ESPON Action 2.1.5: Territorial Impacts of European Fisheries Policy.

This report represents the final results of a research project conducted within the framework of the ESPON 2000-2006 programme, partly financed through the INTERREG III ESPON 2006 programme.

The partnership behind the ESPON programme consists of the EU Commission and the Member States of the EU25, plus Norway and Switzerland. Each country and the Commission are represented in the ESPON Monitoring Committee.

This report does not necessarily reflect the opinion of the members of the Monitoring Committee.

Information on the ESPON programme and projects can be found on www.espon.lu

The web site provides the possibility to download and examine the most recent document produced by finalised and ongoing ESPON projects.

Foreword

This report presents the final results of the research which was undertaken in Project 2.1.5 "Territorial Impacts of European Fisheries Policy" as part of the ESPON 2000-2006 Programme. The objective of the project has been to strengthen the knowledge of territorial, social and economic cohesion through an analysis of territorial impacts of the European Fisheries Policy (CFP).

The Norwegian Institute for Urban and Regional Research has been Lead Partner and co-ordinated the project, and has been responsible for the work packages on data, indicators and typologies (WP1); impacts on environment and integrated coastal zone management (WP5); and for the final comprehensive analysis in the project (WP6). Institute for Fisheries Management and Coastal Community Development (IFM) has been responsible for the work package on the diagnosis of the development of the fisheries sector in Europe (WP2). Norut Group (Norut NIBR Finnmark as and Norut Social Science Research) has been responsible for the work package on impacts on employment, cohesion and demography (WP3). The Institute for Economic Research in Fishery and Aquaculture (IREPA) has been responsible for the work package on impacts on regional economic strength (WP4). All partners have contributed with data and substantial inputs to the different work packages in the project, and each partner have also produced a case study.

The project has included the following partner institutions and personnel:

Norwegian Institute for Urban and Regional Research (NIBR), Norway

Olaf Foss
Frants Gundersen
Dag Juvkam
Ove Langeland (Project Leader)
Knut Bjørn Stokke

Norut Group (Norut NIBR Finnmark as and Norut Social Science Research), Norway

Sveinung Eikeland
Bernt Holst
Anne Katrine Normann

Institute for Fisheries Management and Coastal Community Development (IFM), Denmark

Troels Jacob Hegland
Sten Sverdrup-Jensen

Estonian Marine Institute, University of Tartu, Estonia

Markus Vetemaa

CEDRU – Centro de Estudos e Desenvolvimento Regional e Urbano, Lda., Portugal
Inês Andrade
Jorge Gaspar

The Institute for Economic Research in Fishery and Acquaculture (IREPA), Italy
Monica Gambino
Loretta Malvarosa
Vincenzo Placenti

Universidade de Santiago de Compostela (IDEGA), Spain
Angeles Piñeiro Antelo
Rubén Camilo Lois González
Xosé Manuel Santos Solla

University of Akureyri Research Institute (UARI), Iceland
Grétar Thór Eythórsson
Hjalti Johannesson

The contents of this report are the responsibility of the authors and do not necessarily reflect the opinion of the ESPON Monitoring Committee. More information about the ESPON programme and the project can be found on the ESPON web page:

Table of Contents

Foreword	1
Tables	10
Figures	13
PART 1: Summary	17
1 Executive summary	18
1.1 Introduction	18
1.2 Social Cohesion Impacts	23
1.3 Economic Cohesion Impacts	24
1.4 Environmental impacts and integrated coastal zone management (ICZM)	26
1.5 Conclusion and policy recommendations	28
1.5.1 Conclusions	28
1.5.2 Policy recommendations	31
2 Scientific summary	35
2.1 Concepts, methodologies, typologies and indicators	35
2.2 Indicators, typologies and methodology	35
2.2.1 Indicators	35
2.2.2 Typologisation	35
2.3 Networking and co-operation	42
2.4 Data gaps and their research consequences	43
2.5 Future research	43
PART 2 Results of the Project: Mapping	45
1 Introduction	46
1.1 Background and aim of the project	46
1.2 Impact analysis and geographical level	47
1.3 Project meetings, networking and references to other ESPON projects	48
1.4 Final report and further research	49
1.5 Expected results in the final report and structure of the report	50
2 Indicators, typologies and territorial methodology	53
2.1 Territorial impacts studies on fisheries	53
2.2 Suggested main indicators	54
2.3 A typology of coastal regions	54
2.4 Typologies, classifications and indicators; a conceptualisation	55
2.5 NUTS 3 as territorial level for construction of typologies	56
2.6 Coastal NUTS 2 and NUTS 3 territories within ESPON space	57
2.7 Basic requirements for a standard typology of coastal regions	62
2.8 Classification of NUTS 3 territories according to Functional Urban Areas – an urban-rural classification according to functionality	64
2.8.1 Population density	65
2.8.2 Proximity/accessibility	66
2.8.3 Regions with structure fund support	68
2.8.4 Fishery dependency/specialisation	69

2.9	The main typology	69
2.10	Territorial typologies for EU15	72
2.10.1 ..	Dominant Structural funds spending	72
2.10.2 ..	Structural Fund spending and regional performance	73
2.10.3 ..	Structural Fund spending and change of regional performance ranking	73
2.11	For descriptive purposes	73
2.11.1 ..	Regional R&D performance	74
2.11.2 ..	R&D and innovation capacity	74
2.11.3 ..	Urban – rural typology – 10 types	74
2.12	Further typological work for ESPON 2	74
2.13	The coastal typology and fisheries specialisation	74
2.14	A warning	75
2.15	Interreg – a tool for interregional cooperation and networking	76
2.16	TIA as methodology for impact analysis	77
2.17	Specifics on mapping and example studies	81
2.18	Experiences with TIA	81
2.19	Experiences from the data collection and the data quality	82
2.20	Hypotheses on territorial effects of CFP	86
3	Diagnosis of the Development of the Fishery Sector	89
3.1	Introduction	89
3.2	Hypotheses for the Fisheries Sector in the EU, Iceland and Norway	89
3.3	The Global Context	90
3.3.1	Overall Fisheries Production	91
3.3.2	The State of Fishery Resources	91
3.3.3	Use of Fish Products	92
3.3.4	Trade in Fish Products	92
3.3.5	Fisheries Regulations	92
3.3.6	Future Prospects for Fish and Fish Products	93
3.3.7	Fish Consumption to 2030 in the European Union	93
3.4	The Fisheries Sector in the European Union	94
3.4.1	The Common Fisheries Policy	95
3.4.2	The Capture Fisheries Sub-Sector	121
3.4.3	The Aquaculture Sub-Sector	137
3.4.4	The Fish Processing Sub-Sector	143
3.5	The Fisheries Sector in Norway	146
3.5.1	Policy	147
3.5.2	The Territorial Implications of the Norwegian Fisheries Policy	151
3.5.3	The Capture Fisheries Sub-Sector	151
3.5.4	The Aquaculture Sub-Sector	155
3.5.5	The Processing Sub-Sector	159
3.5.6	In Sum	160
3.6	The Fisheries Sector in Iceland	161
3.6.1	Policy	162
3.6.2	The Territorial Implications of the Icelandic Fisheries Policy	164
3.6.3	The Capture Fisheries Sub-Sector	165
3.6.4	The Marine Aquaculture Sub-Sector	168
3.6.5	The Processing Sub-Sector	169
3.6.6	In Sum	171
3.7	EU, Norway and Iceland compared	172
3.8	Conclusion / Revisiting the Hypotheses	173
3.9	Policy Recommendations	176
4	Environmental impacts and integrated coastal zone management (ICZM)	178

4.1 European fisheries and environmental impacts	178
4.1.1 Fishing fleet trends	179
4.1.2 Development in catches	180
4.1.3 Percentage of stocks outside safe biological limits	181
4.1.4 Fisheries impact on habitats and ecosystems	184
4.2 Development of aquaculture and environmental impacts	185
4.2.1 Aquaculture production relative to coastline length.....	189
4.2.2 Environmental impacts of aquaculture.....	190
4.3 Conclusion.....	192
4.4 Policy Recommendation	193
4.5 Integrated coastal zone management (ICZM).....	193
4.5.1 Example studies regarding ICZM	195
4.5.2 The EU Water Framework Directive (WFD) – impacts for ICZM.....	204
4.5.3 Conclusion.....	208
4.5.4 Policy recommendations	209
5 Territorial Social Cohesion Impacts.....	210
5.1 Introduction	210
5.2 Hypothesis on territorial social cohesion impacts of the CFP.....	211
5.3 Data on fisheries socio-economics and social cohesion.....	211
5.4 The territorial system of European fisheries: “Dependencies”; “employment concentration”; “specialisation”	212
5.4.1 Fisheries employment in European nations.....	216
5.4.2 Fisheries specialisation in national economies.....	218
5.4.3 National fisheries employment averages.....	218
5.4.4 Coastal territories included in the sample	220
5.4.5 Regional fisheries specialisation indexes	220
5.4.6 Fisheries specialised territories	220
5.4.7 Changes of the position of the fisheries territories in European territorial system?.....	228
5.4.8 The fisheries specialised territories and the territorial fisheries system.....	229
5.5 Exemplification of territorial allocation of fisheries policies measures: The territorial distribution of FIFG	230
5.5.1 The territorial distribution of economic policies measures of CFP (FIFG)	230
5.5.2 FIFG Territorial distribution indexes	233
5.5.3 FIFG Territorial distribution indexes per territories.....	234
5.5.4 FIFG and the territorial fisheries systems	240
5.5.5 The territorial dimension of the fisheries conservation policies of CFP	241
5.6 Exemplification of the direct impacts on social cohesion: Changes in fisheries employment after 1995	241
5.7 Exemplification: Indirect Socio-economic Impacts of CFP.....	246
5.7.1 Population changes in fisheries specialised territories (1995), coastal territories and all territories (NUTS 2), ESPON space (e.g. total number of population	247
5.7.2 Exemplification: Changes in living conditions in Fisheries territories compared with the the European development	255
5.8 Revisiting the cohesion hypotheses.....	260
5.9 Territorial Impact Assessment (TIA) and the assessment of CFP	261
5.10 Conclusion.....	264
5.11 Summary	265
5.12 Policy recommendation.....	265
6 Territorial Economic Cohesion Impact.....	267

6.1 Introduction	267
6.2 Hypothesis related to economic cohesion	268
6.3 CFP measures and impacts in the light of economic cohesion	270
6.4 Characteristics of the EU fishery sector	271
6.4.1 Regional Inequality	271
6.4.2 A cluster analysis	275
6.4.3 Trends in European fishery sector	282
6.5 Ex-post assessment of the territorial impacts of European fishery policies	290
6.6 Conclusions	298
6.7 Policy recommendation	299
7 Conclusions and policy recommendations	300
7.1 Conclusions	300
7.1.1 NUTS territories as territorial units for analysis, classification and typologisation	300
7.1.2 Conclusion chapter 3 - Diagnosis of the Fishery Sector	301
7.1.3 Conclusion chapter 4 - Environmental impacts and ICZM	304
7.1.4 Conclusion chapter 5 - Social cohesion	309
7.1.5 Conclusion chapter 6 - economic cohesion	310
7.2 Hypotheses on territorial impacts of CFP	311
7.3 Policy recommendations	315
PART 3	Results of the project: Example studies	320
1 Introduction	321
1.1 Classification of example studies in relation to typology	322
2 The Westfjords region in Iceland: An Icelandic fisheries region in times of depopulation	325
2.1 The region	325
2.2 Population development	326
2.3 Employment structure and income	328
2.4 Quota and its relative development in the Icelandic regions	329
2.5 Catch and catch value	330
2.6 Regional development and infrastructure	334
2.7 Future prospects	334
2.8 The Westfjords example study and its relation to the main hypotheses of the project	335
3 Territorial variations in the fishery sector in Norway	338
3.1 Introduction	338
3.1.1 The importance of fisheries and aquaculture in Norway	338
3.1.2 Regional employment in the fishery sector	339
3.1.3 The industrial structure in counties with the largest fishery sectors	340
3.1.4 Demographic structure and population development	341
3.2 Data and methodology	343
3.3 Employment in Fisheries – analysis on NUTS 3 level	344
3.4 Employment in aquaculture – analysis on NUTS 3 level	345
3.5 Employment in fisheries - analysis on LAU 2 level	347
3.6 Employment in aquaculture – analysis on LAU 2 level	349
3.7 Employment in the fish processing industry	352
3.8 Employment in relation to Functional Urban Areas (FUAs) in Norway	353
3.9 Conclusions related to the hypotheses	356

4 Forcing territorial differentiation? The Norwegian Example - Fisheries policies allocated by market models.....	357
4.1 Introduction	357
4.2 Analyses themes and hypotheses	358
4.3 Norwegian territorial organisation and the territorial level of analyses	359
4.4 Territorial distribution of the Norwegian fisheries measures.....	361
4.5 Impacts for the territorial systems of Norwegian fisheries	363
4.6 The Ålesund region	366
4.7 The loser region's resistance	367
4.8 Summing up results and revisiting the hypotheses	368
4.9 Policy recommendations	369
5 Example study: Island of Bornholm, Denmark.....	370
5.1 Introduction	370
5.2 NUTS in Bornholm	371
5.3 Overall Development of Bornholm.....	372
5.4 Fisheries Sector	375
5.4.1.... Past Fisheries Studies	375
5.4.2.... Capture Fishing	375
5.4.3.... Aquaculture	382
5.4.4.... Processing	382
5.5 Impact of the CFP	384
5.6 Revisiting the Main Hypotheses	385
6 Example study of the West-Estonian Hiiu county. The transition from Soviet system to market economy: the cause of “end of fisheries” on Estonian islands.....	389
6.1 Introduction	389
6.2 Study area.....	390
6.3 Administrative distribution and economic overview	391
6.4 Demography and salaries	393
6.5 Overview of fisheries	394
6.5.1.... Coastal fishery.....	394
6.6 Open-sea fishery.....	395
6.7 Conclusion, main trends in Hiiu county fisheries	397
6.8 Future prospects	397
6.9 Developments related to CFP, national implementation of CFP	398
6.10 CFP impact analysis.....	399
6.10.1.. General impact hypotheses:	399
6.10.2.. Social and economic impact hypotheses:	400
6.10.3.. Fishery hypotheses:	401
6.10.4.. Specific hypothesis related to post-soviet Member States of the Baltic Sea:	402
7 Example study: Ría de Arousa (Galicia, Spain).....	403
7.1 Introduction	403
7.2 Ría de Arousa	406
7.2.1.... Demography	406
7.2.2.... Employment	408
7.3 Fisheries sector.....	409
7.3.1.... Fishing fleet.....	409
7.3.2.... Catches by fish markets.....	411
7.3.3.... Shellfish fishing and Aquaculture	413
7.3.4.... Canning industry	413
7.3.5.... Research and development.....	414

7.4 Impact of CFP	414
7.4.1 FIFG Funds	415
7.4.2 Problems of the implementation of the CFP in Galicia.....	416
7.4.3 Position of the Autonomous Government on the CFP	416
7.4.4 ICZM.....	417
7.5 Revisiting the Hypotheses.....	418
7.5.1 General impact hypotheses.....	418
7.5.2 Social and economic impact hypotheses.....	419
7.5.3 ICZM/environment hypotheses.....	420
7.5.4 Fishery hypotheses.....	422
7.6 Perspectives and policy recommendations.....	423
8 Example studies: Nazaré and Peniche. (NUTS 3 Oeste, Portugal).....	423
8.1 Introduction.....	424
8.2 Example study: Nazaré.....	426
8.2.1 The Geography.....	426
8.2.2 Demographic structure	427
8.2.3 Economic overview.....	428
8.2.4 The fishery sector.....	428
8.2.5 Perspectives.....	430
8.2.6 General Impact Hypothesis	430
8.2.7 Social and Economic Impact Hypothesis.....	431
8.2.8 Environment Hypothesis.....	431
8.2.9 Fishery Hypothesis.....	432
8.3 Example study: Peniche – a major fishing pole	432
8.3.1 The Geography.....	432
8.3.2 Demographic structure	433
8.3.3 Economy and Employment.....	435
8.3.4 The fishery sector.....	436
8.3.5 Perspectives.....	438
8.3.6 General Impact Hypothesis	438
8.3.7 Social and Economic Impact Hypothesis.....	438
8.3.8 Environment Hypothesis.....	439
8.3.9 Fishery Hypothesis.....	439
9 CFP impacts on the province of Salerno, ITF35.....	441
9.1 Introduction.....	441
9.2 The geography.....	442
9.3 Demographic structure	442
9.4 Economic overview.....	444
9.5 The fishery sector.....	446
9.5.1 Fleet.....	446
9.5.2 Production	447
9.5.3 Processing	448
9.5.4 Employment in the fisheries sector	449
9.6 CFP impact analysis.....	450
9.6.1 General impact hypotheses:	452
9.6.2 Social and economic impact hypotheses:	455
9.6.3 ICZM/environment hypotheses:.....	455
9.6.4 Fishery hypotheses:	456
9.7 General conclusions and recommendations	456

PART 1: Summary

1 Executive summary

1.1 Introduction

The European fisheries policy (CFP) is regarded as one of the sector policies with substantial implications for amongst other employment, cohesion and regional economic strength, particularly in some coastal regions and in fisheries dependent areas. In accordance with this, the purpose of ESPON Project 2.1.5 is to strengthen the knowledge of territorial, social and economic cohesion through an analysis of territorial impacts of the (CFP).

Fishing and aquaculture are two of the most important sectors which use and produce living resources (European Environment Agency 2002), and both sectors are undergoing profound changes. The most recent changes in the European Fisheries Policy (CFP) were adopted in late 2002, and a number of measures will be implemented in the near future. The main aim of the changes is to strengthen the competitiveness of the sector and to ensure its sustainability.

Fisheries and aquaculture plays a varying role in the economy of different countries and regions within the ESPON space, and impacts from structural changes and policy regulations will accordingly vary in different parts in Europe. A main tendency in recent years has been a concentration of activity within fishing to urban centres, but in many cases seafood industries are still located in areas outside commuting distance to cities and with few alternative income sources. In some parts of Europe, the fishing industry still plays an important role in an otherwise underdeveloped rural economy.

Aquaculture plays an increasing role in the supply of seafood and may represent an important factor of the reinforcement of territorial and socio-economic cohesion in some regions. The challenges within this industry differ from those in the fishing industry, as the aquaculture industry is more regionally concentrated. It is located in the coastal zone, and competes with or has impacts on other activities and interests in the coastal zone.

Processes of restructuring, reduction, expansion and development are occurring side by side and in various combinations within the seafood industry in Europe. The effect of this will vary between regions and the territorial impacts on short and long term will also be different. The changes, the diversity of effects, the potentials and the spatial impacts constitute the thematic frame for the project on fisheries and aquaculture.

Development of the fisheries sector in Europe

Conservation of the fish stocks is probably the largest challenge to European fisheries policy due to the heavy exploitation of a number of commercially important stocks, of which a number are outside what is defined as 'safe biological limits'. Over the last decades fish has become the single most internationally traded food in the World. The continued globalisation of the trade in fish and fish products has a major impact on the

structure of the European fisheries sector. EU is the World's biggest market for fish and fish products and increasingly the European fish processing sub-sector is sourcing raw material and semi processed products from suppliers all around the globe. This development together with increased both horizontal and vertical integration within the fisheries sector affects the localization of the industry.

The CFP and related policies have territorial impacts for coastal regions throughout Europe. The main impacts within the capture fisheries sub-sector in EU are fleet reduction, and fleet segments from regions that exploit threatened stocks are particularly affected. A chronic overexploitation of fishery resources is the greatest current environmental concern of the fishery policy in Europe, and according to EEA, most fish stocks of commercial importance in European waters appear to be outside safe biological limits of the assessed stocks.

EU countries have also experienced a decreased value of landed catch in real terms, and employment reduction within the fisheries sector. The problems in the capture fisheries sub-sector affect different EU countries and regions differently, due to geographical differences and differences in types of fishes carried out, different national implementation, impacts of structural policy (FIFG) and market regulations. The EFTA countries Iceland and Norway are better off with regard to the development within the capture fisheries sub-sector since the resource situation is relatively good. However, both countries have experienced reduced employment but this is primarily due to technological changes.

The development in the aquaculture sub-sector exhibit many similar features in Europe. There has been an increase with regard to volume, value and employment in both EU and EFTA countries. In 2002, aquaculture represents 17 % of total fishery production in Europe, and it is projected that aquaculture will increase dramatically in importance relative to capture fisheries in the coming years. The growth in aquaculture will, however, increase pressure on adjacent water bodies and associated ecosystems in the coastal zone, and may enhance competition for space in some areas. Fish diseases may also hinder the growth in aquaculture, and Iceland and Norway may experience restricted access to EU markets.

In EU countries problems facing the fish processing sub-sector are primarily related to employment, raw material supply and competition from extra-EU imports. There is general movement in the EU towards added value and away from primary processing, which for the most part can be done more cost-effectively outside the EU in regions with closer access to raw material and/or far lower labour costs. The fish processing sub-sector is becoming less distinct from the wider food processing sector as raw material sourcing is less associated with local landings. In EFTA the processing sub-sector is in a more difficult situation than the other two sub-sectors in both Iceland and Norway. This is mainly due to the reason that more processing takes place on board in factory trawlers, and to effects of globalisation, which makes it easier and increasingly cheaper to export raw material for processing in countries with lower costs.

Impact analyses

The analysis of territorial impacts of changes in CFP, will concentrate on the following elements:

- Impacts on employment, social cohesion and demography
- Impacts on regional economic strength
- Impacts on environment and integrated coastal zone management (ICZM)

The study of territorial/ spatial impacts has been done with references to the aims of cohesion, territorial balanced and sustainable development and also ESDP-perspectives focusing on polycentric development (cf. ESPON 1.1.1). In particular, the project has studied:

- The position of coastal regions in developing of the territorial system of EU and of specific countries. Of particular importance is CFP impacts on the disparities between regions within EU and inside the different nations.
- The position of the coastal regions in the overall Community policies (as the ESDP) and the structural policies (as the Cohesion fund, ERDF, ESF). Questions related to the coastal regions' in-/out phasing in different types of regional policy measures, are of specific importance in the study. Cf. those questions mentioned above and the need for specific policies interventions in fisheries regions as "restructuring of the fisheries sector outside the objective 1 area".
- The territorial development inside coastal regions. The project has through several example studies conducted regional/area analyses on different geographical levels, amongst other by using data on LAU levels for spatial analyses inside selected NUTS territories. The analyses has been related to ESDP perspectives as polycentric development and a balanced rural-urban development.
- Demographic-, social- and economic changes inside coastal regions, and inside different types of coastal regions in order to identify the regions which most negatively and positively affected by changes in European fisheries policy.

Due to large problem with data collection, and lack of data on NUTS 3 level, it has not been possible to carry out so extensive analyses as planned for in the project, cf. scientific summary. However, as mentioned in the second and the third interim report example studies have become more important in the project, and the final report presents eight example studies based on data on a lower geographical level, i.e. below NUTS3 level.

Expected results

The draft final report should cover the following elements listed in Terms of Reference (ToR):

- a) Final report covering the issues mentioned below (under point m)) with clear policy recommendations in relation to coastal regions and impacts of ICZM processes, including possible policy adjustments regarding the sector policy in order to avoid unintended spatial effects in relation to policy orientation in the ESDP and future Structural Funds policy (taking into account as well the international factors affecting the European fishery sector);
 - b) Methodological paper on the method used in project on territorial impact assessment of the investigated sector policy
 - c) Presentation of final territorial indicators and maps for the ESPON database and map collection;
 - d) Formulation of the further research necessary in field of territorial impacts of European Fisheries policies.
- m) Presentation of a comprehensive working report on tentative results of the research, applying the methodology, analysis of the hypothesis previously developed, including the following elements:

- Draft final analysis /diagnosis of the fisheries and aquaculture sector in Europe as well as the existing territorial imbalances and regional disparities in fisheries/aquaculture;
- Presentation and description of a European coastal typology and the diversity of the fishing industry related to the typology;
- Tentative results on the spatial effects at European level, in individual countries and their coastal areas in terms of the economic, social and environmental factors;
- Tentative results on territorial impacts in relation to ICZM activities in different types of coastal regions;
- Draft policy recommendations on improvement of the sector policy and the instruments in favour of territorial cohesion, balance and polycentrism, including institutional aspects.

Hypotheses on territorial impacts of CFP

Processes on restructuring, reduction and expansion of the fishery sector will probably occur side by side and in various combinations. We also assume that economic, social and demographic impacts of the CFP will vary between urban and remote areas. Impacts may also differ to the extent the regions are dominated by small-scale coastal or offshore , fishing, landings, fishing processes or aquaculture. Four general impact hypotheses have been generated and checked in the project:

General impact hypotheses

1. *The CFP will have different impacts between coastal regions, and within regions.*
2. *Socio-economic effects related to employment, migration, age structure of the labour force etc., may be less devastating in urban regions than in fisheries dependent regions and areas.*
3. *Territorial impacts of CFP will vary with different structures of the fishing and aquaculture industries of the regions.*
4. *Territorial impacts of the CFP may contradict with the aims of cohesion, territorial balanced development and polycentrism.*

The CFP is regarded as one of the sector policies with substantial implications for amongst others employment, territorial cohesion and regional economic strength, and particularly in some coastal regions and in fisheries dependent areas. The impacts of the CFP on regional level may not always be consistent with the social and economic cohesion objectives. The following social and economic impact hypotheses have been generated and checked in the project:

Social and economic impact hypotheses:

5. *The CFP has unintended side effects in coastal regions or fishery dependent regions. Significant territorial impacts may be:*
 - *Economic effects such as increasing unemployment*
 - *Decreasing regional economic productions (GDP)*
 - *Population decreasing due to out-migration particularly in fisheries regions*

- *Altered age composition in fisheries dependent regions, with an increasing share of elderly*
 - *Population. Indication of gender and age biases in fishing dependent regions*
 - *Change in population density in fisheries regions*
6. *As the restrictions on harvesting activities mainly target the fishing fleet these measures have strongest negative impacts in remote, coastal region, while the more urban regions involved in fish processing still are able to source raw fish through e.g. import from 3rd countries .*
 7. *More favourable regions are able to take greater advantage of the measures included in the FIFG due to closer access to products and markets.*

Industrialised countries are particularly concerned with overexploitation aspects, and due to biological constraints, fishing subsidies mainly aim at capacity reduction through different measures in order to achieve a sustainable development. The following hypotheses on ICZM and environmental impacts have been generated and checked in the project:

ICZM/environment hypotheses:

8. *Subsidies to support incomes or costs reduction in the fisheries sectors result in an increase of the fishing effort which has undesirable effects on social and environmental sustainability.*
9. *The changes in CFP from 2002 will contribute to a faster reduction and restructuring of the fishing fleet, both in absolute numbers, tonnage (GT) and engine power (kw).*
10. *Changes in CFP will probably be directed towards improvement of the marine environment and marine resources.*
11. *Aquaculture will continue to expand, but the further development may be more regional concentrated both with regard to value added and employment.*
12. *A management based on ICZM principals will contribute to a further sustainable growth in aquaculture.*

The description and diagnosis of the fisheries policy lay down the basis for the territorial impact studies, and the fishery hypotheses deals with questions of structural changes in the seafood industry, innovation in marine sectors, financial instruments etc. The following fishery hypotheses have been generated and checked in the project:

Fishery hypotheses:

13. *Changes in CFP may contribute to increased concentration and centralisation of the seafood industry. This will be a particular*

disadvantage for the most fishery dependent and remote areas, which are often underperforming regions in an accessibility perspective.

14. The potential and the preconditions for innovation and restructuring in this sector are probably highest in regions with larger cities or in close distance to larger cities (FUA).

15. Territorial impacts of the CFP measures are dependent on how the measures in use are implemented in the various regions.

16. Less prosperous regions of the EU receive more CFP support through the FIFG (Financial Instrument for Fisheries Guidance) than the more prosperous regions.

1.2 Social Cohesion Impacts

The Common Fisheries Policies (CFP) may have impacts on employment, social cohesion and demography, and the most important conclusions (based on studies on NUTS 2 level) are summarised below:

- The European fisheries can be divided into separate territorial social systems of fisheries contenting specific pattern of harvesting (as use of fishing grounds, capacity, technology), different types of relative employment dominance in fisheries and specific positions in particularly policies implementation processes on national level.
- CFP has contributed to strengthening some of these territorial systems, and probably thereby weakened others. The major findings are that in the north of Europe southern territorial systems in the respective countries are strengthened, while in the south of Europe the northern systems are strengthened.
- Positive fisheries employment is more frequent in regions outside of the centres of these territorial systems than in these systems. This is probably caused by the relative strengthening of “new” parts of the economic chains of the fisheries; these are functions close to the markets for fish products. Therefore, the fisheries employment close to big population settlements far from the fishing grounds is strengthened.
- Fisheries regions, also those having demographic growth figures the previous years, will experience specific demographic problems caused by aging and migration imbalances in the future. Coastal regions in which fisheries are important experience population declining processes more frequent than other coastal regions.

Employment and territorial fisheries systems

Fisheries employment in harvesting and aquaculture from 26 European countries show that fisheries employment is most frequent in Spain (58820), Italy (37120), France (33460), Portugal (20750) and Greece (19450). These figures demonstrate the “Southern” embedding of the EU fisheries. In France, however, a lot of the employment is in Northern regions. Moreover, using the national level as a reference, demonstrate that the

fisheries have a relative important position in about 30-50 per cent of NUTS 2 European regions with coast lines.

Even though these types of estimation exaggerate the role of fisheries in certain regions in countries with big capital areas which have specific characteristics of its labour markets (as UK and the London area), the region list contributes to extend the picture of the European fisheries as mainly Southern based.

