribute to community cohesion and economic vitality when used as public spaces which accommodate certain activities.	Lahart et al, 2013; Bertolini, 2020
Shared space	Shared space streets eliminate barriers hindering movement between transportation modes, cultivating vibrant urban environments with outdoor activities for children and pleasant spaces for walking and cycling.	Lahart et al, 2013; Peters, 2017; Hamilton-Baillie, 2008
Boulevards from main street	Boulevards are broad streets that divide large urban areas into connected zones, acting as a barrier between the edges of commercial or residential streets and fast-moving traffic lanes. They achieve this by incorporating multiple lanes and frontage roads.	Jacobs et al, 2002
Promenades	Promenades serve as expansive avenues, blending leisure walking with recreational activities, offering lively environments for public activities	Miaux and Garneau, 2016
Low speed-limit street	Low-speed streets and slow zones aim to reduce injuries and enhance safety and comfort for non-motorized users by reducing vehicle speed limit up to 30 km/h and prioritising pedestrians and cyclists.	Neki et al, 2021
Parklets	Parklets can be defined as the temporary transformation of on-street parking spaces into semi-public areas by installing simple structures like seating, bike racks, public art, or exercise equipment.	Bertolini, 2020; Speck, 2018
Cycling infrastructure	It contributes to maximizing the use of limited public space, addressing climate change, reducing air and noise pollution, promoting public health, and enhancing overall accessibility.	Tosics et al, 2022; Hofmeister and Stibe, 2017
Urban signage	An urban sign integrates various elements like verbal, architectural, graphic, and pictorial aspects, reflecting a pressing concern in modern urban planning, requiring an interdisciplinary approach.	Sokolova, 2018
Urban furniture	Urban furniture encompasses aesthetic and comfort elements that reflect a city's identity and enhance urban livability by improving comfort and meeting resident needs.	Bolkaner et al, 2019; Lahart et al, 2013

Figure 1. Categorisation framework for interventions that encourage active mobility: 'hard' interventions (source: authors)

3.2 'Soft' interventions - Travel behaviour change

Without any doubt, robust infrastructure is pivotal in urban planning to reduce individual car dependency. Despite vital elements like public transport networks, pedestrian-friendly infrastructure and cycling facilities, addressing transportation behaviour complexity is crucial. Human behaviour significantly shapes travel patterns, often maintaining car reliance despite alternative options. Changing this behaviour requires diverse interventions such as awareness campaigns, modal shift incentives, education and policies encouraging alternative travel modes. While infrastructure forms the backbone, a comprehensive approach addressing social, cultural and psychological factors is key to achieving meaningful behaviour change.

In addition to altering the travel environment, behavioural strategies like mobility management have been implemented to raise awareness and influence psychological factors, encouraging voluntary shifts from car dependency to non-auto travel modes. These strategies often involve providing tailored information on public transportation, launching travel campaigns and offering travel education programs (Fujii and Taniguchi, 2014).

Several subcategories of possible interventions fall under the travel behaviour change measures, each targeting distinct aspects of individual and collective transportation choices (Figure 2).

(1) *Educational campaigns* represent an encouragement strategy for active mobility, aimed at raising awareness of multimodal and sustainable travel practices (Haufe et al, 2016). (2) *Zoning regulations* delineate permissible land use and operational activities to shape transportation patterns within comprehensive master or zonal plans (Chriqui et al, 2016). (3) *Parking policies* aim to optimise parking utilisation and turnover, often through strategies such as time restrictions, paid parking zones and

workplace parking fees to discourage car commuting (Tosics et al, 2022). (4) *Congestion pricing* aims to align driving costs with demand dynamics. This mechanism typically involves elevating the cost of driving on congested routes or within densely populated downtown areas to better reflect demand patterns, thereby incentivizing the use of alternative modes of transportation (Speck, 2018). (5) *Incentives and rewards* engage stakeholders in tracking and rewarding sustainable mobility habits, encouraging sustainable travel behaviour through a system of rewards facilitated by merchants and mobility service providers, often employing ICT technologies to monitor citizens' mobility habits - i.e. GPS tracking systems (Ricci et al, 2020). (6) *Behavioural nudges* represent subtle interventions designed to influence individuals' transportation choices and encourage more sustainable travel behaviours by providing information and manipulating specific factors to encourage desired outcomes (Barr et al, 2021). (7) *Technology solutions* promote alternatives to single-occupancy vehicle trips. These solutions encompass various techniques, including sensor-driven lighting, enforcement and security measures, as well as real-time data collection, all aimed at enhancing street efficiency and encouraging sustainable travel practices (Duncan et al, 2016). Together, these interventions form a comprehensive toolkit for fostering behavioural change and promoting more sustainable urban mobility patterns.

Travel behaviour change		
Sub-category	**Definition**	**Source**
Educational campaigns	) Educational campaigns represent an encouragement strategy for active mobility, aimed at raising awareness of multimodal and sustainable travel practices.	Haufe et al, 2016
Zoning regulations	Zoning regulations delineate permissible land use and operational activities to shape transportation patterns within comprehensive master or zonal plans.	Chriqui et al, 2016
Parking policies	The parking policy, within an organization, is the set of regulations governing parking lot management. Its aim is to improve parking management through the implementation of diverse strategies and functions, tailored to address specific challenges as they arise.	Tosics et al, 2022
Congestion pricing	Congestion pricing is a strategy aimed at aligning the cost of driving with its inherent value by increasing fees for driving on congested roads or within densely populated downtown areas, thus reflecting demand dynamics more accurately.	Speck, 2018
Incentives and rewards	An incentive-based solution in the mobility sector entails a specialized business model centered on a tracking and reward system involving four primary stakeholders: citizens, municipalities, merchants, and mobility service providers.	Ricci et al, 2020
Behavioural nudges	Behavioural nudges in Travel Behaviour Change encompass subtle interventions strategically crafted to sway individuals' transportation decisions and foster the adoption of more sustainable travel behaviours.	Thaler and Sunstein, 2008; Barr et al, 2021
Technology solutions	These solutions utilize advancements in information technology, data analytics, and communication to shape travel behavior and advocate for alternatives to single-occupancy vehicle trips.	Duncan et al, 2016

Figure 2. Categorisation framework for interventions that encourage active mobility: 'soft' interventions (source: authors)

Integrating 'soft' and 'hard' measures maximises effectiveness in driving cities towards sustainable mobility patterns, mitigating the adverse effects of car reliance and promoting a culture of sustainable mobility (García-Garcés et al, 2016). Therefore, the combination of street redesign actions, targeted incentives, educational campaigns and zoning regulations offers a powerful tool for encouraging active mobility and discouraging car use, changing the travel behaviour of citizens, as well as strengthening the political will and commitment to implement the transformation. As such, CityWalk 2.0 project relies upon these elements in its approach to promote energy-efficient urban mobility, encompassing interventions at both the city and citizen levels. Moreover, the project aims to stimulate political will and commitment to drive

systemic change, recognizing that effective urban mobility transformations require a collective effort from policymakers, stakeholders and the broader community.

4. Case studies of Active Mobility interventions in CityWalk 2.0 Pilot Cities (Nyiregyhaza/ HU, Ptuj/ SL, Valjevo/ RS)

The CityWalk 2.0 project has brought together a consortium of pilot cities to explore innovative approaches aimed at promoting sustainable urban mobility and enhancing the pedestrian experience. Across diverse urban landscapes, these pilot cities have embarked on a collective journey to reimagine streets as vibrant public spaces, prioritising the needs of pedestrians and fostering active transportation modes. Through collaborative efforts, each pilot city has implemented in CityWalk project a unique set of strategies and interventions tailored to its specific context and mobility challenges, continuing these efforts in CityWalk 2.0. The three selected case studies namely Nyiregyhaza (Hungary), Ptuj (Slovenia) and Valjevo (Republic of Serbia) (Figure 3) implemented actions in CityWalk and proposed a set of actions for CityWalk 2.0 which cover the two main intervention categories, respectively street redesign and travel behaviour change.

4.1 Active mobility in Nyiregyhaza, Hungary

Nyíregyháza, located in northeastern Hungary, holds the status of a city with county rights and serves as the capital of Szabolcs-Szatmár-Bereg. With a population of around 118.000 residents, it holds the seventh position among Hungary's largest cities and it is the second largest in the Northern Great Plain region. Its historical evolution positions it as a significant economic and cultural centre in the area. Nyíregyháza developed the Sustainable Urban Mobility Plan in 2018, which sets the proper context for the CityWalk objectives. Its main actions include the completion of walking and cycling infrastructure and the induction of zoning regulations.

Firstly, the 'Downtown Pedestrian Streets' project in Nyíregyháza addressed the challenge of excessive car use in the city centre, leading to air pollution and traffic accidents. The solution involved a comprehensive pedestrianisation effort spanning from 1987 to 2012. The downtown area was transformed into a car-free pedestrian corridor adorned with green spaces, restaurants, cafes, fountains and sculptures. This created a peaceful urban oasis suitable for outdoor events and featuring Hungary's largest bridge between buildings. Emergency and cargo vehicles are the only authorised vehicles, ensuring barrier-free traffic for pedestrians and cyclists. The investment resulted in decreased car traffic, greener and safer surroundings, attracting more pedestrians and cyclists who contribute to the local economy by frequenting restaurants and outdoor cafes.

Secondly, the purchase of technological equipment for passenger counting (sensors) and user feedback (tablet with suitable software) is vital for the pilot activity in Nyíregyháza. It aims to assess public transport utilization and user experiences, with the goal of improving public transport service quality. The pilot seeks to provide the city with current data on public transport usage and gather feedback on satisfaction, problems and needs. Ultimately, it aims to boost public transport usage indirectly. The device will be deployed on local government-owned buses operated by Volánbusz Zrt, promoting a change in the citizens' travel behaviour.

4.2 Active mobility in Ptuj, Slovenia

The city of Ptuj, situated in northeastern Slovenia, serves as the administrative center. As Slovenia's oldest documented city, Ptuj traces its roots back to the late Stone Age and evolved from a Roman military stronghold. Positioned strategically at the intersection of the Drava River and a historic trade route linking the Baltic Sea with the Adriatic, Ptuj holds significance in the traditional region of Styria and was historically part of the Austria-Hungarian Empire. The Municipality of Ptuj adopted in 2017 the Sustainable Urban Mobility Plan for the Maribor Functional Urban Area, of which it is a part. The main objectives of SUMP are: (i) to have a better traffic planning and management (ii) to promote walking as one of the most important ways of travelling, (iii) to further promote cycling and creation of additional cycling infrastructure in the city, (iv) to improve public transport to be more appealing and (v) to enforce rational use of motorized vehicles (Letnik et al, 2019).

In the first CityWalk project, Ptuj focused on a single action, combining both street redesign actions such as completion of pedestrian streets (walking infrastructure) and low speed-limit streets with zoning regulations that encourage travel behaviour change. The renovation of Ptuj's city marketplace, completed in 2020, addressed limited pedestrian accessibility due to interior and exterior poor conditions. The comprehensive solution included renovation, new facility establishment and traffic regulation adjustments. The outcomes of this actions were increased attractiveness, equitable access, as well as cultural and economic stimulation.

For CityWalk 2.0, Ptuj City pilot investment will introduce an innovative strategy to tackle travel behaviour challenges and gather insights beneficial to the program area. With a focus on enhancing pedestrian infrastructure, encouraging walking, minimising car dependency and fostering behaviour change, this small-scale initiative aims to advance urban mobility development. The proposed intervention will promise a fresh visual identity for the city while enhancing safety and mobility for residents and tourists alike through the implementation of parklets, urban furniture/ amenities and behavioural nudges. By addressing traffic concerns, it aims to cut CO2 emissions caused by congestion. This initiative will highlight the power of urban design and small interventions to enrich an area and address various issues resulting from neglectful urban development.

4.3 Active mobility in Valjevo, Republic of Serbia

Valjevo serves as both a city and the administrative hub of the Kolubara District in western Serbia. As of the 2022 census, the administrative region of Valjevo boasted a population of 82.169 residents, with 56.145 residing in urban areas. The Sustainable Urban Mobility Plan for Valjevo was designed under the first CityWalk project and it aims to enhance walking conditions to reduce emissions, noise and enhance safety, fostering sustainable urban transport, particularly walking and cycling (Danilović and Đorić, 2020).

Within the first CityWalk project, the City of Valjevo focused on traffic calming measures, urban signage and furniture, as well as zoning regulations. Therefore, a pilot action for active mobility was undertaken to enhance the city's walkability and promote healthier lifestyles. This initiative encompassed the design and implementation of thematic walking routes, accompanied by clear signage and signalization for pedestrians, cyclists, and tourists. Furthermore, recognizing the need to educate citizens on traffic safety and the benefits of walking and cycling, a series of educational workshops and promotional events were organized.

The pilot action envisaged by the City of Valjevo in CityWalk 2.0 project refers to tactical urbanism and street design interventions, aimed to regulate pedestrian, bicycle and vehicles traffic and parking, enhance mobility, increase safety and improve the appeal of the Valjevo's central area. By implementing innovative solutions, the city centre will benefit from reduced emissions, green areas and infrastructure dedicated to walking and cycling. The main challenge addressed by the Čika Ljubina Street refers to the lack of organisation and usage regulations for pedestrian, bicycle and car traffic intersections. The proposed action will renovate the physical infrastructure and green areas, differentiating between car and pedestrian routes and includes horizontal markings for pedestrian pathways. Additionally, the city will acquire equipment like solar decorative lighting, vertical signalling, traffic calming devices and bicycle parking facilities. Upon completion, the area will be more walkable, attractively designed, safer and friendlier for pedestrians and cyclists.

4.4 Comparative analysis

Despite the distinct local contexts of these cities, positive outcomes have been demonstrated through actions such as improvements in traffic safety, adoption of active mobility means and diversified transport modes. The three pilot's concepts, methodologies and tools can be replicated or adapted in other EU cities facing similar challenges, accelerating efforts to improve urban mobility. Therefore, documenting results, challenges and successes can serve as a valuable resource for other cities, aiding knowledge sharing and understanding of potential benefits.

In this context, a brief comparative analysis has been conducted between the approaches of the CityWalk 2.0 pilot cities. The results showcase the evident impact of 'soft' and 'hard' actions across various dimensions. Common walkability issues, as well as the elevation of pedestrians and cyclists to the apex of the "traffic pyramid" are highlighted in the cities' approaches to achieve sustainable urban mobility. The comparative analysis reviews the pilot actions in the three cities according to five main criteria: (1) effectiveness of implementation, (2) impact on urban mobility patterns, (3) socio-economic benefits, (4) accessibility/ inclusivity measures and (5) sustainability and resilience of the initiative (Tabel 1).

Tabel 1. Comparative analysis results

Criteria	Nyiregyhaza (Hungary)	Ptuj (Slovenia)	Valjevo (Serbia)
Effectiveness of implementation	Successful pedestrianization efforts	Renovation of city marketplace	Enhanced city's walkability
	Proactive measures to improve public transport services	Low speed-limit streets with zoning regulations that encourage travel behaviour change	Promotion of healthier lifestyles
Impact on urban mobility patterns	Likely shift towards reduced car traffic and increased walking/ cycling	Potential positive changes in urban mobility patterns	Improvement in pedestrian routes and signage for different traffic categories
Socio-economic benefits	Improved air quality, increased foot traffic for local businesses	Stimulated economic activity and cultural events, increased attractiveness	Urban design improvements
	Enhanced public space utilization	Benefited local businesses and residents	Citizens' education and awareness-raising campaigns

Accessibility and inclusivity	Improved accessibility for pedestrians and cyclists	Planned enhancements for barrier-free environments	Improved accessibility for pedestrians and cyclists
	Promotion of inclusivity and community engagement	Creation of inclusive environments for diverse user groups	Prioritization of pedestrian safety and accessibility
Sustainability and resilience	Alignment with sustainability goals and long-term resilience	Contribution to sustainability and resilience in urban mobility	Promotion of active transportation modes
	Investment in sustainable mobility solutions	Preparation for future environmental and social challenges	Enhancement of the city's resilience to future challenges

Source: authors.

In what concerns the effectiveness of implementation, Nyiregyhaza's pedestrianization efforts have been successfully implemented over several years, transforming the downtown area into a car-free pedestrian corridor. Additionally, the city's proactive measures to improve public transport services through the acquisition of equipment for passenger counting and user feedback demonstrate effective implementation strategies. Ptuj's intervention of city marketplace renovation and the planned initiatives for CityWalk 2.0, indicate a commitment to enhancing pedestrian infrastructure and addressing traffic concerns. Valjevo's interventions have been effectively implemented to improve pedestrian accessibility and safety.

Regarding the impact on urban mobility patterns, Nyiregyhaza's pedestrianization project has likely led to a noticeable shift in urban mobility patterns, with reduced car traffic and increased walking and cycling. While the full impact may require longitudinal studies, initial observations suggest positive changes in travel behaviour. The proposed interventions for Ptuj aim to encourage walking, minimize car dependency, and enhance safety, potentially leading to positive changes in urban mobility patterns. However, the true impact will depend on the effectiveness of CityWalk 2.0 initiatives in promoting active transportation modes. Valjevo's interventions have likely influenced urban mobility patterns by improving pedestrian accessibility and promoting healthier lifestyles. The city's focus on sustainable mobility solutions indicates a commitment to creating a more walkable and bike-friendly environment.

As far as socio-economic benefits are concerned, Nyiregyhaza's transformation of the downtown area has likely generated socio-economic benefits, such as improved air quality, increased foot traffic for local businesses, and enhanced public space utilization. These benefits contribute to economic vitality and social cohesion within the city. Ptuj's interventions, including the renovation of the city marketplace, are expected to stimulate economic activity and cultural events, benefiting local businesses and residents. By creating vibrant public spaces, Ptuj enhances the city's appeal and promotes community engagement. Valjevo's interventions have likely resulted in increased attractiveness of the urban space and an increased awareness of citizens in what concerns the importance of active mobility.

In terms of accessibility and inclusivity, Nyiregyhaza's pedestrian-friendly environment improves accessibility for pedestrians and cyclists, ensuring equitable access to transportation services. By prioritising active transportation modes, Nyiregyhaza promotes inclusivity and fosters a sense of community within the city. Ptuj's planned interventions for CityWalk 2.0 aim to enhance pedestrian infrastructure, making the city

more accessible and inclusive for all residents and visitors. These efforts contribute to creating barrier-free environments and promoting social inclusion. Valjevo's interventions have likely improved accessibility for non-motorized traffic participants, creating urban environments that accommodate diverse user groups.

Sustainability and resilience are present in all three pilot cities. Nyiregyhaza's focus on reducing car dependency and promoting active transportation aligns with sustainability goals, contributing to long-term environmental resilience and resource efficiency. By investing in sustainable mobility solutions, Nyiregyhaza enhances the city's ability to withstand future challenges. Ptuj's interventions, particularly those aimed at reducing CO2 emissions and enhancing safety through pedestrian infrastructure improvements, contribute to sustainability and resilience in urban mobility. By prioritizing sustainable transportation options, Ptuj prepares for future environmental and social challenges. Valjevo's pilot actions contribute to sustainability by improving environmental quality and promoting active transportation modes. These efforts enhance the city's resilience to future challenges and support long-term environmental goals.

To sum up, the comparative analysis of interventions in the three cities sheds light on the effectiveness of various strategies in promoting sustainable urban mobility. Each city's approach, tailored to its specific context and mobility challenges has demonstrated notable successes in improving pedestrian infrastructure, reducing car dependency and enhancing the overall quality of urban mobility. From successful pedestrianization efforts in Nyiregyhaza to the revitalization of public spaces in Ptuj and Valjevo's interventions of urban streets' signage, these interventions have generated socio-economic benefits, improved accessibility and contributed to long-term sustainability and resilience. While challenges remain, such as the need for longitudinal studies to assess the full impact of interventions and ongoing efforts to address cultural attitudes towards transportation, the comparative analysis underscores the importance of proactive measures and collaborative approaches in creating more liveable, walkable, and inclusive urban environments.

Lessons learned from the CityWalk pilot cities' interventions can inform future initiatives aimed at advancing sustainable urban mobility and fostering resilient cities for all. To achieve this goal, a set of five key policy recommendations are proposed for other cities based on the results of the CityWalk 2.0 pilot actions, tools and methodologies:

1. Encourage active transportation through investments in dedicated bike lanes, pedestrian-friendly streets and safety measures.
2. Expand public transportation accessibility, reliability and affordability to incentivize its use over private car ownership.
3. Implement congestion pricing schemes to discourage single-occupancy vehicle trips and alleviate urban traffic congestion.
4. Create standard street design models for various urban street categories, prioritizing walking, cycling and public transport over personal vehicle usage.
5. Implement behavioural strategies like mobility management to influence psychological factors, encouraging voluntary shifts from car dependency to non-auto travel modes.

By adopting these policies, cities can effectively reduce carbon emissions, enhance urban liveability by prioritizing pedestrian-friendly infrastructure, cycling networks and create more resilient urban environments for their citizens.

5. Conclusions

In conclusion, the literature review underscores the multifaceted nature of sustainable urban mobility, highlighting its significance in contemporary urban planning and transportation discourse. Current mobility policies aim to reduce car usage and promote changes in travel behaviour among car users, driven by the recognition of the social costs associated with car dependency, such as traffic congestion, accidents, air pollution and global warming. Furthermore, the synthesis of existing literature reveals a growing emphasis on active mobility as a pivotal component in promoting sustainable transportation systems. Active mobility interventions, encompassing both 'hard' interventions like street redesign and 'soft' interventions like travel behaviour change programs offer promising avenues for fostering more equitable, energy-efficient and environmental-friendly urban mobility. Strategies such as pedestrianization, cycling infrastructure development, educational campaigns, zoning regulations and congestion pricing demonstrate the diverse approaches cities can adopt to promote sustainable urban mobility. Furthermore, the integration of 'soft' and 'hard' measures emerges as a key strategy for maximizing the effectiveness of urban mobility interventions. By combining infrastructure improvements with initiatives aimed at influencing individual travel behaviours, cities can create more walkable pathways.

In summary, the comparative analysis of the CityWalk 2.0 pilot cities located in Central and Eastern Europe (Nyiregyhaza, Ptuj, and Valjevo) reveals a diverse array of interventions aimed at promoting sustainable urban mobility. Each city has implemented unique strategies tailored to its specific context and mobility challenges, encompassing both 'hard' interventions such as street redesign and 'soft' interventions like travel behaviour change programs. Despite their differences, all three cities share a common commitment to promote active mobility as a core strategy. The findings highlight the importance of adopting a holistic approach that addresses infrastructure improvements, behavioural change and political commitment. Through collaborative efforts, the CityWalk 2.0 pilot cities are pioneering new pathways towards energy-efficient urban mobility, serving as beacons of innovation and inspiration for other cities dealing with similar challenges as decreasing the carbon intensity of urban transportation systems.

The outcomes of CityWalk pilot cities' interventions can inform future initiatives aimed at advancing sustainable urban mobility through the following policy recommendations: promote active transportation infrastructure, enhance public transport accessibility and reliability, introduce congestion pricing, develop standardized street designs prioritizing walking, cycling, and public transport, as well as implement behavioural strategies to reduce car dependency.

In future research, it is essential to delve into the longitudinal effects of sustainable urban mobility initiatives on various aspects of community well-being, including health outcomes, economic growth and environmental resilience. Understanding the interplay between these factors over time can provide invaluable insights into the effectiveness and sustainability of different mobility interventions. Additionally, initiatives should prioritize the integration of emerging technologies, such as smart transportation systems, flow counting sensor and electric mobility solutions to optimize the efficiency, accessibility and environmental impact of the urban transportation.

Track 06: Governance

GOVERNANCE - Planning and democracy: contradictions, failures, and agonistic alternatives in shaping urban spaces and in urban planning practices

Chairs:

- Enrico Gualini, TU Berlin
- Joel Idt, Université Paris-Est
- Donato Casavola, Politecnico di Torino

Keywords: *agonistic democracy; conflict; co-production; experimental governance; local democracy; Planning practices and instruments; public-civic cooperation*

Can conflicts and contradictions be at the heart of urban policy-making and planning practices? After decades during which viewing the production of space from a 'governance' perspective (for instance, focusing on the dialogues, partnerships, negotiations, etc.) appeared to be commonsense, times are ripe now, more than ever, either for critical assessments and for experimental alternatives to this narrative. Conflicts are no longer systematically seen as problems. Through local experiments and networked exchange, urban political communities have started addressing tensions,contradictions, and failures of established governance practices. In doing so, they are turning critique and agonistic engagement into opportunities for cooperation and materials for innovation in urban planning and policies. At the core of these new emerging practices is the struggle for recovery and – as it were – for the reinvention of the role of the public in producing urban policies. New local democracy experiments thus dwell on a problematisation of governance that highlights such contradictions as well as the quest for alternatives.

This track aims at exploring the current state of local planning and governance as practices developing in a dialectic environment of de- and re-politicisation in agonistic arenas where the struggle for change is at the same time a struggle for new formats and principles of co-production that is at least partly based on conflicts, tensions and contradictions between stakeholders. The track welcomes contributions that aim at promoting scholarly analysis of current practices dealing with issues such as:

- emerging contentious issues of urban development, for which planning and governance struggle to find effective balances of divergent positions and interests;
- experimental governance initiatives by introducing new patterns of interaction and leaving some room for conflict;
- the role of conflicts and contradictions in urban planning techniques and in public policy instruments, which bring technical debates to a political level.

- new forms of public-civic cooperation potentially capable of introducing policy change and institutional innovation, despite (or rather thanks to) the tensions that can exist in this type of situation;
- directions towards overcoming formal-institutional ‘invited’ citizen participation and towards ‘inventing’ new forms of participatory governance;
- critical reflections on achievements of the ‘new municipalism’ in reinventing urban governance as well as on the mid-to-long-term challenges facing it.

Conflictual Natures: the role of architectural imagination in building paths for ecological transition in the city of Goias – Brasil

Abstract (up to 125 words)

This article addresses the intertwined history of Goias City and Vermelho River to show how social perceptions about nature evolve alongside social dynamics. Different nature perspectives were interpreted as tools shaping the socio-natural phenomenon. The study analysed nature's social construction across history by treating it as a design object and by aligning a new right to nature akin to Lefebvre's right to produce the city as a work of art. Design workshop was used to analyse societal perceptions of the river and it uncovered conflicting views. It explored micro-utopian approaches to foster counter-hegemonic ecological transitions by merging utopian ideals with practicality and challenging conventional nature narratives. This perspective can help establish benchmarks for alternative practices and build a socially active approach to ecological transition strategies.

Keywords: environmental conflicts; micro-utopias; design-thinking.

1. Introduction

The city of Goiás, Brazil, has evolved closely attached to its main river, called Vermelho River. However, this relationship was quite conflicting and changed overtime as nature gained different social meanings. Thus, the aim of the current study is to investigate nature as a social product by revealing its different social performances at different times in Goiás City's history. In order to do so, a design workshop was held in the investigated city, with support of professor Wagner Rezende from UFG, to develop and explore a regressive-progressive analysis of the role played by nature in it. First, a photographic analysis aimed at identifying conflicting trends towards nature and different aspects of social perception about Vermelho River was carried out. This procedure enabled exploring virtualities and blind fields to imagine ecological transition paths in the city. Arguably, this grounds a 'right to nature', in the same terms that for Lefebvre (2000) the right to the city meant the right to produce the city as work of art. Likewise, the 'right to nature' in the city means the possibility of citizens to produce nature as work of art.

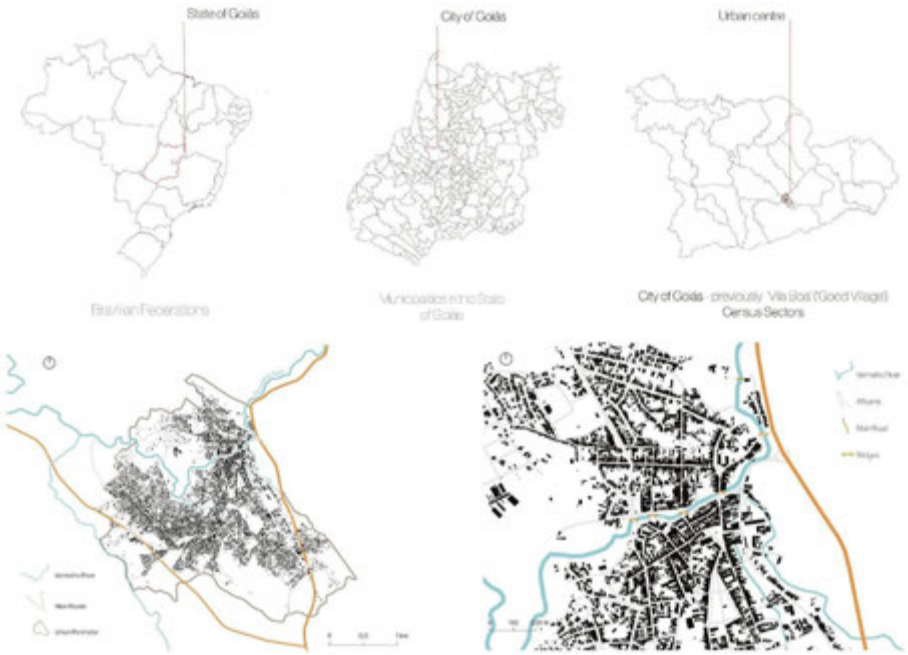

Figure 01: The city of Goias and the Vermelho River

A workshop/seminar event developed by UFG and POLITO was held to discuss the social implications of dynamics between rivers and Goiás City. It focused on addressing conflicts, social impacts, changes in social perception, and how people actually live these dynamics in their daily lives.

The workshop explored critical theories of nature and environmental planning, approaches to Urban Political Ecology, the production of subjectivities, and critical postcolonial approaches to nature. It aimed at investigating the role played by design and architecture in developing immanent possibilities for social-environmental alternatives. In order to do so, it explored design-thinking to visualise hidden aspects of urban nature through cartography, critical representation, diagrammatic interpretation and photographic *dérives*; and to envision new possible futures through utopian imagination and by seeding immanent micro-utopias.

Short lectures and discussions aimed at building a critical view and at developing tools to interpret nature as an object of design were held. Round tables were performed with, and short presentations were introduced to, the local community. Field trips produced photographic *dérives* and interviews, whereas workshops based on the flipped classroom methodology developed utopias and micro-utopias.

Visitors arriving in Goiás City will find a city immersed in nature. Yet, its history is full of complex nature-artificiality interactions ranging from negation to valorisation. Nature has always been there in the city, although it had different roles and values. The current study took some steps towards deconstructing values attributed to nature in the city, mainly by focusing on Vermelho River to find new potentials for nature's different historical blind fields. It was

done to develop an approach focused on critically dealing with history in order to set new paths for ecological transition visions.

Associations between social and natural ideas were herein explored to approach Goiás City's environment, but not with the aim to investigate nature as abstract ideal, but to analyse how it concretely performs social interactions. This approach was adopted to highlight how radical ideas about nature could point out some blind fields of, and new possibilities for, society's socio-environmental structure and its contradictions.

The herein adopted approach was based on Henri Lefebvre's (2003: 111-120) regressive-progressive method, which, in its turn, is based on two steps that were herein used to , later on, formulate micro-utopias. The first (horizontal) step focused on identifying current contradictions, according to which, a given historical moment can be read as antagonistic social phenomena. This step enabled understanding that reality is a complex field full of 'virtualities' and 'blind-fields'. The second (vertical) step comprised the process to search for the root of such contradictions and complexity back in history by analysing the paradoxical juxtaposition of archaic and modern formations. Finally, the aforementioned blind fields and virtual elements were explored using design-thinking tools to imagine ecological transition paths for both the city and its river.

2. Natural Contradictions

The current section explores living contradictions observed in the relationship between Vermelho River and Goiás City. For that, initially, a series of lectures were held to introduce the main contradictions inherent to the neoliberal context, namely: its instrumental logic, the parasitic exploitation of nature, the commodification and objectification of both nature and subjects, as well as the financialisation, individualism and spectacle observed in current times. The lectures also introduced alternative topics, such as postcolonial approaches, coexistence, ethics of care, mobility of frontiers and co-poiesis of nature.

Later on, a lecture held by the*Paesaggi Sensibile* group (conducted by Viviana Rubbo and Alessandro Guida) introduced a photographic approach to the landscape to help developing territorial narratives. Their office uses photography as a method to explore the way landscapes are perceived and have deep roots to be sought back in time. They aim at "listening" to the territory in order to find the values governing and emerging from landscapes by developing it as an interdisciplinary narrative tool to merge different participants and imaginaries. They aim at decoding, understanding and communicating key aspects to foster territorial policies. This approach was used to develop a photographic *dérive* to identify the 10 main trends towards, and views on, nature in Vermelho River context.

2.1. Concrete contradictions

The 10 conceptual perspectives about the main contradictions observed during the photographic *dérive* carried out in Vermelho River, at Goias City, are presented below.

Conflicting exchanges

The interchange between city and river unfolds amid conflicts that highlight a dynamic relationship full of tension. Although mediation mechanisms ostensibly aim at regulating the flow between these two entities, they often operate recklessly by exacerbating instead of mitigating issues. Unwanted waste streams into the river, whereas sediments encroach upon the cityscape. The river receives polluted water and retaliates through violent floods that cover the urban landscape. Consequently, it is imperative to promote a paradigm shift towards a more conscientious exchange and care based on innovative approaches to harmonise the relationship between the investigated city and its aquatic counterpart.

The problem arises from not acknowledging the city-river interdependence. , These entities are treated as separate and opposing forces, rather than as interconnected entities relying on each other for sustenance purposes. This failure to acknowledge their mutual dependence and the reckless operation of mediation mechanisms further exacerbates conflicts and tensions. It is essential promoting a shift towards a more conscientiousness about the inherent interdependence between city and river to address this issue.

Figure 2: Conflicting exchanges

Care and abandonment

There is evidence of people actively engaged in planting activities everywhere along the river banks, and it depicts people's deep connection to the environment. Ornamental plants adorning backyards, windows and verandas indicate locals' willingness to nurture and to take care of their surroundings. Ornamental plants add aesthetic appeal, as well as emphasise community members' collective willingness to take care and improve the appearance of their shared spaces. Despite these positive initiatives, several riverbank sections are left abandoned and neglected, and it emphasises their stark contrast to areas flourishing with greenery.

However, it represents a significant opportunity for transformation, rather than being seen as a setback. Communities can unlock their potential to provide a more inclusive and sustainable future by acknowledging and addressing these neglected areas.This is a unique opportunity to ground care in a local existing ethics. These abandoned spaces can be revitalised and repurposed for the benefit of all by harnessing the collective efforts of individuals and investing it in their communities' well-being. This approach not only fosters the sense of belonging and connection among residents, but it also promotes environmental stewardship and resilience. Ultimately, embracing this *ethos* of care and solidarity has the potential to turn riverbanks into vibrant community-life hubs, where everyone plays an essential role in shaping a brighter future.

Figure 3: Care and abandonment

Fruit Surplus

In addition to their connection with ornamental plants along riverbanks, people also maintain traditional relationships with rural practices. Beyond the mere presence of ornamental greenery, backyards produce a surplus of several fruits, and it is a testament to the community's agricultural heritage. Traditionally, locals freely share excess production by placing fruit boxes in front windows and by fostering a 'sharing of abundance' culture. However, despite these generous gestures, the sight of fruits rotting on the ground is all too common, and often locals insist with visitors to bring some of the fruits with them. These behaviours highlight the paradox between surplus production and waste, desire of sharing and lack of consumption.

Nevertheless, a great opportunity to promote an economy rooted in both solidarity and sharing lies amidst this apparent challenge. Communities can harness resources' abundance to create a more equitable and sustainable economy by acknowledging and addressing inefficiencies observed in the current system. This process encompasses implementing strategies to effectively use production surplus through community-wide sharing initiatives or food security programs and networks. Moreover, integrating agroforestry practices along riverbanks is a sustainable way to revitalise the landscape, enhance biodiversity and improve soil health. Communities can unlock the full potential of their resources to foster resilience and cohesion in this process by embracing the *ethos* of solidarity and mutual support.

Figure 4: Fruit Surplus

Bonding Frontiers

Symbolic lines divide anthropic and natural spaces. They simultaneously establish domains and connection points. Thus, the lines separating the river from the urban fabric are more than mere geographic contours. They are permeable borders between the natural and the built environment, between waters' fluidity and human structures' solidity.

These delimitations, which are intertwined like the lines of a poem, reveal the duality inherent to coexistence, where the winding river water meets the rigidity of urban lines. This dichotomy is not just geographic, it is a metaphor for the constant clash between nature and human creation. However, instead of rigid divisions, these lines subtly intertwine and remind us that, even in the sharpest borders, there is an eternal dance between the wild and the domesticated, between the free flowing of waters and the ordering of urban constructions.

Figure 5: Bonding Frontiers

River gateways

The quiet backyards in the neighbourhoods along the riverbanks flourish with an array of gates leading directly to the edges of water. These passages are foundational gateways that work both as guardians and mediators by controlling the dialogue between city and river. Each door is a symbolic element embodying both residents' desire for security and the desire for connection between urban life and the river's natural flow. They are mainly symbolic, and in some only the portal remains, in others there is the gate but the fence is missing. Nonetheless its symbolic protection and demarcation remains.

There lies an inherent tension between access control and yearning for connection. Thus, although these gateways frame and structure exchanges, they also embrace nature by echoing the eternal dance between the need of security and the desire for freedom. Moreover, these gateways are also frames selecting views of the calm river water current to revive the city's dynamic pulse. Although these gateways work as barriers, they are also a symbolic longing for the river's fluidity and serenity. A mosaic of gates and windows unfolds as passersby cross these spaces. Thus, these gates have the potential to recreate a harmonious experience between homes and the river.

Figure 6: River Gateways

Fluid Backyard

Houses near Vermelho River reveal an intricate dance between the need of proximity to water and caution towards nature's unpredictable pace. The carefully tended backyards at the back of the lots play a crucial role in spatial dynamics, since they outline the border between the private sphere of homes and the tortuous paths leading to the river. Solid walls emerge as guardians against natural dangers by separating everyday life from likely agitated waters. However, although these defensive barriers provide security, they often imply loss of direct contact with the riverside environment. The delicate balance between desire for protection and preserving the intimate contact with nature is revealed in this complex spatial arrangement, where architecture acts as mediator between human comfort and the unpredictability of natural settings.

Although backyards present fluid boundaries encroaching one another and extending towards the river, they lack structure. They are non-integrated landscape units. Some spaces are abandoned, whereas others are carefully tended. They form another urban ambience that is neither entirely nature-based nor completely structured. Furthermore, the boundaries between public and private properties are not clear. Locals blame the municipal administration for neglecting the river, and they see themselves as lacking agency to take care of these spaces. In this limbo, the riverbanks work as a non-activated field of potentialities.

Figure 7: Fluid Backyards

Connecting Devices

Locals have scattered DIY benches on the riverbank and created places for contemplation purposes. These seats are not only resting spaces and work as small devices capable of creating places for people to take a break, while they feel the murmurs of the river and the city's pulsating energy. Thus, the water and the streets converge to provide meeting arenas where people punctually explore the potential of calm spaces and viewpoints towards nature. This factor shows both lack of structured initiatives to explore the landscape potential of the area and the local population's willingness to adopt a hands-on approach to improve their surroundings.

Figure 8: Connecting Devices

Ordinary Invaders

Brachiaria is an exotic grass genus used to feed cattle. Species belonging to this genus provide tall and large bushes, as well as feature a common state landscape element. They outcompete native species, reduce biodiversity and create a monotonous landscape. These *brachiaria* spaces indicate places people do not approach and do not interact with. Thus, most spaces in riverbanks do not have native plants or orchards. Both natural and community ecosystems disappear in these places. Thus, *brachiaria* grass grows like a green desert in places lacking care, accessibility and backyards, in places people do not take ownership of, do not plant anything, do not take care of nor cultivate in. Nevertheless, the living river still lies there, in the middle of that place, behind that sharp, stinging curtain.

Figure 9: Ordinary Invaders

River Words

Words stand like silent sentinels arranged on plaques that trace a peculiar narrative along the tortuous paths leading to the river. Each plaque is a link in a series of discourses as an attempt to tame the fluidity of ideas that continuously seek a broader meaning. These words, like 'tributaries', intertwine to form a fabric that reflects the diversity of calls to experience, protect and take care of the river. However, these texts reflect the continuous flow of thoughts unfolding before us. As we follow the signs, we are encouraged to contemplate not only the destination, but the journey itself, and it enables shaping the course of our reflections and sculpting different lenses to look at the environment. This journey of language invites us to delve into the waters of meaning, where words reveal the constant process to keep on looking to common places.

Bruno Latour's (2004) call for scientists to be democratic representatives of non-human entities finds echo in these local practices. The community crafted these signs to communicate both human and non-human concerns by acknowledging the river's agency and intrinsic values. Scientific knowledge is translated into small slogans and the river gets a voice through the action of external subjects. Although these signs aim at education, they also promote the deeper aesthetics of interdependence and coexistence, as well as other ways to approach the local environment.

Figure 10: River Words

River Voices

“The river is used for swimming purposes, but it is not like it used to be. Nowadays, it is very dirty and disasters happen when the floods come."

“The river is used for bathing purposes, as well as for catching and eating fish. It is also used to supply tap water to the city.”

“The river is everything. It is used for bathing and refreshing purposes. The river is nature.”

“A few years ago, there was an artistic demonstration that was considered inappropriate by the natives; after that, the river lost the incentives that encouraged more people to use it.”

"We only use the river for bathing purposes. But it also plays an important role in supplying and maintaining the city."

“It is used for everything, such as giving water to and bathing animals. A few minutes ago, my daughter was asking to get in the water.”

Figure 11: Local Inhabitants giving voice for the river

2.2. Abstracting contradictions

On the one hand, the main current social contradiction lies on the almost hegemonic common sense about the need of developing sustainable alternatives, in contrast to a social performance that is leading us to a catastrophic Anthropocene. This contradiction is deeply rooted in our modern epistemology, which performs through the domination and instrumental use of nature, humans and non-humans, while having a hard time dialoguing with what is outside its own logic.

On the other hand, ecosystems are supposed to be synonyms of nature. However, the two parts of that word are already full of social and cultural assumptions. According to Juan Martinez Alier (1988), the Greek root "Oikos" means space of life, and it encompasses both the community and its territory. It is also shared by the economy, which accounts for managing this space of life. Therefore, the concept of ecology is intricate with political economy.

Moreover, systems are theoretical instruments. Adam Curtis' documentary 'All Watched Over by Machines of Loving Grace' charmingly captures how systems' theory prevail in contemporary culture, mainly through a specific branch of ecological thinking. According to Kasper (2000), the General Theory of Systems became a scientific movement in the 20th century in order to approach complex problems not as a sum of small problems, but in an integral approach focused on acknowledging the complex interactions of a set of elements (organised complexity). Nonetheless, according to Lefebvre, social reality is not 'a pre-existing system':

> …it follows that the 'real' cannot be enclosed. It is not a situation where there is no possible outcome, nor is the only outcome global collapse; for the contradiction themselves develop though unevenly. And finally, theoretical concepts may escape the system, even though they are born in it and have emerged from (…) space dominated by the strategy of homogenization and of the programmed everyday. But they still have to free themselves from that system (Lefebvre, 1976, pp. 90-91).

Furthermore, Alberto Toscano (2006, pp. 136-156) introduced dynamic system theories to discuss concepts of subjectivity. According to him, systems can be conceived without a previous hierarchical order, in a complex interaction between the internal and the external, and with no stable and distinct objects. Jameson (2002, pp. 75-78), in his turn, has stated that these positions within a 'total system' can trace their roots to Weber's 'iron cage', which rules out the possibility of dissent, and reintegrates any form of struggle as a functional part of the system.

In addition, Lefebvre (1967, 375-377) advocates that poiesis creates a new reality by operating in residual fields left untouched by current epistemologies. According to him, every epistemology has 'virtualities' and 'blind-fields' (Lefebvre, 2003b, pp. 23-44), and it means that every epistemology has specific potentials that are explored and specific fractions that remain hidden. These fractions are unarticulated into potential deeds; therefore, they are the limits of any form of reasoning. Based on his approach, poiesis creates reality by disclosing the obscure, blind and hidden part of reality. Therefore, the limits seen by a given epistemology are the source to create (possible) new realities.

Lefebvre (1967) called the possibility of having ideas creating reality poiesis. According to him, poiesis is the production of concrete experiences through ideal representations, in opposition to praxis, which focuses on real practical experiences, and to mimesis, which focuses on ideal representations in the mind. Thus, the concept of poiesis refers to how ideas can change reality; it aims at understanding the foundations, the groundwork and the decisions made within the process of creating truth/reality (Lefebvre, 1967, p. 64-65). The aforementioned author states that the creation of new possibilities is the factor driving changes in reality. This process operates just like that of a seed, which cannot simply be explained by its current reality, namely: being a seed, but by the prominent nature of its virtual reality, in other words: the possibility of becoming a tree.

3. Present past future

The current section explores the roots of the observed contradictions. Diving into the history of the relationship between the city and the river enables identifying different moments and approaches to nature. Arguably, this regressive movement focused on understanding the roots of these contradictions may be a source of 'blind fields' to be explored as 'virtualities' for future transition strategies to be implemented in the city. Present, past, future; contradictions observed between river and city were "excavated" in 5 paradigmatic periods (see Figure 12) to meet the scope of the exploration process developed during the workshop.

Figure 12: Evolution of the River and City relations

(1) Goiás City was founded as an 'arraial' (village), back in 1727, for gold mining in the margins of Vermelho River, but the State had little presence. During the first two decades, the river was a dangerous place, since the gold mining process was based on slaves' toiling and degrading the environment, increasing the spread of several diseases. In this context, the city developed with its back to the river, and its main urban spaces (also known as 'largos') were away from it, on high and dry plans.

(2) The city became the capital of 'Capitania de Goiás' in 1748, as gold mining developed. A Jail and Chamber House was built in the city in 1766, and a baroque plan was developed after 1778. On the one hand, nature in this colonial context was seen as wild and as a threat. On the other hand, it was welcome in backyards as heavenly gardens replicating gifts from God in a very catholic society.

(3) The gold production declined after the 1780's and, in 1822, Brazil became an independent state with the ambition to become a modern empire under the British empire's influence. The 19th century experienced changes in the subjective approach to nature. A series of governmental measures and laws aimed at changing citizens' relationship with nature, functioning as a means for the modernization of society . For instance, hunting was prohibited to implement modern labour practices, whereas green areas in the city were introduced to forge romantic delightful experiences.

(4) After the city lost its gold mining economic source, it turned into a rural economy based on livestock farming. The city froze and became stagnant, without almost any changes, for one century. Nonetheless, an important transformation changed the city's relationship with the river. In 1869, a new road was built to provide access to the new Central Market (finally built in 1926); it created a new entrance to the city and cut the old backyards facing the river. Although inverting the face of the river to the city, the road remained mostly empty, only holding backyard doors and few new modern institutions.

(5) An Environmental Film Festival was launched in the city, in 1999. Since 2001, the city and the local mountain range became Unesco Heritage; the river became the ecological symbol connecting them. Furthermore, the current environmental crisis has changed urban nature values and subjectivities. Local communities often engage in practices and new attitudes towards nature. These new forms of valuing and conservation practices have turned the river into the central point in the city, and it encouraged the construction of new stores and restaurants.

Different perspectives have emerged from this brief excavation of the city's relationship with nature, and it highlighted unique ways through which this relationship was perceived and connected the natural to the human world. This process led to perspectives, according to which, nature can be seen as a social innovation technique, as well as emphasised the dynamic interplay between society and the environment. Therefore, nature transcends its traditional portrayal as a separate entity and displays its phenomenon shaped by socio-natural interactions. This perspective invites us to re-imagine our approach to nature by not merely seeing it as a passive backdrop, but as an active participant in our socio-cultural fabric. By embracing this paradigm shift, we unlock the potential to conceive nature as an object of design and to foster innovative solutions that include human needs and the metamorphic rhythms of the natural world.

4. Micro-utopian perspectives and the Right to Nature

In 'Spaces of Hope', David Harvey (2001) advocates for the concept of dialectical utopias to avoid the simple 'imagination' of alternative worlds. These utopias should be conceived as counter-utopias, as devices negatively related to reality. This is fundamental to enable imagining future alternatives rooted in the concrete world. Similarly, Henri Lefebvre (2000), in his book "The Right to the City", proposed an experimental utopia developed in an intellectual

operation he called ‘transduction’: the production of a possible theoretical object as reference, as strategy designed to change society.

In a similar, but distinct, line, Sande (2013) defends the creation of ‘micro-utopias’ or ‘acting as if one is already free’ (Sande 2013). Ringel (2012) adopted the ‘anthropological-anarchist approach’ to state that micro-utopias should be dedicated to creatively produce free spatialities. It is done to avoid the neoliberal evacuation of the future by developing a ‘creative presentism’, which, in its turn, creates new grounds for hope. Webb and Lynch (2010) analysed how the post-punk scene built new experiences of reality that were momentarily actualised in ‘pirate spaces’ of globalisation and, then, into ‘lifeworld’.

According to Bourriaud (2002a, p. 31), the traditional critical theory can no longer substantiate artistic strategies, since the total negation and society transformation strategy is no longer available. He defends everyday tactics that work within and against the system, promoting new forms of conviviality and encounters. According to him, contemporary art already works through the invention of idiosyncratic ‘vanishing lines’. What ‘artists are trying to do now is to create micro-utopias, neighbourhood utopias, like talking to your neighbour’ (Bourriaud, 2002b). These micro-utopias are a new form of ‘possible’ micro-politics. Similarly, John Wood (2007) proposes designing micro-utopias in a less rational, critical and negative way by dismissing the ideas of monolithic utopia and Western mechanistic individualism to benefit the multifaceted proliferation of imaginative ‘miracles’ and ‘dreams’ in the ethics of flow.

Micro-utopias can be used as a strategy to articulate counter-hegemonic approaches in order to envision political green transitions. This methodology requires exploring utopia through a dialectical lens by engaging in discourse that acknowledges both concrete and creative elements. Thus, a concept of Right to Nature can emerge from this framework and advocate for citizens' entitlement to shape nature as their own work of art. This assertion underscores the transformative power inherent to human interventions within natural systems and frames such actions as acts of design. Thus, those who intervene in the nature of nature are not merely passive observers, but active participants in the ongoing process to design nature.

The designing nature endeavour operates at multiple levels and each level contributes to a given approach towards reshaping our relationship with the environment. At a visual level, it involves visualising the often-overlooked facets of urban nature. Techniques, such as cartography, critical representation, diagrammatic interpretation and photographic *dérives*, reveal the hidden layers of the natural world, which is embedded in urban landscapes. Concurrently, designing nature involves imaginative exercises through which one can envision alternative and sustainable futures. Utopian imagination enables exploring possibilities beyond the constraints of present times, as well as envisioning harmonious coexistence between humanity and the environment.

Finally, the seeding process involves cultivating immanent micro-utopias — small-scale initiatives that embody principles, such as sustainability and ecological transition, within urban contexts. The work to design nature becomes a multifaceted endeavour aimed at fostering meaningful transformations to both society and the environment by integrating visualisation, imagination and seeding. Three different conceptual perspectives were used as lenses through which one can engage in these latent possibilities to confront the immanent potentials, or virtual elements inherent to the place: commons, dark ecologies and postcolonial perspectives.

The lens of commons emphasises the collective ownership and stewardship of resources by challenging traditional concepts of private property and by promoting communal responsibility. Dark ecologies, on the other hand, delve into the complex entanglements between human and non-human actors within ecosystems, as well as acknowledge the often obscured or overlooked ecological interaction aspects, such as disturbances and disruptions. Finally, postcolonial perspectives provide critical insights to the legacies of colonialism and to the ongoing dynamics of power and oppression within different spaces and communities. Micro-utopian proposals emerged from this framework to transcend utopia as a mere apolitical and abstract ideal.

This process resulted in the overall acknowledgement that the urban stretch of the investigated river is structured as a rosary, with rooms and lines. Instead of having this configuration challenged, it was explored to enrich and nurture the existing potentials. The main proposal comprised a series of rooms, each one of them with different features and solutions that were intertwined by connection lines: streets, pathways, among others. Thus, the master plan strived to engage in the tangible realities of both the place and the context by addressing social, environmental and political concerns. It was done through practical and interactive procedures grounded in local specificity and communal agency.

Figure 13: General Concept

4.1 Micro-utopia 01: Backyard Commons

Figure 14: Map locating micro-utopia 01.

The process of restructuring backyards along Vermelho River banks transcends barriers by simply rearranging barbed wire and small pathways, by embodying a poetic transformation from the intimate to the common. The once-dominant exotic undergrowth in public spaces disappears and is replaced by areas taken care of with affection, where vegetation intertwines with both houses and the river. These open backyards are not mere physical extensions of dwellings; they are spaces capable of fostering sensory and emotional connections by inviting us to engage in silent contemplation and in interactions with neighbours.

The backyards of houses lining up along Vermelho River are teeming with orchards presenting abundant fruits on the ground. Dwellers insist that visitors should take the surplus fruits in a practice known as "pegue e leve" ("pick-up and go"), according to which, generosity works as a form of assistance and prevents fruits from just rotting on the ground. It has become a local tradition to leave surplus fruits in boxes for anyone to take. This proposal aims at enhancing this practice. The proposed fruit-sharing boxes symbolise a gift from nature to be shared among people, and it strengthens community bonds and enables the collective construction of a harmonious environment.

Common Edges (Figure 15) emerge as spaces behind houses along the river, as well as promote a deep redefinition in residents' relationships with their backyards, the river and their neighbours. As "common goods" managed by local groups and communities, these edges work as coexistence and exchange settings. Living by the river becomes a collective celebration of harmony between people and the environment. Common Edges are the backyards' transition from simple private extensions to sites of encounter by fostering shared experiences.

The pathway amalgamated with the existing ecosystem, the built environment, the river and the trees seamlessly connects these elements for users and the community. Households have designated spaces to share their traditions with visitors through simple provisions that, in their turn, can be referred to as 'commoning' the spaces. They have tables set to place boxes filled with fruits to be taken by visitors. This new connection device brings visitors together with the local community and the river. Moreover, seating areas are provided for visitors so they can observe the affection of sharing local traditions with them.

Figure 15: Shaping Common Edges with the local tradition spirit of 'pegue e leve'.

4.2. Micro-utopia 02: Interweaving River and City

Figure 16: Map locating micro-utopia 02.

This micro-utopia aligns with the concept of weaving by interweaving the urban landscape along the river. Its core goal is to draw people closer to the river by providing opportunities for contemplation and unique experiences to help establish a direct link between the urban area and river. The sinuous pathways aim at both connecting and creating microenvironments suitable for several activities. This vision goes beyond mere urban development; it strives for a symbiotic relationship by intertwining lines of life between the built environment and nature to foster a transformative journey for local residents. This proposal not only enhances connectivity but also paints a picture, wherein weaving becomes an urban life narrative by stitching together physical structures, as well as experiences and narratives along the riverbank. This process gives users the opportunity to observe and analyse different aspects, be it the urban transformation of Goiás City, the river, biodiversity or introspective exploration.

Proposals (Figure 17) include small pedestrian networks resembling bridges to enrich the urban fabric along Vermelho River. In addition to these bridges, one finds contemplation squares, as well as the provision of spaces for people to connect and enjoy the river flow. Both the bridges and the squares are linked to adjacent sidewalks through permeable pathways, and they provide perfect connectivity for users to access both sides of the river and its surroundings. Moreover, circles of Goiás' native species were created to reintroduce local species to the riverbank, to connect users to the region's biodiversity. The existing trees are preserved, and the positioning of bridges, squares and circles merge with the urban context.

Figure 17: Act of Weaving: panorama of an urban narrative

4.3. Micro-utopia 03: Connecting Strategies

Figure 18: Map locating micro-utopia 03.

Contemplation stands as a crucial aspect of human existence inviting deep reflections. The proposal aims at making a subtle shift of attention by moving away from the usual focus on human constructions towards the river. This reversal aims at inverting what is seen as backward to help improve individuals' perception about riverbank textures. Fragmenting a given wall and reorienting street food trailers to face the river helps breaking barriers to vision, encourages close observation and sparks visitors' curiosity to approach the river and its surroundings. This process fosters an immersive experience. Both solutions enable users' visual connection to the river, which is now blocked either by the wall or by kiosks' arrangement. Thus, replacing the gap in the urban fabric and the relation with the river established by current ordination.

The existing heightened wall (Figure 19), which once acted as a visual barrier, is cut to establish a connection with the river by inviting users to flow towards and engage in it. This visual link is tangibly reinforced by permeable pathways leading to the river zone and bringing users closer to nature. Sitting and contemplation spaces are proposed along the riverbank after crossing the wall.

Kiosks (Figure 20), which once obstructed users' view of the river, are now systematically arranged to allow an immersive experience with natural sounds and sights of the river, and with its surroundings. The open spaces between these kiosks invite users to engage in the river, whereas pathways guide them towards the riverbank for contemplation purposes.

Imaging 19: Towards contemplation: Fragmenting Walls to Connect with the River

Figure 20: Towards contemplation: Re-orientation of spaces

4.4. Micro-utopia 04: Green Streets

Figure 21: Map locating micro utopia 04.

It is essential re-imagining the streets in Goiás City's urban landscape to reinforce the sense of belonging among its citizens. This re-imagination process aims at cultivating connections between individuals, as well as between humans and the environment, through the seamless integration with the river's edge. This merger is essential to help instil in users' confidence in the accessibility to Vermelho River. It aims at encouraging pedestrians to navigate these spaces, as well as to feel connected to the river and to its surrounding environment.

The existing streets are re-imagined as green streets to give users the sense of ownership over the city and its natural surroundings through their design (Figure 22). Wide sidewalks, along with greenery, bioswales and a two-way bicycle track flanked by proposed avenues of trees take one step forward in the re-naturalisation of what were green backyards, until 100 years ago. The street seamlessly merged with the river edge, and contemplative spaces were defined. Consideration was given to the flow and potential rise of the river's level, and stepped seats were implemented.

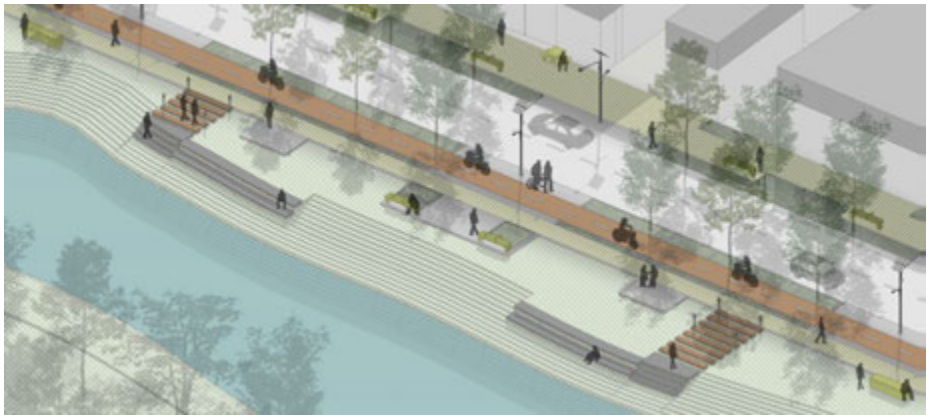

Figure 22: Re-imagining green streets

4.5. Micro-utopia 05: From Grey to Green Infrastructures

Figure 23: Map locating micro-utopia 05.

The proposal aims at transforming what previously were grey infrastructures (car parking areas) into a new green infrastructure focused on regulating the exchange of waters between the city and the river. The prototype proposal for different parking areas incorporates two key elements, namely: deployment of solar panels and implementation of bioswales. The solar panels can harness energy, whereas the bioswales help manage stormwater and create a sustainable and resilient urban ecosystem by filtering the city waters through bioswales before discharging them into the river.

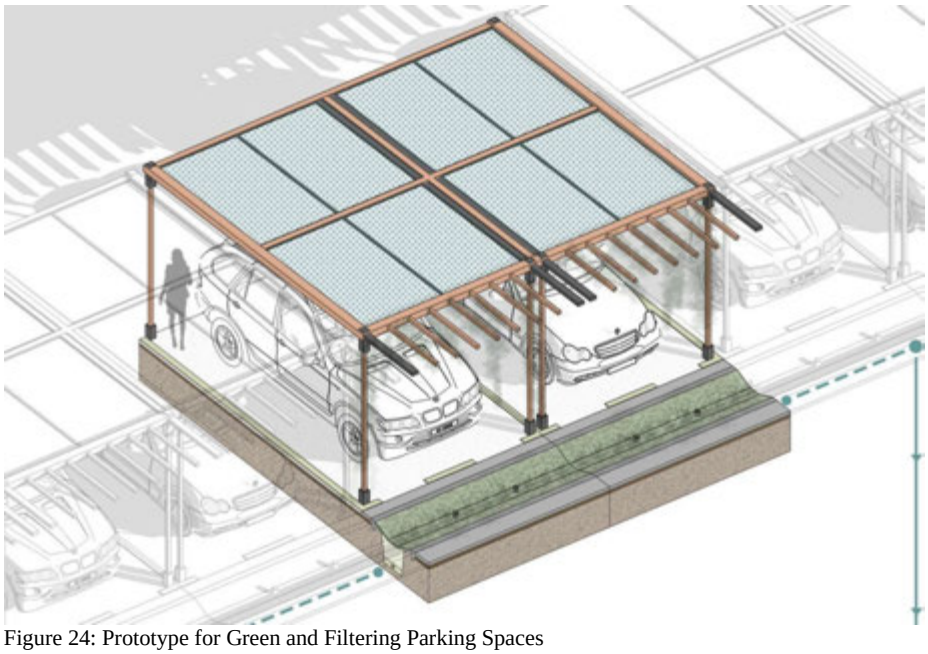

Figure 24: Prototype for Green and Filtering Parking Spaces

5. Final considerations

Subjects can be empowered to shape their environments as active participants in the ongoing social process by dialectically exploring micro-utopias to redesign nature itself, by acknowledging both concrete realities and creative potentials, and by advocating for the Right to Nature. Micro-utopias operate at multiple levels, such as integrating visualisation, imagination and seeding, to re-imagine our relationship with both nature and society. Drawing from perspectives, such as the commons, dark ecologies, and postcolonial insights, micro-utopian proposals seek to address pressing social, environmental and political challenges through practical and transformative actions grounded in local specificity and communal agency. By confronting the immanent potentials of the place, micro-utopian approaches provide a dynamic framework to envision alternative futures and to foster meaningful changes in both urban landscapes and societal structures.

By contemplating the transformative potential of micro-utopian practices, one may wonder: how can these approaches challenge the reproduction of relationships by the social performance of our ideas about nature? The goal is not to discover a swift and universal solution to manage the river and the natural landscape in Goiás City. Rather, it is about shedding light on inherent conflicts arising from the diverse desires and perspectives of several stakeholders. Contrasting visions emerge from this context: some see the river as a mere economic asset to be relentlessly exploited, whereas others see it as something sacred and untouchable.

Similarly, Goiás City's natural environment is susceptible to conflicting desires and visions that range from those advocating for its pristine preservation to those pushing for tourism development. These tensions underscore the intricate relationship between humans and their environment, as well as highlight the need of adopting a balanced approach that respects the manifold perspectives and the needs of communities living in it. The answer mostly lies on stakeholders' capacity to deconstruct prevailing notions of nature that objectify complex social relations within it. By actively engaging with and reshaping our conceptualizations of nature, micro-utopian initiatives have the power to disrupt entrenched power dynamics and to foster more equitable and sustainable relationships between society and the environment. Ultimately, this perspective contributes to establishing benchmarks for alternative modes of practice, as well as building a socially active approach to ecological transition strategies.

Abstract: In the process of rapid industrialization and urbanization, the problem of rural decline has become a global trend. Shanghai is the most economically developed city in China, but its rural areas also have rural decline problems. Therefore, since 2018, the Shanghai municipal government has created 112 model villages for rural revitalization as the pilot projects, introducing the city's capital, talent, management, technology and other elements to them, with the core goal of exploring the demonstration model of rural industrial prosperity. This study selected 18 rural revitalization model villages of Shanghai. Through on-site investigation and interviews with relevant subjects, it concluded that: The essential process logic of multi-subject joint participation in rural industrial development is to increase the value of rural land, buildings, facilities and equipment, intangible assets and other assets by introducing elements, achieve industrial introduction, upgrading or scale expansion, and carry out operations, thus generating cash flow and reasonable distribution. There are three typical governance models: The single-subject dominant mode, multi-subject cooperation mode. intervention mode. We analyzed the characteristics, effectiveness, and issues of each approach and provided suggestions for future development.

Key words: Shanghai, Rural revitalization model villages, Rural industry development, Governance model, Strategic suggestions

1. Introduction

In the process of rapid industrialization and urbanization, the problem of rural

decline has become a global trend. In response to this trend, China's central government put forward the rural revitalization strategy in 2017. Industrial prosperity is the core of the rural revitalization strategy.

Shanghai is the most economically developed city in China, but its rural areas also have problems such as aging, hollowing out and widening economic gap between urban and rural areas. Since 2018, the Shanghai municipal government has created 112 model villages for rural revitalization as the pilot projects, introducing the city's capital, talent, management, technology and other elements to them, with the core goal of exploring the demonstration model of rural industrial prosperity. This process has formed a governance pattern in which multiple subjects such as governments, enterprises, village collectives, villagers, and social organizations jointly participate in the development of rural industries. Clarifying the essential process logic of the common participation of these subjects, integrating the resources and advantages of them and realizing the coordination of their respective rights, obligations and interests, have become the most critical issues to realize the revitalization of rural industries.

This study aims to explore the typical diversified governance models formed by these entities participating in rural industrial revitalization, analyze the characteristics industrial development effectiveness, and existing problems of each model, and provide suggestions for future development.

2. Research methods and data

This study selected 18 rural revitalization model villages of Shanghai. Through on-site investigation and interviews with relevant subjects, we have obtained information on the development status and governance models of the research subjects.

3. Three typical governance models

We found that the essential process logic of multi-subject joint participation in rural industrial development is to increase the value of rural land, buildings, facilities and equipment, intangible assets and other assets by introducing elements, achieve industrial introduction, upgrading or scale expansion, and carry out operations, thus generating cash flow and reasonable distribution. There are three typical governance models: The single-subject dominant mode: The single-subject dominant mode, multi-subject cooperation mode. intervention mode.

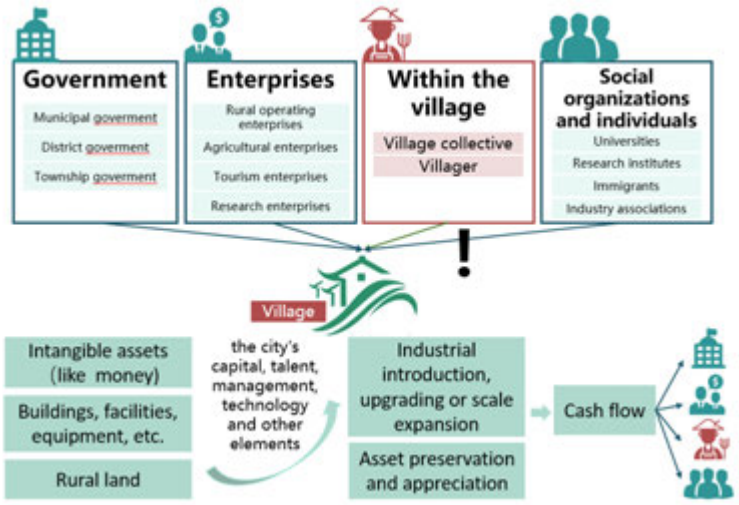

Figure 1. the essential process logic of multi-subject joint participation in rural industrial development

3.1. The single-subject dominant mode

This model generally has a leading body to carry out investment and financing, rural asset management, investment operations and other work. For example, Fengxian District of Shanghai has set up a rural collective assets operation platform "Hundred villages Group" at the district level, which invests through the integration of village collective funds, increases village operational assets, and feeds back the village collective economy with income dividends. At the township and village level, the linkage of collective economic organizations in towns and villages is encouraged, such as the development and establishment of four township platforms in Nanqiao Town, which are responsible for the construction, investment and operation of demonstration villages, the circulation, decoration, leasing, and the investment and operation of village collective and villagers' idle funds. In general, through the "three changes" reform of "resources to assets, funds to shares, farmers to shareholders", the model has formed an effective "state-owned assets to drive collective assets, collective assets to drive farmers to increase income".

3.2. The multi-subject cooperation mode

This mode generally means that all types of entities give full play to their resource advantages, jointly carry out project development, construction and

operation, and share benefits. For example, in Maogang Town, Songjiang District, Shanghai, 12 villages collectively raised more than 60 million yuan, which was held by the town asset company, and jointly established a joint venture company with a foreign enterprise. In one of the villages, the collective construction land was invested in the market pilot, the science and technology park was established, and high-quality enterprises in light industry, high-tech research and development, commercial office and other fields were introduced. Many villages share the benefits of housing rental.

3.3. The intervention mode

This mode generally refers to the involvement of foreign subjects in some links of rural industrial development. If foreign new villagers intervene in the rural development mode, it means that people with lofty ideals from all walks of life settle in the countryside for production and life, bring new ideas and impetus to the countryside, and help the rural revitalization and development. For example, Cenbu Village, Jinze Town, Qingpu District, Shanghai, is the first village in Shanghai to form a group of new villagers. The ecological environment in the village is beautiful, and the water sports are rich. At present, there are 62 new villagers, mainly engaged in scientific research, operating kayak clubs, homestays, cafes, aquaculture and so on. The new villagers have brought the drainage effect of new life, bringing diversified industrial development and emerging vitality to the countryside. Some new villagers have built houses with different styles through house rental transformation, adding differentiated characteristics to the rural style.

4. Problems with three governance models

In essence, the single-subject dominant mode is governance under the strong government's dominance. As district-level governments tend to achieve the concentration and visibility of rural revitalization in the shortest possible time, they focus more on accelerating the implementation of the national strategy of rural revitalization at the grassroots level. Therefore, they tend to let local state-owned enterprises with strong profitability participate in the construction of rural collective economy, which is easy to fall into the low efficiency of mandatory distribution by the government, and the participation of village collectives, villagers and small and micro market entities is not high.

The multi-subject cooperation mode: On the one hand, there are relatively high contractual requirements for the various subjects involved in the cooperation, such as how to reasonably distribute the benefits if it succeeds, how to bear the consequences

if it fails, and how to reasonably withdraw if some subjects want to withdraw. On the other hand, it is also difficult to find profitable assets and achieve sustainable operations, because since each entity invests in a common asset, it needs larger assets with higher returns, but such assets are less common in rural areas.

The biggest problem of the intervention mode is the lack of sustainability, because foreign subjects have their own original living places, and rural areas are likely to be only a place for them to stay for a short time, and how to sustainably use the resources they bring to the countryside is a problem. In addition, the contradictions caused by the different living habits of new villagers and local villagers also need to be paid attention to.

5. Conclusion and suggestions

Conclusion: Different subjects are different in their dominance, power and responsibility distribution, interest needs and income distribution in participating in the revitalization of rural industries. Different combinations lead to different characteristics such as industrial development speed, scale and sustainability. The dominant mode should focus on stimulating the enthusiasm of other participants, the diversified cooperation mode should focus on the establishment of cooperation systems and mechanisms, and the intervention mode needs to consider more sustainability and habit-running. Specific development proposals are as follows:

(1) The establishment of multi-subject joint governance system, whole process supervision mechanism and normal communication mechanism is an effective way to achieve the coordination of co-governance.

(2) In order to realize the revitalization of rural industry, it is necessary to combine the location, resource conditions of the village and the characteristic of each subject to choose, integrate and continue to innovate the governance model.

(3) In particular, for most villages, village collectives and villagers are in a relatively weak position in the co-governance pattern. In the open co-governance pattern, great attention should be paid to the protection of the interests of village collectives and villagers. The village collective governance ability, villagers' self-organization ability, endogenous development motivation and ability should be continuously enhanced.

Abstract: Promoting the integrated development of development zones and towns has become a crucial focal point for achieving high-quality urban and rural development in South Jiangsu, China. This paper commences with an examination of the historical evolution of the relationship between development zones and towns, followed by an exploration of the imperative for their integration. Using the South Jiangsu region as a case study, the paper establishes a framework for analysis based on the theory of scale reconstruction, termed as 'power-space' re-scaling analysis, and delves into the various types and distinguishing features of governance practices concerning the integration of development zones and towns. The research highlights the following key points:(1) The integration of development zones and towns represents an inevitable and progressive stage in the evolution of their relationship, and urbanization in Southern Jiangsu has transitioned into a new phase characterized by the integration of development zones and towns, facilitated by institutional innovations.(2) The reformation of integrated governance mechanisms for development zones and towns manifests in four distinct types: linkage platforms, cooperative agreements, administrative consolidation, and embedded proxies.(3) Examining the subject relationship, spatial domain, and governance structure across various integration practices reveals a discernible pattern of business alienation indicative of re-scaling dynamics."

Key words: Development zone, Town, Integration of development zone and town, Re-scaling

1 Introduction

"Development zone and town integration" refers to the local governance practice of the development zone and its surrounding towns to promote the overall development of the development zone and town through functional space integration, collaborative mechanism innovation, administrative relationship adjustment and other ways. Since the reform and opening up, there is no doubt that development zones and towns are the two core carriers to promote economic development, spatial growth and population agglomeration in southern Jiangsu. However, in the process of rapid urbanization, due to differences in property status and management system, development zones and towns have conflicts of governance in the aspects of functional division, right boundary and social management responsibility. Under the background of new urbanization, in the face of the social needs of high-quality overall development of urban and rural areas, in order to solve the overall imbalance caused by the division of development zones and towns, since 2006, Kunshan Huaqiao Economic Development District and Huaqiao Town implemented the "integration of development zone and town" management system reform, promoting the integration of development zone and town has become an important way to promote new urbanization and overall urban and rural development in southern Jiangsu.

Most of the existing studies on the integration of development zones and towns are carried out under the theme of "linkage between development zones and towns" and "integration of development zones and towns", focusing on the analysis of the development imbalance of development zones and towns[1-2,5], discussion on the purpose and significance of the integration of development zones and towns[3-6], introduction of individual policies and measures[5-8], operation difficulties and countermeasures[9-10],etc. However, the relevant research still has the following shortcomings: First, it focuses on the introduction of the specific type of " development zone and town integration", and lacks the systematic summary of the types and characteristics of the diversified practice of development zone and town integration; Second, the research mostly stays in the macro description of individual policies and measures, and lacks the theoretical traceability and internal logic analysis of the integration practice of districts and towns.

As the dividends of spatial restructuring released by the adjustment of administrative divisions gradually decline, in the later stage of urbanization, the urbanization transformation under the guidance of high-quality economic development

prompts local governments to rely on optimizing traditional administrative management methods to achieve spatial governance in the new era [11]. After the 1970s, influenced by Lefebvre's spatial production theory and neo-Marxist trend of thought, "Scale" and its reconstruction theory gradually became an important object and theoretical tool of political and economic analysis, and was widely used in the study of governance issues at the national and urban regional levels. In the practice of spatial governance of local administrative districts in China, two sets of rescaling system logics, namely "rigid rescaling" and "flexible rescaling ", have been formed for the consideration of differentiated governance objectives such as the construction of government structure network or the restructuring and optimization of economic and social factor relations [11]. The integration of development zones and towns is essentially a flexible rescaling practice of spatial governance of local government districts based on administrative system innovation.

This paper takes 26 development zones and 42 townships in southern Jiangsu Province that have implemented the practice of development zones and town integration as research objects, obtains case oral history materials and policy documents and other data through field investigation and interview, and systematically summarizes the diversified practice types of development zone and town integration governance in southern Jiangsu Province and analyzes its characteristics of rescaling with the help of rescaling theory tools. In order to provide decision-making reference for China's local district spatial governance.

2 The Evolution of "Development Zone-Town Relationship" and the Necessity of "Development Zone-Town Integration" in Southern Jiangsu

2.1 The Evolution Course of Development Zone-Town Relationship: From Separation to Integration

The evolution of the relationship between development zones and towns has always accompanied the development and transformation of urbanization in southern Jiangsu. Since the reform and opening up, the urbanization process in southern Jiangsu has roughly experienced the following four stages: Namely, rural industrialization

driven by town enterprises (1978-1991), centralized development of parks driven by development zone system (1992-2000), new industrialization stimulated by policy orientation (2001-2010), and integrated governance of development zones and towns driven by institutional innovation (2011-present)[13].Due to the institutional arrangement of urbanization in different historical periods in southern Jiangsu, the relationship between development zone and town has gradually changed from the independent development of towns and townships to the development zone, and then to a new stage of interactive integration. The relationship between districts and towns has gradually changed from township independent development, to development zone as the leading, and then to a new stage of interactive integration development.

Since 2006, adhering to the principle that economic construction should be based on districts and social construction should be based on towns, Kunshan has taken the lead in promoting the reform practice of integrating development zones and towns. By endow development zones and towns with county-level economic management authority, unified planning and construction, economic development, organizational personnel and public management measures, and promote the overall development of urban and rural areas and development zones and towns. By the end of 2023, 26 development zones(Figure 1) and 42 towns(Figure 2) in southern Jiangsu have implemented the reform practice of development zone and town integration according to local conditions through different re-scaling strategies.

2.2 The Necessity of Integrated Governance of Development Zone and Town: Build a Community of Development Zone and Town

2.2.1 Coordinate Urban-Rural Areas and Promote the Overall Development of Development Zone and Town

Most of the development zones are set up in the town districts in the urban fringe, and there are many geographical states such as spatial overlap and nesting. Under the spontaneous action of market forces, the development zone with increasing comprehensive strength promotes the evolution and development of surrounding towns through the diffusion effect, but the differences in administrative levels and management systems between development zones and towns lead to conflicts of

governance in areas such as power boundaries and social management responsibilities.

Due to the inherent influence of the city-oriented concept, the development level of development zones and towns have a certain "stopgap" feature [2], which damages the overall interests of the city. Therefore, whether it is to coordinate the interests of multiple subjects such as counties, development zones, and towns, or to coordinate urban and rural development, it is necessary for urban governments to overcome administrative barriers at the macro level, establish an innovative mechanism for the integration and coordinated development of development zones and towns, and promote the overall high-quality development of urban and rural areas.

2.2.2 Learn From Each Other and Coordinate the Functional Division Between Development Zone and Town

Since its establishment, the development Zone has focused on economic development as its core goal. As an agency of the local government, although the development zone has the autonomy of economic development and fiscal and tax management, its ability to provide public services and social security is insufficient [5]. With the transformation of the development zone into an urban comprehensive functional area, taking into account the upgrading of economic functions and the innovation of social governance is an inevitable requirement for the modernization and improvement of governance capacity of the development zone in the new era [15].

As a basic-level government, the town has the right to manage all the elements in its jurisdiction, but because of the influence of the city-oriented tendency and the fiscal and tax system, the town is often in the awkward situation of power and responsibility not corresponding in the development.

Therefore, promoting the integrated governance of districts and towns, forming a "development zone and township community" from the city level, promoting the functions of development zones and townships to complement each other, and overall allocation of resources such as industry and land are not only the objective needs of the transformation of development zones to comprehensive functions, but also the key path

for towns and townships to enhance development with the help of development zones.

2.2.3 Rebuild the Relationship and Improve the Efficiency of Administrative Governance

The difference in management system is the root cause of economic and social friction between the development zone and surrounding areas, and the governance conflict between the development zone and the dependent administrative district has also become a major obstacle affecting the overall high-quality development of the region. Straightening out the administrative relationship between the development zone and the town is an inevitable requirement and the key to the success of the third venture of the development zone and the promotion and development of the town [1]. Implementing integrated governance between development zones and townships, coordinating the interests of multiple power subjects, and coordinating the allocation of resources inside and outside the region [5] is conducive to overcoming the governance dilemma of "two skins" between development zones and townships, and improving the efficiency of administrative governance through restructuring strategies such as administrative structure integration and collaborative management innovation. Promote the development zone and township to form an integrated, integrated development of governance pattern.

3 The Logical Framework For the Integration of Development and Towns: a Theoretical Analysis Based on Scale Reconstruction

3.1 Overview of Scale and Its Reconstruction Theory

Scale was originally a parameter tool in geography for measuring spatial scale. Since the 1990s, with the infiltration of geography into fields such as economics, politics, and society, the connotation of scale has evolved from expressing concepts of

spatial physical scale to a hierarchical epistemological framework, structure, or relationship for dividing, combining, and representing geographic processes of different scopes and dimensions [17]. Research in scale theory has increasingly focused on the shaping of economic space and the influence on social governance by the process of scale production and reconstruction [20]. Represented by Neil Brenner, Western academia has pioneered the study of "reterritorialization" and "scale reconstruction" phenomena of various regional organizations in the context of globalization using scale theory [18]. In recent years, domestic scholars have also utilized scale theory based on the phenomenon of scale reconstruction arising from global economic and political transitions. They have explored governance issues such as cross-domain coordination of urban regions [19], administrative management [11,15], development zone transformation[12,16], and new city construction[20] based on the transformation process of scale elements such as power hierarchy and spatial domains.

3.2 Logical Framework: "Re-scaling" of Power-Space

Scale reconstruction refers to the process of changes in spatial development and power distribution across different scales. Its purpose is for governance entities to employ strategies of rescaling power and spatial capacity to regulate and intervene in urban development in order to maximize interests [12]. As discussed in the introduction, the rescaling of spatial governance of local political regions includes two sets of institutional logics: rigid administrative boundary adjustments and flexible administrative institutional innovations. Institutional innovation in administration, as it neither alters traditional government organizational structures nor involves drastic reorganization of administrative space, is more easily accepted by all parties and smoothly implemented, with generally significant effects [19]. From a governance perspective, the integration of districts and towns is a flexible scale reconstruction of local political region spatial governance based on administrative institutional innovation. According to scale reconstruction theory, scale consists of two core elements: "power"(subject interest relations) and "space"(territorial spatial

environment). Power elements exhibit a vertical characteristic, reflecting intergovernmental interest subject structure relations, while spatial elements possess a horizontal characteristic, representing the physical environment characterization of local political region differentiation and reorganization [11]. The rescaling of local political region governance is the dynamic adjustment and rematching process of the "power-space" scale relationship (Figure 3).

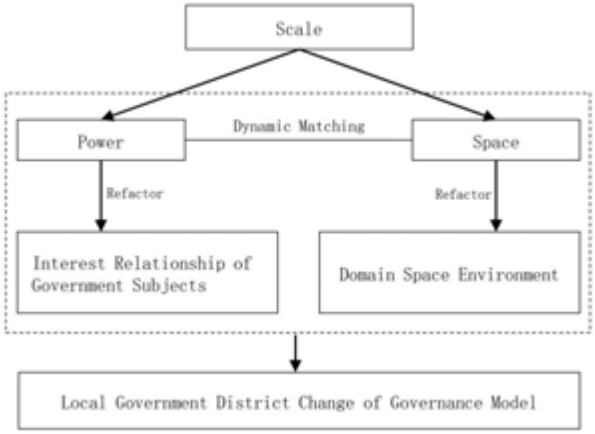

Figure 3 Logical relationship between rescaling and the change of local governance mode

Source: Author's own drawing

The article introduces the theory of scale reconstruction and constructs an analytical framework based on "power-space" rescaling (Figure 4). It uses this framework to analyze the diverse types and differentiated characteristics of scale reconstruction in the practice of district and town integration reforms in southern Jiangsu. Overall, the integration of districts and towns in southern Jiangsu is an initiative by local governments to maximize the overall development benefits of cities. It involves the top-down promotion of scale reconstruction of both the power relations between disjointed and unevenly developed districts and towns and the territorial spaces between them. This process facilitates governance structural adjustments, thereby forming an integrated "district and town community" functional unit. In other words, it is a process of institutional environment reconstruction aimed at achieving coordinated urban-rural development and overall development of districts and towns.

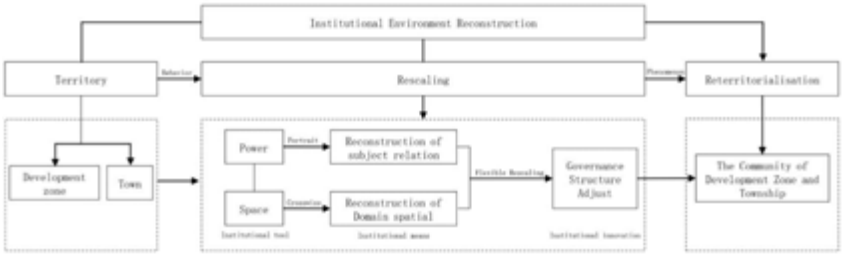

Figure4 Logical framework of rescaling of "Development zone and town integration"

Source: Author's own drawing

4. Practices Types and Re-scaling Characteristics of "Development Zone -Town Integration" in Southern Jiangsu

Based on field investigations of innovative practices in various regional administrative systems and the differential strategies of "power-space" rescaling in each district and town, a summary of the practice types involving 26 development zones and 42 townships in Southern Jiangsu's district-town integration was compiled. These practices can be categorized into four types: platform linkage, agreement cooperation, administrative co-location, and entrusted management embedding (Figure 5 and Figure 6). The diversity of practice types is related to factors such as whether the district and town cross county-level administrative regions, the administrative level of the development zone, and the number of integration subjects, reflecting the pragmatic characteristics of local spatial governance scale reconstruction. Subsequent sections will define the concepts of each type and, based on the logic framework of "power-space" rescaling, analyze the characteristics of scale reconstruction in terms of subject relationships, spatial domains, and governance structures using corresponding case studies.

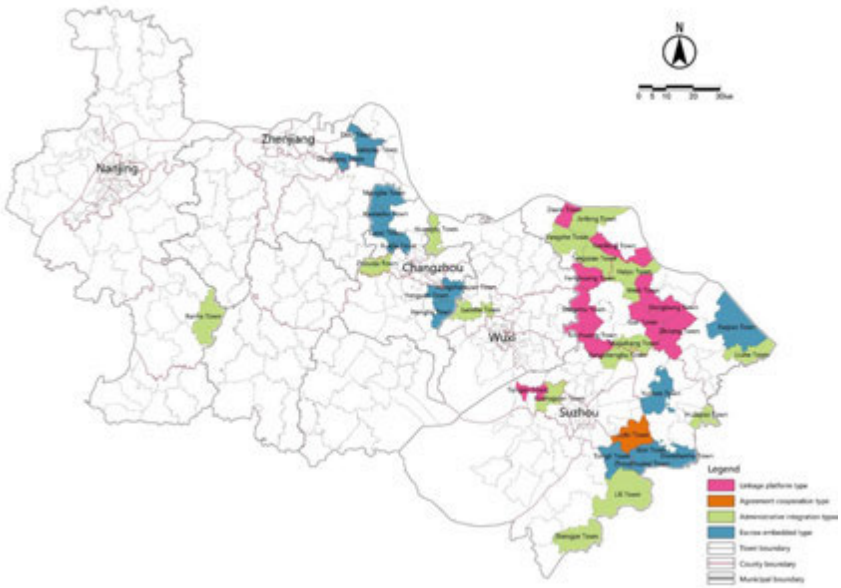

Figure 5 The type distribution map of "development zone and town integration" for towns
Source: Author's own drawing

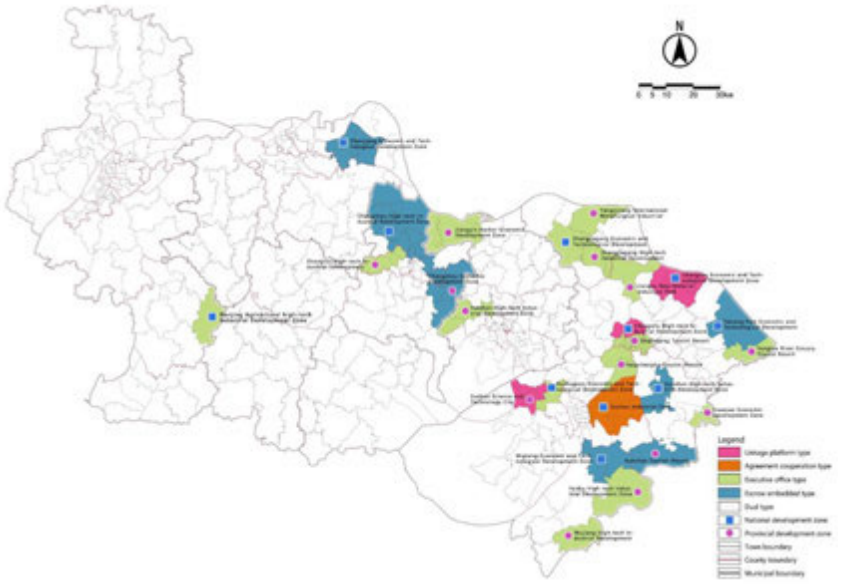

Figure 6 The type distribution map of "development zone and town integration" for development zones
Source: Author's own drawing

4.1 The type of linkage platform: Municipal-level coordination, Industrial Synergy, Enclave Integration

Platform-driven integration of districts and towns refers to the establishment of municipal-level coordination mechanisms between development zones and townships, creating a platform for the coordinated development of district and township industries. It relies on the industrial advantages and investment attraction capabilities of development zones to integrate the industrial space of districts and towns, thereby driving the transformation and upgrading of township industries. This type of integration does not involve traditional administrative restructuring but relies on flexible scale reconstruction. "Top-down coordination of industrial development and spatial layout optimization effectively avoids vicious competition between districts and towns" (Interviewee A). For example, the integration of Changshu High-tech Zone, Economic Development Zone, and surrounding townships is a practice of platform-driven scale reconstruction. Since 2012, Changshu City has established a municipal-level working leadership group to strengthen the role of development zones in attracting investment citywide, enhance the development of township industries and the level of industrial park construction, and fully realize the effective allocation of resources throughout the city. Through measures such as unifying external brand image, promoting coordinated investment attraction between districts and towns, and sharing information resources, each township has been allowed to hang the sign of "Development Zone XX Supporting Industrial Park," forming a new pattern of industrial development with districts leading towns and achieving mutually beneficial interaction in investment attraction. In the past five years, under the promotion of district-town integration practices, various linked townships have introduced nearly a hundred projects relying on development zones, facilitating the settlement of high-quality projects such as Olin Automotive and Linde Electronics in various township industrial parks, accelerating the agglomeration and development of township industries.

4.1.1 Subject Relations: Superior Coordination, Development Zone-Town Collaboration

The linkage platform type of development zone and town integration reflects the characteristic power relations of "superior coordination, development zone-town collaboration" among the three main entities of counties, development zones, and towns. In the organizational framework of the development zone-town linkage working leading group, municipal leaders and the heads of the management committee respectively serve as the leader and deputy leader, while relevant municipal functional departments and each linked town participate as member units. At the municipal level, it undertakes the functions of top-level system design and work coordination supervision, while development zones and towns serve as implementing entities. With the assistance of relevant municipal functional departments, they promote the collaborative development of development zone-town industries through the method of " development zone-leading-town, interactive sharing."

4.1.2 Spatial Domain: Core-Periphery Pattern, Enclave Integration

The linkage platform type of development zone and town integration exhibits the characteristic of spatial scale reconstruction, characterized by a "core-periphery pattern, enclave integration" in industrial spatial organization. Based on the optimization of industrial spatial resources across the entire municipality, development zones primarily focus on attracting leading enterprises in key industries, while industrial parks in each town serve as supporting industrial parks for gathering upstream and downstream manufacturers of these leading enterprises. Through the industrial spillover from development zones, the supporting parks in towns provide spatial carriers for the construction of complete industrial chains in development zones. Towns are effectively integrated into the overall industrial system and spatial pattern of the municipality through the linkage platform. Through the spatial scale reconstruction of industrial space, a pattern of interactive development in the domain space, characterized by "core-

periphery," is formed between development zones and towns (Figure 7).

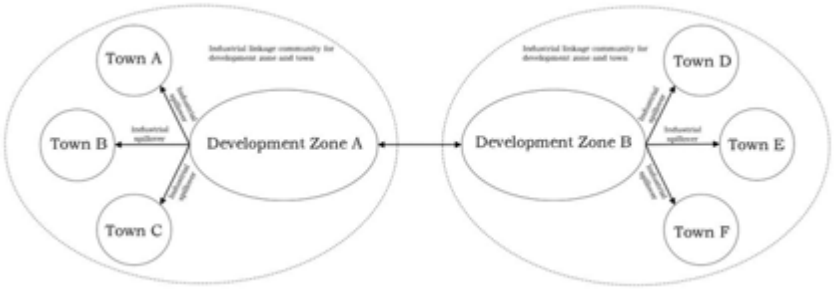

Figure 7 The diagram of domain space re-scaling for the type of linkage platform
Source: Author's own drawing

4.1.3 Governance Structure: Hierarchical Upward Movement, Empowerment Downward

From a governance structure perspective, the linkage platform-type integration of development zones and towns, beyond the traditional administrative system, is based on the governance goal of overall urban industrial development and improving the construction level of town parks. Under the unified deployment of the municipal-level linkage leading group, it coordinates the function of industrial development in development zones and towns, forming an "development zone-town community" for industrial space governance. Essentially, it is a governance action that empowers towns from development zones in a top-down manner.

In the governance process, by establishing clear incentive and constraint mechanisms through specific reward methods and goal tasks, a two-way evaluation system targeting zones and towns is established. The effectiveness of investment attraction in zones is mainly assessed, while the construction level of supporting industrial parks in towns is the main focus of assessment. This ensures the effective achievement of governance goals for the collaborative development of zone-town industries.

4.2 The Type of Agreement Cooperation: Transfer of Development

Rights, Sharing of Benefits

Agreement-based cooperation refers to the practice of scale reconstruction of development zone-town integration through cooperative agreements between development zones and towns across county-level administrative regions. An example is the collaborative development of the Dushu Lake Open Innovation Collaborative Development Demonstration Zone by Suzhou Wuzhong District (Luzhi Town) and Suzhou industrial parks.

According to the agreement, a core area of 26 km^2 was designated within the jurisdiction of Luzhi Town, including a high-end innovation industry agglomeration area of 6.5 km^2 primarily developed and operated by the industrial park. The high-end innovation industry collaborative area of 8.5 km^2 is primarily developed by Wuzhong District according to the same standard, with support from the industrial park. The ecological countryside area of 11 km^2 is jointly developed by the two districts. Within ten years, the Suzhou industrial park will invest no less than 20 billion yuan in education, healthcare, and innovation platforms in Wuzhong District. After ten years of development, the fiscal revenue will be shared and distributed with 20% to the municipal level, 40% to Wuzhong District, and 40% to the Suzhou industrial park.

Through the delineation of inter-district cooperative parks in the critical zones of county-level administrative regions, and by adopting a fusion development approach of transferring development rights and sharing benefits, effective cross-domain integration of production factors such as land and funds has been achieved. This not only provides expansion space for industrial spillover for development zones but also enhances the quality of industrial development and spatial construction in towns. Currently, the core area has attracted industrial projects with a total investment exceeding 15 billion yuan, covering fields such as electronic information, biomedicine, and fund platforms.

4.2.1 Subject Relations: Exchange of Elements, Win-Win Alliance

Outside the statutory administrative system, the rescaling of cross-domain spatial governance power structures is achieved through the establishment of the Working Coordination Council for the Demonstration Zone. According to the "Working Rules of the Working Coordination Council for the Dushu Lake Open Innovation Collaborative Development Demonstration Zone in Suzhou City," the Council serves as the decision-making body guiding and coordinating the construction of the demonstration zone, reflecting the characteristic of hierarchical upward movement in power rescaling. The Council is composed of municipal leaders, main officials from various districts, and leaders of relevant departments at the municipal and district levels. From top to bottom, it establishes positions such as chairman, vice chairman, and members, forming a hierarchical structure. This structure facilitates cooperation among multiple entities including municipal government, management committee, district government, functional departments, and towns, based on the exchange of development elements and cross-domain spatial governance, thereby forming a win-win alliance.

4.2.2 Spatial Domain: Critical Integration, Cooperative Development

The demonstration zone is adjacent to functional areas such as the Dushu Lake Science and Education Innovation Zone and the Huawei Research and Development Center on Sangtian Island. However, it is constrained by administrative boundaries, hindering the effective construction of a mutually beneficial relationship for the development of industries in cross-domain critical areas. Additionally, there are real issues of fragmented and imbalanced urban landscape images along both banks of the Wusong River.

The construction of the demonstration zone is based on the integration of cross-domain critical spaces to form inter-district cooperative parks (Figure 8). This approach, depicted in Figure 8, promotes spatial governance contracts through critical integration and cooperative development without altering the existing administrative affiliations of spatial domains. This process drives the reconstruction of spatial scales, thereby achieving high-quality integrated development of spatial domains for towns.

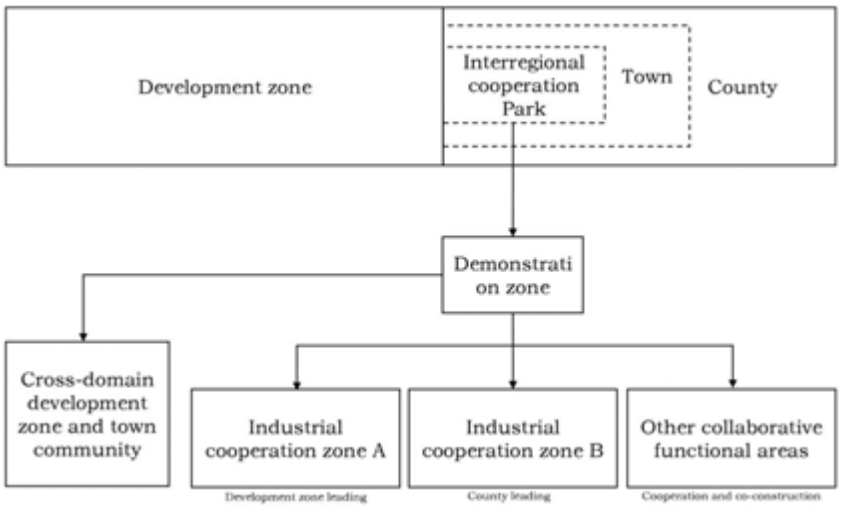

Figure 8 The diagram of domain space re-scaling for the type of agreement cooperation
Source: Author's own drawing

4.2.3 Governance Structure: Top-Level Promotion, Collaborative Construction

Constrained by administrative district economics, any unilateral action between development zones and towns cannot promote spatial governance in cross-domain areas. It is essential to establish a top-level organization beyond development zones and towns to break free from the constraints of administrative district economics. Agreement-based cooperative integration of zones and towns achieves this by establishing a Working Coordination Council mechanism, with municipal-level leadership coordinating the overall efforts. This mechanism clarifies the functions of decision-making and executive bodies within the council, thus facilitating the realization of "cross-domain critical area construction, governance, and shared governance goals" (Interviewee B). From a governance structure perspective, agreement-based cooperative integration of development zones and towns embodies the characteristics of "top-level promotion, collaborative construction" in spatial scale reconstruction.

4.3 The Type of Administrative Integration: Unified Management System, Coordinated Functional Division

The type of administrative integration refers to the integration of administrative management systems between development zones and towns, implementing a practice of "one team, two brands" co-location offices in the scale reconstruction of development zone-town integration. Following the principle of prioritizing development zone-level economic development and town-level social development, it achieves the integration of zone-town management through "six unifications" in the management system, namely unified economic development, administrative approval, planning and construction, management of social public affairs, financial management, and organization and personnel. This type is relatively common, mainly occurring between provincial-level development zones and towns, such as Huishan High-tech industrial development zone (Luoshe Town) and Wujiang High-tech industrial development zone (Shengze Town).

4.3.1 Subject Relations: Parallel Concurrent, Development zone -Town Integration

From the perspective of subject relations, the administrative co-location model of development zone-town integration adopts a strategy of complete integration, implementing a rescaling approach of "one team, two brands." This promotes the rescaling of power subject relations between development zones and towns, achieving "parallel concurrent, development zone-town integration" in the administrative system. Specifically, the Party Working Committee and Management Committee of the development zone correspond respectively to the Party Committee and Government of the town. Moreover, the Secretary of the Party Working Committee and the Director of the Management Committee of the development zone concurrently serve as the Secretary of the Town Party Committee and the Mayor of the town, respectively.

4.3.2 Spatial Domain: Boundary Elimination, Integrated Development

Initially, most of the approved areas for development zones were located within the jurisdiction of towns. As development zones expanded their areas, the geographic phenomenon of development zone and town jurisdictions intertwining became increasingly complex. The administrative co-location model of development zone-town integration relies on a rescaling strategy of "eliminating boundaries, promoting integrated development" to drive the complete overlap of spatial domains between development zones and towns (Figure 9). Within the same spatial domain, unified industrial layout, planning, construction, and land development for both the development zone and the town effectively address spatial governance conflicts between development zones and towns.

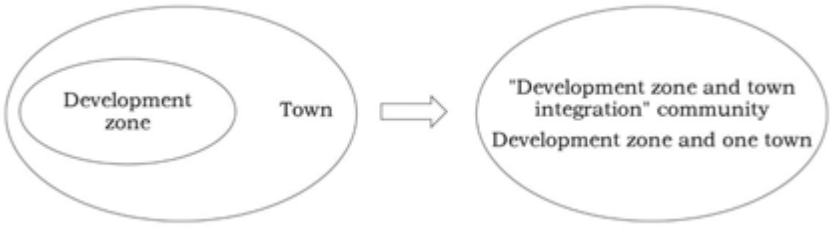

Figure 9 The diagram of domain space re-scaling for the type of administrative integration
Source: Author's own drawing

4.3.3 Governance Structure: Institutional Restoration, Quasi-Governmentalization

From a governance structure perspective, the governance of development zones, with economic development as its goal, significantly differs from urban governance and rural governance, forming a centralized third-region governance model with "integration of government and enterprises" as its core feature [21]. As development zones gradually transition to comprehensive functional areas, besides focusing on economic functions, there is a need to enhance public services and social management functions. The administrative co-location model of zone-town integration achieves mutual complementarity of functional advantages between development zones and

towns by integrating their functions. This promotes the transformation of development zones towards "institutional restoration and quasi-governmentalization."

At the administrative level, provincial-level development zones are mostly at the deputy division level, while towns are generally at the section level. The administrative co-location model promotes the "upward scaling" of town-level power levels, aiding towns in gaining greater influence in the development process. For example, the administrative functional structure of "two offices, eight bureaus, and one platform" in Wujiang High-tech industrial development zone (Shengze Town) is an administrative power structure reconstructed by the city government, granting county-level management authority to zones and towns, thereby enhancing the governance capacity of development zones and towns.

4.4 The Type of Proxy-embedded: Town Leadership by Zone, Unified Management

The proxy-embedded model refers to an innovative administrative system where the administrative functions of towns are embedded into the development zone and managed by it, without complete integration, in the scale reconstruction practice of zone-town integration. This type mainly occurs between national-level development zones and towns, such as Wujiang Economic Development Zone (Tongli Town) and Taicang Port Economic Development Zone (Fuqiao Town). For towns, "as the leaders of the development zones often hold concurrent positions as government committee members, compared to other general towns, towns integrated with zones have greater opportunities for development resource allocation" (Interviewee C). Additionally, towns are government entities at the township level, with relatively abundant administrative staff positions. "Proxy management of towns is beneficial for development zones to manage surplus staff positions in towns systematically, thus solving the problem of employment status for hired employees" (Interviewee D).

4.4.1 Subject Relations: Hierarchical Nesting, Town Affiliation to Development

zone

National-level development zones are often at the deputy department level, while towns are mostly at the section level. The significant difference in administrative levels prevents the formation of unified power subject relations between development zone and town. Therefore, in the process of integrating administrative functional structures, the rescaling strategy of hierarchical nesting of towns within development zones promotes the rescaling of power subject relations between zones and towns, forming a "hierarchical nesting, town affiliation to zone" power subject relationship. Compared to the administrative co-location model, the proxy-embedded model demonstrates that the Party Working Committee and Management Committee of the development zone hold a higher administrative level than the Party Committee and Government of the town, with the town being led by the development zone

4.4.2 Spatial Domain: Geographic Integration, Development zone Encompassing Town

In the spatial domain rescaling of proxy-embedded zone-town integration, there generally exist two scenarios: one development zone corresponds to one town or one development zone corresponds to multiple towns (Figure 10). The former scenario is similar to the spatial domain restructuring characteristics of the administrative co-location model of zone-town integration. Overall, through the rescaling strategy of "geographic integration, zone encompassing town," the previously separate development zones and towns form an integrated community of zone-town fusion and development. Under the management of the development zone, there is a comprehensive promotion of optimal allocation of spatial resources within the zone-town scope, eliminating spatial governance conflicts between zones and towns, and promoting overall high-quality development of zone-town space.

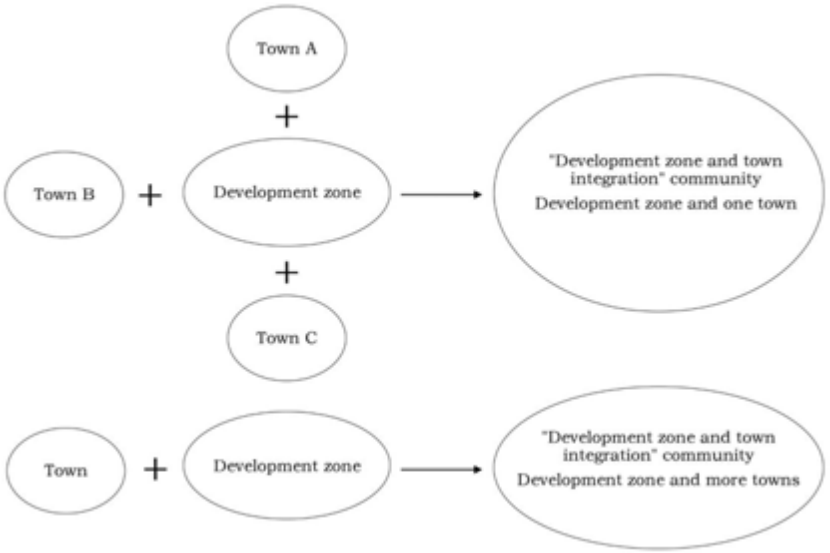

Figure 10 The diagram of domain space re-scaling for the type of proxy-embedded
Source: Author's own drawing

4.4.3 Governance Structure: Development zone-oriented, Unified Management

The proxy-embedded model of development zone-town integration reflects the governance structure restructuring characteristic of being "zone-oriented, with unified management." Taking Wujiang Economic Development Zone (Tongli Town) as an example, after embedding the administrative functions of towns into the development zone, their power hierarchy is scaled up. The administrative structure of Wujiang Economic Development Zone (Tongli Town) indicates that the development zone focuses on investment promotion and economic development functions, while the town emphasizes social governance and rural work functions. In terms of cross-functional areas, the relationship between the development zone and the town is one of leadership and being led in governance, where the "XX Bureau" of the development zone corresponds to the "XX Office" under the town. This helps to streamline the governance relationship between development zones and towns and coordinate administrative functions, promoting the centralized governance of dispersed economy and fragmented

space at the development zone-town level, thereby facilitating integrated urban-rural development.

5 Conclusions

Promoting the integrated development of development zones and towns has practical significance in promoting the complementarity of functional advantages of development zones and towns, the rationalization of administrative relations, the integration of functional space, and the coordinated layout of industries, and is also an important starting point for the redistribution of resource elements in the region and the elimination of conflicts of development zone and town governance. The integration of development zones and towns is an inevitable trend and advanced state of the evolution of the relationship between development zones and towns. In the context of the new urbanization with the overall high-quality coordinated development of urban and rural areas, the reform practice of development zone and town integration has become an important path for southern Jiangsu to seek new "institutional dividends" and improve the spatial governance ability of local political districts.

The development stage, administrative level and the relationship between the development zone and the township determine the diversification of the types of integrated governance practices of the district and town. Taking southern Jiangsu as an example, the integration reform practice of development zones and townships has evolved into four types: linkage platform, agreement cooperation, administrative offices and proxy-embedded. Moreover, the main body relationship, domain space and scale reconstruction of governance structure of each type are different, indicating that the integration development of development zones and townships is a governance reform tailored to local conditions. It also reflects the change of local governance thinking from rigid and radical "space governance" to flexible and flexible "system design".

The scale theory paradigm has a strong explanatory power for the reform practice

of integrated governance between development zones and townships. The essence of integrated governance between development zones and townships is to reconstruct the power relationship and domain space between development zones and towns through the establishment of cooperative mechanisms or innovative management systems and other flexible re-scaling strategies, so as to promote the adjustment of governance structure system. It is the process of institutional environment reconstruction and local governance change under the interest game of multi-level administrative subjects in the city. The integration reform practice of development zones and towns under their jurisdiction is closely related to the stage of urbanization development and institutional environment of the region. Due to space limitations, this paper focuses on the types and characteristics of the practice of integrated governance of development zones and towns in southern Jiangsu Province, such as the adaptability of the integration of development zones and towns, the effectiveness evaluation and the problems still existing in the implementation process are still to be studied in the next step.

Email:hupan@seu.edu.cn

Abstract

As vital components of urban renewal efforts in old city districts, old residential areas play a crucial role in rejuvenating regional vitality, enhancing residents' well-being, and fostering sustainable economic and social development in cities. Taking the example of the transformation of old residential areas in the Zhonglou District of Changzhou City over the past three years, a comprehensive assessment is conducted.By integrating the theory of a full life cycle, a holistic evaluation system for the renovation of aging residential communities is established to assess the project comprehensively. This evaluation system focuses on three dimensions: space, services, and culture, in order to evaluate overall resident satisfaction across all elements.Finally, long-term governance strategies are proposed from four dimensions: government governance, social operations, engineering projects, and economic funding.

Keywords

Old residential area,Renewal evaluation, Spatial governance

Introduction

With the accelerated process of urbanization and rapid population growth, some old residential areas face the imminent threat of decline and contraction, posing a critical issue of how to rejuvenate these communities (Schenkel, 2013). Old residential areas, integral components of urban downtown districts, need to consider various influential factors including multi-stakeholder participation (Bovaird, 2007), preservation of historical heritage (Said, Aksah, and Ismail, 2013), infrastructure upgrading and redevelopment, resident satisfaction (Gu et al., 2019), and the diverse needs of marginalized groups (Clark, Kearns, and Cleland, 2016). The renewal of old residential areas holds paramount significance in revitalizing regional vitality, enhancing resident well-being, and fostering the sustainable development of urban economics and social aspects.

On the practical front, Singapore, Japan, and Western countries initiated urban renewal projects in the 20th century, tailoring innovative transformation models to address issues such as elderly care and employment for low- and middle-income groups based on their respective development contexts. Tokyo actively engages in the transformation of old residential areas, exemplified by projects like Hanada and Takashima, leveraging both governmental and private sector efforts to create multi-party agreement platforms that ensure smooth renovation processes. Regions like Sweden, Denmark, and the Netherlands prioritize community aging adaptation and eldercare service facility configurations. In the Eastern New York Neighborhood Plan in the USA, there's an emphasis on the mixed-use of community street spaces, highlighting the shaping of public areas during transformations.

Compared to international efforts, China's old residential area renovations started relatively late. Since its initiation in 2020, significant progress has been made but challenges such as long-term operation difficulties and governance shortcomings have emerged. In July 2023, China's Ministry of Housing and Urban-Rural Development issued the "Notice on Solid Progress in the Renovation of Old Urban Residential Areas in 2023," proposing qualitative and quantitative analyses to evaluate the current phase of renovations and strengthen the analysis of experiential issues.

As phases of old residential area renovation projects are complete, many Chinese cities are evaluating and providing feedback on completed work at the district level. The Ministry of Housing and Urban-Rural Development surveyed residents of old residential areas in eight pilot cities in Shandong, Zhejiang, Shanghai, and Suzhou in 2022, focusing on residents' subjective satisfaction. Cities like Tianjin's Binhai New Area, Ningbo's Fenghua District, and Nanchang's Donghu District are conducting annual performance evaluations of old residential area renovation projects. Changzhou, as one of Jiangsu Province's pioneering cities in old residential area renovations, has numerous typical samples for evaluation, aiding in systematically addressing issues and demands during renovations and improving management methods and resource allocation for future projects.

Literature review

Research on the renovation of old residential areas mainly includes aspects such as policy analysis, renovation models and strategies, and community governance. In terms of policy analysis, some scholars analyze the advantages and disadvantages of policy samples through textual analysis of renovation policies and quantitative evaluation (ZHANG et al., 2022); while others analyze the policy systems and implementation measures for the renovation of old residential areas in domestic and foreign cities (Lu , 2023). In terms of renovation models and strategies, scholars usually conduct research around a certain element involved in the renovation of old residential areas, such as spatial renovation(MA et al., 2021), sponge-city transformation (LI, GU and WANG, 2019), funding input (LI and ZHANG, 2019), etc.; or from the perspective of micro-renovation (CAI , YANG and LI , 2017), community renewal (Dai , Wang and Dong , 2019), etc., exploring the content and countermeasures of renovating old residential areas. In terms of community governance, some scholars analyze the conditions for social forces' participation and the ways of benefiting, constructing a community governance system for social forces to participate in the renovation of old residential areas (XU and XU, 2020); or from the perspective of resident participation, analyzing the paths and strategies that promote resident participation in governance in the renovation of old residential areas (LI, GU and ZHU, 2020); there are also scholars exploring informal governance models based on communities from the perspective of community administration (ZHAO , LIU and WEN , 2023).

Research on the evaluation of renovation projects for old residential areas is still in its early stages. Researchers usually evaluate the implementation effects of renovating old residential areas from a specific perspective, with significant differences in indicator selection. Some papers have evaluated the effectiveness of renovating old residential areas in a specific aspect

from perspectives such as environmental suitability (LI and WANG, 2016), aging-friendliness (HU, MA and HUANG, 2021), comprehensive environmental improvement (ZHANG, LI and GU, 2021), material space renewal (WEI, 2022), etc.; while others have started from the perspective of project performance evaluation (LI, SI and BAI, 2021), analyzing the comprehensive benefits and outputs of renovating old residential areas.

Through a review of existing theoretical research, it becomes evident that the evaluation of renovation projects in old residential areas encompasses various dimensions. Nevertheless, a comprehensive evaluation system addressing the entire project life cycle remains absent, with a limited number of studies offering comprehensive reviews and summaries of renovation efforts in old residential areas. Drawing upon existing research and practical experiences, this study examines the renovation of old residential areas in Zhonglou District, Changzhou City, employing life cycle theory to develop an evaluation system and establish an evaluation framework at the district level for such renovations. Subsequently, empirical research is conducted.

Research Demands and Objectives

Research Demands

1. The renovation of old residential areas is influenced by various factors such as the scale of construction, construction era, construction subjects, personnel composition, spatial location, and more. It is urgent to propose classified and graded renovation and optimization strategies through scientific evaluation. Effectively enhancing residents' satisfaction is one of the important goals of the renovation work.

2. The factors influencing satisfaction are diversified, including the cultural atmosphere of the community, the organization of activities, personnel composition, and the situation of residents' families. To more effectively guide future work, it is necessary to conduct scientific and systematic research to accurately identify the core contributing factors that enhance residents' satisfaction before and after the renovation, precisely match residents' needs, and effectively improve their satisfaction.

Research Objectives

Based on the two core demands mentioned above, this study aims to establish an evaluation framework with the following objectives:

Incorporating the concept of a full lifecycle, this study comprehensively considers the types of renovation and facilities involved in the renovation of old residential areas. It evaluates the entire renovation process from multiple dimensions, including the output of renovation projects, the quality of renovation works, the management of renovation operations, and the comprehensive benefits of renovation. This evaluation framework encompasses multiple stakeholders, such as residents, community (street) leaders, property management companies, and construction companies.

Furthermore, this study aims to verify the accuracy of the evaluation results by surveying residents' satisfaction after the renovation. Through questionnaire surveys comparing

satisfaction levels before and after the renovation, as well as satisfaction with individual elements and among key demographic groups, this study aims to scientifically identify the proportion of satisfaction improvement brought by the renovation of the community. This will provide sufficient data support for the implementation of future work.

Finally, based on the evaluation content and results of these two parts, this study aims to summarize the experiences and issues encountered during the renovation process and propose long-term governance strategies for community renovation from multiple dimensions.

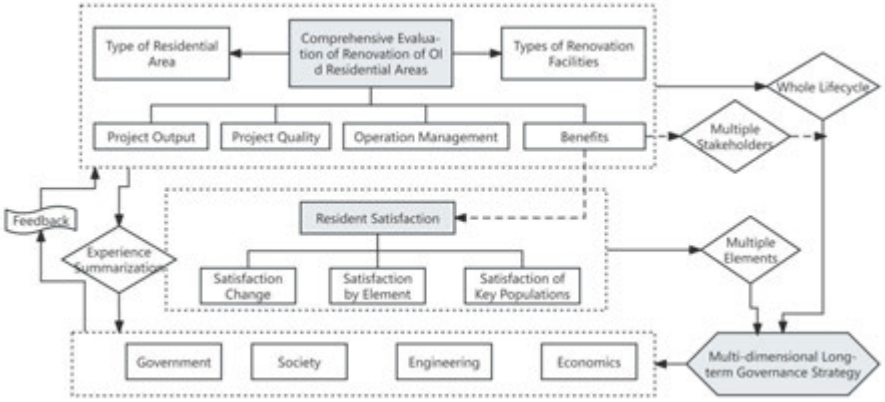

Figure 1 Research Framework

Research Design and Methodology

Construction of a Comprehensive Evaluation System for Renovation

The concept of the whole lifecycle, originating from project management science, is used to describe the various stages of a project from its inception to its completion. The application of the whole lifecycle theory to the evaluation of renovation projects in old residential areas helps align the evaluation chain with the various stages of the renovation project. This approach establishes a comprehensive evaluation process that integrates problem identification, resource allocation, implementation planning, supervision and feedback, as well as summary and improvement. It avoids issues such as incomplete element selection and biases in evaluation focus, providing a basic framework for the implementation, management, and evaluation of future renovation projects in old residential areas.

In light of the planning and construction characteristics of renovation projects in old residential areas, the whole lifecycle of these projects can be divided into four main stages: pre-decision stage, implementation and renovation stage, operation and maintenance stage, and benefit evaluation stage. By further aligning the evaluation process with each stage of the whole lifecycle, an evaluation system for renovation projects in old residential areas can be constructed (Figure 2).

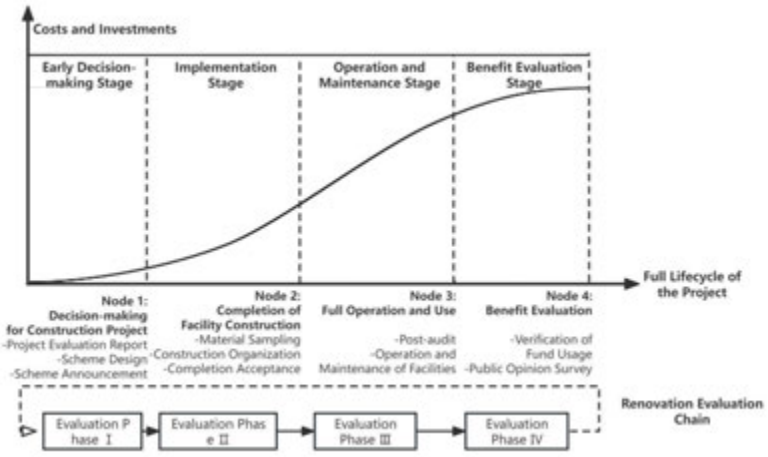

Figure 2 The lifecycle stages of renovation projects in old residential areas

(1) Early Decision-making Stage

Prior to the design of the renovation scheme, it is necessary to conduct a physical examination and assessment of the current operational status of the old residential areas to identify the main issues they face. During this stage, various methods such as field research, interviews, and big data analysis are typically employed to comprehensively evaluate the internal and external environments of the old residential areas. A comprehensive project evaluation report is then formulated. Next, based on the results of the physical examination and assessment, a list of renovation projects for the corresponding old residential areas is compiled. By considering residents' renovation preferences and funding estimations, renovation projects with urgency and feasibility are reasonably selected. This ultimately leads to the formation of a planning and design scheme with clear objectives, reasonable implementation plans, and high recognition among the residents. The indicators of this stage reflect the completeness of the physical examination and assessment results as well as the renovation project list.

(2) Implementation Stage

The implementation stage of the renovation of old residential areas involves multiple aspects such as authorization, execution, supervision, and management control of the renovation projects. During the implementation process, apart from focusing on the completion of construction objectives and the engineering benefits generated by the project, attention should also be paid to residents' satisfaction with the construction progress and the collection and feedback of public opinions. Residents should be encouraged to participate in supervising the renovation process. At the end of the implementation stage, acceptable renovation results should be achieved, with the project accounting settled and residents' feedback addressed appropriately. The indicators of this stage mainly focus on the engineering construction progress during the renovation process as well as the construction status of various facilities at key completion milestones.

(3) Operation and Maintenance Stage

The operation and maintenance stage of the renovation project for old residential areas is a crucial part of the entire lifecycle. At this stage, the spatial renovation and facility configuration for the old residential areas have been fully completed. It is necessary to establish corresponding operation and maintenance institutions or organizations and establish a long-term management mechanism for the residential areas to ensure the sustainable operation of the renovation projects. The quality of operation and maintenance is directly related to whether the project can effectively radiate and drive surrounding areas, and it also influences residents' evaluation of the project. The indicators of this stage assess the operational management status of the old residential areas based on the completeness of institutional systems and actual communication.

(4) Benefit Evaluation Stage

For the completed renovation of old residential areas, a "looking back" process should be implemented. Through the evaluation and measurement of the project's implementation benefits, a comprehensive understanding of the actual outcomes of the project's implementation should be obtained. Incorporating the evaluation and analysis of the renovation benefits of old residential areas into the lifecycle stage of the renovation project helps the government to make a deeper judgment on the social and economic benefits generated by the renovation project. The indicators of this stage demonstrate the benefits brought by the renovation project from both economic and project recognition perspectives (Table 1).

Table 1 Comprehensive Evaluation Index System for Renovation of Old Residential Areas

Primary Indicators	**Secondary Indicators**	**Explanation of Indicators**
Early Decision-making Stage	Type of Residential Area	Proportion of improvement and upgrade renovation projects among the types of community renovation projects
	Types of Renovation Facilities	Whether the types of renovation are comprehensive
	Number of Renovated Facilities Produced	Output of renovation and construction of facilities in old residential areas
Implementation Stage	Civility in the construction process	Whether the implementation process of the project construction meets relevant safety and civilization management regulations
	Qualification rate of renovation works	Operational and maintenance status of completed renovation projects
Operation and Maintenance Stage	Completeness of Management Organization	Whether the organization and business management system of the project implementation unit is sound
	Effectiveness of multi-stakeholder communication	Whether the communication channels between residents, construction parties, and the government are complete
Benefit Evaluation Stage	Project recognition	Residents' recognition of the project
	Efficiency of economic investment	Whether the improvement in residents' satisfaction is proportional to the capital

	investment per unit of renovation area in the community

Satisfaction Evaluation System and Questionnaire Design

Based on the "Technical Guidelines for Renovation of Old Residential Areas in Jiangsu Province (2021)"(jsszfhcxjst.jiangsu.gov.cn, n.d.) and the "Technical Guidelines for Renovation of Old Urban Residential Areas in Jiangsu Province (2022)" (jsszfhcxjst.jiangsu.gov.cn, n.d.), this article draws on the widely referenced evaluation systems for physical spatial environment and public service levels in existing research . By combining emotional value evaluation methods based on residents' perceptions, a comprehensive satisfaction evaluation system encompassing three dimensions of "space + service + culture" and 22 indicators is constructed. The Likert five-point scale is adopted to collect and analyze data on a per-element basis.

Among these, satisfaction with the spatial environment is the most obvious and intuitive aspect of the renovation of old residential areas, and it is also the core content of the early renovation work. Satisfaction with supporting services involves various aspects such as hygiene, parking, elderly care, property management, and safety, reflecting the comprehensive renovation level and humanistic care. Cultural satisfaction covers content such as cultural atmosphere creation, information communication, and dispute resolution efficiency, demonstrating the fine level of renovation and the changes in life brought about by the renovation. In addition, further attention is paid to changes in satisfaction before and after the renovation, as well as the impact of the renovation on surrounding areas and residents' activities (Figure 3).

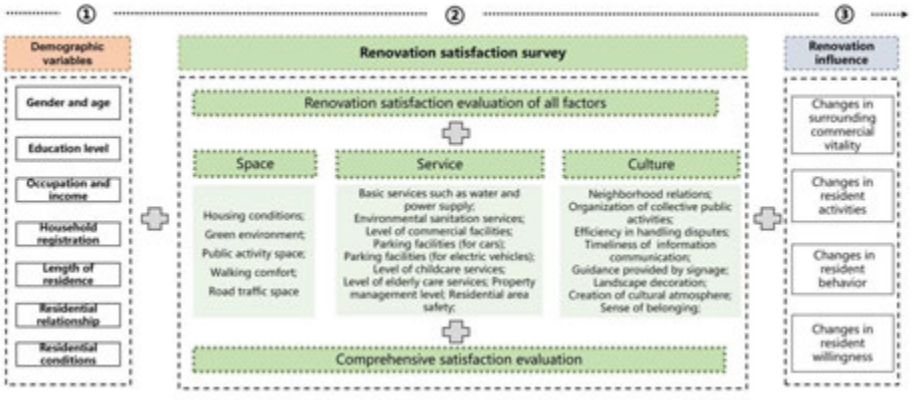

Figure 3 Questionnaire Design and Evaluation Indicators

Research Objects and Data Processing

The Zhonglou District of Changzhou City, located in the central area of Changzhou City, Jiangsu Province, is a core urban area with a long history. In recent years, some old urban residential areas in Zhonglou District have faced issues such as aging infrastructure and incomplete facilities, necessitating renovation and upgrading works. The renovation projects for old residential areas in Zhonglou District of Changzhou City are carried out on a street-by-

street basis, with the old residential areas within the area being classified into two types: improvement type and upgrading type[1].The research objects of this study are 70 old residential areas in Zhonglou District of Changzhou City that started renovation and upgrading from 2020 to 2022 (all built before 2000). More than 90% of them are located in the old city revitalization demonstration area of Zhonglou District, covering both the inner and outer parts of the old city of Changzhou. From 2020 to 2022, a total of 49,126 households were covered by the renovation, with a total building area of 4.0386 million square meters.

Through a comprehensive survey of the implementation of renovation in 70 old residential areas in Zhonglou District, Changzhou City, 1200 valid resident questionnaires and quantitative data on capital investment and engineering construction in each residential area were obtained. Among them, a judgment matrix (see formula 1) was constructed, and the 1-9 scaling method was used to compare the relative importance between renovation evaluation indicators. A questionnaire for judging the importance of indicators was designed. Experts from planning institutions, universities, and street management departments were invited to score the importance of the indicators. Decision-making expert Meta-decision software Yaaph was used to process and analyze the data, obtaining the weight values of the renovation evaluation indicators（Table 2）.

$$A = (a_{ij})_{m\times n} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix} \quad (1)$$

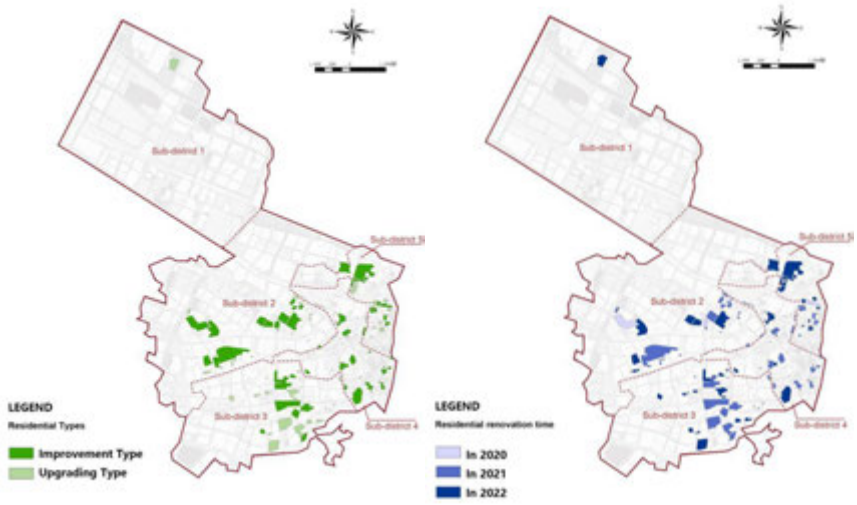
Note: a_{ij} represents the ratio of importance between row factor i and column factor j. When a_{ij} is 1, the two indicators are equally important. The larger the number, the higher the importance of row factor i compared to column factor j.

Table 2 The weight of the evaluation index system

Primary Indicators	Weight Values	Secondary Indicators	Explanation of Indicators
Early Decision-making Stage	15.48%	Type of Residential Area	7.79%
		Types of Renovation Facilities	7.69%
Implementation Stage	39.22%	Number of Renovated Facilities Produced	16.29%
		Civility in the construction process	10.86%
		Qualification rate of renovation works	12.07%
Operation and Maintenance Stage	15.55%	Completeness of Management Organization	10.53%

[1] According to the "Technical Guidelines for Renovation of Old Residential Areas (Creation of Livable Residential Zones) in Jiangsu Province," improvement-type renovations emphasize improving residents' daily lives and enhancing the environmental facilities of the community, while upgrading-type renovations focus more on improving social service provision and enhancing the quality of life.

Benefit Evaluation Stage	29.75%	Effectiveness of multi-stakeholder communication	5.02%
		Project recognition	9.92%
		Efficiency of economic investment	19.83%



(a) (b)

Figure 4 Spatial layout of the old residential areas

(a. Residential Types, b. Residential renovation time)

Results

Comprehensive Evaluation Results of Renovation

In accordance with the performance scoring and rating method outlined in the "Measures for the Administration of Performance Evaluation of Project Expenditures" issued by the Ministry of Finance , the total evaluation score is set at 100 points and divided into four tiers. Specifically, a comprehensive score of over 90 points is considered excellent, 80-90 points is considered good, 60-80 points is considered passable, and below 60 points is considered in need of improvement. For the secondary indicator level, the weights of each indicator are converted into specific scores based on a hundred-point system, and the scoring criteria remain consistent with the comprehensive scoring standards. Based on the comprehensive evaluation results of the renovation, the residential areas can be divided into four categories: demonstration communities with excellent renovation results, communities with good evaluation results, qualified communities with one or two shortcomings, and general communities whose evaluation results need to be improved. Figure 5 displays the comprehensive evaluation results of the four types of communities. It should be noted that some scattered residential buildings, due to the limited scope of renovation and the lack of representative data results, are not included in the evaluation results indicated on the map.

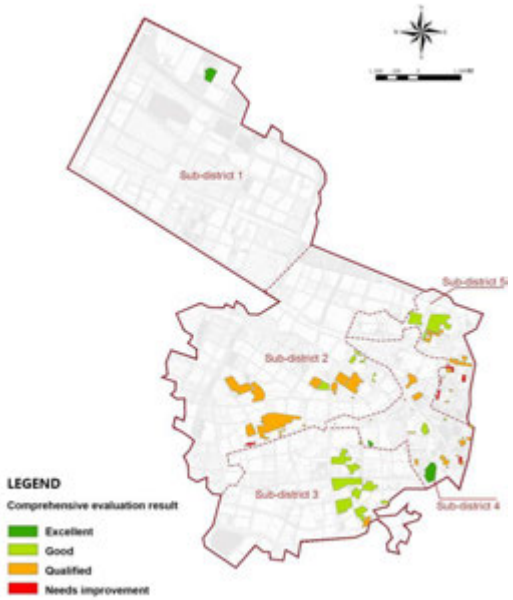


Figure 5 The comprehensive evaluation results of the renovation project

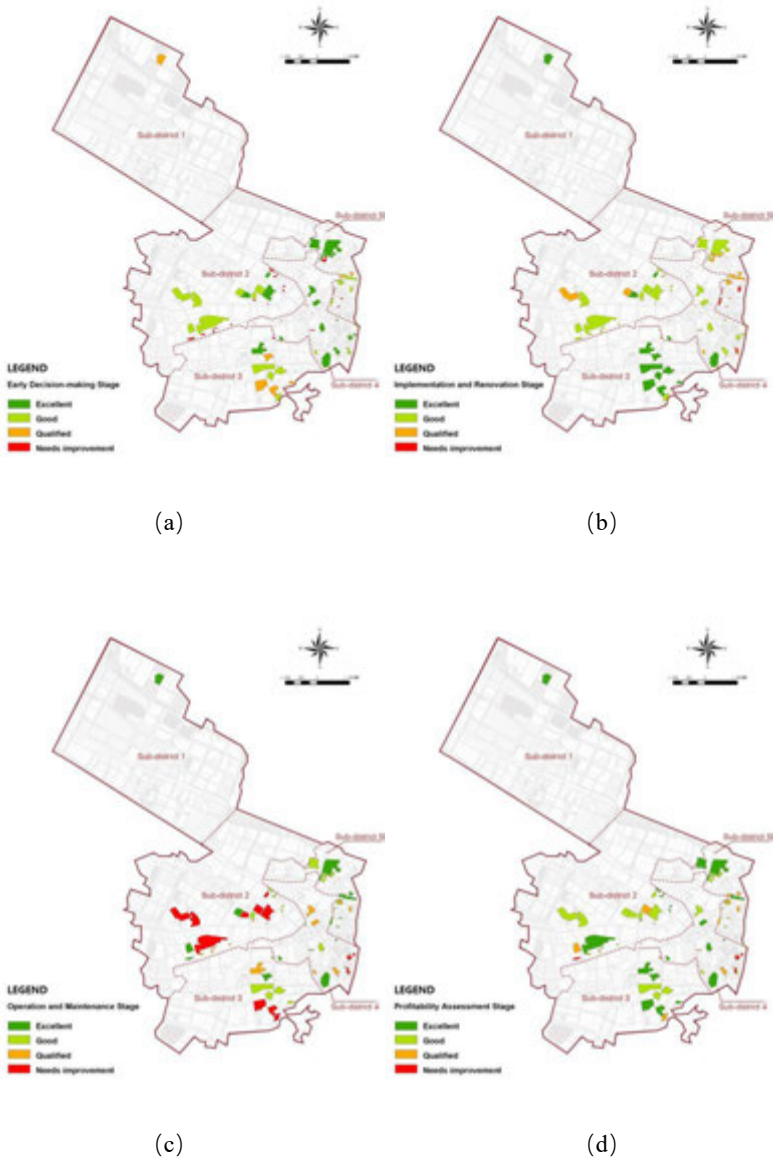
Based on the scoring results of each stage of the life cycle of each residential area, it is found through comparison that:

(1) Excellent and good demonstration residential areas in renovation have made sufficient preparations in terms of preliminary scheme design, engineering construction organization, and later operation and maintenance. Moreover, the construction units have also adopted finer manufacturing techniques, optimized construction methods, and more durable construction materials during the construction process to ensure the effectiveness of various facilities.

(2) For the old residential areas with problems, the main issue is that the effect of the renovation project is difficult to meet various requirements throughout the renovation process of the old residential areas. For example, in terms of building construction, some apartment blocks in some residential areas have issues such as peeling walls and balcony leakage, which have not been promptly addressed during the renovation; in terms of additional parking spaces, some residential areas are limited by their own site conditions and need to vacate parking spaces by reducing green activity spaces, leading to conflicts among residents of different ages; in terms of landscaping, due to the lack of professional greening management teams or property companies, the greening management and maintenance work after the renovation of old residential areas is difficult to carry out in a timely and effective manner; in terms of facility renovation, some old facilities in some residential areas have not been replaced in time, and there are also phenomena of secondary damage after replacement.



(a) (b)

(c) (d)

Figure 6 Evaluation Results for Each Lifecycle Stage

(a. Early Decision-Making Stage, b. Implementation and Renovation Stage, c. Operation and Maintenance Stage, d. Benefit Evaluation Stage)

Evaluation Results of Residents' Satisfaction

The evaluation results indicate that since the renovation of the old residential areas in Zhonglou District, the satisfaction of the residents has significantly improved, with an overall increase of 21.87%. Specifically, the satisfaction levels in the spatial dimension, service dimension, and cultural dimension have increased by 25.32%, 21.44%, and 19.78% respectively (Figure 7). Among the single factors, the improvement in walking comfort stands out the most, as the partial separation of pedestrians and vehicles, road hardening, and the improvement of public spaces have significantly enhanced the quality of daily life for residents. Additionally, through the renovation, most of the residential areas have added access control and garbage classification facilities, leading to a notable increase in satisfaction with environmental hygiene and community safety. Furthermore, the integration of cultural elements of some neighborhoods with wayfinding signage design during the renovation has been widely recognized by residents.

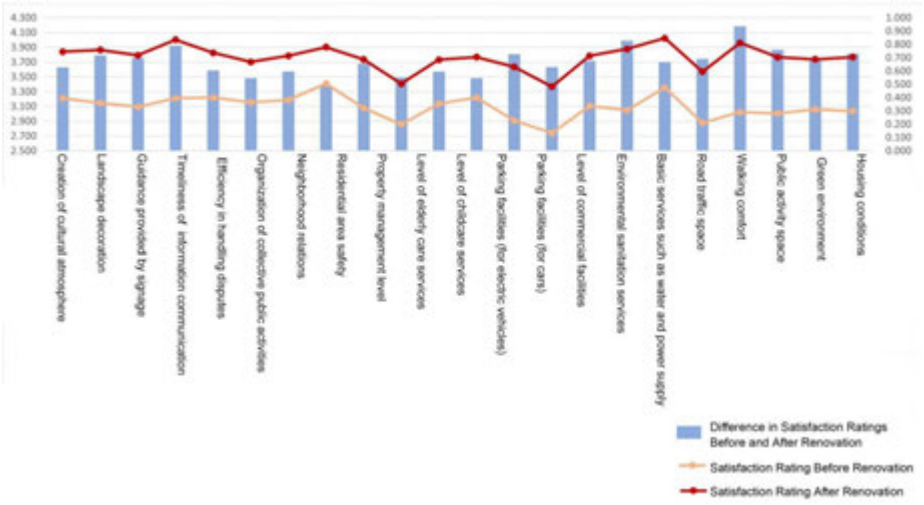


Figure 7 Changes in Satisfaction Ratings for Different Factors Before and After Renovation

However, the difficulty of parking for motor vehicles remains the most prominent issue in old residential areas. Additionally, problems such as inadequate property management, a shortage of human resources, and insufficient introduction of property management companies in old residential areas have generally affected the satisfaction ratings for property management.

The proportion of elderly individuals in the renovated old residential areas is generally high, and whether their living needs have been met during the renovation process has become an important factor influencing satisfaction. The changes in satisfaction among the elderly population towards various facilities before and after the renovation are basically consistent with the overall situation. However, satisfaction levels in areas such as elderly care, parking, and greening are relatively low (Figure 8). The focus on elderly care facilities during the renovation process was not high, and the main renovation content involved elderly canteens and meal assistance services. Although some neighborhoods provide elderly canteens and meal

assistance services on a community-basis during the survey, this service has not yet been popularized in all residential areas. Furthermore, the elderly population often has a high demand for green environments, which conflicts with the demand for parking spaces among other younger and middle-aged groups. The improper management of parking spaces by property management companies later on has led to chaotic parking, which not only encroaches on the activity spaces and green spaces of the elderly but also poses safety hazards for their travel.

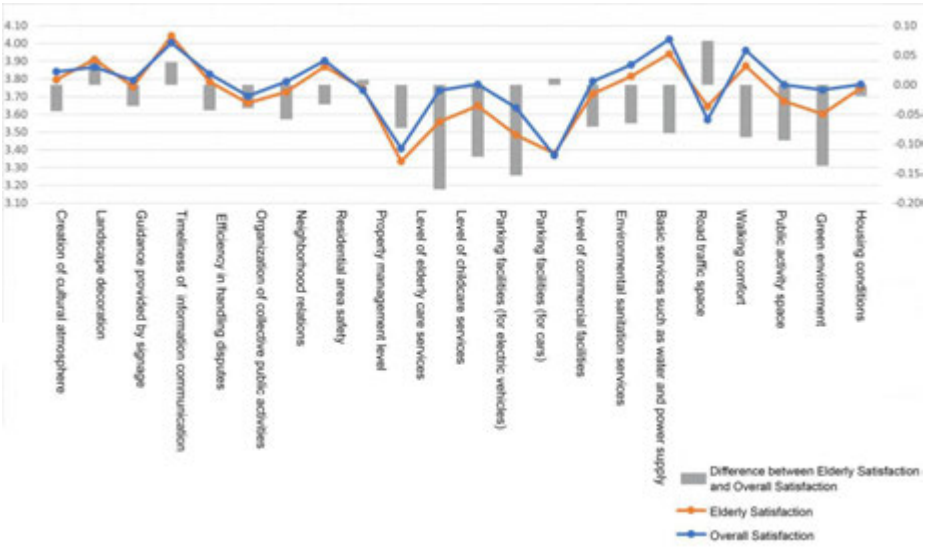

Figure 8 Comparison between Satisfaction of Elderly Groups and Overall Satisfaction

Summary

In recent years, the number of old residential areas included in the renovation scope in Zhonglou District has continued to increase, with the renovation involving a wider range of diverse content and increasingly rich connotations and levels. Through a comprehensive assessment, it can be found that the current core contradiction mainly manifests as a focus on renovation over management. Particularly, difficulties in introducing property management after renovation and the lack of flexibility in using remaining funds have led to a large number of issues arising in the later stages of the residential areas. These issues include patches of bare soil in the green spaces, unmanaged parking spaces, inadequate garbage classification, and difficulties in rapidly accessing firefighting facilities. These problems have seriously affected residents' evaluation and satisfaction with the renovation results.

Suggestions

Based on the analysis of existing issues and the interpretation of relevant policies, this paper draws on the experience of old residential area renovation from both domestic and international contexts to propose targeted long-term governance strategies for the renovation of old residential areas from four dimensions: government, society, engineering, and economy

Dimension of Government Governance: Improving Long-Term Management and Emphasizing Multi-Dimensional Linkages

Optimize the long-term management mechanism, advocate a multi-party co-governance system, and establish a governance system with the participation of grassroots party organizations, community residents' committees, owners' committees, and property management enterprises. Strengthen the leading role of grassroots party organizations in party building and coordinate the handling of various mass affairs; stimulate the supervisory role of owners' committees and actively participate in the follow-up management and effect feedback of the renovation plan; promote cooperation between property management enterprises and party organizations to jointly promote community governance activities. Provide multiple information transmission channels and combine online platforms to timely report community governance information and ensure the right to know for residents in the community. Establish long-term management evaluation standards, normalize the work of conducting "look-back" assessments on the renovation of old residential areas, and conduct graded and categorized acceptance inspections on the management effectiveness of renovated old residential areas.

Dimension of Social Governance: Encouraging Multi-Party Participation and Implementing Classified Management Models

Encourage property management enterprises to actively participate and explore diversified property management models. Research a trinity model combining government underwriting and trusteeship, residents' self-management, and property enterprise management based on the principle of "one community, one policy." For communities that do not meet the conditions for introducing market-oriented property management, an owner self-governance management model can be adopted. For communities that already have property management enterprises, it is necessary to actively promote service upgrades to meet residents' high-quality needs and stimulate enterprise enthusiasm through market-oriented means. Reduce property management costs and minimize "small, scattered, and isolated" communities through management models such as "connectivity, merger, and trusteeship."

Dimension of Engineering Governance: Addressing Facility Shortcomings and Promoting Facility Upgrades

Regularly conduct self-inspections of infrastructure renovation projects, coordinate with communities, and organize construction units to actively make rectifications to ensure smooth and level roads and unobstructed drainage systems in the community after renovation, safeguarding residents' basic daily travel environment. Enhance the quality of housing through improved technological processes, promote the adoption of technologies and materials that are innovative, mature in process, meet quality standards, and have controllable costs, maintain the unity of styles and materials for the renovation of old residential areas in different districts, and achieve organic integration with the cultural heritage and stylistic characteristics of the community. Scientifically assess and accelerate the updating of infrastructure pipelines and ducts with potential safety hazards such as water supply and heating systems, and strengthen the supporting infrastructure for fire safety.

Dimension of Economic Governance: Innovating Financing Models and Using Special Funds Flexibly

Innovate pilot fund sharing and sharing mechanisms, improve fund allocation rules, and raise renovation funds through general public budgets and government bonds. Pilot the introduction of a flexible fund use mechanism, where a smaller proportion of land transfer income from newly added residential land can be extracted as special funds for the renovation of old residential areas, with the remaining portion allocated according to regulations. Increase government financial support, attract market forces to participate, encourage qualified state-owned enterprises to participate in the renovation as scaled implementation and operation entities, and further explore various funding methods.

Conclusion

Based on the concept of a full lifecycle, this article constructs a comprehensive evaluation system for the renovation of old residential areas, aiming to provide a scientific and reasonable evaluation standard for relevant departments to accurately grasp the issues and contradictions in the renovation of old residential areas. An empirical analysis of the renovation of 70 old residential areas in Changzhou City shows that there are still core issues such as insufficient public participation, prominent contradictions in the needs of different groups, inadequate facility maintenance, and a lack of long-term management mechanisms during the renovation process of old residential areas. In the future renovation of old residential areas, it is necessary to further combine the characteristics and needs of the renovation of old residential areas in the region, identify the positioning of the management subject, straighten out various relationships, strengthen the multi-level linkage management model of district-street-community, focus on establishing corresponding operation and management organizations or platforms at various stages of the project's full lifecycle, and explore the formation of sustainable renovation and management models for old residential areas.

How to deal with conflictual central policy incentives? Regional governance dynamics in Flanders unpacked.

Pieterjan Schraepen

Abstract

In most European nation-states, addressing societal challenges demands collaborative approaches and broad actor coalitions. The regional level, often cited as conducive to policy integration, serves as a platform for diverse societal objectives. Despite extensive literature on policy initiatives at the regional level, the configuration and interweaving of the regional space as a result of divergent central policy incentives remain understudied. This paper addresses this research gap by focusing on Flanders, where diverse regional policy initiatives and reforms are shaping a complex ensemble. Specifically, we examine the interplay of three recent central Flemish policy initiatives. We analyze how these initiatives interact, potentially leading to conflicts or innovations, and highlight tensions and trade-offs underlying them. By studying this interplay, we aim to contribute to understanding conflict dynamics in regional governance arrangements and their implications for the academic debate on planning and governance.

DRAFT

Introduction

In many national contexts, societal challenges are more interconnected than ever, necessitating the development of new collaborative approaches and the forging of broad actor coalitions. The regional level is often highlighted in the literature as a suitable scale to achieve various forms of policy integration (Gualini, 2006) and is framed as a platform upon which diverse societal objectives can be realized by facilitating interaction among different actors and policy levels (Fricke & Gualini, 2018).

Various policy initiatives within many EU states attempt to concretely address these societal challenges at the regional level. Policy incentives range from those situated in the relational sphere of projects and programs on one hand to more systemic reforms that are territorially oriented on the other, intervening at the basic tiers of government (Zimmerman et al., 2020). However, the actual configuration and interweaving of the regional space resulting from various, often diverging policy incentives and particularly the tensions that such a fragmented setting can cause, often remains overlooked in literature. To address this research gap, we will focus on the following research questions: how does the region take concrete shape through various and diverging policy initiatives? What roles do central government administrations play in that regard? And to what extent does this interplay of policy initiatives leads towards conflicts and contradictions at the regional level?

This contribution focuses on a specific set of policy initiatives descending from the central government to the regional level. It zooms in on the concrete interplay that can arise between these various policies, examining how they interact with each other, the potential for conflict or innovation, by exposing the tensions and trade-offs that underlie them (Christmann et al., 2020).

Evidence is presented from Flanders (northern part of Belgium), where diverse regional policy initiatives and reforms are being implemented, which gradually seem to form a complex ensemble. This contribution therefore hopes to contribute to the role of conflict in regional governance arrangements within the broad sphere of (spatial) planning.

More specifically, we delve into the interplay of three central Flemish policy initiatives which seem to develop somewhat in parallel within the current regional governance set-up:

1. The establishment of Flemish mobility regions as part of a broader reform of central mobility planning, establishing a more intense intergovernmental cooperation for addressing urban mobility & planning issues.

2. The Flemish regionalization reform (‘regiovorming’) as an overarching central policy initiative, promoting the rescaling of intermunicipal cooperation by installing a fixed ‘reference region’ scale.

3. A new policy approach being developed within the spatial planning domain, aimed towards intergovernmental contractualization via 'region deals', along which local and central stakeholders make goal-oriented and implementation-focused agreements.

We approach the interplay of these different policies towards the region as a specific policy arena where, through confrontation and mutual influence, a new space for collaboration and innovation can emerge, albeit with room for conflict, through which various trade-offs and power dynamics between heterogeneous interests and positions can find its way (Kuhn, 2021; Rangoni, 2020).

Conceptual framework

In this section, we examine how tensions and conflicting policy approaches towards the region are conceptually addressed within the literature and what frameworks are provided to contextualize our own analysis. We focus on both literature that addresses conflicting interests between public sector administrations, as well as conceptual approaches that frame the region as an intermediate coordination space more broadly.

The region as conflicting central interests

One way in which conflicting policy incentives are framed in the literature is through the theoretical concept of 'modes of governance'. Witzel (2019) demonstrates how issues encountered by practitioners within planning practices can be related to organizational and management changes within administrations, which may reflect a broader change in public sector governance, such as neoliberalism, marketization and New Public Governance (Osborne, 2010). A commonly used framework in this regard concerns the concept of ‘governance modes’. Hierarchy, market, and network are distinguished here as ideal types that refer to ways in which organization, coordination, and governance are approached within a particular sector or administration (Hedegaard Sørensen & Gudmundsson, 2010).

Hierarchy in this context refers to a model in which clear dependent relationships are formed between superiors and subordinates, with coordination occurring through an authoritative system of commands and routines. Market refers to an interaction among actors based on self-interest, wherein clearly defined property rights, competition, price signals, and forms of contract formation serve as regulatory elements. A network mode refers to the premise that each participant is mutually dependent on others to achieve desired goals, necessitating reciprocally supported actions. The coordination mechanism crucial within this mode involves mutual trust to foster a collaborative approach.

Addressing conflicting central policy incentives also involves framing them within a broader debate on decentralization and the capacity of central government to maintain a monopoly on control and political power. From this perspective, Ayres et al. (2003) demonstrates how divergent approaches from central government towards the region can be understood through a so-called 'pathology of departmentalism', which has consequences for regional working. Their findings suggest that several influences, including administrative culture, political leadership and historic legacies have therefore played a residual part in determining departmental approaches to decentralization.

Central departments are characterized by their own histories, institutional biases, priorities and leadership and have long-term policy preferences that influence how they respond to new policy initiatives (6 et al., 2002). These will determine the extent to which departments are influenced by pressures to decentralize or devolve functions and the tier of government to which responsibilities are transferred. Their analysis reveals a picture in which departments face contradictory and uneven pressures to meet national delivery targets, respond to demands for

the better co-ordination of policies with a regional dimension and refine policies to more accurately reflect regional conditions.

The region as a gap

Several authors provide insights to frame the region as an intermediate coordination space from a more generic perspective. A common approach in this regard is Hajer's concept of policy making in an institutional void (Hajer, 2003), where clear norms and rules are absent according to which politics is to be conducted and policy measures to be agreed upon.

According to this approach, territorial synchronicity is increasingly being challenged, which necessitates greater attention to the legitimacy of policy interventions. Within the loss of territorial synchrony, actors have to collaborate by transgressing institutional boundaries. As a result, trust cannot be assumed. Policy and politics are therefore not simply about finding solutions for societal problems, but also about finding formats that generate trust among mutually interdependent actors. Within this perspective, the emphasis lies on the limits of knowledge in the light of 'wicked' policy problems and the identification of unawareness as about the provision of knowledge. Policy implementation therefore requires active coordination and an awareness of mutual interdependence.

Hyotonen (2019) frames this issue within the domain of planning via the formation of so-called 'policy vacuums'. According to the author, policy vacuums are connected to the increase of short-termism and market-reactivity in spatial planning. Vacuums have therefore three intertwined dimensions: (1) horizontal, (2) vertical, (3) pervasive. The horizontal dimension arises from inter-municipal rivalry, when there is no governmental scale responsible for planning that transcends municipal boundaries. The vertical dimension refers to potential inconsistencies or mismatches between spatial planning instruments at different scale levels. The pervasive dimension refers to increasing growth-oriented dynamics, land-use practices, particularly among smaller local governments lacking sufficient planning resources.

The region as unfinished institution

Thirdly, we highlight approaches that focus on the framing of the institutional setting of the regional space. Durose (2021) frames the institutional design of governance arrangements at the urban level within a scope of 'incompleteness'. Incompleteness is conceptualized through three alternative design logics: instrumental, pragmatic, emergent.

An instrumental design logic views incompleteness as a 'description', representing a foundational or reformative moment in the institutional design process. Here, institutional design is considered 'incomplete' on its path toward becoming 'complete'. Incompleteness may arise from stalled, failed, or abandoned institutional design efforts, or from a lack of attention to enforcing institutional rules.

A pragmatic design logic approaches incompleteness as 'action', aimed at achieving 'good enough' design. It recognizes the inherently partial and incomplete access to information that designers face, their limited cognitive capacity to model and analyze all possible alternatives, and the stickiness or path dependencies of existing institutions. Finally, an emergent design logic views incompleteness as part of a deliberate and purposeful design strategy. The objective of such a strategy is for institutional arrangements to evolve over time and through usage. In

this approach, incompleteness is valued as a design principle in itself, indicating that intentional incompleteness can be a strategic choice in institutional design.

Incompleteness in institutional design can also be allied with the agonistic perspective in planning literature that values democratic opposition and seeks to realize it through an institutional design process imbued with the principles of contestation, contingency and interdependence (Kuhn, 2020). Agonistic planning theories critically oppose communicative planning theories, which fail in their view to adequately address conflict and overly focus on consensus and cooperation, leading towards a depoliticization of planning theory. Kuhn (2020) distinguishes in this regard three ideal types of dealing with conflict: (a) avoidance, (b) occasion for consensus and (c) acceptance. The agonistic planning approach is situated within the latter type and distinguishes itself from the comprehensive and communicative approach by developing a proactive relationship with conflict, which can assume a transformative function and act as a catalyst for social and institutional change (Mouffe 2013).

Our analysis builds upon the theories and approaches discussed above. Within each case, we therefore highlight the governance mode being developed, how the policy interests of central departments affect the region, and how various actors approach the institutional shaping of the regional space.

Methodology

The analysis in this study is based on a 5-year research project on regional governance arrangements in Flanders (the northern territory of Belgium), which included the three cases discussed. For this purpose, we employed an exploratory and qualitative research approach.

Considering the Belgian federal state structure and after several rounds of Belgian state reform, the Flemish Government is now responsible for most aspects of mobility and spatial planning policy and is the central state in the intergovernmental relationship with the local governments. Given the research focus on divergent central administration approaches, we focus therefore on three cases of Flemish policy initiatives towards the region, which are directed from various central administrations, being the Flemish administrations of Mobility, Environment (spatial planning), as well as Domestic Governance. The three cases can be considered as critical cases of regional reform in public administration in recent years (Yin 2018), being set up by central government during the past legislatures and involving both local and central government actors. Also, the cases concern reforms that are not limited to a few parts of the country, but cover a sufficiently wide area to also detect variation in dynamics between different regions within the same case.

Regarding data collection, interviews were conducted with a broad group of stakeholders and involved actor groups, such as regional administrative coordinators at the central level, civil servants involved in the design of the three policy reforms, officials and politicians of the municipalities involved and staff working within inter-municipal cooperative structures. All the respondents were involved in one of the three cases in some way. Following a bottom-up approach, the focus in the interviews was on both the central motivations behind the policy reforms and assessments of the desired policy objectives, as well on the practical experience of implementing the reform, the consequences this had for cooperation, and the impact on the relationships between the involved actors.

In addition to the interviews, a document analysis was conducted. The selected documents analyzed provided additional insight into the development of legislative framework and included various policy documents, supporting policy research and regional guidelines created by central administrations. Also the data collection builds from a involvement as action researchers in the reform process. The researchers took part as experts both at local level and the Flemish level of the central departments involved in the reforms via the Flemish Policy Research Centre on Governmental Innovation (Steunpunt Bestuurlijke Vernieuwing) and also as members of expert teams brought together to reflect and advise the Flemish government regarding regional reform trends and developments in general.

Analysis

We use the following structure for our analysis. Firstly, the basic characteristics of each of the three discussed cases is outlined below. Subsequently, we analyze the interplay and interaction that develops between the three policy initiatives, building on the distinct dimensions within the developed conceptual framework.

Cases description

1. Mobility regions

The mobility regions were initiated in Flanders since 2019 as part of a new policy approach in Flemish mobility planning.

The new principle of basic accessibility, that underlies the mobility regions reform, propagates a new policy frame, based on the concept of an integrated network approach of public transport designed along the idea of 'combi-mobility' (Weyts, 2015). Basic accessibility prioritizes the development of a mobility network where combinations of different modes of transport (car, bike, bus, train) are facilitated. To achieve this layered type of transportation, a hierarchic model is established that differentiates between various types of public transportation in the region.

With the creation of 15 mobility regions, the Flemish government decided to deconcentrate delegated tasks for mobility planning and policy to 15 groups of local governments via mobility region councils. So far, those tasks were not part of the autonomous realm of local governments. Local governments therefore are now operating as a politico-administrative deconcentrated branch of the central government. The set of delegated tasks includes an advisory role, a role of co-decision with central government and a role of new responsibilities for the mobility needs of targeted groups. These tasks are therefore a mix of own responsibilities, giving advice to the Flemish government and tasks related to the follow-up, but always within a central framework that allows the Flemish government to overturn decisions taken by the mobility region council. The mobility region councils are co-chaired by a political chairperson from one of the local governments and a chairperson from the central department of Mobility. The final approval of a regional mobility plan, however, is still done by the Flemish Government.

Therefore, the mobility region is based not only on a group of local governments within a territory: all the Flemish actors responsible for mobility, within the political realm of the present minister for mobility, have to take part also in the mobility region. In that regard, the mobility regions do not only affect the cooperation between (groups of) local governments, but also have a strong impact on the Flemish government itself. This impact includes an administrative reorganization, a rearranging of working methods, budgets and the reallocation of the staff in

the Flemish Department of Mobility (MOW), the Agency of Roads and Traffic (AWV) and the Flemish Public Transport Company (De Lijn). That is another novelty compared to the historical institutional heritage: the mobility region institutionalizes the intergovernmental cooperation between the two levels of government that really matter, politically: local government and Flemish government (De Rynck et al., 2021).

From an institutional perspective, the mobility reform is facilitated by the introduction of a new framework in which basic accessibility as a new policy approach is anchored by decree (= a Flemish law) (Flemish Government 2019). The decree of basic accessibility, adopted and implemented in June 2019, stipulates the creation of 15 new mobility regions and mandates cooperation between all local governments in each of the 15 regions.

The decree also gave rise to a new geographical demarcation of mobility regions. The delineation process of the mobility regions was the output of an administrative cooperation between the Department of Mobility and the Department of Environment (competent for spatial planning), a new form of cooperation and an exponent of the pressure towards a more integrated approach towards central policy making. In the first phase, 19 draft regions were delineated based on mobility flows, functional relations and existing types of regional cooperation. In a second round, this proposal became the object of a political deliberation which resulted in a final delineation of 15 mobility regions. The political deliberation did not change the map drastically: the technical-scientific work was retained by approximately 80% in the final choices and the political interventions were not at odds with that work. The scale of the 15 regions, the cooperation and the competences of those regions got therefore all imposed and regulated by the Flemish government itself. This is new as it breaks with a strong tradition of sacrosanct 'autonomy' of local government and the free choice for intermunicipal cooperation (Schraepen et al., 2021).

From a local perspective, a key innovation of the mobility regions reform is that the local authorities should have a more transparent and formal say in and control over Flemish mobility budgets. The idea is to give local authorities more influence in public transport on their territory, with a strong say in shaping the two 'lowest' layers of the hierarchical transport model. This approach stands somewhat in contrast with the previous non-transparent lobbying practices from individual local governments towards the Flemish mobility actors in order to obtain more investments and a better public transport offer for their own local territories. Interestingly, many respondents from local government argue that thanks to their involvement in the Mobility Region Councils, the contacts between Flemish mobility actors and (groups of) local government are now much more numerous and intense than before (Schraepen et al., 2023). There seems to be a growing mutual understanding of local political interests and positions, leading towards a growing mutual trust and an enhanced cooperation between the local and central level throughout the mobility regions, on the condition that agreements within the transport region are subsequently sufficiently honored by ministerial engagements at the central Flemish level.

2. Regionalization reform

The current Flemish government Jambon (2019-2024) stated a strong position on the reform of regional governance. The political ambition is set forth to counter administrative burden and the fragmentation of interorganizational collaborative arrangements on the regional level. In the end, the objective is to achieve fewer but stronger regional cooperation structures, a more simplified government apparatus and a strengthened domestic governance.

These political objectives retraces a long-standing policy discussion regarding the intermediate level in Flanders. A turning point in this debate was a regional 'screening' that was conducted about a decade ago. De Rynck et al. (2011) provided an extensive overview of intermunicipal partnerships, informal forms of cooperation, structures and demarcations in which local government were involved at the time. The inventory resulted in a total amount of 2,229 arrangements involving local governments, and an average of 68 arrangements per Flemish municipality (308 at that time). The study raised a broader awareness among stakeholders regarding the complexity of the Flemish intermediate level, which was framed by some as 'administrative cluttering', and the multitude of activities taking place here. This imbroglio of arrangements at the regional level and the lack of coordination created a sense of administrative burden among local government and led to the identification and problematization of several governance issues at that intermediate level: democratic legitimacy, compartmentalization, insufficient transparency, inefficiency, and a general lack of clarity.

As a response, central government aspires to tackle these problems through the regionalization reform. In order to achieve greater coherence at the intermediate level, the Flemish government set up a policy framework for intermunicipal and intergovernmental cooperation to evolve towards fixed regions, so called 'reference regions' (Flemish Government, 2020). Reference regions are conceived as a scale coordination instrument in which all forms of intermunicipal and supra-local cooperation should be clustered. The underlying policy assumption here is that bringing more coherence and consolidation at the intermediate level by rationalizing intermediary structures will lead to a more simplified and transparent government apparatus, fewer mandates and a strengthened, more effective cooperation at the regional level. As a general rule for scale coordination the so-called 'Russian doll principle' is postulated which states that intermunicipal cooperation should coincide with one or more reference regions or fit within one region, with the aim of enabling coordination at the scale of the reference region (Descamps, 2023).

