The **Structural Reliability Theory** papers are issued for early dissemination of research results from the Structural Reliability Group at the Department of Building Technology and Structural Engineering, Aalborg University. These papers are generally submitted to scientific meetings, conferences or journals and should therefore not be widely distributed. Whenever possible reference should be given to the final publications (proceedings, journals, etc.) and not to the Structural Reliability Theory papers.
FEM Modelling of the Evolution of Corrosion Cracks in Reinforced Concrete Structures

P. Thoft-Christensen
ABSTRACT: Corrosion cracks are caused by the increased volume of corrosion products during the corrosion of the reinforcement. After corrosion initiation the rust products from the corroded reinforcement will initially fill the porous zone near the reinforcement and then result in an expansion of the concrete near the reinforcement. Tensile stresses are then initiated in the concrete. With increasing corrosion, the tensile stresses will at a certain time reach a critical value and cracks will be developed. The increase of the crack width after formation of the initial crack is the subject of this paper. New results based on a Finite Element Analysis (FEM) are presented.

1. INTRODUCTION

Only chloride induced corrosion of the reinforcement is considered. If the rate of chloride penetration into concrete is modelled by Fick’s law of diffusion, then it can be shown that the time $T_{\text{corr}}$ to initiation of reinforcement corrosion is

$$T_{\text{corr}} = \frac{d^2}{4D} \left( \text{erf}^{-1} \left( \frac{C_{\text{cr}} - C_0}{C_i - C_0} \right) \right)^2$$

where $d$ is the concrete cover, $D$ is the diffusion coefficient, $C_{\text{cr}}$ is the critical chloride concentration at the site of the reinforcement, $C_0$ is the equilibrium chloride concentration on the concrete surface, $C_i$ is the initial chloride concentration in the concrete, erf is the error function. All the parameters mentioned above are modelled by stochastic variables or stochastic processes; see Thoft-Christensen (2001).

With increasing corrosion the tensile stresses will reach a critical value and cracks will be developed. During this process the volume of the corrosion products at initial cracking of the concrete $W_{\text{crit}}$ will occupy three volumes, namely the porous zone $W_{\text{porous}}$, the expansion of the concrete due to rust pressure $W_{\text{expans}}$ and the space of the corroded steel $W_{\text{steel}}$. With this modelling and some minor simplifications it can then be shown that the time from corrosion initiation to crack initiation is; see Liu & Weyers (1998)

$$\Delta\tau_{\text{crack}} = \frac{1}{2 \times 0.383 \times 10^{-3} D_{\text{bar}} i_{\text{corr}} \rho_{\text{steel}}} \left( \frac{\rho_{\text{steel}}}{\rho_{\text{steel}} - 0.57 \rho_{\text{rust}}} \left( W_{\text{porous}} + W_{\text{expans}} \right) \right)^2$$

where $D_{\text{bar}}$ is the diameter of the reinforcement bar, $i_{\text{corr}}$ is the annual mean corrosion rate, $\rho_{\text{steel}}$ is the density of the steel, and $\rho_{\text{rust}}$ is the density of the rust products. In the derivation of (2) it is assumed that the diameter $D_{\text{bar}}(t)$ of the reinforcement bar at the time $t$ is modelled by
\[ D_{bar}(t) = D_{bar}(T_{corr}) - c_{corr} i_{corr} (t - T_{corr}) \] (3)

where \( c_{corr} \) is a corrosion coefficient.

2. SERVICE-LIFE DEFINITIONS

Several different service-life definitions have been proposed in the literature. Four types of definition are:

(i) Corrosion initiation based definitions
(ii) Corrosion crack initiation based definitions
(iii) Corrosion crack width based definitions
(iv) Spalling based definitions.

All four definitions are illustrated on figure 1 where a deterioration profile and a crack profile are sketched.