European fisheries may be divided into several different territorial fisheries systems including transnational areas, and based on the mapping in the project one can identify at least four different types:

- An East Aegean and East Mediterranean (small scale fishing), embedded on the Greek and Italian islands;
- The global North Iberian fisheries, including regions in Spain, Portugal and France.
- The North Sea/Atlantic fisheries of Denmark, UK, France
- The Barents Sea fisheries of mainly of Norway.

These regions also seem to have a stable position as fisheries regions in the European territorial system.

Allocation of economic support

Fisheries activities decide the absolute amount of support from EU, and significant fisheries regions are the most important target areas for economic support in the fisheries. Spain has received most of the total contribution within EU both in the period 1994-1999 and 2000-2006. The allocation pattern has also been stable over time, and the nine most favoured NUTS 2 territories in 1994-1999 were also the nine most favoured in 2000-2006.

The fisheries regions were not favoured in the distribution of economic support in the fisheries if we compared the support with the number of employees in the fisheries. In contrast, growth regions, often surrounding the capitals has been the relative winners. The differentiation of the NUTS 2 territories according to the fisheries position was more dramatic in 1994-99 than in 2000-2006. The analysis indicate that the fisheries in these regions were able to benefit from the nations allocation process, as well as confirming that the fisheries of these regions were more dependent on state subsidizes than the fisheries in other regions.

The socio-economic development of the identified fisheries regions is more negative than the changes in most of the other European coastal regions. All types of fisheries regions will experience impacts due to actual demographic trends as aging processes and negative migration balances. These challenges will appear also in regions which have experienced demographic growth the previous years. However, these challenges seems to differ between the regions and the countries. While fisheries regions in Portugal, Greece and Spain have to concern with different types of aging problems, - Danish, Norwegian and Italian fisheries regions are affected by migration imbalances.

1.3 Economic Cohesion Impacts

The impact of the European Common Fishery Policy on the economic cohesion has been mainly based on a quantitative assessment of the territorial distribution of FIFG 1994-99

and 2000-06 funds (Financial Instruments for Fisheries Guidance). In particular, we considered that most important changes in terms of size of fishing fleets, landings, share of the fishery sector on total GDP (value added) and employment in fish catching activities.

The minimum regional level of the analysis was NUTS2, as this is the level at which EU structural policies are designed and evaluated. The major problem experienced with this study was the limited number of observations both in terms of time and spatial coverage that has heavily restricted the level of the analysis.

Inequality and Similarity across regions

In a first step, we analysed the main characteristics of the EU fishery sector with the aim to highlight the heterogeneities existing within the EU coastal regions.

The evolution of some indicators, as the GDP per capita e GDP per person employed confirmed the existence of large economic and social disparities. It was also evident the relative stable positions of most fisheries specialised regions and their slow socio-economic development respect to the other European regions.

The application of a cluster analysis allowed to find similarities and differences on the basis of some important social and economic indicators, such as the employed persons in fishing and fish farming, the Structural Fund and Cohesion Fund expenditure (1994-1999), the Structural Fund expenditure related to Agriculture, Rural Development and Fishery (1994-1999), the GDP per inhabitant, the unemployment rate, the total population and the population density, the percent of value added from agriculture forestry and fishery products, the fleet (Number of vessels, Engine power and Gross Tonnage), the landings and share of FIFG funding 1994-99 and 2000-06.

The cluster analysis indicated that the NUTS2 coastal regions can be broadly subdivided in two great groups. A first Mediterranean group, mostly located in Spain, Portugal, Italy, Greece and Malta and more specialized in terms of fishery value added and employment. A second Northern group with larger regional fleets and higher productivity levels, which exhibits lower specialisation fishery degrees and has been less supported by the EU Funds. In addition there is a third restricted group of regions heavily specialized in fishing activity and located in Denmark, Galicia and Andalusia.

Trends in European fishery sector

The picture of the European fleet highlighted the differences existing between the North European and the Mediterranean fishery, where is concentrated the most part of vessels and value of landings. However, also along the Mediterranean shores, there are significant differences between highly specialised fleets and small scale fisheries.

We used the average engine power and gross tonnage per vessel (expressed by the ratios engine power on vessel's number and the gross tonnage on vessel's number) as proxy variables of the fleet capacity. The evolution of these indicators between 1997 and 2005 put in evidence that most specialized regions (according to the share of the fishery value added and employment) exhibit a marked decline in fleet capacity. In most case, the percentage reduction in the number of vessels has been larger than the reduction in capacity, causing unintended effects in terms of composition of fleet and unemployment.

A quantitative assessment of the territorial distribution of FIFG 1994-99 and 2000-06 funds

We first tried to analyse whether Structural expenditure have or not have a progressive effect from the fiscal point of view. The fiscal progressiveness is frequently interpreted as

a symptom of social and economic cohesion or even a necessary condition for economic convergence between the member countries. For each NUTS2 region covered by the FIG programmes, the relationship between the log of the GDP per capita and the amount of FIG funds per head was tested. The regression results suggest that in general FIG funds have been distributed progressively among regions, even if the progressiveness decreased from the 1994-99 programming period to the 2000-06 one.

As expected, the main recipients are regions with larger fleets (in terms of number of vessels, engine power and gross tonnage) and higher level of fishery employment. Also in this case, the lack of data on the classification of fleet by fishing métier or system didn't allow for further differentiations.

It has also been noticed that even if the 2000-06 FIG contribution was reduced of the 6.6% respect to the previous FIG programme, in some 59 regions the assistance increased.

Given that FIG funds are allocated according to the Cohesion objectives, we also tried to assess whether regions which benefits from a relatively larger increase in allocated funds have grown faster than the other regions. For that purpose, we regressed the FIG funds per capita against the growth rate of Value added from Agriculture, Forestry and Fishery. The results gave no evidence that regions receiving largely amounts of funding tend to outperform other regions. However, if we consider only the NUTS2 regions more specialized in fisheries (in terms of the fishery value added), the relation turns out to be positive. The same test highlights different results at level of single countries. Clearly effectiveness of FIG programmes depends heavily on the region's initial economic conditions and on the quality of national and regional administrations.

1.4 Environmental impacts and integrated coastal zone management (ICZM)

Environmental impacts

The size of the European fishing fleets decreased from 1995 to 2003. However, it is too early to see if the changes in CFP from 2002 have contributed to a faster reduction of the fishing fleet. The reduction from 2002 to 2003 was approximately of the same quantity than the years before. The total fish landings of all species in all European sea regions¹ have, on the other hand, increased by 20 % (1.6 million tonnes) between 1990 and 2000. The indicators on stocks outside biological limits indicate that CFP instruments are still not sufficient for a sustainable marine development. To achieve this aim EU is also dependent on coming to agreements with third countries.

Integrated coastal zone management (ICZM)

Integrated coastal zone management (ICZM) is developed as a general tool to coordinate different and competing interests in the coastal zone. Being an integrated approach the ICZM has potential to offer a broader perspective to aquaculture and most of the fishery related activities. ICZM should have a broad "holistic" and long run perspective, integrating all relevant interests and sectors in the coastal zone, and have sustainable development as its goal.

¹ North East Atlantic Ocean (including the Baltic Sea), Mediterranean Sea, Black Sea and Arctic Ocean. The Caspian Sea and Aral Seas are not included, as these are considered to be "inland waters" by FAO.

Experiences from the EU Demonstration programme from 1996 to 1999 indicate that integrated solutions can only be found at the local and regional level. Particular the regional level seems to play a key role in integrated planning and management of the coastal zone. This level of government is still closely aware of the specific context on the ground, but has a broad enough remit to take a strategic outlook. Related to integration between fisheries and spatial planning it is a challenge that the EU Fisheries policy is one of the EU policies that are least adaptable to regional needs, but there is a pressure for a greater regionalisation. One of the suggestions is to integrate the FIFG allocations with other structural policies within a cohesion perspective.

The EU Demonstration programme also shows that the spatial planning system alone has some limitations. To fulfil the ICZM perspective the spatial planning system must cover both the terrestrial parts and the marine part of the coastal zone. The EU Water Framework Directive could secure this element. The spatial planning system also often has a narrow focus on development control rather than a broader ICZM focus. A solution to this could be to combine economic instruments to the spatial planning system. The Interreg IIC project Norcoast recommend to combine the best elements of the statutory spatial planning system with the best elements of the voluntary partnership approach in order to achieve integrated solutions.

In Norway, integrated management of coastal areas is primarily ensured through municipal coastal zone planning, and is seen as an important tool for a balanced and sustainable development of the aquaculture industry and for ICZM more generally. The strong growth in the industry is the most important reason why municipalities integrate the sea areas into their spatial master plans. Municipal coastal zone planning is based on two premises: that it enables adjacent sea and land areas to be considered as a whole, and that the planning takes place in an arena where all the relevant actors can meet. Much has been achieved with regard to the coordination of different local user interests within the municipality, and also with regard to the coordination of coastal water and land areas.

However, there are still great weaknesses in coordination across county and municipal borders, across different public (state) sectors and across levels of government, and regional coastal zone planning has been introduced to deal with these problems.

Norwegian experiences from regional coastal zone planning indicate that an open and inclusive decision process does not alone increase the integration capacity of the regional planning. There is a trade off between the number of actors participating in the decision process and the ability to agree on and implement a joint action which effectively will deal with the problem. The integration capacity of the planning process is greater where the context creates stronger interdependencies probably influencing the actors' interest in co-operation. It may also help with some pressure and incentives from central government, and an institutional framework that facilitate regional co-operation.

The growth of aquaculture industry will increase the pressure on the coastal zone, but a management based on ICZM may contribute to a further sustainable growth. The Norwegian experiences indicate that regional and local coastal zone planning could be a suitable instrument to balance the increase of aquaculture with other coastal interests. A central challenge is to find a balance between the need for long-term steering on the one side, and the need for flexibility on the other side. Greater pressure on the coastal zone could make it necessary with stronger governance and more detailed plans for aquaculture. In any case one precondition is broad participation from the relevant local interests and stakeholders, and the relevant sectoral administrative bodies to find an acceptable balance between growth in aquaculture and other interests as protection, recreation, coastal fisheries, etc. It is, however, a need for a regional approach across the municipalities regarding the development of the industry. Regional coastal zone planning

and eco system based planning in accordance to the Water Framework Directive in the future may contribute to more integration across municipalities and a more ecosystem-based management, also in the case of aquaculture.

1.5 Conclusion and policy recommendations

1.5.1 Conclusions

The Diagnosis of the development of the fisheries sector

The conclusions from the Diagnosis of the development of the fisheries sector are mainly related to the CFP but the findings apply in general also to the situation in Norway and Iceland, which are more or less subject to the same situation as the EU countries. However, the two countries are at present in a better situation in regards to the sustainability of stocks and the economic situation of the sector than the EU countries on average.

The analysis of the development of the fisheries sector indicates that quotas are allocated on the basis of a principle of 'relative stability'. This imply that some nations might be better at matching their allocations to the structure of their sector, which gives them (and their regions) an advantage over other countries. EAF and precautionary approach management implies that fishing effort will have to be reduced in waters/fish stocks involved and that catches from some stocks may be permanently lower but less fluctuating over time. This implies loss of jobs in the affected communities (onboard fishing vessels and in the related trades).

Recovery plans for depleted fish stocks (involving closed areas, closed seasons, catch/effort limitations etc.) may imply that larger vessels might be able to utilise resources far from where they have homeport, whereas this possibility does not exist for smaller coastal vessels. This may constitute a problem for the resources or destroy habitats. The analysis also show that the state of the stocks the fleets utilise are the most important factor determining how negative impacts will be distributed across regions. The conservation policy will primarily affect regions for which it is difficult or impossible to change gear or sea area.

The analysis of the market policy show that this policy may have serious territorial effects, and that the varying territorial impacts are related to the different impacts of tariffs and external trade measures. The extra tax on (especially Norwegian) salmon which should protect salmon producers in Scotland and Ireland had severe negative impact on salmon processors in Denmark, which depend heavily on Norwegian raw material. The analysis also indicate that fish products will increasingly be affected by other policies not directly stemming from the fisheries market policy. The policy on traceability is provided as one example of such.

Fisheries structural policies also have significant territorial impact, for instance when some regions are able to get more funding from the EU based on considerations, which are wholly or partly unrelated to the situation of their fisheries sector. This puts some regions in a better situation than other regions. It is also interesting to see how the structural policy has - until recently - supported modernisation and renewal of the EU fleet in a situation, where overcapacity is considered one of the main problems facing the conservation policy. Although the EU structural policies may have become less important due to globalisation, the FIG support is still significant for handling a situation where the local markets and fleets are increasingly becoming part of a world market. In the new

member states this is happening simultaneously with a demanding transition towards market economy.

The analysis also shows that the external policy has territorial impact, which varies across regions. This relates especially to fisheries agreements, which are of most importance for the southern EU member states. The transfer of money through the fisheries agreement could be seen as subsidies for the vessels engaged in these fisheries. However, also bilateral and international agreements or the failure to conclude these could have significant impact, as illustrated with the failure to get agreement with Norway over Atlanto-Scandian herring, which are of importance to a number of Danish ports.

Environmental impacts and integrated coastal zone management (ICZM)

The conclusions from the analysis of environmental impacts of the fishery policy can be summarised as follows:

- The changes in CFP from 2002 will contribute to a faster reduction and restructuring of the fishing fleet, both in absolute numbers, tonnage (GT) and engine power (kw).
- Changes in CFP will probably be directed towards improvements of the marine environment and marine resources. In the long run this may lead to higher and more stable fish stocks, but only if the fishing effort is sufficiently reduced.

There is a need for a greater emphasise on the whole marine environment and ecosystems, and not only assessments for single species as in CFP, but to adopt a multi-species and ecosystem-based management approach. An ecosystem-based management model are also needed to assess external impacts on fisheries such as accidental and operational discharges from oil exploitation and shipping activities toxic algae blooms, and runoff from land causing eutrophication and contamination (EEA 2002). The EU Water Framework Directive (2000/60/EC) and EUs proposal Marine Strategy Directive is a step in that direction.

The increasing production in aquaculture is important for many countries and coastal regions, particularly since aquaculture is often located in rural zones or peripheral areas depending on fisheries, and where alternative employment opportunities are often lacking. The growth in aquaculture, however, also constitutes a challenge for sustainable growth and coastal zone management and planning, particular with regard to adapt the locations to other coastal interests like tourism, recreation, nature and cultural heritage and coastal fishing.

The hypothesis regarding aquaculture is that this industry will increase the pressure on the coastal zone, but a management bases on ICZM could contribute to a further sustainable growth. The Norwegian experiences with local coastal zone planning indicate that this could be a suitable instrument to balance the increase of aquaculture with other interests. A central challenge is to find a balance between the need for long-term steering and predictability on the one side, and the need for flexibility on the other side. A precondition is broad participation from the relevant local interests and stakeholders, and the relevant sectoral administrative bodies to find an acceptable balance between growth in aquaculture and other interests as protection, recreation, coastal fisheries, etc. However, open and inclusive planning processes do not automatically lead to integrated planning. In the coastal zone there are many strong state sectors, and a will among these actors to find compromises at the regional level seems to be necessary.

Social cohesion impacts

The analysis of social cohesion impacts of the Common fisheries policy has been concerned with building analytical bridges between: the territorial dimensions and systems of European fisheries; the two major types of CFP (the specific economic measures (FIFG) and the “conservation” policies); the direct impacts of the CFP on the socio-economic systems of the fisheries; and the impacts on the position of the fisheries territories in the general European territorial systems. The main conclusions are related to analytical challenges such as:

- The need for building a valid idea about the territorial dimension of the European fisheries. From our point of view there is a contradiction between the enormous dimension of European fisheries and its minor territorial impacts when measuring those by using strict fisheries dependencies indicators. We have tried out a solution by using NUTS 2 territories, and from our point of view we have identified relevant territorial fisheries systems by these analyses.
- The need for establishing a system for territorial distribution analyses of FIFG as well as the regulation policies which integrate these dimension to the territorial systems of the fisheries.
- The need for integrating analyses of fisheries territories and other territories into the general analyses of European territorial development and changes. Here are at least two challenges: The first is to establish typologies that integrate fisheries territories characteristics with other ESPON typologies as information about polycentrism, functional/urban and variables registering the emergence of new types of economics. The other is to develop valid indicators for comparing territorial development. This analyses has used indicators on population changes, income changes and consumption changes. These may not be the most valid indicators for analysing all types of European territories.

Economic Cohesion impacts

The analysis of economic cohesion impact of the European fisheries policy has particularly looked into territorial distributional impacts of financial assistance (FIFG). Bearing in mind the narrowness of the information available the findings show that in general FIFG funds have been distributed progressively among regions, even if the progressiveness decreased from the 1994-99 programming period to the 2000-06 one.

As expected, the main recipients are regions with larger fleets (in terms of number of vessels, engine power and gross tonnage) and higher level of fishery employment. It has also been noticed that even if the 2000-06 FIFG contribution was reduced of the 6.6% respect to the previous FIFG programme, in some 59 regions the assistance increased without any specific reason. On the contrary, it has been observed that institutional obstacles and existing policies can severely limit opportunities of effective utilization of FIFG funds. In fact, the study has demonstrated how effectiveness of FIFG programmes depends heavily on the region's initial economic conditions and on the quality of national and regional administrations.

Finally, the EU enlargement raises another challenge for the cohesion policy. The budgetary proposals of the new European Fisheries Fund for the 2007–2013 period anticipate that the share of funding allocated to the management of ‘natural resources’ (agriculture, rural development and fisheries) is expected to fall of around 36%. As envisaged by Symes (2005), enlargement threatens the achievement of cohesion goals for disadvantaged regions within the EU 15. “Although regional disparities have narrowed, they still persist especially in peripheral Europe. Several less developed regions are certain to fall outside any new thresholds for defining problem regions in the enlarged

EU, including a number of fisheries dependent areas”. In this perspective, the expected restriction of the future fishery funding will further sharpen the disparities among regions in relation to their capacity of utilization of economic support.

1.5.2 Policy recommendations

The policy recommendations take the set of hypotheses which has directed the analyses in mapping and example studies as their point of departure.

General policy recommendations

- As the CFP is likely to have different impacts in different regions, and in different types of regions, the policy should be directed towards (possibly by use of best practises) social, economic and territorial cohesion. Special care should be taken to counteract negative development in lagging regions.
- As the CFP is likely to have unintended side effects in coastal/fishery dependent regions, there is a need to develop policies that can counterbalance the non-fishery aspects of these side effects (as listed in hypothesis 5). The same is the situation if impacts of the CFP should be shown to contradict aims of cohesion, territorially balanced development and polycentrism.
- The development in urban-rural relations in the fisheries should be governed by thoughts about polycentric development, and the assumption that such a development is especially advantageous in countries and territories with lower population densities (which is the situation in many fisheries dependent regions)
- The relation between territorial impacts and the structure of the fishing and aquaculture industries of different regions should be a basis for policy recommendations

Policy recommendations related to environmental impacts and ICZM

- There is a need for a greater emphasise on the whole marine environment and ecosystems, and not only assessments for single species in the fishery policy. The efforts according to this should be further stimulated, also in regard to the development of indicators for environmental impacts of fishery and aquaculture. Today most of the indicators focus on the development of single fish species with commercial interest. An ecosystem approach is also demanded in order to trace environmental impacts of the aquaculture industry.

According to the ICZM example studies, primarily regarding the aquaculture industry, we point out the following policy recommendations:

- It is necessary to further develop the integration of the terrestrial and marine environment in coastal planning and other ICZM activities.
- It seems to be an effective strategy to combine the best elements of the statutory spatial planning system with the best elements of the voluntary partnership approach in order to achieve integrated solutions at the regional level of government.
- To find acceptable balances between further growth in aquaculture and protection and other interests in the coastal zone, it is a precondition with a broad participation from relevant local interests and stakeholders in the planning processes, together with relevant sectoral administrative bodies. Environmental Impact Assessment (EIA) and Strategic Environmental Assessment (SEA) could be useful instruments in the process to find the right balance between protection and use.

- The aquaculture industry is in a continuously technological change, i.e. with introduction of new species and in being more offshore based. It is, therefore necessary with flexible planning approaches in order to be able to deal with the quick changes that may occur. It is, however, also a need to find suitable combination between the need for long-term steering and predictability on the one side, and the need for flexibility on the other side. The specific choice in this regard will be dependent on the specific context on the ground.
- It is a need for a regional approach across the municipalities and other administrative borders regarding the development of the aquaculture industry and other coastal activities. The implementation of the Water Framework Directive may contribute in that direction.

Policy recommendations related to social cohesion

Based on the examination we recommend four main types of recommendations focusing on the policies development. All four are about the question of the need of integrating if integration should take place, and are elaborated in the summary:

- There should be a better co-ordination of the implementation of the economic measures in CFP (the FIFG) and the fish resource regulation policy. Most of data on the latter territory level is not available, but the impression is that there is no co-ordination, and that FIFG in some countries rather targeting new types fisheries models than the specialised territories. Thereby the structure in the latter territories is in danger of being conserved (becoming rawfish satellites) and territorial differential processes are increased.
- The interplay between fisheries policies implemented on national and European level should be better integrated. The national level has a central role in the implementation of the part of CFP focusing of economic support for the fisheries. The distribution analyses as well as the example studies demonstrate that the national implementation processes probably in many occasions vary between the nations, and that these variations can have territorial as well as social cohesion impacts in the respective countries as well as in the European space.
- European sector policies of the fisheries should be adjusted in accordance with the European territorial policies on reduction of social cohesion differences on the European territory. Despite the restriction of the actual data, the conclusion can be that these two types of policies do not pull the European territorial development in the area of social cohesion in the same direction.
- There is a need for integrating territorial characteristics and development trends in to the market policies.

Policy recommendations related to economic cohesion

- A better specification of the concept related to fishery dependency and improvement in the quality of data collected.

The fishery dependency, mainly based on the relative importance of fishery employment and Value Added in the area, is also affected by the characteristics of the fishing activities (artisan or industrial) and by the unemployment rate existing in those areas. In this perspective, restrictive policies could be better calibrated to the different local demands, especially in terms of socio-economic alternatives. For this reason, it is indispensable to improve the quality of economic and biological information collected at low geographical levels in order to integrate the different statistical sources and to improve homogeneity and comparability.

- The economic cohesions should be evaluated both in quantitative and qualitative terms.

CFP affects differently the local economies. This is confirmed by the fact that regions that are in the same initial conditions take different advantages of the resources received. At a lower geographical level, the impact assessment analysis should be better focused on disparities existing also in terms of proximity to resources, economic alternatives, administrative efficiency. In this sense, the example of the more dynamic regions could be deeply investigated in order to furnish a guide for the best practice.

Summary policies recommendation

The policies recommendation can be summarised according to that the CFP categories correspond to the three types of EU objectives (sustainability, competitiveness and territorial and social cohesion); and can be implemented on three different levels (micro, meso and macro). Moreover the fisheries policies can be separated into the conservation policies and the distribution of the economic measures. The present CFP are italicised in the figures:

Table 1.1 The conservation policies

	Micro (enterprises, local, regional)	Meso (nation, bilateral agreements)	Macro (European)
Sustainability (Conservation objectives)	Alternatives: Implementation of local/regional co-management based systems	CFP today by the role of the national level in implementation of CFP	Alternatives: More of the implementation from the main territorial fisheries systems
Competitiveness (Market objectives)	CFP today and in the future by forcing winner regions in the national battles for quotas.	Alternatives: Implement the knowledge of the specific regional characteristics of fisheries in the conservation policies (gear types, species dependence ...) in order to give all regions the same starting point in the quota distribution	Alternatives: Implementation of a common quota distribution policies which give all actors real similar opportunities to get access to the fish resources.
Territorial and social cohesion (structural objectives)	CFP today by forcing territorial cohesion on low level in winner regions in the national battles for quotas. Alternatives: Helping the loser regions by “buying back” quotas	Alternatives: Improve the co-ordination between the conservation policies and the national territorial policies	Alternatives: Improve the co-ordination between the conservation policies and the common policies e.g. the structural funds.

Table 1.2 The economic measures

	Micro (enterprises, local, regional)	Meso (nation, transnation)	Macro (European)
Sustainability (conservation objectives)	CFP today by “buying out” programmes	Alternatives. Co-ordination with ecosystem based management systems	Alternatives: Co-ordination with eventual systems targeting the major European territorial fisheries systems
Competitiveness (market objectives)	Alternatives: Strategic priorities of selected communities	CFP today by the national opportunity for co-ordination of the economic policies measures	Alternatives: Co-ordination according to strengthen of particularly parts of the territorial systems of the fisheries
Territorial and social cohesion (structural objectives)	CFP today by de facto favouring selected locals and regions. Alternatives: Specific support of “buy back programmes” of quotas in regions which have lost in market based allocation regimes as some Icelandic communities and the northern Norwegian counties	Alternatives: Co-ordination with national policies and programmes	Alternatives: Co-ordination with EU-policies and programmes

2 Scientific summary

2.1 Concepts, methodologies, typologies and indicators

This section first presents the main indicators for the project, and examines information concerning territories as statistical, analytical and typological geographical units. Secondly, it gives an overview of the overall methodological framework of the project.

2.2 Indicators, typologies and methodology

Chapter 2 of the Final report Part IIA presents our main indicators for the project, and goes through information concerning territories as statistical, analytical and typological geographical units.

2.2.1 Indicators

The following indicators are presented as the main indicators for the project:

- Unemployment rate 1995-2001, total, and according to age and gender, active population (numbers) (ESPON data base)
- Lagging regions (lagging, non-lagging, potentially lagging) (ESPON database)
- Urban / rural / settlement structure – FUA (ESPON database)
- Fishery dependency indicators, 1997 (Regional Socio-Economic Studies on Employment and the level of Dependency on Fishing, 1999)
- GDP per inhabitant and total, 1995-2000 (ESPON database)
- Population density (1995-99) and average population, 1995-2000 (ESPON database)
- Potential accessibility by road, 2001 and accessibility indicators of population to market by car, 1999 and 2000 (ESPON database)
- Percentage of stocks outside safe biological limits, 1960-2000 (ICES, GFCM)
- Aquaculture production (National sources, FAO/FIDI, Eurostat)
- Regional water indicators (OECD and Eurostat)
- Land use indicators (OECD, Eurostat and CORINE Land Cover database)

2.2.2 Typologisation

NUTS and typologisation

The NUTS territories used for typologisation by ESPON differs from the geographical units you would usually prefer for typologisation (as homogeneous territories as possible) as they are generally very heterogeneous geographical units. Heterogeneous territories

will reduce the possibilities for statistical differentiation between territories in scientific analysis, and will also make the possibilities for and results based on typologisation more diffuse. Heterogeneity can probably in some instances be less of a problem if the territories to be typologised constitute functional urban regions, for even though these regions will have great internal differentiation, they will also constitute separate urban regions and separate parts of larger urban systems, with possible non-urban areas outside the defined urban regions being typologised separately. We can say that:

- The NUTS 3 territories, which are employed as geographical level for most typological work within ESPON can not be looked upon as functional regions in any other sense than as administrative territorial units and/or as territorial units created for a specific purpose.
- With few exceptions, the NUTS 3 level is not constituted by bounded areas with a kind of internal homogeneity that distinguish them from surrounding areas.
- Homogenous geographical units are the units that will give the greatest difference between geographical units.
- Typologies of NUTS regions based on average scores (average in the meaning that it is the aggregate of statistics for smaller territories that is not available) will, by concealing the great internal variation within each territory as a rule conceal more than it reveals, even though the availability of statistics for comparison between territorial levels between nations will often make use of such 'averages' necessary.
- When dealing with NUTS 3 territories one should therefore ideally strive to include information on the heterogeneity of the territories. This can best be done in connection with a kind of criterion for functional regions.
- Whatever technique one might use for the typological work, this can not change the fact that mapping/analysis on the NUTS 3 level still involves the heterogenisation described above.
- Independent of typological methodology, use of NUTS 3 territories as opposed to smaller geographical units reduces variation between the coastal types in the statistical analysis.
- Even though the criteria for a territorial typology might be sound, the fact that internal variation between municipalities in a number of NUTS 3 units will probably be greater than the variation between NUTS 3 units, will imply that the geographical level for which the typology is used to describe differentiation can possibly make it unfit for analysis of certain processes that are primarily operating on another geographical level than the one used for typologisation.
- The typology will however show quite marked differences between different coastal regions for the indicators being typologised.
- As impacts of the fisheries sector will probably be very unevenly spread within most NUTS territories, making the averages of heterogeneous NUTS territories potentially unsuitable in the analysis, classifications that is based on homogeneity instead of averages for entire NUTS territories, like structure fund zones can be very useful
- In many cases, however, typologies that are classified according to situation, i.e. relative location seems easier to use without modification than those based on site, where the problem of heterogeneity will more often present difficulties.
- There is a need for structural indicators that can be used to identify in which kind of economies we will find impacts of the fisheries policy.

Rules for typologisation

For the typological work on the requested main coastal typology, the rules below were made to give structure to the typology. A main typology of coastal regions based on NUTS 3 regions should:

- include every NUTS 3 regions within ESPON with a coastline, i.e. territories bordering an ocean
- partly be based on previous ESPON typologies
- differentiate between typological elements and a main typology
- take specific coastal issues into consideration
- be both site and situation oriented
- to some extent be based on statistics at lower geographical levels than NUTS 3 or typological elements based on such geographical levels – which means that the typology should include internal diversity in each NUTS 3 region as a criterion, and connected to this;
- include a criterion for *functional regions within the territories*, which also means that;
- it should be possible for example studies in smaller geographical areas to be connected to a sub territorial geographical typological level within the NUTS 3 region
- define typologies where the difference between regions within each type should be as small as possible, and difference between types as big as possible for analysis within the aim of the project (which is made difficult by the geographical level to be used for the typology)

The main typology

The purpose behind the typology is to contribute to studies of regional variation in *coastal* territories, where it aims at providing a useful basis for analysing differences between regions according to their relation to Functional Urban Areas and population density.