Despite the ambition to increasingly concentrate and align collaboration forms on the scale of the reference regions, the Flemish government does not want to develop the reference regions as a new tier of government with its proper institutions. The regions do not replace the still existing provincial intermediate level and so far reference regions are merely conceived as a coordination level for various forms of intermunicipal and supra-local cooperation. The Flemish government itself declares to 'lead by example' and will gradually adjusts its regulatory framework for intermunicipal cooperation to align with the reference regions (Flemish Government 2021). In addition, central government imposes local government by decree to align all their cooperation forms within the scope of the reform to align with the reference regions by the horizon of 2030.

3. Region Deals

The Flemish spatial policy currently finds itself in a somewhat schizophrenic situation. On the one hand, significant gaps can be identified in terms of the central policy framework, while on the other hand, we witness also an abundance of policy trajectories, studies, and experiments.

A striking example of a central policy gap is the Spatial Policy Plan Flanders, initiated in 2011 to succeed the Spatial Structure Plan Flanders from 1997, yet in 2024, it has not been fully completed (only a strategic vision has been approved). This situation is often framed as a lack of political courage to proceed with tough central decision-making, for example, regarding the

protection of open space and the compensation issue for affected landowners (Coppens & Vloebergh 2017). At the same time, we observe that similar trends can also be observed in neighboring countries. The Netherlands, often seen as a model case in spatial policy and governance, has also been grappling with its National Spatial Vision for some time. Despite both spatial visions formulating good intentions for major societal transitions, they seem incapable of formulating task-oriented, binding goals, particularly for other policy domains, let alone integrating them all into one central spatial policy.

On the other hand, we observe that spatial challenges in Flanders are being addressed within various trajectories and projects by heterogenous actor constellations. Declerck (2024) distinguishes three prototypical working methods through which spatial societal challenges in diverse policy domains are addressed: (1) incubation projects & platforms; (2) regional area processes & programs; and (3) implementation programs. Within these projects and programs in various qualities, we observe that the concept of 'region' is interpreted in different ways. Intergovernmental area-specific cooperation is on the rise, and the establishment of regional partnerships to address spatial challenges is recommended at regular intervals by various authorities and advisory bodies. All these interpretations given to the concept of 'region' articulate area-based governance forms in which cross-administrative level consultation and area-specific customization are central.

Within this context, thought is also being given to the elaboration of a ‘region deal’- instrument within the spatial domain, in analogy to a similar policy instrument in the Netherlands. The focus is on the development of a contractual approach. The region deal as a possible new instrument in spatial policy is conceived as a policy agreement between different administrative levels. Based on negotiations at the regional level, area-specific agreements are established on spatial choices and cooperation, in accordance with spatial policy plans at the different administrative levels, and which determine how, by whom, and with what resources they will be realized.

Essential to this is that the Flemish central government negotiates with other administrative levels on which instruments will be used to address specific spatial challenges within a particular region, and who will undertake and finance which commitments. In the preparatory study work on this approach, the following principles are proposed (Schoups et al., 2023).

A regional deal is conceived as a form of intergovernmental cooperation. This entails that multiple administrations are involved in the deal, since it is an agreement between various actors. Given the intergovernmental nature, it concerns a government agreement, namely an agreement concluded between parties of which at least one is a government. In addition, a regional deal is goal- and implementation-oriented. It must contribute to the strategic central objectives through area-specific agreements. Given the regional scope of the region deal and the principle of intergovernmental cooperation, the agreements made must exceed the purely local level. Finally, the principle of co-financing is essential. This means that each party participating in a regional deal is expected to make a financial or other contribution. It is conceived not merely a subsidy vehicle from Flanders but a form of co-governance, also financially.

Comparative analysis

Conflicting interests at the central level

When comparing the central policy choices across the various cases, we observe that a lack of coordination and some conflicting administrative visions seem to hinder the potential of the three cases.

In the case of the mobility regions, the lack of coordination between the central administrations of mobility and environment results in a rather weak connection between spatial planning and mobility planning, which potential is not being fully realized. Despite the strong emphasis on coordination and cooperation in the policy discourse of the reform, we note that the effective coordination of mobility planning with the spatial planning policy remains rather limited in practice, with the historically compartmentalized policy approach from the Flemish government still having a strong impact on the current functioning of the policy arrangement.

The ambition of the mobility regions to develop a more efficient mobility system is strongly interwoven with the issue of counteracting urban sprawl, thus requiring a close collaboration between the domains of mobility and urban spatial planning. At an administrative level, we indicated that the delineation of the mobility regions was the result of a close collaboration between the top administrators of both departments, resulting in a mutually agreed scale as a basis for future regional development planning. This collaborative relationship between both domains at the administrative levels is in itself also a breakthrough in administrative traditions, but it stands in contrast with the conflictual interactions within the political sphere of government. For this reason, the delineation of the mobility regions was not retained as a policy scale for spatial planning. The former minister of spatial planning refused to integrate her own plans for a better integrated subregional spatial planning in the concept and the institutional form of the mobility regions. This exemplifying pattern illustrates the way the Flemish Government works and how opposite interests try to find their way throughout the Flemish administrative and political constellation. This feature is reflected directly in the organization and ambitions, but also the ambiguity of the mobility regions.

Also, the relationship with project-based regional arrangements remains unclear due to the policy deadlock and the lack of approved central policy framework within the Flemish spatial policy plan. Moreover, the regionalization reform failed to lead to a breakthrough in the planning domain, as the spatial planning department largely remained outside the scope of this reform, due to numerous exceptions and deviations resulting from political deals between Flemish ministers and departments. Exploring the option of working with regional deals can thus be interpreted as a strategy to make progress within this current setting without getting bogged down in delicate political discussions. This appears to be a politico-administrative strategy also adopted in the Netherlands to develop the Region Deals approach here.

The region as a gap?

When we examine within the three cases how the region is shaped as an intermediate coordination space, we note that certain aspects appear to have been strategically left open, with various causes and motivations seeming to exist for this.

The quest for operational spatial policy frameworks in Flanders, as well as in the Netherlands, appears to be manifestations of a broader crisis within central spatial planning. While both articulate good intentions for all major societal transitions, they appear to lack the capacity to establish binding policy objectives for sectoral administrative actors. Therefore, there also seems to be no consensus on which tasks should be addressed at the central level versus the decentralized level. In addition, the divide between ‘pure’ spatial planning objectives and goals

for other sectoral domains such as water, mobility, healthcare, or energy appears to be increasingly difficult to draw in practice. As a result, many thematic challenges end up at the regional level through bottom-up pressure from local actors, despite a clear central mandate on this matter.

Both within the case of the transport regions and the regional reform, we observe that the institutional design and the governance of the region raises many questions among local stakeholders. The central approach to establish the region not as a governing layer, but as a coordination layer, means that at the regional level, autonomous decisions cannot be made or decisions cannot be implemented autonomously. Therefore, regional consultative bodies for implementing regional agreements usually remain dependent on the policy choices of local, but mostly central policy actors, as well as the instruments and resources they mobilize for this purpose. The lack of clear central task assignment, particularly within regional reform, is a subject of local criticism, given that central administrations, for the time being, do not adopt a clear, joint positioning and commitments towards the region for their own policy objectives. Leaving the institutional design and governance open can therefore also be interpreted as a strategy to conceal the lack of coordination among central administrations, as well as a way to cope with significant differences in central and local path dependencies and administrative cultures.

Institutional incompleteness: room for innovation?

The lack of a clear task assignment and a fixed governance structure poses certain challenges for regional actors but also provides some degrees of freedom. Therefore, a policy space seems to emerge that can be creatively shaped by diverse coalitions of actors, potentially leading to forms of policy innovation.

The discussed cases are policy incentives centrally coordinated by various administrations in parallel, but converge in the region and are generally taken up by the same actor coalitions here, such as regional intermunicipal entities. The latter can therefore act as a 'boundary spanner' to facilitate effective policy linkage for integrated policy coordination. In this way, mutual influence between the different policy tracks, although centrally not initiated in that respect, does indeed occur at the regional level in practice. For example, local experiences with regional cooperation within the transport regions served as a test case and prototype for subsequent collaboration within the reference regions. Furthermore, test cases addressed in the development of regional deals are subsequently taken into account within some reference regions as breakthrough projects to further strengthen intergovernmental cooperation here.

In line with this, we also observe that the framing of the institutional arrangement forming at the regional level is differently contextualized by various actors, wherein we can discern both instrumental, pragmatic, and emergent argumentation lines.

At the local level, the descriptive design view towards the region seems to prevail, wherein the current institutional design is framed as incomplete, given that regional challenges and obligations are primarily oriented towards local authorities. From their perspective, the central Flemish government itself does not sufficiently engage within the region and fails to fulfill its commitments adequately.

From the central perspective of domestic governance, a more pragmatic logic can be discerned. The regional reform, in particular, could only be approved at the level of Flemish government

DRAFT

by allowing a series of exceptions and deviation rules for sector administrations, resulting in many regional collaborations de facto falling outside the scope of this reform. The current institutional set-up is seen as the most achievable, requiring compromises to be made to obtain approval at the level of the Flemish government.

Additionally, within regional reform, and somewhat in contrast with the mobility regions, some elements of an emergent design line can also be discerned. The central government does not impose a uniform governance structure on regions but allows room for regional coalitions to develop their own approach in the shaping of a regional mayors' conference. This seems to be a starting point for a central approach that is more focused on facilitating and empowering local innovations, rather than stifling them.

Conclusion

We started this contribution from the observation that the region is increasingly being emphasized as a scale for policy coordination and interaction between various levels and coalitions of actors. However, the role of central government towards the region and the compartmentalization resulting from a fragmented approach of various central administrations are elements that are not adequately addressed in the literature. Therefore, this contribution focuses on the interplay emerging at the regional level from the various policy initiatives set up from central government to the regional level and the conflicts and tensions such an approach brings about.

Our analysis focuses on three central policy initiatives that interact at the regional level within the current set-up and together form a complex ensemble. On the one hand, mutual confrontations and tensions can be observed, but also opportunities arise to develop new models of collaboration and policy innovation. The analysis demonstrates that the region cannot only be understood as a space for policy alignment among various stakeholders, but also from conflicting approaches and interests stemming from central policy agendas. It also reflects broader policy issues around planning and which policy ambitions can be successfully addressed at which policy scale. Unraveling the various responses and attitudes of central administrations towards the region is crucial to accurately assess the policy dynamics at this level.

From the literature, we witness that the region is framed within a broader context of an institutional void, where clear norms and frameworks are lacking to achieve political policy alignment. We note that this issue is also present in the dynamics that occur at the regional level in Flanders. However, our analysis leads to the question of whether this institutional setting can be merely considered as a given, or if it stems from a strategy of the central government to avoid taking a uniform stance towards the region due to conflicting interests among central administrations and sectoral logics.

In line with this, the question arises as to how the central government should deal with the current policy dynamics and conflicts at the regional level in the future. Within our analysis, we observe various institutional responses to dealing with conflict, ranging from seeking consensus in planning and scale on the one hand, to accepting various governance models and diverse central path dependencies on the other. The future government will determine which rationale will prevail and whether further steps towards coordination and integration of policy initiatives will be taken, or whether, from a rather agonistic perspective, more degrees of freedom will emerge that promote a further fragmentation of the region.

Abstract

The IAD framework was developed in circumstances different from contemporary spatial and governance issues. This article systematically compares Elinor Ostrom's work (1965–2017) and contemporary applications in spatial and governance research using the IAD framework. Findings include firstly that action situations and action arenas are applied inconsistently in contemporary research due to evolution of the concepts throughout Ostrom's own work; secondly, that the IAD is in many researches incoherently used where rules are studied in isolation of their configuration or rule configurations in isolation of the community attributes; and thirdly, that the application of IAD is mostly incomplete, specifically as explicit commons dilemmas, common pool resources and community are frequently undefined. A more consistent, coherent, and complete application better allows reproducible research and is fundamental for a better understanding of the relationship between institutions and communities.

Keywords

Institutional Analysis and Development framework; Commons dilemma; Spatial Planning; Action situation; Rule configuration

Introduction

Elinor Ostrom's Institutional Analysis and Development framework (IAD) is frequently used to study an institutional setting for governance practices in spatial planning. Our impression is that this often happens without awareness of or structural incorporation of conditions under which this frame was developed. We believe that these conditions are essential for the applicability of the framework and therefore the reliability of the institutional analysis. For example, the IAD framework emerged out of a particular set of cases, being small communities dealing with a scarce common. This particular setting is not always identical to contemporary spatial and governance issues (Ostrom, 2005). Moreover, applications of the IAD in contemporary research often focus on one of its working components instead of the complete framework. This raises questions on the extent to which the application of Ostrom's IAD framework has departed from its original premises, and consequently the implications for contemporary analysis of spatial and governance issues.

In this paper, we explore the premises of the IAD framework to the institutional setting of spatial and governance issues as described by Elinor Ostrom herself, to identify the differences in contemporary applications of this framework. To that end, we intertwined three research steps. First, key principles of the IAD framework were derived by analysing 15 key publications, including early empirical research, (e.g. Ostrom, 1965), late studies (e.g. Polski & Ostrom, 2017; Schlager & Villamayor-Tomas, 2023) and comprehensive work (e.g. Ostrom, 2005). Secondly, from these principles, we established an analysis scheme which we, thirdly applied to compare a selection of contemporary research based on institutional analysis in or

related to the field of spatial planning. These include ten years of applied IAD research of the Spatial Planning department of the University of Groningen, who have a longstanding tradition of institutional analyses and the IAD in governance practices and spatial planning, other Dutch universities who have a research tradition in spatial and governance-institutional research, and other contemporary applications of the IAD at other research institutes worldwide.

The IAD framework is an instrument to systematically study institutional arrangements to demarcate established governance practices regarding a commons dilemma or the use of a common pool resource (CPR). Here, institutional arrangements or institutions are understood as the rules, norms, and strategies that prescribe how actors must, must not, or may act in an action situation (Polski & Ostrom, 2017).

Our analysis revealed three main findings. First, the framework is frequently applied in cases that do not resemble the criteria identified by Ostrom herself, i.e. the requirement for an action situation to concern a focused commons dilemma or particular common pool resource. From Ostrom's perspective, this is however vital, because the commons dilemma or common pool resource drives the formation and application of the respective institutional arrangement. Secondly, most institutional analyses using the IAD framework only analyse specific variables or rule types and do not use the complete framework. This may result in a lack of coherence between the rules and/or other elements of the framework, which is a premise of the framework. Lastly, Ostrom herself is inconsistent in definitions of the key concepts including action arena, action situation and institutions. As a result, subsequent studies employ different definitions which make the institutional analyses only limitedly comparable and can produce different outcomes.

Ostrom's (sociological) perspective on institutions

Societies are made up of large numbers of actors, who are constrained or enabled in their actions by structures or institutions. Structure refers to the frameworks within which these actors operate. These frameworks include culture, laws, agreements, material and technical possibilities (Kooiman et al., 2008). The definition of institutions is currently still far from a settled issue, with considerable literature addressing how to define institutions (Alvesson & Spicer, 2019).

Sociologically, institutions can be defined as the *rules* (Ostrom, 2005) that guide human interaction or the *constraints* (North, 1990; 1991) that shape human interaction. The most commonly accepted definition in planning practice is that institutions are the rules of the game in a society, together with their enforcement arrangements and include both formal rules such as laws and constitutions, and informal constraints such as conventions and norms.

Individuals interacting within rule-structured situations face choices, regarding the actions and strategies they take (Ostrom, 2005). Ostrom emphasises that institutions not only delineate constraints, but also those which are permitted. Her construction of the concept 'rules-in-use' allows rule takers to exercise a degree of agency in putting rules into practice.

The principal function of institutions is to create order and reduce uncertainty by providing a structure that guides human interaction and leads to a 'stable, valued and recurrent pattern of behaviour' or 'patterned interaction that is predictable' (Lowndes & Roberts, 2013). According to Ostrom, institutions are the prescriptions that humans use to organise all forms of repetitive and structured interaction (Ostrom, 2005).

Ostrom's IAD Framework

One reason for Ostrom to develop the IAD framework was to coherently analyse a wide diversity of problems through a common and coherent set of elements and their relationships (Ostrom, 2007). Central in the IAD framework is the action situation and the action arena. In an action arena, participants (inter)act given an action situation and this interaction leads to outcomes (Ostrom, 1983a; Ostrom, 2005; Ostrom, 2011). Action situations refer to the social space where individuals interact, exchange goods and services, engage in appropriation and provision activities, solve problems, or fight, among the many things that individuals do in action situations (Ostrom et al., 2006). In the action arena participants actually interact given an action situation which results in outcomes (see Figure 1). Most of social reality is composed of multiple arenas linked sequentially or simultaneously.

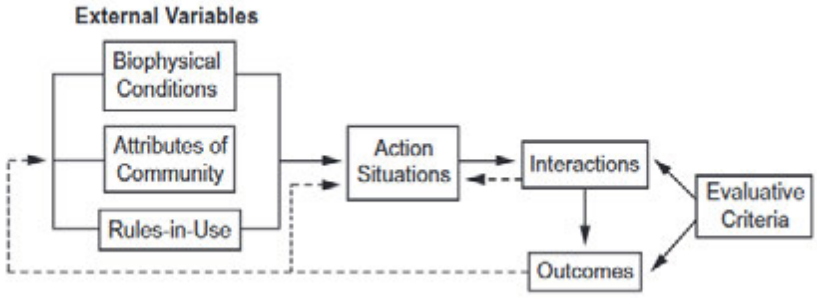

Figure 1: The IAD framework for institutional analysis (adapted from Schlager & Villamayor-Tomas, 2023 and Ostrom, 2005)

An action situation itself can be characterised using (internal) variables (see Ostrom, 2005) such as *actors*, who can be thought of as a single individual or as a group functioning as a corporate actor; *positions*, which associate actors with an authorised set of actions in a process and the *set of (potential) actions* that participants in particular positions can take at different stages of a process; the *information* available to a participant in a position at a stage in a process; the *set of payoffs* that assign benefits and costs to actions and outcomes; the *number of repetitions* of the situation (Ostrom, 1985). According to Ostrom, a particular combination of values for these variables yields an action situation if there is a situation such as 'commons dilemma situation', a 'prisoner's dilemma situation', or a 'free rider situation" (Ostrom, 1985).

A myriad of specific *rules-in-use* (hereafter called 'rules') and *attributes* structure an action situation (see Figure 1). Rules are shared understandings among those involved that refer to

enforced prescriptions about what actions (or states of the world) are required, prohibited, or permitted. All rules are the result of implicit or explicit efforts to achieve order and predictability among participants. Ostrom (2005) discerns seven types of rules that can affect the structure of an action situation. *Position rules* establish the specific positions that actors can fulfil. *Boundary rules* outline the conditions under which actors can access or leave a position. *Choice rules* specify what a participant occupying a position must, must not, or may do. *Information rules* regulate what information is sent and received. *Aggregation rules* influence how actors jointly affect collective decision-making by clarifying the influence of each actor when multiple positions have partial control over the same decision. *Scope rules* define the solution space, the outcomes which may, must, or must not occur. *Payoff rules* affect the benefits and costs that will be assigned to particular combinations of actions and outcomes, and they establish the incentives and deterrents for action. The set of rules is an interdependent configuration (Ostrom, 1983b; 1999; 2005; 2011): changes of one rule can affect other rules.

Attributes of the physical and material world influence what actions are physically possible, what outcomes can be produced, how actions are linked to outcomes, and what is contained in the actors' information sets. Important *attributes of a community* include the norms of behaviour generally accepted in the community, the level of common understanding that potential participants share about the structure of particular types of action arenas, the extent of homogeneity in the preferences of those living in a community, and the distribution of resources among those affected. The term "culture" is frequently applied to this bundle of variables (Ostrom, 2005).

Assumptions underlying the IAD framework

In studying literature about the development of the IAD framework through time we distinguished several assumptions for applying the framework.

A first assumption is that the IAD framework can be used to analyse *institutional arrangements on different 'tiers' or 'levels'* (Ostrom, 2005). A tier or level is not strictly defined by Ostrom. The action situation can be located on an operational tier, consisting of, for example, a free-rider problem, the distribution of a CPR, or a commons dilemma. Alternatively, the problem can be located on a policy tier concerning a collective-choice level. At this tier, policy decisions are made within the constraints of a set of collective-choice rules. These policy decisions affect the structure of the action situation on an operational level, where individuals act. On the institutional tier, decisions concern who is eligible to partake in the policy making process and concern the rules that will be used to undertake policy making (Ostrom, 1999). Actions on the institutional tier influence the action situation on the policy tier. The assumption of tiers poses two premises for institutional analysis. First, the analysed tier must be defined so as to direct the analysis to the appropriate problem and related rules. Secondly, the embeddedness of tiers must be defined, so as to understand the influence of to-be-identified institutions. For example, the nestedness of the operational tier (through the policy tier) in the institutional tier means that institutions of the institutional tier are more inert than those at the operational tier. Without clear tier distinction, such relative inertia may be overlooked.

A second assumption concerns how *the definition of action situations and action arenas* developed over time. Before 2005, the IAD framework was conceptualised as analysing both action arenas and action situations. The action arena consisted of an action situation and the actors acting in that situation. The action situation was defined as an analytical concept to enable the isolation of the direct structure impacting an action arena. However, the definition of action arena and action situation changed between 2005 and 2011 because Ostrom indicated that the difference between the terms generated confusion over the years as it was implicitly understood that action situation include actors. Ostrom started defining action situations identical to action arenas. An action situation is then defined as "the social space where participants with diverse preferences interact, exchange goods and services, solve problems, dominate one another, or fight (among the many things that individuals do in action arenas)" (Ostrom, 2005, p. 13). In her earlier publication this was in fact the definition of an action arena. Her 2005 definition of the action arena is limited to: "in which [...] participants and an action situation interact as they are affected by exogenous variables (at least at the time of analysis at this level) and produce outcomes that in turn affect the participants and the action situation" (Ostrom, 2005, p. 13). Figure 1 represents the latest definition (this evolution is illustrated in subsequently Ostrom, 2005; Ostrom & Schlager, 2014; Schager & Cox, 2018; Schager & Villamayor-Tomas, 2023) showing that interactions structured by an action situation result in outcomes. Despite the turn in definitions, much literature still refers to action arenas as key element in the IAD framework using older definitions. This lack of consistency in definitions may be a cause of inconsequent application of the IAD framework in academic research.

Ostrom refers to the *concept of commons or common pool resources* (CPR) as attractor for community building and enhancer for the creation, development and multi-tier nesting of rules. The term "commons" was popularised by Garrett Hardin in an influential 1968 article called "The Tragedy of the Commons", addressing the problem of humans overusing and depleting a common-pool resource (CPR) even though it is not in their best interest to do so. This trend of over-exploitation particularly plagues commons because the lack of individual ownership and inability to restrict usage incentivises actors to consume as much as possible of the shared resource before others do. The commons can be understood as natural resources that groups of people (communities, user groups) manage for individual and collective benefit (Ostrom, 1990; 2005). Ostrom debunked the inevitability of the tragedy of the commons by the presentation of case after case of resource users effectively self-organising and sustainably managing a common themselves. Successful cases of commons self-governance had in common principles (Ostrom, 1990; 2005) such as clearly-defined boundaries, congruence between the resource environment and its governance structure or rules, the availability of collective-choice arrangements, effective monitoring and rules enforcement and conflict resolution mechanisms. Higher-level authorities recognise the right of the resource appropriators to self-govern the common resource in nested tiers from the lowest level up to the entire interconnected system. These principles imply that a starting point for applying the IAD framework should be a collective action problem (a prisoner's dilemma, a free rider situation or a commons dilemma) positioned in an interconnected nested governance system (Ostrom, 1990; 2005).

Ostrom presents the IAD framework in her publications as *an all-encompassing coherent and interrelated configuration of components*. This implies that one can study a subset only in consideration of the relationship to the other components. Although Ostrom always presented the framework as an integrated set, later studies use components as analytical tools for systematically examining institutional arrangements separate from the framework (see for example Schlager & Villamayor-Tomas, 2023).

A last assumption concerns *the dynamic nature of the IAD framework*. Ostrom's (1990; , e.g.) work emphasises the need for what she refers to as "adaptive governance." Adaptive governance concerns the way in which the structure of rules, norms, strategies and enforcement mechanisms adapt and evolve over time as information about the commons environment expand or change (Ostrom & Jansen, 2004). The term connotes that an institutional arrangement is able to evolve in order to fit current conditions and needs best. As Ostrom puts it: "a set of rules crafted to fit one set of socio-ecological conditions can erode (…) successful commons governance requires that rules evolve" (Dietz et al., 2003). As mentioned above, in her article "A Method of Institutional Analysis" (1985), Ostrom added as variable to characterise the dynamics of an action situation, the number of repetitions of the situation itself. Consequently, to study institutional evolution, one has to apply and compare the IAD framework sequentially.

Methodology

This research aimed to study the use of the IAD framework in planning studies by analysing contemporary (recent 10 years) research articles using this framework. First, we looked into research performed by the Faculty of Spatial Sciences of the University of Groningen (UoG) and research performed by spatial planning departments of other Dutch universities. To make a broader comparison possible we also used a selection of articles based on the diverse application of the IAD framework from different scientific backgrounds.

The book 'Understanding Institutional Diversity' (2005) by Ostrom has served as the start of our study. From this book, key definitions such as action arena, action situation, and rules were derived as discussed above. Based on these definitions, we constructed an analysis scheme[1] (see Table 1) to characterise each article by discipline of the article, compliance to the IAD's original premises and the application of the action arena, action situation, and rules.

We used Google Search and Scopus to retrieve relevant articles from Dutch universities using the search terms "IAD framework" and "Institutional Analysis and Development Framework". This resulted in seven articles from UoG and six articles from the planning departments of other Dutch universities (see reference list). To expand our search to other disciplines we also used Scopus. Again, using the search terms "IAD framework" and "Institutional Analysis and Development Framework", and sorting the results on "Cited" and "Date" we found the following relevant articles: "Stronger together, but how? Lessons from the Walloon dairy

[1] In earlier iterations of the analysis of this paper, the ADICO syntax (Crawford & Ostrom, 1999) was included as criterion. However, the studied empirical material indicated that applying all elements of the ADICO statement often not reflected the studied empirical practice. To avoid verbose theoretical, methodological, and results description of the ADICO statement, ADICO is not further discussed in this paper.

history on the strategic relevance of cooperative models" (De Herde, 2023), "Collective Action within the Household: Insights from Natural Resource Management" (Doss & Meinzen-Dick, 2015), "Governing large-scale marine commons: Contextual challenges in the Coral Triangle" (Fidelman et al., 2012), "A modified diagnostic social-ecological system framework for lobster fisheries: Case implementation and sustainability assessment in Southern California" (Partelow & Boda, 2015). For practical reasons we limited ourselves to four articles outside of spatial planning.

An overview of the studied articles is given in the reference list.

Table 1: Analysis scheme as used in our study to characterise publications

Components		***Application***
1) Research background		From what background is the article written and what is the nature of the similarity with Ostrom's background? For what purpose is the article written, and is the IAD framework (as Ostrom described it, i.e. a CPR) appropriate for this purpose?
2) Research aim		What is the aim of the article?
3) Action arena		Does the article use the concept of action arena?
4) Action situation		Does the use of action situation match Ostrom's premises? How (clearly) is the action situation demarcated in the article?
5) Tier of IAD framework		Is the IAD framework approached from the operational, policy, or institutional tier? How is tier embeddedness addressed?
6) Rules	*General*	How are the rules generally elaborated within the articles, based on the workable definition of Ostrom (2005). Are the definitions corresponding or are there similarities?
	Position rules	How are the rules generally elaborated within the articles, based on the workable definition of Ostrom (2005). Are the definitions corresponding or are there similarities?
	Boundary rules	How are the rules generally elaborated within the articles, based on the workable definition of Ostrom (2005). Are the definitions corresponding or are there similarities?
	Choice rules	How are the rules generally elaborated within the articles, based on the workable definition of Ostrom (2005). Are the definitions corresponding or are there similarities?
	Aggregation rules	How are the rules generally elaborated within the articles, based on the workable definition of Ostrom (2005). Are the definitions corresponding or are there similarities?
	Information rules	How are the rules generally elaborated within the articles, based on the workable definition of Ostrom (2005). Are the definitions corresponding or are there similarities?
	Payoff rules	How are the rules generally elaborated within the articles, based on the workable definition of Ostrom (2005). Are the definitions corresponding or are there similarities?
	Scope rules	How are the rules generally elaborated within the articles, based on the workable definition of Ostrom (2005). Are the definitions corresponding or are there similarities?
7) Focus on rules or action situation		Is the action situation more highlighted or the rules?
8) Function of the rules		What is the function of the *rules* within the article (contextualise, demonstrate, describe)?
9) Correspondence to IAD framework		Does the use of the IAD framework, to achieve the purpose of the article, align with Ostrom's premises? Is there a clear dilemma outlined?

Findings

To identify how Ostrom designed the application of the IAD, we evaluated Ostrom's own applications. However, our desk research indicated that only a limited number of usable case studies exist in which Ostrom clearly applies the IAD framework. Pivotal is her case study analysing the use and governance of the West Basin aquifer in California (Ostrom, 1965). In this (doctorate) study, she approached the action situation from an *operational tier*, and the components as identified in table 1 are applied. Later, Ostrom published three other case studies that were smaller in size (Ostrom, 1988). In all these studies Ostrom applied the framework on an *operational tier*, specifically to a CPR in which a commons dilemma was present. Ostrom described and demarcated the action situations clearly in all her articles where she applied the IAD framework herself. To illustrate, in the case of Ostrom's 1965-study, it is the aquifer of the West Basin in California and the stakeholders that made use of the aquifer for various uses, such as agriculture and drinking water. However, it is important to note that the rule types are mentioned implicitly in this study, potentially because the IAD concepts and their definitions have not been introduced yet. Ostrom approached the rules as a configuration and they are therefore not handled individually. Consequently, the causation between the rules and their effect on the action arena is clearly visualised. Ostrom uses the different parts of the IAD framework to explain the operation of the institutional structures within the action arena, and to explain the relation between the different parts.

Research by the Faculty of Spatial Sciences of the University of Groningen

Each analysed study of the Faculty of Spatial Sciences of the UoG employs the concept of action situations as multiple linked situations, i.e., governance systems. This complicates the demarcation of single action situations. To illustrate, Van Geet et al. (2019) applies the IAD framework to the action situation of "land use and transport integration", which is constructed of linked action situations on different tiers, namely the policy and the institutional tier. Similarly, Neef et al. (2023) apply the IAD framework on multiple Dutch infrastructure networks, specifically aimed at identifying how rule directions influence actors to achieve collective actions on both a policy and institutional tier. Spijkerboer et al. (2019) apply the IAD framework solely on the institutional tier. The study's focus on spatial integration of renewable energy and other land use functions indicates interlinking different action situations at a single tier. Neither of these study's explicitly empirically distinguish the different linked action situations. While this lacking distinction is thus methodologically different from the IAD's premise, it is unclear whether or how problematic this is. However, focussing on the action situation on the operational tier, misses the consequences of the relationships to the policy and institutional tier.

Further, some studied articles employ the term action arena, despite Ostrom's shift in focus to action situation. More so, the concepts action arena and action situation are used interchangeably, and refer to articles before the amalgamation of the definitions by Ostrom. To be clear, the last definition of Ostrom for the action situation was "a social space where individuals interact, exchange goods and services, solve problems, dominate one another, or fight…" (Ostrom, 2011), and no longer "the immediate structure affecting a process of interest

for the purpose of explaining regularities in human actions and results, and potentially to reform them" (Ostrom, 1999, p. 43). The interchangeable use by Leani et al. (2021) start by introducing and focusing on the action situation as "The core analytical concept of the IAD framework is the action situation…" (p. 13). However, later they employ the concept of action arena when introducing the rules. Alternatively, Hijdra et al. (2015) use the concept of action arena, and do not mention the concept of action situation, e.g. "The IAD framework defines the action arena as the relevant unit of analysis …" (Hijdra et al., 2015, p. 66). Other articles do only apply the concept of action situation, such as Van Geet et al. (2019) and Wu et al. (2022). This raises the question on mutual comparability between the articles.

Lastly, the studied material has a strong focus on separate rules, and excludes the influence of attributes of the physical and material world and attributes of a community, and have less emphasis on the configuration of rules. For example, Hijdra et al. (2015), Wu et al. (2022), and Lee et al. (2022) apply the rules of the IAD to describe the action situation. This differs from the IAD's premises, where the *configuration* of rules and *attributes* co-determine the action situation, and indirectly shape the interactions and outcomes of an action situation. Additionally, Neef et al. (2023) applied the IAD framework to identify how rules affect actors to achieve collective actions. Van Geet et al. (2019) stay closer to the original premise of the IAD framework by using rules to contextualise the action situation. The situatedness of the outcomes in particular communities raises the question what communities are actually presented or analysed in the papers, and to what extent the findings can be extrapolated.

Research by Spatial Planning Departments of other universities in the Netherlands

A similar application of the IAD application occurs in the studied articles of Spatial Planning disciplines at other Dutch universities as compared to the UoG. To illustrate, multiple articles apply the IAD framework on two tiers, the policy and institutional tier. For example, Lammers & Hoppe (2019) apply the IAD framework on institutional conditions that enable or disable decision-making processes and the impact of the selection of smart energy systems, applying the IAD framework on both the policy and institutional tier. Alternatively, Vitale & Meijerink (2023) and Van den Hurk et al. (2024) apply the IAD framework on only the institutional tier. They apply the IAD framework to study an action situation of the management of (national) policies. Warbroek et al. (2023) do explicitly mention the tier of focus in their research, being the operational tier defined as concerning "individual actor day-to-day decision-making" (Warbroek et al., 2023, p. 100). Such a clear demarcation did however not withstand an explicit description of the CPR that demarcates the action situation. Rather, the focus is on the decision-making process or the management of policies. Hence, a clear tier demarcation and a clear CPR definition may go hand-in-hand.

Next, also similar to the UoG, the studied articles portray a mixed use regarding action arenas and action situations. To illustrate, Klok & Denters (2018) initially state that the action arena is the central unit of analysis in the IAD framework, but later refer to an action situation. Thereafter, they continue to focus on the action arena. Moreover, whereas Van Karnenbeek & Janssen-Jansen (2018), Lammers & Hoppe (2019), and Warbroek et al. (2023) only use the action situation when applying the IAD framework by referring to Ostrom (2011), Van den

Hurk et al. (2024) and Vitale & Meijerink (2023) use an action arena by referring to Ostrom (2005). To add to the mixed image, while Warbroek et al. 2023 do focus on action situations, action arenas are mentioned in an undefined manner. Hence, contemporary applications of the IAD in the Netherlands do appear to raise a mixed use of action arenas and action situations.

The reason to conduct institutional analysis differs per article, but two main differences may be distinguished. On the one hand, Vitale & Meijerink (2021), and Klok & Denters (2018) apply the IAD framework in order to contextualise the action situation, which corresponds with the defined use as determined by Ostrom. Alternatively, and similar to the UoG, the other studied articles aim to reveal institutional rules, conditions, barriers, and/or opportunities with a focus on the institutional design of the action situation or action arena (Van den Hurk et al., 2024; Lammers & Hoppe, 2019; Van Karnenbeek & Janssen-Jansen, 2018; Warbroek et al., 2023). This subtly, but crucially, departs from the premise of the IAD. Whereas, originally, the institutional rules *reflect* the institutional situation as is, here, the institutional rules are to be redesigned so as to *change* the institutional situation. This is different from Ostrom's understanding of rules contextualising an action situation: other rules presuppose other action situations. This different use of the AID raises questions on the appropriate use of the IAD (further discussed below).

Furthermore, the rule configuration is assessed in most articles, such as Warbroek et al. (2023), Lammers & Hoppe (2019), and Klok & Denters (2018). Van Karnenbeek & Janssen-Jansen (2018) apply the rules in an individual manner in which the rules are analysed individually, however they do not consolidate the rules as a configuration afterwards. They argue that this application of the framework "reveals a hierarchy in the rules" (Van Karnenbeek & Janssen-Jansen, 2018, p. 408). Vitale & Meijerink (2021) and Van den Hurk et al. (2024) study the rules individually, but recognise the configuration, and put the rules together in their discussion.

Lastly, the analysis highlighted a factor not explicitly incorporated in the analysis scheme. Lammers & Hoppe (2019) acknowledge the static nature of the IAD framework, whereas decision-making commonly comprises a (dynamic) process. They address this nature by applying the framework with causal process tracking. In a follow-up study, Neef & Verweij et al. (2023) also address this dynamic nature by applying a decision-making rounds model. Both approaches introduce a temporal dynamic in the IAD, which merits from further scrutiny into how the IAD addresses this dynamic.

Research outside of Spatial Planning

In comparison to the application of the IAD framework within spatial sciences, the IAD framework is approached differently outside of spatial sciences.

First, it is observed that the IAD framework in the articles outside spatial planning is applied on a single tier. In general, the selected tier is the operational tier, which is directed at a common action problem. For example, Fidelman et al. (2012) applies the IAD framework on the operational tier in order to "examine the contextual complexity facing organisations attempting

to coordinate regional-level action" (p. 43). Also, Partelow & Boda (2015) apply the IAD framework on the operational tier, as they aim to improve the management of the natural resource system. Additionally, the IAD framework is applied on rather static, not consisting of sequentially or simultaneously linked action situations. The demarcation of the action situation is in most articles clearly defined, however varying from an area demarcation to a governance system. To illustrate, in Fidelman et al. (2012) the action situation is demarcated as the Coral Triangle, which allows for a geographic boundary. An exception is De Herde (2023), who applies the IAD framework on the policy affecting the dairy industry in Wallonia. Consequently, this action arena consists of sequentially or simultaneously linked action arenas, resulting in a less concrete demarcation of the action situation.

Moreover, it is found that the articles focus only on the action situation, such as Partelow & Boda (2015). On the other hand, Fidelman et al. (2012) only use the action arena in their application of the IAD framework. The publication date of this article is close to the change in focus initiated by Ostrom, which can explain this focus.

Additionally, most articles outside spatial planning aim at contextualising the action situation by means of the IAD framework. To illustrate, Fidelman et al. (2012), De Herde et al. (2023), and Dos & Meinzen-Dick (2015) applied the IAD framework in order to contextualise the situation at hand. On the other hand, Partelow & Boda (2015) aim at analysing and describing the maintenance of natural resources. Last, there are differences in the application of the rules in the action arena or action situation. In the articles outside spatial sciences, the focus is directed at the action arenas. Therefore, in these articles, the rules are studied in a configuration, and therefore contribute to the contextualisation of the action arena. This is in accordance with the described application of Ostrom. Consequently, by doing so, the aim of the framework of contextualising the action arena, is reached.

Discussion and Conclusion

In this paper we explored the premises of the IAD framework to the institutional setting of spatial and governance issues as described by Elinor Ostrom, to identify the differences in contemporary applications of this framework. To this end we explored literature describing and elaborating the IAD framework to signify key elements as meant by Ostrom when applying the framework. We further explored contemporary articles describing research using the IAD framework both inside and outside spatial planning.

We discovered that Ostrom changed definitions of elements of the frame through time especially concerning her definitions of action arena and action situation. In her most recent description of the framework, she considers the action situation in the centre of the IAD framework. This includes actors, but not the interaction itself. Consequently, the action situation seems static, a photo. Interaction as a separate component in the framework leads to outcomes. However, by adding an extra variable to characterise to the action situation, being the number of repetitions of the situation itself, she defined institutional evolution as a sequence of changing action situations, a film consisting of photos. Rules she positions as variables,

besides physical and community attributes, influencing the action situation and not as part of the action situation itself.

The researches we studied do not use these definitions consistently. Especially, the action arena and the position of the rules, which Ostrom in her earlier publications positioned in the centre of the IAD framework, is regularly used following older definitions. Further, the demarcation of the action situation differs per research, be it a spatial area, a governance system or a cooperative setting. As a consequence, it becomes hard to compare the different studies. Our advice for future studies using the IAD framework is to use the latest description and definitions as given by Ostrom.

In most researches only one action situation is analysed. However, Ostrom explicitly mentions in her publications, the nested nature of an action situation, being different linked tiers and parallel linked action situations. Because these actions situations are linked, they influence each other. Not taking this in account limits the strength of the institutional analysis.

Ostrom presents her IAD framework as a coherent, interrelated and interdependent configuration of components. This means that an analysis using this frame should describe all elements in mutual coherence. Recent publications, for example Schlager and Villamayor-Tomas (2023) even propose to use components of the IAD framework as analytical tools for systematically examining institutional arrangements separate from the framework. However, many of the studies we examined only described and employed a part of the framework, in spatial planning especially focusing on the rules or just some rules. This raises the question on how problematic analysing rules in isolation of the IAD really is.

To feed that particular debate, we suggest to further scrutinize the concept of rules (institutions) and community. One interpretation, found in many of the scrutinized articles, is that rules are mechanisms that structure behaviour. Such an approach allows researchers to propose changes of rules so that behaviour changes, i..e., they propose institutional (re)design. Another interpretation, closer to Ostrom her original work (1965), is that rules *are* communities. This finding is based on the large number of cases where Ostrom herself found that if there is a community, they can be caught in a coherent set of rules, not the other way around. Hence, this metaphysical or philosophical understanding of rules vis-a-vis communities would deter such mechanistic institutional (re)design. Hence, this finding begs the question if, and if so how, the IAD may be applied to inform how to initiate or navigate institutional change. Suggestions may be found in Lammers & Hoppe (2019) and Neef, Verweij et al. (2023) as they provide suggestion on dealing with the temporally static instrument that the original IAD is. A more fundamental answer to how rules (institutions) and community relate does merit further discussion and research.

Ostrom explicitly mentions the necessity of a collective action problem to motivate resource users in effectively self-organising and sustainably managing a common themselves i.e. community forming. Interestingly, in most of the research we studied there was no or hardly

any description of the collective action problem. The question is then what 'drives' the self-organisation of the community and in this the development of rules.

To conclude, our study left us with some questions, which are in our opinion worthwhile to further discuss:

1. Does the framework provide a coherent language for identifying universal elements to analyse and explain how self-organisation in action situations develops or is the framework just limited to specified action situations?
2. Is the framework conceptually 'open' enough to stimulate new theoretical developments, for example in the field of spatial planning?
3. Since we live in an increasingly dynamic world and studying dynamic social and institutional development becomes more important, is the institutional evolution as presented by Ostrom consistent with contemporary theories of system evolution?
4. Does the framework sufficiently support the analysis of multi-tier or multi-level interaction or governance, a field of theoretical research currently strongly in discussion?

Ostrom herself identified these questions as relevant as early as 1999. "I would answer these questions positively, but the real assessment will be made by other scholars over the next several decades" (Ostrom, 1999, p. 63-64).

ENTERPRISE-LED OR GOVERNMENT-LED? RESEARCH ON THE CHARACTERISTICS AND MECHANISMS OF RURAL GENTRIFICATION IN METROPOLITAN SUBURBS DRIVEN BY SIGNIFICANT PROJECTS， TAKING LIANMIN VILLAGE IN SHANGHAI AS AN EXAMPLE

Liu Zhuyang[1], Yang Wenxiao[1], Ni Beiyin[1]
[1]Tongji University, College of Architecture and Urban Planning
2330323@tongji.edu.cn

Abstract
Under the combined influence of factors such as the implementation of the rural revitalisation strategy, superior geographical location, and the implementation of significant projects such as Disneyland, the suburban villages of Shanghai's metropolitan area have experienced similar characteristics of rural gentrification in rural revitalisation in Western countries. According to the differences in driving forces, rural gentlemen are divided into two types: enterprise-led and local government-led. There may also be complex interactive relationships between the two kinds of gentrification. Then, this article takes Lianmin Village in the suburbs of Shanghai as an example, organises three panoramic surveys on it, summarises the characteristics of rural gentrification, and then constructs actor networks to explain the formation and interaction mechanisms of the two types of rural gentrification.

Key words
actor network; rural gentrification; interaction; social mechanism

Introduction

In recent years, the construction of super-large cities such as Shanghai, Beijing, and Guangzhou has gradually expanded from inner cities to suburbs, and large-scale entertainment projects such as Universal Studios, Chimelong Paradise, and Disney have been put into operation. The strong brand appeal attached to these projects has quickly made them popular tourist destinations, attracting many domestic and foreign tourists [1]. At the same time, with the successive introduction of strategies such as beautiful countryside and rural revitalisation, a large amount of government counterpart funds continue to flow to the countryside. In addition, due to the pressure of urban life in recent years and the promotion of social media such as Xiaohongshu, Bilibili, and Douyin, the rural "pastoral pastoral" in sharp contrast to the fast pace of the city has gradually become a new ideal lifestyle [2, 3]. Under the combined effect of the above multiple factors inside and outside the countryside, the spatial pattern and landscape style of the rural areas in the suburbs of metropolitan areas have been profoundly reshaped, similar to the characteristics of rural gentrification in rural revitalisation in Western countries. Based on differences in driving forces, the rural gentry can be divided into enterprise-led and local government-led [4, 5].

Previous studies on rural gentrification in China often focused only on a single type of rural gentrification. However, gentrification may have various characteristics in China's megacities' suburbs and rural areas. The complex dynamic mechanisms behind them must be further studied using more effective methods. In addition, there may be complex interactions between various types of gentrification, which differ at different stages of development. This article constructs a "conjugate rural gentrification interaction model". Then, this article took Lianmin Village in the suburbs of Shanghai as an example and organised three panoramic

surveys. Based on the survey results, this study summarises the characteristics of rural gentrification and then combines semi-structured interviews and actor networks to explain the formation mechanism of rural gentrification. Finally, this question believes the research results can reference similar rural development around metropolitan areas.

1. Literature review

British urban sociologist Ruth Glass first proposed the concept of "gentrification" in 1964 to explain how the middle class in inner cities replaces the working class and triggers changes in population, society, culture, landscape, and other aspects. Later, "gentrification" was expanded to mean replacing the lower middle class with the upper middle class [6]. Research on rural gentrification began with the rural revitalisation of Western countries in the 1970s and 1990s. China's rural gentrification did not receive attention until 2010, showing many differences from the West [7]. First of all, the characteristics of rural gentrification generally include spatial commodification, changes in economic structure, change or replacement of social structure, increase in rural housing prices and housing shortage, relocation and displacement of original residents, etc. [8-10]. However, in recent years, some studies have found that rural indigenous people are not always victims of gentrification but have become active actors and beneficiaries and can often coexist with indigenous residents [11, 12]. Secondly, in China, the state's will and the government's decisive intervention in rural development are apparent, and much money has been invested in transforming rural space. The government also plays a role in maintaining and promoting rural gentrification. We call it "organised rural gentrification," in which the government plays a leading role.

Rural gentrification in China is still in the initial stage of development, and the phenomenon of "spontaneous rural gentrification" led by enterprises and individual gentlemen is still growing. There is currently an increasing number of studies on the two types of rural gentrification in China. However, they may coexist in the same rural area, especially in rural areas surrounding metropolitan areas with abundant funds and substantial potential markets.

2. Research objects and methods

2.1 Research objects

The case study selected for this study, Lianmin Village, is located in Chuansha New Town, Pudong New District, Shanghai, only 5 kilometers north of Shanghai Disney International Tourism Resort, and contains 23 natural villages(Figure 1). Lianmin Village covers an area of 4.62 square kilometers, rich in natural resources, and crisscrossed by rivers and water bodies. One thousand seven hundred thirty-seven farmers live by the water. In addition, Lianmin Village has also achieved remarkable results in rural construction. In June 2017, based on obtaining the Shanghai Special Industry B&B License No. 01, Lianmin Village has been engaged in "B&B + Internet," "B&B + Cooperation Base," and "B&B + Agricultural Cooperatives." "Three directions go hand in hand. These measures have made Lianmin Village one of the first pilot villages for characteristic B&Bs in Shanghai and the second batch of demonstration villages for rural revitalisation in Shanghai. Especially up to now, there are more than 20 B&B clusters and other individual brand B&Bs under the unified management of Suyu Group.

2.1 Research methods

Actor-network theory (ANT) regards human and non-human factors that can change things by creating differences as broadly equal actors and incorporating them into a unified action explanation framework. The dynamic process in which actors build networks through actions is defined as translation, in which actors' role functions and value positioning change and are redefined. Translation analysis includes five stages: problem presentation, benefit conferment, recruitment, mobilisation, and elimination of objections (Figure 2). Actors form networks through translation, and the essence of the ANT network is a tool to describe the development of things. The countryside is increasingly understood as a complex space where endogenous and external factors interact, and rural revitalisation requires cooperation between actors within and outside the region. The ANT method based on relationship and process thinking can intuitively, systematically, and dynamically display the interactive connections of actors. Therefore, ANT has become an effective methodological and conceptual tool for studying rural gentrification, which is convenient for capturing the activities of actors and the spatial linkage projection of functional elements in the evolutionary process.

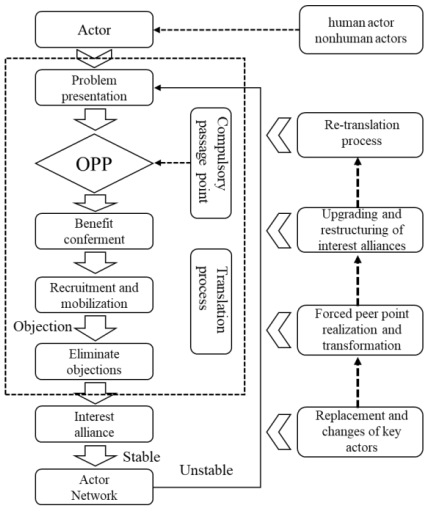

Figure 2 Analytical framework of the evolution of rural gentrification from an ANT perspective

3. Characteristics of rural gentrification

3.1 The overall pattern continues, but the local texture has been destroyed.

With the rapid development of the tourism service industry driven by homestays as the mainstay, Lianmin Village has continued the overall pattern of "transportation along the road, agglomeration along the line." Most of the natural villages in Lianmin Village are laid out along the river. More than 1/3 of the existing more than 1,000 residential buildings have been built along the water, a typical Jiangnan water town. Residential self-built houses are mainly located on the east side of Liufeng Highway, relegated to the second-line area along the river. The better-looking residential houses and iconic B&Bs are primarily distributed along both sides of Liuzao Port, enjoying the first-line riverside scenery (Figure 3). In addition, most of the B&Bs in the village were mainly renovated based on the original buildings, so they have little impact on the overall living pattern. However, there is still a tiny number of B&Bs that are newly built and mainly distributed on both sides of Wuzao Port. Their top contours differ from traditional houses, so they present new planar features based on continuing and strengthening the conventional residential pattern built along the water (Figure 4).

Image source: Author's drawing

3.2 Architectural diversification and urban aesthetic interest

With the successive intervention of B&B owners and other rural operators, the rural architectural style of Lianmin Village has been diversified, and the urban aesthetics have become more attractive. Diversification is reflected in the current situation of Lianmin Village, which includes not only traditional architectural styles and new rural residential styles but also a certain number of modern architectural styles and collage architectural styles that combine traditional local elements and contemporary elements. White walls and black tiles with strong Jiangnan charm characterise the traditional architectural style. The modern architectural styles in the village are mainly consumer spaces such as B&Bs, cafes, and wedding halls. Their

architectural forms mostly adopt simple and contemporary forms, with pure white paint as the background color and large-area glass windows, and rarely use other complex decorations. On the one hand, this design caters to the cultural aesthetics of urban tourists. In cities, simple style is usually synonymous with high-end. When simple modern buildings suddenly appear among many ordinary houses in the countryside, it is easier to become the visual focus and popular. Second, to meet the needs of tourists for taking pictures, simple and clean buildings are more suitable as background boards for taking photographs, reducing the visual interference of other decorations and highlighting the main image of tourists to a greater extent in the composition (Figure 5).

4. Explanation of social mechanisms

There are complex social mechanisms behind the spatial representation of rural gentrification. First of all, multiple subjects are participating in the process, as well as different economic and social attributes and interest demands. Secondly, various subjects gradually form complex social networks in daily interactions and interest games, and development factors such as capital and human resources also flow and make active choices through social networks. Furthermore, multiple actor networks may coexist in rural areas, co-constructing each other to form a more complex actor-network. Therefore, it is necessary to conduct further research on the explanation of social mechanisms of rural gentrification, and actor networks can be used to visualise rural social mechanisms due to their intuitive, systematic, and dynamic characteristics. In the actual investigation of Lianmin Village, it was found that there are two types of actor networks led by enterprises and elites and actor networks led by local governments.

4.1 Composition of actors

A complete actor network generally includes human and non-human actors (Figure 6). The human actors in the actor-network led by enterprises and elites in Lienmin Village and the actor-network led by the local government mainly include the government and village committees, villagers and elites (returning college students, individual entrepreneurs, etc.), and comfortable immigrants (rural pension, taking care of children in the countryside, periodic vacations, etc.), as well as enterprises (collective enterprises, private enterprises, etc.) and tourists. Non-human

actors are mainly environmental resources and stock projects, including land resources, characteristic dwellings, water system networks, farmland, and unique rural features and lifestyles.

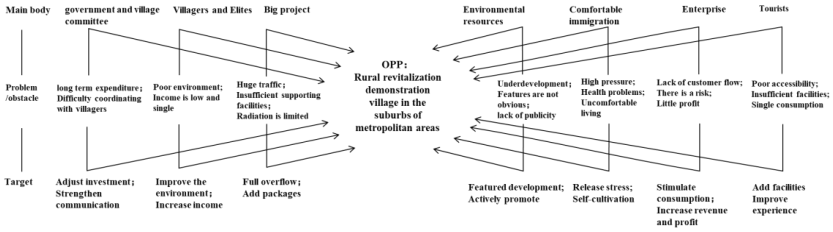

Figure 6 Composition of Lienmin Village activists
Image source: Author's drawing

4.2 Translation, recruitment and mobilisation

Actors will encounter various problems or obstacles. Among them, the actors with the most significant demands for solving their problems are most likely to become the key actors that guide the establishment of actor networks. Key actors also differ between business- and elite-dominated actor networks and local government-dominated actor networks. Among them, urban tourists who are tired of urban work and life and come to the countryside to pursue the poetic life of "pastoral pastoral" are the initiators of rural gentrification led by enterprises and elites in Lienmin Village. The enormous potential of the rural tourism market, which tourists form, attracts companies, villagers, and elites to join it. The critical actors in the actor network led by local governments are local governments, mainly village committees and town governments. As the rural tourism industry in Lianmin Village gradually takes shape and expands, local grassroots governments have also begun to encourage and control rural construction actions through policy means. In the end, the two types of gentrification form the only way to jointly build a demonstration village for rural revitalisation in the suburbs of a metropolitan area (OPP), to give full play to the local high-quality natural environment and cultural resources, creating economic benefits and improving the quality of life.

Recruitment and mobilisation are critical steps in the translation process. Key actors try to respond to and coordinate the interest demands of various actors through the OPP vision. Multiple actors can clarify their roles and assign tasks during the interest negotiation and action connection between recruiting and being recruited. At the same time, they can mobilise resources, implement actions, and respond to tasks. Specifically, rural enterprises and elites sent to the countryside have become the most active promoters and actual implementers of the entire actor network. They coordinate with other actors to strengthen cooperation during the implementation process and, at the same time, avoid friction and conflicts as much as possible to fully utilise the value of the natural and cultural resources of the countryside and form interest connections. These connections are constantly adjusted and strengthened through interaction.

4.3 Actor Network

Various actors establish weak and strong ties through translation, recruitment and mobilisation. The connections between critical actors, as well as between key actors and other

actors, are usually strong ties, which form stable strong ties that fit or evolve strong ties that conflict.

In rural gentrification led by enterprises and elites, enterprises and elite villagers are key actors (Figure 7). There are direct economic connections between tourism companies and tourists, and between village elites and tourists, thus forming solid ties. Since corporate operations have relatively sufficient funds, the consumer products such as homestays they can provide are generally higher in scale and quality than those hosted by elite individuals, thus giving tourists more confidence when making consumption choices. Therefore, forming relatively stable and robust ties between village elites and tourists is easy. However, due to the limited funds of the village elite, the image of homestay decoration and other products is more straightforward, and their appeal to tourists needs to be improved. Moreover, the management and services are also quite different from similar products operated by enterprises, making it difficult to form "repeat customers." Therefore, the solid and unstable ties formed between village elites and tourists are usually unstable. Tourism companies and local elites will also communicate in a long-term relationship, thus establishing social connections.

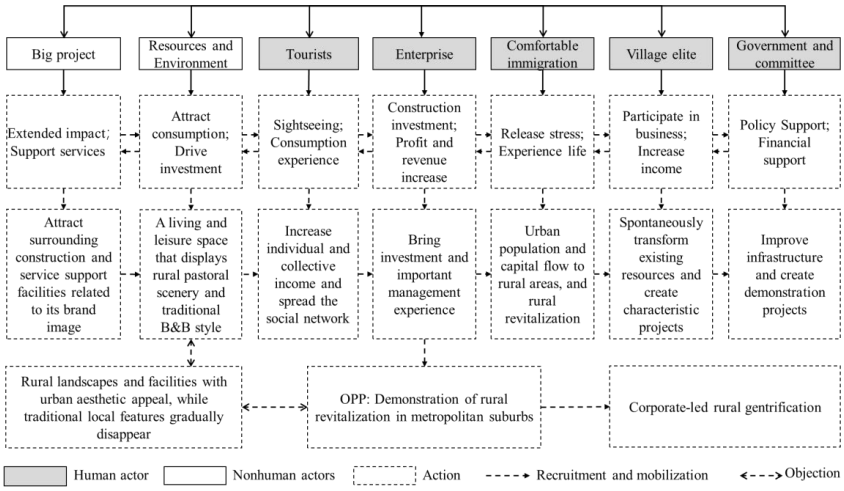

Figure 7 Actor network behind corporate- and elite-led rural gentrification
Image source: Author's drawing

In government-led rural gentrification, local grassroots governance represented by village committees and town governments are vital actors (Figure 8). Although they did not provide direct financial subsidies to village enterprises and individual elites for order management and promoting prosperity, they supported their industrial development by constructing basic service facilities such as roads and environmental governance. In addition, grassroots governments are also responsible for attracting investment and mediating conflicts, acting as an "intermediary" for housing rentals and labor hiring, and coordinating and promoting win-win cooperation between new and old residents. If the government aligns with the original villagers, it will support new villagers who carry out new business activities. This overall macro control combined with practical problem mediation leaves much room for rural development and allows the market to choose suitable industries independently. In addition, the local government

of Lianmin Village has also taken the initiative to negotiate brand cooperation with Shanghai Shendi Group, the developer of Shanghai Disney.

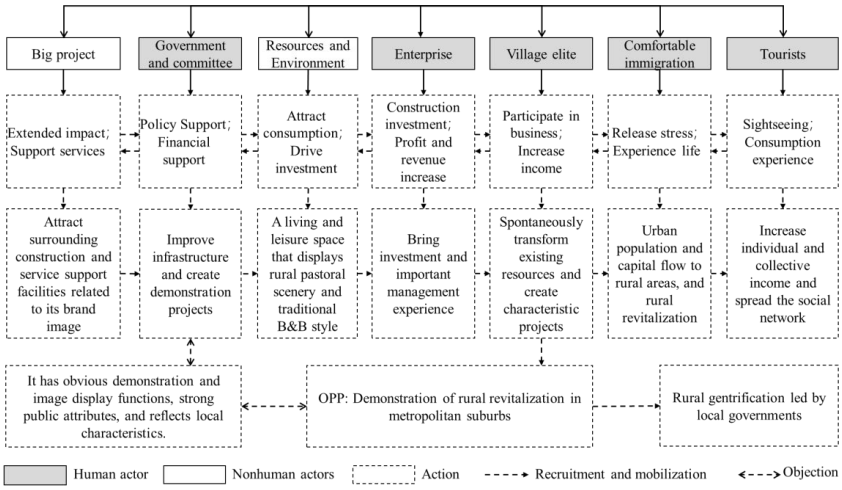

Figure 8 Actor network behind government-led rural gentrification
Image source: Author's drawing

5. Conclusion and discussion

This article uses the case of Lianmin Village. It uses the actor network analysis method to explore the characteristics and mechanisms of rural gentrification: rural gentrification led by enterprises and elites and rural gentrification led by the government. The research found many things. Firstly, Lianmin Village has the characteristics of enterprise-led rural gentry and local government-led rural gentrification in terms of rural population structure, industrial structure, and landscape style. The former has higher flexibility and reflects more urban aesthetic interest. Organised rural gentrification, with local government investment and construction as the primary mode of participation, focuses on public actions such as road widening, blackening of basic service facilities, and river ecological improvement, showing obvious public attributes and local characteristics preferences. Second, the mechanism behind the above characteristics may differ from local enterprises and governments' independent driving roles in their respective fields. Instead, the above two main actors are interconnected through other actors such as village elites, comfortable immigrants, tourists, etc., forming a complex joint action network. Market resources and government resources are efficiently allocated and reorganised through the actor-network.

In the context of China's rural revitalisation policy, rural gentrification has become the only path for developing most rural areas in our country. It is also helpful under our country's urban-rural dual-land system. However, most rural gentrification in China is still in the brewing or initial stages, and its subsequent development results and sustainability remain to be further observed and demonstrated. This article only selects a typical case in the suburbs of Shanghai, a megacity, for in-depth comparative discussion, but China also has vast underdeveloped and underdeveloped areas. Whether the two rural gentrification development models are applicable in their rural revitalisation process still requires in-depth research by multiple parties.

Abstract

This study investigates variations in carbon reduction willingness among households across different regions of China, exploring associations with household structure, economic status, and living conditions. A methodology was developed to calculate households' willingness to reduce carbon emissions. Efforts were made to assess carbon reduction willingness across various provinces and cities in areas such as transportation, food, products, energy usage, and awareness of carbon neutrality. The findings suggest that while Chinese households demonstrate a proactive willingness to reduce carbon emissions related to food and products, there is an evident need to enhance their willingness in the areas of transportation and energy usage. Furthermore, the research identifies household income, geographic location, residential area, and length of residence as significant determinants of household carbon reduction willingness.

Keywords

Households carbon footprint; Carbon reduction willingness; Household structure

1 Introduction

The substantial increase in carbon emissions constitutes one of the most urgent challenges faced by the contemporary world. Since the Industrial Revolution, human activities, particularly the combustion of fossil fuels, have become the primary drivers of increased greenhouse gas emissions. The IPCC's Sixth Assessment Report underscores that in 2019, atmospheric concentrations of carbon dioxide (410 parts per million) exceeded levels from any time in the past two million years. Managing carbon emissions has thus become central to mitigating climate change (IPCC, 2022). Excessive carbon emissions not only contribute to global warming but also heighten the risk of extreme weather, climatic, and hydrological events (Miner et al., 2021; UK-China Cooperation on Climate Change Risk Assessment, 2021). In response to this crisis, nations worldwide have formulated various international policies and agreements, such as the Paris Agreement (UNFCCC, 2015), aiming to limit the global temperature increase to within 2 degrees Celsius and thereby promote a low-carbon economic transition globally. These agreements stipulate that greenhouse gas emissions must peak by 2025 at the latest and reduce by 43% by 2030. The severity of climate change necessitates immediate and large-scale carbon reduction actions by the international community to alleviate the escalating impacts of climate change (An et al., 2024).

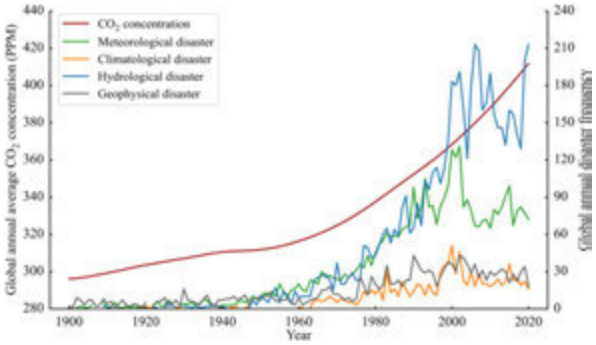

Figure 1: The correlation between extreme events caused by global climate change and the increase in CO2 concentrations(Jiang et al., 2022; SCPRC, 2021)

Facing stringent carbon reduction targets, household carbon footprints (HCF) constitute a significant portion of overall emissions, with households being major contributors to greenhouse gas emissions (Ivanova et al., 2016). The HCF measures the greenhouse gas emissions produced by households in daily life, encompassing both direct consumption of fossil fuels and indirect emissions from the use of products and services, typically calculated in terms of carbon dioxide equivalents (CO2 eq) (An et al., 2024). Reducing household carbon emissions can mitigate climate change and contribute to achieving carbon neutrality. According to research by the Potsdam Research Institute for the Effects of Climate Change, in 2021, China emitted 14.3 billion tonnes of CO2 equivalent, making it the largest emitter globally. Over the past two decades, alongside significant economic growth and urbanization, household carbon footprints have not only increased substantially but also varied greatly (Wang et al., 2022), necessitating greater focus on the potential for household carbon reduction. However, proposing effective, accurate, and reasonable policies for reducing household carbon footprints presents a complex challenge for policymakers.

Understanding the composition and determining factors of household carbon footprints (HCF) has become crucial. Existing research has explored the impact of socio-economic characteristics, such as household income, as well as household features including the age of members, household size, and education levels, and geographical factors like the location of the household (Zhang et al., 2015). There is also scholarly focus on the inequalities within HCF, highlighting that affluent households emit significantly more carbon than poorer ones (Wiedenhofer et al., 2017). However, there has been limited investigation into the role of lifestyle changes on HCF. To date, only a few scholars have studied the awareness of households regarding reducing their carbon footprint. Khanam et al. assessed the awareness and willingness to reduce HCF in daily consumption from an expert perspective (Khanam et al., 2022), while Brounen et al. discovered that awareness of social and environmental issues can inspire lifestyle changes (Brounen et al., 2013). Li et al. examined the impact of different subjective social awareness indicators on the carbon emissions of Chinese households (Li et al., 2019). This indicates that under the goal of carbon neutrality, adopting sustainable lifestyles and consumption behaviours can significantly reduce carbon emissions (Koide et al., 2021). For example, using energy-efficient appliances (Dias et al., 2019), reducing the use of disposable plastic products (Senturk & Dumludag, 2022), opting for local seasonal food (Tantiwatthanaphanich et al., 2022), minimizing food waste (Parashar et al., 2020),

and reducing car ownership are all sustainable practices that can significantly control HCF. Therefore, it is necessary to conduct focused research on the behaviours and awareness of Chinese households in reducing their carbon footprint in daily life, to thoroughly understand how different levels of awareness impact HCF and thus develop tailored emission reduction strategies and sustainable development plans for diverse families.

Consequently, this study aims to assess the willingness of households across different regions of China to reduce their carbon footprints (CF), categorizing this willingness into five levels: transportation, food, products, energy, and carbon neutrality awareness. It also provides a regional distribution of these indices, seeking to identify which type of willingness in different regions can encourage families to adopt low-carbon lifestyles, thus proposing suitable policies for household carbon reduction in various areas to balance the reduction of HCF with climate change mitigation. To this end, the study collects baseline data on China's HCF for 2021, including various household characteristics (such as number of family members, ages, gender, and employment status) and socio-economic levels (such as household income, geographical location, and living area). It combines these with a regional analysis of the five fundamental sectors: transportation, food, products, energy, and carbon neutrality awareness. The HCF considered in this study includes CF based on daily and usual consumption (for example, the transportation category considers the everyday and regular modes of transport used by people, while the food category accounts for local sourcing and packaging levels). The study attempts to identify the factors influencing HCF in different regions and their emission reduction potential. It also advocates assigning higher reduction tasks to households in high-emission areas, which is crucial for mitigating climate change, ensuring social equity, and maintaining sustainable development.

2 Method

2.1 Questionnaire Design and Data Collection

The primary data for this study was collected as part of a summer social practice project, "Exploring HCF Potential," conducted by a university from July to October 2022. The project received university approval, and the HCF questionnaire was disseminated online. A total of 3,839 respondents from 1,132 households participated in the survey, with 1,099 of the responses being valid, yielding a response validity rate of 97.0%. The data collection did not involve any sensitive information such as respondents' names, focusing solely on households' daily consumption habits. To ensure the ethical standards of the survey, all participants were provided with an informed consent form before participating.

Given that the data originated from a questionnaire survey, the questionnaire's validity was ensured through a pilot survey, which led to revisions based on the findings. The pilot phase also revealed a significant number of incomplete responses, prompting a revision of the approach to actively contact respondents by phone before the official survey. This method encouraged respondents to read questions carefully before answering, to prevent casual or incomplete responses and ensure the accuracy and authenticity of the data provided.

The questionnaire data was divided into two main parts: (1) Basic Household Information: This section collected data on basic demographic and socio-economic conditions, including population, gender, age, and employment status. (2) Household Consumption Preferences: This section gathered information on daily lifestyle choices, such as dietary habits, the proportion of organic foods consumed, frequency of dining out, use of disposable products, choices of reading materials,

clothing purchases, and frequency of household appliance updates. It also included data on carbon neutrality behaviours and awareness, such as the frequency of community promotions on low-carbon knowledge.

Through the data collected via the questionnaire, this study aims to understand Chinese households' awareness of carbon neutrality and their everyday behaviours to explore the drivers behind the transition towards household carbon neutrality in China. Compared to previous studies based on expert samples (Bai & Liu, 2013; Khanam et al., 2022), the sample size of the current study is significantly larger, providing a more robust basis for analysis.

2.2 HCF calculation formula

The questionnaire comprised a total of 37 questions, with questions 1-11 dedicated to gathering basic information about the respondents. This section included questions on household population size, gender, age, and employment status. Questions 12-37 were related to carbon reduction willingness (WRCF), divided into categories of transportation, food, products, energy, and carbon neutrality awareness, as detailed in Table 1. The questionnaire can be found in the supplementary file.

Table 1. WRCF Questionnaire and Scoring

Category	Question	Scoring				
		Strongly disagree	Disagree	No opinion	Agree	Strongly agree
Transportation	Q12: Does your family own a private car?	Yes=0 No=2				
	Q13: Is your family's private car electric?	Yes=2 No=0 (For those without a private car, score this item as 0)				
Food	Q14: Does your family often eat meat?	2	1.5	1	0.5	0
	Q15: What percentage of your family's food is unprocessed/natural?	100%=2	75%=1.5	50%=1	25%=0.5	0%=0
	Q16: How much of the food your family consumes is unpackaged?	100%=2	75%=1.5	50%=1	25%=0.5	0%=0
	Q17: What percentage of the food your family consumes is locally sourced?	100%=2	75%=1.5	50%=1	25%=0.5	0%=0
	Q18: How often does your family consume takeout/dining out?	2	1.5	1	0.5	0
Household Products	Q19: What new clothes, shoes, or sports equipment does your family purchase monthly?	2		1	0.5	0
	Q20: How often does your family purchase new household items?	2		1	0.5	0
	Q21 How frequently does your family purchase household appliances	2		1		0
	Q22: How frequently does your family purchase electronic devices	2		1		0

	Q23: How frequently does your family purchase paper-based books, magazines, and newspapers?	2		1	0.5	0
	Q24: Does your family engage in paper recycling?	0	0.5	1	1.5	2
	Q25: Does your household engage in plastic recycling?	0	0.5	1	1.5	2
	Q26: Does your family use second-hand clothes and books?	Yes=0 No=2				
	Q27: Does your family have heating/cooling equipment?	Both heating and cooling=2 Only one type=1 No=0				
	Q28: Does your family's electricity come from renewable sources?	0	0.5	1	1.5	2
Energy	Q29: How would you rate your family's energy efficiency?	0	0.5	1	1.5	2
	Q30: Is the energy label an important factor for you when purchasing appliances?	2		0		1
	Q31: Do you understand the meaning of carbon neutrality?	2		1		0
	Q32: Do you believe that household carbon emissions contribute to global warming?	2		1		0
	Q33: .Do you prioritize comfort in your daily life over energy consumption?	0		1		2
	Q34: Are you willing to change your personal lifestyle for energy efficiency and participate in family energy-saving and emission reduction activities?	2		1		0
Carbon Neutrality Awareness	Q35: Does your family include individuals working in the environmental industry?	Yes=2 No=0				

Q36: How often do you pay attention to energy and environmental issues?	2	1	0
Q37: Does your residential community or neighborhood take relevant low-carbon actions?	2	1	0

2.3 Measuring Household.WRCF

This article references the definitions of willingness to pay (WTP) values as outlined by Le Gall-Ely and Venkatachalam (Le Gall-Ely, 2009; Venkatachalam, 2004). WTP is the maximum amount an individual is willing to sacrifice or pay for a service or product. It serves as a crucial indicator for measuring consumers' perceived value and demand intensity for a good or service. WTP represents the peak of a consumer's demand curve, indicating the price point at or below which a consumer is prepared to purchase a particular good or service. Consequently, this paper, drawing upon Khanam et al.'s discussion on European carbon reduction behaviours and awareness (Khanam et al., 2022), employs the term Willingness to Reduce Carbon Footprint (WRCF) to denote the inclination of households to reduce carbon emissions in their daily lives. The calculation of WRCF involves dividing the total scores obtained across various sectors by the total number of questions in those sectors, encompassing current daily activities, performances, and consumption habits of households.

$$WRCF_t = \frac{WRCF_T}{q_t} \quad (1)$$

$$WRCF_f = \frac{WRCF_F}{q_f} \quad (2)$$

$$WRCF_p = \frac{WRCF_P}{q_p} \quad (3)$$

$$WRCF_e = \frac{WRCF_E}{q_e} \quad (4)$$

$$WRCF_n = \frac{WRCF_N}{q_n} \quad (5)$$

Equations (1), (2), (3), (4), and (5) each represent the willingness to reduce carbon emissions in the areas of transportation, food, products, energy, and carbon neutrality awareness, respectively. The calculation of WRCF for each sector involves dividing the total scores obtained in that sector by the total number of questions for that sector. The total scores for different sectors are denoted as $WRCF_T$、$WRCF_F$、$WRCF_P$、$WRCF_E$ and $WRCF_N$, which represent the sum of all values within each section as detailed in Table 1. The number of questions in each part is represented by qt, qf, qp, qe, and qn respectively (with a total of q=26, excluding demographic questions). Thus, $WRCF_t$、$WRCF_f$、$WRCF_p$、$WRCF_e$ and $WRCF_n$ each reflect the willingness of households in various provinces to reduce their carbon footprint in the areas of transportation, food, products, energy, and carbon neutrality awareness.

$$WRCF_{total} = \frac{WRCF_t + WRCF_f + WRCF_p + WRCF_e + WRCF_n}{q} \quad (6)$$

In Equation 6, the overall willingness of households to reduce their Carbon Footprint (CF) is estimated. Here, WRCFt, WRCFf, WRCFp, WRCFe, and WRCFn represent the willingness of

individual respondents from specific sectors to reduce their CF in transportation, food, products, energy, and carbon neutrality awareness, respectively. The total number of questions is represented by q (total q=26).

Based on the calculated scores, values below 0.5 indicate almost no willingness to reduce the carbon footprint (WRCF), scores from 0.5 to 1 indicate a low level of willingness, scores from 1 to 1.5 suggest a moderate level of willingness, and scores above 1.5 denote a strong willingness to reduce the carbon footprint. This scoring system provides a quantitative measure to assess the degree of engagement across different areas of carbon reduction efforts.

2.4 Correlation Analysis of Household WRCF

Considering that household WRCF may be influenced by various demographic factors such as age and gender, this paper employs SPSS software to process and analyze the data. This analysis evaluates the correlation between different factors and HCF to identify the most significant factors impacting carbon reduction behaviours in households.

$$r = \frac{\sum(X - \bar{X})(Y - \bar{Y})}{\sqrt{\sum(X - \bar{X})^2(Y - \bar{Y})^2}} \quad (7)$$

Where

r represents the Pearson correlation coefficient. X and Y represent the values of WRCF and various household characteristics, respectively. $\bar{X}$ and $\bar{Y}$ are the mean values of WRCF and the different household characteristics,

3 Result

3.1 Questionnaire

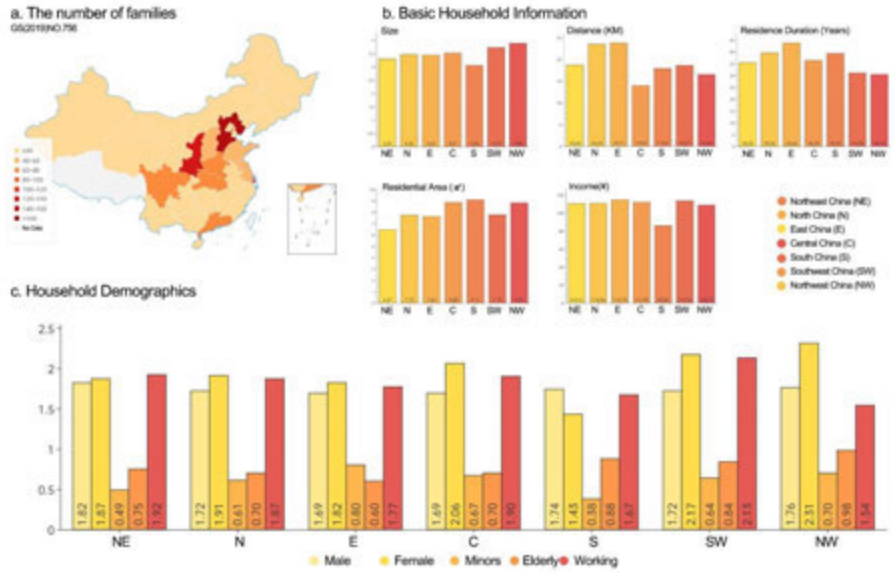

Figure 2: Basic Household Information. a. The number of families; b. Basic Household Information; c. Household Demographics

Figure 2 presents the foundational results of the survey. In terms of household composition, families of three constitute nearly 40% of the household population, with an average household size of 3.5 people. On average, each household comprises 0.67 children, 0.74 elderly individuals, and 1.85 working adults. Forty-six per cent of households have children, with an average annual family income of 186,500 RMB. Seventy per cent of respondents live within 20 kilometres of urban centres, and 57% of households occupy homes smaller than 100 square meters. Given that the survey encompasses the entirety of China, for ease of calculation and analysis, this paper divides the study area into the following eight regions based on geographical and climatic differences: Central China, Eastern China, Southern China, Northeast China, North China, Southwest China, Northwest China, and the Hong Kong, Macau, and Taiwan regions. Specific provinces and areas included are listed in Table 2. The questionnaire did not gather data from the Hong Kong, Macau, Taiwan, and Tibet regions; hence, these are treated as no data.

Table 2.The study area

Region	Included Provinces and Cities
Northeast China (NE)	Liaoning, Jilin, Heilongjiang, Inner Mongolia
North China (N)	Beijing, Tianjin, Hebei, Shanxi, Shandong
East China (E)	Shanghai, Jiangsu, Zhejiang, Anhui, Fujian, Jiangxi, Shandong
Central China (C)	Henan, Hubei, Hunan
South China (S)	Guangdong, Guangxi, Hainan
Southwest China (SW)	Sichuan, Guizhou, Yunnan, Chongqing, Tibet
Northwest China (NW)	Shaanxi, Gansu, Qinghai, Ningxia, Xinjiang
Taiwan, Hong Kong and Macao regions of China(THM)	Taiwan, Hongkong, Macao

Overall, Regarding household size, regional differences are relatively small, with the average household size in the Northwest being 3.88 people, slightly higher than 3.29 people in the Northeast, suggesting a more relaxed family structure in the Northwest. There are more significant differences in living space. Data indicates that the living area in North China is the largest, nearly 34% higher than in South China, reflecting differences in economic development levels and living conditions between regions. The duration of residence in homes varies from 6.47 years in the Northeast to 9.11 years in South China, which may relate to the stability of the real estate market and residential migration habits in these regions. Differences in the distance from residential areas to city centres are not substantial, but the greatest variance between North China and Northwest is about 13 kilometres, with the furthest distance in North China being 43.64 KM and the closest in Northwest being 30.44 KM, indicating that residents in North China may tend to live further from city centres.

Regarding household demographic composition, the Southwest region has the highest number of employed individuals, averaging 2.13 per household. Across all surveyed regions, the proportion of elderly in households generally exceeds that of minors, with the most significant difference in South China, where the elderly population is 1.3 times that of the minor population. Additionally, the male-to-female ratio also shows notable differences across regions; the Northwest region has 30% more females than males, while South China is the only region where the male population exceeds the female population. These data reveal regional characteristics and differences in family structure, living conditions, and gender ratios across various areas of China. These differences reflect the diverse impacts of economic development, cultural backgrounds, living habits, and social policies between regions.

3.2 WRCF in different regions

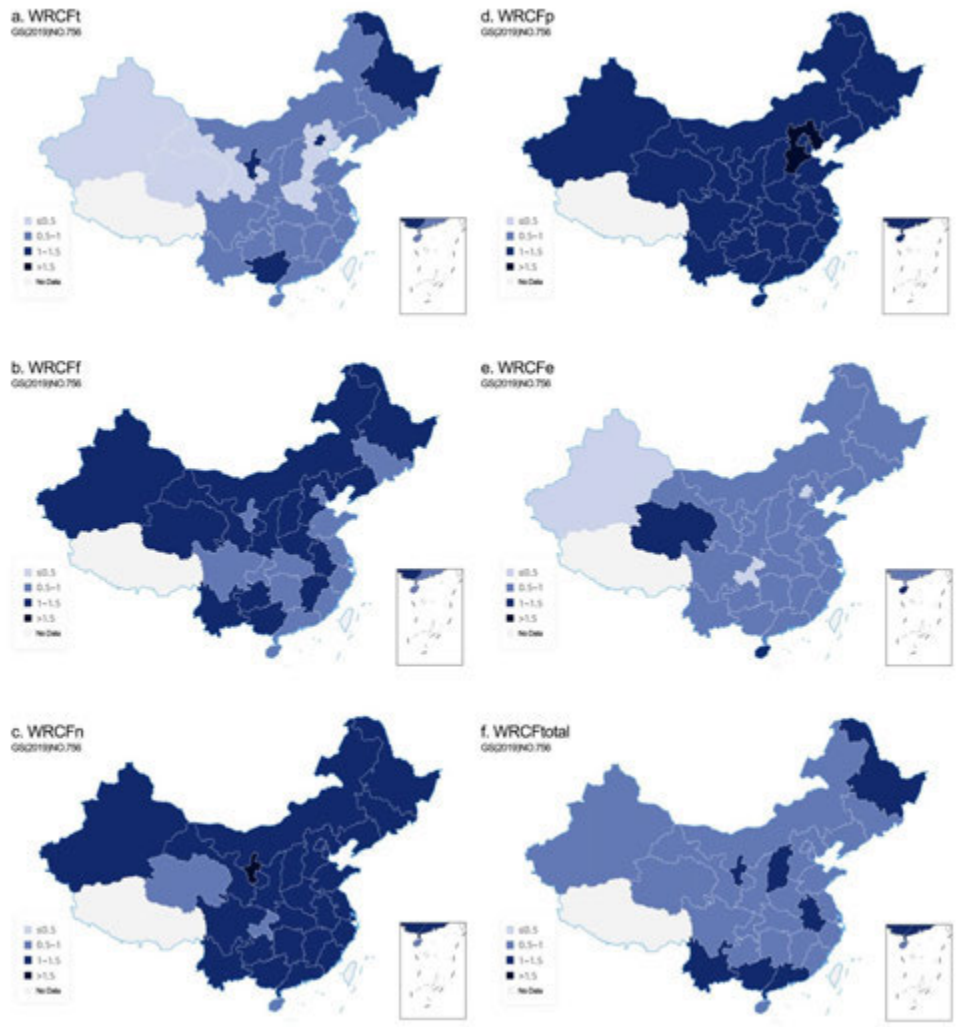

Figure 3 Different categories of WRCF

The study on the distribution and impact of WRCF demonstrates significant regional variations in different types of WRCF. Specifically, in the transportation sector, Heilongjiang Province, Beijing, Ningxia Hui Autonomous Region, and Guangxi Zhuang Autonomous Region exhibit strong

WRCF, likely due to aggressive local government promotion of low-carbon transportation policies. However, in other provinces and regions, the WRCF related to transportation is relatively low, possibly due to a lack of effective incentives or insufficient public awareness of the importance of carbon reduction in transportation.

Compared to transportation, the willingness to WRCFf is more pronounced nationwide. A substantial number of families across almost all regions show a willingness to reduce their food carbon footprint, especially notable in North China, Northeast China, and Southwest China. This reflects the growing concern among Chinese families about the carbon footprint associated with food consumption and their willingness to adopt measures to reduce food-related emissions. The willingness to reduce carbon emissions from household products (WRCFp) is similar to that for food, with a positive attitude observed across all provinces, particularly pronounced in Hebei Province. This indicates that an increasing number of consumers prefer eco-friendly and low-carbon products, reflecting a rise in public environmental awareness and market demand for such products.

However, the WRCFe across the country is not ideal. Apart from Qinghai Province, the desire to reduce energy consumption is generally low throughout the country, especially in Chongqing, Beijing, and Xinjiang, where there is almost no inclination to reduce energy consumption. This could be related to the energy structure and pricing policies in these areas, or possibly due to inadequate public understanding of the importance of energy carbon reduction. Apart from Qinghai Province, the national willingness to reduce energy consumption is low, with almost no willingness observed in Chongqing, Beijing, and Xinjiang. Regarding WRCFn, there is a strong awareness of carbon neutrality nationwide, particularly in the Ningxia region. This indicates that national campaigns on carbon neutrality have been somewhat effective, with most families having a fair understanding and support for it.

In terms of overall WRCF (WRCFtotal), only a few provinces like Yunnan, Guangxi, Shanxi, Heilongjiang, Gansu, and Anhui show significant overall WRCF, while other provinces exhibit lower WRCF. This disparity highlights the uneven distribution of environmental awareness and practices across China, suggesting that future efforts should not only maintain the willingness to reduce carbon in food and products but also enhance the promotion of energy carbon reduction.

3.3 Correlation-based influences on WRCF

To further analyze the primary factors influencing WRCF, we employed Pearson correlation analysis to explore how household characteristics (such as household size, ages of members, gender, and employment status) affect the willingness to reduce carbon emissions in various aspects including transportation, food, products, energy, and carbon neutrality awareness across different provinces. Figure 4 illustrates the main influencing factors for different categories of WRCF, where the significance levels (two-tailed) indicate whether these relationships are statistically significant. Except for household population, gender, elderly, minors, and working population, the correlations for all other factors were found to be significant (p-value <0.05 or <0.01).

Figure 4 Main influencing factors for different categories of WRCFs

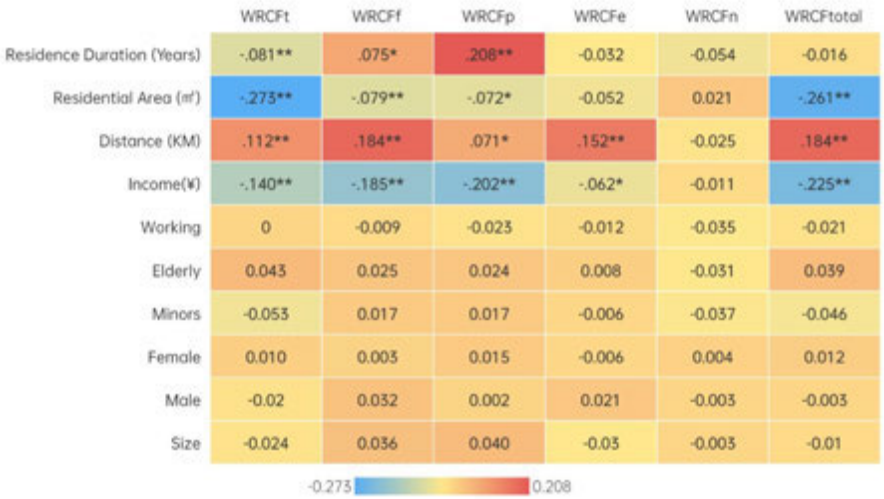

Figure 4 indicates that the gender ratio, total population, and number of employed individuals in households do not significantly influence the WRCF, suggesting that these factors may not directly determine a family's carbon reduction behaviours. However, other aspects such as household income, geographical location, residential area, and duration of residence significantly affect carbon reduction awareness in households. Specifically, the size of a household's living area shows a significant negative correlation with their awareness of transportation carbon reduction. This may be because families with larger living areas typically own more vehicles or use private cars more frequently, which reduces their focus on reducing carbon emissions in transportation. Additionally, such families are likely to reside in suburban or peripheral urban areas, increasing their dependency on vehicles. The proximity of residences to city centres is positively correlated with the household's awareness and actions toward reducing carbon emissions in transportation, food, and energy. Families living near city centres tend to adopt a low-carbon lifestyle, such as using public transportation, opting for local food, and utilising energy more efficiently, likely because of better accessibility to transport and environmental resources in city centres. Household income is also a crucial factor affecting carbon reduction consciousness. Data shows that higher-income families demonstrate a lower willingness to reduce carbon emissions in food, products, and energy, possibly because such families have greater financial flexibility for consumption, may not focus on conserving resources and protecting the environment, or their lifestyle and consumption patterns are closely linked with higher carbon emissions. This observation aligns with the findings of researchers like Wiedenhofer et al(An et al., 2024; Gao et al., 2024; Wiedenhofer et al., 2017). The duration of residence is positively correlated with the willingness to reduce the carbon footprint of products; families residing longer in their homes are more likely to adopt measures to reduce product carbon footprints, such as choosing sustainably produced goods and reusing products. Overall, the general awareness of carbon reduction negatively correlates with the size of a family's residential area but positively with their geographical location. This suggests that families living in smaller residences closer to city centres are likely to exhibit

stronger environmental awareness and behaviour, possibly due to stricter environmental policies in these areas or because residents in smaller spaces focus more on efficient resource use.

Overall, the general awareness of carbon reduction is negatively correlated with the size of a family's living area and positively correlated with their geographical location. This suggests that households with smaller living spaces and those closer to city centres are more likely to exhibit stronger environmental consciousness and behaviours. This could be due to stricter environmental policies in these areas or because residents in smaller spaces focus more on efficient resource use.

4 Discussion and Conclusion

This study integrates the WTP approach and survey methods to explore the variations in WRCF among different types of households across various regions of China, and their relationship with household structure, economic status, and living conditions, providing a basis for future differentiated low-carbon policies. The results show that while there is little variation in family size across regions, there are significant differences in living space, duration of residence, and distance from city centres. These variations reflect regional differences in economic development, real estate market stability, residential migration habits, and urban planning. Additionally, the composition of household populations in terms of gender ratios and age structures also shows regional characteristics; in South China, the elderly population exceeds the minor population, while in Northwest China, the female population significantly outnumbers the male population. These findings reveal the diversity and specificity of family structures and living conditions across different regions of China.

Significant regional differences are evident in the types of WRCF. Chinese families have made some progress in WRCF related to food and products, but there is still room for improvement in transportation and energy use. Nevertheless, there is a strong national consciousness about carbon neutrality, and promotions regarding carbon neutrality have been somewhat effective, with most families having a fair understanding and support for it. Future efforts should maintain the progress in food and product WRCF while enhancing the promotion and policy guidance on energy carbon reduction to ensure a comprehensive advancement of low-carbon lifestyles.

Factors such as household income, geographical location, residential area, and duration of residence significantly correlate with household carbon reduction consciousness. Families with larger living areas tend to have a lower awareness of transportation carbon reduction, possibly due to greater reliance on private vehicles. Meanwhile, families living closer to city centres are more likely to adopt low-carbon lifestyles due to convenient transportation and efficient resource utilization. This insight suggests that policymakers should consider carbon reduction factors in urban planning and housing policies, such as encouraging the development of compact cities and enhancing the convenience and efficiency of public transportation systems (Souaid et al., 2024). Research has found that high-income families generally have lower WRCF, which may be related to their greater consumption power and lifestyle choices (Sommer & Kratena, 2017). Therefore, enhancing environmental education and improving the availability of eco-friendly products and technologies might be effective strategies to increase WRCF among higher-income groups (Wiedenhofer et al., 2017).

Future government carbon reduction strategies could consider the specific circumstances of households, such as income level, residential location, and type of housing, to design more targeted incentive measures. For example, families living in small residences in city centres could be provided with more low-carbon lifestyle conveniences, such as discounted public transportation services and expanded public resource-sharing facilities. Simultaneously, differentiated educational and promotional strategies should be launched for various income levels, particularly emphasizing the importance of a low-carbon lifestyle to high-income families to motivate their participation in carbon reduction. In addition, effective carbon reduction promotional activities should be implemented to widely communicate the importance and urgency of carbon reduction to the public. Currently, China has introduced a series of policies to reduce Household Carbon Footprint (HCF), such as promoting low-carbon buildings, developing new energy vehicles, advocating low-carbon lifestyles, enhancing energy conservation, and using new energy sources, aimed at reducing HCF, promoting sustainable development, and improving the quality of life. These measures not only aim to reduce carbon emissions, promote sustainable development, and enhance the quality of life but also make significant contributions to global climate governance and international cooperation, advancing global efforts to combat climate change and helping achieve the long-term goals of reaching carbon peak by 2030 and carbon neutrality by 2060.

This paper still has some limitations, such as potential biases in the survey or questionnaire design that might affect the respondents' answers, thus impacting the reliability and validity of the data. Future research should consider improving the design issues in the survey to enhance the reliability of the study.

Stakeholders of participatory planning: a comparison between Megacities and Cities in Europe

Hana Elattar
Affiliation: HafenCity University Hamburg
Email: hana.elattar@hcu-hamburg.de

Abstract

Participatory planning is regarded as an accelerator of sustainable development, it comes however with its own set of challenges. In this paper, we study the challenges that are explicit to the case of Megacities. As they are more prominent in our current years, megacities form a large portion of their countries' population, not to mention they constitute an issue when combatting climate change. In the context of megacities, the analysis of the participation process requires a breakdown of the biggest difference between its application in cities and that in megacities: the stakeholders and their extrapolation. At the end, a solution for its conduction in megacities is proposed following the learnings from the city of "Vinnytsia" and applying them to the case of the megacity of "London".

Keywords: *Participatory Planning – Megacities – City Development – Planning Stakeholders*

Introduction:

As urban areas are rapidly growing, with more than 4 billion people, representing more than 50% of the world's population currently living in urban areas (Ritchie et al., 2018), handling each type of urban space individually is necessary for sustainable planning. This is to allow the shaping of processes tailor-made to fit the type of communities living in it and most importantly to keep up with its rate of expansion. An extraordinary phenomenon of urbanization is the formation of Megacities. Megacities are defined by their population size, which crosses the threshold of 10 million inhabitants (World Urbanization Prospects The 2018 Revision, 2018). Other than their defining aspect, the unique characteristics of megacities include their expansive size, intricate infrastructure, rapid growth, and socio-economic diversity ((Wenzel et al., 2007) and (Buehler, 2003.)). These necessitate a re-evaluation of traditional planning methods including participatory planning approaches. As megacities form a complex eco-system, their development elements are usually differentiated between one another during the planning process. This is already true in other types of cities and leads to the shift of power structures between the different stakeholders depending on the objective of the development. This division of elements shows, nevertheless, a higher level of disconnect in megacities due to their high level of complexity, which results in most cases in a top-down approach in decision making. Megacities are furthermore characterised by two attributes, their high population density, and the speed in which they expand. Currently, there are 33 megacities worldwide, a number expected to rise to 44, as projected by the United Nations Department of Economics and Social Affairs (United Nations, 2018). A megacity forms a complex organism where the race between sustainability and growth is fierce. With high speed expansion, pollution becomes just as fast on the rise. This is then worsened by the difficulty of controlling and maintaining sustainable development with the high number of stakeholders involved. A common trend to overcome this obstacle in recent years, has been to regard megacities as agglomeration of neighbourhoods.

Planners breakdown the megacity into neighbourhood islands, where development could be controlled and to an extent monitored. This has proven however ineffective in recent studies, as the case in the research conducted in Eastern megacities such as Hong Kong ((Edermann et al., 2023). Such methods tackle the centres of neighbourhoods and fail at their border. In their attempts to remedy such failures, the authorities create new masterplans with overarching policies. These in turn suffer under the magnitude of the challenge and resolve into one of two faults: failing to account for the individuality of established communities in each neighbourhood or expanding the city more to cater for the residents' needs, an endless loop as the megacity becomes even more difficult to contain and manage. On the other side of the spectrum, small cities have mastered the art of maintaining an identity whilst creating their overarching plans. As planning methods were created with cities of medium and small scale in mind, their application proves more effective. Adaptations are in any case needed to match with socio-economic and administrative contexts, nevertheless, the tools in themselves do not need to change. A good witness is reflected in the use of participatory planning as a sustainable development method.

In this research, we discuss the use of small cities to provide a blueprint for the translation of urban planning processes. The focus point in this method is to tackle the division and boiling down of stakeholders in small cities and allocating their counterparts in a megacity as a whole. As part of the SURPRISE project[1] we will investigate the research question at hand by dissecting the processes taking place in the Ukrainian city of Vinnytsia and translating the learnings into the European Megacity of London.

To tackle this challenge, we will start by understanding participatory planning and the stakeholders that are involved. We will then move on to studying the two cities in question, mapping out their stakeholders and comparing them to one another. At the end, we will be deriving conclusions, highlighting what solutions megacities could adopt and what could be enhanced in small cities planning.

2. Participatory Planning:

2.1 – Its definition and principles

Participatory planning signifies the involvement of all stakeholders and end-users of an area in its development plan. This method has been commonly used since the 1960s and has been referred to as a tool for sustainable development. In itself, participatory planning was the result of the shift from urban planning to strategic planning development. The main pillar of this method is the inclusion of different stakeholders in the decision-making process while urban planners play the role of mediators between the different stakeholders (Steinberg, 2005).

Researchers such as Jane Jacobs (Jacobs, 1961) and Sillak et al (Sillak et al., 2021) have studied how the involvement of citizens is related to the durability of the development. Jacobs has discussed this topic from the perspective of ownership. She explains in her book how citizens who are involved in the planning phase tend to protect said developments, e.g. against vandalizers in the case of small developments, and maintain the developments as a community. Sillak et al, amongst other researchers, have perceived the question of sustainability from a knowledge perspective. They have investigated participatory planning in topics such as energy planning and perceived the citizens as holders of first-hand experience on the place, and therefore having communicated to them any missing knowledge such complex topics and

[1] The Sustainable Urban Planning and Resilient Reconstruction In Ukraine with Spatial Data Science (SURPRISE) project is conducted by HafenCity University in Hamburg, Germany. It focuses on creating a pathway for sustainable planning in Ukrainian cities.

through working with the experts, are guaranteed to communicate a development masterplan that will correspond to the needs of the place. This helps prevent the repetition of work through the modification and readaptation of development plans during the operational phase.

2.2. - Obstacles in participatory planning:

Whether in megacities or small towns, participatory planning forms consistently a challenge for modern-day planners. From the start of the process, the challenge rises in managing and engaging stakeholders into the conversation (Cohen et al., 2015). The risk is this challenge resulting in only having a small sample of the society joining the decision-making process. More often than not, if this issue is not resolved, the sample in itself is then over-dominated by city officials and authoritative figures (Innes and Booher, 2004).
The second challenge is apparent when discussing more technical sectors related to planning, such as energy topics, governance, and economic issues among others. In this scenario, it is the case that there is a gap between the knowledge required for an effective debate, and that which the general public possesses. In energy topics for example, this problem is caused due to the discrete nature of the field. From complicated energy bills, lack of available open-data on the topic, to the complex theories behind its planning process, many energy topics present a black box for the normal citizen (Crippa et al., 2021). This to say that such lack of knowledge is not of the citizen's fault and therefore the job of the mediator urban planner in the participatory process is to ensure a levelling of all involved stakeholders in terms of knowledge. This solution adds in turn to the timespan of the planning process as a whole. This latter issue of time, with its different scales is one of the challenges in every planning process as they are viewed by experts as lengthy add-ons to the development process. To tackle this issue, developers resolve to the inclusion of citizens at the last phase which is the reviewing of the resulting plan, leading to a frustration from the citizens end and with it a lack of enthusiasm in joining the conversation for future projects and thus the cycle continues. The last common challenge of participatory planning is the translation of plans made by citizens into effective plans that could be used on site. This issue related and adds to two of the previously mentioned challenges: the lengthening of the process due to reformation of the plans, and the overruling of some of the citizens additions resulting once again in their frustration.

2.3- Breakdown of participatory planning stakeholders in megacities vs cities:

Finding the solution to the first obstacle of the subsection above, starts with understanding the stakeholders necessary for participatory planning. In its essence and as presented by Jacobs in her book (Jacobs, 1961), participatory planning is only effective if all samples of the community take part, arguing that minorities are often overlooked although they bring a unique perspective to issues at hand. Other researchers, such as Siliak et al (Sillak et al., 2021) and Voorberg (Voorberg et al., 2015) have expanded on the need for experts to join the conversation in the technical development areas such as energy and traffic. Since our research is discussing the overarching concept of city developments, we have also taken into the work of researchers tackling large-scale issues of development, such as the work of Arlati et al in discussing the CLEVER Corridor project in Hamburg, Germany (Arlati et al., 2021). From merging the literature, we can divide the stakeholders into 4 different categories: Experts, planners, stakeholders with economic interest, Authorities.

- Experts:
  Needed especially in complex technical issues, such as sustainability, water management, energy, traffic, among others. This category of holds deeper knowledge

on the topic in question. Their presence helps with asking and answering case-specific questions which then bridges the gap between the resulting masterplan and what can be realized on site.

- Planners:
  Planners are first and foremost mediators of the conversation. Equipped with the right tools, they guide the different stakeholders to reach the wanted results. They are sometimes hired by the city directly or are part of development consultancy and planning offices that are responsible for the project.
- Authorities:
  Comprised of government representatives and city offices, the level of authoritative figures involved on a project depends to its scale and its implication on local politics
- Economic-Interest Stakeholders:
  This last category is for private entities including, among others, funding agencies, energy companies and real estate developers. Despite them not being present in all types of projects, their involvement provides a challenge as the ideals they are reflecting has economic interest in their centres instead of general-interest questions such as sustainable development. Their contribution, however, provides a good inside on the feasibility of suggested plans.

The citizens, despite being at the centre of the process, constitute several intersections with each of the 4 mentioned categories, as they are workers, experts, city officers as well as citizens. They are therefore encompassing all the categories, as shown in Figure 1 below.

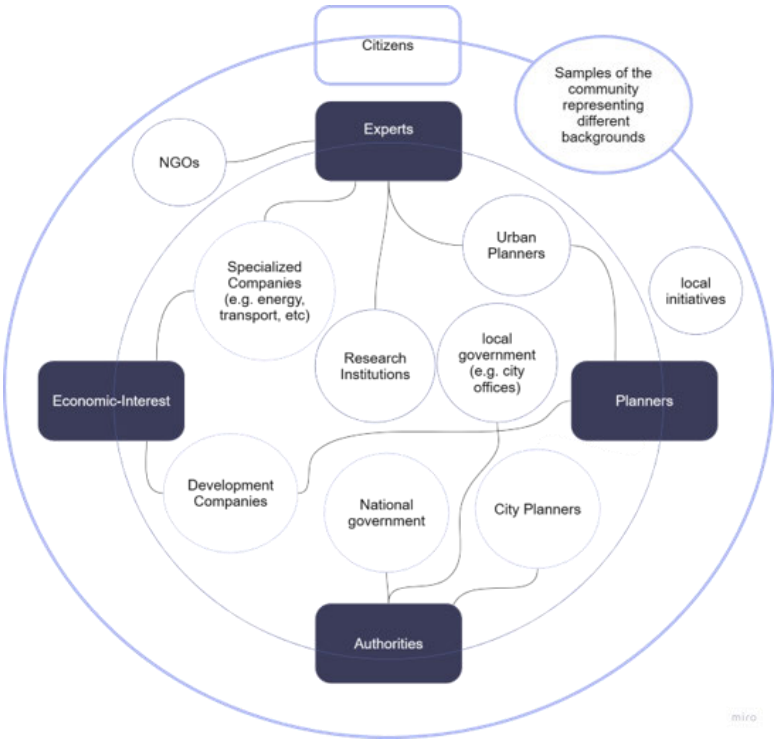

Figure 1: Categories of stakeholders in participatory planning

3 – Stakeholders distinction between cities and megacities

This stakeholder's breakdown, has been made in studying participatory planning in cities. The question rising here, is whether this categorization could be applicable to megacities in their large-scale development processes. In this section, we will study the 2 examples of Vinnytsia, Ukraine, and London, England to view what the above-mentioned categories translate into in the small city and how such learnings can be applied into the megacity.

3.1- Vinnytsia, Ukraine as a city example:

The first city of our study, is the city of Vinnytsia located in west-centre Ukraine. As Ukrainian administrative boundaries follow the hierarchy adopted from the traditional Soviet planning, the name Vinnytsia is given to both the Oblast and the Hromada as shown in Figure 2. With a population of over 350000 in the Hromada and 1.5M in the Oblast, the general population density of Vinnytsia amounts to 56.98/km² (City Population, 2022). As is the case in most post-Soviet cities, Vinnytsia currently faces a shift in identity where the current population is inclined to a more European image and development trends. A change is also obvious in its economy, where traditional industries are fading and their sources of income are shifting. Previously known as "Small Kyiv", the actors in Vinnytsia are conducting big movements to

reassign the city's urban identity. It is currently regarded as a power-player in its local region and in Ukraine (Melnychuk and Gnatiuk, 2019)

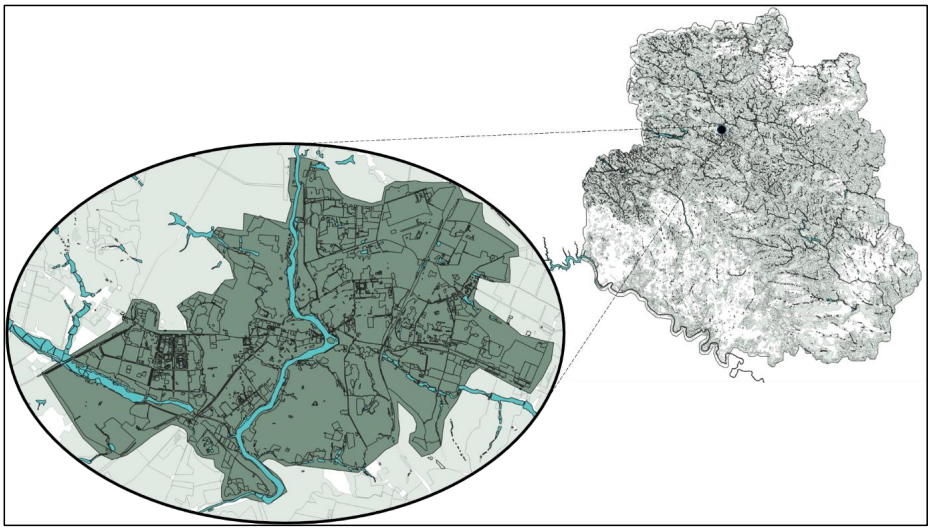

Figure 2 Map showing the position of the Hromada Vinnytsia in the Oblast of Vinnytsia using OpenStreetMap data

3.2 – Stakeholders in Vinnytsia, Ukraine

Currently in a wake of development, the Ukrainian city is following a plan to derive a more sustainable development path for its citizens. One of the pillars of which is the planned increased involvement of citizens in decision-making. To carry this task, and in the frame of work of the SURPRISE project, the degree of involvement of different stakeholders has been identified through conversations held with the local representatives. As explained in Figure 3 below, some stakeholders in Ukraine contribute only at the Oblast level. Translated into Western European planning definition, an Oblast could signify a municipality while the Hromada is the city. In the context of Vinnytsia, it could be regarded as an Oblast encompassing a town, prompting two different layers of intervention depending on the project. One main learning from from this division, is the stakeholders' categories themselves do not differ based on the development scale, but rather stakeholders themselves are distributed throughout the different scales. For example, authorities are needed at both scales, however the level of jurisdiction needed is the variable.

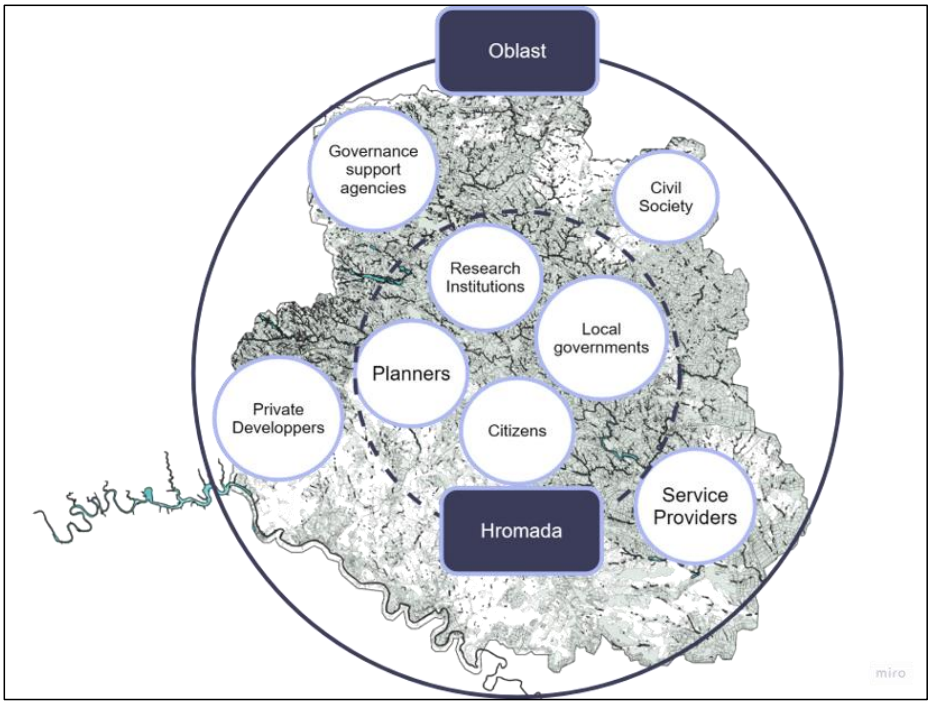

Figure 3 Distribution of participatory planning stakeholders between the Oblast and the Hromadas based on conversations with local actors in the frame of the SURPRISE Project

3.3- The Greater London area as an example of Megacity:

England's London is one of the two megacities of Western Europe, the other one being Paris, France. In 2024, London is house to a population of 9.7 million. The megacity encompasses the greater London area which has the city of London at its centre, forming only 2.9 sq.KM out of the 1569 sq.Km of the Greater London Area. London (referring to the greater London area in this research) has a population density of 5596 residents per sq.Km. (World Population Review, 2024). It encompasses an exceedingly diverse population, with 41% of its population formed by immigrants. With a very rich history, London is currently a global economic hub. As a megacity, London faces challenges such as traffic congestion, housing affordability, air pollution, and income inequality (Wenzel et al., 2007). Urban planning and sustainability initiatives are being implemented to address these issues. Although London is technically not a coastal city, it is often studied as a coastal megacity thanks to the Thames river crossing the city, connecting it to the North Sea, and its very close proximity to the coast.

3.4 – Comparison between stakeholders of Vinnytsia and London:

To understand the development of megacities, researchers have distinguished between the megacities in the western and eastern parts of the world. The development of the megacity of London has been studied as shown in Figure 4 (Li et al., 2019). A trend that has been spotted amongst them, is the tackling of problems through construction of satellite cities to fulfil the needs of the residents. The question we are investigating however is focused on a process encompassing the megacity as a whole.
Following the blueprint of the city of Vinnytsia, the inclusion of all stakeholders' categories remains a defying aspect to achieving effective participatory planning. To understand the difference between the two different city types, we resolve to extracting the stakeholder examples from Vinnytsia and assigning their counterparts in London as seen in Table 1.

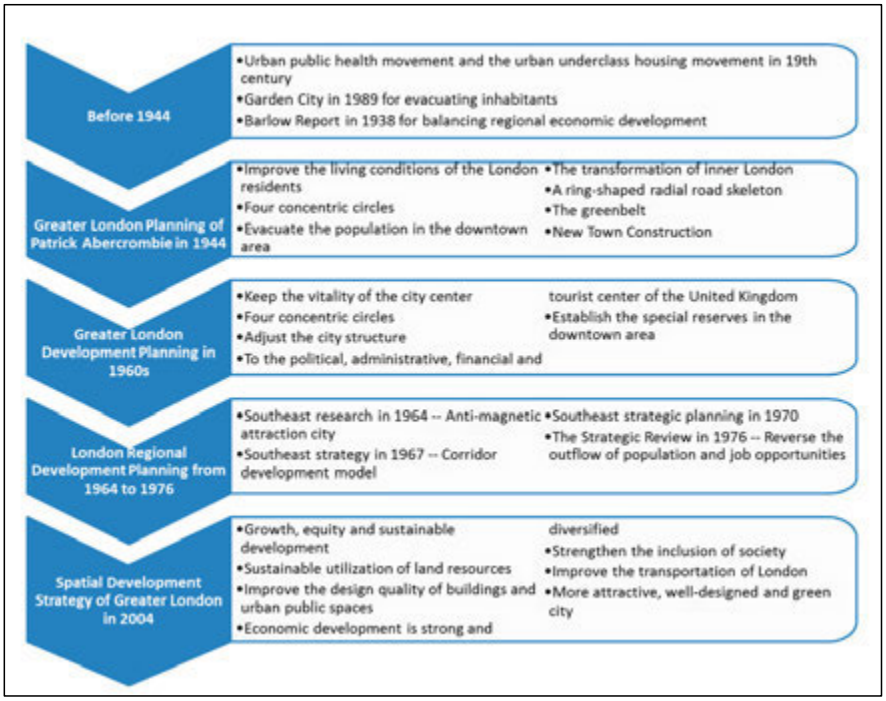

Figure 4 Development history of the Greater London area - Extract from Li et al (2019)

One stakeholder category that stands out as differing greatly between the megacity London and the city of Vinnytsia, is the "Authorities" category. In the example of Vinnytsia, Ukraine, the authorities are divided into local authorities and central government (Vinnytsia City Council, 2024). Their bodies are divided such as:

- Local authorities:
  - Mayor's office
  - City Council: includes several deputy mayors responsible for the different sectors, such as the deputy mayor of urban mobility and transport.
  - Executive bodies of the city council: working under control of the city council

- Central government:

The central government in Ukraine is divided into several ministries that are involved to different degrees in urban planning development. Some ministries such as Ministry of Restoration and the Ministry of Infrastructure, are conducting more fast-paced work in the domain of sustainable development. The involvement of ministries in participatory planning can only happen at the oblast level.

In the city of London, and as the case in metropoles and large cities, the city is divided into several boroughs, signifying the different neighbourhoods with their different uses. The division of authorities and their inclusion in planning processes in London are as follow (London Councils, 2022):

- The boroughs: they manage the neighbourhoods, and are in charge of planning applications, maintain the roads and deliver environmental and leisure services. They can be regarded as a union of the different neighbourhoods.
- The city of London: works on a smaller scale than the boroughs but is responsible for the communication of the image of London to the outside world.
- Greater London Authority: includes the mayor and is the authority responsible for the overall development vision of the megacity. We can understand from there their indispensability in the participatory planning process.
- Local government association: representing the council on the national level. As it deals with issues concerning England as a whole, its presence in the development process can be referred to at the later phases.

3.5 – Process differences between cities and megacities:

Taking the case of Vinnytsia as an example, we can see how the Hromada involved less stakeholders in its process than the Oblast. This is however justified by the character of these two different spatial contexts, where each Hromada comprises one centre, specific communal characteristics, and specific challenges. This scenario is different when breaking a megacity like London into boroughs. Despite the different boroughs facing different sets of challenges, their impacts on one another are inevitable. The points elaborated upon provide examples of the aspects that result in the difference of the processes between the cities and megacities.

(a) Financial centres:

A city centre is easily allocated on the map of a small city. In the case of Vinnytsia, tackling issues regarding the centre of the city can be done individually by each Hromada, meaning the participatory process can be divided by Hromada, with a bigger set of contribution to tackle the Oblast as a whole. The city of London, however, not estranged to other megacities around the world, comprises of several financial centres (Roberts, 2008). Such centres are visited on a daily basis by inter-city commuters. These are residents of the city of London, who live in a residential borough but work in one of the many financial centres. The further development of London's industrial district for example cannot be carried without the inclusion of neighbouring citizens that are not part of this specific district but are influenced by its impact on pollution and on the traffic condition among others.

(b) Environmental issues:

Environmental sustainability is a subject controlled first and foremost by local developments. In the megacity, the degree of contributions of different neighbourhoods to the issue at hand

varies. As explained in previous sections, such issues are mostly tackled by further development of the megacity with minimum contributions to existing constructions.

Stakeholder	Vinnytsia (Hromada)	London
Governments	- City offices - Local governments for Oblast - Central government ministries	- Wards - The boroughs - The city of London - Greater London Authority - Local government association - Transport for London
Private Entities	- Private businesses	- Private businesses
Research Institutes	- Research Institutes in the Hromada - Research Institutes in the Oblast - International Partners - Institute of development studies as a main player	- Research Institutes and university all over the Megacity act independent of their location - International experts
City Planners	- Government assigned planners (Oblast) - Private planning offices	- The mayor's planning consultants (London.gov.uk) - Private planning offices
NGOs	- Working together with research institutes on development topics - Shift in focus into post-war and post-soviet developments - International NGOs with presence Vinnytsia	- A big focus of NGOs is the raising of the voice of minorities - A focus on human rights issues on the local and international level

(c) Energy issues:

In Europe, and with the provided legislations for energy communities, small cities residents have proven to have more ownership over the energy discourse in their cities. Energy communities, defined as stakeholders of energy in the urban setting, are more prominent in cities where ownerships of houses are more common than apartment buildings. This provides cities with the characteristic of having residents with more knowledge and involvement in such a technical topic than a megacity. This solves, to a certain degree, the knowledge issue prominent in participatory planning.

(d) Community engagement:

The sense of community in the megacity is far from non-existent. It is however more obvious on small scales, such as a sense of community in the neighbourhoods themselves. Small city communities possess feelings of ownership over the city as a whole. This makes the inclusion of citizens an easier task.

Table 1: assigning the stakeholders to the contexts of Vinnytsia and London

4 - Proposed Stakeholders involvement strategy in megacities

The challenge at hand is understanding how megacities can conduct an effective participation process on its large scale. Studying the two examples at hand, it can be seen how the involvement of all stakeholders' categories is easier to be achieved in smaller cities than in megacities. To achieve the up-scaling of the process without losing its integrity, a proposed solution can be the division of the process through the timeline rather than spatially as shown in the figure 5 below. This solution is proposed to tackled the obstacles elaborated upon in section 3.

As opposed to the usual spatial division of stakeholders, the timeline division attempts the inclusion of all categories of stakeholders concerned with the megacity. It solves the issue of the enlarged scale by dividing the process into 2 phases. In the first phase, directly-impacted stakeholders are included to have a first-hand discussion of the needs and problems of the development location. The first phase would include the definition of the problem at hand, the co-creation of a solution through collaborative work with the stakeholders, and the reduction of the knowledge gap on the topic which is easier to achieve with the smaller group.

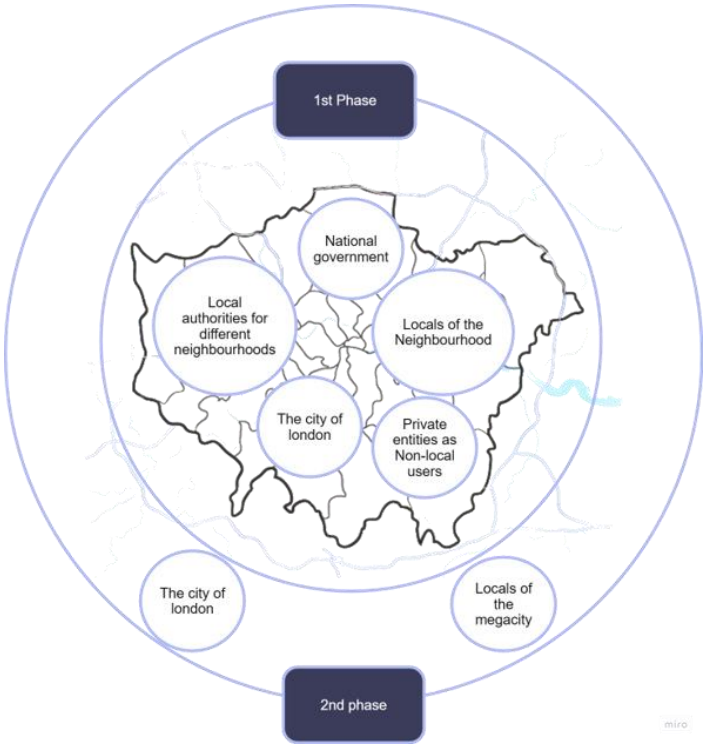

Figure 5 Proposed division of stakeholders through the development timeline of the megacity of London

Whereas the second phase involves larger contributors to the decision-making. It assures the acknowledgment of the impact of the development on the larger scale, be it a larger radius of neighbourhoods or the megacity as a whole. The involvement of larger scale authorities in the second phase ensures the feasibility assessment of the development and prevents the overshadowing of the voices of local communities that are more involved during the first phase.

4.1 - Digital tools as a future solution

Smart cities have been an expanding concept in cities regardless of their scale. They are regarded as a solution to a big portion of the sustainability question. One of the tools in which this is achieved is the introduction of digital tools for sustainable planning, including digital tools for participatory planning. Initiatives have been carried out in both of our study cities to accelerate their development into smart cities and their use of digital tools to ensure a better inclusion of the public in participatory planning. In this regard the movement towards such tools depends greatly on the political and economic contexts. Nevertheless, the methods to conduct this shift can be learned from set examples.

5 - Conclusion:

This paper has revisited the planning method that is participatory planning from the perspective of megacities, by studying the European city of Vinnytsia and the megacity of London. Through the analysis, differences were extracted between the two cities in respect first and foremost to stakeholders, but also with regard to the general challenges faced by the two cases when it comes to sustainable development. It is important to note that some factors were not considered in this analysis, as is the case that, despite the inclusion of the city governance structures in both scenarios, some political constraints still do exist that could limit the participation of some of the mentioned stakeholders. A number of political and socio-economic differences also exist between the two cities, that affect highly the public perception of such exercises. The goal of the study remains to showcase the possibility to derive learnings from cities and to adapt them into the cases of megacities instead of regarding megacities as islands in urban planning learnings.

In the case of Vinnytsia, it was concluded that the inclusion of stakeholders, namely authoritative figures, is dependent on the scale of the development. This was then explained as a symptom of the scale of the city (mentioned as a Hromada) and its individuality in the municipality (or the Oblast). This individuality is shared by all small cities, and result in the lack of justification for the inclusion of residents and stakeholders from outside the city itself if the development is of small scale. Different actors are then called upon for Oblast development projects. These can share similar categories as those included for Hromada development but are of different specialities and interests.

While studying the city of London, it was noted how the development of satellite cities followed the trend set by western megacities. It also corresponds to the pattern of megacities to fulfil their residents needs through further development. We addressed therefore the challenge of attempting to regard the megacity as a unified entity during the participatory planning process. The blueprint derived from Ukraine was therefore altered to a different concept which is the distribution of stakeholders through the phases of the project, to allow for a more inclusive

process. Such alterations allow the carrying of successful processes and their exchange between different cities.

Adding to this, more research needs to be carried out to study the tools used for conducting participatory processes. One remarkable addition is the introduction of digital tools for participatory planning, which provide a fast solution for large-scale citizens inclusion as is the case for megacities.

Lastly, understanding the history of cities developments and the reasoning behind the methods used in conducting urban planning are a mandatory step to their re-adaptation. This could however only be achieved when transparency exists in the planning process, which allows for a more in-depth look on the conditions in which planning decisions were made.

Acknowledgment:

This research was conducted as part of the work of the research project “Sustainable Urban Planning and Resilient Reconstruction In Ukraine with Spatial Data Science” funded by the Deutsche Gesellschaft für Internationale Zusammenarbeit (GIZ). This body of work represents the idea of the researcher alone and does not necessarily reflect the opinion of the funding agency or the project partners.

Planning for proximity in a fragile urban context. The case of Tirana

Giulia Spadafina

https://orcid.org/0000-0002-5400-6470

Abstract (up to 125 words)
Tirana is the only city in Albania to have experienced a steady population increase over the past thirty years, due to strong internal migration and its attractiveness due to its great economic, social and cultural development. Its urban development is recent and relates to its political history. The demographic context nevertheless shows a high percentage of families at risk of poverty The contribution attempts, by analysing one of the strategic projects of the new Tirana2030 Urban Plan, the one concerning schools and education, to reflect on the role of planning in the challenge towards the transition to an urban proximity model.

Keywords
Proximity, urban planning, governance

Introduction

In Western cultures, as Bernardo Secchi states in his book *The City of the Rich and the City of the Poor* (Secchi, 2013), the city has always represented the ideal place for social and cultural integration but, in its evolution, it has also become the scene of phenomena of separation and marginalisation, both physical and social. The geographer Edward Soja, in his book *Seeking spatial* justice (Soja, 2010) defines the concept of Spatial Capital as that wealth, or poverty, dependent on a person's ability to access social, cultural and professional life in the urban context in which he or she lives. The strong relationship between the city and the communities that inhabit it is thus evident. Sennett refines the reflection on the relationship between context and community in the book *Building and Dwelling, Ethics for the City* (Sennett, 2018) by introducing the concept of *ville* and *cité. The* term *ville* can be used to indicate the city as a whole, the built territory, understood in its physicality and spatiality, while the term *citè* indicates all the ways in which the territory is experienced, and therefore all the relationships that are established within it. The crises that the city has faced in the course of history are numerous, they are more or less of an economic, financial, institutional, political, social and cultural nature…

During the 20th century, cities developed following an idea, based on efficiency maximisation, of polarisation and hyper-specialisation of urban functions, a phenomenon that caused the monofunctionalisation of certain areas of the city such as, for example, areas entirely devoted to work, commerce, university, health, residence, and so on. In 2000, Nobel laureate Crutzen and biologist Stoermer[1] proposed the term 'Anthropocene' to indicate that human impact had become predominant on the earth's ecosphere. The result is that the way in which the city is used has been changed to include the use of the private car. The city structured in this way is defined by Ezio Manzini as the *city of* distances (Manzini, 2021). Further disrupting the dynamics of city development and organisation is the Covid-19 pandemic in 2020. The limitation of travel and the lack of a capillary network of services and commercial activities have made all the limitations of contemporary urban systems, based on the aforementioned concept of polarisation and hyperspecialisation, evident. In fact, urban

[1] Paul J. Crutzen and Eugene F. Stoermer, The Anthropocene, 'Global Change. NewsLetter', No. 41, 2000

areas were the most affected with over 90% of confirmed Covid cases concentrated in cities. The economic consequences of the pandemic will also mainly affect urban areas with over 120 million people at risk of new poverty. According to the report *Cities and Pandemics: Towards a more just, green and healthy future* (UN-Habitat, 2021) the issue is not so much human (and thus urban) density but the disparity between urban density and adequate services, and thus local governments play a key role. In particular, the report focuses on four main points with related policy proposals:

- Rethinking urban form and functions, in this sense the idea is one of compact design, widespread and accessible mobility and diversification of functions.
- The issue of poverty and inequality, through a widespread dissemination of services, both physical and digital
- Supporting the urban economy at the neighbourhood scale
- The need to improve multi-level and multi-actor planning and governance systems.

In recent years, partly and certainly as a result of the pandemic crisis, but also as a result of a heightened awareness of environmental issues and questions of how to work (Manzini, 2021) the so-called urban model of *distance* has been strongly challenged.
The urban model that has emerged as an opportunity for change and regeneration of urban systems is that of proximity. The term proximity refers to the condition of being physically close in space. Proximity understood in its plural sense, in all the forms in which it can present itself at the urban scale (Manzini, 2021). In the urban model of proximity, the key points are: the enhancement of public space that becomes a space for relationships, the progressive disincentivisation of the use of private vehicles in favour of slow and public mobility, the creation of neighbourhood networks, the spread of public services and commercial activities.
The transition to an urban proximity model has entered the public agendas of many cities around the world, with different implementation methods and instruments. Consider that according to data collected by c40, a global network of large cities working to develop and implement policies and programmes aimed at reducing greenhouse gas emissions and environmental damage and risks caused by climate change, which have been collected, analysed and classified, the implementation modalities of initiatives towards more sustainable cities can refer to: urban projects, urban plans, architectural projects, infrastructure projects, landscape projects and strategic programmes.
The core principles that c40 presents[2] are:

- Residents in every neighbourhood have easy access to services.
- Each neighbourhood has a variety in the type of housing and different levels of accessibility to it.
- Residents in every neighbourhood have access to green spaces within walking distance of their homes.
- The possibility of working close to one's home or having spaces for those working remotely.

Among the best-known initiatives is certainly that of the city of Paris, which, starting in 2020 under the leadership of mayor Anne Hidalgo, is experimenting with the transition to the *15-minute city* theorised by Carlos Moreno. The project envisages that all urban residents can perform the six essential functions (living, work, commerce, health care, education, and entertainment) in about fifteen minutes on foot or by bicycle from their homes. The model theorised by Moreno is based on four main components: proximity, density, diversification of functions and digitisation (Moreno et al., 2021). As an example, and useful for the analysis of

[2] https://www.c40knowledgehub.org/s/article/How-to-build-back-better-with-a-15-minute-city?language=en_US

the case study, one of the main actions of the Parisian project is the one centred on schools. There are mainly two strategies: the pedestrianisation and landscaping of the urban area near the school buildings in order to generate public and relational space, and the opening up of schoolyards to increase the amount of public space[3] .
The contribution, through the case study analysis of the plans and projects underway in the city of Tirana, aims to deepen the ongoing projects and strategies that aim at the transition towards an urban model of proximity and in particular the relationship of the urban plan in the management of these processes. Specifically, the contribution will delve into policies, projects and strategies that have the school as a protagonist and that respond to objective 07 of the Urban Plan TR2030 "A new and wide network of open schools".

Tirana, a brief analysis of the context
Tirana is the capital of Albania, a state on the Balkan peninsula bordering the Adriatic and Ionian Seas. The urban area of Tirana is home to more than a third of the Albanian population and is also the only city to have a positive demographic variation, due to the strong internal migration that began in the early 1990s. Albania's political history has greatly influenced the country's demographic and spatial dynamics. Albania was under communist rule for almost fifty years, from 1946 to 1990, and during these years the country remained completely isolated from the rest of the world, including the other countries of the Soviet area. Before the communist period, Albana was mainly a rural state, while during the regime the first significant urbanisation undergone by the nation began, in this case homogenous throughout the territory and not concentrated only in the main cities; furthermore, there was a strong policy of controlling the territory and, above all, the location of families, which is why, following the fall of the regime, a strong movement of internal migration began (Dino, 2020). In this sense, it is interesting to focus research and analysis on the city of Tirana, which since the fall of the regime and particularly in the last twenty years has practically doubled its population and experienced a major transformation from a car-free *garden city* (Battiata, 1992) communist style to a city full of commerce, new buildings, and a vibrant social life (Pojani, 2010). The fall of communism in Albania marked the beginning of a complex transition from a centralised socialist state to a free market economy (Pojani, 2010). On an urban planning scale, a new phenomenon developed, that of illegal construction, due to the reintroduction of private property and a total absence of development plans, it is estimated that over 70% of the buildings constructed after 1990 were built without building permits (Aliaj et al., 2003). The result of this phenomenon is massive urban and suburban *sprawl.* The process of demographic increase due to internal migration, which also causes urban sprawl, renders the capacity of the city's infrastructure networks insufficient. The result is a disastrous situation from a sanitary and environmental point of view. Moreover, these areas, being unplanned, lack schools and public services. The Albanian socio-demographic situation is not the most rosy, Albania being one of the poorest states in the Balkan Peninsula. Moreover, although slowly improving, the data on indicators of risk of poverty and social exclusion remain worrying, in 2021, in fact, more than 40% of the population was at risk of poverty or social exclusion, and the percentage increases greatly when talking about families with dependent children[4] .
Turning to urban planning, a key element in these transformations and the new vision for the city is the entry into force of the new Urban Plan, Tirana 2030, in April 2017.
The premise of the planners is that the TR2030 plan should, while following in the footsteps of previous *zoning* plans, govern complexity while avoiding the rigidity typical of a *zoning*

[3] https://www.paris.fr/dossiers/paris-ville-du-quart-d-heure-ou-le-pari-de-la-proximite-37
[4] https://www.instat.gov.al/media/11137/silc-2021_final_anglisht.pdf

plan. Within it will be the territorial strategies and vision of Tirana to 2030 and will serve as the basis for the development of sectoral and detailed plans. In this sense, therefore, drafting a plan that provides a master plan for the city becomes unsuitable when considering the dynamism of urban development and economic, demographic, social and environmental changes. Therefore, the plan will be useful in re-establishing a norm for future urban development but will also be flexible in being able to be supplemented and implemented by new actions.
The plan identifies and defines ten strategic objectives to guide Tirana's urban, economic, and social development:

- An intensive, polycentric city
- An accessible city
- A city with biodiversity
- A sustainable city
- A Mediterranean centre
- A creative city
- A smart city
- An inclusive city
- A Balkan garden
- A 24-hour city

The plan document then contains a framing and cognitive analysis section from a geographical, demographic, social, urban planning, environmental, economic perspective...

- Strategic Project 1 - Metrobosco
- Strategic Project 2 - Nature Oases
- Strategic Project 3 - Second and Fourth Green Ring
- Strategic Project 4 - New World Park
- Strategic Project 5 - Three Green and Blue Rings
- Strategic Project 6 - New Dynamic Epicentres
- Strategic Project 7 - A New and Wide Network of Open Schools
  This strategic project, which is also the one that will be explored in this contribution, has schools as its main focus. The current situation is that of a highly densified city with few services. The idea of this strategic plan is to start from the school building in order to build the public city, in particular to diversify the functions within the schools with openings beyond school hours and to redevelop the urban space next to the schools so as to take it away from car traffic and transform it into public space. For the construction of new schools, the plan envisages the use of the PDV instrument with transfer of public space, instead of expropriation. In addition, the possibility for the administration to collaborate with local associations and NGOs to develop these projects is expressly provided for.
- Strategic Project 8 - Preserving the Architectural Richness of the 20th Century
- Strategic Project 9 - A new agricultural system and a new network of farmers' markets
- Strategic Project 10 - High-Quality Transport
- Strategic Project 11 - Mobility Networks
- Strategic Project 12 - Tirana City for All
- Strategic Project 13 - A New Energy Corridor

A new and extensive network of open schools. Current situation, regulations for new construction and current policies

The current situation presents a serious shortage of school facilities in terms of capacity in relation to the population concerned. In order to cope with this shortage and to avoid excessive, albeit present, class overcrowding, with all the consequences of the case, it has been necessary for the secondary school to provide teaching in two shifts, one in the morning and one in the afternoon, again with not a few difficulties, including the poor concentration of the children. The policies and strategies implemented by the administration about education and school buildings are presented below.

Construction of new schools
One of the objectives of the Urban Plan is to implement the school network so that the capacity is adequate for population growth and the distribution allows everyone to access school services, with the goal that they become community centres within neighbourhoods. The location of new schools is defined by the PPV tables and the locations defined by the *Visibility Plan,* the rules for the construction of new schools are regulated by Article 83 of the Cabinet Act (VKM) No. 671/2015.

Act of the Council of Ministers (VKM) No. 671/2015- Article 83
Article 83 of the aforementioned regulation defines rules for the location and design, on an urban scale, of school buildings. The parameters are: definition of the number of inhabitants (non-students) for each school, definition of the size of the radius of influence of each school, declined on urban and rural areas, and the square metres per student to be guaranteed in the building.

	Kindergartens	Secondary schools	High schools
Building per tot. inhabitants	1500 inhabitants	6000 inhabitants	9000 inhabitants
Urban area of influence	250/350 metres	500/600 metres	1000/1500 metres
Rural area of influence	500/600 metres	1000/1500 metres	2000/4500 metres
Square metres per student	18/25 square metres per student	20/25 square metres per student	20/30 square metres per student

PPV/PDV
The new TR030 Plan divides the territory into minimum intervention units and defines their intended use. Regarding the realisation of public services, the urban planning instrument is similar to the Italian system that provides for the free transfer of areas to the municipality, in the event of the start-up of a subdivision plan. The system is that of the PDV (*Plane të Detajuar Vendore)*, i.e. local detailed plans of public or private initiative that allow the development and implementation of the plan. The administrative units that define the boundaries of the PDVs are detailed in the plan documents and on the Tirana Municipality's webGIS[5] . Each area is identified by a unique code (e.g. TR/01-TR/02...) and by a use destination, to which the functions defined in the plan are to be incorporated in case of PDV implementation.

Visibility plan
Given the demographic growth, the increase of informal settlements and the emptying of some peripheral areas, also as a result of the administrative reform of 2014, the Municipality

[5]https://akpt.maps.arcgis.com/apps/webappviewer/index.html?id=ff270e99f5be45f19c7b7a1e3e618b27

of Tirana has prepared a study, the *Visibility Plan, with the* aim of identifying the medium and long term needs for the construction of educational facilities of the pre-university cycle. In particular, the plan foresees, according to the provisions of Law No.125 of 2013, the possibility of granting and activating a public-private partnership, in order to achieve the objective, considering the impossibility of bearing all the expenses. The plan starts from the analyses already made in 2016 for the drafting of the previous urban plan, which localised the new interventions in the most peripheral and informal areas of the urban fabric; in this update, however, the entire municipal territory is analysed. The plan, in its public-private partnership mode, became necessary considering the insufficiency of funds collected through the Temporary Tax for Educational Infrastructure, which, as of the beginning of 2016, collects funds useful precisely for improving the school system. An analysis of the data showed that in order to solve the problems of school sizing, 17 new schools need to be built in Tirana Municipality, 10 of which are secondary schools. The total cost of building these schools is estimated at over six billion lek[6] , a figure that is unsustainable for municipal budgets. In Albania, the Public Private Partnership (PPP) is regulated by Law 125/2013, which aims to create a favourable and sustainable framework for the promotion and facilitation of investments made as concessions or partnerships between public and private entities. The model used is the *Design-Build-Finance-Operate (DBFO)* model*,* in which contractors assume responsibility for the design, construction, financing and maintenance of the work for the duration of the contract. In this way, the schools can be built quickly and the burden on the municipal budget diluted over time, making the operation sustainable.
The *visibility plan* is based on the four main pillars defined in the TR2030 Urban Plan:

- Intensive and polycentric city
- Tirana Smart city
- Accessible city
- Inclusive city

The specific objectives that, based on these four pillars, the plan pursues are:

- The elimination of two-shift teaching due to the high number of students and the shortage of school buildings
- The normalisation of the student to class ratio, with the goal of an average of thirty students per class
- Improving accessibility and distribution of schools
- Improving learning conditions and thus the quality of school facilities (gyms, canteens, laboratories, etc.)
- Improving the quality of teaching following the normalisation of the number of students per class
- Regenerating urban areas around school buildings, following the idea that they can also *become* centres for the development of social activities, also with the help of the *School as a community* project

Policies in place

School as a community

With City Council Resolution No. 144 of 23/12/2022 'For the approval of the use of pre-school gyms for extracurricular sports activities and on days off', the *School as a Community* project was launched.

The Project envisages the possibility for Sports Federations, Associations, Sports Clubs to use the sports facilities of the public schools of the Municipality of Tirana to practise their activities but also to educate and raise awareness on sports issues. Specifically, gyms and complementary facilities (changing rooms, toilets, material storage areas) can be used during extracurricular hours and on holidays up to a maximum of five hours per week for each Federation free of charge. The aim of this project is to promote sport as an opportunity for physical education but also for social inclusion and integration for all those children and young people who find themselves in situations of hardship. Hence, a project that aims on the one hand to develop the idea of the school as a community centre, as a multifunctional place open even beyond school hours, and on the other hand to generate a culture of sports education to combat sedentariness and promote sociality and social integration.

The application process is relatively simple: at the beginning of each month, the Municipality of Tirana publishes a call for applications on its notice board, and interested parties have three weeks to submit their application by filling in an annex. The only requirement to be able to participate is to be a duly registered organisation in accordance with current legislation, and the documents to be attached to the application are: a deed of registration with the Court, a copy of the Statute, a programme of activities to be carried out, documentation proving at

least three years of activity in the provision of sports services, fiscal regularity and court certifications.
There are currently more than fifty gyms involved in the project.

Streets for schools and streets for kids
Another important strategy that the administration is implementing relates to the redevelopment and pedestrianisation of some streets near the school buildings. The projects have different funding and actors. An important reality in the Albanian context is the presence of NGOs[7] that, through access to funding from large foundations or European cohesion projects, implement projects and processes in different sectors. The pedestrianisation projects of the streets around schools in Tirana were mainly implemented by the NGO *Qendra Marrëdhënie*[8] with the support, in addition to the municipal administration, of foreign

[7] Non-governmental organisation is a non-profit organisation that is independent of states and international governmental organisations. They are very diverse organisations engaged in a wide range of activities, often of a humanitarian or social character, taking different legal forms in different parts of the world: some may have the status of charities, others may be registered for tax exemption based on recognition of social purposes. Still others may constitute fronts for political, religious or other interests. They are typically financed by donations or handouts from philanthropists, while the larger ones are also supported by public money.
[8] https://www.qendra-m.org/en

foundations and associations such as: NACTO[9] , BVLF[10] , FIA[11] , UN UNHABITAT[12] , GIZ Albania, Bloomberg, European Community through European Education and Culture Executive Agency and others.
Qendra Marrëdhënie (QM) is a non-profit urban design and research group based in Tirana. The organisation consists of architects, urban planners, geographers, community organisers, graphic designers, experts in nutrition and food systems, transport engineers and social workers. Their main objective is to improve the quality of the environments in which children live and to do this they provide technical assistance and design services to local authorities and neighbourhood institutions such as parents' councils, student governments, residents' committees, and other associations.
Foundations, as referred to above, are, in general, bodies constituted by assets preordained for the pursuit of a specific purpose. The way in which foundations, each according to its purpose, intervene as actors in this project is through the allocation of funds, which NGOs can access, to implement projects. Specifically, therefore, QM had access to funds that enabled the realisation of projects for the pedestrianisation and landscaping of the perimeter roads of some schools. The Administration, through the Infrastructure and Mobility, Urban Planning and Public Works sectors, verifies, approves and implements the projects.
The first funding is from the BVL Foundation for the implementation of the Urban95 Agenda. Urban95 is an initiative to help administrations and planners understand how their work can influence the development of children, 95 being the average height of a three-year-old child, Urban95 takes an integrated approach combining the improvement of urban spaces and the provision of services. Additional funding comes from NACTO's *Streets for Kids* programme within the *Global Designing Cities Initiative. Streets for Kids* is a multi-year programme to develop guidelines and promote street designs that create safe and fun streets for all children to learn, play and move around the city. A third grant also comes within the *Streets for Kids* project from GIZ Albania. Another interesting intervention, financed by Bloomberg Philantrophies as part of the *Asphalt Art* project, is the renovation of the space around the Gustav Mayer and Naim Frasheri schools. The project consisted of the landscaping and pedestrianisation of 1700 square metres of school yard and almost 2000 square metres of driveway within a block shared by four schools.

By design, schools in Tirana all have, in most cases, large courtyards and open spaces. QM's goal is to be able to open up these courtyards to make them public space. According to Ray Koci, a QM member interviewed during the research, opening up school courtyards in Tirana would double the amount of public space available.
There are currently eight secondary schools on which road repair projects have been implemented through foundation support and administration funding: Gjon Buzuku, Osman Myderizi, Fan Noli, Shkolla and Kuqe, Edith Durham, Gustav Mayer, Naim Frasheri, and Mihal Grameno. The idea, however, is to assimilate this practice at the administrative level so that it no longer depends on external funding but can become a practice implemented directly by the municipality.

The relationship between the Urban Plan and current policies

The analysis of current policies and strategies about schools in Tirana, as shown by the analysis made, demonstrate that they fit perfectly with the strategies outlined in the Urban Plan to pursue its strategic objectives. Municipal regulations, European policies, public-private partnerships and other instruments work together to achieve the Plan's objectives. In this process, a great responsibility lies with the urban planning and public works sectors of the Municipality of Tirana, which are responsible for coordinating the various actions in the field. As can be seen from the conceptual image (Fig. 5) all the policies and strategies in place (PDV, *visibility plan*, *school as a community* and *streets for kids* project) respond to and follow the vision defined by the objectives of the urban plan. In this sense, the evaluation of the tool of strategic objectives is interesting insofar as it defines strategic actions and objectives giving the public administration the possibility of activating numerous solutions for their pursuit. The complexity of urban transformations, therefore, is not only relegated to the spatialisation and norms of the plan but to the possibility for the Administration to evaluate and define the instruments and actors with which to implement the actions. This type of planning is open to pathways and experimentation of new ways of doing urban planning, which makes consolidated urban planning tools adaptive and flexible (zoning, subdivision plans, etc.) but leaves room for the affirmation of innovative instances and practices that arise from the reading of urban and human needs.

If the PDV tool is related to the classical rules of a town-planning scheme, with the well-known mechanisms of disposals and service provisions, the projects, implemented by the NGO *Qendra Marrëdhënie* working on the school building and the urban space close to it, are in the vein of those practices of 'social innovation' from below that have emerged on the urban

scene in recent years (Orioli & Massari, 2023). The *visibility plan* strategy, on the other hand, uses public-private partnerships to speed up the construction of new schools, the main objective of the urban plan, while the *school as a community* project is one of those *top-down practices* promoted by the administration with the active involvement of sports associations and the community, fitting in as a practice that relates to both spatial and *welfare* policies.

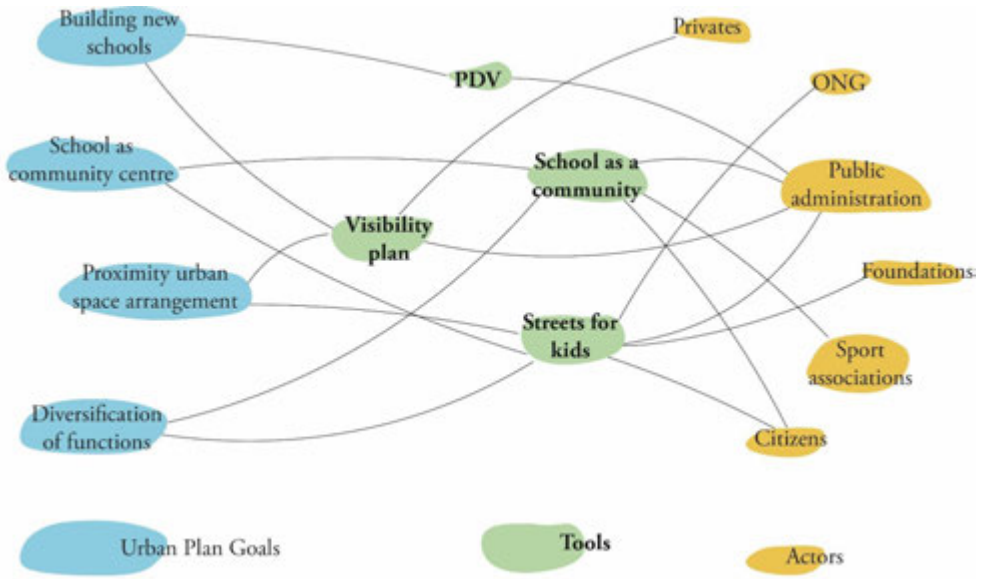

Figure 5 - Overview of the Tirana Urban Plan's objectives, instruments and strategies and the actors involved. Source: Author's elaboration

Conclusions

Urban issues are complex, if we understand the discipline of town planning "not so much as a set of works, projects, theories or norms" but as "the traces of a vast set of practices: those of the continuous and conscious modification of the state of the territory and the city" (Secchi, 2000) and as 'the science that studies urban phenomena in all their aspects, having planning as its aim' (Astengo, 1966) then a contemporary reflection on the role of the Urban Plan in the governance of the territory, and of the transitions with which cities (and Administrations) are called to deal, becomes fundamental. As Orioli and Massari state, "If, therefore, we want to resume reflection on the plan, questioning its credibility and its possible forms today, we must start from this node: from the relationship with policies and the project(s)." (Orioli & Massari, 2023). The context in which cities live today is a complex one, made up of transversality, interrelationships, and interdependencies (Moreno, 2024). A Plan must be able to hold together the complex dimension of policies and projects. The dimension in which the Plan, of course, is placed is the municipal one, the Plan is a political act and as such entrusts much responsibility to Administrations and Mayors, as Moreno states in his last book: "Mayors are not a transmission belt between national political life and local life: they are the backbone and the full protagonists of political life in our countries. Urban life requires strategic vision, dynamism, commitment and constant participation of the community. (Moreno, 2024)". Today, as Edgar Morin stated, we live the tendency of reductive thinking, the one that reduces the city to questions of architecture and circulation, the challenge of the Plan today, instead, is

to get rid of the restrictive "zoning questions" and leave more space and listening to social innovation, to new practices, to the so-called *cité* defined by Sennett (Sennett, 2018).
If, therefore, the challenges of innovation call for more reflection on issues such as environmental sustainability, mobility, education, work, and care (Moreno, 2024), then the proximity model appears as a valid response to this urban challenge and the Plan as the tool through which to govern this complexity.
The case of Tirana shows how an Urban Plan capable of defining strategic thematic objectives for urban development and leaving room for a variety of implementation practices and tools such as: public-private partnerships, cooperation with associations, bottom-up projects involving local communities, and more 'classic' projects, can be the answer and the key in the hands of Administrations to govern the new urban challenges. The issue of education and schooling is of particular interest when one finds oneself in contexts, such as Tirana, of strong social inequalities and a high rate of poverty. Working as a public administration on the school that becomes not only a public service available to all but also the community centre in which the public life of the local community develops is a fundamental issue. The work carried out by the Municipality of Tirana on schools has therefore achieved several objectives among those that hinge on the proximity model expanding the network of services through the construction of new school buildings and the upgrading of existing ones, improving the quantity and quality of public space through the opening up of large schoolyards and the landscaping and pedestrianisation of the threshold space around schools, differentiated the functions of the school building and offered *welfare* services with the project of entrusting the gyms to sports associations, woven a network of communities into the relationship through the work of the NGO *Qendra Marrëdhënie*, which took care of both the physical design of the space and the involvement of the communities in the co-design.
The Plan, therefore, puts itself at the service of a transition process that builds on the existing and tries to indicate a direction in which to direct transformations. (Bianchetti, 2021) (Orioli & Massari, 2023).

Biographical Note: Verena Lenna, a post-doctoral researcher at Brussels Centre for Urban Studies, is interested in how rights shape the city and its governance as an instituting process. She currently investigates emerging forms of welfare as a cultural shift between community empowerment and the reclamation of urban vacancy.
She has a PhD in Architecture and Urbanism from Università IUAV di Venezia and KU Leuven. For her doctoral research, she explored the relationship between property rights, space and the architectural project in the Community Land Trust of Brussels case. Since 2011, as an activist, designer and researcher, she has been building transversal expertise on urban commons by contributing to various projects and initiatives, such as the foundation of Commons Josaphat in Brussels (2012-2017); gE.CO, a European project for the generativity of urban commons (2019-2022); a regional study aiming at designing policies and regulations to support commons in the Brussels Capital Region (2022-2023). She researched the dynamics of inclusion and individual and collective emancipation through participatory action research, as well as art and cultural projects in Rome, Venice, Milan, Brussels, New York, and Athens.

Abstract

If care is one dimension of welfare we need to reappropriate to protect the foundations of a democratic society and democracy, publicness is the other. As Ota De Leonardis pointed out, the final consolidation of the institutions and the operating systems of the welfare state corresponded to the loss of a lively public sphere - as an essential, fundamental public good.
While her observations were formulated at the end of the 90s, in the context of an emerging welfare mix season and growing privatisation, they appear very relevant today, given the more recent developments of the welfare systems, particularly the proliferation of urban commons. While almost inherently representing a complementary layer of existing welfare infrastructures, their operational systems and conditions may fuel the risk of increasing privatism in the welfare sphere.
Vis-à-vis, such a risk, looking at the case of Brussels, I will investigate the publicness of the urban commons as a capability to contribute to the identification of welfare problems and issues and the elaboration of solutions in the public sphere.

Keywords: urban commons – publicness – public sphere – welfare - Brussels

1. Introduction

If care is one dimension of welfare we need to reappropriate to protect the foundations of a democratic society and democracy (Tronto, 1998, 2009, 2013), publicness is the other. Well before and independently from the current privatisation processes resulting from the market intervention, 'the organisational mould of the welfare state at the various levels in which it translates collective, public values, interests, and goals - from everyday practices to systemic organisational effects - tends to generate communication blocks, separations, and segmentations of social relations, isolation, irresponsibility, indifference, privatisation of issues - in short, privatism' (De Leonardis, 1998, p.18). The final consolidation of the institutions and the operating systems of the welfare state corresponded, in fact, to the loss of a lively public sphere - as an essential, fundamental public good - which was animated and precisely constituted around the collective definition of welfare problems and solutions.
While these observations were formulated at the end of the 90s, in the context of an emerging third sector, of a welfare mix season and its ambiguities, they appear to be still very - or even increasingly- relevant today, given the more recent developments of the welfare systems and in particular, given the proliferation of urban commons. Centred on care practices and fuelling social cohesion while improving the conditions of our living environments, urban commons almost inherently represent a complementary layer of existing welfare infrastructures - as the working hypothesis at the core of my ongoing research project. However, their operational systems, rationalities and conditions may fuel the risk of increasing privatism in the sphere of welfare.

Vis-à-vis such a risk, I will investigate the publicness of the urban commons as a capability to contribute to the identification of welfare problems and issues and the elaboration of solutions in the public sphere, as they concern the very social bond we share. To critically assess such a capacity, I will examine the commoning scene of the Brussels Capital Region (BCR), based on my direct implication as an activist and researcher since 2011 and having co-coordinated a regional study on the local urban commons (2022-2023)[1]. I will focus on three initiatives, considering their long-lasting and mature trajectory, which led them from being bottom-up, precarious initiatives and the initiators of the commons movement in Brussels to becoming influential policymakers. The Community Land Trust of Brussels (since 2012) is an organisation aiming at making homeownership accessible for low-income families; États Généraux de 'Eau de Bruxelles (since 2002) aims at the collective and individual re-

[1] *Etude Participative sur les communs bruxellois* (2022-2023), realized by the CLTB, Communa, Ecores and Equal partners, funded by Bruxelles Environnement and Bruxelles Economie et Emploi.

appropriation of water management infrastructures, from the micro-scale of a private garden to the macro-scale of a valley; Communa (since 2013) operates as a platform for the temporary occupation of vacant buildings.

After having briefly framed urban common's contribution to the welfare system, based on De Leonardis's analytical grid for the so-called *impresa sociale* – social enterprise- (De Leonardis 1998), I will address the following levels: the first level is about the existence of a public mandate, coherently supported by public funds and accompanied by administrative interfaces. The second level is the political one, and it is about creating the conditions for the negotiation of different interests and the interpretation of needs as rights as part of larger societal projects. The third level is about institutional care, creating the conditions for the continuous work of institutional transformation, institutions being meant as constructs of social intelligence, domains in which this is deposited, and employed in elaborating shared versions of common goods and further social learning.

2. Questioning the publicness of urban commons

The last 10 to 15 years have seen the proliferation of urban commons as political and civic laboratories generated for a variety of reasons, spanning from the reclamation of abandoned buildings to the expression of new individual and collective needs and rights, as well as organisational capabilities. In many ways and from many angles of observation, urban commons developed in the voids left by an overstretched welfare system[2] because of its inefficiency vis-à-vis well-known expectations, or incapable to define and give an answer to emerging needs. Institutions can be stupid and stop working (De Leonardis, 2011). Before introducing the research question addressed by this paper, as part of my current research project[3], it is important to mention here a few almost self-evident arguments supporting on a substantial level the understanding of urban commons as a complementary or additional layer of existing welfare systems[4]. To begin with, the needs urban commons respond to are quite close to those traditionally fulfilled by welfare systems since the early days of welfare history. A community garden is probably the answer to the need for green and community spaces within the neighbourhood, where people can get in contact with the other, both the human and the non-human. Cultivating vegetables is almost an excuse to get the body active and busy while meeting neighbours and like-minded inhabitants. Also, the community-based organisation of cultural activities provides the occasion for creative expression, artists looking for a space to produce their art, and new newcomers joining the local inhabitants while offering their traditional cuisine. On a more engaged level, other initiatives are developed to provide material support and solidarity to the most fragile individuals: refugees, people experiencing homelessness, and people in precarious life conditions. More complex and solid initiatives -

[2] I use the expression welfare system to include welfare infrastructures and approaches including and beyond the state mechanisms.

[3] WELCOMIN investigates the potential in Brussels of what I call community welfare infrastructures -whence the acronym-, as another way to depict urban commons to highlight their contribution to the welfare system. The complete title is *Reclaiming vacancy, federating capacities and empowering communities towards an ecological welfare*. The project is funded by the Brussels Regional administrative actor for research and innovation Innoviris. https://welcomin.brussels

[4] Commons and urban commons are conceptualised as fundamental resources for the fulfilment of basic needs, for individual and collective emancipation (Rodotà, 2013; Rodotà, 2013; De Angelis, 2017; Stauridēs, 2019) -thus, in this sense, implicitly supporting the purpose of the welfare systems, allegedly.

such as CLTs- finally programmatically address needs classically covered by welfare infrastructure, such as housing or daycare centres.
Besides what they do deliver, at the level of their core values and ethics, what they all have in common is care. Looking at the activities commoning initiatives are concerned with, we can recognise pretty accurately the definition of care as provided by Fisher and Tronto (1990, p.40): 'On the most general level, we suggest that caring be viewed as a species activity that includes everything that we do to maintain, continue, and repair our 'world' so that we can live in it as well as possible'. Federici in fact, famously theorised the work of commons as a work of care (Barbagallo and Federici, 2012; Federici and Linebaugh, 2019)
While care work has been appropriated at some point first by the welfare state and subsequently by the market—including the hybrid forms of welfare mix—in the last 15 years, urban commons have reclaimed care at the core of their practices and in the hands of the concerned communities.

Last but not least looking at their genealogy, urban commons represent in fact the resurgence of the solidarity mechanisms and forms of reciprocity suffocated by private property, a paternalistic welfare state (Grossi, 2017) and the development of the service market subsequently, but required as an interstitial layer to complement public and privately provided forms of social support, the State and the market dynamics, as theorised by Polanyi (Polanyi, 1944).
These arguments framing urban commons as a complementary layer of the existing welfare system are on the level of a theoretical conceptualisation of these initiatives, built around their core values and speculating on their potential societal role, before any measurement of their actual impact on or inclusion in the existing welfare system and programs[5]. On the other hand, on the level of urban governance, the multiplication of policies and funding programs supporting urban commons seem to demonstrate that their value is increasingly appreciated and finally strategically promoted on the side of public administrations. Across many European cities policies supporting the commons emphasise their direct or indirect contribution to the overall and final well-being and emancipation of individuals and collectives. While in their narratives welfare is not necessarily explicitly mentioned as the realm urban commons are supposed to contribute to, the needs they are *de facto* called to fulfil are those usually covered by a welfare system -and in particular by the spatial infrastructures or the welfare space [6], as suggested in the above mentioned few examples: housing, leisure, a good living environment, daycare centres, green spaces, spaces for public debate and gathering. Because of their highly

[5] The appreciation on a conceptual and theoretical level of the urban commons' potential in relation to a decaying welfare system and austerity regimes is frequent in the literature and narratives produced by engaged scholars and activists. While their interest in the measurement of their actual economic performance or impact is debated, the appreciation of their contribution to dynamics of social inclusion and individual and collective empowerment is often highly advocated, to counterbalance a purely efficiency-centred or market-oriented evaluation of their activities (Castro Coma and Forné Aguirre, 2021). The definition of performance measurement systems is a crucial step in the process of trust building between administrations and commoners willing to collaborate around new forms of management of public or shared resources (Patti and Polyak, 2015; Petrescu *et al.*, 2021).
[6] In the Western world, welfare systems traditionally provide social security and support to individuals' emancipation not only through the financial redistributive system but also through spatial infrastructures, such as mobility infrastructures, spaces for leisure, schools and hospitals, and social housing. Amongst others on the topic of the welfare space, see the work of Munarin and Tosi (Munarin and Tosi, 2014) and Swenarton (Swenarton et al., 2015). Focusing on urban commons as the commons built around spatial resources, this paper addresses their contribution as happening through or at the level of the welfare space.

innovative profile, being generated to respond to specific and emerging needs, and because of their ecological approach to the management of resources, urban commons not only complete but additionally redefine and reinvent the scope of welfare in the direction of what I suggest defining as an ecological welfare.[7]
To conclude: the collective generation and protection of resources that sustain well-being and emancipation; the centrality of care, solidarity and forms of reciprocity in these practices; the increasing number of funding and support programs provided by public administrations validating their contribution allow us to reasonably assume that urban commons are increasingly recognised and integrated into existing welfare systems.

While commoning practices provide an occasion to re-appropriate and bring care back home, as advocated by Tronto, as a condition for a more democratic society, this paper would like to address another dimension of welfare, also supporting a democratic societal project jeopardised by privatisation processes and austerity regimes. Publicness is not a dimension that derives from the implication of the public administration in the delivery of welfare services. In other words, the state does not equal the public, as it is clear by now. Publicness is meant here as the capability to generate and fuel the Habermas' public sphere as a condition allowing citizens to gather and discuss common concerns (Habermas, 1989). As pointed out by De Leonardis, what the welfare state represented until the 80s and before the beginning of privatisation processes and austerity regimes, was not limited to the material and social infrastructures required for the well-being and safety of all individuals. It was the very process and the forum where to discuss about common problems and experiment with solutions, continuously under transformation. The making of the welfare state provided the occasion for the public sphere to exist and take shape, identifying the social quality of life as essential for a good life. Without a well-developed social dimension that allows balance and redistribution of wealth, economic growth is unsustainable and leads to injustice. While this is increasingly acknowledged, the conditions for a continuous debate around the form welfare infrastructures should take must be created and cherished. It is more in the debates that precede and accompany the making of welfare infrastructures and institutions that a societal project unfolds rather than in delivering those infrastructures per se. As Nancy Fraser pointed out (Fraser, 1989), talking about needs is even more important than the needs themselves, as it is during the talking phase that those needs can be properly shaped and defined, including in the definition process the concerned individuals and communities.
On the background of a shrinking public sphere (De Leonardis, 1997), the increasing interest and support of public administrations towards urban commons and the embedding of these initiatives and the related policies in the larger schemes of the welfare system raises a question: to what extent and under which conditions are urban commons creating an opportunity for publicness? Publicness -in this case- being meant as the capability to fuel or contribute to a public debate and public sphere around the ongoing re-organisation and re-definition of welfare as a societal project, whose shared values, needs and rights require to be collectively discussed and negotiated before pursuing their very realisation as a collective responsibility.