Definition (i) is based on an estimation of the corrosion initiation time \( T_{corr} \) and may be written

\[ T_{service}^{1} = T_{corr} \] (4)

Definition (ii) is based on an estimation of the corrosion crack initiation time \( T_{crack} \) and may be written

\[ T_{service}^{2} = T_{crack} = T_{corr} + \Delta T_{crack} \] (5)

where \( \Delta T_{crack} \) is the time from corrosion initiation to formation of the first corrosion crack.

Definition (iii) is based on an estimation of the time to formation of a certain corrosion crack width \( T_{crack width} \) and may be written

\[ T_{service}^{3} = T_{crack width} = T_{corr} + \Delta T_{crack} + \Delta T_{crack width} \] (6)

where \( \Delta T_{crack width} \) is the time from corrosion crack initiation to formation of a given critical corrosion crack width.

Definition (iv) is based on an estimation of the time to first spalling \( T_{spalling} \) and may be written

\[ T_{service}^{4} = T_{spalling} = T_{corr} + \Delta T_{crack} + \Delta T_{spalling} \] (7)

where \( \Delta T_{spalling} \) is the time from corrosion crack initiation to first spalling.

Figure 1. Service-life definitions. ? indicates the area of major interest in this paper.
3. CORROSION CRACK EVOLUTION

After formation of the initial crack the rebar cross-section is further reduced due to the continued corrosion, and the crack width $w_{\text{crack}}$ is increased. Several researchers have investigated the evolution of corrosion cracks in reinforced concrete beams experimentally. In most experiments, see e.g Andrade, Alonso & Molina (1993), the function between the reduction of the rebar diameter $D_{\text{bar}}$ and the increase of crack width $w_{\text{crack}}$ measured at the surface of the concrete specimen can be approximated by a linear function.

$$\Delta w_{\text{crack}} = \gamma \Delta D_{\text{bar}}$$  \hspace{1cm} (8)

where $\gamma$ is the crack width coefficient.

Andrade, Alonso & Molina (1993) have investigated experimentally the evolution of corrosion cracks in reinforced concrete beams. In the paper four simple test specimens have been investigated. In all four experiments the function between the reduction of the rebar diameter and the maximum crack width measured in the surface of the concrete specimen can be approximated by a linear function, see figure 2. The crack width coefficient $\gamma$ depends on the cross-sectional data and is of the order 1.5 to 5.

![Figure 2. Loss in rebar diameter $\Delta D_{\text{bar}}$ versus the crack width $\Delta w_{\text{crack}}$. Andrade, Alonso & Molina (1993).](image)

4. FEM ESTIMATION OF THE CRACK WIDTH COEFFICIENT $\gamma$

For illustration purposes the coefficient $\gamma$ in equation (4) was estimated using FEM analysis by Thoft-Christensen (2003) using FEMLAB/MATLAB. A rectangular beam cross-section with
only one reinforcement bar was considered, see figure 2. The diameter of the hole around the rebar at the time of crack initiation is $D_{\text{hole}} = 20$ mm and that the cover is $c = 10$ mm. The initial crack width is 0.01 mm.

![Figure 3. FEM net. The total net to the left and the local net near the crack to the right.](image)

In the FEM modelling the rectangular cross-section is assumed to have a hole at the location of the reinforcement and a crack (0.01 mm) from the hole to the boundary. The number of constant strain elements is 5580 and there are 3066 nodes. The material is assumed to be linear elastic with the elasticity module $E = 25 \times 10^9$ Pa and the pressure from the increasing corrosion products is modelled as a uniform loading (pressure) $p = 1 \times 10^6$ N/m at the boundary of the hole. The result of the analysis is shown in figure 3. The increase in the crack width in the considered time interval $\Delta t$ is $\Delta w_{\text{crack}} = 0.67$ mm and the average increase in the hole diameter is $\Delta D_{\text{hole}} = 0.31$ mm.