As stated in chapter 2 in the Final Report Part IIA, the main typology should express information from some of the typological elements. The most basic requirement for being included is of course that the NUTS territory should have a coastline. It seems necessary also to include the FUA typology. The last element of the typology is population density. The main classification of the coastal regions is (for meaning of the coding, see chapter 2 Final Report Part IIA).

	FUA coding	Population density coding	Description
1.	000, 00, 01, 02, 03, 04	1, 2	NUTS 3 territories with no FUA centre, and very low population density
2.	000, 00, 01, 02, 03, 04	3	NUTS 3 territories with no FUA centre, population densities at least 50 per cent of European average
3.	000, 00, 01, 02, 03, 04	4, 5	NUTS 3 territories with no FUA centre, population densities at least on European average
4.	21, 22	1, 2	Regional/local FUAs, not regional demographic dominance, low population density
5	21, 22	3, 4, 5	Regional/local FUAs, not regional demographic dominance, medium or high population density
6.	23, 24	1, 2	Regional/local FUAs, regional demographic dominance, low population density
7.	23, 24	3, 4, 5	Regional/local FUAs, regional demographic dominance, medium or high population density
8.	31, 32, 33, 34	1, 2, 3, 4, 5 1, 2 1	Transnational/national, not regional demographic dominance
9.	33, 34	3, 4, 5, 2, 3, 4, 5	Transnational/national, regional demographic dominance
10.	41, 42, 43, 44	1, 2, 3, 4, 5	MEGA, regional demographic dominance

For NUTS territories of the transnational/national and MEGA types, there will not be any NUTS region with low population density unless most of the territory is without population, making a distinction according to population density meaningless.

A map of the typology of coastal regions at NUTS 3 level is presented below.

There is an option for reducing the number of types to eight when analysing on the NUTS 3 level by reducing the number of hinterland types to one by including the hinterland 3 type NUTS territories with their central city. The typology as presented above should still be regarded as the main typology, as one of the principles behind its structure is the possibility of using it on different geographical levels. At the NUTS 3 level there is no territory within the hinterland 2 type, automatically reducing the number to nine, but, essentially, without changing the rules for inclusion in hinterland 1. The three territories in the hinterland 3 type are included in the city regions where they belong to the suburbs. Reduced to eight coastal types, the list of types is:

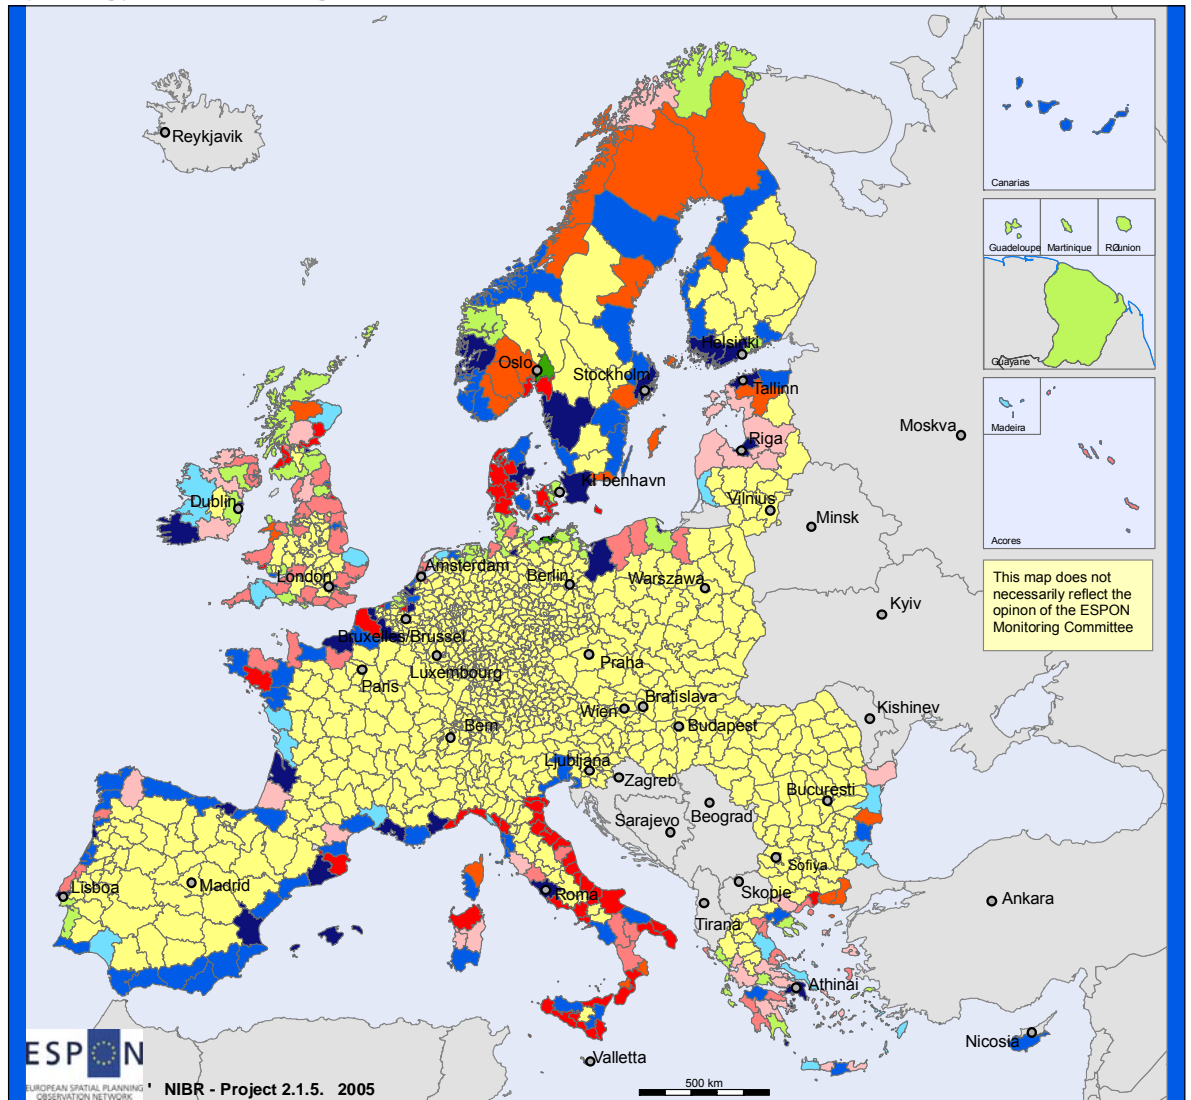

1. Hinterland
2. Regional/local 1
3. Regional/local 2
4. Regional/local 3
5. Regional/local 4
6. Transnational/national 1

7. Transnational/national 2
8. Mega

Chapter 5 presents a typology of fisheries specialisation on the NUTS 2 level for Norway and EU15 (except Ireland, the Netherlands and Belgium, with NUTS 3 level used for Denmark). The indexation is at the national level in each country, which means that what we get to grips with is the differentiation within each nation. Differences in the statistical sources means that a serious presentation with index level = 100 for ESPON Space is ruled out for presentation. This means that we have a map that can be related to national implementation for the EU countries, but at the same time should be very carefully interpreted, as the highest levels of employment in the fisheries sector will not necessarily have the highest indexes for fisheries specialisation. When not considering the problems of geographical level, the methodology is however both simple, sound and to the point. The fact that this typology is at the NUTS2 level and that the coastal typology is on the NUTS3 level mean that no direct comparison between the two levels is possible, but some indications can be made. The higher levels of national fisheries specialisation is however principally found in regions with smaller FUA centres or with no FUA centre at all.

Figure 2.1 Typology of coastal regions (NUTS 3)

Typology of coastal regions (NUTS 3)

NUTS 3 Coastal Typology

- No coast
- Hinterland 1
- Hinterland 3
- Regional/local 1
- Regional/local 2
- Regional/local 3
- Regional/local 4
- Transnational/national 1
- Transnational/national 2
- Mega

2.2.3 Methodology for territorial impact analyses

The overall framework for the methodology in the project is founded on:

- (i) the tender document of the project, where its thematic scope and context have been decided and the general objectives have been addressed
- (ii) the Territorial Impact Analysis (TIA) as elaborated by ESPON project 3.1

In ESPON and ESDP the term TIA is related to Territorial Impact Assessment, which has been used as “a tool for analysing, assessing and evaluating the impacts of certain projects on the spatial development of the surrounding territory”. At the most basic level, the specific methodological shape of the TIA of any ESPON impact study is said to relate to on the one hand territorial data characteristics (relevance, reliability etc.) and on the other hand to subject matter data characteristics: policy with or without endogenous territorial intentions, certain programmes, single interventions/projects. There has, however, not been established a common assessment methodology within the ESPON impact studies as it is acknowledged that it is hardly possible to use one assessment methodology for the entire range of sectoral policies of the EU. This is partly due to the fact that:

- the EU policy programmes concerned are still far away from actually taking into account territorial objectives despite having clear potential territorial impacts
- they show a dramatic lack of territorial differentiation of data on policy implication
- the elaboration of spatial development goals in the wake of ESDP is still going on, and has hardly achieved results operational for assessment application so far

Two key concepts are regarded to have a “genuine territorial dimension”, namely: ‘territorial cohesion’ and ‘polycentric development’. Polycentric development, however, can be seen as a spatialised expression of territorial cohesion.

Territorial cohesion is a concept for the balanced distribution of human activities across the EU, translating the EU goal of sustainable and balanced development into territorial terms. It is a complementary concept to economic and social cohesion. The following dimensions are relevant for an operationalisation of territorial cohesion:

- domains (thematic layers) – for ESPON the most relevant are probably ESDPs “triangle of sustainability”; economy, environment and society
- components of territory – its own features (potential), its features with regard to those of other territories (position) which enables potential interactions with them, and its effective interactions (exchanges, cooperation) with other territories (integration)
- scale(s) – for the ESPON project a three level reference set have been developed; macro (European level), meso (transnational/national level) and micro (regional/local level)

Polycentric spatial development is regarded as a ‘bridging concept’ as it merges the two policy aims of ESDP; economic growth and balanced development. Polycentricity can refer to different geographical levels (cf. scale in the discussion of territorial cohesion). The most important level for ESPON 2.1.5 is the regional/local level. The aim here is to increase the number of centres providing regional services from one or a few dominating ones, in which fisheries should be viewed in the light of the division of labour and functional specialisation within the regional urban system. Polycentricity on the transnational/national level might also be of importance, as the fisheries in some instances can

be an aspect of the aim of a more balanced tissue of cities. For polycentricity at the global or European level fisheries are of only minor importance today. Polycentricity can also be linked to the division into micro, meso and macro perspectives.

The TIA manual has been, as proposed by project 3.1, regarded as a kind of check-list for scoping, analysing and assessing within the impact chapters.

Mapping and example studies

When looking at impacts of fisheries policies in polycentric terms, the national level and levels below the national one stands out as the most relevant ones for impacts on the geographical levels defined by ESPON. This implies that example studies should be central in the 2.1.5 project, and that the European level primarily constitutes a geographical level for mapping fisheries and for typological work, and to a lesser extent is a feasible reference territorial level for much of the analysis. Due to statistics deficiencies, the example studies have become more central for the Final report than originally perceived. The use of example studies might imply a:

- Compilation of the policy measures in *certain regions*, recording what spatial development goals they follow, and that
- The structural status/changes in these regions should be evaluated against the chosen spatial development goals

The TIA manual emphasise the importance of using cause-effect relations in the past as the basis for predicting the effects of future interventions. Since changes in CFP are quite new this implies that the project must focus on similar experiences of former changes in CFP in order to make evaluations of new changes in EU policy.

Specific comments based on the experiences of the different WPs with the TIA are included in the impact chapters. One important general experience when considering the use of TIA in territorial impact analysis of fisheries policy is the lack of data at the relevant geographical level, i.e. on the NUTS 3 level or lower. This is related to the fact that territorial impacts of fisheries policy primarily are territorially significant on lower geographical levels.

2.3 Networking and co-operation

There has been all together four project meetings in the project period. First, a kick-off meeting in Oslo, Norway, 1st November 2004, then a meeting in Salerno, Italy, 7-8. February 2005, the third meeting took place in Tallin, Estonia, 15-16. September 2005, and the last meeting was in Santiago de Campostela 6-7th April 2006. Preparation of the interim reports has been the main topic at the different meetings. Discussions have concentrated on indicators, typologies, tools, methods and policy recommendations, and to questions of scientific harmonisation and ESPON guidelines. Particular attention has also been paid to the increased significance of example studies in project 2.1.5, due to lack of appropriate data on NUTS 3 level.

The lead partner has also attended lead partner meetings and ESPON seminars in the project period. Several of these meetings and seminars have focussed on the scientific platform for ESPON projects, and particularly on indicators, typologies and methods for territorial assessment. The project leader and the Norwegian ECP which also takes part in the 2.1.5, have participated in all ESPON seminars during the project period, and latest at ESPON ECP SEMINAR – COBALT on Territorial Cohesion & Coordination in the BSR, 24-25th April 2006.

The lead partner has been and still is involved in other ESPON projects (1.1.1, 1.1.4, 2.4.2 and 1.4.5), and has previously commented on drafts for the final reports of ESPON projects, such as the CAP impact study 2.1.3 and on the Urban-rural project 1.1.2. All this ESPON activity has clearly benefited the project.

2.4 Data gaps and their research consequences

The data gaps in the project are many, but we have managed to include much relevant statistics from many of the most important countries within the European fisheries. This has influenced our decision of a stronger focus on example studies than originally intended. Even if the statistical catch had been perfect at the NUTS 3 level, many of our hypotheses would require the inclusion of example studies based on statistics for smaller geographical territories. The data gaps are further discussed in chapter 2.19.

The need for example studies was originally seen as essential for the ability to look into matters concerning developments on the urban-rural dimension, like possible tendencies for concentration of activity within fishing to urban centres (even though in many cases seafood industries are still located in areas outside commuting distance to cities and with few alternative income sources). The local context is important also when excluding an urban-rural focus, as the fishing industry still plays an important role in an otherwise underdeveloped rural economy in some parts of Europe.

We relate the ESPON Space analysis to the macro scale, viewing the macro scale as directly related to CFP, and use the example studies for analysis from the national perspective (micro scale), where this perspective is related to the national implementation of the CFP. When discussing the impacts of fisheries policies, the meso scale seems to be of minor relevance. The meso scale seems more relevant for ICZM than for the fisheries sector.

2.5 Future research

Below is listed several topics for further research based on ideas with the work on ESPON 2.1.5. The proposals are more elaborated later in the report.

- One should compare several sector policies in different coastal regions (area studies) in order to analyse territorial impacts in a more comprehensive way, and to search for possible potentials and obstacles in different regions. The typology for coastal regions (NUTS 3) developed in 2.1.5 could be used for selecting the different regions.
- Typologies on ESPON space do not always function well and particularly in territorial impact projects one should try to combine European typologies with national typologies (use national average) as a kind of combined macro and micro approach in analyses.
- Data and indicators are key elements in ESPON programmes and one should strive for a better organisation of collection and use of data, for instance by developing a common Eurostat/ESPON database which is divided in a statistical database and an indicator database. Data should also be regionalised as far as possible.
- The RACs will possibly play an increasingly important role in future EU fisheries management, and it is worth looking into what kind of statistical data will be most relevant for the RACs in their future work.

- With regard to fishery one should undertake a dedicated pan-European data-collection study within the fisheries sector, supplementing the experiences in ESPON 2.1.5.
- There is need for more research on the status and the content of the territorial fisheries system in Europe, based on both statistical indicators as well as case studies.
- One could put more effort into in-depth analysis of territorial aspects of the implementation of financial instruments such as FIFG.
- Fisheries and aquaculture should be analysed in a polycentric perspective and promote the creation of specialization poles/clusters and innovation
- Study the promotion of improvements related to the recovery of immaterial and material aspects of fisheries heritage and other coastal cultural heritage as new strategies for revitalization of the coastal regional economy
- Study strategies that are developed in order to promote a better integration of immigrants in order to meet the decline in labour supply, and which may introduce a new logic of spatial concentration in small-medium size urban settlement
- Carry out more in-depth analysis of economic diversification in regions highly dependent on fishing, study best practice, and use models which are also applicable to other areas
- The strong promotion and spread of aquaculture within fisheries communities are creating new patterns of socioeconomic relations which should be further analysed.
- Further analysis of social problems, immigration into coastal areas, the matters of gender in a changing sector, and particularly the role of the female labour force in this sector
- The implications of the CFP taking an ecosystem approach to fisheries (EAF) on the attainment of social objectives that are defined for terrestrial, administrative areas, should be further analysed. The socio-economic information needed for EAF should be available at scales that match the availability of biological and other natural science based information.
- There is a need for more research on how different ICZM approaches function as tools for a sustainable and balanced development of the aquaculture industry. The role of the Water Framework Directive should also be focused because it gives a common framework for an ecosystem management of water resources across European countries.

PART 2 Results of the Project: Mapping

1 Introduction

1.1 Background and aim of the project

The European fisheries policy (CFP) is regarded as one of the sector policies with substantial implications for amongst others employment, cohesion and regional economic strength, and particularly in some coastal regions and in fisheries dependent areas. In accordance with this, the purpose of ESPON Project 2.1.5 is to strengthen the knowledge of territorial, social and economic cohesion through an analysis of territorial impacts of the (CFP).

Territorial cohesion calls for policies that reduce disparities and promote a more balanced and sustainable development of the European territory in line with the European Spatial Development Perspective (ESDP). It was presented as a third dimension of cohesion in addition to economic and social cohesion in the Second and Third Report on Economic and Social Cohesion from January 2001 and February 2004 respectively. Territorial cohesion calls for a better coordination of territorially relevant decisions. This implies for example the identification of needs for further studies of territorial impacts of structural as well as sector policies.

Fishing and aquaculture are two of the most important sectors which use and produce living resources (European Environment Agency 2002), and both sectors are undergoing profound changes. The most recent changes in the European Fisheries Policy (CFP) were adopted in late 2002, and a number of measures will be implemented in the near future. The main aim of the changes is to strengthen the competitiveness of the sector and to ensure its sustainability. The policy includes:

- Conservation of fish stocks
- Restructuring of fishing and fish farming
- Organisation of the market for fish and associated products and agreements on fishing with third countries (European Commission 2004)
- Agreements on fishing with third countries (European Commission 2004)²

The most important changes with likely implications for the fishing industry, and particularly for employment in the sector are:

- Multi-annual management plans for all stocks
- Reductions in quotas
- Reductions in the fishing fleet
- Limitations on how, when and where fishing can take place

² A new partnership for cohesion. Third report on economic and social cohesion.

- Limitations on financial support for modernizing and building of new vessels

There has been a significant change in the fishery policies and fisheries sector within the EU and in the EFTA area (Norway and Iceland) even though the CFP is not a part of the EEA agreement. Fisheries and aquaculture plays a varying role in the economy of different countries and regions within the ESPON space, and impacts from structural changes and policy regulations will accordingly vary in different parts in Europe. A main tendency in recent years has been a concentration of activity within fishing to urban centres, but in many cases seafood industries are still located in areas outside commuting distance to cities and with few alternative income sources. In some parts of Europe, the fishing industry still plays an important role in an otherwise underdeveloped rural economy. The Third Cohesion Report points out that CFP will have significant effects on a number of regional economies within the EU, and especially in Spain and Portugal.

Employment in the aquaculture sub sector has increased in recent years and this development is expected to continue. Aquaculture, therefore, may represent an important factor of the reinforcement of territorial and socio-economic cohesion in some regions. Aquaculture also plays an increasing role in the supply of seafood. The challenges within this industry differ from those in the fishing industry, as the aquaculture industry is more regionally concentrated. It is located in the coastal zone, and competes with or has impacts on other activities and interests in the coastal zone. Balancing of the different interests has to be solved through the concept of integrated coastal zone management (ICZM). Processes of restructuring, reduction, expansion and development are therefore occurring side by side and in various combinations within the seafood industry in Europe. The effect of this will vary between regions and the territorial impacts on short and long term will also be different. The changes, the diversity of effects, the potentials and the spatial impacts constitute the thematic frame for the project on fisheries and aquaculture.

There are some specific challenges with regard to the time period for the impact analysis. The planned reference period for the project is from 1990 – 2003/2004. Changes in CFP, however, did not take place before late 2002 and many measures have just been implemented or are about to be implemented. Data for many of the indicators will at best be available up to 2003/2004 within the project period. It will therefore be difficult to relate impacts directly to the 2002 changes in CFP. However, structural changes have taken place in the fisheries and aquaculture, and policy measures have also been carried out within the fishery policy during the years prior to 2002 in many European countries. Therefore, it should be possible to analyse the impact of almost similar type of changes which are assumed to follow from CFP. Fleet reduction and quotas, for instance, have been introduced long time before the CFP was implemented.

1.2 Impact analysis and geographical level

Changes in European Fisheries Policy (CFP) involve capture fisheries, processing and aquaculture. These sub-sectors have different dynamics, different technologies, and different use of territory. Fishing and aquaculture, however, are both elements in what may be called the European Seafood Industry. They are often located in the same regions and they are subjected to the same sector policy. Changes in CFP, however, are only one of several external factors which may have territorial impacts on coastal regions and fishery dependent areas. Methodological questions related to impact analysis are discussed in chapter 2, and in the specific impact chapters 4-6 in the final report Part 2.

The analysis of territorial impacts of changes in CFP, will concentrate on the following elements:

- Impacts on employment, social cohesion and demography
- Impacts on regional economic strength
- Impacts on environment and coastal zone management

The most central impacts resulting from changes in the CFP are probably connected to a decrease of landed fish resources. The project examines these impacts with regard to territorial balance and cohesion on different geographical levels. Changes in CFP do not affect all regions in the same way, and to the same extent. However, a large majority of fisheries dependent regions are in objective 1 or objective 2 areas (or similar outside the EU). Accordingly, a starting point for our study has been to identify and categorise the diversity of coastal regions in Europe, cf. chapter 2 Indicators, typologies and territorial methodology in final report Part 2.

The study of territorial/ spatial impacts has been done with references to the aims of cohesion, territorial balanced and sustainable development and also ESDP-perspectives focusing on polycentric development (cf. ESPON 1.1.1). In particular, the project has studied:

- The position of coastal regions in developing of the territorial system of EU and of specific countries. Of particular importance is CFP impacts on the disparities between regions within EU and inside the different nations.
- The position of the coastal regions in the overall Community policies (as the ESDP) and the structural policies (as the Cohesion fund, ERDF, ESF). Questions related to the coastal regions' in-/out phasing in different types of regional policy measures, are of specific importance in the study. Cf. those questions mentioned above and the need for specific policies interventions in fisheries regions as "restructuring of the fisheries sector outside the objective 1 area".
- The territorial development inside coastal regions. The project has through several example studies conducted regional/area analyses on different geographical levels, amongst other by using data on LAU levels for spatial analyses inside selected NUTS territories. The analyses has been related to ESDP perspectives as polycentric development and a balanced rural-urban development.
- Demographic-, social- and economic changes inside coastal regions, and inside different types of coastal regions in order to identify the regions which most negatively and positively affected by changes in European fisheries policy.

1.3 Project meetings, networking and references to other ESPON projects

There has been all together four project meetings in the project period. First, a kick-off meeting in Oslo, Norway, 1st November 2004, then a meeting in Salerno, Italy, 7-8. February 2005, the third meeting took place in Tallin, Estonia, 15-16. September 2005, and the last meeting was in Santiago de Campostela 6-7th April 2006. Preparation of the interim reports has been the main topic at the different meetings. Discussion has concentrated on indicators, typologies, tools, methods and policy recommendations, and to questions of scientific harmonisation and ESPON guidelines. Particular attention has also been paid to the increased significance of example studies in project 2.1.5 , due to lack of appropriate data on NUTS 3 level.

The lead partner has also attended lead partner meetings and ESPON seminars in the project period. Several of these meetings and seminars have focussed on the scientific platform for ESPON projects, and particularly on indicators, typologies and methods for territorial assessment. The project leader and the Norwegian ECP which also takes part in the 2.1.5, have participated in all ESPON seminars during the project period, and latest at ESPON ECP SEMINAR – COBALT on Territorial Cohesion & Coordination in the BSR, 24-25th April 2006.

The lead partner has been and still is involved in other ESPON projects (1.1.1, 1.1.4, 2.4.2 and 1.4.5), and has previously commented on drafts for the final reports of ESPON projects, such as the CAP impact study 2.1.3 and on the Urban-rural project 1.1.2. All this ESPON activity has clearly benefited the project.

1.4 Final report and further research

Due to large problem with data collection, and lack of data on NUTS 3 level, it has not been possible to carry out so extensive analyses as planned for in the final report, cf. scientific summary, Part I. However, as mentioned in the second and the third interim report example studies have become more important in the project, and Part IIB of the final report presents eight example studies based on data on a lower geographical level, i.e. below NUTS3 level.

Some of the statistics for certain countries which were made available for the project has not been utilised by all work packages. This is the case for Norway, for instance. It is therefore necessary to adjust and supplement some of the analyses in the draft final report, amongst other some of the impact analyses in WP4.

Completed files of specific fishery data for the project will be delivered, including Iceland which do not take part in ESPON. However, the central position this nation have in European Fisheries makes it necessary to include it in order to get a comprehensive picture of these fisheries.

Topics for further research:

- One should compare several sector policies in different coastal regions (area studies) in order to analyse territorial impacts in a more comprehensive way, and to search for possible potentials and obstacles in different regions. The typology for coastal regions (NUTS 3) developed in 2.1.5 could be used for selecting the different regions.
- Typologies on ESPON space do not always function well and particularly in territorial impact projects one should try to combine European typologies with national typologies (use national average) as a kind of combined macro and micro approach in analyses.
- Data and indicators are key elements in ESPON programmes and one should strive for a better organisation of collection and use of data, for instance by developing a common Eurostat/ESPON database which is divided in a statistical database and an indicator database. Data should also be regionalised as far as possible.
- The RACs will possibly play an increasingly important role in future EU fisheries management, and it is worth looking into what kind of statistical data will be most relevant for the RACs in their future work.

- With regard to fishery one should undertake a dedicated pan-European data-collection study within the fisheries sector, supplementing the experiences in ESPON 2.1.5.
- There is need for more research on the status and the content of the territorial fisheries system in Europe, based on both statistical indicators as well as case studies.
- One could put more effort into in-depth analysis of territorial aspects of the implementation of financial instruments such as FIG.
- Fisheries and aquaculture should be analysed in a polycentric perspective and promote the creation of specialization poles/clusters and innovation
- Study the promotion of improvements related to the recovery of immaterial and material aspects of fisheries heritage and other coastal cultural heritage as new strategies for revitalization of the coastal regional economy
- Study strategies that are developed in order to promote a better integration of immigrants in order to meet the decline in labour supply, and which may introduce a new logic of spatial concentration in small-medium size urban settlement
- Carry out more in-depth analysis of economic diversification in regions highly dependent on fishing, study best practice, and use models which are also applicable to other areas
- The strong promotion and spread of aquaculture within fisheries communities are creating new patterns of socioeconomic relations which should be further analysed.
- Further analysis of social problems, immigration into coastal areas, the matters of gender in a changing sector, and particularly the role of the female labour force in this sector
- The implications of the CFP taking an ecosystem approach to fisheries (EAF) on the attainment of social objectives that are defined for terrestrial, administrative areas, should be further analysed. The socio-economic information needed for EAF should be available at scales that match the availability of biological and other natural science based information.
- There is a need for more research on how different ICZM approaches function as tools for a sustainable and balanced development of the aquaculture industry. The role of the Water Framework Directive should also be focused because it gives a common framework for an ecosystem management of water resources across European countries.

1.5 Expected results in the final report and structure of the report

The Final report should cover the following elements listed in Terms of Reference (ToR):

- a) Final report covering the issues mentioned below (under point m)) with clear policy recommendations in relation to coastal regions and impacts of ICZM processes, including possible policy adjustments regarding the sector policy in order to avoid unintended spatial effects in relation to policy orientation in the ESDP and future Structural Funds policy (taking into account as well the international factors affecting the European fishery sector);

- b) Methodological paper on the method used in project on territorial impact assessment of the investigated sector policy
- c) Presentation of final territorial indicators and maps for the ESPON database and map collection;
- d) Formulation of the further research necessary in field of territorial impacts of European Fisheries policies.

m) Presentation of a comprehensive working report on tentative results of the research, applying the methodology, analysis of the hypothesis previously developed, including the following elements:

- Draft final analysis /diagnosis of the fisheries and aquaculture sector in Europe as well as the existing territorial imbalances and regional disparities in fisheries/aquaculture;
- Presentation and description of a European coastal typology and the diversity of the fishing industry related to the typology;
- Tentative results on the spatial effects at European level, in individual countries and their coastal areas in terms of the economic, social and environmental factors;
- Tentative results on territorial impacts in relation to ICZM activities in different types of coastal regions;
- Draft policy recommendations on improvement of the sector policy and the instruments in favour of territorial cohesion, balance and polycentrism, including institutional aspects.

1.

The letter m) concerns aspects which are dealt with in all work packages in the project. The first bullet point is dealt with in WP2, whereas the second point is dealt with in WP1. The third bullet point is dealt with in WP 3, 4 and 5 respectively, while WP5 also deals with the fourth bullet point. The last bullet point is dealt with in WP3, 4 and 5. Maps are an integrated part of the Final report.