What most of the current scholarly debate and even the activists' attention is focusing on is the emergence of new public-collective institutional arrangements and the organisational aspects making them suitable to the needs and expectations of both commoners and public

[7] This is in fact the working hypothesis of my research project WELCOMIN. I understand the word ecological as meant by the deep ecology theorizations (Naess, 1973; Capra, 1997), which urban commons represent quite effectively because of their systemic and transcalar governance schemes. (Lenna, 2023, 2024)

administrations. From defining the deliverables and criteria for performance measurement to the systems allowing the building of trust and shared responsibility between collective and public actors: what seems to be mostly at stake is to design policies and programs where the two opposed risks of institutionalisation of the commons on the one hand, and commonification of the public on the other are satisfactorily negotiated for all involved parties. However, no attention is dedicated to critically evaluating if the emerging policies and programs will, in fact, contribute to fuelling publicness around the needs and rights at stake, towards a new societal project and the welfare system that could support it. The collaboration with a public actor does not necessarily mean a public debate is engendered: on the contrary, it may in fact mask a privatist approach under the form of a multiplication of public-collective partnerships. Beyond the specific needs of a given initiative, the singularities of pilot projects, the proliferation of temporary arrangements, and the pacts culture, what is the space left for a societal project? Is the design of larger frameworks such as urban policies and programs supporting commons sufficient to evoke a public sphere around topics such as how we live together, fulfil different or even conflicting needs, care for ourselves and our living environment, and talk about all these?

While the proliferation of unique, site-specific projects may be considered typical of an experimental or transition phase during which indeed innovative arrangements require case-specific approaches and tests, we cannot avoid considering that in many cases the policies and programs designed to sustain the urban commons are inherently conceived to valorise the site-specificity and uniqueness of the concerned initiatives[8]. Furthermore, we must consider that this is the very first requirement by many activists involved in commoning experiences, who believe the core potential of commoning initiatives would be lost under prefabricated protocols or infrastructures.
If the organisational modalities are a good prefiguration of the societal project that is meant to be achieved and its underlying culture, then the ongoing embedding of urban commons initiatives within welfare systems requires an evaluation of their capacity to fuel publicness on two levels. On the first level, what needs to be addressed is the publicness of urban commons per se, at the level of their original organisation, before and independently from any policy or program. On a hierarchically second, more complex level, the publicness of the conditions generated by the commons supporting programs and policies should be addressed -where possible- as they may amplify, reduce, and, in any case, alter the urban commons original organisational modalities and, therefore, their publicness potential.

3. The making of welfare as a societal project

The relevance of collectively discussing needs and care practices at the core of welfare infrastructures and programs was initially pointed out by Nancy Fraser from a feminist point of view in 1989 (Fraser, 1989,p.292). ‘Needs-talk has been institutionalised as a major vocabulary

[8] In many cases, they are, in fact, taking the form of pacts or agreements specifically designed to respond to the site-specific conditions of a given urban commons. See, for example, the regulations produced in many Italian cities. In other cases, the programs specifically emphasize their flexibility as an answer to the concerned communities' different needs -or even political orientations and origins. This is the case of the Patrimoni Ciutada policy in Barcelona for example, whose design explicitly aimed at keeping into account the variety of practices of commoning(Castro Coma and Forné Aguirre, 2021). Finally, in Brussels, the mentioned study on the urban commons’ conditions funded by the Region, which I contributed to design and develop, revealed the resistance of many initiatives to preconceived frameworks or protocols, whilst on the other hand advocating for platforms and networking structures that could allow for an exchange of tools, knowledge, forms of expertise, ways of doing things.

of political discourse. It coexists, albeit often uneasily, with talk about rights and interests at the very center of political life. Indeed, this peculiar juxtaposition of a discourse about needs with discourses about rights and interests is one of the distinctive marks of late-capitalist political culture.' In her article, Fraser points out that much before the (third) struggle for the fulfilment of a given need, the first struggle is to validate and legitimate a given need as a matter of legitimate political concern and subsequently, as a second struggle, to collectively define how to fulfil such a need. These processes necessarily allude to the need for an inclusive conversation allowing different publics to share their interpretations of needs as a precondition for these needs to be recognised and finally addressed by the welfare system.
Once the needs become the objects of a purely administrative, competent or expert service to be provided, once care becomes a private or market matter, instead of being everybody's business and responsibility, as pointed out by Tronto (Tronto, 1998, 2013), the occasion is lost to seize and change the unjust societal mechanisms trickling down to care dynamics. Though from slightly different perspectives of feminism[9], both Fraser and Tronto argued about the need for care practices to be publicly framed and discussed -the public in both cases not coinciding with the State- as an occasion to dismantle power dynamics, reveal the roots of unjust mechanisms and collectively discuss possible solutions, and through these processes lay the foundations for a truly democratic societal project[10].

A few years later, in 1998, in Europe, these arguments were embedded by Ota De Leonardis in her investigation on the transformation of the European welfare state, on the background of the emergence of the social economy, as a combination of state, market and third sector (De Leonardis, 1998). Also defined as a welfare mix, they represented a main object of observation for the post-welfare speculations. To what extent do the different forms of welfare mix fuel the *social* characterisation of the goods, the actions and the actors implied in the social policies? What matters in De Leonardis's investigation is not an evaluation of the performance of services and policies delivered under the welfare mix approach. The point is rather to capture the publicness of the transformation of social policies. How policies and social services are organised and function determines whether goods, problems, and solutions can be considered common or objects of collective, social, and public action and discussions. The risk to be vigilant about and addressed by De Leonardis's analysis is that of privatist attitudes that could be recognised beyond privatisation, even in formally "public" apparatuses and that are leading to 'indifference towards social bonding, de-responsibilisation towards common goods, withdraw of the individual aspirations within the domestic sphere, separation of different conflicting communities, avoidance of mediation processes and of the otherness they make possible […] Beyond the threshold of privatism, there is no public life and no shared world, but only winners and losers and the competitive dynamics of the market.' (De Leonardis, 1998, p.19)

At the end of the 90s, the risks of privatism and the shrinking of the public sphere were associated with the rise of the third sector, the proliferation of not-for-profits, and the hybrid dynamics of the welfare mix. Today, the new phase in the process of welfare transformation - possibly building on the previous one- is characterised by the increasing implication of urban commons in the delivery of care and welfare infrastructures. The public-collective nature of

[9] Fraser is ultimately concerned about recognizing differences and the creation of conditions that allow interpreting the needs of even marginal communities as rights.
[10] Nancy Fraser uses the expression social welfare, possibly to depict a different version of the welfare different than the welfare state, where needs would not be addressed and defined only by the State as an administrative agent but taken care by society and the different public spheres.

policies and programs involving the urban commons and their potential molecular organisation similarly prompts the question of their publicness -beyond the public support. The analytical grid suggested by De Leonardis – which I will introduce in the following lines- is centred on the organisational dimension, as 'it is through these that social relations are shaped and shared meanings are generated'. Organisations are not simply efficient machines, but they are cultural devices. Even before a given service is delivered, how it is delivered is, *per se*, the expression of a given purpose and cultural imprint. In this case, the question is, are care and welfare practices delivered in ways that foster a culture of the public or, rather, a culture of the private? Learning from what she calls impresa sociale[11], De Leonardis suggests three levels of observation to seize the publicness a given organisational form engenders. Not all of them necessarily fully adhere to the operational conditions of any urban commons.

This proves that the social enterprises -*imprese sociali*- and urban commons are not the same[12], thus pointing out a cultural and political shift, the beginning of another welfare season, making it necessary to ask the same questions again[13].

The first level concerns their public mandate, coherently supported by public funds and accompanied by administrative interfaces. Such a public-state profile allows these organisations to operate at the level of rights, to legitimate needs as rights, even as a result of conflictual dynamics that are, in fact, typical of the public sphere.

The second level is the political one and concerns creating the conditions for the negotiation of different interests and for the implied actors to have a role and impact in the decisional projects.

The third level is about institutional care[14], about creating the conditions for the continuous work of institutional transformation. It is essential to point out that De Leonardis defines institutions from a sociological point of view as social practices structured by - and generative of - shared norms, cultures, and meanings. In this key, institutions are constructs of social intelligence: domains in which this is deposited, partly crystallised in routines, and employed in elaborating shared versions of common goods, problems and solutions; and domains, therefore, of possible, further social learning (De Leonardis, 1998, p.25)

[11] The social enterprise as meant by De Leonardis is a form of organisation strongly valorising and fostering the public statute of (their) actions in the realm of social services.

[12] I refer here to a possible overlapping between third sector initiatives and urban commons. While this aspect cannot be addressed in this paper, it is important to stress a major difference as pointed out by many commoners (but not necessarily shared by all). While the third sector initiatives by definition are delivering a service, very often for/in collaboration with local administrations, urban commons are initiated with a purpose of organising activities that would first of all directly benefit the commoners and their communities, therefore not in a service logic, though not excluding a collaboration with local administrations. Nonetheless, given the variety of political orientations and operational conditions -juridical frameworks, funding programs, policies- amongts commoning initiatives, ambiguities are increasingly possible.

[13] While the topic of commons was already well-known in the 90s, those years represented somehow the protohistory of the movement of urban commons emerged after the financial crisis of 2008, responding to increasing privatisation processes and austerity measures.

[14] According to De Leonardis, as repositories of consolidated knowledge and shared meanings, intitutions necessarily exclude other ways of doing things, as during the time something consolidates in finally shared and recognised rules, protocols, organisational structures, the context is already changed and new cultural triggers or needs already started to emerge. Insitutional care is necessary when insitutions do not work anymore. They teherfore 'become visible and object of collective elaboration' (De Leonardis, 2011, p.157). For this reason, conditions should be provided for a continuous exchange of practices and ways of doing and thinking, so that insitutions could constantly evolve.

This grid indicated proves pertinent and suitable to address the publicness of urban commons, not only to continue the investigations of a fruitful line of research which started at the end of the 80s[15] but also in consideration of the constitutive, foundational value of sharing[16] in the case of commons-oriented initiatives. As a value, sharing shapes not only the way a given pool of resources is made accessible but the very life of the commons initiative built around it. Sharing is not only a purpose but also a way of operating and an organisational principle[17]. It is about structuring caring practices by sharing knowledge; it is about communicating and creating the conditions for communication to be effective; it is about access, justice and distributing responsibilities. It is expressed in organisational modalities continuously and reflexively evolving, producing shared meaning and knowledge, potentially fostering publicness, but whose concrete modalities and operating contexts may reduce or alter. Vis-à-vis these general and abstract characterisations, each form of commoning and the context within which they operate – and therefore their organisational cultures – are necessarily unique. The purpose of this paper, looking at the case of Brussels, is to question to what extent the culture of publicness of urban commons is enacted through their operational conditions and to what extent they could allow reclaiming the publicness of the societal project previously implied in the making of the welfare system.

4. The molecular scene of Brussels: three case studies.

The word commons started to circulate in Brussels around 2011, revealing a subterranean landscape of still isolated, disparate and very fragile micro initiatives, mostly based on the curiosity and activism of small groups of citizens, some of them coming from local civil society organisations. The seeds of the urban commons I will synthetically analyse in these pages were planted in those years, and even before in the case of EGEB.

A Community Land Trust (CLT) is a non-profit organisation that aims to acquire, develop and steward property for the common good. Operating for the benefit of a community, CLT's core purpose is to make real estate ownership -particularly homeownership for most of the initiatives situated in an urban context- accessible for low-income households (Davis and Lincoln Institute of Land Policy, 2010). According to the classic model (Davis and Lincoln Institute of Land Policy, 2010), a CLT achieves its goals by dividing the ownership of land from the ownership

[15]In fact we should go back to the work of Habermas on the public sphere -which Fraser criticised and updated from her feminist perspective in the same years of her article on the need-talk (Fraser, 1990). De Leonardis also mentions Marshall and Titmuss for their theorisations on the relationship between democracy and social policies. Given the relevance and continuity of this line of research, and given the increasing relevance of commons-oriented policies and programs, raising the question of their publicness seems not only necessary but also timely.

[16] As a matter of fact deeply intetwined with caring: there is no sharing witout caring, and viceversa, there is no caring without sharing.

[17] Commons are consituted or instituted around the need to jointly establish rules, forms of governance, practices with the purpose of preserving a pool of shared resources. The dimension of sharing defines a porous organisation, whose organisational modalities, rules and the decisional system are continuously evolving as a result of changes affecting the commoners or the pool of resources and therefore requiring adjustments for the sustainability of the commons as a whole. Because of their reflexivity that allows their sustainability Dardot and Laval define commons as instituent practices (Dardot and Laval, 2014).

of built structures. The land is permanently removed from market dynamics, making ownership of the built parts affordable in perpetuity[18].
The Community Land Trust of Brussels (CLTB), the first European CLT, was established in 2012 as a result of the mobilisation of local organisations and grassroots initiatives aiming to address a long-standing housing issue, therefore based on solid political and institutional motivation. Supported by the political constellation of those years, from the very beginning, the CLTB has been established as a "foundation d'utilité publique" (FUP) or a public interest foundation, with a mission centred on the right to housing as recognised in the Belgian constitution. While having a public-regional mandate, the CLTB manages to preserve a commons-oriented governance system, as the decisional power is equally distributed amongst the public, private and civil society involved actors, both in the non-profit organisation and in the FUP[19]. On the level of funding, the solid and regular public support allows them to operate at the large scale of the Region. However, the number of projects is still limited by land availability and accessibility, as well as by some operational conditions.

The political dimension of the CLTB is substantially defined by its effort to provide accessible homeownership to the families that need it most in a global city exposed to intense real estate speculation. It, therefore, characterises the whole process of delivering the projects and the organisation's life.
The tripartite governance structure of the two boards, the Assemblies, the participatory activities supporting the realisation of their projects, the membership campaigns, the site-specific frameworks of collaboration established with other local organisations for the realisation of each housing project: all these activities are conceived and organised and create a public space to talk about and define different needs, to transcend them from an individual to a collective or regional level, to negotiate them across scales and social segments, to distribute the (care) responsibilities. The operational levels of the CLTB – from the microscale of a single housing project to the macroscale of lobbying towards a more supportive framework in terms of policies and land accessibility- articulate the right to housing within the larger urban and societal projects. Homeownership is made possible *through* addressing speculative dynamics and the need for a more inclusive and porous urban project (Lenna, 2020).
Finally, on the level of institutional care, the very approach to property rights and the strong implication of the regional public, together with the mentioned transversal political work, necessarily produce a multifaceted institutional transformation. To begin with, as I have shown (Lenna, 2019), the very concept - the institution - of (private) property rights as a way of protecting a given asset is reshaped from the right to exclude to the right to govern, by equally distributing the decisional power across public, collective, and private actors. While such a change is mainly established by a combination of technical and juridical arrangements, it does make possible a cultural shift regarding homeownership and land tenure models. By contributing at different levels to making real housing projects, all involved actors and inhabitants reappropriate the use value over the speculative value. Material and organisational conditions are provided for a mentality and approach change to individual property, the ownership of land as a commons, and the right to own as a right to govern, between recognition and shared responsibilities. As a result of their multiscalar operational conditions involving various actors and communities, the CLTB managed to influence the land tenure model of other

[18] The land is leased to property owners, who can be private individuals but also other juridical persons.
[19] The CLTB has a dual legal structure: the FUP acquires and holds property, while the non-profit organization handles the development of housing projects. This includes organizing project calls and supporting future homeowners with various participatory activities from the start of their application process.

regional real estate administrators and developers. Recognised by Royal Decree, the model has also finally been established in other Belgian cities, such as Ghent and Leuven. The process of diffusing the realisation of the model – at the national and international level- also substantially fuelled public conversations about the right to housing as part of a societal project.

The second urban commons are the Etats Généraux de l'Eau à Bruxelles (EGEB)[20]. EGEB slowly originated from the political mobilisation of a small group of citizens willing to react to the realisation of a *basin storage,* a water retention basin in the area of Place Flagey, a decision taken by the Region without proper public communication and debate (2002). As an alternative to this decontextualised technological device, the inhabitants proposed to address the issue of flooding with a hydro-ecological approach by considering the hydrography and topography of the whole concerned valley. This would have meant taking into account not only technical issues of the water infrastructures at the scale of the whole valley or the morphological characteristics of the valley and of the urban fabric but also the anthropic components: the culture of water management from the macro scale of the competent administrative actors to the micro-scale of individual households dealing with flooded basements or watering their gardens. At the core of such an approach, EGEB proposed the concept of reclaiming water ecologies and their landscapes as a commons [21], which means establishing a transcalar, multilayered governance system based on the recognition of multiple competencies and forms of expertise and distribution of responsibilities. Their approach developed and was refined through the years through a variety of projects and initiatives: from regionally funded projects in collaboration with local organisations, universities, civil society and municipalities of the BCR; to collective cartographies and walks across the most problematic neighbourhoods designed to increase the awareness and exchange knowledge about water management and water ecologies, between the human and the non-human.
Each activity has a political profile by creating the conditions for negotiating different interests and reframing individual and specific needs into larger societal and ecological projects. The nature of many of their activities also creates a public arena where water management and water ecologies can be addressed from different perspectives and angles, taking into account the similarities and differences of diverse hydrographic conditions, the conflicting interests, and the unequal wealth distribution across the Region.
The purpose of EGEB's activities and their *raison d'être* is deeply institutional and oriented towards what De Leonardis defines as institutional care (De Leonardis, 2011). From the beginning, their goal has been to reshape the culture of water management in the BCR by instituting a common-public perspective to avoid the risk of a private and technographic approach. Each of their projects, particularly those involving actors from the regional public administration, is conceived to prefigure and possibly enact new approaches to water management. Independently from their results, they offer the occasion to explore different mindsets and the hypothesis of a cultural shift: from pipe-based water management to a landscape-based generative[21] governance. Such a clear mission is not always adequately supported. The discontinuity and irregularity of public funding -in contrast to the case of the CLTB- jeopardises and slows down the transformative process, which therefore occasionally shrinks on the level of small-scale, informal initiatives, perhaps more accessible to other social segments and nevertheless relentlessly contributing to a capillary mentality change.

[20] EGEB is the acronym for Etats Generaux de l'Eau de Bruxelles. The organisation is regularly mentioned in the plural form on the web page and other official documents. https://www.egeb-sgwb.be

[21] I use the word generative as De Leonardis does (De Leonardis, 1998), to refer the richness and resourcefulness of organizational arrangements focused on fostering sharing, relational exchanges, debate and publicness.

Despite not having a public mandate, the EGEB are increasingly recognised as a valuable expert in establishing ecologically sustainable water management systems. Their holistic approach to the living environment of humans and non-humans embeds the complexity of interweaving scales, forms of competencies, and the pedagogical frameworks to develop and support them. EGEB are increasingly involved as experts in the elaboration or revision of regional policies and Master Plans or in the implementation of pilot projects, thus furthering the required cultural change.

The third case study is Communa, established in 2013 by the initiative of a few students willing to experiment with sharing a living space while organising activities for the neighbourhood. Today, Communa is a professional actor organising temporary occupations of vacant sites and buildings in the BCR. As the landscape of temporary occupations can be very diverse in terms of purposes and, as a consequence, organisational modalities, it is important to point out that while not defining themselves as an urban commons, the organisational profile and the core values of Communa substantially align with the spirit of commoning: sharing and taking care of resources, learning how to live together, empowering involved individuals and communities. To briefly synthesise the occupation process here, once an agreement has been made with the owners, the building is renovated to comply mainly with safety regulations, and a public call is launched to invite local collectives and organisations to join the occupation. Meanwhile, many activities are organised to develop knowledge about the neighbourhood and establish relationships so that the project can respond to local needs. Within such a process, the shared pool of resources is not only the empty buildings they occupy -mostly publicly owned[22]- but also the forms of knowledge and financial capacities of the involved actors, the site-specific resources and forms of local expertise of a given neighbourhood, the economic contribution of all the involved initiatives contributing to the functioning of the project.

Not only does Communa operate as a commons, but its purpose is to enable communities so that each project can progressively learn how to govern itself and become autonomous. Therefore, it could be said that Communa operates as an infrastructure facilitating the establishment of urban commons. However, to this day, the core team continues to be involved in each of its projects.

On a political level, we may say Communa projects live—and therefore politically expose and deal with—the contradictions of a global city, whose vacant sites simultaneously and paradoxically experience the tension between speculative projects and the needs of the local inhabitants for housing, social and recreational facilities, and good-quality public spaces.

The open configurations of their projects result in heterogeneous mixes of initiatives, combining a diverse range of needs and interests[23]. The morphological quality of their projects reflects and sustains the spirit of their commoning approach. It is the physical space of a building that provides the conditions for the negotiations of different needs and interests. Their porosity combines safety and privacy for the most fragile inhabitants with the public accessibility of other spaces serving as neighbourhood facilities. In the projects of Communa, inner courtyards, wherever possible, tend as much as possible to stay open, as a continuation of the public space. Thorugh space and because of space, living together becomes a political project as these different needs and rights while being recognised, are reshaped within a larger collective project. While this may remind the case of CLTB projects (Lenna, 2019), the

[22] “On a des lignes éthiques assez fortes derrière ça. Quand le projet immobilier n’a pas de sens pour la ville selon notre perspective on fait un choix et en général nous avons une préférence pour les pouvoirs publics ou pour des privés mais qui ont une vision sociale” (interview, July 2022).

[23] Initiatives are chosen based on Communa's social mission, while ensuring compatibility with building activities and the neighbourhood.

operational conditions of Communa are different, primarily because of their projects' short and uncertain duration.
Finally, according to their words, Communa does have an institutional goal. Through their projects and lobbying strategy, their objective is to change the culture of temporary occupations beyond the simple management of an empty building and towards the experimentation of long-lasting infrastructures for social cohesion and the neighbourhood's well-being. Towards this goal, specific juridical frameworks and tools should be provided to improve the feasibility of socially oriented temporary occupations. Vis-à-vis these ambitions, Communa, despite being very well known and involved in a growing number of projects involving regional actors and other community-based organisations, is still suffering because of the irregular funding opportunities or the short duration of their projects.
However, as the CTLB and EGEB, they are also increasingly recognised for their expertise. In addition to their projects and numerous activities open to the large public, their implication in research projects and regional studies represents an occasion to influence further the culture and the public debate on issues such as urban vacancy and waste, the problems of temporary frames of occupations, speculation and gentrification processes.

To conclude, a few transversal observations. While these cases today do not represent the average operational conditions of urban commons -particularly in Brussels- they were also initiated by small groups of individuals. The success of their projects, the support of local and regional public actors, and the lobbying and networking capacity made them grow. Their political impact and their action of institutional transformation started in the embryonic stage of their existence. Relentlessly, project after project, they became more robust as a result of continuously sharing resources and problems, supported by the thin, invisible fabric of commoning that characterises the Brussels scene. Therefore, their projects represent shared solutions, and innovations emerged through public debates and mobilisation around care, welfare and well-being issues. Far from being solidified in a final set of rules, protocols, and ways of doing, their experimentation will continue to address and involve different communities and actors, evolving according to new needs and site-specific conditions. Their projects are multilayered and transcalar operations, enacting the conditions for talking about needs and rights while taking care of care (pun intended). On another level, these urban commons or commons-oriented initiatives, being increasingly recognised as regional experts in their domains of activity, are in the position to influence the public debate when this takes the form of a master plan, a new urban policy or funding program, a study on a given urban issue.
Overall, in addition to the specific and concrete achievements of their projects, they contribute to reclaiming the publicness of welfare as a system in the making and a neverending societal project.
On the other side, different forms of fragility affect them, potentially reducing their publicness. The precarity of funding in the case of EGEB and Communa diminishes their range of actions, impacts their sustainability as organisations and slows down the processes of institutional change as the duration of the projects does have an impact in terms of changing mindset, building shared vocabularies and new ways of doing things. In the case of CLTB, the limited number of realised housing units conveys the idea of a limited impact on the target public. While the narrative is about the right to housing and homeownership for the most fragile households, only a limited number of applicants can have access.
Their recognition of urban commons being increasingly apparent[24], the public-regional actor could also play a re-distributive role (Fraser and Honneth, 2003) by providing more continuous

[24] As expressed by number of programs and policies. In Brussels, waiting to be realised, they have been formulated in the *Etude participative sur les communs bruxellois* (2022-2023).

or substantial financial support, possibly complementing other funding systems for the commons to achieve greater autonomy. This would mean reclaiming the public's- state classic redistributive capacity to fuel societal, decentralised work of welfare transformation.

5. A research plan

As a piece of ongoing research and given the limitations of a paper, the reflections developed in the previous pages are necessarily incomplete, also considering the embryonic stage of the development of policies and programs supporting the urban commons in the BCR. While having been suggested in the mentioned study, they are far from being implemented. Rather than offering an exhaustive evaluation of the publicness of urban commons in Brussels, this paper traces a research plan. In this final paragraph, I suggest two additional levels to be further investigated.

The first one should consider the molecular quality of the commoning landscape in Brussels. While I only addressed three well-established commoning initiatives in this paper, even their understanding remains incomplete without considering the multiplicity of other urban commons that sustain and amplify their actions, possibly increasing their publicness capability. I use the word molecular to describe a condition that is indeed primarily fragmented, characterised by very diverse conditions -but also many similarities- not rarely engendering fragility or a sense of isolation, but that simultaneously allows the more introverted initiatives to stay protected and small. While knowing about other initiatives, many do not have the time and resources to commit to larger projects, networking, or knowledge exchange. What are the characteristics of publicness for such a thin but resilient fabric, if any? Or do they represent another form of privatism? How do smaller urban commons contribute to the life of the larger?

The second level concerns necessarily the policies and forms of public-collective shared governance that still have to be implemented in Brussels. For this reason, in my analysis, I could only address the publicness of urban commons initiatives per se rather than as embedded in supporting policies or programs. On the one hand, this indicates further research and comparative approaches addressing those cities where supportive frameworks operating at a larger scale are already in place: Barcelona, Turin, Bologna, Naples, Grenoble, and Paris, to mention a few well-known cases. Then, having learned from other cities, in the case of Brussels this second level of inquiry becomes, for the moment, an invitation to share the phase of implementation of tools and policies so that in the process of defining needs, rights and finding solutions, welfare could be reclaimed as an instituting -as in French, *instituent*- societal project.

Urban Development Strategies: Navigating the Complexities of Multi-Level Governance in Northern Italy

Sarah Isabella Chiodi, Lorenzo Liguoro
Politecnico di Milano, Department of Architecture and Urban Studies
sarahisabella.chiodi@polimi.it; lorenzo.liguoro@polimi.it

Abstract (up to 125 words)
This study examines multi-level governance in Sustainable Urban Development Strategies (SUDs) across Lombardy, Veneto, Emilia Romagna, and Piedmont in Northern Italy. Utilising stakeholder interviews, document analysis, a CAWI survey, and a thematic laboratory, it explores regional implementation of SUDs. Despite regional variations, two primary needs emerge: policy and planning reforms towards participatory, integrated, and strategic approaches aligned with multi-level governance principles, and strengthened institutional capacity through training to integrate SUD principles and assess their impact. The study concludes by advocating for a cohesive SUD framework with enhanced regional collaboration and capacity building.

1. Introduction

This contribution delves into the intricacies of multi-level governance for Territorial Strategies (TS) in Northern Italy, with a particular focus on the four key regions of Lombardy, Veneto, Emilia Romagna, and Piedmont.
Our analysis draws upon a rich tapestry of data sources:

- **The EU-funded REPLACE project:** This project provides valuable insights through stakeholder interviews, source analysis of Sustainable Urban Development Strategies (SUDs) in Northern Italy, a nationwide urban data collection via a Computer-Assisted Web Interview (CAWI) survey, and an operational thematic laboratory dedicated to urban and non-urban areas within the four target regions.
- **Author expertise:** The authors' professional experience with TS in Veneto and Lombardy further strengthens the research foundation.

Qualitative research forms the backbone of this study, incorporating principles of grounded theory. Additionally, elements of action research are employed.
It's important to clarify that our primary focus is on **Urban Strategies**, not non-urban strategies. We aim to dissect the political and administrative approaches adopted by each region, specifically examining the governance and development process of their urban strategies within the 2021-2027 programming period. This focus stems from two key considerations:

- The urban strategies and their associated actions are yet to be implemented.
- Our primary objective is to navigate the complexities of multi-level governance and assess institutional capacities for planning and managing SUDs effectively.

This exploration will offer valuable food for thought, informing future strategies and strengthening institutional capacities for successful SUD implementation.
The first part lays the groundwork by examining the broader context. It explores the role of Territorial Strategies within the framework of the EU Cohesion Policy, highlighting the goals and funding mechanisms that support regional development. This is followed by a section dedicated to Sustainable Urban Development Strategies themselves. Here, we'll delve into the principles and requirements that guide these strategies, emphasizing their focus on integrated and sustainable urban development.

The core of the analysis lies in Chapter 4. This section zooms in on the specific approaches taken by the four Northern Italian regions. We'll explore how each region implements SUDs, examining their political and administrative frameworks. This chapter draws on a rich data set, including stakeholder interviews, document analysis, and potentially survey data and thematic laboratory findings (depending on availability). Through these diverse sources, we aim to understand the intricacies of multi-level governance within each region.

Finally, the concluding section synthesizes the key findings and takeaways. By analyzing how each region tackles SUDs, the article aims to provide valuable insights for future strategies and strengthen institutional capacities for effective urban development.

2. The Territorial Strategies within the EU cohesion policy

The European Union’s cohesion policy, as is known, develops along a seven-year programming timeline. It is structured on the basis of agreements concluded between the EU and individual Member States (so-called Partnership Agreements - PA) in compliance with shared rules (so-called regulatory package) and it assigns to each programming cycle the

European financial resources of the Structural and Investment Funds (ESI Funds, ESIFs) to which national and regional ones are added. ESIFs includes five main funds, among which two are involved in the SUD: the European Regional Development Fund (ERDF), aimed to promote balanced development in the different regions of the EU, and the European Social Fund (ESF), aimed to employment-related projects throughout Europe and invests in Europe's human capital, focusing on young people, on all those seeking a job, on fragile populations etc.

The 2021-27 programming sets 5 Policy Strategic Objectives (PO) to be pursued through various National and Regional Programs. Territorial Strategies falls within the scope of PO 5 "Europe closer to citizens" through sustainable and integrated development of urban, rural, and coastal areas through local initiatives. The PO 5 supports tailor-made investment strategies at the territorial level, in cities and local communities, to address their diverse challenges, and tap into their development potentials. It offers local authorities or territorial bodies opportunities to build their policy mix to the challenges they are.

PO 5 is realized by Territorial Strategies (TS). A TS is a document that describes (as defined in Article 28 of EU Regulation 2021/1060[1]): the geographical area affected by the strategy (e.g. a specific neighborhood of a city, or an inter-municipal area, if it refers to a grouping of municipalities); the analysis of the development needs and potential of this area, including economic, social, and environmental interconnections (with the support of statistical data, indicators, maps, etc.); the description of the integrated approach to address the identified development needs and to realize the potential of the area (which would be the actual description of the strategy that is intended to be pursued in relation to the achievement of some specific objectives, and through the implementation of a list of operations/actions/projects as well); and the description of the involvement of partners in the preparation and implementation of the strategy. Normally the document includes attachment such as territorial framing maps, project diagrams ad tables (especially in relation to the financial plan), and the list of the implementation projects with further detailed information.

Specific Objective *SO 5.1* is focused on "Fostering the integrated and inclusive social, economic, and environment development, culture, natural heritage, sustainable tourism, and security *in urban areas*". On the other hand, the specific objective *SO 5.2* aims to address the unique challenges and potentials of *non-urban areas*, promoting their sustainable development and enhancing their cultural and natural heritage. Notably, in Italy, has been promoted the National Strategy for Internal Areas (NSIA), which is an innovative policy for development and territorial cohesion that aims to counteract the marginalization and demographic decline typical of the internal areas of the country. National resources have been made available in addition to the allocations from the ESI Funds and other public and private funds, pursuing social cohesion objectives and aiming to slow down and reverse the depopulation phenomena of the Internal Areas in Italy. The NSIA will not be taken into account in this contribution, because it refers to specific objectives and peculiar found mix which differs from urban areas, which are at the core of this research.

ESI funds finance the SUD strategies through multi-year Regional and National Programs. At regional level, they are fund by the RP ERDF and, since the new programming period (2021-

[1] The REGULATION (EU) 2021/1060 of the European Parliament and of the Council lays down common provisions on all the ESI Funds (the European Regional Development Fund, the European Social Fund Plus, the Cohesion Fund, the Just Transition Fund and the European Maritime, Fisheries and Aquaculture Fund and financial rules for those and for the Asylum, Migration and Integration Fund, the Internal Security Fund and the Instrument for Financial Support for Border Management and Visa Policy).

2027), by the RP ESF+ as well. The Regional Programs are promoted by each region autonomously and they are submitted for approval to the European Commission. Along with the RPs, SUD strategies in Italy are also fund by the new National Programme referred to metropolitan cities and extended to medium-sized cities in less developed regions (NP Metro Plus e Città Medie Sud 2021-2027) and, at the European level, by the Urban Innovative Actions through the European Urban Initiative (EUI). All these programs[2] are sustained by ESI Funds and notably by the ERDF.

3. The Sustainable Urban Development Strategies

The SUDs consolidate the EU perspective on the urban question (*urban acquis*) starting from the 2007-2013 programming (Fioretti et al., 2020). Since the ratification of the Leipzig Charter on sustainable European cities in 2007, the European cohesion policy has integrated into its regulatory framework the article relating to Sustainable urban development: first in an optional form (EU Regulation 1080/2006, art. 8), then in a mandatory form in the subsequent 2014/2020 (Regulation 1301/2013, art. 7) and 2021/2017 (EU Regulation 2021/1058, art.11) programming periods. In order to address the economic, environmental, climate, demographic, and social challenges posed by the tendency of 'the complete urbanisation of society' (Lefebvre in 1970), the EU promotes integrated local development strategies for the sustainable development of urban areas; where "integrated" means capable of combining a multi-sectoral approach, multi-level governance, and multi-actor participation. The innovation of this perspective lies in the consolidation of this specific approach and its institutionalization within the cohesion policy (through ESI funds), such recognising it as an ordinary one instead of an extraordinary one, as it was before. Indeed, this approach found reference in the 90s in the Urban Pilot Projects and in the Urban programs financed by the ERDF; which, in turn, moved within the so-called Italian season of "complex programs" partly related to the French policies of the *quartiers en crise* (Saccomani, 2004).

This approach, as implemented by the Urban Agenda for the EU of 2016, suggests integrated strategies for the most disadvantaged urban areas. It follows some fundamental criteria that we can summarize in three points:

(i) the respect for the principle of *partnership*, according to a multi-level governance approach. It respects the principle of subsidiarity as well, which is implemented through the involvement of the local stakeholders and the civil society, making them collaborate in the preparation and implementation of the local development strategies; and

(ii) *the integration* between different sectors of intervention (operating the strategy's objectives and projects not only in different fields and sectors, but also integrating various objectives and projects of the same strategy each other); and the integration between different sources of financing (ERDF + ESFplus + other sources), which also imply a logic of integration between the physical dimension and the social dimension of the interventions; and

(iii) *a place-based approach* (Barca, 2009) focused on the socio-economic, institutional, and spatial peculiarities of places, as well as on local resources and capacities; allowing to develop unique solutions for the specific needs of each territory.

[2] To have an idea of the amount of money involved for SUD within these programs, consider that the EUI involves up to 5M € for all the European cities; while at national level, the NP Metro plus involves for SUDs (referring to the Priority n.7 Urban regeneration of the NP) in metropolitan cities around 10M € (medium cities don't have to develop territorial strategies but sectorial actions), the PRs total size is almost 2B€, and the NSIA's amount is 797.250.529€.

Through territorial instruments (such as Integrated Territorial Investments (ITI), which are the most common in Italy, or Community-Led Local Development (CLLD) or other territorial tools), the SUD can be funded directly from other specific objectives under Policy Objectives (PO) 1-4, in addition to PO 5. They can provide linkages already at specific objective level, which ensures that sustainable urban development strategies demonstrate their contribution to EU and global agendas. Support to territorial instruments under PO1 and PO2 complies with thematic concentration, or with the thematic enabling conditions linked to specific objectives of PO1-4.

The SUDs can be co-financed by additional autonomous regional funds and local funds. The co-funding depends on the type of programme (RP, NP) or action (European Urban Initiative - EUI) which is promoting the SUDs: for example, some regions subsidize 100% of the costs, while other regions subsidize different percentages (from 50% up to 100%) depending on the type interventions; and EUI offers 80% of direct co-funding.

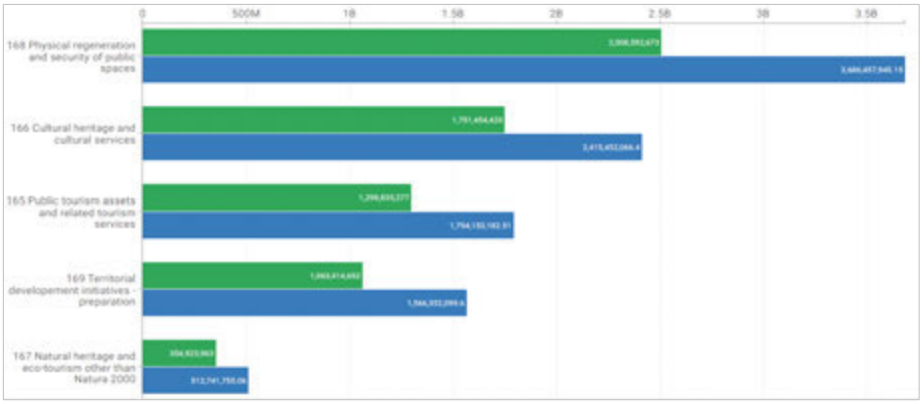

Fig. 1. Sustainable urban development - SO 5.1 Intervention fields and funding[3]

4.1 Regional SUD Strategies in northern Italy

In the 2021-2027 Partnership Agreement (PA) between Italy and EU is taken into great consideration the concept of integrated territorial development, increasing 3 points (over the 8% target[4] required by EU) the national allocation to support Sustainable Urban Development (Cohesiondata, 2023)[5]. In this contribution, as we pointed out in par.2, we will focus on territorial strategies in urban areas, and precisely the ones managed at regional level, without considering the NP Metro plus or the Innovative Actions from the EUI.

Italy in the 2021-2027 includes three levels of regional development, as sown in the image, clearly splitting the country between north and south. This partition implies different levels of EU co-funding and different requirements and targets to observe for the RPs. For example,

[3] https://cohesiondata.ec.europa.eu/stories/s/Sustainable-Urban-development-2021-2027/iw5n-dss9/#:~:text=PO5%20specific%20objective%201%20is,billion%20to%20this%20specific%20objective

[4] This percentage is provided by Article 11 of Regulation 1058/2021, which increases the 5% target of the national allocation of the European Regional Development Fund (ERDF) to sustainable urban development required for the programming period 2014-2020.

[5] Consider that only 13 countries on 27 overcame the threshold of 8%, outstanding Portugal with 25%.

within the ERDF, the less developed regions will benefit from co-financing rates of up to 85% of the cost of projects, while for transition regions and more developed regions it will be up to 60% and 50% respectively (Europarl, 2024)[6]; and 30% of ERDF should be allocated to PO 2 A greener, low carbon transitioning towards a net zero carbon economy.

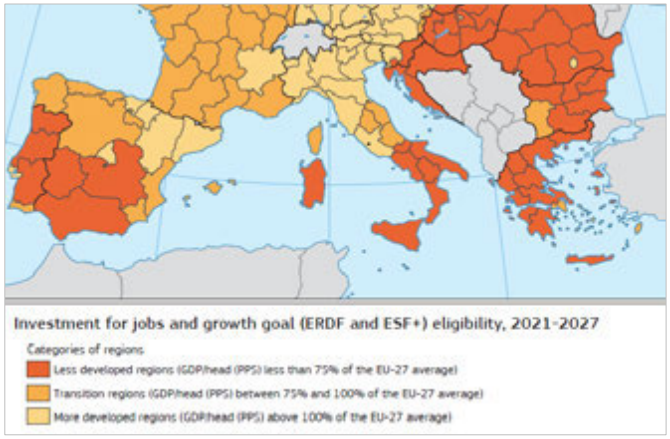

Fig. 2. Level of development of Italian regions within the 2021-2027 programming period[7]

The 2021-2027 SUDs managed by the regions in Italy present different nomenclatures[8] and a significant variety of approaches, in alignment with the place-based model characterizing the European perspective on the urban issue. This variety affects also the other two criteria (partnership and integration) in each local context. However, the progress of their planning and management is not aligned in all the Italian regions: Lombardy is the first region which approved all the SUD Strategies in December 2022; and Emilia Romagna follows approving them in May 2023; but up until today many regions still have to reach the complete approval of all their SUD strategies, including some of the most developed region, such as Piedmont[9].

4.2 Insights from stakeholders' interviews and source analysis

In this paragraph, we will focus on the empirical research made through indirect sources analysis and interviews conducted with the stakeholders of the SUSs of the four main regions of northern Italy (Lombardy, Veneto, Emilia-Romagna and Piedmont). The three key criteria of the European approach to the urban issue introduced in the third paragraph (partnership, integration, place-based approach) will be used here as elements of comparison for the regional approaches.

Regarding to the first criteria, each region has activated different procedures for promoting *partnership*:

[6] https://www.europarl.europa.eu/factsheets/it/sheet/95/il-fondo-europeo-di-sviluppo-regionale-fesr-
[7] Extract from EU regional funding 2021-2027 available at https://ec.europa.eu/regional_policy/information-sources/maps_en#1
[8] Sustainable Urban Development Strategies could be named in different ways in each region. For example, in Lombardy are actually named SUD, but in Emilia Romagna they are called Transformative Urban Agendas for Sustainable Development (ATUSS), while in Veneto are labelled Integrated Strategies for Sustainable Urban Development (SISUS) and in Piedmont Urban Area Strategies (SUA).
[9] We should consider that this delay is affected by the contemporary approval of many actions from the National Recovery and Resilience Plan (NRRP) all over Italy.

(i) at the level of strategy programming, by the management authority of the programme, previewing different methods and weights of involvement of the beneficiaries; and
(ii) at the level of design and then implementation of the single strategies, demanding local authorities the activation of different forms of local partnership, especially in relation to citizen participation; and
(iii) eventually supporting (also economically) the local institutional capacity for the governance of the SUDs. Indeed, the direct participation of citizens and adequate forms of citizens consultation are not binding for all regions. They are encouraged with different degrees of intensity or autonomously promoted by the beneficiaries.

Regarding the principle of *integration*, the region's approach differs for:

- *Intervention Sectors*: different mix of types of interventions (such as new green areas, energy efficiency, cyclable path etc.) and different combination of Policy Objectives (PO from 1 to 5) are included in the SUDs;
- *Resource Types and Amounts*. SUDs imply: (i) different mix of funds types (ERDF, ESF+, other sources) and different amount of financial resources (depending on the development of the region but also on the regional policy); (ii) different emphasis given to the physical and social value of the urban transformations promoted; and (iii) various percentage of co-funds to the total cost. This last factor implies: (a) a different orientations regarding the commitment of the beneficiaries (if the beneficiaries are required to co-finance the SUDs, according to some, they demonstrate greater commitment and interest in its realization); and (b) a more complex administrative management of resources and targets to be achieved;
- *Programming and Design Procedures*: this aspect refers to the different level of flexibility of planning. Some regions imposed top-down elements, such as the articulation and consistency of funds offered in relation to the already decided sector of intervention, while others chose a bottom-up approach offering a range of free choices in terms of internal articulation of resources and topics, with a total fund cap for each single strategy;

Furthermore, we refer to the *place-based approach*, which recognizes that "strategic policy frameworks that support place-based approaches recognise that urban challenges manifest themselves differently in different places." (Fioretti et al., 2020, p.13). In this case the variety among regions concerns the type of urban areas involved within the SUDs. This variety depends on the specific territorial context (historical, economic, social, and cultural) of the region, but also on specific policy choices made by the regional authorities. Areas' typology varies between single municipalities, selected by size or administrative hierarchy (eg. medium-size city of 130,000 inhabitants or provincial capitals over 50,000 inhabitants), and coalitions of smaller municipalities led by a main municipality (for a total number of maximun 20,000 inhabitants in general).

The areas interested by the SUDs differs for an additional factor: the process that has been adopted to select them. The selection has been prior or posterior to the approval of the PRs and it varies by procedure and timing. In most cases, a manifestation of interest has been published, followed by the effective identification of the areas which has been often accompanied by a draft TS. The beneficiaries potentially responding to the call where already identified by name in the most part of cases, with rare exceptions of open call to municipalities not already identified.

Finally, another theme has significant implications in terms of territorialization, it is the institutional capacity:

(a) of the regional institutions who manage the SUDs and their complex internal organization, which often lacks of integration among the various sectors included in the planning and managing of the SUDs; and

(b) of the local municipalities beneficiaries, which often shown a lack of human resources and or specific competencies related to European funds. In response to these institutional weaknesses, some regions promoted forms of direct (or indirect) support to urban authorities rather than for themselves, with RP resources or other funds.

4.3 Insights from the questionnaires collected on SUD.

During March 2024, an online questionnaire was administered to explore various aspects related to the process of formulating and approving Sustainable Urban Development Strategies within the framework of the 2021-2027 Programming. The questionnaire was completed by representatives from six Italian regions: Piedmont and Veneto (North), Tuscany and Lazio (Center), and Calabria and Sardinia (South and islands). In total, approximately 22 million people reside in the regions included in the sample, representing 37% of the Italian population.
This paragraph will analyze the responses gathered to the questions related to local partnership and institutional capacity.

The opening question of the survey investigated the role played by Urban Authorities and Municipalities during the development of the 2021-2027 Regional Programmes. The frequency of responses (indicated in brackets) offers valuable insights into their level of engagement.

In the development phase of the 2021-2027 Regional Programmes, what role did the Urban Authorities and Municipalities play?

They have been involved in the evaluation of the past Programming	3
They were consulted for the acquisition of spatial data	3
They have been actively involved in deliberative processes	2
They have been involved in information and communication activities towards citizens and businesses	2
They were consulted for the acquisition of opinions and strategic guidance	2
They were not involved	1

- **Evaluation and Data Acquisition (3 out of 6):** A high level of involvement was evident in evaluating past programs and contributing spatial data. This suggests Urban Authorities and Municipalities played a significant role in assessing past initiatives and informing the new programs.
- **Deliberation and Communication (2 out of 6):** Engagement in deliberative processes and information/communication activities was moderate. This indicates potential for improvement in actively incorporating their perspectives and contributions throughout the development phase.

While Urban Authorities and Municipalities participated in some key areas, the survey results suggest a **moderate level of overall involvement**. There's an opportunity to strengthen their

engagement, particularly in deliberative processes and communication activities. This could lead to richer programme development that better reflects local needs and priorities.

The second question of the survey focused on the instruments used to implement Local Partnerships for the Regional Programmes. The responses, again weighted by frequency (shown in brackets), reveal the prevalence of different tools:

Which of these tools have been implemented for the implementation of Local Partnerships?

Participatory co-design workshops	3
Listening and interest-gathering groups	2
Co-deliberative arenas	1
Not yet activated	1

- **Widely Used:** Participatory co-design workshops were the most frequently employed tool (3 out of 6). This suggests a collaborative approach where stakeholders actively participate in designing the programs.
- **Moderately Used:** Listening and interest-gathering groups were used somewhat frequently (2 out of 6). This indicates efforts to gather input from various stakeholders.
- **Limited Use:** Co-deliberative arenas, which involve in-depth discussions and potential for consensus building, saw the least reported use (1 out of 6).
- **Non-existent Use:** One region reported not yet activating any of these tools.

The emphasis on participatory co-design workshops highlights a focus on collaborative programme development. However, the limited use of co-deliberative arenas suggests there might be less emphasis on in-depth discussions and consensus building. Additionally, some regions haven't yet implemented any of these tools, indicating potential areas for improvement in fostering local partnerships.

The third question of the survey explored the involvement of various actors in Local Partnerships for the Regional Programmes. The responses, again weighted by frequency (shown in brackets), reveal the prevalence of different stakeholder groups:

Which actors were involved in the Local Partnership?

Local Government Bodies	3
Volunteering Groups	3
Nonprofit Organizations	3
Cultural and Recreational Associations	2
Trade Unions and Professional Associations	2
Research Institutes and Universities	1

- **Core Participants:** Local Government Bodies, Volunteering Groups, and Nonprofit Organizations were all involved in a majority of the partnerships (3 out of 6). This highlights the strong engagement of these key actors in fostering local collaboration.
- **Active Participants:** Cultural and Recreational Associations and Trade Unions and Professional Associations were involved in two-thirds of the partnerships (2 out of 6). This indicates their significant role in bringing diverse perspectives and expertise to the table.

- **Limited Involvement:** Research Institutes and Universities were the least frequently mentioned participants (1 out of 6). This suggests a potential gap in incorporating their knowledge and research capacity into Local Partnerships.

The broad involvement of local government bodies, volunteering groups, and nonprofits demonstrates a strong foundation for community engagement. However, the lower involvement of research institutions and universities suggests an opportunity to better leverage their expertise in informing and supporting Local Partnerships.

The fourth question of the survey explored perceptions of the effectiveness of multi-level co-design between the Region and Urban Authorities in developing the Regional Programmes. The results provide two key pieces of information:

From 0 to 10, how effective do you think the multilevel co-design between the Region and the Urban Authorities has been?

Average	5,80
Standard Deviation	1,64

- **Average Effectiveness:** The average score was 5.80 (out of 10). This suggests a generally positive perception of the co-design process, with most regions viewing it as moderately successful.
- **Variations in Perception:** The standard deviation of 1.64 indicates some variation in responses across the regions. Some regions have had more successful experiences with co-design than others.

The average score suggests that the co-design approach has been perceived as somewhat valuable in facilitating collaboration between the regional and urban levels. However, the standard deviation highlights potential areas for improvement. Some regions might be struggling with implementing effective co-design practices.
The fifth question delved into the specific methods employed by regions to implement multi-level co-design between the Region and Urban Authorities. The responses, again weighted by frequency (shown in brackets), reveal a range of approaches used:

Through what technical and participatory methods was the co-design of the Strategies concretely carried out?

Technical assistance from specialised professionals or consultants	3
Public consultations	3
Support and coaching from experts	2
Participatory workshops open to stakeholders	2
Online collaboration platforms	2
Regular public meetings for monitoring and alignment	1
Thematic seminars and conferences	1

- **Core Techniques:** Technical assistance from external specialists and public consultations (3 out of 6) were the most frequently used methods. This suggests a reliance on expert knowledge and gathering public input as foundational elements of the co-design process.
- **Supportive Measures:** Support and coaching from experts and participatory workshops (2 out of 6), and online collaboration platforms (score: 2) were also used

by two-thirds of the regions. These methods likely aimed to enhance stakeholder engagement and facilitate collaborative discussions.
- **Limited Use:** Regular public meetings for monitoring and alignment, and thematic seminars and conferences, were used less frequently (1 out of 6). This suggests potential areas for improvement in fostering ongoing communication and knowledge sharing throughout the co-design process.

The survey results indicate a focus on technical expertise and public input, which are crucial elements of co-design. However, the less frequent use of methods like regular meetings and seminars suggests opportunities to strengthen ongoing communication and knowledge exchange between regional and urban levels.

The final question of the survey explored the perceived need for strengthening specific institutional capacities related to planning, management, and monitoring of Territorial Strategies. The responses, again weighted by frequency (shown in brackets), reveal key areas for improvement:

Which of the following institutional capacities would you consider most useful to strengthen in relation to the planning/management/monitoring of Territorial Strategies?	
Identify priorities and strategic objectives in line with the principles of Cohesion Policy	5
Develop an implementation plan consistent with regional programming and constraints imposed by Regulations	4
Assess the socio-territorial impacts of implemented operations	4
Monitor the progress of operations and identify effective solutions to unforeseen challenges	3
Collect and identify the needs and opportunities of the territory	3
Evaluate the quality of collected project proposals	3
Analyse data and information	1
Develop transparent and impartial selection criteria	1

- **Top Priorities:** Identifying priorities and strategic objectives aligned with Cohesion Policy principles (5 out of 6) emerged as the most crucial area for capacity building. This suggests a need for stronger skills in aligning territorial strategies with broader European development goals.
- **High Importance:** Developing implementation plans that consider both regional programming and regulatory constraints and assessing the socio-territorial impacts of implemented operations (4 out of 6) were also highly ranked. These highlight the importance of effective planning and understanding the social and territorial effects of strategies.
- **Moderate Importance:** Three areas shared equal weight (3 out of 6): collecting and identifying territorial needs and opportunities, evaluating project proposals, and monitoring progress to address unforeseen challenges. These represent foundational aspects of territorial strategy management.
- **Least Important:** Analyzing data and information, and developing transparent selection criteria received the lowest scores (1 out of 6). This may indicate that some regions already have established data analysis and selection processes, or it might highlight a gap in these areas that requires further investigation.

The survey results suggest a strong desire to strengthen capacities in aligning territorial strategies with broader development goals, effective planning, and impact assessment. While

core management functions are perceived as important, there appears to be less focus on data analysis and transparent selection processes.

4.3.1 Insights and final remarks

This survey of six Italian regions, representing 37% of the national population, provides valuable insights into local partnerships, territorial governance, and institutional capacities for Sustainable Urban Development Strategies (SUDS) within the 2021-2027 Programming framework. The findings reveal a landscape with promising elements alongside areas for improvement.

Local Partnerships: A Foundation with Room to Grow
While Urban Authorities and Municipalities actively contribute spatial data and participate in programme evaluations, their involvement in deliberative discussions and communication during programme development seems limited. This suggests a missed opportunity for richer collaboration.
The widespread use of participatory co-design workshops highlights a commitment to collaborative approaches. However, the limited use of co-deliberative arenas and the absence of these tools in some regions indicate a gap in fostering deeper discussions and consensus building. Additionally, lower involvement of research institutions and universities represents a missed opportunity to leverage valuable academic expertise and research in programme development.

Territorial Governance: Advancing Multi-Level Co-Design
The survey results suggest a moderately successful application of multi-level co-design between regional and urban authorities. However, variations across regions highlight inconsistencies in implementation. This underscores the need for a more standardized approach that leverages best practices in multi-level co-design, ensuring all regions benefit from effective collaboration.
While technical assistance and public consultations are core methods, a reliance on expert knowledge and public input at specific points could be enhanced by fostering ongoing communication and knowledge exchange. Less frequent use of regular public meetings and thematic seminars suggests potential for improvement in these areas. Strengthening these aspects would promote transparency, inclusivity, and a more informed co-design process.

Institutional Capacities: Building on Strengths, Addressing Gaps
The top priority identified by the survey is aligning territorial strategies with Cohesion Policy principles, reflecting a strong desire for coherence with broader European development goals. Additionally, developing effective implementation plans that consider both regional programming and regulatory constraints, alongside assessing the socio-territorial impacts of operations, are seen as crucial for effective planning and impact assessment.
Core areas like identifying territorial needs, evaluating projects, and monitoring progress are considered moderately important, suggesting a foundation for territorial strategy management. Interestingly, data analysis and developing transparent selection criteria received lower importance scores. This might indicate either existing competency or a gap requiring further investigation.

A Call to Action
The survey results paint a picture of regional administrations that are engaged but face challenges in fostering deeper local partnerships, implementing consistent territorial

governance practices, and strengthening certain institutional capacities. The emphasis on capacity building, particularly in aligning with Cohesion Policy and improving planning and impact assessment, reflects a commitment to enhancement.
However, the moderate success of multi-level co-design and the mixed use of participatory tools suggest that significant room for improvement exists. By strengthening local partnerships, promoting more consistent and inclusive territorial governance practices, and enhancing institutional capacities, regions can develop more effective and sustainable SUDS that are better aligned with local needs and broader European objectives. This, in turn, can lead to more innovative, evidence-based, and impactful urban development strategies.

4.4 Findings arisen from the thematic laboratory on the territorial development strategies

4.4.1 Introduction and Methodology

A workshop titled "Territorial Strategies of Cohesion Policy" was held in Milan, Italy on April 15, 2024. Organized by the Craft Competence Centre Anti-Fragile Territories and the Politecnico di Milano's Department of Architecture and Urban Studies, the event brought together 54 stakeholders from diverse backgrounds for a series of afternoon workshops. Representatives from local authorities, trade associations, universities, research centres, and private companies participated, contributing a wealth of experience in territorial governance, cohesion policies, and local development. This rich mix of professions fostered lively discussions on key challenges.

The workshops employed a structured approach, focusing on identifying thematic challenges and then discussing four key aspects of intervention logic: evidence, objectives, solutions, and strategies. Evidence involved analysing data and identifying the consequences of inaction. Objectives outlined desired outcomes and benefits. Solutions cantered on the tools and resources needed to achieve the objectives. Finally, strategies focused on the methods for implementing these solutions.

4.4.2 Participation, Governance, Capacity: Building Blocks of Territorial Strategies

Topic 1: Participation and Engagement of Local Actors
Workshop 1 explored the heart of territorial strategies – the involvement of local actors. Participants examined the structure of local partnerships, delving into the extent of civil society's engagement and the mechanisms in place to ensure the inclusion of vulnerable and disadvantaged groups. The workshop delved into the conditions necessary to guarantee broader participation in the development of strategies, paying particular attention to discriminated or at-risk groups. Methods for addressing informational asymmetry across different levels of the institutional architecture were also explored, ensuring that all voices are heard and considered.

Topic 2: Territorial Governance and Policy Integration
Workshop 2 shifted the focus to the governance and integration aspects of territorial strategies. Participants explored whether regional administrations had the opportunity to fully express their strategic and political vision in defining territorial strategies and how this integration with European and national provisions was achieved. The importance of strengthening policy integration within territorial strategies by creating synergies between

sectors from the outset was highlighted, promoting a holistic and coordinated approach to public policy planning and implementation.

Topic 3: Institutional Capacity for Development and Cohesion
Workshop 3 placed institutional capacity at the forefront, recognizing its pivotal role in developing and implementing territorial strategies. The workshop took the premise that the institutional capacity of entities and actions aimed at its reinforcement, particularly in the context of developing and implementing territorial policies and utilizing European funds, is essential for success. Participants discussed the identified weaknesses in the institutional capacity of regions and local entities during the programming and development of the 2021-2027 territorial strategies, comparing them with the previous 2014-2020 programming period. The workshop also examined the actions taken to address these weaknesses, including collaborations with external entities.

The thematic workshops revealed strong interconnections between the explored topics, and the emphasis on inclusive participation and engagement, which underlines the need for strong territorial governance and policy integration. All workshops highlighted the crucial role of institutional capacity as a foundation for effective policy development and implementation.

4.4.3 Overcoming Challenges in Participatory Processes for Territorial Development

The challenges identified from **Thematic Workshop 1** revolve around the critical themes of inclusivity and standardized practices, insufficient time and resources, and difficulty in demonstrating impact. The workshop highlighted the need to design participatory processes that are inclusive of marginalized populations and youth, while also establishing standardized tools and methodologies to ensure consistency and accessibility. Additionally, effective facilitation of participatory processes requires addressing limitations in time and resources, including securing adequate timeframes, budget, and skilled personnel. Finally, there is a need to design clear and measurable indicators to demonstrate the impact of participation on project outcomes, supported by robust monitoring and evaluation frameworks to track progress and communicate results effectively to stakeholders.

Challenge	**How might we design participatory processes that are inclusive of marginalized populations and youth, while also establishing standardized tools and methodologies to ensure consistency and accessibility?**
Evidence	Marginalised populations and youth face difficulty in engaging with current participatory processes. Lack of standardised tools and methodologies leads to inconsistencies and exclusion of certain groups.
Objectives	Increase participation from marginalized groups and youth. Develop standardized tools and methodologies that are inclusive and adaptable.
Solutions	Implement targeted outreach campaigns and alternative engagement methods. Develop a toolkit of standardized methodologies for inclusivity.
Strategies	Partner with civil society organizations experienced in working with marginalized groups. Organize training workshops for regional authorities on inclusive participatory methodologies.

Challenge	**How might we ensure effective facilitation of participatory processes with limited time and resources, including securing adequate timeframes, budget, and skilled personnel?**
Evidence	Time constraints hinder meaningful participation. Insufficient budget and personnel for facilitation are identified as obstacles.

Objectives	Allocate sufficient time and resources for participation. Secure budget and personnel for effective facilitation.
Solutions	Define realistic timeframes and allocate sufficient budget. Secure dedicated personnel with necessary skills.
Strategies	Develop clear timelines for each stage of the process. Conduct cost-benefit analysis to justify budget allocation. Advocate for dedicated positions within regional authorities.

Challenge	**How might we design clear and measurable indicators to demonstrate the impact of participation on project outcomes, while also developing robust monitoring and evaluation frameworks to track progress and communicate results effectively to stakeholders?**
Evidence	Difficulty in demonstrating the impact of participation on project outcomes. Absence of proper monitoring and evaluation practices.
Objectives	Establish clear indicators to demonstrate impact. Develop robust monitoring and evaluation frameworks.
Solutions	Establish clear indicators to demonstrate impact. Develop robust monitoring and evaluation frameworks.
Strategies	Conduct pilot projects to refine frameworks. Regularly monitor and evaluate processes. Communicate impact effectively to stakeholders.

4.4.4 Enhancing Participatory and Collaborative Frameworks for Effective Territorial Governance

The challenges identified from **Thematic Workshop 2** focus on designing a participatory and collaborative framework for territorial governance, achieving cohesive territorial development through integrated policies, and ensuring transparency, accountability, and efficiency in public resource management. These challenges underscore the importance of inclusive engagement of diverse stakeholders to enhance policy effectiveness, the need for integrated policies and collaborative governance to achieve territorial development objectives, and the necessity of transparent and accountable management of public resources to build trust and ensure impactful interventions.

Challenge	**How might we design a participatory and collaborative framework for territorial governance that effectively integrates diverse stakeholders, considering the complexity of their involvement and the potential for increased policy effectiveness through inclusive engagement?**
Evidence	The complexity of the stakeholders involved necessitates inclusive engagement. Lack of participation can undermine policy effectiveness.
Objectives	Strengthen territorial governance through a participatory and collaborative approach.
Solutions	Establish negotiation and consultation forums. Promote online platforms to facilitate collaboration.
Strategies	Conduct awareness campaigns; promote training on participatory practices. Develop collaborative networks among entities and organisations.

Challenge	**How might we achieve cohesive territorial development through integrated policies and collaborative governance?**
Evidence	Lack of integration can hinder the achievement of territorial development objectives.
Objectives	Promote integration between policies and levels of government to maximise the impact of interventions.

Solutions	Foster collaboration between public, private, and third-sector entities; adopt evaluation and monitoring tools.
Strategies	Develop coordinated planning and programming tools; create networks of entities and organisations for the exchange of experiences.

Challenge	**How might we ensure transparency, accountability, and efficiency in public resource management for territorial development?**
Evidence	Lack of transparency can generate distrust and inefficiency. Dispersing resources on minor projects reduces the overall impact of interventions.
Objectives	Increase transparency and accountability. Focus resources on high-impact interventions.
Solutions	Publish accessible data and information. Establish clear criteria for project selection.
Strategies	Implement a system of participatory governance. Establish a guarantee fund for multi-year projects.

Challenge	**How might we design interventions that are adaptable and sustainable over time, ensuring informed political decisions and achieving lasting impact?**
Evidence	Discontinuity in interventions can hinder the achievement of objectives. Lack of political involvement in the technical phase can lead to uninformed decisions.
Objectives	Ensure the stability and sustainability of interventions. Base political decisions on a deep understanding of issues.
Solutions	Fund multi-year projects; promote continuous learning and capacity-building for policymakers and technicians.
Strategies	Promote co-design and co-management of interventions; develop evaluation and monitoring tools to measure impact.

4.5.5 Strengthening Institutional Capacity and Collaboration for Effective Territorial Strategies

The challenges identified from **Thematic Workshop 3** emphasize the need to bridge gaps in institutional capacity within public administrations, overcome siloed knowledge and limited tools, streamline territorial strategy implementation, and enhance collaboration on supra-municipal strategies. These challenges highlight the importance of capacity building, knowledge sharing, and collaboration to ensure effective management and implementation of territorial strategies, thereby promoting cohesive and sustainable development across regions.

Challenge	**How might we bridge the gap in public administrations' institutional capacity to effectively manage territorial strategies?**
Evidence	Need for strengthening institutional capabilities. Emphasis on structural changes in policy programming and planning. Need for updated recruitment profiles and cultural training identified.
Objectives	Strengthen capacity and foster a collaborative culture. Implement structural changes for better efficiency.
Solutions	Develop and implement capacity-building programs for public administration staff involved in territorial strategies. Invest in cultural training programs to equip staff with the necessary skills and knowledge. Review recruitment profiles to prioritize skills relevant to territorial strategy development and management.
Strategies	Partner with universities and research institutions to design and deliver capacity-building programs. Establish mentorship programs to allow experienced staff to share knowledge with new recruits. Advocate for policy changes that promote collaboration and knowledge exchange across different sectors of public administration.

Challenge	**How might we overcome the siloed knowledge and limited tools that hinder territorial development efforts?**
Evidence	Need for sharing existing analytical tools. Emphasis on developing new integrated tools and indicators.
Objectives	Establish knowledge-sharing platforms. Develop new tools and indicators.
Solutions	Create a central repository for sharing existing analytical and evaluative tools. Invest in research and development to create new integrated tools and territorial indicators. Foster collaborative projects between public administrations and research institutions.
Strategies	Develop an online platform for sharing resources, case studies, and best practices in territorial development. Organize workshops and training sessions on the use of existing and new territorial development tools. Establish joint research projects between public administrations and universities to address specific territorial development challenges.

Challenge	**How might we streamline territorial strategy implementation by addressing workload, skill gaps, and reliance on external expertise?**
Evidence	High workload and lack of personnel. Weak technical skills and over-reliance on consultants.
Objectives	Reduce workload and strengthen technical skills. Reduce reliance on external consultants.
Solutions	Streamline administrative procedures for territorial strategy implementation. Invest in training programs to improve the technical skills of public administration staff. Explore alternative models for accessing expertise, such as knowledge-sharing networks or secondments.
Strategies	Conduct a review of administrative procedures to identify and eliminate redundancies. Develop training programs tailored to the specific needs of staff involved in territorial strategies. Establish partnerships with other public administrations or research institutions to share expertise and resources.

Challenge	**How might we bridge the gap between public administrations to enable effective collaboration on supra-municipal territorial strategies?**
Evidence	Difficulties in cross-boundary collaboration. Individual interests prevailing over collective benefits.
Objectives	Promote systemic approaches and collaboration. Reduce dependence on external assistance.
Solutions	Develop guidelines and frameworks for inter-municipal collaboration in territorial strategy development. Establish mechanisms for conflict resolution and consensus building among stakeholders. Invest in capacity building for inter-municipal cooperation and joint planning.
Strategies	Organise workshops and training sessions on inter-municipal collaboration and shared vision building. Develop model agreements and best practices for collaboration between different levels of government. Provide incentives for local entities to work together and share resources.

4.3.6 Learnings and takeaways

Key Criticisms: Thematic workshops identified several critical issues hindering effective territorial development. First and foremost is the urgent need for inclusive participatory processes that actively engage marginalized populations and youth. Current methods lack the necessary standardized tools and methodologies, resulting in inconsistencies and exclusion of these key groups. Additionally, resource constraints pose a significant challenge. The

facilitation of participatory processes and implementation of territorial strategies is frequently hampered by insufficient time, budget, and skilled personnel.

Another major concern is the difficulty in demonstrating the impact of participation on project outcomes. This is compounded by the absence of robust monitoring and evaluation frameworks, making it hard to track progress and communicate results effectively. Furthermore, the existing siloed knowledge and limited tools are significant obstacles to territorial development. There is a notable gap in effective collaboration between public administrations, especially for strategies that span multiple municipalities.

Identified Solutions and Commonalities: To address these challenges, several common solutions emerged. Investing in capacity-building programs is crucial. These programs should focus on public administration staff, providing cultural training and developing technical skills tailored to territorial strategy implementation. Developing standardized tools is another key solution. Creating comprehensive toolkits and methodologies will facilitate inclusive participation and ensure consistency across processes.

Establishing knowledge-sharing platforms is also essential. These platforms, which could include online repositories, will allow the sharing of analytical tools, resources, case studies, and best practices, thereby fostering a more collaborative environment. Furthermore, promoting collaborative projects and networks between public administrations and research institutions will enhance experience exchange and resource sharing.

Emerging Methodologies: Several methodologies are emerging as effective approaches to these challenges. Leveraging partnerships with civil society organizations and research institutions is a key strategy. These partnerships can help design and deliver capacity-building programs and develop inclusive participatory methodologies. Additionally, pilot projects and workshops are valuable tools. They can refine monitoring and evaluation frameworks while providing training and knowledge exchange opportunities.

Advocacy for policy changes is another important methodology. Promoting policy shifts that enhance collaboration, knowledge exchange, and resource allocation across different sectors of public administration is vital for long-term success. Finally, establishing mentorship programs and exploring alternative models like secondments can reduce reliance on external consultants and foster internal expertise.

5. Final considerations

This analysis has delved into the complexities of multi-level governance within Sustainable Urban Development Strategies (SUDs) in Northern Italy. We examined the approaches adopted by the four key regions of Lombardy, Veneto, Emilia Romagna, and Piedmont, drawing upon a rich data set of stakeholder interviews, document analysis, and potentially survey data and thematic laboratory findings (depending on availability).

Our journey began by establishing the broader context. We explored the role of Territorial Strategies within the framework of the EU Cohesion Policy, highlighting the policy's goals and funding mechanisms that support regional development efforts. We then delved deeper into the principles and requirements of SUDs themselves, emphasizing their focus on achieving integrated and sustainable urban development.

The core of the analysis resided in Chapter 4. Here, we shifted our focus to the specific approaches adopted by each region. By delving into the data, we illuminated the intricacies of multi-level governance within each regional context. This examination revealed a significant variety in how each region implements SUDs, influenced by factors such as nomenclature, partnership approaches, integration of intervention sectors, resource types, and programming procedures.

Key Findings and the Need for Change
The analysis yielded two critical findings that demand attention:

1. **Rethinking Urban Policies and Planning:** The current landscape necessitates a fundamental shift in conventional urban policies and planning practices. The EU's approach to SUDs calls for a more participatory, integrated, and strategic approach grounded in multi-level governance principles. This necessitates a move away from siloed approaches towards a more collaborative and inclusive model.
2. **Institutional Capacity Building:** Strengthening institutional capacities is paramount for effective SUD implementation. This requires comprehensive capacity-building initiatives within institutions, enabling them to seamlessly integrate EU SUD principles into both ordinary and extraordinary urban policies. A particular focus should be on aligning territorial strategies with Cohesion Policy principles, developing effective implementation plans, and assessing the socio-territorial impacts of operations.

These findings raise a crucial question: **how does the diversity of SUD approaches adopted by different regions impact the actual territorial impact of these strategies on SUD and cohesion policy?** Further research is needed to explore this question in greater depth.

The Road Ahead: A Call for Cohesion and Capacity Building
As we look towards the future of SUDs in Northern Italy and beyond, it is essential to address the challenges identified in this analysis. By fostering a more cohesive and effective SUD implementation framework, we can unlock the full potential of these strategies. This necessitates embracing a participatory, integrated, and strategic approach, coupled with robust institutional capacities.
Here are some key recommendations for moving forward:

- **Strengthen local partnerships:** deeper collaboration between regional and urban authorities, research institutions, and civil society organizations is crucial. This can be achieved through co-design workshops, public consultations, and knowledge-sharing platforms.
- **Promote inclusive participation:** it is essential to actively engage marginalized populations and youth in the participatory processes. Developing standardized tools and methodologies can ensure consistency and inclusivity.
- **Invest in capacity building:** programs focusing on cultural training and technical skills tailored to territorial strategy implementation are crucial for public administration staff.
- **Develop standardized tools:** comprehensive toolkits and methodologies can facilitate inclusive participation and ensure consistency across processes.
- **Establish knowledge-sharing platforms:** online repositories for analytical tools, resources, case studies, and best practices can foster a more collaborative environment.
- **Advocate for policy changes:** promoting collaboration, knowledge exchange, and resource allocation across public administration sectors is vital for long-term success.

By implementing these recommendations, we can move towards a future where SUDs are a powerful driver of sustainable and equitable urban development in Northern Italy and beyond.

Abstract
To accelerate the transitions needed to alter current economic and cultural destructive patterns, our social, organisational and democratic structures have to be adapted, which includes a more profound collaboration between public institutions, private actors and citizens. French national and territorial institutions in Marseille and municipal councils in Rotterdam are, each in their own way, introducing and empowering new physical spaces (Tier Lieux and Wijkhub) with the intention to facilitate conditions that enhance active citizenship. In this research we critically analyse both attempts in order to see if these initiatives can be regarded as a form of "external and contextual" Situated Democracy; These places should have the potential to make a contribution towards new forms of situated citizenship, truly transformative based on its multi-scalarity, involving a specific *mixité* of publics and communities and accessible to the majority.

SITUATED DEMOCRACY - POLITICAL MATERIALITY - TIERS LIEUX - WIJKHUB

1. Introduction

1.1 Purpose of the article : how to realise the "Situated Democracy"?

In the face of *climate emergency*, there is a need for institutional and collective citizen engagement to be able to realise the multiple transitions that are needed to reach a more sustainable and just world. At the same time, we see a generalised and global representative-democracy crisis, where distrust between citizens and institutions is growing and democratic participation is dwindling (Lardeux 2019, Bertolone and Winock 2015, Gallo 2021).

Reinterpreting the Situated Knowledge (Haraway 1988) and Actor-network (Latour 2005) theories' principles, we can say that cultural contexts may provide a different way to frame and express needs in lifestyle changing. At the same time, in a globalised world, these are related and dependent on each other. A multi-scalar perspective towards problem definitions is fundamental to realise sustainable and just transitions. This vision of transitions makes explicit that participation of every "visible" or "invisible" actor and public is essential, making the contemporary "right to the city" principle mandatory for the transition paradigm (Lefebvre 1968).

Scholars and practitioners advocate that this shift regards a different way to both relate to Earth and to each other; a relationship based on reciprocity and empathetic understanding (Boella 2006). We are conscious that especially in this Anthropocene era that we as human beings need to rethink our relationship with Earth in order to survive as a species (Crutzen 2006).

However, for transitions to accelerate, an effective re-democratising of our societal organisation that includes collective citizen involvement (in the form of 'publics' or communities) plays a significant role (Horizon Europe …).

This article analyses the role that places can fulfil in contributing to exactly this societal organisation gap in practice, considering and giving consistency to the diversity of publics and communities of a defined context.

Places represent the tangible and local dimension for ‘transition management ‘to materialise (Wittmayer 2016). In addition, the notion of ‘*places of social innovation’ (POSI) can be described as places* where the planning of both physical and social public infrastructure take place (Ardill 2021). In order to be able to measure and understand the transformative social impact of such places of social innovation with transformative power, we should also evaluate the *situated* and contextual dimension of places, as externalised social and ecological assemblages as the building blocks of democratic and just transitions (Haraway 1989). The concept of “Situated Democracy” links both ‘place’ with ‘reimagining and reforming democratic structures’ and has therefore the potential to contribute to analysing this transformative potential of places. These places of ‘situated democracy' are “specific urban spaces, at a neither public nor private use, that looks specifically for concretising inhabitants aspirations in their own cadre de vie fabric”. They are localised, but have at the same time the ambition to influence their own urban scale fabric (Besson et Al 2022).

In Marseille we can detect a number of emergent places of “Situated Democracy”. These places are localised, but have at the same time the ambition to influence their own urban scale. This concept wants to stress the importance of an “internal” place where an initiative is set (not only their public space dimension as it is the case for protests) and where people experience “other ways *of faire la ville, faire société*” in order to build new common values. In other words, the democratic contribution to the urban fabric of places of situated democracy is being "A community of practice, capable of transforming the representation of the problem and constructing the procedural rules likely to solve it. This represents the first stage of the process of empowering actors/publics” (Besson et Al 2022).

This corresponds to the tangible and local “democratic” dimension that is needed for a transformative transitions management perspective (Wittmayer 2016), as an internal practical experience to be linked to complex transitions. The “situated and contextual” notions are in this respect related to an external and diffuse dimension of the local initiative, to how it enters in relation with the complexity of the urban fabric.

The original concept of “Situated Democracy” explains the “internal” democratic contribution of places (the tangible and local dimension), but not the “external” one (the situated and contextual), which is essential in re-imagining democratic structures.

Taking this original concept of “Situated Democracy” as a starting point, we want to add the definitions of “external and contextual” dimensions by deepening the following point:

Places of “Situated Democracy” are close to *Espaces Communs de Proximité - ECP* (Vignes 2021) ou *Communs de capabilités* (Lafontaine 2019), two visions of places inspired by J. Dewey and A. Sen theories. These places multiply occasions of meeting and practising activities with different people, stimulating cognitive *capabilities*. As a consequence, *mixité* (the variety of different social groups in a same area) should be a fundamental defining characteristic of places of “Situated Democracy”.

This article analyses how two European situated contexts and places, “Tiers Lieux” in Marseille and Wijkhubs-network in Rotterdam, foster transformative citizen’ engagement and imagination (“basic” situated democracy), but also to evaluate their kind of mixité, expanding the concept of “Situated Democracy” to its “external and contextual” multi-level dimension.

“Tiers Lieux” have hybrid forms of institutionalisation, Wijkhubs at the other side, are an institutional infrastructure. How do the two typologies of places attract a variety of social groups? How does their (inter)dependency on institutional infrastructure influence this? And

to what degree do these places contribute to a Situated Democracy and, in other words, contribute towards a re-imagining of democratic structures?

This research argues that for these places to really realise this re-imagining of democratic structures, and in order to be able to initiate and sustain these places as places that function as essential building blocks in transitions to a sustainable and just society, there is an apparent need of an institutional involvement that fosters the long duration of the projects and their network dimension.

1.2 Theoretical background - *situating* problems and purpose leading to the the analytical framework

1.2.1 Social or Ecological problems?

Transition or Sustainability are perceived and pursued, in different cultural (or geographical) contexts, in France and in the Netherlands. Generalising the discourse on the international debate, we see how the term “Sustainability” has lost frequency compared to the term “Transition”. The first is more related to development, to a given direction to take (UN 1987). The other seems to keep this discourse more open, in dialogue with anti-system rhetoric (Markard 2012).

In France ‘Sustainability’ is literally translated into “Durable”, focusing on a time dimension of future generations of projects. The associated discourse in planning calls for a real participation of citizens, and a change in procedures to get a less rigid and distant bureaucratic institutional structure (Grimaud and Stavrianakis 2021). Within the historical centralisation of the French government, citizens strive for liberty and appropriation. The “social” side of Sustainability supports hybridisations, fostering citizens' appropriation-participation in processes, where social innovations aim to find new more “personalised” and “alternative” ways of doing. The accent is on the social and organised communities that look for other ways out of the technocratic and capitalistic way of living.

In the Netherlands ‘Sustainability’ is primarily linked to ecological and economic concerns. The focus is related to changing the way human beings produce and consume. Large parts of the Netherlands were built by controlling water, which necessitated a close collaboration and consensus between public institutions, private companies and citizens. This collaboration, often referred to as' Polder mentality’ traditionally stands for this need to reach a shared understanding in order to survive. It results in an attachment to work, on doing concrete things together. Producing economic value is not perceived as “bad” as it could be in France.

1.2.2 Cultural context approach and problematization on transitions

In order to analyse and define the mixité as the external and contextual component of “Situated Democracy”, as Situated Knowledge (Haraway 1988) and ecological-political theories say, cultural context matters.

The “Situated Democracy” concept was issued from a Marseille based research on citizens' initiatives and contributed to the definition of the *not-defined* hybrid French “Tiers Lieux”. Officially originated as bottom-up initiatives, these places have recently been taken to the attention of the national institution by the Levy-Waitz report (2021) as places where to realise “the sustainable transitions of territories”.

If the original “Third Place” Oldenburg’s concept (1989) meant a different place from home or work to meet, the French contemporary *non-definition* took some more typical characters.

Despite doubts about the institutionalisation of the phenomenon that would affect their true experimental nature (Idelon 2020), these places are considered to be issued from bottom-up initiatives, driving the capacity for hybridization of worlds (Gwiazdzinski 2016) and of a highly celebrated new way of being citizens by "doing" (Burret 2013, Bonnot 2019).

However, the true diversity (the mixité) regarding the nature of publics (as gatherings of citizens, local entrepreneurs and other members of communities) *taking place* here is not clear. Several authors have expressed a risk that these third spaces rather foster gentrification than enhancement of a variety of population types (Correia 2018, Watine 2020, among others...).

Tiers Lieux have been presented by institutions, in a way, as places to realise a “Situated Democracy”, referring to these spaces as “neither public nor private initiatives”, or the so-called hybrid and in-between “third actors”. Despite their interest, local or national institutions are not typically providing structural funding for these often temporary experiences to subsist and have a real long term impact.

Institutions do not offer funding since Tiers Lieux cannot prove that they provide a public service. The risk of public services delegation is also seen as a danger for removing institutional responsibility in fundamental public services from French scholars (Richez-Battesti et al. 2012). Wijkhubs in Rotterdam seem to have what Tiers Lieux are lacking: they are sustained by institutions that provide a temporal duration and a network infrastructure dimension.

We argue that giving a contextual and external definition of “Situated Democracy” based upon Tiers Lieux and the Wijkhubs would also help defining their democratic contribution as a public service, to truly bring new *substance* to democratic and active citizenship.

As a *hybrid* initiative, aiming to be neither public nor private, the un-clarity about the definition of publics that visit or make use of Tiers Lieux seems to be one of its defining characteristics. This corresponds also to the still rather opaque notion of mixité, which would need to be analysed in its contextual and external situated dimensions.

We will analyse these dimensions using the Circular Value Flower - CVF method (Leclercq & Smith 2022), a multi-layered analysis method that starts from the actual community initiative and from there unravels the different layers of stakeholder engagements, spatial relational context and the impact the initiative makes by addressing the multiple values that have been created.

2. Methodology

2.1 Marseille and Rotterdam: second cities, major problems or solutions? Tiers Lieux in Marseille and Wijkhubs in Rotterdam; two case studies

2.1.1 A common “port” story

To apply our analytical framework in defining mixité as a contextual and external character, as we said, cultural contexts comparison is fundamental. We have chosen to compare Tiers Lieux in Marseille with Wijkhubs in Rotterdam, in order to say *how* those places are places of “internal” and “external” “Situated Democracy”.

Analysing the cultural context approaches and problematizations on transitions and how they frame to realise them (global/national political background) is the first step of the analysis, necessary to understand how then this can be applied to the urban dimensions of Marseille and Rotterdam, which have many similarities. They are both “second and port cities” in their own national context. On the other hand, it is on this national level that these two are then very different in how their frame “transitions”.

This helps even more the “contextual and external” (*situated*) point of view of the analysis, as it aims to cross perspectives that are common under some aspects, and opposite for some others, enriching the diversity of point of view and so the veracity of the analysis.

Despite the previous general conceptualisations about the two countries, Marseille and Rotterdam are both considered as the “un-disciplined” and “second cities” of their respective nations. Compared to Paris and Amsterdam, these two port cities are the most multi-ethnic, and industrial, not elitist and “cultural”. It is useful to compare these two cities from two different cultural contexts, since they both have a “second-city” and “alternative” perspective in their own contexts. They both have historically been two “délaissées” cities from the central authority, and developed a large number of vacant port related sites and other abandoned spaces. As a reaction, strong feelings of solidarity, stressed by the migrant influence, related to many bottom-up and autonomous citizens initiatives, regard both the two cities.

The energy crisis in the 70’-80’, the progressive dismantling of the city-centred port infrastructure, and the economic crisis of 2000 and 2008, caused decline of both cities physical, social and financial structures, which was followed in recent decades with new “central” funding to renovate these broken structures and to reinvest, in order to re-dynamize the two cities and making their inhabitants more resilient.

In Marseille, the *établissement public d’aménagement* Euroméditerranée in the 90’ was the starting point of this regeneration programme centred around the renovation of the Joliette Port Area. In Rotterdam its regenerative phase was symbolically kickstarted with the construction of the Erasmus bridge and its masterplan of the Kop van Zuid 1989, which included a variety of waterfront projects, led by private-public partnerships of port authority, municipality and private actors.

Both the two cities, especially Marseille, started attracting young artists, even before the institutional renovation processes, as cities of a certain liberty and “un-control”. Rotterdam, bombed heavily during the first WW2 was postwar literally an “empty” space to where creative talents were invited to come and experiment. Both the two municipalities try, more clearly and explicitly or not, to keep these different “creative class” populations in the city and create a more “mixed” and productive environment (Florida 2002).

2.1.2 “Institutional” or “social” lack of democracy?

The same comparable perspective can be seen on how the contemporary and escalating crises of representative democratic systems is presented.

In the last elections inhabitants’ voting behaviour demonstrated the same trends: the most disadvantaged communities perceive an increasing distrust in government and are increasingly less likely to vote, e.g. only 19% of the people in Rotterdam South voted in recent elections (Rotterdam Gemeente 2024).

In Marseille, the popular culture had a tendency to fight against the Paris-centred central state. The city has always hosted localised protests, that however never aimed to organise and

dialogue with institutions, in order to really have an impact on their purpose (Interstice research –Civis Open Lab 2022).

For Rotterdam, and more generally in the Netherlands, Femke Kaulingfreks in her 2023 academic year opening lecture at the university of Amsterdam, says that democratic crisis here is due to a lack of confidence not from citizens in institutions but vice versa: from institutions into citizens.

A cultural context has the tendency to present and then resolve the problem in a particular way. We make some very general considerations about the French and Dutch national contexts, without an anthropological and social-political in depth analysis.

The French academic visions or narratives on “problematization” of their contexts are based on critical philosophy (Lemieux 2012). This push to critique the government, and focus on collective capacity and solidarity, look for SDGs for changing in institutions

The Dutch are closer to a pragmatism philosophy and think more about doing things on their own, individual effort is the focus. The university of Utrecht (Jordan 2021) for example developed the IDGs - internal development goals, in which the focus lies on the individual and the interchange in the way people act, also in groups, to have an impact on the changes of institutions.

We want to understand both the different movements, how institutions can change to arrive at social initiatives and how social groups can organise themselves to change the system.

By analysing places of social innovation - POSI (Adler 2021) and using the concept of “Situated Democracy” (Démocratie située) we say that community-places can allow for materialisation of aspirations, visions and objectives of these “complementary” (and not anymore conflicting) groups and movements towards just transitions, to work as places of *transformative social innovations.*

Many hopes in situating just transitions *are placed* in two different spatial frameworks represented by places imaginary in the two cities : Tiers Lieux in Marseille and Huiskamer-Wijkhub system in Rotterdam.

In Marseille the idea is that Tiers Lieux can reinvent the industrial or other “friches” (empty spaces) of the city, and subsequently repair the territorial fractures of the not-homogenous city-territory.

In Rotterdam, these multi-scalar typology of spaces are financed by the municipality and work as a diffuse infrastructure of “Palaces for the people”(Klinenberg 2019), to enhance citizens’ engagement at the one hand, but also have a degree of control over them and the neighbourhood at the other hand.

2.1.3 How “Tiers Lieux” work

It is by Ray Oldenburg definition (1989) with which most literature introduces the Tiers Lieu (Third Place) - a place where people gather informally as an alternative to the first (home) and the second (work). Actually, this does not include the contemporary characteristic and process of abandonment and recovery in the circular urban fabric, which is therefore essential to the definition of contemporary French Tiers Lieu.

Gilles Clément and Patrick Bouchain's definition of Tiers Paysage helps to understand this. These two concepts both mean “the abandoned” (*le délessai*), neither formal nor informal, capable of embracing the dimension of uncertainty and provisionality - of *Lieux Infinis* (Infinite Spaces) (French Pavilion at the Venice Biennale 2018 - Encore Heureux) and making it a force for sustainable transformations of territories as a space for perpetual social and ecological experimentation.

The rapport Levy-Waitz officially represents the Institutional and academic appropriation and willing definition from the central-state, within its objectives.

This was requested by Jean Castex - French Prime Minister in 2018 - to understand the phenomenon of Tiers Lieux. The national institution was interested in these places for some main characteristics. They are considered the largest urban movement ever observed in France since the popular education movement, as they give concrete and practical contributions to civil society to address the challenges of transitions in our century in the territories. In Tiers Lieux, the creation of economic activities cannot be separated from social utility. They go beyond institutional frameworks and bureaucracy and therefore succeed where public policies fail.

This classification marks the passage for these experiences from “friches culturelles” and anti-system (Lextrait 2017) to the places of “transitory urbanism” for testing “unconventional” politics.

Despite doubts about the institutionalisation of the phenomenon that would actually affect their true experimental nature (Idelon 2020), since they are runned by “third actors”, that are neither public nor private actors but issued from the so-called “third sector” of the *Economie Sociale et Solidaire - ESS* (Social and Solidarity Economy), these places are considered to be issued from bottom-up initiatives, driving the capacity for hybridization of worlds (Gwiazdzinski 2016). They are presented as contributing to democratic and social innovations giving consistency to a “communautés de pratiques” as a new way of being citizens by "doing" (Burret 2013, Bonnot 2019...). Their aesthetic “contribution” is based on frugal and temporary space design, recalling their “not-conventional” dimensions. Many artists also express themselves through testing new styles in spaces design here.

The Levy-Waits report proposes some points of an analytical grid for Tiers Lieux, in order to define their overall contribution: These are their way to promote entrepreneurship in the territory, experimentation and social innovation, cooperation and free contribution, hybridization of activities, openness and conviviality.

Other analyses by independent and publicly co-financed research firms like Agence Phare, tried to understand their social impact under a territorial approach (Klein et al 2008), standing back to the *situated* dimension of these experiences in places.

The “temporary actions” network created by third actors like Yes We Camp association and Plateau Urbain cooperative, are called by the same actors as “urgency and festival urbanism” actions.

The temporal and transitory dimension of these experiences allows for excepting from rules and experiment, to generate “internal” social innovations. The consequences on how the “external” and contextual component then impact on space and time is not really clear.

2.1.4 How “Wijkhubs” work

The Wijkhub system is supported by the municipality of Rotterdam and works on a multi-scalar system of public infrastructure. The municipality of Rotterdam is separated in 39 ‘Wijken’ (districts) (Rotterdam Gemeente 2024) represented by their own council. Every Wijk has at least one Wijkhub, as a public services centre, and a Wijkhouse, for more social and cultural activities. Then, every citizen can present and submit their own initiative to open a Huiskamer (living room) in the neighbourhood. These are literally some “salons on the street” and cover the “buurthuis” street dimension, that is the very proximity of the street.

This is a way for the governmental system to know more from the territory and to test this system in Rotterdam.

Citizens have the opportunity to use municipal funds to support the opening of a Huiskamer, in light of their own interests and to improve the liveability in their direct proximity, for example by greening activities, as ecological function. They have the occasion to make and work together towards just transitions, and see the effect in their everyday life, just in front of their house.

Aesthetics of these places are really like family living rooms, and make people feel atThe most recent and advanced analytical framework used in literature to analyse Wijkhubs experiences is the CVF.

The value flower method (Leclercq & Smit 2022) seek to measure value of circular activities in these places, measuring the following points: Community aspirations and activation capital; Collaboration methods and processes; Resource cycle (from an ecological perspective); Physical development (how initiatives translate into space); Generated values

2.2 Research approach: Data collection and analysis

The research approach is based on quantitative and qualitative data collection and analysis.

Comparing perspectives from two different cities and cultural contexts demonstrates how “sustainability” means differently depending on this. We focus on France and the Netherlands, looking for associated key words to “Sustainability” and/or “Transition”, in the last 10 years academic discourses. For the French context the research was made on Cairn.info, for the Dutch on TU Delft University and Amsterdam University portals.

We also used literature and quantitative data for general description of Tiers Lieux and Wijkhubs typologies, also using local non academic reports.

Qualitative research is based on a participatory-observation (Bastien 2007) experience, in different time and spatial levels. We focused on the Marseille Coco Velten Tiers Lieu that was temporarily installed in Belsunce central and “prioritaire” neighbourhood, from 2018 to 2023. In Rotterdam we observed the vibrant neighbourhood of Delfshaven and its multi-level Wijkhub network including Het Bollenpadje Huiskamer .

We use our analytical framework, inspired by the CVF, to compare Tiers Lieux in Marseille with Wijkhubs in Rotterdam, in order to say *how* these places are places of “internal” and “external” “Situated Democracy”, through their own and *situated-contextual* definition of mixité.

The analysis consider these following steps:

The chapter number 2.1 defined how these two contexts created two different places of “Situated Democracy” in the “internal” dimension: Tiers Lieux origin and problems, framework analysis that already exist (Rapport Levy-Waitz); same for Wijkhubs. In both cases we put into light the “formality” degree of actors initiating and taking place in the initiatives (from un-organised citizen to multi-level institutions) from the “internal” point of view and how the “internal” innovation (the produced value) is realised (what are the “pratiques” of “the communities of pratiques”...). This also means to analyse the context as relational context (who are involved), enabling capital context in spatial context.

We will now define in chapter number 3 how Tiers Lieux and Wijkhubs create “Situated Democracy” in “external and contextual” mixité dimension. As the Circular Value Flower (CVF) does for “circularity values”, we want to analyse the previous points in Tiers Lieux and Wijkhubs as a “mixité degree” value. How does the “formality” degree of actors initiating and taking place in the initiatives (from un-organised citizens to multi-level institutions) link to the produced values from the “external” point of view ? The external point of view is given by situating, describing the spatialisation (acts in real life) or projection (internet or social

network) of the internal particular “Situated Democracy” value into the different levels of the context. Following the CVF the multiple value creation is based on those 5 elements – economic, social, cultural (in this lies the democratic structure) aesthetic and ecological. The different levels of the context are the “buurthuis” or proximity dimension, the neighbourhood, the city, upon different temporalities. We want to measure this capacity by superposing CVF questions in different space and time levels.

In what way and how the element of ‘mixité’ of places of “Situated Democracy” helps define its contextual and external dimension? Among the mixité of differently organised and formally defined publics or citizens’ communities taking place, what is and how does it take place, the role of institutions in ensuring this ? Which publics are included or excluded? But especially, where and when? How do these scales enter into relation among each other?

This will define the mixité degree of a place as an “external and contextual” dimension of “Situated Democracy”, that is able to measure “spatial” and “temporal” value in order to define a place's relations with other different communities.

2.3 Limitations of the research

The research qualitative analysis does not reach and exhaust the variety of these socially innovative experiences, but tries to define two contextual based typologies related to the respective urban fabric dimension. As an ontological limited point of view and analysis, this calls for more perspectives and experiences to be enriched, in space and time dimensions. This makes on the other hand that even a limited number of points of view has an epistemological value for the research.

The case studies are described here under a very succinct synthesis compared to the complexity of the processes. This text wants to only be a first introduction to them.

3. The analysis - Defining how Tiers Lieux and Wijkhubs create “Situated Democracy” in “external and contextual” mixité dimension

3.1 Coco Velten Tiers Lieu and other Marseille networks

3.1.1 Description of the case

In the Ilot Velten block, between the Porte d’Aix monument square and the limit of Belsunce neighbourhood (figure 1), lies Coco Velten. This place is part of the dynamics of temporary occupation of public-owned urban wastelands, to experiment with new uses other than privatisation, to promote a mix of activities and occupants: it combines spaces for professionals and artists who want to engage in the circular and solidarity economy with temporary housing for people in difficulty.

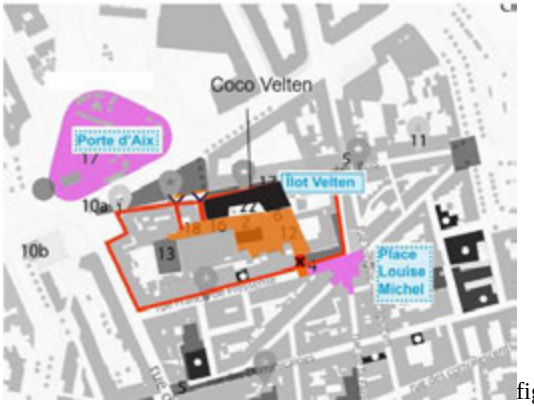

figure 1, schema of the position of the Velten bloc (ilot) in Belsunce neighbourhood nord side, Borrello 2020

3.1.2.Stakeholder network & mixité

The project was led by the association Yes We Camp, supported by the SOS Group and the cooperative Plateau Urbain.Yes We Camp - Ywc was founded in Marseille in 2013 with the acquisition of a temporary permission to occupy a site (that will later become the Foresta project) for camping during the Marseille European Capital of Culture events. However it was in Paris with Les Grands Voisins experience that the “third actor” association model of temporary occupation truly developed. This model was then reproduced and implemented at Coco Velten with the initial support of Lab Zéro, a laboratory of the regional prefecture, and Marseille Solutions, a local association on development of solidarity projects.

Ywc mediates as a third actor as it works by a 60% of self-funding, by the “cantine” bar and restoration sources, and by a 40% of central-state contribution.

Compared to other local actors, they have the possibility to experiment new innovative forms of doing that are still not defined, but they are at the same time structured enough to communicate and have an impact on institutional decisions.

The “internal” innovation of Coco Velten is made by having around twenty regularly paid persons involved in the project (only counting the Ywc side and without counting the other association’s équipes distributed in France), getting open the place almost all week long as any commercial bar activity and also offering a special programmation in week-ends. At the same time employees are often well educated people that chose to earn the minimum wage salary for working in a vibrant environment where competences and skills are, in part, always mixed and evolving following situations.

Inhabitants of the emergency housing have also the privilege to interact with the variety of free cultural activities and participate actively in, becoming strong members of the team.

Also volunteering constitutes a way to integrate the vibrant environment, especially for running the bar during the events. As we said, the bar is the first source of financial support.

Coco Velten is a central-state property building set in a municipality block, where other actors of the ESS take place.

figure 2. La terrasse de la cantine, Yes We camp 2021

figure 3. View of the block “coeur d’ilot” from Coco Velten rooftop - the closed access on Belsunce nord side. Borrello 2022

3.1.3 External and contextual situated democracy

The municipality decided for security reasons to only open the block on the Porte d’Aix side, without relating it with the other Belsunce entrance (figure1). The cantine’s terrace also needed to be protected by some opaque barriers separating from the rest of the bloc-ilot space (figure 2).

Because of these physical barriers and limitations, Coco Velten was not visible for the majority of citizens’ of Belsunce (figure 3)

On the other hand, thanks to Yes We Camp reputation in France and its big network, Coco Velten managed to create some occasions to coordinate and impulse some cultural common activities among the associations of Belsunce, attracting many participants from all the city, like in the occasion of the Babelsunciades Festival, that re-impulsed an ancient local festival initiative (figure 4).

Nevertheless, as it was planned to be, even after a two-years prolongation, this experience only lasted from 2018 to 2023.

The many disadvantaged and excluded people that found here a welcoming and free place where to be appreciated and “valued” are now back to their “abandon”.

figure 4. Communication flyer by Yes We Camp 2020

3.1.4 Other networks

The experience of La cité des Transition is an essay of a municipal initiative network around associations and companies involved in the ecological and social transition in Marseille. The *Transition Ecologique* delegation at the municipality financed a three year research project for tracing local initiatives on the whole urban territory. After having constituted a group of interested and involved organisations, the guide of the project passed to a temporary private or third sector “bureau” that organised the elections of the permanent *Conseil d’Administration*. This initiative is in 2024 at its early stages, but the common objective and “manifest” of the cité is clear: to take Marseille to a just ecological and energetic transition and imagine working on a project-based methodology to collaborate. The democratic participation on this network process shows a private and public collaboration under this objective, as well as the long length of the ongoing process. For the moment, the cité hasn’t found a physical open infrastructure to situate and after an open public meetings phase for building its governance model, and when losing its institutional support, it’s now more retracted and focused into its internal construction.

3.2.2 Het Bollenpadje Huiskamer in Rotterdam Delfshaven Network

3.2.1 Description of the case

As it is the case for many Rotterdam Huiskamers (Avest et Sepp 2015) Het Bollenpadje was born from another project in another location of Rotterdam, before getting permission and funding from the municipality to set up in Bospolder side of Delfshaven neighbourhood.

Three women founded the place in 2021 and are responsible for it, since they have some paid hours from the municipality, even though the time spent for the initiative is never counted. One of them needs to respond to regular municipal controls on activities and demonstrate the positive impact of the initiative on the “buurthuis” street dimension.

3.2.2.Stakeholder network & mixité

This place should be a collective public living room, where everyone can enter and feel at home. Its aesthetic follows this principle as everything is curated and cocooned as we would like to be at home (figure 5). Habitual people from the neighbourhood have keys and can open and go there whenever they want. Everyone that passes in the street is welcome for a coffee. The open and buurthuis-central position of the place invites to get in or to know more about (figure 6)

figure 5. View from the inside. Borrello 2023

figure 6. Het Bollenpadje is situated at the intersection of Rosier Faassenstraat and Catharina Beersmansstraat. Borrello 2023

This place is very important for intergenerational exchange and fighting against isolation. “While making things together, we open our earth to each other” says one of the officially responsible people of the place.

Anyone who has a project can be helped in realising this, and every event is welcomed and can be hosted there.

3.2.3 External and contextual situated democracy

The strong externalised dimension is not only visible from the street, but thanks to many outdoor activities. More than greening, the “Bospolderplein soup time” is a moment when habitual neighbours go together and stay in this huge close open space, that in normal times is not always welcoming for everyone (figure 7).

figure 7. A cart is used to take soup and drinks in the close Bospolderplein

A habitual neighbour explains: “You can organise things yourself as a resident group up to a certain point, after that you need the municipality and systems to tackle bigger things. Entering into that collaboration is possible here.”

All the variety of Huiskamers in Delfshaven, that are an exceptionally high number compared to other parts of the city, are related to the central Pier 80 Wijkhouse, where primary public services are provided.

3.2.4 Other networks

The network dimension of these local experiences, is for example also given by energy cooperatives initiatives, like the DelftshavenCooperatie. This is a grassroots initiative (in some parts financed by the municipality) that links the different wijk of the macro-area of Delfshaven, Bospolder, Spangen and Tussendijken.

In this same neighbourhood we see other examples of both municipal or independent networks to strengthen forces. This is the case of the BoTu alliance of Huiskamers, where Het Bollenpadje is also part, related to the broader programme BoTu (figure 8). This program aims to mix and influence de Tu (Tussendijken) wijk, poorer, with the Bo (Bospolder), where residential renovation has already started and a more mixed population is setting in.

figure 8. Picture of the BoTu Huiskamer network flyer, Borrello 2023

3. Discussion

Analysing the contextual and external dimension of two specific innovative experiences, we want to answer the question of how Tiers Lieux in Marseille and Wijkhubs-network in Rotterdam can contribute to democratic and just transitions, from an institutional perspective and a citizen-communities one, from the Marseille “social” and the Rotterdam “technical-ecological” one. These points of views are all complementary and needed.

To what kind of mixité of communities and publics do these places refer? What is their democratic contribution to it?

The democratic value of Wijkhub-network in Rotterdam seems to be linked to the very strict local scale, the ‘buurthuis’, that privileges a more mixed component of publics especially in age gap.

If the “exhaustive” mixité is not always guaranteed, municipality “officially” gives the possibility to create a large number of different places for differently mixed communities.

Superdiversity is often related to Rotterdam particular identity (Scholten et al 2019) and our analysis showed how this identifies with the ‘buurthuis’ communitarist spatial dimension. It is not clear then how these different communities interact with each other.

Huiskamers in the Wijk-network depend on public financing and have a very “technocratic” way to demonstrate social impact, that exhausts social workers and distorts the “social” and democratic contribution of these initiatives.

For the case of the Tiers Lieu Coco Velten, the autonomous funding by the cantine-bar activity disturbs in a way their democratic component too. In order to offer free public events, bar incomes are very important and the équipes take the habit of inviting the same artists they know, since they have a lot of not preview “social” work and less time.

As a hybrid initiative, the other side of dependence is on institutions. Coco Velten had also a particular case of conflicts among different institutional levels since the building where the initiative set was of the central-state property while the coeur d’ilot block was a municipal

property. The misalignment of visions and wishes contributed to the isolation of Coco Velten from the neighbourhood of Belsunce.

Furthermore, the équipes didn’t have enough competences and the time to focus on the social value of a complicated neighbourhood as Belsunce, without the urban dimension institution of the municipality.

Especially, the contextual and social contribution was not really possible since the experience was imagined as temporary, even though everyone implicated was hoping this not to be the case.

The national Network of Tiers Lieux Cooperative asks for a durable support by institutions as these are places offering a public service, but they are not able to demonstrate social or public impact.

They are places of “the right to test and risk” (Besson 2021), where different people mix and foster hybridity, scaling up “transformative” messages from there to the institutional scale. Technocratic ways to demonstrate mixité or participation of citizens, or to produce economical value are often excluded as qualities of these places.

On the other hand, the street and neighbourhood dimension here seems to be farther. Tiers Lieux are places of the “exception” and are less numerous and diffuse than Wijkhubs-network.

4.Conclusion

Defining how (where and when) places foster “Situated Democracy” allows to define their contribution to the urban fabric as a public service.

Our analysis has shown a method to define the mixité degree of a place as an “external and contextual” dimension of “Situated Democracy”. This answered the two main questions of understanding if these external and contextual elements can be found in these examples of Tiers Lieu and Wijkbub as a form of ‘situated democracy’, and if these dimensions are a valuable contribution to the concept itself.

Wijkhubs are very well contextualised and externalised in their proximity-buurthuis dimension, but less on a neighbourhood and even less on an urban scale. The mixité of publics, if realised, is stuck into these territorial short dimensions. The role of the institutions through its infrastructure should facilitate the network dimension, but in practice this is not really the case.

Tiers Lieux are well connected to the urban-fabric dimension, but not really to their proximity environments. The kind of mixité comes from people from different parts of the city. Indeed they are represented by people having a specific and homogenous aesthetic taste, that looks for the “exceptional” and “alternative”, anti-ordinary-

The role of institution is officially for fostering hybridisation and institutionalisation of bottom-up initiatives, but here we don't know where “the bottom” comes from.

In Marseille Tiers Lieux are not related to elected councils like it is in Rotterdam and they don’t have this “vocation” not even in the institutional narrative. Tiers Lieux are places where to experiment, where institutions meet citizens. Tiers Actors would like these initiatives to stay hybrid on one side, but having structural and long-term public funding on the other. Is this a contradiction or a force point of Tiers Lieux?

(Multi-level) Institutions seem necessary to guarantee coordination among the parties, as different communities are in order to assure the citizen-individual engagement and action, for appropriating future common visions and actualising change. A Rotterdam ‘buurtuis’ institutional approach based on proximity and practical activities to “circularity” foster a mix of participation, but lacks on coordination among the different groups in the city. A Marseille Tiers Lieux approach doesn’t relate to definable territorial or spatially exteriorised dimensions and is a short and limited experience in time. The mixité of people taking place here is not measurable under these dimensions, as is their democratic contributions.

These outcomes open for more research on how defining public(s) identities to realise just transitions and on the role of spatiality, in giving consistencies to identities and so to possible common directions to transitions.

Track 07: Environment And Climate

ENVIRONMENT AND CLIMATE - Planning for resilience, sustainability, climate change and the environment

Chairs:

- Mauriel Maillefert, Université Jean Moulin Lyon 3
- Francesco Musco, IUAV Venice
- Subhashree Nath, Technische Universität Dresden

Keywords: *circular economy models, nature-based solutions, socio-ecological-technical systems, planetary boundaries, resilience, biodiversity, urban greenery, urban metabolism, social and environmental justice, urban and regional planning, climate change mitigation, sustainability, climate action, climate justice*

Faced with the challenges of climate change at different levels (international, national, regional), public policies and local authorities need to adapt quickly. Various legislative measures have already been put in place, particularly in France, in line with European directives. For example, the Lyon metropolitan area has proposed a territorial climate and energy plan and a health and environment plan to address the health issues associated with air pollution. Measures to reterritorialise agriculture, in line with the challenges of the circular economy, are also being taken. As far as businesses are concerned, circularity initiatives (Vallée de la Chimie) and even model transformation initiatives (textile revival, urban renewal, regeneration of urban wasteland) are under discussion or are starting to take effect.

Public authorities are also putting forward a new argument for accelerating change and making urban areas more resilient and less dependent: promoting a transformation in uses and lifestyles. For example, the city of Lyon offers training courses to its employees to raise their awareness and motivate them to take action. These actions support a number of different initiatives, such as the introduction of organic food programmes in school canteens, which is currently a very important issue, as it highlights different aspects of changing practices and access to healthy food, which also helps to address certain issues of equity in changing models for children.

In academic terms, these issues are addressed in a number of ways: through discussions on transitions, changes in models or, on the contrary, resistance to change. Through work on ways of bringing about change, in particular by favouring a more co-constructed vision of public policy that goes beyond the legal mechanisms for participation. Finally, field experiments are carried out at the local level to initiate and test model changes.

This track aims to address some main issues and innovations in spatial planning coping with current global challenges such as climate change. Theoretical debates and planning practices that make urban and territorial systems more resilient and support the transition towards more sustainable scenarios on a local and global scale may be welcome.

Possible topics to include:

- Circular economy and new urban economic models
- Transition drivers for a sustainable development
- Local actions vs. global imbalances
- Spatial planning for climate resilience
- Methods, tools, and practices to address climate change and disaster risk
- And more.

Urban heat mitigation effect and affordable housing greenery injustice measured by Green View Index (GVI): A case study in Washington, D.C.

Abstract
The deterioration of living conditions is highlighting the benefits of urban greenery for creating sustainable cities. Using Washington D.C. as a case, we demonstrate the performance of GVI and examine disparities in greening surrounding affordable housing. With the pre-trained segmentation model, we generated GVI based on 54,691 Street View images and applied the Spearman's correlation analysis to examine LST cooling effect. We found that LST shows significant negative correlations ($p<0.001$) with GVI and newly developed GVI-3D with coefficients of -0.60 and -0.73. The distribution of GVI in residential zoning was polarised, affordable housing projects have less greenery. In conclusion, we argue that it is of practical significance to monitor GVI instead of large scale NDVI for urban environments due to its controllability and human-centric attributes.

Keywords: Green View Index, Temperature mitigation, Street greenery, Housing environment, Environmental justice

1 Introduction

Our human society just experienced the warmest decade on record between 2011 and 2020 (WMO, 2023). For the global majority living in cities, urban heat islands represent an issue for both livability and health. Given the heat-absorbing properties of greenery, researcher have developed a range of vegetation-related indices to examine the climate change mitigation potentials such as (Normalised Difference Vegetation Index) NDVI (Yue, W., et al., 2007; Chun, B. and Guldmann, J.M., 2018.), and examine distributional equity such as park areas (Nesbitt et al., 2019), while they are all plat 2-dimensional indices which cannot drill down to accurate small-scale space analysis and vertical vegetation detection. The Green View Index (GVI) (Yang et al., 2009; Li et al., 2015) provided a refined and 3-dimensional metric for quantifying urban greenery by authentically simulating pedestrian's visual experience and perception, thus reflecting the actual exposure of humans to greenery (Cho et al., 2010). Advances in computer vision and image processing tools now make it more feasible to examine the impact of GVI on urban environments. In this paper, we add to the literature by measuring the relationship between urban green space and land surface

temperature (LST). Using Washington D.C. as a case, we demonstrate the performance of the GVI, and use it to examine disparities in urban greening surrounding affordable housing.

2 Literature Review

Urban Heat Island (UHI) effect is the thermal aggregation issue coming with urbanisation and industrialisation, which leads to increased human health risks (Heaviside et al., 2017) and influences socioeconomic development (Rizwan et al., 2008). In the 21st century, an increasingly urbanised population over 3 billion are directly exposed to UHI in worldwide (Rizwan et al., 2008). Simultaneously, cities' physical environment and spatial structure (Shaker et al., 2019; Cao et al.,2022; Gage & Cooper, 2017) greatly influence the distribution of UHI causing environmental justice issue where different groups suffer distinctly due to their locations, greenery environment around housing and demographic characteristics. Affluent neighbourhoods, high-income groups and the white population in United States (Harlan et al., 2007; Mitchell & Chakraborty, 2015; Hsu et al., 2021) were widely considered to have environmental advantages and low heat exposure risks, while the vulnerable populations suffer more.

Even though a large amount of greenery indices were invented (Bannari, 1995; Huete, 2012) to respond the UHI exposure problems based on different criteria, "the most widely used index remains the NDVI" (Bannari, 1995, p.114). The impact of significant greenery index NDVI on the urban environment, especially the thermal environment was meticulously examined by many scholars. Lo et al. (1997) verified that irradiance with an emphasis on commercial and services land cover contributed to the development of urban heat islands, he found there was a negative correlation between NDVI and irradiance of different land covers. In addition, Li et al. (2011), Grover & Singh (2015), Jamei et al. (2019), and Chakraborty et al. (2020) all concluded that NDVI, in conjunction with other built environment indices can significantly predict Land Surface Temperature (LST) on the regional scale.

In contrast, GVI, after the automatic extraction and calculation method revolution by Li et al. (2015), as an emergent index measuring urban vegetation in three dimensions, only limited research investigated its impact on the urban environment. Sabedotti et al. (2023) examined the association between GVI and air pollution such as PM 2.5, nitrogen dioxide, and carbon dioxide, and found an interquartile range increase of GVI can contribute to a 7.4 percent decrease in NO2. Other scholars scrutinised the relationships between GVI and greenery accessibility and environmental justice (Li et al., 2015; Li, 2021), human recreational behaviours (Villeneuve et al., 2018; Lu, Y., 2019), walking time, (Ki & Lee, 2021; Lu, Y., 2018), GVI best path (Zhang, J et al., 2022) and road parameters (Dong et al., 2018). These studies present GVI's significant values and exact measurability to the built environment. However, there is simultaneously a deficiency in the study of applying GVI to measure mitigation of the Urban Heat Island (UHI) effects measured by Land Surface Temperature (LST), especially the contribution of the vertical side view of greenery that can closely represent the real volume of the cooling source.

This study thus focuses on temperature mitigation effects and urban greenery environment measured by GVI, which first examined the distributional and genus difference of GVI in Washington, D.C.'s *'Local North'* and *'Local South'* wards with different residential and housing environment. We tried to explore applying GVI and newly refined metric (GVI-3D) to measure and examine the relationship between urban street greenery and UHI represented by LST, and examine the different contribution from street greenspace measured by GVI, GVI-3D and NDVI toward heat mitigation.

3 Data and methods

3.1 Study areas and background

The real estate risk appraisal program conducted by the Federal Home Loan Bank Board (FHLBB) in 1935 assigned a 4-point grade concerning infamous security (Hillier, 2003), which revealed the modern history of inequality in 239 American cities. Since then, the fourth grade and labels of hazardous areas were assigned to most neighbourhoods with African Americans. Since then, inequality transformed into racial steering. Washington, D.C., *'a city with a legacy of Black plurality'* (King et al., 2022), seemingly disenfranchised its Black residents' rights to socioeconomic and political equality (Conrad & McNeil, 2010; Lloyd, 2014; Kijakazi et al., 2016; King et al., 2016; Golash, 2023). The city's diversity and complexity contribute to its local dilemma as a global city where historical and modern inequality exists extensively, nowadays Washington, D.C. has serious polarisation represented by an expensive housing market (Bright MLS, 2023), lowest homeowenership rate nationwide (FRED, 2023) and high unemployment rate (USAFACTS, 2023). On the other hand, urban greenery, as one of the most important built environments, not only plays the role of public infrastructure but also has economic attributes that could affect people's settlement choices. Scholars found that some special income (Ki, D., et al., 2021) or ethnic groups (Li, X., 2021) lived in neighbourhoods with high or low GVI. Washington, D.C. is a model city in the U.S. where the urban greenery work deserves, many actions such as the District of Columbia Urban Tree Canopy Plan, DC State Forest Action Plan (SFAP), and other management strategies and assessment work (Fang et al., 2020) contributed to the improvement of urban greenery environment. Although 9 percent urban tree cover is desirable (Government of the District of Columbia, 2010), detection of local gaps and equitable development are also important. Therefore, we highlighted *'Local North'* Wards 3 and 4 with poverty and *'Local South'* Wards 7 and 8 with study areas. The poverty rates for Wards 3, 4, 7, and 8 were 9.1 percent, 11.4 percent, 27.7 percent and, 36.8 percent respectively according to D.C. State Data Centre Visualisation Portal (Ilena, 2019).

Fig.1 Study areas in Washington, D.C.

Tab.1 Basic information of selected and unselected areas for study

Label	Ward	Population (2014-2018)	Poverty rate (2019)
Selected study areas	3	85,067	9.1%
	4	87,775	11.4%
	7	81,299	27.7%
	8	85,024	36.8%
Other wards	1	85,134	13.6%
	2	77,791	14.3%
	5	87,850	17.7%
	6	94,558	13.4%

3.2 Data and Source

Our workflow is to apply indicators of urban greenery environment including NDVI, GVI, and GVI-3D to examine their different contribution to the indicator of urban thermal environment represented by LST (Fig.2).

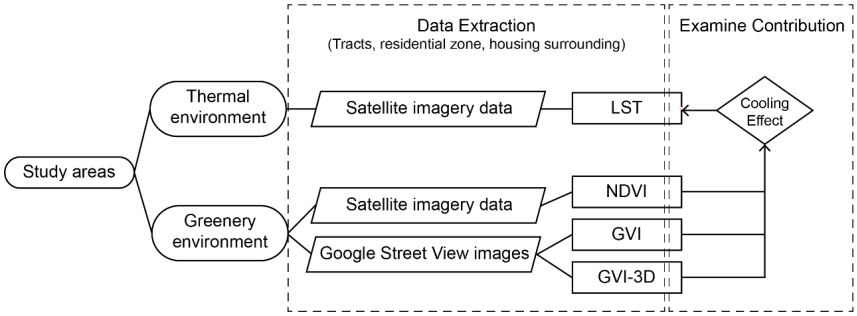

Fig.2 Overall data workflow

3.2.1 Greenery environment data

The image dataset used here is the Auto Arborist Dataset, which is a large-scale dataset extracted from Google Street View images that joins public tree censuses from 23 cities with a large collection of street-level and aerial imagery over 2 million (Beery et al., 2022) taken on or before 1 Jan, 2018. This dataset focuses on street trees containing at least one tree stem captured in each individual image, and Beery, et al. (2022) identified detailed genus information for each image. To align with the image acquisition date from the Auto Arborist Dataset images and conduct comparison analyses with time continuity, we tried to use all other data close to the acquisition time of the street image data. To obtain better resolution for comparison analysis, the Normalised Difference Vegetation Index (NDVI) is calculated based on a cloud-free Sentinel-2 satellite imagery data captured on 30 July, 2017, with 10m*10m grid-cell resolution.

3.2.2 Thermal environment data

Similarly, to respond acquisition time of street view images from the Auto Arborist Dataset and ensure the time continuity of comparison analyses, we calculated the LST based on data collected between 2014 and 2018. The LST dataset is from Open Data DC, it was computed from 2014 to 2018 and the resultant temperatures were averaged together to produce this *'5-year average'* data.

3.2.3 Affordable housing data

Despite there being many policy tools supporting Washington, D.C.'s housing affordability, the 'affordable housing development community relies on heavily is the *Housing Production Trust Fund'* (Brian, 2016). Only in 2003, the HPTF obtained 15 percent of revenue from deed transfer and recordation tax (DC Council, 2004). Housing Production Trust Fund (HPTF) has the form of revolving loan and is entirely funded by money raised within the city, and are therefore closer to the local market and housing supply and demand. HPTF provides developers with "gap financing" to directly build affording housing for low- and extremely low-income groups. Therefore, we believe that the greenery environment around affordable housing projects has strong correlations with HPTF. The HPTF affordable housing data were between 2010 to 2022, their coordinate data and basic information were grabbed from Google Maps using Python programs according to their project names listed in each HPTF annual report. Other Open Data DC datasets include zoning district boundaries in 2016 and ward boundaries in 2021.

3.3 Methods

3.3.1 Street-level indices calculation

With the pre-trained semantic segmentation model of OpenMMLab where the training dataset is Cityscape and the framework is DeepLabV3. Vegetation areas were inferred and GVI was calculated based on 54,691 Google Street View images in study area including Wards 3, 4, 7 and 8. Former studies developed different calculation methods of GVI. Li et al. (2015) revolutionised the calculation method of GVI and the whole workflow by introducing panoramic Google Street View pictures combined with images with more angles and semantic segmentation algorithms, thus automating the extraction of GVI from 6 images

covering the 360° horizontal surroundings. On these bases, some scholars such as Dong et al. (2018), Ki & Lee (2021) and Li (2021) have proposed simplified formula, but they all follow the fundamental logic of calculating the proportion of green pixels in street images using a large amount of data with geospatial locations. This study follows Ki, D. and Lee, S.'s method. The formula is shown below:

$$\mathrm{GVI} = \frac{Number\ of\ Green\ pixels}{Number\ of\ Total\ pixels} * 100$$

The GVI ranges from 0 to 100 percent, where a higher value indicates more greenspace are available in a single image. The green pixels in the example of segmented results represented the greenery on the streets (Fig.3).

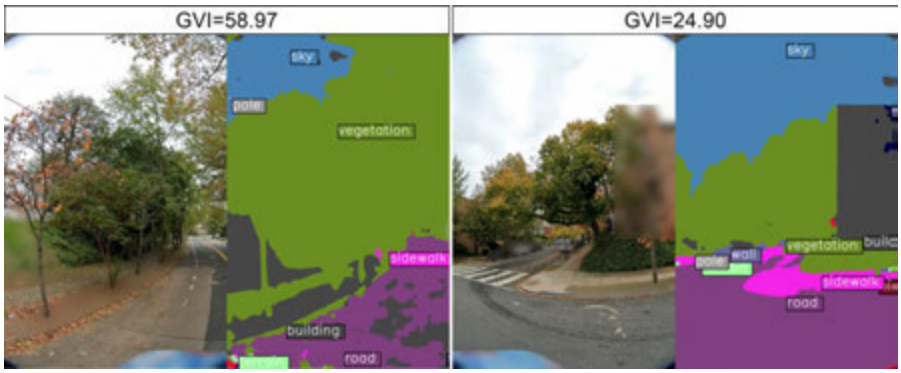

Fig.3 Examples of different GVI images

The NVDI is calculated based on the formula below. In order to better compare NDVI with GVI, we normalise NDVI by multiplying 100, all the following NDVI metrics in this article are normalised NDVI:

$$\mathrm{NDVI} = \frac{NIR - R}{NIR + R} * 100$$

GVI is highly structural data because it is alongside the urban street networks based on Google Street View map. But NDVI and LST are relatively continuous spatial data that cover all land surfaces. Given the width of streets with data collection location and mature tree canopy diameter of less than 18m (Phillip, 2020), we first used segmented street space with 18m width along streets and 30m length perpendicular to extract mean GVI, thus most tree canopy can be included (Fig.4). Same street space was also used to extract mean LST and NDVI. To examine the relationship between the tree genus and LST, other buffer areas with a 10m radius based on each individual image location were used as statistical areas. All analyses were conducted with Python, R, and ArcGIS pro.

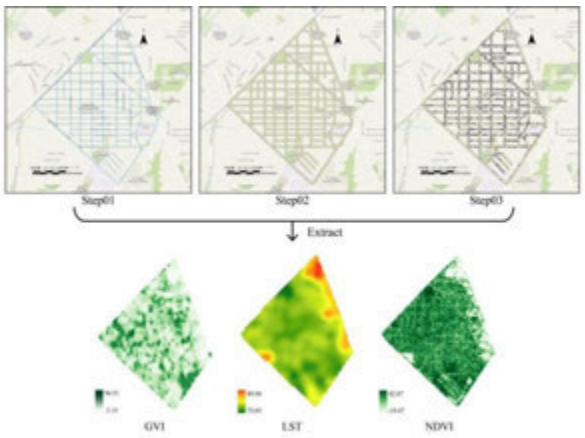

Fig.4 Extracting mean indices from segmented street space in Ward 3's Tract 10.01

Scholars addressed that GVI is a 3-dimensional index, but it virtually only represents vertical greening elevation with depth. To better describe the 3-dimensional greenery volume, we further develop GVI-3D following the logic of calculating the volume of a tree cone (Fig.5). In our study, we think of trees approximately as cones, the NDVI measured from overhead by satellite represents the base area of the cone, the root of GVI represents the height of tree canopy. Therefore, the newly developed GVI-3D can be calculated as follows:

$$\text{GVI} - 3\text{D} = \frac{1}{3} NDVI * \sqrt{GVI}$$

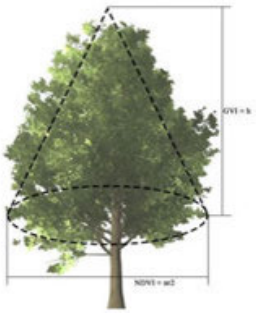

Fig.5 The calculating logic of new developed GVI-3D

3.3.2 Correlation analysis and Linear Regression

This study focuses on the mitigation impact of greenery variables on LST. To investigate the correlation among LST, GVI, and NDVI, Spearman's correlation analysis was applied. To examine and compare the cooling effects, bivariate correlations were first conducted between LST and GVI, and LST and NDVI respectively. To further examine the comprehensive effect of greenery volume measured by GVI-3D, the ordinary least square regression model (OSL) was used to examine the association between LST and GVI-3D. Variables for 4 Wards were calculated both individually and collectively.

3.3.3 Greenery environment examination in residential zones and affordable housing surroundings

Housing greenery environment was conducted at all residential zoning areas including Residential Apartment Zone (RAZ), Residential Flat Zone (RFZ), Residential Zone (RZ), and 22 sub-zoning areas, and 500-meter buffer areas of 98 affordable housing projects between 2010 and 2022 in four wards. We used descriptive statistics to scrutinise the macro-level districts and micro-level housing greenery environment.

4 Results

At the macro-quantity level, the number of street view images containing trees is similar. *'Local North'* Wards 3 and 4 have 12558 and 11559 images respectively, while Wards 7 and 8 have 16871 and 13703 images. However, the urban greenery disparities were clearly revealed in other statistical perspectives including per capita occupancy, mean GVI, temperature cooling effect, tree genus, and residential and affordable housing greening environments. Every 6.79 and 7.32 people share one tree/vegetation point in Wards 3 and 4 compared with every 5.08 and 6.22 for that in Wards 7 and 8 respectively. The spatial distribution of GVI is shown in Fig.5, where the larger radius and greener means the higher GVI. Basically, the GVI under 30 indicates that these vegetation's cooling effects can't break through the threshold of 82.5 Fahrenheit (28.5 degree Celsius) mean LST according to Fig.7, which is nearly at the transition point where Giannros et al. (2014) believed 27 to 29 degrees Celsius can make majority population fell discomfort according to their LST comfort ranges.

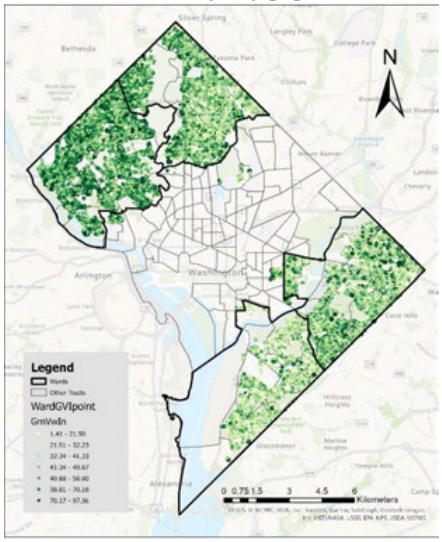

Fig.6 The spatial distribution of GVI in 'Local North' and 'Local South'

4.1 LST Mitigation effect comparison between GVI and NDVI

We next examined the relationship between LST and our two measures of greenspace. We observed negative relationships between LST and these measures, indicating that spaces with greater shares of greening had lower LST relative to areas without. The correlation coefficient of -0.60 between the mean LST and GVI mean was drawn, although less

correlated than that with NDVI (-0.68), their LST mitigation effects are virtually the same as represented by regression lines (Fig.7) and the reduction in LST is between 15 and 20 Fahrenheit degree for both GVI and NDVI. The effective cooling range of GVI is from 15 to 60, and it is from 15 to 75 for that of NDVI, which were manifested by red dash lines in Fig.6. The temperature mitigation effect appears to stop when GVI reaches around 60 representing the 60 percent vegetation proportion, which can guide urban greening work to prevent the tree canopy from becoming excessively large without producing the cooling effect. On the other hand, there is no clear stagnating trend for NDVI, which can be explained by that NDVI is a large spatial scale metric measured by electromagnetic spectrum, while GVI focuses more on middle and micro-scale street space. Meanwhile, the NDVI scatter plot presented an obvious spindle shape when the values were closer to 0.

The newly developed index, GVI-3D, presented the best correlation with LST compared with GVI and NDVI, the coefficient is -0.73 ($p<0.001$), which means this index has high explanatory power for temperature mitigation (Fig.7). The effective cooling range of GVI-3D is from 0 to 175, and GVI-3D scatter plot reflects a better point data distribution than GVI and NDVI.

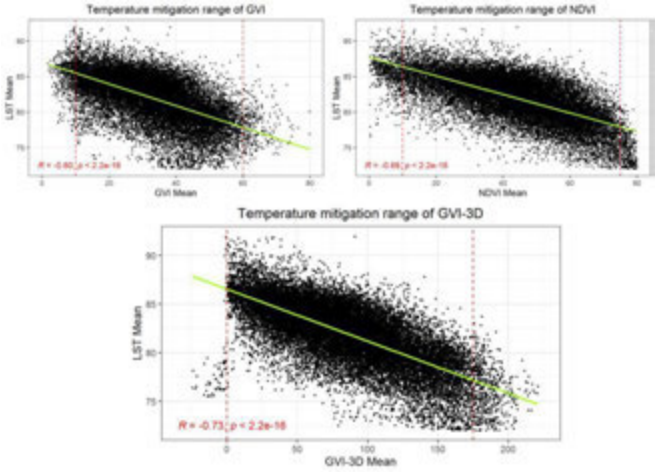

Fig.7 The temperature mitigation effects of GVI, NDVI, and GVI-3D in all wards

4.2 Cooling effect disparity between the 'Local South' and 'Local North'

4.2.1 Disparity by wards

The correlation analysis results by wards demonstrated the greenery environment disparity between the *'Local South'* and *'Local North'*. In Wards 7 and 8, fewer GVI mean values (24.84% and 13.35% respectively) were over than 40, which prevents street-level LST from dropping to 80 degrees Fahrenheit or lower (Fig.8). In contrast, 62.06 percent GVI mean values were over 40 in Ward 3, they played important roles in cooling the surrounding street space. The distribution of point data presented obvious movement to the upper left for Wards 7 and 8 compared with Wards 3 and 4 (Fig.07), which makes the point clusters closer to 90

degrees Fahrenheit, however, there are fewer points close to 90 degrees Fahrenheit in Ward 4, few in Ward 3.

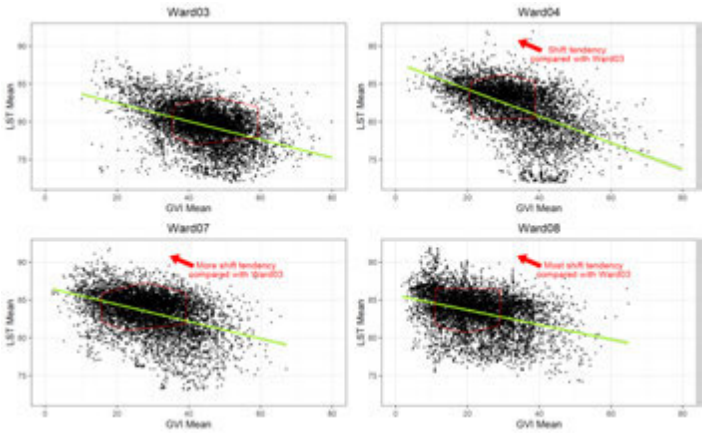

Fig.8 The GVI temperature mitigation effect gaps in Wards 3, 4, 7 and 8

4.2.2 Disparity by tree genus

If we scrutinise the detailed genus of trees in each Ward, we found that the quantity of genus showed a small difference, but GVI by genus showed huge gaps. GVI of all genera was extensively lower in Wards 7 and 8 compared with Wards 3 and 4, and we visualised the GVI of top 20 genera (Fig.09). The value of red dash line is 30, and we found that most top 20 genera have GVI blow 30 in Wards 7 and 8, which the situations are opposite in Wards 3 and 4 (Fig.9). The first-layer genera with the most quantity is either 4 or 3 categories in four Wards. Prunus stood out all genera in Ward 3, followed by Acer, Quercus, and Cercis. Cercis, Zelkova, and Prunus are dominated genera in Ward 4. Acer, Ulmus, Quercus, and Prunus are the first-layer genera in Ward 7, and Quercus, Acer, Prunus and Ulmus are the dominated genera in Ward 8. The number of trees by genus dropped off a cliff in Wards 3 and 8 (Fig.9), suggesting several dominant tree genera, which is closely related to their cooling effect. We used a simple classification to label the cooling effect of different tree genera, and found that the dominant tree genus also presented subtle inequality in terms of their cooling effects on surrounding environments. (Tab.2) More genera with high and medium cooling effects are dominated in Wards 3 and 4, in contrast, Wards 7 and 8 mostly get benefits from genera with medium and low cooling effects, and few genera with high cooling effects are primary in these two Wards. According to Virginia Department of Forestry (2023), the seedling prices for the genus Prunus (with high cooling effect) and Quercus (with medium cooling effect) are both $85 for 50, while Acer with a low cooling effect has the seedling price of $80 for 50, the budget difference might explain the quantity, genus and GVI gaps between the *'Local North'* and *'Local North'* in Washington, D.C.

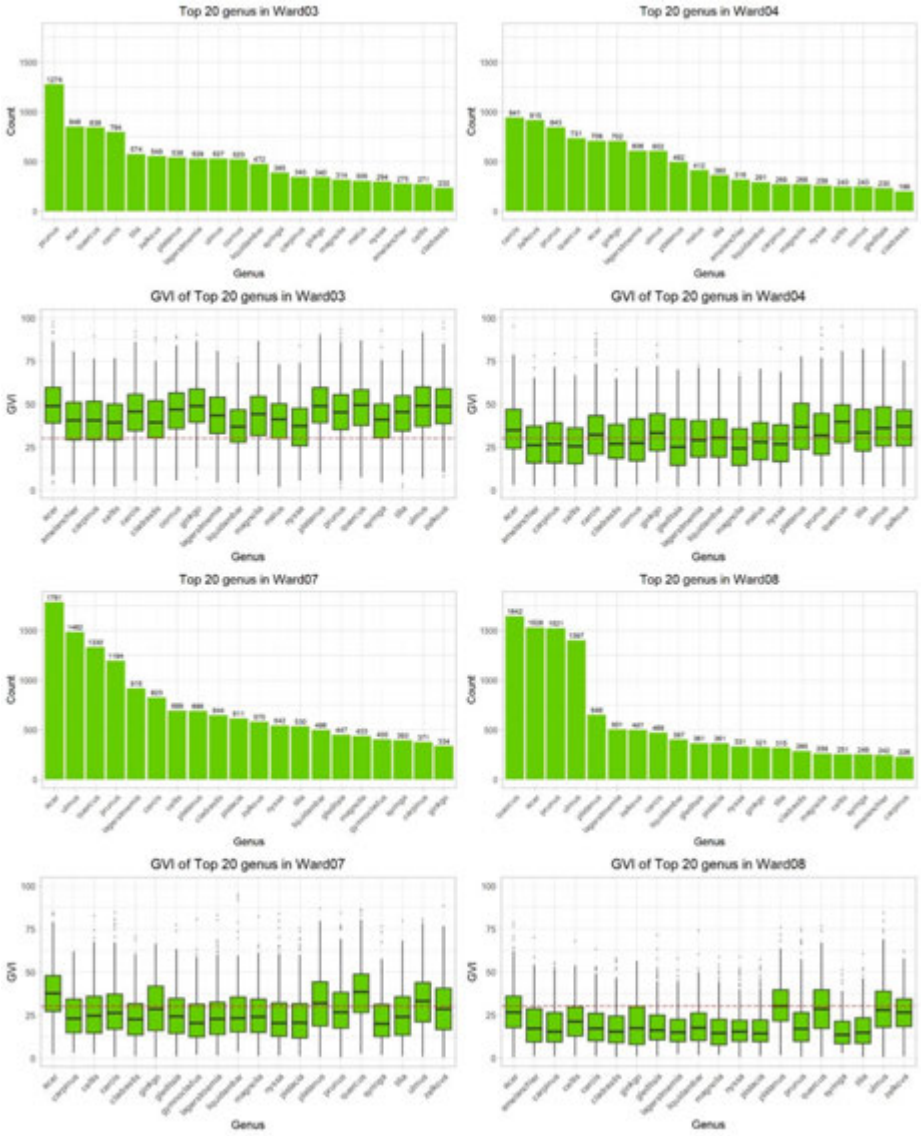

Fig.9 The tree genus distribution and GVI by genus in Wards 3, 4, 7 and 8

Tab.2 The subtle gaps between cooling effect of different dominated genera

Ward	Ranking	Genus	Number	Correlation coefficient (All p < 2.2e-16)	Cooling effect
Ward 3	1	Prunus	1,274	-0.52	High
	2	Acer	848	-0.43	Low
	3	Quercus	838	-0.46	Medium
	4	Cercis	794	-0.49	High

Ward 4	1	Cercis	941	-0.49	High
	2	Zelkova	915	-0.50	High
	3	Prunus	843	-0.52	High
Ward 7	1	Acer	1,781	-0.43	Low
	2	Ulmus	1,482	-0.40	Low
	3	Quercus	1,330	-0.46	Medium
	4	Prunus	1,194	-0.52	High
Ward 8	1	Quercus	1,642	-0.46	Medium
	2	Acer	1,528	-0.43	Low
	3	Prunus	1,528	-0.52	High
	4	Ulmus	1,397	-0.40	Low

4.3 Greenery distribution disparity in residential zones and affordable housing surroundings

The GVI also varies across each different sub-zoning areas. The mean GVI distribution in 3 residential and 22 sub-zoning areas (Appendix) is shown in Fig.10. In general, the mean GVI in the Residential Zone (RZ) is higher than that in the Residential Apartment Zone (RAZ) and Residential Flat Zone (RFZ). The R-1A zone has the highest mean GVI at around 42.5, the RA-1 zone has the lowest mean GVI at around 25. In local perspectives, the opposite mean distribution appears within RZ and RAZ. In RZ, with the increase of housing density, the zoning type transfers from R-1A to R-1B, R-2, and R-3, the mean GVI presented an obvious decrease from around 42.5 to 26, which indicated the normal relationship between land use and urban greenery. All R-1A and variations showed high mean GVI around or above 40, and small deviation from the mean values, the cliffs between R-1A and R-2 or R-3 are distinct.

However, the denser the residential zoning type within RAZ, the higher mean GVI values show out. For example, the RA-4 which provides for areas developed with predominantly medium- to high-density residential has the highest mean GVI of around 37, while the RA-1 which permits low- to moderate-density development, including detached dwellings, rowhouses, and low-rise apartments has the lowest mean GVI around 25. In addition, the mean GVI of RF-1 which belongs to RFZ is neither high nor low, which is around 28.

The distribution difference simultaneously revealed the inequality of residential land use. Zoning types with high mean GVI are mostly located in *'Local North'* Wards 3 and 4, while low mean GVI zoning areas are concentrated in Wards 7 and 8. Wards 7 and 8 have 31 and 26 RA-1 zones (the lowest GVI zoning), in comparison, Wards 3 and 4 only have 7 and 10 RA-1 zones respectively. As for RA-1 zones (the highest GVI zoning), Wards 3 and 4 have 7 and 3 respectively, and Wards 7 and 8 do not have such kind of zoning.

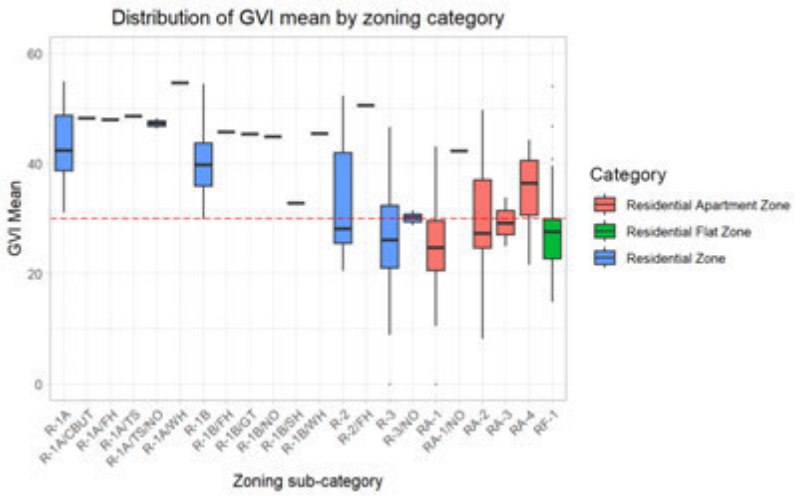

Fig.10 The temperature mitigation effects of GVI, NDVI and GVI-3D

We found that 98 affordable housing projects in different wards and zoning also presented disparity (Tab.3). Due to the wealth of Ward 3, only one HPTF affordable housing project was built between 2010 and 2022, which is Woodley House. Wards 4, 7, and 8 have 38, 32, and 27 affordable housing projects built in during 13 years. The mean GVI of all affordable housing projects is 27.2, which is quite as low as the mean GVI in R-3 zoning. The only project in Ward 3 has a mean GVI of 43.51, the mean GVI of projects in Ward 4 is 31.1, far higher than the projects with the highest GVI of 30.96 and in Wards 7 and 28.24. The average GVI of affordable housing projects in Wards 7 and 8 are only 25.9 and 22.6, indicating the huge gaps between affordable housing projects in different Wards. What's more, the affordable housing project with the highest GVI in Ward 7 is located in Mixed-Use Zones where the commercial and institutional use are prior, the multi-family residential development are secondary residential zoning areas (Appendices).

Tab.3 500-meter buffer GVI differences by HPTF housing projects

Ward	Project name	Zoning	GVI	
			Attribute	Value
Ward 3	Woodley House	RA-2	Only value	43.51
Ward 4	NCCLT-905 R St. NW	R-1A	Highest value	40.20
Ward 7	1847-49 Good Hope Road, SE	MU-7B	Highest value	30.96
Ward 8	Stanton Square Apartments	R-3	Highest value	28.24

5 Discussion

This study contributes to the validation of environmental injustice issues and significant temperature mitigation effects measured by GVI and GVI-3D. Taking Washington, D.C. as an example, we found that the greenery environment inequality, from macro-level to micro-level, extensively existed in the *'Local North'* and *'Local South'* with serious wealth polarisation, which reveals the infrastructure property attributes of street-level vegetation.

GVI and LST are highly correlated, the new index GVI-3D presented a higher correlation with LST, with the increase of these two indices, the street-level space becomes cooler around 10 to 15 degrees Fahrenheit in a linear way. GVI-3D presented a better measurement of LST mitigation, which contributed to establishing the model of a true mathematics mapping of this index to canopy volume in physical urban space. As for the good measurability, we believed that the side views of street greenery images provide more possibilities to measure the actual volume of tree canopies which are the main cooling source for urban street-level microenvironment.

However, the cooling effects of different tree genera differs, some dominant genus has better temperature mitigation effects such as Prunus, Cercis, and Zelkova, while Acer and Ulmus show low mitigation effects. These subtle differences are difficult to spot, and even their cooling effect may be budget-related because we found that affluent wards tend to have more high cooling effect trees compared with non-affluent wards at the local level.

The GVI values also connect with land use type and housing density. The higher the density of detached or semi-detached Residential Zoning, the lower the GVI was found in those areas. In contrast, the higher the density of Residential Apartment Zoning, we get the higher GVI. This may be explained by the degree of intensive utilisation of land that needs to reach a certain value before it can function well. Unlike the average greenery environments of residential areas, the greenery environments of affordable housing were worse measured by GVI. Despite increased greenery is common sense that can mitigate the heat exposure risks, they also mean government or developers need balance investment and budget for targeted neighbourhoods. As for affordable housing, they usually have less accessibility to parks, forests and gardens, thus the urban street greenery becomes the limited or only green environment that affordable housing can directly benefit from so as to decrease heat exposure risks. Therefore, the significance of urban street greenery and its metrics should be addressed.

Some limitations should be addressed. First, despite the accuracy of a similar semantic segmentation model being around 85 percent according to prior research (Ki & Lee, 2021; Li et al., 2019; Zhao et al., 2017), changing the detection image dataset from European based cities to American cities can have an influence on the accuracy of the algorithm. As for the temperature mitigation effect, we only consider the single variable of urban greenery, more variables can be included such as Impervious Surface Area (ISA) (Yuan & Bauer, 2007; Imhoff et al., 2010; Ziter et al., 2019). Besides, more data may give the correlation analysis and regression model better explanatory power. Despite the GVI-3D generated a fine R-squared value of 0.73, the 0.60 R-squared value of GVI still has the possibility of being improved.

6 Conclusion and policy proposals

In conclusion, GVI has virtually the same explanatory power as NDVI when it comes to the LST mitigation effect, while GVI-3D has the best. This study argues that it is of practical significance to monitor GVI and GVI-3D rather than NDVI of small-scale street environments due to their readability, controllability, and human-centric attributes. It is

feasible to adjust GVI by controlling the size, quantity, and density of street greenery, a 60 percent GVI can be a cut-off for urban greening work to prevent excessively large tree canopies concerning their cooling effects. However, large-scale NDVI measurements make it difficult to contribute to improved policy suggestions for street greening. The related housing and greenery policies can have improvements as follows.

6.1 Focus on greenery quality rather than only quantity

According to Fang (2024), *'DC's greenery-related government departments already made huge efforts to plant trees in non-affluent areas such as Wards 7 and 8'*, their achievements can be reflected in the number of tree/vegetation image points mentioned above. However, greenery quality is more essential indicated by GVI and GVI-3D in this study. Through measuring GVI, it is easy to find that vegetation proportion over 60 percent can't produce a substantial cooling effect. Therefore, more emphasis and resources can be invested in the improvements of quality of the greenery environment such as the balance of tree genus and the volume of tree canopies so that we can pursue better temperature mitigation effects by quantifying GVI or GVI-3D. Those resources to manage excessively huge tree canopies can be transferred to *'Local South'* areas by managing the life cycle of the trees.

6.2 Highlight the greenery environment of affordable housing projects

The locations of HPTF affordable housing projects are precise. Ward 3 only built one affordable housing during 13 years. However, the gaps between this only one project and the others were huge. A suitable greenery environment for housing has the significant impact on the health of residents (Hanzl & Rembeza., 2022; Kuchcik et al., 2016), housing values (Zhang & Dong., 2018; Ye et al., 2019), and environmental justice (Schmid & Säumel., 2021; Xiao et al., 2021). The affordable housing projects have the necessitates to set aside a part of the budget and resources for the improvement of the surrounding green environment in terms of tree genus and volume. The density of affordable housing projects can be improved from the evidence that higher density Residential Apartment Zone tends to have better greenery environment measured by GVI. In addition, the assessment of the difference between affordable housing projects and normal housing projects is necessary.

Appendices

Tab.4 The description of residential zoning categories in Washington, D.C.

Zoning	Sub-Category	Description
Residential Apartment Zone	RA-1	The RA-1 zone provides for areas predominantly developed with low- to moderate-density development, including detached dwellings, rowhouses, and low-rise apartments.
	RA-2	The RA-2/RC zone is intended to provide for areas developed with predominantly moderate- and medium-density rowhouses and apartments.
	RA-3	The RA-3 zone provides for areas developed with predominantly medium-density residential.
	RA-4	The RA-4 zone provides for areas developed with predominantly medium- to high-density residential.
	RA-1/NO	The RA-1/NO zone provides for areas predominantly developed with low- to moderate-density development, including detached dwellings, rowhouses, and low-rise apartments in the vicinity of the U.S. Naval Observatory.
Residential Flat Zone	RF-1	The RF-1 zone is to provide for areas predominantly developed with row houses on small lots within which no more than two (2) dwelling units are permitted.
Residential Zone	R-1A	The R-1A zone is intended to provide areas predominantly developed with detached houses on large lots.
	R-1A/CBUT R-1A/FH R-1A/TS R-1A/TS/NO R-1A/WH	All R-1A variations permit detached houses on large lots. They also have the purpose to protect specific areas' low density, natural topography, historic or ceremonial importance, or special missions, including Chain Bridge Road/University Terrace, Forest Hills, Tree and Slope Protection zones, Naval Observatory/Tree and Slope Protection zones and Wesley Heights.
	R-1B	The R-1B zone is intended to provide areas predominantly developed with detached houses on moderately sized lots.

	R-1B/FH R-1B/GT R-1B/NO R-1B/SH R-1B/WH	All R-1B variations permit detached houses on moderately-sized lots. They also have the purpose to protect specific areas' low density, natural topography, historic or ceremonial importance, or special missions, including Forest Hills, Georgetown National Historic Landmark District, Naval Observatory, Sixteenth Street Heights and Wesley Heights.
	R-2	The R-2 zone is intended to provide for areas predominantly developed with semi-detached houses on moderately sized lots that also contain some detached dwellings.
	R-2/FH	The purposes of the R-2/FH zone are to preserve the natural topography and mature trees to the maximum extent feasible in the Forest Hills neighbourhoods, which permit semi-detached houses on moderately sized lots that also contain some detached dwellings.
	R-3	The purpose of the R-3 zone is to allow for row dwellings, while including areas within which row dwellings are mingled with detached dwellings, semi-detached dwellings, and groups of three or more row dwellings.
Mixed-Use (MU) Zones	MU-7B	The MU-7B zone is intended to permit medium-density mixed-use development with a focus on employment.

Urban heat mitigation effect and affordable housing greenery injustice measured by Green View Index (GVI): A case study in Washington, D.C.

Abstract

The deterioration of living conditions is highlighting the benefits of urban greenery for creating sustainable cities. Using Washington D.C. as a case, we demonstrate the performance of GVI and examine disparities in greening surrounding affordable housing. With the pre-trained segmentation model, we generated GVI based on 54,691 Street View images and applied the Spearman's correlation analysis to examine LST cooling effect. We found that LST shows significant negative correlations ($p<0.001$) with GVI and newly developed GVI-3D with coefficients of -0.60 and -0.73. The distribution of GVI in residential zoning was polarised, affordable housing projects have less greenery. In conclusion, we argue that it is of practical significance to monitor GVI instead of large scale NDVI for urban environments due to its controllability and human-centric attributes.

Keywords: Green View Index, Temperature mitigation, Street greenery, Housing environment, Environmental justice

1 Introduction

Our human society just experienced the warmest decade on record between 2011 and 2020 (WMO, 2023). For the global majority living in cities, urban heat islands represent an issue for both livability and health. Given the heat-absorbing properties of greenery, researcher have developed a range of vegetation-related indices to examine the climate change mitigation potentials such as (Normalised Difference Vegetation Index) NDVI (Yue, W., et al., 2007; Chun, B. and Guldmann, J.M., 2018.), and examine distributional equity such as park areas (Nesbitt et al., 2019), while they are all plat 2-dimensional indices which cannot drill down to accurate small-scale space analysis and vertical vegetation detection. The Green View Index (GVI) (Yang et al., 2009; Li et al., 2015) provided a refined and 3-dimensional metric for quantifying urban greenery by authentically simulating pedestrian's visual experience and perception, thus reflecting the actual exposure of humans to greenery (Cho et al., 2010). Advances in computer vision and image processing tools now make it more feasible to examine the impact of GVI on urban environments. In this paper, we add to the literature by measuring

the relationship between urban green space and land surface temperature (LST). Using Washington D.C. as a case, we demonstrate the performance of the GVI, and use it to examine disparities in urban greening surrounding affordable housing.

2 Literature Review

Urban Heat Island (UHI) effect is the thermal aggregation issue coming with urbanisation and industrialisation, which leads to increased human health risks (Heaviside et al., 2017) and influences socioeconomic development (Rizwan et al., 2008). In the 21st century, an increasingly urbanised population over 3 billion are directly exposed to UHI in worldwide (Rizwan et al., 2008). Simultaneously, cities' physical environment and spatial structure (Shaker et al., 2019; Cao et al.,2022; Gage & Cooper, 2017) greatly influence the distribution of UHI causing environmental justice issue where different groups suffer distinctly due to their locations, greenery environment around housing and demographic characteristics. Affluent neighbourhoods, high-income groups and the white population in United States (Harlan et al., 2007; Mitchell & Chakraborty, 2015; Hsu et al., 2021) were widely considered to have environmental advantages and low heat exposure risks, while the vulnerable populations suffer more.

Even though a large amount of greenery indices were invented (Bannari, 1995; Huete, 2012) to respond the UHI exposure problems based on different criteria, "the most widely used index remains the NDVI" (Bannari, 1995, p.114). The impact of significant greenery index NDVI on the urban environment, especially the thermal environment was meticulously examined by many scholars. Lo et al. (1997) verified that irradiance with an emphasis on commercial and services land cover contributed to the development of urban heat islands, he found there was a negative correlation between NDVI and irradiance of different land covers. In addition, Li et al. (2011), Grover & Singh (2015), Jamei et al. (2019), and Chakraborty et al. (2020) all concluded that NDVI, in conjunction with other built environment indices can significantly predict Land Surface Temperature (LST) on the regional scale.

In contrast, GVI, after the automatic extraction and calculation method revolution by Li et al. (2015), as an emergent index measuring urban vegetation in three dimensions, only limited research investigated its impact on the urban environment. Sabedotti et al. (2023) examined the association between GVI and air pollution such as PM 2.5, nitrogen dioxide, and carbon dioxide, and found an interquartile range increase of GVI can contribute to a 7.4 percent decrease in NO2. Other scholars scrutinised the relationships between GVI and greenery accessibility and environmental justice (Li et al., 2015; Li, 2021), human recreational behaviours (Villeneuve et al., 2018; Lu, Y., 2019), walking time, (Ki & Lee, 2021; Lu, Y., 2018), GVI best path (Zhang, J et al., 2022) and road parameters (Dong et al., 2018). These studies present GVI's significant values and exact measurability to the built environment. However, there is simultaneously a deficiency in the study of applying GVI to measure mitigation of the Urban Heat Island (UHI) effects measured by Land Surface Temperature (LST), especially the contribution of the vertical side view of greenery that can closely represent the real volume of the cooling source.

This study thus focuses on temperature mitigation effects and urban greenery environment measured by GVI, which first examined the distributional and genus difference of GVI in Washington, D.C.'s *'Local North'* and *'Local South'* wards with different residential and housing environment. We tried to explore applying GVI and newly refined metric (GVI-3D) to measure and examine the relationship between urban street greenery and UHI represented by LST, and examine the different contribution from street greenspace measured by GVI, GVI-3D and NDVI toward heat mitigation.

3 Data and methods

3.1 Study areas and background

The real estate risk appraisal program conducted by the Federal Home Loan Bank Board (FHLBB) in 1935 assigned a 4-point grade concerning infamous security (Hillier, 2003), which revealed the modern history of inequality in 239 American cities. Since then, the fourth grade and labels of hazardous areas were assigned to most neighbourhoods with African Americans. Since then, inequality transformed into racial steering. Washington, D.C., *'a city with a legacy of Black plurality'* (King et al., 2022), seemingly disenfranchised its Black residents' rights to socioeconomic and political equality (Conrad & McNeil, 2010; Lloyd, 2014; Kijakazi et al., 2016; King et al., 2016; Golash, 2023). The city's diversity and complexity contribute to its local dilemma as a global city where historical and modern inequality exists extensively, nowadays Washington, D.C. has serious polarisation represented by an expensive housing market (Bright MLS, 2023), lowest homeowenership rate nationwide (FRED, 2023) and high unemployment rate (USAFACTS, 2023). On the other hand, urban greenery, as one of the most important built environments, not only plays the role of public infrastructure but also has economic attributes that could affect people's settlement choices. Scholars found that some special income (Ki, D., et al., 2021) or ethnic groups (Li, X., 2021) lived in neighbourhoods with high or low GVI. Washington, D.C. is a model city in the U.S. where the urban greenery work deserves, many actions such as the District of Columbia Urban Tree Canopy Plan, DC State Forest Action Plan (SFAP), and other management strategies and assessment work (Fang et al., 2020) contributed to the improvement of urban greenery environment. Although 9 percent urban tree cover is desirable (Government of the District of Columbia, 2010), detection of local gaps and equitable development are also important. Therefore, we highlighted *'Local North'* Wards 3 and 4 with poverty and *'Local South'* Wards 7 and 8 with study areas. The poverty rates for Wards 3, 4, 7, and 8 were 9.1 percent, 11.4 percent, 27.7 percent and, 36.8 percent respectively according to D.C. State Data Centre Visualisation Portal (Ilena, 2019).

Fig.1 Study areas of four wards in Washington, D.C.

Tab.1 Basic information of selected and unselected areas for study

Label	Ward	Population (2014-2018)	Poverty rate (2019)
Selected study areas	3	85,067	9.1%
	4	87,775	11.4%
	7	81,299	27.7%
	8	85,024	36.8%
Other wards	1	85,134	13.6%
	2	77,791	14.3%
	5	87,850	17.7%
	6	94,558	13.4%

3.2 Data and Source

Our workflow is to apply indicators of urban greenery environment including NDVI, GVI, and GVI-3D to examine their different contribution to the indicator of urban thermal environment represented by LST (Fig.2).

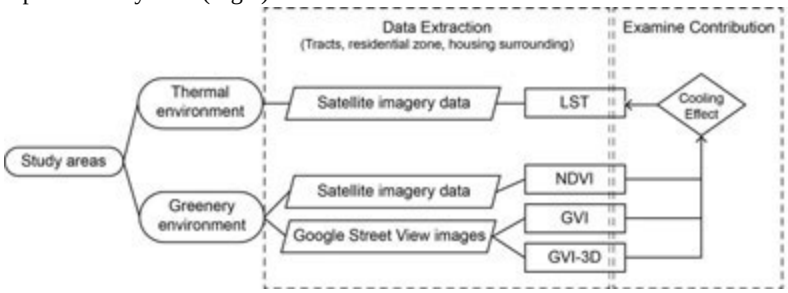

Fig.2 Overall data workflow

3.2.1 Greenery environment data

The image dataset used here is the Auto Arborist Dataset, which is a large-scale dataset extracted from Google Street View images that joins public tree censuses from 23 cities with a large collection of street-level and aerial imagery over 2 million (Beery et al., 2022) taken on or before 1 Jan, 2018. This dataset focuses on street trees containing at least one tree stem captured in each individual image, and Beery, et al. (2022) identified detailed genus information for each image. To align with the image acquisition date from the Auto Arborist Dataset images and conduct comparison analyses with time continuity, we tried to use all other data close to the acquisition time of the street image data. To obtain better resolution for comparison analysis, the Normalised Difference Vegetation Index (NDVI) is calculated based on a cloud-free Sentinel-2 satellite imagery data captured on 30 July, 2017, with 10m*10m grid-cell resolution.

3.2.2 Thermal environment data

Similarly, to respond acquisition time of street view images from the Auto Arborist Dataset and ensure the time continuity of comparison analyses, we calculated the LST based on data collected between 2014 and 2018. The LST dataset is from Open Data DC, it was computed from 2014 to 2018 and the resultant temperatures were averaged together to produce this *'5-year average'* data.

3.2.3 Affordable housing data

Despite there being many policy tools supporting Washington, D.C.'s housing affordability, the 'affordable housing development community relies on heavily is the *Housing Production Trust Fund'* (Brian, 2016). Only in 2003, the HPTF obtained 15 percent of revenue from deed transfer and recordation tax (DC Council, 2004). Housing Production Trust Fund (HPTF) has the form of revolving loan and is entirely funded by money raised within the city, and are therefore closer to the local market and housing supply and demand. HPTF provides developers with "gap financing" to directly build affording housing for low- and extremely low-income groups. Therefore, we believe that the greenery environment around affordable housing projects has strong correlations with HPTF. The HPTF affordable housing data were between 2010 to 2022, their coordinate data and basic information were grabbed from Google Maps using Python programs according to their project names listed in each HPTF annual report. Other Open Data DC datasets include zoning district boundaries in 2016 and ward boundaries in 2021.

3.3 Methods

3.3.1 Street-level indices calculation

With the pre-trained semantic segmentation model of OpenMMLab where the training dataset is Cityscape and the framework is DeepLabV3. Vegetation areas were inferred and GVI was calculated based on 54,691 Google Street View images in study area including Wards 3, 4, 7

and 8. Former studies developed different calculation methods of GVI. Li et al. (2015) revolutionised the calculation method of GVI and the whole workflow by introducing panoramic Google Street View pictures combined with images with more angles and semantic segmentation algorithms, thus automating the extraction of GVI from 6 images covering the 360° horizontal surroundings. On these bases, some scholars such as Dong et al. (2018), Ki & Lee (2021) and Li (2021) have proposed simplified formula, but they all follow the fundamental logic of calculating the proportion of green pixels in street images using a large amount of data with geospatial locations. This study follows Ki, D. and Lee, S.'s method. The formula is shown below:

$$\mathrm{GVI} = \frac{Number\ of\ Green\ pixels}{Number\ of\ Total\ pixels} * 100$$

The GVI ranges from 0 to 100 percent, where a higher value indicates more greenspace are available in a single image. The green pixels in the example of segmented results represented the greenery on the streets (Fig.3).