![Figure 4. Displacements at four points of the circular hole and at the ends of the crack. Magnification factor is 3.](image)

The produced volume (area) of the corrosion products $W_{\text{rust}}$ is related to the corroded steel volume (area) $W_{\text{steel}}$ by $W_{\text{rust}} = \alpha W_{\text{steel}}$, where $\alpha = \rho_{\text{rust}} / \rho_{\text{steel}}$ (the relation between the densities of the rust product and the steel) depends on the type of corrosion products. Typical values are 2 - 4. Therefore,
\[(\alpha - 1)\pi D = \pi D_{\text{hole}} + \varepsilon \implies (\alpha - 1)\pi \gamma^{-1} \Delta w = \pi \eta^{-1} \Delta w + \varepsilon \]

so \( \gamma < (\alpha - 1)\eta \)

and \( \gamma \approx (\alpha - 1)\eta \) for small \( \varepsilon \)

where \( \varepsilon \) is the amount of rust in the increased crack.

For the example shown in figure 3 one gets

\[0.67 = \eta \times 0.31 \implies \eta = 2.2\]

\[\gamma < (\alpha - 1) \times 2.2 = \begin{cases} 1.1 \times 2.2 = 2.4 & \text{for black rust } \text{Fe}_3\text{O}_4 \\ 3.1 \times 2.2 = 6.8 & \text{for brown rust } \text{Fe(OH)}_3 \end{cases}\]

These \( \gamma \)-values are of the same magnitude as the experimental values presented in section 2.

### 4.2 Rectangular beam with one symmetrical rebar

In this section the results of FEM analysis of the cross-section illustrated in figure 5 are presented with 10 different combinations of the cover \( c \) and the diameter \( D \) of the hole.

![Figure 5. Cross-section geometry and numbering of points where displacements are estimated.](image)

The 10 designs A-J are defined and the displacements of the points 1-7 for each design are shown in table 1. The estimates of the coefficients \( \eta \) and \( \gamma \) are shown in table 2.

In figure 5 is to the left shown values of $\gamma$ (black rust) for fixed diameter $d$ as a function of the cover $c$. $\gamma$ increases with the cover $c$. To the right is shown values of $\gamma$ (black rust) for fixed cover $c$ as a function of the diameter $d$. $\gamma$ increases with the diameter $d$.

Figure 6. $\gamma$ for black rust.

5. SPALLING

In this section it is shown on the basis of a number of examples how FEM analysis may help in estimating how and where new corrosion cracks are established with continuing corrosion after the initial (first) crack is formed.

In figure 7 a beam with a single non-symmetrical rebar and an initial crack from the rebar to the lower side of the beam is considered. The FEM method is used similarly to the examples shown earlier. The maximum tensile stress at the boundary of the hole occur in the NE direction indicating that the next crack may occur in that direction. In figure 8 the same beam is shown, but now with two symmetrical rebars. New corrosion cracks seem to occur in the same direction as shown in figure 7 resulting in spalling at the two corners, see the picture in the middle where the first principal stresses are shown. The picture to the right shows the stresses in the $\gamma$-direction (vertical direction). They seem to show that the next spalling will be a vertical displacement of the middle section.
In figure 9 is shown a similar case as in figure 8 is shown, but now with three rebars. Again, the analysis seems to indicate that the spalling will first occur at the two corners and then at the two middle sections.

In the last example a reinforced concrete bridge deck with six rebars is considered, see figure 9. The analysis seems to indicate again that the spalling will first occur at the two corners and then at the five middle sections.

6. CONCLUSIONS

Modelling of corrosion crack initiation and corrosion crack evolution is presented with special emphasis on modelling of the crack evolution. Experiments and FEM analysis seem to show that the function between the reduction of the rebar diameter $\Delta D_{\text{bar}}$ and the corresponding increase in crack width $\Delta w_{\text{crack}}$ in a given time interval $\Delta t$ measured on the surface of the
concrete specimen can be approximated by a linear function, and it is demonstrated how the crack width coefficient $\gamma$ can be estimated using FEM analysis.

ACKNOWLEDGEMENT. The author is grateful to Professor Staffan Svensson, Aalborg University for assistance with the FEM analyses.