The report is organised in four parts. Part 1 contains the executive and scientific summary of the report. Part 2 presents the results of the mapping analyses in the project. Part 3 lines out the example studies in the project, and Part 4 contains the annexes of the report. References in Part 2 of the Final report are organised according to the chapters, whereas annexes are more thematically organised.

Part 1 of the Final report is divided in an executive and a scientific summary in order to present substantial findings and theoretical and methodological questions in a perspicuous manner. Part 2 of the Final report follows a structure that highlights the substantial work packages in chapter 3-6, whereas chapters 2 are of a more general and integrating nature. Part 3 of the Final report gives a short introduction to the example studies and then presents the studies grouped by geographical areas from north to south in ESPON Space.

The structure of Part 2 of the Final report after the introductory chapter is as follows:

Chapter 2; Indicators, typologies and territorial methodology, presents a preliminary list of the main indicators and data to be used for impact analyses of the WPs covered by chapter 3-6. It also includes relevant typologies from other ESPON projects and a typology of the coastal regions. The chapter also contains a discussion of the NUTS territories as territorial levels for typologisation and analysis; a presentation of territorial impact analysis with comments on experiences with TIA; and the hypotheses for the

project, grouped in various categories. During the project the preliminary hypotheses have been applied, further developed and partly revised by the different work packages, and these specific and/or sub hypotheses are included in the respective chapters in Part 2 and in the example studies in Part 3.

Chapter 3-6 are structured in accordance with the different impact WPs. Chapter 3 gives a draft final analysis/diagnosis of CFP and the policy in the EFTA countries Iceland and Norway. Chapter 4 presents the results of environmental impacts and integrated coastal zone management (ICZM). Chapter 5 lays out the results of social cohesion impacts of CFP, looking into demography, unemployment etc, whereas chapter 6 deals with economic cohesion impacts and presents a cluster analysis in order to identify different categories of regions with specific fisheries related characteristics.

Chapter 7 presents the conclusions and policy recommendations according to the rules set down by the Nijmegen Guidance Paper.

2 Indicators, typologies and territorial methodology

This chapter deals with the data situation of the project, and lists the main indicators as defined by the different WPs. It also relates the analysis to relevant geographical levels, to typologies from other ESPON projects, and to typologies developed within the project.

2.1 Territorial impacts studies on fisheries

Territorial impacts are primarily discussed in chapter 4-6, which means that we in this chapter shall make only some general comments for the project at large. The project include three major types of concepts and methodology where the overall research question is how the changes of CFP impacts on:

- The position of coastal regions in the territorial systems of higher level (EU and country level);
- The position of the coastal regions in overall policies and particularly in structural policy;
- The restructuring processes inside coastal regions

The challenge of these three issues is to be able to examine the relations between the implementation of fisheries policy changes and changes in the territorial systems and in the socio-economic structures. The intention has been to solve that problem by putting high effort on developing specific studies of where the policies changes in the fisheries are implemented. With regard to the restructuring processes inside coastal regions, there are several problems related to the geographical levels on which socio-economic data is available, which means that data for the smaller regions can not be presented for ESPON Space. LAU levels are primarily desirable for example studies. There are three possible ways to conduct such example studies for the project that we want to utilise, namely to:

- make use of information from evaluations of Interreg IIIB projects
- make use of relevant research projects already completed
- make an analysis based on statistics from countries with relevant data on lower geographical levels

The use of example studies makes the combination of ESPON macro- meso- and micro scale better for the impact analysis. While the mapping involves the macro scale, the use of Interreg projects and to some extent of relevant research projects already completed involves the meso scale. Other research projects already completed and analysis based on statistics from countries with relevant data on lower geographical levels will constitute our studies on the micro level. For studies of impacts of fisheries policies the meso scale

is more difficult than the others, as this level is really irrelevant for much of the policy impacts, but research on aquaculture can be important, as we recently have witnessed for lobster.

2.2 Suggested main indicators

The analysis on territorial impacts of changes in CFP will concentrate on environment and coastal zone management (chapter 4) employment, social cohesion and demography (chapter 5), and regional economic strength (chapter 6). This means partly to carry out the analysis based on fishery specific statistics, and partly to utilise statistics gathered by and analysed for other sectors by other ESPON impact or thematic projects. Sharing statistics with other impact studies are important for comparability with other impact projects. In developing indicators it is important to bear in mind that they should:

- Be limited in number;
- Be easy to read, relevant and consistent.

As part of the project we have wanted to develop a limited number of indicators that are easy to read, and that are relevant and consistent. The following main indicators were decided upon for the project:

- Unemployment rate 1995-2001, total, and according to age and gender, active population (numbers) (ESPON data base)
- Lagging regions (lagging, non-lagging, potentially lagging) (ESPON data base)
- Urban / rural / settlement structure – FUA (ESPON data base)
- Fishery dependency indicators, 1997 (Regional Socio-Economic Studies on Employment and the level of Dependency on Fishing, 1999)
- GDP per inhabitant and total, 1995-2000 (ESPON database)
- Population density (1995-99) and average population 1995-2000 (ESPON database)
- Potential accessibility by road, 2001 and accessibility indicators of population to market by car, 1999 and 2000 (ESPON database)
- Percentage of stocks outside safe biological limits, 1960-2000 (ICES, GFCM)
- Aquaculture production, (National sources, FAO/FIDI, Eurostat)

Due to the statistical situation for much of the fisheries specific statistics of the project, more of the ESPON Space mapping have had to be conducted on either the NUTS 2 level or on the national level than we would ideally have wanted. The example studies are not limited by availability of statistics to the same extent as the mapping of ESPON coastal space.

2.3 A typology of coastal regions

A typology of coastal regions was mentioned already in the Crete Guidance Paper as one among the typologies for specific geographical situations. All NUTS 2 and NUTS 3 territories with coastline was identified and included in the ESPON data base. As the coastal regions are part of the larger ESPON territory, this could to some extent be viewed as sufficient, as the typologies defined by other ESPON projects could be used to

compare the identified coastal regions with other geographically defined territories within ESPON space. This could answer the need to differentiate between types of coastal regions, and not only tell if a region has a coastline or not. However, a typology is linked to a defined purpose, meaning that a relevant typology is not the same as placing together different typologies or using different typologies developed for other ESPON projects for NUTS territories with a coastline. A specific coastal typology should therefore combine a specific aim with selected techniques of delimitation and relevant available data, where the purpose defined for the typology should guide the construction of it.

The purpose behind this typology is to contribute to studies of regional variation in coastal territories, where it aims at providing a useful basis for analysing differences between regions according to their relation to Functional Urban Areas and population density.

Before presenting the typology, we will make some conceptualisations and make a short evaluation of the NUTS 3 units as geographical level for typologisation, make some preliminary comparisons between coastal and other NUTS territories, and present what we think is the basic requirements for a standard typology of coastal regions.

2.4 Typologies, classifications and indicators; a conceptualisation

When making a typology there is need for a set of concepts to distinguish as clearly as possible between different meanings. For this chapter the following distinctions have been made:

A *typological element* is a classification of a single phenomenon that is developed as one of the building blocks of a typology.

A *typology* is a grouping that is constructed on the basis of at least two typological elements to be used in a specific project.

A *standard typology* is a grouping that is constructed on the basis of at least two typological elements to be used as an authoritative typology also outside of a specific project.

A *classification* is a grouping of a single phenomenon to be used in a specific project. A classification is not developed as a building block of a typology.

A *standard classification* is a classification of a single phenomenon that is to be used as an authoritative classification of the selected phenomenon outside a specific project. The standard classification is not developed as a building block of a typology.

A *key indicator* is a tool developed for the political sphere for selection, filtration, comprimation, and concentration, simplification, processing and making accessible information for clearly defined purposes (Foss 2004), while **a *core indicator*** is an indicator as defined by social sciences.

A number of standard classifications from other ESPON projects should ideally be included in the analyses of the fisheries project, and so should some typological elements for the construction of the coastal typology, with possibly some alternative typologies for coastal regions made for special purposes. It could be argued that classifications and typologies already developed should be of primary importance, for the sake of comparison between ESPON projects. For each typological element there must be available statistics at the NUTS 3 level or a more detailed geographical level that makes it

possible to typologise the entire coastal ESPON. A standard classification on the other hand, can also be used if statistics is not available for the entire ESPON territory. A proposition for standard classifications and typological elements is described below. Indicators will be further discussed as part of the TIA.

2.5 NUTS 3 as territorial level for construction of typologies

The territorial level used for the construction of the coastal typology is the NUTS 3 level. This is also the main level for statistics used by the ESPON projects at large. With the exception of Luxembourg and Cyprus the states that are part of ESPON territory are represented with a national subdivision on this level, varying from Malta's two to Germany's 441 NUTS 3 territories. Being the most detailed of NUTS levels, the territories defined can be aggregated to the NUTS 2 and NUTS 1 levels. For statistical reasons and to secure comparability with other ESPON projects we use the NUTS division from 1999 as the basis for the typologisation.

According to NUTS regulation, NUTS 3 territories should fall within certain population thresholds, the minimum population for NUTS 3 territories should be 150 000 inhabitants, the maximum 800 000. The NUTS 3 territories do however comprise territories with population numbers outside the thresholds laid down by the regulations, as the territories often equals one of the administrative territorial levels within a country.

Territorial levels more detailed than NUTS 3, often referred to as NUTS 4 and NUTS 5, are today named "Local Administrative Units" (LAU), and are not subject to the NUTS Regulation. For typologisation of NUTS 3 territories the LAU levels are primarily of relevance for typological elements used to tell about the inner diversity of NUTS regions. They are also relevant for example studies on impacts of changes in fisheries policies.

The NUTS nomenclature serves according to Eurostat as a reference for:

- a. the collection, development and harmonisation of Community regional statistics
- b. the socio-economic analyses of the regions
- c. the framing of Community regional policies

The regions lagging behind (objective 1) have been classified on the NUTS 2 level, but areas eligible under the other priority objectives have mainly been classified at the NUTS 3 level. When making a typology of the coastal areas, we will in other words use the geographical territorial level most associated with regional priority objectives within the EU, which makes typologisations on NUTS levels seemingly highly relevant.

However; when making typologies based on geographical territories, one has to take into consideration the degree of homogeneity of the geographical units that are the basis for the typologisation. Geographical typologisation will usually be based on territories being as homogenous as possible. This makes typologisation of NUTS regions a great challenge, as they are generally very heterogeneous geographical units, and as such unfit for typologisations. Heterogeneous territories will reduce differentiation between territories, and the heterogeneity will also make the possibilities for typologisation more diffuse. Heterogeneity can be regarded as less of a problem if the territories to be typologised constitute functional urban regions, for even though these regions will have great internal differentiation, they will also constitute separate urban systems, with possible non-urban areas outside these regions being typologised separately.

The NUTS 3 territories which are used as the geographical level for most typological work within ESPON can not be looked upon as functional regions in any other sense than as administrative territorial units and/or as territorial units created for a specific purpose. With few exceptions the NUTS 3 level is not constituted by bounded areas with some kind of internal homogeneity that distinguish them from surrounding areas. In countries where the NUTS 3 territories are smaller and often constitute elements of larger regions, like in Germany, Belgium and the Netherlands, the diversity between NUTS 3 territories will be potentially much larger than in other countries (these more homogenous NUTS 3 territories falls mainly outside the coastal regions), resulting in potentially greater differences between geographical types and less difference within the types. In other words: Homogenous geographical units are the units that will give the greatest difference between geographical units. Typologies of NUTS territories based on average scores (average in the meaning that it is the aggregate of statistics for smaller territories that is not available) for the NUTS territories only, will therefore as a rule, by concealing the great internal variation within each territory conceal more than it reveals, even though the statistical situation can often make use of such averages necessary. To get a better grip on the NUTS 3 territories we will therefore also include some information on the heterogeneity of the territories. This can best be done in connection with a kind of criterion for functional regions.

One should however remember that whatever technical grip that might be used for the typological work, this does not change the fact that mapping/analysis being based on the NUTS 3 level still involves the heterogenisation described above when discussing such crude geographical levels. Independent of typological methodology, use of NUTS 3 territories as opposed to smaller geographical units reduces variation between the coastal types in the statistical analysis.

Even though the criteria for a territorial typology might be sound, the fact that internal variation between municipalities in a number of NUTS 3 units will probably be greater than the variation between NUTS 3 units, will imply that the geographical level the typology is used to describe can possibly make it unfit for analysis of certain processes that are primarily operating on another geographical level than the one used for typologisation. The typology will however be able to show quite marked differences between different coastal regions for the indicators being typologised.

2.6 Coastal NUTS 2 and NUTS 3 territories within ESPON space

The necessary first step in typologisation of the coastal regions is of course to identify the NUTS 3 and NUTS 2 territories with coastline. This has already been done by project 2.1.1 in ESPON. 29 percent of all NUTS 3 territories have a coastline (table 2.1), and as much as 48 percent of NUTS 2 regions (table 2.2). This illustrates well a point discussed above; the larger territories are more heterogeneous than those on more detailed geographical levels, which mean that typologisation based on the larger territories as a consequence of their larger heterogeneity reduces difference between the territories on that geographical level compared to smaller territories. Constructing a typology of coastal regions based on a territorial level that included almost half of the territorial units of that level within ESPON space would also be rather meaningless. If this makes the level meaningless for a coastal typology, it is of course still a level that can be used for analytical purposes in those parts of Europe where the NUTS 2 level is not identical to the national level.

Table 2.1 NUTS 3 territories with and without coastline. Nation and ESPON space.

The countries within ESPON space that will be totally excluded from a coastal typology are Luxembourg, Austria, the Czech Republic, Hungary, Slovakia and Switzerland. All the NUTS 3 territories of Denmark, Cyprus and Malta are on the other hand included. When looking at specific countries, there is a highly expected tendency for island countries and for countries covering a small surface area to have a large share of NUTS territories being coastal. These states also have relatively low population numbers. United Kingdom has the highest share of coastal NUTS 3-territories among the countries with high population numbers, but even being an island state, the share is still not higher than 62 percent. As the territories are generally smaller in countries with high population densities than elsewhere, this influences the share of registered coastal territories negatively. However, the smaller territories can influence results by their smallness. As very few German and Belgian NUTS 3 territories are coastal regions, the number of the small, more homogeneous territories found in these two countries and in the Netherlands has however little influence on the typology.

Table 2.2 NUTS 2 territories with and without coastline. Nation and ESPON space.

The number of countries with all their NUTS 2 territories included increases dramatically compared to on the NUTS 3 level. While all NUTS 3 territories has coastline in Denmark, Cyprus and Malta, the list of countries where all territories have coastline increase with Ireland, Portugal, Sweden, Estonia, Lithuania, Latvia, and Slovenia when looking at the NUTS 2 level. With exception of Ireland (2), Portugal (7) and Sweden (8) all these counties are represented with their national level on NUTS 2. There is in other words no regionalisation present for many coastal states on this level, which also means that a typology on this level would be very inappropriate, comparing regions and states, and with the possibilities for studies of *regional* impacts for the entire ESPON Space disappearing.

When comparing the consequences of using NUTS 2 or NUTS 3-territories for typologisations of coastal ESPON, some maps can be illustrative (figure 1.1 and 1.2). One can see from these maps that the coastal element is very much weaker when looking at the NUTS 2-territories than for the NUTS 3-territories. The map of the NUTS2-territories also shows that only two territories within the Nordic and Baltic countries combined falls outside of being registered as coastal. We do, in other words, not only face

a sub division that in some countries is not a sub division at all (with all the implications of comparing the fundamentally different territories of states with those of sub-divisions of a country), but a situation where the regional distribution of states versus sub divisions in regional meso terms means that the use of this level can bias results between larger European regions. The NUTS 2 level can in other words not be defined as a territorial level for a regional sub division of Europe, as it mixes states and sub divisions of states. It should therefore never be used unmodified in serious matters for comparison of the entire ESPON Space, but even in modified edition, comparisons between states with sub division at the level should really be avoided when possible. It is no coincidence that such a crude geographical level is generally avoided in serious analysis of the development within states.

2.7 Basic requirements for a standard typology of coastal regions

A standard typology of coastal regions based on NUTS 3 territories should:

- include every NUTS 3 territory within ESPON with a coastline, i.e. territories bordering an ocean
- partly be based on previous ESPON typologies

- differentiate between typological elements and a main typology
- take specific coastal issues into consideration
- be both site and situation oriented
- to some extent be based on statistics at lower geographical levels than NUTS 3 or typological elements based on such geographical levels – which means that the typology should include internal diversity in each NUTS 3 territory as a criterion, and connected to this;
- include a criterion for *functional regions within the territories*, which also means that;
- it should be possible for example studies in smaller geographical areas to be connected to a sub territorial geographical typological level within the NUTS 3 territory
- define typologies where the difference between regions within each type should be as small as possible, and the difference between types as big as possible for analysis within the aim of the project (which is made difficult by the geographical level to be used for the typology)

The coastal typology should include elements on the urban – rural dimension according to a division into functional regions. We will in other words not use the urban – rural typology made for ESPON, which is not complete, and is not satisfactory according to thoughts about functional regions. This typology can however possibly be of analytical relevance on its own for analysis of fishery policy impacts.

Some other ESPON typologies have however been used in the construction of the typology of coastal regions. The typology for Functional Urban Areas (FUAs) has been essential, giving the necessary inclusion of a building block for representing functional regions within the NUTS 3 territories. ESPON typologisations on proximity have also been important.

There are a number of standard typologies from other ESPON projects that was suggested for inclusion in the impact analyses WPs:

- Functional Urban Areas (FUAs)
- 6 Type NUTS 3 FUAs
- 19 Type NUTS 3 FUAs
- Rural-urban typology
- Accessibility and GDP
- Lagging regions
- Settlement structure

There are a number of standard classifications and indicators other than the geographical ones from other ESPON projects that might be used in 2.1.5:

- Population change
- Population change in regions with high share of elderly people
- Migratory balances by age
- Depopulation
- Structural fund spending

2.8 Classification of NUTS 3 territories according to Functional Urban Areas – an urban-rural classification according to functionality

A classification of NUTS 3 territories based on Functional Urban Areas (FUAs) is a way of creating a typology telling about the urban-rural dimension within each single NUTS 3 territory. It is also a classification that uses typological work already developed within ESPON as its basis and in combination with one of the reference geographical levels for regional support within the EU. We combine information on the NUTS classification with the classification of FUAs. The classification combines the share of population of the NUTS territories living within FUAs with the population size of the FUAs as typologised within ESPON and the location of the centres of the FUAs. This means that we get information on the urban-rural dimension when typologising to what extent the population of the NUTS regions live within functionally centralised regions, and the size of these regions. This way of classifying the NUTS regions also means that we will be able to use the typology for example studies, being geographically flexible. As the hypotheses of the project takes into consideration an urban/non-urban dimension this is very important. We would not be able to look at these hypotheses without the inclusion of a dimension that makes it possible to reflect the typology on smaller geographical units.

An alternative to population size of the FUAs is to use the combined index for different topics that, like the grouping of FUAs according to size groups place the functional regions into a span from global to local, taking into account the inclusion of more than one FUA in some regions. Choosing the one or the other solution should be done according to the purpose of analysis.

As this classification represents the urban hierarchy to a better extent than size alone, the global – local typology should be included to the exclusion of size. This means a typology combining urban hierarchy with information on each FUAs hierarchical level on several topics, making the assessment of polycentric spatial development and economic, social and territorial cohesion (point 8 of the TIA) better connected to the project. The typologisation attempts to show the level of urbanisation in the territories, implying that the level of urbanisation is highly relevant for amongst others the demographic development of the regions.

NUTS territories with FUAs on more than one level are classified according to the highest level represented within each territory. We don't make any distinction between NUTS territories with one and several FUAs.

The share of the population living in FUAs gives some indication to the level of heterogeneity of the NUTS territory.

The classification is then:

<i>FUA level</i>	<i>FUA population</i>
00 no FUAs	0 no FUA population
0 no centre of a FUA	1 less than 25 %
1 FUA centre on level 1	2 25-49 %
2 FUA centre on level 2	3 50-74 %
3 FUA centre on level 3	4 75-100 %
4 FUA centre on level 4 or 5	

This gives the following 21 *potential* combinations:

000
01, 02, 03, 04
11, 12, 13, 14
21, 22, 23, 24
31, 32, 33, 34
41, 42, 43, 44

An alternative classification of FUA levels, based on the FUA typology into 1 Regional/local FUAs, 2 Transnational/national FUAs and 3 Metropolitan European Growth Areas reduces the typology to 17 potential combinations:

000
01, 02, 03, 04
11, 12, 13, 14
21, 22, 23, 24
31, 32, 33, 34

2.8.1 Population density

Population density is an indicator for potential pressure on environmental resources both of the coastal regions as such and also on the coastal zones. It should therefore be used as an indicator, but not necessarily be included in a standard typology of coastal regions. At the same time as high densities indicates high pressure on coastal areas, very low population densities is a difficulty for certain regions that were acknowledged by the EU with the accession of Sweden and Finland. The low population density regions are primarily found in the Nordic periphery. This periphery constitutes a geographical rarity within Europe not only in that the population densities are especially low, but also because they have centres with generally few inhabitants, and distances between centres are longer than in more central parts of these countries not to speak of in continental Europe. Regional policy has aimed at supporting such peripheries in the Nordic countries. The Nordic periphery was also acknowledged by the EU in the membership discussions with Finland, Sweden and Norway in preparation for the 1995 EU enlargement, a separate structure fund being implemented for geographical areas with low population density and peripheral location. Such regions often have serious problems related to distance factors, influencing also job opportunities. The relative inaccessibility to job opportunities based on the low population density is the most important element of the Nordic periphery in territorial comparisons. At the same time many of the fishery dependent communities within the ESPON territory are located within such geographical areas, which means that population density should be included in the coastal typology.

We propose the following division of coastal regions according to population density:

2. Below level defined for support from EU structure funds for peripheral regions during the time period impacts are analysed for (maximum 12.5 inhabitants per square kilometre)
3. Above 12.5 inhabitants per square kilometre but not more than half of European average (12.6 – 54)
4. Below European average, but above half of European average number of inhabitants per square kilometre (55 - 107 persons per square kilometre)
5. Over European average, but less than twice the EU average (108-214 inhabitants per square kilometre)

6. More than twice the European average (215 or more inhabitants per square kilometre)

The coastal NUTS regions with below European average population density include almost the entire Baltic Sea region and Norway, the NUTS territories where the capitals are located being the major exception. Also most of Greece's coastal regions are included. Even though Spain is generally more densely populated in the coastal territories than in the interior, also many of the coastal ones have population densities below the national one, as does Portugal south of Lisbon. France is, like Spain, more thinly populated in the interior. However, along the Atlantic about half the NUTS 3 territories are below average population density. Most of Ireland and Scotland also falls within NUTS 3 territories with below average population.

The concentration of coastal regions with high population densities is found within the pentagon, and also includes much of the Italian and Portuguese coast. However, the most densely populated NUTS 3 territories in Europe are primarily non coastal NUTS territories located in England, Belgium, the Netherlands, Germany and Northern Italy.

2.8.2 Proximity/accessibility

Development of typologies of proximity or accessibility of different NUTS territories has been included within the frames of other ESPON projects and based on indicators developed by the projects. Such typologies can be utilised by projects on the European fisheries. There is a need for information on proximity for the coastal regions to gain information on the relative location of the coastal regions in a European context. As there has been made several typologies on aspects of proximity within ESPON, these can be used as indicators of territorial situation/proximity.

We propose the following indicators:

Accessibility, multimodal

By using the accessibility indicators, we basically use land logic, finding certain information on proximity between regions on land. In matters concerning the fishing trade, air accessibility is becoming more important. This is however only part of the reality, as the often peripherally located fishing regions might be brought closer together by sea logic. There are still some interesting facts to be commented upon when comparing the coastal and non coastal NUTS 3 territories according to accessibility.

There is a marked difference between ESPON countries in their relative accessibility when measured on basis of ESPON Space (table 2.3). Each nation has been awarded index according to the national distribution of NUTS 3 territories being within five different accessibility classes, where the indexes is average scores for the territories.

Table 2.3 Inland and coastal accessibility

Nation	Accessibility			Coastal accessibility compared to inland accessibility
	National	Inland	Coastal	
Belgique-België	3,8	3,8	3,4	-0,4
Danmark	2,9	-	2,9	-
Deutschland	3,4	3,5	2,7	-0,8
Ellada	1,9	1,6	2,0	0,4
España	2,1	1,9	2,3	0,3

France	2,7	2,8	2,4	-0,3
Ireland	2,4	2,0	2,4	0,4
Italia	2,8	3,1	2,6	-0,5
Luxembourg (Grand Duché)	4,0	4,0	-	-
Nederland	3,7	3,7	3,6	-0,2
Österreich	2,9	2,9	0,0	-2,9
Portugal	1,7	1,4	2,0	0,6
Suomi/Finland	1,9	1,7	2,0	0,3
Sverige	2,3	2,0	2,5	0,5
United Kingdom	2,9	3,4	2,7	-0,7
Balgarjia	1,9	1,8	2,7	0,8
Kypros	2,0	-	2,0	-
Ceska Republica	2,6	2,6	-	-
Eesti	1,6	1,0	1,8	0,8
Magyarország	2,5	2,5	-	-
Lietuva	1,6	1,7	1,0	-0,7
Latvija	1,8	1,0	2,0	1,0
Malta	2,5	-	2,5	-
Polska	2,2	2,3	2,2	-0,1
România	1,8	1,8	1,5	-0,3
Slovenija	2,8	2,8	2,7	-0,1
Slovenská Republika	2,4	2,4	-	-
Norge	2,0	1,5	2,1	0,6
Schweiz	3,4	3,4	-	-
EU27+2	2,9	3,0	2,5	-0,5

1 = very peripheral, 2 = peripheral, 3 = intermediate, 4 = central, 5 = very central

Table 2.3 shows very clearly that there is a marked difference between the more central nations and the more peripheral ones within ESPON Space when it comes to the relative accessibility of the coast as opposed to the inland. For the more accessible nations (accessibility 2,5 or more), the coast has in every one of them lower accessibility than the inland. The opposite is generally the case for nations with accessibility below 2,5 where only three nations with coastline do not have a higher index for coastal than for inland NUTS 3 territories. The three latter are Lithuania, Poland and Romania. What is indicated by this is not only the obvious, that the coastal areas are relatively more central in peripheral nations within Europe than it is within the more centrally located ones. It also shows the traditional pattern of export by sea from the peripheries of Europe towards the central parts of the continent, with trade links being mostly coastal centres.

Table 2.4 Accessibility of coastal NUTS 3 territories by class. Percent within nations.

Nation	Very peripheral	Peripheral	Intermediate	Central	Very central
Belgique-België	-	-	60,0	40,0	-

Table 2.4 shows that very few among the most central NUTS 3 territories within ESPON Space are coastal territories. More than half of the territories are peripheral or very peripheral, and most of the other ones are in the intermediate class, leaving less than ten percent for the two most central classes. At the same time, the table also shows there to be a quite varied accessibility between coastal territories within most nations, even when accessibility are based on ESPON Space. Uniquely, the UK is represented in all five classes. The main countries within European fisheries have a large share of peripheral and/or very peripheral NUTS 3 territories. At the same time, only the Netherlands among all the nations within ESPON Space has more than half of their coastal NUTS 3 territories within the two classes defining the most central territories.

2.8.3 Regions with structure fund support

The regions can also be typologised according to what kind of structure funds are made available within the NUTS 3 territory. This should not be included in a main typology of coastal regions as it is less territorially stable than what should be expected from an element used for the standard typology. Objective 1 and objective 2 territories have been linked to each coastal NUTS 3 territory.

2.8.4 Fishery dependency/specialisation

For a project on impacts of fisheries policies it is of cause essential to include a classification connected to the fisheries. Statistical problems has made it impossible to make a typologisation of fisheries dependency covering ESPON Space, but our work package 3 has developed a typologisation on fisheries specialisation on NUTS 2 level. This is discussed in chapter 5 and also in 2.13.

No NUTS 3 or NUTS 2 territory will be truly fishery dependent, which makes it necessary to typologise differently, and the solution of using fisheries specialisations seems to be more to the pint than a typology of “dependency”.