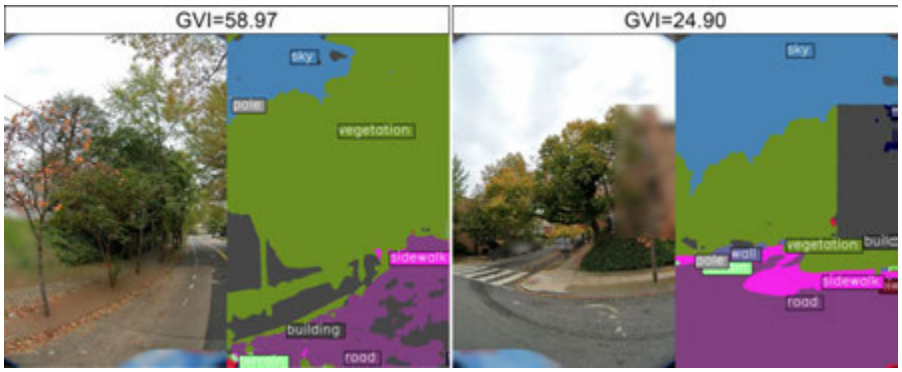

Fig.3 Examples of different GVI images

The NVDI is calculated based on the formula below. In order to better compare NDVI with GVI, we normalise NDVI by multiplying 100, all the following NDVI metrics in this article are normalised NDVI:

$$\mathrm{NDVI} = \frac{NIR - R}{NIR + R} * 100$$

GVI is highly structural data because it is alongside the urban street networks based on Google Street View map. But NDVI and LST are relatively continuous spatial data that cover all land surfaces. Given the width of streets with data collection location and mature tree canopy diameter of less than 18m (Phillip, 2020), we first used segmented street space with 18m width along streets and 30m length perpendicular to extract mean GVI, thus most tree canopy can be included (Fig.4). Same street space was also used to extract mean LST and NDVI. To examine the relationship between the tree genus and LST, other buffer areas with a 10m radius based on each individual image location were used as statistical areas. All analyses were conducted with Python, R, and ArcGIS pro.

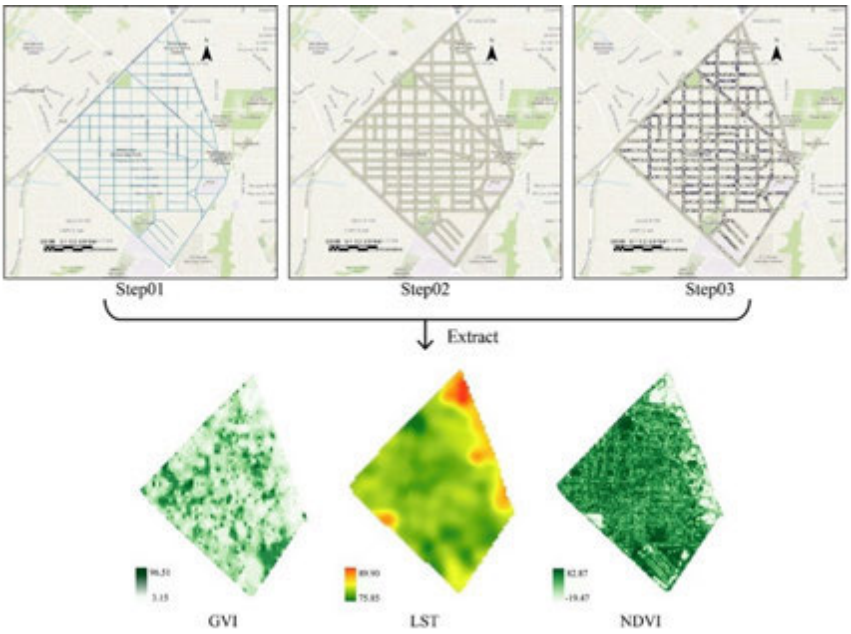

Fig.4 Extracting mean indices from segmented street space in Ward 3's Tract 10.01

Scholars addressed that GVI is a 3-dimensional index, but it virtually only represents vertical greening elevation with depth. To better describe the 3-dimensional greenery volume, we further develop GVI-3D following the logic of calculating the volume of a tree cone (Fig.5). In our study, we think of trees approximately as cones, the NDVI measured from overhead by satellite represents the base area of the cone, the root of GVI represents the height of tree canopy. Therefore, the newly developed GVI-3D can be calculated as follows:

$$\text{GVI} - 3\text{D} = \frac{1}{3} NDVI * \sqrt{GVI}$$

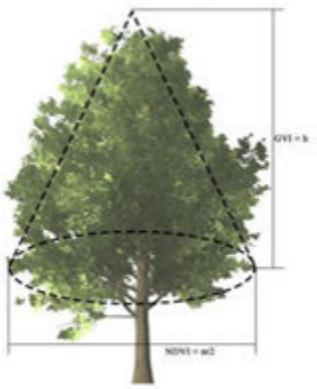

Fig.5 The calculating logic of new developed GVI-3D

3.3.2 Correlation analysis and Linear Regression

This study focuses on the mitigation impact of greenery variables on LST. To investigate the correlation among LST, GVI, and NDVI, Spearman's correlation analysis was applied. To examine and compare the cooling effects, bivariate correlations were first conducted between LST and GVI, and LST and NDVI respectively. To further examine the comprehensive effect of greenery volume measured by GVI-3D, the ordinary least square regression model (OSL) was used to examine the association between LST and GVI-3D. Variables for 4 Wards were calculated both individually and collectively.

3.3.3 Greenery environment examination in residential zones and affordable housing surroundings

Housing greenery environment was conducted at all residential zoning areas including Residential Apartment Zone (RAZ), Residential Flat Zone (RFZ), Residential Zone (RZ), and 22 sub-zoning areas, and 500-meter buffer areas of 98 affordable housing projects between 2010 and 2022 in four wards. We used descriptive statistics to scrutinise the macro-level districts and micro-level housing greenery environment.

4 Results

At the macro-quantity level, the number of street view images containing trees is similar. *'Local North'* Wards 3 and 4 have 12558 and 11559 images respectively, while Wards 7 and 8 have 16871 and 13703 images. However, the urban greenery disparities were clearly revealed in other statistical perspectives including per capita occupancy, mean GVI, temperature cooling effect, tree genus, and residential and affordable housing greening environments. Every 6.79 and 7.32 people share one tree/vegetation point in Wards 3 and 4 compared with every 5.08 and 6.22 for that in Wards 7 and 8 respectively. The spatial distribution of GVI is shown in Fig.5, where the larger radius and greener means the higher GVI. Basically, the GVI under 30 indicates that these vegetation's cooling effects can't break through the threshold of 82.5 Fahrenheit (28.5 degree Celsius) mean LST according to Fig.7, which is nearly at the transition point where Giannros et al. (2014) believed 27 to 29 degrees Celsius can make majority population fell discomfort according to their LST comfort ranges.

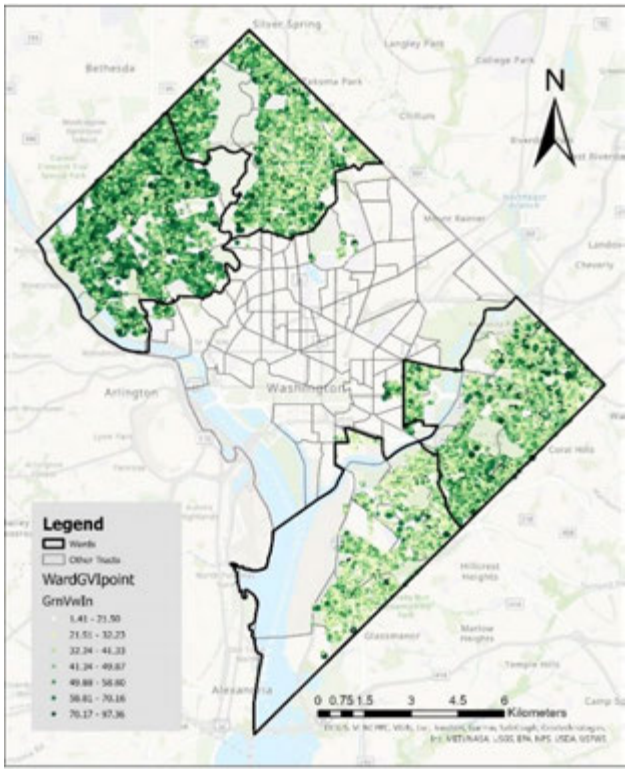

Fig.6 The spatial distribution of GVI in 'Local North' and 'Local South'

4.1 LST Mitigation effect comparison between GVI and NDVI

We next examined the relationship between LST and our two measures of greenspace. We observed negative relationships between LST and these measures, indicating that spaces with greater shares of greening had lower LST relative to areas without. The correlation coefficient of -0.60 between the mean LST and GVI mean was drawn, although less correlated than that with NDVI (-0.68), their LST mitigation effects are virtually the same as represented by regression lines (Fig.7) and the reduction in LST is between 15 and 20 Fahrenheit degree for both GVI and NDVI. The effective cooling range of GVI is from 15 to 60, and it is from 15 to 75 for that of NDVI, which were manifested by red dash lines in Fig.6. The temperature mitigation effect appears to stop when GVI reaches around 60 representing the 60 percent vegetation proportion, which can guide urban greening work to prevent the tree canopy from becoming excessively large without producing the cooling effect. On the other hand, there is no clear stagnating trend for NDVI, which can be explained by that NDVI is a large spatial scale metric measured by electromagnetic spectrum, while GVI focuses more on middle and micro-scale street space. Meanwhile, the NDVI scatter plot presented an obvious spindle shape when the values were closer to 0.

The newly developed index, GVI-3D, presented the best correlation with LST compared with GVI and NDVI, the coefficient is -0.73 ($p<0.001$), which means this index has high explanatory power for temperature mitigation (Fig.7). The effective cooling range of GVI-3D is from 0 to 175, and GVI-3D scatter plot reflects a better point data distribution than GVI and NDVI.

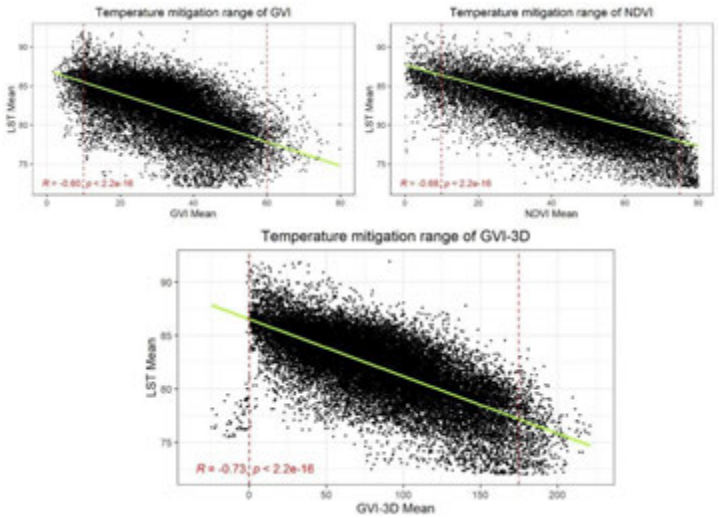

Fig.7 The temperature mitigation effects of GVI, NDVI, and GVI-3D in all wards

4.2 Cooling effect disparity between the 'Local South' and 'Local North'

4.2.1 Disparity by wards

The correlation analysis results by wards demonstrated the greenery environment disparity between the *'Local South'* and *'Local North'*. In Wards 7 and 8, fewer GVI mean values (24.84% and 13.35% respectively) were over than 40, which prevents street-level LST from dropping to 80 degrees Fahrenheit or lower (Fig.8). In contrast, 62.06 percent GVI mean values were over 40 in Ward 3, they played important roles in cooling the surrounding street space. The distribution of point data presented obvious movement to the upper left for Wards 7 and 8 compared with Wards 3 and 4 (Fig.07), which makes the point clusters closer to 90 degrees Fahrenheit, however, there are fewer points close to 90 degrees Fahrenheit in Ward 4, few in Ward 3.

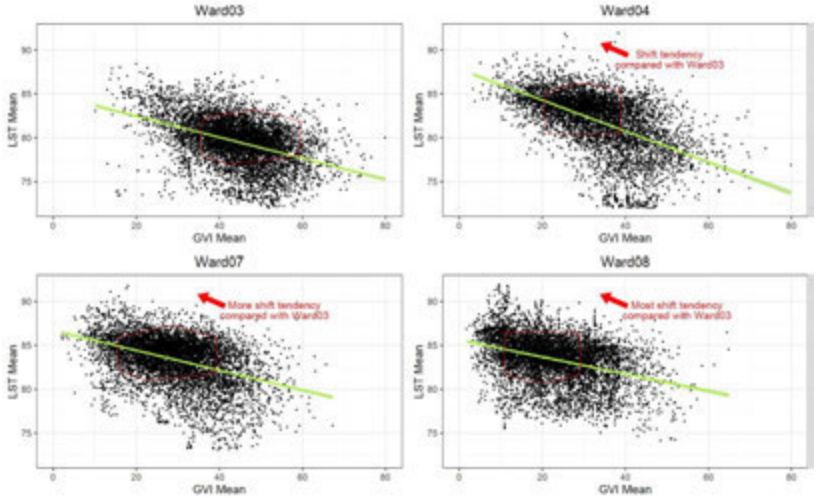

Fig.8 The GVI temperature mitigation effect gaps in Wards 3, 4, 7 and 8

4.2.2 Disparity by tree genus

If we scrutinise the detailed genus of trees in each Ward, we found that the quantity of genus showed a small difference, but GVI by genus showed huge gaps. GVI of all genera was extensively lower in Wards 7 and 8 compared with Wards 3 and 4, and we visualised the GVI of top 20 genera (Fig.09). The value of red dash line is 30, and we found that most top 20 genera have GVI blow 30 in Wards 7 and 8, which the situations are opposite in Wards 3 and 4 (Fig.9). The first-layer genera with the most quantity is either 4 or 3 categories in four Wards. Prunus stood out all genera in Ward 3, followed by Acer, Quercus, and Cercis. Cercis, Zelkova, and Prunus are dominated genera in Ward 4. Acer, Ulmus, Quercus, and Prunus are the first-layer genera in Ward 7, and Quercus, Acer, Prunus and Ulmus are the dominated genera in Ward 8. The number of trees by genus dropped off a cliff in Wards 3 and 8 (Fig.9), suggesting several dominant tree genera, which is closely related to their cooling effect. We used a simple classification to label the cooling effect of different tree genera, and found that the dominant tree genus also presented subtle inequality in terms of their cooling effects on surrounding environments. (Tab.2) More genera with high and medium cooling effects are dominated in Wards 3 and 4, in contrast, Wards 7 and 8 mostly get benefits from genera with medium and low cooling effects, and few genera with high cooling effects are primary in these two Wards. According to Virginia Department of Forestry (2023), the seedling prices for the genus Prunus (with high cooling effect) and Quercus (with medium cooling effect) are both $85 for 50, while Acer with a low cooling effect has the seedling price of $80 for 50, the budget difference might explain the quantity, genus and GVI gaps between the *'Local North'* and *'Local North'* in Washington, D.C.

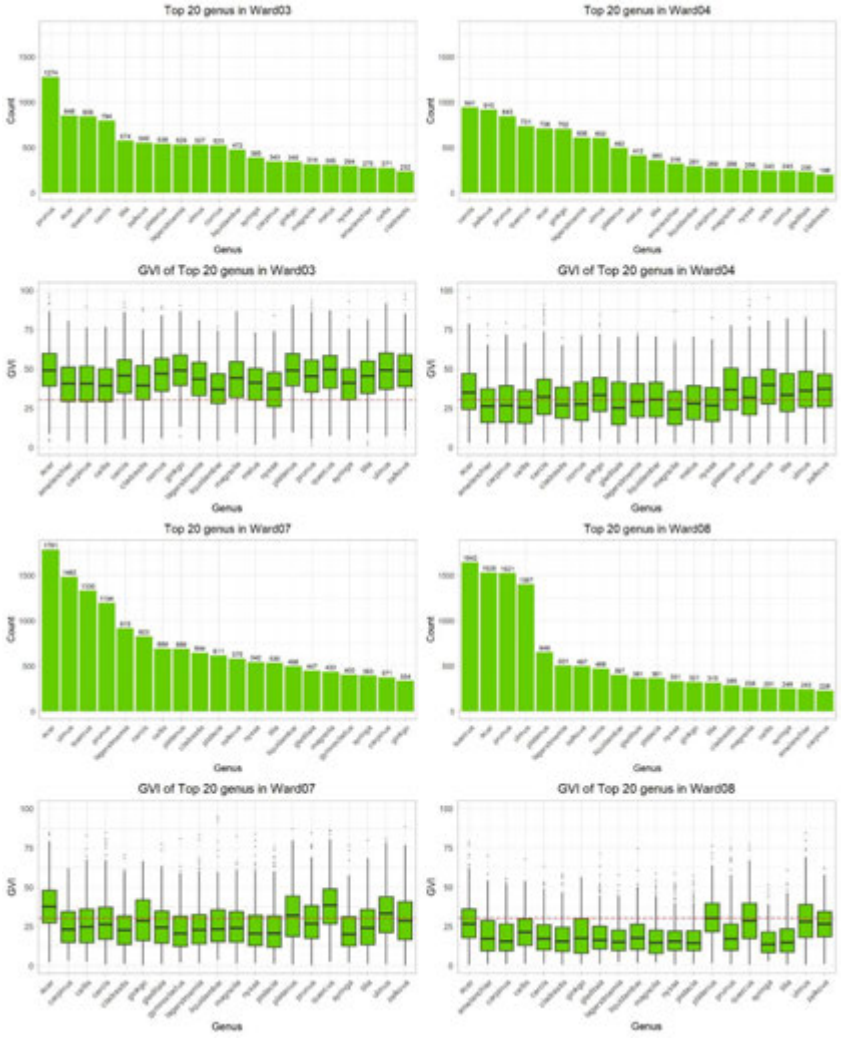

Fig.9 The tree genus distribution and GVI by genus in Wards 3, 4, 7 and 8

Tab.2 The subtle gaps between cooling effect of different dominated genera

Ward	Ranking	Genus	Number	Correlation coefficient (All p < 2.2e-16)	Cooling effect
Ward 3	1	Prunus	1,274	-0.52	High
	2	Acer	848	-0.43	Low
	3	Quercus	838	-0.46	Medium
	4	Cercis	794	-0.49	High
Ward 4	1	Cercis	941	-0.49	High
	2	Zelkova	915	-0.50	High

Ward 7	3	Prunus	843	-0.52	High
	1	Acer	1,781	-0.43	Low
	2	Ulmus	1,482	-0.40	Low
	3	Quercus	1,330	-0.46	Medium
	4	Prunus	1,194	-0.52	High
Ward 8	1	Quercus	1,642	-0.46	Medium
	2	Acer	1,528	-0.43	Low
	3	Prunus	1,528	-0.52	High
	4	Ulmus	1,397	-0.40	Low

4.3 Greenery distribution disparity in residential zones and affordable housing surroundings

The GVI also varies across each different sub-zoning areas. The mean GVI distribution in 3 residential and 22 sub-zoning areas (Appendix) is shown in Fig.10. In general, the mean GVI in the Residential Zone (RZ) is higher than that in the Residential Apartment Zone (RAZ) and Residential Flat Zone (RFZ). The R-1A zone has the highest mean GVI at around 42.5, the RA-1 zone has the lowest mean GVI at around 25. In local perspectives, the opposite mean distribution appears within RZ and RAZ. In RZ, with the increase of housing density, the zoning type transfers from R-1A to R-1B, R-2, and R-3, the mean GVI presented an obvious decrease from around 42.5 to 26, which indicated the normal relationship between land use and urban greenery. All R-1A and variations showed high mean GVI around or above 40, and small deviation from the mean values, the cliffs between R-1A and R-2 or R-3 are distinct.

However, the denser the residential zoning type within RAZ, the higher mean GVI values show out. For example, the RA-4 which provides for areas developed with predominantly medium- to high-density residential has the highest mean GVI of around 37, while the RA-1 which permits low- to moderate-density development, including detached dwellings, rowhouses, and low-rise apartments has the lowest mean GVI around 25. In addition, the mean GVI of RF-1 which belongs to RFZ is neither high nor low, which is around 28.

The distribution difference simultaneously revealed the inequality of residential land use. Zoning types with high mean GVI are mostly located in *'Local North'* Wards 3 and 4, while low mean GVI zoning areas are concentrated in Wards 7 and 8. Wards 7 and 8 have 31 and 26 RA-1 zones (the lowest GVI zoning), in comparison, Wards 3 and 4 only have 7 and 10 RA-1 zones respectively. As for RA-1 zones (the highest GVI zoning), Wards 3 and 4 have 7 and 3 respectively, and Wards 7 and 8 do not have such kind of zoning.

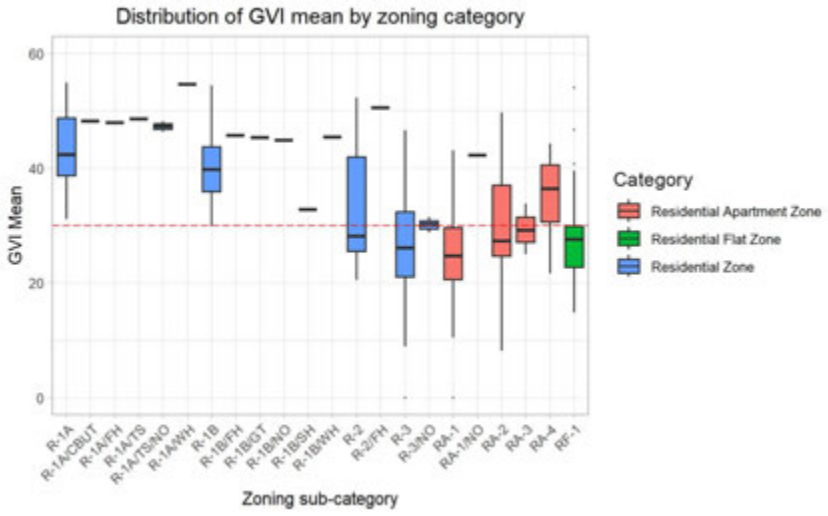

Fig.10 The temperature mitigation effects of GVI, NDVI and GVI-3D

We found that 98 affordable housing projects in different wards and zoning also presented disparity (Tab.3). Due to the wealth of Ward 3, only one HPTF affordable housing project was built between 2010 and 2022, which is Woodley House. Wards 4, 7, and 8 have 38, 32, and 27 affordable housing projects built in during 13 years. The mean GVI of all affordable housing projects is 27.2, which is quite as low as the mean GVI in R-3 zoning. The only project in Ward 3 has a mean GVI of 43.51, the mean GVI of projects in Ward 4 is 31.1, far higher than the projects with the highest GVI of 30.96 and in Wards 7 and 28.24. The average GVI of affordable housing projects in Wards 7 and 8 are only 25.9 and 22.6, indicating the huge gaps between affordable housing projects in different Wards. What's more, the affordable housing project with the highest GVI in Ward 7 is located in Mixed-Use Zones where the commercial and institutional use are prior, the multi-family residential development are secondary residential zoning areas (Appendices).

Tab.3 500-meter buffer GVI differences by HPTF housing projects

Ward	Project name	Zoning	GVI	
			Attribute	Value
Ward 3	Woodley House	RA-2	Only value	43.51
Ward 4	NCCLT-905 R St. NW	R-1A	Highest value	40.20
Ward 7	1847-49 Good Hope Road, SE	MU-7B	Highest value	30.96
Ward 8	Stanton Square Apartments	R-3	Highest value	28.24

5 Discussion

This study contributes to the validation of environmental injustice issues and significant temperature mitigation effects measured by GVI and GVI-3D. Taking Washington, D.C. as an example, we found that the greenery environment inequality, from macro-level to micro-level, extensively existed in the *'Local North'* and *'Local South'* with serious wealth polarisation, which reveals the infrastructure property attributes of street-level vegetation. GVI and LST are highly correlated, the new index GVI-3D presented a higher correlation with LST, with the increase of these two indices, the street-level space becomes cooler around 10 to 15 degrees Fahrenheit in a linear way. GVI-3D presented a better measurement of LST mitigation, which contributed to establishing the model of a true mathematics mapping of this index to canopy volume in physical urban space. As for the good measurability, we believed that the side views of street greenery images provide more possibilities to measure the actual volume of tree canopies which are the main cooling source for urban street-level microenvironment.

However, the cooling effects of different tree genera differs, some dominant genus has better temperature mitigation effects such as Prunus, Cercis, and Zelkova, while Acer and Ulmus show low mitigation effects. These subtle differences are difficult to spot, and even their cooling effect may be budget-related because we found that affluent wards tend to have more high cooling effect trees compared with non-affluent wards at the local level.

The GVI values also connect with land use type and housing density. The higher the density of detached or semi-detached Residential Zoning, the lower the GVI was found in those areas. In contrast, the higher the density of Residential Apartment Zoning, we get the higher GVI. This may be explained by the degree of intensive utilisation of land that needs to reach a certain value before it can function well. Unlike the average greenery environments of residential areas, the greenery environments of affordable housing were worse measured by GVI. Despite increased greenery is common sense that can mitigate the heat exposure risks, they also mean government or developers need balance investment and budget for targeted neighbourhoods. As for affordable housing, they usually have less accessibility to parks, forests and gardens, thus the urban street greenery becomes the limited or only green environment that affordable housing can directly benefit from so as to decrease heat exposure risks. Therefore, the significance of urban street greenery and its metrics should be addressed.

Some limitations should be addressed. First, despite the accuracy of a similar semantic segmentation model being around 85 percent according to prior research (Ki & Lee, 2021; Li et al., 2019; Zhao et al., 2017), changing the detection image dataset from European based cities to American cities can have an influence on the accuracy of the algorithm. As for the temperature mitigation effect, we only consider the single variable of urban greenery, more variables can be included such as Impervious Surface Area (ISA) (Yuan & Bauer, 2007; Imhoff et al., 2010; Ziter et al., 2019). Besides, more data may give the correlation analysis and regression model better explanatory power. Despite the GVI-3D generated a fine R-squared value of 0.73, the 0.60 R-squared value of GVI still has the possibility of being improved.

6 Conclusion and policy proposals

In conclusion, GVI has virtually the same explanatory power as NDVI when it comes to the LST mitigation effect, while GVI-3D has the best. This study argues that it is of practical significance to monitor GVI and GVI-3D rather than NDVI of small-scale street environments due to their readability, controllability, and human-centric attributes. It is feasible to adjust GVI by controlling the size, quantity, and density of street greenery, a 60 percent GVI can be a cut-off for urban greening work to prevent excessively large tree canopies concerning their cooling effects. However, large-scale NDVI measurements make it difficult to contribute to improved policy suggestions for street greening. The related housing and greenery policies can have improvements as follows.

6.1 Focus on greenery quality rather than only quantity

According to Fang (2024), 'DC's greenery-related government departments already made huge efforts to plant trees in non-affluent areas such as Wards 7 and 8', their achievements can be reflected in the number of tree/vegetation image points mentioned above. However, greenery quality is more essential indicated by GVI and GVI-3D in this study. Through measuring GVI, it is easy to find that vegetation proportion over 60 percent can't produce a substantial cooling effect. Therefore, more emphasis and resources can be invested in the improvements of quality of the greenery environment such as the balance of tree genus and the volume of tree canopies so that we can pursue better temperature mitigation effects by quantifying GVI or GVI-3D. Those resources to manage excessively huge tree canopies can be transferred to 'Local South' areas by managing the life cycle of the trees.

6.2 Highlight the greenery environment of affordable housing projects

The locations of HPTF affordable housing projects are precise. Ward 3 only built one affordable housing during 13 years. However, the gaps between this only one project and the others were huge. A suitable greenery environment for housing has the significant impact on the health of residents (Hanzl & Rembeza., 2022; Kuchcik et al., 2016), housing values (Zhang & Dong., 2018; Ye et al., 2019), and environmental justice (Schmid & Säumel., 2021; Xiao et al., 2021). The affordable housing projects have the necessitates to set aside a part of the budget and resources for the improvement of the surrounding green environment in terms of tree genus and volume. The density of affordable housing projects can be improved from the evidence that higher density Residential Apartment Zone tends to have better greenery environment measured by GVI. In addition, the assessment of the difference between affordable housing projects and normal housing projects is necessary.

Appendices

Tab.4 The description of residential zoning categories in Washington, D.C.

Zoning	Sub-Category	Description
Residential Apartment Zone	RA-1	The RA-1 zone provides for areas predominantly developed with low- to moderate-density development, including detached dwellings, rowhouses, and low-rise apartments.
	RA-2	The RA-2/RC zone is intended to provide for areas developed with predominantly moderate- and medium-density rowhouses and apartments.
	RA-3	The RA-3 zone provides for areas developed with predominantly medium-density residential.

	RA-4	The RA-4 zone provides for areas developed with predominantly medium- to high-density residential.
	RA-1/NO	The RA-1/NO zone provides for areas predominantly developed with low- to moderate-density development, including detached dwellings, rowhouses, and low-rise apartments in the vicinity of the U.S. Naval Observatory.
Residential Flat Zone	RF-1	The RF-1 zone is to provide for areas predominantly developed with row houses on small lots within which no more than two (2) dwelling units are permitted.
	R-1A	The R-1A zone is intended to provide areas predominantly developed with detached houses on large lots.
	R-1A/CBUT R-1A/FH R-1A/TS R-1A/TS/NO R-1A/WH	All R-1A variations permit detached houses on large lots. They also have the purpose to protect specific areas' low density, natural topography, historic or ceremonial importance, or special missions, including Chain Bridge Road/University Terrace, Forest Hills, Tree and Slope Protection zones, Naval Observatory/Tree and Slope Protection zones and Wesley Heights.
	R-1B	The R-1B zone is intended to provide areas predominantly developed with detached houses on moderately sized lots.
Residential Zone	R-1B/FH R-1B/GT R-1B/NO R-1B/SH R-1B/WH	All R-1B variations permit detached houses on moderately-sized lots. They also have the purpose to protect specific areas' low density, natural topography, historic or ceremonial importance, or special missions, including Forest Hills, Georgetown National Historic Landmark District, Naval Observatory, Sixteenth Street Heights and Wesley Heights.
	R-2	The R-2 zone is intended to provide for areas predominantly developed with semi-detached houses on moderately sized lots that also contain some detached dwellings.
	R-2/FH	The purposes of the R-2/FH zone are to preserve the natural topography and mature trees to the maximum extent feasible in the Forest Hills neighbourhoods, which permit semi-detached houses on moderately sized lots that also contain some detached dwellings.
	R-3	The purpose of the R-3 zone is to allow for row dwellings, while including areas within which row dwellings are mingled with detached dwellings, semi-detached dwellings, and groups of three or more row dwellings.
Mixed-Use (MU) Zones	MU-7B	The MU-7B zone is intended to permit medium-density mixed-use development with a focus on employment.

Research on spatial optimization strategies of rural settlements in the Loess Plateau from the perspective of disaster prevention and reduction—A case study of Gaoxigou Village,China

Ruonan Jia, Zuobin Wu
Xi'an University of Architecture and Technology
930423661@qq.com

Abstract: The Loess Plateau is one of the regions with the most serious soil erosion and the most fragile ecological environment in the world. In recent years, the fragile rural settlement space is increasingly challenged by extreme weather, and various natural disasters occur frequently.Therefore, exploring spatial optimization strategies for rural settlements in this area from the perspective of disaster prevention and reduction is of great significance to ensuring the safety of residents and achieving sustainable development of rural settlements.Based on the results of natural disaster risk assessment in Gaoxigou Village, this paper analyzes the coupling relationship between different risk areas and various types of current village Spaces, and puts forward spatial optimization strategies from living space, ecological space and road space.

Keywords: Loess Plateau, rural settlement, spatial optimization

Introduction

In recent years, affected by factors such as global climate change and some human behaviors, urban and rural spaces have faced increasingly unstable threats of natural disasters. According to statistics from the United Nations Office for Disaster Risk Reduction, between 2000 and 2019, a total of 7,348 natural disasters were recorded around the world, causing 1.23 million deaths, a total of 4 billion affected people, and causing global economic losses of up to $2.97 trillion.In the urban and rural space, rural areas have the closest contact with the ecological environment and are therefore disaster-prone areas. However, at the same time, rural areas are the weakest areas in disaster prevention, reduction and relief, and their level of natural disaster prevention and control is relatively low. Therefore, studying the optimization of rural settlement space from the perspective of disaster prevention and reduction is of great significance for promoting rural safety development.

At present, the existing relevant research on disaster prevention and reduction is a

combination of disaster systematics, economics and sociology. Through the research on the formation mechanism, occurrence mechanism, damage characteristics and disaster characteristics of various disasters, it combines social disciplines and population , social environment, economy, resources, etc., and for the purpose of disaster prevention and reduction, relevant technologies, measures and policy methods for disaster prevention and reduction are proposed.Scira Menoni evaluated the urban lifeline system from three aspects: organizational, physical and functional vulnerability, and proposed comprehensive planning and improvement of disaster prevention and reduction based on geospatial technology[1].Grange Ken quantitatively analyzes the influencing factors of snowstorm disasters from basic data, construction, material supply and community safety data, and studies ways to improve disaster prevention and reduction capabilities from the perspective of factors[2].Chi Tenglong, Zeng Jian, and Wang Sitong combined the actual conditions of the villages and took Zhujiaying Village in Fuping County as the research object. They analyzed the social, economic, natural and other development conditions of the village through data obtained from field surveys, identified development bottlenecks and safety hazards, and formulated Corresponding industry, site selection and village transformation strategies[3]. However, existing research currently lacks research on resisting and reducing disaster risks through spatial adjustment of potential disaster risks.

The Loess Plateau is a typical ecologically fragile area in my country, with criss-crossing ravines, broken surface, loose soil, and serious water and soil erosion. The depth of the channels in the area is 100-300m, and the average erosion intensity is about 10,000-25,000 tons/square kilometer per year, making the local ecological environment extremely fragile[4]. Under the influence of long-term natural conditions of strong winds, drought and little rain, rapid rainy seasons, and unreasonable utilization, rural settlements in the Loess Plateau face high ecological threats and frequent natural disasters. Therefore, conducting research on the optimization strategies of rural settlement space in this region from the perspective of disaster prevention and reduction has strong practical significance in guiding the optimization of rural space in this region, improving the ability to withstand disaster risks, and achieving sustainable rural development.

1. Reflection on practical issues in rural settlements on the Loess Plateau

The Loess Plateau is located in the northern part of central China, spanning seven provinces and regions: Qinghai, Gansu, Ningxia, Inner Mongolia, Shaanxi, Shanxi, and Henan. It has an altitude of 800 to 3,000 meters and a total area of 640,000 square kilometers.The Loess Plateau is a highly ecologically sensitive area and one of the areas with the most severe soil erosion in the world. It is soil erosion area reaches 230,000 square kilometers, accounting for thirty-four percent(34%) of the Loess Plateau's land area. In addition, the area has been severely eroded by running water for a long time, gradually forming a special natural landscape with thousands of ravines and fragmented terrain. The ravine density is about 2.35-10.9km/km^2. It has typical loess collapsible

geological characteristics and various natural disasters occur frequently. With the continuous advancement of urbanization, urban and rural construction space has further expanded. In addition, this area is an important energy base in China and the area with the greatest coal production potential. Its rich mineral and tourism resources have further promoted the industrial, mining and cultural tourism industries in the area. These reasons have increased the human disturbance of the originally fragile ecological environment.

In recent years, as the global precipitation line gradually moves northward, rainfall continues to increase, and rainfall changes significantly in space and time. In addition, regional instantaneous rainfall in summer is relatively large, which has led to a significant increase in local natural disaster risks. Rural areas are disaster-prone areas, and they are the weakest link in disaster prevention, reduction, and relief. With the continuous advancement of urbanization and the rapid changes in village production and lifestyle, ecologically fragile rural settlements are facing more severe disasters. As a result, rural settlements on the Loess Plateau will face greater disaster threats in the future. Therefore, how to deal with the impacts of fragile ecological background, increased human disturbance, and intensified climate change and minimize disaster risks has become the biggest practical problem facing rural areas on the Loess Plateau.

2. Optimization path of rural settlement space in the Loess Plateau from the perspective of disaster prevention and reduction

Climate change and the original fragile background conditions have caused local rural settlement space to face a high degree of threat. First, local disaster risks were assessed based on factors such as slope, slope aspect, slope type, rock formation, and disaster development density. Then, based on the risk assessment results, a rural space optimization strategy is proposed to reduce the impact of disasters from three aspects: ensuring residential safety, enhancing ecological service functions, and improving road emergency capabilities.

First of all, in terms of residential safety, by identifying areas where medium and high risk areas conflict with the current living space, the layout of the living space is adjusted to avoid medium and high risk areas, and at the same time, hidden danger points of residential disasters are rectified to ensure the safety of residents.Secondly, in terms of ecological space, through coupling analysis of the current ecological space and different disaster risk levels, the functions of ecological space are re-adjusted, and through potential ecological hydrological analysis, the breaking points of ecological space are repaired and the overall service function of rural ecological space is improved.Finally, in terms of road space, the medium and high-risk areas of the existing roads will be renovated, and the road system will be reorganized to improve the emergency disaster relief capabilities of the roads.

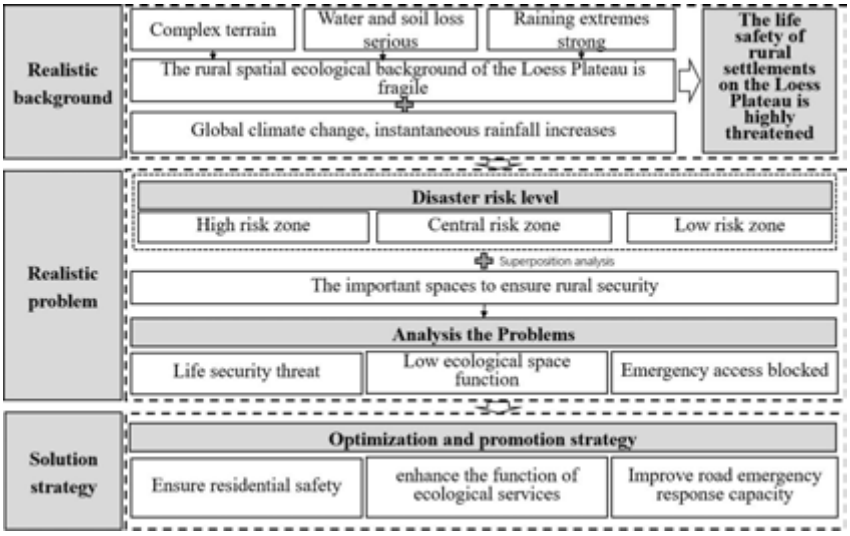

Fig. 1 Rural settlement optimization path

3. An empirical case of spatial optimization in Gaoxigou Village from the perspective of disaster prevention and reduction

3.1 Overview of research objects

Gaoxigou Village is a typical Loess Plateau area located in Mizhi County, Yulin City, Shaanxi Province, China, with a total area of 406.93 hectares. There are 40 mountains in the village. The terrain in the village is undulating and fragmented. The density of ravines is about 5-7 kilometers per square kilometer, and the depth of the gullies is between 100-200 meters. In recent years, with the increase in rainfall, geological disasters such as landslides and collapses have occurred frequently, posing a high threat to the safety of residents' production and life.

Based on the data from the Xi'an Geological Survey Center of the Bureau of Geological Survey, combined with factors such as slope, slope aspect, slope type, rock group, and disaster development density, the Gaoxigou disaster risk area and level were comprehensively evaluated. The evaluation results show that the village area with high disaster risk covers an area of 19.41 hectares, accounting for four point eight percent(4.8%)of the study area. It is mainly distributed on both sides of the ditch, close to the bottom of the ditch, and distributed in a dendritic shape;the medium-risk area is 51.65 hectares, accounting for twelve point six nine percent(12.69%) of the study area, mostly adjacent to high-risk areas and distributed on the slopes on both sides of the ditch; the low-risk area is 335.87 hectares, accounting for eighty-two point five one percent(82.51%) of the study area, and is widely distributed, mainly in areas with gentle slopes within the village.

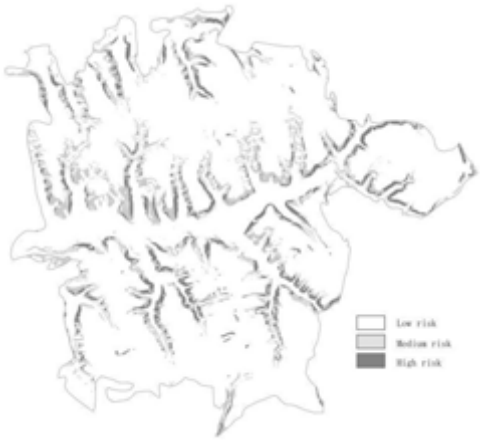

Fig. 2 Disaster risk zoning in Gaoxigou Village

3.2 Analysis of real problems

3.2.1 Lack of planning for living space and high threat to life safety

The risk assessment results were superimposed on the current construction space to identify residential space and medium-risk and high-risk conflict areas.Among them, 15 high-risk residences are located on the north side of the village, 5 of which are located in the main channel of the village, and the remaining 10 are located in the village.There are 27 medium-risk houses in the branch ditch, 2 are located on the north side of the main ditch, 10 are located in the branch ditch on the south side of the village, and 15 are scattered in the north side ditch.

In addition, after on-site investigation, it was found that although some residential spaces are not in medium-risk or high-risk areas for geological disasters, due to the special loess type and the cutting of slopes for building houses, some residences still have disaster hazards.Through household surveys, it was found that 8 houses in the village located in low-risk areas in the branch ditches on the north and south sides of the village still have potential disaster safety risks.

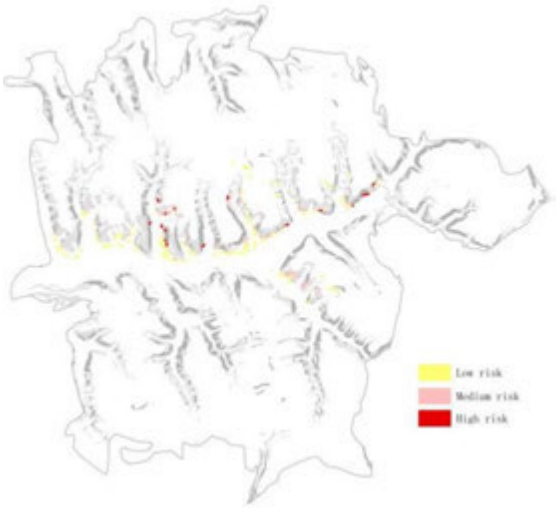

Fig 3. Construction disaster risk level

Fig 4. Hidden danger points of construction disasters in low-risk areas

3.2.2 The ecological environment is fragile and the functional efficiency of ecological space is low

The woodland, grassland, pond water surface, and inland tidal flats within the village area were extracted as ecological land, with an ecological land area of 217 hectares.Superimposing disaster risk zoning and ecological space, the coupling area of high-risk areas and current ecological space is 16.30 hectares, with a coupling degree of approximately eighty-four percent(84%), the coupling area of medium-risk areas with ecological space is 33.05 hectares, and the coupling degree is approximately sixty-four percent(64%).The degree of coupling between medium and high risk areas and the current ecological space is at a medium level.This shows that the coupling relationship

between ecological space and disaster risk in this region is fragile, and it is necessary to further improve its coupling degree and disaster resilience through ecological space adjustment.

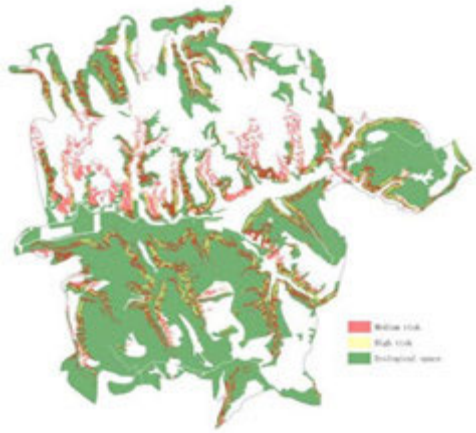

Fig 5. Coupling situation of ecological space and medium- and high-risk disasters

In addition, the local ravines are criss-crossed and the instantaneous rainfall is large. Therefore, the gully space assumes the drainage function during the rainy season and is a potential hydrological space.Through GIS spatial analysis, this paper extracts the hydrological space of three levels in Gaoxigou and compares the ecological space with the hydrological space.Superimposing ecological space and hydrological space, it was found that there are fractures in the existing three-level hydrological space. Among them, the length of the first-level hydrological space is about 3.04km, the length of the second-level hydrological space is about 2.93km, and The length of the third-level hydrological space fault is approximately 1.93km.

Fig 6. Current status of hydrological spatial distribution and systematics

Fig 7. Current status of hydrological space fractures

3.2.3 Road space is not smooth and emergency and disaster relief capabilities are

insufficient

Through the overlay analysis of the existing roads and disaster risk areas in the village, it was found that the existing roads do not have high-risk hidden dangers, but there are moderate-risk hidden dangers in disasters, with the risk area being about 0.39 hectares.In addition, the road space on the Loess Plateau serves as an important lifeline and plays an important emergency rescue function.However, there are many dead-ends roads and the road network cannot meet the needs of emergency rescue.

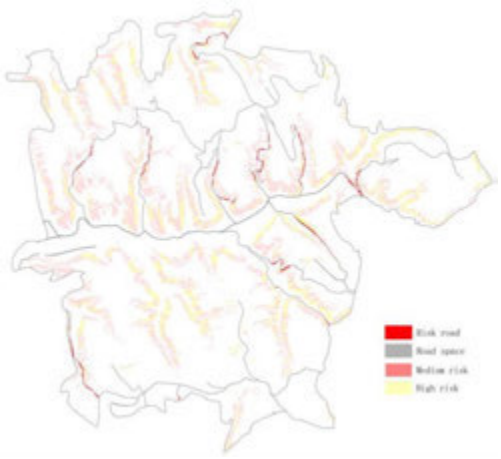

Fig 8. Road disaster risk levels and distribution

4. Space optimization strategy of Gaoxigou Village from the perspective of disaster prevention and reduction

4.1Ensure residential safety

Based on the overlay analysis of residential space and risk areas, the buildings located in high-risk areas are relocated and set aside. Corresponding safety precautions should be taken for areas that are temporarily unavailable to move out, and construction and expansion should be strictly controlled to cause the area to shrink, and ecological restoration should be carried out to gradually restore it to an ecological space.For buildings located in medium-risk areas, ecological retreat can be adopted. On the premise of ensuring safety, the ecological space can be gradually returned by changing the use of the building. For example, it can be used as agricultural housing in the early stage, and the ecological space can be gradually returned to the ecological space as time goes by.

Fig 9. The building layout adjustment

Tab1. Construction risk control measures

Risk source number	Suggestions on risk management and control measures
1	Conduct regular inspections, strengthen monitoring
2	Conduct regular inspections, Clear dangerous rock mass
3	Conduct regular inspections, strengthen monitoring, surface drainage
4	Conduct regular inspections and strengthen monitoring
5	Conduct regular inspections, strengthen monitoring, surface drainage
6	Conduct regular inspections, strengthen monitoring, surface drainage
7	Conduct regular inspections, strengthen monitoring, surface drainage
8	Conduct regular inspections, strengthen monitoring, Clear dangerous rock mass, surface drainage

4.2 Enhance ecological service functions

Based on the risk assessment results, the functions of the existing ecological space should be rearranged. For ecological spaces located in high-risk disaster areas, priority should be given to protecting and maintaining the integrity and functionality of the ecosystem.A strict ecological protection system should be implemented, and any form of farming and construction activities should be strictly prohibited and implement enhanced management measures. For ecological spaces located in medium-risk areas,

ecological spaces for productive restoration can be set up. During the development process, terraces can be constructed to effectively reduce the speed and amount of rainwater runoff, and some fruit tree varieties with better soil-fixing capabilities can be selected to grow. At the same time, some fruit tree varieties with better soil-fixing capabilities can be chosen to plant. This can reduce soil erosion while increasing the scale of agricultural production land. For ecological spaces located in low-risk areas, without destroying their ecological integrity, by combining them with local natural and ecological values, they should appropriately incorporate sightseeing, recreation and other functions, which not only ensures that the ecological environment is effectively protected and restored, but also Significantly improve residents' quality of life.

In view of the actual situation of ecological fracture points, ecological land restoration is required for the fracture areas of the primary hydrological space, and strict ecological priority policies should be implemented. At the same time, the buildings already constructed in the fracture areas should be demolished, and the current production land in the fracture areas should be returned to forest and grassland to ensure the continuity of the primary hydrological space and ecological security.

4.3 Improving road emergency response capabilities

Combined with the results of road risk identification, for road spaces located in medium-risk areas, it is necessary to comprehensively consider the actual road conditions, select appropriate protection measures, prevent the occurrence of disasters such as landslides and collapses, and deal with potential risks in a timely manner to ensure smooth and safe roads.First of all, these road disaster risk types are mainly landslides and collapses. According to the disaster types, the stability of road slopes can be strengthened by using slope protection forms such as mortar-laid stone, mesh shotcrete, and mesh sprayed ecological technology to effectively prevent disasters.At the same time, by strengthening patrol supervision, regularly checking road conditions, and promptly discovering and resolving potential hidden dangers, we can ensure that the roads are always in good condition and provide residents with a safe and smooth travel environment.

In addition, the road system within Gaoxigou Village was reorganized, dead-end roads were opened up, and a circular series road system that conforms to the terrain was adopted. This will help increase the redundancy of emergency escape routes and effectively improve the road emergency response capabilities.While providing villagers with more convenient and safer travel conditions, rescue operations can be launched more quickly when faced with emergencies, thereby improving the village's overall disaster prevention and relief capabilities and protecting the lives and property of villagers.

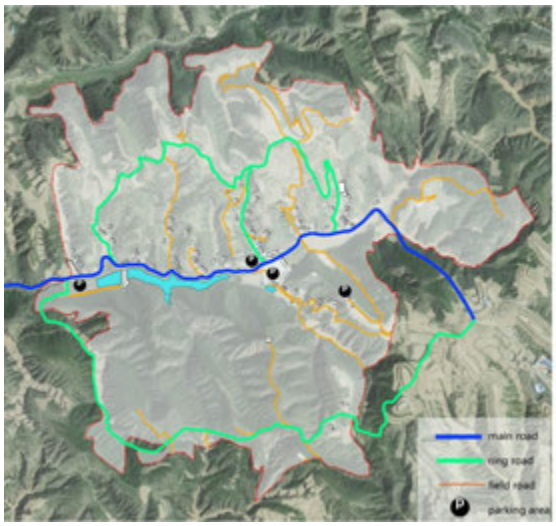

Fig 10. Reorganization of road traffic system

5. Conclusion

Combined with the results of the disaster risk assessment of Gaoxigou Village, the residential space, ecological space and road space in the village were coupled and superimposed, and it was found that there were real problems such as hidden dangers to residential safety, broken ecological space, and insufficient road emergency support capacity in the village.In response to practical problems, a village optimization strategy is proposed to ensure residential safety, enhance ecological service functions and improve road emergency response capabilities, thereby reducing local disaster risk threats and effectively ensuring the safety of residents. Overall, this idea is highly applicable to rural settlements in the Loess Plateau where the ecological background is fragile.

He is chairman of IFAMA Europe (2021-2024) and member of the board of directors of IFAMA. His current research aims to deepen the understanding of governance in organizations, networks and territories in the perspective of sustainable transitions and transformations. Research profile at CV HAL .

Abstract

The spatial expansion of cities results in the loss of natural resources. It is therefore crucial to maintain ecological performance by balancing the land used for human purposes with efforts to restore or protect natural habitats. Here, we investigate how to transform brownfields into multifunctional urban green infrastructure. We use a GIS-based multi-criteria evaluation model to prioritise the brownfields in Rouen metropolis. We show that (1) the integration of site suitability and urban ecological demand is required, (2) Coupling Coordination Degree serves as an appropriate model for determining the interaction and coordination of site suitability and urban ecological demand.

Keywords Brownfield, Urban Green Infrastructure, Site Suitability Analysis, Multifunctionality, Spatial Planning

1. Introduction

Promoting reasonable land development while reducing land use challenges is a fundamental component of sustainable development (Wei & Ewing, 2018). The EU declared its policy of No Net Land Take by 2050, which France adopted in its national law with the policy “Zéro Artificialisation Nette” to encourage the reuse of developed lands (Science for Environment Policy, 2016). To follow these policies, the brownfields need to be redeveloped and given new life (Loures, 2015). It is recognised that brownfield redevelopment could bring a range of environmental, economic and social benefits (Wang et al., 2011). The integration of green infrastructure in brownfields, presents an attractive nature-based solution for addressing environmental concerns at brownfields (Hou et al., 2023). But is there a practical tool to prioritise brownfields for transformation into multifunctional urban green infrastructure? This question becomes crucial as costs involved in brownfield redevelopment can be significant (Bacot & O’Dell, 2006) and to avoid random allocation. We therefore investigated a GIS-based multi-criteria model to calculate the coupling coordination degree between site suitability and urban ecological demands. We demonstrated that 15 high priority brownfields exhibited a significant coupling coordinate degree and matching relationship to develop green infrastructure. This approach can be used as part of a spatial planning process, applicable to any city that faces similar problems. It provides support to identify suitable areas for green infrastructure expansion.

2. Methodology

The Green infrastructure decision-support tool derived from (Feng et al., 2023) is implemented in three phases. During the first phase, site suitability analysis of each brownfield assessed with seven criteria. In the second phase urban ecological demands was considered that could be addressed through green infrastructure planning. Finally, the coupling coordination model is used followed by an analysis of their matching degree through quadrant division.

The study is conducted in the Rouen metropolis, Normandie region, France, which covers approximately 663.8 km2 and includes 71 municipalities *(Figure 1).* Located in the south of the Seine-Maritime department, the area had a total population of 496,629 inhabitants at the end of 2020. The distribution of brownfields within the metropolis aligns with the location of the rivers and valleys, with a few brownfields existing in the plateaus. Specifically, the municipalities situated on the left bank of the Seine, such as Oissel, Rouen (left bank), and Petite and Grand Quevilly, contain a large number

of brownfields, while several brownfields are also present in the municipalities surrounding the Cailly river. In the latest Cartofriches dataset, within the Rouen metropolis, a total of 416 sites have been identified as brownfields.

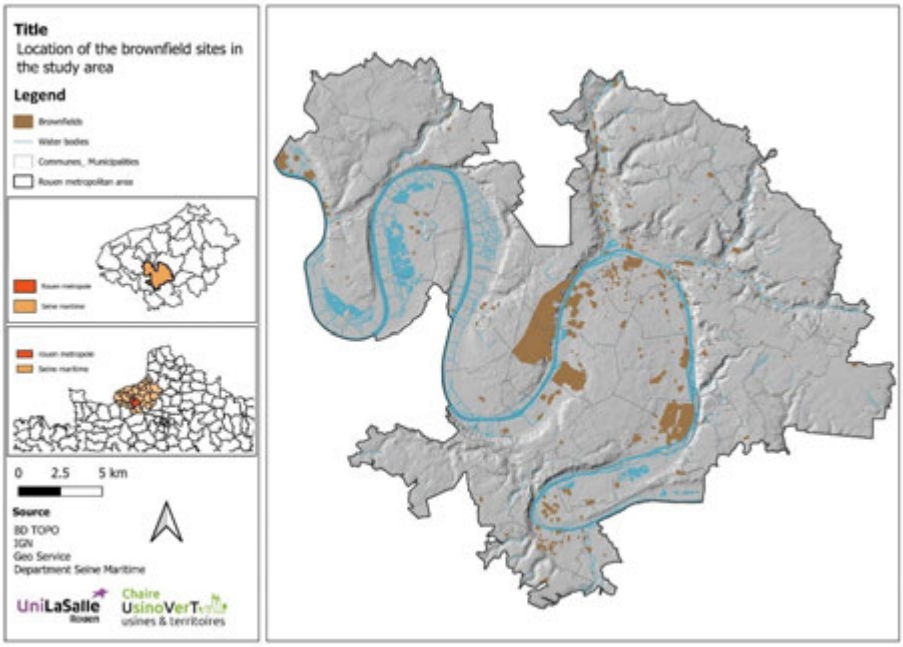

Figure 1: Map of the brownfields' location (Source: Done by the author)

For the site suitability analysis, we developed an index system with seven criteria comprising area, slope, NDVI, suitability of construction land, proximity to green area, proximity to settlement area, and soil contamination. Following this, we examined the attributes of each criteria based on literature and established a rating system. Then we determined the weights for each criteria through pairwise comparisons using the Analytic Hierarchy Process (AHP). For multifunctional green infrastructure planning, four indicators have been selected, including flooding risk, high land surface temperature, habitat fragmentation and air pollution. The urban demand values of brownfields were calculated by the zonal statistical tool in QGIS, which were then divided into five levels using the natural breakpoint method (Figure 2). Then, we calculated the weight of each index with AHP. To establish the coupling coordination degree model, the calculation was done with:

$$C = \frac{\sqrt{S \times D}}{(S + D)}$$

$$T = \alpha \times S + \beta \times D$$

$$CCD = \sqrt{C \times T}$$

S: Site suitability value
D: Comprehensive demand value
C: Coupling degree
T: Comprehensive coordination index
CCD: Coupling coordination degree
(α = β = 0.5)

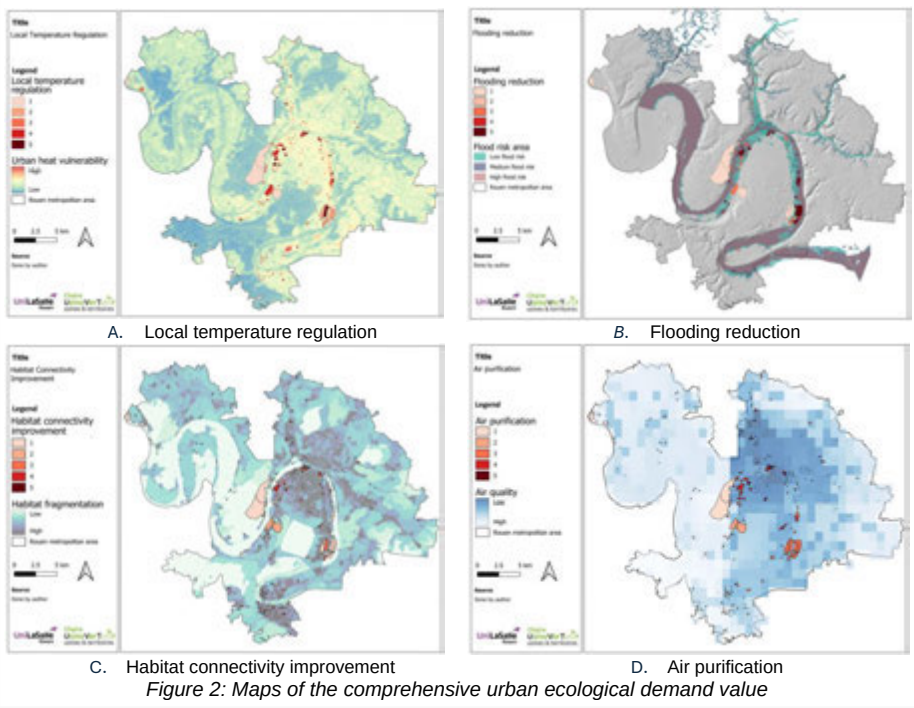

Figure 2: Maps of the comprehensive urban ecological demand value

Furthermore, quadrant division is being used to assess the position of points which represents site suitability and urban demands within a coordinate system. Lastly, we identified the brownfields with coupling coordination degree value greater than or equal to 0.85, and located in either quadrant “high demand–high suitability” or quadrant “high demand–low suitability”.

3. Results

Site suitability analysis was carried out for brownfields. The suitability values ranged from 1.64 to 4.52, while these scores varied, the general trend indicated favorable suitability overall. The analysis revealed that 115 brownfields, 36.05% of the total, had suitability values greater than 3.5. There was no clear spatial pattern of site suitability values, but brownfields located near the Seine river, specifically close to the Rouen and Elbeuf cities, tended to be more suitable for green infrastructure development. For the comprehensive urban demand value, the brownfields with values between four and five comprise 31 sites, representing 9.7% of the total number of brownfields, and there are 71 brownfields with values between three and four, representing 22.2% of the total. The coupling coordination between site suitability and urban demand values range from 0.50 to 0.95, indicating an almost ideal coupling relationship between them. This spatial pattern indicates a harmonious trend between the suitability of brownfields and the ecological demands of the surrounding area. Considering matching relationship (Figure 3), quadrant “high demand- high suitability” consists of 82 brownfields, with 25.86% of the overall total. Quadrant “high demand- low suitability”, hosts 69

brownfields, constituting 21.76% of the total. When considering the high-demand regions, the total count reaches 151.

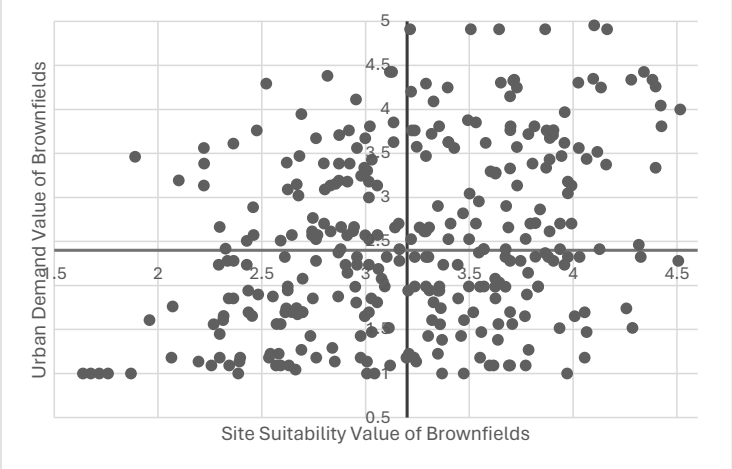

Figure 3: The matching relationship

The model shows 84 brownfields to be integrated into green infrastructure in Rouen metropolis. The brownfields with high site suitability and high urban demand values were categorized into three priority levels based on their coupling coordination degree. Specifically, 15 brownfields were identified as high-priority sites, having a CCD above 0.9. In addition, 28 sites fell into the medium priority category, with CCD values between 0.85 and 0.9, while 41 sites were classified as low priority, characterised by CCD values between 0.75 and 0.85. The spatial distribution of high priority brownfields interestingly shows an agglomeration of eight brownfields located in the Rouen city, in the industrial zone of the Rive gauche. The other priority sites do not show a clear trend but are all located within the alluvial terraces of the Seine and tributaries.

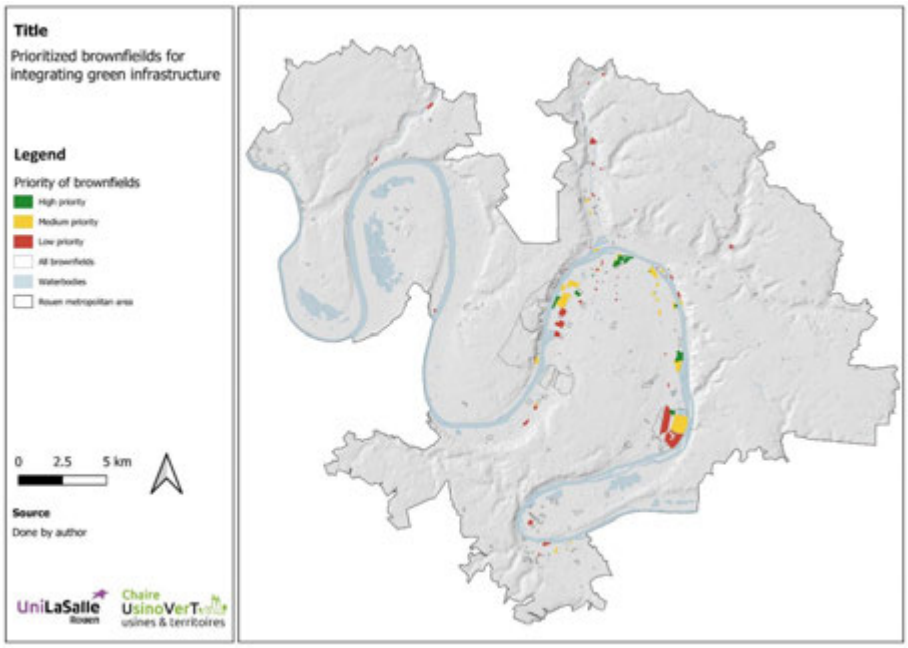

Figure 4: Map of the prioritized brownfields

4. Discussion

In the literature, previous studies have focused on either site suitability analysis or green infrastructure planning. However, the integrated outcomes present a unique perspective distinct from either the site suitability results or the findings on urban ecological demands when considered individually. Using this methodology, we can not only identify sites that are suitable for the implementation of green infrastructure based on a range of criteria such as area, slope, NDVI, etc., but also highlight sites that need intervention to meet multifunctional ecological demands of the area. The emphasis on multifunctionality represents a departure from the conventional approach observed in many previous studies, and potentially unlocks a wider range of benefits that green infrastructure can provide.

High priority brownfield sites are concentrated within the cities of Oissel, Saint-Étienne-du-Rouvray, Sotteville-lès-Rouen, Rouen (left bank), Le Petit-Quevilly, and Le Grand-Quevilly. Notably, all six municipalities out of a total of 71 are situated in close proximity to each other, south of one of the Seine river loops. While the medium and low-priority brownfields are more distributed, a significant portion of them are also concentrated in the same cities. Brownfields are all situated in close proximity to the rivers Le Seine, Le Cailly, and L'Austreberthe. They represent locations where green development is needed to complete the network of natural and semi-natural areas.

The Coupling Coordination Degree Model is a widely used method in environmental studies to determine the interaction and coordinated evolution of different systems, particularly in the Chinese literature. Numerous scientific papers have used the CCDM

to integrate complex systems across a range of disciplines, demonstrating its versatility and applicability (T. Li et al., 2022; Y. Li et al., 2012; Shi et al., 2020; Tang, 2015; Xing et al., 2019) . Despite its widespread use and high citation rate in the Chinese literature, this methodology has not penetrated the academic literature of other countries to any significant extent. Our study sheds light on the effectiveness of the CCDM by demonstrating its utility in analysing the complex relationship between site suitability and urban ecological demands.

This tool is a basis for decision-makers to explore and evaluate options and to conduct different scenarios that can easily be assessed by planners and developers at the beginning of the planning process.

On the one hand, there is a need to explore the application of the model in different regions, especially in different urban settings. On the other hand, it is necessary to collect socio-economic data in order to assess the sustainability of the interaction between brownfield regeneration and the development of multifunctional green infrastructure.

5. Conclusion

In this study, we propose a model to guide practitioners and researchers in identifying and prioritising brownfields suitable for transformation into green infrastructure. The proposed methodology has been developed by overlaying seven site attributes, with ecological demand considerations. Through the application of the coupling coordination degree model and quadrant division, the most suitable brownfields for transformation into green infrastructure have been identified. A total of 84 brownfields were selected for integration into green infrastructure within the Rouen metropolis. Among these, 15 brownfields were designated as high-priority sites, while 28 sites were categorized as medium priority, and 41 sites as low priority.

Abstract:

The European Green Deal's ambition for climate neutrality by 2050 necessitates robust action at all levels of governance. This paper examines the intersection of climate planning and transport actions in European cities, emphasizing the critical role of local authorities in driving sustainable urban development. Drawing on data from 50 European climate plans, the analysis reveals geographical disparities in climate planning efforts. Methodological variations in climate planning approaches are identified, alongside gaps in linking actions to emission reduction targets. Priority transport actions, categorized under the Avoid-Shift-Improve framework, highlight a focus on active mobility, electrification, and public transport enhancements. Recommendations for integrating climate and transport planning underscore the need for clearer target-setting and stakeholder engagement. Future research directions include exploring the efficacy of public participation methods and assessing planning system legitimacy. Overall, this paper contributes insights into advancing climate action agendas in European cities, crucial for achieving the objectives of the European Green Deal and fostering sustainable urban futures.

Keywords: climate plans, transport planning, strategic planning

The EU Parliament and Commission agreed to the European Green Deal in 2020 (EU, 2019), aiming to be climate-neutral by 2050. While National governments are required to develop national long-term strategies, cities and local authorities are the ones dealing with actions to decarbonise urban transport, housing, and waste at the local level.

Transport in particular plays a very important role. The global transport sector is responsible for a quarter of EU CO2 emissions, and while most sectors have started a downward trend to decarbonise, we find that in road transport this is not the case (European Environment Agency, 2022).

Since 2020, with the new net zero vision and the declaration of climate emergencies from local authorities, planning processes aimed at dealing with the emergency have surfaced (Gudde, et al., 2021). Some cities are implementing measures to try to achieve some reductions, but these are scattered, and a systems approach is needed, not only to think about the technological or

operational solutions (innovations) but also to be more democratic and include stakeholders views.

Moreover, all sectors need to be working in collaboration to achieve a net zero goal for the whole city. Therefore, at the strategic level, transport-specific planning tools such as sustainable urban mobility plans (SUMP), transport strategies, and local transport plans need to be integrated into climate plans. Such integration and the implementation of actions within the plans depend on local capabilities and resources (Lee, 2024). A interesting initiative born in Germany in the 1990's called the A-S-I approach can be used to structure policy to reduce the impact of transport on the environment. This is done through a three-pillar strategy: avoiding/reducing the need for motorized travel and trip length by improving the efficiency of the transport system as a whole, shifting/maintaining towards more environmentally friendly modes of transport to improve individual trip efficiency, and improving vehicle and fuel efficiency as well as the operational efficiency of public transport while introducing renewable energy sources (Bongardt, et al., 2019).

Some planning tools such as the Sustainable Energy and Climate Action Plans from the Covenant of Mayors, do include transport as one of their main sectors. This initiative has been growing gathering more than 7,000 local and regional authorities across 57 countries. In 2016 the 5,403 CoM signatories' overall commitment for 2020 was a reduction of the total GHG emissions of 27%, 7 percentage points above the minimum requested target of 20 %. Results from the plans monitoring reported, reveal an already achieved 23% overall reduction in emissions (Bertoldi, 2018).

In turn, the SUMP Guidelines prioritise accessibility and quality of life. Environmental quality is mentioned in the guidelines as one of several sub-goals (Rupprecht Consulting, 2019). Further, the SUMP Guidelines do not mention that the EU 2030 and 2050 climate targets are (or will soon be) legally binding for all Member States, requiring urban GHG emission reductions. Carbon emission reduction is discussed alongside other objectives of sustainable urban mobility planning, such as visioning, targets, and measure appraisal (steps 5-7 of the SUMP cycle). The lack of climate goals has been identified as one of three gaps, alongside framework conditions and enabling actions for long-term implementation and guidance on short-term measures (Smeds & Jones, 2020).

However, the planning tools mentioned above are just some of a few available to cities. They have the freedom to choose how to plan according to their ways.

In this context, we can ask ourselves:

- What are the main standards in city climate planning in European cities?
- Is transport planning considered a main topic in city climate planning?
- What are the prioritized transport actions in European cities within the context of their climate plans?

In section 2 I present the Climate Plans and Transport Actions database and explain the methodology to answer the research questions. In section 3 I present the analysis of the database and in section 4 I discuss the main findings as well as provide policy recommendations for the integration of climate and transport planning.

2. Methods

The Climate Plans and Transport Actions database is a set of Excel spreadsheets that contains information from 50 European cities' action plans. It is based on the Carbon Disclosure Project 2021 Cities Mitigation Plans database (CDP, 2022).

The CDP database has more than 1300 entries. The database was simplified by using the following criteria:

- Geographical scope: CDP region Europe
- Time scope: year of adoption of the plan: from 2020 onwards (included)
- Duplicate entries were excluded, for example iterations of plans
- Regional-level plans were excluded: to the best of our understanding only city-level (or unitary) plans were selected. Metropolitan level accounts as city level.
- Faulty entries: entries with no links or faulty links were excluded. Four exceptions to this rule were added to the database: Athens, Sofia, Ljubljana and Izmir. These entries didn't have links, however as they represented countries that were not included in the database until that moment, it was decided to look for the links and include them to enlarge the sample (14 countries and 1 city state).

The Climate Plan and Transport Actions database is a set of spreadsheets that contains data on 50 European Climate Plans approved after the EU net-zero targets. The user can search for transport actions and identify which cities are planning to apply them. Once the city/cities are identified, the user can use the third sheet to get a link to the Climate Plan, with further information about that action. The goal of the database is to help cities to identify suitable transport actions to include in their climate planning strategies.

The database is made of 3 sheets:

1. Grouped actions: this spreadsheet includes the list of aggregated transport actions from 50 European climate plans. Categories were created to aggregate similar actions from different cities. Actions are categorized using the Avoid-Shift-Improve approach. This sheet can be used to search for categories/actions and identify which city is planning to implement them.
2. Individual actions: this spreadsheet includes the full list of actions from 50 European cities' action plans without being aggregated.
3. Cities Climate Plans: this spreadsheet is based on a CDP database (CDP, 2024). The spreadsheet was completed by reviewing all Climate Plans. It includes a weblink for each plan. User cities can assess whether the actions and cities are closer to their local environment or landscape by using a city with a similar population, similar strategic planning background, level of autonomy index, etc.

The Cities Climate Plans includes columns where the assessment was done:

- LOAI: level of autonomy index: is based on a study by Heinelt (Heinelt, 2017) and the study of the University of Agder (Baldersheim, et al., 2019).The index has 11 variables: institutional depth, policy scope, effective political discretions, fiscal autonomy, financial transfer system and self-reliance, borrowing autonomy, organizational autonomy, legal protection, administrative supervision and central or regional access.
- Strong strategic planning background: (yes/no) based on mention of previous plans related to mitigation, energy, and environment.

- Socioeconomic environmental analysis: based on data on considerations and/or the impact of climate change on humans, the economy, and the environment.
- Quantify the impact of change: (yes/no) depending on whether the plan has some level of quantification of how climate change will imply a change in the city or the change is exemplified.
- Includes M&E or KPIs: (yes/no) whether it includes a monitoring and evaluation framework, even if general or if it includes specific KPIs to measure the plan.
- Target date: the date by which the city is expected to achieve carbon neutrality. Not all plans have the level of detail on projects or measures to get to net zero (non-demonstrable that the city will achieve the target).
- Mention of Sustainable Urban Mobility Plans or Transport Plan (yes/no).

3. Analysis

There is a good representation of cities of varying sizes that have produced a Climate Plan and disclosed it, according to the analysis of the Database (table 2). When we take a look at the geographical representation, we can see that the cities in the United Kingdom are at the forefront of climate planning in the two years after the year 2020 (table 1). These cities account for 32 percent of the entries.

Many of the cities have some level of experience in the planning process. Only 12% of cities listed no prior experience in their plans (figure 1). There appears to be no relationship between previous experience and level of autonomy. Surprisingly, most of those cities with no previous climate planning were from the UK, which also have a low level of autonomy. When it comes to planning, the degree of autonomy that a city has can be connected to the authority that it possesses to carry out the plan. Climate plans from UK cities frequently distinguish what is a local, regional, or national responsibility, or highlight actions that rely on other bodies such as electricity, water, and waste companies.

Table 1 Geographical distribution of climate plans

Country	**Count**
United Kingdom	16
Denmark	8
Italy, Sweden	5
Norway, Portugal, Spain, Switzerland	2
Bulgaria, Finland, Gibraltar, Greece, Iceland, Netherlands, Slovenia, Turkey	1

Figure 1 Experience in climate strategic planning

Table 2 City size distribution

Size	Count
Very small (less than 50,000)	6
Small (50,000-100,000)	4

Medium (100,000-250,000)	13
Large (250,000 – 500,000)	11
X-Large (500,00 – 1,000,000)	8
XX-Large (1,000,000 – 5,000,000)	8

The main methodologies used for the plans can be grouped into three, those who use SECAPs, those who use the Tyndall Centre methodology (Tyndall Centre, 2024) ,and a third larger group who uses an ad hoc methodology. Thirty out of 50 plans include a comprehensive social, economic and environmental assessment, and 12 plans have at least some assessment (either economic, social or environmental) (figure 2). About 80% of the cities have quantified the impact of climate change at some level, however when we look at the actions within the plans, we see there is no clear indication as on how much those actions will help get to the targets proposed. This means that cities understand the impacts but don't have a clear idea of how the actions in their plans will be enough to get to their goal. This is demonstrated as 36% of plans don't have monitoring and evaluation frameworks nor strong key performance indicators. With uncommitted actions, not linked to reduction targets or an estimation of reductions from those actions, some plans could be deemed as a narrative with a menu option with low certainty it can be implemented. The challenge around implementation and evaluation is not new. Prior studies on climate plans have identified that there is a lack of importance placed on this stage of the planning process (Aboagye & Sharifi, 2023).

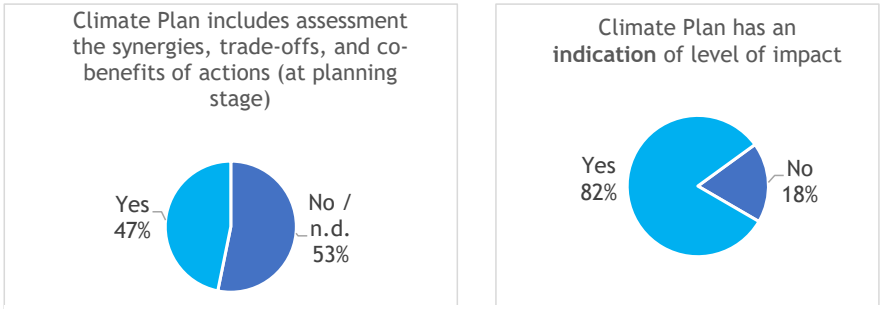

Figure 2 Climate plans availability of assessments (left) and indication of impact (right).

From the analysis of the Climate Plans included in the database, several baselines assessments have been identified as good practice for the development of such plans.

Crucial to the development of a sound transition pathway, climate action plan or strategy, is to understand the local context, gather information and determine what methodologies (or questions) will be guiding the discussions that stakeholders will have in order to prioritise strategies and policies.

The following assessments could be considered secondary processes done by the technical staff and feed into a bigger narrative of a climate plan. However, the technical baselines can also inform about the applicability and feasibility of the implementation of specific actions.

A. Emission assessment

▪ How high are the consumption-related emissions of the city? Are these distributed among the various consumption areas?
▪ What are the most influencing variables for greenhouse gas intensity of the individual consumption areas (e.g. electricity mix in the producing countries,trends in agricultural production, technology development, etc.)? What other important aspects have an influence here (e.g. proportion of animal products in the demanded diet)?
▪ What developments can be expected for the exogenous context factors and the other aspects realistically expected by 2050 (for example, investment in electrification)?
▪ Which opportunities and risks or synergies and conflicting goals with regard to ecological, social and economic aspects must be taken into account?
▪ Which administrative level owns the power to influence emission sources?

Emissions reporting is becoming a standard practice and most cities will have their methodology. Organisations such as international banks or third sector parties would have also developed methodologies (Greenhouse Gas Protocol, 2024). Alignment between them could streamline finance flows and improve accountability of climate projects financed by multilateral organisations.

B. Climate impact assessment

There is an assessment of all significant climate risks in terms of frequency and severity as well as the extent of the consequences up to 2030, as well as an obligation to assess up to 2050. This assessment includes:

- Risk scenarios are, where possible, based on local standard methods or on typical discharge scenarios (eg the IPCC's representative concentration course culminating at 4.5° C in 2100). For a general risk assessment cities could use the IPCC regional map (IPCC, 2024).
- A qualitative assessment of the impact on the city's systems, sectors and vulnerable social groups is prepared based on the climate risk assessment.
- Consequences for the city's inhabitants and necessary infrastructure (e.g. utility companies, hospitals) are seen in relation to how exposed they are and their ability to adapt.

C. Socio economic assessment.

This assessment is used to understand critical points and groups that are relatively more vulnerable to climate change impacts. It includes:

- Description of the existing administrative and physical geography, which is relevant to climate change (coastal proximity, flooding areas, topography, elevation)
- Social analysis to identify demographic changes and resilience (focus on disadvantaged groups likely to be impacted by climate change)
- Analysis of the economic mix of the city, including major economic activities, economic strengths related to climate supply chains (technical schools that could support upskilling for green jobs, manufacturer of sustainable materials, availability of entrepreneur and innovation environments, etc).

D. Technology assessment

Technology is considered a key factor in every climate plan, however it is mostly considered as the availability of certain technology without a long term consideration of its impacts or its regulatory needs.

- Which technology trends may have the greatest impact on emissions from transport, for example batteries, sensors, big data, drones? In the short, medium and long term
- What do we know today with a certain degree of certainty about technological changes in the transport sector (2030-2050)
- Will new technology require the development of new regulations, and what kind of regulation if any?
- What kind of new infrastructure must be developed to adopt new transport technology?
- What can the city do to facilitate the use of key technology?
- What kind of competence and capacity does the municipality need more towards 2030 to facilitate technological change in the transport sector?
- Are there any areas that the city can focus on in particular, which will be valuable in the global environment perspective?

E. Institutional and policy assessment

This entails a two stage assessment. The first stage should be done before the visioning step (SUMP-PLUS, 2021, Halpern, et al., 2022). This stage includes:

- Identification of relevant national and regional obligations: includes the overview of goals and initiatives that are shared with or owned by other bodies and actors
- The municipality's structure and scope of the plan
- The municipality's powers and capacity: An assessment is prepared of the powers that the municipality has with regards to other relevant sectors, assets and functions or measures, which also determines where it is necessary to further cooperate to accelerate the implementation of climate action
- Review of the integration of the plan into existing regulations, plans, statutes, policies and local institutions necessary to accelerate implementation and involved in the development of the plan

A second stage of institutional assessment can be used after high level strategies and actions have been selected to determine gaps in policy and linkages between vulnerable groups, emission reducing, strategies and economic opportunities.

The second stage should is designed to match the local authority institutional capacity at the baseline with the institutional capacity needed to deliver on the high level strategies that are selected. To do this, the Strategies selected need to be reviewed and assessed in light of the local environment. This second stage is closely related to the assessment of weaknesses, strengths and barriers that were researched in the previous assessments and the concept of enabling actions.

Following their technology and institutional assessments, Oslo considered Data to be of upmost importance to achieve its transition (City of Oslo, 2024). The city is working to identify its own role with regard to the ownership and operation of data. It will also be useful to go through the data sources that the municipality actually already owns, and assess how this data can be used to develop services and tools that contribute to reduced emissions. The development of the

platform itself for sharing data is probably something that should be located somewhere other than at the Climate Agency, but the agency can represent a good case for the utilization of current data with its clear goals of reducing emissions from the transport sector. Smart use of data can make a major contribution to streamlining the transport business and form the basis for the development of good services and products.

Citizen support and public participation

Climate plans surfaced as a consequence of a varied of causes, mainly the real impacts of climate change but also because of the perception of the citizenship and the policy push by the EU. The 2021 barometer shows that the most serious problem facing the world is climate change above poverty, hunger and the spread of infectious diseases. The same survey saw an increase in allocating responsibility for tackling climate change for all political strata. National governments, businesses and the European Union are seen as the main responsible. However, local governments have seen the bigger increase in perception of responsibility going from 33% to 43% in 2 years (European Union, 2022).

Climate plans can be seen as a policy response in the sense that they have yet a short trajectory. These type of plans are not statutory as it are National Determined Contributions or SUMPs or Local Transport Plans in the transport sector (for cities above a threshold). Even SECAPs which have a longer trajectory are not subject to a regulatory obligation. This brings shadow on the role of the citizenship role. About half of the plans in the database do not include public consultation, which represents a gap between one of the main driving force of plans and the planning in itself.

About 8% of plans have some type of public participation as they include a bigger range of stakeholders including universities, faith groups and industry professionals (figure 3). Some cities have developed digital tools to support the development of the plan like Stockholm. Developing such tools can be help bridge the gap mentioned before. Other public participation tools mentioned are calls for evidence (pre plan participation), regular engagement through communication channels, climate talks, and ad hoc events such as Climathon's or People's Assemblies.

An avenue for future research could be to link public participation methods, the efficacy of the plans and the legitimacy of the planning system.

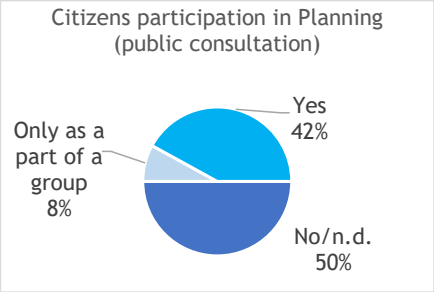

Figure 3 City plans and public consultation

Priority transport actions

It was previously mentioned that the link between climate and transport planning is not always clear at least at the strategic level. The analysis of the database shows that while all plans have at least some transport actions included, only 60% mention SUMPs and LTPs. 373 transport actions were identified and classified in 148 groups. Actions were also classified on whether they belong to any of the A-S-I categories. Two additional categories were created: avoid/improve (for example alignment of land use planning for sustainable mobility) and shift/improve(for example low emission zones). The majority of actions correspond to shift and improve actions (figure 4). Even when shift actions represents the majority of actions, the top 5 actions include improve cycling and walking infrastructure (S), E-charging infrastructure, hydrogen and EV public transport, the electrification or decarbonisation of public fleets (I), Improve accessibility and frequency of public transport (S) and car sharing (S). This result validates previous research looking at the candidate cities for the EU programme Climate Neutral and Smart Cities (Christidis, et al., 2024).

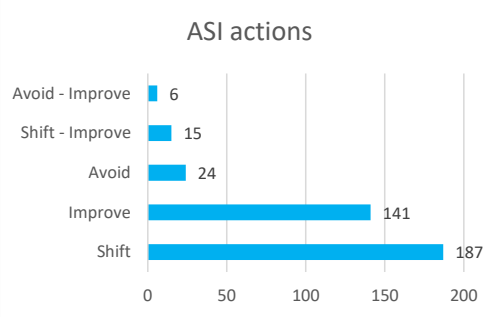

Figure 4 Transport actions A-S-I distribution

The level of detail of the actions is uneven. For example, within cycling we find the development of cycling strategies, monetary incentives for cycling uptake, road redistribution for active mobility, improvement of cycling infrastructure and promotion of cycling operations. On the freight side we find options such as the use of drones for freight, promotion of sustainable freight, electrification for urban boat freight, incentives for green freight, a roadmap for freight decarbonisation and “last mile and freight”. As shown actions can be very specific or high level according to each plan.

Considering prioritised actions according to level of autonomy, we see that active mobility improvements, electrification and infrastructure and improved public transport are the main actions considered (figure 5). We can see more collaborative actions prioritised in the low level of autonomy group with the inclusion of park and rides with other municipalities and car sharing schemes. For the high level of autonomy group we can highlight operational improvements for public transport (while in the low level of autonomy group we find infrastructure improvements) and hydrogen or EV public transport.

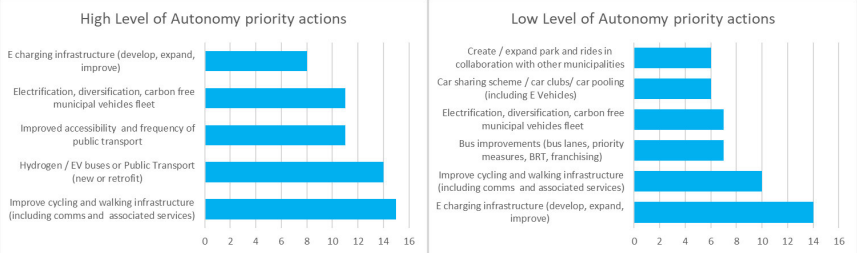

Figure 5 High (left) and Low (right) level of autonomy prioritised actions

4. Discussion

Despite the novelty of city climate plans, local authorities possess some prior knowledge and expertise in this particular planning methodology. Considering the methodologies employed, this does not appear to be related to the quality of the plans. While 88% of cities have some experience, the majority do not use a systematic approach that includes an assessment of synergies, trade-offs, and co-benefits among various urban systems. There is an opportunity to provide additional training to the employees of the local government in order to enhance their ability to make policies based on scientific evidence and to use methods that consider the impact of climate change and systemic factors.

Also, baseline assessments range from simple narratives to doing very in-depth analyses and numbers-based calculations of effects. Regarding the transport section of the plans, it would be interesting to connect the technical work required to establish baselines to the overall narratives of climate plans.

Recent endeavours have been made to establish a connection between these two aspects and address the obstacles identified in implementing plans and managing the transition (Geels, 2011, Sovacool, et al., 2020). The European Union has released new guidelines that can enhance the relationship between climate and transport planning by focusing on the bottom-up approach, specifically from transport to climate (Polis & Rupprecht Consult, 2021, EIB/Jaspers, 2022) . From climate to transportation, specific strategic links should be included in climate plans. Stakeholders should also be told to think of urban systems as being linked, such as water, biodiversity in cities, and transportation and urban planning. Still, the fact that some cities are making their plans public is a good start, and it could be seen as a response to the public's growing awareness of climate risks.

As a main takeaway from this research, it is important to evaluate the institutional capacity and level of autonomy in terms of the actions that need to be done first. Additional research that establishes a connection between climate plans and their actual effectiveness in reducing emissions presents a valuable opportunity to enhance monitoring and evaluation frameworks. Enhancing public engagement through conventional or innovative approaches could also enhance the credibility of plans.

Regarding prioritised actions, electrification, public transport, and active mobility appear to be the highest-ranked items on the list.

Avoid actions that are overlooked in favour of shifting and improving policies. Reducing the demand for trips and tackling trip generation by collaborating with sectors that produce the demand for trips can be a good approach (OECD, 2022).

Generally, climate plans are well-received and indicate progress in planning capabilities, although they have not yet attained the level of being legally enforceable and methodologically rigorous. Local authorities play a crucial role in addressing climate change due to their citizenship, which entails the responsibility to both mitigate and adapt to its effects. Granting cities enhanced authority and financial resources to address the issue could lead to improvements, alongside fostering partnerships with research institutions to oversee the process and integrate evidence-based approaches and objectives into practical measures.

Chlorophyll City: Regenerative and Restorative Urban Planning for a Sustainable Future through Extensive and Branching Reforestation Initiatives

Lucrezia Gelichi
Affiliation: Department of Architecture in University of Florence
Email: lucrezia.gelichi@unifi.it

Abstract
The problems arising from the expansion of cities are global challenges that require innovative and sustainable solutions. This paper explores the beneficial potential of urban forestation with regenerative and restorative urban planning. Focusing on the reuse of marginal, empty and abandoned areas, it proposes to transform them into smart parks to mend the green spots of cities and to reconnect the empty and degraded urban tissues, but would also offer tangible services and benefits to the local community. All connected through eco-human networks to make urban spaces relatable and give species the opportunity to move freely in uncontrolled cities. This integrated approach to urban planning could play a crucial role in shaping chlorophyll cities, sustainable for the future.

Keywords: Urban environmental sustainability, Restorative and Regeneration, Natural Based Solution, Cultural Based Solution, Eco-Human corridors.

1.1 Introduction

A great contemporary challenge and a problem now in extreme territorial growth is urban pollution, a cause of environmental and natural degradation, that pushes our cities, sources of a good part of these deprecated pollution and environmental disasters, to urgently reorganize given the speed of these changes, designating a turning point. Citing Richard Rogers (1998) *"The future of cities will be determined by its cities and cities"*.
Urban areas are vibrant and complex entities, comprising a heterogeneous blend of built environments, plants, animals, and habitats modified for human use.
A new planning and management of cities would report the creation of preventive and sustainable balances. The goal is to develop plans defined in advance and compatible with the environment itself, adopting a global vision that focuses on sustainable development and conservation of the territory. Spatial planning emerges as a key tool to address this challenge, offering the opportunity to study, design and achieve a harmonious balance between human pressures and available resources. This implies the need to balance human activities with the skills and needs of the territory, finding solutions that guarantee a basis for an ecological and social balance.
Unfortunately, over the last few years, many cities have experienced poor planning and management of the urban environment, compromising both the natural environment (water, atmosphere, green) and the socio-cultural part (urban landscape, cultural heritage, social cohesion)bringing increasingly pressing environmental and social challenges, including daily stress and lack of green spaces.
A large part of air pollutants is attributable to heating and urban traffic, while many of the water and soil pollution comes from solid and liquid waste in the city, because of an imbalance of settlements and an ineffective distribution of functions on the territory. At the moment global warming, the catastrophic consequence of these climate changes, is following an exponential trend whereby cities, for a matter of survival, must transform, change in values

and behavior to resist these variations. In the context just outlined, it is natural to consider technology as a possible response to this crisis. However, it is important to stress that it should not be seen as the only solution or as the only actor capable of solving environmental problems. Rather, technology can act as a support and complementary tool, intervening where resources require support to grow and become essential to the success of policies to promote a regenerative city. For example, innovative technology solutions could be used to monitor and manage water and energy resources, reducing waste and optimisting the use of available resources more efficiently. In addition, technology can play a key role in promoting more efficient and environmentally friendly public transport, thus helping to reduce air pollution and improve air quality in cities. However, it is important to remember that technology alone cannot solve environmental problems. It is necessary to adopt a holistic and multidisciplinary approach, involving a wide range of actors and interests, including governments, businesses, local communities and individuals.

1.2 Theoretical framework

Urbanization has been defined as the movement of population from rural areas where agriculture is the predominant economic activity to urban areas dominated by industry and services.[1]

With the demographic increase and urbanization that we are witnessing today, the number of people living in cities will continue to grow rapidly, predicting that by 2050, (70%) of the world's population will live in urban areas, putting increasing pressure on resources and the environment[2].

The continuous growth of urban population inevitably leads to the disorderly expansion of cities, which have long-standing habits of resource consumption and waste disposal. Consequently, a series of complex issues have emerged, such as environmental degradation, biodiversity loss, social dysfunction, scarcity of natural resources, and the increasing anthropogenic climate change[3]. As our societies become more complex and the urban environment deteriorates, the built environment upon which we rely will become increasingly unsustainable.

Despite occupying only (1.6%) of the earth's surface, cities produce a disproportionate amount of waste and harmful emissions. This tiny fraction of territory could be compared to a stone on the Praia do Cassino Beach in Brazil, one of the longest beaches in the world. This comparison helps us to visualize the enormity of environmental challenges: despite the limited extent of cities, which, although occupying only a tiny portion of the planet, have become places of environmental aggression, with devastating consequences for biodiversity and the quality of human life. This parallel "urban stone" generates a disproportionate amount of waste, carbon dioxide and harmful emissions, about the (80%) of the total environmental load, making the most of the resources available on our planet. The final price of this overproduction should be defined by a rebalancing of resources: everything that is taken away from the Earth, should be returned, a sort of virtuous cycle that maintains the natural balance. Reflecting on this comparison, one can realize that life on Earth is concentrated in a thin layer, just 20 kilometers high, known as the biosphere, extending 10 kilometers below sea level and 10 kilometers above. Of all this living, only the (0.3%) represents animal life, the total weight on the whole planet, of which only the (0.01%) belongs to human beings. And the remaining (89.7%) to whom does it belong? About (1.2%) it belongs to fungi and microorganisms, but

[1] He, Reith, (2022)
[2] (CORDIS, 2019)
[3] He, Reith, (2022)

the remaining (87%) of the biomass weight is made up of plants[4]. This percentage may surprise, as it indicates that the predominant weight of life on Earth is represented precisely by plants. However, the question arises as to how it is possible that, despite the domination of plant-related biomass, our planet is facing unprecedented rapid climate change.

In the course of 2020, a surprising fact was recorded: the material produced by man exceeded the weight of life itself on Earth. This comparison becomes even more significant if we relate it to the situation of just a hundred years ago: in 1900, the anthropogenic mass was almost negligible. It is incredible how in a century things have changed so radically, highlighting a devastating impact of human activity on the environment and a concomitant reduction in life as a whole.

In 2021, for example, China produced the same amount of cement that the United States used over a century. This extraordinary volume was consumed in just twelve months.

Speaking of cities, we talk about urban metabolism, which is like exploring the meanders of a living organism, a sort of pulsating entity that swallows and transforms the resources it receives. It is an intriguing concept, which drives us to consider cities not only as agglomerates of cement and asphalt, but as complex organisms able to interact with the surrounding environment in surprising ways. This analogy leads us to reflect on the similarities between the functioning of a city and that of a biological organism. At the heart of this notion is the concept of the circular economy, a principle that recalls the life cycle of nature itself. Imagine a constant flow of resources entering a city, like the blood flowing into the veins of an organism. But what really makes urban metabolism fascinating is its ability to transform these resources into something new, regenerated, just like the cells of the human body that transform food into vital energy. However, this change is not always as efficient as it should be. Unlike plants that exploit photosynthesis to maximize resource utilization, cities often operate with dysfunctional metabolism. Many resources enter, but too often excess waste is produced, generating an ecological footprint disproportionate to the size of the city itself.

The ecological footprint, in this context, reminds us that every human action has an impact on the surrounding environment. Measure the area of land needed to support a specific lifestyle and dispose of the waste produced. It is a powerful indicator that drives us to reflect on our habits and how we interact with the world around us.

One of the main problems facing European cities today is urban organisation, which manifests itself in the conflict between two objectives, both crucial for urban policy. On the one hand, the need to ensure high access to high-level urban services that define the very essence of a modern city, an aspect that no citizen is willing to give up, on the other hand, the challenge of preventing the concentration of such services from leading to an overload that threatens environmental and social sustainability, making the city unlivable.

Reflecting on this dynamic, it emerges clearly that large cities are in a situation of overcrowding compared to the available territorial resources and the degree of concentration. This uncontrolled expansion, which also extends beyond the historic center, has serious consequences: the loss of human sociality (sociality), the decrease in the sense of belonging and identity (identity), and the compromise of environmental sustainability (sustainability)[5].

The fundamental question is therefore: how to decentralise urban functions to reduce congestion and relieve the pressure on the historic centre, without compromising the quality of life?

This tendency for citizens to concentrate in or near urban areas is fueled by the search for advanced urban services. However, it seemed that the advent of modern telematic

[4] (Stefano Mancuso, 2023)
[5] (Franco Archibugi, 2002)

technologies had offered a solution to this phenomenon, reducing the need for spatial concentration: with access to the same services without the constraint of physical presence, The city could no longer be conceived as a collection of physical distances, but as a network of abstract communications. Unfortunately, the intrinsic attractiveness of cities cannot be completely replaced by the convenience of digital technologies as cities continue to offer a variety of social opportunities, cultural and economic that attract people not only for the services available, but also for the energy and diversity that characterize urban life. The vision of a clean and ecological city, regenerative, is what should be investigated, where technology acts as a stimulating and educational element for a better quality of life and a sustainable urban environment. But how can we keep the soul of cities alive in a digital age? How can we ensure that everyone has access to the opportunities that cities offer, regardless of their physical location? In this new world, the very concept of the city is constantly evolving, so we must have the ability to adapt to these sudden changes that will determine our urban destiny. We must recognise that we face a great challenge, not only in terms of adapting and mitigating climate change, but also in terms of restoring the balance between man and the natural environment. And this challenge begins right in our cities.

1.3 Research methodology

Looking at cities, we see that urban forestation plays a crucial role in rethinking and redesigning our urban landscape. It is necessary to go beyond aesthetics, considering urban forestation and its methodologies as a fundamental strategy to address environmental challenges and improve the quality of urban life, to restore the lost balance, especially in urban suburbs and in those urban places of environmental and social degradation.
We need to broaden our concept of the urban landscape, considering it not only as a collection of buildings and streets, but as a living organism. This means recognizing the interconnectedness between the natural and artificial elements of our urban environment and adopting a holistic approach to city design and management.
The concept of urban forestation has its roots in the United States, thanks to Frederick Law Olmsted, who adopted an interdisciplinary approach, combining the natural sciences, humanities and landscape design, to develop a new vision of the relationship between man and environment.
The development of effective urban forestry plans requires a collective commitment and an integrated vision, taking into account the environmental, social and economic needs of urban communities.
A significant example is the *"five-finger"* plan of Copenhagen, a 1947 urban plan that included an urban forestation strategy along the *"fingers"* of urban design. The "fingers" represented the backbone of the metropolitan urban railway network, while the interstitial spaces between them were left as green areas, including urban forests, wetlands and agricultural areas. These ecological corridors, in addition to their function of preserving biodiversity, also had to promote creativity and interaction among the inhabitants of the city. In this way, urban forestry is not just a matter of green belts, but a complex system of ecological connections that define and enrich the urban environment.
Recently, there was talk of *"Greening Green Belt"*, an approach that aims to strengthen the existing green belts. This is particularly important in view of the increasingly serious and evident effects of climate change, providing a unique opportunity to redevelop degraded urban areas, including derelict industrial areas and abandoned sites, contributing to urban regeneration and the creation of green spaces vital to the community.
A fascinating example is the landscape plan developed by Ian McHarg, who in the 1960s was commissioned to conduct a study for the city of Philadelphia, which at the time faced serious

pollution problems, especially in the city centre. McHarg, in his book "Design with Nature", highlighted the need to reduce pollution sources to solve the problem and through investigations, McHarg developed indicators based on wind direction and thermal inversion, which revealed how during the winter months, with poor air circulation, the pollutants remained trapped in the atmosphere. Using this data, McHarg identified the so-called *"wind pools"*, or areas crossed by prevailing winds, and established that along these corridors should not be built industrial polluting complexes, but suggested to strengthen urban forestry to improve air quality. These concepts demonstrate the ability to recognize the importance of nature and its integration in urban planning and it is surprising to note that these principles are still current and relevant, also in Italy, where we have only recently begun to consider in more depth the importance of urban forestation and landscape planning to address environmental challenges.

In 2020, in the capitals of the Italian region, the average annual temperature showed an anomaly of (+1.2)°C against thirty years 1971-2000. At the same time, there was a fall in rainfall of (-91) mm on average[6]. Cities have become places of increasing vulnerability to climate change, called hot spots, due to the high population concentration and density of infrastructure. At the same time, however, they present great opportunities for climate adaptation/mitigation actions. 2020 is the least rainy year of the last ten, together with 2011, with a total annual precipitation of 661 mm, reporting, as in 2020, in the capitals of the region, a quantity of water that could meet the needs of about 10 million people was lost daily. The greatest difficulties have been found in the southern regions: in more than one capital out of three there have been total losses percentages above (45%)[7]. In Southern Italy, it was even necessary to take rationing measures in the distribution of water to end users, through the reduction or suspension of the supply.

Due to the concentration of paved and built surfaces, interspersed with a few green spaces, as well as the presence of diffuse thermal sources, such as vehicular traffic, heating or cooling systems, large cities suffer the effect "Urban Heat Island" (UHI).

The term indicates the presence of a warmer microclimate in the city areas than in the surrounding peripheral areas, with average annual temperatures of 1-3°C higher than in the surroundings.

A possible solution to this problem, which is recognized as a valid tool, both of mitigation and adaptation by scientists of the IPCC and is provided for in European (Green Deal) and national (PNRR) plans, is precisely urban and periurban forestation. The vegetation is able to refresh the urbanized areas thanks to the shading and the evotranspiration process.

In addition, the urban greenery performs climate mitigation actions, capturing the CO2 present in the air and absorbs and reduces some air pollutants, making the soil more permeable, thus containing the impact of violent rains, and last but not least, makes our cities more pleasant, liveable and welcoming.

"The protection and promotion of urban greenery is a natural solution that, by increasing the resilience of cities, can play an important role in climate change strategies and, more generally, in improving the sustainability of urban systems and the quality of life of citizens" (Elisa Terenghi, 2022).

An excellent news is given precisely with regard to the urban green area where the total area of urban green areas is constantly increasing: in the last decade there has been an increase of green (15%) thanks to urban and suburban forestry works[8]. The distribution of these green lungs is far from uniform in the Italian peninsula, with maximum availability in the capitals of

[6] (Elisa Terenghi, 2022)
[7] (Terenghi, 2022)
[8] (Terenghi, 2022)

the Northeast and minimal in those of the South. This should give us an awareness of how urban forestry is an excellent path to pursue in spatial planning.

1.4 Case study

The challenges of demographic, energy and climate change need to be tackled rigorously, innovatively and in research, pluri- and inter-to formulate design responses that will promote sustainable development in the years to come. To re-establish a more direct and lasting relationship with the soil while waiting for a reinterpretation and a wise re-functionalization, in relation to the territorial urban location. There is no more space available to build something new, but we must work in the intermediate bands of different densities, on the brittle margins, on the edges of scattered and weak spaces that require care and maintenance[9]. Therefore a project fot the recovery and regeneration of what remains is urgent: degraded and forgotten enclosed spaces, the post-industrial decommissioning, the areas flattened by the heat islands, the cutouts between the motorway junctions, the illegal construction of buildings, the fallow countryside, all those residues of margin, surrounded by buildings mostly "disinterested" and consisting of spaces without relations and resonances, still free, available for transformation.
How can the architectural and urban project intervene for the requalification of degraded contexts? Is it possible that through waste, you create urbanity and quality landscape, able to regenerate the city and the contemporary territory?
We need a practice of defense, recovery and redevelopment of the interstice, which can become a park, open space, landscape, path and place of exchange to restore a balance between man and nature. Nature and culture can resume a dialogue, trying to relate the signs of the landscape (often anthropic and ideally wild and natural) and even dense artificial presences (built, infrastructure, etc.).
The concept and practice of sustainability are progressively evolving towards a design approach that not only seeks to avoid further damage to the status quo but rather aims to remedy the harm caused by previous practices through a reparative and regenerative approach. The term 'regenerative' denotes a process that repairs, recreates, or revitalizes energy sources, air, water, or other resources. Furthermore, regenerative urban design is seen as a process to replace the current linear system with a cyclical one, aspiring to regenerate life itself and thus offering prospects of hope for the future[10]. Similarly, restoration implies correcting damages resulting from human activities and returning the environment to its original state through deliberate development. The intermediate areas, marginal, of environmental and social degradation, would become compensations that go to rebalance what has torn, injured, saturated and polluted our cities and their surroundings out of control. Spaces that are designed for the community, starting from considerations on the nature of their limits and the most degraded portions, putting them in reciprocal dialogue with the external context, from the scale of the city to the territory itself, in a vital osmotic exchange.
Gilles Clément, landscape gardener, in his Manifesto of the Third Landscape said that the waste is a constituent material of the Third Landscape, a scenario located on the urban edges, uncertain and changeable, place of abandonment and neglect that defines and gathers the whole of abandoned spaces, pockets of acceptance of diversity. The Third Landscape includes all the territory left free, rural and urban, degraded or excellent: the edges of roads and plots of land, the margins of industrial areas, nature reserves.

[9] (Anna Arioli, 2012)
[10] He, Reith, (2022)

"It is the space of indecision and the living beings who occupy it act in freedom. Consider in the third landscape a biological need, which affects the future of living beings, changes the reading of the territory and enhances places usually neglected" (Gilles Clément, 2015). The project is called into question for an integrated and multi-scale intervention with particular attention to the naturalistic dimension and the design of the connections (paths, accesses).

Considering urban forestry plans and supporting the related ideologies, such as the creation of green belts and ecological networks, is a method of rebalancing the urban ecosystem. This implies the integration of green areas with spaces dedicated to services and cultural, physical, work, social, connected by a minor network, light and slow, of discontinuity in full, but also of continuity within areas that are polluted, fragmented and isolated. The landscape enters the city, the open space designed and recomposed, no longer residual, discarded, becomes a place of propulsion of relationships and energies[11].

Indicators related to space and infrastructure are crucial in sustainability-oriented urban design. While some findings regarding infrastructure suggest a return to human-centric design, physical proximity does not always imply a significant connection between spaces[12]. Hence, it is essential to create a "network of places" to foster deeper connectivity and better integration among urban areas. Regenerative urban design tackles urban challenges from an integrated perspective of economy, society, and environment, not only seeking to increase conventional indicators such as employment and biodiversity but also restoring and establishing adaptive capacity. Additionally, reparative urban design not only restores polluted and damaged ecosystems to a healthy state but also integrates nature into daily life through appropriate design models, while promoting interaction and contact with nature to enhance the physical and mental well-being of inhabitants. Regenerative urban design goes beyond conventional indicators to include those emphasizing nature as a form of self-regeneration, such as solid waste reuse, renewable energy, and the development of a sense of place. Physical connectivity does not erase boundaries between various spaces, as people tend to mentally separate these elements[13]. However, the geometric relationship between places influences the type of feeling a place conveys to individuals. Here is how eco-human paths, where species can wander without the constraints of suspension, sudden or gradual, which can occur in an urban or non-urban setting, represent new strategies for eliminating boundaries. Chlorophyll connections provide the possibility of a continuum, a transition from one space to another, immersed in the well-being gifted by greenery. A design that we can define as "biophilic urban planning" that aims to mend the dynamics of marginal landscapes, degradation, abandonment, and the city with its anthropic behaviors, rendered polluted and uncontrolled in its social and geographical growth.

Eco-human paths in which species can walk without conditions of suspension, sudden or gradual, that can occur in an urban or non-urban path, chlorophyll connections that give the possibility of a continuum, a transition from one space to another, immersed in the wellness given by the green. New strategies that go to mend the dynamics of the landscape of margin, of degradation, of abandonment and the city with its anthropogenic behavior, made polluted and uncontrolled in its social and geographical growth.

Through the vegetation it’s possible, not only to absorb carbon dioxide and release oxygen, helping to reduce the greenhouse effect and alleviate the negative effects of air pollution, such as reducing urban temperature, mitigate the effects of heat islands, but these realities also offer a regenerating space for citizens, promoting well-being and reducing stress, helping to create a more comfortable climate in the cities. These urban forestry initiatives and the creation of green rings transform the forgotten areas of the city into more sustainable and

[11] (Anna Arioli, 2012)
[12] He, Reith, (2022)
[13] He, Reith, (2022)

welcoming places for their inhabitants, re-educating and transmitting all those environmental and social benefits that are now lacking in the territories of dispersion of the saturated city and its very margins, building new centralities open to the landscape, to put into system redeveloped complex spaces, disoriented inhabitants, energies and structuring dynamics. Making those forgotten, empty places become protagonists and material of composition to give a new structure to those fragments of a degraded city. The residues, the free portions of space, emptied but almost never empty, constitute the weak and yet fertile framework on which to fix new reference points[14].

Imagine a city where nature and urbanization are not in conflict but harmoniously integrate to create a healthier, more sustainable, and welcoming urban environment for all its inhabitants. This is the vision of a reparative city, one that utilizes afforestation and ecology to regenerate its abandoned spaces into oases of life and well-being. Urban afforestation is not merely an aesthetic concern; it is an intelligent strategy to address multiple urban challenges. However, this process is not without its challenges. We must carefully consider crucial issues such as accessibility, safety, sustainability, and social inclusion. How to address the practical challenges related to transforming abandoned urban spaces into green areas, such as accessibility and safety? In the context of urban repair, one of the fundamental questions is how to design and plan a safe city through forestation and the creation of intelligent urban parks. The presence of trees and green spaces is essential to improve urban life quality and promote citizen well-being, but it also presents practical and safety challenges that must be carefully addressed. One critical aspect, for instance, concerns the access of emergency vehicles to various points in the city, including fire trucks, ambulances, and law enforcement, to operate effectively. However, the presence of obstacles such as trees and dense vegetation along streets and in parks could compromise their proper positioning and swift access in case of emergencies. This challenge raises significant urban planning and design issues, particularly concerning public space planning and the arrangement of green elements in cities. It is essential to provide dedicated areas for emergency vehicle transit and ensure the presence of escape routes with alternative access in case of emergencies. To address this challenge more broadly, it is important to consider the safety of the cities from various aspects, such as crime prevention, traffic management, protection from extreme weather events, and more. Solutions could include the integration of surveillance and lighting systems in urban green areas, the design of safe roads and sidewalks for pedestrians, and the implementation of traffic management policies that promote safe and sustainable mobility. Addressing the issue of safety in cities in urbanized contexts with a strong presence of trees and vegetation requires an integrated and collaborative approach that takes into account safety needs, environmental sustainability, and community involvement.

In the context of the urgent need to address contemporary urban challenges related to climate change and quality of life, the innovative perspective of using artificial intelligence (AI) emerges and advanced technologies to drive urban regeneration through forestation.

Within these parks, a network of biological sensors would be installed to monitor the health of urban ecosystems in real time, to detect changes in air, soil, water and biodiversity, providing detailed and predictive environmental health data.

In parallel, the system could include a community engagement component, through the implementation of digital platforms and mobile apps that allow residents to actively participate in the planning and management of urban forests. This platform could facilitate communication and collaboration between residents, local organizations and public authorities for the management and animation of green spaces. Users could share ideas, projects, and initiatives to enhance and enrich the city's green spaces, thus promoting greater

[14] (Arioli, 2012)

community involvement, aware of which aspects of their cultural heritage need to be protected and preserved. All of this can lead to educating and raising awareness within the community about the importance of urban green spaces for health, well-being, and the environment. The shared information becomes educational resources and success stories to inspire greater appreciation and use of green spaces. An innovative way to promote environmental sustainability, improve urban quality of life, and encourage greater community involvement in the management of urban green spaces.
In the digital age in which we live, we must rethink art as a tool and support to improve urban quality, no longer confined to the walls of galleries or museums, but spread among urban contexts, interacting with our daily environment in innovative and exciting ways. The installation of digital art and immersive arts in eco-human paths is a powerful tool to raise awareness of environmental and climate issues that we face today.
These works of art not only decorate public spaces, but also serve as a vehicle to convey important messages about the environmental crisis we are experiencing. Using advanced digital technologies, such as lights, colors and projections, artists can represent in a tangible way the climate changes and environmental pollution that directly affect our lives and our habitat. A tangible example of this approach is the integration of sensory elements into digital artworks, which allow environmental data such as air pollution or temperature to be detected and displayed in real time. In this way, citizens who go through these eco-human paths can immediately understand the impact of their actions on the surrounding environment.
In addition, 3D installations representing models of facilities and services in the area add an additional layer of interactivity and information. These representations can be enriched with additional data, such as statistics on energy consumption or emissions produced, to educate the public on sustainable practices and innovative solutions available. In summary, the use of digital technologies in urban art not only enriches the aesthetic experience of citizens, but also promotes awareness and action towards the preservation of our planet. This form of artistic expression is thus an essential bridge between human creativity and the global challenge of environmental sustainability. It becomes crucial to consider the crucial role of education and awareness in promoting sustainable practices and encouraging the adoption of eco-responsible behaviour. Educational programmes and awareness-raising initiatives in the form of digital art would help actively involve citizens in the care and enhancement of urban green spaces, transforming them into places of learning and personal growth. Through environmental education and the promotion of sustainable lifestyles, we can create a more conscious and committed urban culture in protecting our environment and future generations.

1.5 Conclusion

This approach aims to create sustainable and resilient cities that grow together and with green photosynthesis, can address the environmental and social challenges of the 21st century in an effective and collaborative way. New urban parks, "Intelligent Urban Ecosystems" (IUE), inserted in those marginal realities of degradation and pollution, restoring a new identity, reversing the approach, so as to redevelop the city itself that tried to destroy them, making them empty spaces. These places will not become static green parks, but real dynamic ecosystems and interconnected by eco-human networks, managed through the use of artificial intelligence and emerging technology: a regenerative break and synthetic photo for the entire city and its territory. Within these reforested spaces or parks, we could find functions and services suitable for the city, where citizens can identify their activities.
Any buildings and infrastructure within these parks would be designed with an *"intelligent green"* approach, including plant facades integrated with irrigation and self-powering systems, green roofs equipped with photovoltaic technology and rain water collection facilities. Roads

and pavements made of permeable materials that allow water to infiltrate the ground, reducing the risk of flooding and recovering water that would otherwise be discarded.
Design with a focus on resilience to climate change, integrating infrastructure and adaptation practices that protect the city from the effects of extreme events, such as floods, drought and heat waves. An urban planning project that addresses the environmental, social and economic challenges faced by modern cities, integrating innovative and sustainable solutions to create more prosperous and resilient urban environments.
The landscapes of the peri-urban countryside connote memories and call for redevelopment to bring benefits and values to the city, which has grown away from the countryside, placing it on the margins of an increasingly rampant expansion. Today, urban agriculture is gaining popularity: from hydroponic crops on roofs to vertical gardens on the walls of buildings, becoming real centers of local food production. These initiatives not only provide fresh and healthy food to urban residents, but also reduce dependence on long-distance transport and promote environmental sustainability. Urban gardens are not only places of food production, but also community meeting points. People come together to cultivate, share knowledge, and socialize, creating stronger bonds between residents and fostering a sense of community. These spaces foster cultural exchange and social cohesion, helping to create more livable and resilient cities. Traditional coworking spaces are evolving to include elements of biophilic design in green design, with a focus on the psycho-physical well-being of individuals[15]. The goal is to (re)create a powerful connection between urban spaces and nature, making our habitat greener through osmosis between design, architecture, and natural elements, symbolizing vitality par excellence. Plants, in fact, not only improve air quality and reduce stress but also create a more stimulating and creative work environment.These hybrid spaces integrate digital connectivity with the sensory experience of nature, offering a green haven for urban professionals.
We must also imagine the cities of chlorophyll as a hub for the circular economy and sustainability: catalysts for a more sustainable approach to the use of natural and renewable resources, collected within the parks, such as solar energy through photovoltaic panels and rainwater collection through drainage and filtering systems, exploited to feed local production processes. In this context, innovative solutions for waste management, such as organic composting and the production of biogas from food waste, could be implemented to create a virtuous cycle of recycling and reuse of resources within the urban community. The adoption of circular economy practices would reduce the consumption of finite resources and the environmental impact associated with the production and disposal of materials, while promoting greater resilience and local self-sufficiency.
In some chlorophyll parks space will be given to living laboratories for the research and development of innovative technologies and business models oriented towards sustainability. Through collaboration between public authorities, research institutes, businesses and local communities, initiatives are promoted to stimulate innovation and the adoption of sustainable solutions in key sectors such as energy, mobility, construction and urban agriculture. These projects promote social inclusion, offering spaces for meeting and public use for people of all ages and socio-cultural backgrounds, becoming a reality to improve the physical environment of cities and a driver of growth and social cohesion.
Ultimately, these smart parks and eco-human networks would represent not only an opportunity to strengthen the connection between man and nature in regenerative cities, but also an engine of transformation towards a more sustainable and resilient future.

[15] Braga, (2020)

In chlorophyll networks, space is given to intelligent mobility, addressing current challenges related to pollution and traffic congestion, promoting a more balanced and harmonious urban environment.
Integrating eco-human corridors and linear parks along transport infrastructure such as cycle paths, sidewalks and roads can create ecological corridors that allow plants and animals to move freely within the urban environment. These infrastructures not only improve the air quality and aesthetic appearance of the city, but also promote biodiversity by offering natural habitats and corridors for urban wildlife.
The integration of electric vehicles with sharing systems would reduce the total number of vehicles in circulation, freeing space for the creation of green zones to preserve the urban landscape. Parks, public gardens and green corridors provide vital habitats for plants and animals, increasing the quality of life for urban dwellers and promoting nature conservation even in urban areas.
Urban regeneration through forestation and the creation of eco-human corridors offers an innovative solution to environmental and social challenges. With smart urban parks equipped with biological sensors and green networks that aggregate services to the community, we create intelligent and resilient ecosystems, actively involving the community, trying to reduce the growing crowding in the cities and bringing people back to live even in peri-urban areas, dark and forgotten. These parks not only improve air quality and biodiversity, but also become vital centers, with a cutting-edge approach to a more sustainable city, connecting through more ecological culture, art and services, a city that grows thanks to chlorophyll and its photosynthesis.
To conclude, urban regeneration through forestation and the creation of intelligent urban parks offers an innovative and vital solution to the environmental and social challenges of our time. This approach not only improves air quality and promotes biodiversity, but also transforms urban spaces into vital hubs of connection and resilience. By actively involving the community in this process, these parks, reachable and connected through eco-human corridors, become places of encounter, learning and collaboration, creating a more sustainable and supportive urban fabric. Through chlorophyll and its photosynthesis, we guide the growth and the journey towards a city that embraces nature and culture as fundamental pillars of its development. It is smart urban parks, equipped with biological sensors and integrated green networks, that offer us a brighter future, where connectivity, ecology and community well-being are at the heart of urban design. In this context, the city is not only a place of residence, but becomes a dynamic and interconnected ecosystem, able to adapt and thrive in the face of the challenges of climate change and urban growth.
Reparative and regenerative urban design is closely related to the goals of sustainable development, mitigating and minimizing the negative impacts of design and development on natural systems, while also using the built environment to promote a closer relationship between humans and nature. Urban development must go beyond simply maintaining sustainability; urban design thinking must transcend the dialectic of coexistence between humans and nature, pursuing the logic of coevolution between humans and nature.
Chlorophyll thus becomes our ally, guiding us towards a greener, regenerative city in harmony with our planet.

Biographical note on authors

Rita Nicolau is a principal researcher at DGT (Directorate-General for Territory) and a research collaborator of CiTUA (Center for Innovation in Territory, Urbanism, and Architecture of Lisbon University). Her background is in environmental engineering (undergraduate in 1996 and PhD in 2002, by New University of Lisbon) and operational research and systems engineering (Master by Lisbon University in 1994). She is a GIS specialist accredited by the Portuguese Engineers Order.
Until 2002, she worked at the National Centre for Geographic Information in the National Spatial Data Infrastructure (SNIG) implementation.
During 2003-2006, she lectured courses on GIS, standards for geographic data, land use planning and cadastre, and statistics at the University of Coimbra.
From 2006 to 2010, she researched at the National Institute of Health Doutor Ricardo Jorge (INSA), participating in projects concerned with the spatial analysis of mortality and morbidity and their determinants, and assessment of the impact of atmospheric pollution on human health.
Since 2011, at DGT, she has participated in research projects that have entailed the analysis of urban systems, the identification and delineation of settlements and built-up structures, the delimitation of rural-urban interfaces, land use change assessment, and the creation of indicators for monitoring sustainable urban development and spatial planning in general. Her current research relates to land consumption for urban development (land take, soil sealing, developed land recycling and re-naturalisation).

Beatriz Condessa is assistant professor at IST. She obtained a degree in Environmental Engineering – Specialization in Spatial Planning (1986, New University of Lisbon, Portugal) and a PhD in Geography (1999, Barcelona University, Spain).
She has carried out research activities since 1992. Firstly, in CNIG (National Centre for Geographic Information), mainly in developing databases using GIS tools to facilitate urban management and promote public access to information. Between 1998 and 2004, she coordinated the CNIG research team on Spatial Planning.
Since 2004, in IST, she has taught and researched urban management, focused on integrating urban planning, law and urban economics. More recently, she was PI of PERCOM project (Equity and efficiency in the urbanization process: a land readjustment execution model), of LANDYN (Land use cover change in continental Portugal: characterization, driving forces and future scenarios) and RIPROCITY (Rivers in Cities: potential for urban sustainability).
During 2014-2015 she coordinated the master programme in Urban Studies and Territorial Management at IST. She is a GIS specialist accredited by the Portuguese Engineers Order and a member of the Portuguese Urbanists Association and the International Academic Association on Planning, Law, and Property Rights (PLPR).

Abstract

The "No Net Land Take by 2050" target, set by the EU, has been reshaping European urban development. The main goal of this research is to compare the processes related to net land take and soil sealing in the Portuguese metropolitan regions (AML and AMP) and to assess their situation regarding the 2050 target.
During 2007-2018, the artificial land area increased by 4.9 percent in AMP and 4.6 percent in AML. Net land taken averaged 0.6 ha/day in the AMP and 0.7 ha/day in the AML. Reuse of artificial land was rarely practised, at 0.02 ha/day in the AMP and 0.03 ha/day in the AML. Given that the share of sealed artificial land in both regions was already close to 60% in 2018, thereby jeopardising urban biodiversity, to reduce net land take it is recommended that future infrastructure and housing needs be met by reusing already sealed artificial areas.

Keywords: Urbanisation; Reuse of developed land; Re-naturalisation of developed land; Urban land use efficiency

1. Introduction

Urban development in Europe is being shaped by the "No Net Land Take by 2050" target, set by the 2011 Roadmap to a Resource Efficient Europe (EC, 2011a) and reinforced by the EU Soil Strategy for 2030 (EC, 2021). In pursuit of sustainable use of soil, this strategy recommends that Member States set, by 2023, their targets aimed at net land take reduction by 2030 and report on their progress by making measurable contributions towards the 2050 target. The first draft of the Soil Monitoring Law (SML) was launched in July 2023 (EC, 2023) to ensure healthy soils across the EU by 2050. It establishes a regulatory framework for sustainable soil management, which mandates Member States to monitor land take and soil sealing.
Land take conveys the 'loss of undeveloped land to human-developed land' (EC, 2016, p.4) over a given period. In practice, it represents 'the surface of agricultural, forest, semi-natural and natural areas, wetlands and water bodies artificialized in a given period' (Nicolau and Condessa, 2024, p.1). Net land take accounts for the difference between land take and re-naturalisation of developed land, which is the reverse process of land take. A reduction in net land take is only attainable through the reuse of developed land (i.e. artificial or urban areas) or by increasing re-naturalisation, a rarely practised land use transformation (Nicolau and Condessa, 2022).
Soil sealing is considered the most intense form of land take, as it causes a total and irreversible loss of ecosystem services and functions provided by soil (Scalenghe and Marsan, 2009; EC, 2011b; Tobias et al., 2018). To prevent cities' biodiversity from declining, some experts (Decoville and Feltgen, 2023) advocate keeping soil sealing levels within urban areas below 40 percent, a threshold supported by a study on urban plant diversity loss caused by soil sealing in a rapidly urbanising Chinese city (Yan et al., 2019). Nonetheless, research applied to the Paris Metropolitan Area (Tardieu et al., 2021) showed that the level of soil sealing is insufficient to predict a large part of the variations in ecosystem services at the landscape level. Therefore, their authors argue that planning decisions affecting ecological functions on which the well-being of urban citizens depends should be based on regular assessments of these services.
To limit land take and soil sealing, the Soil Strategy (EC, 2021) also proposes the adoption of a hierarchy in land use planning that prioritises the reuse of developed land. Whenever land take cannot be avoided, measures should be implemented to compensate for the loss of ecosystem services (e.g. re-naturalisation of artificial areas, development of green infrastructure).
This research aims to compare the processes related to net land take and land take driving forces between Portuguese metropolitan regions (Área Metropolitana de Lisboa - AML and Área

Metropolitana do Porto - AMP) to assess their progress towards meeting the 2050 target. In addition to sensitising decision-makers and public authorities to the European goal, the research also intends to support the setting of regional and local land take targets, which do not exist to date, and the definition of reduction strategies for land take. Although the Portuguese National Spatial Planning Policy Programme recognises the need to protect the soil as a natural capital asset and to control land artificialisation, these objectives have not yet been translated into quantitative targets (national, regional and local) that can contribute to the successful implementation of a "no net land take" policy.

2. Materials and Methods

2.1. Methods and Data

The study assessed land use changes between 2007 and 2018 and the degree of soil sealing in 2018, based on Portuguese land use/cover maps known as COS (Costa et al., 2023), municipal boundaries maps for 2018 (both produced by the Directorate-General of Territory - DGT), and the Imperviousness Density (IMD) layer produced by Copernicus Land Monitoring System (CLMS, 2023). Annual population estimates launched by Statistics Portugal were employed to analyse population dynamics. COS are vector maps with a minimum mapping unit of one hectare and the IMD 2018 is a raster product with a spatial resolution of 10 metres.

The research assumed that the COS classes relating to artificial surfaces represent developed or urban land, including both sealed and unsealed areas, and that the remaining COS classes represent undeveloped or non-urban land.

The sealing level of each spatial unit and its artificial land was assessed in three stages. First, pixels covering the spatial unit and its artificial land were identified; Next, the product of the IMD value by the surface area of each pixel was totalled for all pixels of interest; Finally, the percentage of the area of interest that was sealed was calculated.

The processes described by the study regard surface areas per spatial unit over a specific period. Due to the unequal sizes of spatial units, the study reports them in $m^2/year \cdot km^2$, which allows comparison of the same process across different spatial units, or in ha/day, which only enables comparing processes relating to the same spatial unit between different periods.

2.2. Study Area

The study examines two NUTS III regions of mainland Portugal (Figure1) during 2007-2018 and at the end of this period: the Lisbon Metropolitan Area (AML) and the Porto Metropolitan Area (AMP). The AML is the most populous area in the country, with almost 2,9 million inhabitants (2021). It is subdivided into 18 municipalities, one of which (Lisboa) is the largest city in Portugal. The AMP covers 17 municipalities and is the second most populous region in the country (nearly 1,8 million inhabitants in 2021). In 2018, almost half (47 %) of the mainland's population was concentrated in the AML and the AMP, justifying these regions having the highest proportions of their surface area covered by artificial land (25.1 % in AMP and 21.7 % in AML). Although the AML has over a million more inhabitants than the AMP, in 2018 the artificial land per capita was higher in the AMP (297 m^2/inhabitant) than in the AML (230 m^2/inhabitant), which shows that the latter region is denser than the AMP. According to the Municipal Plans in force in 2018 and the population estimates for that year, the availability per inhabitant of parks, gardens and forests in areas classified as urban in the AML (39 m^2/inhabitant) was much lower than in the AMP (83 m^2/inhabitant).

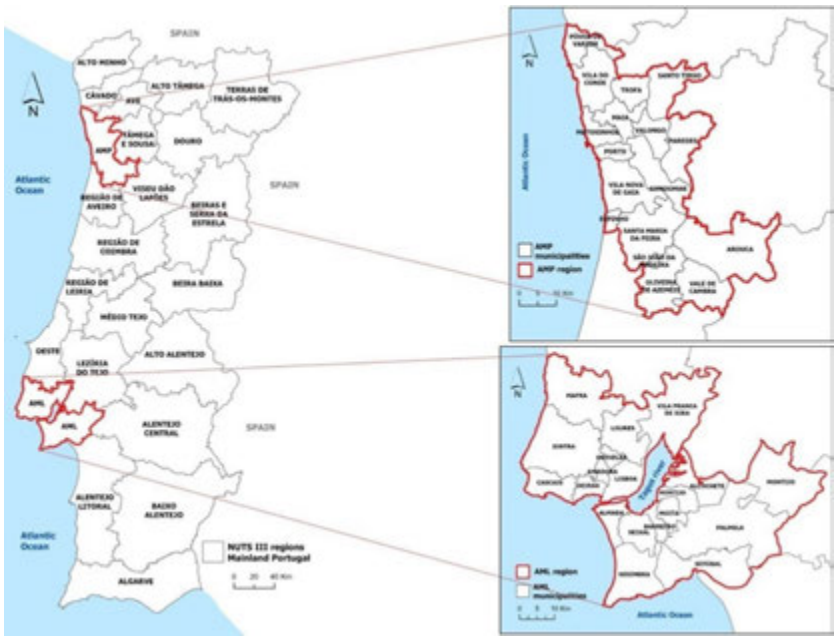

Figure 1 – Study area

3. Results

3.1. Land Take, Land Re-naturalisation and Net Land Take

During 2007-2018, the AMP land take rate (1153 m^2/year·km^2) was the highest among the NUTS III regions of mainland Portugal (Nicolau and Condessa, 2022), while that of the AML was the second highest (1021 m^2/year·km^2). These rates corresponded to an average consumption of undeveloped land of 0.6 ha/day in the AMP and 0.8 ha/day in the AML.
The main drivers of land take in AML were the development of new industrial and commercial sites (27 %), construction sites (26 %), transport networks (13 %), dispersed residential areas (12 %) and mining and quarrying areas (7 %). In the AMP, the four main driving forces of land take were similar, but their relative importance changed: transport networks (31 %), industrial and commercial units (27 %), construction sites (21 %) and dispersed residential areas (10 %). The low population densities that characterise much of the AMP territory with linear settlements mostly made up of detached houses interspersed with economic activities (AMP, 2014), and the high frequency of commuting by private vehicles (INE, 2018), explain the importance of strengthening transport networks in this region, where public transport is less used than in the AML (INE, 2018).

Table 1- Land take drivers in the AMP and AML, 2007-2018 (Percentage of non-artificial land consumption)

Drivers of Land take (2007-2018)	**AMP**	**AML**
Transport networks	31%	13%
Industrial and commercial units	27%	27%
Construction sites	21%	26%
Urban diffused residential	10%	12%
Urban green areas	3%	6%
Mining and quarrying areas	1%	7%

Re-naturalisation of artificial land rates were 93 m^2/year.km^2 (0.05 ha/day) in the AMP and 158 m^2/year.km^2 (0.13 ha/day) in the AML, evidencing the shortage of their practices. Figure 2 compares these rates between both regions municipalities, showing that Amadora, in the northern AML, made the most use of re-naturalisation (1054 m^2/year.km^2) in the period under review. The land use transformations most commonly associated with re-naturalisation in both regions were converting mineral extraction areas and construction sites into bushland. These changes result from land abandonment and increase the risk of forest fires, so they are the least desirable re-naturalisation type.

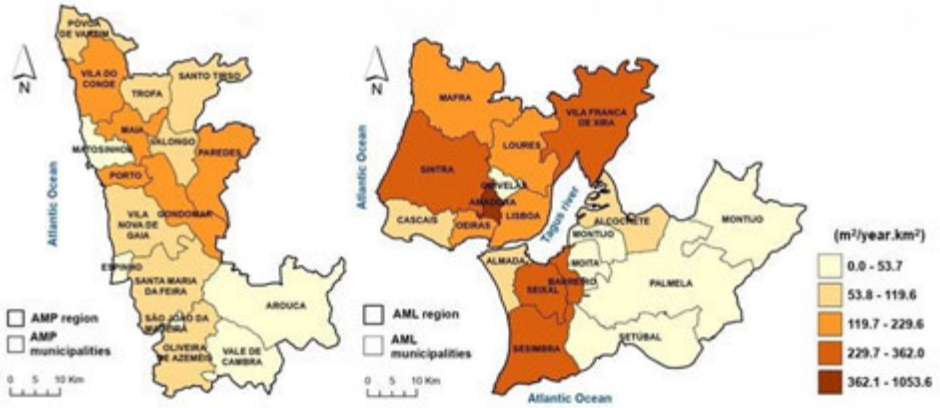

Figure 2 – Land re-naturalisation rate by AMP and AML municipalities, 2007-2018 (m^2/year.km^2)

The net land take rate in the AMP was also the highest among mainland Portugal regions (1060 m^2/year.km^2), immediately followed by that of AML (863 m^2/year.km^2). These rates represent net daily consumption of undeveloped land of 0.6 ha and 0.7 ha respectively, which still needs to decrease to meet the 2050 target.

The highest net land take figures within both regions (Figure 3) stood out in the municipalities bordering the most densely populated cities (Lisboa and Porto) and the municipality of Seixal (in the AML South), which recorded the highest rate (3133 m^2/year.km^2).

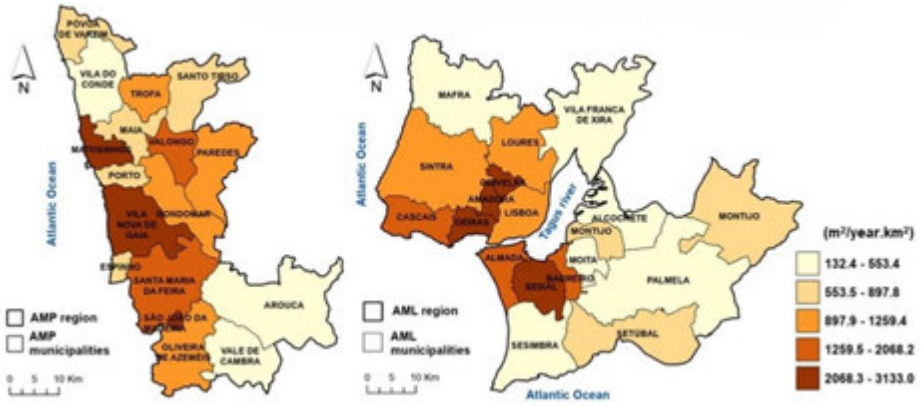

Figure 3 – Net land take rate by AMP and AML municipalities, 2007-2018 (m^2/year.km^2)

3.2. Reuse of Artificial Land

The reuse of artificial land was also little practised in both regions during 2007-2018, averaging 0.02 ha/day in AMP and 0.03 ha/day in AML (i.e. 28 m^2/year.km^2 and 38 m^2/year.km^2, respectively).

Despite this trend and the fact that three municipalities did not apply this process (Vale de Cambra and Arouca in the AMP, and Moita in the southern AML), two AML municipalities (Amadora and Lisboa) stood out for having the highest rates of land reuse (289 m^2/year.km^2 and 267 m^2/year.km^2, respectively) (Figure 4).

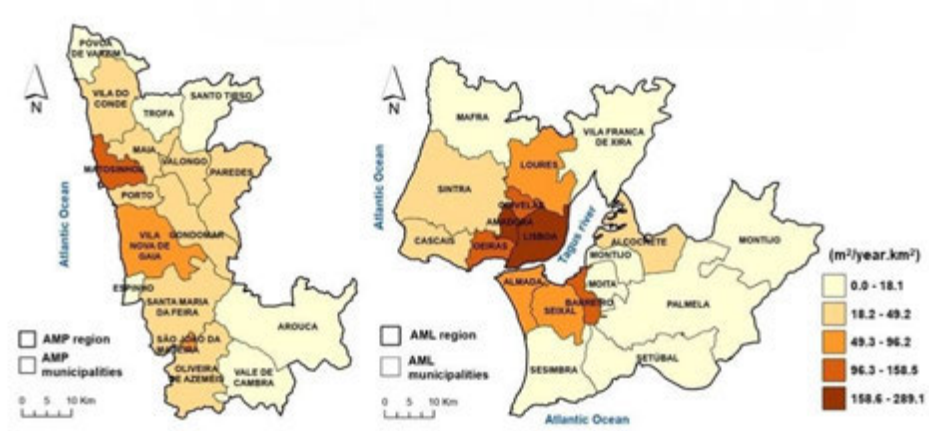

Figure 4 – Artificial land reuse rate by AMP and AML municipalities, 2007-2018 (m^2/year.km^2)

3.3. Urban Soil Sealing

In 2018, the degree of imperviousness of the artificial land was 56 percent in the AMP and 58 percent in the AML. At the municipal level (Figure 5), it ranged from 28 to 69 percent in both regions. Only two municipalities in the AMP (Arouca and Vale de Cambra) had levels of urban

soil sealing below 40 percent, which is recommended by some experts (Decoville and Feltgen, 2023) to prevent cities' biodiversity from declining. In the same year, the availability of unsealed artificial land per capita was 132 m^2/inhabitant in AMP and 97 m^2/inhabitant in AML.

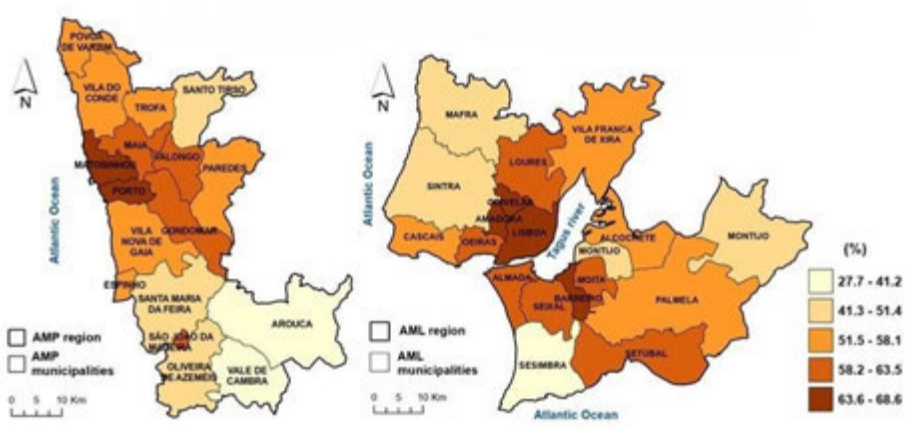

Figure 5 – Soil sealing level within the artificial land by AMP and AML municipalities, 2018 (%)

3.4. Artificial Land and Population Dynamics

During 2007-2018, the artificial land area expanded by 4.9 percent in the AMP and 4.6 percent in the AML (Figure 6), while the resident population of the AMP decreased by 2.4 percent, that of the AML increased by 2.5 percent. The expansion of artificial land was coupled with a population loss in most of the municipalities in the AMP and a group of five in the AML (Lisboa, Almada, Barreiro, Moita and Setúbal).

Population growth was only faster than that of artificial land in Maia (in the AMP) and eight AML municipalities (Cascais, Mafra, Vila Franca de Xira, Odivelas, Alcochete, Montijo, Palmela and Sesimbra), which experienced a decrease in artificial land per capita that is considered desirable to achieve the European target (EC, 2016).

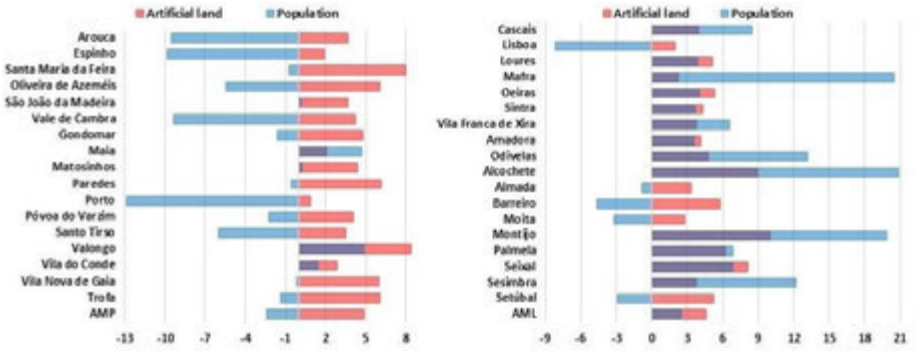

Figure 6 – Growth in resident population and artificial land by region and municipalities of AMP (left) and AML (right), 2007-2018 (%)

4. Discussion and Conclusions

During 2007-2018, the expansion of the artificial surface area in Portuguese metropolitan regions was mainly intended for infrastructure (expansion of transport networks, industrial and commercial sites and areas under construction). This increase (4.9 % in the AMP and 4.6 % in the AML) was in absolute terms almost double that of the resident population (-2.4 % in the AMP and 2.5 % in the AML). Although the AMP has seen a population loss in this period, the 2021 Census indicates that its inhabitants and those of the AML continue to grow, which leads to an increase in demand for housing.

To meet the European target by 2050, the net land take rates during this period (0.7 ha/day in the AMP and 0.6 ha/day in the AML) have to drop. To this end, in addition to publicising the European target among regional and local decision-makers, stricter control mechanisms must be implemented to reduce the consumption of non-artificial land and increase the reuse of artificial land, which has been under-implemented (0.03 ha/day in AML and 0.02 ha/day in AMP).

As the share of sealed artificial land in both regions was already close to 60 percent in 2018, a level that according to some experts compromises urban biodiversity (Yan et al., 2019; Decoville and Feltgen, 2023), to obtain net land take reductions, it is recommended that future infrastructure and housing needs must be met by reusing already sealed artificial areas. However, intensifying land use in these areas can reduce urban resilience and must be compensated for by increasing the surface covered by green spaces and other nature-based solutions (EC, 2012).

In line with the recommendations of the EU Soil Strategy (EC, 2021), the authorities of both AMP and AML should also define quantitative targets (regional and local) for net land take reduction by 2030 and monitor its progress.

Meeting the 2050 target requires intra-urban densification without neglecting the unique features of each city (Nicolau and Condessa, 2024), such as its availability of brownfields, vacant lots and underused areas (Schiller et al., 2021) and ecosystem services (Tardieu et al., 2021), as well as legal, economic, environmental, and social aspects, which have not been addressed in this study. Given that a single strategy that can be applied universally to achieve this target does not exist (Decoville and Feltgen, 2023), defining a policy for its fulfilment demands a more in-depth analysis encompassing those aspects and the specificities of each city.

loujiankun@tongji.edu.cn

Abstract
The urban wind-heat environment is a critical component affecting residents' health. This research investigates the impact of urban morphology on the heat and wind environment, focusing on three distinct residential blocks in Beijing's Nanluoguxiang Historic District. The three neighborhoods represent ancient, modern, and a mix of historical and modern urban forms. The ENVI-met was utilized to simulate wind speeds and temperatures for ancient times (1880) and modern times (2023). The results reveal that traditional urban forms with compact buildings and courtyards create more moderate wind and heat conditions. Modern urban forms with high-rise buildings and open spaces result in higher wind speeds and temperatures. The findings highlight the importance of preserving traditional urban layouts for comfortable microclimates.

Keywords: Urban microclimate, Urban design, Historic district, Numerical simulation, China

1 Introduction

Climate change has stood as one of the most formidable global challenges, with far-reaching implications for the environment and human societies. This challenge pertains to urban areas, where most of the world's population resides. The urban wind-heat environment, an integral component of the urban climate system, profoundly influences city residents' health and well-being. The morphology of modern cities often plays a crucial role in the urban wind-heat environment. Research has shown that urban morphology, including building layout and street design, can either facilitate or obstruct natural ventilation, with implications for heat dissipation and air quality management (Yuan *et al.*, 2014; Tsichritzis and Nikolopoulou, 2019; Palusci *et al.*, 2022). The concept of urban morphology has also been extensively studied in the context of the heat environment. The increase in global average temperatures has intensified the urban heat island effect, resulting in significantly higher temperatures in city centers than in suburban areas (Zhao *et al.*, 2011; Zhang *et al.*, 2022; Wu *et al.*, 2022). Numerous studies have delved into the role of building height, street orientation, and density in modifying urban temperatures (Johansson, 2006; Apreda *et al.*, 2020). This elevates the risk of residents experiencing heat stress and heat-related illnesses such as heatstroke, dehydration, and cardiac arrest. Therefore, improving the urban wind-heat environment is increasingly receiving attention from scholars and city administrators. However, most of these studies have been conducted within the context of modern cities. The research of microclimates in ancient cities or historical urban areas can assist in urban construction in two key respects. Firstly, it

aids in enhancing the understanding of the microclimate within traditional urban form districts in modern cities, thereby safeguarding the health of residents. Secondly, it offers references and support for the climate adaptability design of future cities.

The harmonious coexistence of ancient cities with the natural environment contrasts sharply with the modern approach of reshaping the natural environment through planning, reflecting different philosophies and methods of human adaptation to and transformation of the environment (Shi and Zhao, 2022). The study of ancient urban forms provides traditional architecture, and planning often includes elements that enhance natural cooling and ventilation (Yang *et al.*, 2022). Indraganti's (2010) research on Indian settlements also emphasized the strategic use of layout, street design, and materials for climate adaptation, noting the effectiveness of centralized, narrow streets in xerothermic conditions. Dili *et al*. (2010) analyze the passive environment control systems inherent in Kerala's vernacular architecture, demonstrating how traditional design principles effectively address the region's warm-humid climate. Arrar *et al*. (2022) investigated the outdoor thermal comfort levels in the historical urban fabric of Algiers Casbah, which informs urban design strategies to mitigate heat stress in traditional city settings. These findings suggest critical insights into sustainable design principles, particularly in their adaptive response to climate. The research of these ancient urban forms can inform modern urban planning and design practices, particularly in the context of climate change adaptation. The design of traditional Chinese cities often reflects a profound understanding of the local climate. Research on the renovation of traditional blocks guided by wind-heat environment simulations is also gradually emerging in China (Liu et al., 2022; Xiong et al., 2023; Zheng and Wang, 2019). However, given the vast territory of China and the complexity of various traditional blocks, fundamental research on the microclimate of different urban blocks is still relatively weak.

Historical blocks, characterized by a concentration of cultural relics and landmarks, or those broadly reflecting the traditional style and ethnic local features of a particular historical period, are integral to the urban fabric. In northern China, the morphology of historical blocks often evolves from the traditional Chinese courtyard, with building heights typically ranging from one to three stories. These structures generally incorporate construction techniques tailored to address the local climate conditions (Jin *et al.*, 2018). These areas, designed in response to the social context and climate of their time, offer urban residents natural, safe, comfortable, and pleasant spatial environments, thereby contributing significantly to urban construction, the preservation and enhancement of urban history and culture, and the quality of life for city dwellers. Therefore, this study selects the Nanluoguxiang Historic District in Beijing, China, which includes an area representative of ancient cities, a modern urban area, and an area that integrates ancient and modern elements, each representing different periods of urban development, and aims to address these gaps by examining the relationship between urban morphology and the wind-heat environment across different temporal scales, from ancient to modern cities. Through a series of simulations by ENVI-met under various climatic conditions, the research aims to analyze the differences and advantages and disadvantages of the three urban form types in terms of the wind-heat environment, providing insights and

inspiration for the construction of climate-adaptive cities and the preservation and development of historic districts.

2 Methodology

2.1 Study Sites

China's urban construction boasts a long history, extensive distribution, and a multitude of cities, making it an excellent subject for studying ancient human settlements. The forms of ancient Chinese cities evolved under various historical, geographical, cultural, and economic conditions, reflecting the ways and characteristics of how ancient Chinese people organized and utilized urban space, as well as the extent and manner in which they met the needs of social life. With its long history, Beijing is among the first batch of China's national historical and cultural cities and holds immense research value. Beijing Old City (39°28′ ~41°50′ N, 96,115°25′ ~117°30′ E), located in the center of Beijing. It has been developed for 3000 years and has been the capital city for 800 years. The Old City represents the unique scenery of traditional Beijing, featuring Siheyuans (courtyards with buildings on four sides) and Hutongs (lanes between Siheyuans). Beijing is rich in research materials, with a wealth of historical maps, documentary records, and numerous cultural heritages and historical blocks, making it feasible for research.

The Nanluoguxiang Historic District, the focus of this study, is situated in the northeastern part of the Beijing Old City, covering an area of 0.84 km^2. It was established during the same period as the Yuan Dadu(the name of Beijing in the Yuan Dynasty) and has a history of over 740 years. During the Ming and Qing dynasties, it was an upscale residential area for officials and gentry, and in modern times, it became a cluster of former residences of notable figures. In 1990, it was designated as one of Beijing's first historical and cultural protection areas. It is the only area that has preserved the Yuan Dynasty's "Li Fang System" of alleys and is the largest, most prestigious, and most resource-rich traditional residential area within the Yuan Dadu site (Fig.1). In 2016, the Design Guide for the Preservation and Renewal of Nanluoguxiang Historic and Cultural District was implemented, and the residential function began to be restored.

For this study, three sites within the Nanluoguxiang Historic District were selected as experimental sites. All three sites are located in the core area of the Historic District, on Mao'er Hutong, and are predominantly residential in function (Fig.1, 2). Site A is the courtyard at No. 5 Mao'er Hutong and the surrounding area of Ke Garden, representative of ancient cities. They are critical national and Beijing's cultural relics, preserving many historical features. Site B is the "Old Residence" and its surrounding area, which includes cultural relics, general traditional buildings, and many modern buildings constructed later that are in harmony with the traditional style. It represents the basic situation of a larger area of the Nanluoguxiang Historic District and is also the essential condition of many historical blocks in China. Site C is the courtyard at No. 45 Mao'er Hutong, located on the westernmost side of the Historic District. This group of residential buildings, constructed after the 1980s and

approximately six stories high, is consistent with the large-scale commodity housing communities built in China in the last century, representing a modern urban area.

Fig.2 Computational models

2.2 Numerical Simulation

Beijing experiences a monsoon-influenced humid continental climate, marked by hot and humid summers and generally cold, windy, and dry winters. As the capital city for both the Ming and Qing dynasties, Beijing has an extensive record of climate observations. From the first year (1875) to the fifth year (1880) of the Guangxu period, the Russian Church, located at the northeast corner of Beijing city, used meteorological instruments calibrated by the Central Observatory of St. Petersburg to measure meteorological data, resulting in the average monthly meteorological data for Beijing during the first to fifth years of the Guangxu era (Zhu, 1936). This data is consistent with the recent collection and organization of historical documentary records of warm and cold temperatures, which indicate that since the Yuan Dynasty, the eastern region of China has essentially been in a cold period, with a temperature

difference of approximately 1-2°C compared to the present (Fig.3) (Ge *et al*., 2002). Intensive urbanization during recent decades has dramatically modified the urban heat environment (Yan *et al*., 2010).

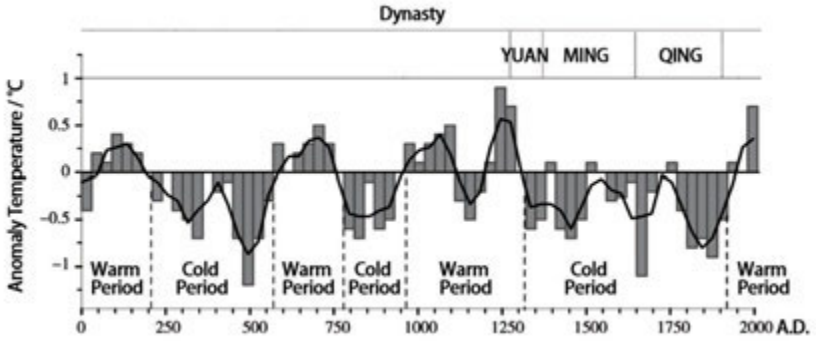

Fig.3 The sequence of average temperature changes in the winter half-year over the past 2000 years in the eastern region of China (Ge *et al*., 2002)

The simulation analysis software adopts the ENVI-met. It can simulate the energy, momentum, and material exchange processes between buildings, the ground, vegetation, and the atmosphere in small-scale urban spaces with the function of calculating the wind field, turbulence, radiation, air temperature, and humidity, which is based on the related theories of fluid mechanics, thermodynamics, and urban meteorology. ENVI-met has been widely used in urban microclimate research in different regions of the world (Andreou and Axarli, 2012; Ng *et al.*, 2012).

The ENVI-met numerical simulation encompasses two fundamental steps: constructing the computational model and setting parameters. The computational domain for Sites A and B is 100m×200m, while for Site C is 200m×200m, with a grid resolution of 4m. The computational model for the study area is constructed based on the building outlines within the modeling range (data sourced from Baidu Maps Open Platform at https://lbsyun.baidu.com), delineating elements such as buildings, underlying surfaces, and vegetation (Fig.4). The parameter settings for the data are primarily derived from the measurement data during the Guangxu period (1880). The observational data from the meteorological station (2023) (Tab.1). Site A, representative of ancient cities, underwent simulation for the year 1880. Site C, representative of modern cities, was simulated for 2023. Meanwhile, Site B was subjected to simulations under both meteorological conditions.

Tab.1 Wind-heat environment parameter settings

	Parameter setting 1880	Parameter setting 2023
Wind speed (m/s)	1.20	1.94
Average Air Temperature (℃)	26.9	28.5
Air Temperature at 14:00 (℃)	33.2	35

Humidity (%)	72	60

3.3 Data Analysis

The study simulated the variations in the wind-heat environment throughout the hottest day of the year in Beijing, July 30th, focusing on the pedestrian-level (1.4m above ground) wind speed, temperature, and relative humidity at different time points of a typical meteorological day. For this paper, the numerical simulation maps of the wind-heat environment at the peak heat of the day, 14:00, were selected for detailed analysis. The simulation results were analyzed to compare the wind and heat conditions across the three study sites.

4 Results

4.1 Wind Environment

Representing the ancient cityscape, Site A's simulation for the year 1880 reveals an average wind speed of 0.57 m/s, which is a significant deviation from the parameter wind speed of 1.20 m/s, indicating a -52.83% difference (Tab.2). The maximum wind speed recorded was 1.12 m/s, which also saw a decrease, dropping by 0.08 m/s. That is to say, the wind speed in all areas of Site A was less than the ambient wind speed.

Site B, which includes both cultural relics and modern buildings, was simulated under two different sets of meteorological conditions, allowing for a temporal comparison. In 1880, the average wind speed was 0.56 m/s, with a deviation of -53.75% from the parameter. By 2023, the average wind speed slightly increased to 0.82 m/s, a deviation of -58.00%. The comparison between the two time periods suggests that the overall impact on pedestrian-level wind conditions remains moderate. Among them, the simulation for the year 1880 showed no particularly significant difference compared to Site A. However, the simulation for the year 2023 exhibited the greatest proportionate decrease in wind speed among the four simulations.

As a representative of a modern urban area, Site C's simulation for the year 2023 shows the highest average wind speed among the three sites at 1.01 m/s, which is the greatest of all simulations. Among the four simulations, Site C's wind speed deviation from the parameter is the smallest, at only -15.83%. At the same time, the maximum wind speed was recorded at 3.37 m/s, which is significantly higher than the ambient wind speed and also the highest among all simulations. Compared to Site B's simulation for the year 2023, Site C's average, maximum, and median wind speeds are all considerably higher.

Tab.2 Simulation results of the wind environment

	Site A (1880)	Site B (1880)	Site B (2023)	Site C (2023)
Wind Speed Parameter(m/s)	1.20	1.20	1.94	1.94
Average	0.57	0.56	0.82	1.01

Wind speed (m/s)				
Deviation from the Parameter (m/s)	-0.63	-0.65	-1.13	-0.19
Deviation from the Parameter (%)	-52.83	-53.75	-58.00	-15.83
Maximum (m/s)	1.12	1.40	2.15	3.37
Minimum (m/s)	0.00	0.00	0.00	0.00
Median (m/s)	0.64	0.59	0.84	1.11

4.2 Heat Environment

The simulation results for Site A in the year 1880 indicate an average air temperature of 32.22°C, which is slightly below the parameter setting of 33.2°C, showing a deviation of -0.99°C or -2.97% (Tab.3). This change represents the only instance of a temperature decrease among all simulations. The maximum temperature recorded was 35.58°C, the minimum was 30.74°C, and the median temperature was 32.18°C.

For Site B, the comparison between the simulations of 1880 and 2023 reveals a gradual increase in the average air temperature. In 1880, the average temperature was 33.26°C, with a deviation of 0.06°C or 0.19% from the parameter. By 2023, the average temperature rose to 35.10°C, a deviation of 0.10°C or 0.28%. The difference between the simulations of the two meteorological conditions is not significant. Among them, the simulation for the year 1880 showed a distinct difference compared to Site A. The average value increased by 1.04°C, and the difference from the ambient temperature changed from negative to positive. Site B's highest temperature was 35.71°C, 0.13°C higher than Site C. Meanwhile, Site B's lowest temperature was 32.10°C, 1.36°C higher than Site C's. Regarding the median, Site B was 1.07°C higher than Site C.

Representing the modern urban context, Site C's simulation for 2023 shows the highest average air temperature among the sites at 35.33°C, with a deviation of 0.33°C or 0.94% from the parameter. This site represents the most significant increment among the three simulations with increasing temperatures. The maximum temperature reached 38.79°C, a 3.79°C increase from the ambient temperature. The median was 35.21°C, a 0.21°C increase from the ambient temperature, indicating that most of the area's temperatures are above the ambient temperature. Compared to Site B's simulation for the year 2023, Site C's average, maximum, and median temperatures are all significantly higher. However, Site C's minimum temperature, which was 33.41°C, is lower than the minimum value of Site B's 2023 simulation, which was 33.91°C.

Tab.3 Simulation results of the heat environment

	Site A (1880)	Site B (1880)	Site B (2023)	Site C (2023)
Air Temperature Parameter at 14:00(m/s)	33.20	33.20	35.00	35.00
Average	32.22	33.26	35.10	35.33

Air Temperature (℃)				
Deviation from the Parameter (℃)	-0.99	0.06	0.10	0.33
Deviation from the Parameter (%)	-2.97	0.19	0.28	0.94
Maximum (℃)	35.58	35.71	37.43	38.79
Minimum(℃)	30.74	32.10	33.91	33.41
Median(℃)	32.18	33.25	35.08	35.21

4.3 Comparison of Urban Morphologies

Site A represents the ancient city form, characterized by traditional courtyards (Siheyuans) and narrow lanes (Hutongs). This area is rich in cultural relics and historical features, providing a unique landscape preserved over time. The simulation results for Site A in 1880 indicate that the wind environment is influenced by the compact arrangement of buildings and the narrow streets (Fig.4a). The maximum wind speed is observed in the open courtyard areas, where the flow is less obstructed. Conversely, the minimum wind speed occurs in the confined spaces between buildings, where the flow is restricted and turbulence increases. The heat environment of Site A is moderated by a dense network of courtyards and Hutongs (Fig.5a). The extensive greenery within the courtyards played a significant role, providing shade and promoting natural ventilation. The lowest temperatures are observed in the shaded areas under the plants within the courtyards. The highest temperatures occur in the courtyards without plants that are directly exposed to sunlight. There is no significant difference between the south and north of the buildings.

Site B encompasses a mix of cultural relics, traditional structures, and modern constructions harmoniously integrated with the traditional style. This site represents the evolution of urban form over time, reflecting both historical preservation and modern development (Fig.4b, c). Similar to Site A, Site B shows a wind environment influenced by the traditional urban layout. The maximum wind speed is recorded in the open areas, while the minimum is found in the narrow passages between buildings. Similarly, Site B's air temperature is akin to Site A. Courtyards filled with vegetation offer better cooling effects. In contrast, enclosed courtyards without plants experience the highest temperatures (Fig.5b, c).

Site C represents the modern urban form, characterized by high-rise residential buildings and large-scale housing communities. This area resembles the urban development patterns seen in many contemporary Chinese cities. The simulation for Site C in 2023 shows that the wind environment is significantly different from the traditional forms (Fig.4d). The taller and more widely spaced buildings result in larger open areas with higher wind speeds. The wind speed at the edges of high-rise buildings is higher than the lowest at the edges of buildings, as in Sites A and B. The minimum wind speed for Site C is found within the central open spaces where the flow is more turbulent than elsewhere. The highest temperature at Site C occurs on the south side of the high-rise buildings, even though some plants are present (Fig.5d). The temperature on the north side of the buildings is comparatively lower. The lowest temperature

is found in the courtyard enclosed by several buildings at the northeast corner. This courtyard is surrounded by three buildings, with some plants in the middle.

5 Discussion

5.1 Urban Morphology and Wind Environment

Urban morphology profoundly influences the wind environment at the pedestrian level. The study's findings from the three sites in Beijing reveal that traditional urban forms, characterized by low-rise buildings and narrow streets, tend to create a more sheltered microclimate with reduced wind speeds. This is particularly evident in Site A, which represents the ancient city form, where the compact arrangement of buildings and the presence of courtyards and narrow lanes act as a buffer against the wind, resulting in a more moderate wind environment.

However, the modern urban form, exemplified by Site C, presents a different scenario. The taller and more widely spaced buildings in the modern urban area create larger open areas prone to higher wind speeds. While increased wind speeds can enhance natural ventilation and dissipate heat, they can also lead to discomfort and potential safety hazards, such as the risk of blown debris or difficulties walking against strong winds.

The transition from the traditional to the modern urban form, as seen in the evolution of Site B from 1880 to 2023, highlights the impact of urban development on the wind environment. The modernization process, marked by the construction of taller buildings and wider streets, has increased wind speeds at the pedestrian level (Kubota *et al*., 2008). This shift underscores the need for urban planners to consider the wind environment implications when designing modern cityscapes, ensuring that the benefits of increased ventilation are balanced against the potential discomfort and safety concerns associated with higher wind speeds (Yang *et al.*, 2013).

5.2 Urban Morphology and Heat Environment

The heat environment analysis in this study offers a perspective on how urban morphology can shape the thermal conditions experienced by city residents. In the traditional urban form, such as that represented by Site A, the compact building arrangement and the presence of courtyards and narrow streets contribute to a cooler microclimate (Nasrollahi *et al.*, 2017). The courtyards, often filled with vegetation, provide shade and promote natural ventilation, which can help to reduce the urban heat island effect (Su *et al.*, 2022). The dense network of courtyards and Hutongs in Site A creates shaded areas cooler than the surrounding environment, providing thermal comfort during the hot summer months. From 1880 to 2023, the rise in temperature at Site B was mainly due to the increase in ambient temperature. This change reminds us to pay attention to the new requirements for urban form design posed by global warming (Tringa and Tolika, 2023).

As seen in Site C, the modern urban form presents a different set of challenges. Taller buildings require greater distances between them, leading to larger open spaces and a more distant relationship between the buildings and the vegetation. These morphological characteristics can exacerbate the urban heat island effect. The simulation results for Site C indicate the highest average air temperature among the sites, highlighting the potential for increased heat stress on residents and the need for effective strategies to mitigate this impact.

5.3 Limitations and Future Research

While the study offers valuable contributions to the field, it has limitations. The simulations, though based on detailed urban models and climate data, represent a controlled environment and may only partially capture the dynamic nature of real-world urban spaces. Future research could enhance the accuracy of these findings by incorporating real-time meteorological data and conducting field measurements to validate the simulation results. Additionally, the vegetation modeling in this simulation is not sufficiently detailed, and there may be considerable variations in the plants over time, which is also a limitation.

Additionally, the study focused on a limited number of urban districts in Beijing, which may only represent some urban environments. Expanding the scope to include a diverse range of cities worldwide and climates would provide a more comprehensive understanding of the relationship between urban morphology and the wind-heat environment. In particular, there should be more exploration of the relationship between ancient urban forms and meteorological conditions. Urban form can not only be based on existing historical districts with characteristic features but also modeled according to records from historical maps to further investigate the interplay between urban form and other environmental factors of the microclimate, such as air quality and noise pollution.

6 Conclusion

Understanding the relationship between urban morphology and the wind-heat environment is crucial for creating urban spaces that are comfortable and sustainable. This study's comparative analysis of urban morphologies within Beijing's Nanluoguxiang Historic District reveals that traditional forms, characterized by compact buildings and courtyards, foster more moderate wind and heat environments. In contrast, the modern urban form exhibits higher wind speeds and temperatures, potentially intensifying the urban heat island effect. The comparison of urban morphologies across the three sites reveals the complex interplay between architectural form, urban layout, and microclimatic conditions. It emphasizes the need for a balanced approach to urban planning that respects historical contexts while addressing contemporary environmental challenges. The findings underscore the importance of preserving traditional urban layouts for comfortable microclimates and suggest that urban planning must adapt to mitigate the impacts of modernization and global warming on urban thermal comfort.

A balanced approach to urban form design is essential, one that respects historical contexts while addressing contemporary environmental challenges. On one hand, attention should be paid to the adaptability of historical blocks to the contemporary climate. The current protection of historical blocks often needs more consideration of the microclimate environment, with related regulations and standards having broad indicators. It is necessary to refine these standards to protect historical blocks from extreme climate damage and provide residents with a climate-appropriate place. On the other hand, the climate adaptability design of new buildings should be emphasized. The experiences and lessons from ancient cities' architectural styles and planning principles can be utilized to adapt the urban form to climatic conditions effectively. For instance, controlling the building heights in residential areas and enhancing the integration of architecture with vegetation can be adopted.

Regenerative Public Space as game-changing option for Thriving Communities

Karina Landman
Professor, University of Pretoria, Department of Town & Regional Planning
Karina.landman@up.ac.za (Orchid: 0000-0003-2734-4930)

Abstract
There is currently growing evidence of many conflicts and intolerance at both macro and micro levels in the world. These trends question the future of public space as a peaceful and inclusive commons. This paper focusses on regenerative public space in South Africa and its potential to contribute to thriving communities. By exploring the paradigm, process, and product, the discussion shares critical challenges facing public space development in the Global South while offering pathways for regenerative development and design applicable everywhere globally. The paper argues that regenerative public space can become a game-changer for peace construction and inclusion in diverse societies and contribute to healthy and thriving communities in global South and North cities.

Keywords: Regenerative public space; potential, process, peace, SDG 11.7, South Africa

Introduction

The world is witnessing many volatile situations. Wars are raging, populations are fighting for political justice, and in cities and towns, people are facing desperate conditions in a struggle for survival while the fear of crime creates growing intolerance. These events give rise to growing insecurity and the re-negotiation of territoriality at many scales. Re-territorialisation concerns more than just countries and regions but also spaces within cities. Public spaces are often reconsidered or re-negotiated through appropriation, either by those without space for survival or those who want to reserve the space for a select few through fortification. Hence, public space has become a place of selection based on the various needs contained within the survival or fortified city, and more often than not, creating a maze of juxtaposed entities varying between these two opposites. These trends raise many questions for the future of public space as a common collector and facilitator of inclusion, or as places of peace and prosperity.

Public space is considered to be spaces owned by the state and accessible to the public (Madanipour, 2003). They are very important as the glue in the city that ties together all the private spaces and allow people to move between them. Public spaces are also important as gathering spaces where people can interact and exchange ideas or goods in a peaceful manner. This is critical to allow social relationships to grow, flourish and thrive. Public spaces, such as streets, sidewalks, plazas and parks, also offer access to nature, through trees alongside roads, formal vegetation in plazas and a celebration of the nature in parks. However, exclusion and violence threaten access to public spaces and peaceful co-habitation in these spaces. “One of the important qualities of Positive Peace is that it creates societies that are more resilient. In

other words, better capable of adapting to their changing environments." (Killelea, 2024). This calls for resilient and regenerative public spaces.

Regenerative development and design extend the work of sustainability and resilience. The emphasis is shifted from existence to potential and recognises the interdependent web of multileveled structures of complex living systems. Regeneration acknowledges the unrealised potential inherent in a given system and its broader system. Its exploration enables the residing systems to evolve by expressing their latent potential (Hes & Du Plessis, 2015; Mang et al., 2016; Du Plessis, 2022). Finding the potential paves the way for a trajectory of responsible design, moving from conventional and green practices to restorative and reconciliatory practices toward regenerative development and design (Reed, 2007). Such an approach is relevant to address the challenges facing public space and urban transformation (Landman, 2019).

This paper focuses on regenerative public space in South Africa and its ability to contribute to thriving communities. Drawing from four case studies in the City of Tshwane (the municipality that includes Pretoria), South Africa, it unpacks an alternative paradigm for public space, proposes a different process for (re)development and design and offers examples of a few regenerating public spaces. These case studies were carried out as part of a National Research Foundation (NRF) funded Project (Grant: 137981) focussing on Regenerative Public Space. The NRF project focusses on the manifestation of regenerative public space and set out to develop a methodology to facilitate this in practice and ensure ongoing collaboration through an online digital platform.

By exploring the paradigm, process, and product, the paper shares critical challenges facing public space development in the Global South while offering pathways for regenerative development and design applicable everywhere globally. The paper argues that regenerative public space can become a game-changer for peace construction and inclusion in diverse societies and contribute to healthy and thriving communities.

Changing paradigm and the call for regenerative sustainability

Sustainable development has become an important concept worldwide to guide development practices to alleviate the harmful impact of urban development in the past century, adapt urban practices to be less dependent on finite resources, mitigate the impact on climate change, and transform cities and urban spaces to regenerative places. In essence, sustainable development is concerned with reducing the use of scarce resources to ensure prosperity for all, while minimising the impact on the planet and people. The United Nations developed the eight Millennium Development Goals to establish a joint base to guide interventions. These were replaced in 2015 by the 17 Sustainable Development Goals (SDGs) set out in the Agenda 2030. The SDGs are a collection of goals developed to serve as a "shared blueprint for peace and prosperity for people and the planet, now and into the future". The New Urban Agenda, highlights public space as a critical lever to transform urban areas through "multifunctional areas for social interaction and inclusion, human health and well-being, economic exchange and cultural expression" (2016:13). Goal 11.7 of the SDGs explicitly promotes "universal access to safe, inclusive and accessible, green and public spaces, in particular for women and children, older persons and persons with disabilities explicitly".

This goal, therefore, highlights the need for safe and inclusive public space to enable peace and prosperity.

However, to be sustainable, people and places need to adapt to changing needs and environments. Resilience is related to the ability of a particular geographic area, settlement, group of people or person to deal with a specific shock or disturbance in the system. In other words, resilience refers to the adaptive capacity of a particular place or people to respond to a crisis or changing conditions through particular responses in the socio-ecological system. However, change is not linear and emerges from complex relationships between multiple actors and environments (Walker & Salt 2006, Nel et al 2018). Resilience thinking offers a mechanism to work with change to adapt to disturbances in the system and transform those that are not conducive to the reorganisation of the system to bring forth new life, forms and functions (Du Plessis 2022). Urban resilience, dealing with ability of the urban system to adapt and transform, does not only depend on local authorities and their ability to develop resilience policies and plans to deal with natural hazards and disasters. Involving the skills of academics, practitioners and communities is far more likely to produce more robust strategies while enabling some level of flexibility to respond to the actual disturbance through increased awareness and knowledge (Walker & Salt 2006; Nel et al 2018; Orsetti et al. 2022)

Nevertheless, change should not just respond to a crisis or attempt to recreate the same places again. Regeneration is about improvement - not just maintenance – to create healthier and thriving people and places. More recent definitions highlight the importance of regenerative sustainability that goes beyond an attempt to maintain the status quo, and create opportunities for the environment and people to flourish in a harmonious and symbiotic relationship. Regenerative sustainability aims to "cultivate relationships that sustain the ability of the global social-ecological system to provide not just life-supporting, but also life-enhancing conditions for the global community of life" (Hes & du Plessis, 2015:39).

Regenerative development and design incorporate but goes beyond resilience thinking and are concerned with the co-evolution of humans and nature. All living systems survive by adapting in evolving environments (Mang et. al. 2016). This means that people do not need to be afraid of change, but use the opportunities to create different places that relate to the local place and the people living there. The aim is to ensure that both humans and nature can work together to create increased well-being.

> "*Thriving is possible for life on earth because of regeneration. All organisms including humans, live and breathe and continue to exist because they regenerate ... Thriving is a natural process*" (Visser, 2020:3).

Drawing from several authors who pointed out various issues related to regenerative development and design (Reed, 2007, Mang & Reed 2012, Du Plessis, 2012, 2022, Hess & Du Plessis 2015, Benne & Mang 2015, Mang et. al. 2016, Gibbons 2020, Landman et. al. 2019, Landman, 2024) and looking at various initiatives in South Africa, it is possible to highlight a number of principles of regenerative public space. These principles are a) the essence of place, b) evolutionary protentional, c) value-adding role, d) leverage points and e) control the hard lines.

Essence of place

Interventions should be based on an understanding of the essence of place, ensuring that they are specific and fit in the environment to allow co-evolution to occur. The essence of place emerges from the entire network of ecological and cultural systems within a specific geographic area. Revealing the essence of place shows the relation to broader environment and the history of the place to open up the potential of the place. Many stakeholders need to collaborate for this to emerge.

Evolutionary potential
The evolutionary potential seeks to uncover the unmanifested latent energy inherent in unused resources or locked up capital in rigid systems. It is the seed that enables the system's evolution to flourish and thrive. An awareness of the notion of evolutionary potential, together with a substantial effort to look for it in and around public spaces, can enable planners and urban designers to respond to change and transform if necessary, e.g. through spatial transformation.

Value-adding role
Livings systems continuously regenerate and depends on many subsystems to do this. The health of the whole-system depends on each member fulfilling its role to benefit each other. Public space, as a subsystem of the larger socio-ecological system in the city, need to add value and contribute to the whole-system's evolution. Examples may include public space's role in contributing to the ecological regeneration of a river system and the socio-economic uplifting of a marginalised community through improvement opportunities linked to the transformation of a space and its broader environment.

Leverage points
Energy or opportunity is created through opportunities for exchange, for example trading goods, sharing ideas and relaxing in nature. These activities happen in various nodes across many scales. Nodes are leverage points for transformation through interaction and exchange. Public spaces have the potential to act as key leverage points to initiate transformational exchanges through, for example, approaches such as urban acupuncture and tactical urbanism. Identifying leverage points implies considering which types of public spaces should be developed in which locations and how many, which links back to the necessity of considering the whole system.

Control the hard lines
Controlling the hard lines means only doing what is essential to meet, support or detract from the objective. It refers to the development of preconditions to enable the system to emerge, thus enabling rather than controlling actions by identifying absolute no-go areas and upper/lower limits. It deals with the 'operating rules' that determine behaviour and what is possible, bearing in mind the characteristics of a healthy system, such as emergence, self-organisation, complexity and open-endedness.

Regenerative sustainability offers a pathway to not only change mindsets to facilitate co-evolution, but also to guide built environment practitioners and other stakeholders to facilitate the process in practice.

Transforming process and the need for regenerative practices

Applying the concept and principles of regenerative development and design in practice is very context-specific and generally centred on three phases. Mang and Reed (2012) describe these

phases as 1) understanding of the place – as a way for people to unify nature and humans in a concrete way; 2) aligning place and people through the harmonisation of buildings and infrastructure with the patterns of the land and the cultural systems and 3) co-evolving mutualism to ensure continuous improvement through beneficial stakeholder relationships.

Broadly guided by this process and the local dynamics and conditions of the four case study areas (see the next section), the NRF project team - representing multi-disciplines - worked with four diverse communities from different parts of the City of Tshwane Municipality to develop a process that would contribute to regenerative public space in South Africa. This process involves three ongoing phases.

1. Reconnect through co-conceptualisation and collaboration

The first part of the process revolves around the potential value and evolutionary potential of the specific public space. This is usually centred upon questions that could involve the following. Why are we doing this? What is it that we want to change? Who is doing it? Who needs this? What do we care about? The value of a specific public space is often hidden in the characteristics of the space, the skills of the people, its distinctive patterns and relationships and the value to the broader environment. For example, linking back to the principles, the role of a public space to contribute to a larger ecological system or boost an existing social system.

The first part of the process requires all the relevant stakeholders to meet on site and think through a variety of issues. Delving deeper into the story of place, could involve the following questions:

1. What is distinctive about the place? (e.g. special places, structures, trees, vegetation, etc.)
2. What is distinctive about the people? (e.g. history, memories, skills, knowledge, etc.)
3. What is the value-adding role of the public space in the broader environment (precinct, neighborhood and city)?
4. What is the higher potential of the public space for all the people involved?

This part of the process can involve storytelling, interactive mapping, dashboards, surveys, etc. The main goal is to assist with the determination of the role of the space for the everyday users and the broader community or environment. Given this, it is important that people identify and discuss special places, share precious photos and memories and tell stories about historical and current day people and events.

The aim of phase 1 is, therefore, to reconnect the people to each other and the specific space through co-conceptualisation and collaboration to develop a common story and a vision to go forward. Working with specific communities in particular places allows for a common sense of purpose to develop. This in turn creates opportunities to bring different stakeholders together to foster the seeds for inclusion and peace, not only related to the exterior landscape, but also towards inner healing.

> *Social-ecological systems are far more than coupled human-nature systems in which humans rely on ecosystem services. Instead, social-ecological systems represent the combination of the 'exterior', as created by biogeochemical processes and activities (in which humans and their technologies have come to play a disproportionate part), and*

> *the 'interior', as created by, and experienced through, processes of thought and shared cultural phenomena* (Hes & du Plessis 2015:27).

Therefore, considering cities as socio-ecological systems and public spaces as a critical value-adding component of this systems, requires a focus on both the exterior landscape and the interior spaces of people to enable peaceful and inclusive transformation.

2. Revitalisation through co-creation and participation

The second phase of the process is concerned with the concrete manifestation of the vision in practice. It relates to interventions in a public space to revise or revitalise the existing landscape through the addition or modification of existing buildings and infrastructure to enable the public space to reflect the land patterns and the ecological and cultural systems towards the improvement of the broader socio-ecological system, the city. Initial questions could include the following: Who is the core team? Who can assist to manifest the vision? What do we need to start? Who can provide this?

This phase requires the relevant stakeholders to make decisions around the physical transformation of the public space and key actions that is needed to realise this. While architects, urban designers and planners can play an important role, they should be careful of dominating the process. Critical questions to facilitate the process, may include:

1. What can be or has been done to enable the space to realise its higher potential for the broader environment?
2. How have / can different interventions work with and connect different socio-ecological systems in and around the public space?

During this part of the process, stakeholders can co-design interventions utilising maps, models and on-site demonstrations during small community workshops. The aim of phase two is therefore to revise or revitalise the state of the public space through co-creation and participation to plan and design an accommodating and liveable space. Working with the specific community to develop and design the specific space, enables the seeds of inclusion and peaceful co-habitation to grow and flourish in an open and vibrant manner. This part of the process holds within it the potential to allow for the restoration of the balance between humans and between humans and nature. Healing is concerned with the reconciliation of different agendas and aspirations, working together to rebuild a specific space and allow it thrive in the broader socio-ecological system through the restoration of the flows of life.

> *Every development, no matter how small, enters and unspoken contract with the world that it inhabits from the moment that it is commissioned until it is torn down. It can be a burden on resources and disrupt life-sustaining processes, or it can contribute positively to the commons, the network of spaces and flows* (Kishnani, 2017:22).

In this way, public spaces can act as key leverage points to initiate transformational exchanges where small conscious and conscientious interventions in the right place can create beneficial, system-wide effects.

c) Reinvigorate through co-mutualism and cooperation

The third phase of the process is concerned with the ongoing care of the public space and its continuous evolution to ensure that it keeps on flourishing. Useful questions could include the

following. What do we need to do to ensure continuous care? How do we engage the larger community of care in the neighbourhood and city? How can the space allow possibilities for others to grow and thrive? How do we allow for evolution?

This phase involves the core team and wider stakeholder network to ensure the ongoing management, maintenance and care of the public space to allow it to spread its ripples of positive benefit outward into the larger environment. Key to consider is:

1. Who has or will ensure that there is ongoing care in the future? (partnerships, community groups, etc.)
2. What resources are necessary to manage and maintain the space?

This part of the process can utilise online platforms such as community websites, WhatsApp groups, and other Applications to build communities of care and spread the value of the public space to a wider audience. The development of a digital platform assists to facilitate an ongoing process of co-evolution through 1) access to data and information to highlight potential within the four communities and allow others to learn from it, 2) taking research activities outside the university to accommodate co-production of knowledge and facilitate participation, and 3) building ongoing cooperation between communities, academia and professionals from private practice towards greater knowledge sharing and integration (Landman & Guest, forthcoming). The purpose of these actions would be to maintain the momentum created by the interventions and ensuring ongoing care of the space in the future. In addition, it can enable the creation of wider networks of communities to allow for the evolution of multiple public spaces over time. This would allow for the reinvigoration of the public spaces and others in the larger environment through co-mutualism and cooperation.

> *The potential of a neighbourhood park lies in the health and well-being of the human and natural communities that it may benefit and the social bonds that it fosters. As the neighbourhood evolves, a well-designed park evolves with it. This implies that a park is more than its physical elements (playgrounds, benches, trees, fountains). From a living systems perspective, it also includes the process by which it is used, maintained, improved and celebrated over the years* (Mang et. al. 2016:118).

Regenerative Development and Design should therefore focus on co-evolution, requiring whole-systems re-orientation that connects human activities with the evolution of natural systems (Mang et al 2016). This is an ongoing process that involves continuous evolution, similar to the creation and maintenance of peace. There have been many misconceptions of peace and how it can be attained. It often implies that once the guns fall silent, peace has been achieved (Kallelea, 2024). This closes opportunities for everyday renewal and reinvigoration of peace through inclusivity in specific urban spaces (Figure 1).

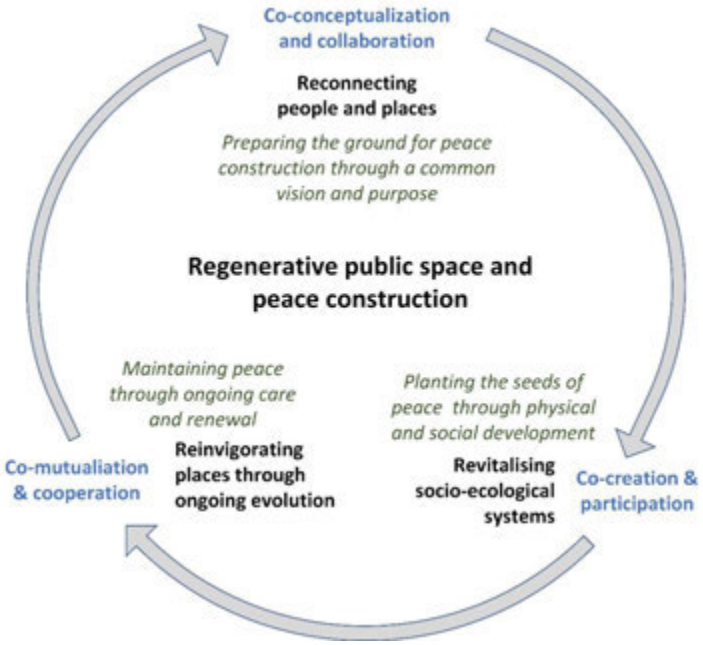

Figure 1: Regenerative public space and peace construction

Peace construction in public spaces should therefore also be concerned with finding new approaches to peacebuilding and development that extend beyond security to restructure societies and their relationship to nature so that they have the capacity to adapt and modify constantly changing environments. This could offer a pathway for continuous reinvigoration to create more resilient peace and other social characteristics, including stronger economic outcomes, better measures of well-being and more sustainable environmental performance (Kallelea, 2024). However, constant reinvigoration through co-mutualism and cooperation also implies that it may be necessary from time to time to revisit the vision of the space and restore the balance; hence the need for a continuous process of transformation and regeneration as indicated in Figure 1.

Transitioning spaces and requirement for ongoing care

As mentioned, applying the concept and principles of regenerative development and design in practice is very context-specific. Consequently, the process could vary in different contexts and conditions. Similarly, the outcome or product may be quite different. This is illustrated through the four case study areas located in the City of Tshwane, a large municipal area located in the Gauteng Province in north of South Africa. The municipal area (Figure 2) includes Pretoria, and covers an extensive area of 6,345 km². In 2017, the population was 3.31 million, as the municipal area housed 6% of the national and 25% of the provincial population. The principal economic activities included government and community services (30%), finance (25%) and manufacturing (13%). In 2017 Tshwane contributed to 28.4% of Gauteng's GDP and 10% of national GDP. However, despite the concentration of economic and research activities, unemployment was estimated to be around 24% in 2017. In addition, there are a growing

number of informal settlements with an estimated 19% of the population in 2017, residing in informal dwellings (City of Tshwane 2020/2021 IDP). The economic conditions have since deteriorated due to the Covid-19 pandemic, contributing to rising levels of inequality, poverty and unemployment and challenges related to service delivery and urban management and maintenance.

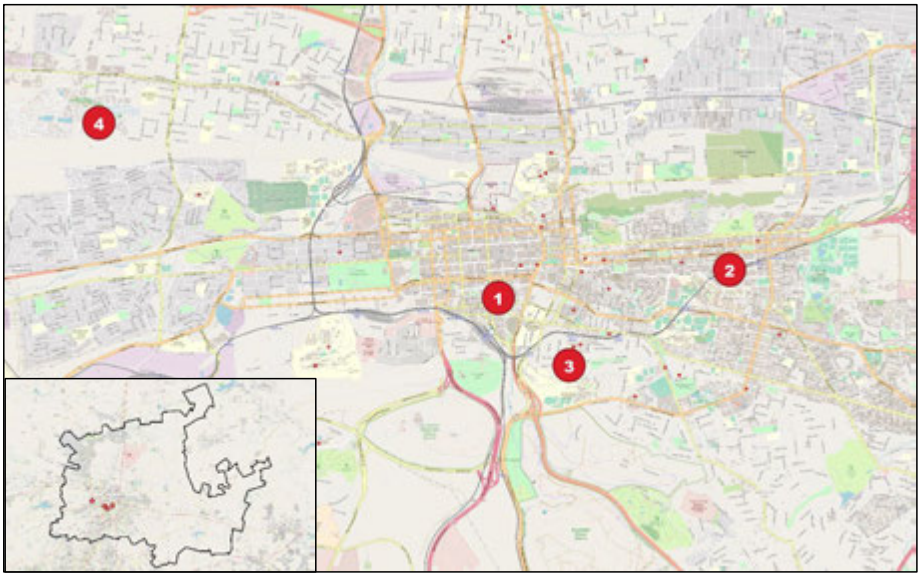

Figure 2: Location of four public spaces in the City of Tshwane (insert). They include 1: Burgers Park; 2: Moja Gabedi; 3: Muckleneuk Commons; 4: MYDO & Melusi Clinic (Source: Landman & Guest, forthcoming).

The NRF project focussed on four public spaces located in different parts of the municipal area (Figure 2). The four spaces were selected based on their ability to show various phases or notions of regenerative development and design in different socio-economic and physical conditions. The team worked closely with the core stakeholders to find out what happened in spaces, why and what they are planning for the future. The main intention was to find out what the regenerative development and design of public space could entail in South Africa. Each public space embodied a specific reality and transition story.

a) Burgers Park

The park is one of the oldest parks in the inner city of Pretoria, serving a very diverse population in a high density and mixed-use area (Figures 3 & 4). The Victorian Garden of 47,678 m^2 was completed in 1874. One of the key stakeholder groups involved in the regeneration of the park is *Friends of the Park*. They focus on mobilising resources, engaging stakeholders and ensuring security in and around the park through collaboration with local and private law enforcement entities. The Community-Based Organisation (CBO) also work with entities and institutions surrounding the park, including schools, churches and businesses, as well as those affected by it. Additionally, they try to foster a sense of ownership within the community and advocate the community's goals, needs and ideas to the city of Tshwane. The primary organisation overseeing several social programmes is the *Tshwane Leadership Foundation* (TLF), which manages and

repurposes buildings in the area to address social needs, including housing for women, young girls, homeless individuals, and those with chronic illnesses. They are assisted by Urban Studio, a partnership between the representatives, the Centre for Faith and Community, and the University of Pretoria. The Urban Studio focuses on providing social housing for homeless community members and women escaping from Gender-Based Violence situations.

Figure 3: Location and form of Burgers Park.

Figure 4: Nature of Burgers Park with high density buildings in the background.

The nature and use of the park changed several times over the years. Being located in the inner-city it caters for a diverse group of people form the surrounding higher-density housing in need to relax, recreate, connect to nature and meet other people. Despite challenges related to management, maintenance and security, the park is extensively used by people from all ages. However, over the years, the park struggled with ownership. Although formally under the care of the local authority, they have often failed to maintain the park, leaving it to the local NGOs and CBOs to care for the park. In spite of these challenges, ongoing initiatives, such as the annual Feast of the Clowns ensure that the importance of the park is re-emphasized. The Feast of the Clowns is an inner-city festival in Pretoria centered in and around Burgers Park. It was created and is still hosted by the TLF as a festival celebrating the city, building community and creating awareness of social justice issues. It is an annual proclamation of the city as a good place, lamenting actions that seek to rob the city of its soul and its people of access, dignity and justice (De Beer, 2020:234). The TLF, and the Centre for Faith and Community is working with many other stakeholders, including business owners, academics and other community organizations to find new ways to reconnect, revise and re-invigorate the park. These efforts are not only focusing on ways to address the lack of maintenance, but also finding ways for peaceful interaction of people from diverse backgrounds and socio-economic conditions sharing the park.

b) Moja Gabedi

This public space is located on an open space situated in a dense and rapidly growing area of Tshwane, namely Hatfield. The neighbourhood is one of the most dominant nodes in the City of Tshwane and is not only home to the University of Pretoria, but also includes prominent schools, large corporations and office blocks, and higher-density, mixed use housing developments. The representatives from Moja Gabedi and Reliable House, an institution focusing on homeless people, recognised the urgent need for addressing the negative space in the community. The strong influence of churches and religions in the area played a significant role in mobilising the community. Churches organised prayer sessions, providing food to participating community members. Reliable House offers homeless individuals access to food,

prayer and accommodation, while Moja Gabedi, a garden in the city, provides working opportunities for recovering drug addicts from Reliable House. In addition, it is an open space that any member of the public can use. Over a period of five years the space was transformed from a neglected and vacant open space to a vibrant, luscious garden with flowers, vegetables and fruits.

Figure 5: Location and form of Moja Gabedi

Figure 6: Nature of Moja Gabedi indicating a space to sit and relax with housing in the background.

The park is a result of people who cared about others and the waste in the city and who dreamed to heal a wound in the urban fabric. Building on the vision of a healing space and working with people who are trying to find their place in society alongside students doing community service, the space created new purposes for derelict land. Together, the Faith Based Organization, the University of Pretoria and the local City Improvement District continue to care for the thriving food garden, recreation space and small coffee shop. Students can also hire small allotments to plant food for themselves and the broader community. Working together, does not only foster inclusion, but also peacebuilding between different age and socio-economic groups in Hatfield and the larger city.

c) Muckleneuk Commons

Muckleneuk is an older, upmarket suburban neighbourhood close to the inner city of Pretoria. The community members shared a passion for nature and desire to revitalise a former neglected and unsafe space. To improve and connect the community, they formed a neighbourhood association and developed an urban design framework to identify areas to promote safe and community-friendly public spaces. However, they faced a backlash from some community members who were concerned about attracting drug-users, loud music and alcohol abuse in the public space. The representatives and residents were responsible for drafting the design, and physical elements were added in different phases as needed. The Cool Capital Festival in the Pretoria offered the impetus for the transformation of the space. Resources were obtained through donations, connections and community contributions. Telkom (a large telecommunications organisation), located next to the commons, donated a significant amount and provides electricity and water. Maintenance and combating challenges like vandalism and misuse requires constant involvement and active maintenance efforts.

Figure 7: Location and form of Muckleneuk Commons

Figure 8: Nature of the small park with rapidly growing vegetation.

The park is used by community members and people who pass by on a daily basis. The community also organizes regular events to raise funds for the ongoing maintenance and community-building. These events include movie-nights under the stars, informative talks on nature and self-development and Sunday food markets. These events that have also been able to extend the impact beyond the local neighbourhood and attract people from further away. While the land is owned by the municipality, the park is maintained by a few community members. The action of the core group shows how an idea to heal a scar in the urban environment can bring about a thriving space for both locals and visitors. Places of peace and inclusivity therefore does not have to be big spaces with large budgets, but could be the result of a small tactical intervention to unite people and place.

d) Melusi community spaces

Melusi is a predominantly informal settlement with a very high density including approximately 30,000 residents and 900 households located in the west of the City of Tshwane. The area includes inadequate service provision and many of the housing units are informal. The Melusi Youth Development Organisation (MYDO) was created to assist the youth with their schoolwork, providing food and extracurricular activities focused on sports and art programmes. MYDO coordinated with community health workers and stakeholders to provide resources and health services to the youth in a community that faced many challenges related to service delivery and maintenance of services. The MYDO centre developed into a prominent public space and community centre, with infrastructure sponsored by large donors such as Coca-Cola, other businesses and NGOs. The MYDO Project has become the heart of the community, and the organisation is registering as an NGO to facilitate involvement from sponsors and stakeholders. They assist around 200-300 students and aftercare learners per day. They have also partnered with the Faculty of Health Sciences at the University of Pretoria, located opposite the Community Centre to offer health services. Next to the clinic (Figure 9) is an abandoned municipal nursery. MYDO is investigating the possibility to work with the municipality to revitalise the space a green open space and sportsgrounds for the Melusi community.

Figure 9: Location and six of the MYDO center (top) and clinic (bottom). The municipal open space is located just south of the clinic.

Figure 10: MYDO community center and open space.

The MYDO center is a space of healing that allows the youth to develop and thrive through access to study rooms, computers, tutors and spaces for relaxation. It is a place of inclusivity that creates a peaceful environment where young people can study in a safe environment under the protection of capable guardians. It is an example where this public space has become a point of exchange to facilitate the flows of information and goods to assist the development of marginalized youth. The public space is a pulsing point that ripples through the community and vibrates its energy to build the larger system. MYDO is constantly evolving and searching for new ways to assist the youth and the broader community, for example through their efforts to repurpose the green open space next to the clinic for sportsgrounds and a park.

These four public spaces indicate that there are many challenges facing communities and institutions towards regenerative public space, especially in the Global South. The challenges in the City of Tshwane are related to a lack of funds for development, management and maintenance, as well as issues related to safety and security. This is especially true in public spaces that have to accommodate a diverse population from different ethnic groups and socio-economic backgrounds. However, despite the challenges, these cases have indicated that there are examples of regenerative public spaces, albeit at different phases, that offers hope for the establishment of peaceful and inclusive public space. Given this, regenerative development and design offers a pathway for peace construction in public space.

Conclusion: public space as game-changer for peace construction and inclusion

Drawing from four case studies in the City of Tshwane in South Africa, the paper explored an alternative paradigm for public space, proposed a different process for (re)development and design and offered examples of four regenerative public spaces to highlight the value of regenerative development and design as a game-changer for peace construction and inclusion.

Regenerative sustainability, as alternative paradigm, extends the work of traditional and contemporary sustainability (including resilience thinking) to focus on the improvement and regeneration of living systems to enable the co-evolution of humans and nature interacting in cities. This evolving paradigm emphasises the need to work with change and transformation of socio-ecological systems to enable both external (biophysical space) and internal (mental and social space) space. This process of transformation could be guided by five over-arching principles, namely a) the essence of place, b) evolutionary protentional, c) value-adding role, d) leverage points and e) control the hard lines.

The process to enable regenerative practices involves three phases. The first phase is concerned with reconnection of people and places through co-conceptualisation and collaboration of multiple stakeholders in a specific public space to develop a common story and vision. This creates the opportunity to identify the potential and the value-adding role of the space and foster the seeds of inclusion and peace through acknowledgement and inner healing. The second phase involves revitalisation through co-creation and participation to work with the socio-ecological systems to enable the vision to manifest. This part of the process facilitates the co-design of various initiatives to restore the balance between humans and between humans and nature to encourage healing and the development of thriving communities and places through inclusion and peaceful participation and co-habitation. The third phase relates to reinvigoration through co-mutualism and cooperation. It requires ongoing communication, support and involvement to ensure the continuous care of the public spaces and the people using them. Thus, allowing for evolution opens opportunities for everyday renewal to foster peace and inclusivity over a longer period of time.

Although the implementation of the process varies in different public spaces and contexts, the four case studies (products of various elements of regenerative development and design) illustrated the potential to assist with peace-making and peace-building in an inclusive and evolutionary manner. The discussion therefore highlights the value of regenerative development and design as a game-changer for peace construction and inclusion in diverse societies in the Global North and South contributing to healthy and thriving communities.

Abstract

Due to an ever-increasing change towards a circular economy and energy self-sufficiency, the energy production and the use of it must be redefined. This does not stop at the water- and wastewater industry, which is responsible for a large amount of a municipality's energy consumption. However, WWTPs can also make a significant contribution to the energy transition and circular economy. Sustainable hydrogen, produced decentrally, regionally and for regional consumers, will play a important role in the future energy supply. The aim of this study is to identify possible potentials and technologies for local hydrogen production, conceivable alternative uses, research programmes, funding opportunities, but also challenges and limits with regard to the possibilities of hydrogen production at the approximately 10,000 municipal WWTPs in Germany.

Key words

Hydrogen production, regionality, wastewater management, circular economy, sustainability

1. Hydrogen demand and production options

In order to reach climate goals and achieve deep decarbonisation of the society, transformation of our entire industrial landscape towards a circular economy, sustainable production, and renewable energies is needed. Of course, the wastewater sector must also be considered and contribute to the energy transition. Some sectors already have obligations to save energy, recycle raw materials by comitted recovery rates or using a certain proportion of recyclates. In Germany and Switzerland, for example, phosphorus will have to be recovered from sewage sludge in the future. In other areas of wastewater treatment further research and development are being carried out so that wastewater management contribute further towards sustainable industries, including nutrient recovery (Nitrogen) excess energy usage (Heat or hydrodynamic) (Qadir, M. et al., 2020; Nagpal, H. et al., 2021).

Here, the revision of the Urban Wastewater Directive (in German - Kommunale Abwasserrichtlinie) will bring about a lot of positive changes across Europe in terms of circular economy, Electricity consumption, reuse, recycle and the production of green energy to cover self-consumption. However, this will also lead to major challenges for wastewater treatment plant (WWTP) operators. Many innovations are to apply to WWTP with a size of 10,000 PE (Population equivalents; in German - Einwohnergleichwerte/EWG) or more. Financially, in terms of personnel and organization, all of this must be managed.

The availability of sustainable hydrogen as an energy carrier and as an indispensable raw material is an important key technology. For example, the German National Hydrogen Strategy focuses on green hydrogen (Schuberth, J., 2023) and its production potential. By 2030, instead of 5.000 MW (5 GW), 10.000 MW (10 GW) of Electrolyser capacity must be created (Federal Ministry of Education and Research – BMBF et al., 2023). There are various ways to produce hydrogen in wastewater treatment. Several ways and possible synergies, but also their disadvantages, will be shown.

Apart from providing suffient amounts of hydrogen by centralized or decentralized production sites, the hydrogen distribution is also a very demanding task. The transition of natural gas pipelines to be “hydrogen-ready” will cost 45 billion Euros (DVGW, 2021). For the transition period, short and long term storage options and conversion methods für hydrogen will play an important role.

For this purpose, biomethanation is an interesting area of application, in which hydrogen and carbon dioxide are converted into methane. We would also like to take a closer look at this in this study.

Green hydrogen can be produced at WWTP and thus synergies, such as the use of the resulting oxygen or wastewater as a raw material, can be used.

In addition to green hydrogen as a possible energy carrier, the oxygen also obtained during water electrolysis can be used in the biology of the WWTP or as a starting material for a so-called fourth purification stage in order to remove further pollutants from the wastewater stream. The resulting wastewater is purified in the sewage treatment plant and thus serves as an additional raw material. The electrolyser waste heat can also be used in the wastewater treatment plant. Nitrogen-rich side streams in the WWTPs have great potential to produce hydrogen from them. This also applies to the biogas produced y digestion of raw and/or excess sludge. Furthermore, wastewater or sewage sludge can also be used as sources of supply for extraction via biological or thermal processes. The potential hydrogen production and therefore the optimal production technology is heavily depending on the situation of the WWTP, like influent, sludge composition, biogas production, or synergies on site.

In addition, using synergies with nearby industries, cycles can be closed in the sense of the circular economy. WWTPs are given great potential (Jentsch, M. F. et al., 2019). Regional electricity surpluses can also be used, and CO_2 emissions and energy dependencies are reduced.

The mentioned technologies are presented in more detail in the study and their feasibility in municipal WWTPs is evaluated. The findings can also be used as a basis for industrial wastewater treatment plants.

At the end of the introduction, however, a distinction should now also be made as to what type of hydrogen is involved. The most common term is grey hydrogen. The grey hydrogen is produced from fossil fuels. Blue hydrogen, on the other hand, is when the carbon dioxide produced during hydrogen production from fossil fuels is used and not simply released into the environment. Green hydrogen means that no additional carbon dioxide is produced during its production process (Federal Ministry for Economic Affairs and Climate Action – BMWK et al., 2023).

Current estimates assume that up to 800 TWh of hydrogen will be needed in Germany alone by 2050 (German Bundestag et al., 2022), whereby green or at least blue hydrogen in particular should be purchased and used in order to achieve the climate targets.
Germany was produced and consumed around 55 to 60 TWh of hydrogen in 2020, but this is mainly grey hydrogen from natural gas and only about 5% green hydrogen (Noack, C. et al., 2015; Merten, A. et al., 2020).
In 2019, German WWTPs produced around 1.515 GWh or 1.5 TWh of electricity (Federal Statistical Office – Destatis et al., 2020).
To calculate the amount of hydrogen that can be produced with 1.5 TWh of electricity, we assume an efficiency of 75%. Depending on the type of electrolysis, the efficiency is around 70% to 80%.

$$Amount\ of\ hydrogen = Electricity\ in\ TWh\ x\ Efficiency$$

$$Amount\ of\ hydrogen = 1{,}5\ TWh\ x\ 0{,}75$$

$$Amount\ of\ hydrogen = 1{,}125\ TWh$$

This would allow the WWTPs to cover around 0.14% of the hydrogen demand forecast for 2050. As a rule, however, the WWTPs use the self-generated electricity themselves, which would make the proportion for hydrogen even lower.
The following text shows the various technologies, research projects, funding opportunities, corresponding laws and obstacles.

2. Presentation and explanation of the different technologies

a. Electrolysis of water

Various processes and technologies can be used to produce hydrogen. This study explains how electrolysis of freshwater, treated wastewater, desalinated seawater, or direct electrolysis of saltwater works. Alkaline water electrolysis (AEL) is very widespread. It is the most established technology among the proven electrolysis processes. However, it has the most problems in intermittent operation associated with renewable energy. Polyelectrolyte membrane electrolysis (PEM), also known as proton exchange membrane electrolysis, is therefore becoming increasingly important. Very large research efforts are being made in the field of anion exchange membrane electrolysis (AEM) and high-temperature electrolysis (HTEL). The efficiency, the lifetime of the electrodes and the operating costs of the electrolysers vary greatly depending on the technology used. In addition, the operating costs are influenced by the purity of the water, which material is used for the electrodes (Aluminum, Copper, Iron, Nickel, Zinc), whether the waste heat from the electrolyser can be used and how high the electricity demand is.

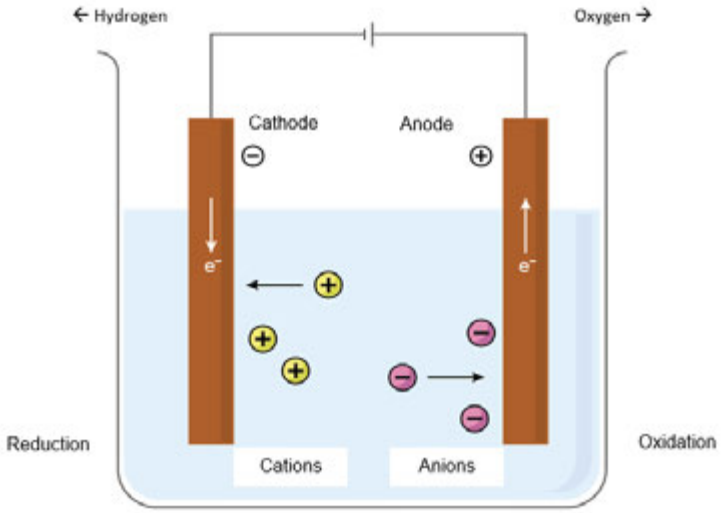

Figure 1: Basic design for water electrolysis (Vögtil, Dr. A., 2024), with own modifications

Electrolysis is the process of using electrical energy in the form of electric current to break down water into hydrogen and oxygen, as you see in figure 1. Electrolysis can take place in an acidic, alkaline and neutral solution. Figure 2 shows the three different electrolytes.

In acidic solution:

Cathode: $4\,H_3O^+ + 4\,e^- \longrightarrow 2\,H_2 + 4\,H_2O$

Anode: $6\,H_2O \longrightarrow O_2 + 4\,H_3O^+ + 4\,e^-$

Overall reaction: $2\,H_2O \longrightarrow 2\,H_2 + O_2$

In alkaline solution:

Cathode: $4\,H_2O + 4\,e^- \longrightarrow 2\,H_2 + 4\,OH^-$

Anode: $4\,OH^- \longrightarrow O_2 + 2\,H_2O + 4\,e^-$

Overall reaction: $2\,H_2O \longrightarrow 2\,H_2 + O_2$

In neutral sodium sulphate solution:

Cathode: $4\,H_2O + 4\,e^- \longrightarrow 2\,H_2 + 4\,OH^-$

Anode: $6\,H_2O \longrightarrow O_2 + 4\,H_3O^+ + 4\,e^-$

Overall reaction: $10\,H_2O \longrightarrow 2\,H_2 + O_2 + 4\,H_3O^+ + 4\,OH^-$

By neutralization: $10\,H_2O \longrightarrow 2\,H_2 + O_2 + 8\,H_2O$

After shortening: $2\,H_2O \longrightarrow 2\,H_2 + O_2$

Figure 2: Representation of different electrolytes (Kurzweil, P. et at., 2022), with own modifications

To produce one kilogram of hydrogen, you need about 9 to 10 liters of water. In addition, you need about 53 kWh of electricity. The degree of utilization is about 60 - 85% (GASAG et al., 2022).

Probably the best known and most widespread electrolysis application is the electrolysis of fresh water (drinking water or well water).
Before that, however, the drinking water must be purified of disturbing minerals, i.e. salts. Only ultrapure water can be used to prevent salt deposits on electrodes or the membranes. As a result, the service life can be shortened and the service life of the system components can be increased (Jabs, F., 2021).
Important in terms of utilization: The calculated efficiency depends on how the energy content of the hydrogen is calculated. You can use the HHV (Higher Heating Value) or the (significantly lower) LHV (Lower Heating Value). In relation to the HHV (Higher Heating Value), this results in correspondingly higher values.

b. Electrolysis of treated wastewater

Due to the ever-increasing shortage of freshwater, attempts are being made to utilize treated wastewater instead of freshwater in electrolysis. However, it should be noted that due to the substances still contained in the treated wastewater, such as organic compounds, bacteria and salts, a great deal of effort must be made in the purification of the wastewater. Tests at the Straubing sewage treatment plant have shown that the wastewater from a partial flow of the sewage treatment plant after the normal purification cycle and an additional ultrafiltration overloaded the test downstream test activated carbon filter within a very short time, making it no longer possible to regenerate the activated carbon. Thus, ultrafiltration with an activated carbon filter is unsuitable for providing water for desalination and further for the supply of an electrolyser, at least in WWTPs with trickling filters. Alternative pretreatment technologies of wastewater are nanofiltration or reverse osmosis before the water can be fed to the desalination plant and an electrolyser. This not only increases the energy requirement, but also the amount of water, because, for example, process-related water losses have to be compensated for during reverse osmosis. Electrolysis would then take place in the same way as freshwater electrolysis.

c. Electrolysis of desalinated seawater

Here, too, the salt water must be specially pre-treated. There are, especially in the Arab world, many seawater desalination plants that desalinate the seawater to supply of potable water and also for the supply of electrolysers. However, a lot of energy is needed for desalination and hydrogen production, which is mostly obtained from fossil fuels. Therefore, it is mainly grey hydrogen that is generated here. In addition, the degree of utilization is even lower, as the purification of the salt water is time-consuming. Certainly, many more countries and regions will be dependent on saltwater desalination plants in the future due to global warming and the lack of precipitation. Therefore, this would be a way to combine both, i.e. the provision of drinking water and ultrapure water for electrolysis.

d. Direct electrolysis of salt water

Recent research and experiments have shown that direct electrolysis of salt water is quite possible, at least on a smaller scale. For this purpose, Tianjin University in China operates a pilot plant that produces about 40 liters of hydrogen per hour from salt water (Klatt, R., 2023). The main challenges in seawater electrolysis are that the chlorine (Cl-) contained in seawater has an extremely corrosive effect on the electrodes. In addition, there are many other components that attack the electrodes and membranes. These include calcium and magnesium, which are deposited as hydroxide precipitates on the cathode and anode, thus

reducing performance and service life. Tianjin University has protected the electrodes from these influences with a special nickel coating.

WWTPs are usually the largest energy consumer in a municipality. In 2021, 31.6 kWh were needed to treat approx. 82 m³ of wastewater per PE (Population equivalents; in German - Einwohnergleichwerte/EWG) per year. The share of self-generated electricity generated by the WWTPs participating in the performance comparison is less than 40% (DWA Working Group BIZ-1.1 "Wastewater Treatment Plant Neighborhoods" et al., 2022). If, in the future, electrolysers are also to be established at WWTPs for the production of hydrogen, the demand for electricity will increase significantly. If the supply of green electricity cannot be secured, hydrogen production will not produce green hydrogen and should therefore be viewed critically. In addition, WWTPs will have to supply themselves with green energy in the future in order to achieve their own energy self-sufficiency. As a result, there may be a certain amount of competition between the company's own energy supply and the production of hydrogen. The investments must be covered by subsidies, or at least largely covered, to minimise negative effects on wastewater charges for the inhabitant of a municipality or city. Of course, it would also be conceivable to install hydrogen-capable CHP (Combined Heat and Power) units on the wastewater treatment plant, which would then convert the hydrogen produced in-house into electricity and heat. However, the usefulness, cost-effectiveness and operational safety of all concepts must be carefully examined. Likewise, the safety of handling hydrogen, the effort required for certifications and the need for qualified specialists must not be ignored.

e. Hydrogen production from nitrogen-rich material flows

i. Wastewater Plasmalysis

By means of the so-called wastewater plasmalysis, hydrogen can be obtained from effluent from sewage sludge dewatering, slurry or vapours from sewage sludge drying. These media contain high nitrogen-rich loads, mostly ammonia, which are ideal for the process. Graforce has developed, patented and implemented an established process in various plant sizes.

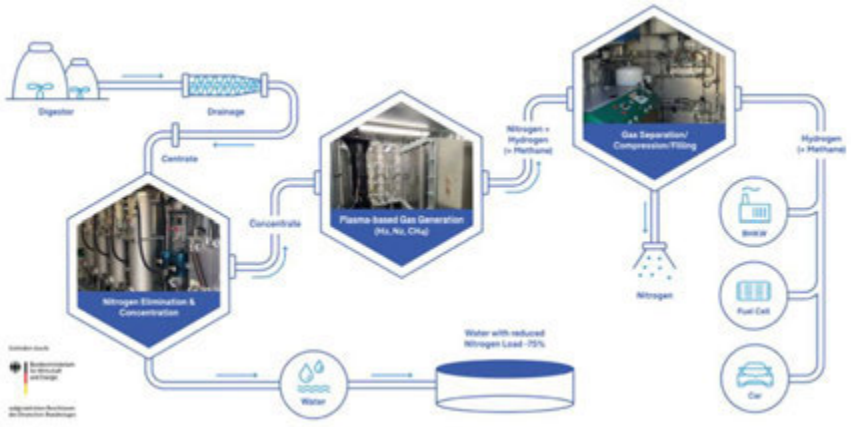

Figure 3: Production of green hydrogen from ammonium-containing wastewater (Cronenberg, A. 2020)

In this process, which is shown in detail in figure 3, a plasma is generated from (green) electricity. In this high-frequency plasma field, the nitrogen and carbon compounds in the water are split. In fact, the reverse reaction of the Haber-Bosch process occurs in the case of nitrogen compounds:

$$2\ NH_3\ (g) \xrightarrow{Plasmalysis} N_2(g) + 3\ H_2\ (g)$$

The energy requirement of this process is significantly lower than that of conventional electrolysis. Such a process reduces the Nitrogen chargeback from sludge treatment and facilitates the subsequent treatment of this effluent and produces green hydrogen. Prerequisite is obtaining chemically pure and concentrated soluten of ammonia, impurities can produce unwanted by-products and hamper the hydrogen production. A corresponding plant is operated in Berlin Waßmannsdorf as a demonstration plant for the treatment of the centrate of sewage sludge dewatering.

ii. Plasmalysis of biogas

Here, too, there is great potential to produce hydrogen and also to establish a solid carbon dioxide sink. The so-called carbon black can be obtained as carbon in solid form for other branches of industry, e.g. for asphalt or tire manufacturers. The company Graforce has also developed a corresponding process here.
Clearly explained in figure 4, in this process, a plasma is also generated from (green) electricity. In this high-frequency plasma field, methane, which is contained in biogas (or

natural gas), is split into its two molecular components, hydrogen and carbon. Thus, 4 kilograms of methane and an additional 10 kWh of electricity produce 1 kilogram of hydrogen and 3 kilograms of elemental carbon. The hydrogen produced in this way is also known as turquoise hydrogen. Such a system is operated on the roof of the MOA Hotel in Berlin. Here, natural gas is split into carbon and hydrogen by means of plasmalysis, the hydrogen fires a heating boiler, and the carbon is collected and reused for further processes.
The application for biogas is more efficient, if the methane content is high. WWTPs can raise the methane yield by adding high caloric wastes like fat float to the biogas digester.

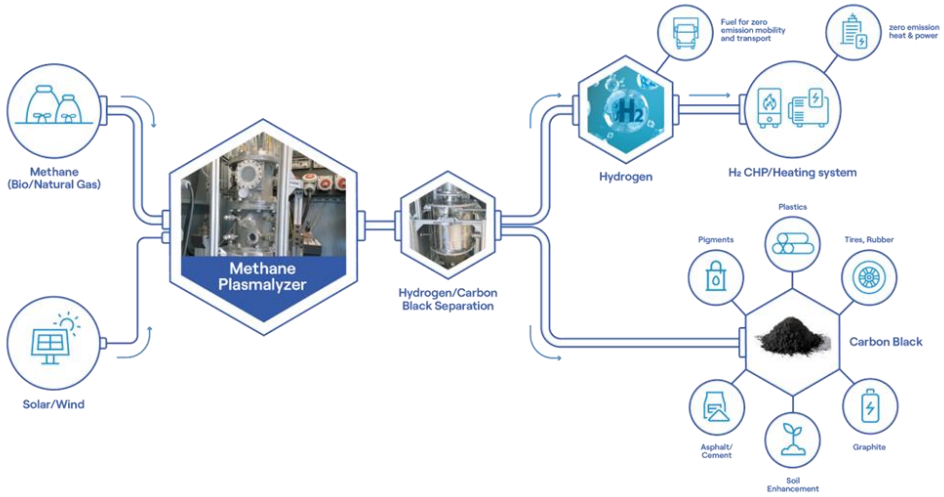

Figure 4: Production of green hydrogen from methane plasmalysis (Graforce GmbH, 2020)

f. Thermal sewage sludge treatment

Sewage sludge contains large amounts of organic compounds. Non-stabilized sewage sludge contains up to 75%, anaerobically stabilized sewage sludge contains 50 – 55% organic compounds. These can be converted into hydrogen, carbon monoxide, carbon dioxide and methane by substoichiometric combustion or gasification. Water vapour is a suitable oxidizing agent here, a large part of the hydrogen produced also results from the water, not from the organic compounds. Air is also possible, but not favored due to the dilution of the product gas with nitrogen and nitrous oxides.
Gasification takes place optimally at temperatures higher than 850°C and in a fluidized bed reactor, analogous to thermal combustion. Ideally, this also makes it possible to recover phosphorus from sewage sludge ash, as required by the Sewage Sludge Ordinance (in German - Klärschlammverordnung - AbfKlärV), which was amended in 2017, for sewage treatment plants > 100,000 PE or > 50,000 PE from 2029 or 2032. The necessary heat can be provided by simultaneous incineration of part of the sewage sludge in the combustion chamber or by separate incineration of sewage sludge or other energy sources and the subsequent transport of the heat by means of heat pipes or heat exchangers.
In addition to the gaseous compounds, the flue gas also contains tar compounds, which must be condensed. The gas must then be purified, and the hydrogen yield can be increased by means of water gas shift. The hydrogen must then be removed from the gas mixture. Possible

methods for this are pressure swing absorption or organometallic frameworks. The lean gas must be treated, for example by off gas burning, in order to prevent the emission of harmful gases.

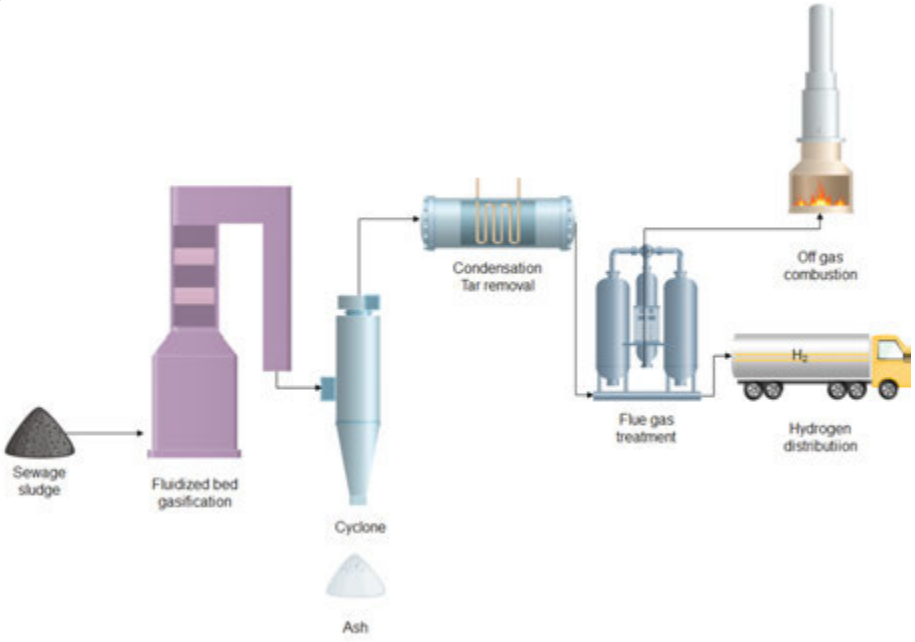

Figure 5: Schematic structure of sewage sludge gasification, own scheme by Jürgen Pettrak

As can be seen from the figure 5 above, many process steps are required to produce renewable hydrogen from sewage sludge. The advantages are that raw materials such as phosphorus can be recovered and the production of hydrogen can contribute to the energy transition. However, studies currently suggest that economical operation for gasification is only possible in very large plants (Lumley, N. P. G., 2013), with hydrogen separation being added as an additional treatment step. The gas quality depends strongly on the composition of the sewage sludge and therefore has a very strong influence on economic efficiency. Depending on the process technology, up to 50% hydrogen can be achieved in the gas mixture.
For this purpose, suitable locations must be sought and found, as is currently often planned with mono-incineration plants for sewage sludge, in which sufficiently large quantities of sewage sludge are available and there are customers for the hydrogen produced. To comply with german or swiss legal regulations, phosphorus recovery must be possible, in order to be able to carry this out economically, sewage sludge with high phosphorus contents is necessary, and in addition, little or no bed material may be discharged so as not to further dilute the phosphorus content. Economic feasable operation of such plants either require centralized sites or close proximity to WWTPs.
There are some pilot plants in operation, such as Green Hydrogen Technology in Leoben, but there are currently no large-scale plants planned.

g. Biological processes

Sewage sludge or wastewater can also be used to produce hydrogen via biological processes.

The principle in a nutshell:
Microorganisms break down organic compounds and produce hydrogen under anaerobic conditions. These microorganisms can represent pure cultures, i.e. a selected strain, co-cultures, i.e. several selected strains, or a mixed flora. Hydrogen is already produced in the digester during normal operation of a biogas plant and is needed to convert CO2 into methane. By acidifying the fermentation substrate to pH 5-6, methane formation can be inhibited and only CO2 and hydrogen are produced (Cai, M. et al., 2004).
There is a variety of hydrogen-producing microorganisms, from mesophilic (25 - 40°C) clostridia to hyperthermophilic (65 - 90°C) thermotogales (Kengen et al., 2009). The greater the load of organic matter in the water, measured by the chemical oxygen demand (COD), the higher the theoretical yield, but bioavailability, which can be determined by the biological oxygen demand (BOD), also plays an important role here.
The hydrogen yield from sewage sludge decreases rapidly with the degree of sewage sludge stabilization (Kim, S., 2004). This is not surprising, since the easily degradable organic load has already been metabolized in both aerobic and anaerobic sewage sludge stabilization, making the residue difficult to degrade.
For both sewage sludge and raw wastewater, pre-treatment of the substrate is therefore necessary to increase gas yields (Mohan, S. V. et al., 2008). The most efficient pre-treatment depends on the type and composition of the substrate. For example, larger aggregates are broken down into smaller, more easily accessible flakes by physico-chemical processes such as thermal pressure hydrolysis or acid treatment. Longer, difficult-to-degrade molecules can, for example, be broken down into shorter molecules by acidification, which are then more bioavailable.
For biological hydrogen production, it is also promising not to focus on municipal WWTPs, but rather to use wastewater streams rich in organics, such as wastewater from breweries, milk processing industries, oil mills, or similar industries that produce oil, protein and/or sugar-rich material streams, which can then be used for hydrogen production by means of selected cultures. Often, an increase in efficiency can be expected through pre-treatment, but the gas yields are much higher than with wastewater or sewage sludge (Preethi et al., 2019).

i. Biomethanation

Biomethanation uses the methane-forming microorganisms of the Archeen type. They can withstand extreme living conditions, such as high temperatures and pressures (Bär, K. et al., 2015). However, the process usually takes place between 30–70 °C in the technical reactor and a distinction is made between the in-situ and the ex-situ process:
In the in-situ process, the hydrogen produced from electrolysis is introduced directly into the digester (Bär, K. et al., 2015). This has the advantage that existing fermenters can be used for power-to-gas concepts without additional reactors. However, since other steps take place in anaerobic fermentation in parallel to methanation, the conditions in the fermenter are not specifically tailored to the archaea. This results in lower methane formation rates. In addition, large quantities of hydrogen are needed immediately, as the volumes of the fermenters are very large.
External reactors (ex-situ methods) are quite efficient (Bär, K. et al., 2015). This has the advantage that the microorganisms can obtain the perfect framework conditions and the use of hydrogen can be better regulated. In addition, the required carbon can also be used from external sources. The most relevant reactor concepts for process engineering are stirred tank, trickle bed and bubble column reactors (Manig, R. et al., 2023).
Another advantage of biomethanation is the elimination of hydrogen storage facilities, which are not available in Germany in the required quantity and size. Either disused salt caverns,

exhausted oil or gas fields are used, or containers built above ground that first have to be produced and erected. Among other things, lengthy planning procedures are necessary for both, and the metabolism of hydrogen by microorganisms in the exhausted oil and gas production fields is another problem. There is an urgent need for further research efforts with regard to underground storage options, as many safety questions and which chemical reactions take place, among other things, remain unclear (Heinemann, N. et al., 2021). In addition, the biomethane obtained can be used directly as fuel for agricultural vehicles, for city buses or the waste collection fleet of cities or companies.

3. Hydrogen Research projects at wastewater treatment plants

As the use of hydrogen as a clean energy carrier becomes increasingly important worldwide and efforts to combat climate change and reduce dependence on fossil fuels are intensified, WWTPs are of course also increasingly becoming the focus of research and technology companies in this context. They are trying to optimize the purification of wastewater and also to harness the potential for the production and use of hydrogen.
Research projects on hydrogen production at WWTPs are the focus of this chapter. These projects aim to optimise wastewater treatment processes by using innovative technologies to produce hydrogen from biological waste streams. Not only are environmentally friendly alternatives to conventional energy generation being explored, but synergies between wastewater treatment and the renewable energy industry are also being created.
Table 1 takes a closer look at the various research projects on hydrogen production in WWTPs.

Project Name	Project Partners	Goal	Technology	Performance	Synergies	Project Status	Reference
ARRIVED	Wirtschaftsbetrieb Mainz, TU-Kaiserslautern	Oxygen, hydrogen as a by-product	Water electrolysis and extension of the 4th purification step for the elimination of trace substances from ozonation and a filter stage with granulated activated carbon	ca. 1,25 MW	Oxygen for ozonation, waste heat, hydrogen for blending into the natural gas grid	Electrolysis is an out-of-budget tender	(Environmental Innovation Program et al., 2024)
SeWAGE PLANT H	Stadtentwässerung Hannover, Siedlungswasserwirtschaft und Abfalltechnik (ISAH), Institut für Elektrische Energiesysteme (IfES)	Hydrogen, oxygen as a by-product	Water electrolysis	1st. Stage: 2,5 MW; 2nd. Stage: 17 MW	Oxygen for ozonation, waste heat for the district heating network, hydrogen for the natural gas grid	In implementation	(Leibniz Universität Hannover et al., 2024)
WaStraK	Emscher-genossenschaft, Forschungsinstitut für Wasserwirtschaft und Klimazukunft an der RWTH Aachen e. V (FIW), TUTTAHS & MEYER Ingenieurgesellschaft mbH, Ingenieurbüro Redlich und	Methanoal, synthesis gas, hydrogen as a necessary substance for the process	Steam reforming, water electrolysis, methanol synthesis reactor	This is not clear from the literature	Waste heat	Pilotphase finished	(EGLV et al., 2024)

	Partner GmbH						

Table 1: Overview of different projects - own illustration

Projects in this direction are also being driven forward in other countries such as Japan, the UK and the USA.
As an example, Thames Water, the UK's largest water treatment company, is working to design a pilot plant that produces hydrogen from wastewater. This plant uses electrolysis to use excess renewable energy from solar panels and produce hydrogen.
In the USA, the Mazzei Injector Company, in collaboration with a wastewater treatment plant in California, has launched a project to produce hydrogen from biogas using high-performance nozzles. This hydrogen can then be used as a fuel or to generate electricity.

4. Funding systems

Subsidies play a crucial role in hydrogen projects for several reasons.
Research and development are to be promoted. Hydrogen technologies are still at a relatively early stage of development, and funding can help drive innovation and improve the efficiency and economics of hydrogen projects. This includes research into new production and storage technologies as well as the development of applications for hydrogen in various sectors such as transport, industry and energy.
The market launch can and must also be supported. Hydrogen is not yet economically competitive on a large scale with conventional energy sources such as natural gas or gasoline. Subsidies can help accelerate the market introduction of hydrogen technologies by supporting investments in infrastructure projects such as hydrogen refueling stations, electrolysis plants and fuel cell vehicles. Subsidies can also be used to incentivize to increase demand for clean hydrogen solutions in various industries.
Subsidies can also lead to cost reductions and economies of scale. Subsidies can reduce the initial costs of building hydrogen infrastructure and producing hydrogen. This can help to achieve economies of scale and reduce the cost of hydrogen technologies in the long term by increasing production and realizing efficiency gains.
Of course, support programs also have a positive impact on environmental and climate protection. Hydrogen is considered a promising clean energy carrier that can help reduce greenhouse gas emissions, especially when produced from renewable energy sources. Funding can help accelerate the transition to a low-carbon hydrogen economy and achieve climate and environmental goals.
Overall, grants play an important role in supporting hydrogen projects by promoting the development, market uptake and scaling of hydrogen technologies and accelerating the transition to a sustainable and low-carbon energy future. Table 2 briefly summarizes some funding opportunities.

Funding Institute	Institute	Amount	Recipient	Reference
Germany for inland and for international cooperation	BMWK, KfW	project budgets range from several thousand euros to several of millions of euros per project	Municipality, company, association, university, research institution, etc.	(BMWK et al., 2024)
Germany for inland and for international cooperation	BMWK, KfW	project budgets range from several thousand euros to several of millions of euros per project	Municipality, company, association, university, research institution, etc.	(DIHK et al., 2022)
European Union	European Commission, Connecting Europe Facility for Energy (CEF-E),	project budgets range from several million euros to several	Municipality, company, association, university, research institution, etc.	(Hydrogen Public Funding Compass et al., 2024)

	Connecting Europe Facility for Transport (CEF-T), European Regional Development Fund (ERDF) and the Cohesion Fund (CF), etc.	hundreds of millions of euros per project		
European Union	European Commission, Horizon Europe 2021-2027	project budgets range from several million euros to several hundreds of millions of euros per project	Municipality, company, association, university, research institution, etc.	(HORIZONT EUROPA et al., 2024)
European Union	European Commission	project budgets range from several million euros to several hundreds of millions of euros per project	Municipality, company, association, university, research institution, etc.	(IPCEI Hydrogen et al., 2024)

5. Overview of the Urban Wastewater Directive, Regulations and Legislation

a. Urban Wastewater Directive

The Urban Wastewater Directive (Kommunale Abwasserrichtlinie - KARL), also known as Council Directive 91/271/EEC from 21st of May 1991 on urban wastewater treatment, is a legal instrument of the European Union that deals with the treatment and protection of urban wastewater. It lays down minimum requirements for the collection, transport and treatment of wastewater in the Member States in order to protect the environment and ensure human health.

The main objectives of the Municipal Wastewater Directive are:

- To ensure the protection of waters from pollution by wastewater, in particular by reducing the discharge of pollutants such as nitrogen, phosphorus and organic matter.
- To promote sustainable wastewater treatment by setting minimum treatment quality requirements and compliance with emission limits for WWTPs.
- Ensuring adequate collection and treatment of wastewater in urban areas in order to minimise the burden on the environment and reduce the risk to human health.

The Directive requires Member States to draw up wastewater management plans to ensure that the objectives are met and specifies that WWTPs should be operated in accordance with the best available techniques. It also establishes monitoring and reporting obligations to verify implementation and ensure that requirements are met.

The Urban Wastewater Directive has made a significant contribution to the protection of European waters and has driven the development of modern wastewater infrastructure in the Member States. It is an important tool in the EU's water policy and helps to improve the quality of the environment and ensure citizens' right to clean water.

At the beginning of April 2024, the revision of this directive was approved by the EU. Important innovations are listed here:

- Polluter pays principle: The Directive implements the polluter pays principle by imposing requirements on Member States to better protect the environment and human health.
- Fourth purification stage: The European Commission wants to make the fourth purification stage mandatory for all sewage treatment plants with a size of 100.000 population equivalents (PE) or more by 31.12.2035. For settlement areas between 10.000 and 100.000 inhabitants, this level is to be introduced by 31.12.2040 if higher concentrations of micropollutants pose a risk to human health or the environment.
- Extended producer responsibility: To finance these measures, the Commission proposal provides for the implementation of the polluter-pays principle through the introduction of

extended producer responsibility. Manufacturers are to be obliged to make individual contributions based on the quantity and toxicity of the substances they put into circulation.

- Energy neutrality: The draft provides for energy audits for WWTPs with a population of 100.000 or more by the end of 2025 and for WWTPs with a population of 10.000 or more by the end of 2030. In addition, the total amount of energy produced annually from renewable energies generated by WWTPs (≥ 10,000 PE) is to cover 50% of the energy demand of these WWTPs by the end of 2030. By the end of 2040, this share is expected to increase to 100% (Wasser 3.0 gGmbH et al., 2024).

b. Regulations and Legislation

Laws and regulations are important for the hydrogen economy for several reasons. They are intended to ensure safety and health protection. Hydrogen is a highly flammable gas and therefore requires strict safety standards for production, transport, storage and use. Laws and regulations set these standards to prevent accidents and ensure the safety of employees, the public, and the environment.
Quality standards are also required for the various applications of hydrogen to ensure that the hydrogen meets the respective requirements. For example, hydrogen fuels must have certain levels of purity to ensure efficient combustion and proper operation of fuel cells. Laws and regulations can set these standards and monitor their compliance.
The development of a hydrogen economy requires appropriate infrastructure, including production facilities, transport networks, refueling stations and storage. Conditionality can support the development of this infrastructure, for example by incentivising investment, providing access to public land and facilitating planning and permitting procedures to promote the production and use of green hydrogen and accelerate the transition to a low-carbon economy.
Clear and uniform rules prevent a patchwork quilt, which can become more complicated and even less transparent depending on the federal state.
Legal certainty can strengthen economic development and create a positive investment climate for the hydrogen economy. Facilitating market access and ensuring a level playing field can help to increase private and public investment and enable job creation and economic growth.
Overall, laws and regulations are crucial for the development and successful operation of a hydrogen economy by ensuring safety, quality, infrastructure, environmental protection and economic development. Otherwise, there is a risk of a patchwork quilt (DIHK et al., 2023).

6. Discussion, Challenges and Outlook

For water management, there are a variety of technologies that open up the possibility of contributing to the coverage of hydrogen demand. These are not universally applicable. There is a need for an evaluation of the potential of the technology on the ground.
In addition to the production of hydrogen, electrolysis also offers the strong synergy that the oxygen produced can be used for biological processes in the wastewater treatment plant or for the ozone production of the 4th purification stage. However, green electrolysis hydrogen is characterized above all by the fact that the operation of these plants is intermittent. This also means that there is no continuous supply of pure oxygen. As a result, a high level of control for wastewater treatment must be expected. In the worst case, the biological processes in wastewater treatment can be negatively influenced. Electrolysis would therefore only be an option for WWTPs that generate green surplus electricity. This is the case for very few WWTPs in Germany.

The treatment of nitrogen-rich fractions, for example by plasmalysis, is more promising. The higher the nitrogen content of the material flow, as is the case with co-fermentation, for example, the more economically this process can be operated.
Plasmalysis of biogas offers the possibility of producing blue hydrogen, but reduces the degree of self-generation of WWTPs and therefore only makes sense for surplus plants.
In central sewage sludge utilization plants, there is great potential for the production of hydrogen by means of gasification, but the process needs to be further developed and implementation by 2029 or 2032 is rather critical.
The production of hydrogen from wastewater streams, which have a high organic content, is exciting and independent of WWTPs. Here, hydrogen can be produced by degrading the organic matter and at the same time pre-purification of the wastewater can be achieved. In this way, the energy demand of wastewater treatment can be reduced and there is a double contribution to achieving climate targets.
Challenges are, depending on the federal state and the responsible licensing authority, requirements and regulations. It is important to involve the public, associations, nature conservation organizations or the surrounding residents in the process at an early stage in order to minimize fears, resistance, misinformation or lawsuits. Of course, the process must be cost-effective and be able to compete with established, mostly fossil technologies. Industry partners or suitable (IPCEI) funding opportunities are also of great importance.
The transport and marketing of hydrogen must also be organized and ensured. Network operators or suppliers must work hand in hand with WWTPs, authorities and other key stakeholders and define solutions on an equal footing. Therefore, local production and consumption is very important.
In order for all this to succeed, funding opportunities must be expanded, awareness raised and any hurdles for the application process lowered.

Assessing regional potentials for green hydrogen infrastructure planning in Germany

Caroline Andersen, Martin Schulwitz
Affiliation: Chair of Ressources and Energy Systems, Department of Spatial Planning, TU Dortmund University
Email: caroline.andersen@tu-dortmund.de; martin.schulwitz@tu-dortmund.de

Abstract
Green hydrogen offers significant advantages in terms of sector coupling and electrification of energy systems. To ensure a reliable hydrogen supply chain in regions, there is a growing need for hydrogen infrastructure planning. Strategies need to take into account spatial characteristics of supply and demand as well as existing regional potentials. The aim of this study is to develop a holistic approach to assess regional potentials in the context of green hydrogen infrastructure planning by considering both technical and socio-economic factors. A principal component analysis was carried out in NUTS-3 regions throughout Germany. We identified four indices representing regional hydrogen and location potential. A cluster analysis was used to identify region-specific needs and requirements. This will benefit the planning process for developing regional hydrogen strategies.

Keywords
Green Hydrogen; Regional Planning; Planning Methods; Energy Infrastructure; Assessment Concept

1. Introduction

In the process of global sustainable energy transition, green hydrogen is often referred to as a game changing technology. As a carbon-free energy carrier, green hydrogen provides options for storing and delivering volatile renewable energy and is an integral part of sector coupling. However, the role of green hydrogen in future energy systems remains controversial, due to uncertainties about supply, demand and cost of system integration during the rollout phase (Ren et al., 2023). This poses major challenges to the development of hydrogen infrastructure, which relies on a stable and long-term framework for initial investments.

In recent years, the European Union and several European countries have published strategies to increase green hydrogen production capacities. For example, the European hydrogen strategy for a climate-neutral Europe (EHS) increases their target for green hydrogen production capacity significantly to 40 gigawatts by the year 2030 (European Commission, 2020). With the expected increase in green hydrogen production and imports, a need for a reliable infrastructure to transport hydrogen from areas with high renewable potential to demand centres and hydrogen storages is emerging (Baufumé et al., 2013).

In this context, different planning approaches for the development of green hydrogen infrastructure can be observed in hydrogen strategies of the European Union and Germany. The development and implementation of the suitable strategic approach for hydrogen infrastructure planning is highly dependent on the spatial context (Mai et al. 2023). In this way, the assessment of regional location potentials is seen as an essential component. While the EHS refers to a wider range of location potentials such as spatial connectivity and socio-economic factors, the current focus of assessments is still on technical potentials such as green hydrogen supply and demand. However, as a basis for planning and decision-making, it is important to examine and assess all relevant potentials in detail.

This raises the question of how to develop an assessment of regional potentials for green hydrogen infrastructure planning in order to derive context-specific planning strategies. The

study aims to develop a holistic concept for the assessment of regional potentials related to the planning of green hydrogen infrastructure. During the study we examine regional hydrogen supply and demand potential, as well as a selected range of location potentials. Using spatial clustering methods, we explore region-specific requirements in the process of green hydrogen infrastructure planning.

The concept is intended to support the planning and decision-making process by exploring suitable strategies for hydrogen infrastructure planning. By saving valuable time and resources, the concept accelerates the planning and decision-making process at the regional level. In particular, regional planners benefit from the systematic assessment in order to adapt hydrogen strategies with location-specific actions and measures.

2. Theoretical Framework

The deployment of green hydrogen depends mainly on future supply, demand and cost developments that accumulate along the hydrogen supply chain (HSC). The HSC refers to the entire process from the production of hydrogen gas to its use by the final consumer. It includes hydrogen infrastructure for production, transportation, storage and utilisation (Changjong et al., 2022). However, the process of green hydrogen infrastructure planning is challenged by uncertainties such achieving competitive costs and mass market acceptance (Mai et al. 2023). In this section, we focus on green infrastructure elements across the HSC and on planning strategies to implement these infrastructures. The EHS will be considered in this context, as well as the role of assessing regional potentials for green hydrogen infrastructure planning.

2.1 Green hydrogen infrastructure

Hydrogen can be produced through various pathways using fossil fuels, nuclear energy or renewable energy. For the generation of carbon-free or green hydrogen, only renewable energy sources (RES) are utilised to dissociate water into hydrogen and oxygen (Xu et al. 2023). This process, called water electrolysis, is widespread and uses volatile RES such as wind, solar or bioenergy. Global electrolysis capacity is expected to increase from 0.5 million tonnes in 2022 to over 21 million tonnes in 2028 (Al-Douri and Groth, 2024, p.777).

The cost of producing hydrogen from electrolytic water (between $5.78 and $23.27/kg) is currently significantly higher than the cost of producing hydrogen from gas ($2.08/kg) (Nikolaidis and Poulikkas 2023, p.621). Although costs for electrolysers are expected to halve by 2030, another challenge in this regard is meeting the increasing demand for electricity from RES. A study by Kakoulaki et al. (2020, p.9) predicts that major hydrogen production regions, especially densely populated regions, will not have enough green electricity to cover both current electricity consumption and electrolytic hydrogen production. However, given the overall surplus of electricity from RES across the European Union, this challenge could be met by interregional electricity transmission.

Hydrogen is supplied to the final consumer at hydrogen refuelling stations. Currently, hydrogen is used as a chemical feedstock and as a raw material in heavy industrial processes such as oil refining or fertiliser production. In general, these sectors are particularly difficult to decarbonise, which underlines the crucial role of hydrogen (Abdalla et al. 2023). Typically, the amount of hydrogen used in these industries is produced on-site or near the location of its use, in quantities that meet the needs of these industries (Steen, 2016).

By focusing on future decarbonisation scenarios and considering the use of power-to-gas or power-to-X technologies, the potential for hydrogen applications in other sectors is expected to increase further (Kakoulaki et al 2020). There are application potentials in the transportation sector and in the building sector as a fuel in combined heat and power systems. But hydrogen demand in the building sector is highly dependent on regional conditions such as renovation rates and the mix of heating technologies used (Wang 2021; Ge et al., 2024). The future global market for hydrogen is expected to grow significantly to between 115 and 130 million tonnes by 2030 (Dou et al., 2023; Al-Douri and Groth, 2024, p.775).

As noted by Baufumé et al. (2013) hydrogen transport and storage infrastructure should be designed to suit spatial and temporal distribution of demand and supply. If hydrogen production plants are located far from energy consumption sites, storage and transportation methods are necessary. Hydrogen can be stored in either gaseous or liquid state depending on its use in low-, medium- and high-pressure storage tanks (Mai et al., 2023). Whereas subsurface hydrogen storage in salt caverns or abandoned mines is a suitable option for large-scale and long-term storage uses (Ge et al., 2024). To connect relevant areas of supply and demand, a ubiquitous hydrogen transportation and distribution infrastructure is essential.

Hydrogen can be transported via trailors or pipelines. The former is used to transport gaseous and liquid hydrogen, while the latter is used to transport gaseous hydrogen only (Abdalla et al. 2023). The choice of transport mode depends on the delivery costs, which are influenced by the quantities transported, the delivery distances and local circumstances (Hugo et al., 2005; Ball and Weeda, 2015). Because fixed costs for initial construction of pipelines are relatively high (around 80,000 USD per 100m), this investment is only economical when transporting large quantities over longer distances (Changjong et al., 2022, p.1706). Therefore, transportation through pipelines is considered as the most cost-effective option for distances up to 3,000 kilometres, when there is high demand for hydrogen (Abdalla et al. 2023; Lipiäinen et al., 2023). For longer distances, sea transport by ship is an option.

Using the existing gas network by blending hydrogen into natural gas pipelines is expected to achieve significant savings (Jens et al. 2021, Moultak, et al. 2023). The European Union and several of its Member States are in the process of developing hydrogen transport projects, some of which are even planned to carry exclusively hydrogen (Lipiäinen et al., 2023). To reduce costs and improve infrastructure design and operation, coordinated support and strategic planning across the HSC is essential.

2.2 Strategic hydrogen infrastructure planning

According to Luise et al. (2023), the selection of an appropriate strategic concept is essential for the planning of hydrogen infrastructures across the HSC. Different planning concepts are distinguished according to their degree of centralisation and decentralisation with regard to production, storage and transport infrastructures. The EHS published in 2020 pursues both concepts simultaneously. While long-term initiatives such as the European Hydrogen Backbone (EHB) take a centralised approach in planning large interconnected transport networks, the focus lies also on the development of local hydrogen clusters.

The EHS aims to establish a hydrogen ecosystem by 2050 in close cooperation with the European Member States. The target for 2030 is to increase electrolyser capacity by 40 gigawatts by 2030 (European Commission, 2020). To achieve this, key actions are described, such as the establishment of an investment agenda for the European Union or the expansion of hydrogen supply and demand across the HSC. In this context, a suitable hydrogen infrastructure will be developed in stages, from a decentralised to an increasingly centralised system.

In the initial phase, local hydrogen valleys with on site production, closely located to consumption and distribution network systems will be developed. Afterwards, the strategy intends on progressively connecting emerging hydrogen valleys, import terminals, large-scale storage facilities and industrial clusters to an initial backbone transmission infrastructure. In this regard, eleven transmission system operators presented plans in 2021 for an integrated European hydrogen network largely based on repurposed and existing natural gas infrastructure (Jens et al., 2021). Since then, the vision of the EHB initiative has grown fast into a pan-European pipeline network of almost 53,000 kilometres to be established in 2040 (Moultak et al., 2023).

As noted by the EHS, to ensure the implementation of infrastructures across the HSC, further research and innovation efforts are required. This refers to the development of hydrogen technologies such as large scale, efficient and cost-effective electrolysers, large scale end-use applications and infrastructure to distribute, store and dispense large quantities of hydrogen (European Commission, 2020). To address these challenges, the EHS aims to coordinate and financially support European projects for research, development and demonstration of hydrogen technologies. Changjong et al. (2022) state that providing demonstration projects is a central part of the European roll-out strategy for developing hydrogen infrastructure.

Several European countries have published their own national hydrogen strategies to support the deployment of green hydrogen. It has been criticised, that these strategies often focus on policy making rather than concrete actions and local measures (World Energy Council 2020; BMWK, 2023). However, as noted by Mai et al. (2023), the development and implementation of strategic concepts or planned projects is highly dependent on the spatial context. In this regard, analysing the availability of RES or the expected demand for hydrogen is already considered as an essential part for the implementation of hydrogen strategies.

While hydrogen demand and supply potentials are assessed comprehensively at the national scale, e.g. for the planning of the EHB, the regional perspective is rarely taken into account (Moultak et al., 2023). Nevertheless, regional assessments offer a higher spatial resolution and are therefore able to detect regional impacts at a smaller scale, an advantage that has already been recognised and applied in the field of national grid planning for volatile renewable energy sources across Europe (Ebner et al. 2019).

Although several studies focus on the assessment of regional potentials, they usually solely consider the technical potentials for green hydrogen production such as RES potential, electricity demand or current hydrogen production (Kakoulaki et al., 2022; Okunlola et al., 2022). While Okunlola explores the impact of spatial distance to gas pipelines and population clusters for green hydrogen production, neither study considers socio-economic factors to contribute to the implementation of the EHS.

3. Methodology

In order to provide a reliable basis for the planning of green hydrogen infrastructure we developed a holistic concept for assessing regional potentials across the HSC. In addition to the consideration of demand and supply potential, this concept has been extended to include other location factors relevant to the implementation of the EHS. In this regard, we focused on socio-economic location factors related to research and development and energy infrastructure.

3.1 The case of Germany

In this study, we use Germany as a test case to assess regional hydrogen and location potentials for green hydrogen infrastructure planning. In the context of the EHS, the German national hydrogen strategy was released in 2020. The target for domestic electrolysis capacity in 2030 will be doubled from five gigawatts to at least ten gigawatts (BMWK, 2023, p.1). Efforts are currently focused on implementing power-to-gas technology and model regions with hydrogen-related concepts across the country (Changjong et al. 2022; BMWK, 2023).

The German industrial sector has a great need for decarbonisation, especially in high-temperature applications such as the primary steel production and in the chemical industry. The forecast for hydrogen demand in the German industry is between 290 and 440 terawatt hours by 2045. (BMWK, 2023, p.20). Although the share of RES in the electricity sector is increasing, the potential for domestic production of green hydrogen is limited. Therefore, in the long term, most of the demand will have to be met by imports (BMWK, 2023; UBA 2024).

At first, import of hydrogen and its derivatives is planned to be largely ship-based, with the possibility of pipeline expansion to European countries. As Lipiäinen et al., (2023, p.31322) note, Denmark is already planning a pipeline of 350 to 450 kilometres to export green hydrogen to Germany. Germany has ambitious plans to build a hydrogen network that consists of repurposed and newly constructed hydrogen pipelines. An initial core network of hydrogen transmission pipelines with more than 9,700 kilometres is expected to be completed by 2032 (FNB 2023). In addition, two hydrogen pipeline networks are currently in operation located in the Rhine-Ruhr area (220 km) and at the outskirts of Leuna and Bitterfeld (100 km) in eastern Germany (Baufumé et al., 2013).

3.2 Data and methods

Following the Nomenclature of Territorial Units for Statistics (NUTS) level three[1], a total of 400 cities and counties were considered as research units. NUTS is a geocode standard for referencing spatial units for statistical purposes. We used a variety of official and open databases to collect measurable indicators for the empirical examination. Relevant geospatial data was pre-processed using GIS software. Through a theory-based analysis of relevant aspects of the HSC, the EHS and the German hydrogen strategy, we compiled a dataset from an initial set of 65 variables, selecting proxy variables related to the socio-economic situation, municipal finance, public funding, renewable energy production and the hydrogen production chain. Table 1 provides an overview of the dataset used in the further research process, including 20 relevant indicators and their data sources.

[1] With the exception of the city of Eisenach, which was merged with Wartburg County in 2021. To ensure data consistency, only Wartburg County was included in the analysis.

Table 1. Used dataset

Source	Indicator / Variable	Year
Global Wind Atlas	Average wind power density at 150m height (in W/m^2)	2023
Leibniz Institute of Ecological Urban and Regional Development	Area % of windfarms out of total area	2021
Federal Ministry of Transport and Digital Service	Minimal distance to seaports (in km)	2022
Federal Office of Cartography and Geodesy	Area % of 2km-corridores around electricity transmission lines out of total area	2022
Federal Institute for Research on Building, Urban Affairs and Spatial Development	Average age of population (in years)	2022
	% of employees at professional level	2022
	Students in vocational schools (per 1,000 inhab.)	2019
	Students at universities (per 1,000 inhab.)	2021
	% of graduates with higher education level	2022
	Expenditure on direct project funding (in € per inhab.)	2021
	Federal expenditure on university funding (in € per inhab.)	2021
	Tax revenue (in € per inhab.)	2021
	% of households with min. bandwidth of 1,000 Mbit/s	2022
	% of residential buildings with renewable energy sources	2022
	Travel time to intermodal terminals (in min)	2021
	% of employees working in the industrial sector	2021
	% of employees working in the secondary sector	2021
	% of gross value added in the secondary sector	2021
	Passenger car density (per 1,000 inhab.)	2022
Association of supra-regional gas transmission companies Germany	Minimal distance to planned hydrogen core network pipelines (in km)	2023

To create indices for assessing regional potentials we used an exploratory principal component analysis (PCA) (Jolliffe, 2002). After testing for suitability using Kaiser-Meyer-Olkin test and Bartlett's test of sphericity, we conducted three separate PCAs to identity relevant indicators for constructing representative indices of location factors and hydrogen potential from the above dataset. Following Mayer (2018), we first computed PCA based on eigenvalues to determine the number of relevant components in an iterative process by analysing the respective screeplots. The resulting components were then interpreted in terms of their factor loadings in the component matrices (using varimax rotation if applicable). Each index variable was normalised using z-score transformation.

Finally, the compiled indices were used to perform a cluster analysis in order to detect and classify regions with similar potentials. Based on the analysis of these cluster specific potentials it is possible to draw conclusions about cluster specific needs and requirements for hydrogen infrastructure planning. Following Backhaus et al. (2017) and Kimes et al. (2021), we conducted a hierarchical cluster analysis using the Ward method with a subsequent cluster centre analysis. For the cluster centre analysis, we use k-means clustering to extract eight clusters in the process.

4. Results

This section describes the results of the exploratory principal component analysis and the subsequent cluster analysis. Following our research objective, we first constructed indices from different regional location potentials in order to analyse their prevalence and spatial distribution in the following. Finally, we derived context-specific planning strategies based on the results of the cluster analysis.

4.1 Measuring of regional potentials

In total, four indices were created. According to the research concept, two indices describe the regional hydrogen demand and supply potential while the other two represent regional location potentials. We named each index variable according to their most influential indicators[2].

First, the index, *Knowledge and Innovation Potential* (RIP), was created in a separate PCA. It explained 49 per cent of the total variance between variables used (Table 2). Table 2 shows that the RIP index is predominantly characterised by educational indicators such as the number of students at universities or the level of expenditure on university funding. While the RIP index shows positive factor loadings for indicators that measure education, it is also compromised by negative factor loadings. In this respect, the percentage of employees at the professional level and the average age of the population indicate a possible shortage of skilled workers and a younger population at the same time. We use the RIP index as representative to assess regional location potential for the development of hydrogen research and innovation centres.

Table 2. Factor loadings of the Research and Innovation Potential (RIP) index

	Research and Innovation Potential (RIP)
Average age of population (in years)	**-0.720**
% of employees at professional level	**-0.812**
Students in vocational schools (per 1,000 inhab.)	0.630
Students at universities (per 1,000 inhab.)	**0.777**
% of graduates with higher education level	0.625
Expenditure on direct project funding (in € per inhab.)	0.636
Federal expenditure on university funding (in € per inhab.)	**0.736**
Tax revenue (in € per inhab.)	0.652
% of households with min. bandwidth of 1,000 Mbit/s	0.707
% of variance explained by the factor	49.4

Second, the indices, *Infrastructure and Connectivity Potential* (ICP) and *Hydrogen Supply Potential* (HSP) were created in a combined PCA. The HSP index, as the first principal component, explained 41 per cent of the total variance (Table 3). As Table 3 shows, the HSP index is characterised by indicators of RES such as average wind power density and the area share of wind farms. There are negative factor loadings for the minimum distance to seaports, indicating close access to import opportunities from overseas. We use this factor to assess regional hydrogen supply potential.

[2] To facilitate labelling the indices, the dominant indicators (factor loadings >0.75) are marked bold in the tables.

The second principal component, the ICP index, explained 26 per cent of the variance (Table 3). It is mainly characterised by positive factor loadings for travel time to intermodal terminals and negative loadings for the area share of corridors of electricity transmission lines. The factor loads were reversed for this index with higher loadings representing lower potential. In order to ensure consistency with the other indices, we inverted its score values so that positive scores represent higher potential. This third index is likely to represent regional location potential for the availability of energy infrastructure and spatial connectivity in the assessment.

Table 3. Factor loadings of the Infrastructure and Connection Potential (ICP) index and the Hydrogen Supply Potential (HSP) index

	Indices	
	1 – Hydrogen Supply Potential (HSP)	2 – Infrastructure and Connectivity Potential (ICP)
Minimal distance to seaports (in km)	**-0.884**	0.118
Average wind power density at 150m height (in W/m^2)	**0.929**	0.055
Area % of windfarms out of total area	**0.778**	0.132
Travel time to intermodal terminals (in min)	0.005	**0.832**
Area % of 2km-corridores around electricity transmission lines out of total area	-0.177	**-0.758**
Minimal distance to planned hydrogen transmission pipelines (in km)	-0.427	0.518
% of variance explained by the factor	41.1	26.2

Finally, the fourth index *Hydrogen Demand Potential* (HDP) was created in another separate PCA and explained 63 per cent of the total variance (Table 4). For this index table 4 indicates high factor loadings for the share of employees working in the secondary and the industrial sector as well as for the share of gross value added in the secondary sector. Since the HDP index is highly influenced by indicators of industrial density, we use this index as a representative to assess regional hydrogen demand potential.

Table 4. Factor loadings of the Hydrogen Demand Potential (HDP) index

	Hydrogen Demand Potential (HDP)
% of residential buildings with renewable energy sources	0.625
% of employees working in the industrial sector	**0.808**
% of employees working in the secondary sector	**0.936**
% of gross value added in the secondary sector	**0.878**
Passenger car density (per 1,000 inhab.)	0.673
% of variance explained by the factor	62.8

The scores of each index and its spatial distribution are presented in Figure 1 to 4 for administrative units at NUTS-3 level in Germany. In all cases, higher value scores represent a higher regional potential and vice versa.

For both the RIP and the ICP index, there is a spatial concentration of high scores in high density urban areas. We assume that this is due to the amount of educational and technical infrastructure such as universities or electricity hubs provided in cities. The HSP index shows an increasing

gradation of higher values towards the northern regions. As data of the Global Wind Atlas (2023) indicates, this is closely related to the wind power density and in coastal regions. This pattern is further reinforced by including seaports. The HDP index shows higher values in rural regions with an increasing gradation towards the south.

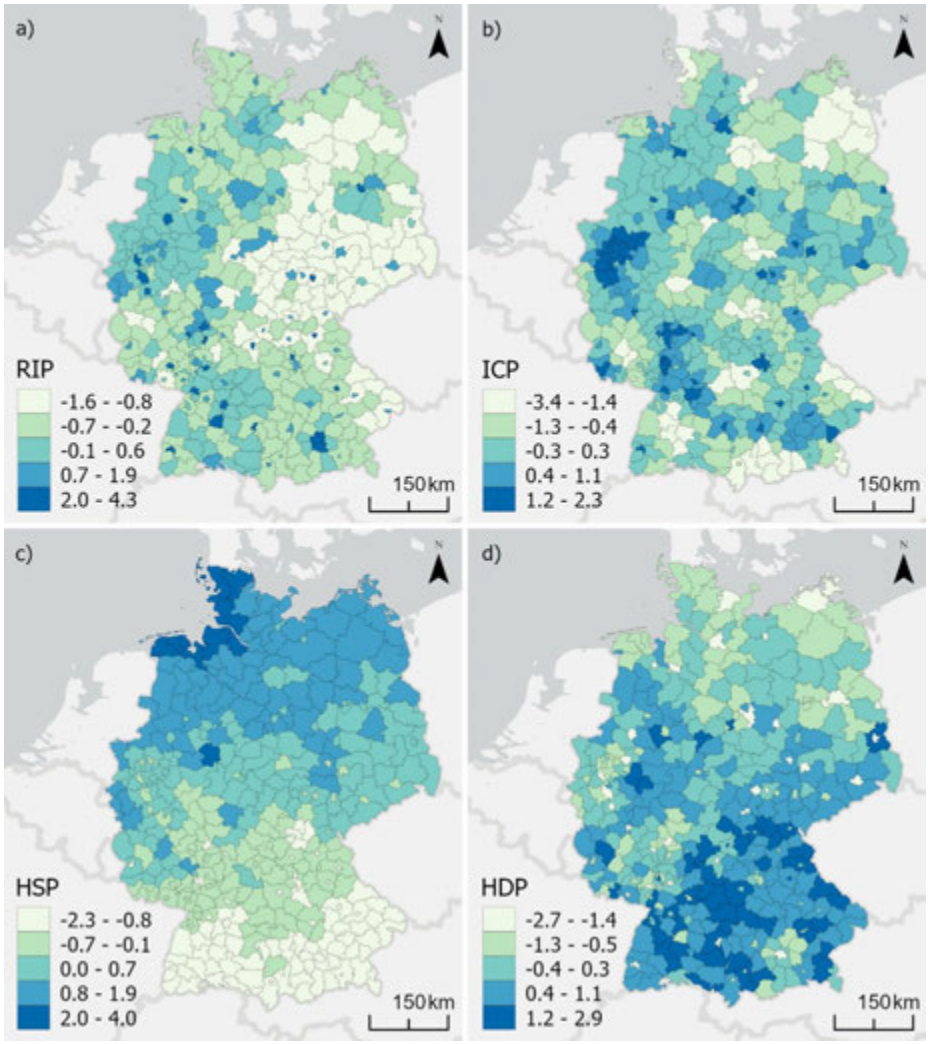

Figure 1-4. Spatial distribution of indices: RIP (a), ICP (b), HSP (c) and HDP (d) at NUTS-3 level in Germany

4.2 Clustering of regional potentials

Following the holistic approach all indices were considered equally in the analysis. As Table 5 indicates, we identified and extracted eight distinctive clusters in the research process. The average cluster distance indicates the heterogeneity that occurs within a formed cluster and allows the identification of cluster representative regions.

Table 5. Results of cluster analysis: Average cluster distance and average scores of indices

Cluster	**Average cluster distance**	**Average score values**			
		RIP	ICP	HSP	HDP
1 – Supply region with needs for infrastructure	0.97	-0.68	**-1.27**	**1.02**	-0.46
2 – Demand region with needs for infrastructure	1.03	-0.56	**-1.33**	-0.89	**0.98**
3 – R&D region with needs for infrastructure	1.24	0.66	-0.44	-0.80	-0.76
4 – Supply region with connectivity potential	1.04	-0.13	0.08	**1.54**	-0.25
5 – Activatable supply and demand region	0.77	-0.81	-0.11	0.23	0.34
6 – Infrastructure hub regions	1.05	0.54	**1.36**	-0.19	-0.78
7 – R&D centres with connectivity potential	1.38	**2.45**	0.95	-0.23	**-1.49**
8 – Demand region with connectivity potential	0.90	-0.16	0.26	-0.69	**1.03**

Each cluster is associated with corresponding mean value scores, representing the standard deviation from mean, of the compiled indices. We use these values for the characterisation and interpretation of the respective clusters[3]. The spatial distribution of the compiled clusters is shown in Figure 5 for administrative units at NUTS-3 level in Germany. Additionally respective cluster representatives are labelled on the map.

Cluster 1 (n = 29) is characterised by *supply regions with needs for infrastructure*. It contains a below average score on the ICP index and an above average score on the HSP index. These regions are suitable to supply hydrogen with renewable energy production and import possibilities. However, location potentials are indicating regions with low connectivity and a need for infrastructure development. A representative region in this cluster is Ostprignitz-Ruppin, a region with rural character in northern Germany.

Cluster 2 (n = 52) contains regions described as *demand regions with needs for infrastructure.* The value scores on the HDP index are above average and the ICP index is expressed below average. These regions are suited to apply hydrogen with a predominance of the secondary sector and energy intensive industries. On the other hand, location potentials confirm these regions a low connectivity and a need for infrastructure development. Calw, a region with rural character in southern Germany, is the representative region in this cluster.

Cluster 3 (n = 33) represents *research and development regions with needs for infrastructure.* The cluster contains below average score values on all indices except for the RIP index. These regions are considered unsuited to supply or apply hydrogen in the near future and have a need for infrastructure development. However, the RIP index suggests locational potentials for research and development in these regions. The cluster is represented by Chemnitz, a region with an average urban character and a medium-sized university. The high degree of heterogeneity in this cluster suggests that there are deviations between the regions in this cluster.

Cluster 4 (n = 57) represents *supply regions with connectivity potential* and contains the highest average score values of the HSP index. All other indices contain score values in the average range. Regions in this cluster are highly suitable for hydrogen supply. Additionally, locational

[3] To facilitate characterising different clusters, the dominant values (average score value >1.0) are marked bold in the tables.

factors are indicating average connectivity potential to existing networks of energy infrastructure. A representative region in this cluster is Steinfurt, a region with rural character in north-west Germany.

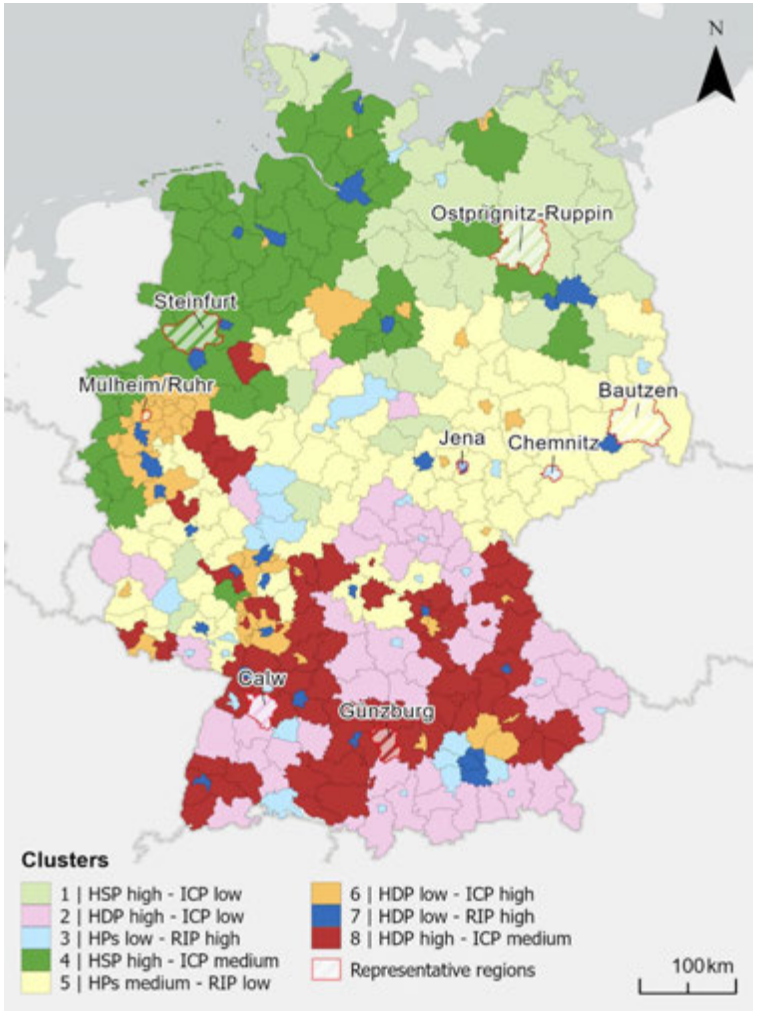

Fig 5. Spatial cluster distribution and related cluster representatives at NUTS3-level in Germany

Cluster 5 (n = 76) is labelled as *activatable supply and demand regions*. These regions contain a slightly above average score on the HSP and the HDP index indicating a general suitability for regional hydrogen potenials. Whereas, the average score on the RIP is below average, which points to a lack of regional locational potential in terms of expertise. Bautzen, a rural region in eastern Germany is considered as a representative region within this cluster. Heterogeneity is least pronounced in this cluster, suggesting a homogeneous composition within the cluster.

Cluster 6 (n= 57) focuses on regions described as *infrastructure hub regions*. It contains the highest average score value of the ICP and HSP and HDP values below average. These regions are unsuited to supply or apply hydrogen within their region, but contain a high regional potential to be connected to existing networks of energy infrastructure. A representative region for this cluster is Mülheim an der Ruhr, a region with urban character in western Germany.

Cluster 7 (n = 31) consists of *research and development centres*. It contains the highest average score values of the RIP index. While the ICP index scores above average both HSP and HDP index contain below average scores. Although these regions are considered unsuitable for hydrogen supplying and applying hydrogen, location factors indicate a high potential for research and development centres. A representative region in this cluster is Jena, a region with urban character and a large university in eastern Germany. There is a high degree of heterogeneity within this cluster.

Cluster 8 (n = 65) is composed by *demand regions with connectivity potential* and contains the highest average score values on the HDP index. This implies a high suitability for hydrogen demand due to the industrial character of the region. Additionally, these regions contain an above average score value on the ICP index, indicating a potential to connect these industrial regions to existing energy infrastructures. A representative region in this cluster is Günzburg, a region with an average urban character in southern Germany.

Our results indicate increased needs for action in cluster regions one, two, four, five and eight. In particular, clusters one and two show high potentials for hydrogen production and consumption while being poorly connected to the existing energy infrastructure. Due to the potentially large amount of green hydrogen produced or consumed in these regions, they should be given priority when connecting to infrastructure networks such as the hydrogen core pipeline network. Regions in clusters four and eight, with exceptionally high production and consumption capacities, should also focus on connecting to a centralised green hydrogen infrastructure network in the near future.

Concerning cluster five, there are average potentials for producing and consuming hydrogen with relatively low regional location potentials. Because these areas are classic remote and rural regions, the focus should be on decentralised strategies for hydrogen infrastructure planning. This means focusing on local on-site production, appropriate storage facilities and transportation via trailers. With the development of initial projects and model regions new expertise in the field of hydrogen infrastructure planning can be acquired.

In cluster three and seven there are high location potentials for research and development. Especially cluster seven contains potentials in becoming centres for hydrogen related research and development when granted appropriate support and funding. The conditions for connecting to existing infrastructure networks are also relatively high in cluster seven. Regions of cluster six are considered to be future infrastructure hubs that can be connected to central infrastructure networks in the process of expanding the hydrogen core pipeline network.

Discussion and Conclusion

Strategies for green hydrogen infrastructure planning need to consider spatial characteristics of demand and supply (Baufumé et al., 2013) as well as existing regional potentials (Mai et al.,

2023). Selecting suitable concepts in alignment with the respective regional context is essential when planning green hydrogen infrastructure (Luise et al., 2023). In accordance to the literature, we developed a holistic concept for the detailed assessment of relevant regional potentials for green hydrogen infrastructure planning.

Our results determined four main regional potentials of importance, which were derived from a selected dataset of 20 indicators: research and development, infrastructure connectivity, hydrogen demand and hydrogen supply. After assessing these potentials, we were able to characterise eight clusters. By applying these clusters to the regional dataset, we identified different type regions with context-specific suitabilities, opportunities and needs for action and planning throughout the case of Germany. This will provide the basis for developing strategic approaches to green hydrogen infrastructure planning. In conclusion, by combining technical with socio-economic location factors at a regional scale, we developed a holistic concept for assessing regional potentials for green hydrogen infrastructure planning.

Nevertheless, it should be noted that the conducted assessment is not a true reflection of the reality and that a detailed analysis of the specific region is still required. As the statistical analysis only shows indicator-based suitability, the selection process of variables has a strong influence on the results. In the course of the analysis, seemingly relevant factors were excluded from the data set due to statistical insignificance. In the case of the HSP index, photovoltaic production was excluded, which should be viewed critically in terms of its interpretative value. Also, large-scale storage facilities and existing hydrogen projects were not included in the analysis due to low data availability and missing or inconsistent values.

Furthermore, the reduction of information density during the PCA should be viewed critically. The data set used is not considered exhaustive for all relevant regional potentials for hydrogen infrastructure planning. Whether or not the predictive power of the indices holds true in reality needs to be verified in a detailed analysis. However, for an initial assessment and exploration of possible actions and strategies, this method can support and accelerate the planning process.

The application of the developed concept is generally possible, but highly dependent on the availability of data at regional level. Significant differences in factor loadings are highly likely not only depending on the spatial but also on the temporal relation of the used data (Jolliffe 2002).

Finally, a critical look at hydrogen as an energy carrier is in order. Although currently the use of hydrogen energy technologies seems promising, there is still great debate on it. (Dou et al., 2023). The true potential of this climate-friendly technology will be revealed in this decade as the hydrogen infrastructure develops. In addition to green hydrogen, other production pathways and technologies may need to be applied.

Removing cultural barriers to climate change adaptation in Tuscany

Giulio Giovannoni
Department of Architecture, University of Florence, 50100, Florence, Italy
Email: giulio.giovannoni@unifi.it

Abstract
The paper investigates the role of cultural factors in hindering climate change mitigation and adaptation policies. The importance of historical landscape in Tuscany makes it difficult to accept transformations necessary to adapt to the new climate. After reviewing available data on climate transformations in Italy and taking stock of the status of mitigation and adaptation planning, some projects of renewable energy production facilities are analysed. The media debate and the legal and bureaucratic oppositions to them are discussed. The idea of landscape emerging from the debate is related to the musealised conception of the same that has been established in Italy. The concluding section discusses the policy implications of the present work.

Keywords: urban landscape; climate change adaptation; cultural barriers; Tuscany; Italy.

1. Introduction

We live in an increasingly urban and hot world. According to United Nations projections in 2050 68% of the world's population will live in cities (United Nations, 2019). Over the same period, the planet's average temperature is expected to rise between 1.5 and 2 degrees (IPCC, 2023). These two simple figures place at the forefront the need to rethink urban landscapes in order to adapt the living environment of the majority of the world population to exceptionally rapid change. This rapidity is at odds with the long time frames in which cities undergo change and transformation. Planning can only play a central role in such processes (Norman, 2022, IPCC, 2021). The long timescales of urban change partially depend on the symbolic and psychological meanings cities hold for their inhabitants (Lingiardi, 2017, Ulrich, 1979). This raises the issue of cultural barriers to climate change adaptation, a topic that is particularly relevant in Italy, as demonstrated by the numerous cases of nimbyism and 'administrative resistance' to mitigation and adaptation projects (Fanetti, 2012, Fraioli, 2022). This paper aims to investigate this issue, with specific reference to the cultural, political and administrative situation in Italy, and to put forward some working hypotheses aimed at identifying procedures and tools to promote socially sustainable climate change adaptation measures. The first section summarizes available data and research on climate change that has occurred so far in Italy and Tuscany. The second section reviews planning aimed at climate change mitigation and adaptation in the same area, showing its inadequacy to achieve zero CO_2 emissions by 2050 and to make the territory resilient to the changing climate. The third section presents some cases in which climate change mitigation and adaptation plans and projects face procedural and administrative difficulties that can be attributed to cultural barriers arising from a static and immutable conception of the landscape. The conclusive section draws policy implications from the present research.

2. Materials and Methods

The first part of the essay introduces the topic of climate change and of the relationship between planning and climate. After some general considerations on global trends, climate transformations in recent decades in Italy and Tuscany are examined, with an in-depth look at the city of Prato. These transformations are derived from statistical elaborations on

temperature and precipitation and from research conducted by research institutes specifically dedicated to the study of climate change and environmental protection in Italy, including the Euro-Mediterranean Centre on Climate Change and the Istituto Superiore per la Protezione e la Ricerca Ambientale (Ispra). The set of systematic studies on climate change in Italy conducted so far, albeit based on pre-2012 data, shows a considerable increase in the risks of extreme weather events and poses the urgent need for climate change adaptation and mitigation planning. The numerous disasters due to extreme rainfall, extreme heat and prolonged droughts that have occurred in recent years confirm the urgency and seriousness of the situation.

The second section reviews climate change mitigation and adaptation planning in Italy and in Tuscany. Planning at the national level was reviewed through existing literature on the subject. Data obtained from literature were checked and updated by consulting web portals of institutions and administrations responsible for climate change mitigation/adaptation planning. The analysis regarding the Tuscan area was conducted by consulting plans and policy documents prepared by local governments and by the Tuscany Region through their web portals. For reasons of time and research opportunities, we only focused on provincial capital cities. The choice was motivated by the fact that these accommodate most of the regional population, are the major greenhouse gas polluters, have a higher degree of vulnerability compared to the rest of the region, and have a political-institutional environment that is relatively committed to climate change mitigation and adaptation.

The third section analyzes the role that historical and cultural factors play in hindering climate change mitigation and adaptation processes in Tuscany and more generally in Italy. Firstly, we describe some cases of conflict over mitigation and/or adaptation projects. The cases were selected using journalistic sources and by talking to local technicians and administrators. The journalistic sources were identified using the search engine news.google.com and setting different keyword strings in order to intercept articles from national and local newspapers that dealt with different types of mitigation and adaptation interventions in the period between 01/01/2023 and 30/09/2023. Secondly, we analyze the role that historical and cultural factors play in these conflicts. The discussion of cases is made using the concept of sostalgia developed by Glen Albrecth (2005) and relating the idea of landscape that implicitly emerges from the debate with the static and musealised conception of the same that has been established in Italy through the protection laws enacted since the 1930s. The concluding section of the essay discusses the policy implications of the present work.

3. Results

3.1. Climate change in Tuscany and Italy and future urban scenarios.

As is well known, there is now almost unanimous consensus among scientists that the change in the Earth’s temperature observed in recent decades can be attributed predominantly to anthropogenic climate-altering emissions (NOAA National Centers for Environmental Information, 2023, Lynas, Houlton and Perry, 2021, Myers et al., 2021, Powell, 2019). The increase in the earth's temperature and the aggravation of the often disastrous impacts due to it have seen a significant acceleration in recent years (Portner et al., 2022). This determines the need for rapid adjustment of urban landscapes in order to ensure that inhabitants have an adequate living environment even in the new climatic conditions.

Building systems and urban layout are largely determined, especially in the historic city, by climatic conditions. It is a well-known fact that the historic Islamic city had various spatial and construction devices aimed at ensuring environmental well-being in very hot climates: narrow streets and tall buildings to increase shading, domed buildings to minimise the surface area exposed to the sun, extensive use of arcades to provide shaded open spaces, and the use

of materials such as unfired earth mixed with straw to improve insulation performance in masonry (Sahebzadeh et al., 2017). The correlation between variation in climate and in building systems has also been studied in typological analyses of traditional rural constructions, whose building features were adapted to the negative thermal gradient associated with altitude in various ways: reducing the size of openings, optimizing their exposure so as to maximise sunshine, increasing the slope of roof pitches, making the most of the heat produced by animals by positioning stables so as to heat the rooms above, etc. (Biasutti 1938).

The increase in Earth's global temperature, while still relatively small to date compared to the various change scenarios projected from now even to 2050 (IPCC, 2023, Vince, 2022, Smith, 2010), is already driving a shift in Earth's climate belts toward the poles (Jones, 2023, Fin, 2022). This is of course a simplification, and the reality is far more complex: for example, the arid part of the tropical belt is expanding both toward the equator and toward the poles; the Sahara Desert, whose area is roughly the same as the entire United States, is extending further both northward and southward; the eastern arid zone of the United States is moving eastward, at the expense of the wetter, more fertile zone (Jones, 2023). At the level of biological systems, this is evident from the migration of some species that are more free to move, particularly those belonging to the insect class, with sometimes disastrous consequences on the ecosystems that receive them, or even from the increase in their reproductive cycles due to rising temperatures. The situation is particularly alarming in Trentino-South Tyrol, where the multiplication of the bark beetle's reproductive cycles due to the excessively mild temperature has resulted in a spruce-fir ecatomy (Fin, 2022). This insect has also spread to the boreal forest of Finland producing similar problems (Zimmer, 2023). One of the main difficulties ecosystems face in adapting to the rapid rate at which the climate changes stems from the varying difficulty of their component species to move. Different living species could be classified according to their respective time required to move through space so as to follow the shift in climate zones brought about by the increase in Earth's temperature. Such a classification, in fact, could also be made in relation to different variables in urban landscapes that exhibit greater or lesser inertia to change-more specifically to the changes that would be required to align and adapt our cities to the new climate framework.

It should be pointed out that rising temperatures do not simply imply a shift in latitude and altitude of climate zones, but a broader and more general upheaval of the climate. Currently [May 2024] the level of CO_2 in the atmosphere is about 426 ppm, up from 316 ppm in 1959 (Pro Oxygen, 2024). The level of 500 ppm today corresponds to the most ambitious and optimistic scenario for limiting future emissions and is roughly the same as it must have been during the Miocene, when the temperature was about 4°C higher, sea levels were about 40 meters higher than today, and lush forests grew in Antarctica and the Arctic (Vince, 2022). Therefore, it is evident, as indeed we are continually told by climatologists, that we are venturing, or rather have already ventured, into unknown territory, in which it is not possible to speak simplistically about a shift in Earth's climate zones, nor to apply any more of the knowledge and experience accumulated in relation to them. That said, it is all too obvious and evident, that we are witnessing an unmistakable as well as rapid trend of increasing intensity of four categories of phenomena, which immediately need structural adaptations of urban landscapes: heat waves, floods, fires and drought. In her book The Nomadic Century, Gaia Vince (2022) calls these phenomena "the four horsemen of anthropocene."

Table 1, prepared by the City of Prato, shows the change in average and maximum temperatures, rainy days, and total mm of water rained annually between 1990 and 2022. These data show a very significant increase in temperature and an equally pronounced transformation in rainfall data, from which it appears that while the amount of water falling each year has remained essentially unchanged, the number of rainy days has decreased

significantly, which explains the increasingly frequent phenomenon of so-called 'water bombs.' It is clear that we are witnessing an alternation of periods of drought, often associated with heat waves and fires, and very heavy rainfall, which in turn is associated with increasing frequency with landslides and floods. This trend has seen an impressive acceleration in recent years and it is reasonable to assume that it will continue to grow in frequency and intensity in the coming years.

Table 1. Temperature and precipitation in Prato from 1990 to 2022.*

	Temperatures (°C)				Rain	
Year	Absolute		Mean			
	max.	min.	Max.	min.	mm	days of rain
1990	34,4	-4,5	19,8	11,4	899,5	119
1991	33,5	-7,4	18,7	10,4	1.199,0	111
1992	37,0	-3,6	19,4	11,2	1.153,4	122

1996	33,5	-6,8	18,6	9,9	1.080,4	121
1997	35,2	-1,1	20,5	10,1	951,2	118
1998	38,1	-5,0	19,5	10,1	902,0	113
1999	34,6	-4,1	19,6	10,5	1.000,2	125
2000	36,0	-5,7	20,0	10,9	1.004,8	115
2001	38,0	-5,7	20,0	10,2	921,6	132
2002	36,0	-5,9	19,9	10,5	971,4	139
2003	40,4	-3,8	21,2	10,6	809,0	106
2004	35,2	-3,3	19,2	9,9	928,0	140
2005	37,5	-5,2	18,6	9,3	951,8	128
2006	35,7	-4,4	19,9	10,1	810,4	133
2007	36,4	-3,2	19,9	10,2	770,0	113
2008	35,0	-3,4	19,5	10,3	908,4	147
2009	39,0	-6,0	21,1	11,6	815,8	78
2010	37,0	-5,7	19,3	10,8	1.255,2	108
2011	40,2	-2,6	21,3	11,5	694,6	59
2012	39,5	-3,7	21,0	11,5	763,4	83
2013	38,1	-1,6	20,1	11,5	1.076,0	109
2014	36,4	-0,5	21,2	12,5	1.410,8	110
2015	38,5	-0,1	21,3	12,2	723,6	71
2016	36,0	-1,8	21,1	12,1	1.035,2	99
2017	40,8	-3,1	21,6	11,5	808,4	72
2018	38,0	-5,1	21,4	12,4	927,0	100
2019	39,9	-3,5	21,6	12,2	1.017,2	95
2020	37,9	0,3	21,4	12,0	934,4	94
2021	39,9	-2,5	21,1	11,7	884,8	82
2022	40,0	-0,3	22,5	12,8	734,0	65

* The table is available in the 'climatology' section of the portal of the Prato Municipality's statistics office: https://www.comune.prato.it/it/statistica/aree-tematiche/climatologia/pagina2298.html (accessed on 08 May 2024).

The above data are in line with the more general picture regarding climate change in Italy. The Euro-Mediterranean Centre on Climate Change report finds, for the period 1961-2012, changes of 1° C every 10 years in the annual maximum and minimum temperature values, an increase in warm nights by about 14 days in 10 years and in warm days by about 21 days in 10 years (Spano et al., 2020). Alongside this generalised warming of the climate there is evidence of a statistically significant increase in the intensity of precipitation events in both the North and the South of Italy. These data are in line with reports prepared by other research and land-government institutions, including the Italian Atlas of Climate and Climate Change

(Esposito et al. 2015), the ISPRA report on variations and trends in temperature and precipitation extremes in Italy (Fioravanti et al., 2013). All of them highlight significant increases in the risks of extreme weather events such as exceptionally intense and spatially concentrated rainfalls, heat waves, ruinous forest fires, and periods of prolonged drought. More recently, the annual report on climate change already occurring in Italy provided by Legambiente confirms the picture outlined above (Nanni, Minutolo, eds., 2022). These changes immediately require decisive action through urban planning aimed at mitigating, as far as possible, the effects on human health, the built and environmental heritage, food security and the economy as a whole. In the following section we will analyze the state of planning for climate change mitigation and adaptation in Italy, with a special focus on Tuscany.

3.2. Climate change mitigation and adaptation planning in Tuscany and Italy

The Paris Agreement on Climate Change, adopted at COP21 in December 2015, set the goal of limiting global warming to below 2°C and also committed subscribers to continue efforts to contain it to 1.5°C. The agreement also commits governments to increase their capacity to adapt to the effects of change that have already occurred and that, albeit to varying degrees depending on the ability to cut future emissions, will continue to occur in the decades to come (UNFCCC art. 2b, 2020). Since the conclusion of the agreement, the situation has further worsened. Extreme weather events occurred during 2023, are in some cases in the upper range contemplated by models and have caused concern and even astonishment among many scholars. It is possible that our fragility to extreme weather events has been underestimated, which is why some scholars argue that Paris agreements are inadequate to avoid the most severe consequences and that it is absolutely necessary to contain global warming well below 1.5°C (Carrington et al., 2023).

Italy is highly vulnerable to the climate crisis and to extreme weather events (European Environment Agency, 2019). There are several reasons for such vulnerability: geological instability of much of its territory; high population density; coastal extension and high urbanization of it; location in the centre of the Mediterranean, a hotspot of climate change, and astride the North African and North European climate zones, the clash of which often results in extreme weather phenomena. According to a study by the Euro-Mediterranean Centre on Climate Change, the risk from extreme weather events increased for the entire country by 9 percent during 1999-2018 compared to the previous 20 years (Spano et al., 2020). Urbanised areas are the most vulnerable, especially in relation to heat waves and heavy rainfall.

On the institutional level, the growing awareness about the impacts of climate change is attested by the number of Italian local governments (114, corresponding to 47.6 percent of the population, by May 10, 2024) that signed the Climate Emergency Declaration (Climate Emergency Declaration, 2024). In any case, although Italy is one of the signatory countries of the Paris Agreement and despite the growing awareness of the high vulnerability of the Italian territory, legislation and planning for mitigation and adaptation to climate change are still very incomplete. Planning activity in Italy is based on four territorial levels: national, regional, provincial and municipal. Following the constitutional reform of 2001, regions have acquired important competencies in the field of energy and environmental policies (De Gregorio Hurtado et al., 2015), as well as in the field of planning, whose tools and procedures are now highly differentiated at the regional level (Mazzeo et al., 2021). In essence, state and regions have competing competencies in climate change mitigation and adaptation and are in charge of providing the regulatory framework to be followed by local authorities.

In 2019, the national government submitted the National Energy and Climate Plan (NECP) to the European Commission (Ministero dello Sviluppo Economico, 2019). The plan sets

national targets and measures by 2030 on energy efficiency, renewables and CO2 emissions cuts, as well as goals on energy security and connectivity, competitiveness and unification of energy markets, and sustainable mobility. The NECP is in fact the main national tool for mitigation policies. Adaptation policies, on the other hand, are based on the National Strategy for Adaptation to Climate Change (NSACC), approved in June 2015 by the Ministry of Environment and Land and Sea Protection (Ministero dell'Ambiente e della Tutela del Territorio e del Mare, 2014). This provides for the adoption of a National Climate Change Adaptation Plan (NCCAP), which has begun to be developed based on a participatory process, but has not yet been approved. Thus to date there is no regulatory and legislative framework for climate change adaptation, so municipalities, provinces and the regions themselves are basically acting on a voluntary basis (De Gregorio Hurtado, 2015).

At the regional level, by November 2019 plans aimed at climate change mitigation and/or adaptation had been adopted only by eight regions (Pietrapertosa et al., 2021): the Mitigation Plan by the autonomous province of Bolzano (which has similar competencies to regions); the Integrated Mitigation and Adaptation Strategy by the Emilia-Romagna Region; the Regional Adaptation Strategy by the Sardinia and Lombardy Regions; and the Environmental Energy Plans (EEPs) by the Valle D'Aosta, Liguria, and Friuli Venezia Giulia Regions and by the Autonomous Province of Trento, that although not specifically dedicated to climate change mitigation/adaptation, contains binding targets aimed at cutting CO2 emissions. Provinces were not very active in planning for climate change mitigation and adaptation, only four (corresponding to 6 percent of the population) having developed a plan.

Municipalities undoubtedly were (and are) the most active and dynamic institutional level, mainly due to their numerous adherence to the Covenants of Mayors, the network of cities promoted by the European Commission to fight climate change. Joining this network is an important step, as it commits the adhering municipality to draw up a Sustainable Energy Action Plan (SEAP) within two years and assume emission reduction obligations based on a baseline emission inventory, as well as to monitor progress in biennial reports. Until 2015, the greenhouse gas reduction target was 20 percent by 2020. Since then plans were renamed Sustainable Energy and Climate Action Plans, the reduction target was increased to 40 percent by 2040, and adaptation targets were also introduced.

3.3. Local and institutional opposition to climate change adaptation and mitigation

The state of CC mitigation/adaptation planning demonstrates a progressive awareness among the main local governments in Tuscany of the climate emergency in which we find ourselves and of the need to drastically reduce greenhouse gas emissions and to adapt cities and territories to the new climate situation. However, while a number of mitigation and renewable energy production projects have been promoted, mostly by private operators, adaptation policies are still more or less stuck on declarations of intent. However, in Tuscany, and more generally in Italy, almost all interventions aimed at renewable energy production (wind farms, photovoltaic plants, and biomass production plants) encounter significant obstacles and opposition, at the bureaucratic level and in local communities. I argue that these obstacles are due to a misconception of the idea of landscape.

This emerges, for example, in the case of wind farms, on which we will dwell here. According to Terna's data, the total energy generated in Tuscany in 2020 by all existing wind power plants was 250.2 GWh, corresponding to about 1.5 percent of total energy production from both fossil and renewable sources (Terna, no date). According to the inventory of wind farms built in Tuscany, as of the beginning of September 2023, there were ten wind power plants in the region, four of which were located in the province of Pisa, two in the province of Arezzo, and one in each of the provinces of Florence, Livorno, Massa, and Grosseto, with a total combined power of 140.3 MV (Wikipedia, 2024a). According to the same inventory as

of the same date, seven more plants with a total capacity of 66MV had been authorised and an additional ten plants with a total capacity of 426.6 MVh were in the planning stage. The implementation of the set of wind farms both authorised and in the planning stage would expand the total wind power capacity in Tuscany by 3.5 times and would significantly contribute to the goals of climate neutrality and energy security. However, as mentioned above, renewable energy plants face a lot of opposition, both at the bureaucratic level and from local communities and interest groups.

It is interesting to look at the media debate that has developed around these projects. We will focus in particular on two interventions: that of Monte Giogo di Villore, in the Tuscan Apennines-the mountain ridge that crosses the northern part of the region in a northwest/south-east direction-and that of Montauto, a place in southern Tuscany that is popular among elite tourists. Both projects were met with strong opposition and were widely debated in national and local newspapers. In the case of the Monte Giogo di Villore wind farm, counter initiatives were led by Leonardo Rombai, a professor emeritus of historical geography well known for his research on the Tuscan territory and president of the Tuscan section of the 'Italia Nostra' association. In an interview with a national newspaper, Rombai associated this project with the "business eagerness of major works," pointing out that it would "irreversibly alter what remains of pristine land and biodiversity." The Apennines, Rombai says, cannot be regarded as "a resource for industrial development." Among the grounds for the appeal to the administrative court filed by Italia Nostra are: geomorphologic, ecological, forestry and aesthetic changes to ridge, failure to fit into the landscape, visual impact on listed cultural heritage, and impact on tourist trails. (Rombai, 2023).

The media debate concerning the Montauto wind farm was even more heated, this area being known for its beauty and wilderness and encountering the attentions (and reactions) of numerous VIPs, including Vittorio Sgarbi, undersecretary for culture in the Meloni government, a renowned art historian and television journalist. In an interview with a newspaper Sgarbi called the wind farm "a criminal project, an abominable thing," whose implementation was the result of madness and would have disastrous impacts on Italian tourism (Mugnaini, 2023). Again, the local branch of Italia Nostra appealed to the administrative court. This same association was simultaneously engaged in several other legal and media battles against interventions aimed at renewable energy production and at climate change adaptation, including forest fire prevention cuts in the coastal pine forest of Tombolo and the construction of a photovoltaic plant in the province of Grosseto. Interestingly, Italia Nostra, throughout its nearly seventy-year history, has gathered around its ranks the elite of Italian culture and aristocracy. Although some of its environmental 'battles' had considerable relevance during the years of economic boom and of housing speculation, it, unlike other associations, has a strongly elitist character. Many of its media campaigns and legal battles are the result of an ideological view of the landscape, on which I will elaborate later. In the case of Montauto's intervention, for example, Legambiente, another major Italian environmental association, expressed its disagreement with Italia Nostra. In the words of one of its members, Angelo Gentili, given during a newspaper interview, "Cutting fossil fuels is fundamental and necessary. [...] Legambiente is not against renewable forms of energy and says yes to wind power and yes to photovoltaic. A shovel does not constitute a monstrosity." (La Nazione, 2023).

Beyond the positions expressed by different interest groups on individual interventions, the fact remains that cultural and bureaucratic obstacles to the implementation of climate change mitigation and adaptation projects in Italy remain huge. Although the business community is dynamic and has submitted many permit applications for renewable energy plants-potentially capable of making Italy carbon-neutral in a few years-most of these applications remain frozen for years and only a very small number are finally approved (Fraioli, 2022).

We could dwell on a great many other cases, including the total ban on photovoltaic roofs in much of the municipality of Florence and the regular aversion that solar farm projects encounter in the media and the courts. The debate that emerges in all these cases highlights the role played by cultural and affective factors that certainly bind us to the existing urban and rural landscape inhibiting an already difficult and problematic, but all the more urgent and necessary, adaptation to new conditions.

4. Discussion: removing cultural barriers to climate change mitigation and adaptation

From the debate on climate change mitigation and adaptation projects emerges an idea of landscape understood as fixed and unchanging--a kind of landscape-museum--and not as a flexible and adaptable living environment, to be continually transformed according to changing social, economic, environmental and climatic conditions.

In the absence of an awareness of the urgent need to adapt our living environment to the new climate, the market will take care of it, through the choices of millions of small property owners and buyers, but even more so through the choices of insurance companies and real estate operators, who will inevitably try to minimise the risks associated with climate change. As of the end of May 2023, the leading U.S. insurance company, has decided not to insure properties in the entire state of California against fire risk in order not to jeopardise its financial stability (Oladipo, 2023, Hao and Said, 2023). This resounding but at the same time entirely rational decision has, if nothing else, the advantage of providing the Golden State's political, economic and social system with a huge incentive to take all possible steps to counteract through planning and land management the phenomenon of forest fires, which has been out of control for a few years now.

In a state like Italy, and even more so in a region like Tuscany, the problem of cultural and affective barriers to the adaptation of the urban and rural landscape to the new and as far as possible future climatic conditions is particularly strong and evident. In fact, in this political decision-making context, resistance and friction to change are also determined by the fact that the cultural, pictorial and literary history of the urban and agricultural landscape have a very special weight and significance. There is an element of rationality in this attitude to preservation, both economically (for example, for the purpose of tourist exploitation of heritage) and psychologically. Studies in environmental psychology teach us that the landscape in which one is born and raised and with which one has a prolonged and lasting familiarity is an essential component of our psychological well-being (Lingiardi, 2017). Substantial alteration of it can be highly traumatic for each of us.

Philosopher Glen Albrecht coined the term solastalgia to describe the existential and emotional stress brought about by an environmental change that leads to profoundly altering the connotations of the landscape in which one lives (Albrecht 2005, 2007). This is described as "the homesickness you have when you are still at home." One could easily apply the term solastalgia to literary and musical works that described the alteration of the environment brought about by the 'building boom' in post-war Italy. Among these, Italo Calvino's *La speculazione edilizia* [The Building Speculation] (1963) and Adriano Celentano's song *Il ragazzo della via Gluck* [Gluck Street's Boy] (Wikipedia, 2024b) come to mind. However, while climate change mitigation and adaptation interventions may be perceived as worsening the aesthetic qualities of the environment in which they are implemented, it should be noted that solastalgia has been recognised by the medical journal *The Lancet* as a useful concept in understanding the impact of climate change itself on human health and well-being. It has also been used in various empirical research measuring the psychological consequences of environmental crisis situations (fires, floods, heat waves, droughts) attributable to climate change (Watts et al., 2015). So, on the one hand there is certainly a rational and 'self-protective' component (in that it is aimed at the preservation of one's psychological well-

being) in a certain amount of conservatism in urban and rural landscape management; on the other hand, it can produce inaction and immobility that could even prove disastrous in the current climate context.

Studies in environmental psychology are helpful in understanding some of the psychological dynamics that are potentially present in these attitudes. Alongside the 'healthy' tendency to preserve our living environment, we have in fact a much more dangerous and harmful propensity to fictitiously 'adjust' in our imagination an undesirable or even frightening reality, removing it and thus avoiding having to deal with the anxieties and psychic 'pain' that would result. According to several psychologically based researches, climate change would fall into this case (Hoggett, 2021, Hamilton, 2013, Norgaard, 2011, Stoll-Kleemann, O'Riordan and Jaeger, 2001). This is justified by the frankly very worrisome scenarios foreshadowed by studies and models on climate evolution in the not-too-distant future, such as 2050 or 2100, such as to heavily impact our future and even more so that of our children and grandchildren.

So the protection of the landscape 'as it is' to which we are affectively attached should be mediated with the adaptation of this same landscape to the new climate, in order to avoid in the near future even greater disruptions of our living environment. Instead, in the Italian and even more so in the Tuscan bureaucratic and administrative system, 'the instinct' for the integral protection of a landscape conceived as a museum prevails. Let us then try to imagine some mitigation and adaptation interventions that we might have to resort to in order to make our settlements more resilient. As known, in the literature on the subject, a distinction is made between mitigation and adaptation interventions. The former serve to make the effects of climate transformation less severe by reducing greenhouse gas emissions or enhancing the storage of climate-altering gases. The latter aim to contain the damage done by adapting cities and land to the new climate and weather situation. These two types of actions are equally urgent and necessary and cross different scales: from wide-area land-use planning, to urban and neighbourhood planning, to architectural design. Both mitigation and adaptation actions strongly require cross-sector and interdisciplinary approaches.

Transformations aimed at climate change mitigation mainly aim to contain emissions by improving the energy performance of the building stock, or to produce energy from renewable sources by building new energy production facilities. While the former generally have a limited landscape impact, the latter are at the centre of the nimbyism phenomena highlighted above, which, more generally, characterise much of the public and private interventions of urban and building transformation (Stoll-Kleemann et al. 2001, Bianchi, 2023). The words expressed by Undersecretary for Culture Vittorio Sgarbi against the installation of new wind farms, and the actions taken by him to prevent their implementation, are emblematic and demonstrate the inherently cultural and ideological roots of the problem.

In the urban context, adaptation will be mainly aimed at managing the water cycle and at contrasting heat waves. The metaphor of the sponge city summarises the urban planning approach needed to mitigate the effects of the increasing meteorological polarization consisting of alternating phases of prolonged drought and phases of intense and potentially devastating rain. A general multiplication of hydraulic risk will also necessitate typological transformations aimed at clearing the floors of buildings subject to flooding in high-risk areas, as well as the abandonment of those parts of the city that are excessively exposed. Problems arising from heat waves, where well managed, will result in a significant transformation of the urban landscape through the adoption of more reflective materials than traditional ones and the widespread creation of shading systems on facades, roofs and urban public spaces. It is also likely that the plant species we are accustomed to in our cities will have to be replaced with others more apt to the new climate. Once again there are numerous cases of cultural and administrative resistance to these types of landscape transformations.

All of this once again brings to light the cultural roots of bureaucratic inertia that makes permitting processes for renewable energy plants and for climate change adaptation projects particularly lengthy and cumbersome. In fact, underlying the administrative behaviour of the public administration is a static conception of the urban and rural landscape, which is implicitly believed to have attained a virtually perfect and final arrangement in its configuration immediately prior to the great demographic and urban port-WWII development. This approach has its roots in the landmark landscape and historical heritage protection laws enacted in Italy in 1939, during the Fascist regime. It is significant in this regard that Article 1 of Law 1497 of 1939 uses expressions such as "natural beauties considered as natural pictures," "viewpoints or belvederes, accessible to the public, from which the spectacle of those beauties is enjoyed," "complexes of properties that make up a characteristic view having aesthetic and traditional value". This idea of a definitive landscape, to be admired comfortably from the benches of the belvedere, is transmitted in the daily administrative practice of municipal landscape commissions and Superintendencies for cultural heritage, whose supervisory activities have resulted in the production of purified landscapes that are in fact 'made perfect.'

The purification of the landscape carried out, especially in Tuscany, since the Second World War, has resulted in the removal of all those elements that were in conflict with this static, abstract, idealised and ahistorical -or rather referred to imaginary historical situations and depending on the case vaguely and generically medieval, Renaissance, pre-industrial- idea of landscape. One can borrow the term 'fantasy restoration,' used to describe the nineteenth-century interventions promoted by Viollet le Duc and aimed at restoring medieval monuments according to canons that were as abstract and perfect as they were distant from their historical and material reality, and apply it to the administrative behaviour of landscape protection agencies. The 'fantasy landscape' realised in Tuscany is in fact a perfected and purified one, quite distant from the historical and material reality of the landscape prior to its purification (Giovannoni, 2017). It is quite evident how this landscape, because of its rigidity, is completely incompatible with the need to adapt our living environment to the rapid transformation of climate.

5. Conclusions and policy implications

Climate change poses unprecedented challenges to the adaptation of urban and territorial systems because of the rapidity with which it is taking place and the intensity of the transformations already detectable at the level of the water cycle, heat waves, and fire risk. Our cities are the spatial synthesis of ways of inhabiting space that are often rooted in cultures and traditions thousands of years old and have long transformation times that tend to be incompatible with new scenarios. This paper has shown that in Italy, more than in other countries, there are cultural and psychological barriers that strongly hinder the necessary process of adaptation. The operational and policy implications of the analysis conducted so far are twofold: first, we should combat, especially on a cultural and communication level, the museification of the landscape, emphasizing and stressing its dynamic and adaptive character; second, it is necessary to conceive procedural and regulatory innovations aimed at simplifying climate change mitigation and adaptation planning and at realigning, as far as possible, urban and regional policies to the current operational context so that they can provide a timely response to current climate challenges.

The increasing entry of the energy subject in spatial planning policies: new visions for energy landscapes

Pistoni Roberta
École nationale supérieure de paysage de Versailles Marseille, LAREP
r.pistoni@ecole-paysage.fr

Abstract

The energy topic is of great concern to our society, because of the increasing tensions of fossil resources supply and emission of greenhouse's gas to the atmosphere resulting in climate change. The landscapes we live in are transforming and becoming increasingly complex in their relationship to energy and we can observe an evolution of the European and national directives and laws progressively increasing the place of energy in spatial planning policies as well as the subject of the ordinary landscape. The spatial planning documents are participating in changes and the evolution of landscapes and they are developing new visions for future energy landscapes. The research explores and compares the spatial planning system in France and the Netherlands, enabling to follow the evolution of two different planning cultures, as they incorporate new relationships between energy and landscape.

Key words: France, Netherlands, renewable energy production, energy sufficiency

1. Energy Transition and Changing Landscapes

From an energy point of view, each territory is an open thermodynamic system with inputs and outputs of energy (Stremke, van den Dobbelsteen and Koh, 2011). In every territory, whether urban or rural, energy is more or less intensely consumed and potentially produced; these actions are closely dependent on local characteristics, both natural (such as topography) and human (technical, economic, etc.) (Mérenne-Schoumaker, 2007). However, over the centuries, we have witnessed a progressive disconnection between society, its territory, and its resources (Magnaghi, 2010), and consequently its landscape. Gradually, due to the exponential use of fossil resources, the link between consumption and production sites has been broken. This rupture has led to the forgetting of the 'localization' of energy resources and has been accompanied by the decline in knowledge and know-how in energy management, which, for example, used to guide the construction of houses according to the correct orientation to benefit from maximum solar gains. Suddenly, all of this was no longer necessary: the power of energy seemed to solve all problems thanks to technological development.
Today, the ecological awareness of the depletion of fossil resources and the environmental destruction associated with their exploitation changes the game. With climate change as a contributing factor, we are witnessing attempts to reverse this trend, and the stakes for a transition towards a low-carbon and efficient energy system are becoming increasingly important in national and international discourse. The current energy transition requires space, with all the implications this entails for the landscape in a nearby 'here' instead of the indefinite 'elsewhere' of fossil resources. On the stage of the energy debate, localization thus brings with it the question of the landscape, where are combined functions related to energy production

from renewable sources, reduction of energy consumption as well as the optimization of energy flows (Stremke, Oudes and Picchi, 2022).

Landscape is here addressed according to the European Landscape Convention (2000) as perceived and conceived by the people and whose character is the result of the action and interaction of natural and/or human factors. So this convention puts a dynamic approach towards landscape and in the Recommendations on the guidelines for its implementation is stated at point E to 'Integrate the landscape dimension in territorial policies' that 'The landscape dimension should be included in the preparation of all spatial management policies, both general and sectoral, in order to lead to higher-quality protection, management or planning proposals' (CM/Rec(2008)3, 1-E). So ELC encourages including landscape concerns in the national planning systems and after the ratification of the convention by the different nations these systems are progressively including landscape, potentially going beyond the preservation of exceptional landscape and in the direction of a more operational and extended concept of ordinary landscape.

Moreover in Europe, after several directives (e.g. energy package 20-20-20 of 2009, REpowerEU 2022) and national laws (e.g. LTECV in France) the energy topic has entered the spatial planning system in national contexts (Lopez, Pellegrino and Coutard, 2019), due to the need to give a regulatory framework, for examples of the choice of sites for renewable energy technologies in territories but also to improve the energy sufficiency in the built environment.

Therefore, potentially planning instruments could combine the landscape and energy topics and address them together. The understanding of this connection could be useful because it is recognized that the planning instruments participate in changes and the evolution of ordinary landscapes (Labat and Donadieu, 2013), so their analysis leads to an understanding if landscape is consciously addressed in these documents and if these landscapes 'changes' are intentionally thought out. Otherwise landscape, conceived as our living environment, could be an unplanned consequence, resulting from the superposition of different planning strategies and actions for energy management.

The research establishes an international comparison between France and the Netherlands, two nations that have integrated strategies for transitioning from fossil fuels to renewable and decarbonized energy sources into their political agendas, as confirmed by the latest documents: 'Klimaatakkoord' 2019, 'Loi Climat et Résilience' 2021. However, there are differences in the timing of their commitment as well as in the public policies and planning instruments linking space and energy that allow to put the results into perspective. Moreover the Netherlands is a nation with a surface area of 1/13 of the French one with a population density about four times higher than the French one, differences that could lead to differences in the way to approach spatial planning.

In the following section we explore the French and Dutch planning instruments to study if, and to what extent landscape and energy are treated together. The guiding questions are: in planning documents when addressing the energy transition process is landscape considered mainly in its visual and esthetical component as something to be preserved? Or is landscape addressed as an evolving and dynamic entity to be planned and designed?

2. The Potential relation between energy and landscape in the planning system in France and the Netherlands

This section is not an exhaustive vision of all the documents and ways in which energy is addressed in the planning system, but the goal is to give a general overview illustrating the type of documents existing in the two nations and their possible link with the energy and landscape topic.

In France we assist to a progressive inclusion of the energy topic in the spatial planning documents, in particular with the two Laws 'Grennelle de l'Environnment' (2009-20010), which emphasised the trend for a territorialization of climate and energy policy in France (Nadai et al. 2015) and which introduced a new planning documents the 'Plan climat énergie territorial' [Territorial climate energy plan] (PCET) compulsory for municipalities or inter-municipalities with more than 50.000 inhabitants. Subsequently with the law 'Loi transition énergétique pour la croissance verte' [Law energy transition for the green growth] (LTECV) the PCET become the 'Plan climat aire énergie territorial' [Territorial climate air energy plan] (PCAET), becoming compulsory for all municipalities and inter-municipalities counting 20.000 inhabitants, therefore greatly expanding the number of local communities that need to develop this plan, compared to the PCET.

In France, the energy topic seems to be more prominent in the planning system when compared to the Dutch one, because there are compulsory and specific documents which have to treat the energy subject at all the territorial levels, such as the 'Schéma régional d'aménagement de développement durable et d'égalité des territoires' [Regional scheme for spatial planning, sustainable development and territorial equality] (SRADDET) setting energy ambitions for the region and the PCAET a document that focuses on climate, air and energy to establish goals for a territory (inter-municipality) on short and long terms and to define actions, to implement them. Moreover there are other planning documents that address several subjects including energy. One is the 'schémas de cohérence territoriale' [Territorial Coherence Scheme] (SCoT) a planning instrument that guarantees the implementation of strategic inter-municipal planning and it ensures the reference framework and coherence with different sectoral policies such as infrastructure, mobility, energy and climate, etc. Another document is the 'plan local d'urbanisme intercommunal' [Local urban inter-municipal Plan] (PLUi), a planning instrument at inter-municipal scale, that determines a global project for spatial and urban planning and which determines the conditions for land use and its development. This document could integrate several energy topics, such as the development of wind parks, photovoltaic parks, heat networks and energy sufficiency. For example, the PLUi could impose on new construction a minimum amount of renewable energy production and insulation.

In the Netherlands, the planning system, fixed by the 'Wet Ruimtelijke Ordening' [Spatial planning act] (WRO) of 2008, is more flexible and seems to favour integrated planning instruments (Janssen-Jansen and Woltjer, 2010). Compulsory energy focused planning documents that all provinces or municipalities have to elaborate do not exist. However the importance of introducing energy in planning instruments is recognized and it is compulsory to deal with energy, both from a renewable energy production than energy sufficiency perspective, in the *structuurvisie* [structural vision] which defines the strategic point of view for spatial development, and set actions for the provinces and for the municipalities. Every tier could

develop several *structuurvisie* that could be centered on a specific topic (e.g. agriculture) or that could be cross-sectoral. Moreover in the zoning plan (*bestemmingsplan*), which establishes the land uses, their development and regulations at municipal level, energy topics could be included for example defining the areas for renewable energy production and the rules on how to implement them.
A particular approach is reserved, however, for the wind turbine planning policy, following the Energy Agreement for Sustainable Growth (2013), which settles the national objective of 6000 MW of electricity production from onshore wind turbines. The national government required provinces and municipalities to integrate it in their planning instruments, defining suitable areas on national territory for its implementation, in a very top-down perspective. The only national *structuurevisie* that is energy focused deals with wind energy development (Structuurvisie Windenergie op land, 2014). This planning system is now in progress of changing due to the Environment and Planning Act [Omgevingswet] that came into effect in 2024.
Concerning the connection between landscape and energy in several French and Dutch planning instruments there is the possibility to establish a connection, but this is left to the discretion of local institutions in both countries. This means that in the Netherlands in the *structuurevisie* of provinces and municipalities or in the municipal *bestemmingsplan* these topics could be adressed together, although there is no obligation to do so. France seems to be potentially well equipped to enhance this integrated vision through the PLUi and SCoT, that operate at an inter-municipal level and deal with both energy and landscape concerns, and therefore could create synergies between the two subjects.
In particular now, the relationship between landscape and energy is specifically mentioned for the elaboration of the SCoT. It can be read in the orientation and objective document in Article L. 141-4 3° of the Urban Planning Code that the SCoT relies, among other things, on 'the preservation and enhancement of landscapes, with the objective of integrating and enhancing the landscape quality of various human activities, notably renewable energy production and transportation installations.' On the other hand, the French PCAET which is the energy and climate focused, do not have to address any link with landscape, and often even a spatial approach is not addressed.

3. The Path towards Energy Transition of three Territories

In order to give insight on how these energy landscape topic is treated specifically in planning documents, at different scales, three territories are analysed: two 'Territoires à énergie positive' [Energy positive territories] (TEPOS) in France, the Community of Communes (CC) des Monts du Lyonnais and the CC du Thouarsais, and one in the Netherlands, the municipality of Goeree-Overflakkee (Province of Zuid-Holland/South Holland). All three territories have set ambitious energy goals both from renewable energy production and energy sufficiency at the horizon 2030-2050, with an affirmed intention to integrate them with landscape considerations. Although they could not be defined as representative for other territories, the reason to choose them was: to inquire about possible 'best practices' of what is feasible to accomplish. The results, however, draw attention to several limits on how landscape and energy transition are

included in these documents. These territories, comparable in dimension and are rural, but also include urban areas, and are they are characterised by 'ordinary' landscape, meaning that they are not the object of particular degree of safeguards for heritage or natural characteristics (e.g. UNESCO).
The case studies were explored through an analysis of the different planning documents, from the regional to the inter-municipal and municipal scale and completed by semi-structured interviews with the technical services in charge of the development of the planning documents as well as elected representatives.

3.1 *Communauté de communes* Monts du Lyonnais

The idea of commitment to the energy transition process of the CC of Monts du Lyonnais started in connection with the building sector in 2006. According to the interviews developed with the energy transition technical service and an elected representative, the starting point of the gradual commitment to the transition process was the creation and development of the 'Parc Eco Habitat' a resource and information centre about retrofitting techniques and environmentally friendly construction.
Subsequently the local institutions of the CC Monts du Lyonnais were awarded the call for 'expressions of interest' (AMI) launched by ADEME and the Rhone-Alpes region in 2012, to encourage territories to commit and achieve TEPOS objectives for 2050. So in 2013, territorial local institutions engaged in a volunteer PCET thanks to the economic support of the AMI-TEPOS award call. Subsequently and according to the news rules settled by the law LTECV of 2015 the CC Monts du Lyonnais developed a compulsory PCAET.
The landscape perspective was introduced in 2013 through the development of a landscape plan financed by the ministry of environment and finalised in 2017, in order to be included in the SCoT that was in the process of revision and update. In the commission of the landscape plan the energy issue was not explicit in the initial request, but it emerged as a priority during a public workshop with local stakeholders such as elected officials, technicians, and residents, organised by the landscape architect responsible for developing the landscape plan. Several topics were displayed based on the landscape analysis, and the present stakeholders had to choose among the priority objectives, with energy being highlighted. However, according to the interviews the landscape plan, even if it was centred about energy, it was not really used to support the elaboration of the PCAET which started in 2016.

3.2 *Communauté de communes* Thouarsais

The local institutions have since long addressed the energy subject in the territory of CC Thouarsais, through the development of renewable energy projects, where in 1984 a swimming pool heated with solar panels was constructed. Since then several projects followed, one of the bigger was the 'Technologies Innovantes pour la Production d'Énergies Renouvelables' [Innovative technologies for renewable energy production] (TIPER); with the objectives of high rates of renewable energy production from several different technologies: photovoltaic, wind energy, biogas, in an area with polluted ground soil. This interest and commitment towards the

energy subject, that also allowed economic implication, brought the CC Thouarsais to be one of the founder territories of TEPOS network in 2010.
In this context the elaboration of the landscape plan of the CC Thouarsais has been conceived from the beginning by local institutions with a primary focus on achieving energy objectives to become TEPOS. The landscape plan comes in 2017-2018 at a time when the CC was developing a PCAET in which the development of additional wind turbines, photovoltaic and biogas projects were addressed. The landscape plan was seen as a tool capable of informing a renewable energy development more grounded and integrated in the landscape. Moreover the landscape plan fed into the PLUi, which was being developed during the same period, and particularly the territorial institutions decided to elaborate an 'Orientation d'aménagement et de programmation' [Planning and Programming Orientation'] (OAP), a part of PLUi, on the theme of 'Energy and Landscape' focused on wind energy development to establish a framework and a support tool for deploying new parks well integrated into the landscape. It is interesting to note that this OAP is binding for local institutions, whereas a landscape plan is not, stressing the importance for the CC to develop defined orientation for the development of wind parks on the territory, which were starting to raise some opposition.

3.3 The municipality of Goeree-Overflakkee

In Goeree-Overflakkee the starting point to engage in energy spatial planning has been the Energy Agreement for Sustainable Growth (2013), which sets goals at national scale for energy sufficiency of 100 PJ and a production of 6,000 MW of onshore wind energy by 2020. The local institution of Goeree-Overflakkee in 2013 commissioned a landscape architecture firm to create a document linking landscape and energy: 'Goeree-Overflakkee, Sustainable Energy in the Landscape.' This document was developed following the definition of national goals, distributed top-down among the different provinces, where the municipality, given its low population density, was identified for the production of 300 MW of onshore wind turbines.
The aim of this landscape study was to analyse the current state and develop different scenarios for analysing local resources and the location of renewable energy production facilities in the landscape going beyond just wind energy. This study served as a tool for understanding and supporting negotiations with the Province of Zuid-Holland for a reduction to a wind production of 225 MW, filling the gap with an energy mix from photovoltaic panels and biogas production, considering the agricultural and breeding activities of the territory.
Moreover the document contributed to developing the provincial-level planning *Structuurvisie Ruimte en Mobilitiet* (2014) [Structural Vision for Space and Mobility] and at the municipal-level the urban documents like *Structuurvisie Goeree-Overflakkee windenergie* (2014) and *bestemmingplan* [zoning plan]. This landscape document was particularly used for defining wind development zones and criteria on how to implement them.
Recently, following the 'Nationaal Klimaatakkoord' [National Climate Agreement] in 2019, a new national program called 'Regionale Energie Strategieën' [Regional Energy Strategies] (RES) has been introduced in the Netherlands. This program, led and coordinated from national to municipal level, mandates the development of territorial energy strategies for the 30 identified territories covering the entirety of the Netherlands. Each territory must outline in its RES how and to what extent it will contribute to the production of renewable electricity, the

transition of the heating system in the built environment, as well as energy storage and infrastructure. The national objective is to produce at least 35 TWh of electricity from renewable sources and reduce CO2 emissions by 49% by 2030. It is explained that the different territories have 'to make the *Regionale Energie Strategieën* (qualitative and quantitative) spatially possible' (Climate agreement., p. 223). The local institutions of Goeree-Overflakkee were among the first to commission a consortium of architects, landscape architects, urban planners, and engineers to conduct a study on three spatial and landscape energy scenarios for the development of Regional Energy Strategy: 'Energy Production in Goeree-Overflakkee. Scenarios for Sustainable Energy Supply by 2030' (2017). The three scenarios address renewable energy production through a technologies mix, as well as consumption reduction and optimization of flows, also addressing building renovation and transport infrastructure systems. These documents are the basis for developing and implementing the new Environment and Planning Act [Omgevingswet], which is in progress, and changing the content and process of the previous planning system.

4. A Crossed Perspective of the Planning Documents of the French and Dutch Territories

4.1 Connection between Landscape and Energy in the Planning Documents

Table 1 sums up the results found in the analysed documents between energy transition, operational principles and their connection or not to the word landscape. I inquired about energy principles which are defined both as operational principles which implementation could impact landscape changes (e.g. development of wind turbine and photovoltaic panels), but also as spatial/landscape design principles which, if implemented, could improve energy management (e.g. building orientation to maximise solar gains). In the table renewable energy production and energy sufficiency measures are addressed separately, because they are each energy transition pillars for which distinctions appear in planning documents.

Table 1, Sum up the energy transition highlighted actions appearing in planning documents in the three analysed territories, highlighting their connection with landscape. The landscape plan and the Dutch landscape focused report. Green background colour corresponds to the explicit connection of the energy action with the word 'landscape' word. The white background colour means that the action detailed could lead to landscape repercussion but the connection is not established in the document.

	Renewable energy production	**Energy sufficiency**
CC MONTS DU LYONNAIS (FR)		

SRADDET- Schéma régional d'aménagement de développement durable et d'égalité des territoires - 2019	Wind turbine implementation: landscape preservation	Compact settlements form, building retrofitting, slow mobility, etc.: spatial design principles for low energy consumption

Province Zuid-Holland Structureevisie Ruimte & Mobilitet. Verordening ruimte (spatial regulations) - 2014	Wind turbines implementation	/

The first visible result is that landscape direct concern both in France and in the Netherlands is associated with wind parks. The landscape impact of renewable energy technologies implementation remains the most debated landscape issue towards energy transition in France as in the Netherlands. Wind turbine implementation principles are directly related to their landscape impact most of the time. Here is where landscape is mostly addressed by a preservation point of view. This is followed by the landscape concerns around PV parks on the ground, connected to the visual impact and also about preserving agricultural land.

The preservation of landscape aesthetics is a point of view broadly addressed everywhere and to which is recognized much attention especially for the development of renewable energy technologies in order to 'preserve scenic values' (e.g. Apostol *et al.*, 2016) even if aesthetics and sentiment of beauty is recognized to be something variable through time and space.

However the majority of documents address several types of renewable energies technologies implementation, such as biogas power plants, but there is no direct connection with landscape characteristics in these cases. We find this primary focus on wind turbines also because there are several specific planning instruments devoted to wind turbines, for instance, the obligatory 'Scheme regional eolienne' [regional wind turbine scheme] (SRE) at regional level in France, or the wind energy and landscape OAP voluntarily developed in the CC Thouarsais, or in Goeree-Overflakkee the *structuurvisie windenergie*. There are no other documents specifically developed about other renewable energy technologies such as photovoltaic parks. However, in France, the law LTECV introduced a new document the 'schéma régional biomasse' [regional biomass scheme] with the goal to estimate biomass potential and its accessibility in the region in order to facilitate the development of renewable energy production. This shows an enlargement, compared to the sole wind turbine SRE focus, but in the territories under analysis these documents were still under elaboration with no possibility to examine them. In the Netherlands it is possible to develop several *structureevisie* about different topics estimated to be of relevance for the territory. In Goeree-Overflakkee, regarding energy transition, only the one wind-energy exists, showing that, as compared to other sources, their site plans and implementation remain the main concern. Indeed, the binding regulations of the Province Zuid-Holland in its *structuurvisie Ruimet & Mobilitat*, relating energy transition concerns, addresses only wind turbines.

Another point that the Dutch and French planning documents have in common is that energy transition and landscape are developed in separate chapters (e.g. SCoT Monts du Lyonnais, *structureevisie GoereeOverflakkee*), complicating the articulation between the two and showing how they are not easily associated.

Another result identified is that none of the French and nor Dutch planning instruments have landscape associated with energy sufficiency measures, except for the French landscape plans and the second landscape report of 2017 of Goeree-Overflekkee, but these documents are not regulatory and binding. Compulsory planning instruments highlight principles that, from a spatial/landscape planning and design perspective, could encourage reducing energy consumption. However their potential landscape effects are not addressed at all, even if the changes required in urban areas could be extensive (e.g. external isolation, compact urban form).

Moreover, for the French case, the PCAET document being energy-climate-air centred is a very relevant document for territory analysis and fixing energy goals. Nevertheless, it lacks explicit

insight into spatial/landscape dimensions that could be a significant and valuable support in establishing energy goals (e.g. exploration of available surface area and sites for photovoltaic or wind turbines) as well as the way to achieve them (e.g. establishing synergies among functions). An interesting tool could be the introduction of energy potential maps (e.g. Oudes and Stremke, 2018) representing solar or wind but also biomass potentials as well as heat cold storage sites that could be further exploited through a cascading process. Indeed this kind of representation requires reliable data at a local level, that are in many cases not available and needs to be crossed references with the other characteristics and resources of the territory (e.g. topography, etc.).
In the Netherlands there is not a specific energy planning instrument even if *structuurvisie* could be dedicated to energy topic. However, a new instrument has been recently introduced through the Dutch *Nationaal Klimaatakkoord* (2019): the *Regionale Energie Strategieën*, that, as explained above, aims to define energy targets while considering its spatial component, for all Dutch territories covering all the Netherlands. Unfortunately, the translation of this instrument in the new planning system introduced by the environmental act is still ongoing and no further exploration could be done during the research period. However, this shows how, in the Netherlands as in France, energy transition development is left less to the discretion of local institutions and strongly encouraged.

4.2. The need for quantitative high resolution energy data for spatial planning

Another point of discussion is the accessibility of spatial data for energy. The difficulties to access statistical disaggregated data on energy could be defined as an impediment for further insight about the spatial components of energy within territories. Indeed, it is needed in order to develop more spatial conscious and efficient projects that connect energy supply and demand. We acknowledge that for now, in France as well in the Netherlands, the electricity produced is injected in the main power grid, so the energy produced somewhere in a photovoltaic park could be used at a distance far away, and the grid handles fluctuations that are intrinsic to renewable energy production. Nevertheless, the idea to have a better comprehension of the local consumption and production from a spatial perspective is valuable in order to better answer the needs of the territory and to establish synergies among functions.
Several critical points could be stressed, in particular a difficult access to statistical data about energy at local scale. Not all territories have stats available on general energy production or consumption nor by sector for each municipality. For example, for CC Thouarsais, data about energy for the development of the PCAET is only at the *communauté de communs* (grouping many municipalities) scale, and lacks precise information about locations. The CC Monts du Lyonnais benefits from the more complete open statistical data provided by the region, 'Observatoire Régional de l'Energie et des Gaz à Effet de serre' (OREGES), which provides energy data at municipal level as well as from a historic perspective. But the data remains incomplete and figures about industries are almost totally absent. The CC are using them to develop the PCAET. In the Netherlands for the province of Zuid-Holland, data are at the territorial (group of municipalities) level, and in some cases at the municipal level. However

this topic has been directly addressed in connection with the development of the *Regionale Energie Strategieën* for all the Dutch territories and the construction of a database is in progress. In order to better understand the topic I led a parallel investigation in order to find the energy data used for the planning documents, and see if other more local high resolution data were accessible. I contacted the offices that backed the technical services departments of the territory under analysis and other accessible databases, such as the regional office. One of the main problems is that for privacy issues the data on energy consumption for the industrial sector are not made public. This absence is, for example, mentioned in the PCET of CC Monts du Lyonnais that underlines this approximation ('PCET SIMOLY'2015, 26). This difference in data disaggregated is found in the lack for example of maps in the PCAET of CC Thouarsais, resulting in no illustrations of spatially local potential and consumption.
The need for high resolution data on energy and their difficult access aligns with the results from other research that explored this gap, showing how the connection between local data on energy and territorial characteristics (e.g. building age) could actively support the definition of a strategy for energy consumption reduction (Pincetl *et al.*, 2016). Some research also emphasises the need to access spatio-temporal dimension and how this data could be useful for environmental designers and urban planners to implement tailor-made energy strategies (Voskamp *et al.*, 2016).