2.9 The main typology

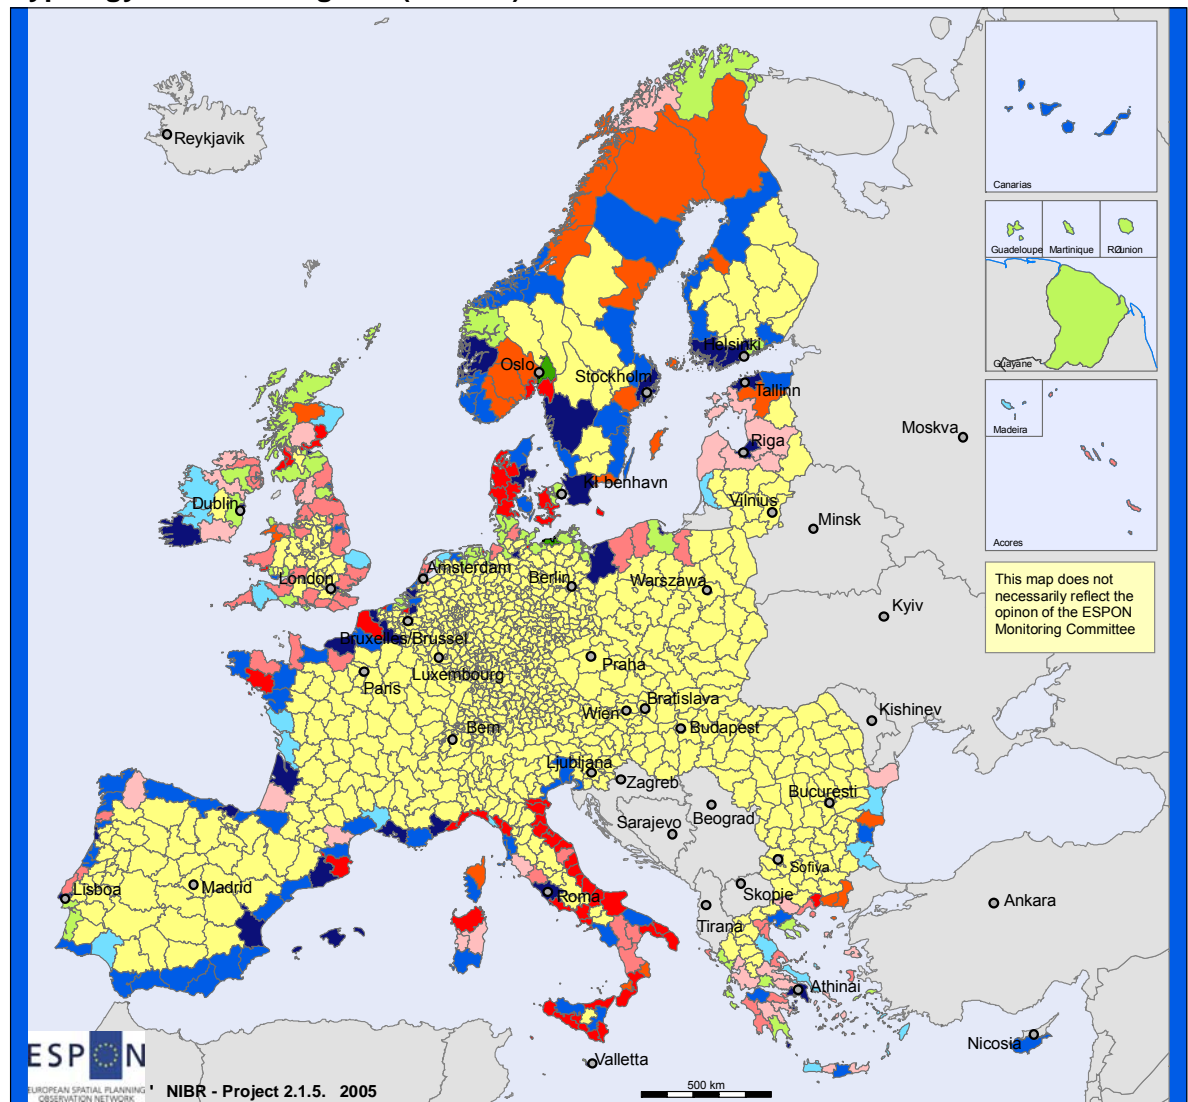

As already mentioned, the main typology should express information from some of the typological elements. It seems necessary to include the FUAs. For the main typology we have chosen the FUA typology rather than the FUA classification according to population size. The other element of the typology is population density.

	FUA coding	Population density coding	Description
1.	000, 00, 01, 02, 03, 04	1, 2	NUTS 3 territories with no FUA centre, and very low population density
2.	000, 00, 01, 02, 03, 04 population average	3	NUTS 3 territories with no FUA centre, densities at least 50 per cent of European average
3.	000, 00, 01, 02, 03, 04 population	4, 5	NUTS 3 territories with no FUA centre, densities at least on European average
4.	21, 22	1, 2	Regional/local FUAs, not regional demographic dominance, low population density
5	21, 22	3, 4, 5	Regional/local FUAs, not regional demographic dominance, medium or high population density
6.	23, 24	1, 2	Regional/local FUAs, regional demographic dominance, low population density
7.	23, 24	3, 4, 5	Regional/local FUAs, regional demographic dominance, medium or high population density
8.	31, 32 demographic 34	1, 2, 3, 4, 5 1	Transnational/national, not regional dominance
9.	33 34	3, 4, 5 2, 3, 4, 5	Transnational/national, regional demographic dominance

10. 41, 42, 43, 44 1, 2, 3, 4, 5 MEGA, regional demographic dominance
For NUTS territories with the European/MEGA types, there will not be any NUTS region with low population density, making a distinction according to population density meaningless.

Figure 2.3 Typology of coastal regions (NUTS 3)

Typology of coastal regions (NUTS 3)

NUTS 3 Coastal Typology

- No coast

Source: ESPON Data Base

The coastal typology shows some national patterns. There is a tendency for Spanish coastal territories to have a larger FUA located within their borders, and the NUTS

territories are also demographically dominated by the FUAs. This is also quite common in France, but not to the same extent. Most coastal territories located within the so called “Pentagon” do not include a transnational/national or a Mega FUA. It is possible to single out a western Mediterranean coastal territory pattern of NUTS 3 territories dominated by FUAs, where the FUAs of Spain and France are located higher in the FUA hierarchy than the ones in Italy.

In the UK, there is a tendency for the coastal territories not to be dominated demographically by their FUAs, and for the FUAs to be on regional/local level in the FUA hierarchy. Also the new EU member states in the Baltic Sea region mostly include territories not dominated in demographic terms by their FUAs. This is also the situation for the German territories bordering the Baltic sea. When the patterns seem to concentrate certain types of coastal regions in certain parts of Europe, there is a need for a warning concerning the use of a typology, as it can easily underestimate national conditions. This is exemplified in chapter 2.14.

There is an option for reducing the number of types to eight when typologising on the NUTS 3 level (but the typology as presented above should still be regarded as the main typology, as it has also been constructed for covering also other geographical levels). The reduction is done by reducing the hinterland types into one, being identical to what is called ‘Hinterland 1’ in the map. On the NUTS 3 level there is no territory in the hinterland 2 type, so this one can easily be taken away. The Hinterland 3 type is a very special one, with only three territories included. The three are København Amt, which should really be seen as part of Copenhagen, Akershus, which is the suburban part of Oslo, and Bad Doberan, which constitute much of suburban Rostock. When reducing the number of hinterland regions to only one, oriented towards the very thinly populated regions, Akershus and Københavns Amt are given status as Megas and Bad Doberan is placed in the Transnational/national 2. In many instances the suburbs are part of the same NUTS territory as the central city. This is therefore only a small adaptation related to the variation in delimitation principles for NUTS territories. The eight types, which should be the types for the NUTS 3 level, are then:

7. Hinterland
8. Regional/local 1
9. Regional/local 2
10. Regional/local 3
11. Regional/local 4
12. Transnational/national 1
13. Transnational/national 2
14. Mega

2.10 Territorial typologies for EU15

It can be argued that, as CFP impacts study is an ex post evaluation there can also be included some territorial typologies based on EU15 only, as we will mainly look into a time period prior to enlargement. In a study of EU15, some relevant territorial typologies would be:

2.10.1 Dominant Structural funds spending

(TPG: 2.2.1. Spatial scope: EU15. Territorial level: NUTS 3)

R Regional development, productive infra-structure
A Agricultural, fishery, rural development
S Social integration, human resources
C Basic infrastructure, European cohesion

2.10.2 Structural Fund spending and regional performance

(TPG: 2.2.1. Spatial scope: EU15. Territorial level: NUTS 2)

Low Spending – High Performance
Low Spending – Medium Performance
Low Spending – Low Performance
Medium Spending – High Performance
Medium Spending – Medium Performance
Medium Spending – Low Performance
High Spending – High Performance
High Spending – Medium Performance
High Spending – Low Performance

2.10.3 Structural Fund spending and change of regional performance ranking

(TPG: 2.2.1. Spatial scope: EU15. Territorial level: NUTS 2)

Low Spending – Rise in Ranking
Low Spending – Stable in Ranking
Low Spending – Fall in Ranking
Medium Spending – Rise in Ranking
Medium Spending – Stable in Ranking
Medium Spending – Fall in Ranking
High Spending – Rise in Ranking
High Spending – Stable in Ranking
High Spending – Fall in Ranking

2.11 For descriptive purposes

For the description of the fisheries dependent regions, one could also possibly include Settlement structure from TPG 3.1, with ESPON space as spatial scope, and with NUTS 3 as territorial level, even though it has little meaning to include this typology in the analysis. The regional types are:

15. Central areas in agglomerated regions
16. Highly densely areas in agglomerated regions
17. Densely areas in agglomerated regions
18. Rural areas in agglomerated regions
19. Central areas in densely populated regions
20. Densely areas in densely populated regions
21. Rural areas in densely populated regions
22. Rural area more densely populated
23. Rural area less densely populated

2.11.1 Regional R&D performance

24. Weak at undertaking R&D and innovation
25. Average strengths in R&D
26. Mixed fortunes in undertaking R&D and innovation
27. Strong system of R&D and innovation
28. Exceptionally strong system of R&D and innovation

2.11.2 R&D and innovation capacity

High R&D capacity and high innovation capacity
High R&D capacity but low or medium innovation capacity
Low or medium R&D capacity but high innovation capacity
Medium R&D capacity and medium innovation capacity
Low R&D capacity and low innovation capacity

2.11.3 Urban – rural typology – 10 types

1. Urban, densely populated and high urban integration
2. Urban-rural, densely populated and high urban integration
3. Urban-rural, not densely populated but high urban integration
4. Urban-peripheral, not densely populated and low urban integration
5. Rural-urban, densely populated and high urban integration
6. Rural-urban, not densely populated but high urban integration
7. Rural-peripheral, not densely populated and low urban integration
8. Peripheral-urban, densely populated and high urban integration
9. Peripheral-rural, densely populated but high urban integration
10. Peripheral, not densely populated and low urban integration

2.12 Further typological work for ESPON 2

1. As much of the statistics on levels below the national will be used in example studies within a perspective of national implementation, there is ideally a need for additional typologies based on the different nations, and not on ESPON Space
2. There can be a need for typologies combining typologies based on ESPON Space and on the different nations (like accessibility – where one could single out central regions within nations that are peripheral on the European scale etc.)

2.13 The coastal typology and fisheries specialisation

Chapter 5 presents a typology of fisheries specialisation on the NUTS 2 level for Norway and EU15 (except Ireland, the Netherlands and Belgium, with NUTS 3 level used for Denmark). The indexation is at the national level in each country, which means that what we get to grips with is the differentiation within each nation. Differences in the statistical sources means that a serious presentation with index level = 100 for ESPON Space is ruled out for presentation. This means that we have a map that can be related to national implementation for the EU countries, but that at the same time must be very carefully interpreted, as the territories with the highest levels of employment in the fisheries sector will not necessarily have the highest indexes for fisheries specialisation. When not considering the problems of geographical level, the methodology is however both simple

and sound. The fact that this typology is at the NUTS 2 level and that the coastal typology is on the NUTS 3 level mean that no direct comparison between the two levels is possible. We can however still see that the higher levels of national fisheries specialisation is principally found in regions with smaller FUA centres or no FUA centre at all.

2.14 A warning

There are reasons to be careful with using ESPON typologies for research covering ESPON Space. To make an example, we shall take a look at the indicator for lagging territories, which is divided into lagging, potentially lagging and non lagging.

Table 2.5 Share of lagging, potentially lagging and non lagging territories. Percent. Coastal types.

Coastal type	Lagging	Potentially lagging	Non lagging
Hinterland	21,4	24,3	54,3
Regional/local 1	40,7	40,7	18,5
Regional/local 2	18,6	45,8	35,6
Regional/local 3	20,0	15,0	65,0
Regional/local 4	29,6	12,7	57,7
Transnational/national 1	38,9	16,7	44,4
Transnational/national 2	27,5	22,5	50,0
Mega	11,6	27,9	60,5

Source: ESPON Data Base

From the table it is quite clear that the territories not having any FUAs within their borders is not negatively affected compared to most others when using this particular indicator. At the same time the lagging territories are particularly often found in two of the types where the FUAs constitute a low share of total population (regional/local 1 and transnational/national 1). As could be expected, the Megas are the category where the lowest share is lagging.

When it comes to non lagging territories, there is seemingly a very interesting situation where the hinterland type, the two types of regional/local FUAs that constitutes a large share of the population of their territories and the Megas has the highest shares. The highest share is actually found in the regional/local type with low population density. We shall not make a complete description of the table here. The point is quite an other one: The distribution for nations (table 2.6) reveal that all coastal territories within several countries fall into one group only, with Northern Europe being dominated by Non lagging territories (for example all territories within the three Scandinavian countries) and Eastern Europe by lagging ones. This shows that an analysis of this indicator using the coastal typology on ESPON Space would clearly be a misinterpretation, as the results show that what matters is not so much the coastal type as the fact that certain types are more common in certain countries, where national conditions are the more important ones. A more varied approach is needed when analysing, taking into consideration differentiations within nations, and not only base the analysis on ESPON Space.

Table 2.6 Share of lagging, potentially lagging and non lagging territories. Percent. Nations.

Nation	Lagging	Potentially lagging	Non lagging	Total number
Belgique-België	0	0	100	5
Danmark	0	0	100	15
Deutschland	31	24	45	29
Ellada	45	55	0	40
España	63	25	13	24
France	23	60	17	30
Ireland	0	0	100	7
Italia	50	13	38	56
Luxembourg (Grand Duché)
Nederland	0	6	94	18
Österreich
Portugal	0	57	43	14
Suomi/Finland	10	40	50	10
Sverige	0	0	100	14
United Kingdom	0	17	83	82
Balgarjia	100	0	0	3
Kypros	0	0	100	1
Ceska Republica
Eesti	100	0	0	4
Magyarország
Lietuva	100	0	0	1
Latvija	100	0	0	4
Malta	0	100	0	2
Polska	83	17	0	6
România	100	0	0	2
Slovenija	0	100	0	3
Slovenská Republika
Norge	0	0	100	17
Schweiz
EU27+2	25	24	51	387

Due to the insights above, the typology of coastal regions has not been used for analysing the fisheries sector on ESPON Space, but the typology has been used when selecting example studies for the project. Use of the coastal typology and other ESPON typologies in ESPON projects, with the exception of typologies based on results, is really dependent upon analysing the situation within each single nation within the analysis on ESPON Space, as the importance of nation is difficult to underestimate for much of the analyses.

2.15 Interreg – a tool for interregional cooperation and networking

The Interreg III-programmes terminates at the end of 2006, and it is therefore too early to conclude to what extent the programmes have contributed to interregional cooperation and networking across countries. The Interreg programmes are regarded as important instruments in the EUs “community initiatives”, which strive to strengthen economic,

social and territorial cohesion and regional balance across Europe. Moen and Skålnes (2005) give summaries of all the seven mid-terms evaluations of Interreg III programmes that were performed by external researchers and consultants. All evaluations were undertaken during 2003, which meant that some of the programmes had advanced to the mid-term stage “formally”, but not in reality since some of them were started rather late. This was especially the case for the Interreg III B and C programmes that work with bigger and broader partnerships than what is generally the case in Interreg III A programmes and projects.

According to Moen and Skålnes (2005:20) “all the seven programmes get good marks from the evaluators. In most cases the recommendations concern only minor matters of fine-tuning the programmes’ courses or some extra effort to achieve a better balanced project generation between the programmes’ priorities and measures in order to achieve the planned mix of activities as stated in the programme documents and – complements. Between two thirds and three quarters of the resources from the Structural Funds were already committed to projects. One common theme in many of the MTEs was that successfully operating Interreg programmes and projects are not only a question of *what* is being done in the programmes and projects. Very often, the important question is *how* things are done: in short: *participation and partnership building* are often the clues to successful Interreg engagements”.

Interreg can be seen as a sort of course in cooperation between regions across different countries and an arena for mutual learning. The experiences from the Norwegian participants are that “Interreg is considered as a new and powerful policy instrument for regional development and as a way to innovate the Norwegian interventions for a more balanced regional development. An additional effect is the accumulation of knowledge by learning to work together across borders in big projects within a broad partnership with members from different “walks of life” as well as educational backgrounds” (ibid:23). Further, the Norwegian engagement has been an important part of the modernisation of Norway’s policies for regional development: “Cross-border, trans-national and interregional cooperation in the framework of Interreg is best conceptualized as a modernization of Norwegian regional policy development with important implications for approaches as well as tasks and partnership building as a way of working together at the regional level” (ibid:24). One important condition for these positive impacts of the Interreg programmes is their long term programming with perspectives reaching six to seven years.

Despite the positive experiences with Interreg cooperation, it is, however, often difficult and time-consuming to establish well-balanced partnership. This has mostly been “a problem for projects in the Interreg B and C programmes where many of the partnerships are big, broad and far reaching which entail long distances between partners and high travel costs” (ibid:27).

2.16 TIA as methodology for impact analysis

The overall framework for the methodology is founded on:

- (i) the tender document of the project, where its thematic scope and context have been decided upon and the general objectives have been addressed
- (ii) the Territorial Impact Analysis (TIA) as elaborated by ESPON project 3.1

In ESPON (and ESDP – European Spatial Development Perspective) terms, TIA means Territorial Impact Analysis. The term is related to Territorial Impact Assessment, which

has been used as “a tool for analysing, assessing and evaluating the impacts of certain projects on the spatial development of the surrounding territory” (ESPON 3.1 final report, page 425). What is new with the ESPON TIA compared to its use so far in ESDP is its application for EU policies and programmes. This has, however, proved difficult as these policies and programmes have not been committed to goals of territorial development.

At the most basic level, the specific methodological shape of the TIA of any ESPON impact study is said to relate to on the one hand territorial data characteristics (relevance, reliability etc.) and on the other hand to subject matter data characteristics: policy with or without endogenous territorial intentions, certain programmes, single interventions/projects. There has, however, not been established a common assessment methodology within the ESPON impact studies as it is acknowledged that it is hardly possible to use one assessment methodology for the entire range of sectoral policies of the EU. According to ESPON project 3.1 this is due to the very different character of the spatial dimension and implications of the different policy areas, and the different theoretical state of the art of applied research and planning in the different areas. ESPON 3.1 also state that “Current techniques are not sufficient to meet the challenge presented by the desire to consider the spatial implications of different policy interactions” (page 429 of the final report).

The project mentions the following deficiencies of subject matter to be assessed and for assessment criteria for a TIA of EU policies and programmes:

- the EU policy programmes concerned are still far away from actually taking into account territorial objectives despite having clear potential territorial impacts
- they show a dramatic lack of territorial differentiation of data on policy implication
- the elaboration of spatial development goals in the wake of ESDP is still going on, and has hardly achieved results operational for assessment application so far

Among key concepts 3.1 regard only two to have a “genuine territorial dimension”; ‘territorial cohesion’ and ‘polycentric development’. At the same time, polycentric development can be seen as a spatialised expression of territorial cohesion.

Territorial cohesion is a concept for the balanced distribution of human activities across the EU, translating the EU goal of sustainable and balanced development into territorial terms. It is a complementary concept to economic and social cohesion. According to ESPON 3.1 the following dimensions are relevant for an operationalisation of territorial cohesion:

- domains (thematic layers) – for ESPON the most relevant are probably ESDPs “triangle of sustainability”; economy, environment and society
- components of territory – its own features (potential), its features with regard to those of other territories (position) which enables potential interactions with them, and its effective interactions (exchanges, cooperation) with other territories (integration)
- scale(s) – for the ESPON project a three level reference set have been developed; macro (European level), meso (transnational/national level) and micro (regional/local level)

For an impact study, time is also essential for the analytical work.

Polycentric spatial development is by 3.1 regarded as a ‘bridging concept’ as it merges the two policy aims of ESDP; economic growth and balanced development.

Polycentricity can refer to different geographical levels (cf. scale in the discussion of territorial cohesion). The most important level for ESPON 2.1.5 is the regional/local level. The aim here is to increase the number of centres providing regional services from one or a few dominating ones, in which fisheries should be viewed in the light of the division of labour and functional specialisation within the regional urban system.

Polycentricity on the trans-national/national level might also be of importance, as the fisheries in some instances can be an aspect of the aim of a more balanced tissue of cities. At the global or European level fisheries are of only minor importance today.

The ESPON 3.1 studies found it feasible to develop a common methodological approach (the TIA manual) instead of a common assessment policy for the ESPON impact projects. In the final report from ESPON 3.1, the TIA manual is regarded as a kind of check-list and it contains the following elements:

Scoping

1. Reference to policy interventions;

Designation of the causing interventions assignable to the EU budget development

Question to be answered: What is causing the impact?

29. 2. Hypothesis on cause-effect-relations;

Basis: hypothesis concerning cause-effect-relations (with varying empirical proof)

Question to be answered: What is changed by the intervention(s)?

30. 3. Regional scale of observation;

Designation of geographic reference to be used: regions concerned by intervention/effect; territorial level(s) of observation; covering all or selected (by what criteria) regions cause-effect-relations

Question to be answered: What is the level of observation and analysis?

31. 4. Reference to past and future;

Cause-effect relations in the past as the basis for predicting the effects of future interventions; empirical experiences as well as outlooks to the future crucial for analytic treatment and political perception

Question to be answered: What has happened, what may happen in the future?

Analysing

32. 5. Interventions and effects measured;

Implementation of the hypothesis concerning cause-effect-relations

Question to be answered: What is registered, measured, appraised?

33. 6. Quantitative/qualitative appraisals;

Designation of type of indicators selected

Question to be answered: By what kind of indicators is the topic described?

34. 7. Technique of analysis;

Designation of type of analysis used

Question to be answered: How is the analysis performed?

Assessing

35. 8. Goals referred to;

Designation of criteria for evaluation derived from the two ESPON key concepts focusing on the spatial dimension. Other goals derived from official documents may also be taken into account if they are related to types of regions or particular spatial entities mentioned below in point 9.

Polycentric spatial development

- at the European level: several metropolitan regions as global integration zones
- at the transnational level: enforcement of a polycentric system of metropolitan regions, city clusters and city networks
- at the national level: systems of cities including the corresponding rural areas and towns, development within city regions (intra-regional)

The manual acknowledges that polycentric development at one level does not necessarily go along with the same at the other levels.

Cohesion (economic, social and territorial)

- *economic*: balanced territorial development concerning economic performance
- *social*: balanced territorial development concerning employment, income, education, population
- *territorial*: fair access for citizens and economic operators to services of general economic interest; balanced distribution of human activities

Question to be answered: What goals are referred to?

36. 9. Applied meaning of ‘spatial/territorial’;

Designation of the concept of ‘spatial/territorial’ used according to the policy area concerned

Question to be answered: What concept of ‘spatial/territorial’ is applied?

37. 10. Territorial coverage of outcome;

Designation of the general format of results

Question to be answered: What do the results look like?

Experiences with using the TIA in the different parts of the project is found in the different analyses chapters.

2.17 Specifics on mapping and example studies

When it comes to regional scale and its relation to polycentrism the European level seems not to be relevant for 2.1.5. The transnational level also seems to be of minor relevance. This means that when looking at impacts of fisheries policies in polycentric terms, the national level and levels below the national one stands out as the most relevant ones for impacts on the geographical levels defined by ESPON. This implies that example studies should be central in the 2.1.5 project, and that the European level primarily constitutes a geographical level for mapping fisheries and for typological work, and to a lesser extent is a feasible unit of analysis. Compared to what was originally planned, the data situation on fisheries has meant that example studies has had to be more strongly emphasised.

ESPON 3.1 has argued that as impacts can only roughly be isolated from the effects of other measures of influences, this might imply a:

- Compilation of the policy measures in *certain regions*, recording what spatial development goals they follow, and that
- The structural status/changes in these regions should be evaluated against the chosen spatial development goals

We understand this as a support for conducting example studies. With regard to both choice of geographical level and the time frame of analysis, point 4 of the TIA manual emphasise the importance of using cause-effect relations in the past as the basis for predicting the effects of future interventions. Considering that the changes in CFP are too new for empirical analysis, this represent an argument for focussing on empirical experiences of former changes in CFP, and potentially for using much of the resources on example studies which are already finished or are in preparation.

As mentioned, the TIA manual is to be considered as a check list, not as a standard assessment tool for ESPON projects. This means that there are no methodologies for impact projects that have been recommended, so the points under analysis and assessment will have to be decided upon either in the single work package or by the work packages together with the lead partner. For scope, we intended already in IR1 to:

- Distribute the hypothesis on the work packages
- Use NUTS 3 as regional scale of observation when mapping the ESPON coastal regions, but more detailed geographical levels for example studies
- Base analysis on former changes in the fishery policies, and using these to make evaluations of new changes in EU policy

The second of these points have proved impossible to fulfil, as there has been far less statistics on NUTS 3 have been made available for the project than anticipated. Much more of the ESPON Space analysis have been conducted on national level or on the NUTS 2 level, and more specific regional impacts have been looked into in the example studies.

2.18 Experiences with TIA

The specific experiences with TIA are presented as part of the impact chapters. One important general experience, that shall also be presented here, is the lack of data at relevant geographical levels, i.e. on NUTS3 level or lower. This point is clearly stated particularly in the work packages that have analysed social cohesion and regional

economic strength. Data on territorial distribution of fisheries policy measures, socio-economic development and regional performance are scarce or not available at the most relevant geographical levels unless they are paid for. It is clearly a fact that territorial impacts of fisheries policy first and foremost are significant on lower geographical levels. Some regions and municipalities are heavily dependent on fisheries but changes in fisheries policy are hardly or not at all traceable on a national or European level. Fisheries policy, therefore, are a rather “constricted” policy area and territorial impacts are usually only observable in particular regions and areas.

2.19 Experiences from the data collection and the data quality

The fisheries project has documented a huge lack of fisheries data available for free in European databases that can be used for Territorial Impact Analyses (TIA) of the common fisheries policies (CFP). Despite sincere and time-consuming efforts of the 2.1.5 research partners, we have not been able to overcome all of the challenges that we have run into in terms of obtaining all the necessary data and fill in the missing spaces.

Therefore, the main advice to ESPON on data collection is to initiate an extensive data collection project led by Eurostat and involves the national statistical institutes, ESPON researchers and ESPON CU. The advantage of doing this is that it enables a standardisation of data collection methods that will serve ESPON’s purpose, by co-ordinating strategies with relevant institutions in each country. It will also mean the possibility of developing a high quality statistical data base. EUROSTAT/ESPON carry authority to a larger degree than social science researchers on a string budget in scattered institutions phoning and e-mailing relevant institutions for data, often in vain, as it depends on the means, time at hand, goodwill and understanding of the public employees contacted. Furthermore, we recommend that ESPON address the quality of the data that is in the database already, and make sure that the variable labels in the metafiles correspond to their actual contents.

The collection of statistics for the project has been organised with the following division of labour:

Table 2.7 Division of labour of data collection.

Organisation	Collected data from
Norut, Norway	Finland, Sweden, Norway
UARI, Iceland	Iceland
EMI, Estonia	Estonia, Latvia, Lithuania, Poland, Romania, Bulgaria
IREPA, Italy	Italy, Greece, Slovenia, Malta, Cyprus
IFM, Denmark	Denmark, Germany, UK, Ireland
IDEGA, Spain	Belgium, Netherlands, France, Spain
CEDRU, Portugal	Portugal

Below, we show some data problems reported by the three impact work packages of the project.

WP 3

Data needed to undertake TIA analyses in fisheries

In order to undertake a socio-economic study and analyses of fisheries in a TIA frame, we need regional data and figures on developments of population, total employment, fisheries employment and income (household, disposable). Moreover, in order to analyse the interconnections between the CFP and the socio-economic development we need regionalised fisheries data on catches and landings as well as data on the territorial distribution of financial measures in the fisheries policies where the Financial Instrument of Fisheries Guidance (FIFG) is the most important.

We have not been able to establish a regional database on catches and landings on NUTS 2 and NUTS 3 levels. In order to clarify the regional implementation of the protection policies we refer to analyses in WP 2 and WP 5 undertaken at NUTS 0 level. The regional distribution of FIFG can be analysed on NUTS 2 level.

It has not been possible to explicitly split between employment in fisheries and aquaculture in most of the countries. Information on employment in the fish processing industry is missing for several countries, also in the ESPON database. Moreover, it has not been possible to obtain socio-economic data for identical time series in the different ESPON countries, which means that data often are not consistently comparable from year to year.

Data of relevance for TIA on fisheries in the ESPON databases

Some of the socio-economic data needed could be obtained from the ESPON database, mainly data related to regionalised total employment figures. After having scrutinised the database, WP3 concluded that there was no data on fisheries employment except for from a select number of nations on NUTS 2 level. Under

031_Employment_by_economic_activity_02_P31_N2, under the variable name NACEB02N2, the fourth column in the file is where some fisheries employment statistics is found, but according to the corresponding metafile, this variable name referred to *agriculture*, which obviously is misleading. The seventh column has the same label and does relate to agriculture. A lesson from this is that there should be a quality check of the files and metafiles.

There are huge variances between the data in this ESPON file and the corresponding data that we have collected ourselves. For instance, according to ESPON table **031_Employment_by_economic_activity_02_P31_N2** for NUTS 2 territory NO7 Northern Norway, 6300 people were employed in fisheries and aquaculture in 2002, and for the year 2001 the corresponding file the number was 8800. According to the data WP3 has collected, which are reliable, there were 4100 employed in the fisheries and aquaculture in 2002 in NO7 Northern Norway, i.e. a discrepancy of 50 per cent for 2002, and more than 100 per cent for 2001. For Bulgaria, the ESPON database operates with 1210 employed in fisheries and aquaculture for 2002, while EUROSTAT's corresponding figure is close to 7000.

The above is but one demonstration of the ESPON database's incompleteness and in some instances, unreliability. Apparently, there has been a lack of quality control, and/or a lack of alert when entering the data in the database. Other examples: **ESPON table 032_Employed_Persons_by_Sectors** is erroneous and incomplete. For the year 1997, the figures are too deviant from the other years to be reliable, and there has obviously not been a quality check of the data before entering them. This is valid for all territories. Furthermore, there are no data for 1999 in either region. Some territories are worse than others, for example Germany, where there are sudden holes for certain territories for certain years. This makes it complicated to undertake any analysis with respect to

employment for Germany. In order to be able to do that, WP3 used approximate figures, based on information from other years.