4.3 Sectors including energy goals and a landscape perspective in planning documents

Throughout the studied planning documents, energy transition is addressed across sectors, housing, transport, agriculture, and industry. However, the connections between these sectors and landscape are few and not clearly established in the documents.
I noticed that all the actions regarding energy sufficiency such as the implementation of external insulation in buildings or the implementation of paths and streets for low mobility are not directly associated with landscape.
The same could be said for the agricultural sector that, especially considering the rural character of the analysed cases, could play a major role toward achieving energy goals, through biogas production, biofuel production, wood energy, etc. For this sector, again connection with landscape is under-evoked. Yet all these actions could induce major landscape changes through possible changes in agriculture: the type of crop cultivated, new trees and hedges plantations, etc., beyond the installation of the biogas power plant itself. We found some association made to landscape in the CC Thouarsais's PCAET relating to the implementation of a hedge system for wood-energy sector development. However, the connection is absent in the regional planning instrument (SRCAE). Landscape is mentioned in connection to agriculture when these documents explain how the implementation of PV parks should respect and preserve food production.
Beyond the landscape impact, some research has shown how a better analysis of biomass production for energy from a spatial perspective could lead to better choices in scale for implementation and improving positive social impact (van der Horst and Vermeylen 2011). Moreover it is explored how landscape viewpoint could sustain conscious choices on more suitable areas for biomass development (Howard et al. 2013).

Another sector for which landscape is not entered in the discussion is the industrial sector. Even if the industrial sector is stressed in the French document, such as the PCAET, and in the Dutch ones there is no clear connection with spatial perspectives. The industrial sector is primarily connected to improvements for energy efficiency where machines are used to reduce energy demands, an aspect hardly connected with landscape. However, in the planning document some focus exists on identifying waste energy/heat to be re-used in other nearby manufacturing facilities, companies, etc. For this energy cascade a spatial analysis of proximity among industries and areas could back the process.
However, in the Dutch case, it is mentioned the idea of heat energy cascade from Rotterdam's industrial harbour to the residential areas in the landscape report of 2017. This gives prominence to the idea that these two topics are starting to be linked.

5. Are Planning Documents Moving towards Integration between Energy Transition and Landscape?

Planning instruments carry a project framework to shape the future of territories. In this paper I explored the way they address energy transition and landscape together and what role is given to landscape design and planning from an institutional perspective in the energy transition process.
Generally speaking, from the French planning documents emerge a preservation, aesthetic vision of landscape, connected to heritage and natural beauty, which persists in connection with the energy transition issues and renewable energy technologies in particular. The same attitude was found in some Dutch documents as well, however it is accompanied by a more explicit landscape design attitude. In Goeree-Overflakkee, every time that local institutions settled energy goals a landscape document was commissioned to inform the decision-making, and integrate the planning system. This difference could have its roots in the traditional attitude towards landscape, which varies between the two nations. In France, landscape has long been associated with nature and heritage in legislation (Donadieu, 2012). In the Netherlands, this attitude coexists with a strong planning and project perspective (e.g. de Jonge, 2009), in a land that is mainly considered as man-made.
It would be interesting for the years to come to follow this inquire questioning the 'Zone d'accélération de la production d'énergies renouvelables' [Renewable energy production acceleration zone] introduced by the law accelerating the production of renewable energies (APER) in 2023, and see if an evolution in the relations with landscape will occur. The same could be said for the Netherlands where the enter into force of the Environment and Planning Act [Omgevingswet], at the beginning of 2024 introducing a new planning system will lead to changing in the relations between landscape and energy.
Moreover another path to further explore is that, the actual results show an understanding that spatial organisation could affect energy sufficiency but it is not directly connected to the idea that it could lead to landscape impact or change. And vice versa, the landscape viewpoint is not considered to be useful as leverage to improve energy sufficiency. Nevertheless, in the Dutch context, with the progressive entry into force of the Environmental act [Omgevingswet], a connection could be observed between reduction of energy consumption and landscape. Indeed

even if renewable energy technologies are visible in landscape energy sufficiency measures remains one of the major challenges for the years to come, requiring a profound restructuring on how to plan, design and inhabit our territories, cities and their landscapes.

Abstract
Central Business Districts have always been the loci of major transformation, redevelopment and constant re-definition(s) regarding their role within large urban territories. Climate Change combined with Urban Heat Island, could render CBDs particularly vulnerable to extreme heat conditions and persistent heatwaves, affecting their key functions and quality of life. This work investigates the above issue through a case study in Athens, a densely populated Mediterranean urban agglomeration. Methodology involves identification of key aspects of the CBD structure that increase its vulnerability to extreme heat waves and related hazards and pressures. Our conclusions state that Climate Change could eventually lead to changes in urban structure, affecting existing CBDs and possibly favoring relocation of activities towards other city zones, where climatic conditions will be more favourable.

Keywords: Central Business District, Climate Change, Heatwaves, Urban Structure, Urban Planning, Athens

1. Introduction

In the summer of 2023 an extreme heatwave stretching from Miami and Texas to Arizona and California has led to unprecedented record-breaking temperatures, most notably in Phoenix with a 31-straight-days with over 43.3 °C record. During the same period, in the Mediterranean air temperatures hit 46°C in Rome and Madrid, with major cities suspending certain functions, temporarily banning outdoor working and outdoor events, and taking precautionary measures to protect human population from extreme heat conditions and consecutive heatwaves. Generally, the persistent heatwaves of July 2023 have largely affected several Mediterranean capital cities including Madrid, Rome, Athens and Lefkosia (Figure 1). More cases worldwide have been reported where extreme heatwaves due of unprecedented nature are linked to partial lockdowns in urban metropolitan areas, putting urban life on pause[1].

The common driver and accelerator behind such conditions is Climate Change. Since the last quarter of the 20th Century, Planet Earth has entered an accelerating global warming phase, with the mean surface air temperature on land reaching about 15°C (14.98°C in 2023), i.e. a +1.09 in 2011–2020 period in respect to the pre-industrial levels and the 1850–1900 average (IPCC, 2022). This increase practically means that winters are expected to be less cold, while summers will be warmer and with more heat extremes. Globally, the last ten years have been the warmest on record, while the summer of 2023 has official been declared as the hottest summer on record (https://climate.copernicus.eu/summer-2023-hottest-record).

https://www.telegraph.co.uk/global-health/climate-and-people/sudans-heatwave-school-closures-children-lockdown-africa/

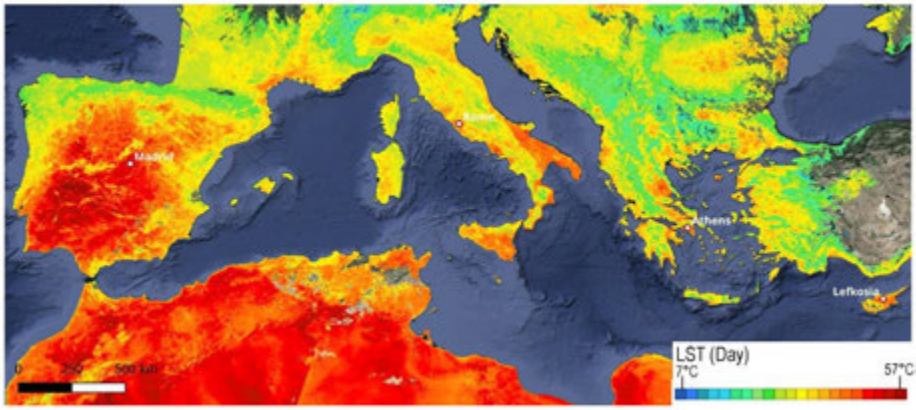

Figure 1. Land surface temperature (day time) across South Europe and parts of northern Africa during the heatwave of 10 July 2023 (source: Google Earth Engine, 'MODIS/061/MOD11A1').

While significant uncertainty remains regarding the exact future climatic conditions and related hydrological phenomena at the regional level, one thing is certain: Global warming will result into longer and more frequent extreme heatwaves in many regions, directly affecting current standards of living, and causing an increase of human thermal discomfort. This can be translated into significant problems predominantly in urban areas of high exposure to such climatic conditions, where the concentration of people and infrastructure in maximized. According to the Intergovernmental Panel on Climate change (IPCC, 2022), in urban areas climate change has caused adverse impacts on human health, livelihoods and key infrastructure including transportation, water, sanitation and energy systems, with resulting economic losses, disruptions of services and negative impacts to well-being. Moreover, compound hazards are expected to occur more often as heatwaves could possibly be accompanied by droughts, wildfires, flash-floods and other weather extremes, that could expose the fragility of urban infrastructures and resources.

A major parameter of climate change in urban areas is that heatwave impacts are multiplied by the Urban Heat Island (UHI) effect. UHI is a phenomenon where urban centers experience higher ambient air temperatures than surrounding suburban and rural areas, that are less urbanized (Sánchez-Guevara et al., 2017). UHI is often quantified through air temperature differences or surface temperature differences (Peng et al., 2012). UHI is most notable during the evening and night hours, as impervious surfaces and buildings release the heat absorbed by solar radiation during the daytime. The relationship between Urban Heat Island and urban form is a complex one, with street canyon effects, wind speed, blue and green urban infrastructure, along with traffic conditions, and energy functioning of buildings playing a crucial role (Xu et al., 2019; Luo et al, 2020). Generally, the spatial distribution of heatwaves within urban areas is influenced by building density and impervious surfaces (do Nascimento, 2022), land use structure, and intra-urban microclimatic variation (e.g. due to the effect of a coastal zone) (Luo et al., 2020). Researchers are also exploring the linkage between urban heat island and urban pollution island, as heatwaves are associated with higher concentrations of pollutants (Ulpiani, 2021). Heatwaves in urban areas result into positive heat loops at a local scale: a heatwave is followed by a rise in energy use for cooling, and the associated discharge of anthropogenic waste heat from the buildings to the environment increases (Luo et al, 2020).

The above remarks are particularly relevant when considering the South European/Mediterranean context. At a general level, Europe is considered to be a Climate Change hotspot, warming more rapidly than the rest of the planet (EEA, 2023). Heatwaves in Europe are responsible for more deaths than other natural hazards and disasters, including floods, hurricanes and earthquakes, with the highest heat-related mortality rates reported in Italy, Greece, Spain and Portugal (Ballester, et al., 2023). While in Central and North EU cities like London, Paris, and Warsaw, heatwaves last for just a few days and are mostly perceived as "Climate Change evidence", in EU-South capitals like Madrid, Athens, and Rome, record-breaking temperatures and heatwaves are largely undermining the citizens' quality of life lasting for several weeks or even months. Mediterranean ranks among the top five regions globally demonstrating significant increasing trends in the intensity, maximum duration, frequency, and cumulative heat of heatwaves (Perkins-Kirkpatrick & Lewis, 2020). In such cases, heatwaves could pose particular stress on energy systems, have drastic consequences on food production, discourage tourism traffic, while everyday functioning is also severely affected.

In this research I focus on how central city areas widely known as the Central Business District (CBD) are be affected by extreme heat conditions and persistent heatwaves as Climate Change unfolds. CBD areas have long been the nuclei of economic and social life within metropolitan areas, while being particularly dynamic, undergoing major changes through different urbanization cycles, including suburbanization, de-urbanization and re-urbanization processes. Climate Change could impose a new process of urban restructuring, particularly affecting CBD areas in certain metropolitan regions where extreme heat risk is maximized. Our main hypothesis is that the "vibrant" character of such central districts could be largely undermined for considerable periods of time, possibly resulting into a redefinition of their role and imposing changes in the city form and structure in the long term.

To examine this hypothesis, I first delve deeper into the historical role of CBDs, also examining recent transformations taking place in terms of urban form and structure. At a next section I present the major challenges posed by extreme heat conditions on CBD areas, through a case study in Athens, i.e. a typical large metropolis of the Mediterranean region. Methodology is based on the identification and examination of the key dimensions of the urban spatial structure of the city center, and the assessment of their vulnerability to the increased exposure on heatwaves. The conclusions provide links to urban planning and spatial adaptation issues, while considering the possibility of new climatic conditions favoring more decentralized spatial arrangements.

2. Central Business Districts: Conceptualizations and dynamics

Cities are usually conceived as the spatial outcome of economic processes, with contemporary city growth being driven by agglomeration economies. Since the early scientific conceptualizations of city-structure by scholars of the Chicago School of Anthropology, the crucial role of Central Business District has been underlined. Ernest Burgess in his concentric rings model identifies CBD as the focus of commercial, social, civic life district, and also the headquarters of economic, social civic and political life. According to Murphy and Vance (1954), CBD is the heart of the city where the greatest concentration of offices and retail stores is found, reflected in the cities highest land values and tallest buildings, while it is also the focus of pedestrian and automobile traffic. According to Drozdz & Appert (2010) a CBD is a "unique area of massive concentration of activities and focus for the polarisation of capital, economic and financial activities in cities". Key geographical attributes of CBD are: a) prime

accessibility/centrality in transportation terms (Murphy, 1979) and b) concentration/density of key urban activities and land uses McColl, 2005).

Based on a concentric rings' approach (Park & Burgess, 1925), CBD zones are usually coinciding with the oldest and more central city parts with large-scale redevelopments and high-rise office and administrative buildings pushing housing further out. CBD monofunctionally in US cities can be explained by economic rand rent processes: As a city grew in size, competition for land at the center resulted in land values so high that only business could afford. It is certain though that CBDs also present considerable internal variation, even within the same city. According to Murphy (2007), there is a tendency toward regionalization of specific functions (financial areas, hotels sections, theater grouping, night clubs and other specialized localities).

A relatively different context regarding CBD structure is observed in the EU-Mediterranean model of urbanization, where central city areas have traditionally been the place of residence of the upper class, while the labor class has settled in the periphery. This is what Leontidou (1990) has defined as an inverse-Burgess model. CBD areas in the Mediterranean, usually coincide with historical city centers and have been characterized by high population densities. Urban layout can be more organic, especially in the oldest parts of the city where streets are narrow and built-up coverage is very high. Land uses are highly mixed and differentiated vertically, with commercial shops occupying the ground-floor and apartments occupying the rest floors. Unlike American-style cities where a sudden collapse of built-up density and building heights is observed as one moves out from the CBD, in Mediterranean cities density gradients are "smoother", following a pyramid-like structure of building heights from the core to the outer rings. Particularities of urban form and structure of the Mediterranean core-city zones are important parameters related to the distribution of public spaces and green urban areas, also affecting microclimatic conditions and energy behavior at the urban scale (Tsirigoti & Bikas, 2017).

It is important to note that CBDs are not static but rather dynamic elements within the city structure, usually undergoing major changes. Conceptualized in functional terms and not as spatially fixed high-rise structures around central metro stations, CBD zones could expand their boundaries, spread into new areas or withdraw from others. Deteriorating housing conditions and social deprivation has been a well-documented process of urban decay of city-core areas (Broadway, 1989; Hall & Barrett, 2012). Dynamics are also particularly important at the metropolitan/regional scale. According to Soja (2000), in the postmodern metropolis the periphery is gaining more importance with the emergence of a polycentric or even totally dispersed urban form. Under such de-urbanization processes, downtown areas can lose their significance. Recently, however, processes of re-urbanization are being observed at least in the European territory (Salvati et al., 2019). Large-scale urban regeneration projects, real-estate driven gentrification of central city areas, and expansion of the tourism sector, are key factors currently affecting CBDs in Europe. In the Mediterranean context such processes are particularly intense with gentrification of inner-city areas affecting major cities like Madrid (Sequera & Janoschka, 2015), Barcelona (Arbaci & Tapada-Berteli, 2012) and Athens (Balampanidis et al., 2021).

Based on this understanding of CBDs as dynamic city element, it becomes particularly important to delve deeper into the effects of Climate Change. The ongoing climate crisis has already heavily impacted urban areas, that become particularly vulnerable to compound risks including extreme heatwaves, sea level rise and floods, wildfires. In the following case study, I intend to sketch such vulnerabilities by identifying key urban functions and how they can be

affected by extreme heat conditions in the Mediterranean context. Adopting an urban planning perspective when addressing such problems is crucial and it could lead into new insights on how cities could adapt or be transformed by unfolding environmental challenges.

3. Athens case study

3.1 Heatwave impacts and compound risks in Athens metropolitan area.

Athens is located at 37°58' N (Latitude), 23°42' E (Longitude) with a population of 3,81 million at the level of urban agglomeration (Attika Region, census of 2021). The metropolitan area is located in the Attika peninsula. The compactly built-up part of the city (Lekanopedio of Athens) is bounded by large mountains to the North, West and East, while towards the south the city is stretching along the coastal zone. Along this coastal metropolitan axis between Piraeus Port and municipality of Vouliagmeni, the new development project of the Ellinikon is currently taking place (Figure 2). An extended periurban zone surrounds the city from the east (Mesogeia Plain) where the international airport is located, from the west (Triasio Plain) where industrial activities mostly concentrate and from the north where residential suburbs and commercial activities surround the national highway connecting Athens to Central and Northern Greece.

The climate is characterized as subtropical Mediterranean with mild winters and warm summers (Georgakis & Santamouris, 2017). Athens, like other big cities of the eastern Mediterranean, belongs to the top-ranked European capitals with respect to heatwave severity and urban thermal risk (Smid et al., 2019). According to a recent study by Kartalis (Kartalis, 2024), heatwaves have significantly increased in the period 2001-2020 in respect to 1971-1990, both in terms of frequency and duration. According to climate scenarios adopted by the Regional Climate Change Adaptation Plan of Attika Region (https://www.patt.gov.gr/category/koinonia/perivallon/pespka/), the increase of mean annual days of very high temperatures (>35 °C) in the near future (2030-2060 period) will reach 15-19 days (RCP 4.5 and RCP 8.5, respectively), and 22-55 days (RCP 4.5 and RCP 8.5, respectively) up to 2100. Tropical nights (>20 °C) will also increase by 27-33 (RCP 4.5, RCP 8.5 respectively) per year. Table 1 summarizes expected changes in Heat Extremes, Humidex index, Mean Moisture and air pollution (PMs) under RCP8.5 scenario in central Athens zone, based on the Greek Ministry of Environment & Energy data.

Figure 2. Case study area, with demarcation of CBD area, Piraeus Port, International Airport and the new Ellinikon Project site on the coastal zone.

Table 1. Projections for period 2031-2060 in central Athens (change in comparison to baseline time period 1971-2000, under RCP8.5 (source: https://mapsportal.ypen.gr/maps, own elaboration).

Very Hot days (>35) baseline	Change in Very Hot days (>35 °C)	Days with Humidex (>40 °C) baseline	Change in days with Humidex (>40 °C)	Mean Moisture (RH) change
14.4	19.9	15.1	30.6	-2.1
PM2.5 (Mean annual) baseline	PM10 (Mean annual) baseline	Change in Mean Annual Highest temp (°C)	Tropical nights (>20 °C) baseline	Change in Tropical nights (>20 °C)
43.6	47.1	2.1	44.8	39.0

Due to the rapid and largely unplanned urbanization process mostly occurring through the 20th century, the city of Athens is characterized by a considerable lack of green and blue areas that could possibly improve microclimatic conditions. The unsustainable paradigm adopted during Athens urbanization process can be clearly demonstrated by the artificialization of the main river (Kifisos) spanning west of the central zone, where most part of the river's route has been transformed into a major highway, and also to the considerable absence of parks and public spaces within the urban fabric.

High density of development and high levels of impervious surfaces in Athens, are parameters linked to a considerable UHI effect (Papamanolis, 2015), with UHI intensity estimated at 5–6 °C between central urban parts and the surrounding periurban areas (Roukounakis et al, 2023). According to a study by Giannopoulou et al. (2011) mean air temperature is maximized in the area north-west of the CBD. Difference can reach 2-3 °C in comparison to the south coast zone and as one moves to the east-west-north suburbs. Generally, the center of Athens and the western part are found to present a similar temperature regime due to the lack of green, the densely built areas and the increased traffic (Giannopoulou et al., 2011). In a similar way

Roukounakis et al. (2023) state that under heatwave conditions and in the absence of strong air circulation, areas of intense daytime UHI effect are observed in central as well as western parts of the urban complex. This is partly confirmed by examination of Land Surface Temperature (LST) distribution during the most recent heatwave (Fig.3). Based on the corresponding maps, it becomes evident that the heat island effect is more intense in the central and west zone, while the southern coastal metropolitan zone benefits from relatively lower temperatures. It is also notable that LST is maximized during the daytime in agricultural and bare ground areas of the periurban zone.

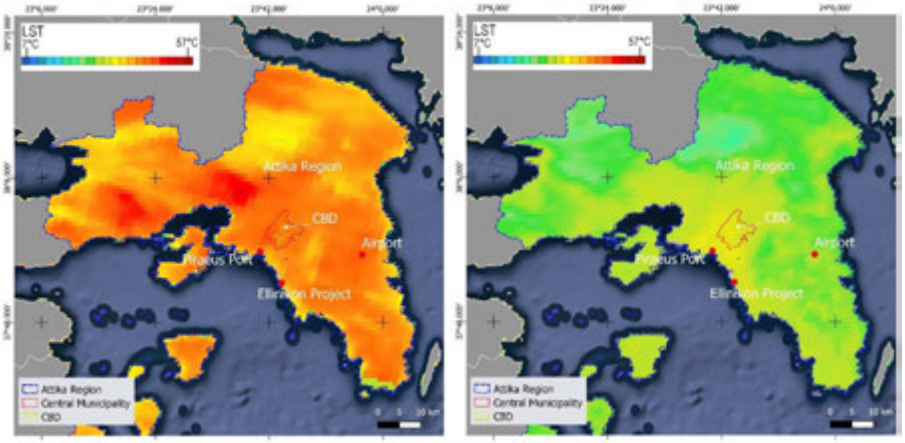

Figure 3. Land Surface Temperature for daytime (left) and nighttime (right) during the heatwave of 15 July 2023 (source: Google Earth Engine, 'MODIS/061/MOD11A1')

Recent evidence shows that Climate Change is already affecting key functions of the city. On 15 July 2023 during the heatwave ‘Kleon’, the archaeological space of Acropolis suspended its functioning for several hours, while the same happened a few day later. During the same heatwave, the Train Administration (TrainOSE) had to adjust several train schedules and speed limits for security reasons. Also, precautionary measures have been taken by public administration, with several municipality services and tax offices switching to remote work, flexible working schedule and special work permits. Private sector was also affected, as there have been orders to stop open-ground work at least during the afternoon hours (12:00 -17:00). Partial lockdowns of schools have also been reported during similar heatwave conditions during the past years, this issue being related to insufficient air-conditioning systems.

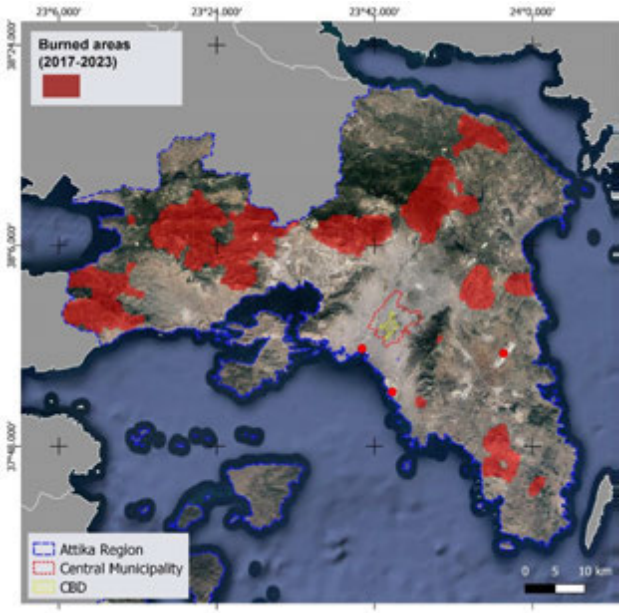

Figure 4. Burned areas during the period 2017-2023 in Athens Metropolitan area (source: Google Earth Engine, MCD64A1.061 MODIS Burned Area Monthly Global 500m).

Compound risks of heatwaves in Athens are related to air pollution and wildfires. Heatwaves in central Athens are usually combined by high levels of particulate matter (PM) concentrations, that are also maximized in the city core (Moustris, 2017). Vulnerability of Athens metropolitan area to fire risk is also a major problem, with most recent fires resulting into significant loss of periurban vegetation and forest land. Extreme fire risk is highly dependent on a combination of windy conditions and extreme heat. Forest fires in the Attika area are increasing during the past years, as shown in figure 4 where burned areas are mapped per time period; this being partly attributed to climate change. During the heatwave of 2021 with temperatures reaching up to 46 °C, a wildfire in the area of Varypompi near Parnitha Mountain, resulted into smoke covering the Athenian sky and rendering respiration very difficult for millions of people. As part of the emergency measures taken, access to major city parks has been occasionally suspended (including the central park of Pedion Areos and all big metropolitan parks) due to anticipated extreme fire risk. Closing down of parks is usually combined by cancellation of cultural activities that have been programmed within their infrastructures. The reasoning, as explained by the Prefectural Administration of Attika during heatwave 'Kleon', was one of "*precautionary reasons, reducing heath risk and malicious actions*". Closing down of public parks for several days has raised protests from citizen groups defending their right to public access into green urban spaces.

3.2 Central Business District in Athens: Key dimensions and vulnerability

The central municipality of Athens counts 643,4 thousand with a population density of 17.102,9 people/km^2, recorded as one of the highest urban densities in Europe. Building blocks are compactly built, with narrow streets at the neighborhood level and considerable lack of green infrastructure and lack of public spaces. Notable open space in the central part is related to the

presence of large archaeological spaces, and there are several areas with significant tree coverage around Acropolis, in Lykabetous hill, in the National Garden and in the large park of Pedion Areos (Fig.5). Microclimatic conditions around such green areas are considerably improved, however their influence is mostly local, limited to the surrounding building blocks. A considerable increase in tree coverage is notified in the eastern and northeast axis, just outside of the central municipality and towards the high-class municipalities of Papagou, Psychiko and Neo Psychiko, and Imyttos mountain (Fig.5).

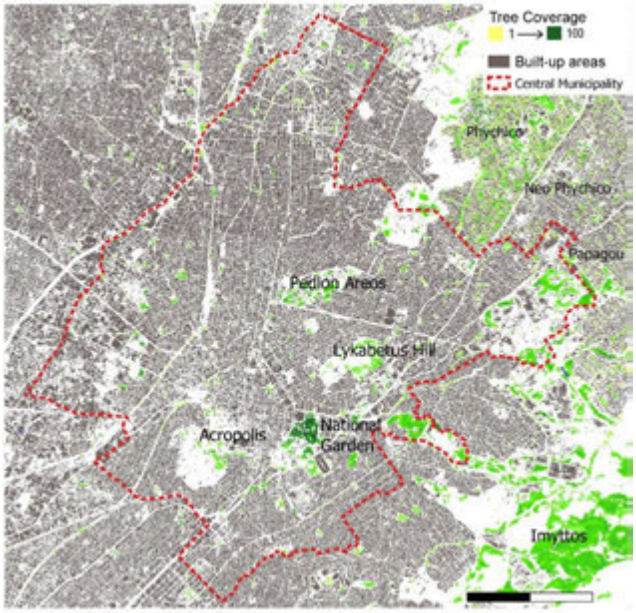

Figure 5. Built-up areas and Tree Coverage in the central zone of Athens (source: own elaboration on data obtained from Copernicus Land Monitoring Service).

To identify the Central Business District within the central municipality of Athens, the combined concentration of several activities has been examined. More specifically, libraries, banks, bars/pubs, cinemas, courthouses, restaurants, malls, museums, clubs, theaters, hotels, department stores and public buildings, have been considered, and to identify the distribution of those activities within the urban fabric, data were obtained from Open Street Map (https://download.geofabrik.de/). A Kernel Density estimation was applied resulting into the spatial pattern of Figure 6. Results show that the highest concentration is identified in the triangle between Acropolis, Lykabetus Hill and Pedion Areos, also expanding towards Piraeus Str. (south-west), Sygrou highway (south) and Patision Str. (north). This area can be perceived as the CBD of Athens, coinciding with the highest concentration of business and recreation activities.

To further support this delineation, I have also consulted the Google maps 'commercial corridors' data, where zones with high concentration of people are identified and marked as 'busy areas' during the daytime and nighttime. Such data are reported in the graphs of Figure 7 for characteristic central locations mapped by numbers (C1-C7) in Figure 6. Based on data retrieved from Google maps on a normal-temperature day of April, peak hour is observed at

noon (12:00-15:00), though the temporal patterns can vary between the different central-city spots.

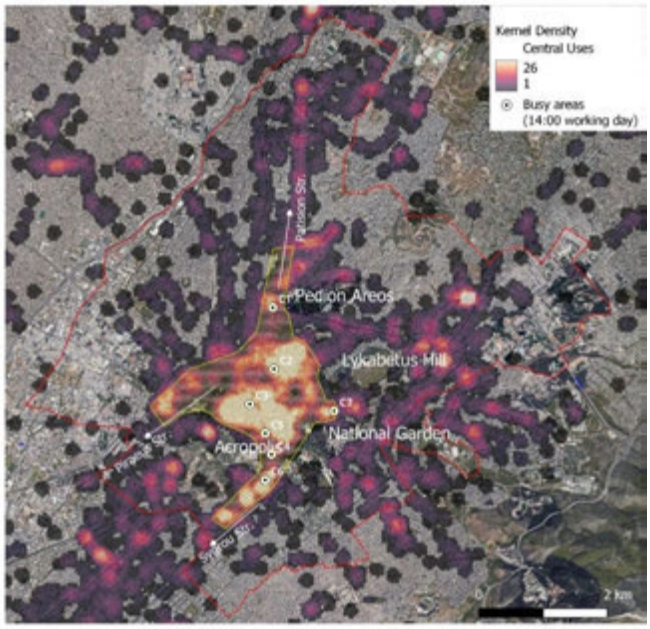

Figure 6. Kernel Density maps (50m pixel, 150 radius, method: quartic) with concentration of land uses and activities linked to CBD functioning.

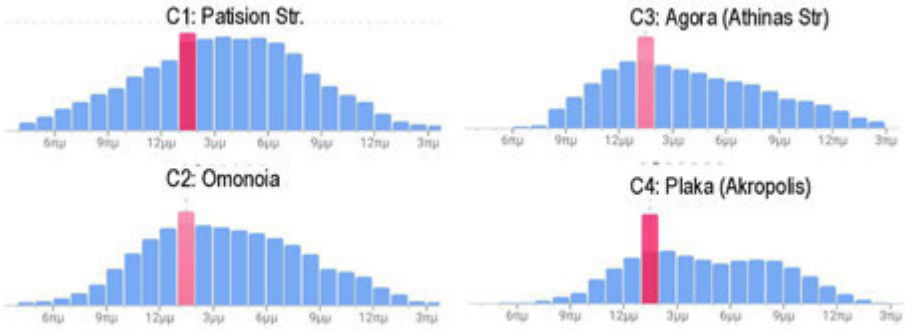

Figure 7. People concentration in characteristic central-city spots on a normal-temperature day of April. Blue bars represent average values, while purple bars represent actual concentration of people at 14:00 on a working day of April (source: Google maps/Busy areas).

Tourism activity is another important dimension of the central zone in Athens. To analyze tourism patterns within this zone I have applied Airbnb data as obtained from InsideAirbnb platform (https://insideairbnb.com/). Airbnb is an activity free to locate anywhere in Athens, overruling existing land use regulations. Generally, it tends to concentrate in areas with high accessibility to tourism-related activities especially museums, archaeological spaces and recreation. As shown in Figure 8, Airbnb concentration is largely spotted inside the CBD zone,

with a major focus on a semicircle around Acropolis (Psyri-Plaka-Koukaki neighborhoods) and an expansion towards Kolonaki and Exarcheia neighborhoods on the northeast, and Metaxourgeio and Thiseio on the west.

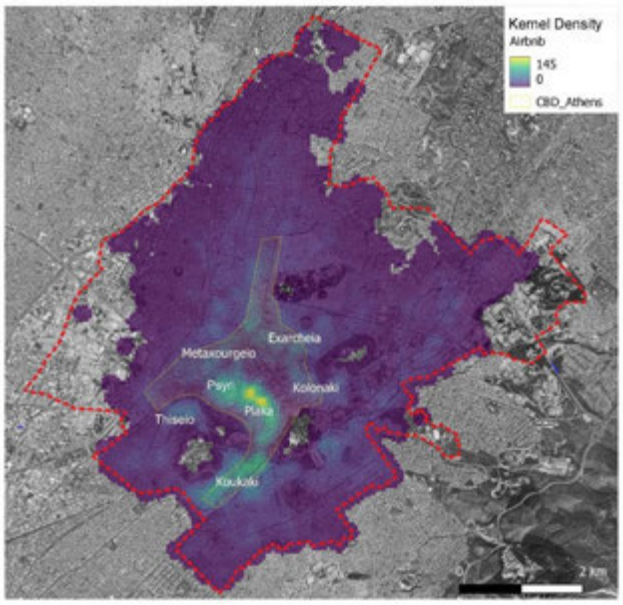

Figure 8. Tourism activity concentration (kernel density, 50m pixel, 150 radius, method: quartic).

Both of the above key dimensions of CBD functioning in Athens (i.e. business/recreation and tourism), are highly dependent on outdoor activities and pedestrian mobility, including street shopping, archaeological space exploration and sightseeing, visiting cafeterias and restaurants etc. These activities can be rendered particularly vulnerable in the case of heatwaves as people become unwilling to move, or even the authorities might decide to pose restrictions to protect public health (see Section 3.1).

A third dimension of CBD Athens is what I define as "housing/population". Generally, housing within a CBD zone remains a key parameter in order to preserve a sustainable mixed-use zone. Historically, the center of Athens has been a densely populated area, with a major concentration of people within the boundaries of the current CBD and its surrounding neighborhoods. However, since the 90's, an important suburbanization process has resulted into a loss of 22.5 percent (186,000 people) of the central municipality's population. The suburbanization process was largely driven by the deterioration of quality of life in the center due to traffic congestion, air pollution, lack of public spaces and overbuilding. As middle-class and high-class residents were moving out, immigrants and refugees were moving in, based on the well-known invation-succesion processes (Lee, 2015). Loss of population combined with the economic crisis of 2009-2019 period, left the central area in a degraded condition, with thousands of empty shops and apartments, further deteriorating the conditions of the housing stock and public spaces especially in the north central sector where social deprivation, unemployment and poverty are more intense (Arapoglou et al., 2021). Such processes have largely affected CBD functioning as many office buildings were practically abandoned (Cheirchanteri, 2023), and economic activity was considerably reduced.

In the most recent period (2011-2021) population loss is practically stabilized, with a marginal 3.1 percent decrease. Figure 9 shows a dot density distribution of population in the central municipality, with respect the current CBD boundary. Data are obtained at the level of Urban Analysis Units (EKKE-ELSTAT, 2015), using Hellenic Statistical Authority (ELSTAT) population census data for 2011. The map shows that significant population still resides within the CBD boundary, especially in the neighborhoods of Koukaki, Exarcheia, Kolonaki, and Metaxourgeio, where large scale gentrification processes are currently taking place. Conversion of apartments to Airbnb accommodation along with a major trend of replacing neighborhood-level shops with tourism-oriented stores and recreation facilities, are pushing land values up, this ultimately resulting into a major relocation of permanent residents out of the CBD nuclei.

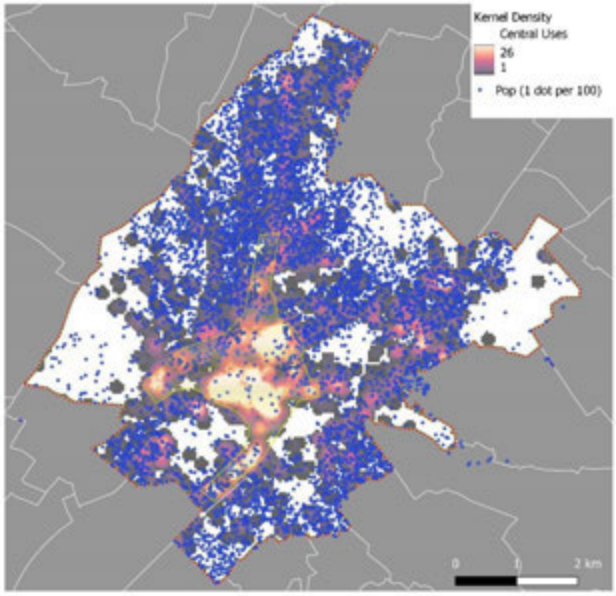

Figure 9. Population distribution (2011) in comparison to CBD boundaries and commercial/recreation activities concentration (Population data obtained from EKKE-ELSTAT, 2015)

Overall, it can be stated that despite considerable population relocation towards the suburbs during the 1991-2011 period, Athens CBD still acts as a key market area for over half a million residents mostly located in the adjacent neighborhoods. However, poor environmental conditions and Climate Change are imposing stress to this population, while considerable vulnerabilities in respect to the housing/population dimension are identified. Data show that the majority of population (75,8%) resides in old apartments constructed before the ‘80s, usually with very low energy standards and without thermal insulation. At the same time, population is considerably aging. About 19 percent (19%) of the population in several central municipality is above 65 years old, this fact rendering a significant proportion of residents particularly vulnerable to the impacts of persistent heatwaves. Based on the spatial distribution presented in the corresponding map (Figure 10) these two major vulnerabilities in respect to heatwaves (old housing stock and aged population) are maximized within the CBD, this fact raising important concerns regarding quality of life conditions and public health, and also regarding future energy demands for cooling. Another important social issue to be considered is the high poverty rate in Athens municipality, estimated to be around 24 percent (Petraki, 2013), and

geographically concentrated in poverty pockets close to the center (Kypseli, Kato Patisia), or even within the CBD (Omonoia square, Victoria square, Metaxourgeio etc).

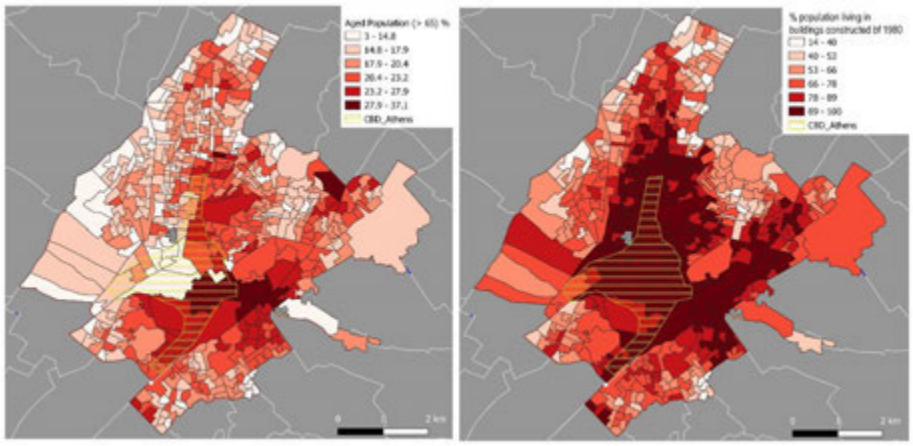

Figure 10. Aged population and old housing stock in Central Municipality of Athens (source: own elaboration on EKKE-ELSTAT 2015 data).

3.3 Overall assessment and discussion

To assess the overall vulnerability of the CBD of Athens to heatwaves, the three key dimensions and related functions (i.e: Business & recreation, tourism, housing/population), and their respective vulnerabilities are combined to a single graph (Figure 11). Exposure to hazard and compound risks are also included; while increase of adaptation capacity remains to be investigated, with the role of urban planning being particularly crucial in order for the CBD to retain its attractiveness & functioning during future heatwaves. The major risks identified are related to the loss of vibrancy and decreased quality of life, followed by population moving out. Such processes might be accompanied by a possible decrease in tourist flows, especially during the summer period.

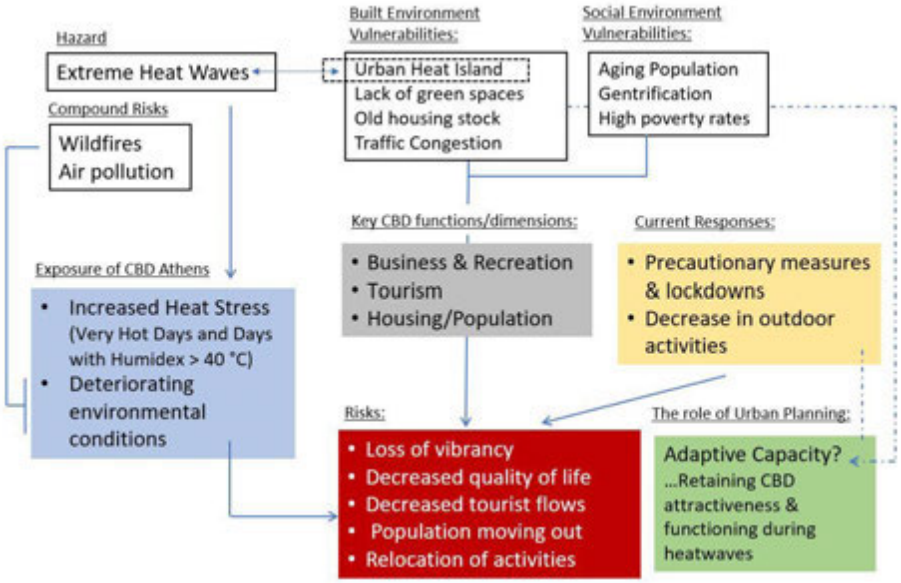

Figure 11. Connections between hazard, vulnerabilities and risks regarding extreme heatwaves in CBD of Athens.

From the preliminary research and data analysis presented, it becomes evident that the future role of the CBD of Athens will be largely dependent on urban planning strategies applied, with respect to land use policies, handling of the gentrification processes, and embracing a climate-resilient and sustainable agenda. As the CBD of Athens in its current state is particularly vulnerable to heatwaves, it is probable that it could face the consequences of certain activities relocating towards more favorable locations. A key example is the new mixed-use hub currently created on ex-brownfield land (the Ellinikon project, https://theellinikon.com.gr/), where large investments are taking place within a large coastal zone accompanied by skyrocketing land values. Consequently, favorable climatic conditions due to less intense Urban Heat island effect could render the coastal zone of Athens most attractive in the future -especially during the expanding summer period- possibly challenging the traditional role of the CBD.

4. Conclusions

Dependencies between Climate Change and urban structure should be at the core of current urban planning discourse and practice, opening up new fields of research exploration. CBD areas are persistent structural elements of a city with their historical role mainly based on a very high concentration of people and business facilities that are particularly dependent on face-to-face interactions, vibrant streets and outdoor activities. Regardless of the varying socio-spatial context in different geographical regions and the fact that they are going under considerable changes through time, CBDs are steadily perceived as key elements of the city structure, functioning as economic “hearts” of cities. Current evidence shows that as the Climate Crisis unfolds, such areas might be heavily affected, while climate-related risks could challenge existing urban structures and hierarchies. Evidence from this work sets the ground for more elaborated studies on this crucial topic, opening up the question of possible re-definition(s) of the role of Central Business Districts under the effect of Climate Change.

Results from the case study in Athens reveal three key dimensions supporting the current CBD role: Business & recreation, tourism, and housing/population. All three dimensions are particularly vulnerable to increasing heatwaves and compound risks like increasing air pollution, mainly due to parameters related to urban planning, including lack of green infrastructure and poor housing conditions, while social inequality and aging population add another important dimension to be considered. The cumulative impact of increased heatwaves could greatly affect CBD functioning and quality of life of citizens during the summer period, and have a direct impact on economic activity, tourism flows, and productivity levels. Moreover, it could pose important stress on critical infrastructure, including the heath system, while outdoor activities and outdoor work would be largely discouraged.

In the long term, such conditions could possibly result into a relocation of activities towards other city zones where climatic conditions will be more favorable. Based on current evidence, Athens is undergoing large-scale gentrification processes in the central zone, and also impacted by large-scale investments along the coastal zone. In this scenario, the center of Athens will be facing major challenges in the future and an integrated spatial adaptation plan would be needed in order to ensure quality of life and reduce the adverse impacts of Climate Change.

Abstract

The aim of this paper is, starting from the problem of peripheral landscapes produced by urban sprawl forms, to define a methodology for analysing the quality of peripheral public space in municipalities surrounded by natural spaces of environmental value, in order to evaluate their potential quality as environmental corridors, civic axes and natural gateways. To define the evaluation with proper indicators the investigation is based in the origin of the urban greenbelts and in the case study of the northern boundary of the municipality of Fuenlabrada (Madrid, Spain) with the Bosque Sur Periurban Forest Park and its comparison with Midden-Delfland, a buffer-zone belonging to the area known as Randstad Holland.

Keywords: greengates, periurban territories, green infrastructure

1. Introduction. Urban sprawl as a form of urban growth

Peri-urban territories have evolved since the mid-20th century towards a remarkable dispersion of their built space, with a large proliferation of industrial land infrastructures and operational landscapes (Brenner & Nikos, 2020) which have led to the fragmentation of originally natural areas.

The dynamics of urban growth resulting from the so-called Capitalocene (Moore, 2017) have caused a substantial reduction of the natural space which, originally, due to its size, was the container of the limited built space of the isolated municipalities and which has become a stressed "edge" space in which its natural and landscape qualities are strongly altered.

The European Union, through the European Environment Agency (Agency, 2016) has issued reports on the situation in such territories, warning about this complex problem and proposing measures to build detailed guidelines and support for national operational policies.

The report *Urban sprawl in Europe* highlights the environmental and socio-economic problems of these growth patterns. Even in areas where the expansion of built-up space has continued to take place despite a declining population (Haase, et al., 2014).

In addition to proposing parameters for measuring urban sprawl, the report proposes different methodologies for its analysis: those that insist on the need to work with as many variables as possible, others that propose integrating the different variables and the third, which opt for measures based on one or a few variables.

Spatial policy measures propose a review of spatial and urban planning, but also highlight the relevance of possible actions in favour of biodiversity recovery and enhancement and nature conservation.

Reflection on how to analyse and plan these complex territories, made up of overlapping layers like a palimpsest (Corboz, 1983). Built up over the years, it has developed in Europe from examples such as the Dutch Randstad, the Italian Veneto, the Flemish Diamond or the German Ruhrgebert.
The need for an integral conception of the territory from a strategic vision implies an architectural understanding of the territory, with a special sensitivity for the exploration of the structures and formal features of different natural and rural spaces and the effects of urban sprawl (Alonso Teixidor, 2024).

1.1 The empty territories of urban sprawl

In peri-urban landscapes shaped by the urban sprawl growth model it is essential to consider spaces not colonised by urbanisation, such as protected natural spaces, as vital nuclei of the territory, from which green infrastructures can cushion the effects of the urban continuum and provide natural continuity in already urbanised territories.
In addition to the areas protected for their natural and environmental value, it is necessary to point out the relevance of the areas bordering the municipalities, which are usually places with a higher level of biodiversity, as opposed to some large open spaces. The so-called *third landscape* (Clèment, 2020), the one that escapes from territorial exploitation practices, which does not belong to a protected natural environment and is not considered as a place to be designed, is an agglutinating space of great biodiversity with a great regenerative capacity in natural and environmental terms.
These hinge spaces, between the naturalised urban space, the third landscape, and the protected natural spaces, can be considered as greengates, gateways to nature from the city, and at the same time, as connecting focal points and carriers of biodiversity.
In this research we approach two areas: the model set by Midden-Delfland and the southern periphery of Madrid, with Bosque Sur, as a study of a complex peri-urban space. The work intends to emphasise the strategic spaces of connection between the urbanised space and the peri-urban green areas, based on a historical review of the origins of the recognition of the need for a link between city and nature, in order to promote a healthy habitat.

2. The origins of green belts. Boundary and landscape

The edges of growing cities are often areas of ambiguity, particularly unstable in their forms and uses. Many of the peripheries of post-industrial Europe's urban areas show considerable differences with those built along the growth of industrialisation: unstructured territories, made up of pieces of fragmented urbanisation in their forms and functions, physically connected -or segmented- by motorways, roads or railway lines. The underlying territorial processes have been overwhelmingly dominated by markets, often under conditions of high uncertainty, and with environmentally unsustainable outcomes (Teixidor, 2014).
The pressure exerted by residential and industrial growth and the growth of the operational landscapes serving the urban has led to the fragmentation and atomisation of undeveloped spaces, as well as to a formal lack of definition of the urban edges, which are configured as heterogeneous territories, not very permeable with their surroundings and disconnected from their territorial support.
However, they can be considered spaces of opportunity as growth buffer zones, as naturalisable territories, capable of hosting greater biodiversity and functioning as ecosystem services providing green and blue infrastructure to existing urbanised areas.

The integration of the city and nature was consolidated at the end of 19th century and beginning of the 20th century with Ebenezer Howard, intellectual father and promoter of the so-called English garden city, which can be seen -as Rasmussen (2010, p. 235) does in his work *Londres, ciudad única*- in continuity with the English tradition that proposes an alternative to the compact city that recovers an idealised vision of medieval England in which the city is situated in balanced harmony with the countryside and nature.

But the concept of preserving green zones as limits to growth in the city is also complementary to that of shaping and defining a peripheral landscape that is easily accessible to citizens. So green belts have a dual function: that of containing growth and that of providing healthy uses and natural landscapes.

One of the most important aspects of Howard's proposal is the awareness of the vertiginous increase in the size of a city like London and, therefore, his model of the city uses the idea of the limit as a fundamental instrument. A conception of the limit that is irremediably linked to the possibility of reaching it on foot, of being able to feel close and easily accessible the end of the urban environment and the beginning of another type of environment that is sometimes formalised as countryside and at other times as nature.

2.1 Ebenezer Howard and the notion of limit in the English Garden City

This idea of Howard (2018), which is an emancipating idea with respect to the confinement and overcrowding that the industrial city represented for most people, is linked to the image that English Romanticism had been creating since the 18th century, that of an inhabitant of the countryside -identified in Romantic imagery with a shepherd- who enjoys an ideal freedom that he uses to wander around the territory. This identification between walking and freedom is precisely what will make the proximity between the urban core and its surroundings so important in Howard's conception, introducing as a guarantee of this proximity the idea of a limit to urban growth as opposed to unlimited sprawl, an issue that in later developments of this same idea will also be taken up, both in Unwin's proposals and in the Green Belt of Abercrombie's Greater London Plan.

Howard's work abounds in references to walkable distances between its various parts (Howard, 2018) and it is a quality, its walkability, that determines so many of the characteristics of the proposed city: its dimensions, the proximity between its different elements and the construction of its clean and green atmosphere that makes walking a pleasant and liberating experience.

‘(…) so that from any part of the city perfectly fresh air and grass and sight of far horizon might be reachable in a few minutes' walk. This the final aim’ (Ruskin, 1865 in Howard, 2018, p. 53). This is part of the second of the three quotations with which Howard begins the first chapter of his work and with it he states that his urban proposal contains the idea of the proximity between the countryside and the city, that is, that the undeveloped outdoors should be within easy walking distance of the city (Fig. 1). It is not only that the city and the countryside merge -the city in the garden-, that the dwellings of its inhabitants are surrounded by trees or that these and the streets are part of the garden, but also that the countryside must always be close by. And close means on foot, i.e. walking a reasonable distance.

Figure 1. Diagram by Howard in which he tries to explain the relationship between the different garden cities. The commentary accompanying the diagram states 'open country ever near at hand'.
Source: Howard, 2018, p. 195

2.2 The proximity between the countryside and the city in Arturo Soria's Linear City

This idea, for example, was perfectly embraced by Arturo Soria. His linear city contains a city that can be infinite in one direction, along the line, but which always has the countryside nearby, at a walkable distance in the transversal direction (Fig. 2). Indeed, This is another urban model -contemporary to Howard's- which also raised this issue even in its formal conceptualisation. Here, its creator assumes the idea of proximity between the city and its surroundings and makes it more radical in formal terms: The linear city of Arturo Soria is urban –endlessly urban- in one direction -the longitudinal- but at the same time, if in Arturo Soria's time it had been crossed transversally, it would have been possible to be completely outside the urban environment in barely three minutes on foot. Its linear configuration imposes -from its very form- that proximity between the countryside and the city that is so important for the formalisation of the new urban model.
The city envisioned by Howard is not only a city in the garden but, above all, a city close to the garden, or rather, a city within walking distance of the garden. As the famous diagram of the magnets so aptly expresses it, Howard (2018, p. 47) does not despise the advantages of the city, but thinks it is possible to reconcile them (Howard, 2018, p. 50) with the benefits provided by the countryside. With those advantages that life in small communities had. Among others, with the advantage of proximity to the non-urban environment, i.e. the countryside and nature.

Figure 2. Oblique view of Arturo Soria's Linear City with the city in the foreground and the nearby rural landscape extending from its edges to the horizon.

2.3 Limits, nature and proximity in the Australian city of Adelaide

Howard (2018, p. 193) mentions in his work the case of the Australian city of Adelaide, designed by Colonel Light, which, according to Hall (1996, p. 99),, was instrumental in providing the idea that once a city had reached a set population limit, another settlement should be created, separated from the first by an undeveloped area. The proposal for Adelaide, a typical colonial grid, included a substantial land reserve surrounding both the original core and its subsequent growth to the north of it. Light's proposal included in this wide belt -originally nine hundred and thirty hectares- just a few amenities, but above all it was dominated by the course of the Torrens River -or Karrawirra Parri River, according to the aboriginal name- as the main natural element that articulated this space and the relationship between the two settlements. This prominent inclusion of the river -with its natural course highlighted- also brings Light's proposal (History Trust of South Australia , 2019) closer to the contemporary sensibility regarding the value of primal nature as opposed to that which has been modified by human intervention.
However, Light was at least sufficiently skilful and pioneering to formalise that reserve of land which guarantees immediate contact between either of these two Adelaide urban centres and a green belt dominated by the River Torrens (Fig. 3), while, for example, in Hampstead, the city built by Unwin and Parker following Howard's teachings, and in Arturo Soria's Linear City, where this immediacy with respect to the countryside was fundamental, the growth of their respective metropolises has ended up absorbing the garden city proposed in each case, completely erasing the countryside from its surroundings.

Source: https://adelaidia.history.sa.gov.au/panoramas/lights-plan-of-adelaide-1840

2.4 The challenge of the endless city

The city proposed by Howard was designed from the perspective of walking. It has behind it a tradition of rediscovering the landscape from the perspective of the walking human being as opposed to the acceleration proposed by the automobile. The image of medieval England as a country of villages that characterised the imagery of the Romantic period was also key to Howard's conceptualisation and is precisely illustrated in the idea of direct access to the environment. Even in medieval towns, their size was also adjusted to distances that allowed them to be easily traversed or exited in the direction of the surrounding countryside in a short time. In the collective memory of Ebeneezer Howard's contemporaries, the image of pre-industrial London portrayed, for example, by Daniel Defoe, is still vivid. Defoe's work (1986), *A Tour through the Whole Island of Great Britain,* is considered by scholars of British history as a fundamental text that allows to visualise -despite some inaccuracies and inventions- the image of Britain just before the emergence and consolidation of the Industrial Revolution (Rogers, 1986, pp. 10-11). In the case of London, especially, this transformation moves between the beginnings of suburban expansion -intensely speculative- after the Great Fire of 1666 and the definitive demographic explosion of industrialisation. And although Defoe himself is astonished at the size the city has recently acquired (Defoe, 1986, p. 286), in fact, it is still a contained and manageable city, especially from the perspective of the stroller, and he himself walks without difficulty from the centre of London to some of the first suburbs -Islington, Newington, Chelsea, London, Newington and Chelsea (Defoe, 1986, pp. 287-288) or Hackney, Newington, Tottenham, Edmonton (Defoe, 1986, p. 337)- which are now just parts of the immense city.
London at that time was of a contained size that allowed access on foot to its natural and rural perimeter. From what is probably the earliest description of London by Thomas Becket's twelfth century biographer -William Fitz-Stephen-, Ackroyd (2012, pp. 83-84) highlights the immediate countryside and nature surrounding the city: past the wall, to the west 'were gardens and vineyards among which were the mansions of the noble and powerful'; to the north, 'stretched meadows and pastures bordering on 'an immense forest', of which Hampstead and

Highgate are now its only remnants'; to the north-west 'there was a meadow now known as Smithfield, where every Friday horses were sold'; and in other meadows around 'pigs and oxen were slaughtered and sold'. Even in the 16th century, cities were still relatively small and, although part of the population might live outside the city walls in the emerging suburbs, these were far from being extensive. And so, what still distinguished medieval cities like Exeter, capital of a vast province, from the sprawling patches that would emerge after the Industrial Revolution, was that 'one could have walked around the entire circuit of the city walls in half an hour, or could have reached the open country form the centre of the city in any direction in fifteen minutes' or ' Even London, with its sixty or seventy thousand people, was soon left behind if one had in mind to see the green fields and natural heaths' (Hoskins, 1981, p. 147).

3. Urban Green Rings and Greenheart as contemporary territorial strategies

Indeed, several authors (Freestone, 2002) claim that the origin of the Green Rings lies in the proposals made by Ebenezer Howard at the end of the 19th century. The background described above pointed to a problem -that of the unrestricted growth of the metropolis and to the need for a new form of urban development-, but they also opened the way to address a response, indicating to planners the inescapable need to maintain or generate links between the intensely built space of the city and a contrasting rural or natural environment.
The consideration of this system of open spaces as a tool for urban planning has served, in the development of numerous European cities (London, Vienna, Frankfurt, etc.), not only to combat sprawl, but also to provide solutions of a social and environmental nature, promoting the protection of natural areas and the conservation of agricultural and livestock areas, providing leisure and recreational areas for citizens.
Green Rings are not instruments that have served to formalise similar peri-urban spaces, but they have become a tool to define new concepts such as urban green infrastructures, so recurrent in the design of new urban models aligned with the fight against climate change and environmental responsibility (Ahern, 2007).
The classic form of green belts is that of a ring of open spaces surrounding the city, although it can often take on irregular shapes depending on the geographical characteristics of the area. (Aguado, et al., 2017)

However, growth containment associated with green buffer spaces has historically been conceived primarily with three formal outcomes: Greenbelt, Greenheart and the Finger Plan (Vejre, et al., 2014). There are studies that assess the effectiveness of some versus others in terms of growth restriction (Kuhn, 2003). However, they all agree on the clear social benefit they provide as spaces for the use and enjoyment of citizens and for the definition of a habitable landscape connected to the urban environment.

4. Midden Delfland in Randstad Holland

With the double purpose of understanding Bosque Sur -the study area where the Green Arc of Madrid meets the northern edge of Fuenlabrada- and having a reference on this type of space, a comparison and contrast area has been chosen in the Netherlands: Midden-Delfland. This is a buffer zone between Rotterdam and The Hague, two of the largest cities in a country credited for its culture of spatial planning.

The meaning and role of Midden-Delfland, are better understood it in its context, within the Dutch multi-scale territorial system where landscape and planning intersect. A good approach to this system is provided by the short section on the Netherlands in Peter Hall's classic book

'Urban and Regional Planning' (Hall, 1992, pp. 197-202), which is complemented by the much more recent and extensive 'The Randstad: A Polycentric Metropolis', edited in 2021 by Vincent Nadin and Wil Zonneveld (Nadin & Zonneveld, 2021). The following text draws on both sources, as well as on unpublished academic work by Ignacio Bisbal, Marcos Delgado, Javier Malo de Molina and Emilio Ontiveros, which also drew on the sadly no longer available bulletins of the Netherlands Institute of Geography, IDG.

4.1 The Randstad, the denser urban structure of Western Europe

The west of the Netherlands lies at the centre of a metropolitan belt, with an axis between London and Milan, which concentrates a high proportion of Europe's economy and urban population. There, at the mouth of the Rhine, is one of the most important urban regions in Europe, with a population of around 7 million inhabitants. Almost 40% of the Dutch population is concentrated in just 5% of the country's surface area, reaching a higher degree of metropolitan concentration than in Great Britain or France.

4.1.1 A polynuclear model

Despite the high density, an observer's impression is not that of a large, saturated metropolis. What was once a medieval network of small towns, became an important enclave in the 19th century thanks to its industrial and commercial development. The transformation of the Rhine into a major artery in Western Europe made its mouth the prize for the Netherlands. Thus, as Germany became an industrial power, the Netherlands also developed as a trading power. In 1850, the cities in the west of the country were separate entities. By 1950, these cities had extended to almost touch each other, forming an urban perimeter. This territorial structure is called the Randstad (edge city or ring city), a term coined in 1938 by Albert Plesman, founder of the Dutch airline KLM, describing what the view from his aeroplane (Nadin & Zonneveld, 2021, p. 10)

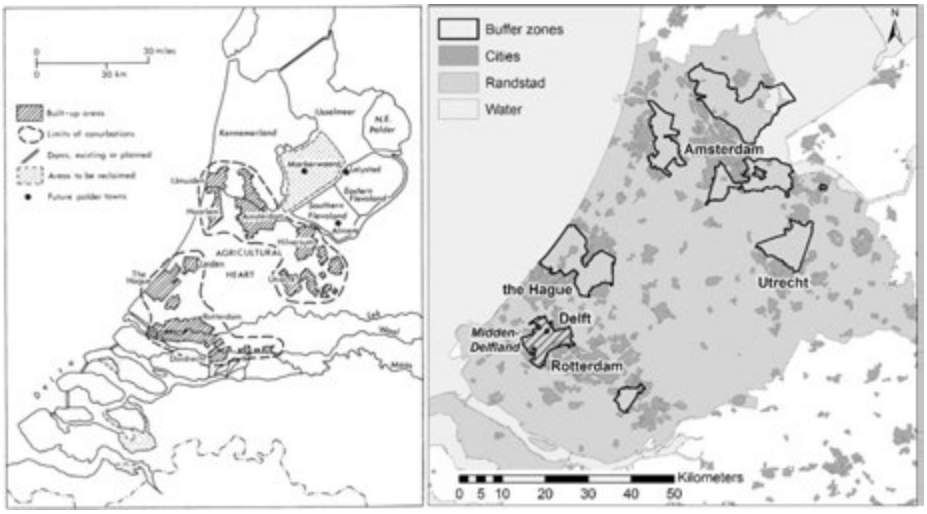

Figure 4. Left: Randstad Holland (Hall, 1992, p. 198)
Right: Midden-Delfland and other buffer zones in the Randstad (Koomen, 2008, p. 38)
Sources: Referred bibliography

4.1.2 Morphology and programme

The Randstad adopts the layout of a ring of cities physically separated along a 180 kilometre horseshoe-shaped line. The ensemble comprises the four most populous cities in the Netherlands: Amsterdam, Rotterdam, The Hague and Utrecht, as well as a number of intermediate cities such as Haarlem, Leiden, etc. Each city is separated from its neighbours by green zones and all of them overlook a large, less urbanised inner area, called Green Heart, which is protected by planning (Fig. 4). This polycentric territorial model is not limited to a physical aspect but is also operational. The larger cities in this structure adopt differentiated functions: the seat of government and international justice are in The Hague; the largest port and heavy industry in Rotterdam; the financial world, tourism and culture in Amsterdam; congresses and research and development venues take advantage of the railway node in Utrecht. This configuration avoids certain problems of large mono-nuclear cities, shortening commuting times and reducing traffic jams (Hall, 1992, p. 197).

4.2 The Randstad's metropolitan *Green Heart*

4.2.1 Evolution of the concept

Historically, the Green Hart had been a marshy area unsuitable for the development of cities, which sought dry and elevated sites. From the early Middle Ages onwards, thanks to windmills, this land was drained for agricultural use (Korthals Altes, 2018). The area remained as such until the development of settlements around its perimeter began to threaten it. In 1960, the 1st Dutch Spatial Planning Guideline highlights this area and decides to preserve it as an agricultural area free of urbanisation. The 2nd Guideline (1966) sought to control the growth of settlements within the Green Heart by designating a few suitable localities and thus maintaining the defensive sense of planning. It was not until the 3rd Guideline (1973) that other functions of the area, compatible with its agricultural status, were considered: recreational programmes and the development of ecosystems through planting. Until then, the Green Heart had an almost conceptual character, lacking clear boundaries. Although in theory residential growth and new roads were to be avoided within it, in practice its extension was reduced in areas close to large cities.

Figure 5. The Randstad's Green Heart. To the left, Midden-Delfland.
Source: Prepared by the authors of the paper

4.2.2 The role of the Green Heart in planning

In 1990, with the 4th Guideline, its boundaries were precisely delimited and in 1996 the Green Heart Administrative Platform was established. This platform, although it had no legislative powers, was the forum for discussion of Green Heart issues. This made it possible to gather precise statistical data on the Green Heart municipalities, their population, land use, etc. In terms of growth within the Green Heart, restrictions were set for businesses, offices and new communication infrastructures, and residential growth was limited to the six historic urban centres. Three landscape types associated with specific uses were delineated: a) the lake environment (for ecosystem conservation and recreational programmes); b) the marsh and grassland areas in the north and on both banks of the Lek River (subsistence agriculture and ecosystem conservation); c) grasslands in the west (agricultural farms, greenhouses, and forestry). In addition, it was decided to invest in creating new ecosystems, developing new networks of canals for recreational boats and cycle paths, and planning the transition areas between the large cities and the Green Heart.

4.2.3 Tensions over the Green Heart

A prevailing idea in successive planning guidelines in the Netherlands has been the fundamental need to keep the Green Heart of the Randstad undeveloped. However, demographic and economic pressures ignored this recommendation and resulted in the Green Heart being diminished: south of Amsterdam, at Schiphol airport, east of Utrecht, along the Rotterdam-Delft-The Hague-Leiden line, and on the periphery of inner towns.

4.3 ***Midden-Delfland: a buffer zone between Rotterdam and Delft***

4.3.1 Countering the Randstad' saturation

In a context of high population growth, buffer zones emerged as areas of containment of urbanisation in the 1st Guideline to preserve the historic cities of the urban ring as separate and distinct points. These zones were designated as spaces for parks, drainage areas and public bathing areas. The treatment of these areas has evolved in a similar way to that of the Green Heart, from an exclusively defensive origin to a key role in planning as agricultural and recreational areas. Although they were planned as open spaces between cities to promote the active perception of the territory, since their conception these territories have been associated with important infrastructures and, therefore, exposed to high noise and environmental pollution, as well as to continuous pressures to take away part of their surface. However, it was not until the 3rd Guideline that eight buffer zones were identified on the Randstad map and a specific plan was proposed for the one known as Midden-Delfland (Fig. 6). That buffer zone status saved the Midden-Delfland polder landscape from housing development and the expansion of glasshouse horticulture (Feddes/Olthof, 2017).

Figure 6. Midden Delfland. The buffer zone of southern Randstad.
Source: Prepared by the authors of the paper

4.3.2 Origin, evolution, extent and functional division since the Reconstruction Act

Midden-Delfland was an intermittently inhabited peatland landscape until the Middle Ages, when it was drained for exploitation, and sandy-bedded hillocks emerged as a unique landscape. After the Second World War, the growth of the surrounding towns gradually reduced its extent, leading to the passing of the Midden-Delfland Reconstruction Act in 1977, which remained in force until 2010. As a result, 'green belts' of recreational areas were placed between the peripheral towns and the agricultural core of Midden-Delfland. In 2004, Midden-Delfland became a municipality by merging the municipalities of Maasland and Schipluiden (Midden-Delfland, 2024) with Den Hoorn. The buffer zone maintains an area somewhat larger than that of the municipality itself, covering 6,700 hectares, of which 68% is used for agriculture, 28% for recreational purposes and the remaining 4% for natural areas. The area is divided into three main zones with 27 subdivisions to which one or two main functions are associated. Near the settlements, the recreational function is predominant (playgrounds and rest areas, facilities for windsurfing, sailing, rowing, sport fishing, campsites and leisure in forest areas). In the rest of

the areas the original agricultural function prevails, shared with recreational use (footpaths and cycle paths).

Source: Google Street View

4.3.3 The Midden-Delfland® Vision 2025

At the initiative of the municipality of Midden-Delfland, in 2005, the central government, the province, local municipalities and civil society organisations promote the Midden-Delfland® Vision 2025, which includes the report 'Midden-Delfland Gateways'. These gateways are conceived as strategic entry points connecting the city to the countryside, articulating various functions: enhancing the urban-rural relationship, making landscapes and their transitions accessible and legible, providing information and orientation, serving as parking, transfer and departure points for recreational, cultural and historical routes, etc (Fig. 7).

Understanding the sequence in which these gateways serve as a passageway to a buffer zone - Midden Delfland- which itself constitutes a major gateway to the Green Heart landscape, may help conceiving the possibility of a similar articulation in the relationship between Fuenlabrada and its surroundings.

5. Fuenlabrada, Madrid Sur and the Green Arc

5.1 Fuenlabrada and Madrid Sur

Fuenlabrada shares with the rest of the cities in the southern belt of the city of Madrid a similar origin and evolution: old rural settlements born next to crossroads in the territorial structure of the south of the region which, especially from the 1950s onwards, took in -precariously arranged as commuter towns- the population that emigrated from various rural areas of the country -mainly Andalusia and Extremadura- in search for employment in the capital, a movement that was accentuated in the 1970s (Cabrero Garrido, 2004, pp. 407-408) which promoted an indiscriminate and sprawling growth that will begin to be managed, by providing facilities and infrastructures, in the 1980s after the arrival of democracy in Spain and economically boosted by its entry into the European Community (now the European Union).
Fuenlabrada sits on a very flat territory on the border between the sub-basins of the Jarama and Guadarrama rivers. It is an area that has left behind the steep slopes of the north of Madrid and has entered the flat territory, with no significant elevations, of the area of the middle course of the Tagus River basin. However, it is also a scarcely consolidated space, with some valuable interventions that need to be reinforced, but which is exposed to the persistent pressure of urban

growth -from all the surrounding settlements- which, at the very least, compromises its identity and dilutes its potential and its value as a civically and ecologically valuable space, threatening its long-term survival. It is a territory that historically has been home to agricultural fields (Cabrero Garrido, 2004, p. 396) whose activity is still relevant and remains settled on an east-south-west arc around the city.

The northern fringe has long since abandoned its agricultural condition and, in fact, composes a metropolitan void that transcends the limits of the city itself and forms part of a wider structure that forms the backbone of a sort of incipient conurbation formed by the larger cities to the south of Madrid, known as Madrid Sur (Fig. 8). Fuenlabrada is thus, together with the cities of Móstoles, Alcorcón, Leganés and Getafe, part of a kind of archipelago of cities that make up the southern sector of the metropolitan ring of Madrid which together have a total population of 948,337 inhabitants (INE, 2023), a population that, if it were considered as a single municipality, would represent the third largest city in Spain, behind only Madrid and Barcelona, but ahead of Valencia.

Figure 8. Madrid Sur. The conurbation that forms the southern metropolitan fringe of Madrid and the open space between its five cities (Fuenlabrada, Móstoles, Alcorcón, Leganés and Getafe).
Source: Prepared by the authors of the paper

All these cities in the conurbation (Fuenlabrada, Móstoles, Alcorcón, Leganés and Getafe) are separated from each other by an open space that accommodates some recreational uses, but which, above all, serves as a base for the layout of major infrastructures such as the railway, an arc of the third major ring road around the municipality of Madrid (M-50) and some radial roads. It is a space with enormous potential as a buffer zone that can accommodate the large infrastructures mentioned above -especially the M-50-, act as a barrier to the sprawl that would eventually lead to the merging of all these cities into one urban continuum and provide citizens with an open space with facilities and leisure activities incorporated into an area that should take advantage of the natural and ecological conditions of the place, providing an habitat that is clearly differentiated from the urban environment. However, it is also a scarcely consolidated space, with some valuable interventions that need to be reinforced, but which is exposed to the persistent pressure of urban growth -from all the surrounding settlements- which, at the very least, compromises its identity and dilutes its potential and its value as a civically and ecologically valuable space, threatening its long-term survival.

5.2 Green Arc / Arco Verde

This space around which the cities of Fuenlabrada, Móstoles, Alcorcón, Leganés and Getafe orbit is also linked to a larger initiative, known as Green Arc (Arco Verde), that connects the three natural parks of the Madrid region (Cuenca Alta del Manzanares, Curso Medio del Río Guadarrama and Parque Regional del Sureste) and other natural areas of interest through the network of cattle trails and other paths and tracks, creating a great corridor of more than 200 kilometres that surrounds the city of Madrid and connects the municipalities of its metropolitan area (Fig. 9) (Comunidad de Madrid, 2024).

Figure 9. The Green Arc around Madrid.
Below left, the area of Madrid Sur where Fuenlabrada and Bosque Sur are located.
Source: Prepared by the authors of the paper

Therefore, the potentially valuable heart that articulates the southern conurbation of the metropolitan crown acquires a greater dimension by entering into synergy with the structure of the Green Arc, a ring that links the most valuable natural landscapes of the Madrid region. Thus, any resident of Fuenlabrada would have at his disposal -from the gateways that this research proposes (Fig. 10)- both the wide space that separates it from the bordering cities to be found in the south of the metropolitan crown, as well as access to a vast territory of enormous landscape and ecological value, a connection that allows a restoration of equilibrium between life in the intensely urban environment of the cities and the beneficial contrast offered by the contact with open spaces of diverse ecological value. Both projects -the heart of the southern conurbation and the Green Arc- represent an opportunity to reconsider and restore many ecosystems that have been degraded from their natural condition as a result of human activity. In the case of Fuenlabrada and the southern conurbation, the space that articulates it is a space historically linked to agricultural activity whose abandonment should be taken as the starting

point for a process of renaturalisation that counteracts the climatic urgency by investing in ecological improvement. Access to these territories must also contribute to their recognition by citizens. Recognition that should lead to their enhancement and, consequently, to the demand for their conservation, maintenance and protection. It is in this initiative that the present research is framed.

6. Evaluation of peri-urban greengates in quantitative and qualitative terms. Indicators and design criteria

Understanding the city as an ecosystem implies redefining our conception of the urban from a holistic approach to the dialogue between nature and the city. The return to nature, its recovery or reintroduction on the support of the consolidated city, situates our research in the contemporary framework of the renaturalisation of cities. Urban renaturalisation is a multiple challenge: economic, social and physical-spatial. Economic, because it involves reversing a development system linked to the urbanisation of grey infrastructure. Social, because of the need to transform the collective thinking that links progress with consumption and individual freedom towards a purpose of environmental commitment. And physical-spatial because all regeneration relies on existing support, image and formalisation of decision-making over decades that have not had the possibility to build with nature. The emergence of the concept of 'nature-based solutions' has meant the integration of multiple strategies with a multi-scalar multi-functional and place-specific approach. In addition, we can add the conditions of connectivity, strategy, inter- and transdisciplinarity, and social inclusiveness (Tzoulas, et al. 2021).

In order to implement measures aligned with nature-based solutions, it is necessary to define a systematic prior assessment of the areas where improvements are intended to be made in order to reveal shortcomings and assess possible opportunities.
To this end, a methodology is proposed based on the analysis through indicators that provide us with a prior diagnosis, with the aim of implementing appropriate measures that respond effectively through tools supported by nature-based solutions.
Focusing the problem on the case study of peripheral landscapes, we must define specific indicators that allow us to bring together the varied characteristics of these heterogeneous areas.

6.1 Indicators and reference methodology

Recent studies assessing both quantitative and qualitative indicators of green areas are referenced.
The so-called Grenn Area Indicator GEA is a basically quantitative indicator, that does a valoration of the area of biologically available surfaces (i.e., those covered by vegetation, open water, permeable paving and storm water infiltration, etc.) compared to total parcel area. Likewise, ecosystem approaches provide a conceptual framework to aid decision making in urban planning for green infrastructure (Stange, et al., 2022).
Despite their complex development, the GEA indicators, used as ordinances to guarantee a minimum of green areas in new developments, are exclusively quantitative in nature and are, therefore, incomplete for assessing edge areas, which are located on the boundary between urbanised and undeveloped territory.

Other indicators such as sustainability indicators related to green areas add aspects related to proximity to green spaces and urban green corridors, recommending maximum distances depending on the size of the green area under consideration (Barcelona, 2008).
With regard to the quality of green spaces, other authors add other aspects (de la Barrera, et al., 2016) associating size with greater diversity in the ecosystem services provided, also point to the greater capacity to host cultural offerings of those green areas that have the capacity to host a greater variety of people. (older people, young people or children) favouring greater social interaction. Greater vegetation cover is also considered to provide greater biodiversity and environmental comfort.
If we interpret green areas as part of other natural or naturalised superstructures, we can also add topological indicators, that can assess the potential of defining green infrastructures capable of connecting natural areas of regional character with other smaller areas of peri-urban and urban scale. The valuation of green areas, not only for their isolated status as environmental havens, but also because of its capacity to connect with others of greater or lesser size, it adds a more complex vision that makes it possible to contribute to territorial environmental improvement at different scales (Lafortezza, et al., 2013).

Another key aspect is related to the accessibility of green areas, which is particularly important given the particularities of the peri-urban landscape.
In terms of equity and inclusion, other authors propose indicators to measure the Quality and accessibility of green spaces: (Yao, et al., 2014)
‘(i) the Effective Green Equivalent (EGE) referring to the GS area that effectively has a benefit for each inhabitant; (ii) the Average Effective Green Equivalent (AEGE), which is the average of EGE for all inhabitants; and (iii) the Inequality Coefficient (IC) which is based on the Gini coefficient of income inequality, exchanging income with the EGE of residents’

As for the methodology of analysis, we propose as a methodological basis the one proposed by Fariña, Higueras, Román and Pozo in the Guide for Planning Healthy Cities (Fariña, et al., 2022) in its section on the Introduction of nature in the city, referring to peri-urban green areas in the vicinity of the city. The proposal consists of mapping existing public spaces and urban green areas, also representing the peripheral open areas and valuing the identified green areas as a whole from their potential to generate a green infrastructure. In this way, the value of the existing green is signalled and enhanced in order to connect it and shape a resilient continuous system.

7. Conclusion

7.1 Possible indicators for the evaluation of green areas in the peri-urban landscape

We found a series of indicators associated with green areas, which we could characterise and qualify for application in the analysis and diagnosis of peri-urban areas (Fig. 11)
We therefore define several groups of indicators:
- Intrinsic indicators: quantitative and qualitative indicators of the areas to be analysed such as size, heterogeneity, biodiversity, landscape quality, environmental comfort,
- Contextual indicators: proximity to protected natural areas, proximity to areas of agricultural or livestock use, proximity to residential areas, continuity with urban public spaces, pedestrian, cycling or public transport accessibility.
- Extrinsic indicators: fragmentation due to large infrastructures, edge uses with environmental impact: landfills, industries, logistics centres, power stations,
- Social indicators: daily use of the space, citizen involvement in the implementation, transformation and design of the green area, citizen involvement in the care and maintenance of the space, identification with the place, physical and mental health.

Figure 11: Proposal of indicators for green areas of the peri-urban space. Based on benchmark indicators in Point 6 (Indicators and reference methodology)
Source: Prepared by the authors of the paper

Social indicators are especially relevant, as they reflect the impact that a green area can have on the population that can enjoy it, providing health benefits, as long as the open space has quality, provides environmental comfort and is well connected and easily accessible to citizens of any age and condition.
Just as the search for a healthier city generated the first garden city and infinite city models, nature-based solutions are well suited to respond to basic social needs for health and well-being. The permeability of natural spaces to urban spaces on the periphery is a fundamental factor in ensuring a better quality of life. For this reason, it is necessary to emphasise the strategic character of greengates as places of connection of urban edges with quality and wide-ranging natural spaces.

7.2 Greengates as a strategic enclave for integration between nature and city. Identification and Project

With the use of the proposed indicators and being aware of the problem of peri-urban areas and the existing situations of disconnection between urban peripheries and nearby natural spaces, the analysis and design of greengates is key to their role as nodes of continuity of green infrastructures.
Taking as a model the design of the urban edge elements of the cities that make up the Midden-Delfland and assuming as a case study the northern periphery of the municipality of Fuenlabrada, we can propose a working methodology for the identification of those spaces that can be transformed into greengates favouring green and natural continuity.
With the aim of ensuring greater continuity between urban and peri-urban green spaces, it is proposed:

- Represent, characterise and quantify the system of urban green spaces, with their hierarchy, such as neighbourhood parks, urban parks, ornamental gardens, boulevards, street trees, etc. And also, if there are private landscaped areas of interest (because of their size or the size of the vegetation).

- Represent, characterise and quantify the peri-urban green system, with protected natural spaces on a territorial scale, blue infrastructure, reforested areas, wetlands, orchard areas, paths, etc., and all spaces with environmental or landscape potential in the surrounding area.

- To analyse, with the help of the proposed indicators, this structure from the point of view of quantity and quality of the green system, so that it can become a green infrastructure, capable of generating a healthy physical and mental environment for the entire population.

- Finally, in the potential green infrastructure revealed, key nodes or transition points between the peri-urban public space and the immediate natural space will be identified. These greengates will be defined in order to prioritise continuity from the built space and to encourage the shaping of the previously identified green infrastructure.

The project and design of connection nodes between the urban and its natural environment is relevant in peripheral areas. The complexity and growth of cities has created barriers and blurred spaces of natural value that are beginning to be recovered through the definition of green infrastructures. The proposal and development of the greengates could reduce uncertainty and respond with contemporary criteria to the necessary proximity between the urban environment and the natural environment, as already announced by the first visionaries and creators of the garden city.

Rethinking the waste of planetary urbanization for urban challenges: Potential, Strategies and Governance in Terrain Vague projects

Krystallia Kamvasinou

Abstract

Planetary Urbanisation puts pressure on undeveloped spaces in cities. Although perceived as wastelands, such spaces are of unacknowledged socioenvironmental value. Conceptualised as *Terrain Vague*, they have potential to address social and ecological urban challenges. This paper demonstrates how the Terrain Vague can be activated through alternative repurposing strategies and governance. We present three case studies indicative of diverse strategies adopted from different European contexts: Porto Healthy Corridor, a nature-based solution part of URBINAT research project; R-Urban (2013-2017), a community garden in Colombes, near Paris, managed as Urban Commons; Cody Dock, a community-led regeneration and river revitalisation project in London. The analysis shows how rethinking the waste of planetary urbanization can support the circular economy, biodiversity, urban ecology, community development and climate sustainability.

Keywords: wastelands, strategies of repurposing, socioenvironmental value, urban commons, urban ecology

1. Introduction

In a world of cities and of Planetary Urbanisation (Brenner and Schmid 2011; Brenner 2013) advancing with increasing speed and frequency, the scale of the urbanization process, the alternation between sprawling and urban shrinking, and the complexity and ineffectiveness of planning processes have led to the emergence of uncertain urban spaces that seem to challenge the traditional dichotomies between urban and rural, city and countryside, value and use.

To refer to such spaces, we adopt the term 'Terrain Vague' coined by Catalan architect and academic Ignasi de Sola-Morales (1995) as a more pluralistic, metaphorical framing, allowing multiple interdisciplinary interpretations. The origins of Terrain Vague spaces can be of different natures (Berger 2006; Clément 2022; Kamvasinou 2011): geography, the presence of particular natural elements, alternating sprawling and shrinking, processes of deindustrialization, ineffective planning or lack of cooperation between different political entities, the abandonment or obsolescence of large built-up areas, spaces awaiting future development, leftover spaces related to large infrastructures such as bridges, motorways, railways, and the design and construction of large public buildings. Such spaces are not integrated into the urban system of public spaces and are temporarily cut off from the city's productive system, usually unnamed and without a specific productive function. In contrast to traditional public spaces of collective use, nowadays increasingly controlled and institutionalized, these spaces are often reclaimed for activities not allowed elsewhere (Kamvasinou 2011). Although often identified as problems and sites of precarity, they have great potential for addressing socioecological challenges.

Indeed, Terrain Vague spaces are refuges for plant and animal species at risk and dynamic places of encounters between different species, generating a rich biodiversity (Gandy 2022, 2013; Clément 2022). They are places of spontaneous appropriation by different communities, informal uses, community gardens, informal agriculture, artistic experimentation (Kamvasinou and Roberts 2014; LaFond 2010). Alternative practices in these spaces challenge traditional planning dichotomies between temporary use and long-term visions, between ownership and use, between top-down and bottom-up planning. Even initial spontaneous and temporary occupations can both bring immediate benefits (such as the strengthening of a sense of community) and influence long-term transformation; even if the property is private, it may be granted temporary public status through concessions to incentivize use of space, bringing benefits to both the user and the owner; finally, there may be an integration of spontaneous and bottom-up initiatives with top-down planning policies and visions (Kamvasinou, 2017).

2. Theoretical Background

Since the late 20th century, terrain vague spaces have been the subject of increasing multidisciplinary interest and study (from architecture to biology, from urban planning to economics, from social sciences to geography). Due to their ambiguous, uncertain, and changing nature, their peculiar characteristics, the inapplicability of the traditional categories of urban public space theory, and the wide variety of disciplines that study them, there isn't one single and unequivocal definition or term for these spaces. Many authors have attempted definitions using varied terms, including Terrain Vague (Solà-Morales 1995; Mariani and Barron 2014; Lévesque 2001), Urban Voids (Lopez-Pineiro 2020), Vacant Land/Lot (Kamvasinou 2011; Bowman and Pagano 2004; Accordino and Johnson 2000; Northam 1971), Drosscape (Berger 2006), Third Landscape (Clément 2022), Urban Wildscapes (Jorgensen and Keenan 2012), and Wasteland or Brownfield (Gandy 2013; Berger 2006). While the specific terminology differs, this range of scholarly attempts to categorize such interstitial spaces not

integrated into the formal urban fabric highlights their ambiguous yet increasingly recognized potential from multidisciplinary perspectives. Although these definitions refer to essentially the same object of study, each of them reveals a disciplinary perspective, a particular nuance, a set of values and visions for the future of these spaces. In a generic and synthetic form, these spaces can be described as open, abandoned, underdeveloped and underused, without a specific function and outside the city's productive circuit, which are not traditional public open spaces such as squares, plazas, or gardens, nor formal agricultural spaces. Among the various definitions, we prefer the definition of Terrain Vague, for several reasons.

First, this definition represents a turning point in the 1990s, because for the first time it values emptiness positively, not as a lack but as freedom, hope, possibility. Secondly because, by tracing the first discovery of these spaces back to artists and photographers, it reveals their close connection with artistic practices and activities and with a free, creative, and utopic vision for these spaces. Finally, because Ignasi de Solà-Morales (1995) advocates the need for a new approach, a new vision for these spaces, which goes beyond functionalism and the traditional dichotomies of urban planning, to preserve and fully exploit the potential of terrain vague spaces.

2.1 From Waste to Terrain Vague

The causes behind the creation of Terrain Vague spaces are undoubtedly the processes of urbanisation and the ineffectiveness of urban planning in controlling the scale of these processes. In the last thirty years, increasingly invasive and rapid urbanisation processes, have challenged traditional definitions of the city. Many authors have attempted to define this form of urbanisation (Sieverts 2003; Brenner and Schmid 2011; Balducci, Fedeli, and Curci 2017; Soja 2000; Brenner 2013), with some common points: i) the end of the traditional dichotomy between urban and non-urban, between town and country; ii) a new scale of urbanisation, reaching as far as the regional, national or global scale, generating increasingly hybrid and blurred boundaries; iii) the creation of a new urban form, which often lacks the fundamental characteristics of the city (Sawyer et al. 2021), characterized by sprawl and dispersion. Furthermore, it is possible to think of wastelands as urbanisation's inevitable by-product (Berger 2006).

However, if we turn upside down our way of thinking, in a vision of recycling and reuse, valuing the local dimension rather than the large scale, we can conceive of these spaces as valuable resources, easily accessible and with great social potential: "Spaces discarded by productive logic but valuable for local communities" (Perrone and Russo 2019, p. 13).

2.2 Social and Ecological Value of Terrain Vague

Terrain Vague spaces intersect social and ecological interests, functioning as sites of daily informal appropriation by local communities (Kamvasinou and Roberts 2014; Careri 2006; Brighenti 2013; Iannizzotto 2023; Mariani and Barron 2014) and biodiversity hotspots where species prohibited elsewhere find refuge and coexist (Gandy 2022; 2013; Clément 2022; McPhearson, Kremer, and Hamstead 2013). Their abandoned state devoid of human control enables spontaneous community uses revealing local needs (Kamvasinou and Roberts 2014), catalysing relationships between residents, collective space management, and an enhanced sense of community (Iannizzotto 2023).

Terrain Vague spaces also hold immense ecological value, already performing vital environmental functions like absorbing rainwater, cleaning air, enabling biodiversity corridors, and providing ecosystem services (McPhearson et al. 2013; Cortinovis and Geneletti 2018). Studies highlight their richness in rare wild species (Gandy 2022, 2016, 2013, 2011; Clément 2022), revealing potential for enhancement through simple interventions and design as nature-based urban solutions (Nunes et al. 2021).

2.3 Terrain Vague as Urban Commons

A reciprocal relationship exists between terrain vague spaces and Urban Commons, allowing projects and practices in these spaces to be viewed through the Urban Commoning lens (Akbil et al. 2022; Dellenbaugh-Losse et al. 2018; Borch & Kornberger 2015; Petrescu et al. 2021; Stavrides 2016). First, the origin and history of many terrains vagues link to common lands, like the UK's common land system, Portugal's rural baldios (Travasso 2022), and Italian movements reclaiming abandoned spaces (Perrone et al. 2022). Second, the informal everyday practices (Chase, Kaliski, and Crawford 1999) and experimental projects occurring in these spaces exemplify "commoning" - managing urban resources not-for-profit and participatorily as Urban Commons (Dellenbaugh-Losse et al. 2018). The Terrain vague suits such projects due to immediate availability, existing community management, its green potential, and separation from market logic favoring use over exchange value (Moniz 2021; Petrescu & Petcou 2023). Urban community gardens epitomize this ecological Urban Commons model (Urban Commons Research Collective 2022).

3. Methodology

We present a qualitative comparative case study analysis of three projects indicative of different strategies adopted for repurposing terrain vague spaces, intentionally chosen from different European contexts - Southern (Porto Healthy Corridor, a nature-based green corridor realized through co-creation processes as part of the URBINAT research project in Porto, Portugal), Central (R-Urban, a community garden with agriculture and cultural events managed as Urban Commons in Colombes near Paris, France from 2013-2017), and Northern Europe (Cody Dock, a community-led post-industrial site regeneration, river revitalization and social enterprise project in Newham, East London, UK). By analysing these varied case studies from different scales, terrain vague types, time durations, strategies and governance models presented side by side, we aim to demonstrate how rethinking the waste of planetary urbanization through alternative repurposing approaches can support the circular economy, biodiversity, urban ecology, community development, and sustainability against climate change.

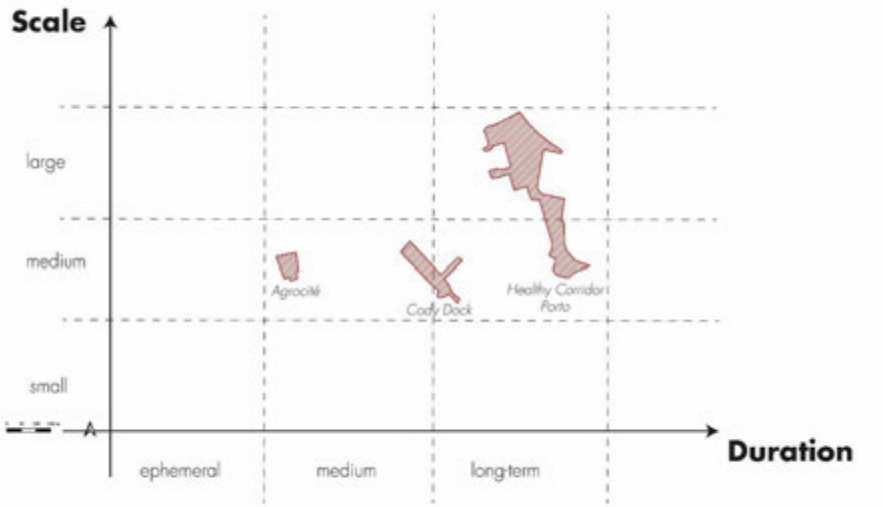

Image 1. Graphical comparison of case studies, represented according to scale and duration.

4. Case studies

4.1 Porto Healthy Corridor

Urbinat (2018-2024), whose acronym stands for 'URBan Inclusive and Innovative NATure', was a six-year project funded within the Horizon 2020 programme, focused on the regeneration and integration of underserved city districts through the design and implementation of nature-based solutions and using participatory and co-creation methodologies (Nunes, Björner, and Hilding-Hamann 2021). The consortium, consisting of partners from public institutions, universities, and private entities from seven European cities (Porto, Nantes, Brussels, Høje Taastrup, Siena, Sofia, Nova Gorica) and other institutions from all over the world, was based on the simultaneous achievement of academic goals and realization of concrete examples, the work of local units and network collaboration at European and international level.

The Project interventions focus on the design and realization of a new type of urban green corridor in the seven partner cities, called healthy corridor, conceived as linear public spaces and clusters of different nature-based solutions, through the inclusion and involvement of residents and local communities in the different project phases, using participatory and collaborative methodologies and the co-creation process. For the entire duration of the process, the Project operates simultaneously through the integration of two different scales: a local scale, through the creation of local living laboratories, relations with the municipality and institutions, involvement of residents, the community, local associations, with events and activities; the international scale of the network, coordinated mainly by universities and academic entities, with the main objective of developing and sharing a single language, a catalogue of solutions,

methodologies, processes and toolkits in common, through continuous activities between partners, meetings, workshops, shared platforms, publications.

The Healthy Corridor concept and strategy, as it was conceived and defined by the network, is based on the creation of linear parks or green corridors connecting different areas, specifically social housing neighborhoods, that are clusters of different nature-based solutions, which are chosen, designed and implemented in stages through a process of co-creation, thus initiating an attempt to connect human and ecological interests and goals (Moniz 2021).

Since the objective of the healthy corridor is the creation of new paths and green public spaces in neighborhoods with fewer services and infrastructures, by intervening in the existing city and without proposing major demolitions, it is consequently quite clear that one of the privileged sites of intervention are the terrain vague or abandoned spaces. Indeed, in the first conception and theoretical definition of the healthy corridor, terrains vagues are proposed as privileged intervention spaces, implicitly revealing their social and ecological potential: "the Healthy Corridor is a cluster of NBS that can occupy urban voids or common ground that is not being used or needs regeneration, becoming a link between different areas of the city, contributing to avoidance of the segregation effect and to the promotion of social and urban cohesion" (Moniz 2021, p.19).

In the city of Porto, *Campanhã* parish has been identified as one of the priority areas to intervene on and chosen for the design of the healthy corridor. This area, mainly residential and with a high percentage of public social housing, presents some criticalities and challenges, mainly due to partial isolation, fragmentation, lack of accessibility, lack of a sense of security or safety itself, scarcity of quality public spaces and public services. However, this area is particularly rich in Terrain Vague spaces, which are, from the early stages of study, analysis, and diagnosis, identified as possible areas for intervention and as spaces with high potential. As in many other cases, as we have reported previously, the presence of terrain vague spaces is due to the fragmentation of the territory, which, from being an agricultural area until the relatively recent past, has been subjected to rapid, invasive processes of urbanization, punctual, zonal and in the absence of an effective overall plan or vision, which, together with the creation of various road infrastructures (motorways and railways) has contributed to the fragmentation of the area.

In fact, even today these abandoned spaces retain ruins, traces, and memories of their agricultural past, blending in and almost disappearing amidst the new residential buildings, and “this represents a unique opportunity to properly occupy such areas in order to connect key areas and create a multifunctional green continuum in the territory – a Healthy Corridor” (Moniz 2021, pp.36-37).

From the very first phases carried out together with the residents and the population, i.e. the phase called co-diagnosis, these spaces were immediately identified both by the community as priority spaces on which to intervene, and by the experts who recognized their ecological and social potential. An initial phase of identification and mapping of these voids was followed by a second phase in which cadastral checks were carried out to identify abandoned areas owned by the municipality, with the aim of selecting the areas on which it was easiest to intervene. Then, through local activities with residents and the community, solutions and functions began to be outlined. Thanks to the flexibility of the proposed solutions and the methodology used, the consortium's catalogue of solutions was enriched with solutions proposed during the activities, and it was also possible to think up solutions that were suitable in specific contexts and in accordance with the community's wishes, as in the specific case of the historical ruins of

an old farm, which it was decided to keep because it was part of the inhabitants' collective memory.

In fact, the diversity and peculiarity of terrain vague spaces stimulates a variety of different solutions, difficult to design or plan a priori, without knowledge of the context and the actors involved. Due to the large scale, the large number of institutions, bodies, associations involved, the costs and the complexity of the healthy corridor, the project envisaged several implementation and feasibility phases, thus taking time into account as a factor in the project.

At the end of the Research Project, the Project was presented to and accepted by the municipality and all the various stakeholders, and on 20 February 2024 the Porto Healthy Corridor was officially realised, inaugurated and opened to the public: "The realisation of the Campanhã URBiNAT Healthy Corridor is a good example of how collaborative planning and community involvement can lead to meaningful and beautiful urban transformations, setting a precedent for future projects in Porto, in other cities across Europe, and beyond" ('[Porto PT] Inauguration of the URBiNAT Healthy Corridor in the District of Campanhã, Porto', n.d.).

4.2 R-Urban, Paris

R-Urban (Petcou and Petrescu 2020, 2015; Petrescu and Petcou 2023; Atelier Architecture Autogérée 2022) is an ambitious strategy, conceived by Atelier Architecture Autogérée, based on the introduction of a network, entirely managed by the residents in a bottom-up way, made up of a series of hubs, each with its own specific function but interconnected with each other, with the objective of managing material and immaterial flows by promoting a new model and lifestyle, sustainable and resilient, managed directly and autonomously by the residents and alternative to the capitalistic and profit oriented model of the city.

R-Urban, was conceived after three years of research by the collective platform Atelier Architecture Autogérée as a model, as a theoretical network that can be applied and implemented in various contexts, then adapted to the specificities of the local context; some hubs have already been tested in Colombes (near Paris), Paris and London. The concept, which is inspired by models of resilient cities from the history of architecture and town planning (Garden City, Regional City and Transition Town), is guided by a clear ecological and political approach based on Lefebvre's concept of the right to city (Lefebvre 1968) and especially Harvey's more recent reformulation of it (Harvey 2008) as not only the right to live, but above all the right to decide and change the city by residents.

The Project is conceived as an infrastructure, a network capable of managing material flows (production, consumption) but also, and above all, immaterial flows (exchange of knowledge, relationships), which proposes another model of urban lifestyle, alternative to that of profit, the capitalist state and the logic of the market and exploitation, based on flows of production and consumption based on sustainability and resilience and entirely managed from below, in accordance with the vision that sees closely correlated ecological, social and political instances.

The fundamental concept is resilience, "…a dynamic concept, which does not have a stable definition and identity outside the circumstances that produce it… resilience is adaptive and transformative, inducing change that offers huge potential to rethink assumptions and build new systems" (Petcou and Petrescu 2020). R-Urban operates simultaneously at the global, regional and local scales: while on the one hand it proposes almost a concrete utopia, a strong political critique realized in practice, on the other hand it proposes a system of resource flows and

exchanges that functions on a regional scale, at the same time it is based on the complete and direct bottom-up management of residents, thus absolutely flexible to local peculiarities and contexts.

In fact, the aim is to boost, together with experts and institutions, a process that will later be completely autonomous and managed directly by residents and associations. Finally, it is useful to note that in the case of R-Urban, but also of other projects, Atelier Architecture Autogérée, on the basis of its direct experience, prefers as intervention spaces abandoned or underused, easily accessible and outside the city's production and profit circuits, i.e. exactly the terrain vague spaces, revealing a real strategy of interstices that “involves spaces, actors, local partners, time” (Petcou and Petrescu 2020).

There are at least two reasons for this: it enables prompt action by avoiding lengthy negotiations over private property, and more importantly, it redefines and devalues the power of private property as the basis for urban planning choices, instead revaluing the use value of spaces. After three years of research, the collective proposed R-Urban to local authorities and grassroots organizations in France. In 2011, the first implementation began in Colombes, a Parisian suburb of 84,000 residents with a "typical mix of private and council housing estates," with support from local institutions, associations, and residents. Three interconnected hubs were planned, though only two were realized: Agrocité, an agricultural unit with a small farm, community gardens, and educational spaces on sustainable resource management; and Recyclab, a space for recycling, tool storage, and resident-built eco-housing using discarded materials. The unrealized Ecohab was envisioned as a cooperative, partly self-built eco-housing project with shared spaces. Significantly, all the realized Colombes hubs occupied abandoned spaces resulting from large-scale planning oversights, exemplifying the potential of terrain vague: "Agrocité was located on a 2000 sqm vacant lot near Fossés Jean; Recyclab was built on a disused road; and Ecohab was planned for a vacant plot between the other two hubs" (Petrescu and Petcou 2023), demonstrating in practice the value of these ambiguous urban spaces.

During the period of regular activity, from 2011 to 2016, the Colombes R-Urban network achieved important objectives and results and a considerable involvement of the population, in fact from the ecological point of view, it has initiated processes of information, sustainable production and consumption of food, agriculture and livestock, recycling, rainwater absorption, air cleaning, and many others; from the social point of view, around 6900 people have participated in the site's activities, 400 of whom have become active stakeholders, learning and sharing skills, techniques and knowledge on agriculture, recycling and sustainability, as well as participating in workshops and cultural activities of various kinds; some residents have started small business activities within the network, thanks to the skills acquired and the voluntary work carried out. Paradoxically, the greatest threat and difficulty for the project came from the municipality and politics: in the name of a phase of urban regeneration of the neighborhood and social housing complexes, and following a change in the city's political direction, the mayor of Colombes decided to replace Agrocitè with a car park and to dismantle Recyclab to clear the space for new projects in the future.

This negative and unexpected occurrence demonstrates both the fragility and transience of projects implemented in terrain vague spaces, especially of a temporary and tactical urbanism nature, when they are not adequately foreseen, framed and protected within the legislative framework; and the difficulty of proposing and implementing real alternatives to speculation and the private market linked to investment and profit in the context of the contemporary city.

However, this threat stimulated several interesting reactions and reflections. First, it gave rise to a protest movement against the demolition by residents, thus demonstrating people's attachment to the project and the community's positive assessment of the benefits.

Then, in order to counter the municipality's main thesis, i.e. a faster economic return resulting from the activity as a car park, it stimulated a research aimed at calculating the economic value of the value produced by urban commons and resilience, i.e. calculating quantitatively and economically, in a language more easily understood by the business enterprises and the municipality, all those advantages, benefits and acquired values, both material and immaterial, resulting from the network's activity in those years.

Finally, despite the decision of the court and the municipality in 2017 to proceed with the actual demolition of the two R-Urban hubs in Colombes, the project and the community showed a great spirit of adaptation that brought the project to a second life, in another location. In fact, following negotiations with some neighbouring municipalities that were more attentive to the project, both Agrocité and Recyclab were dismantled and reconstituted in other locations, in Gennevilliers and Nanterre respectively, thus testing and demonstrating both the conception and adaptability of both the project (conceived with recycled material and following the principles of resilience, ready to be quickly assembled and disassembled) and the community, which had over time acquired the knowledge and experience necessary to carry out and manage this type of relocation.

4.3 Cody Dock, London

Cody Dock is a community-focused environmental project that aims to promote ecology, biodiversity, and creative industries in an urban setting. It is located in a post-industrial site along the River Lea in the East London borough of Newham. It has undergone a transformation from an industrial dock used for transporting coal and byproducts in the Victorian era, to a derelict and contaminated brownfield site after its decommissioning as a port in 1967. The surrounding area features a mix of warehouses, industrial parks, cement works, and vacant post-industrial sites.

In the early 2000s, Simon Myers, the current CEO of the Gasworks Dock Partnership (GDP) who are the legal tenants and manage the site, discovered the dilapidated Cody Dock while living on a boat on the River Lea (Interview with Myers 2013). He began engaging with the key stakeholder, Thames Water who owned the site, to acquire a lease. After initial failed attempts, the 2008 economic crash provided an opportunity and in 2009 Myers secured a 999-year lease for the site (Kamvasinou 2017). GDP was established first as a social enterprise in 2009, and later formalized as a charity in 2011. Its mission was to transform Cody Dock into a working marina and arts hub through providing moorings for live-in boats, renting artist studios, and restoring public access to the River Lea. Environmental restoration, education about local history and ecology, and community-building through events and partnerships were core aims (Kamvasinou 2017).

The project’s governance model is anchored in GDP as the lead organization, but involves collaborations with numerous other charities, businesses, individuals and community groups who help shape the site through partnerships (Interview with Myers 2013). An openness to unexpected events, like increased visitors during the Covid-19 lockdowns, allowed new meanings around health, wellbeing and greenspace to emerge.

While Thames Water owns the dock itself, the London Borough of Newham controls the access points. This multi-stakeholder situation, along with Cody Dock's complex history across pre-industrial, industrial and post-industrial eras, creates challenges but also opportunities for innovative governance models bridging top-down and bottom-up approaches.

Over time, the focus evolved from temporary activities like music events and art exhibitions, to more permanent facilities like an exhibition space, a therapeutic horticultural classroom ('The Growing Space'), and ecological infrastructure like floating reedbeds, the last two interventions associated and built in collaboration with live studio student work at the School of Architecture and Cities, University of Westminster (see https://www.architectsjournal.co.uk/buildings/university-of-westminster-completes-community-space-at-londons-cody-dock). Community participation and an incremental, organic approach to placemaking have been central philosophies in the evolution of the project from temporary to permanent, and from a physical site to a site of education and knowledge exchange, including the University of Westminster's research, teaching projects and community engagement exercises exploring topics like temporary urbanism, climate urbanism, biodiversity, socio-ecological relationships, and skills for interdisciplinary climate/health projects (Kamvasinou et al 2023).

The project combines ecological conservation efforts with artistic and creative installations. For instance, as Gino Brignoli, biodiversity officer, informed us on the occasion of a University of Westminster staff and students visit in March 2024, they are currently working with an artist to install a sound art piece that incorporates recordings from the area and involves placing hydrophones in the river to allow visitors to listen to the underwater sounds and aquatic life. Cody Dock also provides affordable studio spaces for artists, sculptors, sound designers, and architects, helping to keep the creative industries alive in the area. However, the demand for these studios far outweighs the supply.

Cody Dock aims to enhance biodiversity along the River Lea corridor through habitat creation and management efforts on their site. Part of Cody Dock's work involves ecological restoration of the dock area, carried out largely by volunteers. The charity collects ecological data and conducts biodiversity monitoring and conservation through various means. For example, as Brignoli mentioned, they conduct regular bird surveys every Friday along the river, culminating in collecting 8 years' worth of data that are shared with the British Trust for Ornithology to contribute to nationwide monitoring efforts. They host monthly "Beer and Bats" events where they teach about bat identification and conduct bat surveys, sharing the data with the Bat Conservation Trust, thus contributing to national databases and research.

Brignoli highlighted that the project heavily relies on volunteers who participate in various ecological activities, such as identifying bumblebees, bird watching, bat monitoring, and gardening. Field training and workshops are provided to volunteers to equip them with necessary skills, while community engagement is a significant aspect of the project. They host seasonal open days, film clubs, and workshops that are open to the public. They also work with local schools, bringing students to the site and conducting educational activities. A major focus is providing environmental education opportunities, especially for urban youth who may have limited exposure to natural areas. To this end, they bring school groups on boat trips on the river to experience being on the water in a natural setting. Some of the school children visiting have never even sat on grass before, so they aim to connect urban communities to local ecology. They are transitioning from movable planters to building permanent brick planters with help from local college students and volunteers, establishing more permanent green spaces.

Not everything is easy, however. As Brignoli confirmed, the project faces challenges in securing long-term funding. While they receive grants and funding from sources like the National Lottery, many of the staff positions are grant-funded and have limited duration. There is an ongoing conflict with local developers who sometimes engage with the project for consultation but then proceed with their plans without fully considering the recommendations. The project aims to expand its operations to other parts of the dock area, with plans to build a musical pavilion and restore an old lifeboat if funding becomes available.

Overall, Cody Dock represents a unique initiative that combines environmental conservation, community engagement, artistic expression, and support for creative industries in an urban setting. Particularly biodiversity conservation through monitoring, habitat restoration, and promoting awareness and appreciation of local ecology and wildlife seem to be core tenets of their environmental efforts at Cody Dock. They encourage volunteer participation and partnerships to achieve these goals, highlighting the importance of such projects in promoting biodiversity, education, and sustainable development.

5. Discussion: Potential, Strategies and Governance in Terrain Vague projects

The three case studies provide an overview of the potential of projects in Terrain Vague sites. Below we discuss this potential and compare and contrast the strategies and governance models adopted in the three case study projects as well as how these projects support the circular economy, biodiversity, urban ecology, community development, and sustainability against climate change.

5.1 Potential in Terrain Vague

By approaching terrains vagues as not just 'empty' or 'abandoned' but as transitional spaces with the potential for transformation, architects, planners, nonprofits and community stakeholders can draw upon their inherent ambiguities to reimagine and revitalize the urban narrative and to integrate with formal design and planning practices on terrain vague sites. The abundance and variety of Terrain Vague spaces in urban areas, as seen in Porto and Colombes, highlights their potential for repurposing.

The socio-ecological value of these neglected spaces lies in offering opportunities for nature integration and community appropriation, both crucial for a more resilient and regenerative approach to urban development. In this process, important features are the flexibility and adaptability of Terrain Vague projects, as showcased by R-Urban's relocation capabilities. Temporary uses of such sites contain clues to the potential diversity of future activities they might contain (Mostafavi and Najle 2003, p.7). The theory of Urban Political Ecology discusses the concept of nature as ‘a constructed rather than a pre-given concept…subject to political re-definition and re-articulation’ (Keil 2003, pp.726-27). Indeed, the Landscape Urbanism movement supports the idea that urban and natural landscapes come together in complex and important ways; under this theory, abandoned terrain vague sites form part of a larger urban ecosystem (Corner 2003). Vacant land is thus an opportunity, not just a problem, more easily incorporating interim uses that can reveal potential for bottom-up, community-driven placemaking that creates more inclusive spaces than top-down imposed development.

5.2 Strategies applied

Several distinct strategies can be discerned through the case studies. First, co-creation and participatory processes, as employed in Cody Dock's community-focused and participatory approach involving volunteers, local communities, and local partnerships, and in the Porto Healthy Corridor project, involving residents and local communities in various project phases of design and implementation. This strategy involved also a multi-scalar approach, operating at both local and international levels, with local living laboratories and a network of partners sharing knowledge and resources. Similarly, R-Urban employed a bottom-up, resident-managed network of interconnected hubs, each with specific functions (e.g., agriculture, recycling, eco-housing), suggesting a model that be adapted to local contexts and specificities. In addition, this strategy was enhanced through environmental education in the case of Cody Dock.

Second, tactical urbanism and temporary interventions acting as experiments, exemplified by R-Urban's temporary hubs that can be relocated and reassemblied in different locations when necessary, and Cody Dock's incremental and organic placemaking approach based on community engagement through temporary events, artistic installations and workshops, evolving over time to more permanent facilities.

Third, Terrains Vague spaces as intervention sites for the implementation of nature-based solutions (NBS) and ecological restoration, as seen in the green corridors and clusters of Porto, and in the ecological conservation and habitat creation efforts at Cody Dock.

Finally, intentional focus on intervening in abandoned or underused urban spaces (terrain vague) like R-Urban's approach, promoting adaptive reuse and repurposing of post-industrial sites in a way that respects their inherent qualities and history, like Cody Dock's transformation from an industrial dock to a community hub.

5.3 Governance models

The case studies show that temporary interventions allow for more experimentation, iteration and organic evolution based on diverse users and that partnerships between grassroots groups, local authorities, and developers can be mutually beneficial if balanced. Programming and activities are important - physical spaces alone don't guarantee inclusivity.

In the Porto project, a collaborative governance model operated at two scales involving a local scale consortium of local authorities, public institutions, universities, private entities, and local communities, engaged as stakeholders in the project, and an international scale a network of partners, universities, and academic entities. Community involvement and co-creation processes allowed residents to participate in the decision-making and design of the interventions.

R-Urban championed a bottom-up, resident-led governance and management of the hubs and network, involving local institutions, associations, and residents in the implementation process. This model was conceptualized as an alternative, autonomous model managed by residents, independent from capitalist urban development.

Collaborative and multi-stakeholder governance with the Gasworks Dock Partnership (GDP) as the lead organization was the model at Cody Dock while partnerships with various charities, businesses, individuals, and community groups contributed to shaping the site. An expansion of this model included the involvement of the University of Westminster through research,

teaching projects, and community engagement exercises, culminating in the building of structures on the site as part of live student projects. GDP had also to navigate a complex governance situation with multiple stakeholders, including Thames Water (site owners) and the London Borough of Newham (controlling access points).

In conclusion, Terrain Vague projects tend to promote bottom-up, community-led initiatives, and multi-stakeholder collaborations and partnerships, as demonstrated by Cody Dock's evolution and governance by the Gasworks Dock Partnership, as well as urban commons and collective management, as practiced in the R-Urban project's resident-managed hubs. However, these models of governance are not without their challenges, exemplified in the role of municipalities and potential conflicts, as seen in R-Urban's clash with the municipality of Colombes, and a precarious balance relating to funding (of jobs, maintenance works and everyday running costs) seen in the case of Cody Dock.

5.4 Addressing Urban Challenges

Circular Economy
The reuse and repurposing of Terrain Vague spaces could be considered a form of urban resource optimization. For example, Cody Dock has been turned from a working dock and industrial site to a community and arts hub, working marina for live-in boats and river restoration project.
Practices of material reuse and recycling are at the foreground, highlighted by R-Urban's Recyclab hub and the reuse and recycling of discarded materials in their eco-housing construction, as is promotion of sustainable resource management and urban agriculture, as illustrated by Agrocité in R-Urban and the community gardens in Porto.

Biodiversity
Both Cody Dock and the Porto Healthy Corridor project demonstrate significant efforts in habitat creation and ecological restoration, like the floating reedbeds and horticultural interventions at Cody Dock, enhancing biodiversity along the River Lea corridor through habitat creation and management, or the bird surveys and bat monitoring activities contributing to national databases and research. Similarly, integration of nature-based solutions and green corridors, which can contribute to enhancing urban biodiversity and creating ecological connections, as seen in the Porto Healthy Corridor project. Crucially, awareness and appreciation of local ecology and wildlife can be strongly promoted through educational activities and community engagement, as seed in Cody Dock, reiterating the importance not just of the physical space but of programming and appropriate activities to provide an alternative experience of the urban environment that can have transformational effects in addressing urban challenges.

Urban Ecology
The role of Terrain Vague projects in enhancing urban biodiversity and creating ecological corridors is exemplified by all three case studies. The implementation of linear green corridors and nature-based solutions can support urban ecology by introducing green infrastructure, creating habitats, and promoting ecological connectivity within the urban fabric. The projects chart the evolution of the potential for spontaneous nature to thrive in these neglected spaces, free from human control, to a purposeful integration of urban agriculture, community gardens, eco-housing principles, and promotion of rainwater absorption and air cleaning through green infrastructure as seen in the work of R-Urban. The projects connect urban communities to local

ecology through educational and community engagement activities, like Cody Dock's river trips and educational work with local schools, especially targeting urban youth, or their ecological restoration work of the dock area, carried out largely by volunteers, including integration of ecological infrastructure like floating reedbeds and permanent green spaces (brick planters).

Climate and Sustainability
The ease of integration of green infrastructure and nature-based solutions in terrain vague sites can contribute to urban greening, climate resilience and sustainability by mitigating the urban heat island effect, promoting rainwater absorption, and enhancing air quality. The promotion of green spaces and ecological conservation efforts as seen in Cody Dock and the Porto Healthy Corridor can contribute to urban resilience and sustainability Community gardens and urban agriculture, as seen in R-Urban, can contribute to local food production and reducing carbon footprints, while putting emphasis on resilience, adaptability, and sustainable urban lifestyles as an alternative to profit-oriented urban development through promotion of sustainable resource management, production, and consumption practices.

Community Development
The case studies demonstrated diverse strategies for fostering community development through participatory processes, capacity building, and the creation of shared spaces and resources.

In Porto, the Healthy Corridor project actively involved residents and local communities through co-creation processes, participatory activities, and capacity-building initiatives. This approach promoted social cohesion and cultivated a sense of community ownership over the urban interventions. Similarly, Cody Dock adopted a community-led approach, emphasizing strong community participation, engagement, and capacity building through various activities, workshops, and volunteer opportunities.

The R-Urban project placed significant emphasis on community involvement, facilitating skill-sharing and knowledge exchange through workshops and cultural activities. It provided shared spaces for collective resource management and enabled residents to initiate small business activities based on the skills and voluntary work within the network. Crucially, R-Urban championed the "right to the city" principle, empowering residents to actively shape their urban environment.

All three projects contributed to enhancing community connections and environmental awareness. For example, Cody Dock collaborated with local schools and hosted educational programs, strengthening community ties and promoting appreciation for local ecology. Similarly, the provision of affordable creative spaces, such as artist studios and moorings for boat dwellers, supported alternative lifestyles and artistic expression within the community. Overall, by creating green public spaces and integrating community-driven activities, these projects aimed to improve the well-being and quality of life for residents, particularly in underserved areas, promoting social and environmental sustainability.

6. Conclusions

This analysis has demonstrated the immense potential of rethinking and repurposing terrain vague spaces beyond their perception as ‘waste’ through alternative strategies and governance models. The case studies of the Porto Healthy Corridor, R-Urban in Colombes, and Cody Dock in London reveal how activating these neglected urban sites can powerfully address critical

urban challenges related to the circular economy, biodiversity conservation, urban ecology, community development, and sustainability against climate change.

The projects exemplify diverse approaches ranging from participatory co-creation processes involving residents and multiscalar collaborations, to tactical urbanism through temporary interventions acting as urban testing grounds. A unifying strategy lies in the intentional focus on terrain vague as prime intervention spaces - embracing the inherent ambiguities and indeterminacies of these sites to integrate nature-based solutions, test alternative living, and enable community appropriation.

Significantly, the cases point towards governance models promoting urban commons and bottom-up, resident-led initiatives over profit-driven urban development. Multi-stakeholder collaborations between grassroots groups, local authorities, NGOs and academic partners enabled knowledge exchange and capacity building. However, the projects also navigated complex stakeholder relationships and precarious balances relating to political conflicts and funding insecurities.

Ultimately, rethinking terrain vague through an ethos of shared resources, environmental stewardship and community empowerment can catalyse more equitable, resilient, and regenerative forms of urbanism. As cities grapple with intensifying social and ecological pressures, the latent potential of terrain vague offers an opportunity to re-envision the urban experience through smaller-scale, locally-attuned interventions capable of transformative impacts.

Abstract
More than a passing trend, urban agriculture (UA) has become a part of modern cities. According to some authors, it provides some ecosystem services (well-being, food, water catchment, biodiversity…) contributing to creating more liveable cities. Although these functions are recognised, not all municipalities integrate those functions into urban planning. The survey conducted on 240 land-use local plans and their integration of UA and Urban Domestic Gardens functions and issues reveal that the most expected functions are environmental, landscape management and social. We also observe that these topics are considered more in the presentation part of the plan that remains more declarative than operational and regulatory. There seem to be contextual and technical constraints on the implementation of regulatory mechanisms to preserve and develop these areas.

Keywords: land-use plan, functions, zoning, resilient cities

1. Introduction
More than a passing trend, urban agriculture (UA) has become a part of modern cities. According to some authors, it provides some ecosystem services (well-being, food, carbon storage, water catchment, biodiversity…) contributing to creating more liveable cities (Stella *et al.*, 2022). Although these functions are recognised, they cannot be generalised. The various forms of urban agriculture[1] (e.g. urban domestic gardens, allotment and community gardens, multifunctional urban micro-farms, peri-urban farm in short chain) provide specific services. Home gardens, despite the non-commercial nature of food production can also contribute to the food and ecological resilience of cities by reducing the vulnerability of households in the event

[1] Urban agriculture is considered as all agricultural practices and forms which supply products and/or services to the city (Aubry *et al.*, 2022) and whose use of space and resources competes with other urban activities (Moustier and Mbaye, 1999).

of economic, supply or other insecurity crises (Seeth *et al.*, 1998, Buchmann, 2009, Cerda *et al*., 2022) and by providing a range of ecosystem services (Cameron *et al.,* 2012).

Reliable methodologies to characterise and quantify these services and their interactions are still lacking. Concerning the contribution of UA to food resilience, the literature is fragmented and not consensual. The estimations depend on UA forms and the calculation methods. On the one hand, some forms of UA have been studied more than others where home domestic gardens now seem to be gaining more attention (Marie, 2019). On the other hand, data are still needed to assess their contribution. Methods of analysis also vary from surveys that rely on declarative data to photo-interpretation estimations. Payen *et al.* (2022) examined urban agricultural productivity by a meta-analysis literature review. They demonstrate that the productivity varies according to the location (e.g., ground-based, roof-based, indoor), growing systems (e.g., hydroponics, vertical or horizontal, controlled environment or open-air, soil-based agriculture), and crops. It is even more complex to understand the correlations between functions. For example, there are still discussions with respect to the environmental efficiency of urban agriculture, which is questioned (Goldstein *et al.*, 2016) and vary according to growing systems and agricultural practices (Hawes *et al.*, 2024). As a result, statements are highly variable, and may be conflicting, depending on the context, practices and methods used. Despite this context of scientific 'uncertainty' and the absence of robust methods for calculating and valuating their contribution, local stakeholders enhance and implement agricultural activities into urban and peri-urban areas to expect different functions. The proliferation of public actions in favour of the development of UA seems to be mainly motivated by the potential contributions expected from the various UAs in accelerating territorial transitions (food, ecology, agriculture).

In France, the debate on sustainable cities has been profoundly impacted by legislation on planning and environment in the late 2000s, known as the "Grenelle laws" (2009-2010). This legal framework promoted the integration of environmental objectives in planning policies. It was implemented through a national action plan for "sustainable cities" (*Plan Ville Durable*, 2010), which included the program "Restoring and enhancing nature in the city" initiated by the French State Secretary for Ecology.
Maintaining urban and peri-urban agriculture has been therefore recognised as a major challenge for sustainable land management. Ten years later, in 2020, the Ministry of Social and Ecological Transition and the Ministry of Territorial Cohesion launched a new '*roadmap for the city of tomorrow*'. In this context, the National Agency for Urban Renewal (*Agence Nationale de la Rénovation Urbaine)* started in 2020 a call for "Fertile Neighborhoods", to support urban agriculture in deprived districts.
These urban planning policies identify UA as a lever for urban transformation in several dimensions which are economic (promoting the attractiveness of neighbourhoods through job creation), social (through improved living conditions and social cohesion), and environmental (through the preservation of natural resources). This transformative capacity of UA is also highlighted by the French Economic, Social and Environmental Council (CESE) in its opinion on "Urban agriculture". However, the CESE's recommendations point to the need to better integrate UA into regional planning, and to develop policies and projects that complement peri-urban and rural agriculture (in particular, food planning projects, in French "*Plans alimentaires territoriaux*"). These recommendations suggest to adapt the legal, regulatory (local land-use plans, zoning, building design) and fiscal regulations, as well as research into sustainability by taking into account the diversity of UA forms in order to promote sustainable development on a territorial scale. As noted by Consalès *et al.* (2018) it seems that only allotment gardens are truly integrated into land-use plans.

More recently, planning policies in France have moved to quantitative objectives regarding land take limitation. The 2021 Law for Climate and resilience set out a binding objective of "no net land take" ("*Zéro artificialisation nette*"), fostering a renewed interest for conciliation between urban densification and preservation of green spaces. According to the law, the planning principles may avoid damage to biodiversity, and where such damage is unavoidable, reduce it as far as possible before offsetting any residual impact that could not be prevented. These objectives are supposed to guide planning principles in terms of biodiversity protection.

In this contribution we question the role play by urban agriculture and private gardens have in the city fabric. We aim to demonstrate how urban agriculture is being integrated into urban planning, and what functions it may fulfil. How do municipalities integrate UA and UDG in territorial projects? Which issues and functions are related to UA and UDG? How does the territorial context determine the consideration for those functions?

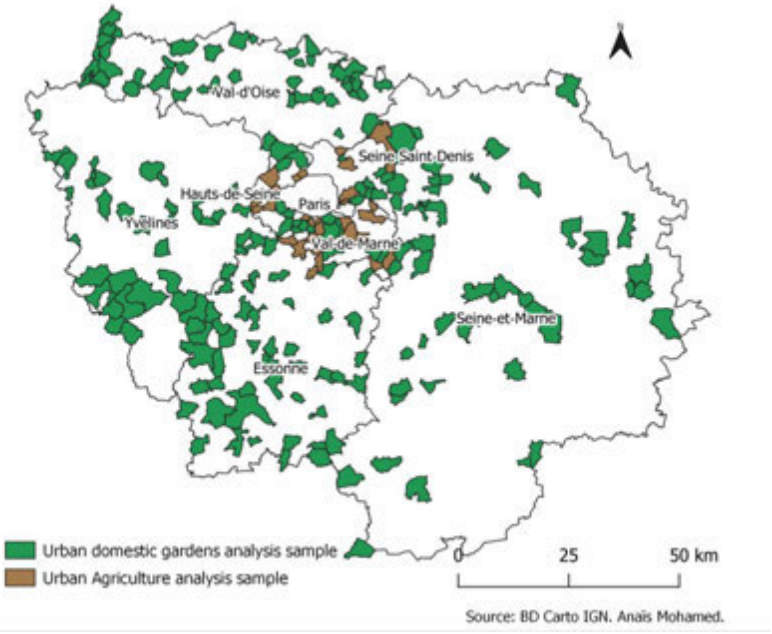
2. Methods

This article is based on two lines of work carried out by the authors: one specifically on domestic gardens and others on urban agriculture. These research thus have two different objects of study, on the one hand, private domestic gardens on individual housing plots in urbanised areas and, on the other hand, on urban collective agriculture's forms: allotment gardens, community gardens, and urban microfarms (Fig.1).

Fig. 1 Urban Agriculture's Forms

Although distinct, the two surveys both question the integration of those forms of urban agriculture into the urban planning at municipal level within the Ile-de-France Region. The scope of the study focuses on urban planning documents respectively on 200 municipalities for the UDG and 40 municipalities for UA located in the Ile-de-France Region. The data set presented in this paper covers the 240 local land use plans (Fig.2).

Fig. 2 Samples of municipalities in the Paris region according to datasets



The interest to explore this geographical area is based on several criteria. First it is the region that concentrates the most UA projects, around 900 according to the French Professional Urban Agriculture observatory. Second, it is the most populated area and most of the population lives in an urban unit. Finally, the urban fabric is very heterogeneous including many private gardens. Indeed, in a geographical analysis of two intercommunal territories inside the Paris Region, Darly *et al*. (2021, p. 18) stated that *'vegetable home gardens account for almost half of the urban cultivated surfaces dedicated to domestic self-provisioning (alongside allotment gardens), and therefore, should be considered as a significant element of a sustainable suburban food system'.*

The analysis was conducted on the four main documents composing the local land-use plans. Those plans are composed of the overview report, the strategic project ("*plan d'aménagement et de développement durable*"), the urban design guidelines ("*orientations d'aménagement et de programmation*") and the bylaw. The overview report sets out the characteristics of the municipality and the reasons for the choices made in the more binding documents, the strategic project and the urban design guidelines. The strategic project summaries the major planning issues and objectives that guide a municipality's planning. The urban design guidelines focus on a limited number of major urban projects that the town hopes to implement and the specific terms and conditions for each of these projects: landscape aspects, objectives in terms of urban renewal and social diversity, targeted land and terms and conditions of acquisition, etc. Only the bylaw has legal power, as they set out the rules to be respected by each land stakeholder (developers, builders, residents).

A quantitative lexical analysis was first carried out by counting the number of occurrences of a selected word (collective or private or community or allotment garden, urban microfarms, urban agriculture, private gardens, etc...) in the urban plans. The goal was to quantify the presence/absence and frequency of different terms within the different part of those plans. This

quantitative analysis was then supplemented by a thematic analysis (Thomas, 2006) to detect the role assigned to collective urban agriculture and UDG. We choose to group the functions provided by them as faithfully as the meaning given in those documents and without applying the ecosystem services grid (biodiversity, landscapes, food provisioning…) to avoid interpretation bias.

We delved deeper with some interviews to local stakeholders (10 for collective urban agriculture and 17 for UDG). Those local stakeholders were deputy mayor delegate to town planning or environment from our respective samples who answer us positively for an interview and members of town planning firms working on the Paris region.

3. Results

The date of approval of the 240 selected documents varies between 2005 and 2021. After this date, certain municipalities approved an urban planning plan at the inter-municipal level. However, it seemed interesting to present this photograph at the municipal level. At the municipal scale, it is easier to territorialise the issues and to better appreciate a diversity of treatment according to the municipalities and the UA's forms. At this scale the differences between political and territorial contexts emerge which are sometimes hidden at the inter-municipal scale.

3.1. Mention of urban agriculture in local land-use plans: a limited use of the concept

We quickly notice that there are significant differences in treatment: i-among the municipalities selected but also ii-between the presentation report, the strategic project and the urban design guidelines.

Regarding the first point, there are some municipalities that mentioned the different forms of urban collective agriculture 52 times at most and 84 times at most for urban domestic gardens, and other municipalities only once in a passive form such as *'there are urban domestic gardens in this area'*. Furthermore, concerning the urban collective agriculture, few municipalities (n=6) do not refer to any forms looked for in the text (collective gardens, community gardens, allotment gardens, urban microfarms and urban agriculture). The reasons for their absence in the land-use plans could be manifold. For example, some territories seem not to have developed such projects yet (e.g. Levallois-Perret municipality), or their implementation does not entail integration in the documents. For example, the Clichy municipality which established its plan in 2010 and modified several times till the 2019 does not mention the allotment gardens despite the fact that they have been renewed in 2018 and have been considered, as it appears on the city's website, as an '*island of freshness within a very mineral environment*'. Conversely the municipality of Boulogne-Billancourt launched a modification procedure to allow '*the introduction of provisions to promote the development of urban agriculture*'.

Concerning the second point, the presence and frequency of UA forms are greater in overview reports than in strategic projects and in urban design guidelines (document in which there are fewer). On average, the keywords researched are much more frequently mentioned in the presentation reports: an average of around 10 occurrences can be observed in these reports, compared with around 1 occurrence in strategic projects and in urban design guidelines. If we assume that there is an upward hierarchy in terms of political commitment between these documents, we can therefore say that those terms are less frequently stated in the context of concrete measures, implying a regulatory implementation. Even more so as most occurrences - regardless of the document - are passive uses of the term where 'garden' is a qualifier to describe suburban landscapes without any targeted issues being raised.

3.2. What functions for urban agriculture and domestic gardens in cities?

The thematic analysis of references in the local land-use plans carries out to highlight a ranking of stakes according to municipalities and UA forms (Tab.1).

Tab.1 Functions associated to selected keywords.

Functions associated with UA	Datasets		
	Urban collective agriculture (n=40)*	Urban domestic gardens (n=200)*	
Environmental functions	50 %**	Services for biodiversity	68.5%**
		Green and blue networks	51%
		Water management	34.5%
Landscape planning functions	45 %	76.5%	
Social functions (living environment, social life)	45 %	28%	
Economic	10 %	N/A	
Food self-production	5 %	4%	

**number of local land-use plans analysed within the two surveys*

** % of the number of local land-use plans *that mentioned* related functions

In the table 1 we considered all forms of urban collective agriculture have been considered without making a distinction by type, which has been done in the following analysis.
Environmental functions are one of the most highly quoted in the two datasets, all land-use plan parts combined. For urban collective agriculture, they are in first rank, quoted by 50% of municipalities they also appear to be a quarter of the total functions identified by the survey. They are related to allotment (46.8%) or community (23.4%) gardens and professional urban agriculture (14%). Most of these issues concern their contribution to the green grid and corridor, and biodiversity protection. There are specific features based on the UA types. Concerning professional urban agriculture, it is also cited as a tool to fight against heat islands and be more resilient to climate change. Furthermore, the roofs are identified to few municipalities as an undeveloped space to enhance those projects. Regarding community gardens those stakes are often associated with the social ones. For example, by emphasising that gardens are spaces where biodiversity and social bonds can be strengthened: '*Biodiversity protection must be seen as an element of "living together": community gardens or planted terraces, these spaces are meeting places that strengthen social ties, enabling people to play an active role in their well-being in the city'* (Nanterre, Local land-use plan). Regarding UDG, biodiversity support functions are in second rank, after landscape functions and are quoted by 68.5% of local-land use plans. There, advantages of UDG for green and blue networks (51%) and for water management (34.5%) are less often quoted. The pollution issues are considered in two different ways: on the one hand making sure the quality of the soil is not polluted to allow cultivation, and, on the other hand, pointing out how these spaces can contribute to reducing air pollution. One can see that municipalities do not have the same perception and management of risk (Baudelet, 2015).

The functions related to 'landscape planning' are quoted by 45% of the urban collective agriculture dataset and 76.5% of the UDG dataset. Two main issues emerge regarding urban collective agriculture. On the one hand, the desire to maintain and enhance UA areas to guarantee a balance between greens and built spaces (42% of local land-use plans). The

presence of green areas in some municipalities is also identified as characterise the territorial identity: '*Chevilly-Larue is an urbanised town with a combination of urban forms and an interweaving of planted and built-up areas that give it its identity and landscape*.' (*Chevilly-Larue's land-use plan*). On the other hand, UA projects as indicated as a tool to reclassify and manage the border and the fringes (17% of local land-use plans). For UDG, landscape planning - first quoted function- is related to urbanisation fringe issues too. It is also cited related to residential area identity issues because they are recognised as an important element of this area's aesthetics.

The social function emerged in second position for urban collective agriculture (45%) and lower down the ranking for the UDG dataset. For urban collective agriculture, they concern 22% of total issues quoted. Differences between urban agriculture forms emerge for the social dimension. Regarding UDG, they are associated with leisure and relaxation needs of inhabitants in an intimate space hidden by vegetation and also to the idea that UDG improve their living environment beyond private areas boundaries by greening streets. The allotment gardens are also associated most to leisure and relaxation (e.g. allotment *'gardens provide a previously underestimated means of evading the world through nature and gardening' – Montreuil's land-use plan*). The community gardens there are more references to the reclaim and opening of space to citizens and to the convivial dimension. They can also be seen as places to create new social relations between social groups based on shared issues, as in this case between peri-urban farmers and urban allotment gardeners: *"This area is also a meeting place for the gardens and the farming world. A shared space could be created to perpetuate the crops of yesteryear while fostering social links."*(*Soisy-sur-École's land-use plan*).

The economic functions are cited only by 10% both of municipalities and issues count and it is related to professional urban agriculture. In the Morangis urban development plan, urban agriculture is perceived as a tool for revitalising agricultural areas suggesting innovative projects and activities. In other municipalities it is more traditionally identified as promoting local activities that encourage short chains and local production. For UDG, this dimension didn't rise during the inductive thematic analysis given the non-market nature of individual gardening. The economic benefits of self-produced food for households were not discussed either.

Among the least mentioned is the food function. The issue of self-production is mentioned by only 4% of municipalities. In the following extract, the most detailed one on self-consumption that we could find, the idea of urban food governance emerges: vegetable garden would be a means of overcoming socio-economic inequalities between resident: "*However, it is worth noting the importance of gardens to local residents, as they contribute to a comfortable lifestyle (leisure gardening, production of fruit and vegetables for household consumption, for example). They also play an economic role for modest households, by encouraging the self-production of vegetables*" (*Brunoy's land-use plan*). Out of 200 local land-use plans, this is unfortunately the only time this dimension has been substantiated. Paradoxically, the feeding function of vegetable gardens is emphasised more often, not for human consumption, but for wildlife. They are thus seen as favourable to urban biodiversity: *"Orchards, gardens and, more generally, the 'urban' environment should be taken into account for their ecological function, particularly those linked to older housing, which can host and provide food resources for a whole range of wildlife adapted to these environments."* (*Bouray-sur-Juine's land-use plan*). Concerning urban collective agriculture, the supply function is cited only in two plans and it is associated with allotment and community gardens respectively as spaces that fulfil '*space for harvesting own*

grown fruit, vegetables and flowers' (*Champigny-sur-Marne's land-use plan*) and '*nourishing production function'* (*Boulogne-Billancourt's land-use plan*).

3.3 Implementation in planning bylaws

For the moment, we focused our analysis on the more descriptive parts (overview reports, strategic projects and urban design guidelines), where the issues and functions associated with urban agriculture are detailed. However, it is in the bylaw that the general rules and land-use restrictions required to achieve the objectives are set up, in line with the strategic development vision. The bylaw is binding on all public and private bodies for the execution of any works or constructions and specify the use of the land (use, nature of activities). The affectation uses are regulated by zoning according to the French Urban Planning Code: 'Urban zones' for already urbanised areas (i.e. developed areas already served by water and electricity networks), 'development zones' for underdevelopment zone, 'agricultural zones" for fields and others cultivated areas and 'natural zones" for forests, meadows and other areas of environmental interest. Each type of zone permits or prohibits specific land uses. For the dataset on collective urban agriculture, we analysed which of these zoning types was used to classify the surface areas occupied by allotment gardens, micro-farms and so on.

Almost half of the documents analysed do not address collective urban agriculture in their bylaws. Furthermore, their integration into town planning regulations is often limited to building regulations. The rules often concern the size of garden sheds regarding allotment gardens or infrastructures for urban agriculture. The French Urban Planning Code does not identify an exclusive zoning for urban agriculture. So, the municipalities care therefore free to allocate zoning according to function's priority and their development strategy. In terms of zoning, most cases of collective urban agriculture are in urban or natural zones.

If we examine in more detail, those zoning have some limitations. On the one hand, urban zones are specifically intended for urbanisation because are the '*already urbanised areas and areas where existing public facilities or those have sufficient capacity to allow constructions to be built*' (*article R151-18 of French Urban Planning Code*) and this zoning does not in itself protect urban agriculture forms. Collective urban agriculture can be incorporated into some sectors of this zoning, often those designated for green spaces. However, as the emphasis is elsewhere, the protection is not fully guaranteed in these zones, complementary protections should be associated. Regarding the natural zones, the article R151-24 of the French Urban Planning Code defines them as areas of the commune areas of the commune to be protected '*their character as natural areas*' or the need to '*preserve or restore natural resources*'. Construction is limited in these areas, to preserve the zone as much as possible, and thus the gardens. The written regulations may modify the rules of constructability, by accepting garden sheds, for example. The natural zone is well suited to this purpose because, in addition to including the protection of gardens in the territory's objectives, it allows the definition of specific and customised rules. However, there are also cases where these projects can be installed in all zones. For example, the municipality as Boulogne-billancourt allows the implementation of urban agriculture projects in almost all areas without confining them to a specific zoning. However, they do not think that this choice has had an impact in the development of these areas.

In very limited cases are allocated to specific zoning or agricultural (A) zones. The first solution is the least chosen, the municipality of Thiais or Vitry sur Seine mobilised a specific zoning: Nj defined respectively as a '*reserved for allotments or collective garden sites*' (*Vitry's land use plan*) or "r*eserved for leisure activities (archery, allotment gardens)*" (*Thiais' land use*

plan). The Montreuil's land-use plan zoned the major agricultural area of '*Murs à Pêches*' as agricultural zones and the municipality identified a "derogatory area". These derogatory areas are defined in the French legislation as "sectors with limited size and capacity" where limited building rights are allocated although in agricultural or natural zones.

The exception of a few derogatory areas in natural zones is also implemented to UDGs, which are almost always located in urbanised areas. So, in the UDG survey, we focus more on sub-zonings of urban areas. Municipalities can use different kinds of rules, set out in bylaws such as sub-zonings which limits the uses and actions on both public and private land within a freely defined perimeter of the urban territory:
First, there is 'protected cultivated land': It applies to land in urbanised areas such as allotment gardens, tree nurseries, orchards and any other land with agricultural vocation that has been cultivated in the past, if it is not currently being cultivated at the time of its classification. In theory - by its title - this is the protection zoning most likely to maintain the food production purpose of UDG. However, the goals of this sub-zoning defined in the national urban planning code are above all focused on the functions of maintaining biodiversity and ecological corridors: *'It may locate, in urban areas, cultivated land and undeveloped areas necessary to maintain ecological continuities to be protected and non-constructible regardless of the facilities, if any, that serve them.*' (Article L.151-23 of the French Town Planning Code). It is also used in setting up landscape buffer zones in some municipalities: "It should also be noted that to preserve landscapes, a steeper setback from agricultural and natural zones is imposed in the parts of land covered by the 'cultivated land to be protected' grid in order to ensure smoother landscape transitions." (*Longevlliers' land-use plan*). In terms of regulation, just like zoning based on 'landscape components' - defined by the same article - the defined perimeter is considered un-buildable. Unlike 'classified wooded areas' and other 'landscape features', no prior declaration is required for work on or removal of orchards. Furthermore, there are no specific rules to guarantee the quality of cultivated soil, for example, or to ensure the continued presence of certain inherited or vulnerable cultivated species. This raises the question of the relevance of this regulation in relation to its theoretical aims.

Municipalities can therefore choose to classify their UDG as 'landscape features', which gives them greater control over their land use. To justify this classification, but also because it is a function perceived more systematically than their self-production function, municipalities justify the vegetable garden's contribution to urban landscapes. It brings a hint of 'countryside' to the city: '*A significant amount of greenery, in the form of vegetable gardens, fruit trees and climbing plants on the party walls bordering the Yvette, gives the whole area a rural feel.*' (*Bures-sur-Yvette's land-use plan*).
More indirectly, vegetable gardens appear to be a positive externality on land that has been classified as un-buildable for other motives. As for example, in this commune crossed by a river, with a 'flood risk area' perimeter: '*We do have a few plots that remain, particularly at the bottom of neighbourhood X, on the banks of the Yvette, so we are in a flood-risk area. So, thanks to that, it has kept a bit of its use as a vegetable garden'* (elected town planners from an intermediate density municipality).

On the contrary, other rules that do not aim to protect these cultivated areas can have a negative impact on the practice of vegetable gardening by limiting the potential for cultivation, as illustrated here by a member of a town-planning firm interviewed: *"You have to be careful when you introduce such zoning or rules, with the actual design of the rules and the way in which they are superimposed, because you can block any use of the garden, the possibility of installing a garden shed or cultivation by prescribing too many trees, and that can also be negative for*

biodiversity because people say: "well we can't do anything about it.". Similarly, in an almost all municipalities studied, legal uncertainty surrounding infrastructures such as greenhouses, resulting from a poor foresight by planning authorities and consultants, may be a disincentive to the establishment of perennial crops in UDGs.

4. Discussions

4.1. Integration of UA and UDGs in urban planning is heterogeneous

Although we did not carry out a comparative analysis between our keywords and other topics of interest to the planning as transport, as realised by Blanchart *et al.* (2019) concerning their survey on soil and biodiversity integration on land-use planning, the results seem similar. The findings reveal that UA and UDGs are issues which are not largely addressed in studied land-use plans. The number of occurrences is relative (52 times at most for urban collective agriculture and 84 times at most for urban domestic gardens) considering the size of these documents, which can lay 1000 pages. Moreover, it has been observed a diversity of treatment of the subject according to the municipalities based on their territorial context and willingness to integrate or not this matter in their political and territorial project. However, even when this topic is addressed, we observe that they are regarded more in the presentation part of the local land-use plan that remains more declarative than operation and regulatory.

Other unequal treatment also appears according to the urban agriculture forms. If the UDGs are almost always considered because they are associated with specific urban fabric (suburban area or individual housing), our results regarding the collective urban agriculture confirmed, as demonstrated by Consalès *et al.* (2018), that the allotment gardens are one of the forms of UA best considered by urban planning.

4.2. A food function not contemplated in urban planning.

We would like to emphasise that not all functions are equally considered. If environmental, social and landscape planning functions and associated issues (biodiversity support, flood risk management, balancing of urban and unbuilt space, social bonding…) are more or less quoted, the food production function is largely omitted. We noted a discrepancy between the functions provided by UA identified in land-use plans and those highlighted in the academic literature. Although there is still no precise estimation of the food contribution as indicated in the introduction, some authors underline vegetable gardens contribution to the food resilience (Taylor and Lovell, 2014). They increase the food security of low-income individual households (Kumar and Nair, 2004; Buchmann, 2009; Gerster-Bentaya, 2015; Siegner *et al.*, 2018), decrease the vulnerability of households in times of economic, supply or other crises (Seeth *et al.*, 1998; Buchmann, 2009) and enhance social resilience in unsecured context by promoting values such as *"diversity, self-organisation, and adaptive learning and management leading to and positive feedback loops"* (Tidball and Krasny, 2007, p. 151).

For UDG's this lack of consideration from urban planning actors can be attributed to several factors: firstly, a difficulty in identifying the extent of the vegetable gardens within UDGs: aside from food production, UDGs support a diversity of practices. When they are cultivated, it is difficult, without photo-interpretation analysis, to identify the extent of cultivation.
Secondly, there appear to be some cultural obstacles. Indeed, there seems to be a prejudice on planners' perceptions that any resident who owns a house with a garden would have an above-average income and would therefore have no economic interest in cultivating their own garden. However, some research conducted on vegetable gardens showed an important intra-

urban variation in the spatial distribution of vegetable gardens depending on the social composition of neighbourhoods and the structure of the housing stock: proportion of houses with gardens, proportion of homeowners (McClintock, 2016; Marie, 2019) and parcel size (Darly *et al*., 2021). Furthermore, drivers for self-production may have other purposes than just economic ones, as the literature on food production in UDGs and collective gardens has shown (Schupp and Sharp, 2012; Pourias *et al*., 2012) it can be led by rejection of unsustainable industrial food (Weber, 1998; Kortright and Wakefield 2011), cultivation of varieties or species that are not or no longer found locally - which could also be seen as an interest in the biological conservation of biodiversity (Aguilar-Støen *et al.*, 2009; Galluzzi *et al*., 2010); or maintenance of inherited practices and varieties that contribute to the cultural identity of the inhabitants (Kortright and Wakefield, 2011; Mazumbar, 2012). However, the local urban plans analysed for this study do not take account of such issues. At urban planning scale, the food self-production is still not recognised as they should by cities to enhance local resilience.

4.3. In search of zoning regulations suited to the multifunctionality of agricultural spaces

Lastly, we would like to stress that they are no common and dedicated planning tools for UA regulation. UA projects are mostly classified in natural or urban zones, but more rarely in agricultural zones. This could be explained by the fact that the classification of an agricultural zone by national urban planning code is based on the agronomic, biological or economic potential of the agricultural land. Therefore, development rights are restricted and should be connected to agricultural activities. The urban and natural zones in some cases may be more relevant for environmental and social functions of UA. At the same time, planning regulations in urban zones allow a reversibility of land use (and greater flexibility for building rights supporting diversification in farming activities (conditioning, on-farm sale, agri-tourism, etc.). By contrast, agricultural zones may be more restrictive, except in except for derogatory areas. Aragau and Desrousseaux (2023) explored the difficulties and barriers to the implementation of agriculture into planning, through field surveys in the Paris region, and underline that local planning authorities are reluctant to implement protective regulations for farming activities, in order to give some flexibility for future housing projects. But in some cases, local initiatives promoting re-territorialisation of agriculture may help to design adapted regulations for these farming activities. A better integration of agricultural activities in planning policies is in line with on-going initiatives to connect urban and food planning (Liu, 2023).

Furthermore, the adoption of the Climate and Resilience Act[2] edicting the no net land take objective by 2050, will sharply limit urbanisation of forested and agricultural areas and favour densification in already urbanised areas. However, according to recent implementation decrees (Decree nr. 2023-1096, 27 November 2023) a typology of urban soils has been drawn up in which 'Areas used for residential purposes, secondary or tertiary production, or for infrastructure such as transport or logistics, where the soil is covered by herbaceous vegetation' under 2500 m² – in which most of UA could belong- will be considered as artificialised and could be used in building projects. If UA projects are not conceived and protected over a long-term period, they may be vulnerable to pressure on land in a context of intensifying urbanisation. In our opinion, the ability of stakeholders to perceive issues involved in this relocation of agriculture within cities is the main condition for the introduction of regulation protecting urban agriculture.

Our study also leads to recommendation for a dedicated legal framework (with both flexible and protective zoning) taking into account all the functions and related differences among the urban agriculture types. We suggest that specific assessment tools could be designed for UA,

[2] Law n° 2023-630, 20 July 2023, facilitate the implementation of objectives to reduce land take and strengthen support for local elected representatives.

providing analysis of their potential contribution to local food consumption and to ecosystem services taking account of spatialised social inequalities (Qiu *et al.*, 2023). All forms being multifunctional, it remains a specificity linked to the vocation of market or non-market production. The challenges among the different forms of UA are not the same: a distinction should be made among the amateur gardening and the professional urban agricultural. The challenge is to be able to manage the trade-offs between social, environmental and food production functions according to the specific vocation of those different forms.

5. Final Remarks

The survey conducted on 240 local land-use plans and their integration of UA and UDGs functions and issues highlight that the most expected functions are related to environment, landscape management and social dimensions. The economic and food production functions are limited and not considered yet. These findings are consistent with the analysis of bylaws (which concerns in particular urban and natural zones). With our approach taking into account the various forms of urban agriculture, we were able to show that both domestic garden and collective agriculture functions need a better understanding of their functions and better tools in local land-use plans for cities' resilience.

Rethinking the place of agriculture in the city has become all the more urgent in the context of the battle against urban sprawl, which recently led to the adoption of the Climate and Resilience Act. Local authorities should increasingly be looking at the place of non-urbanised spaces and the renaturation of towns and cities including UA and UDGs' protection. Urban agriculture and urban domestic gardens are likely to contribute to cities' resilience at the lever for climate change adaptation but also for food provisioning. To be more effective the land-use planning should be integrated. Policies at a greater scale and sensitisation of local stakeholders on UA's function could lead to a better integration of environmental, social, and economic resilience provided by UA in local land-use plans.

Acknowledgments

The authors acknowledge the support of the CBASC (Université Paris Saclay) for their founding of PERIJARDIN project, and the French National Research Agency (ANR) for their funding of GARLAND project. Furthermore, the authors thank Valentine Temple for having carried out preliminary investigations in the framework of the SEMOIRS project (2018-2020) funded by ADEME and Oriane Bonnal that continued those investigations thank to Urban Agriculture Chair of ParisTech Fundation funding.

Planning tools and building regulations towards greening densely-built Greek cities: scales of 'urban green grabbing'

Keywords: urban green grabbing, planning tools, environmental incentives, Greek crisis

Abstract
'Green' urban development is the dominant paradigm of spatial planning and is framed by changing overarching concepts such as sustainability, resilience and more recently climate neutrality. As the Greek spatial planning system has incorporated the objectives of greening cities, the paper highlights the need to assess new tools of urban development and planning in Greece in terms of their cumulative impact on the urban landscape, both in terms of the image of the city and their actual contribution to the pressing goals of improving environmental conditions and adapting to climate emergency. The paper activates the concept of 'urban green grabbing' as introduced by Garcia-Lamarca et al. in 2022, that studies green urban development through a socio-political lens and highlights the grabbing of urban common resources that is promoted in the context of environmental protection and energy conservation. Through this perspective, the paper critically presents the nature of environmental incentives and planning tools related to urban greening, that were introduced during the financial crisis and discusses the outcomes of such tools in the image and the environmental conditions of densely built Greek cities.

1. Introduction

Urban development in tandem with the natural environment, from the local to the planetary, has been a dominant 'paradigm' of spatial planning since the early 1990s, promoted through international organisations and networks, national and urban policies and framed by changing concepts such as sustainability, resilience, and more recently climate neutrality. Planning at all scales, from regional planning to urban design and the regulation of development of individual plots, has been driven by the environmental protection mandate. There is common understanding that this mandate does not anymore concern only untouched landscapes of exceptional aesthetic or ecological value or tamed agricultural land. Environmental protection, during the last decades, has been extended to include socio-natural urban ecosystems, which are recognised as a critical spatial level for promoting sustainability, resilience and, more recently, targets such as decarbonisation and climate neutrality. These changing framings of environmental protection are introduced as global goals, through non-binding documents of international organisations, such as the UN Sustainable Development Goals (SDGs) and the European Green Deal. They have also been incorporated into the institutional framework of spatial planning in Greece and have been integrated into the discourse and targeting of urban interventions, through EU funding programmes and international networks.

The economic crisis that broke out in 2008, starkly affected Greece since 2010, while its ending year is debatable and blur. Between 2008 and 2016, private construction activity in the country recorded a continuous decline (ELSTAT, 2019). Amidst the full spectrum of austerity

politics, spatial policies acquired a prominent position. The years of the crisis have been rich in the production of laws and regulations, reforming the legal framework of urban planning and land development. Notwithstanding the environmental rationale of many introduced tools and codes, the dominant imperative of this period was to accelerate the implementation of land use plans, facilitate land development and overall 'improve the business environment' in the country. Construction activity started to recover reluctantly since 2017 (ELSTAT, 2019). Thus, the effects of new planning tools and regulations concerning development of public and private land started to become visible in cities from 2020 onwards.

The paper focuses on new planning tools and building codes that were introduced in the Greek framework of spatial planning and land development, during the period of the economic crisis, with the stated intention to promote sustainability & energy transition and more specifically to "green" densely-built cities.

First, the concept of 'urban green grabbing' is introduced and its application is extended to the 'commons' of the urban landscape, as produced cumulatively by the development of small individual plots of private property, as well as through larger and more salient urban development projects, led by public or private actors, or the combination of the two. Then, the characteristics of urban green grabbing in the urban landscape of densely built Greek cities are explored in the contemporary condition of the presumably post-crisis era. Specifically, the paper examines the incentives introduced by the New Building Cod (NBC) of 2012 and the environmental objectives embedded in the relatively new planning tool of Special Urban Plans (SUPs), which concerns usually large properties or areas, within urban areas or beyond.

It is argued that urban green grabbing, performed through new planning tools introduced by the state to regulate land development and promote urban greening, concerns 'urban commons', such as the image of the city, the urban landscape, public space and ultimately the quality of life of the city's inhabitants.

2. Urban Green Grabbing

Land grabbing is a global phenomenon and refers to encroachment and illegal use, selling off in terms that harm the public, privatisation and changing institutions that create conditions for land privatisation (Hadjimichalis, 2014). Green grabbing refers to land grabbing legitimated on the grounds of environmental protection. Like land grabbing in general, 'green grabbing' is an international trend with local manifestations and specificities and with a clearly more pronounced appearance in poor countries of the Global South. The term belongs to the Guardian journalist John Vidal (2008), who referred to the privatisation of land to protect biodiversity, to capture carbon dioxide, to reduce global warming and climate change, to grow energy crops in order to make the energy transition from fossil fuels to renewable sources. In the post-financial crisis period, the term can be used with reference to large-scale renewable energy installations - wind farms and photovoltaics - which, in the name of mitigating the planetary problem of climate change, degrade landscapes and ecosystems and legitimise the grabbing of land in Greece and other countries (Apostolopoulou & Adams, 2015).

Land grabbing for the promotion of environmental goals is part of the general discourse on 'green economy', i.e. the possibility of accumulating capital and at the same time promoting environmental protection, or better still, accumulating capital through processes aimed at protecting nature. This is a dominant approach, developed as early as the 1990s, in the context of 'ecological modernisation' (Mol & Spaargarden, 2000) and the related target concept of sustainable development. Environmental protection has since been placed at the

centre of the global economy and is no longer associated with a critical discourse towards the dominant development model, as was the case with earlier manifestations of the environmental movement. Instead, 'ecological modernisation' supports that the only way to protect the environment is through economic growth within the capitalist model.

As Fairhead, Leach and Scoones (2012, p. 242) observe, this entanglement of environmental protection with market mechanisms "is doubly valuing nature: for its use and for its repair". The first valuing refers to the use, degradation, and depletion of any kind of natural resource by humans, and the second refers to the production of value from the very need to protect and repair nature. The former creates the basis for the later to occur, and the two together create the full value of nature.

Garcia, Lamarca et al. (2022) explore the urban dimensions of land grabbing in cities, introducing the concept of "urban green grabbing". They examine the role of "greening" projects in urban areas in extracting greater value from investment in housing construction in European and North American cities. Adopting a socio-political lens, "urban green grabbing" illuminates the ways in which, interventions to "repair" the urban environment, adapt to climate change or mitigate its impacts are linked to the production of additional economic value. Urban land investors appropriate greater profit, social capital and prestige by locating their investments in close proximity to new "green" projects, near parks, greenways, green and blue infrastructure. At the same time, Garcia Lamarca et al. highlight phenomena of 'green gentrification' and intensification of social inequalities associated with urban strategies aimed at urban sustainability, climate change adaptation and resilience.

In the quaternary constitution of land proposed by Hadjimichalis (2014, pp. 28-30), inspired by Lefebvre, land is not just its physical-geographical delineation on the map, but also the intangible relations that are created between specific parts of land and specific individuals, groups and regions. In this sense, urban plans, land use and other conditions that regulate the terms of use and development of land constitute one of the four dimensions of land. These intangible relationships are created by the state, that still allocates development rights and designates land uses. Thus, they selectively assign "the privilege of collecting high rents", in other words, the privilege of extracting high value from their land (ibid. p. 29).

Through such an understanding of land, the concept of urban green grabbing is extended to highlight how, privileged development conditions are created for specific parts of land, development rights and permissible building heights of specific urban plots are haphazardly increased, and thus the urban landscape is unpredictably transformed and cumulatively undermined through specific institutional provisions that seek to promote environmental objectives for Greek cities.

3. "Greening" with incentives

In Greece, the introduction of incentives aiming at producing environmentally friendly buildings was introduced with the New Building Code (NBC) of 2012 (Government Gazette 79/A/9-4-2012). The NBC provides voluntary incentives for high environmental performance certified through Leadership in Energy and Environmental Design (LEED) or other international rating system, for renewable energy installations and for reducing buildings' coverage on the ground to increase green spaces in densely-built urban areas.

In particular, Article 10 of the NBC gives incentives for "environmental upgrading and improvement of the quality of life in dense urban areas". These concern the entire territory of the prefectures of Attica and Thessaloniki, as well as the municipalities of Patras, Larissa, Heraklion, Volos and Nea Ionia, Magnesia and Ioannina. Traditional settlements, traditional parts of towns and areas designated as historical sites are excluded.

The main aim of these incentives is to increase the amount of unbuilt open space in urban areas. Thus, new buildings constructed in the aforementioned areas are given a bonus of floor area and bigger permissible height, with the precondition that they cover a smaller proportion of the plot, than permissible in the area. Under certain conditions, a bonus of additional floor area is allowed on properties that reduce the coverage implemented to between 10 and 35 percent (%). The bonus of additional floor space can be up to 25 percent (25%), in excess of what is permissible in the area, when public access is granted to the resulting unbuilt part of the plot and a pre-existing "lower energy class" building is "withdrawn", i.e. demolished, from the same plot. However, the bonus is also given for smaller reduction of ground coverage, and without the condition of public access to the remaining unbuilt space (Article 10, paragraph 1, case a). As permissible plot ratio is linked to permissible height, the incentive to increase building automatically means a corresponding increase in permissible building height.

For large properties of at least 4000m², which concede 100% of their unbuilt part of the plot to public access, the bonus provided increases the permissible floor space by 35 percent (35%), also adding up to 30 percent (30%) extra height, again subject to a reduction of ground coverage (Article 10, paragraph 1, case g). The resulting unbuilt area is open to public use, and is landscaped and maintained by the municipality.

Article 10 seems to be inspired by the 1961 New York City Zoning Resolution, which is one of the first planning tools based on incentives to achieve goals for the common good. The ordinance incentivised additional building rights and height to buildings that reduce coverage of the plot and conceded the remaining unbuilt surface - small plazas or arcades - to common access. It allowed up to a maximum of 20 percent (20%) more floor area above that permissible in the area, in exchange to the creation of accessible open space on the ground (New York City Planning n.d.). This law became very popular among developers and led to the creation of the so-called POPS (Privately Owned Public Spaces). There are currently more than 550 POPS (NYC Planning n.d.) in downtown New York City, including high-profile examples such as Paley Park, notable for its design and handling of environmental conditions, and Zuccotti Park where the Occupy movement unfolded in 2011. New York City Zoning Resolution, through successive amendments, set a number of restrictions regarding the location, the size and the shape of the resulting open spaces, as well as design specifications with regards to the orientation, amenities, accessibility, planting and interior pathways. However, the "publicness" of POPS has been widely questioned. It has been observed, that POPS are not really open to the public, who are often actively discouraged from using the plazas, either through design strategies or with a variety of operating rules introduced by the owners and managers (Smithsimon, 2008).

In the case of Article 10, the bonus of additional floor area is granted, even when there is no public access to the resulting unbuilt area on the ground (case a). For higher percentages of coverage reduction, common access is required, and is granted to the municipality by a notarial deed. The municipality is responsible for landscaping and maintenance of the ceded open space. However, there are no restrictions regarding the shape and size of the accessible

part of the plot, except that it must be "continuous with a common use area as designated at the urban layout and one side of the ceded space, must coincide with the entire length of the plot's boundary towards the street, provided that it [the ceded open space] is at least 1.5 metres deep" (Government Gazette, 2012).

Figure 1 A newly built apartment block in Thessaloniki, utilising the combined effect of several environmental incentives of NBC and its publicly accessible open space

Given the small size of plots in Greek cities, the benefits of granting public access to these unbuilt remnant spaces are debatable. The case shown in Figure 1 is indicative. The 486.05m² plot is located in Kalamaria which is one of Thessaloniki's municipalities, at the eastern part of the urban conglomeration. It is a relatively large plot, given that the minimum buildable plot size in the area is 200m². Taking advantage of the provisions of Article 10 of the NBC, (paragraph 1, case d), a bonus of about 25% extra floor space and 5.4m extra height - from 26m, which is the permissible height in the area, to 31.40m - was granted to this plot. These bonuses were won by reducing the plot coverage by 12 percent (12%), providing public access to 97.22m² of open space, creating a green roof and a swimming pool on the roof and demolishing a pre-existing building "of lower energy class". The space granted for common use is distributed on two sides of the corner plot and is L-shaped, while the depth of it measured from the property's boundary towards the street to the building is a maximum of 4.85m (Figure 1). As the example illustrates, the publicly accessible space produced in a relatively big plot is rather small and divided into two parts. At the same time, the combined effect of different NBC incentives, result in a building that stands out in the neighbourhood, with its enlarged volume and protruding height.

In addition to Article 10, Article 15 of the NBC gives bonus height of 1 metre when a green roof is constructed. The resulting height may exceed the height permissible in the area and the maximum permissible anywhere in the country, which is 32 meters. Also, Article 19 allows a main use built space of 35m² in excess of the permissible height, when a green roof is

constructed. The same bonus applies when renewable energy facilities are installed on the roof.

Finally, Article 25 provides height and floor area incentives to new buildings with reduced energy consumption. In particular, a 5 percent (5%) increase of the plot ratio, i.e. more floor space, is granted to buildings with up to 10 kWh/m^2/year energy consumption for heating, air conditioning, ventilation and lighting, and a 10 percent (10%) increase to buildings certified by an international rating system, such as the American LEED.

It should be noted that in addition to the above, which can be utilised in combination when applying for planning permission, permissible floor area is increased by other NBC provisions, that do not have an environmental objective. For example, stairwells, attics and mezzanines are not calculated in the building's gross floor area.

The specific urban planning regulations, through an environmental protection rationale, promote the increase of built floor area and, thus, urban densities in the already densely-built Greek cities, increase pressure on existing technical and social infrastructure, create contestations between neighbouring sites in the name of increasing green spaces and saving energy.

Incentives promoting green practices for new buildings also lead to increased building height, which often far exceeds what is permitted in urban plans, currently in force. Increased building heights contribute to the production of a new haphazard urban landscape, characterised by lack of control, coherence and continuity, and unpredictably interspersed with salient 'landmarks' of 'green architecture'.

These extra building heights are introduced randomly, without any documentation, without any control of the desired urban image and without addressing the negative impacts and planning for the necessary infrastructure. In addition, they degrade the environmental conditions of the neighbourhood, in particular the conditions of insolation and ventilation of the streets and surrounding buildings, and restrict the views of buildings adjacent to them. At the same time, the actual gain in accessible green spaces, mostly because of the small size of plots in Greek cities, is disputable. Lack of detailed design specifications regarding the size, shape and amenities of these spaces also reduces their positive impact.

The effects on the structure, function and image of the city from the implementation of the above have already become apparent, as many new apartment buildings under construction seem to far exceed the heights of their neighbouring buildings. Given that designated historic areas are excluded from these provisions, these random additions of incongruent heights, protruding several storeys above their neighbouring builidings, do not occur in historic centres, but in the densely built neighbourhoods beyond the centres, which lack infrastructure, identity and general care as they are not particularly visible, adding a further layer of degradation.

Moreover, incentivising additional built square metres of floor area and greater height for new buildings to "withdraw buildings of lower energy class" promotes the demolition of older uninsulated building stock. These older builidngs, may not be listed, but contribute their smaller scale, rich texture, architecture and memory, thus enriching the identity of neighbourhoods. It seems predestined that, not only unbuilt plots will take advantage of the voluntary environmental incentives of the NBC, producing enlarged and taller buildings, but

also that there will be a swift "withdrawal" of any remaining evidence of past architecture and memory from the neighbourhoods of Greek cities.

It should also be noted that, although the aim of the incentives of the NBC is to increase open space in densely-built urban areas, excessive volumes and heights also materialise in suburban neighbourhoods that are not densely-built and do not lack green spaces, undermining the urban landscape and the quality of life in these areas. Such suburban municipalities in Athens have recently appealed to the Constitutional Court to block buildings, that utilize such incentives from being constructed in their territory (Lialios, 2024).

4. Green landmarks

All the above, have started to become apparent in recent years as construction activity in the country was relaunched, after years of almost total halt. At the same time, proposals for new large-scale developments utilising the planning tool of Special Urban Plans (SUPs), as well as other types of legitimate exceptions to existing plans and regulations, are proliferating. Introduced in planning legislation, initially as Special Spatial Plans, during the crisis in the context of the so-called 'urban planning reform', SUPs '.... may modify previous Local Spatial Plans and any general and specific planning regulations applicable to the area of the project, in particular as regards permitted landuses and building codes and restrictions'[1].

The introduction of the Special Urban Plans (SUPs) legitimates bypassing existing planning provisions for projects of "supra-local scale or strategic significance", including programmes of urban regeneration or environmental protection or plans dealing with the consequences of natural disasters and when there is 'the imperative for rapid completion of first-level urban planning by the state, due to critical spatial problems that require immediate action or the prevention of the creation of ad hoc conditions, due to a lack of or inadequate planning". Special Urban Plans may be initiated by different agents, public or private, and may concern different scales of planning and different themes.

It should be noted that, the 2020 Law (Government Gazette, 2020) that finalised the specifications of SUPs, was aimed at "simplifying, accelerating and improving the efficiency of the spatial planning system" (Chapter A). Through this selective "acceleration" of spatial planning processes, the possibility of comprehensive planning and regulation of urban space is undermined or even substituted. In Thessaloniki, in particular, more than 10 such plans are currently being discussed, are at different stages of development or have already been approved, most of which are located in the central municipality and are initiated by private actors.

The most recently approved SUP in Thessaloniki (Government Gazette 734/D/15-9-2023) is indicative of the way environmental rationale is utilised to legitimate bypassing existing regulations and restrictions in force. The SUP concerns the development of an abandoned industrial complex, Kerameia Allatini, which is owned by a local entrepreneur. It envisages, for the first time in the city, the construction of a tall building 100 meters high (Figure 2). As mentioned above the maximum permissible building height anywhere in the country is 32m. The tallest building in the country so far, is the Tower of Athens which is 100m. The Tower and a handful of other buildings in Athens were mostly built during the dictatorship, taking

[1] Initially, Law 4269/2014 Spatial and Urban Planning Reform - Sustainable Development introduced the Special Spatial Plans. Then, they were amended by Law 4447/2016 Spatial Planning - Sustainable Development and took their current form in 2020 by Law 4759/2020 when they were called Special Urban Plans.

advantage of Compulsory Law 395 (Government Gazette 1968) "About building height and the system of fee-standing construction".

The choice of a tall free-standing tower, instead of the typical configuration of the urban bock, for the development of the site of Kerameia Allatini, is legitimated in the SUP on the basis of the reduction of ground coverage and the creation of a publicly accessible green park. It is also argued, that the tower endows the project with characteristics of metropolitanism and supra-locality and "materialises the concept of a landmark". The 100-metre tower will be located only 50 metres from the south side of the listed buildings of the historic industrial complex, which are maximum four storeys tall. In this case, as in other cases of SUPs, important qualities of the urban landscape seem to be undermined, and the image of the city is being transformed *ad hoc* in the name of a dubious environmental benefit. Moreover, the remaining open space, although publicly accessible, introduces a new hybrid type of public space, which is privately owned and managed.

5. Grabbing the urban landscape

According to Article 24 of the Constitution of Greece, "the formation, development, planning and expansion of cities and settlements in general is subject to the regulatory competence and control of the State, with the aim of serving the functionality and development of settlements and ensuring the best possible living conditions" (Constitution of Greece, 2019).

Figure 2 The tower proposed at the Special Urban Plan for the development of the site of Kerameia Allatini in Thessaloniki. Source: Sovitsli 2022.

Both in the Constitution of Greece and arguably throughout most of the history of urban planning, there is an implicit assumption that planning provisions, which regulate, among other things, landuse and land development, aim at promoting the common good or the public interest (Lennon, 2022). This concept is, of course, difficult to define and recent approaches to urban planning have challenged or undermined it (ibid.) However, urban plans and codes that regulate land use and development rights remain the responsibility of the state and are intended to manage urban space, to control density, height, volume, incompatibilities of landuses and contestations and thus, influence positively and equitably the urban conditions and the image of the city. Indeed, the quality of life, environmental conditions and the overall

image of the city are gradually and cumulatively produced by the development of individual plots of land, large and small, public or private.

The legal excesses of floor space and height of new buildings and of the large developments of the SUPs undermine the very identity of the landscape of Greek cities as it has been shaped since World War II, with the medium-rise building block, of predominantly 5 to 7 storeys, produced through the mechanism of *antiparochi* (see Maloutas, Siatitsa & Balabanides, 2020, Theocharopoulou, 2022) as its cell of increment. Architecture historian and theoretician Kenneth Frampton (1987, p.14) described this landscape as a "special civilised level of urban construction, without equivalent in any part of the modern world. ...a very dense and unique texture, woven, one might say, into the fabric of the 19th century, with the weave of a disciplined modern building regulation, which determines both the coverage of the plots, and the height of buildings."

The incentives of the NBC may contribute to achieving the global mandate of reducing greenhouse gas emissions and, thus, mitigating climate change in a measurable manner. However, the environment is not only planetary and measured, but also local and lived. These provisions cumulatively undermine the urban landscape, the image of the city as perceived in the neighbourhoods where city residents live their everyday lives and the environmental conditions of the immediate urban environment (Papageorgiou, 2022). At the same time, the loosely controlled property-led developments facilitated by SUPs, often adopting an environmental rhetoric and a "greening" agenda, introduce new scales and typologies of development to the fabric Greek cities and greater building heights.

The environmental incentives for the development of individual urban plots, the incremental cell of urban development, combined with the large developments of SUPs prescribe the new incoherent landscapes of "urban green grabbing", which is dotted with unpredictable "green landmarks" and new types of public spaces. Through the planning tools of the period of economic crisis, the objective of environmental upgrading of the building stock and improvement of the environmental conditions in cities became inextricably linked to the mandate of accelerating processes of land development and, thus, boosting the economy. A more flexible framework for the production of the urban landscape, is thus sought after, one that encourages more investment on construction and partially outsources the obligation to produce public space to private investors. The open spaces produced, which in some cases may not even be accessible to the public, depart from the traditional model of publicly owned and managed public space and shift to different hybrid models, whose "publicness" is debatable.

Greening the void: actions for the de-sealing and renaturalisation of soils in brownfield regeneration processes

Emanuele Garda
Affiliation: Department of Engineering and Applied Sciences, University of Bergamo (Italy)
Email: emanuele.garda@unibg.it

Abstract
The decommissioning of industrial sites has started a complex 'season' in which different actions for their reuse have emerged. In addition to the preservation of existing structures, projects have emerged that have chosen to combine the actions with soil de-sealing interventions. This 'demolition without reconstruction' has generated a new permeability and created the conditions for new public facilities and the partial renaturalisation. The analysis of a selection of brownfield redevelopment experience makes it possible to compare both the spatial effects and the relative variety of planning policies adopted. The contribution proposes the identification, analysis, and comparison of some regeneration processes of large brownfield sites, selected in two different Italian cities, which are characterised by the promotion of soil de-sealing and the implementation of NbS.

Keywords
Browfield, de-sealing, Nature-based Solutions, Urban regeneration, Urban planning tools

Introduction

We often make the mistake of considering human settlements as natural events because they are influenced by autonomous, uncontrollable, and unpredictable laws of development like those of biological organisms. Cities do not grow out of their own, inscrutable instincts, but are built piece by piece by their inhabitants (Rykwert, 1976). With deliberate actions, communities continue to modify the city, increasing it with multiple elements according to an alternation between use, disuse and reuse that appears as an entirely physiological fact in the history of human societies (Scaramellini, 2018). Within this latter assumption, we can place those phenomena of the decommissioning of large industrial areas, which took place from the 1980s onwards, and which triggered a long phase of investigations, reflections, and applications. It was a complex season that recognised in the recovery of brownfields a common challenge for public policies (Atkinson at. al., 2014) and a relevant factor for the activation of territorial redevelopment processes (Erba, Guastamacchia, 2002).
In the transition from a society with a strong industrial identity to a new post-industrial one (Arcidiacono et al., 2015), different approaches have arisen to rethink these places (Garda, 2018). In addition to the maintenance and re-functioning of existing structures - for only those cases worthy of conservation - and the construction of new buildings by means of demolition and reconstruction, one can recognise experiences that have taken a different approach. As in the two cases discussed in the following paragraphs, one can recognise transformation processes that have also adopted partial or total demolition of the built-up areas with consequent increase in soil permeability and renaturalisation. With this third approach, which is more oriented towards promoting an idea of 'urbanism of demolition' (Rusci, 2021), it is possible to obtain the liberation of areas previously 'sealed' by volumes or built-up areas, increasing soil permeability, creating the conditions for the restoration of certain functions inhibited by sealing processes (Garda, 2020) and promoting the activation of renaturalisation processes. This idea of the removal of built-up spaces as a precondition for the return of soil permeability and nature is recognised in the concept of de-sealing (Garda, 2022) which 'means restoring part of the former soil profile by removing sealing layers such as asphalt or concrete, loosening the underlying soil, removing foreign materials and restructuring the profile' (EU, 2012).

In the paper, going just beyond the definition just mentioned to include interventions of greater entity and complexity, with the concept of de-sealing we intend to consider a set of actions that foresee, in addition to the removal of two-dimensional elements, such as parking surfaces, also the demolition of three-dimensional elements, such as unused buildings, to guarantee the achievement of different benefits. The advantages that can be obtained by interventions to increase the permeability of soils and the consequent renaturalisation, acquire great importance for urban areas, especially those characterised by intense soil sealing processes (Adobati, Garda 2020) due to the numerous negative effects produced by anthropogenetic soil sealing (Scalenghe, Marsan 2007; EEA, 2013). With de-sealing it is possible to mitigate or compensate for this negative situation by ensuring: i) increasing green areas that are crucial for the health of inhabitants (Kabish et al. 2015); ii) reducing the urban heat island phenomenon (Magliocco, Perini 2014); iii) restoring soil infiltration and improving the water cycle management capacity (Brears, 2018); iv) recovering the ecological function of soils by promoting ecological reconciliation (Francis, Lorimer 2011). Through these new urban porosities (Viganò, 2010), it is also possible to (re)activate ecosystem functions (Garda et al., 2023) and promote the application of Nature-based Solutions (NbS).
This contribution confronts the issues just presented through the analysis of two experiences of redevelopment in the Italian cities of Trento and Milan. In both cases we are dealing with complex processes of radical transformation of physical and morphological assets that have favoured the creation of new green areas through de-sealing, albeit with dissimilar results in terms of green areas created.
The two case studies were selected because of certain common features:
- These were two redevelopment processes in which all the interventions included in the projects were almost fully realised.
- The industrial areas were unified in terms of architectural and ownership structure.
- Before the transformation, the areas had high levels of soil sealing.
- The projects that guided the transformation reconfigured the two areas morphologically and functionally.
- The creation of new green areas was an aspect that characterised both urban planning instruments and specific urban projects.

Case Studies Presentation
The former Michelin of Trento includes a rather important area for the city, located in the south/west area of the urbanised territory and about half a kilometre away from the historic centre of the city. The history of the industrial site began in the 1920s when Michelin took the decision to build an initial production plant in Trento to manufacture tyre materials. The company, after several reinforcements, reached its maximum level of development in the 1970s, involving approximately 1,800 workers to become the most important labour pole for the province. The importance of this place for the city was not only due to its territorial extension, albeit considerable with its 116,000 square metres, but was justified by other reasons. A significant role was played by the economic operator who for decades owned and employed this site, profoundly conditioning the labour market and community life. Even the functional choices hypothesised and then realised during the transformation process have connoted the new district because of new territorial relations, as well as the interaction with territorial elements that have been at the centre of political and urban planning debate (e.g. the role of the Adige River). At the same time, the former Michelin can be considered as the metaphor of a city that in recent decades, like other Italian cities, has been confronted with structural phenomena (Mazzeo, 2016) such as the end of the long cycle of demographic growth, the progressive ageing of the population, the decommissioning of some military structures and the crisis of the industrial sector (creating some 'urban voids'). The spatial conditioning of these

irreversible processes has long influenced the debate and characterised the scenarios adopted in municipal urban planning instruments, also because of the strategic role attributed to many of these areas (Franceschini, Ulrici 2011). After Marcello Vittorini's new urban plan of 1989, many modifications to the plan alternated, attempting to confront the needs of an area in search of a new balance, until assimilating the development hypotheses proposed at the beginning of the 2000s by the Catalan urban planner Joan Busquets and the subsequent master plan for the city of Trento (Cerone, 2004).

The new district that replaced the decommissioned industrial structures, now known as Le Albere, is the outcome of a long process of transformation that since 1998, the year in which the Michelin company decided to shut down operations, has solicited stakeholders, places, and planning tools. The first hypotheses for the area had already been proposed by the 1989 Urban Plan, which had envisaged a fragmentation of the structure into mixed-residential blocks set in green spaces, aimed at inserting a new centrality in the city system. This forecast, given the criticism raised locally with respect to fears of an acceleration of the process of dismantling, had been eliminated with a variant to the urban plan in 1994 (Ulrici, 2011) to postpone an inevitable change to the future. A few years later (1998), the Trento City Council returned to this specific case, undertaking to start the process of revising the urban plan with the aim of reconsidering the urban destination hypothesised in 1989.

The 2001 update of the urban plan played a fundamental role in the new trajectory. Alongside the management of some general issues, such as the need to consider the river Adige as a structuring element for future urban planning policies and environmental requalification actions, the updating provided for the former Michelin the need to draw up a 'guiding plan' to which to subordinate the subsequent drafting of implementation plans.

The masterplan was drafted in 2003 by the Renzo Piano Building Workshop, which had been commissioned directly by the new owner of the area (‘Iniziative Urbane’). The study proposed for the masterplan dealt with themes that have become recurrent throughout the Le Albere experience, such as the desire to promote the reconnection of the area with the rest of the city and the recovery of the relationship with the river Adige. The two main design choices proposed by the project concerned the creation of a multi-scalar mix of functions. The second theme dealt with the choice of concentrating the new building volumes in a limited part of the area, creating the minimum conditions for the formation of a large park. The masterplan, in addition to more specific choices on different issues (tree-lined paths, road network, building fabric, etc.), provided for a series of interventions along the boundaries of the project area at the expense of the public administration, fundamental to accelerate the realisation of a more comprehensive urban redevelopment of the district (Antoniaconi, 2010). These interventions concerned the construction of several pedestrian subways under the railway (elevated), road and pedestrian bridges over the Adige, and the construction of interchange car parks. These works also included a project of particular importance for the new park and for integration with the Adige, namely the burying of Via Sanseverino as an element of strong separation between the area and the river.

After the City Council's approval of the masterplan (2004), the following year it was the turn of the subdivision plan, the drafting of which was once again assigned to Renzo Piano's Studio, guaranteeing a certain continuity in the design approach. This further refinement involved the definition of six design guidelines that dealt with four different 'systems' (energy, water, green and built), the road system (including paths) and the relationship between park and water. The importance given to the green system and, above all, the hypothesis of creating a large park area were again recognised as fundamental and characterising aspects for the new district.

The building works begun in 2008 led to the construction of new structures for residential (approximately 44,000 square metres), tertiary (approximately 29,000 square metres) and commercial (approximately 10,500 square metres) use. Another important and symbolic

intervention implemented concerned the construction of the Science Museum (MUSE), again designed by Renzo Piano, located in the northern part of the district. In addition to an important share of mainly underground parking areas (about 2,000 parking spaces), the interventions on the open spaces must also be mentioned, which involved both squares, pedestrian paths, and water channels (about 28,000 square metres), and the construction of the new public park that affected a large portion of the district (about 50,000 square metres).

The biography of the former OM of Milan, an area located to the south in a particularly urbanized context, is rather extensive. Its history began at the end of the nineteenth century when the Miani Silvestri industry, then engaged in the manufacture of railway materials, decided to settle in this part of the municipal territory. A few years later (1899) the area took on the name Officine Meccaniche (OM) and in a short time, thanks to the positive effects of its proximity to the Porta Romana railway station, it became one of Milan's most important industrial realities (4,000 workers). Starting in the 1930s, this company underwent various changes in its management and ownership structure, gradually becoming part of the FIAT Group and modifying its production of vehicles destined to operate in different economic sectors. Between the Eighties and Nineties, just a few years after the definitive replacement of the OM trademark with that of 'Iveco' (1975), the gradual process of divestment of production activities began at a historical moment that for Milan, as for other major urban areas in Europe and North America, represented the start of that powerful season of planning, political and cultural reflection about abandoned areas.

In Milan, the debate on the fate of large ‘urban voids’, from the point of view of urban policies, was tackled by means of newly planned instruments that were often far from the more traditional town-planning schemes at the municipal level then governed by national and regional regulations. Since the 1980s, Milan has decided to adopt rather innovative 'Documents', not without criticism for their reference to deregulation aspects, which, moving away from the ordinary and regulated forms of planning, have taken on a look more interested in promoting the strategic dimension.

A first relevant act produced by the municipal administration, created to go beyond the urban plan and take advantage of the start of works for the construction of the new commuter train (Oliva, 2002), was the ‘Documento direttore per il progetto passante’. This was a tool introduced as a strategic and management contribution to coordinate public and private interests (Bolocan, 2009) and to stimulate reflection on certain areas worthy of reconfiguration through the activation of urban projects. Many of the areas considered by this tool, then affected by phenomena of progressive decline, have frequently returned in the reflections of the following years also because of their size and strategic location in the metropolitan system. Among the various proposals identified by the cartographic elaborations of the Document, the former OM still appeared with a secondary role and as an area of possible redefinition because it was susceptible to urban redevelopment through the rethinking of permitted uses and the redesigning of substantial parts of the territory (Doni, 2009). Parallel to the first Director's Document was another document (‘Studi di inquadramento’) which, through a more in-depth analysis of Milan's disused or underused areas, came to suggest new transformation strategies. For the OM area the theme and the potential role of urban greenery emerged for the first time, suggesting the need to build a 'green system' capable of redefining the relations between the city and the external agricultural spaces (Doni, 2009).

In the mid-1990s, a second important moment for urban planning policies, especially for future decisions concerning the former OM area, was the project ‘Nove Parchi per Milano’ (1995). This design experiment proposed a set of urban transformation measures for extensive peripheral areas of the city that were to take place around a large new park. Through the creation of new neighbourhoods equipped with public spaces and facilities, the aim was to define new centralities in the peripheral areas with the aim of contrasting the monocentrism that

traditionally characterised the forma urbis of the city. Similarly to the experiences proposed for Barcelona and Paris, there was a tendency to rethink the structure of the city starting from the identification and action of urban projects characterised by the foundation of a new urban park (Marinoni, 2007). In this new vision for the OM area, several hypotheses were envisaged, later taken up in subsequent years in other more concrete and effective initiatives with respect to the real transformations of the area. For example, an expansion of the existing Parco Ravizza, located north of the area, was suggested, through the creation of new green areas in the industrial area, obtained by demolishing the industrial buildings. The Nove Parchi per Milano Project also envisaged the creation of new connections, called promenade, between the project and other significant areas. With this indication, the OM area found itself inserted along the 'Naviglio Romana' promenade, which also included the Porta Romana railway station and part of the railway belt.

The process of radical transformation of the area began institutionally with the municipality's participation in a national funding call intended to support building and functional redevelopment of urban areas. After the preliminary identification of the urban areas to be evaluated for a possible request for financing, some real estate companies responsible for the area submitted a proposal for the ‘Programma di riqualificazione urbana’ (PRU) of the former OM (later named 'PRU OM-Pompeo Leoni'), for a total area of 313,652 square metres, which was subsequently approved by the Municipality and forwarded to the Ministry for evaluation. Following the positive outcome and the allocation of the financing, the Programme Agreement was signed in 1997 between the Municipality, the Lombardy Region, and the Ministry of Public Works. With the Agreement, all the fundamental design indications were defined to start the subsequent technical design phases and, at the same time, guarantee the simplified modification of the 1980 town-planning scheme in force, which did not provide for the transformation of the area. Work began in 1999, while construction was mainly concentrated between 2003 and 2005. The reconversion of the area led to the creation of a new neighbourhood characterised by a rather ordinary mix of functions common to the urban projects promoted in Milan. On the whole, of the approximately 153,000 square metres of floor area ratio, a very significant part was destined for residential use, i.e. 79,000 square metres, following the strong demand for housing present in the local market. The remaining quantities were destined for commercial structures (9,000 square metres), spaces for the tertiary sector (34,000 square metres) and, finally, spaces for manufacturing functions (approximately 31,000 square metres).

Of the approximately 116,000 square meters that made up the project for the former Michelin (later renamed ‘Quartiere Le Albere’) a considerable part was allocated to the formation of the new green areas and a new public park (about 43%), which, as mentioned in the previous paragraph, represented a characterized and identifying choice for the entire redevelopment process. The creation of these new green areas was made possible by a combination of the complete demolition of existing building structures and the concentration of building potential in the eastern part of the neighborhood. The new fabrics created were designed with the aim of defining a specific relationship between built volumes, open spaces and building heights, comparable to that present in the historic center of the city of Trento. The increased permeability of the areas was manifested as the result of the conversion project of an area that, due to the morphological and functional conditions of the previous activities, was characterized by a high degree of soil impermeability.

De-sealing took the form of a necessary action to facilitate the creation of the new public park and meet certain needs (Garda, 2020). The first need, emphasized by the planning documents, concerned the attractive role given to the large, equipped park, which was supported by the provision of specific elements. The spatial components, intended to ensure attractiveness and that characterized its spatial composition and organization, concerned the creation of paths, equipped meadows, and wetlands. The second requirement proposed by the project was related

to the desire to restore connections with the Adige River by encouraging a return to the dialectical relationship that had been denied with the progressive urbanization of these areas. The park was, likewise, considered as a connecting element between the consolidated city and the river and between the latter with the new architecture of the neighbourhood and the planned receptive/commercial functions. The specific choices adopted included both the proposed burying of Via Sanseverino, which was essential to give continuity to the park given its condition as a physical barrier, and the creation of a network of canals and bodies of water intended to serve different functions.

Water represented a complex issue for the project because of the functions: i) recreational due to the presence of ponds made swimmable thanks to a phyto-purification system; ii) technological due to the realization of water surface ponds to be used as storage basins for irrigation, firefighting or first rainwater lamination; iii) didactic-scientific due to the possibility of intercepting a cultural type of fruition.

The proposed design framework for the final subdivision plan adopted a taxonomic approach because in it the different elements that made up the large, equipped park are treated separately. In the technical-descriptive report and the in-depth documentation, the organization of the spaces took place through the use of "diversified landscape environments" that corresponded with: i) a central environment treated as a lawn and equipped with paths; ii) a wet garden composed of essences usual for river environments; and iii) groves consisting of prime tree essences distributed along the edges. It is an archipelago of spaces with a strong ecological, physical, and functional characterization that has found, as stressed in the project, in the tree rows a connective system together with the networks of pedestrian paths and water channels.

The complex system of green areas that now characterize the Le Albere neighborhood faithfully return the principles and design directions provided by the former Michelin transformation project. In it it is possible to recognize both the spatial design imagined in the various elaborations of the project, and the variety of elements that characterize it which return a certain complexity in the interpretation of the concepts of urban nature.

The principles adopted in the design of the new green areas planned for the former OM area in Milan centred on a different approach than in the Trento case. According to the design proposed by French landscape architect Frederic Cristophe Girot, the new park was organized into different spatial and thematic areas. This hypothesis compared with the indications included by the PRU project carried out by the municipal administration albeit with some difficulties and limitations related to the impossibility of surmounting the physical barrier constituted by the railway line and Viale Toscana. The obvious criticalities prevented the implementation of the idea of creating a unified public park, as also envisaged by the Nine Parks for Milan project, achieved through the connection and continuity between the existing Ravizza Park, located north beyond Viale Toscana, and the new park planned for the former OM area. The architect proposed a park structured in three environments alternating with the new buildings, organized along east-west directions, and integrated with the Vettabbia canal that ran through the entire area (for which reclamation and redevelopment were planned).

Further north, between the railway and Toscana Avenue, the Culture Park was planned, characterized by the construction of a large amphitheatre for 1,500 people, new wooded and planted areas with fruit trees and outdoor sports facilities. In the center was planned the Park of Industrial Memories instead intended to ensure a possible integration between new green areas (lawns and rarefied trees), bicycle and pedestrian paths and some technological and architectural elements maintained to preserve the historical memory of the industrial area. To the south, the project envisioned the Vettabbia Park, which derived its name from the presence of the Vettabbia canal and its relationship with this hydraulic element. In this case, the design indications were oriented toward the enhancement of the canal through the creation of bicycle and pedestrian paths, tree-lined strips, and small squares that overall related to the new lawn

areas to be placed between the Vettabbia and the new built-up areas. Between the Memorial Park and the Vettabbia Park were the areas intended for the construction of the new residential and tertiary buildings.
In the center of the built-up spaces, again along the east-west axis, was the main road axis for the entire project (the present Giovanni Spadolini and Carlo de Angeli streets) whose design was characterized by the presence of paths alternating with green spaces (lawns and tree rows) aimed at improving the aesthetic and environmental quality of the new road system. Given the current condition of the area, this specific part of the new neighbourhood can be considered as a boulevard and a characterizing thematic section.
The various thematic sections were connected along the north-south axis by pedestrian-cycle paths intended to provide continuity between the areas due to the discontinuities planned to interrupt the otherwise wide frontage of new blocks and buildings. Girot's proposals were later considered in the project carried out in 1998/99 by the Land studio and renowned landscape architect Andreas Kipar, who developed the executive proposal by adapting it to new requirements agreed upon with the City of Milan without radically altering the original layout of the project. Park construction was started immediately and completed in 2006 except for the Culture Park, which is currently still being concretized following the decision, after several decades of disuse and the formation of large fragments of the ‘third landscape’, to build an underground station for electric buses and new green roofed areas set aside for loisir-related functions.

Discussion

The proposed Trento and Milan case studies allow us to reflect on some issues while recognizing common or, in some cases, divergent elements. The first aspect to remember inevitably concerns the concept of de-sealing, which in the two processes found full implementation through the demolition of buildings and covered surfaces, the increase in the permeability of the freed soils and the consequent creation of new equipped green areas and new NbS. In both cases, the new permeability was more the indirect result of a design approach more interested in building a new ecology or supporting the demand for new recreational spaces (e.g., new park facilities).

This first consideration is linked to the issue of the design and technical language that guided the two proposals, which is characterized by the use of concepts that are not directly aligned with the current debate on urban regeneration, on opportunities to contribute to the fight against climate change through the reconfiguration of urban spaces, or by concepts that are increasingly usual (e.g., NbS, Ecosystem Services, Green Infrastructure). Despite this distance, if only from the concept of de-sealing, which is almost absent, the two neighbourhoods make an active contribution to the urban contexts in which they are embedded, for example, in terms of ecosystem services provided (for microclimate regulation and temperature reduction). Another aspect concerns the urban planning tools used in guiding the transformation of the two industrial areas. With the same starting conditions, i.e., areas with relatively similar architectural and morphological characteristics, the two cases show the adoption of different planning and design tools.

For the former Michelin, the redevelopment process was sustained with a traditional approach both with respect to the direct relationship between the indications of the municipal plan (always updated to encourage transformation) and the subsequent implementation plan, which was approved and used in full compliance with the municipal plan, and with respect to the type of instrument used (this type of instrument was introduced in Italy in the late 1960s). For the former OM, it was a different path that benefited from some instruments introduced at the local

scale directly by the City of Milan (such as the Director Documents as a variant to the municipal plan) or from instruments adopted at the national scale such as complex programs like the Urban Redevelopment Programs (indifferent to the indications of municipal plans). Given the fairly similar results at least in terms of high allocation of vacant areas, it could be argued that the adoption of new instruments is not always essential for the implementation of an innovative idea.

Comparison of the structure and composition of the green spaces created in the Le Albere neighborhood and in the former OM area shows important differences with respect to the overall organization of the various components that make up this system and the characterization of the individual elements. In Trento, the new park and the network composed with the other secondary elements have the function of ensuring integration between the various spaces, but, above all, of creating strong relationships with an important territorial and ecological element present beyond the boundaries of the new neighborhood. The concentration of the new green spaces, especially of the more forested areas, along the west side, the burying of Via Sanseverino (a previous element of separation between the former Michelin and the River) and the creation of a green point, are part of a strategy to redefine the dialogue between the city and the Adige River. With respect to the individual elements that make up the overall system, there is considerable variety and diversity among spaces intended to provide outdoor recreational functions (equipped gardens, pedestrian paths), forested areas and wetlands.

This variety not only ensures a certain diversity in the ecological and ecosystem functions provided, but also pursues an objective of education and dissemination consistent with what is proposed by the Science Museum (MUSE) present in the Le Albere neighborhood. These are spaces that between two-dimensional (meadows) and three-dimensional elements (rows or forested areas) are characterized using vegetation essences consistent with the territorial context of reference.

The overall structure of the green system present in the former OM area of Milan, shows different characters. Its division by thematic areas and the absence of prominent structural and multiscalar elements, as in the case of Trento, reduce the perception of the presence of a general pattern of organization. Observing these spaces, one has the perception of a buffer zone role to separate and distance (Bricocoli, Savoldi 2010) the new architecture built at the center of the neighborhood and the urban context of reference, seeking a spatial, psychological, and symbolic isolation that has characterized many other interventions of similar size proposed in Milan in recent decades. From a compositional point of view, the new surfaces present less articulation due to the greater presence of lawns and trees that on the whole respond more to recreational purposes for the residential functions of the neighborhood and the urban context of reference. From an ecological-environmental and biodiversity point of view, therefore, the case of Milan shows less variety research in contrast to the case of Trento.

Conclusions

In the transformation processes of large brownfields, renaturalization interventions play a key role in fostering the improvement of the well-being of built spaces (Lehmann, 2021) due to their ability to remind people of the importance of biodiversity, ecosystem services, and green infrastructure.

The two proposed cases offer an opportunity to observe how topical issues and needs, for example, increasing soil permeability and promoting renaturalization interventions to improve the urban environment and counteract the problems generated by soil sealing and climate change, can also find ‘unconscious’ support within urban design experiences that arose at a stage that anticipates the full awareness we now have toward the many global crises (Garda, 2022).

The unawareness referred to concerns the adoption of design approaches and concrete interventions that, although supported by a language seemingly distant from the concepts adopted today, such as Nature-based Solutions, we can nonetheless reinterpret with today's sensitivity and awareness, thanks above all to the actual outcomes of such choices. This also supports the idea that, to implement innovative interventions consistent with current needs, we should not necessarily wait for the introduction of new technical and regulatory tools, but on the contrary seek to reorient even the most traditional methods.
The redesign of brownfields and the concomitant release of soil are the first step in a series of possible choices for the return of nature to denser urbanized areas after the long season of growth.

Abstract
This paper title provokes us and brings us back to the New Athens Charter published in 2003 by the European Council of Town Planners[1]. The aim is to discuss the city's planning based on the urban features we have inherited from the past, with the understanding of history in its evolutionary form and the city as an open-ended process in continuous construction. It's not about preserving, but adapting, reusing and creating again, reinforcing urban resilience and the identity of each place. Today's needs and the crises we face - climate change, the housing crisis and migration - call for a transformation of the city and behaviour so that cities become sustainable, healthy habitats that guarantee quality of life for all.

Keywords: reuse, heritage, sustainability

Introduction
In 2015, the United Nations defined a set of goals for 2030 aimed at sustainable development, which included the 11th Goal: Inclusive and sustainable cities and communities (UNDP, 2015). This reveals, on the one hand, the awareness of the impact on citizens' health, quality of life and well-being of the space where they live and use, particularly in terms of work and other activities, and, on the other hand, that urban areas are crucial because the majority of the world's population lives in urban areas. Several studies (Marans and Stimson, 2011; Ballas, 2013, M. van den Berg et al, 2015, Kostas, 2021) have addressed the impact of space and environment on human life, from air quality, lighting and noise, to functionality, aesthetic quality and cultural value (Shekhar et al., 2019). Thus, it is recognised that cities can be a catalyst for transformation. This awareness has also led the EU to prioritise a New Urban Agenda focusing on a set of urban goals. The Leipzig Charter affirms the responsibility of cities to 'lead the transformation towards just, green and productive societies' and states further that 'cities are unique historical centres of exceptional cultural value that shape Europe's urban heritage and the identity of its citizens' and culture must be at the heart of any sustainable urban development, including the preservation and development of built and other cultural heritage' (EU, 2020, p. 2).

In this sense, urban transition to meet the new challenges must be achieved by planning and intervening in the existing city and valuing its social and cultural values. This awareness requires that urban planning acts in the city built over time, reading the various marks of time and the associated social values. This does not intend to prevent transformation but should inform and contextualise it. Urban planning must be place-based and sensitive to the physical, historical and social context. Throughout time, cities have been built in this way and we can

[1] In a conference held in Athens in 1998, the ECTP-CEU adopted the New Charter of Athens: A Vision for Cities in the 21th Century, and resolved it should be kept under a constant process of revision and updating. Symbolic this happened in Athens, where the original Charter was adopted during the International Congress of Modern Architecture in 1933. This was revised during the ECTP-CEU's 2003 General Assembly in Lisbon, the New Charter of Athens and promotes a vision for The Connected City.

learn from the past and previous processes of change, also from the social processes that support cities today.

This article aims to discuss the planning and transformation process of the existing city to meet the current challenges, in a sustainable way and through a circular approach, supported by sensitive thinking to each city's context, history and social values. It is organised into two parts: a brief analysis of the historical process of building cities, which marks the evolution of urbanism, with processes of continuity or radical change. Next comes a reflection on the intervention in the existing city, understanding that this intervention has sometimes been trapped in a conservationist policy of heritage protection but today, with the widening understanding of what heritage is, it can be seen as part of the urban change and development for more sustainable, resilient and inclusive cities. We conclude with some recommendations for achieving urban planning that can create more sustainable and resilient cities that favour quality of life for all.

Cities as a dynamic and open process

Most European cities result from years of transformation, adaptation and growth. Marked by processes of continuity and sometimes rupture, cities are both a reflection of and one of the main manifestations of a culture. However, as living spaces, they are also dynamic spaces that are constantly changing to meet the needs and expectations of each time. So continuous change is an intrinsic part of what characterises and defines cities. History reveals the processes of building and transforming the city, usually through continuity, punctual changes and extensions. However, history also shows a series of events, typically catastrophic and related to natural phenomena or the result of man's actions, which have led to processes of rupture and transformation of the existing city. Still, we can say that these are the minority. In the majority, urban development occurred through additive processes of extending the urban fabric, filling urban voids or small urban reforms.

The history of urbanism shows that these urban enlargement and transformation processes took place very slowly until the 2nd Modernity (Ascher, 2012) and gained expression after the Industrial Revolution and the urban growth of the 19th century all over Europe. Thus, in most European cities, the structure of the old town, or the so-called historic centres, is the result of several years of adaptation and it is this slow process that makes these the most characteristic areas, marked by a specific urban morphology, defined by the grid of streets, plots and buildings defining their identity and heritage. Beyond the possible monuments that may punctuate the city, the collective ensemble produced over time is now recognised as heritage, as a manifestation of local culture and as part of its identity.

Urban fabric reform also happens in the history of cities, whether due to catastrophic events (fires and battles, for example) or to reform the cities and demonstrate the power of the king, or other entity. Examples include the rebuilding of Rome after the Great Fire, the remodelling of London after the Great Fire or the Baixa Pombalina after the great earthquake. For beautification, the remodelling of Rome by Pope Pius V, or more recently the remodelling of Paris by Haussman (Lavedan, 1959). All these examples led to a more or less radical reform of large urban areas. But after they were also subject to the natural change that happens to every city.

As Corboz (2001) argued, the city is a palimpsest, which recognises that the city is a complex entity made up of overlapping layers which each time is relevant to the construction of the

contemporary city. Each time is a new layer, the mark of an epoch, a style and a way of life. But beyond this overlap, it is important to emphasise that it assumes an evolutionary process, preserving what has value, use and utility and replacing what has no or little value/function for something new that responds to new needs, be they taste, functional or cultural.

This notion of a palimpsest also emphasises the need for each era, each period to write its city, each time to leave its cultural mark on the city. And this doesn't mean erasing previous traces or starting from scratch, as we've seen rarely happens. The palimpsest to which Corboz refers is a continuous rewriting, a sensitive selection of what needs to be adapted to meet the needs of each time, and this is precisely what we are defending here. This change and evolution are evident in all our cities and are related to the idea introduced by Geddes of the city as a living organism in continuous change (1915), which also meets the idea of circularity that we now defend as essential for sustainable development.

It is important to emphasise that this evolution is a response to the needs that arise, but it depends on a value system and a hierarchy that values some elements and discards others. It's not a question of changing everything or conserving everything, but a sensitive selection process that must be understood to recognise how it was made and how it can be used nowadays. In other words, this selection is characterised by looking to the future rather than the past.

This idea of the future inspired the decision to rebuild Baixa de Lisboa in Portugal with a new plan after the 1755 earthquake. This catastrophic event that led to the destruction of the entire downtown area inspired a radical reform of the city of Lisbon and the development of Portugal's first urban plan. We know the layout of the old city well, recorded shortly before the fateful event by Manuel da Maia in 1716. And we know the hypotheses studied by the reconstruction engineering team. The final decision was hypothesis 6, which envisaged rebuilding the entire area with a new grid of wide, orthogonal streets in opposition to the previous layout. However, despite the novelty of the layout, it's interesting to note that the new plan didn't reject everything, but rather replicated the original organisation of the urban fabric from the previous plan, organised around two squares, one by the river and the other on the edge of the built-up area, and kept the vast majority of the churches, even though this included the construction of new façades. The image and shape of the new neighbourhood are completely new, but it replicated the previous urban structure with a new morphology. The choice to discard the previous morphology is justified for safety and health reasons, reinforced by functional and aesthetic reasons.

Figure 1 – Manuel da Maia, *Levantamento da Baixa de Lisboa em 1716*, drawing from 1756 [Gabinete de Estudos Arqueologicos de Engenharia Militar, Lisboa]

Figure 2 – Eugénio dos Santos e Carlos Mardel, *Estudo para o Plano de reconstrução da Baixa*, 1756 [Instituto Geográfico Português]

In addition to this example, there are countless examples of buildings and groups of buildings that have been transformed over time, such as the Machado de Castro Museum in Coimbra, located in the former Bishop's Palace, which was built on top of the old Cryptorchid created to support the Roman Forum. Today this remarkable building shows the practice of reuse very clearly. Its ground floor occupies the area of the old forum and the buildings reuse parts of other buildings, mostly former college buildings that were sold or converted to other functions during the 19th century. For example, it reused the Santa Ana's portal. This portal belonged to the College of Santa Ana, transformed into a barracks in the 19th century after the religious orders were disaffiliated and whose portal was moved to the Church of St. Salvador (Calmeiro, 2015). By reusing the portal of the College of Saint Thomas, which belonged to the college of the same name located in Sofia Street and which in the 19th century was converted into the residence of the Counts of Ameal, the portal was reused in the museum's courtyard and today forms an integral part of the Machado de Castro Museum.

Figure 3 - Portal of Santa Ana in its original location (early 20th century) [AMNMC, Photographs folder]. Figure 4 - Its reuse in the S. Salvador Church (c.1930) [AMNMC, Photographs folder]. Figure 5 – St. Salvador Church today

Figure 6. College of St. Thomas at the end of the 19th century [AMNMC, Photographs folder]; Figure - 7. Construction works visible the reuse of the St Thomas portal on the back façade of the Machado de Castro Museum (1935 and 2022). [AMNMC, Photographs folder]. Figure 8 - Today

Like this, there are countless traces of the change of buildings to respond to new uses and needs, such change represents one of the essential characteristics of the city, its ability to adapt and evolve. Although the image of buildings is easy to change, sometimes even reusing elements from other buildings, the urban fabric has a greater tendency to remain, with minor adaptations. It is this apparent permanence that justifies the importance of the urban heritage and intangible heritage that characterise the historic urban landscape because it is these elements that, often unconsciously, allow the community to recognise the spaces and their identity beyond the constant image changing.

Heritage from conservation to transformation and sustainable development

This idea of building the city as a palimpsest recognises the city's stratigraphy and the mark of each one of its periods, acknowledging the value of every change. This idea is linked to the broadening of the concept of heritage. The concept of heritage and the need to protect and safeguard it for future generations arose in reaction to the changes wrought by the French Revolution and the reforms of the 19th century, aimed at establishing a new social order and a new regime, destroying the marks of the past, in consequence, it adopted a very restrict concept, limited to monuments (Choay, 1965).

In reaction to this destruction and to prevent the loss of memories and traces of the past, monument and heritage protection was institutionalised through the first national monuments service in France. This approach and concept expanded and densified throughout the 20th century and across Europe. In the aftermath of the war, in 1945, UNESCO was created and the debate on the protection of urban heritage and the connection between heritage, development and sustainability began to be institutionalised (Labadi and Logan, 2016).

The beginning of the 20th century was also a fruitful period for the development of urban planning theories and for the definition of new models to meet the challenges of the industrial and modern city. The Modern Movement presented its alternative, radically breaking with past forms and endeavouring to establish a new, fairer and more egalitarian society through urbanism and architecture, where everyone had the best living conditions. The rejection of traditional models was justified by their unhealthiness and the alternative was urban renewal and renovation of old urban areas. This was set out in 1933 by the CIAM Charter of Athens, aimed at launching a new way of designing cities. However, apart from the theories, in practice cities experienced accelerated growth towards peripheral and rural areas and the progressive

abandonment of old urban areas or their sanitation with the opening up of wider streets and larger blocks.

In 1972, UNESCO adopted the Convention Concerning the Protection of the World Cultural and Natural Heritage (the World Heritage Convention), precisely in the same year that the book Limits to Growth (Meadows, 1972) commissioned by the Club of Rome was published, calling attention to the dangers of growth and the depletion of existing resources. This Convention signalled the concerns existing at the time about ongoing changes and unsustainable development and its impact on heritage.

There was a bridge between the desire to preserve the marks of the past and heritage for future generations, and at the same time preserve natural resources and nature. However, in practical terms, this vision does not coincide, and planning practices are not aligned with heritage conservation practices. In fact, throughout Europe, there have been distinct policies and institutions opposing heritage conservation and urban development (Jokilehto, 2007). This perpetuates a perception of incompatibility between modernity and the vestiges of the past.

Despite this, post-war reconstruction allowed for the development of more culturalist visions, valuing existing urban tissues and advocating the need for their reconstruction. A few conservation plans for Italian cities stand out, such as the Bologna conservation plan developed by Leonardo Benevolo, which managed to reconcile urban planning and safeguarding heritage in an exemplary way (Bandarin, 1979).

However, these two approaches seemed difficult to reconcile, due to the limited understanding of the concept of heritage, limited to historical, aesthetic and identity values that should be preserved and was mainly limited to the scale of the object or monumental structure. The extension to areas and sites with historical and heritage value embodies a paradigm shift based on recognising the citizen's perception. This perception of the urban by the citizen, explored in the theory of urbanism by Gordon Cullen and Kevin Lynch, was very important for broadening the theories of heritage conservation, focusing on people and questioning what to conserve and for whom. This emphasises not the value of the heritage itself, but the importance of the attribution of value by someone or a group. This later enabled heritage to be recognised as a social and political concept and allowed it to be extended to other typologies (Smith 2006; Veldpaus and Pereira Roders, 2017).

In the 21st century, this broadening took on a new dimension by recognising the value of intangible heritage in the Convention for the Safeguarding of the Intangible Cultural Heritage (UNESCO, 2003). Two years later the Faro Convention stressed the role of heritage in the development of communities (CE, 2005). These documents opened the way to the Historic Urban Landscape Recommendation (UNESCO, 2011), which endeavours to reconcile urban development with heritage management to achieve the sustainable development desired. Heritage is thus recognised as a continuous construction over time, close to Geddes' thinking, and understood as a process of continuous construction of overlapping layers that broadly includes the historical context, the geographical characteristics (article 8), also the parcel, the spatial, social and cultural organisation, the practices and values and the intangible dimension of heritage.

The recommendation aims to establish a new approach to managing change, advocating a set of tools such as the involvement and participation of the population, the production of new knowledge and planning tools, and the definition of new legal mechanisms and funding

strategies. On the other hand, this recommendation establishes a link between heritage conservation and economic and social development, emphasising the opportunities for economic development through tourism and the valorisation of traditional practices and knowledge as a way of promoting economic and social development. However, it also draws attention to several threats that can make the sustainable management of historic urban landscapes unviable and even put it at risk, such as accelerated urbanisation and densification, and tourism that can lead to gentrification and climate change. From these dangers emerges the perception that despite the broadening of concepts and the discourse used, the scope of this document and the conservation it defends is still restricted to the conservation of images and materialities (Fouseki and Nicolau, 2018), ignoring what we defend as one of the essential characteristics of the city, which corresponds to its need for change and adaptation.

Despite the enlargement of concepts and the inclusion of the role of communities in recognising what heritage is and the definition of innovative instruments, such as the urban development plan, the discourse remains very much marked by the idea of containment and management of change.

However, if we recognise values in the continuous process of urban transformation, we also have to accept that their preservation requires this same continuity. Change must be seen as an engine of development. This doesn't mean that we should think of change *per se*, but change is based on valuing and boosting what exists. The change and dynamics are behind the city we recognise as having an identity and heritage value.

The question that remains is how to continue transforming the city, respecting the essence of change that characterises the city and responding to the challenges of the 21st century.

The 21st century faces many challenges that have given rise to new city models that aim to help overcome and achieve more sustainable, resilient and inclusive cities (UNPD, 2015). New technologies and the "smart cities" model make it possible to simplify and optimise the city to better serve citizens' needs (Ekman, U. (2018). Beyond the utopian visions, technologies have gradually made cities more functional and efficient, and some of these technologies, related to infrastructure, are barely perceptible to citizens. We also advocate the need for greener cities that reinforce the relationship with nature through Natural Base Solutions and that make it possible to overcome some of the risks caused by climate change, such as floods and heatwaves, and also capture pollution (Seddon et al, 2020), as well as providing areas for socialising and quality of life, which have been highly valued since the COVID-19 crisis. In addition to these, there are proposals to change the way spaces and buildings are used, creating shared-use spaces and services such as cohousing and car sharing. Although disruptive, all these solutions can be made compatible with the existing city. But despite these attempts, there are still unresolved issues, particularly in terms of social cohesion and sustainability.

The issue of valuing the social has been promoted by governance policies and strategies involving the citizen and with measures centred on improving the quality of life of the most vulnerable groups. However, the idea of a liveable city includes not only physical health issues but also well-being, which has to do with some non-material factors, such as community involvement, a sense of belonging, culture and traditions. In this sense, it is important to create spaces that provide not only healthy living conditions but also mental health conditions. The idea of belonging to a place plays a fundamental role here, and cultural value is one of the main ways to reach it.

On the other hand, the need to reduce the negative impacts of urbanisation on the environment accentuated the need to focus on energy efficiency, spreading renewable energy production systems, and above all imposing an energy-saving strategy through a wave of renovation of Europe's building stock to improve energy efficiency and reduce consumption. To this end, states have created incentive and funding programmes for the refurbishment of existing buildings. Moreover, the need to promote circularity in the city led to a growing emphasis on the need to take advantage of existing vacant buildings, imposing regeneration policies for vacant areas, particularly former industrial and brownfield sites.

With these motivations, it is important to discuss intervention in the existing city, either to improve buildings thermally or to give them new uses and, in the case of urban areas, to create dynamic and attractive areas by reusing vacant areas within urban fabrics or in peripheral areas. The aim is to promote circularity and the reuse of installed resources, both in terms of infrastructure and building materials. The construction industry is one of the industries with the greatest impact in terms of resource consumption and a larger carbon footprint. Thus, intervention in the existing city and its buildings can combine the valorisation and reuse of resources, promote energy saving and contain the consumption of urbanised areas, which justifies the new emphasis that has been placed on a set of intervention strategies in vacant areas and unused buildings. A wide-ranging debate is emerging on a set of concepts such as the concept of reurbanisation, regeneration, revitalisation and reuse as ways of creating more sustainable urban areas. Although distinct, all these concepts relate to the principles of making cities more sustainable by valorising what is already there.

However, the existing city, besides the material resources that we value and reuse, is defined by a set of immaterial values, adding a social layer, and allowing important feelings of belonging, identity and memory.

It is therefore possible to create a bridge between intervention in the city to reuse its material resources and the enhancement of the immaterial resources that characterise each urban area and define its identity. The connection is established within the *genius loci*. This provides the opportunity not only to valorise and promote the tangible but also the intangible, so these interventions in the existing city are an excellent opportunity to improve living conditions and a sense of belonging. Focusing on dynamic practices and networks, including social capital, community involvement, participatory engagement, cultural traditions and inclusion and the mitigation of social inequalities (Dempsey et al., 2011). The social use of heritage in the mix of historic and renovated urban environments promotes identity, belonging, happiness and health for all citizens.

However, for this to happen, these interventions need to be planned in an integrated way with the city as a whole. And also, with the communities that live there or have some relationship and bond with those places. Therefore, it is not enough for these interventions to be supported by detailed historical research, based on the methods of type-morphology analysis that we have already experienced since the intervention in the Bologna Conservation Plan, but besides studying the history of the transformation of the site and the place, it needs to based on the values that the communities recognise and what characterises each area. There have been several studies that have debated the contribution of these reuses to the collective memory of the place and to how communities perceive and receive these interventions, and they can make some contributions to the way we act (Florentina-Cristina et al, 2014; Vardopoulos, 2023) and despite the studies that already exist, more initiatives need to be put into practice.

The ability to adapt reinforces urban resilience and has an enormous capacity for transformation. It is argued that the city is a collective construction that continues over time, in which the past and cultural heritage is an important asset for the development and planning of the city (Teran, 2009). Using the concept of "deep cities" (Fouseki et al., 2020), we recognise that past and historical change are a fundamental resource for current urban planning, as long as they are supported by interaction with the community. Places are socially constructed and therefore can only be conceived with communities.

Planning and heritage experts have to work with stakeholders to build a commitment to the future. This also opens up new possibilities to care for and conserve valuable sites. Empathy with the places guarantees their continuity, dynamics and vitality. Thus, the city of the future will be a collective construction, recognising the values of the past, and its resilience and ensuring its future success. As long as everyone is committed, the changes that guarantee resilience and continuity over time will also be guaranteed.

Abstract
Cities are currently confronting with a variety of challenges stemming from climate conditions, urbanization, and urban planning, resulting in increasing social, health, and economic issues. This study specifically examines the Mediterranean coastline promenades in Albania, France, and Italy as a unique type of built environment. The aim of this study is to examine the influence of different cooling system scenarios on the thermal comfort experienced by pedestrians, while considering climate data. We generate multiple scenarios by analyzing ways to mitigate urban heat island (UHI) effects. These strategies include revitalizing promenades by replacing current pavements, utilizing water bodies and sprays, increasing the presence of artificial shade, considering the proper greenery, and implementing advanced cooling systems using smart technologies.

Keywords:

Mediterranean coastal promenades, urban heat islands, outdoor thermal comfort

1. Introduction

In recent decades, climate change, urbanization, urban structure, architecture, and urban planning have all had a significant impact on urban thermal comfort. Over the past few decades, developed nations have conducted extensive research on climate change, urban heat islands (UHI), and cooling systems in the built environment (M. Giorio, 2023). Urban areas are currently grappling with a wide range of difficulties stemming from climate conditions, urbanization, and urban planning, resulting in rising social, health, and economic concerns. Distinct urban features have a direct impact on the microclimate of outdoor areas, as well as the general climate of the city. The Intergovernmental Panel on Climate Change (IPCC) reports that the average global temperature has increased by around 1.1°C since the late 19th century, with the recent decades having the most dramatic increase in temperature (Change, 2021). The Climate Pulse interactive web application, which is developed and maintained by the Copernicus Climate Change Service (C3S), allows users to observe the variations in daily surface air temperature from the past to today, as shown in Figure 1. Urban areas have a direct impact, not only on the microclimate of outdoor spaces, but also on the overall climate of the city. Particularly in urban settings, microclimates naturally form and can exist on various scales. This study will primarily focus on the micro-scale, based on Oke's climatic scale classification (Oke, 1987), specifically in relation to urban-level readings. Oke defines the space encompassing buildings, streets, trees, squares, and parks as the urban canopy layer (UCL), which extends from the ground to the top of buildings. Within this layer, the microclimate varies depending on the region's environmental conditions. Figure 2 displays a drawing of the UCL study's urban size.

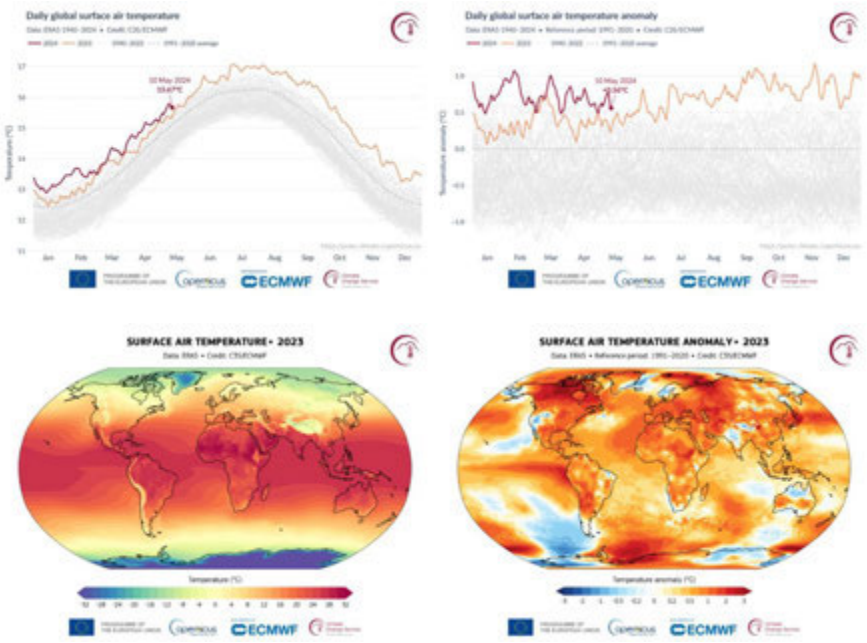

Figure 1 Daily global surface air temperature and anomaly rate **(Copernicus, 2024)**

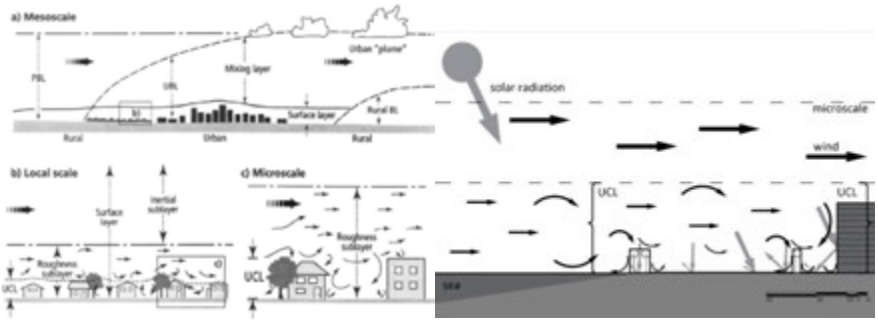

Figure 2 Climate Scale in urban areas, according to Oke 1987 (lef); The urban scale in the study (right) (source: author)

The presence of urban water bodies has a significant impact on lowering air temperatures by up to 6 °C in their vicinity, particularly in the summer months. This effect yields comparable outcomes to the situation observed in the microclimate parks (Grant, 2016, p. 76). As a result, in coastal cities, particularly in the sections of the promenade along the coast, the sea breeze plays a significant role in shaping the microclimate. (Fig. 2.1-2). Nevertheless, we observe that the sea breeze effect occurs in the late evening hours.

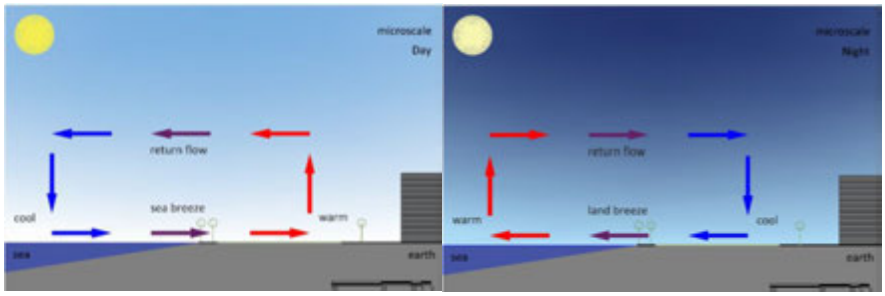

Figure 3 Sea breeze (left), Land breeze (right) (source: the author)

This study will exclusively focus on outdoor thermal comfort, which is described as "the psychological state that reflects satisfaction with the thermal conditions" (ASHRAE, 2005). Thermal comfort significantly affects the usability and livability of a space (Nikopoulou, M., Beker, N., Steemer, K., 2001). The livability of a space is determined by users themselves, taking into account their identity and how often they utilize the space. A livable place refers to an area that is accessible to pedestrians and is used at any time of the day or year. What makes a space attractive to a pedestrian or resident then? While functionality and design are undoubtedly crucial, it is equally necessary to prioritize user comfort. In the preface of the book "Cities for People" by Jan Gehl, Richard Rogers asserts that a well-planned city, with thoughtfully built streets, squares, and parks, brings enjoyment to both tourists and residents who live, work, and engage in recreational activities there on a daily basis (Gehl, 2010). Aside from its functionality and aesthetics, it is crucial that you experience a sense of comfort while standing or walking in it.

Research on urban thermal comfort is predominantly undertaken in developed countries and to a lesser extent in underdeveloped ones. These studies typically focus on analyzing public spaces in urban areas, with a specific emphasis on a single factor. This study, on the other hand, specifically examines the Mediterranean coastline promenades in Albania, France, and Italy as a unique type of constructed environment. The aim of this study is to examine the effect of different cooling systems on thermal comfort at the street level, while considering climate data. This study initially highlights the issues that arise from an analytical examination of the promenades in six cities located in the Mediterranean basin. The research specifically focuses on doing field measurements and computer simulations of one case study, namely the promenades in Durres. These case studies are notable for their Mediterranean climate according to the Köppen-Geiger climate classification (M. Kottek, 2006). Subsequently, we create scenarios using computer simulation, taking into account the intricate specifics of the built environment. Subsequently, we assess the outcomes by considering the degree of urban thermal comfort. The study aims to find out the impact of physical elements in the built environment on the improvement of urban thermal comfort, while also considering climatic aspects. When evaluating the level of urban thermal comfort, especially in coastal promenades, it is essential to evaluate both the physical and climatic factors together, as they are interconnected. The study will examine the impact of urban design and architecture on the thermal comfort of pedestrians in urban areas. Furthermore, this methodology can serve as a fundamental approach not just for promenades in Albania, but also for all public spaces, including promenades and squares, in the Mediterranean basin and other regions with different climate conditions. It is important assess thermal comfort in promenade, to encourage more outdoor activities for all day long and to prevent people staying indoor using air condition (Liang Chen; Edward Ng, 2012). Architects, urban designers, and decision-makers should reconsider public spaces being aware of thermal comfort and prioritizing it. It

2. Methodology

The study combines quantitative and qualitative methods, integrating three complex methodologies: experimental, semi-experimental, and comparative research. An assessment of the urban texture is undertaken in the coastal promenades of Durres and Vlora in Albania, Cannes and Nice in France and Genoa and Sanremo in Italy. Following a comprehensive analysis of the urban environment, measurements were taken and computer simulations were conducted for a section of the promenade in the city of Durres, located in Albania. The field measurements in the promenade of Durres were carried out through thermal camera, and weather instruments (Fig.4). We measured the temperature using a digital thermometer and compared it with the temperature obtained from the local weather station. At the same time, thermal camera measurements were added to these measurements. An infrared camera identifies the infrared energy emitted, transmitted, or reflected by all materials at temperatures above absolute zero (0°Kelvin) and converts the energy factor into a temperature reading or thermogram (FLIR, 2018). After the site measurements we utilized the ENVI-met software to conduct computer simulations. The software enables urban planners, architects, and engineers to create sustainable living conditions in a dynamic environment by thoroughly examining all components of the microclimate system and evaluating the effectiveness of urban design (Anon., 2021). It calculates the values of the degree of thermal comfort by setting the parameters for geographical position, solar access, wind, air temperature, and humidity (Arens, E. and Bosselmann, P., 1989). The index of physiologic equivalent temperature (PET) measures the level of thermal comfort (Matzarakis, A.; Mayer, H.; Iziomon, M.G., 1999).

Figure 4 Instruments used for site measurements

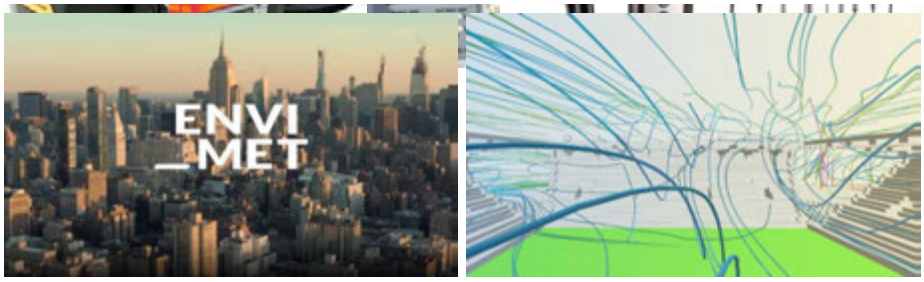

Figure 5 ENVI_met software for computer simulation

The initial scenario is executed considering the current conditions, with an emphasis on PET (Physiological Equivalent Temperature) and STS (Simulation-derived Material Surface Temperature). We generate different scenarios by analyzing diverse mitigation strategies for tackling UHI (Urban Heat Island) , such as revitalizing promenades with cool pavements (Ani Tola, Paul Louis Meunier, Parashqevi Tashi, Elton Hala, 2017), integrating green areas and

trees (Fazia Ali-Toudert, Helmut Mayer, 2005), utilizing water bodies and water spray systems, enhancing the availability of both artificial and natural shade (P J Littlefair, M Santamouris, S Alvarez, A Dupagne, D Hall, J Teller, J F Coronel, N Papanikolaou, 2000), and implementing smart cooling technologies. We evaluate the outcomes of these scenarios by comparing them to the current situation specifically examining the two parameters indicated earlier, PET and STS. A typical summer day is selected to replicate the present state of the promenade in the city of Durres. The field measurements and simulations of the existing condition (scenario 0) of the promenade are analyzed to determine the level of thermal comfort. Subsequently, a hypothetical scenario (scenario 1) is developed under the same weather circumstances to examine the impact of each parameter in reducing thermal stress. Scenario 1 is compared to scenario 0 in order to determine the impact of pavement material properties, water bodies and sprays, as well as natural and artificial shades on outdoor thermal comfort at the pedestrian level.

3. Case studies

Globally, Mediterranean cities are renowned for their "La Dolce Vita" lifestyle, characterized by leisurely strolls along the coastline and a greater preference for outdoor activities due to the delightful Mediterranean climate. The architects, urbanists, and decision-makers must not overlook the substantial potential of this. In order to get optimal results, it is crucial to consider not only the visual and functional aspects but also the methods to guarantee consistent thermal comfort and livability throughout the entire year (Massa, 2005). Assessing the thermal comfort of the promenade is critical for encouraging long-term outdoor activities and decreasing dependence on indoor air conditioning. The chosen cases in this research consist of the Genoa and Sanremo promenades in Italy, the Cannes and Nice promenades in France, and the Durres and Vlora promenades in Albania (Fig. 6). Before choosing them, we carefully considered the Mediterranean lifestyle and the city's development. The objective was to identify promenades in Mediterranean cities that shared the same geographical region, had similar terrain characteristics, but featured distinct urban layouts and somewhat different climate conditions. Another factor considered was the size of the urban population and the level of development in the same tourism sector. Furthermore, these cities have nearly identical needs for promenades and share similar urban structures and features. Sea breezes frequently create the impression that urban microclimate is not a concern in coastal communities. Furthermore, it is generally believed that significant levels of anthropogenic heat, which have an impact on the urban microclimate, are mostly found in major cities. Previous case studies have shown that coastal cities, whether located downtown or near the coast, also experience significant levels of thermal discomfort.

According to the Köppen-Geiger climate classification, the six cities chosen for this study have a typical Mediterranean climate with a temperate, dry summer (Cs category). Seas and cold ocean currents inextricably link the Mediterranean climate zones. This climate extends beyond the Mediterranean region to many parts of the world, albeit with varying temperatures (Köppen, 1918). The cities were chosen to represent Mediterranean climate zones, including historical Mediterranean basin cities such as Athens, Algeria, Barcelona, Beirut, Istanbul, Izmir, Jerusalem, Marseille, Rome, and Tunisia. Additionally, cities within Mediterranean climatic zones like Lisbon, Casablanca, Cape Town, Adelaide, Pert, Santiago, and Los Angeles, Tashkent, and Dushanbe were included (Figs. 8 and 9). Much of the Mediterranean coast enjoys a hot, summer Mediterranean climate. However, most of its southeastern coast has a hot desert climate, and much of Spain's eastern (Mediterranean) coast has a cold semi-arid climate, while most of Italy's northern (Adriatic) coast has a humid subtropical climate. Although they are rare, tropical cyclones occasionally form in the Mediterranean Sea, typically in September–November.

Figure 6 Case studies location in the Mediterranean basin

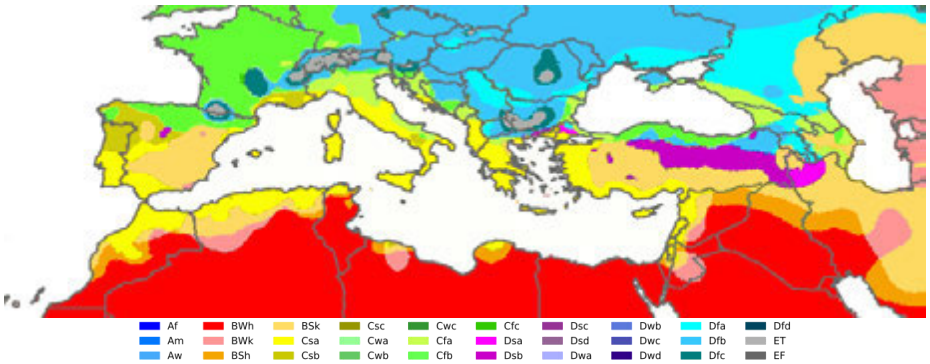

Figure 7 Climatic classification, Köppen – Geige World Map, Mediterranean Sea Area

3.1. Genoa Promenade in Italy

Genoa is a port city and the capital of northwest Italy's Liguria region. The population record in 2023 is 558,745. It is known for its central role in maritime trade over many centuries. The topography of the city rates with an elevation from 0-50m. The city promenade extends along the seaside and in between the sidewalk and buildings lies the road for vehicles, bus and motorcycles. From the photos, we can notice that the promenade is fully exposed to the sun, due to the urban design and its geographical position. The trees are missing, only some palm trees and shrubs are present.

Figure 8 Genova Promenade map and photos (source: google, 2024)

Genoa has a Mediterranean climate (Csa) in the Köppen climate classification, with plentiful precipitation due to its location on a common storm track. Due to its position between the sea and mountains over 1000 meters high, each neighborhood of Genoa has specific climatic characteristics. In Genoa, the summers are short, warm, humid, and mostly clear and the winters are long, cold, and partly cloudy. Over the course of the year, the temperature typically varies from 5°C to 27°C and is rarely below 2°C or above 30°C.

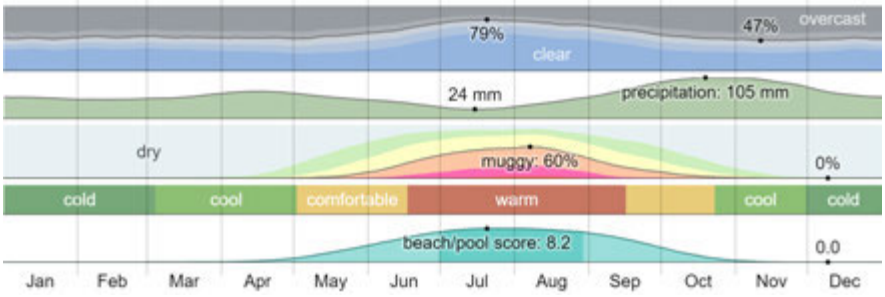

Figure 9 Climate Data, Genoa (weatherspark, 2024)

3.2. Sanremo Promenade in Italy

Sanremo is a coastal city in northwestern Italy. The population record in 2021 is 55,000Its green spaces include the park of Villa Ormond, with a Japanese garden, palm trees and ancient olive groves. The topography of the city rates with an elevation from 0-15m. The promenade is located in the southern part of the city, where by the coast are the beaches and smalls piers. The promenade is fully exposed to the sun due to its geographic position but also the urban design. We can clearly notice from the photos that there is vegetation but only palm trees by the coast.

Figure 10 Sanremo Promenade map and photos (source: google, 2024)

Sanremo experiences a hot-summer Mediterranean climate (Köppen climate classification Csa). In Sanremo, the summers are short, warm, humid, dry, and mostly clear and the winters are long, cold, and partly cloudy. Over the course of the year, the temperature typically varies from 7°C to 28°C and is rarely below 4°C or above 31°C.

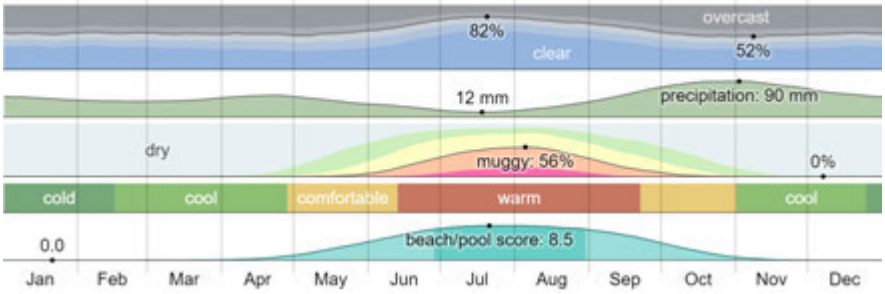

Figure 11 Climate Data, San Remo (weatherspark, 2024)

3.3. Cannes Promenade in France

Cannes, a resort town on the French Riviera, is famed for its international film festival. Its Boulevard de la Croisette, curving along the coast, is lined with sandy beaches, upmarket boutiques and palatial hotels. City elevation is 0-260m. The population record in 2021 is 73,255. The promenade is located in the southern part of the city. From the photos we can notice the presence of pine trees with big crown, alongside the promenade. In between the promenade and the buildings are located the path for cycling and separately the lane for vehicles.

Figure 12 Cannes Promenade map and photos (source: google, 2024)

Cannes has a subtropical Mediterranean climate (Köppen: Csa) and the city enjoys 11 hours of sunshine per day during summer (July), while in winter (December to February) the weather is mild. Cannes summers are long and warm, with summer daytime temperatures regularly hitting 30 °C, while average temperatures are about 25 °C (Anon., 2023). Temperatures remain high from June to September, the busiest time of the year. Over the course of the year, the temperature typically varies from 4°C to 28°C and is rarely below 0°C or above 30°C.

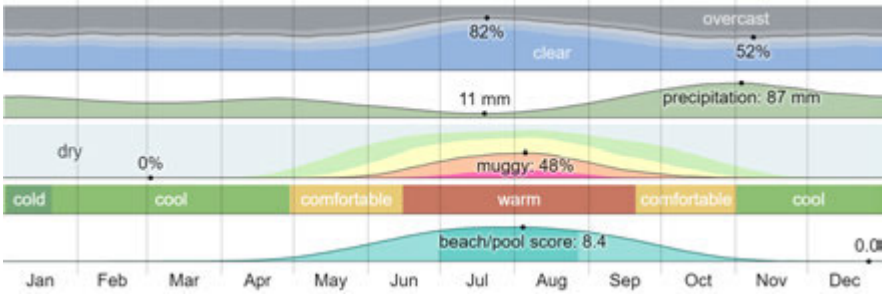

Figure 13 Climate Data, Cannes (weatherspark, 2024)

3.4. Nice Promenade in France

Nice, capital of the Alpes-Maritimes department on the French Riviera, sits on the pebbly shores of the Baie des Anges. Founded by the Greeks and later a retreat for 19th-century European elite, the city has also long attracted artists. The population record in 2021 is 348,085. The promenade is located in the southern part of the city. From the photos we can notice that the promenade is fully exposed to the sun due not only its geographic position but also for its design. There are only some palm trees alongside the road between the promenade and the buildings.

Figure 14 Nice Promenade map and photos (source: google, 2024)

Nice has a hot-summer Mediterranean climate (Köppen: Csa), enjoying mild winters with moderate rainfall. It is one of the warmest Mediterranean climates for its latitude. Summers are warm to hot, dry, and sunny. The temperature is typically above 26 °C but rarely above 32 °C. Summer temperatures, therefore, are often higher in the city. The average maximum temperature in the warmest months of July and August is about 27 °C (Anon., 2023). Over the course of the year, the temperature typically varies from 5°C to 28°C and is rarely below 2°C or above 30°C.

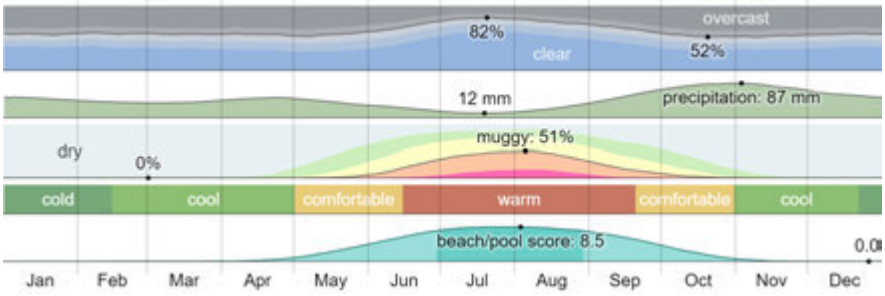

Figure 15 Climate Data, Nice (weatherspark, 2024)

3.5. Vlora Promenade in Albania

Vlorë is the third most populous city of the Republic of Albania. Located in southwestern Albania, Vlorë sprawls on the Bay of Vlorë and is surrounded by the foothills of the Ceraunian Mountains along the Albanian Adriatic and Ionian Sea. The population record in 2021 is 187,675 (Instituti Kombetar i Statistikave, 2021). The promenade is located in the southeastern part of the city, east part of the port. The first phase of the promenade was reconstructed on

2017, by considering not only a sidewalk, but also having different activities. From the photos we can notice also a green park and Aleppo pine trees alongside the promenade in 2 rows.

Figure 16 Vlora Promenade photo 2018

In Vlorë, The summers are predominantly hot and dry, the winters relatively mild, and falls and springs mainly stable, in terms of precipitation and temperatures (Anon., 1992). According to the Köppen climate classification, has a hot-summer Mediterranean climate (Csa) zone. Over the course of the year, the temperature typically varies from 6°C to 30°C and is rarely below 1°C or above 33°C.

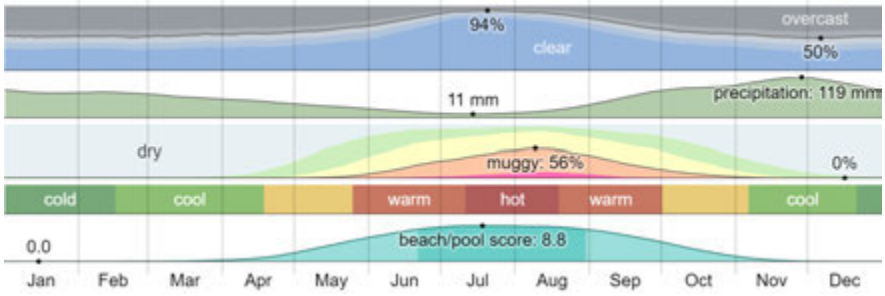

Figure 17 Climate Data, Vlore (weatherspark, 2024)

3.6. Durres Promenade in Albania

Durrës is the largest port city in Albania, and lies in the western part of the capital Tirana. It is also a main port city on the Adriatic Sea in western Balkan. It's known for its huge Roman amphitheater. Nearby is a 9th-century church with mosaic-covered walls. The bay of Durrësi has shallow waters. The population record in 2021 is 292,029 (Instituti Kombetar i Statistikave, 2021). The promenade is located in the southern part of the city, western part of the port. On 2020 one part of the promenade was reconstructed by replacing the pavement, changing the

geometry, adding greenery and trees with a small crown. Even having a new promenade, it is still fully exposed to the sun.

Figure 18 Durres Promenade photo 2020

According to the Köppen climate classification, Durrës is classified under the periphery of the hot-summer Mediterranean climate (Csa) zone. The summers are predominantly hot and dry, the winters relatively mild, and falls and springs mainly stable, in terms of precipitation and temperatures. Over the course of the year, the temperature typically varies from 4°C to 30°C and is rarely below -1°C or above 33°C.

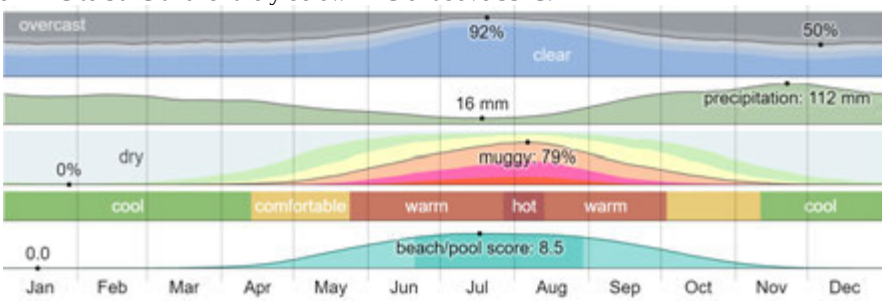

Figure 19 Climate Data, Durres (weatherspark, 2024)

4. Results and discussion

The field study begins with on-site measurements conducted in Durres Promenade utilizing thermometers and weather data obtained from IGEO[1]. The entire Durres Promenade is oriented towards the sun, with limited presence of natural or artificial shade. The presence of light color

[1]Institute of GeoScience, Albania

materials and trees with small crown causes thermal and visual discomfort. Field measurements are capable of detecting thermal stress. Discrepancies in air temperature were observed between on-site measurements and data collected from the local weather station.

Figure 20 Durres Promenade map and photos

4.1. The field measurement results for the current condition were obtained on September 5, 2020.

We conducted field measurements on September 5, 2020, at 08:00, 12:00, 16:00, and 20:00, due to the completion of implementation works on the Durres' promenade. Initially, we obtained weather data from the local weather station via the IGEO, including air temperature, relative air humidity, wind speed, average radiation temperature, dew point, visibility, cloud height, water vapor tension, precipitation, wind gusts, and UV index. According to site measurements, the air temperature on site (Tup at 1.7 m) is higher than that from IGEO (Tair), with an average difference of 4.3 °C at 08:00, 5.7 °C at 12:00, 0.5 °C at 16:00, and 0.6 °C at 20:00, depending on the surface temperature of each material and sun hours of exposure. Furthermore, the average air temperature recorded at 0.0 m (Tdo at 0.0 m) compared to Tair is 4.2 ˚C higher at 08:00, 6.4 ˚C at 12:00, and 0.5 ˚C at 16:00, while it is 1.7 ˚C lower at 20:00 (Fig. 2). When comparing the relative humidity on site (H1) to that obtained from IGEO, it was 55% lower than the average. During the day, the STT per material on site is higher in a range of 2–24 ˚C than the Tair, mainly due to the absence of shade. After 19:00, the STT is lower than Tair 3.7-8.2 ˚C, due to the light-colored pavement materials (Tab. 1).

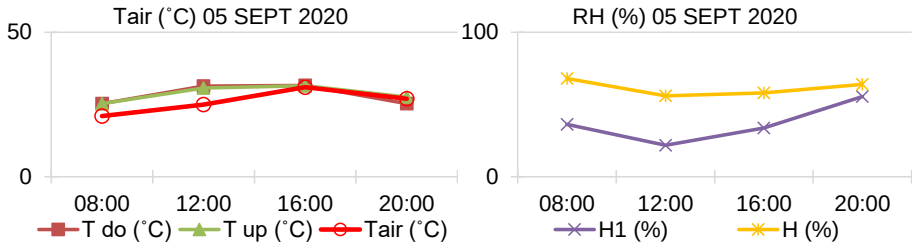

Figure 21 Air Temperature (left) and Relative Humidity (right), 5 Sep 2020, Durres Promenade

Table 1 Sample of Surface Temperature measured with Thermal Camera, 05 September 2020, Durres Promenade

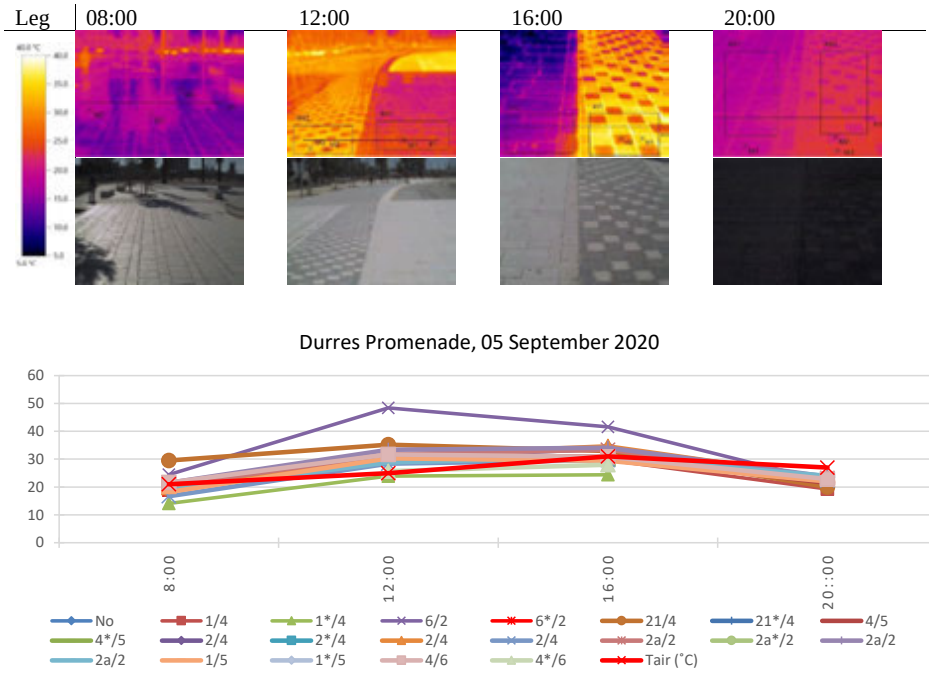

Figure 22 Durrës Promenade – Material Surface Temperature with thermal camera (STT), 05 September 2020

4.2. Simulation results

In each simulation, we entered Durres promenade's geographic position, time zone, and geometric pattern, as well as weather data from the local weather station. We only simulated a portion of the large-scale model, measuring X = 100 m, Y = 120 m, and Z = 40 m, using a grid of dx = 1 m, dy = 1 m, and dz = 1 m. We ran the simulation at the same time and under the

same weather conditions as the field measurements. Results indicate a high degree of thermal stress on September 5, 2020, throughout the entire day until 8 p.m. After these result we chose July 20, 2020, a typical summer day, to run the simulation for the hypothetical scenarios. We used the current promenade simulation (Scenario 0) as a benchmark to validate the hypothetical scenario (Scenario 1). Scenario 0 depicts the existing promenade with light-colored paving materials, a grass surface without an irrigation system, and rare small-crown trees like palms, Tamaris gallica, and Eleagnus angustifolia. The model sets the trees at maturity rather than their current age. We have placed 12 receptors in this section of the promenade to monitor the simulation results as of July 20, 2020. In the scenario 0 we have kept the same design as the current situation. The paving materials in the southern part of the promenade are primarily gray, in other parts are white cube stone in 60%x40% and 75%x25% combinations, along with local white stone, beige-colored chromofiber concrete, gray-colored concrete curbs, and steps. The beach boasts a kelp-covered surface, while paving materials, including beige chromofiber concrete, green surfaces, and local white stone, adorn the north of it. Most of the promenade's greenery is low, but we have planted new trees like Tamarix galica and Eleagnus angustifolia alongside the existing palm trees to create high greenery.

In scenario 1 we modeled Durres promenade by incorporating all the urban design elements explored in previous studies. We added more green surfaces into replacement pavements with abundant Ceratanio Siliqua and Aleppo Pine; installing shades as canopies with varying levels to generate the Venturi effect (Fig. (Tola (Panariti), Ani; Veleshnja, Juljan; Meunier, Paul Louis; Bisha, Geri, 2023). We positioned water surfaces and sprinklers at a height of 30 cm near the curb on the promenade's edge. Receptor R10 is located close to the sunshades, while receptors R8 and R9 are close to the Ceratanio Siliqua trees and the artificial shades. Receptor R2 is close to the water sprinkler, whereas Receptor R5 is near the water surface. The other receptors maintain the same position and material surface as in scenario 0. By combining all four variables, we can determine the extent to which urban thermal comfort will change while keeping the promenade's built environment unaltered.

We independently ran both of these computer models under the same climate conditions, time, and date. Then, we looked at the simulation results for the sky view factor (SVF), the surface temperature from the simulation (STS), and (PET) one by one and in relation to each other to see if there was a dependency ratio between these three factors for the two scenarios.

Figure 23 Urban furniture considered in scenario 1

Table 2 2D and 3D presentation of 2 scenarios in the Durres Promenade

Scenario 0	Scenario 1

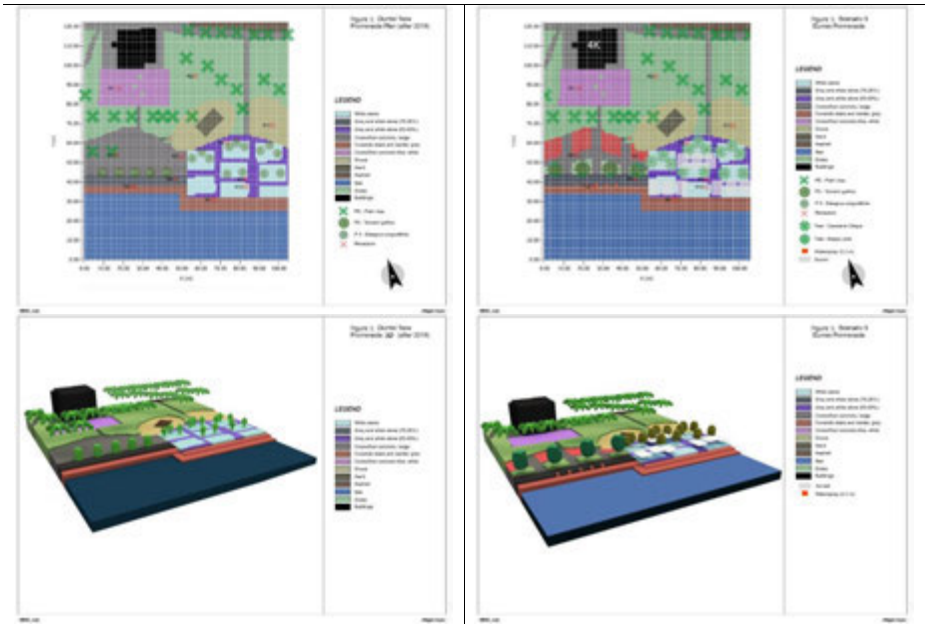

Table 2 presents the 2D and 3D models of scenarios 0 and 1, which include 12 receptors for reading the findings. The table provides information on sun hours, shade hours, and sky view factor (SVF).

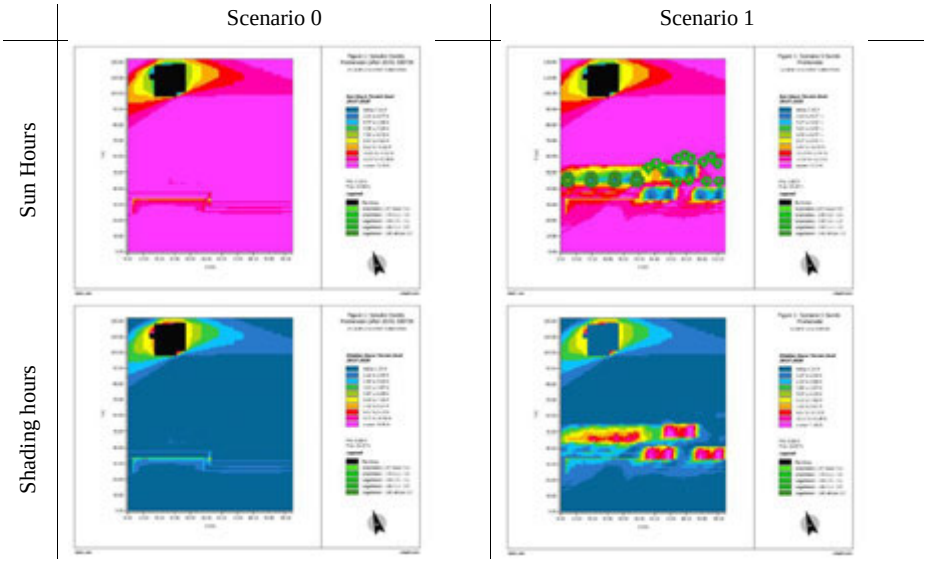
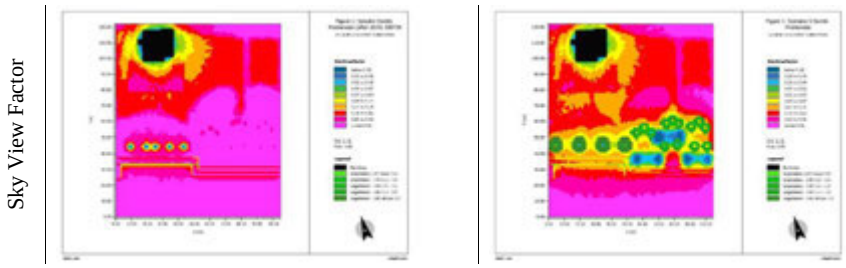
Table 3 Sun and shading hours, Sky View Factor 20 July 2020 for two scenarios





The simulation results indicate that the current Durres promenade (scenario 0) is exposed to the sun for more than 12.07–13.28 hours in the uncovered areas, where the SVF ranges from 0.78 to 0.92, and 1.28–10.27 hours in the spaces occupied by the shadow of the four-story structure, where the SVF ranges from 0.35 to 0.71. According to scenario 1 (mixed design), the part of the promenade is exposed to the sun for 3.1 to 11.97 hours, with SVF values ranging from 0.28 to 0.83 in the area close to the building. While in the part of the promenade covered by artificial shades, tree sun exposure varies from 3.1 to 8.17 hours with an SVF between 0.28 and 0.59 (Tab.3).

According to the simulation results, in Scenario 0, thermal comfort reaches a neutral level after 19:00, and there are three levels of thermal comfort from 08:00 to 18:00: warm, slightly warm, and very hot. Interpreting these results in terms of stress levels, we found moderate stress, strong heat stress, and extreme heat stress. In scenario 1, we achieve neutral thermal comfort after 19:00 on July 20, 2020, mirroring scenario 0. During the daytime hours from 08:00 to 18:00, there are five levels of thermal comfort, such as neutral, slightly warm, warm, hot, and very hot. Interpreted as a stress level, we have no thermal stress, moderate stress, strong stress, and very strong heat stress. Unlike scenario 0, where three levels of thermal stress were present, in scenario 5, the level of thermal stress decreases by one degree as it improves between the hours of 08:00 and 16:00. In addition, note that in scenario 5, the daytime PET has lower average values than in scenario 0, namely 2.4˚C at 08:00, 2.8˚C at 12:00, 2.5˚C at 16:00, 1.3˚C at 17:00, and 0.5˚C at 18:00. This difference is also observed after 18:00 to 04:00, but in values of 0.5-0.6˚C.

Table 4 PET section at 1.5 meter, ENVI-met, 20 July 2020, for Two Scenarios

Time	Scenario 0	Scenario 1	SC1-SC0
08:00			12:00

Stress Level	No thermal stress	No thermal stress	Moderated heat stress	Strong heat stress	Extreme heat stress

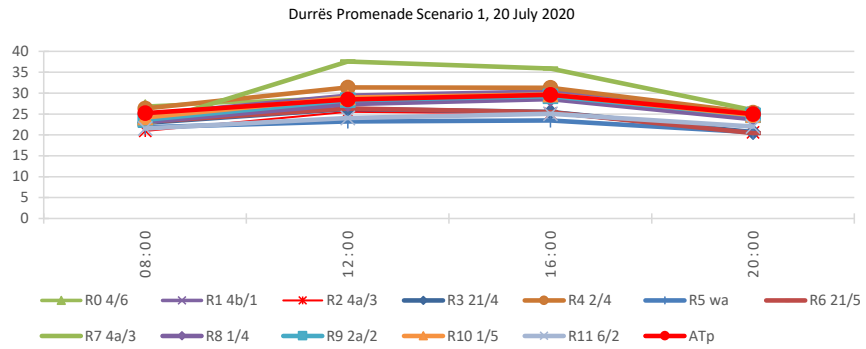

Figure 19: Durres Promenade Scenario 1, 20 July 2020, comparing STS with ATp

5. Conclusions

Site measurements obtained with a digital thermometer and thermal camera have revealed that the temperature measured on-site is 2,8 to 7 degrees Celsius higher than Tair as a result of urban heat emission and the lack of shading. Due to the promenade's complete sun exposure without any shade, surface materials like concrete and gray stones radiate intensely throughout the day. The on-site humidity is less than 55 percent, which is less than the humidity measured by the local weather station.

The simulation results reveal an improvement in the relative PET difference between scenario 1 and scenario 0, particularly in areas with altered paving materials, water surfaces and sprinklers, trees with a large crown, and artificial shade. The temperature ranges from 0.1-13.7 °C at 8:00, 0.3-9.2 °C at 12:00, 0.1-12.1 °C at 16:00, 0.1-10.7 °C at 17:00 and 0.4-5.7 °C at 18:00, and further represents a difference of 0.1-2.4 °C. Depending on the direction of the shade, STS presents values 0.3–8.9 °C lower than in scenario 0, in areas where natural and artificial shades have replaced the paving materials. According to the results of the simulations, proper consideration of the types and positions of greenery and artificial shading during the planning phase would improve the thermal comfort at pedestrian level in the built environment of the Durres coastal promenade by between 12 and 45 percent. For the greenery, it is necessary to note that the outdoor thermal comfort will appear sooner the larger the trees are on the site. Examining the relationship between STS and PET reveals that some light-colored materials have reduced STS compared to dark-colored materials, but PET has higher values. This is due to the complete exposure of these "white" surfaces to sunlight, which in turn raises the air temperature on site through reflection. Promenades, particularly during midday and afternoon hours in the summer, have become a "dead space" (Ranasinghe, 2004) due to temperature stress, rendering them unsuitable for pedestrian use, irrespective of any activities or events that may take place there.

6. Recommendations

The results obtained for the coastal promenades presented in this study serve as guidelines for the measurable improvement of the level of urban thermal comfort in any new or built urban areas.

When designing new or newly built urban spaces, it is advised to:

First, examine the climatic factors such as air temperature, solar radiation, relative humidity, wind speed and direction, precipitation, cloudiness, atmospheric pressure, direct and reflected short-wave radiation, as well as the UV index.

Consider appropriate paving materials (neither too open nor too dark), the presence of water (water surface and water sprinkler), the proper selection of the type of vertical greenery (tree with large crown) and its position (ways of placement to make shadows), maintenance of grassy surfaces, and placement of artificial shades (tents of unleveled pieces to create the Venturi effect).

Perform environmental and thermographic analyses using field measurements and computer simulations to predict the level of thermal comfort in urban spaces during each season of the year.

7. Further studies

This study focused on specific days during the summer months. Despite only running the scenarios for the Durres Promenade, the cities of Vlora, Genoa, Sanremo, Nice, and Cannes are very likely to experience a common summer day, such as July 20, 2020. Future research should examine the role of urban design in outdoor thermal comfort in any season of the year, whether in Mediterranean cities or elsewhere. It would also be essential to investigate the relationship between architecture and urban planning. Because of the complexity of an urban environment, it is necessary to employ computer models to predict and understand how urban design might affect the urban microclimate and the level of outdoor thermal comfort. This study used the computer software ENVI-met and BioMet to jointly evaluate climate conditions and various urban aspects. Note that the larger the simulation space with a small modeling scale, the closer the conclusion is to reality. Large-scale modeling necessitates the use of computer equipment or specialized modeling labs with high computational capacity. This enables the acquisition of results for every day of the year within a shorter timeframe.

This future study will deepen and widen architects', urban designers', and decision-makers' understanding of urban thermal comfort analysis and the factors that affect it. It will provide the necessary guidelines for sustainable urban development, improving the quality of urban spaces and cities by making them healthy and livable, so that people can breathe and enjoy them at any time of the year. Other countries in the Mediterranean basin will adopt it, and it could serve as a fundamental approach for countries with diverse climates.

Abstract
Household energy consumption constitutes approximately 30%, of India's overall energy consumption, with cooking alone accounting for about 40% of this household energy usage. According to the recent consumer survey of India, approximately 30% of the population is still using polluting fuels in India, and several policies like the Pradhan Mantri Ujjwala Yojana have been launched to improve the penetration of LPG as the primary cooking fuel in households. While studies have examined the influence of socio-economic factors on household fuel choices, research focusing on spatial socio-economic dynamics remains limited. This study seeks to fill this gap by investigating the role of regional economies in shaping household cooking fuel preferences, thus addressing concerns related to sustainability and indoor air pollution. This study hypothesises that regional economies might play a significant role in influencing the cooking fuel choice of households. Given the fact that the subsidies and policies governing the cost and distribution of fuel are implemented on national or regional levels, coupled with existing regional disparities in India, studying the influence of spatial variables is imperative. Utilizing Spatial Regression Analysis, specifically the Spatial Lag Model, this research examines the impact of various regional variables on household fuel choices. Findings indicate that GDP per Capita, Built-up Area per 100 sqm, Percentage of main workers in the district and Percentage of households with land ownership exceeding 1 Ha significantly influence the prevalence of LPG usage as the primary cooking fuel in Indian households. For instance, an increase of INR 20,000 in GDP per capita of a district causes a 1% rise in LPG adoption among households in that district. Furthermore, the spatial lag coefficient highlights the spillover effect, indicating that a 1% increase in LPG usage among all the neighbouring districts leads to a 0.42% rise in LPG adoption among the households of the target district. This study underscores the implications of improved technology or new policies on energy usage patterns, suggesting a need for nuanced policy measures tailored to regional disparities. The insights generated from this analysis offer valuable guidance for policymakers and regional planners in formulating targeted interventions to address regional inequalities and promote sustainable development. Additionally, this spatial perspective enables an understanding of resource allocation for efficient regional development. Future research could enhance these findings by incorporating more detailed datasets and refining the Spatial Weights Matrix to account for factors such as connectivity and policy influences..

Keywords
Spatial Regression Analysis, Urban Energy Economics, Household Energy, Cooking Energy

1. Introduction
Approximately 29 percent of the net national energy consumption is in the residential sector, and cooking represents the largest portion of consumption within this sector (IEA, 2020). Specifically, for rural and urban areas, cooking constitutes for 78 percent and 66 percent of the net household energy usage respectively (Yawale et al., 2021).

A business-as-usual scenario of cooking fuel use might lead to approximately 2.7 billion people using unclean fuel by 2030 globally (Stoner et al., 2021). In India, approximately 115 million of its urban population still relying on unclean fuels as of 2012, while only 68.7 percent of utilizes Liquified Petroleum Gas (LPG) for cooking.

Given this substantial reliance on unclean fuels, research has exhaustively examined the factors influencing their usage. The existing literature has extensively explored regression techniques like logistic regression to establish that the household characteristics play an important role in

defining household cooking fuel choice, thus suggesting that with the socio-economic upliftment of the household, the population shifts towards using cleaner fuels. Such outcomes often suggest subsidy-based policies to promote cleaner fuel use, specifically in the developing countries like India.

However, the studies on the influence of spatial factors on household cooking fuel usage is limited. Variables like per capita GDP might indicate the overall socio-economic upliftment of a region, and thus might positively influence the uptake of cleaner fuel for cooking in the households. The variables like connectivity and electrification, which show spatial clustering, might also produce errors in in simple regression methods. Moreover, the subsidies and policies governing the cost and distribution of fuel are implemented on national or regional levels. Such uniform policies, coupled with existing regional disparities in India, might not produce the desired results, leading to inequity among population groups and regions. Thus, studying the influence of spatial variables for cooking fuel choice becomes imperative.

This study hypothesises and demonstrates using Spatial Lag Model that spatial factors play a significant role in influencing the cooking fuel choice of households. Thus, suggesting that merely promoting cleaner fuels using schemes like subsidies might not be effectively successful in influencing the household fuel choice. For developing and highly populated countries like India, which aims to reduce its net carbon emission, more efficient and multi-pronged approaches are necessary to reduce emissions. This study provides such opportunity by studying the influence of spatially autocorrelated variables on the uptake of household cooking fuel choices.

2. Literature Review

Studies classify cooking fuels as traditional (unclean or polluting) or modern (clean or non-polluting) fuels (Katutsi, Dickson and Migisha, 2020). Common traditional cooking fuels include biomass, charcoal, coal, and kerosene, while their modern cleaner counterparts typically comprise gas and electricity (Stoner *et al.*, 2021). Apart from the concerns about pollution, efficiency also varies among traditional and modern fuels, with biomass at 8 percent, coal at 18 percent, charcoal at 25 percent, kerosene at 45 percent, and gas and LPG at 50 percent (Dzioubinski and Chipman, 1999).

Research literature has extensively studied the variables influencing households cooking fuel choices. Studies classify these variables into into demographic, economic, consumer attitude, and climatic factors climate (Bhattacharjee and Reichard, 2012). Demographic and economic variables have been extensively studied in the literature (Kastner and Stern, 2015).

The literature has established that the demographic variables such as household size, age of household/head (Yu, Zhang and Fujiwara, 2011; Aslam and Ahmad, 2018; Katutsi, Dickson and Migisha, 2020), gender of household head (Katutsi, Dickson and Migisha, 2020), marital status (Katutsi, Dickson and Migisha, 2020), and level of education (Katutsi, Dickson and Migisha, 2020; Mperejekumana *et al.*, 2021), influence the cooking fuel choices of households.

Similarly, the significant economic variables are GDP (Garba and Bellingham, 2021), employment status, income (Acuner and Özgür Kayalica, 2018; Kuo and Azam, 2019; Katutsi, Dickson and Migisha, 2020), expenditure, land ownership, number employed, type of employment (Liao *et al.*, 2019), credit access (Mperejekumana *et al.*, 2021), ownership of ICT (Acharya and Marhold, 2019), ownership of housing (Pundo and Fraser, 2006; Acharya and

Marhold, 2019), housing type (Pundo and Fraser, 2006; Yu, Zhang and Fujiwara, 2011) and area of housing unit.

Literature has also shown the relationship between use cooking fuels with initial investment cost of modern fuels (Pohekar, Kumar and Ramachandran, 2005; Reddy and Balachandra, 2006), lack of LPG distribution networks (Reddy and Balachandra, 2006), ingrained habits of using traditional fuels like cow-dung or firewood (Sharma, Parikh and Singh, 2019), the availability of Solid Biomass Fuel (SBF) through agricultural produce (Sharma, Parikh and Singh, 2019), culinary preferences (Sharma, Parikh and Singh, 2019), HDI (Dutta and Sahu, 2022), and electrification (Gupta and Pelli, 2021).

These studies have attempted to estimate the influence of various factors on each of the cooking fuel being used in the households. As the fuel choices are polychotomous variable with a dominant category, Multinomial Logistic Regression is a popular regression method in such studies (Danlami, Applanaidu and Islam, 2019; Baek, Jung and Kang, 2020; Katutsi, Dickson and Migisha, 2020; Kapsalyamova *et al.*, 2021; Mperejekumana *et al.*, 2021; Niyonshuti, 2021). Moreover, some works have also employed the Ordered Probit Model (Rahut, Behera and Ali, 2017) and Multiple Discrete-Continuous Extreme Value (Biying, Zhang and Fujiwara, 2012; Yu, Zhang and Fujiwara, 2013; Acharya and Marhold, 2019) for analysis.

However, few research works have attempted to study the influence of spatial factors such as GDP of the region, regional employment type or the extent of urbanisation, specifically using spatial regression analysis methods. Searching for the following code on Scopus outputs 15 studies, only one out of which by Wang *et al.* (2021) suggest that the per capita gross regional product and per capita disposable income of urban residents influence fuel choice of the households.

Most of the studies which have used spatial regression analysis in the context of fuel or energy are related to air pollution or electricity consumption. Studies suggest that total population, population density, urbanisation rate, per-capita gross regional product, economic growth, industrial structure, road density and climatic factors influence air pollution (Zhou, Chen and Wang, 2018; Ren and Matsumoto, 2020; Tan *et al.*, 2021). Whereas, income, employment density, ratio of employee in retail department, transit fare, and distance to city centre (Yin, Mizokami and Maruyama, 2013; Li *et al.*, 2022). These studies suggest policy improvements related to spatial pricing policies (Zhang *et al.*, 2023), transition of the economic structure (Ren and Matsumoto, 2020), and influencing built-up and employment density (Yin, Mizokami and Maruyama, 2013). Several variables in these studies are common with the variables which have been found to be significantly influencing the household cooking fuel choices.

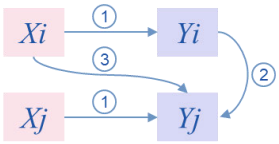
Moreover, variables like population density, urbanisation rate, electrification and connectivity exhibit spatial clustering, and hence considering this characteristic is required during analysis. However, the studies focusing on household fuel choices have failed to take the spatial clustering or spatial autocorrelation into account. To address this gap, this study utilises spatial regression method for the analysis.

3. Methodology

Research highlights that the spatial regression models perform better than the Ordinary Least Squares (OLS) regression when there is spatial interaction between the variables (Ward and Gleditsch, 2008). While linear or logistic regression techniques study the relationship between the dependent and corresponding independent variables, the spatial regression models often

incorporate the influence of variables corresponding to spatially neighbouring entities (spatial units) on the target variable of the target spatial unit. The description of simple regression models and spatial regression models is shown in Figure 1.

Figure 1 Description of Simple regression and Spatial Regression Techniques



1. Regression Model: $Xi \rightarrow Yi$ or $Xj \rightarrow Yj$
2. Spatial Lag or Lag Y Model (SAR): $Yi \leftrightarrow Yj$
3. Spatial Cross-Regressive or Lag X Model (SLX): $Xi \rightarrow Yj$

As established in the literature, several variables shown to influence household fuel choices significantly might be spatially correlated. To address the spatial influence of such variables, using spatial regression models for this study is required. The influence of the socio-economic variables explored in the previous studies is limited to the same spatial unit, and their influence might not directly extend to the neighbouring spatial units. However, the socio-economic upliftment of the population in the neighbouring spatial unit might also cause a similar development in the target spatial unit, leading to a spill-over effect in the uptake of cleaner fuels for cooking. Since the socio-economic factors of one spatial unit might not affect the fuel choice in the neighbouring spatial unit, the SLX model is out of scope, and the SAR model is used for the study.

The spatial lag model considers the effect of one dependent variable on the neighbouring one, and is represented by the Eq. 1.

$$\boldsymbol{y} = \rho \boldsymbol{W y} + \boldsymbol{\beta X} + \boldsymbol{\varepsilon} \qquad \textbf{Eq. 1}$$

where,

y = Dependent Variable
ρ = Spatial Lag Coefficient
W = Spatial Weights Matrix with size a '$n \times n$', where n is the total number of observations
β = Coefficient of Independent Variable
X = Independent Variable
ε = Error

However, it is necessary to find out the extent of spatial autocorrelation in the dataset to perform the spatial regression analysis. Spatial autocorrelation is indexed by calculating Moran's I, which measures the spatial clustering of the variables (Moran, 1950; Cliff, Ord and Cliff, 1981). The value of Moran's I ranges from -1 to +1, negative value representing no clustering or dispersed features, and a positive value representing clustered features, corresponding to a z-score greater than 1.96, at a 0.05 significance level (Ord and Getis, 1995).

4. Data Description and Pre-processing

A district level dataset for 601 districts of India was created for this study. The data was available from various sources listed in Table 1. All the datasets were then transformed at the district level resolution, where districts will be acting as one spatial unit. Since LPG is the predominant fuel choice with 68.7 percent of the Indian population using it as the main cooking

fuel (MoSPI, 2014), the fraction of households using LPG in the district as their main cooking fuel was considered as the dependent variable for the analysis.

Table 1 Sets of independent variables were considered for the study

S. No.	Variables	Source
Dependent Variables		
1	Fraction of Households using LPG as main cooking fuel	Household Consumption of Various Goods and Services in India, 2011-12, NSS 68th Round, Sch 1.0, Type 2, National Sample Survey Office (NSSO), Ministry of Statistics and Program Implementation (MoSPI, 2014), Government of India
Independent Variables: Spatial Economy		
1	Gross District Product (GDP) (in Crores INR)	NITI Aayog (2016), Government of India (For the states with no data for GDP, the state GDP was distributed according to the population weightage of the districts)
2	GDP per Capita (in Crores INR)	GDP divided by the population of the district (obtained from Census of India, Government of India (MoHA, 2014))
Independent Variables: Household Economic Status		
3	Average Household Expenditure (in Thousands INR)	Household Consumption of Various Goods and Services in India, 2011-12, NSS 68th Round, Sch 1.0, Type 2, National Sample Survey Office (NSSO), Ministry of Statistics and Program Implementation (MoSPI, 2014), Government of India
4	Fraction of Households with more than 1 ha of Land Owned	
Independent Variables: employment types		
5	Fraction of Working Population	Census of India, Government of India (MoHA, 2014)
6	Fraction of Main Workers	
7	Fraction of Agricultural Workers	
Independent Variables: Socio-Demographic Status		
8	Total Population	Census of India, Government of India (MoHA, 2014)
9	Total number of Households	
10	Average Household Size	
11	Fraction of Households with Head having a Graduation Degree	
12	Fraction of Literate Population	
13	Average age of Household Head	Household Consumption of Various Goods and Services in India, 2011-12, NSS 68th Round, Sch 1.0,

		Type 2, National Sample Survey Office (NSSO), Ministry of Statistics and Program Implementation (MoSPI, 2014), Government of India
Independent Variables: Spatial Development		
14	Fraction of Population living in Urban Areas	Census of India, Government of India (MoHA, 2014)
15	Average Night Time Light in W/cm²/sr	Average Night Time Light (NCEI, 2013)
16	Built-up area per 100 m^2 of Land	Built-up density (GHSL, 2023), European Union

Spatial Weights Matrix

The calculation of W matrix is important in determining the model properties. W is defined as a '$n \times n$' matrix, where n is the total number of observations. Creating the W matrix for the study included following steps:

1. Initially, the value of n_{ij} is kept equal to 1 if the i^{th} and j^{th} entries are neighbours. But that ensures that all the neighbouring districts will have a unit impact on a district, essentially meaning that if a district has more neighbours, then it will have more impact on its dependent variable.
2. To overcome the error, row-wise normalisation is done. This ensures that the unit effect is observed. But practically, not every district will provide a uniform impact, and the districts which are highly influential might impact more.
3. To overcome this error, the values were weighted by district GDP and then normalised to ensure justified impacts. The current W matrix can be described as Eq. 2.

$$W_{ij} = GDP_j \,/\, \sum_{j=1}^{N} GDP_j \qquad \textbf{Eq. 2}$$

where,

GDP_j = GDP of the District j

$j \in \{1,2,3,\ldots,N\}$ is the set of neighbouring districts of the district i

Spatial Autocorrelation

It is necessary to find the extent of spatial autocorrelation or clustering in the dataset to perform the spatial regression analysis. The clusters of developed and under-developed regions can be observed primarily through the maps shown in Figure 2 and Figure 3.

Figure 2 Fraction of Households in the district using LPG as Main Cooking Fuel

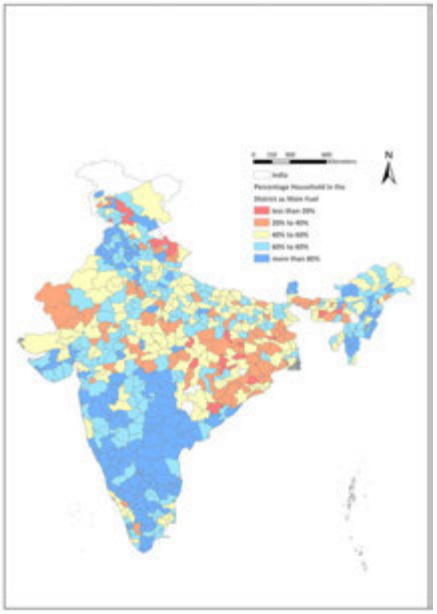


Figure 3 Gross District Product (GDP) (in Crores INR)

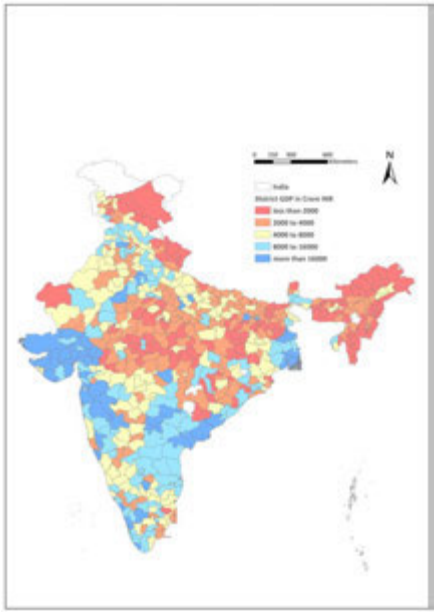

To study the extent of clustering, spatial autocorrelation analysis by calculating Moran's Index was done on the dependent variable i.e. Fraction of Households in the district using LPG as the Main Cooking Fuel in Districts as spatial units. The results showed that the value of Moran's I is 0.335299 and the z-score is 22.58 for the Fraction of Households in the 601 districts using LPG, at less than 1 percent likelihood of clustered pattern being result of a random chance.

Correlation Analysis

The correlation analysis is conducted and at least one from each set of correlated variables is to be chosen as the final independent variable. The correlated sets are:

1. GDP, GDP per capita, Total Population, Total number of Households, Fraction of Population living in Urban Areas, Night Time Light Intensity and Built-Up Density are highly positively correlated to each other.
2. The variables describing employment types, Night Time Light Intensity and Built-Up Density are negatively correlated with the Fraction of Households with more than 1 ha of Land Owned.
3. The fraction of main-workers in the district has a higher and positive correlation with all variables depicting higher development than the fraction of the working population in the district.

5. Results and Discussion

High spatial autocorrelation was observed in the dataset and hence the spatial lag model was implemented to consider clustering of the dataset, as suggested by previous research (Yin, Mizokami and Maruyama, 2013). The results of the analysis are depicted in Table 2.

Table 2 Description of Spatial Regression Analysis results for Fraction of Households in District using LPG as Main Cooking Fuel

Variable	Coefficients
Constant	-0.16**(0.073)
GDP per Capita in Crores	0.005**(0.002)
Built-up Area per 100 m^2	0.01***(0.002)
Fraction of main workers in the district	0.871***(0.111)
Fraction of households with land owned more than 1 ha	0.238***(0.067)
Spatial Lag	0.42***(0.045)

- Number of Observations: 601
- Number of Variables: 6
- Degrees of Freedom: 595
- Akaike info criterion: -398.995
- Schwarz criterion: -372.603
- Mean dependent var: 0.6178
- S.D. dependent var: 0.2147
- Pseudo R-squared: 0.3839
- Spatial Pseudo R-squared: 0.2752
- Log-likelihood: 205.4975
- Sigma-square ML: 0.0285
- S.E of regression: 0.1687

The results can also be described in the form of Eq. 3:

$$\boldsymbol{y} = \rho \boldsymbol{W y} + \boldsymbol{\beta 1 X 1} + \boldsymbol{\beta 2 X 2} + \boldsymbol{\beta 3 X 3} + \boldsymbol{\beta 4 X 4} + \boldsymbol{\varepsilon} \qquad \textbf{Eq. 3}$$

where,

y = Fraction of Households using LPG as the Main Cooking Fuel
ρ = 0.42, W = Spatial Weights Matrix
$\beta 1$ = 0.005, $X1$ = GDP per Capita in Crores
$\beta 2$ = 0.871, $X2$ = Built-up Area per 100 m^2
$\beta 3$ = 0.238, $X3$ = Fraction of main workers in the district
$\beta 4$ = 0.01, $X4$ = Fraction of households with land owned more than 1 ha
ε = -0.16

Four independent variables, namely GDP per Capita, Built-up Area per 100 m^2, Fraction of main workers in the district and Fraction of households with land owned more than 1 ha, were significant. Their description is given below:

1. GDP per Capita in Crores: GDP per capita showed a better significance than net GDP as some of the districts have extremely high or low populations as compared to others. With highly industrialised as well as remote districts present in the dataset, a measure which could depict the economic characteristic at a disaggregate level shows better

results. As the coefficient for the GDP per capita is positive, an increase in the GDP per capita of a district causes a rise in LPG adoption among households in the district.

2. Built-up Area per 100 m^2: Built-up density is a measure of urbanisation as well as accessibility, which ensures the uptake of cleaner fuels. As higher night-time light intensity can be obtained from industries, built-up density showed a higher significance. The positive and significant coefficient shows that if the total built-up land increases, the LPG usage will increase as well, irrespective of all other factors.
3. Fraction of main-workers in the district: The fraction of main-workers depicted the state of employment in the district, and since more stable employment types increase the uptake of cleaner fuels, it provided significant results. The coefficient values depict that a percentage increase in the main workforce of the district increases LPG adoption among households.
4. Fraction of households with land owned more than 1 ha: The average land ownership of Indian households is approximately 1 ha, and better economic well-being increases the uptake of cleaner fuels. Coefficient values depict that an increase in the proportion of households owning up to 1 ha land leads to an increase in LPG usage of the households in the district.
5. Spatial Lag Coefficient: The Spatial Lag Coefficient depicts the effect of LPG usage in neighbouring districts on the target district. Moreover, the effect of independent variables on the LPG usage in the target district also shows up in the coefficient ρ. An increase in LPG usage among all the neighbouring districts leads to a rise in LPG adoption among the households of the target district without any change in the socio-spatial characteristics of the target district. However, LPG usage changes in neighbouring districts with higher GDP would be proportionately higher. However, the value of ρ can also be understood as a limiting factor, meaning any amount of increase in LPG consumption in the neighbouring district cannot lead to more than ρW times of increase in the target district.

6. Policy Implications

In India, subsidy policies like Ujjwala Yojana, which subsidises LPG for a defined socio-economic group, are implemented uniformly nationwide. However, the spatial socio-economic disparity might hinder uniform regional development. Moreover, previous research has extensively explored the influence of socio-economic upliftment on the uptake of non-polluting fuels, suggesting an improvement in such variables to ensure higher uptake of cleaner fuels. However, this research shows the influence of spatial proximity on the uptake of cooking fuels like LPG, indicating a need for nuanced policy measures tailored to regional disparities.

The study indicates that improving the economy or technology or implementing new policies in any urban area might sub-urbanise its periphery by a defined amount. This can be known as an energy usage spill-over effect limited by the value ρW.

Additionally, this spatial perspective enables an understanding of resource allocation for efficient regional development. Such studies can also assess the regional changes in the energy usage scenario after a greenfield development. The insights generated from this analysis offer valuable guidance for policymakers and regional planners in formulating targeted interventions to address regional inequalities and promote sustainable development.

7. Conclusions

This study contributes to the existing literature by introducing the use of the spatial lag model to study the factors influencing cooking fuel choices in households in India. This study

quantifies the spatial influence of socio-economic variables and the spill-over effect of LPG usage on its usage in the target spatial units. The findings of this study are:

1. The positive and significant coefficients for GDP per Capita, Built-up Density, State of Employment and Land Holdings in the Spatial Lag Model indicate that an improvement in these variables leads to increased uptake of LPG as the main cooking fuel in Indian households.
2. The spatial lag coefficient indicates that the uptake of LPG as the main cooking fuel in neighbouring districts positively influences the uptake of LPG in the target districts due to the spill-over effect. Moreover, improvements in GDP per Capita, Built-up Density, State of Employment and Land Holdings in the neighbouring districts influence the LPG uptake of those districts, causing an indirect influence on the target districts.
3. Several socio-economic variables previously used in the studies show spatial clustering or autocorrelation, and the phenomenon must be accounted for. The spatial regression models perform well in such cases and explain the effect of variables influencing household cooking fuel choices while accounting for spatial clustering.
4. To promote cleaner fuel usage in households, the policies must consider the spatial aspects of the region, specifically regional economy and spatial inequalities, instead of proposing uniform blanket schemes.

8. Limitations and the Way Forward

Methodologically, inputting variables such as built-up height or forest cover, and considering weightage dependent on connectivity, policies or state boundaries (which govern fuel pricing) for the calculation of the Spatial Weights Matrix might produce better model results. The data resolution can be further improved to achieve better results. Since socioeconomic disparities and heterogeneity exist in India (Reddy and Balachandra, 2006; Balakrishnan, 2016), and barring a few studies, fuel choices of the population in a region has been assumed to be homogeneous, improving on socio-economic variables, specifically in spatial aspects might be helpful for future studies.

Moreover, since that dataset used for the analysis is from 2011-12, it merely depicts the cross-sectional pattern of consumption among Indian Population. A panel analysis might provide even better insights into the fuel usage pattern, impact of new policies such as Ujjwala Yojana, and future policy improvements.

The Built Environment Policy and Practice Context to Facilitate Climate Change Action - the Role for Planning and Design

Author's Name: Alan March, Anna Hurlimann, Sareh Moosavi, Judy Bush
Affiliation: University of Melbourne
Email: alanpm@unimelb.edu.au

Abstract
Human settlements are key sites in which there is a need for effective climate change action. This paper reports findings in summary of a wider study into the integration of climate change adaptation and mitigation actions across the built environment in Australia. It reports on a process map of the built environment, describes Australian built environment policy; the preparedness of Australian built environment professionals; identifies action across the life cycle of the built environment; and barriers and facilitators experienced by Australia urban designers.

Key words: climate change, built environment, professionals

1 - Introduction

In its 6th Chapter, the Intergovernmental Panel on Climate Change's (IPCC) Sixth Assessment Report, "Cities, settlements and key infrastructure" (2022), states that planning and urban design are essential to climate change action. However, it also highlights that impediments to action must be overcome. With this in mind, finding ways for planning and built environment practitioners to take meaningful action on climate in circumstances where there is a lack of clarity is important. This often takes place within complex urban management processes and systems (IPCC, 2022: 6-90, 6-105).

This paper reports summary findings of a large Australian Research Council funded study into integrating climate change action (adaptation and mitigation) across the built environment. It explored how climate change action could be facilitated from the viewpoint of built environment practitioners in Australia, paying heed to the policy context. The research brought together an interdisciplinary team of built environment researchers, with a range of academic and practice backgrounds. Considerable engagement with practitioners and policy makers was included. Its overall aim is to identify actions in policy and practice that assist to achieve effective and efficient climate change adaptation and mitigation actions in the main sectors of Australia's built environment, including: design (architecture, landscape architecture and urban design); urban planning; construction; and property. Policy is understood in this work to include policies, strategies, regulations, codes and legal Acts (A. Hurlimann et al., 2024; A. Hurlimann & A. March, 2012).

Caused by anthropogenic greenhouse gas (GHG) emissions, climate change is having increasing impacts on systems globally. Considerable international recognition exists of the urgent need for reduced GHG emissions to avoid catastrophic climate change, and adaption

to deal with changes in climate that are unavoidable (IPCC, 2015). This action of climate change mitigation, in addition to climate change adaptation dealing with existing and future impacts has particular importance in cities (Gleeson & Steele, 2010; McGuirk, Dowling, & Bulkeley, 2014). Built environments are where the majority of the world's population live and produce the most GHG emissions. The impacts of climate change such as extreme weather, wildfires, floods, storms and sea level rise are also increasingly felt in cities, including in Australia (BoM & CSIRO, 2020).

Australia is a highly urbanised country and has an urgent need to address climate change. In this paper the manner in which production and modification of the built environment occurs focussed on, including the activities of the design, urban planning, construction and property sectors. Australian governments at federal, state and local levels have developed many policies to address climate change (A. Hurlimann et al., 2024). While action to address climate change has occurred, it appears unlikely to be of a scale extensive enough to deal with the problem. Effective policy that can achieve climate change targets are an essential factor in dealing with this challenge (IPCC, 2022).

Built environments, also known as cities, urban areas, or human settlements are defined variously. For this research we follow the 2016 Australian State of the Environment report definition:

…the human-made surroundings where people gather to live, work and play. It encompasses both the physical structures where people do these activities and the supporting infrastructures, such as transport, water and energy networks. The built environment is a material, spatial and cultural product of human labour and imagination." (Coleman, 2017: 2).

To consider barriers and facilitators of climate change adaptation and mitigation, the paper reports findings relating to: 1) mapping the Built Environment Life Cycle; 2) describing the Australian built environment policy context; 3) assessing the preparedness of Australian built environment professionals, including planners; 4) identifying the mechanisms for influence and action across the life cycle of the built environment; and, 5) the barriers and facilitators experienced by Australia urban designers.

2 - Climate Change and the Built Environment Life Cycle

This section sets out a process map to describe the production of the built environment as a life cycle developed at the beginning of this project (Hurlimann et al 2022). Process mapping allows the development of a model to show "relationships between the activities, people, data and objects involved in the production of a specified output" (Biazzo, 2002: 42). They are recognised for their descriptive value in assisting defining, improving, and re-designing processes (Biazzo, 2002). Biazzo (2002 p.43) sets out four common perspectives represented in process maps: 1) the process or fundamental activities; 2) when and how the elements of the process are carried out; 3) where and by whom they are undertaken; and 4) the structure and relationship between the stakeholders in the process. The process map developed and presented of the built environment in this paper identifies key activities in producing the built environment. At the same time, it identifies the key sectors and actors contributing to the production of the built environment across life stages.

Distinct phases were followed to develop built environment process map (Hürlimann et al., 2022). Drawing on the methods of Sanders, Ross, and Coleman (1999) and Biazzo (2002),

the following actions were taken 1) establishment of temporal via life stages 2) identification of the activities contributing to producing the built environment 3) identifying key sectors' involvement across life stages 4) identification of key actors and professionals across the life stages (Sanders, Ross, & Coleman, 1999). Diagramming was developed to describe the arrangements showing the structure and relationships between stakeholders.

Following internal development, external input from industry professionals assisted to verify and further refine the process map. An expert reference group comprising 18 members met to critique and discuss the preliminary process map was undertaken, including breakout sessions. Outcomes of meeting with the expert reference group led to a number of changes and ongoing iterations of the process map. Further feedback was then sought from the expert reference group for verification, thus finalising the built environment process map. The final built environment life cycle map is shown in Figure 3 below (Hürlimann et al., 2022).

into a new loop

The design of the built environment life cycle map highlights the non-linear nature of the ways that the built environment is produced and maintained over time, represented by a horse-shoe shape. This is because the renewal/recovery/decommissioning stage may lead to initiation of a new projects, rather than rather than the same cycle. The diagram sets out eight main stages, demarcated by shifts in actors' involvement, the roles taken on, and their influence. Internal connections between stages represent non-linear and iterative characteristics fundamental to the process. While some projects may follow a linear progression through the stages, more often the processes include numerous feedback loops, short-circuits and iterative modifications.

This process map developed seeks to improve understandings of the ongoing production of the built environment. It addresses gaps in current approaches by describing the extensive range of life stages. It considers diverse built environments sectors and articulates the role of key actors, and the relationship between them, while visualising the process. There are limitations to the process map, particularly regarding its complexity being represented in a simple two-dimensional form and acknowledging the diversity of different and particular context-specific circumstances. Notwithstanding, this representation contributes to understanding how the built environment is produced, as a step to finding ways to make transformative changes in practice to address climate change. This could be applied to contexts ranging from climate change action, sustainability objectives, to the incorporation of improvements to address disability.

3 - Understanding the Built Environment Policy Context

Built environments are important places in which social and economic activities are focused. They are also sources of significant GHG emissions. To transform built environments so that they can facilitate and incorporate appropriate action to address climate change, appropriate policy instruments must exist. Typologies suited to describing and analysing built environment policies in an holistic way are limited.

Based on a wide review of literature we developed (see Table 1) a 'built environment policy framework' consisting of a policy instrument typology (strategies, laws, regulations, guidelines, voluntary instruments and programs) and a built environment policy setting (governance level, sector, property type, life stage, timeframe) (A. Hurlimann et al., 2024).

Policy categories from existing literature:	Regulatory	Regulatory	Informational	Informational	Financial/other incentive	Government provision and direct action
Policy instrument Types and examples	Law • Legislation • Statutes	Regulation • Building regulations/ standards • Codes •Development controls e.g., zoning, overlays,	Strategy • Strategic plans • Spatial plans	Guideline • Policy advice/guidance • Guidelines	Voluntary instrument • Voluntary standards • Awards • Voluntary certifications • Grants and subsidies	Program •Implementation of projects/ programs of action • Professional education •Experimentation

		growth boundaries •Environmental and other impact assessments • Taxes / rebates / buy-backs • Financial levers				
Definition	Rule/s enacted and recognised as requiring or forbidding certain actions. Binding force.	Prescribed rules to guide practice and implement law/s. Can include those with financial implications.	Long term plan or policy which articulates goals and methods of achieving them.	Principle/s guiding or directing action. Can be compulsory or non-compulsory, depending on how it is implemented.	Non-compulsory instruments to guide practice, including fiscal incentives.	Planned activity/ies to assist realisation of goals.

Table 1 - Policy instruments typology with relevance to the production of the built environment
Source: (A. Hurlimann et al., 2024: 5)

The framework was tested in Australia to consider three local municipalities. Policy instruments that influence decision making regarding, and management of, the built environment in Victoria, Australia were identified and analysed using an iterative process. Policy instruments that met the key criteria were selected: influential in explicitly guiding decision-making (of public or private actors) regarding the built environment of the jurisdiction; local, state, national, international and non-government. In assessing relevant local governments, policy emanating from international, national and state levels was included if it met the inclusion criteria.

The first local study area, The City of Melbourne, centres on a high density, globally-connected central business district within greater metropolitan Melbourne in the context of surrounding suburbs. Its population is 154,000 (greater metropolitan Melbourne has a 4.9 million 2021 census population), a land area of 37.33 km^2. The City of Greater Geelong (Geelong) second largest city in Victoria and includes urban settlements, growth areas, regional towns, rural land, and has a coastal location. Its population is 271,000, with a land area of 1252 km. Wellington Shire Council (Wellington) is a regional municipality, including 45,000 persons and an area of 10,811km^2.

Overall, Melbourne had 33 built policy instruments, Geelong 23, and Wellington nine. By a considerable amount (as shown in Figure 1), the dominant policy instrument type was ‘strategy’. Melbourne and Geelong had many biodiversity, environmental, sustainability and climate change strategies, while the more remote regional Wellington municipality had few. Across the all governance levels, with a focus on the City of Melbourne at the local level, the policy instrument type were ranked in order: strategy (44), guideline (30), law (17), regulation (12), voluntary instrument (9), and program (5). State government had the most policy instruments (47), followed by the local government (37), federal government (21), international (7), then non-government (5). State government had more than double the number of laws than the federal level, while local government had more strategies than any other level of government. This may be due to their role in the built environment, which differs in comparison to the federal and local levels, with more responsibility distributed. The mapping identified that strategies were the dominant policy instrument. Fewer policy instruments were found to directly address the built environment’s later life stages, and there were fewer at federal and international levels of governance.

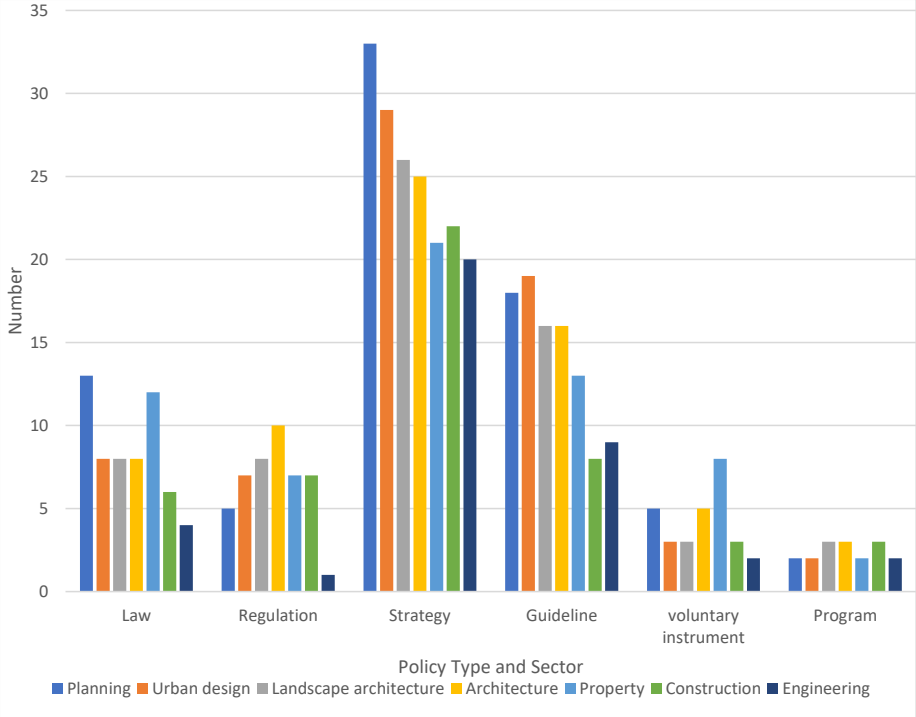

Figure 1 - Victoria's Built Environment Policy Instrument type by built environment sector

Examination of the documents revealed that, according to sector, they were applied across the life cycle of built environment elements revealing distinct, albeit overlapping, stages as shown in Figure 2 below.

Change Initiation
Strategic Planning
Project Consideration and Initiation
Design
Costing and Approvals
Construction
Use and Ongoing Management
Renewal, Recovery, Decommissioning

Figure 2 - Built Environment Life Cyle Application Evident in Policy instruments

Overall, the results show a relative dominance of 'strategy' compared with the limited amount of implementation via 'programs' that guide action and achieve goals. This suggests that there is a need to seek greater diversity of policy instruments at all levels government. Generally, strategies appeared to be non-binding and more easily prepared, without certainty of action. Broadly, there appears to be a need to have more effective policy in the later life stages of the built environment, suggesting that identification of and augmentation of policy gaps in stages such as 'renewal and recovery' would facilitate transition to a more circular economy. It is noted that actions taken by the European Union, specifically, the Circular

Economy Action Plan (European Commission, 2020);(Spani, 2020) recognises the environmental and climate change impact of resource extraction and greater circularity. Federal government in Australia appears to have insufficient policy instruments if it is seeking greater influence to enhance its climate change leadership and to meet international goals (such as the Paris Agreement). There is a general lack of strong 'command and control' policy instruments of regulation and law implemented across the entirety of life stages and governance levels. These will be necessary to allow government to achieve increased uptake of climate change goals. The next stage of the research is to assess the extent to which these policies address climate change and this is currently under peer review.

4 - The Preparedness of Planners and other Built Environment Professions for climate change action

We now turn to considering the preparedness of planners and other built environment professionals to take climate change action, based on a review of literature in English. The research assessed existing scholarship that considered climate change preparedness of professionals within built environment sectors (A. C Hurlimann et al., 2022). The problematizing review was an 'opening up exercise' to enable researchers to rethink existing knowledge in a generative manner (Alvesson & Sandberg, 2020).

Moser and Luers's (2008) framework for climate change preparedness was followed. Accordingly, this examined awareness, analytical capacity, and action of built environment professionals in the context of their sectors (Moser & Luers, 2008). The review assessed reported facilitators and barriers of climate change action. The main data base used was Scopus, in parallel with discipline-specific journals. Scopus is a source-neutral abstract and citation database curated by independent subject experts (Elsevier 2020). The database includes 25,000 titles from over 5000 publishers, the majority being published after 1996. The research reported here (A. C Hurlimann et al., 2022) was guided by the following two questions:

1. What barriers exist to climate change action in and across the built environment sectors: urban planning, property, construction, and design (including urban design, landscape architecture and architecture)?

2. What facilitates action to address climate change in and across these built environment sectors?

Following the screening and selection methods of Moher et al., 175 articles were included in this research (Moher, Liberati, Tetzlaff, Altman, & PRISMA Group*, 2009), with 50% of the articles published in the period between 2017 and 2020. Detailed analysis was undertaken in an excel spreadsheet. The review began with the collection of basic meta-data such as sector of focus; type of research (empirical/non- empirical); details of the method; location of the research; and whether climate change adaptation, mitigation or both, were examined. In terms of overall numbers, papers addressing barriers, facilitators, and climate change awareness were highest in urban planning, property, and construction literature, whilst urban planning also had a strong focus on climate change action as shown in Figure 4 below.

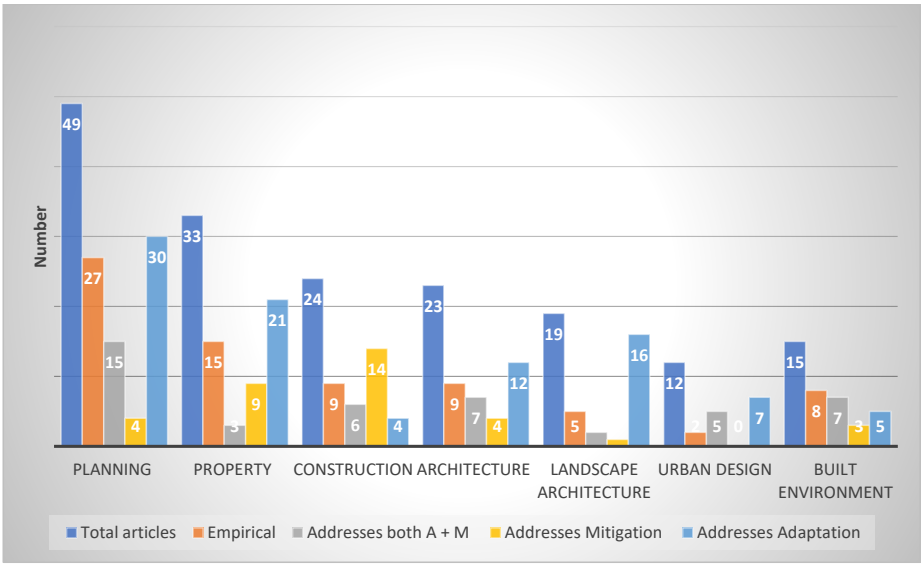

Fig. 4. Literature review results: number of papers that addressed: climate change preparedness (awareness, analytical capacity and action); barriers or facilitators of climate change action - across built environment sectors (note: papers could be in multiple categories). (source: A. C Hurlimann et al., 2022)

Table 2 below shows the key barriers to climate change action identified in literature reviewed across the built environment. The left column shows the broad themes of barriers identified from across the literature, with the right column showing specific barriers. The three major barriers to climate change action identified in the literature are funding and cost, knowledge, and time frames.

Category	**Specific Barriers to Climate Change Action**
Risk Evaluation	First movers' risk Pricing climate change risk into asset values
Roles and Responsibilities	Lack of leadership Not viewed as responsibility among developers
Funding/ Cost	Perceived high cost Lack of resources Budget constraints
Policy/ Regulations	Limited regulations Policy/ regulatory confusion Uncertainty of planning policy
Knowledge	Inconsistent and unclear language Lack of awareness/ belief of CC Lack of knowledge/ scientific information Uncertainty of CC impacts Lack of adequate education
Time Frames	Short political time frames Short budget time frames Short local need time frames Long term adaptation horizon

Clients/ community engagement	Low demand from residential sector Lack of interest from clients Community opposition
Conflicting priorities	Influence of CC works on amenity values Low priority among developers Climate change versus economic growth Environmental performance versus social values
Tools	Lack of domestic tools Lack of tools for performance metrics

Table 2 - Barriers to climate change action across built environment sectors – reported in literature. Source (A. C Hurlimann et al., 2022).

Table 3 shows the primary facilitators of climate change action distilled from literature. The most reported facilitator was financial levers, mainly in the construction, property, and urban planning literature (Gurran, Norman, & Hamin, 2013; Lützkendorf, Fan, & Lorenz, 2011). Improved climate change knowledge, its effects, and practical or viable strategies for action were reported to be important facilitators, across all sectors, but particularly within urban planning. The third highest identified facilitator was disciplinary capacity and skills, identified mainly within the design sub-sectors, as well as the need for more integrated approaches and use of knowledge from related fields such as ecology. “Supporting actors and champions’ beyond the discipline, were also identified as critical, notably in the urban planning literature, which often seeks to achieve integrated and multiscale approaches to taking climate change actions (A. C. Hurlimann & A. P. March, 2012).

Category	Specific Barriers to Climate Change Action
Knowledge	Increased awareness/ education Consideration of long terms CC impacts Access to technical support Place based knowledge Effective communication of risk
Financial Levers	Financial stakeholders Access to international/ national aid Incentives for innovation Customer demand Lower green premiums Value discounts/ Brown discounts
Policy / Regulations	Carbon pricing Performance-based decision making Energy efficiency standards Rating tools
Organisational Governance	In-kind support Organisational values/ strategies Breath of sectoral support
Supporting actors/ champions	Environmental NGOs Frontline practitioners Community Innovators
Political support	Political will and commitment Supportive multi-level political environment
Climate related disasters	Severe weather events
Disciplinary capacity/ skills	Ecological knowledge Integrated and multi-stakeholder processes Visual communication techniques Considering uncertainty and time horizons

Table 3 - Facilitators of climate change action across built environment sectors – reported in literature.

Being able to apply generally agreed upon high-level concepts, evidence and thinking to practical, complex and non-routine problems is the basis for professionals taking action (Webber & Ruge, 2019), and will be critical for climate change action. A starting point for this is the existence of trustworthy sources of fundamental knowledge, such as evidence-based literature suitable for application by built environment professionals, decision makers and educators. This review of literature raises many implications for the built environment professions, and for the achievement of climate change goals in the production and use of built environments. It suggests a need for increased strategic action to locate climate change capacity-building on the agenda of both private and public built environment actors. There may be opportunities to improve preparation for climate action within the professions. This could include professional education; improved climate change accreditation of university education; and membership of professional associations. However, the review has shown that research in some built environment sectors is not well covered (e.g. for urban planning see (Hamin & Marcucci, 2013; Anna C Hurlimann, Moosavi, & Browne, 2021; Preston-Jones, 2020). The review highlights the limited integration of skills and resources across built environment sectors and professionals within them to maximise climate change knowledge capacity and action.

5 - Barriers and Facilitators to Urban Design Climate Change Action

The ability professionals to take climate change action is fundamental to finding ways to transform the built environment via climate change adaptation and mitigation. This final section reports results of an empirical study of the main categories of action which urban designers in Australia are taking to address climate change, and the barriers and enablers that they face in doing this (reported by March et al., In-press). The large Australian Research Council Grant is taking a focused look at practice across each built environment sector, which in addition to urban design are at various stages of publication including urban planning (under review), landscape architecture (Moosavi et al., 2023); architecture (under review) and sustainability (under analysis); in addition to earlier studies focused on the construction (Anna C Hurlimann, Browne, Warren-Myers, & Francis, 2018) and property sectors (Warren-Myers, Hurlimann, & Bush, 2020).

Here we focus on urban design, and begin by considering the practice of urban design itself, we argue that, despite some variations across urban design practices, shared goals and core challenges exist. They are into five categories. The first, Inter-relationships and Integration, acknowledges that urban design action in complex arenas of diverse interests, actors and responsibilities is both a core benefit or, and challenge to, its effectiveness (Elrahman & Moureen, 2021). The second, Scalar Connections seeks to understand that urban design acts at a range of scales: the macro scale, encompassing planning, transportation and infrastructure systems, narrowing down to small -scale matters such as street lights, materials and furnishings (Department of Infrastructure and Transport, 2011). Third, urban design is deployed for increasingly Diverse Aims, while seeking simultaneously seeking integration (Carmona, Heath, Oc, & Tiesdell, 2021: 3). Fourth, Public Values and Regulation via integration of disparate goals is central to effective urban design (Carmona et al., 2021; Moughtin, 2003) often taking the form of state sanctioned intervention (Carmona, 2016). Finally, Urban design's orientation is towards Strategic Public Orientation and Professional Legitimacy, such seeking to further the interests of public, common, or interstices land's "values" that are otherwise afterthoughts (Elrahman & Moureen, 2021).

Urban design practice includes overarching themes seeking to make the links between human settlements, natural systems and environmental sustainability. However, it is also the case that when climate change action is included, even a goal, its manifestation is often contextual or an aside rather than being core. Limited direct urban design scholarship examines barriers and facilitators to climate change mitigation and adaptation.

Hebbert (2009) highlights that while exemplary case studies exist, a lack of substantive knowledge within practice is a barrier to turning existing climate change focused urban design decision-making tools into action (Hebbert, 2009). He suggests that there is tension between public spaces aimed towards resilience and good place-making outcomes. Other state that urban design concepts such as the *compact city* may challenge adaptation efforts, such as in relation to flood control. Others such as (Childers et al., 2015) and (De, Kerselaers, Van, & Rogge, 2017) maintain the potential for urban design to play an important role in helping to develop solutions to climate change adaptation. Urban designs abilities in collaboration and sectoral knowledge integration were seen as potential facilitators of climate action (Childers et al., 2015), as well as using design workshops to develop grounded local climate adaptation needs (Jones et al., 2018). Lenzolzer et al (2020) sought to understand urban climate awareness and the urgency to adapt internationally among citizens, local politicians, urban planners and designers.

Uncommon until the 1980s, urban design is now prominent in Australia. Kozlowski (2006) noted that most major strategic plans in Australia have made some reference to urban design. Almost all design and planning programs in Australian universities now include urban at least some design. Similarly, the majority of large city-based municipalities now employ urban designers. Urban design does not have a dedicated professional body in Australia and it is not included in the Australian census as a job, nor are there statutes governing qualifications, roles and responsibilities. A quasi-accrediting agency for urban design is the Planning Institute of Australia (PIA) which can accredit planning programs with an urban design emphasis (Planning Institute of Australia, 2020: 13, 16, 22). Five currently have an urban design focus (Planning Institute of Australia, 2022). The Australian Institute of Landscape Architecture (AILA)'s recognise urban design projects in its annual awards.

To understand climate change actions taken by Australian urban designers and the barriers and facilitators for climate change action that they face, interviews with 22 urban designers from diverse locations and firm types within Australia were conducted, as reported in March et al In Press. Practitioners from diverse locations, agency and firm types within Australia were identified and interviewed. Semi-structured interviews focused on the participants' practice, organisation, and profession at large, seeking to understand the barriers and facilitators to climate change action in the built environment.

A qualitative thematic analysis was undertaken using a quasi-inductive or abductive approach (Piekkari 2018). Seven key types of climate change action were identified across the practitioners interviewed, as shown in Table 4 below.

Policies and Strategies (establishing, enforcing or following)
Education & research
Project designs & practices
Reducing carbon footprints
Advocating or lobbying
Sustainability measures & ratings
Type of projects & tenders undertaken oriented to climate change action

Table 4 - Type of Climate Action Taken (ranked: highest incidence at top)

While the themes above emerged strongly across the interview subjects, the ways they took these actions were diverse, reflecting the breadth of activity inherent to urban design, the respondents' diverse roles and the need for urban designers to be interdisciplinary. While a relatively small sample, the results indicate that the practices of these Australian urban designers are strongly linked with climate change action. When the results were analysed in terms climate change the five top *facilitators* were found, as shown in Table 5 below.

Culture, values, expertise, or reputation that prioritises sustainability measures & CC action to influence positive outcomes
Government targets, priorities, resources, & regulations
Building, promoting, & refining CC awareness
Design practices & outcomes that improve the ability to produce sustainable built environment outputs or inherent consideration of sustainability and climate change (e.g. passive design)
Accessibility of sustainable materials & practices. May include increasing accessibility through affordability, supply chains, information or resources

Table 5 – Climate Action Facilitators: Experienced or Observed by Respondents

Note: Ranked in order of mentions from most frequent at top, to least at bottom.

It is noteworthy that the theme of *culture, values, expertise, or reputation that prioritized sustainability measures & climate change action to influence positive outcomes* emerged as important. Similarly, most respondents indicated the importance of *government targets, priorities, resources, & regulations* facilitating climate change action in the broader built environment. However, it is important to recognise that only two suggested this was the case within the urban design sector itself, but rather in the wider suite of policies described above in *Understanding the Built Environment Policy Context*. This is likely to be a result of urban design being largely unregulated as a profession in Australia, but rather, being a bridging or facilitating role. The *building, promoting, & refining climate change awareness* and *culture, values, expertise, or reputation* were also reported as important facilitators. In contrast, the five main barriers to climate change action by urban designers interviewed are presented below in Table 6.

Limited influence, reach, or decision-making capabilities
The externality of sustainability leading to a lack of accountability, including the ability to get away with greenwashing, or lack of incentives
Management or structural issues pertaining to things like available resources or power distribution
Competing project deliverables and constraints on budget, time, and resources
Poor government policies & leadership

Table 6 – Barriers to Climate Action Experienced or Observed by Respondents.

Note: Ranked in order of mentions from most frequent at top to least at bottom.

Most respondents indicated that a key barrier across the broader built environment was *limited influence, reach, or decision-making capabilities* and that the *effects of non-sustainability being externalised* and a *lack of accountability (including ability to get away with greenwashing) or lack of incentives to action*. Many also indicated that *poor government policies & leadership* across the built environment was a barrier.

Overall, the results indicate ways that urban designer practitioners, the organisations within which they work, and government agencies, can facilitate greater climate change action. Demonstration of strong leadership, whether at state or local government level, or within the private sector was seen by practitioners to be an important enabler. Establishing key targets and firm regulations assisted in association with financial and other relevant incentives was considered fundamental. The provision of accessible and trusted information for practitioners and decision makers was considered essential and a facilitator of integration in actions across multiple temporal and spatial scales. This aligns with the general understanding expressed amongst urban design practitioners that collective outcomes going beyond single projects or interests are a defining characteristic of the profession. Organisational leadership and culture, allied with a need for government to provide avenues for integration of outcomes was also highlighted.

6 - Conclusions

While there is now widespread recognition internationally that urgent action is needed to reduce GHG emissions to avoid catastrophic climate change, and that adaption is needed to deal with changes in climate that are unavoidable (IPCC 2015; 2018) actual action in the built environment is challenging and complex. This paper set out in summary a number of

findings of a project that considered the integration of climate change adaptation and mitigation action in Australia's built environment. It took the viewpoint of built environment practitioners in Australia, while seeking to understand the complexities of policy.

The paper began with a description of the Built Environment Life Cycle, set out so that diverse built environment sectors could be understood across sectors that are typically understood in isolation, including the articulation of key actors' roles, their relationships, and the potential for key transformative actions to be taken. The paper then presented a framework to describe built environment policy, including policy types and tiers of governance. By application to the Australian case via assessment of three municipalities', it was shown that there is a dominance of 'strategy' compared with the limited amounts of implementation via more direct 'action programs'. Further, it was seen that there was a need for more effective policy that considered the end of life cycle in the built environment, and a need for more instruments of direct regulation and law implemented to encourage meeting of targets.

The paper then reported on the preparedness of Australian built environment professionals, including planners, based on a wide review of literature in English. It showed that there is a strong need for trustworthy, evidence based literature that can be used to take action by practitioners, for improved education and accreditation, and for more strategic, integrated and long term approaches to be developed. Finally, findings of a more detailed study into the perceptions of Australian urban designers were reported. It showed that the main climate change action taken by urban designers are via establishing, enforcing or following clear policies and strategies, by preparing or undertaking education or research, and by direct action via design. It also highlighted the importance of strong leadership at all levels and across public and private sectors in providing opportunities and examples for climate change action – typically in association with strong regulatory and incentives-based contexts.

Overall, this research suggests that climate change action in the built environment requires understanding of the entire built environment life cycle, the various actor's roles in this, and ensuring integration is occurring. For example, it appears that in Australia, there is a need for additional work in the renewal/ recovery/ demolition phase to close the loop. There is for greater leadership across tiers of government and in the private sector, allied with easily access information to aid decisions.

The self-government approach to the planning of the Gran Sasso Laga Park

Giovanni Ottaviano, Luciano De Bonis
Affiliation: Department of Biosciences and Territory, University of Molise, Italy
Email: giovanni.ottaviano@unimol.it; luciano.debonis@unimol.it

Abstract
Thanks to the substitutive function of every other planning tool, recognised by law for any Italian park plan, the Gran Sasso Laga National Park Plan was conceived, within the Italian system of hierarchical cascade planning, as vice versa a non hierarchical coordination tool of a co-planning process based mainly on self-government patterns of the communities that live and act in the park territory. Such a co-planning process can be considered as an inherent part of the broader co-evolutionary dynamics of relationships between humans mediated by non-human elements of the environment, according to a specific interpretation of Socio-Ecological Systems (SES), which we in turn interpret as Socio-Cultural-Ecological Systems (SCES), recognising humans as eco-factors and referring to the eco-diversity of SES/SCES rather than simply their biodiversity.

Keywords
Natural parks; Self-government; Territorial co-planning; Coevolution.

1. Introduction
The approach followed in planning the Gran Sasso Laga National Park, in which the authors participated through a collaboration agreement between the University of Molise and the Park Authority, envisions the park plan as a coordination tool for the territorial co-planning process.
The conceptual framework critically examines the technocratic and economistic approaches to environmental issues, which are becoming increasingly prominent. These approaches often lead to externally directed and centralised environmental protection policies aimed at reducing human activity in natural contexts. In addition to exacerbating inequalities among different communities in defining autonomous development paths, these approaches do not recognize the co-evolutionary role of the human eco-factor within ecosystems. As a result, they do not allow the protection of ecodiversity, which also derives from human action.
Instead, the Gran Sasso Laga National Park is conceptualised as a Socio-Cultural-Ecological System (SCES), in which the complex of (human) social relations mediated through interactions with non-human entities is crucial. The interactions between human and non-human factors in the cooperative SCES, which can also be considered a landscape (sensu European Landscape Convention), also include the processes of co-planning and territorial co-design, thereby establishing coevolutionary paths within the SCES.
This innovative approach has been fitted into Italy's existing institutional and regulatory framework for environmental planning, which, on the other hand, is really rigid and unwilling to rapid changes. Some agreement tools encompassed in the co-planning and territorial co-design process have been linked to objectives of the National Strategy for Biodiversity, supporting the development of a continuous co-planning and co-design process of the park's territory.
In this way it was intended to trigger a dynamic, flexible, and adaptive method for managing and envisioning territorial evolution, utilising tools that can contribute to the activation of forms of commoning of environmental resources.

2. Environmental policies and technocratic approaches
As a consequence of the increasing prominence of environmental issues in the public, scientific and governmental debate, particularly in the Western world over the last decades, numerous

policies and measures have been introduced to mitigate the negative effects of human activities on environmental balances.

A common element in policies developed by institutions at various levels is the persistent underlying division between the categories of human society and natural environment. This division simplifies the complex relationships and socio-ecological balances between humans and their environment, often reducing them to paternalistic-conservationist approaches or technical-functionalistic tools.

The first group includes policies based on the principle that humans must take care of nature and which tend to exclude, in whole or in part, the possibility of carrying out human activities in certain areas.

This approach suggests a view of nature as incapable of self-preservation and in need of human action to be protected (by man himself), in which it is considered as 'the nature of nostalgia, of conservation' (Fabbri, 2019, p. 115). This perspective emphasises the need to bring nature back to an original, untainted state, ignoring that nature 'has no origin and it is perfectly indifferent to our concepts of origin and purpose' (Baudrillard, 2019, p. 103).

The second group includes policies that support forms of valorisation of biotic and abiotic elements based on their usefulness for human survival and the financialisation of natural capital. This approach involves an ontological shift in nature, which goes from being 'the material basis of the reproduction of living things to a provider of biological or eco-systemic services' (Leonardi, 2017a, p. 183). While this concept has increased awareness of the value of natural elements for human life, it has also led to the creation of markets and institutional structures to support their functioning (PES - Payment for Ecosystem Services, carbon credits market, PPP - Polluters Pays Principle).

This process presupposes the creation of fictitious goods, corresponding to the services offered to man by natural elements, which can be sold or exchanged on the markets. Going beyond the strictly regulatory approach to resource consumption and pollutants release, these new valorisation mechanisms position natural capital as an active market factor (Iannuzzi, 2018).

In addition to the intrinsic criticality of the ontological change, the technical-economic approach to the environmental issue also poses problems of inequality. There are in fact large grey areas regarding knowledge and sovereignty over the goods included into the markets, which produce improprieties and accounting biases (Iannuzzi, 2018), as well as on the political fairness of economic-social compensations for the negative effects induced by polluters (Leonardi, 2017b).

While recognizing that these policies can lead, in general, to an improvement in the effects of human actions on environmental balances compared to those from the industrial era, it is necessary also to note that the persistent split between the human and non-human realms continues to reflect an anthropological need to establish dominion over natural things.

3. Environmental protection and neo-colonial approaches

The considerations on the critical issues emerging from technocratic approaches to environmental issues, as illustrated in section 2, are significant in the field of planning studies because they produce relevant effects on the organisation of land uses. This is particularly evident in the case of protected natural areas, which we can broadly define as those parts of territory (regional, national, or global) deemed necessary to preserve in their ecological form or functionality by limiting or inhibiting substantial human activities.

Studies on international contexts indicate a greater presence of protected areas where there are low-income communities, with reduced access to services and minimal political representation in government institutions (Hammer et al., 2012). These socio-economic vulnerabilities make such communities particularly exposed to authoritative environmental protection regimes imposed from above, which hinder the possibility that the communities themselves can

establish autonomous development paths due to restricted access to territorial resources (Hammer et al., 2012).
Through this large-scale compensation approach, according to which compensation can be made towards nature in some places (Magnaghi, 2010) for the environmental damage caused in more economically developed places, forms of spatial injustice are perpetrated, as it enables some populations to maintain high quality of life and consumption levels thanks to the imposition of development limitations on territories inhabited by weaker populations.
Environmental policies conceived according to dualistic, globalised and economistic approaches are configured as forms of cultural neocolonialism, in which solutions are imposed by the centres of power that rely on the ideology of centralised knowledge, which suppresses local knowledge, believing that 'it is possible to save nature regardless of the indigenous people or local populations who in reality are the only ones who can safeguard it' (La Cecla, 2019, p. 73).
The presence of such neo-colonial approaches is noted by many, even within ecological movements. For example, the KBA Partnership highlights the need for the 30x30 initiative (the international community's commitment to protect 30% of the earth's surface by 2030), signed by The High Ambition Coalition (HAC) for Nature and People, to ensure that the protected 30% is 'the right 30%'. This means that areas designated for protection should primarily be 'key biodiversity areas', since instead 'areas are often designated as protected or conserved where it is convenient rather than because they are important for conserving biodiversity. Protected areas tend to be created in remote places (...)' (Plumptre et al., 2021).
The challenges that environmentalism poses today, however, require the introduction of radically new relational paradigms between human societies and the natural environment (Guattari, 2019), which also recognize the central role of the recovery of local sovereignty in defining solutions (La Cecla, 2019).