Moreover, there is disharmony between different ESPON-tables, which at the outset should contain the same information. According to **ESPON table 022_Pop-change_95-99_p114_N2**, Estonia has had a population decline of one per cent from 1995 to 1999. According to ESPON tables **021_Population_age_groups 1995-1999_p31_N2**, a calculation shows that there has been a three per cent population decline for the same period. This means that we have had to make a choice of which of the files in the ESPON database to rely.

Another example relating to population figures: According to ESPON table **021_Population_age-groups_1995_P31_N2: Table**, the population in Cyprus is 841000 (1995). According the corresponding table the following year, **021_Population_age-groups_1996_P31_N2: Table**, the Cypriot population has dropped to 755500 (1996). Unless there has been a massive exodus, there is an error in the database.

These examples demonstrate that analyses based on the official ESPON database carry a probability of inaccuracies, which in turn leads to a questionable reliability of the ESPON research based on the ESPON database. This underlines our opening argument that ESPON should endeavour to undertake a systematic, standardised and longitudinal data collection procedure, with a quality check before and after entering them into the data base. This way, reliable and consistent research and analyses can be facilitated.

Socio-economic data related with fisheries in national sources

The partners have spent significant effort in collecting data. This has been a challenging and time-consuming undertaking, and the results have been varying. For some of the countries there are relatively rich data, from others data are meagre or absent. The indicators that have been the most accessible relate to fisheries employment data, and to a varying extent aquaculture and fishing industry employment data on NUTS 2 level. For Denmark and Norway there are data on NUTS 3 level, and for Iceland on LAU level. The whole of Denmark is defined as a NUTS 2 territory, so that NUTS 3 is important in order to be able to show internal differences. Norway consists of seven NUTS 2 territories and 19 NUTS 3 territories; using NUTS 2 territories in Norway displays differences between territories. For further information, see annex 19

Data – WP4

The minimum regional level of the analysis was NUTS2, as this is the level at which EU structural policies are designed and evaluated. The major problem experienced with this study was the lack of information that has heavily limited the possibility of comparison of the main economic indicators and from year to year. Some important variables, as those related to the fleet segmentation, were completely missing while others as landings were accessible only for a limited number of NUTS2 regions and years. Data on composition of fleets by vessel gears and data on the value of the landings were available only at the NUTS0 level.

The results refer to 124 observations. Since the variable landings were available only for 101 NUTS2 regions, we used the mean substitution for the missing values. It should be noted that missing values affect different countries unequally. For Norway and Poland, no data on landings were available from international sources. For Greece, Portugal, Netherlands, Sweden and Germany the only data available refer to 1997 and 1998.

From this first overview of the EU fishery, it's clear that the importance of the fishery sector differs considerably not only from one country to another but also within each

country. As no official data on volume of landings are available at NUTS3 level, we have collected data only for 101 NUTS2 regions of the 137 coastal regions considered in the ESPON space. From these data, it emerges that over the 50% of total landings are concentrated in 5 NUTS2 regions, such as *Denmark*, *South Western Scotland* (UK), *Zuid-Holland* (NL), *Galicia* (ES) and *Border, Midlands and Western Ireland*.

Since no data on the value of landings were available at NUTS2 level, we have considered the information of the “Annual report 2004” on Economic performance of selected European fishing fleets, which contains economic indicators regarding fisheries in sixteen European countries (Commission of the European Communities, 2004). These data confirm the importance of the Mediterranean areas and of Spain and Italy in particular, where 23% and 18% of the total European revenues are concentrated (Fig. 6.1).

If we look at the composition of the fleets by vessel gears, the most part of the EU fleet is composed by passive gears vessels with an average length of 19 metres and an average age of 24 years (Fig. 6.2). Some 70059 EU vessels are non trawlers under 12 meters in length. Passive gears include mostly set gillnets (anchored), trammel nets and pots. Beam trawling is the most important segment of the towed gears fleet. Unfortunately no data about the composition of the fleet and its evolution are available at a lower geographical level.

Our main concern in this study has been the lack of sufficient information in order to assess the economic impact of the CFP in the ESPON area. The limited number of observations both in terms of time and spatial coverage has heavily restricted the level of the analysis.

Data – WP5

EEA has developed an indicator based approach to assessing the environmental performance of European marine fisheries and aquaculture, based on statistics from ICES, GFCM, FAO, Eurostat, etc. However, the majority of the environmental data is on national level or for ocean areas and it is a general problem with geographical breakdown. In addition, according to EEA data on small-scale fisheries for Mediterranean are often not registered or are very difficult to obtain. The available indicators are nevertheless important to highlight the changes and status for the environment, e.g. fishery and habitat resources.

One central indicator in the EEA list of environmental impact indicators in relation to CFP is commercial fish stocks outside safe biological limits (EEA Indicator Fact Sheet: FISH1a in

2002). Data for this indicator are only available for the North East Atlantic and the Baltic Sea, and many commercial fish stocks are not assessed (see figure 4.3). In the North East Atlantic, the percentage of non-assessed stocks of economic importance range from a minimum of 13 % (North Sea) and maximum 59 % (West Ireland).

There is particular concern about the impact of fishing on marine mammals, turtles and birds. Cetaceans (whales, dolphins and porpoises) are accidentally caught in drift nets and are in competition with fishermen for small pelagic resources. Drift nets and pelagic long lines are the major threats to birds and marine turtles. Even though there are no comparable datasets to properly assess the extent of the problem across Europe, there has been some efforts nationally or regionally to monitor the by-catch of mammals, birds and turtles. Fishing seems to have a significant impact on cetacean, turtle and birds populations, but comparable datasets are not available to properly assess the extent of the problem.

With regard to data availability, the study uncovered significant gaps. Data for describing the defined quality elements in the WFD, i.e. on pollution, water biology and water uses, are not consistent and quality varies considerably. These gaps have to be gradually filled through stepping up monitoring activities and/or through modelling and interpolation.

Only part of the existing information, especially data for small, local recipients are stored electronically. The report published from the project presents a detailed overview of the WFD tasks, the related data requirements and the various available data-sources.

2.20 Hypotheses on territorial effects of CFP

The formulated hypotheses referred mainly to CFP and their respective measures and to some extent also to the development of aquaculture and integrated coastal zone management (ICZM). The fishery policy in Iceland and Norway is also included in this analysis. Related territorial impacts projects within the ESPON program was taken into consideration in the development of the hypotheses. The development of hypotheses have been done continuously in the project and connected with the work with TIA. Some hypotheses are more general whereas others are more specific, and we have divided them according this principle. The hypotheses are grouped in four different categories: General impact hypotheses, Social and economic impact hypotheses, ICZM/environment hypotheses and Fishery hypotheses. The general impact hypotheses are holistic and important for the structure of the project and reports as such whereas the specific hypotheses relate to more explicit research questions concerning certain impacts. The hypotheses are highlighted in the conclusion, based on both the mapping study for ESPON space and the example studies for selected European coastal regions.

General impact hypotheses

Processes on restructuring, reduction and expansion of the fishery sector will probably occur side by side and in various combinations. We also assume that economic, social and demographic impacts of the CFP will vary between urban and remote areas. Further it is likely that impacts will differ in accordance with the extent the regions are dominated by coast fishing and small vessels, fishing in distant water with greater vessels, landings, fishing processes or aquaculture. The CFP may favour the prosperous regions and disfavour the most remote regions, i.e. favour regions which are not particularly fisheries dependent at the coast of regions which are strongly dependent of fisheries. In general, the impacts of CFP will be more significant the lower the geographical level. On this basis we have formulated four general impact hypotheses.

38. *The CFP will have different impacts between coastal regions, and within regions.*
39. *Socio-economic effects related to employment, migration, age structure of the labour force etc., may be less devastating in urban regions than in fisheries dependent regions and areas.*
40. *Territorial impacts of CFP will vary with different structures of the fishing and aquaculture industries of the regions.*
41. *Territorial impacts of the CFP may contradict with the aims of cohesion, territorial balanced development and polycentrism.*

Social and economic impact hypotheses:

The CFP is regarded as one of the sector policies with substantial implications for amongst others employment, territorial cohesion and regional economic strength, and

particularly in some coastal regions and in fisheries dependent areas. Territorial cohesion calls for policies that reduce disparities and promote a more balanced and sustainable development of the European territory. However, the incidence of the CFP on the regional level is not always consistent with the social and economic cohesion objectives of the EU due to the unintended territorial effect of CFP, which lead us to the following social and economic impact hypotheses. To what extent the development is a product of CFP or other driving forces is however rather uncertain in many cases.

17. The CFP has unintended side effects in coastal regions or fishery dependent regions. Significant territorial impacts may be:

- Economic effects such as increasing unemployment
- Decreasing regional economic productions (GDP)
- Population decreasing due to out-migration particularly in fisheries regions
- Altered age composition in fisheries dependent regions, with an increasing share of elderly
- Population. Indication of gender and age biases in fishing dependent regions
- Change in population density in fisheries regions

42.

18. As the restrictions on harvesting activities mainly target the fishing fleet these measures have strongest negative impacts in remote, coastal region, while the more urban regions involved in fish processing still are able to source raw fish through e.g. import from 3rd countries .

19. More favourable regions are able to take greater advantage of the measures included in the FIFG due to closer access to products and markets.

ICZM/environment hypotheses:

Industrialised countries are particularly concerned with overexploitation aspects, and due to biological constraints, fishing subsidies mainly aim at capacity reduction. Increasing awareness of the need to assure resource sustainability and to preserve the whole marine environment, FFP measures aim at reduction of quotas and/or to the reduction of fishing efforts. In the long run this may lead to higher and more stable fish stocks but only if the fishing efforts is sufficiently reduced. According the growth in aquaculture, ICZM is an important tool for a sustainable development. We have formulated the following hypotheses on ICZM and environmental impacts.

20. Subsidies to support incomes or costs reduction in the fisheries sectors result in an increase of the fishing effort which has undesirable effects on social and environmental sustainability.

21. The changes in CFP from 2002 will contribute to a faster reduction and restructuring of the fishing fleet, both in absolute numbers, tonnage (GT) and engine power (kw).

22. Changes in CFP will probably be directed towards improvement of the marine environment and marine resources.

23. Aquaculture will continue to expand, but the further development may be more regional concentrated both with regard to value added and employment.

24. A management based on ICZM principals will contribute to a further sustainable growth in aquaculture.

Fishery hypotheses:

The description and diagnosis of the fisheries policy lay down the basis for the territorial impact studies. The fishery hypotheses deal with questions of structural changes in the seafood industry, innovation in marine sectors, financial instruments, etc. Impacts of CFP will vary by the structure of the fisheries in the respective regions and the access to alternatives, such as fishing opportunities, sources of fish raw material for processing, alternative job opportunities, etc.

- 25. Changes in CFP may contribute to increased concentration and centralisation of the seafood industry. This will be a particular disadvantage for the most fishery dependent and remote areas, which are often underperforming regions in an accessibility perspective.*
- 26. The potential and the preconditions for innovation and restructuring in this sector are probably highest in regions with larger cities or in close distance to larger cities (FUA).*
- 27. Territorial impacts of the CFP measures are dependent on how the measures in use are implemented in the various regions.*
- 28. Less prosperous regions of the EU receive more CFP support through the FIFG (Financial Instrument for Fisheries Guidance) than the more prosperous regions.*

3 Diagnosis of the Development of the Fishery Sector

3.1 Introduction

This chapter provides a diagnosis of the development of the fisheries sector. First, it outlines a set of hypotheses applicable to the fisheries sector in the EU, Iceland and Norway. Second, it gives a comprehensive overview of the development within the European Union focusing on different aspects in the Common Fisheries Policy. Third, the chapter presents fisheries policies and overall developments in Norway and Iceland. It is recognised that the national implementation of the CFP is important, but the CFP is nonetheless the dominating policy framework within the EU, wherefore national policies of EU member states will not be dealt with individually. As Iceland and Norway are not members of the EU - and both countries are very important fishing nations - separate descriptions of their fisheries policies are justified. However, after the separate descriptions some comparisons of the EU, Iceland and Norway are made in a separate section.

3.2 Hypotheses for the Fisheries Sector in the EU, Iceland and Norway

Conservation policy

43. 1. TAC management allows for quantitative allocation of fishing resources (catches) at all territorial levels (EU/international, regional and local) and the establishment of “relative stability” between geographical areas/territories; adopted at international level in the EU (and in some cases at national level, e.g. by the UK - via allocation to Producer Organizations). This implies intentional territorial impact.
44. 2. EAF and precautionary approach management implies that fishing effort will have to be reduced in waters/fish stocks involved and that catches from some stocks may be permanently lower but less fluctuating over time. This implies loss of jobs in the affected communities (onboard fishing vessels and in the related trades). The economic outcome may be positive but will directly benefit fewer people. The less fluctuating catches, which are also expected, will provide improved opportunities for investment planning. Unintentional negative territorial impact in the short and medium term is one result.
45. 3. Applying market principles in the allocation of access rights to fish resources (e.g. ITQs) implies concentration of the fishing industry in territorial terms and fewer, larger and more efficient production units in the fisheries sector. Territorial impacts

are not intended and sometimes negative impacts can be counteracted by policy measures.

46. 4. Recovery plans for depleted fish stocks (involving closed areas, closed seasons, catch/effort limitations etc.) will in the short and medium term have negative impact on the fishing communities dependent on these resources. The more immobile and inflexible the fishing fleet is and the more species dependent the processing industry is, the more significant will the impact be. Coastal communities dependent on small-scale fishing may be particularly vulnerable. This implies unintentional territorial impacts in the short and medium term.
47. 5. Fishing communities, dependent on the exploitation of fish stocks that are within safe biological limits (e.g. North Sea herring and mackerel), are operating on a more stable resource basis and are thus experiencing less negative territorial impacts from fisheries resource management measures at both political and private business levels.

Market policy

48. 6. Fisheries market policies counterbalancing the free market forces have intended territorial impacts that may be on international (EU), national and local levels. Unintended impacts may occur in other territories/territorial levels.
49. 7. The territorial impact of specific fisheries sector oriented market policies is of decreasing importance compared to the impact of general international and national market and food policies. This especially counts for territories dependent on import or export of fish products (fish as raw material for processing value-added products). The territorial impacts are unintended.

Structural policy

50. 8. Fisheries structural policies have intended territorial impacts that may be on international, national, regional and local levels. Unintended impacts may occur in other territories or on other territorial levels.
51. 9. Territorial impact in fisheries dependent areas are increasingly determined by global or national agendas, developments and policies rather than by EU sector specific structural policies.

External policy

52. 10. The policies relating to fisheries agreements with third countries have territorial impact in regions with fleets, which utilise these agreements. Failures to renegotiate agreements or changes in circumstances around agreements have unintentional negative impact in affected regions. Impact can also be felt in regions not exploiting the agreements because they serve to keep some excess capacity out of Community waters.

3.3 The Global Context

The following sections from 'Overall Fisheries Production' to 'Fisheries Regulations' are largely quoted from Greenfacts' summary of the FAO report on the *State of The World Fisheries and Aquaculture*, 2004 (<http://www.greenfacts.org/links/webmaster/summary-page/fisheries.htm>). The section 'Future Prospects for Fish and Fishery Products' is quoted from the FAO report itself (http://www.fao.org/documents/show_cdr.asp?url_file=/docrep/007/y5600e/y5600e00.htm).

3.3.1 Overall Fisheries Production

In 2002 the global production from fishing and aquaculture combined reached about 133 million tonnes. Capture fisheries are stagnating, but aquaculture has been expanding.

Capture fisheries remained stable at about 93 million tonnes per year between 1999 and 2002. The quantities fished in seas and oceans increased from 1998 to 2000, and stabilized at a slightly lower level since 2001 (84 million tonnes). This slight decrease is mainly due to lower catches in the Southeast and Northwest Pacific, but trends vary greatly between regions and for different species. During the past decade marine catches brought to land increased slightly compared to the preceding decade. Most marine catches take place in coastal waters. However, the share of catches from the open ocean have increased in recent decades and reached 11% of all marine catches in 2002.

Catches from inland waters accounted for a little less than 10% of the total catch in 2002. The bulk of world production came from developing countries, particularly in Africa and Asia. China alone accounted for a quarter of global inland water fishing. Statistics of inland catches are, however, unreliable.

Aquaculture is the fastest growing animal based food-producing sector, particularly in developing countries. This sector alone contributes nearly a third of the world's supply of fish products. China and other Asian countries are by far the largest producers. Unlike terrestrial farming, where the bulk of production is based on a limited number of species, aquaculture produces more than 220 species. Of these species, carps and related fish form the largest group in terms of quantity. Other groups include molluscs and aquatic plants. Emerging and fast growing activities are for instance the farming of Atlantic cod and fattening of wild-caught tuna.

3.3.2 The State of Fishery Resources

In many areas, traditional fish stocks have been depleted and less valuable species are being targeted by fishers. About three quarters of monitored marine stocks are now fully exploited, overexploited, or even depleted. The remaining quarter are under or moderately exploited. Available data indicate that the global maximum potential for marine capture fisheries has been reached and that restrictive management measures are needed. Therefore, there seems to be no further potential for increasing marine catches. The current state of fish resources and their ecosystems allows little room for delay in actions that should have been taken in the last three decades.

Fishery policies and management have usually focused on single fishery stocks. Growing concerns about ecosystems have prompted a call for increased research into processes that affect, or are affected by, fisheries. Much more needs to be known about interactions with habitats, aquatic communities, land-based activities, climatic changes, and so on. However, the current state of fish resources and their ecosystems allows little room for delay in management actions that should have been taken in the last three decades.

Inland fish resources are often undervalued and under threat from unsustainable fishing activities, as well as from habitat alteration or degradation. Many river basins, especially in developing countries, support intensive fisheries, and in many cases catches are increasing.

3.3.3 Use of Fish Products

More than three-quarters of the world fish production is consumed by humans, fresh or processed in frozen, canned, or cured form. Most of the remaining portion is fed to animals, particularly in the form of fishmeal.

Fish and seafood consumption vary greatly between different regions of the world, from 1 kg to more than 100 kg per person per year. The worldwide average use of fish food reached 16.2 kg per person in 2002. Per capita production and consumption is particularly high in China and in other Asian countries. Developing countries now supply 70% of all the fish for human consumption, making an important contribution to their economy.

3.3.4 Trade in Fish Products

World fish trade has increased in terms of both value and quantity. In 2002, China overtook Thailand for the first time to become the world's main exporter of fish and fish products, with exports valued at an estimated US\$ 4.5 billion. The largest importer in 2002 was Japan, with over one fifth of the world's imports.

As fish is highly perishable, more than 90% of internationally traded fishery products are processed (frozen, canned, or cured). Products derived from aquaculture account for an increasing share of the international trade in fishery commodities.

Fish exports are an increasing source of foreign exchange earnings for many developing countries. These earnings are significantly higher than those coming from other commodities, such as rice, coffee, and tea. Exports from developing countries are gradually shifting from providing raw material for the processing industry in developed countries to selling high-value live fish or processed products. Trade in fishery products is increasingly covered by international agreements. Major market segments for fishery products include salmon, tuna, other finfish, shrimp, squid, and octopus, as well as fishmeal used to feed animals. Increased international trade offers many benefits but also presents new safety and quality challenges.

3.3.5 Fisheries Regulations

International interaction and collaboration on fishing matters relies on a large number of regional fishery bodies. In the last 50 years, these have gained a more active role in decision-making. Their role changed particularly after the early 1990s as a result of the growing awareness of the scarcity of fishery resources. However, strengthening regional bodies does not always translate into more effective fisheries management. Their actions can be limited if countries do not give them enough power or do not implement their decisions.

Aquaculture is being increasingly regulated by measures such as labelling for origin, traceability, and veterinary drug residues. Major importing regions and countries have begun to set stringent standards and regulations to ensure quality and safety and to reduce the social and environmental impacts of production. In many developing countries, however, progress towards sustainable practices is slow.

Development policies increasingly perceive aquaculture as an engine for economic growth. The aquaculture sector does indeed expand, diversify, intensify, and advance technologically at a faster pace than any other animal-producing sector.

The "The State of the World Fisheries and Aquaculture" concludes that developments in world fisheries and aquaculture during recent years have continued to follow the trends that were already becoming apparent at the end of the 1990s: capture fisheries production is stagnating and aquaculture output is expanding faster than any other animal-based food sector.

There are growing concerns with regard to safeguarding the livelihoods of fishers as well as the sustainability of both commercial catches and the aquatic ecosystem from which they are extracted.

3.3.6 Future Prospects for Fish and Fish Products

According to the projections there would be a global shortage of supply of fish in future. Although the severity of the shortage would differ among countries, the overall effect would be a rise in the price of fish. Prices for all types of fish would increase in real terms by 3.0 and 3.2 percent by the years 2010 and 2015, respectively.

At world equilibrium prices, growth in world fish production is projected to slow down from the rate of 2.9 percent per year recorded during the past two decades to 2.1 percent per year between 1999/2001 and 2015. Global fish production in developing countries is projected to grow at 2.7 percent per year during the projection period, which is at half the rate recorded, on average, during the past two decades. In these countries, capture fisheries are expected to grow at only 1 percent per year. Therefore, most of the increase would come from aquaculture, which is expected to grow at 4.5 percent per year. The share of developing countries in world fish production is expected to increase from 75 percent in 1999/2001 to 81 percent by 2015. Total fish production in developed countries would only grow at 0.3 percent per year. This, however, represents an improvement with respect to the negative growth experienced during the past two decades. As a result, the share of developed countries in total world fish production is expected to fall from about 25 percent to 19 percent by 2015. Capture fisheries production in developed countries is expected to stagnate or even decline in absolute terms during the projection period.

On average, people will be consuming more fish in 2015, but increases henceforth are likely to accrue more slowly than in the past two decades. At equilibrium prices, global per capita fish consumption would increase at an annual compound rate of 0.8 percent from 1999/2001 to 2015, down from the rate of 1.5 percent achieved over the past 20 years. Developing countries would lead with per capita demand growth projected at 1.3 percent per year, while per capita demand would decrease yearly, on average, by 0.2 percent in developed countries.

3.3.7 Fish Consumption to 2030 in the European Union

FAO has commissioned a study³ on the long-term projections for fish consumption in the EU. The study indicates that, compared with 1998, per capita fish consumption⁴ in the

³ The projections of future fish consumption are based on assumptions derived from past trends, literature review and expert consultations. More than 1 200 assumptions were made for growth rates in capture fisheries, aquaculture, commodity production, and imports and exports of commodities. For capture fisheries, it is likely that the European vessel production will face zero growth up to 2030. Aquaculture is growing at a substantial rate for salmon, sea bass and sea bream, but environmental constraints, coastal zone occupation choices by civil society and health regulations will not allow fish farming to continue its exponential trends in the future.

⁴ Total apparent consumption (net supply for human consumption) divided by the number of inhabitants of a country.

EU-25 countries⁵ during the period 2005–30 will show an increasing trend (varying from 1 to 12 percent) in 19 countries⁶ and a decreasing trend (from 1 to 4 percent) in 6 countries.⁷

General consumption trends for the pre-2004 EU-15 countries reflect an increase in the consumption of seafood products. This rise is supported by an increase in the consumption of convenience products. Frozen products tend to be on a downward trend, while the consumption of fresh fish will stagnate or decrease. The rising share of supermarkets in the retail of seafood products will also increase their availability, leading to increased consumption, while growing consideration of the health benefits of seafood may further fuel the positive trend in consumption.

Improvement of economic conditions is the main force behind the increased per capita consumption in the new member countries. Frozen fish still represents the bulk of fish consumption, but the variety of species in this group will increase, with small pelagic species losing ground to demersal or other more exotic species, such as crustaceans, molluscs or cephalopods. Freshwater fish will gradually be replaced by marine species, as the latter are often easier to prepare, offer wider variety in terms of taste and are becoming increasingly available owing to the spreading of supermarkets.

The increase of the net supply will be possible because of a rise in imports from third countries (mainly Asian, African and South American countries) and an increase of aquaculture production in some countries (Greece, Spain, Norway and the United Kingdom). The addition of new countries to the EU will increase intra-European trade: first, because a large proportion of external European trade is currently between Western countries and Eastern and Northern countries; secondly, as a consequence of the relocation of Western plants to newly joined Eastern countries such as Poland or the Baltic States; and, thirdly, because of a reduction of re-export mechanisms among Western countries. In the same vein, decreasing trade barriers and improvements in the quality of processed fish products from developing countries will lead to restructuring within the European processing industry.

3.4 The Fisheries Sector in the European Union

The European fisheries sector is changing rapidly. Processes of restructuring, reduction and expansion are occurring simultaneously in the various sub-sectors as a response to numerous developments. The effects of these changes vary, clearly, among member states. Conservation of the fish stocks is probably the largest challenge to European fisheries policy due to the heavy exploitation of a number of commercially important stocks, of which a number are outside what is defined as ‘safe biological limits’. In the last decades the overcapacity of the EU fleet has put considerable pressure on fish stocks, best exemplified by the development and current situation of the cod in the North Sea. Hence, a major challenge of the CFP has been and still is to improve the balance between harvesting capacities and fish resources available for exploitation. Over the last decades fish has become the single most internationally traded food in the World. The continued globalisation of the trade in fish and fish products has a major impact on the structure of the European fisheries sector. EU is the World’s biggest market for fish and fish products

⁵ Austria, Belgium, Luxembourg, Cyprus, the Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Malta, the Netherlands, Poland, Portugal, Slovakia, Slovenia, Spain, Sweden and the United Kingdom.

⁷ Cyprus, Estonia, Ireland, Portugal, Sweden and Spain.

and increasingly the European fish processing sub-sector is sourcing raw material and semi processed products from suppliers all around the globe. This development together with increased both horizontal and vertical integration within the fisheries sector affects the localization of the industry.

In the context of this study it is interesting that the agreed measures within the framework of the CFP have important territorial impacts in the regions, where fishing and related activities take place – usually coastal regions and often areas where there is little prospect of growth in alternative economic sectors. This makes the CFP and related policies important for coastal regions throughout Europe. The situation is most outspoken in the areas most dependent on fisheries and related activities. Such areas can – depending on the level of disaggregation - be identified in many European countries. Furthermore, the impact of the measures varies between the fisheries dependent regions, as not all regions are equally well suited to face the processes of restructuring, reduction and expansion. This means that some regions might benefit from the measures agreed while others might not. Taking into account the severity of the present situation for the EU fisheries, it might be more fair to say that most fisheries dependent regions are facing problems but some regions are facing more problems than others.

The European Union accounts for approximately 5 percent (7,414,166 tonnes in 2001, EU15) of the world's fish production (catch and aquaculture) in terms of volume. This makes the EU the World's third largest producer, capture fisheries remain the most important primary activity but aquaculture is becoming increasingly important, not least because demand is increasing and yield from capture fisheries are decreasing. However, the internal aquaculture and capture fisheries production is not nearly enough to satisfy the demands of the Union's more than 450 million consumers and the EU is therefore net-importer of fish products both in terms of value and volume. This makes the Union an important market for a number of exporting countries, including Norway and Iceland. The trade deficit in fish products of EU15 was in 2002 around € 10.5 billion, based on total exports amounting to approximately € 14 billion and total imports amounting to approximately € 24.5 billion.⁸ Most individual EU member states are net-importers, the most notable exception being Denmark, which had a trade surplus of a little more than € 1 billion in 2002. The largest individual net-importers are Spain, France and Italy, which all had trade deficits of more than € 2 billion including intra-EU15 trade in 2002 (European Commission, Eurostat, 2003, p. 50ff). Fish related activities take place almost everywhere in the European Union, mainly in the forms of freshwater aquaculture in inland areas and capture fisheries and marine aquaculture in the coastal areas. The most important activities are capture fisheries and processing in coastal areas.

3.4.1 The Common Fisheries Policy

The requirement to adopt a common policy in the area of fisheries was provided already by the founding Treaties from 1957 by including products of fisheries in the definition of agricultural products, for which the Treaties required that a common market should be established. However, not much happened in the area of fisheries before the end of the 1960's. The Commission issued the first report regarding the prospect of a common fisheries policy in 1966 and two years later concrete proposals were presented. Actual decisions were, nevertheless, not taken until Denmark, Norway, Ireland and the UK applied for membership; all four countries had comparatively important fishing sectors. This made the majority of the six original member states favour agreement on a common fisheries policy before the accession of these states. The basic principles of the CFP were,

⁸ Note that the figures for import and export, which are for EU15, include intra-EU trade.

consequently, agreed on 30 June 1970 - one day before negotiation with the four applicants began. The content of Council Regulation (EEC) No 2141/70 on structures and Council Regulation (EEC) No 2142/70 on markets became as a result part of the *acquis communautaire*. Especially one provision in the regulation on structures was problematic in the eyes of the four applicant countries: the principle of 'equal access', which meant that Community vessels would have equal access to the waters of all Community member states. No conservation policy was agreed at the time, partly because it had not been requested by any of the six member states and partly because an effective conservation policy needs to cover the whole area. This area is inhabited by a fish stock, and at the time the exclusive economic zones (EEZ) claimed by the EU member states were 12 nautical miles. The 200 nautical miles EEZs of the EU member states were not claimed until later. Denmark, Ireland and UK joined the Community as from 1 January 1973; whereas Norway following a negative referendum, in which the issue of jurisdiction over fisheries played an important role, stayed outside.

In 1976 the EU member states decided - prompted by the spirit of emerging international law - to collectively extend their EEZs to 200 nautical miles from 1 January 1977 (with special provisions applying inside the 12 miles zone). Following the provisions of the regulation on structures a Community sea with equal access was automatically created, something that made the adoption of a comprehensive conservation policy a *de facto* possibility for the first time. Moreover, the Commission was granted the right to negotiate agreements with third countries and represent the member states in relevant international fisheries organisations. This established a Community external fisheries policy.