4. A political ecology approach to planning

A substantial potential for supporting transformative change in the definition of spatial policies and planning practices lies in recognising human societies as eco-factors, that is, viewing humans as elements interacting equally with other non-human natural elements, rather than as separate entities affecting nature from an external standpoint. It means acknowledging that human societies exhibit behaviours with varying degrees of adaptability or maladaptivity (Mainardi, 2008), through which the human species is fully immersed within ecosystem dynamics (Soave, 2010) interacting via a 'ecological intelligence', that is, its ability to adapt biologically, technologically (Goleman, 2009), and culturally (Mainardi, 2001) to their environment. Through ecological intelligence, infinite local behaviours adapted to the specificities of the environment and adaptation of the environment to human needs have therefore developed, demonstrating the deep immersion of humans in ecosystem dynamics. Therefore, especially in the definition of spatial planning policies and practices aimed at leveraging transformative change, it is more useful to refer not just to biodiversity, but rather to the concept of ecodiversity. Ecodiversity operates at the landscape scale, accounting for the environmental complexity of organisms and processes, including biodiversity, environmental heterogeneity, and geodiversity, thereby incorporating the human eco-factor (Conti and Soave, 2006; Farina, 2001; Halvorsen et al., 2020; Jedicke, 2001; Naveh, 1994).
Incorporating ecodiversity into planning processes means considering land use organisation paths that foster human interaction with environment components and the development of local solutions that enable mutual adaptations, leading to the progressive enrichment of ecodiversity within the territorial system. To overcome technocratic and economic approaches to environmental issues, which, despite their effectiveness, carry intrinsic ethical-political issues, a shift in planning paradigm is needed to allow the proliferation of local experiences and

'particular cultures' through 'new contracts between citizens' (Guattari, 2019). Such a change can 'derive from a political and cultural choice' (Gorz, 2015), enabling social formations and individuals to interact co-evolutionarily with the environment, regaining sovereignty over land use practices through self-regulated forms of territorial planning.

5. (Protected) territories as Social-Cultural-Ecological Systems (SCES)

With regard to the above self-organising and coevolutionary processes, it is very useful to refer here to that specific interpretation of SES, Socio-Ecological Systems, which identifies them as a 'subset of social systems in which some of the interdependent relationships among humans are mediated through interactions with biophysical and non-human biological units' (Anderies et al., 2004), and in which the cooperative aspect of these relationships may be sometimes fundamental (Anderies et al., 2004). In particular, referring to the example of a fisherman who can change the outcomes of another fisherman's activities 'through the interacting biophysical and non-human biological units that constitute the dynamic, living fish stock' (Anderies et. al, 2004), it seems quite clear that the interdependence relationships between humans (fishermen) mediated by the common pool resource (CPR) (the fish stock) exist regardless if they take on a cooperative nature or not. But it is equally clear that the less the relationships take on a competitive or even conflictual nature, the more easily the sustainability of the living fish stock will be ensured. Regarding this last aspect, we believe it is useful to further develop the fruitful concept of SES mentioned above in the direction of those that we have proposed to define anew, not having found specific traces of it in the literature, such as SCES, namely Socio-Cultural-Ecological Systems. (De Bonis and Ottaviano, 2023). In the SES concept proposed by Anderies et al. (2004), the co-evolving unit coinciding with it, more or less cooperative, by definition cannot be homogeneous (cospecific), but must always be formed by different species. In other words, it cannot be delimited without including the non-human factors through which the human factors interact, moreover in a variable way depending on the human behaviour considered (Bateson, 1976). This means that it can be likened to both the landscape as defined in the ELC, European Landscape Convention - 'an area, as perceived by people, whose character is the result of the action and interaction of natural and/or human factors' (Council of Europe, 2000) - and to 'cultural landscapes' identified by UNESCO (1994) as those 'sites' created by the 'combined works of nature and man' (UNESCO, 1972), 'illustrative of the evolution of human society and settlement over time, under the influence of the physical constraints and/or opportunities presented by their natural environment ad of successive social, economic and cultural forces, both external and internal' (UNESCO, 1994, p. 13). Such assimilation to some form of landscape makes the 'cultural' aspect of the SES evident, which is self-evident considering the intimate interrelation between human and non-human entities that characterises them, and therefore authorises us to define them as SCES. But what really matters in identifying the landscape with the SES as defined by Anderies et al. (2004), and/or with a SCES, is the *advantage* of these concepts compared to the *objectifying* perspective found in other definitions of SES, which are still focused on an ecological system (external to us) with which the (our) social system interacts, as well as compared to the definition of landscape in the ELC, where the interaction between humans and nature shapes an objective entity (territory), which is then subjectively perceived by humans (thus shaping a landscape). In the concept of SES/SCES, instead, the distinction (and latent dualism) between objective/subjective disappears completely, making room for a notion of *mediation* entirely internal to social (human) relations. It is closer to this kind of *mediation* the UNESCO definition of cultural landscape when it refers to 'human society and settlement' and to *their* environment, despite the evocation, again latently dualistic, of both *external* and *internal* dynamics. However, our analogy is based on the complete abandonment of UNESCO's view of (few) cultural landscapes as *illustrative*, or as having 'outstanding universal value', to instead consider the

complex of SCES potentially extended to the entire territory (like the landscape in the ELC), as well as of its purely conservationist purpose.
In this regard, it should be noted that even in the field of nature conservation the mainstream seems to be a long way from a conception of SES/SCES like the ones mentioned above, as well from a vision that seeks to encourage the preservation of the natural environment through inherently protective human activities (Dematteis and Magnaghi, 2018).
About this, what we find particularly problematic is the fact that according to IUCN the primary management objective of a national park is that of ecosystem conservation and recreation. This unique alliance mirrors the prevailing attitude in the international arena towards cultural heritage. The tourist-recreational use of the latter is in fact generally considered as the only form of compatible utilisation of cultural resources, even though contrary evidence is becoming increasingly apparent in certain instances of overtourism. Our main concern, in this regard, is precisely the limited effectiveness of the exclusive association between conservation and recreation. Indeed, this association can be *sterilising* in terms of regenerating the natural and cultural heritage, as it fails to re-establish the relationships between people and nature by which they have been generated and/or sustained over time (De Bonis, 2020).

6. The Gran Sasso Laga Park Plan as a coordination tool for a continuous co-planning process

In order to counteract the above sterilising drifts, the Gran Sasso and Monti della Laga National Park Plan (hereinafter GSLPP) has been conceived since its inception to promote forms of autonomous initiative by social actors, provided that such initiatives align with the requirements for the protection and enhancement of the park area. Nevertheless, to achieve this objective, the relationship between the Park Plan and the Italian planning system needed to be carefully considered.
In Italy, urban planning (at municipal level), territorial (at provincial level), landscape, (at regional and state level): i) constitutes a *system*, composed of different interacting tools, ii) is *formal*, in the sense that it is defined by law as a permanent procedure of government activities (Mazza, 1996), iii) is *public*, i.e. it falls within the competence and responsibility of a public administration, iv) is *cogent*, i.e. it produces effects to which the actors operating in the planned territory must compulsorily conform, v) is *rigid*, i.e. every modification of a plan instrument entails the need to go through the entire approval procedure. Furthermore, and above all, the fundamental principle of interaction between the different elements of the planning system is based on the so-called *cascade hierarchy*, according to which the plan formed at a certain administrative level prevails (is *superordinate*) compared to the one formed at an immediately lower level (and the latter is naturally subordinate to the former).
But, within this general framework, the park planning presents a non-negligible peculiarity: in accordance with the law governing the establishment, management, and planning of protected areas (No. 394 of 1991) the park plan, a unique case in the national planning system, *substitutes* for all other plans concerning the territory of the protected area, instead to be hierarchically superordinate to them. The sole exception to the substitution regards the provisions for the protection of the landscape contained in the landscape plan (not the latter as a whole).
It is precisely on the basis of such a substitutive nature of the park plan, in combination with other legislative devices, that we have been able to set up the GSLPP as a non-hierarchical coordination tool, inside a hierarchical planning system, for a continuous co-planning process, based mainly on patterns of self-government of the communities that live and/or act in the park territory.
Title III of the Zoning Bylaw, 'Planning Process', is the plan document that most reflects that pattern, while fully adhering to legal requirements for format and content. In fact, it defines the GSLPP as a 'planning coordination tool' aimed at incorporating and enhancing any other plans

and project initiatives developed within the park territory, that pursue the management objectives and policies for areas referred to in Title II of the Zoning Bylaw, or at least do not conflict with them. These plan and project initiatives can be: 1. general and implementation urban plans; 2. detail plans or territorial projects; 3. specific interventions for the protection, enhancement and compatible use of the park's environmental resources, requiring clearance by Park Authority.

The planning process is thus aimed at creating a circular connection between the environmental planning of park sites and the environmental planning of the entire park region, through the interpretation of local authorities' plans, detail plans/territorial projects and specific interventions projects not as merely *executive* tools, but as feedback devices capable of initiating the process anew continuously (Rolli and De Bonis, 2001).

In other words, this strategy recognizes the *substitutive* nature of the park plan as an opportunity to fully implement the principle of subsidiarity in physical planning, transferring responsibilities and possibilities from the Park Authority to other entities. Within this framework, the aspects of vertical subsidiarity (predominant in co-planning agreements) and horizontal (dominant in specific interventions clearances) tend to blend into a form of subsidiarity that could be described as 'holistic' (De Bonis, 2019) or 'circular' (Zamagni, 2018).

In this regard, however, it is necessary to clarify that we did not intend to assimilate these forms of subsidiarity characterising the GSLPP to any kind of *participatory* planning (or *collaborative*, *communicative*, etc.); i.e. to any kind of planning, in which the multitude of interactions are once again reduced, arbitrarily and also unrealistically, to a dyadic interaction (Mandelbaum, 1986) between planners and the planned, promoters of participation and participants, etc.; and in which professionals, technicians, consultants, are the sole operators of knowledge production and use (Crosta, 1998). On the contrary, in the GSLPP we did intend multiplicity as the coexistence of multiple forms of knowledge (professional and non-professional) and multiple forms of action by individual actors or groups of actors (Crosta, 1996).

7. The co-planning of the park as a framework for territorial self-government

The innovation introduced in the GSLPP acknowledges the double evidence that the classic planning system, envisaged by Law 394/1991, is mostly unimplemented, and that the effectiveness of the co-management experiences of protected areas between environmental authorities and local communities is well-documented (García López, Concepción and Torres Abreu 2018; Iannuzzi, Mourato and Santos, 2020; Oldekop et al. 2015; Pallares-Blanch, 2012).

Building on these observations, the GSLPP proposes a significant advancement that could extend beyond park planning, interpreting planning as a co-evolutionary process in which the planning action is implemented through continuous formation of territorial self-government tools. These tools enable the autonomous definition of the multiple practices that express the relationality between human societies and the environment. Coevolutionary approaches redefine the planning system in a trans-scale and nonhierarchical manner, implemented through detail and thematic plans in which territorial entities interact with the Park Authority to define territorial visions, realising 'forms of multi-actor, multi-sector and multi-functional contracts and agreements to address the governance of the territory as a common good' (Magnaghi, 2015, p. 151). A potential application of these paradigms was prefigured in the context of the approval process of the GSLPP, and in particular in the definition of the monitoring plan envisaged in the environmental report of the Strategic Environmental Assessment (SEA). In this circumstance, it has been decided to consider, as indicators of the effectiveness of the PP, the arrangement of agreements on detail plans and territorial projects related to the GSLPP and the NSB objectives. Some land management tools usable for this purpose were identified, referring to Section 24 of the Zoning Bylaw, which describes potential plans and projects that could be

implemented in the park. Connecting the SEA monitoring plan and the PP objectives has been conceived as a way to support the realisation of the planning process scenario envisioned in Title III of the PP.

These detail plans and territorial projects serve as frameworks for practices that are continuously redefined, in which planning tools rely on dynamism and flexibility to respond effectively and quickly to socio-environmental needs, mirroring the adaptive processes of ecosystems (De Bonis, 2019).

The co-planning process can support an incremental identification of the territorial resources as common goods, expanding upon existing collective domains recognised in the park area and assuming the paradigm that community usage practices define the *commonality* of the goods, beyond its legal status (Capone, 2016). The tools for implementing this scenario may take on a contractual nature, involving agreements between various social, economic, and institutional entities that share interests in defining some kind of land use and transformation of the territory, Thus, they shape new frameworks of local (self) governance through agreements for specific purposes and themes, also drawing upon existing tools such as river contracts, landscape contracts, etc. (Dematteis and Magnaghi, 2018). The planning framework of the GSLP is intended as an application of new paradigms that could be extended to general planning, supporting the reactivation of practices that express fecund relationships between human societies and the non-human natural environment.

8. Conclusion

A vision far from both the technocratic setting of dominant environmental policies (see section 2) and the neo colonial leanings of mainstream environmental protection (see section 3), and vice versa grounded on a political ecology approach (see section 4), as well as on a consideration of the territories, starting from protected areas, as SCES, Social-Cultural-Ecological Systems (see section 5), led the authors to interpret the planning activity conducted for the Gran Sasso Laga National Park as a continuous process, mainly based on schemes of territorial self-government (see sections 6 and 7).

In essence, the latter are attributable to emerging or consolidated forms of commoning, in turn based on the identification of the park with a set of Common Pool Resources (CPRs, see again section 5), i.e. as a set of (collective) natural or man-made resource systems, potentially providing a flow of (individually) usable resource units (Ostrom, 1990).

With particular reference to the consolidated forms of commoning mentioned above, it is worth specifying that the identification of the park with a set of CPRs is not merely hypothetical, as the majority of its territory is made up of collective domains (Catonica et al., 2017). This circumstance, however, transcends itself, revealing an issue that is perhaps of the greatest importance among those discussed so far.

In short, the GSLPP, conceived as a stage in a continuing planning process aimed at promoting forms of sustainable self-government of the CPRs (already existing or emerging), deliberately offered itself, at least in the planners' intentions, as a sort of meta-institutional framework, or more precisely as a state institutional framework of the self-governed institutions of the CPRs (Ostrom, 1990).

But what types of self-government institutions are we referring to here precisely?

The subtitle of the well-known Ostom book 'Governing the Commons' reads: 'The Evolution of Institutions for Collective Action'.

In this regard, already in the prefaces of the same book the belief is clearly expressed that 'stable institutions of self-government can be created if certain problems of supply, credibility, and monitoring are solved' (Ostrom, 1990, p. xi), as demonstrated through the rich collection of cases study gathered by the author and several colleagues of her. Furthermore, the author herself, basing on the observation 'that neither the state nor the market is uniformly successful

in enabling individuals to sustain long-term, productive use of natural resource systems' (Ostrom, 1990, p. 1), declares that her book is an 'effort to develop better intellectual tools to understand the capabilities and limitations of self-governing institutions for regulating many types of resources' (*ivi*, p. 2).

Well, taking up the subtitle of Ostrom's book, we conclusively advance here the hypothesis that a possible evolution of the institutions for collective action, in the very complex current socio-technical-cultural context, can be constituted precisely from those kind of territorial agreements (see again section 7) to which the GSLPP entrusts the continuous development of the planning process.

In other words, we posit that a planning no longer understood as a hierarchical form of government of the territory, but rather as a set of territorial self-government and self-organising governance tools, can not only escape from the declining parabola to which it now seems destined (at least in Italy), but evolving the fruitful Ostromian legacy, it can even aspire to identify in its own devices the contemporary forms of institutions of collective action, which according to Ostrom are the only ones capable of ensuring adequate management of natural resources.

Author Contributions

Although this work as a whole arises from the close collaboration between the authors, the writing of § 1, 2, 3, 4, 7 is by Giovanni Ottaviano, the writing of § 5, 6, 8 is by Luciano De Bonis.

Track 08: Public Space

PUBLIC SPACE - Planning for cultural diversity, peace and the experience of places

Chairs:

- Dimitra Kanellopoulou, Ecole Nationale Supérieure d'Architecture Paris-Malaquais
- Christine Mady, Aalto University
- Margherita Gori Nocentini, Politecnico di Milano

Keywords: *care, culture, digitalisation, diversity, identity, inclusion, memory, political urban space, spatial justice, temporality, transformation*

Public spaces were always at the forefront of urban life, playing significant roles and functions in shaping urban settings. Although the progressive complexity of a clear definition of what public space is, the track draws on the hypothesis that this polysemous concept is exemplary in expressing political and social realities but also thrives debates around physical, tangible space as a pillar space of urban experience. Our first encounter with cities and urban experiences occurs in their public spaces. These spaces represent current lifestyle trends but also echo memories. Public spaces are often "game changers" that herald alternative urban realities. One example includes transformations following the COVID-19 pandemic. Public spaces accommodate a panoply of activities, from mundane acts of conviviality to demonstrations or endeavours that try to belong and partake in democracy and different expressions and claims for spatial and social justice. Public space as a "game changer" is ironically the time-space of conflict and its dissolution. These spaces reflect the discourses and practices of tolerance towards differences and display or disguise the tensions immanent in encounters and exchanges across diverse urban cultures.

Several authors in urban studies have underlined public space as a central element of the built environment for the community and public life. Since the 1990s, the concept has attracted researchers from diverse disciplines, leading to the emergence of transdisciplinary debates on public space. Several scholars have had critical insights on the social impacts and risks associated with the profound transformation of urban public space, especially with recent environmental constraints and challenges on life quality faced with increasing densities in global metropolises. The complexity of the open public space's landscape underlines the elusive character of the subject while continuing to stimulate new streams of methodological investigations and theories.

This track aims to engage in a debate confronting contemporary realities of mass immigration, global conflicts, recurrent financial crises, and environmental urgency. We are particularly interested in discussions highlighting the potential of public space as an act of negotiation of territorial thresholds at different scales. Within a more homogenised world (through the globalisation of trends, norms, and costumes), we seek to revisit the discussion on public space

planning and the significant challenges of addressing questions of appropriation (from minorities or marginalised populations), dominance (of gender, political groups), and belonging (ethnic, geographical, cultural, religious groups). The entry of cultural diversity could be a legitimate one to unveil dynamics of creation, practice and representation of public spaces outside the geographical dominance of the Western world but also by tending to bridge regions with significant differences in terms of political and social organisation (for example countries of the Mediterranean Bassin). The continuing debate and understanding of public space as a construction of tremendous volatility could offer the necessary decentring of planning to questions of tolerance, differentiation, civic power, and justice. This 'step aside' will allow Occidental and European planning to learn by examples of Global South & East regions and establish dialogue on new toolkits of analysis and understanding of public space through citizens' aspirations, engagements and beliefs.

This track invites abstracts that explore the construction of peace or "game-changing" at different scales and through diverse disciplines to reflect the position of urban studies within this process and build on observations, experimentation, and narration of the transformative power of peace within public spaces. We particularly encourage papers that examine how bottom-up initiatives, out-of-the-box policies, and internationally constructed movements find anchorage in public space transformations and shaping within their political position, cultural identity, and the demand for peace.

"GAME CHANGER? Planning for just and sustainable urban regions"

TRACK 08: PUBLIC SPACE

Planning for cultural diversity, peace and the experience of places

The Open Orchestra project in the public spaces of Athens: an urban utopia with transformative power?

Ifigeneia KOKKALI, PhD
Assistant Professor, Department of Planning & Development, University of Thessaly

ikokkali@uth.gr

ORCID: 0000-0003-4851-787X

Abstract

The Open Orchestra is a group of about 150 professional artists and amateurs, founded in spring 2021, in Athens, Greece. Its establishment is directly correlated to the Support Art Workers Action Group that has emerged during the pandemic of Covid-19, as a way to resist to the depreciation of culture and art-workers themselves, many of whom remained unemployed and with no support from the state, during the long quarantines imposed as a protection measure[1]. Even more importantly, the Open Orchestra comes as a continuation of the Paris Occupation of Odeon, when, on March 27, 2021, during the Agora organized by the occupants of the Théâtre de l'Odéon, professionals from the French Symphonic and Lyric Orchestras, musicians from specialized orchestras, occupiers of the Odéon, and students formed a large orchestra of solidary musicians[2]. Following this line, in spring 2021, the Support Art Workers Action Group gathered in Propylaia, Athens, sang and played the piece "El Pueblo Unido Jamas Sera Vencido", exactly as did the solidary orchestra at Odéon, Paris, a couple of months earlier.
This has been the starting act of the Open Orchestra (O.C./ A.O. in Greek). Which started rehearsing once a week, at the Filopappou Hill, in a central public park of Athens, yet derelict and merely abandoned by the Municipality of Athens. It is called Open Orchestra, because anyone who wants to rehearse with it can do it at any time: there is no limitation on artistic level or degree of commitment (one can enter and leave the Orchestra at any time). Organizationally, there is a solid core of 100 people, who rehearse every Sunday. There exists a coordination group, yet decisions are made through open circles organized regularly, in which the whole group participates. This is particularly relevant to the organization of different projects. Every one or two months, rehearsals take place in a deprived neighbourhood of Athens (Victoria square, Perama, Amerikis Square[3], etc.),

instead of the regular one at the Filopappou Hill, and messages such as "Lively Squares" or "We want to danse in squares, streets and neighbourhoods" are delivered in any possible means (e.g. banners, posters, etc.).
The A.O. also gives an open concert every June, in vicinity to the archeological site of Kerameikos and the Acropolis. Yet, most importantly, it provides solidarity to several people and events: performances in several trials of public interest (trial for the murder of Zac/Zackie[4]; trials for victims a sexual violence, rape[5] & murder; etc.), as well as campaigns for social justice and peace, with the most recent example concerning the war in Gaza and Palestine[6].
The aim of this presentation is to explore how this impulsive bottom-up initiative can/has become "game-changer" at the local (city) and the very local (neighbourhood) level, essentially as an antidote to the harsh regeneration and touristification policies that hit actually the Greek cities. Building upon my own participation to the A.O. during 2021-2022, I seek to understand to what extend such an initiative – a community of joy, care and solidarity, and an urban utopia, as I would like to call it – may be capable of transforming, in the mid-term, both public space and the relations performed within public space. Considering its ephemeral and sporadic performances and actions, to what extend can an initiative such the A.O. play a role in shaping the neighbourhood and the city fabric overall? I am particularly interested in examining the potential of such initiatives yet also the significant challenges they pose as regards appropriation, belonging, and reclaiming the city. After all, what would be needed, from a planner's perspective, to enhance and leverage such initiatives in a view of coming closer to the ideals of the Just City and the Right to the City? How can planners ensure that such bottom-up initiatives can be taken under consideration in decision-making processes? What kind of spaces could accommodate such initiatives that promote interaction among diverse people yet often they challenge the established status quo?

Keywords: Open Orchestra/Athens, culture, art/ist, solidarity, political action, spatial justice, public space appropriation, transformative power

1. Introduction: getting to know the Open Orchestra, Athens, March 2021

This is an early stage and exploratory research endeavour that emerged literally from the very title of the annual conference of AESOP this year (2024): "GAME CHANGER? Planning for just and sustainable urban regions". It concerns my personal experience with the Open Orchestra, which could provide a potential example of Game Changer in the city of Athens, Greece, for the transformation of urban everydayness towards ideas and ideals related to the Lefebvrian 'Right to the City'.

The Open Orchestra, that was established in spring 2021, in Athens, is a group of about 150 professional artists and amateurs. It emerged from the Support Art Workers Action Group (#SupportArtWorkers), which was 'born' during the pandemic of Covid-19 to resist to the depreciation of culture and art-workers. Many of those latter remained jobless and without support from the state, after the closing down of theatres, cinemas and arts spaces imposed as a protection measure from the pandemic, in the period 2019-2021[7]. The Support Art Workers Action Group and accordingly the Open Orchestra come partly after the Paris Occupation of Odeon; namely, a large orchestra of solidary musicians, consisted of the occupants of the Théâtre de l'Odéon, professionals from the French Symphonic and Lyric Orchestras, musicians from specialized orchestras and students, who were united at Odéon, Paris, on March 27, 2021, and played the protesting piece "El Pueblo Unido Jamas Sera Vencido"[8]. Some months later, the Support Art Workers Action Group gathered in Propylaia, Athens, repeating the same symbolic move: the performance of "El Pueblo Unido…".

This has been the starting act of the Open Orchestra (in Greek Ανοιχτή Ορχήστρα/ A.O.). It is called 'Open', because anyone can rehearse with it at any time: there is no limitation on artistic level or degree of commitment: one can come and go at any time. Organizationally, there is a solid core of people who rehearse together every Sunday at the Filopappou Hill, a central public park of Athens. There exists a coordination group, yet decisions are made through open circles organized monthly. This is particularly relevant to the organization of different projects; for instance, instead of the regular Sunday meeting at the Filopappou Hill, rehearsals may sporadically take place in deprived neighbourhoods (Victoria square, Perama, Amerikis Square[9], etc.); in which, messages such as "Lively Squares" or "We want to danse in squares, streets and neighbourhoods" are delivered in banners, posters, etc. The A.O. also gives an open concert every June, in vicinity to the archeological site of Kerameikos (near the Acropolis).

Most importantly, however, the orchestra provides solidarity to several people, groups and events that are thought to need support: performances in trials of public interest (trial for the murder of the queer activist Zac/Zackie[10]; trials for victims a sexual violence, rape[11], femicide; etc.), as well as campaigns for social justice and peace, with the most recent

[11] https://www.koutipandoras.gr/article/anoihti-orhistra-emeis-georgia-se-pisteyoyme/

example concerning the war in Gaza and Palestine.[12] The A.O. also provides support to groups of residents who fight against urban interventions that are contrary to public interest (e.g. Metro station in Exarchia square in central Athens, etc.). It is important to note that this support usually comes after invitation to the Open Orchestra. The family of Zak/Zackie, after getting in touch with the coordination group, asked the A.O. to perform the day of the trial for the murder of Zak/Zackie in front of the court to provide visibility to a trial that would otherwise struggle to find its way in the Greek media. Similarly, it was the Exarchia Inhabitants Initiative that invited the Open Orchestra to support them. On the contrary, the support to the Palestinian question derived as an initiative of the A.O.

The aim of this presentation is to explore whether this impulsive bottom-up initiative could be considered as – and, even more importantly, could become – a "game-changer" at the local (city) and the very local (neighbourhood) level, as a response to the constant crises that have been hitting the inhabitants of Athens and Greece, in the recent years: debt crisis and austerity, refugee and migration crisis, Covid-19 pandemic crisis, housing crisis, also as a result of tourism regeneration and touristification practices over the last decades.

I seek to understand to what extend an initiative like this – a community of joy, care and solidarity, and an urban utopia, as I like to call it – may be capable of transforming, in the mid-term, both public space and the relations performed within public space. Considering its ephemeral and sporadic performances and actions, to what extend could an initiative such the A.O. play a role in shaping the neighbourhood and the city fabric overall?

I would also be interested in examining, in the future, the potential (if any) of such initiatives as regards appropriation, belonging, and reclaiming the city. And also, what would be needed, from a planner's perspective, to enhance and leverage such initiatives. Which, to my mind, struggle in favour of the ideals of the Just City and the Right to the City. What kind of spaces could accommodate such initiatives that promote interaction among diverse people yet often they challenge the established status quo?

To comprehend and problematize the Open Orchestra project, analytically, my study is primarily based on the Lefebvrian concept of 'the right to the city' (1968). At a second stage, literature related to this concept is also employed (Harvey, 2008; Marcuse, 2009; Merrifield, 2009 & 2011; Hess, 2021), as well as literature on the more recent discussion on urban and social commons (Ostrom, 1990; Bollier, 2016; Hess & Ostrom, 2011; Bollier & Helfrich, 2012 & 2015; Tsavdaroglou & Kaika, 2022; Tsavdaroglou, 2018; Πεχτελίδης, 2020; Αρβανιτίδης & Νασιώκα, 2015). Methodologically, the present research endeavour is based, insofar, on my own personal experience with the Open Orchestra between autumn 2021 and summer 2022 (precisely from October 2021 until September 2022). The method applied could be thus described as a retrospective participant observation. I also rely on a transcript of the discussion that took place on March 2023 with the members of the A.O. in the context of the doctoral thesis of another researcher from the Department of Geography, University of the Aegean. In the future, I intend to analyze more materials related to the A.O., such as

[12] https://www.youtube.com/watch?v=OEokUPSWKfg&ab_channel=%CE%91%CE%BD%CE%BF%CE%B9%CF%87%CF%84%CE%AE%CE%9F%CF%81%CF%87%CE%AE%CF%83%CF%84%CF%81%CE%B1%7COpenOrchestraGreece

the minutes of the Open Circles, where the members of the Orchestra discuss about everything: its function, the realization of new projects, etc.

The structure of the paper is as follows. The next section discusses the Lefebvrian concept of the right to the city, while drawing on the linkages of the praxis of the Open Orchestra with the theory of H. Lefebvre. In the following section, attention is paid to the literature on commons that has recently enriched the radical spatial vocabulary (Tsavdaroglou & Kaika, 2022). In the final section, I draft some preliminary conclusions based on my reflection on the Open Orchestra as commons and as potential game-changer practicing the Lefebvrian 'right to the city' in Athens. And, also, some insight is provided about whether it would be useful and meaningful to question the possible ways (if any) to leverage this kind of socially shared experience, as well as to 'contaminate' the planning practices, the (re)production of urban space, and the city fabric overall.

2. Recalling 'the Right to the City' ('*Le droit à la ville*'): rehearsals with the Open Orchestra in the public spaces of Athens

Tourism regeneration and touristification of urban centres are processes that have been key for urban transformation worldwide in the recent decades. Mega events and mega projects, local cultures and landscapes, Airbnb expansion even in the most remote places, golden visa incentives, yet also digital nomads, pioneer artists and other social groups included in the so-called 'creative classes' (that cities are supposed to attract in order to become more cosmopolitan, smart, entrepreneur and so on) have all become parts of the storming processes that affect the 'urban' in the twenty-first century. Among the contemporary cities, many are treated by their local and national authorities as 'commodities', while their residents and inhabitants as 'customers' (Tsavdaroglou & Kaika, 2022: 1134).

Against such developments of neoliberal take, it is not without relevance to rethink the Lefebvrian concept of the 'right to the city', introduced by French philosopher Henri Lefebvre, in the eve of the remarkable events of May 1968, in Paris. I draw on purpose on the original text ([1968], 3rd Edition/ 2009)[13], and this for several reasons; the main lying in the belief that, in the recent years, 'the Right to the City' has become a fashionable motto, a slogan and a panacea[14], which, to my mind, alienates us from some fundamental ideas of

[13] All reference to and quote from the Lefebvrian text in French is freely translated in English by the author, unless if else indicated.

[14] Analytically speaking, the 'right to the city' may be related to various urban issues, from gentrifying urban districts to neighborhood conflicts revolving around the location of a casino, and so on (see for instance John E. Balzarini & Anne B. Shlay (2016) Gentrification and the Right to the City: Community Conflict and Casinos, Journal of Urban Affairs, 38:4.). See also international agencies, such as UN-Habitat (https://unhabitat.org/sites/default/files/documents/2019-05/wuf-5.pdf). Nevertheless, it is to note the materialization of the 'right to the city' in national law in countries such as Brazil and Colombia, which resulted in that the 'right to the city' became a legal right. See the approval of Law no. 388/1997 in Colombia and Law no. 10.257/2001 in Brazil (see also https://www.cnm.org.br/cms/images/stories/Links/29092016_WhatisR2C24June2016.pdf; Fernandes, 2007).

Lefebvre, that were expressed in his text. Either applied in a variety of campaigns for a 'right to the city' across the globe (Mayer, 2009), or in scholarly debates on urban struggles, there seems to be an ambiguity in the use of the concept (Huchzermeyer, 2013): first, its meaning is taken for granted (ibid.); second, its mainstreaming in the recent literature is often summarized, thus deprived from some of its fundamental assumptions. It is not a coincidence that the 'right to the city' was translated into English only from 1996, and, still, only in part (Huchzermeyer, 2013).

Against this background, I opted for re-reading Lefebvre's original text and his own writing[15]. Which, among other things, is highly polemical towards the experts of the 'urban', such as architects, planners, sociologists, etc., as much as towards research laboratories, universities, intellectuals'[16]... This is probably not irrelevant to that Henri Lefebvre (H.L.) believed that any change in the urban everydayness will emerge from below, from the city-dwellers, 'the many' or else '*the masses*'...

According to Hess, Deulceux and Weigand (2009: xi), H.L. expresses the thought of the possible, the achievable – what *can* happen –, and he envisions it. H. Lefebvre describes an *achievable utopia*, which he outlines throughout his text: how may be transformed everydayness within and via the *urban*.

To begin, it is worth noting one of the starting points of his reflection related to centrality:

'It would be more reasonable, pleasant and meaningful to live in the city and work in the suburbs – some of which are far from inhabitable –, and not the other way around, right?' (Lefebvre, 2009 [1968]: 76).

In relation to this idea, Lefebvre sets some key questions:

'What are they – what will be – the "socially successful places"? How to identify them? According to what criteria?'

To immediately precise that by 'socially successful places' he intends those that are conducive to happiness ('*lieux socialement 'réussis', 'favorable au bonheur*') (ibid.: 100). Implying that our cities are not places conducive to happiness. Even more importantly, he posits:

'Every society, every era, every civilization imagined its heaven and hell, its ideal city, its utopia. Utopia is tied to multiple realities, more or less distant, but nowadays, in the 21st century, it is not tied to the real – to the everyday life. [...] The gaze turns away, abandons the horizon, disappears into the clouds, elsewhere...' (ibid.: 112).

This perception of today's utopia(s) is closely articulated to his description of today's everydayness. H. Lefebvre describes all those who suffer from a very arranged daily life, the catastrophic misery of housing and of suburban dwellers, of those living in housing ghettos,

[15] On this, see also Huchzermeyer (2013).
[16] For instance, H.L. writes about research laboratories, universities, experts and intellectuals: "they clash with each other in such a competitive way, with a zeal worthy of a better job, for the benefit of the great Master of economics and politics..." (1968: 111).

in derelict old city-centers, and in successive urban expansions far from downtown. He writes:

'It is enough to understand the daily life of someone who runs from his home to the nearest – or not so close – station of the overflowing subway, to the office or to the factory, to take the way back in the evening, to come home, to regain his strength, and start again, the day after. This generalized misery goes hand-in-hand with the 'pleasures' that disguise it and, which become therefore the means of escape' (ibid.: 108). However, 'neither holiday departure nor industrialised cultural production nor leisure activities solve the problem. The image of all this hinders the problem from being set. The problem is to end with the divisions between 'everyday life/ leisure activities' or 'everyday life/ feast'. The point is to restore celebration, transforming everyday life' (ibid.: 118).

The Open Orchestra comes close to this perception of everyday life and celebration: during the Sunday rehearsals, everydayness changes and it seems to convert *inter alia* to joy, happiness, and sharing. At the same time, the action of the A.O. becomes a claim and an appropriation of public space, and the city overall. The appropriation of the city, even in its most contested and derelict places, when rehearsals take place in neglected public spaces and degraded neighborhoods, becomes – among other – a social demand. Experientially, therefore, following Lefebvre, the A.O. seems to enable celebration to return into the everyday life and to transform this latter into joy yet also into claim, at least temporarily.

In the proper words of one of the oldest members of the A.O., it is explained what the Orchestra is and what it serves:

[EXTRACT 1]

"I've come up with it and I think we all agree that it serves 3 things. On the one hand it is a need for musical and artistic expression, so it has a purely musical and artistic part. On the other hand, it covers a need for a political way out in the dark times we live in, activism and political action from coexisting for 3 hours playing music to going to join other groups to, say, demonstrate in favour of a demand. And the third part has to do with socialization and the pleasure we derive from meeting people, interacting and essentially enjoying this coexistence. [...] I believe that the orchestra [...] has done many things in the public space [...] and I think it has left its imprint in a more or less obvious way at various conjunctures. [...] [The] orchestra is definitely an extroverted ensemble that intervenes in public space, that plays music and attracts people, states things. On the other hand, however, I think it changes us as well very much. [...] It has made me change attitudes, values, mood, to raise questions and motivation to develop more as a person..."

Everyday life is a central concept in Lefebvre's reasoning, and everything contributes to transform it: 'Techniques, art, knowledge, pass into the service of everyday life in order to transform it' (ibid.129).

Art in particular, is put at the service of the urban: 'Leaving aside representation, ornament, decoration, art can become "*praxis* and *poiesis*" '(poetry') on the social scale: the art of living in the city as an oeuvre/ work of art' (Lefebvre, 2009 [1968]: 124).

Into his reasoning, Lefebvre drew the term 'poetry' (or the Greek word 'poiesis'), referring to the making of creative work; or, said alternatively, the making of 'oeuvre' that is the creative as opposed to productive –profit-motivated– work[17] (Huchzermeyer, 2013). Lefebvre's engagement with people's desire for creative work was incorporated into his conceptualization of the 'right to the city'; together with everydayness and celebration (the importance of the lived experience and space), happiness, utopia and centrality, are all key – intertwined – elements of this 'right'.

As regards the importance of centrality, in Lefebvre's own words, the right to the city is the right to the 'urban life, to renewed centrality, to places of encounter and exchange, to life rhythms and time uses, enabling the full and complete usage of these moments and places' (Lefebvre,1996 [1968]: 179).

H. Lefebvre also wonders about the relation of centrality with the ephemeron:

'Why not prioritize over the eternal city the ephemeral cities, and the moving centralities over fixed centers?' (Lefebvre, 2009 [1968]: 104).

And elsewhere:

'The ideal city would be the ephemeral city, an endless oeuvre/work (of art) of the inhabitants, who themselves are moving and are mobilized by and for this oeuvre' (ibid.:124).

And, I think, again, of the Open Orchestra (A.O.), which concerns artists and amateurs, yet certainly inhabitants of Athens. Who are both *mobile* – from neighborhood to neighborhood, from protest gathering to solidarity gathering (to claim rights, justice, commons, art, the public space overall, and so on) – and *mobilized* by and for this oeuvre of transforming everyday urban life from misery and desolation to celebration (yet also to claim and demand). From this point of view, centralities are indeed shifting, depending on where are set the stakes of the A.O.: a rehearsal in Victoria Square, Amerikis Square, some derelict sites in Perama (Piraeus), the 1930s dilapidated refugee settlements in Alexandra's Avenue, or outside the Evelpidon courts ahead of the trial for the murder of the queer activist Zac/Zackie, and so on. These moving centralities are set against a fixed and eternal center, in Syntagma Square or even in the Propylaea (University of Athens).

Propylaea, being indeed the core city of Athens and its historic center, played a role in the primary act of the making of the Open Orchestra. Let us recall that the first concert took place in Propylaea, in spring 2021, when the Support Art Workers group performed the piece 'El Pueblo Unido…', just like the solidarity orchestra of the Théâtre de l'Odéon in Paris, some months earlier. It is no coincidence or surprise that this 'eternal city' center – the business and administrative center, as explained elsewhere by H.L.– did not remain on focus by the Open Orchestra; because real life and everydayness 'happen' elsewhere. Furthermore, as Lefebvre underlines, the eternal-city-center is out of reach for the majority of the city dwellers, let alone the (im)probability to live and inhabit there.

[17] Huchzermeyer (2013) notes that earlier translators of Lefebvre's subsequent book 'The Production of Space' use the English word 'work' instead of 'oeuvre' (see, Lefebvre, 1991 [1974]:73).

Lefebvre does not equate centrality with the physical centre of the town. As he will argue in a later work, 'virtually, anything is possible anywhere' [...]; 'centrality is always possible' (Lefebvre, 2003 [1970]: 130; quoted in Huchzermeyer, 2013). In other words, as above quoted, centrality is conceived as moveable and moving, entangled, therefore, to the idea of the ephemeral. Hence, the perpetual movement of centralities is intrinsic to the concept of the ephemeral city. And, as above described, the A.O. practices in purpose this volatility of centralities.

For H. Lefebvre, 'the future of art is not artistic but urban' (Lefebvre, 2009 [1968]: 125). Because, as he explains: 'the future of humans is not found in the universe (the cosmos) neither in the people nor in production, but within urban society' (ibid.: 125).

This echoes his deep interest in the everyday life, that is the importance of the lived experience (with)in the urban, which informed his thinking on the right to the city.

H. Lefebvre raised the issue of rights together with the social consequences that come as a result of – precisely – the lack of rights, or, said alternatively, the misery of everyday life, and the pressure exercised to the many – to '*the masses*': rights of age and gender rights, rights to education and training, the right to work, to culture, to rest, the right to health, to housing (Lefebvre, 2009 [1968]: 107). And yet, the right to the city is not understood as a simple right to visit or return to the traditional city: the 'urban', as a meeting place, social right and use value, but also 'as inscription into space of a time which has become a supreme good, finds its morphological basis, its realization, through people's everyday practices' (ibid.: 108). Hence, the right to the city concerns those who *inhabit* the city, and not some Olympian Gods of the new aristocracy, who 'fly' from palace to palace or from tower to tower, transcending everyday life, as Lefebvre eloquently stresses (ibid.: 108). The right to centrality is therefore in the core of Lefebvre's reflection, as much as the concepts of habitat and inhabiting, appropriation and use value (in contrast to exchange value), and, essentially, as aforementioned, the concept of the everyday life of common people.

All in all, for Henri Lefebvre, the right to the city is:

'a superior form of rights: right to freedom, to individuation in socialization, to habitat and to inhabit. The right to the *oeuvre* (the participatory activity), and the right to appropriation (clearly distinct from the right to property), are implicated in the right to the city' (Lefebvre, 2009 [1968]: 125).

The right to the city – the right to urban life – is, for H. Lefebvre, a condition for a renewed humanism and for democracy (Hess, 2009: 3). To understand the essence of Lefebvre's 'right to the city', we need to take into account, apart from his consideration of the everyday, his ideas of the city together with his critique of the state (ibid.: 4). Among other things, this is not without relevance with more recent theory on commons.

3. '*Commons*', '*commoning*', and '*the Right to the City*'

Theory on commons is not without relevance with the modus operandi of the A.O. In this section, we draw attention to the literature on commons, briefly evoking some key points of this seminal body of research.

The discussion on commons often refers to private, state and collective models for managing 'common pool resources' (CPR), that is to say resources without a clearly defined ownership status (Ostrom, 1990). CPRs or 'commons' (Bollier, 2016) are vibrant and dynamic social systems which evolve around values of self-management, collective ownership and the equitable administration of resources or goods created by different communities to ensure the survival and well-being of each of their members individually, yet also collectively through the community (Bollier, 2016; Ostrom, 1990; Πεχτελίδης, 2020: 26).

Still, commons are not simply resources or goods we share, they are the social dimension of the shared (De Angelis, in An Architektur, 2010: 5). Massimo De Angelis (ibid.: 2) points that 'conceptualizing the commons involves three things at the same time. First, all commons involve some sort of common pool of resources, understood as non-commodified means of fulfilling people's needs. Second, the commons are necessarily created and sustained by communities[18]... [...] [T]he third and most important element in terms of conceptualizing the commons is the verb "to common" – the social process that creates and reproduces the commons'. This *commoning* activity or '*commoning*' further describes the social relations that are capable of producing and reproducing, establishing and re-establishing, inventing and reinventing the commons (Tsavdaroglou & Kaika 2022).

Commons flourish and expand in all the sectors of life. They are not only material, such as earth, the oceans, energy and water, but can also be intangible, such as education and knowledge (Πεχτελίδης, 2020: 27, 29). Even more importantly, commons 'are a socially minded way of thinking and doing that crosses times and cultures and can be used in very different realms, from community-supported agriculture to software programming to cooperative forms of drug development' (Bollier & Helfrich,2019; see also https://freefairandalive.org/learning-to-see-the-commons/).

A famous critique of the commons came as early as 1968, with the article of economist Gerrit Hardin "The Tragedy of the Commons". Hardin argued that common resources will inevitably lead to a sustainability tragedy, because the individuals accessing them would always try to maximize their personal revenue and thereby destroy them. The policy implications of this approach are eloquent, as it is implied that the best way to sustain the resource in question would be through privatization or state control (quoted by De Angelis in An Architektur, 2010: 4).

[18] [...] 'Communities are sets of commoners who share these resources and who define for themselves the rules according to which they are accessed and used. Communities, however, do not necessarily have to be bound to a locality, they could also operate through translocal spaces. They also need not be understood as "homogeneous" in their cultural and material features' (De Angelis, in An Architektur, 2010: 5).

Against this conceptualization, Ostrom (1990), at the first place, and later other researchers as well, showed that there exists, indeed, a third way – beyond markets and states – and this concerns community self-management and self-government. Furthermore, in a completely different vein from standard economics and the rationale of Hardin's "tragedy" – for whom "rational" is the action of taking more than one's fair share of collective wealth, while displacing unwanted costs onto nature – Bollier & Helfrich (2019) propose the idea of "Ubuntu Rationality"; that is a different worldview, ethic, and set of social practices. As the authors explain, the Bantu tribal worldview could be summarized by the axiom "*I am because we are"*. In this perspective, they postulate that commoning does not refer to some distant utopia but constitutes an unacknowledged "Nowtopia" (ibid.) Said alternatively, commoning is a "realistic utopia" (Wright, 2018; quoted in Πεχτελίδης, 2020: 39), implemented here and now.

This conceptualization of commoning and commons resonates with the idea of utopia that goes through the text of Henri Lefebvre on his 'Right to the city'. Lefebvre writes about a realizable utopia through the transformation of everyday life *in* and *by* the "urban". This idea of a realizable utopia, that is a utopia that can be realized right here right now, or –to employ Bollier's & Helfrich's (2019) neologism – a "Nowtopia", is directly correlated to Lefebvre's questioning about the "socially successful places", which, as aforesaid, are those that promote happiness (Lefebvre, 2009 [1968]: 76). In this reasoning, realizable utopias are conducive to happiness, and this could also be the case of commons and commoning.

Stavros Stavrides suggests an additional reason that leads us towards Lefebvre and his notion of the "right to the city". For Stavrides, 'to think about a city based on commons we have to question and conceptualize the connection of space and the commons' (quoted in An Architektur, 2010: 16)). To think about space as related to the commons means to conceptualize it, after Lefebvre, as a form of relations rather than an established arrangement of positions. In this way, as Stavrides points, space becomes intrinsic to social action and "happens" through different social actions, which nurture different spatial qualities. This then means that when claiming space as a form of commons, we oppose the idea that each community exists as a spatially defined entity; rather we opt for a network of communicating and negotiating social spaces which retain a "passage" character (ibid.: 16).

This "passage" character– or versatility of commons (Bollier & Helfrich, 2019) – echoes again H. Lefevbre's urge to prioritize the ephemeral over the eternal: as briefly discussed in the previous section, Lefebvre suggests that the ideal city is the ephemeral city. The ideal city would be an endless work of art on behalf of its inhabitants, who would both be moving and mobilizing by and for this work of art (Lefebvre, 2009 [1968]: 104, 124). This mobilization to which refers H.L. is nothing less than social action, that is to say *praxis*. As Stavrides points, space becomes intrinsic to social action. Commoning, on the other hand, does become a social praxis (De Angelis quoted in An Architektur, 2010: 4). In this line of thoughts, we could maintain that the A.O. is social praxis and commons. Besides, "praxis and poiesis" '(poetry') on the social scale is 'the art of living in the city as a work of art' (Lefebvre, 2009 [1968]: 124), according to the Lefebvrian concept of the 'right to the city'[19]. Said alternatively, as pointed by Stavrides, for Lefebvre, the 'right to the city' is the right to

[19] And it also, as aforementioned, what H.L expects art to become (Lefebvre, 2009 [1968]: 124).

create the city as a collective work of art. Therefore, the city can be fashioned 'through encounters that make room for new meanings, new values, new dreams, new collective experiences' (Stavrides quoted in An Architektur, 2010: 16).

Against this background, it is worth exploring the idea of the Open Orchestra as commons. This hypothesis needs further research which lies beyond the scope of the present paper.

4. Who can do it? Planning, planners, game-changers and the A.O.

The Open Orchestra seems to enact many of the ideas that shape the concept of the 'right to the city' as theorised by H. Lefebvre. To paraphrase Stavrides (op. cit.) this is *inter alia* the right to create the city as a collective work of art. Without any doubt, the A.O. challenges the established status quo, claiming more democracy, more justice, peace, equal rights for all, open spaces in the city – beyond exchange values, regeneration programmes and hasty touristification. Despite all the above, the question remains about whether this impulsive bottom-up initiative and socially shared experience named Open Orchestra (A.O.) is somehow practicing the 'right to the city'. Similarly, we could hypothesize that, in the way that it has been created and functions, the Orchestra could be considered as commons as well. Yet, for the time being, this remains a hypothesis that needs further investigation.

The difficulty to assert whether the Open Orchestra practices the 'right to the city' as outlined by Henri Lefebvre resonates with a question which remains dominant in the existing literature: '*Who can do the Right to the City*?'

H. Lefebvre is very explicit about this:

'No one is authorized to make the synthesis of the signals of the city. Neither the sociologist, nor the economist, or the architect... Only a praxis can assume the possibility and the demand for synthesis: the 'gathering' of what is segregated, isolated...' (Lefebvre, 2009 [1968]: 92).

As a praxis, the right can only be brought about by 'groups, social classes and class fractions capable of revolutionary initiative' posits elsewhere Lefebvre (Lefebvre, 2009 [1968]: 113). These are the ones to indicate their social needs, to overturn existing authorities, and to 'claim a future that will be their own work' (ibid.).

In other words, the 'right to the city' has to be asserted from below and connected to social movements (Harvey, 2008; Mayer, 2009). Even more importantly, Lefebvre calls for a reversal of roles between 'the experts' and the many:

'Only the taking in charge by the working class of planning and its political agenda can profoundly modify social life and open another era: that of socialism in neo-capitalist countries' (Lefebvre, 1996/1968:179; quoted in Huchzermeyer, 2013).

And elsewhere:

'Urbanism' (as a profession) should 'try to model space as a work of art' (Lefebvre, 2003/1970:180; quoted in Huchzermeyer, 2013). The 'sense of the oeuvre' must be shared

also by ordinary people, or else 'urban consciousness will vanish' (Lefebvre, 1996/1968:77; quoted in Huchzermeyer, 2013).

Against this background, I am wondering whether my starting questions – regarding a planner's perspective on initiatives like the Open Orchestra – are opposing the essence of the Lefebvrian concept of the 'right to the city'. I think that, among other things, Lefebvre urges the 'experts' of the urban to find a common step with the non-experts, i.e. the city dwellers – the many. Does this mean to promote more participative planning practices? Does this mean to reflect on how such initiatives, which do shape social relations in the city even in some micro-scale, could also shape space at the metropolitan scale?

In any case, it is interesting to recall the reflection of Massimo De Angelis on commons, who suggests that it not possible to name the subject of change; expressions such as working class, proletariat, multitude, etc. – he says – 'may be more or less useful depending on the situation, but generally their usefulness is mainly correlated to crucial questions of ''frontline''' (quoted in An Architektur, 2010: 5).

At the closure of this final section, it seems that the stakes set by H. Lefebvre in the eve of the events of May 1968 are still very up to date, while the transformation of the everyday life in and by the "urban" – that is the realization of a realizable utopia – are not yet achieved. Does the A.O. succeed in getting closer to such stakes in today's Athens? This remains another open question. In this text, I tried to provide some insight based on my reflection on the Open Orchestra as commons, but also as potential game-changer that is practicing bits and pieces of the Lefebvrian 'right to the city'. I remain concerned about the possible ways to leverage this kind of socially shared experience, and how these could 'contaminate', if possible (and meaningful), the planning practices, so as to impact the (re)production of urban space and the city fabric overall.

On freedom, public space and women's experiences of prostitution. The (in)visible world of the Bois de Vincennes in Paris[1]

Brigida Proto
CEMS, EHESS
brigida.proto@ehess.fr

Abstract.
This paper focuses on Nigerian women's experiences of prostitution in a public space, the Bois de Vincennes in Paris, as democratic experiences questioning the value of freedom in pluralistic societies. It is based on the very provisional outputs of a collaborative field-research. It relies on an ecological-pragmatist perspective of analysis that suggests to consider public spaces as frontiers of capacitation: in-between spaces where Nigerian women reinvent themselves in the face of international and local, planned and unplanned, events. The aim of the paper is to rethink the political and cultural value of public spaces for just and inclusive territorial transformations.

Key-words: prostitution, freedom, public spaces, social justice, cultural pluralism

Prostitution constitutes a moral controversy, a public problem but also an urban and regional issue. On the one hand, diverse social groups, considered "undesirable" or "deviant", experience prostitution in public spaces by practicing their own forms of territorial appropriation and rights claiming. On the other hand, a public debate trapped in the ideological opposition abolitionists/pro-sex workers and, therefore, in the binary logic forced/free prostitution, tends to invisibilize experiences that question what human freedom means in the face of extreme human rights violations taking place in cities.

Nigerian women in situation of prostitution have been mainly represented as victims of human trafficking for sexual exploitation. Their freedom is supposed to be inhibited by traditional family and gender relations, Nigerian organized transnational networks and the black magic. Research on this topic has been conducted in clinical and court settings or in ngos. This paper extends the insight to Nigerian women's experiences of prostitution in a public space, the Bois de Vincennes in Paris, and is based on the very provisional outputs of a collaborative field-research combining ethnography, life histories and participatory research[2].

The following research questions will be taken in account: How has the relationship between prostitution and public space been studied? Can we confine

[1] The project leading to this paper has received funding from the European Union's Horizon 2020 research and innovation programme under the "Marie Sklodowska-Curie grant agreement No 844164".
[2] I was engaged as a volunteer for three years in the activities – mainly street unit and reception of Nigerian women in situation of prostitution – of the Saint Rita branch of the association *Aux captifs, la libération* in Paris. The ethnographic work I conducted would not have been possible without cooperating with Charlotte Sarah and Amel Selka, social workers in the association, who were also strongly involved, along with a few Nigerian women, Latin men and women, in the activities of the "Zuzulab", a pioneer experiment of participatory research addressing the issue of sexual exploitation, which took place at the EHESS in Paris from April 2023 to January 2024. The results of the "Zuzulab" are not reported in this paper.

Nigerian women's experiences of prostitution in the Bois de Vincennes to the horizon of the virtues of public spaces as spaces of co-presence of strangers? What arrangements do Nigerian women practice in the face of local and international, planned and unplanned, events affecting their margins of action? To what extent these women's experiences of public spaces can give a contribution to cities and urban regions more sensitive to the defense of human rights and cultural pluralism?

1. Prostitution as a territorial issue: Chicago, between Spain and the Balkans, the Bois de Vincennes

It was in the days of the Chicago School of Sociology that the social and territorial consequences of the moral crusades against prostitution were studied and the abolitionist model of care was questioned (Reckless, 1933). The red-light district was depicted as a zone of transition between the working men's world, the business district, and the women's world, the residential neighborhoods. It was an area where identities and cultures used to freely collapse and fuse. The repression of prostitution had unexpected consequences. On the one hand, vice migrated from the city to the borderlands outside city limits, making emerge a new area of transition where gang syndicates practiced their traditional tactics of invasion and occupation through intimidation of police graft and political alliances. On the other hand, women got through a new process of emancipation and individualization, rather than be redeemed by abolitionists. The brothel prostitutes, expression of organized vice business, were replaced by the "call girls", that is, a class of unregimented women outside the brothel, working in independent, emancipated and clandestine basis in apartments and flats and vice resorts in decentralized areas in Chicago, preserving their individual freedom and avoiding stigma and hardship of prostitution.

Following the Chicago School of Sociology, Tarrius (2022) extends the insight to the territories of transnational circulation traced by prostitutes who, moving between the Balkans and Spain, adjusted themselves to regional forms of cooperation between organized crime, migrant populations, illicit trafficking and local politics. Tarrius distinguishes three cross-border "moral regions": (a) around the Black Sea with the purpose to manage the traffic of women for prostitution in the Arabs Emirates and in Spain; (b) the transition area between the Balkans and Italy where the management of drug trafficking is handled by Calabrian, Apulian and Albanian-speaking mafias; (c) the French-Spanish Catalan space where the new mafias succeed in expelling the Neapolitan camorra in the management of drug trafficking and prostitution.

Unlike the individualization of prostitution undertaken by the Chicago's "call girls," women of the Balkans, moving throughout these moral regions, acquire a cosmopolitan sense of living. They propose their own idea of collective empowerment through the establishment of an NGO that supports projects of development in the Balkans thanks to earnings coming from prostitution, gives rise to an immense network of out-of-customs trade throughout Europe, reveals the force of emotional bonds shared by women having the painful experience of prostitution in common.

This paper focuses on Nigerian women's experiences of prostitution in a public space, the Bois de Vincennes in Paris, as democratic experiences questioning the meaning of freedom in pluralistic societies.

Nigerian prostitution has been represented as a story of globalization rooted in organized and transnational movements of trafficking and in a system of pawning and debt developed in West Africa in the context of colonial urbanization (Naanen, 1991).

Research conducted in clinical settings shows the magical-religious dimension of Nigerian prostitution: a ritual, the *juju*, is practiced to validate the asymmetrical power between the madame and the cadet, guarantees the paying off of the debt; regulate women's desire for migration and emancipation from generational, familial, and gender relations in Nigerian society (Taliani, 2019). In France research has also focused on ngos and courts (Jakšić 2016; Jakšić and Ragaru, 2021) and relationships between prostitution, organized crime and ethnic community (Lavaud-Legendre, 2013).

This paper adopts an ecological-pragmatist perspective to explore Nigerian women's experience of prostitution in a public place. It relies on the notion of "experience" as the result of interaction between living creatures and the environments, the "close connection between doing and suffering" that can arise from interaction, the reflective nature of such a connection (Dewey, 1920). It puts in the foreground the notion of freedom, not as freedom of will, but assuming that it is: (a) rooted in the environment, in and among actual facts and events (Dewey, 1922); (b) based on the ability to carry out plans; on the capacities to vary plans, change the course of action, experience novelties; on the power of desire (*ibid.*); (c) the result of the creative and reflective integration of impulses and interests of the self in social relationships (Mead 1938a).

Thomas (1923) studied how the young prostitutes' behavior was regulated by four wishes: desire for new experiences, desire for security, desire for response, desire for recognition. To address Nigerian women's experiences of prostitution in the Bois de Vincennes in Paris, the focus is on a public space as a "milieu of life" (Cefaï, 2019) where Nigerian women try to integrate different impulses, emotions and desires, deal with moral, affective and cognitive troubles, as well as with concernments and problematic situations, reinvent the frontiers between different "webs of life" (Mead 1938b) – inside and outside prostitution. Thus, we definitely leave the long-standing dominant horizon of the virtues of public spaces as spaces of co-presence of strangers and we enter an ecological-pragmatist perspective on urban public spaces sensitive to the notion of transaction (Crosta, 2010; Proto, forthcoming), to the study of the relations between activities and movements in urban public spaces and the political controversies in democratic political spaces (Terzi and Relieu, 2003), to the urban and regional analysis of the relations between globalization, social injustices and cultural pluralism (Cefaï, 2024; Proto, 2023), to the current debate on culture and policy-making (Cremaschi et al., 2021).

2. Route de la Pyramide: an archipelago of trajectories of freedom[3]

The Bois de Vincennes is the largest green space in Paris. Located in the 12th *arrondissement*, it is separated from it by the passage of the Boulevard périphérique, a beltway encircling Paris. Route de la Pyramide is a street, 3 km in length, within the Bois the Vincennes, connecting the suburbs of Vincennes and Joinville-le-Pont. Everyday Nigerian women reach by public transportation this street for prostitution in the afternoons or evenings while they live mainly in apartments managed by "maman" or "brokers" in suburbs of the northern metropolitan Paris region, as Sarcelles, Villier-le-Bel, Aulnay-sous-Bois or Saint-Denis.

Their journeys to Europe mainly began in Benin City. By bus they reached Kano and, crossing the border with Niger, passed through Maradi or Zinder to arrive in

[3] All Nigerian women's names as of this paragraph are not real.

Agadez. They then crossed the border to Libya, continued to Qatmmu or Sebha, and reached the coastal cities of Zuwara, Tripoli or Missatah. Others say that they crossed multiple African states before reaching Libya. The routes differed considerably upon their arrival in Italy. Women reached by boat Lampedusa, some of them moved to Catania and lived there for two or three years, before coming to Paris. Others have slowly made their way up Italy - Bari, Naples, Rome, Milan – before arriving in France. Others ones moved by sea from Libya to Lampedusa, from Lampedusa to Sardinia, from Sardinia to the North of Italy and, then by train, from Bergamo directly to Paris.

There's a strong connection between international events and changes in the presence of Nigerian women on route de la Pyramide.

First, as long as the civil war starting in 2014 in Libya strengthened cooperation between Nigerian trafficking organizations and Libyan militias, the journey to Europe turned into a real opportunity for so many Nigerian women arriving to Italy by boat. Their number soared from 1,500 in 2014 to 9,000 in 2016 and to 11,000 in 2017[4]. Meanwhile, in Paris, their presence on route de la Pyramide grew dramatically: social workers used to encounter 175 women in one hour in 2017, rather than 50 as it was in 2014. During these years judges and police officers raised awareness on the criminal evolution of Nigerian human trafficking. At the end of 2018, according to OCRTEH (*Office central pour la répression de la traite des êtres humains*), the management of prostitution in France was based on closer collaboration between "maman" and members of Nigerian cult organizations[5]: a highly organized money laundering system related to prostitution was identified and was based on the collection of proceeds from multiple cities, their transfer to Paris - to a hairdressing salon and a grocery store in the 18th *arrondissement* that acted as a depository of funds - and their sorting, by bus or by plane, to other European and African countries before reaching Nigeria.

Second, in Nigeria, on March 9 2018, Oba Ewuare II, the King of Benin ordered native doctors of Edo State to revoke all of the curses and oaths – the *juju* - placed on women exposed to human trafficking, himself invoking a curse on all those native doctors who continue to force or coerce girls into taking oaths. If the *juju* was the arrangement supposed to guarantee the paying off of the debt to the "maman" who sponsored the journey toward Europe, Nigerian women experienced the Oba edict as a liberation from debt while cultists and "maman", scared by the edict, were supposed to leave young women ready to reach Europe in Libya. The number of Nigerian women crossing the Mediterranean to arrive in Italy decreased significantly in 2018: 1250 out of 23370[6]. They disappeared altogether from the landing statistics as of 2019 in Italy and also on the streets of many Italian cities in 2019.

Nonetheless, Nigerian women remained in large numbers on route de la Pyramide in Paris until the Covid-19 crises. During the first confinement in spring 2020, they disappeared from the street and then gradually returned to it, albeit not in the same large numbers. If Nigerian women experienced the Oba edict in 2018 as an opportunity of debt liberation, the Covid-19 crises controversially extended their

[5] Nigerian cults are criminal organizations that have arisen in Nigeria since the 1970s, initially configured as secret student associations, later devoted to criminal activities.

[6] http://www.libertaciviliimmigrazione.dlci.interno.gov.it/it/documentazione/statistica/cruscotto-statistico-giornaliero.

margins of freedom. Many of them realized that they could live without prostitution and asked aid to associations to get out of prostitution in large numbers. Meanwhile, route de la Pyramide has become a key-reference for inter-urban and intra-European circulations of adult Nigerian women in search of higher profits.

There are women still stable for years on route de la Pyramide, who try to maintain their own spheres of action on the street.

Camille is the oldest presence on the street. She works in a van and is familiar with social workers on the street but never asks for assistance. She lives in Saint Denis suburb. She stays in the van, in bra and loincloth, behind the wheel, without a license, playing video games, talking on the phone. Sharing the van with her means for women to pay a percentage of their earnings directly to her, rather than only to the owner of the van. She leaves every three months to Grosseto in Italy where she has lived for many years. There, she lost a 5-year son in 2016 but has a 4-year old daughter who lives with her sister, an employee in a cleaning company. Sometimes she talks about a husband living in the UK whom she would like to join, other times she complains because she cannot get papers to work in France. One evening in March 2022, she was very upset. Although she was the eldest daughter, she was unable to leave Paris while her younger brother and sister were moving to England for study and would have soon been joined by their father[7].

In addition to Camille, at least two other women are present steadily on route de la Pyramide. Both of them, not in a van. The first one is Helene. She stays at the edge of the woods, at the margins of the street, always in the same spot for years, since 2016. Determined. She wants to remain in Paris. Different girls follow next to her. Starting in December 2022, a woman in her fifties, just arrived from Marseille, appears next to her. Helen is friendly with her but aloof. Both are always hungry and ask for condoms. The other woman stable on the street is Joan. Robust, provocative and ironic, she too wants to remain in Paris. She does not hide in the bushes but sits on the sidewalk. Landed in Sicily, she was taken to a reception center in Milan and after a few days was on a train to Paris. Her grandmother, mother and aunt live in Ventimiglia, on the border between Italy and France. The aunt is married to an Italian. Joan flaunts daily contacts with Lampedusa from where she receives news of shipwrecks and deaths during the landings. "The destination is assigned to you in Libya. If the destination is France, you must go to France," she repeats forcefully as she laughs on the sidewalk and responds in kind to the insults the women receive from speeding motorists on the street.

As long as the Covid-19 fosters Nigerian women intra-European circulation, the Bois de Vincennes turns into a milieu of multiple fast outsiders' accommodations. They all practice prostitution on foot.

Violet appears in the bushes on an afternoon in June 2021. Far away from the road. She looks uncomfortable. Her eyes are dull. She has been a week in Paris after six years in Spain. She lives in Sevran, 20 km north of Bois de Vincennes. She says that it was she of her own accord who left Spain. Then, a "we passed through Marseille but there is too much violence there and too many people of different nationalities. Here are my people." A week later, Violet has already changed her attitude. Long hair with blond braids, confident, smiling, she no longer stands hidden in the bush but laughingly negotiates with men on the sidewalk and disappears with a few of them into the bush.

[7] Many of the Nigerian women sexually exploited are the eldest daughters in their families.

Cherry is at the margins of route de la Pyramide in February 2023. She is kind and smiling. She was transferred in a very few days from Lampedusa to Verona, where she stayed for six months before reaching Paris. "In Verona it's very difficult to get regularization. The documents have greater strength depending on the city. Those in Verona are stronger than those in Milan and even stronger than those in Turin," she tells social workers showing her clear vision of the attitudes of Italian institutions. She is trying to obtain documents in France and then return to Italy, to her boyfriend. She underlines that she is very attached to Italy. One evening she kneels to thank God for sending the Italians to rescue her at sea. Another night she brings dinner to social workers because she considers them part of her family in France. Still another night she cries because her friends encourage her to file a complaint against a woman as her "maman" by perjuring herself: this is the new strategy of hierarchical inversion among Nigerian women in order to regularize themselves quickly. After a little more than a year, in March 2024, she is still there, on foot, at the margins of route de la Pyramide.

Prostitution is practiced on route de la Pyramide even for very short periods. They come from Turin, Milan, Southern Italy, as well as from Normandy or other French cities to spend a few weeks or months in the Bois de Vincennes thanks to local connections. There are also women travelling between multiple French cities. At the same time, women in Paris may come back to the Bois after a long time. On March 2024 Pumpkin, purple curly wig, stands alone, on foot, on the sidewalk at the very beginning of route de la Pyramide. She looks scared, hesitant. She lives in Paris and works as a caregiver to the elderly but must pay her rent in a lull between the end of one job and the beginning of a new commitment. She stresses that she will only be on route de la Pyramide that evening. Two weeks later she is behind the wheel of a van, smiling and thanking friends who have allowed her to work inside the van in a more protected way, as many others women who prostitute themselves in the Bois de Vincennes on weekends, despite having papers.

3. Vans & bushes: a "precarious habitat" towards the Olympic Games.

Nigerian women have come to Europe pushed by the desire for emancipation and found themselves in street prostitution. They have learnt how to use route de la Pyramide to maintain peace. Who practices prostitution on foot in the afternoon reaches a sandy path next to the sidewalk, turn trees on the sandy path into hangers for their bags and vests, and wait for clients by sitting at the edge of the bushes and sharing the sandy path with families, children or groups on horseback. In the evening they move to the sidewalk and arrange themselves mostly in pairs, always keeping a distance of 20-25 meters each other, this time sharing the sidewalk with a few joggers and bike riders.

In the post-pandemics, although the Bois de Vincennes is becoming a key-reference for intra-European circulation of Nigerian women, fewer and fewer practice prostitution on foot. Many of them move to the system of prostitution inside vans.

About 20 vans station on route de la Pyramide in the evening. Women change their clothing, put on makeup, and put their wigs directly inside the van, which is organized in a "control-zone", behind the wheel, and a "work-zone" separated by a curtain. Lit lanterns on the dashboard indicate the women's availability. A heater warms the van cockpit in winter. Women inside vans may be about 30-40 in the evening. Two women usually share the van, sometimes as many as three, one of which, prostitutes herself in the bush.

In the early 2000s, when Nigerian girls appeared in the Bois de Vincennes, there was an agreement between the BRP (*Brigade de répression du proxénétisme*) and the "*tradis*" ("*les traditionnelles"*) - those women - French or French-speaking - who used to practice prostitution in the Bois after abandoning the streets and apartments of rue Saint-Denis, in the 2nd *arrondissement*, in the late 1990s. To prostitute in a van, one had to have a driver's license; be alone; comply with all sanitary regulations for the prevention of any sexually transmitted disease; and not work on Wednesdays and weekends. Nigerian women transgressed the agreement. The stationing of the vans became a disturbance of urban decency for residents of the municipalities on the edge of the Bois and caused their protests, the adoption by municipalities of special measures to prohibit the stationing of the vans, various appeals to the Minister of the Interior and, finally, in 2003, the approval of the law for internal security - Law 2003-239 of March 18 2003. It was presented as a way to fight against the rise of foreign prostitution networks and pimping starting from the end of the 1990s. It reintroduced the crime of solicitation and also the crime of human trafficking: Nigerian women found themselves both as criminals and victims at the same time. Court convictions for soliciting increased more than threefold in less than just three years, rising from 291 in 2003 to almost 1,000 in 2005. In 2004 alone, 2,000 vans were seized. Pimping crimes remained stagnant.

The van constitutes a cell of intimacy and protection in public space for women but also an essential economic unit of Nigerian pimping. In the summer of 2022, stationed in single file, morning and afternoon, alongside the Castle of Vincennes, are as many as thirty Nigerian vans, together with the vans of Moldovans, Ukrainians, and Romanians who practice import-export of food products along that road. They are stationed within the administrative area of the municipality of Paris, albeit on the edge with the territory of the municipality of Vincennes. Actually, no prostitution is practiced inside the vans when stationed alongside the Castle of Vincennes, but following protests by the Mayor of Vincennes in November 2022, only a few remain there. Some are left all day on route de la Pyramide; others find space on avenue de Saint Maurice, still inside the Bois de Vincennes, albeit further away from route de la Pyramide.

Managing the circulation of the vans requires "disguised engagements" in the public space. We are not in the horizon of Goffman's civil inattention (1963), i.e., unfocused interaction between strangers aimed at maintaining public order, but in the course of situations of "false inattention", i.e., in the course of brief focused interactions - the delivery of a van - between young Nigerian men and young Nigerian women who pretend not to know each other. In June 2023, at dusk, while the green area near the Castle of Vincennes is crowded with passersby, a young woman, in her mid-20s, warms up a white van's engine. A young man, jeans, blue polo shirt, sunglasses, in his mid-20s too, down below checks the tires, opens the rearview mirror. They don't talk to each other. While she warms the engine looking straight ahead, he uses a tablet with his back to her. When the girl moves the white van from the parking lot, he looks at the tablet for a few more minutes, crosses the street, and gets into his turquoise car. The white van heads toward route de la Pyramide, the turquoise car in the opposite direction, toward Paris.

Still moments of "disguised engagements" are those involving the removal of the vans from route de la Pyramide. In the evenings, elderly white men take the vans away, keeping the Nigerian girls hidden below so that they are not visible on the street. Other times, in the morning, around 9 a.m., white men in their 40s move the vans from route de la Pyramide to Alfortville or Maison Alfort.

The circulation of vans shows that the management of Nigerian prostitution is not a matter of ethnicity, nor of woman-to-woman interaction but the result of a multiscale and interethnic symbiosis made of disguised engagements involving "maman", cult members, money collectors, drivers, garage owners. This symbiosis can still be disrupted.

The displacements of the vans can cause frictions with other social groups. At the end of September 2021, a few months after the Nigerian vans have reappeared on route de la Pyramide, following the Covid-19 deconfinement, a group of about ten white men jump out of a truck. They are not clients. They argue animatedly with a few black women. Speaking in English, they seem to threaten them. Then, they get back into the van and drive away. Are these conflicts with the drivers who take the vans off the road in the morning, or with the Moldovan, Ukrainian, and Romanian traders from whom they take space by parking on the same street beside the Castle of Vincennes?

With regard to client violence, Nigerian groups have to find more visible arrangements to protect prostitution in the Bois. Lurking in the bush with clients exposes girls to all sorts of violence. On the street they limp as a result of scuffles with clients to defend themselves from assault and theft - of money or cell phones. At night women are exposed to vandalism by speeding cars that throw firecrackers into the street or shatter van windows by firing air guns. Violence against women can become extreme. On the night of June 8-9, 2022, a man from Guadalupe, who had just entered as a client in a van, attempts with a knife to slit the girl's throat from behind, while she was busy picking up a condom. It is her friend behind the wheel who intervenes: she puts the man on the run, calls the police in vain, calls for help on route de la Pyramide looking for someone who knew how to drive. She finds only one girl out of about twenty vans on the street, and with the latter driving the van, she manages to take the bleeding girl, saving her, to the Vincennes police station, which alerts firefighters and the Samu (*Service d'Aide Médicale Urgente*) for emergency hospitalization. After this event, for the first time, black watchmen appear on route de la Pyramide: they stand on the sandy path near the bush and show familiarity with the woman by calling the few girls still on foot and those inside the vans by name.

Protecting prostitution inside vans finally requires the elimination of any autonomous women's group. In June 2021 five girls stand on foot at the margins of route de la Pyramide. They all move together along the street. One of them keeps a bottle of whiskey in her purse because "she thinks too much". Two women share a purse where they collect the money they earn. They joke, entertaining potential clients by dancing. The fourth woman provokes: "Am I Purity or Anti-Purity?". The fifth woman follows them, smiling silently. In October 2022 the group no longer exists. One of them has not been on route de la Pyramide for some time. The woman with the whiskey bottle stands alone across the street, ignored by all the others. She says she is leaving Paris because of what "bad boys" are doing. All the other girls who were part of the group are inside vans.

Nigerian women who integrate prostitution inside vans are guided by a desire for security and search protection in ethnic community ties. But approaching the Olympic Games, their troubles and concerns are increasingly related to police violence, rather than clients. Wednesday is police day. "Fanno il giro" ("They patrol"): some girls use this expression learned in Italy to refer to police patrols. Their problem is not the police presence on the street but understanding their motives: arresting clients or girls?

In fact, what they experience more and more often are moments of suspension of human rights that reduce freedom to impulses to escape. Police officers arrive in

threes or fours, with flashlights and dogs. They look for the girls, ask them for IDs and driver's licenses. They order OQTF (*Obligation de Quitter le Territoire Français*) over the weekend making it difficult to appeal in the following 48 hours as the law requires. Other times they tell the women they have one month to appeal, forcing them to be repatriated once the 48 hours have expired.

Escapes into the woods provide the only chance to protect themselves from the cops. They run away terrified. They jump out of vans to run toward the woods. Sometimes police dogs bite their arms and legs. When they return to the sidewalk, they limp from the pits they have fallen into or touch their hair, head and eyes from the pain it causes to be caught in the branches.

The organization of the Olympic Games goes hand in hand with a repressive evolution of police practices: so many Parisian associations see it as an experiment in urban gentrification that will have consequences far beyond the end of the event, especially because of the approval of the national immigration law 2024-42 of January 26 2024. As of fall 2023, twenty police operations have been conducted in the Bois de Vincennes in nine months: 203 people checked, 44 in retention administrative for verification of right of residence, 37 in QTDF et two placements in administrative detention center before forced referral[8]. In the media, the Prefecture claims to be countering the increased risk of exploitation of prostitution. According to OCRTEH, on the other hand, no significant increase in supply was reported during the Rugby Cup in 2023, which was considered as a "test" ahead of the Olympic Games. A camp for 4500 soldiers - an extraordinary operation last conducted during World War II - will be installed in the Bois de Vincennes to ensure security throughout the Olympic and Paralympic Games.

Meanwhile, the women of the Bois have been informed that very strict police officers will replace the police teams familiar to them. What is actually changing is the way familiar police officers patrol the street. On a Wednesday evening, in May 2024, a group of police officers, all women, arrives on route de la Pyramide. Familiar faces. All, perhaps, not even 30 years old. All in plainclothes. "One black, one with Indian features, one stout, one short": that's how Giorgia, a Nigerian woman who witnessed the scene up close, describes them.

They stop Cherry, the girl from Verona, but when they ask for her papers, she runs off into the woods. Rather than letting her escape, as the police usually does, this time it is the black policewoman who runs into the woods chasing her in vain. Cherry disappears into the bushes and manages to hide in Giorgia's van while the four policewomen, who have not noticed anything, continue patrolling the street. "How could a black policewoman turn in such a way against a girl almost her own age and as black as she is?", wonders Giorgia very upset. A week later, on a Wednesday, almost all the vans are empty and without lit lanterns on the dashboard.

4. The Bois: a frontier of capacitation?

Despite turning into an ever more "precarious habitat" that exposes Nigerian women to human rights violations, route de la Pyramide is also an "in-between space" where women begin a transition of their self in the welcoming society, dealing with conflicting impulses, emotions and desires (Proto, 2023).

[8] https://www.francetvinfo.fr/les-jeux-olympiques.

On route de la Pyramide, afternoon or evening, Nigerian women express their ambivalent moral feelings in interaction with social workers. They can quickly move from shame to kindness, from embarrassment to bravado and, still, from bravado to unexpected moments of confidentiality. Route de la Pyramide is the origin of a new process of capacitation: a process of "socialization of justice" (Addams, 1902) that creates a new "web of life" (Mead, 1938b) and through which they reinvent their "public morality" (Cefaï, 2019) and develop a new civic imagination, that is, the ability to "awaken emotions, make assessments, generate representations" but above all "to act and materially reorganize the environment" (*ibid.)*.

A few of them may thus decide to reach out to social workers for the first time at the "permanence" of the association, seeking for domiciliation, French or computer classes. Then, they can enter a non-linear process of capacitation by engaging themselves in the different processes of association, cooperation and communication pertaining four spheres of action: play, inter-religious dialogue and participation, relationship with nature, engagement with justice.

First, moments of play foster out-of-ordinary horizontal forms of collective communication and association among women who are in prostitution, between the latter ones and women who are out of prostitution, among these two groups, social workers and volunteers. The Uno card or the photo-language act as "membranes" (Goffman, 1962) that momentarily disconnect them from the rest of their world and let unexpected personality traits kept hidden emerge, thus giving them the opportunity to exhibit attributes valued in the wider social world, such as knowledge, intelligence, courage, and self-control (*ibid.*).

Second, Nigerian women experiment with inter-religious imagination. On Sunday they attend Pentecostal churches in suburbs but during the week they attend Parisian associations. Symbols may create unexpected troubles. A woman arrives at the permanence but she doesn't want to play with the other women. Walking on her own in the room, she stops and stares at a wooden statue of Joseph, Mary and Jesus in a corner of the permanence for a few minutes. She takes small steps back and forth while continuing to look at the sculpture and then walks away, saying to a volunteer: "If I will have the courage, I will be back next week". Before the Oba edict, although Nigerian women are Pentecostal, catholic rituals to liberate them from the juju were extremely successful in making them stop paying debts, denounce trafficking networks and becoming activists. This doesn't work anymore after the Oba edict in 2018 but so many times the boundaries between the French Catholic church and the Nigerian Pentecostal church become porous when Nigerian women bring the sound of African drums and their singing in English to the small church close to the association.

Along with the moments of play and inter-religious experimentation, there are moments of intense emotional processing of their experiences when Nigerian women interact with unknown natural environments, as in the case of the breakup-stays, short periods – from 2 to 5 days – of time away from Paris, organized by the association. During a stay in the Jura mountains at the frontier between France and Switzerland in February 2022, a group of 5 women visit a cow farm for organic milk production. When they come back to the guest house, Pink, one of them, barely hold back the disgust she feels at how that organic milk is produced. "Producing milk needs exploitation, like prostitution!", she angrily comments and rejects a glass of organic milk given by the personnel of the guest house. She ran away from home when she was 13 because her father wanted to marry her off to a man much older than her. Then, she was forced in prostitution in a connection house in Libya in 2015 and in the Bois de Vincennes in Paris until the edict of the Oba in 2018. At that time she had given the "maman" 20000

euros out of 350000 euros of debt to be repaid. She stopped paying her but continued to prostitute herself because in a very precarious situation. One month after her travel to the Jura mountains, she goes to the BRP to file a complaint against trafficking networks but, terrified, remains very vague about her story.

The activities Nigerian women practice at the "permanence" don't act as techniques of neutralization of deviance (Sykes and Matza, 1957) but create unexpected situations of capacitation through which they reinvent themselves in the welcoming society.

Becoming familiar with the association, Nigerian women experience a new sense of home: the "permanence", equipped with a kitchen and a large room for meetings and training activities, turns into a hybrid space mixing a sense of intimacy and a sense of school. They might still share a room with eight women in apartments managed by "maman" or brokers in suburbs but each week they reach the "permanence" in Pigalle to feel their new "family of France", a few say. Little by little, they can develop a new reflexivity on their experience of prostitution. The first sign of a change in their attitude is the demand for housing to social workers: this implies that they have broken up their ties with Nigerian brokers and are eager to begin the path towards status regularization most appropriate to their situation.

The desire for affective response may strongly shape women's capacity for self-determination throughout her pathway from the Bois to the Court. Marguerite was prostituting herself in the Bois de Vincennes since early February 2016. She escaped from her "maman"'s home in Cagliari, in Italy, where she had started prostitution to repay an initial debt of 60000 euros, later negotiated to 40000 euros. The "maman" was married with a member of the cult organization Eiye Confraternity and, although she lived in Italy, Marguerite prostituted herself in Paris under the "maman"'s blackmail to kidnap her sister in Benin City. In 2016 Marguerite's boyfriend in Benin City, who acted as a broker between her and the "maman", moved from Milan to live in a Parisian suburb with Marguerite and gave her contacts to prostitute herself in the Bois de Vincennes. On March 2017, Marguerite reached at the association the social worker she used to meet in the Bois and told her about her relationship with the "maman" without mentioning the man. Marguerite didn't return to the association because the man beat her violently upon learning that she had told about the "maman" and that it could easily be traced back to him. Marguerite reimbursed the madame only 20000 euros until August 2017, she told the family that she had decided not to prostitute herself anymore but continued by handing over everything she earnt to her boyfriend to help him open a hair salon and marry her. Marguerite suffered repeated violence from the man when she used to express her desire to leave prostitution. Meanwhile, she got in touch with another association and she applied to OFPRA (*Office français de protection des réfugiés et apatrides*) for asylum, which was rejected in July 2018. In August 2018 she definitively broke up with her boyfriend and returned to the first association in September 2018. In March 2019 she filed a complaint against her "maman" to the BRP but in October 2019 her appeal to the CNDA (*Cour nationale du droit d'asile*) for asylum was rejected because her story was deemed stereotypical and not credible. In April 2022 Marguerite finally decided to provide a supplement to the BRP in which she revealed for the first time her boyfriend's role as broker with the madam, the latter's husband belonging to a cult organization and the network allowing the woman to move between France and Italy. In January 2023 she takes her ex-boyfriend to court and obtains his conviction while she falls in love with a Nigerian man who supports her for the trial. She becomes mother of two children while, engaging herself in training activities, she discovers her aptitude for construction painting and

obtains a contract of employment. She lives with her family in a social housing apartment but motherhood has forced her to give up the job.

The desire for social recognition is strong among women who file a complaint against trafficking networks. Apple bursts into tears of happiness when she realizes she has gained the freedom to work in Europe after her engagement with the French system of justice. Apple trembles as she holds in her hands the document authorizing her to work in France. "I went through five years of hell just because I wanted to work as a caregiver to elderly people", she repeats as she continues to cry in front of the Prefecture of Paris on June 2022.

The justice system however exposes women to re-traumatization. At the end of the trial against her ex-boyfriend Marguerite is shocked. He is sentenced to two years but he will not spend one in prison: only electronic bracelet and house arrest were provided. Furthermore, he leaves the court alone and some days later tries to get in touch with her again on Facebook but she will block him terrified. In 2020, the first trial took place in Paris in which a group of sixteen Nigerian girls who came of age, albeit as minors in 2015, filed as plaintiffs against Nigerian trafficking networks. Since then, they are still waiting to close a dramatic chapter in their lives that the justice system's timeframe does not allow an end to. Hearings and trials postponed, testimony repeated over and over again, on video and in person. But above all, what has been extremely controversial, as a lawyer notices, is the charismatic influence that men, rather than the "maman", exert on young women. When faced with the accused, one of them loses her words, remains silent, looks terrified and then unexpectedly becomes saddened and expressed compassion for the accused despite having received the maximum sentence as the girl herself wished.

There's another path, however, Nigerian women are increasingly practicing to leave prostitution. The law 2016-444 of April 13 2016 for the criminalization of clients decriminalizes prostitution and provides a new arrangement, the PSP (*Parcours de Sortie de la Prostitution*), with the aim to leave prostitution without declaring oneself victim of trafficking and going to Court. This law has for sure exacerbated the opposition abolitionists/pro-sex workers but little attention has been given to the results of the PSP. At only one association, from 2017 to the end of 2021, 38 persons started the PSP, 13 persons completed it. At the beginning of 2024, 67 persons are in PSP and 34 have completed it, have a contract of employment and residence papers. Despite initial resistance, the PSP is increasingly being used even by specialized associations on human trafficking for sexual exploitation. What is required is to provide firm evidence of interruption of prostitution on the basis of regular monitoring carried out by territorial commissions and social workers for two years.

Those who apply for PSP are mostly Nigerian women. They feel freer because they no longer need to persuade the court, as in the case of filing a complaint or applying for asylum. Hesitantly, they speak of new travel routes to Europe by plane, rather than Mediterranean crossings. Of interethnic networks forming around the institutional visa racket, rather than criminal traffickers. Of acts of disobedience to exploitation networks, rather than obedience to the juju. Of emotional isolation and sharp cuts with families in Nigeria. Of difficult entanglements between motherhood, housing and work in France. Of problems in re-entering ordinary life situations after a temporary "deviance", as Becker (1963) would say.

5. Conclusions

Nigerian women's experiences of prostitution in the Bois de Vincennes give research and policy-making three suggestions for understanding public spaces.

First, the moral and affective dimension of experience should be put in the foreground. Nigerian women's freedom does not coincide with the individualization and invisibilization of prostitutes as in the 1920s Chicago. Nor with a collective capacity to convert the troubles of prostitution to projects for sustainable development of the countries of origin, as in the case of the women of the Balkans. On route de la Pyramide freedom has a threefold nature. It is an impulse, with its visceral, unreflective, dimension of action. It is a desire, when a horizon of action appears. It is a non-linear process of capacitation when desire turns into ability to carry out plans, experimenting and changing plans.

Second, public spaces are frontiers of capacitation where material and immaterial transactions between human and non-human agents take place at different degrees of accessibility, publicity and visibility. Vans and their circulation turn public spaces into sites of disguised engagements and symbiosis with the world of Nigerian prostitution: Nigerian women's freedom, thus, collapses into an impulse for protection. Streets encounters between Nigerian women and social workers may disclose other possible horizons of life. Public spaces, thus, turn into "in-between spaces" where women experiment displacements towards new webs of life, partial replacements of old webs of life, accommodations between old and new webs of life, permanently in search of new balances between the desire for affective response and the desire for social recognition in welcoming societies.

Finally, we need to recover the political/cultural value of public spaces from the life histories of social groups in precarious living conditions. It has to be acknowledged that, despite constituting an international long-planned event, the Olympics Games – thanks also to the immigration law approved in January 2024 - are silencing public spaces as spaces of human capacitation, thus questioning what institutional accountability means in pluralistic societies. Only when research and policy-making will be really rooted in forms of experimental collaboration between people concerned by problems, experts and politicians, public spaces may turn into sources for just and inclusive territorial transformations.

Study on Spatial Distribution of Fresh Supermarket Based on Street View Data

Abstract: People's demand for fresh agricultural products of fruits and vegetables is absolute, and the demand for fruits and vegetables is also continuous and regular. The outbreak of COVID-19 has increased people's requirements for food safety. At the same time, the emergence of the digital economy has gradually increased the number of take-out shopping methods that reduce contact with people. Based on open data such as Baidu map and Dianping combined with field research, this paper analyzes the distribution and use of fresh supermarket before and after the epidemic. The results showed that the epidemic further reduced the service radius of fresh supermarkets and reduced the accessibility of the roads where the stores were located. However, regional fresh markets with different online degrees have different degrees of change. Under the influence of the epidemic, fresh markets that are easier to reach and have distribution services have developed more strongly, thus distinguishing the distribution pattern of fresh stores in different regions. To a certain extent, Internet services have given stores stronger stability, and areas with perfect online development have been developed after the epidemic, and store location distribution is more closely related to geographical factors.

Key words: Fresh supermarket; Space Syntax; Space law; Accessibility

1 Research Background

In daily life, the fresh market, as an indispensable commercial type, provides people with fresh fruits and vegetables necessary for life. Under the impact of the epidemic, the importance of fresh markets has further increased, while take-out shopping methods that reduce human contact have gradually increased. During the pandemic, the daily necessities provided by the fresh market are relatively less affected; As a product supply business that must be consumed, fresh supermarket is closely related to the social economy, and the evolution of this business form can reflect the economic behavior pattern under the new purchasing environment.

At present, the use of big data for commercial spatial analysis has gradually become a new trend in commercial quantitative research. The public-oriented commercial institution point of interest (POI) data contains the spatial information of retail store location and the attribute information of business type, which is characterized by large data volume and strong real-time performance. It can improve the objectivity and accuracy of the hot spot identification of the commercial center and the analysis of the characteristics of the retail agglomeration area. With the development of information technology, the spatial analysis of commercial agglomeration by big data has gradually become a new trend of commercial quantitative research, providing more accurate judgment criteria and comprehensive technical support for urban planning and governance.

Most studies on open network data analyze the urban spatial structure through the overall business composition and apply it to urban assessment and guide urban design. For example, Zheng Xiaowei (2017) analyzed the urban and community-level service industry based on open data. The urban center system determined in the overall urban planning should be identified, and the main business forms and spatial agglomeration degree of various urban center service industries should be clarified to guide urban design [2]. On the block scale, the factors that affect the vitality of the site are judged by the quantitative evaluation of the component elements in the local area. For example, Zhao Nannan et al. found the influencing factors that affect the vitality of the commercial street of Binjiang Road through the analysis of the Dianping data [3]. Some scholars also analyze the composition of regional formats based on open data to know relevant designs. For example, Professor Sheng Qiang conducted regional potential evaluation through open data and applied it to the quantitative evaluation and comparison of different schemes [4]. Tan Xin obtained the data and attribute information of restaurants in the main urban area of Beijing and analyzed the influencing factors according to the Sixth National Population Census, Beijing Statistical Yearbook, Beijing Master Plan, Beijing Municipal Commission of Tourism Development, basic Geographic Information Network, Baidu Map, Dianping, Fantong, etc. [5]. Jiao Yao et al. obtained the business distribution of Guangzhou through Baidu map POI, and analyzed the relationship between urban land expansion, real estate expansion and commercial business space [6]. Yan Longxu obtained and distinguished the locations of catering shops and online shops under Shanghai's inner ring Road through open data such as Ele. me and Dianping, and summarized the distribution characteristics of the two [7]. Xia Lingjun et al. obtained the catering data of 355 cities in China through Dianping data and analyzed its distribution pattern, characteristics and influencing factors [8]. Wu Jianxun et al. obtained the location data of catering shops in Nanning through the open data of AmAP and analyzed the distribution and evolution of catering space [9].

Theoretically, Space Syntax theory holds that the topology of street network determines the state of motion distribution, while commercial functions are directly dependent on traffic flow [10]. For example, Shengqiang's team also found that the overall business distribution topology was obvious in many cases in Jilin and Beijing [11,12]. Through the correlation between the composition ratio of housing service facilities and syntactic parameters, Zhu Xuhuan obtained the business formation and layout rules of typical residential areas where commerce meets residents' needs [13]. In addition, the distribution law of a certain type of business is studied. For example, Tao Wei et al. explored the spatial layout law of the hotel industry from three perspectives, including the urban road network form [14]. Most studies on fresh supermarkets focus on the sales model or distribution law of certain fresh supermarkets. For example, Wang Lei et al. found the effectiveness of the hybrid innovative sales model through the case analysis of Metro Fresh supermarket [15]. As well as Wang Yun's analysis of the distribution of S fresh supermarket, the optimal site selection scheme was obtained [16]. Xiang Persisted et al. obtained the influencing factors by constructing the structural model of customer satisfaction of Hema Fresh Food [17]. On the whole, there are few researches on the distribution law of fresh supermarket at the block level by using Space Syntax.

In the study on the impact of the epidemic on industrial distribution, before the epidemic, domestic and foreign studies were carried out on the impact of various epidemics and treatment measures on the economy, including the impact of the epidemic on the market economy [18, 19] and the impact on the hotel and catering industries [20]. In the existing studies related to COVID-19, most scholars believe that COVID-19 has caused a serious negative impact on China's macro economy, but also triggered structural changes in the industry [21]. In the recent studies, Wang Yangjie et al. also proposed that the epidemic will promote the development of industry digitalization [22, 23]. In terms of the development of fresh e-commerce, the impact of product supply, logistics distribution and other aspects has been mostly analyzed [24, 25], while there are few studies on the actual distribution of business formats after the epidemic.

Based on the above background, this study, based on open network data, applied Space Syntax to study the distribution and evolution rules of fresh supermarkets in three regions of Beijing during the epidemic period, and tried to analyze the change rules and influencing factors of fresh supermarkets under the influence of the epidemic.

2. Research Data And Methods

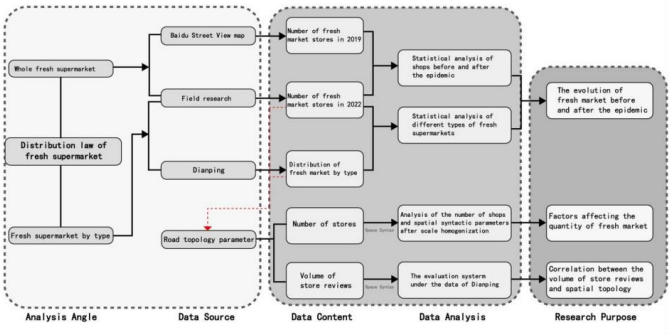
2.1 Research Object And Technical Route

The fresh market in three regions of Beijing is selected as the research object in the research area (FIG. 1). After comparing and screening the surrounding environment, road network characteristics, permanent population and other data, three similar plots located in Haidian District, Fengtai District and Chaoyang District of Beijing are finally selected. Since the constituency does not cover the whole district, the plots within the research scope are named A, B and C respectively.

Figures 1. Study area diagram

The data of fresh supermarket in three regions are studied in multiple dimensions, which can be divided into two perspectives: the whole fresh supermarket and the sub-type fresh supermarket. For the overall analysis of fresh supermarkets, Baidu map and Baidu Street View map data were used to obtain the number and location of fresh supermarkets in 2019 and 2023. The changes in the number

and distribution of fresh supermarkets before and after the epidemic were obtained through statistical analysis and Space Syntax analysis, and the correlation between their distribution and surrounding influencing factors was also analyzed. The factors affecting the quantity of fresh market are analyzed. According to the information of stores on Dianping and Meituan, the fresh supermarket is divided into offline stores and online stores. Through the regression relationship of Dianping data and Space Syntax parameters, the difference between the distribution of the fresh supermarket in store mode and the fresh supermarket in store plus distribution is analyzed.



Figures 2 Technology roadmap

2.2 Data Processing Method And Model Independent Variable Selection

2.3.1 Analysis Of Changes In The Quantity Of Fresh Market

The subjects were selected as markets, supermarkets, vegetable shops and other stores that provide daily food. In the analysis of changes in the fresh market in 2019 and 2023, the market in 2019 was obtained by the street view pictures provided by the Baidu Map time machine, and the market in 2023 was obtained by the POI capture and proofread combined with field research (Figure 4). In the comparison of the period before and after the epidemic, the changes in the overall number of fresh market were divided into three conditions: new (no stores in 2019, no stores in 2023), stable (no stores in 2019, no stores in 2023), and disappeared (no stores in 2019, no stores in 2023).

2.3.2 Selection Of Influencing Factors Of Fresh Market Distribution

The Integration of Space Syntax refers to the shortest topological distance between a certain street segment and all other street segments within a certain geometric distance, which measures the spatial potential of reaching a certain street. Choice is the number of times a certain street segment is crossed by the shortest topological path of any two other streets within a certain geometric distance, which measures the spatial potential of crossing the street [1]. On the basis of these two indicators, Bill Hillier et al proposed standardized Angle selection (NACH) and standardized Angle integration (NAIN), aiming to further eliminate the influence of the number of line segments on the analysis, so as to realize the comparison of spatial systems with different scales and complexity. On the basis of the four types of

parameters, five different distance radii representing walking, non-motor vehicle and motor vehicle were selected for analysis, namely 750m and 1000m for walkers, 2000m and 3000m for non-motor vehicles and 5000m for motor vehicles, and the syntactic parameters were analyzed respectively.

Fresh supermarkets are generally located near living areas, and their main consumers come from surrounding residents. Therefore, the number of residents in mobile signaling data is selected as the population influencing factor. For road factors, parameters such as degree of selection and degree of integration in Space Syntax are selected. At the street level, the number of shops is correlated with population and road through the homogenization process of street summing.

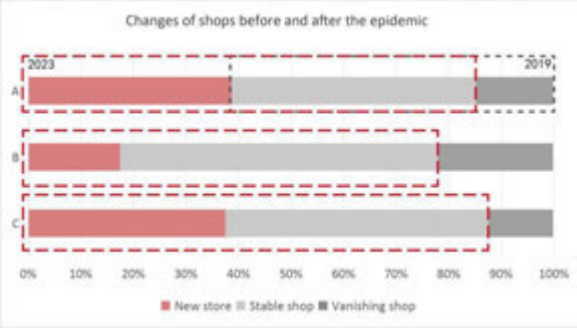
2.3.3 Classification Fresh Market Data Processing

The fresh market is divided into two types. According to the store information on Dianping and Meituan, the fresh supermarket is divided into offline stores that only rely on customers' offline purchase, and online stores with review and delivery services on Dianping, Meituan and other online stores.

3 Analysis Of Changes In Fresh Market

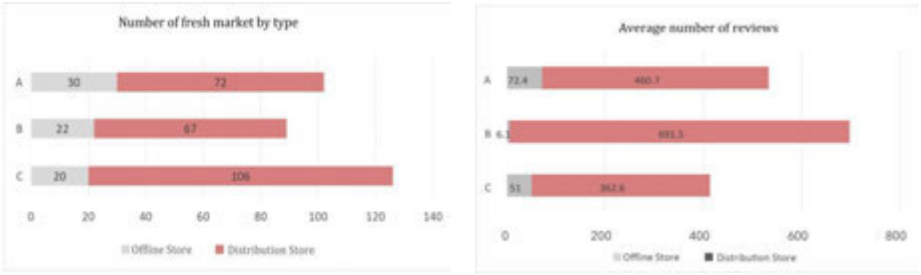
3.1 The Number And Online Presence Of Fresh Supermarkets Before And After The Epidemic

The distribution location of fresh supermarket in the region is obtained according to Baidu map (Figure 5), and the information of fresh supermarket is corrected through Baidu Street View map and POI data. Among the data in 2023, there were 132 effective fresh supermarkets in region A, 60 were added after the epidemic, 72 remained stable, and 23 disappeared. There are 126 effective fresh supermarkets in region B, 30 new after the epidemic, 104 stable, and 38 disappeared; There are 115 effective fresh supermarkets in area C, 54 new after the epidemic, 72 stable, and 18 disappeared.



Figures 3 Changes in the quantity of fresh market

Through Dianping and Meituan Distribution, fresh supermarkets in the region are further classified into online and offline types. Among them, online market refers to stores with a large number of comments on the cable. Citizens can obtain their location from Dianping software and understand the comment information such as product quality and service, and have distribution services. The offline market requires citizens to buy offline, and some markets have review services, but they do not have delivery services.



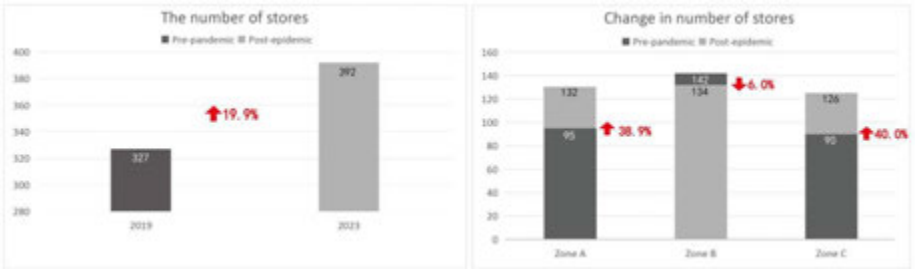
Figures 4 Number of stores in the three regions (left) and number of comments by type (right)

According to the proportion, the number of two types of supermarkets in the three regions is similar. When analyzing the volume of reviews, the volume of reviews of online stores is much higher than that of offline stores. In the comparison of the number of comments in the three regions, the average number of comments in the B region is much higher than that in the AC region, which further indicates that under the influence of the overall business atmosphere in the Chaoyang region, the fresh supermarkets in the region show strong information characteristics.

In the analysis of stores by type and the average number of reviews, the stores with delivery service in the three regions all showed a higher number of reviews. Based on the comparison of the comment rate and the average number of comments, relatively speaking, region B has a relatively concentrated online fresh market, and the online market has a considerable number of consumer audiences. The proportion of online stores in AC region is less, and consumer groups tend to choose offline purchases.

3.2 Changes In The Number And Distribution Of Fresh Supermarkets Before And After The Epidemic

Based on the overall number of fresh markets in the three regions and the online situation, the change of the number and the average distance between stores before and after the epidemic were analyzed.



Figures 5 Changes in the quantity of fresh market before and after the epidemic

For the whole study area, the number of fresh supermarkets increased significantly after the epidemic. For the fresh market in each region, the number of fresh market in AC region increased significantly, while the number in B region decreased slightly. For the average store spacing, the average store spacing in AC region decreased during the epidemic period, while it increased slightly in B region.

Figures 6 Changes in average store spacing

Under the influence of the epidemic, the quantity distribution of the fresh market has changed, and the overall trend is growing. At the same time, its distribution position also changed. This paper used Space Syntax software to position the market before and after the epidemic, and calculated its walking accessibility and vehicle accessibility respectively. The accessibility changes within the whole region were compared with the accessibility changes in each sub-region, so as to judge the distribution trend.

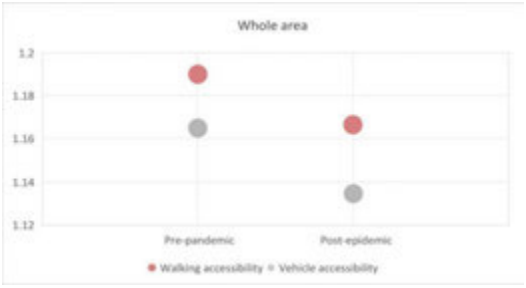


Figure 7 Changes in accessibility before and after the epidemic

Figures 8 Total number of reviews of stores in the three regions (left) and average number of reviews by type (right)

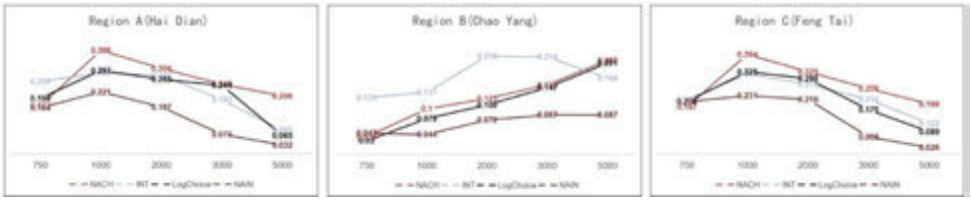
According to the analysis of the above figure, the walking accessibility and motor vehicle accessibility of the fresh market both show a downward trend; In the comparison of the three regions, the accessibility of shops in the three regions decreased, but to different degrees. The distribution accessibility of region B was lower than that of AC, but the accessibility changed little under the influence of the epidemic, and even the accessibility of motor vehicles was slightly improved.

The results showed that the total number of fresh market increased when people reduced long-distance shopping after the epidemic. But the impact varies in different regions. The obvious increase in the number of markets in AC region reflects the further increase in the demand for fresh markets under the epidemic situation. However, judging from the stable or even reduced number of stores in B region, the growth of the fresh market is limited to a certain extent. The average distance between stores in the three regions is also related to the quantity change, and the distribution radius of AC fresh market is further reduced, and finally reaches the same as that of region B. At the same time, this change may also be related to the degree of regional market online, the high-line B region showed stronger stability during the epidemic, while the AC region with a lower degree of network distribution service had a greater impact. In addition, under the impact of the epidemic, the distribution of shops has further reduced the requirements for road accessibility, and shops located in hard-to-reach back streets and alleys have become relatively more "safe" shopping choices.

4 Factors Affecting The Distribution Of Fresh Market

4.1 Distribution Law Of Fresh Market Quantity After Epidemic

The distribution of the fresh market is often related to road accessibility. When Space Syntax parameters are applied to analyze the distribution of the number of shops and the number of comments, in order to eliminate the interference of accidental factors in the space and reduce the numerical differences of adjacent space units, the number of shops within a 500M radius along the street is added up, and the parameters of integration degree and selection degree in Space Syntax are selected. Then the correlation analysis is made with the syntactic parameters in five different radii.



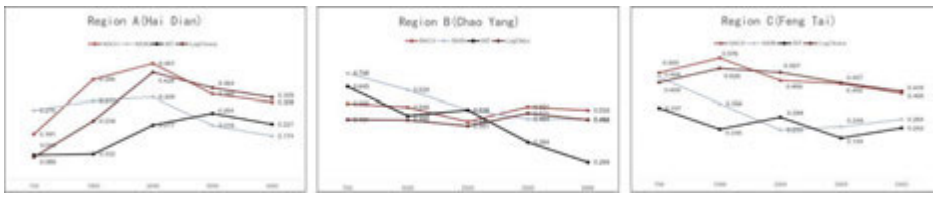
Figures. 9. Three-region regression analysis in 2023

In the analysis of the correlation between the number of fresh supermarkets and the urban topological structure, AC region has the highest correlation with the traversability parameter of 1000m radius, which indicates that supermarkets are greatly affected by the accessibility potential, and the number of supermarkets is significantly affected by the walking flow. However, the correlation between the number of fresh supermarkets and the pedestrian flow in area B is not strong, and the highest correlation is the travel degree parameter of the radius of 5000 meters. This phenomenon may be caused by the influence of the concentration of business districts in Chaoyang District, which makes the fresh supermarkets in this area have more characteristics of urban commerce.

Overall, when there is a high correlation between the number of fresh markets and road influencing factors, walking flow is often the decisive factor. In the case of the same radius, the traversal parameter correlation tends to have a higher correlation, which proves that the fresh market tends to be distributed on streets that are easier to cross. They tend to be on streets that are easier to cross.

4.2 Distribution Law Of Online Fresh Market

Since the online degree of shops in the three regions is different, the number of shop comments is taken as the research object to further explore the relationship between online shop sales and road topology.



Figures. 10 Correlation between review volume and accessibility in the three regions

On the whole, the number of shop reviews in region A is highly correlated with the selectivity parameter, indicating that shops distributed on roads with high travel are more likely to be patronized by customers. The peak values of integration parameters are all at R2000m, indicating that their distribution is more susceptible to the influence of non-motor vehicle flow. The number of shop comments in area B is highly correlated with the parameters of the integration degree system, indicating that shops are greatly affected by the accessibility potential, and the peaks of the integration degree parameters are all at R750m, indicating that their distribution is more susceptible to the influence of walking traffic. The number of shop comments in area C is highly correlated with the selectivity parameter, indicating that shops are greatly affected by the degree of travel, while the peaks of the integration parameter are all at R1000m, indicating that their distribution is more susceptible to the influence of walking traffic.

According to the parameter analysis of the three regions with the highest correlation, the stores in AC region are more inclined to be distributed in the area with high intensity of pedestrian traffic, while the stores in B region are distributed in the area with high degree of road aggregation. Among them, the regularity of store distribution in area B is relatively weak, which may be related to the high degree of online. The correlation between the number of fresh markets and the number of reviews and the urban topological structure is confirmed, while in the area with the gradual improvement of online development, the store location is to a certain extent free from the influence of geographical factors, which is also verified in area B.

5 Conclusion and discussion

The results showed that: in terms of the overall fresh market, the epidemic increased the number of fresh supermarkets and further reduced the service radius, and the service radius after the epidemic was about 350M. At the same time, the accessibility of store distribution was reduced, and stores located on remote roads were more easily selected by customers. In the comparison between regions, the regions with a relatively high proportion of online stores were less affected, and the number of stores in the region did not change significantly before and after the epidemic, and the business format was more resilient, while the number of fresh supermarkets in the regions with a low proportion of online stores increased significantly after the epidemic.

In the analysis of market and road accessibility after the epidemic, the regions with more online markets are correlated with the degree of road integration, and the market is concentrated in the regions with more dense roads, while the regional market distribution with more offline markets is correlated with the degree of road travel, and is more dependent on the intensity of road traffic flow. The number of shops in the two types of areas is greatly affected by the demand for short-distance travel. In the comparison of the correlation between the number of online fresh market reviews and accessibility, the stores with higher review volume were distributed in the sections with better accessibility and were more affected by geographical factors.

Therefore, the epidemic may have the following impacts on the distribution of fresh markets: In terms of the quantity change and distribution law, the number of fresh markets increased, and the relative distance between markets decreased, which proved that the demand for fresh products by surrounding residents further increased, and they were more inclined to reach the purchase demand in a small range. After the epidemic, the geographical location of the newly added markets tended to be far away from the area where people and vehicles gathered. The distribution characteristics of different regions showed similar accessibility in small-radius road distribution, which indicated that the construction purpose of fresh market was similar to that of nearby communities and easy to walk during the epidemic period. In terms of online service and distribution service stores, because online delivery service can ignore the impact of the actual geographical factors of the market on consumers, the fresh market is less affected under the epidemic situation, and the number of regional stores with a high degree of online service can provide distribution services changes less. However, in areas with insufficient online access, people often choose to buy consumer goods in nearby fresh markets under the impact of the epidemic, and the demand for smaller markets increases, resulting in an increase in the number of fresh markets. In short, under the impact of the epidemic, more accessible store locations and contactless delivery services have been stronger development, and therefore affect the distribution pattern of these fresh stores in the region.

Repurposing abandoned transport infrastructure towards social inclusion: The case of Baana, Helsinki

Christine Mady
Aalto University, Department of Architecture
christine.mady@aalto.fi
https://orcid.org/0000-0003-2808-8705

Abstract

With globally increasing challenges for the role of public spaces and their contribution to inclusion and justice within urban settings, this article examines the repurposing of transport infrastructure to provide dedicated walking and cycling public spaces, specifically the case of Baana in Helsinki, Finland, a former freight railway conduit. Building on the concepts of mobility design and walking as a social experience, the article examines Baana's role both as a non-motorised transit space, and one supporting fluid encounters among diverse users. The impact of Baana's design is examined – in terms of utility, attractiveness, and symbolism – on pedestrians' activities, experiences, and perceptions. Initial findings reveal Baana's barriers and potentials and serve to develop further research on addressing differential pedestrian experiences, to inform future mobility design processes.

Keywords: Baana, fluid encounters, Helsinki, inclusion, mobility design

Repurposing abandoned transport infrastructure towards social inclusion: The case of Baana, Helsinki

1. Introduction

Concerns with the environment have triggered interest in non-motorised mobility, with a focus on its utilitarian performance within transport planning (Maciorowski and Souza, 2018). Yet, non-motorised mobility affects liveability, including aspects of justice and inclusion. Cities have resorted to different approaches to promote walking and cycling, sometimes through repurposing transport infrastructure as in New York's Highline project (Davis and Gray, 2019; Lang and Rothenberg, 2017; Millington, 2015), or redesigning public spaces, including streets, which was prominent following the COVID-19 pandemic (Mukhtar et al., 2024). Understanding the relation between non-motorised mobility environments and social aspects requires an investigation beyond exploring the physical environment that addresses the utilitarian, physical act of commuting, towards considering influences of and on social practices and experiences during mobility (Sheller and Urry, 2006). Building on concepts of walking as a social practice, and mobility design, this article presents an understanding of design for walking, while considering the value of walking beyond the necessary or optional commuting activity. This research could inform planning for 'walking-friendly cities' often characterised by the environment supporting social inclusion, health, and economic benefits, and walking's potential role in generating inclusive individual experiences and social encounters (Middleton, 2018, p. 299).

Literature on mobility design identified several research gaps, one being the lack of combined analysis of functional, aesthetic, and symbolic aspects of urban environments and their impact on mobility at micro-scales (Blitz and Lanzendorf, 2020; Mehta and Bosson, 2021). This article provides such an analysis at the micro-scale for one case study through a mixed-methods methodology. The case study focuses on the initial segment of Baana in Helsinki, a network for cycling and walking, which transformed a former railway corridor for non-motorised mobility. This article presents the initial phase of a broader research on Baana, and addresses the following questions: What design elements, aesthetics, and symbolic aspects in Baana promote walking beyond the necessary activity? How is Baana perceived while walking?

2. Framing walking in lived public space beyond a transit activity

Walking is simultaneously a human right and a social practice, which enables different types of interactions based on the pedestrian's positionality (Creswell, 2009; Kanellopoulou, 2017; Scarponi et al., 2023). Walking is the oldest and least environmentally impactful mode of mobility, yet within transport planning it is often considered as secondary compared to other modes, and is reduced to a necessary linear, transit, commuting function, which occurs on the street or while traversing other public spaces. The utilitarian perspective has been questioned with the mobility turn, to emphasise walking's several 'types, forms, and characteristics' including the experiential, perceptual and social (Gehl, 2011; Middleton, 2018, p. 299; Sheller and Urry, 2006).

While walking, urban spaces unfold sequentially, affect the pedestrian, and change the experience of a place depending on pedestrians' flows and practices (Kanellopoulou, 2017; Lehtovuori, 2012). Walking is differential and relational; it varies depending on the combination of the environment comprising actors and objects simultaneously present, with a grafting of perceptions, meanings, memories, and experiences onto the space (Koohsari, Karakiewicz, and Kaczynski, 2013). The relational perspective is tied to Lefebvre's (1991) production of space explained as the interaction of planned and designed physical space, symbolism and users' social practices that affect space.

Walking is a multisensory activity that allows the pedestrian to reinterpret or even reconfigure them or interact with the city. The aesthetics and symbols generated within the environment, objects and 'human and nonhuman agents' interacting with the pedestrian, walking as a multisensory experience allows the pedestrian first to interpret stimuli – both material and immaterial such as signs, or mnemonic triggers – and second to attribute meanings to urban locations – including those related to safety, and inclusion (De Certeau, 1984; Hebbert, 2005; Kanellopoulou's, 2017, p. 188; Middleton, 2018; Mehta and Bosson, 2023; Sheller and Urry, 2006, p. 214).

The sociality of urban walking explores the actors involved, the type of involvement (how or why) and the consequences of this interaction. Depending on socio-cultural factors, encounters while walking could generate different verbal and non-verbal social interaction to various degrees, or even exclude users (Blokland, 2017; Middleton, 2018). Walking 'provides opportunities for social interaction' that could be direct or indirect, serendipitous 'fluid encounters' occurring once, or more enduring 'public familiarity', with others including maintenance staff, or law enforcement personnel, unhoused persons, youth, elderly and so on (Blokland, 2017, p. 553, 561; Kanellopoulou, 2017, p. 188; Sheller and Urry, 2006). Public familiarity refers to recognising strangers through recurrence or shared social practices, and actively or passively communicating among individuals based on tacit knowledge and unspoken norms (Blokland, 2017; Middleton, 2018, p. 308; Scarponi et al., 2023). Walking as a social practice varies in purpose and type, and entails improvisation, 'tactical learning' and adapting to different spatio-temporal rhythms while walking (Blokaland, 2017). Examples of interactions range from encounters while walking a dog, strolling, pushing a buggy, jogging, taking a shortcut, or 'emergent issues' such as an object, animal or person traversing one's path (Koohsari, Karakiewicz, and Kaczynski, 2013; Mehta and Bosson, 2021; Middleton, 2018, p. 305; Scarponi et al., 2023). It is the diverse types of sociality at the micro-scale that leads to negotiation, contestation, degrees of inclusion in public spaces, or the right to determine one's position as a pedestrian in urban spaces (Blokland, 2017; Middleton, 2018). While walking, sociability, and encounter 'are central components of urban public space' and become a resource for ensuring inclusion (Blokland, 2017, p. 560). The seemingly arbitrary encounters along the spectrum from the incidental to the sustained are often tied to spatio-temporal rhythms (recurrences at specific locations), which could be facilitated by mobility design. It is this simultaneous experience of individualism or being part of a crowd, which affect social interaction that urban spaces enable, (Blokland, 2017). While designing for walking, all types of encounters should be considered to understand and address the potentials and risks of 'subtle

forms of exclusion and the resulting reinforcement of structural inequalities' (Blokland, 2017, p. 554). This is where the investigation of aesthetics and symbolism of walking environments that could have exclusionary or inclusionary roles, is important.

Therefore, a micro-scale analysis is needed to understand the multisensory, dynamic walking experience – which is based on synergies rather than isolated elements – to ensure that designing for walking encourages social encounters essential for inclusive urban experiences (Middleton, 2018, p. 301; Scarponi et al., 2023; Spinney et al., 2015).

3 Designing for walking

Non-motorised mobility design covers various aspects of the built environment, starting with environmental considerations based on promoting a modal shift to impact travel behaviour away from the automobile, rather than promoting health and wellbeing (Blitz and Lanzendorf, 2020; Cook et al., 2022; Lozzi and Monachino, 2021; Mehta and Bosson, 2021). Planning for integrated, well connected, and continuous pedestrian flows, which are safe vis-à-vis vehicular traffic, are among the factors considered to encourage panoply of activities by diverse users (Blitz and Lanzendorf, 2020; Maciorowski, and Souza, 2018). The focus is often on ensuring travel safety while paying little attention to walking as a social activity, reducing it to a mode among other, which could be excluded in some urban environments (Maciorowski, and Souza, 2018). On streets, priority is given to automobility flows, while pedestrians wait for green signals along traffic-control barriers, which raises concerns about spatial justice, affects the experience and social practice of walking (Cohen and Almarwani, 2022; Kanellopoulou, 2017).

Cervero and Kockelman's (1997) seminal work on non-motorised mobility design refers to the impact of density of users, diversity of land use and building configuration, and design of the street network, with less emphasis on the aesthetic and symbolic, for instance how benches, lighting or vegetation affect walkability. Other considerations have been added such as accessibility and travel distances (Ewing and Cervero, 2010). Equally, considerations of pedestrians' needs, attitudes, perceptions, and experiences, relate to design's functional, aesthetic, and symbolic aspects of mobility spaces. Blitz and Lanzendorf (2020, p. 1) explain these three interrelated aspects as: the utilitarian dimension offering the possibility to commute on foot; attractive environments that trigger appreciation to walk through; and the 'semantic content' and signs that support pedestrian's construction of meanings attached to these environments. These aspects recall literature on liveable streets, which offer sufficient support from the surroundings for diverse activities that encourage spontaneous interaction among strangers (Sauter and Huettenmoser, 2008). This space-object relation together with the users' experiences, generates meanings, creates affordances that could contribute to pedestrians shaping or redefining the space with opportunities for social interaction (Mehta and Bosson, 2021). Lively streets require collaborative design processes for permeability, interaction with street frontages, designating areas for non-motorised mobility, and considerations for integrating various amenities including vegetation, and 'community-gathering places' (Al Mushayt et al., 2021; Mehta and Bosson, 2021: p. 160). In relation to the three aspects, material and immaterial obstacles could discourage walking and reduce social interaction.

On the functional level, planning and design implicitly outline power relations among urban modes of mobility, defining when, where and what pedestrians can do (Middleton, 2018). Obstacles to walking could relate to speed, ability to stay stationery, waiting at intersections, and issues of safety in shared mobility spaces, where different mobility modes negotiate priority, with limitations for the visually or hearing impaired as an example (Curl, Ward-Thompson and Aspinall, 2015; Middlteon, 2018). Aesthetically, spaces for walking should be designed as physically attractive and positively stimulating the senses through colours, materials, sounds, light, vegetation, amenities, comfort from weather conditions, providing vistas, and maintenance, which have an impact on mental wellbeing and perceptions of safety (Blitz and Lanzendorf, 2020; Koohsari et al., 2012; Scarponi et al., 2023). Symbolically, the provided information with direct or indirect signifiers could register different interpretations for the pedestrian, which are socio-culturally embedded. This includes signage, advertisements, presence of specific amenities, art, the design of the space and the objects in it, which could signify safety, who and how to use them – based on age, gender, or other user traits – and whether interaction within and with them is possible (for example changing surface material to designate walking or cycling, edges that provide affordance and so on).

Further attention should be given to safety as it is influenced by functional, aesthetic, and symbolic aspects, especially if different user groups are considered (Scarponi et al., 2023). The term safety refers to harm from vehicles or cyclists (clearly delineated paths or separate paths – addressed by transport planning), harm from the physical space (egress points, visibility, lighting, provision of amenities – addressed by designers) or harm from other people (addressed by security and governance). Safety varies temporally according to the pedestrian's positionality (considering the complexity of safety perceptions that are embedded in the pedestrian's individual past experiences and influenced by socio-cultural factors).

In summary, mobility design contributes to the design of public spaces at the intersection of transportation and urban planning and at the scales of urban design, landscape design, and architecture. The output should address the individual who makes decisions whether, when, and where to walk. Spaces designed for mobility become the communication medium between the city and the pedestrian, determining walking duration, and types. Spaces designed for walking should be functional, attractive, comfortable, safe, and enable social encounters (Scarponi et al., 2023).

4. Methodology

To identify opportunities and obstacles for social encounters and inform future considerations towards increasing the role of walking in social inclusion, a micro-scale approach enables juxtaposing planning and design aspects of the public space with walking experiences. The relations between utilitarian walking and walking as a social, multisensory practice are analysed in relation to Baana's planning and design.

Several methods are used to respond to the two research questions (Table 1). Mapping using existing City of Helsinki maps served to position Baana contextually in relation to the street network. In addition to information available on the city's website, three interviews with

planners and one designer from Helsinki City served to inform considerations for walking and pedestrians related to the research questions. A walk-along observation method akin to 'mobile ethnography' was conducted to locate while walking aspects related to comfort, attractiveness, and safety. This method allowed for describing the multisensory experience along the unfolding of the path while walking (Kanellopoulou, 2017; Middleton, 2018; Sheller and Urry, 2006: p. 217-218). Participant observation in the form of 'copresent immersion' for one year by walking along Baana served to directly observe copresence and types of interactions, while 'time-space diaries', and taking photographs were used in both observation methods (Middleton, 2018; Sheller and Urry, 2006: p. 218).

Table 1: Methodological overview

Method	Input	Output
Mapping	. Helsinki City maps (City of Helsinki 3) . Kartta Helsinki maps (City of Helsinki Map Service 4) . Openstreet maps . Helsinki transport HSL (Helsinki Regional Transport Authority) . Helsinki Region Infoshare . Google Earth	- Sub-districts - Roads and urban blocks - Main landmarks - Traffic intersections - Public transport stops - City bicycle seasonal locations - Baana initial segment
Interviews	Helsinki City planning department: . Interview 1 with transport planner 19 January 2024 . Interview 2 with non-motorised mobility planner 26 March 2024 . Interview 3 with architect, urban design 25 April 2024	-Inclusion and justice -Connectivity and networking of Baana -Considerations while designing for pedestrians -User feedback -Design considerations for the southern part of Baana
Walk-along observation	. Epicollect5 mobile application with questionnaire conducted on 30 March 2024 . QGIS	-Photographs and sound recordings (traffic, birds, other) at 94 spot locations with short notes -Map of spot observations on: . pleasant the spot is (scale 1 to 3, very, neutral, unpleasant) . safety perception (scale 1 to 3 very safe, unsure unsafe) . windy or sheltered (scale 1 to 2) . sunny or shaded (scale 1 to 2)
Participant observation	Mobile phone camera and voice recorder Visits between May 2023 and May 2024	Walking all along the segment and registering recording: -Seasonal changes -Construction-related changes -Users -Activities, events -Posts on bins and utility boxes -Materials

		-Signage -Art -Urban furniture -Vegetation -Types of walls

5. The Baana

The segment researched in this article is the former seven-metre-deep freight railway corridor that was constructed in 1894 and divided the city despite the seven bridges across it. This corridor stopped working in 2008 when the cargo port was relocated and the western harbour was transformed to a residential area, which required establishing connectivity with the city centre (Bravo, 2022). Following participatory planning, with residents and university students, and a competition for the transformation of this conduit, the Baana transformation was completed in 2012. The design maintained the industrial memory of Baana, first with the name referring to the railway, 'the series of landscaped and garden areas full of suggestive railway motifs', maintaining the existing wild vegetation and adding 'flowering creepers, several varieties of tall grass, and different types of bushes with perennial foliage to give an individual touch to each section of the cutting', keeping the original colours, materials and structures – including the seven bridges, while adding stairs to increase permeability along Baana – except for the sports zone, which alluded to the colourful containers once transported on the freight trains. The sports facilities include a basketball court, table tennis and pétanque pitches (Morethangreen, n.d.). Baana is described as 'austere, versatile and resistant project of recycling the railway track … so enthusiastically received by very different kinds of users.' In 2014, Baana received a special mention in the European Public Space prize for the collaboration and repurposing of obsolete infrastructure for non-motorised mobility, reducing the barrier effect and reconnecting the city with a non-commercial public space for 'recreation, sports and art' (David, 2022; Good News Finland, 2014; Nordregio, 2018). The provided amenities from sports to green spaces and 'picnic tables' converted Baana to 'an urban living room' (Nordregio, 2018). Moreover, Baana's success sparked the city authorities to consider implementing a non-motorised network starting from the centre, a project that has also inspired other countries (Nordregio, 2018). The initial 1.3-kilometre Baana stretch replacing the abandoned railway, became a concept for cycling highways as part of Helsinki City's vision to promote sustainable mobility and complete 150 kilometres of cycling paths (see City of Helsinki 3). (Figures 1).

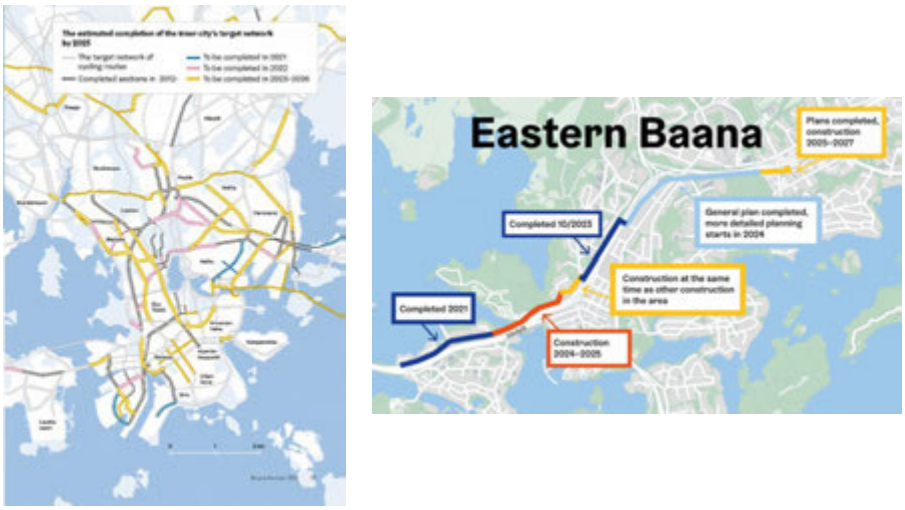

Figure 1: The cycling network and the Baana alignment (source: City of Helsinki 1, 2)

6. Analysis of findings

The analysis first positions Baana contextually, analyses it through functional, aesthetics, and symbolic design aspects. Next these findings are juxtaposed with findings from walking as a dynamic, multisensory social experience, to reveal levels of social interactions, and how Baana encourages or deters them.

Within the Helsinki City district, Baana is orientated north-east to southwest, which in this analysis is referred to as 'north' and 'south'. To the north, Baana starts at the cultural hub with the largest linear park in Helsinki, surrounded by the parliament and its extension, Oodi central library, the Music Hall, and Kiasma museum. The hub is in proximity to the central railway station, other museums, and cultural buildings. To the south, the Ruoholahti (west harbour) is a mixed-use area, predominantly residential, with offices, commercial, educational, and cultural activities. Between Baana's two ends, there are ten sub-districts, with different character areas, including mixed building uses with diverse architectural characters (Figure 2). Public transport stops are located along Baana with tramway routes at both ends, bus lines along the parallel and traversing roads. The nearest bus and metro station is east at Kamppi. Seasonally, there are four city bicycle points along Baana, one at the south end, and several in its vicinity. To the south, the tramway passes through a shared space with vehicles, bicycles, and pedestrians.

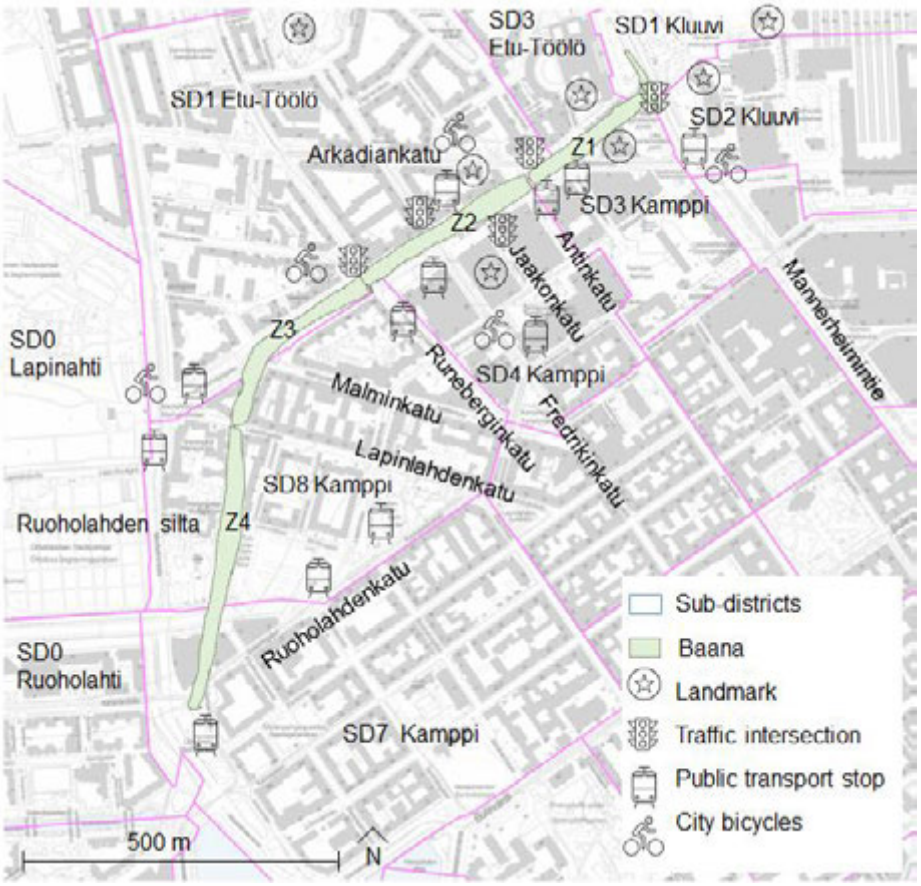

Figure 2: The Baana in between Oodi north-east and Ruoholahti south-west (Source: by author and basemap from City of Helsinki Map Services)

The decision to transform Baana aligns with Helsinki's city planning principles for 'social security, feeling of safety and attractive urban spaces, and provision of a cycling network.' (Interview 1) However, walking is still considered as a mode of transport, whereby one planner emphasised on 'understanding the term 'pedestrian' in relation to 'mobility and to streets and crossing' (Interview 1). The other planner stressed 'that everybody can walk and should walk more, and the goal is to provide safer, liveable streets and choices for the modes of transport on an everyday life basis.' (Interview 2) Both planners indicated 'the focus is on street liveability, creating places and connections to encourage short-distance walking and pedestrian routes' (Interview 2), and 'an 'environmentally friendly space that provides people with a vibrant and liveable atmosphere.' (Interview 1) Both indicated that inclusion is another principle applied to public spaces in Helsinki, yet inclusion was interpreted as facilitating the safe mobility of users with special needs – wheelchairs and visual impairment – that is supported through ramps, and cobbled stone to divide cycling and pedestrian lanes (Interview 2). When asked about gender

and age categories, ‘gender is not that much considered in the design, though the space can be experienced differently based on gender, so lighting matters in this case, and has been considered in the design; also the presence of street art and other activities (basketball) to invite other users, not only as a transit space.’ (Interview 2) When asked about seasonal conditions, one planner indicated that ‘salt and brushing’ method is used for melting ice rather than spreading gravel as in other streets (Interview 2). However, this applies to the cycling rather than the pedestrian lane as noted during the observations (Figure 3).

Figure 3: clearing ice from cycling but not pedestrian lane (Source: by author 13 January 2024)

Both planners indicated design considerations and limitations in Baana’s transformation, initially designed as a public space, with cycling being integrated later. ‘Baana was originally more a public space, inclusive for people of all age and abilities, which should apply to all city streets, so the plinth and edges needed to be reconsidered, to enable social activities’ (Interview 1). The importance of establishing connections with the surroundings and other public spaces was stressed: ‘the surroundings are very important rather than straight direct lines, as a long-distance pedestrian attraction’ (Interview 2). Baana also connects to the park in front of the parliament extension, the square in front of Oodi, the shared space at the Ruoholahti, and currently the newly planned Maria area (Interview 2). Another limitation is the corridor width ‘causing bicycle congestion and spillover to the pedestrian path as user numbers increase’, while it widens near Oodi due to space availability (Interview 1). Also, the lack of optimisation of the ‘drainage and other spaces’ was noted (Interview 2). A third concern at Ruoholahti is the

shared space design where ‘cyclists find it difficult to see where other people are walking, but for pedestrians it is easy to choose routes as it is an open ground.’ (Interview 2) In presenting these limitations, the planners did not mention shortcomings from the pedestrian perspective.

The planners indicated some concerns coming from the public, ‘Baana is considered a symbol and landmark of bicycle and walking infrastructure in Helsinki, especially in social media. Yet, a loud minority call it a waste of space or a waste tube.’ (Interview 1) No further explanation was provided regarding the criticism. Nevertheless, this segment ‘initiated the network idea’ (Interview 2), which would be applied throughout the city: ‘We want to turn interactive inclusive public space into a norm and not a highlight for people on foot, for activities, on street or on-site businesses.’ (Interview 1)

City level improvement of public spaces and non-motorised mobility network expansion directly impact Baana, which is part of this system. At the northern end, the ongoing renovation works along Mannerheimintie (City of Helsinki, 3) have temporarily disrupted Baana’s direct extension to the north-eastern public spaces (Figure 4).

Figure 4: Mannerheimentie street upgrading and impact on Baana’s northern end (source: by author 15 April 2024, 31 August 2023)

At the southern end, the upgrading of the Maria area is affecting Baana, though the cycling and pedestrian paths are not interrupted as in the northern end (Figure 5). The official city website states that the renovated southern part will shift the cycling path eastward to make space for a new ramp; relocate the ‘Helsinki’ art bench and basketball court; replace the pétanque with vegetation; renovate the benches and planted area and plant more trees (Helsinki City3, 22 March 2024). Further explanation of the project’s impact on Baana was obtained from the third interview.

The city’s concern was to connect the currently disconnected Maria area once upgraded. Therefore, changes at Baana were consequences rather than goals. Critical voices came from the public, particularly those in Baana’s vicinity. Concerns included the safety of children with the new bridge, shading Baana from the new taller buildings in the Maria area. The city authorities responded by conducting a traffic impact study with safety measures, with the design ‘mostly concentrated on the school children and their safety’ indicating that Baana’s ‘quality

remains the same, more greenery and trees and planted areas, most important functional spaces are kept but in different places.' (Interview 3) Also, the graffiti removed due to the new bridge construction will be replaced by new art (Interview 3). When asked about designing for pedestrians and their inclusion in this project, the designer indicated that there were 'no pedestrian counts, … Pedestrians were not considered as much as the bikers, though in the south there are the functional areas for people walking.' (Interview 3) (Figure 6).

Figure 5: Maria area upgrading and impact on Baana's southern end (source: by author 18 April 2024)

Figure 6: southern Baana dismantled bench and graffiti to be replaced (Source: by author 18 April 2024)

Baana's mobility design

In the interviews with planners, one indicated: 'Baana is formed of segments that vary from purely functional to stay and gaming.' (Interview 1) The current 1.3 kilometres strip accommodates parallel cycling and pedestrian lanes that diverge in two locations due to the corridor's widening, creating four zones (Figure 1).

Starting from the north, **Zone 1** is centrally located crossing Mannerheimintie, connected with a shared ramp above, and tunnel underneath, which offers vistas to the cultural hub and connects to its open public space with ample seating. This zone connects with a pedestrian ramp and two concrete stairs to the adjacent park of the parliament extension, which is monitored by a CCTV. A third steel staircase is at Arkadiankatu. Zone 1 includes art but not seating, though there are some affordances along the planted terraces. Ardkadiankatu tunnel is deep with a wide unused shoulder and is poorly lit. The cycle and pedestrian paths are divided with paint until Arkadiankatu (Figures 7, 8).

Figure 7: Zone 1 functional, aesthetic and symbolic features (Source: by author)

Figure 8: Oodi seen from the tunnel and under Arkadiankatu (Source: by author 31 August 2023 and 5 March 2024)

Zone 2 continues until Runeberginkatu with Fredrikinkatu, Antinkatu and Jaakonkatu in between, and is less connected to the west side. Antinkatu has no vertical circulation. The stair at Jaakonkatu is directed to the north, while at Fredrikinkatu is directed south. Fredrikinkatu is a new concrete bridge with columns and a CCTV underneath. Jaakonkatu comprises two separate steel and wood bridges for cars and pedestrians. Under Jaakonkatu the wider east shoulder is unused. The west side in zone 2 has no lighting, piping crosses overhead near the bridges. Seating, amenities, and art are provided. The paths are divided with paint (Figures 9, 10).

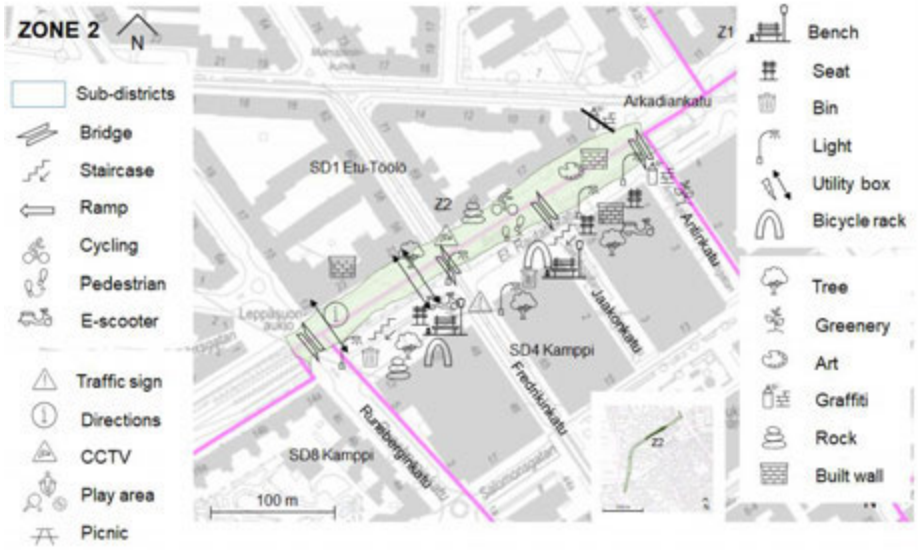

Figure 9: Zone 2 main features (Source: by author)

Figure 10: Top left: from Antinkatu looking towards Arkadiankatu; top right: from Fredrikinkatu towards Runeberginkatu; bottom left colonnade of Fredrikinkatu; bottom right pipes between the two bridges (Source: by author 30 March, 1 May 2024)

Zone 3 continues passing through the staircase at Malminkatu to Lapinlahdenkatu. It is the most visually permeable, connected to the east and west with stairs facing each other and directed towards Baana, and two ramps. The west ramp directed south joins the upper street, and the ground floor of the adjacent buildings. The east ramp is directed north at Runeberginkatu and leads to the Kamppi metro. Zone 3 lanes and ramps are divided with cobble stone for cyclists and pedestrians, yet there is a cross-circulation between cyclists and pedestrians traversing east and west (Figure 11).

Zone 3 offers diverse seating arrangements, and affordances along the planted areas on both sides. Though it has less art, it has direction signage to the nearest metro and Baana's surroundings. Between the new buildings adjacent to Baana and until Malminkatu, Baana narrows significantly, and cyclists then transgress onto the pedestrian lane if there are two and no pedestrians coming. Under Runeberginkatu with two graffiti, a pink bird house was added to the west wall, which has a wider unused shoulder that connects with the planted area. On the bicycle lane going north and just before Runeberginkatu is the only electronic panel, which is occasionally used. South just before Fredrikinkatu to the east there are two niches in the wall, with linear lights inside (Figure 12).

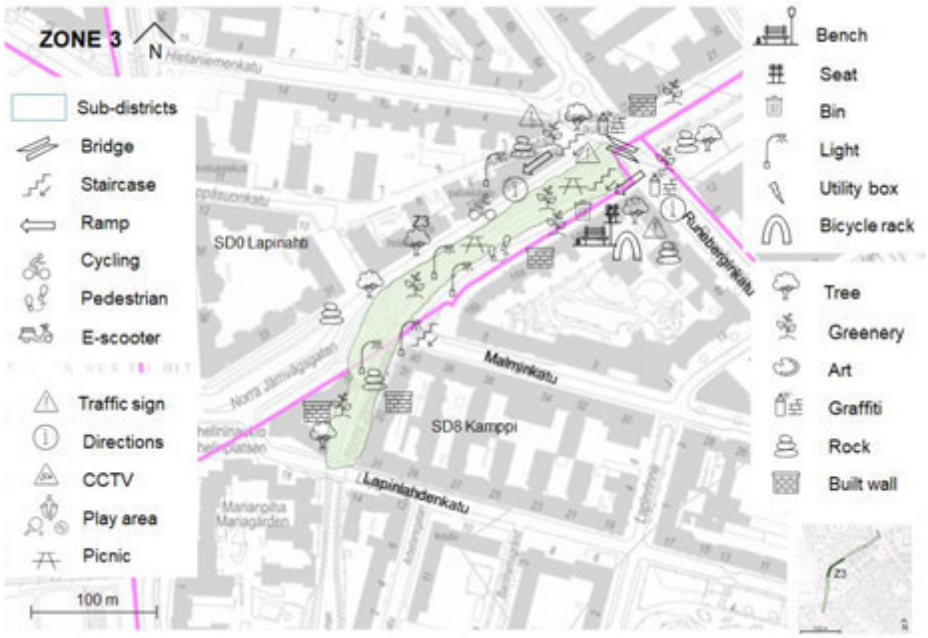

Figure 11: Zone 3 main features (Source: by author)

Figure 12: Top left stairs east and west; top right narrow part and contact with residential building; bottom left and right seating area in two seasons (Source: by author 27 April24 March, 6 January, and 17 April 2024)

Zone 4 passes by the ramp perpendicular to Lastenkodinkatu directed south, is traversed on top with the Ruoholahden silta bridge with an access stair facing Baana and ends with the shared space at Ruoholahdenkatu, thus forming two sub-zones (Figure 13).

Under Lapinlahdenkatu is the pigeon graffiti and round light. The paths divided with cobbled stone, are separated in the sports and recreation area. This area provides affordances especially on the eastern side, adjacent to the children's playground next to the ramp at Lastenkodinkatu. Moving towards zone 3, zone 4 has less visibility due to the narrow corridor. The construction in the Maria area partly blocked the open space in this zone and temporarily dismantled most of the sports activities. Zone 4 has essential signage, but less than in Zone 3. Moving towards Ruoholahti, the bridge partly blocks the view. In between, there is a picnic area, the only digital advertisement display panel located facing Ruoholahdenkatu, and a city bicycle station. Here zone 4 has direct contact with the street leading to the shared space, including one school building, with a supermarket on the ground floor (Figure 14).

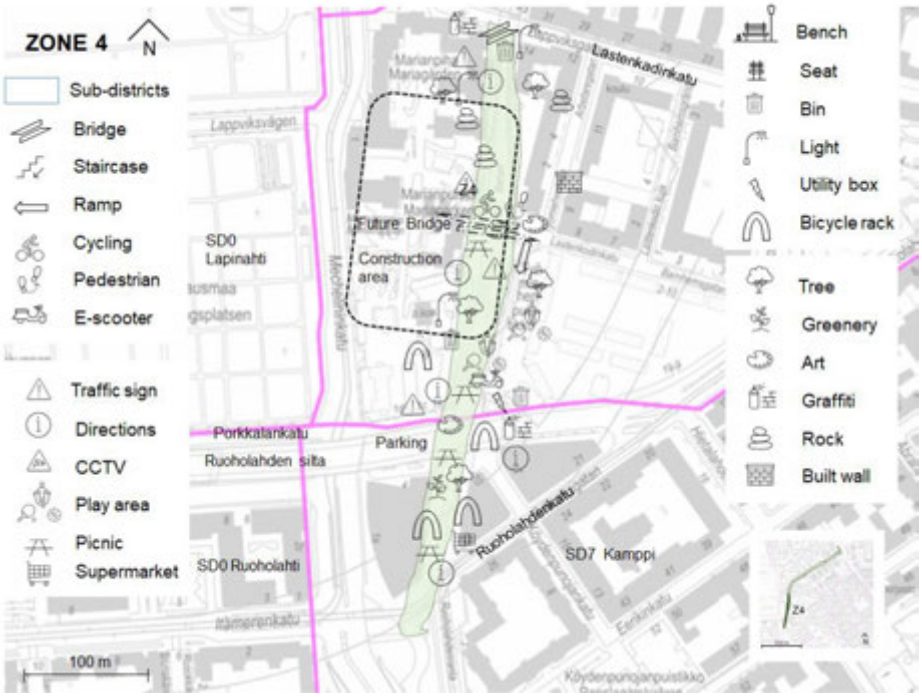

Figure 13: Zone 4 main features (Source: by author)

Figure 14: Top left basketball court; top right shared space; bottom left: Rouholahden bridge; bottom right Lapinlahdenkatu bridge (Source: by author- 6 and 30 March 2024)

To summarise, connectivity and permeability vary across the zones, with less linkages to the west. Regarding attractiveness, some zones are mainly utilitarian transit strips, while others incorporate art, seating, and diverse amenities, inviting diverse users to stay. Regular maintenance, and the presence of bins contribute to perceptions of safety, while lighting in some segments is insufficient. The non-uniform width of Baana indicated in the interviews allows for changes in levels of activities, the separation of different mobility modes, and reveals vistas, expanding cones of vision beyond the Baana to the surroundings (Figure 12). However, as mentioned in the interviews, this width variation is not optimised, with many shoulders left unused, noting their potential to provide more vegetation, art, and amenities. It is evident that zones 3 and 4 that are wider, with other amenities, offer more encounter opportunities. Signage for directions is mainly in zone 3, while in other zones it serves to inform about construction works and diversions. Safety from cyclists includes bottlenecks, crossings with pedestrians, and only paint separation in some segments. The tunnel closure north and construction of the new bridge south contribute to emerging disruptions that could impact some users from walking along Baana.

Baana's walking experiences

Walking types along Baana include mornings and evenings commuting possibly between home and work; walking to reach a destination along Baana, away from traffic intersections; taking a

shortcut across zone 3; walking a dog; pushing a buggy; leisurely walking and talking on the phone; strolling; jogging or running; walking individually, in pairs or groups.

While walking and depending on the time of day, non-humans include squirrels and hares in the early morning hours traversing Baana, especially in zone 4; ducks in zone 3 during summer; birds all around, especially in zones 2 and 3 as evident in the sound recordings. Other users include children in the adjacent play area also visiting zone 4; maintenance staff in the morning and on rare occasions police; runners at regular hours signal their fellow runners with acknowledgment; residents from the adjacent building in zone 3 walking a dog or smoking a cigarette; dogs with their owners sometimes interacting with passersby; people seated talking on the phone, eating, drinking beverages or simply looking; first-time visitors exploring Baana, youth in the sports area or sitting on the picnic places in zones 3 and 4; celebrating events, such as Vappu end of April (Figure 15). Observations indicate that the above activities provide interaction opportunities, and that different age groups and users with diverse capabilities walk along Baana. Stationery activities are reduced during harsh weather conditions, and footfall could be affected by ongoing city projects, yet children from nearby schools still come here for the outdoor hour (City of Helsinki5), and youth gather to celebrate events, such as Vappu or labour day celebration in May (Figure 15). Walking along Baana, some of the observations were validated with spot checks (Figure 16).

Figure 16: Perceptions of pleasant, safe, shaded, or windy locations (Source: by author using QGIS)

While walking, other senses are activated, and stimulated by cultural and natural elements. Art and vegetation are positive visual stimuli. Shading and wind are seasonal, favoured more in summer than winter, and often necessitating design interventions. Stairs have no cover but are

designed with the perforated metallic grid to prevent snow accumulation. The presence of deciduous rather than evergreen trees limits providing sheltering from wind and sun. The different types of seating areas cannot be used in rainy or snowy weather, something to be revisited together with the use of shoulders. Noise from the bridge in zone 4, the tramway in zone 1, and to some extent the parallel street to the west along Baana are considered noisy. However, all along, vegetation and trees offer refuge for birds, whose singing is a positive audio stimulus. In zones 3 and 4, especially in the mornings, the smell of buns from nearby bakeries provides pleasant olfactory stimuli, connecting Baana to the surroundings, while depending on wind direction, car exhausts along the western side are unpleasant. Baana is full of textures stimulating the tactile: different types of stone, concrete, wood, metal, and vegetation, combined with earth colours, or primary colours in the sports area. The rhythms of materials and colours provide a visual sequence while walking along Baana, sometimes inviting pedestrians to stop there, where the vertical blank walls disappear.

The users seem to have tacit walking rules, such as walking slowly on the right side, while keeping the left open for fast walkers and runners; wheelchair users use both cycling and pedestrian lanes; small children on bicycles could cycle on the pedestrian lane without causing discomfort; groups walking next to each other would make way when they see another pedestrian; cyclists and pedestrians equally transgress each other's lanes when there is little or no traffic; utility boxes and bins are used to display different announcements for cooking classes, gatherings and parties, entertainment shows and other (Figure 15).

Figure 15: Top left: Vappu celebration; top right graffiti indicating less visibility. Centre left: ramp adjacent to play area: centre right: post for cooking classes; bottom left: metallic stairs; beottom right: seating area (Source: by author 27 April, 5 March, 24 April, 30 March and 29 April 2024)

Redefining the functional and aesthetic aspects to shape pedestrian spaces by users not by design, is evident along Baana. Drawing graffiti or posting advertisements on bins and utility boxes codes Baana, while decoding is based on the receiver and their knowledge of what the meanings are – example classes for cooking, dancing, a concert, or jobs – which are signals for establishing encounter beyond the space for walking, whereby 'the capacity to provoke relations' unfold outside the space itself (Blokland, 2017). Sitting or walking dogs in areas non-designated places such as in zones 3, 4 opens the possibility for other users to follow. Occasionally, pedestrian groups congregate on the picnic areas or near the sports area, and temporarily reconfigure it Baana (Figure 15). These signifiers define for whom Baana is, and the 'etiquette' in Baana leads to inclusion/ exclusion.

Regarding barriers and 'subtle forms of exclusion', the variation in lighting, leaving some segments along Baana as dim especially in winter, would discourage some users, for example vulnerable individuals. While the cycling lanes are kept clean in winter, ice forms on the pedestrian lane, especially in zone 4, and the ramp leading to the parliament extension in zone 1, which would deter some users. The design of the seating and its positioning limits interaction, noting that seats are mostly at the foot of the stairs, and face blank walls. The art provided, mainly graffiti, is not to everyone's taste, though the addition of the contemporary art display in Zone 2 in summer 2023 attracted the attention of many passersby (Figure 10). The offered sports do not cater for the very young or elderly, like other public spaces in Helsinki. The lack of a public toilet or at least clear signs to where some are located at both ends indicates that the duration of stay along Baana is limited.

Regarding safety, there are few hidden or less visible areas along Baana, under some bridges, the niches between two bridges or decreased visibility between zones 4 and 3. More importantly, almost along all Baana, there is visibility from above, overseeing from the bridges or along the streets. Design considerations for safety indicate risks when stepping down from stairs, or next to shoulders that are not levelled with the pedestrian lane (zones 1, 2). Safety from others during daytime does not seem to be an issue, expect in the segments where the lanes seem visually or physically disconnected. The presence of CCTVs could instigate

contradictory feelings of safety. Walls with informal graffiti suggest poor visibility, which also relates to issues of safety (Figure 15).

Summing up from the analysis, what aspects of Baana encourage what types of walking experiences and social encounters? Baana offers traversing the city and cutting through different architectural character areas, a perspective not commonly possible along the street network. Walking along Baana is comfortable and safe, with only few interruptions, no waiting time, dwarfing the railway conduit, and paying attention to the human scale. Experiencing Baana on foot reveals differences marked by opportunities and barriers for pedestrians and possibilities for social encounters. The dynamic interplay of stimuli for different senses from the physical surroundings and the designed space create transit nodes from one experience to the next. Walking along Baana is not limited to the necessary or optional, it offers a range of fluid encounters with diverse human and non-human users, as well as exchange with familiar strangers – familiarity built on recurrence, or similarity of the type of walking, for example with children, with dogs or running. There are implicit rules that give meaning to Baana, which are accessible even to first-time users, such as when to give way, negotiate one's pedestrian status, or learn about upcoming events. 'Subtle forms of exclusion' exist, for the three aspects. Functionally, accessibility from the west is still limited, with the new Maria area project promising to mitigate this. Aesthetically, asymmetrical attention is given to different user groups in the design. Symbolically, the choice of signage, art and design of amenities communicates to some user groups better than others. Though memory of the railway is important, it is worth questioning the extent to which its preservation is enhancing current walking experiences, or whether other interpretations could serve both purposes better through the choice of art, use of shoulders, or vegetation.

7. Conclusion

This article addressed two questions in ongoing research: *What design elements, aesthetics, and symbolic atmospheres in Baana promote walking beyond the necessary activity? How is Baana perceived while walking?*

Considering walking as a social activity beyond the utilitarian mobility need, and the importance of fluid encounters, the article presented an approach to analyse pedestrian urban spaces. This approach conflated the design and experiential aspects of function, attraction, and signification to identify barriers and potentials for supporting social encounters. Unpacking walking as a social activity revealed its multi-sensory experience, social connotations, and potentials to support interaction and sociability within urban spaces for walking, ranging from public familiarity to sustained social interaction.

The article presented preliminary findings from the initial research phase, which prepares the basis for the next phase that addresses some of the research limitations. The first is the absence of information about diverse experiences based on the pedestrian's intersectional identities (both internal from the individual and external from the socio-cultural background shaping the surrounding context) to examine the extent of how just or inclusive Baana is as a pedestrian environment. The second relates to user demographics, information on origins and destinations,

choice frequency and purpose of walking, and how they link to socio-economic distributions in the city more broadly, and opportunities for long-distance walking. Third, investigate the temporal aspect and dynamism of the walking experience depending on the time and seasons. In the second phase, a survey will be developed to identify differential experiences, and could be based either on visuals analysed by respondents, or user input that is georeferenced using an application like Epicollect5. The questionnaire could be replaced with walking narratives for a smaller sample that focuses on a specific user group (Kanellopoulou, 2017; Middleton, 2018; Scarponi et al. 2023).

While the current research serves as a steppingstone for further in-depth and participant-based research, it nevertheless proposes some suggestions for planners with possibilities to enhance functional, aesthetic, and symbolic aspects of the Baana towards addressing experiential asymmetries and reinforcing social encounter that is essential within urban environments.

Abstract

In the Portuguese coastal city of Quarteira, a case study of the research, the seafront is composed by two fixed linear infrastructure systems - the seashore streets and a dune park, *Passeio das Dunas* - succeed each other, separated by the port area.

Methodologically, drawing as a qualitative tool allowed us to decompose the layers that compose the public space, thereby enabling us to represent the formal characteristics and thus highlight the material and immaterial characteristics of the place.

Aim of the research is to describe the compositional grid of Quarteira urban public space, its formation and transformation process over time, as well as to debate the recent missed opportunities for effective adaptation to the effects of extreme weather events.

In conclusion, we consider that a critical theoretical reflection on the spatial planning and design of public space in coastal cities permits the definition of operative compositional parameters - which make it possible to overcome project theories that, in the face of the effects of climate change, have become obsolete.

Introduction

Since the modern era, one of the major urban transformations that affected cities was the delimitation and channelling - in pipes, embankments and conduits - of water bodies (Marsalek et al, 2008). Water bodies were progressively demarcated by rigid infrastructures that delimited their limits and distanced them - physically and/or visually - from the city.

Nowadays, because of the necessity to cope with the effects of climate change on the urban environment, a conceptual paradigm shift is taking place, choosing to "make room for water" as opposed to the idea of delimiting it (Sijmons et al, 2017). Although water has always been a shaping and structuring element of the landscape, the contemporary necessities that have arisen with the climate crisis require a more conscious management of the element, and it is in this sense that the role of public space design in the face of extreme events is strengthened (Matos Silva in Brandão, 2019). Therefore, by integrating local wisdom with scientific and technological knowledge in a design adapted to uncertainty, public spaces can improve climate change awareness and promote vulnerability reduction (Matos Silva in Brandão, 2019).

The case study, discussed in the article, is Quarteira, a coastal city located in the Algarve region of southern Portugal. Until before the 1950s, the coastal area in front of the historic core of the fishing agglomeration of Quarteira consisted merely of a long, low, sandy seashore with dunes. From the second half of the twentieth century, due to the new socio-cultural needs related to tourism, and the economic boom, the urban limit - the seashore street - was built. Moreover, the most significant urban transformation took place in the threshold space between the city and the beach. The seashore street is a linear urban public space bounded on one side by the facade of buildings and on the other by the beach and the sea. This channel space articulates the relationships between the city and the beach, and is where the main socio-cultural activities of the city take place.

Fig. 1: Quarteira. Author's editions, 2022

Nowadays, the seashore street as an infrastructural system is the first line of defence of the urban agglomeration against erosive and flooding phenomena caused by extreme climatic events. Indeed, it is estimated that, along the 943 km of Portuguese coastline where around 70 per cent of the population lives (Bigotte et al, 2014), a percentage that rises to around 80 percent in the summer months, thanks to the phenomenon of tourism (Andrade et al, 2002), urban areas are the most vulnerable in Europe to the effects of rising mean sea level.

To cope with the effects of the rise in the average sea level, in 2019, with the aim of supporting the protection, redevelopment and valorisation of the coastal strip, the Algarve's Intermunicipal Climate Change Adaptation Plan, PIAAC-AMAL (*Plano Intermunicipal de Adaptação às Alterações Climáticas do Algarve*) was approved. The plan has as its objective the adaptation of coastal cities, and in the case of Quarteira it describes scenarios of shoreline retreat, for which it suggests the continuation of artificial beach nourishment, as well as stating the need to relocate the first line of buildings after 2040. However, the continuous urban expansion of coastal areas, to meet the needs of tourism, requires the implementation of adaptation projects that do not consider the urban relocation and thus the distancing of the city from the coastline.

Among the projects reconfiguring the space next to the sea is the *Passeio das Dunas* (sea promenade), designed by João Nunes, *PROAP: Landscape Architecture and Design Studio*, inaugurated in 2016, which connects the city of Quarteira with Vilamoura, to the west along the seashore. João Nunes' project involved the creation of conditions for the dune system to settle and develop as a natural process supported by the anthropic elements created. Aim of the project was building with nature, creating and recovering the existing dunes and vegetation in the adjacent natural area. However, during implementation it was decided, by the project's controlling entities, that the dune system would be fixed, preventing its natural movement; thus, the construction of the project was conditioned regarding its initial design assumptions.

Quarteira therefore becomes a case study in which it is possible to decode the embryonic paradigm shift underway, albeit with its weaknesses and paradoxes. Indeed, along the same coastline coexist both the conventional idea of a limit defined by a fixed layout, the seashore street, and an initial attempt to create a space composed of non-linear forms/layouts related to living and evolving ecological systems such as green and blue infrastructure. Although the *Passeio das Dunas* (seafront promenade) was not constructed as designed, we consider that it remains an initial starting point for a long theoretical discussion and one of the possible paths on the future formal definition of the space between the city and the sea.

If the urban public space adjacent to the sea is the area most vulnerable to climate risks, it is simultaneously the most favourable urban space for transformation and adaptation to cope with erosion and flooding phenomena due to the effects of extreme events associated with the rise in mean sea level. A threshold space that can accommodate externalities from the effects of mean sea level rise; and thus protect the coastal agglomeration. Purpose of the article is to describe, by comparing, two possible design approaches, constituted through rigid limits or through the implementation of green and blue systems, articulating dual theories in the landscape design debate. In conclusion, we consider that the reading of the formal characteristics of the space between the city and the sea provides an opportunity to rethink the design processes of urban adaptation.

This article is inscribed in the research project *"MAR - As Marginais Atlânticas Portuguesas. Leitura interpretativa e Projecto em contexto de Alterações Climáticas. / The Portuguese Atlantic Seashore Streets. Interpretative reading and Design in Climate Change context"*, and the embryo project *"[ENTRA]MAR. Sea intertwined city. Interpretation and Design of Portuguese Seashore Streets vulnerable to sea level rise"* coordinated by Sérgio Barreiros Proença, funded by FCT exploratory projects through CIAUD - Research Center in Architecture, Urbanism and Design at the Lisbon School of Architecture, Universidade de Lisboa (Portugal).

The Time of water in the city

The duality between the desire to dwell near the water body - the riverbanks and coastal locations - has become more ambiguous and paradoxical nowadays caused by the high exposure to climate hazards (Hunt et al, 2011).