The first basic regulation of the CFP, Council Regulation (EEC) No 170/83, was agreed on 25 January 1983 together with a number of other regulations relating to fisheries. Based on the agreed principle of equal access between 12 and 200 miles it was clear that some system to limit the catches was necessary to prevent overfishing in the Community waters. The system agreed was to be that of TACs broken into national quotas, mostly because a system of TACs was familiar to fisheries administrators from the North East Atlantic Fisheries Commission (NEAFC). It was agreed that the TACs should be set on the basis of scientific advice from the International Council for the Exploration of the Sea (ICES). However, the connected issue of allocating the catch possibilities between the member states proved hard to settle. The outcome of the negotiations was the establishment of the principle of 'relative stability' meaning that the member states were allocated a fixed share of the agreed TACs for the different stocks. This core element of the present CFP must be seen as one of the most concrete testimonies of the recognition of the potential territorial impact of EU fisheries policy - here with the member states as the principal territorial unit.

The regulations of 1983 completed the establishment of a CFP with the introduction of a conservation policy. Many of the contours of the present CFP became clear with the adoption of the first basic regulation but the CFP has been under major reform in two rounds, in 1992/1993 and most notably as late as 2002/2003.

A number of measures have been implemented and others are foreseen/in the pipeline to achieve a sustainable fisheries sector in the EU. Total allowable catches (TAC) and quotas, fleet reduction schemes, effort regulation schemes, minimum landing size and mesh limitations are some of the most important. The scope of the CFP as it is outlined in the current basic regulation can be examined in box 1 in the *Annex on the Common Fisheries Policy*.

A description and discussion of the CFP and its reform can be structured in various ways. However, the Common Fisheries Policy has traditionally been thought of as consisting of

four main areas: Conservation⁹ (which is arguably just as much about allocation), structures, markets and relations with third countries. The area of conservation is usually understood as the cornerstone of the CFP and is dealt with in the basic regulation - after 1 January 2003: Council Regulation (EC) No 2371/2002 - which the other areas of the policy have to relate to although their basic provisions are set out in separate regulations. In the following sections each of these four areas will be dealt with. Some of the actual policy-elements of the area and some of the changes, which were the result of the recent and ongoing reform of the CFP, will be the main focus. Along the way the potential territorial impact of the policies will be discussed.

Conservation Policy

The conservation policy is the centrepiece of the Community's fisheries policy. The basic regulation of the CFP is both the legislative act, whose objectives the remaining fisheries policy areas have to relate to and have to draw their justification from, and the act, which outlines the basic framework for the protection of fisheries resources in Community waters. The basic regulation, Council Regulation (EC) No 2371/2002, is consequently the key EU legal act specifically relating to fisheries.

A basic regulation was first agreed upon in 1983 as described in the introduction. Many of the key elements are today in essence the same but especially the reform of 2002 put increasing focus on multi-annual management and fishing effort limitation and supposedly set a new course for the future by changing the balance of the policy towards a more holistic environmental perspective rather than a more narrow fisheries perspective. In other words, the basis for the development and management of the fisheries sector in the EU changed significantly with the adoption of the new basic regulation of the CFP in December 2002. The regulation includes the basic provisions for the measures relating to the protection of resources, fishing fleet, monitoring/control and governance.

The Objectives of the CFP and the Conservation Policy

Certain changes in the objectives of the basic regulation, which are outlined in box 2 in *Annex on the Common Fisheries Policy*, can be considered important in relation to the future course of the CFP. Most notable in relation to conservation is the commitment to an eco-system-based approach and the application of a precautionary approach¹⁰, which are mentioned in the objectives of the new basic regulation as opposed to the previous. This can *ceteris paribus* be expected to lead to less fishing pressure in the short and medium term with negative impact in the affected coastal regions in general. However, in the longer term the regions will possibly benefit from more stable and possibly higher catches.

The eco-system approach can be described as a marine strategy, which entails that, on one hand, eco-system considerations (in this case fisheries' impacts on eco-systems) are taken into consideration when developing management strategies and, on the other hand, that eco-system considerations are implemented where such effects are known and can be integrated into management

Protection of and Access to Resources

⁹ Incl. resources, fleet (an overlap with the structural policy), monitoring and governance issues.

¹⁰ Application of a 'precautionary approach' to fisheries management "means that the absence of adequate scientific information should not be used as a reason for postponing or failing to take management measures to conserve target species, associated or dependent species and non-target species and their environment" (Council Regulation (EC) No 2371/2002, art. 3(i)).

The objective of the conservation policy is primarily to protect the fish stocks by limiting the amount of fish taken out of the sea each year and to ensure that this is respected. This is mainly done through a system of TACs for each stock, based on advice from the International Council for the Exploration of the Sea (ICES)¹¹, which are divided into national quotas¹² on the basis of the core principle of 'relative stability' (see box 3 in *Annex on the Common Fisheries Policy*).

Relative stability means that the quotas are calculated on the basis of a combination of 1) historic catches, 2) special provisions for coastal communities, which are heavily dependant on fishing, and 3) compensation for jurisdictional losses in catches in third countries' waters, which were the result of the creation of 200 nautical miles exclusive economic zones (EEZ) by the coastal states in the mid-70s (Holden, 1994, pp. 41-45). The member states manage their own quotas and they have thereby the possibility to take special regional considerations into consideration when allocating the quotas as long as the chosen approach does not conflict with the provisions of the CFP or other Community legislation.

Relative stability is a popular principle among most member states (with the most notable exception of Spain) but the Commission has nonetheless announced that it will look into how market forces can be allowed to play a greater role in the allocation of fishing opportunities within the Community.¹³ Depending on the mode of implementation this might give rise to the same issues as experienced under the Icelandic ITQ system (see section about Iceland), where the smallest fishing communities have lost access to resources compared with the larger communities. This might change the balance between the regions across the member states by allowing fleets with for instance excess capital to gain access to quotas from other fleets. This has to some extent already been experienced with the so-called 'quota hopping', which refers to the situation where economic actors in the form of shipowners - invoking Community laws giving them the right to exercise their activity in any of the member states - buy up used or license new vessels in other member states allowing them to fish on those member states' quotas. This has especially been the case with Spanish and Dutch shipowners. Although some countermeasures – in the shape of demands for a 'real economic link' - have been taken by the targeted member states, the phenomenon of quota hopping highlights the challenges in upholding a territorial logic of an economic sector within a single European market (Lequesne, 2000a). The EU framework does in this way in itself create a push toward more market based management options - also within the fisheries sector. Consequently, a possible change towards a market based management system will have territorial impact, but the form and extent of the impact will be very much depending on the actual mode of implementation.

The concrete measures, which are used to govern access to waters and resources, are outlined in the basic regulation and can be found in box 4 in *Annex on the Common Fisheries Policy*. Specific measures have assumed increasing importance in relation with the reform in 2002.

One of the most important new elements in relation to the resource policy is the obligation or possibility for the Council to adopt multi-annual recovery or management

¹¹ The final decision on the TACs is taken in the Council and the decision is political, although the scientific advice is the background of the decision.

¹² In case the stock in question is shared with one or more third countries, agreements are initially made with these on the allocation of the total TAC for the species.

¹³ DG Fish website: http://europa.eu.int/comm/fisheries/reform/access_en.htm (8 March 2005).

plans for certain fish stocks, which are “*outside safe biological limits*”¹⁴ or “*at/or within safe biological limits*” (Council Regulation (EC) No 2371/2002, art. 5, para. 1 and art. 6, para. 1). This is by many considered to be one of the main achievements in relation to protection of resources of the reform in 2002. Linked to this is the increasing focus on fishing effort (in terms of vessel days-at-sea) as a useful and necessary policy instrument. The instrument is not popular in all member states, and it has so far been applied in the most critical situations in relation to the recovery plans.¹⁵ The focus has so far been on the recovery plans (see also box 5 in *Annex on the Common Fisheries Policy*), which should be agreed for the most threatened stocks, but it is also expected that the management plans will prove important and be part of the general shift towards more long-term planning of management. This shift has presently very high - if not the highest - priority among the changes currently being implemented.

The starting point for the negotiations on the reform was a situation, which had developed and persisted over many years, with overcapacity of fishing fleets (estimated to be up to 40%) relative to the fishing opportunities and several fish stocks in a depleted state. The management strategy that the EU adopted in connection with the reform in 2002 will among other things aim at limiting the fishing effort through application of the days-at-sea instrument and possibly closed areas for the most depleted fish stocks. This strategy will, as described above, be implemented within a multi-annual quota-system, in which the quotas are combined with days-at-sea restrictions. The days-at-sea instrument implies that the number of vessel days-at-sea for those fleet segments that are fishing on the stocks that are managed under recovery plans, will be reduced. The days-at-sea instrument will increasingly expose the economic consequences of the excess capacity as is already seen in those fleets which depend on stocks for which low quotas have been set. This can be expected to lead to capacity reductions and can in the short and medium term be expected to lead to smaller allowable catches and consequently smaller landings. In the long run this should ideally lead to larger and more stable fish stocks. However, in a more pessimistic but likely scenario, the fishing effort will not be sufficiently reduced because of the size of the present overcapacity. This will imply the continuation of the crisis management of fish stocks in many years to come. In other words, if the increasing economic incentives for reducing capacity do not bring about the needed reductions, the quotas and/or combined days-at-sea restrictions will continue to work restrictively with negative effects for the affected regions.

The reduction of quotas that will most certainly be implemented in the short and medium term implies that for economic reasons (namely the cost of having unused excess capacity) it will be necessary to reduce the capacity of important segments of the fishing fleet until the depleted fish stocks have recovered. The segments, which are under most pressure, are those exploiting depleted stocks such as most cod stocks, some sole, nephrops and hake stocks. In this respect it is useful to distinguish between, on one side, the fleets targeting pelagic species where it generally speaking seems that a reasonable balance has been found, which means that the quotas are not restrictive in the sense that there is not severe overcapacity, and, on the other hand, the very diversified group of vessels targeting demersal species where such a balance has not been found, which means that overcapacity is a major problem and that quotas and quota reductions and/or effort reductions are more restrictive and have larger negative impact. It could be added that the

¹⁴ ‘Safe biological limits’ is defined as the point where the indicators of the state of a stock predict a low risk of transgressing certain ‘limit reference points’, for instance values of biomass or fishing mortality rate, which are to be avoided (Council Regulation (EC) No 2371/2002, art. 3(j) and (l)).

¹⁵ The first multi-annual recovery plans were adopted for the most depleted cod stocks by the Council in December 2003 and included fishing-effort limitation.

pelagic species are from a biological point-of-view on average in a better condition than the demersal. Regions with pelagic fleets are consequently in a better position to cushion the effects of the future fisheries restrictions than regions with demersal fleets. In relation to this it should be added that the fleets targeting pelagic species have, to a certain extent, been forced to restructure at an earlier stage and are now run as efficient enterprises.

Most of the pressure of quotas is obviously on the fleets, which exploit specific threatened stocks. This has important territorial implications, in so far as fleets from different regions traditionally exploit different stocks - both because of tradition and because of geographical proximity. Vessels from the regions, which exploit the most threatened stocks, can consequently expect to be worse off than vessels from the regions, which exploit less threatened stocks. This is reasonably fair considering the objectives of the conservation policy and the state of EU fish resources. However, as just described, this policy is by no means territorially neutral. There will, furthermore, be differences among the regions, which are affected negatively by the quotas. Some regions have fleets, which are able to redirect their fishing effort to other species, either by changing gear type or simply sailing to another area or a combination of the two. Other regions have fleets, which have physical constraints making them more vulnerable to the restrictions imposed by the policy, e.g. lack of ability to change gear or travel long distances.

Consequently, the different coastal regions can in theory be placed on a continuum, ranging from regions with fleets that are not targeted by quotas which are restrictive relative to the regional fishing capacity, over regions with fleets that are targeted by restrictive quotas but if necessary able to redirect effort, to regions with fleets that are targeted by restrictive quotas without being able to redirect fishing effort.¹⁶ The first group includes regions, which have fleets that fish either on species not subject to quotas or species where there is enough quota or at least not decreasing quotas. The second group includes regions with fleets, which fish on stocks with low and/or declining quotas that are able to redirect fishing effort to other species. These include for instance larger, modern vessels. The last group includes regions, which have fleets that are targeted by quota reductions and have little possibility of redirecting fishing effort. It seems likely that the small, traditional coastal vessels will form a significant part of those. A quota system, which at first glance is protecting the resources and being reasonably 'fair' by targeting the fleets that are fishing on these species, can consequently involve less reasonable or rational distribution of disadvantages across different regions. However, it should be remembered that the member states have something to say on this matter because the allocation of the national quota is up to the member states.

The days-at-sea instrument, which in connection with the recovery plans has been introduced in connection to the TAC system, distributes on its own disadvantages territorially unevenly, too. Again the issue is the flexibility of the vessels. The days-at-sea system means that certain vessels targeting specific species will only be allowed to be in a certain geographical area for a period corresponding to their awarded number of days-at-sea. This does not, however, prevent the vessels from targeting other species outside this area in the remaining time. For this to be feasible, the vessel must - like in the case of the quotas - be able to travel to another place and possibly change gear. This puts different fleet segments in qualitatively different situations, something which cannot be explained with reference to the objectives of the CFP, and thereby also different regions in different situations because similar types of vessels often concentrate in certain regions or ports.

¹⁶ A region can of course have parts of a non-targeted fleet and parts of a targeted fleet without alternatives. This is probably how it will most often be. However, the distinction between the three types is analytically useful but it should be kept in mind that the reality is more mixed.

The TAC and days-at-sea system is supported by a number of technical measures, which are directed mainly at preventing the (by-)catching of juvenile fish or non-target species. The technical measures include: minimum mesh sizes, minimum landing sizes, rules as to what fishing gear to be used and where, seasonal bans on fishing, closed areas/marine protected areas (MPA) etc. (see also box 4 on measures governing access to waters and resources and the sustainable pursuit of fishing activities in *Annex on the Common Fisheries Policy*). These measures are not territorially neutral and they can potentially have severe impact on the general situation of the fishing dependent regions, which host fleets fishing under these restrictions. This is in some sense self-explanatory since the technical measures restrict and regulate fishing activities in order to protect the resource base. However, like in the case of quotas and days-at-sea the technical measures can also have unintended side-effects, which place different regions in unequal situations. The explanation for this is basically the same as in relation to the quotas, namely that some vessels are more flexible than others, which means that they can, for instance in the case of areas being closed, sail to other open areas to fish (this equals a situation with no days-at-sea in a certain region).

Another important element of the CFP's resource policy is the core principle of equal access for EU vessels to the EU waters, which was described briefly in the introduction. However, special provisions apply within the member states' 12 nautical miles zone, where only foreign vessels with a historic record in the area are allowed to fish between 6 and 12 nautical miles off the coast. This exemption to the principle of equal access was upheld with the reform of the CFP in 2002 and must now be considered an institutionalised feature of EU fisheries policy, which has important regional implications. The 12 miles zone protects, on one hand, national (small-scale coastal) fleets by reserving a special area for them. This has, on the other hand, negative effects on vessels from other member states' regions, which are excluded from the area. The regions and member states, which benefit the most from this arrangement, are those with a sound fishable resource base inside the zone and in general a long coastline.

The Mediterranean

The Mediterranean Sea constitutes a special case within the area of conservation policy and is only fully integrated into the CFP in the areas of structural and market policies. In regards to the conservation policy, the main measure of TACs has traditionally not been applied in the area (COM (2002) 535 final, p. 4 and 9) and the only species in the Mediterranean, for which there is presently a TAC applying (since 1998), is bluefin tuna.¹⁷

Two regional fisheries organisations (RFO) are active in the Mediterranean: the International Commission for the Conservation of Atlantic Tunas (ICCAT) and the General Fisheries Commission for the Mediterranean (GFCM) (COM (2002) 535 final, p. 10). The fact that the conservation policy of the CFP has not been extended to the Mediterranean Sea can be explained with reference to a number of specific characteristics regarding the fisheries in these waters:

- A distinctive feature of the fisheries in the Mediterranean Sea is that most fishing takes place near to the coast within the territorial waters of the member states. The EEZs in the Mediterranean Sea is generally not extended beyond the 12 nautical miles territorial sea although some countries (for instance Spain and Malta) have claimed larger fisheries protected zones (FPZ), which opposed to EEZs only concern the fish resources. Consequently, there is a large area of

¹⁷ DG Fish website (TACs and quotas 2004):
http://europa.eu.int/comm/fisheries/doc_et_publ/pub_en.htm (3 December 2004).

international waters relative to the area under national control in the Mediterranean Sea. Connected to the fact that most stocks (excluding some highly migratory) concentrate within the 12 miles zone is the fact that relatively few fish stocks are shared between nations. The number is, however, increasing due to the development of new fisheries. Also, the perception of what fish stocks are shared is changing due to new scientific knowledge (COM (2002) 535 final, p. 4-5).

- The average size of the vessels in the Mediterranean Sea is smaller than in the rest of the European Union. The landings constitute a modest share of EU landings in terms of volume but a significantly higher share in terms of value, because most of the catches are used for human consumption. The large number of fishermen (42 percent of the jobs in the capture fisheries sector in the EU15 are found in the four member states bordering the Mediterranean Sea) operating small vessels from mostly small landing sites makes control and enforcement particularly difficult in this area, even though the control provisions of the CFP apply (COM (2002) 535 final, p. 5-6).
- The GFCM has a Scientific Advisory Committee but its role and importance is not comparable to that of ICES in regard to the North Atlantic. Consequently, the institution, which should coordinate and promote scientific activities, is not sufficiently developed (COM (2002) 535 final, p. 6).

The state of the resources in the Mediterranean Sea is problematic in so far as most species are considered to be overexploited. This, among other things, has led to low catch in several fisheries. However, only few stocks have been reported in risk of collapse. Estimates by ICCAT and GFCM suggest that fishing effort in fisheries targeting overexploited stocks should be reduced by 15 to 30 percent (COM (2002) 535 final, p. 6). Furthermore, the total volume of catches in the Mediterranean has been declining significantly from the mid-nineties until today (Eurostat database, 3 December 2004).

This situation has led to action from the European Commission in relation to the ongoing reform of the CFP. Until now the main CFP legislation in relation to management of resources in the Mediterranean Sea has been a regulation from 1994 on technical measures (Council Regulation (EC) No 1626/94). However, due to the developments in the area in regards to fishing pressure and declining catches, the Commission has proposed a Mediterranean Sea regulation (COM (2003) 589 final), which aims at introducing for instance strengthened technical measures, stronger control measures and effort regulations in the area. The fate of this proposal is at present not predictable, but it will surely not go unaltered through the legislative system of the European Union.

A likely future development in the Mediterranean is lower catches - either because of increasing and continued overexploitation or because of more structured management initiatives and/or Mediterranean policy agreements, for instance reinforcing effort control policy. Both scenarios can potentially lead to lower catches in the short term. This development could have severe negative regional impact in the area since many of the most fisheries dependent areas are traditionally found there.

Fleet

Among the major changes in the conservation policy from 1 January 2003 was the adoption of overall fishing fleet capacity ceilings (see box 6 in *Annex on the Common Fisheries Policy*) and discontinuation of the capacity reduction programmes in the form of Multi-Annual Guidance Programmes (MAGP I to IV), which had been in place since 1983 with mixed success. Especially the last MAGP IV (1998 to 2002) was deemed

inefficient, mainly because the objectives agreed were modest to the extent where it was questionable whether it was actually possible to talk about a *de facto* decrease in fishing effort due to technological advances in the corresponding period. Instead of setting targets for capacity reduction for different groups of vessels, as it was done in the MAGPs, the new strategy aims at creating an environment, which makes it increasingly profitable to reduce capacity in order to be more in line with the available resources. This is for instance done through the multi-annual recovery plans where excess capacity will be excluded from the affected areas by restricting fishing effort through use of the days-at-sea instrument, which will, as earlier mentioned, expose the economic consequences of not having a reasonable balance between capacity and available resources. It will be up to the member states to get rid of excess capacity.¹⁸

Monitoring and Control

Control and enforcement remains after the reform largely the responsibility of the member states, as was the case before the 2002 reform, although the Commission's role in this area has been slightly strengthened in the new basic regulation and some movement towards more uniform control and sanctioning can perhaps be expected (Council Regulation (EC) No 2371/2002, art. 26 and 27). The Commission has lately put forward a proposal (COM (2004) 289 final) on the creation of a Community Fisheries Control Agency (to be established in Spain), which must be seen as a move towards more uniform control and enforcement. Anyhow, the role of the Community will still mainly be to inspect and control; sanctioning will remain the responsibility of the member states.

Strengthening of Community control and monitoring will benefit regions in which control is already efficient in comparison with regions where lean control is being traded for social peace (House of Lords, Select Committee on the European Union, 2003, p. 16). However, in the short term stronger control and enforcement must be expected to have a general negative impact on the fisheries dependent regions because of the increased difficulties in supporting the vessel with money earned on for instance 'black fish'. Nevertheless, it should not be ignored that control and enforcement serves an important goal by protecting the resource base. In economic terms it could also be argued that stricter control serves to ensure fair competition between the regions; stopping the supply of illegal, possibly undersized fish would serve to increase prices, which would have a positive effect in the affected areas.

Governance and Regional Advisory Councils

A reoccurring critique of the CFP has been its failure to include stakeholders in the decision-making process. An innovative element and response to this criticism is that the new basic regulation provides the legislative basis for the creation of Regional Advisory Councils (RAC), which should be established in order to provide advice on management in fishing zones covering areas under the jurisdiction of at least two member states – ESPON meso level. Representatives of the affected interests (commercial fishermen, representatives of aquaculture or processing industries, environmentalists, consumers, and scientists) can participate in the RACs as members. Also regional or national administrators can be accepted as members (see box 7 in *Annex on the Common Fisheries Policy*).

This new creation is directed at removing the feeling among the affected interests¹⁹ that EU fisheries policy is unnecessarily top-down, command control and created by faraway

¹⁸ DG Fish website: http://europa.eu.int/comm/fisheries/reform/q&a_en.htm#9 (10 March 2005).

¹⁹ Especially the commercial fishermen, who to a certain extent feel that the EU does not take due account of their experience-based knowledge.

central institutions (Grieve, 2001, p. 13). The specifics regarding the RACs have subsequently been set out in a Commission decision in which it is stated that there can be seven of these councils: Baltic Sea, Mediterranean Sea, North Sea (operational as the first from 9 November 2004), north-western waters, south-western waters, pelagic stocks and high seas/long distance fleet (Commission Decision 2004/585/EC, art. 2(1)). It is not at this point in time possible to give a feasible prediction of the territorial impact of these councils, which have not been granted decision-making powers in relation to management. An interesting question is if the RACs will acquire such powers in the future and if so, the extent of those. If that turns out to be the case, this will open up for new perspectives on regional fisheries management. Nevertheless, it is clear that the establishment of the RACs serves as an indicator of the increasing awareness of the importance of thinking in regional terms in relation to EU fisheries management.

At the time of writing the North Sea RAC is the only RAC, which has been operating for more than one year. Besides responding to requests and proposals from the Commission etc. the North Sea RAC has so far put considerable emphasis on socio-economics and the issue of data on fisheries dependency. As a result of this the North Sea RAC has set up a socio-economic focus group to coordinate work on these issues. This group is working on developing procedures for integrating socio-economic considerations into the advice of the RACs; the questions that should be asked to each proposal are: *What positive socio-economic implications does the policy proposal/advice have for any sector of the fisheries industry or for associated communities? What negative socio-economic implications does the policy proposal/advice have for any sector of the fisheries industry or for associated communities? Are these positive and negative implications acceptable and how can they best be managed? eg – by using management instruments, compensatory schemes, subsidies or incentive schemes.* In order to be able to approach these questions the working group is looking into the possibilities of having a study of socio-economic fisheries dependency around the North Sea carried out. The study should include the areas around 70 ports in the UK, Denmark, Netherlands, Germany, France, Belgium and Norway. The finished project is intended to provide a dynamic overview of fisheries dependency around the North Sea, which can identify and explain the vulnerability of the fishing industry and associated sectors and communities to changes in fisheries policy. Consequently, the project will be providing data, which can be used to assess the impact of management measures (www.nsrac.org).

It seems obvious that data from the ESPON database will also be of interest to the RACs in this respect - even though that the RAC uses ports rather than the NUTS regions as its point of departure.

Summing up the Territorial Implications of the Conservation Policy

In general it could be said that none of the restrictive conservation measures - be it quotas, effort control or marine protected areas etc. - are territorially neutral since they in general aim to restrict fishing pressure, which might in the long turn lead to higher catches but in the short and medium term reduce catching possibilities and increase costs for the fleet.

As described, the measures can furthermore be expected to increase regional disparities unintentionally in some cases because certain fleet segments will be better physically equipped to 'circumvent' the restrictive measures, e.g. a larger range of operation. This must be considered an unintended side effect with regional implications. Furthermore, this inequality in handling the measures might in itself be counterproductive for the CFP since there is no guarantee that the fleet best able to circumvent the measures are those, which are preferably seen in the light of the objectives of the CFP (e.g. fishing with little damaging impact on the eco-system) - perhaps on the contrary. To describe these

mechanisms with reference to the entire European space on NUTS3 level is not possible but example studies will highlight some of these issues on a more concrete level than what has been presented above.

An innovative governance element of the reformed CFP is the creation of RACs. It is not at this point in time possible to give a feasible prediction of the territorial impact of these councils, which have not been granted decision-making capabilities in relation to management. An interesting question is if the RACs will acquire such powers in the future and if so, the extent of those. If that turns out to be the case, this will open up for new perspectives on regional fisheries management.

Structural Policy

The EU structural policy for the fisheries sector relates to the Community's Economic and Social Cohesion Policy. The main measure of the CFP's structural policy is the Financial Instrument for Fisheries Guidance (FIFG), the objectives of which are presented in box 8 in *Annex on the Common Fisheries Policy*. The FIFG provides support to the development of the capture, processing, aquaculture sub-sectors, for protected areas and for harbour development etc.

The allocation of funds through the FIFG has clear territorial implications as some regions get more EU support than others and some get none. Since all regions contribute to financing the EU budget (through the member states), the allocation of funds redistributes money between the regions; this is also in general the idea. In ideal terms the regions, which receive the most, should also be the ones with the greatest need for structural aid for fisheries. This is, however, not necessarily always the case due to the criteria (for instance average GDP) establishing, which regions can get the highest share of EU support. Furthermore, the enlargement of the Union with 10 new member states, of which the majority has greater need for structural support than the regions of the old member states, might have disproportionate implications for the regions, which will in the future receive less funds. The funds have consequently 1) direct impact on the wellbeing of eligible regions because of the transfer of money and 2) impact on the balance between regions, which are not necessarily able to receive the same share of funding to similar fisheries related projects.

The structural policy of the CFP is increasingly being seen as an integral part of the conservation policy; a development, which can be traced back to the beginning of the nineties. This is also indicated by the fact that some structural policy provisions were incorporated in the reform in 2002 and written into the basic regulation under the heading 'Adjustment of Fishing Capacity' (Council Regulation (EC) No 2371/2002, ch. III). It can be expected that the links between the conservation and structural policies of the CFP will continue to be strengthened in the years to come.

The multi-annual guidance programmes (MAGP) have in the past been one of the main ways of coordinating the structural policy with the conservation policy. However, these programmes were deemed too ineffective with respect to the aim of reaching a better sustainable balance between resources and fishing pressure. The MAGPs involved the setting of targets for capacity reduction for different groups of vessels for each member state in order to bring capacity in line with the available resources. If these targets were not met, the member state could for instance not receive aid for fleet renewal and modernisation. A new approach, which is described in the previous section on the conservation policy and in the section on the FIFG 2000 to 2006, was decided in connection with the reform in 2002. The last MAGP (IV) ended on 31 December 2002

and no new MAGP was proposed. However, the targets as of December 2002 were used as reference levels in the new scheme.²⁰

The current FIGF programme runs from 2000 to 2006 but the measures, for which assistance can be given, were changed in connection with the reform of the CFP in 2002. However, information on the actual regional implementation of the FIGF programme, which ran from 1994 to 1999, is more complete than for the current programme.

The present discussion of the CFP's structural policy will take its point of departure in and focus on the FIGF programme from 1994 to 1999. In the following section the present FIGF programme and the changes, which were decided in December 2002 will be examined. The provisions of the programme, which will run from 2007 to 2013, have not yet been finally decided upon but the Commission has presented a proposal containing the contours of a European Fisheries Fund, which will also be presented. Finally, the territorial implications of the structural policy will be summarized.

Although the FIGF is the main financial instrument, which targets the fisheries sector, other programmes have targeted the sector. One of these is the Pesca initiative (1994-99), which had a clear territorial focus. This initiative is presented in box 9 in *Annex on the Common Fisheries Policy*.

FIGF 1994 to 1999

The projects, which were funded by the FIGF programme 1994 to 1999 had in total a budget of a little more than € 5 billion. The EU contributed with € 2.125 billion (hereafter referred to as EU FIGF support, expenditure etc.) and the member states with a little less than € 1 billion. The rest was financed by local and private funds, in other words the beneficiaries.

That a certain share has to be paid by the beneficiaries themselves has potential territorial implications. There is an obvious risk that financial support may not always go into the regions, which have the greatest need for support. This might be especially relevant for countries, where most of the country is defined as objective 1, despite the fact that there are differences between regions within the countries. In other words, all the regions are lacking behind but some are lacking more behind than others. This issue is particularly relevant in relation to the new member states, which are generally defined as objective 1 areas (minus Cyprus and very small areas around the capitals of the Czech and Slovak Republics), but the problem is by no means restricted to these member states.

The problem is that due to the better economic situation (and the possibility to finance for instance 50% themselves) enterprises situated in more developed areas are also those, which send in more applications. Poor enterprises in poor areas are in contrast possibly not able to cover self-financing and are thus not eligible. In conclusion there is a very real risk that most of the money may fall into the more developed areas of the generally underdeveloped areas. This is contradictory to the objectives of the structural funds including the FIGF.

A similar idea has been put forward by Lequesne (2004, p. 94) - although not with a specific territorial perspective but the parallel is obvious: *"Admittedly, European distribution and redistribution are not necessarily synonymous with a reduction in individual inequalities. In the case of structural funding, the professional actors who are locally the best organised, and particularly the industrial shipowners, often demonstrate*

²⁰ DG Fish website: http://europa.eu.int/comm/fisheries/news_corner/press/inf02_61_en.htm and http://europa.eu.int/comm/fisheries/pcp/faq2_en.htm (9 March 2005).

a capacity to take maximum advantage of Community subsidies to which the territory in which they are established can lay claim".

The areas, for which assistance could be given under the FIFG programme, were the following (see also *Annex on the FIFG 1994 to 1999*):

- (a) adjustment of fishing effort (27.1% of EU FIFG support);
- (b) renewal and modernisation of fishing fleet (26.3% of EU FIFG support);
- (c) aquaculture (8.0% of EU FIFG support);
- (d) protected marine areas (0.9% of EU FIFG support);
- (e) fishing port facilities (6.0% of EU FIFG support);
- (f) processing/marketing of products (22.1% of EU FIFG support);
- (g) promotion (2.8% of EU FIFG support);
- (h) other measures (6.5% of EU FIFG support);
- (i) socio-economic measures (0.4% of EU FIFG support).

The areas of assistance can furthermore be broken down to specific measures. A list of these measures can be found in the *Annex on the FIFG 1994 to 1999*. Data on the financial implementation of the programme (divided on respectively area of assistance plus specific measure and on member state) can be found in the same annex.

Three areas of assistance accounted for more than 3/4 of the total EU FIFG support given, namely 1) adjustment of fishing effort, 2) renewal and modernisation of fishing fleet and 3) processing/marketing of products. Inside these areas most EU FIFG support was given for these specific measures: scrapping of vessels (€ 376.64 million), construction of new vessels (€ 367.57 million) and increasing processing capacity (new production units and/or extension of existing production units) (€ 267.95 million). These three specific measures accounted for close to half of all EU FIFG support given in the period. It is noticeable that the Union supported construction of new vessels with almost the same amount of money as scrapping of vessels in a situation with a generally accepted overcapacity of the European fleet in the neighbourhood of 40 percent. This paradox was not approached until the reform of the CFP in 2002, which will be touched upon in the section on the FIFG from 2000 to 2006.

However, in the context of this study it is just as interesting how the support was distributed between the different member states.²¹ In the *Annex on the FIFG 1994 to 1999* the distribution between the different member states is presented. However, the figures cannot be compared directly because the presence of fishing activities differs throughout the Union as does the size of the member states in terms of population. It is noteworthy, though, that Spain received almost half of all EU FIFG support in the period from 1994 to 1999.

The regions, which could get up to 75% (collective infrastructures and premiums) or 50% (investment in businesses) of the eligible costs of the projects funded by the EU, were those lagging behind in development (objective 1 of the EU structural funds) or regions with very low population density (objective 6 of the EU structural funds).²² Regions

²¹ Sweden, Austria and Finland were not eligible until they entered the Union on 1 January 1995.

²² The eligible regions in objective 1 or 6 areas were: Belgium: Hainaut; Denmark: none; Germany: Berlin-Öst, Brandenburg, Mecklenburg-Vorpommern, Sachsen, Sachsen-Anhalt, Thüringen; Greece: whole country; Spain: Andalucia, Asturias, Canarias, Cantabria, Castilla y León, Castilla la Mancha, Ceuta y Mellila, Extremadura, Galicia, Murcia, Comunidad Valenciana;

outside objective 1 or 6 areas were eligible to up to 50% (collective infrastructures and premiums) or 30% (investment in businesses) cost sharing. Whether a region is defined as an objective 1 or 6 area or not is therefore important. This places (in some cases) fishermen from different regions in different situations with regards to EU support. This is not necessarily 'fair' - in the sense that the ones with most need for support should also have access to most support. The criteria for being an objective 1 or 6 region is not linked specifically to the situation of the fishermen but rather to the GDP or population density of the region as a whole. A specific example is the fact that the Spanish NUTS2 region of Galicia was and is defined as an objective 1 region, while the NUTS2 region of the Basque country (Pais Vasco) is not. The fishermen in Galicia and the Basque country are more or less equally in need of support but the former can nonetheless get more co-funding from the EU to FIFG projects (Lequesne, 2004, p. 363). Similarly it is not always obvious that fishermen in areas with low population density are in a worse position than fishermen in densely populated areas.

The fisheries and aquaculture sector appeared in 32 FIFG programmes in total.²³ 15 of these programmes were integrated regional development programmes in objective 1 or 6 areas:

- Belgium: Hainaut (1 programme);
- France: Corse & Départements d'Outremer (5 programmes);
- Netherlands: Flevoland (1 programme);
- Austria: Burgenland (1 programme);
- Portugal: Açores & Madère (2 programmes);
- Finland: Etelä-Savo, Kainuu, Lappi, Pohjois-Karjala (1 programme);
- Sweden: Jämtlands län, Norrbottens län, Västerbottens län (1 programme);
- United Kingdom: Highlands & Islands of Scotland, Northern Ireland, Merseyside (3 programmes).

Another 6 FIFG programmes were specific fisheries programmes in objective 1 areas (one programme per member state):

- Germany (Berlin-Öst, Brandenburg, Mecklenburg-Vorpommern, Sachsen, Sachsen-Anhalt, Thüringen);
- Greece (whole country);
- Spain (Andalucía, Asturias, Canarias, Cantabria, Castilla y León, Castilla la Mancha, Ceuta y Melilla, Extremadura, Galicia, Murcia, Comunidad Valenciana);
- Ireland (whole country);
- Italy (Abruzzo, Basilicata, Calabria, Campania, Molise, Puglia, Sardegna, Sicilia);

France: Corse & Départements d'Outremer; Ireland: whole country; Italy: Abruzzo, Basilicata, Calabria, Campania, Molise, Puglia, Sardegna, Sicilia; Luxembourg: none; Netherlands: Flevoland; Austria: Burgenland; Portugal: whole country; Finland: Etelä-Savo, Kainuu, Lappi, Pohjois-Karjala; Sweden: Jämtlands län, Norrbottens län, Västerbottens län; United Kingdom: Highlands & Islands of Scotland, Northern Ireland, Merseyside. From DG Fish website: http://europa.eu.int/comm/fisheries/structures/objectif_en.htm (3 March 2005).

²³ From DG Fish website: http://europa.eu.int/comm/fisheries/structures/liste_en.htm (3 March 2005).

- Portugal (mainland).

The remaining 11 FIFG programmes, of which there were one for each of the following member states, were outside objective 1 or 6 areas: Belgium, Denmark (whole country), Germany, Spain, France, Italy, Luxembourg (whole country), Netherlands, Finland, Sweden and United Kingdom. The funds for these projects were given through the FIFG under the specific objective 5a in order to accelerate the modernization of agricultural and fishery structures.

For the FIFG 1994 to 1999 it is possible to get information on the regional distribution of the support on NUTS2 level (see *Annex on FIFG implementation NUTS2 1994 to 1999*). It is consequently possible to see, which regions benefited the most from EU FIFG support (in absolute terms). The table beneath gives an overview of the nine NUTS2 regions, which have each received more than 2 percent of the total EU FIFG support given in the period 1994 to 1999. It should be kept in mind that this is by no means a perfect indicator for the impact of EU FIFG support, which very much depends on the level of fisheries related activities and the size of the region in terms of population.

Table 3.1 The nine most favoured NUTS2 regions in relation to EU FIFG support

Member state	NUTS2 code	Region	EU FIFG support	Share of total
Spain	ES11	Galicia *	€ 433.49 million	20.39%
Spain	ES61	Andalucia *	€ 192.93 million	9.08%
Denmark	DK00	Denmark	€ 95.25 million	4.48%
Spain	ES21	Pais Vasco	€ 75.22 million	3.54%
Spain	ES70	Canarias *	€ 65.27 million	3.07%
Germany	DE80	Meckl. Vorp. *	€ 54.88 million	2.58%
Spain	ES52	C. Valenciana *	€ 54.23 million	2.55%
Italy	ITG1 ²⁴	Sicilia *	€ 48.88 million	2.30%
Portugal	PT16 ²⁵	Centro *	€ 46.05 million	2.17%
* = objective 1 region			€ 1,066.20 million	50.16%

The nine NUTS2 regions, which received the most EU FIFG support in the period from 1994 to 1999, accounted for more than half the total support given; this has to be compared with the fact that more than 150 NUTS2 regions received EU FIFG support in the period. The Spanish region of Galicia received more than 20 percent of the total and constitutes in this way an extreme. Most EU support in Galicia targeted 'adjustment of fishing effort' (€ 146.54 million) followed by 'renewal and modernisation of fishing fleet' (€ 125.71 million) and 'processing/marketing of products' (€ 107.43 million).²⁶ It can furthermore be concluded that seven of the nine regions were defined as objective 1 regions.

²⁴ New NUTS code compared to data in *Annex on FIFG implementation NUTS2*. Same geographical region.

²⁵ New NUTS code compared to data in *Annex on FIFG implementation NUTS2*. The new Centro region includes part of the former PT13 region, which means that the support given to the new Centro region in the period from 1994 to 1999 was probably larger than indicated here.

²⁶ Galicia had furthermore access to approximately 12 million ECU under the Pesca initiative. From DG Fish website: http://europa.eu.int/comm/fisheries/doc_et_publ/liste_publi/ifop/esen.htm (3 March 2005).

Lequesne (2004, p. 363) mentions Galicia, Brittany and Scotland as examples of areas where the EU (FIFG and Pesca, combined with national and regional) structural aid for the fisheries sector constituted a significant injection of money in the period from 1994 to 1999. However, the amount of money has - in all fairness - also to be seen in relation to the fishing activity of the regions. Although this is not easy due to data-availability problems, an attempt at this will be made in Chapter 7.

FIFG 2000 to 2006

The FIFG programme 2000 to 2006 is now under implementation. A mid-term evaluation was conducted in 2004. Information on the projected implementation of the programme divided on area of assistance and member state is presented in *Annex on the FIFG 2000 to 2006*. The total budget of EU support to the programme is a little more than € 3.7 billion. Spain is once again the main beneficiary member state, receiving 46.3% of the EU aid. Approximately € 1.1 billion are likely to be allocated to areas not defined as objective 1 regions.²⁷

Preference is still given to regions in objective 1 areas, which now covers both low population density and low GDP, but some regions are no longer eligible under the criteria and therefore receive transitory support.²⁸ As mentioned earlier this has implications for fisheries in these areas because the criteria for being an objective 1 region depends on the average level of the GDP pr. capita and population density, and not on the actual situation of the fisheries sector. The former objective 6 areas (low population density, FIFG 1994 to 1999) have been merged with the present objective 1 areas in connection with a general reduction of the number of different objectives under the structural funds. The maximum rate of assistance to investments in businesses in objective 1 areas has been reduced from 50% in the previous FIFG programme to 35% in the current; outside these areas the reduction has been from 30% to 15%. The maximum support rates for collective infrastructures and premiums (respectively 75% and 50%) have been maintained. Objective 5a has ceased to exist but funds are made available from the FIFG outside objective 1 areas (with the reduced support rates), which creates a situation similar to the previous system.²⁹

The legal basis of the current fisheries structural policy programme is Council Regulation (EC) No 2792/1999 and Council Regulation (EC) No 1263/1999. The objectives are presented in the beginning of this section on the structural policy (see box 8 in *Annex on the Common Fisheries Policy*). The specific areas of assistance in the FIFG programme 2000 to 2006 are:

- fleet renewal and modernisation of fishing vessels,
- adjustment of fishing effort,
- joint enterprises,
- small-scale coastal fishing,
- socioeconomic measures,

²⁷ From European Union website: <http://europa.eu.int/scadplus/leg/en/lvb/l60017.htm> (4 March 2005).

²⁸ These regions are: Belgium: Hainault; France: Corse and the arrondissements of Valenciennes, Douai and Avesnes; Germany: Ostberlin; Ireland: Southern and Eastern; Italy: Molise; Netherlands: Flevoland; Portugal: Lisboa e Vale do Tejo; Spain: Cantabria; United Kingdom: Northern Ireland, Highlands and Islands of Scotland. From DG Fish website: http://europa.eu.int/comm/fisheries/news_corner/doss_inf/ifop4_en.htm (3 March 2005).

²⁹ From DG Fish website: http://europa.eu.int/comm/fisheries/news_corner/doss_inf/ifop4_en.htm (6 March 2005).

- protection of marine resources in coastal waters,
- aquaculture,
- fishing port facilities,
- processing and marketing of fishery and aquaculture products,
- measures to find and promote new market outlets,
- operations by members of the trade,
- temporary cessation of activities and other financial compensation,
- innovative actions and technical assistance.

(Council Regulation (EC) No 1263/1999, art. 2, para. 3)

An overview of the distribution of the planned allocation of aid between the different areas of assistance (slightly different categories than mentioned above) can be found in the *Annex on the FIFG 2000 to 2006*. Again fleet renewal, scrapping and measures supporting processing and marketing are the areas with the largest budget - accounting for more than 60 percent of the total funds.

An important discussion in relation to the FIFG in the negotiations of the reform of the CFP in 2002 was whether or not to continue public aid (EU or national) for the construction and modernisation of fishing vessels. This would - without any action taken - be continued under certain conditions until 2006. The granting of aid for building or modernising of fishing vessels in a situation with severe overcapacity was by many thought to undermine the objectives of the conservation policy. However, it has to be kept in mind that aid can be given for modernising without increasing the fishing capacity. This goes for instance for aid given for improving the working conditions on board. Consequently, one thing is to give aid, which results in increasing fishing capacity, another thing is to give aid for modernising to live up to sanitary regulations. Important elements of the (complex) final compromise on structural support were the introduction of a transition period until 31 December 2004 where aid could still be given for building of new vessels under 400 gross tonnes under conditions of an equivalent or larger capacity withdrawal and an overall three percent capacity decrease in 2003-2004 in those member states, which chose to give public support to fleet renewal (Council Regulation (EC) No 2369/2002, point 9 and Council Regulation (EC) No 2371/2002, art. 13, para. 1 and 2). After the end of 2004 it is not possible to give public aid to the construction of new fishing vessels in the EU (see box 10 in *Annex on the Common Fisheries Policy*).

The decision to phase out aid for new vessels was the result of a compromise between two major blocks in the Council, namely the 'Amis de la Pêche'³⁰ group (consisting of Spain, France, Greece, Italy, Portugal and Ireland) and the 'Friends of Fish' network (consisting of Germany, Sweden, UK, the Netherlands, Belgium and to some extent Finland, although not on the issue of aid). The alliances within the Council give some evidence to the different member states' general perspective on the importance of public aid to fisheries - perspectives which were also influenced by the member states' different perceptions of whether or not public aid to renewal or modernisation would in one way or the other eventually result in increasing fishing capacity or could be limited to improving e.g. hygienic standards. However, other factors were also decisive in the way the discussions evolved; for instance the lack of involvement of the Scottish Parliament on EU matters, the strong involvement of the Galician local government, as well as the fact that a 'green' party was in government in Germany and another constituted the parliamentary basis of the Swedish government.

³⁰ In English: Friends of Fishing.

In the context of the multi-annual recovery plans a 'scrapping fund' - operational from 2003 to 2006 with a budget of € 32 million - was established in the context of the reform in December 2002 in order to assist member states in balancing fishing effort with the available resources. Decommissioning premiums, which were up to 20% higher than under the FIFG, were made available to vessels whose fishing effort had to be reduced by at least 25%.³¹

The new member states are eligible for EU support under the present FIFG from May 2004 to the end of 2006. Information on the allocation of possible EU support between the different new member states is included in *Annex on the FIFG 2000 to 2006*. Poland will be the main beneficiary and the country is projected to receive more than 3/4 (in absolute terms a little more than € 200 million) of the total amount allocated to the new member states. The impact of the enlargement of the EU on the regions of the old member states with respect to the present FIFG programme is probably marginal as the programme was negotiated before the enlargement. However, the impact in the new member states could be substantial because of the increased access to EU funds compared to the pre-accession period. In relation to the old member states it should be expected that the enlargement will have more significant impact in the coming programming period.

The European Commission has kindly provided information – based on member states' reports - on the allocations of EU aid under the FIFG to NUTS2 regions in the period from 2000 to 2004 (see *Annex on FIFG implementation NUTS2 2000-2004*). The programme has not come to an end yet. However, the data provided in the sheets seem to indicate that Spain's share of the FIFG is still substantial. However, the figures have to be treated cautiously since the programme is still running and the sheets do not even cover one full year with 25 member states in the EU. Several member states have, furthermore, not provided these sheets (at least they have not been provided to us by the Commission); among these is most importantly Portugal. However, based on the information provided in the sheets, Spain has received more than 62% (954.92 million €) of the total EU aid of the member states accounted for in the sheets from 2000 to 2004 (1533.52 million €). Galicia remains the most-favoured NUTS2 region in the EU with more than 24% of the EU funds; and Andalusia is still number two with almost 8%. It is clear that these figures will be reduced somewhat when figures for especially Portugal are included.

However, again it is necessary to stress that these figures have to be seen in the light of the fishing activity taking place in the different regions. In this respect we refer to Chapter 7.

European Fisheries Fund 2007 to 2013

A new European Fisheries Fund (EFF) with a total budget of € 4,963 million has been proposed by the European Commission as the new instrument for the structural policy of the CFP from 2007 to 2013. The proposal aims to amend the relevant FIFG regulations (Council Regulation (EC) No 1263 and Council Regulation (EC) No 2792/1999). It is estimated that approximately 3/4 of the overall budget under the EFF will be allocated to the least-favoured regions (of which many are situated in the 10 new member states). For the remaining regions, the funds will be distributed between the member states according to the size of the fisheries sector, the number of people working in the sector and the adjustments considered necessary for fisheries and the continuity of measures in hand.³²

³¹ DG Fish website: http://europa.eu.int/comm/fisheries/news_corner/press/inf02_61_en.htm (10 March 2005).

³² From European Union website: <http://europa.eu.int/scadplus/leg/en/lvb/l66004.htm> (4 March 2005).

The future allocation of structural funds has important territorial implications. The amount, which will be available for the old member states' regions through the EFF, will be smaller in the period from 2007 to 2013 than it is in the current FIG programme 2000 to 2006. The total aid in 2004 prices for the new member states is proposed to be € 1,702 million (see figure beneath), which means that the old member states will receive a little more than € 3.25 billion compared to € 3.7 billion under the FIG 2000 to 2006. The regions lagging behind in the old member states will be receiving approximately € 2 billion compared to approximately € 2.6 billion under the FIG 2000 to 2006.³³ The annual amount of aid to the new member states will increase over the period from 2007 to 2013.

Figure 3.1 Proposed annual EFF support for new member states

Data from DG Fish website:

http://europa.eu.int/comm/fisheries/news_corner/press/inf04_31_en.htm (4 March 2005)

The EFF aims to support the overall objectives of the CFP and will help to implement the changes made with the reform in 2002. In view of the developments in the sector and the recent enlargement of the Union, the EFF will, among other things, aim at ensuring sustainable fisheries and diversify economic activities in fishing areas.³⁴ The proposed objectives of the EFF are to:

- ensure the long-term future of fishing activities and the sustainable exploitation of fishery resources;
- reduce pressure on stocks by matching Community fleet capacity to available fishery resources;
- strengthen the development of economically viable enterprises in the fisheries sector and make operating structures more competitive;
- foster the protection of the environment and fishery resources;

³³ From DG Fish website: http://europa.eu.int/comm/fisheries/news_corner/press/inf04_31_en.htm (4 March 2005).

³⁴ From European Union website: <http://europa.eu.int/scadplus/leg/en/lvb/l66004.htm> (4 march 2005).

- encourage sustainable development and the improvement of the quality of life in marine, lake and coastal areas affected by fishing and aquaculture activities;
- promote the development of human resources and equality between women and men active in the fisheries sector.

(COM (2004) 0497 final, art. 4)

Compared with the objectives of the current FIFG 2000-2006, it seems that there is a redirection of focus (at least in wording) towards the environmental aspects of the CFP, and a stronger link with the objectives of the conservation policy. This is reflected in the areas of assistance and the associated measures (see box 11 in *Annex on the Common Fisheries Policy*).

However, it should be kept in mind that the provisions for the EFF have so far only the status of a proposal from the Commission. Taking into consideration that the Commission is usually more inclined towards environmental and sustainability concerns than the Council it might not be unreasonable to expect some changes. In any case it is still up to the member states to turn the words into action.

Summing up the Territorial Implications of the Structural Policy

It is obvious that the (re-)distribution of money between regions and member states through the FIFG has direct territorial implications. This is the idea of the EU structural funds, which should ideally support a more balanced regional development on a European scale. However, the criteria used for determining the level of EU support are not related specifically to fisheries. This means that there is a potential risk that fishermen in equal need of support but in different territories will be treated differently.

Some regions and countries benefit more from EU FIFG support than others. This picture has probably been more or less stable over the last decade. However, in the future the situation will probably change as the main beneficiaries of the support increasingly will be situated in the new member states. This may also foster new alliances in the Council.

Market Policy

The market policy is, as described in the introduction, one of the two 'original' policy areas of the CFP. The common market policy has since 1970 outlined provisions and measures for 1) common trade standards, 2) price intervention, 3) producer organizations (POs) and 4) trade with third countries. The basic act of the market policy is Council Regulation (EC) No 104/2000 of 17 December 1999 on the common organisation of the markets in fishery and aquaculture products.³⁵ This regulation was the result of a reform of the market policy in response to extensive changes in the markets for fisheries products due to depleted stocks, changing consumer preferences, globalisation of markets etc.

Common trade standards refer to classification by quality, size or weight, packing, presentation, labelling and issues such as consumers' right to know the origin of the fish he or she is buying. Connected to this issue is also the fact that traceability will from 2005 be required for food products (Council Regulation (EC) No 178/2002). The aim of traceability is to be able to carry out a precise and efficient withdrawal of products from the market if something turns out to be wrong with them. Dependent on the mode of implementation this may have important consequences for the supply of fisheries products to the EU in the short and medium term. This could potentially have negative impact in regions depending on raw material for processing from third countries, which may have difficulties living up to increasingly detailed EU regulations in this area.

³⁵ The basic description of the market policy is based on DG Fish website: http://europa.eu.int/comm/fisheries/news_corner/doss_inf/info76_en.htm (10 March 2005).

The Community's market intervention mechanism works mainly through the POs, which are described beneath. The mechanism is activated when the market prices of certain products fall below a defined threshold, guideprices (based on average prices in the preceding three years in representative ports). The Community will in these cases offer some financial support for the POs, which pay for removing (at least for a certain period of time) the products from the market in order to balance supply and demand. The budget of the price intervention mechanism is rather insignificant compared to the FIG as it can be seen from the following two tables, which outline, firstly, the expenditure divided between EU15 member states in the period from 1988 to 1998 and, secondly, the projected total annual expenditure from 2000 to 2006. Although insignificant, compared to the FIG, the support through the market intervention mechanism has direct territorial impact in the regions where fishermen and fish farmers benefit from it. Detailed accounts of this on regional level is, however, not available on a European scale.

Table 3.2 EU assistance under the market policy 1988 to 1998, EU15 (1000 euros)

	1988	1989	1990	1991	1992	1993	1994	1995	1996	1997	1998

Source: European Commission, DG Fish, from Lequesne, 2004, p. 95.

The table indicates that it is difficult to point out main beneficiaries between the different member states. The amounts vary from year to year. Seen over the entire period the UK, Spain and France stand out as the countries, which benefit relatively much from this arrangement, but the amounts are as earlier mentioned modest compared to FIG expenditure. Nevertheless, the subsidies do not support the aim of capacity reductions, which are crucial in other areas of the CFP.

Annual expenditure for the common organisation of markets is projected to decline in the period from 2000 to 2006 as new rules involving smaller aid for withdrawals - decided as part of the reform of the market policy in 1999 - are implemented (see figure beneath).

Figure 3.2 Projected expenditure for the common organisation of markets

Data from DG Fish website:

http://europa.eu.int/comm/fisheries/news_corner/doss_inf/info76an5_en.pdf (10 March 2005)

The *producer organisations* are a key element of the market policy and have a number of functions. They are, as mentioned above, parties in implementing the price intervention mechanism. The POs are organisations set up voluntarily by fishermen, or in the case of aquaculture fish farmers, to achieve the best possible marketing conditions for the products covered by the PO, which is usually geographically defined but also in some cases defined by the stocks exploited. They are due to their position between production and market in a unique position to implement measures relating to resource management, adding value to products and contribute to the stabilisation of markets (like through the price intervention mechanism).

The exact responsibilities and importance of the POs vary to a wide extent from member state to member state. However, the POs could potentially have territorial impact insofar as they are territorially defined. This means that a well functioning PO, which is able to balance the supply from its members to the demands of the market etc., could potentially be a valuable asset for the region in which the PO operates by increasing profitability for its members.

The final part of the market policy relates to *trade with third countries*. The overall framework for this part of the policy is the agreements, which have been made initially within the General Agreement on Tariffs and Trade (GATT) and subsequently by membership of the World Trade Organisation (WTO). These agreements set limits as to what the EU can do or not do in this area of its fisheries policy.

An example, which highlights how the rules for external trade rules can have varying territorial impact, is the recent safeguard measures targeting (especially Norwegian) farmed salmon with the explicit goal of protecting employment generated by salmon farming in parts of Scotland and Ireland (Commission regulation (EC) No 206/2005) (see box 12 in *Annex on the Common Fisheries Policy*). However, the safeguard measures have *de facto* a negative impact on employment in other regions in the Union where the

processing of Norwegian salmon has created employment, even though this is predicted not to be the case in the decision (Commission regulation (EC) No 206/2005, recital 130).³⁶

These safeguard measures have led to loss of jobs in certain enterprises in municipalities depending on processing of Norwegian Salmon in the Danish NUTS3 region of Nordjyllands Amt; a region, which is one of the most disadvantaged in Denmark and has a relatively high unemployment rate. In recital 120 of the regulation it states: *"The areas in which salmon farming is undertaken tend to be remote - mainly on coastal areas of Western and Northern Scotland and the West coast of Ireland. There are limited employment opportunities and the economic activity generated by salmon farming makes an important contribution to these local economies. Without that contribution, many of the small local business which supply goods and services to the Community producers and their employees would cease to be viable. It is therefore in the interests of dependent industries that effective definitive measures are taken."* It is remarkable that exactly the same description could have been applied as regards to salmon processors in Nordjyllands Amt.

Whereas it is not possible to tell if the number of jobs saved in Scotland and Ireland is greater than the amount of jobs lost in the northern part of Denmark, it is certainly a case of benefits and disadvantages being distributed unevenly between regions on a European scale. The use of safeguard measures are consequently not territorially neutral and this should be taken into consideration when applying these measures. This seems to some extent not to have been the case in relation to these specific safeguard measures given that the Commission could claim that no proof of negative effects on employment could be substantiated; at the same time jobs were lost in Denmark as a result of those specific measures.

The case above highlights (as an extreme case) that protective measures are not territorially neutral. Relaxing or lifting the same protective measures (no matter what shape they assume) will likewise also have varying impact in different regions. The most competitive regions will benefit from more free trade while it will have a negative impact in less competitive regions.

Relations with Third Countries

The last element of the CFP is the policy, which deals with relations with the outside world. There are two main elements in this policy area. The first is to set up bilateral fisheries agreements with third countries to grant access for EU vessels and the second is participation in regional organisations, which regulate fishing outside the EEZ areas, also known as the 'high-seas'. Fisheries agreements will be dealt with in the first part of this section, and regional fisheries organisations in the second part.

³⁶ The negative impact of the safeguard measures on the Danish processing industry in the northern part of Jutland has been described in several local as well as national media in the first months of 2005.

Fisheries Agreements

The Community policy on fisheries agreements entered into force with the creation of the Community EEZ in the Atlantic and the North Sea from 1 January 1977. The decision aimed at protecting the economic interests of the Community after unilateral declarations made by other sovereign states. At the same time, it was established that both fishing by third country vessels within the Community EEZ and the fishing rights for EU vessels in third country waters should be laid down in accordance with EU agreements on fisheries.

The first fisheries agreements were concluded in 1977. The number of such agreements increased significantly after the entry of the Iberian countries to the EU in 1986, as well as the entry of Finland and Sweden in 1995.

Since 1990, the fishing activities of Community vessels must observe the practices and measures approved at international level on this matter, in particular the Law of the Sea (UNCLOS) and the FAO Code of Conduct for Responsible Fisheries. This brought a change in the responsibilities of the European Commission on full administration of fisheries agreements.

There are in 'geographical terms' two main categories of bilateral fisheries agreements. The first type is the northern agreements, which in general are reciprocal agreements on exchange of fishing opportunities in each others waters. These agreements have consequently no direct EU budgetary implications. The other type is the southern fisheries agreements, which usually involve some sort of financial transfer to the third country as compensation for fishing opportunities. Both types of fisheries agreements have territorial implications - sometimes important (see box 13 in *Annex on the Common Fisheries Policy*).

Figure 3.3 Vessels operating, solely or partially, outside Community waters (average 1993-97)

Source: European Commission, DG Fish (2001, p. 9)

In relation to this illustration it should be noted that a number of the northern fisheries agreements were rendered obsolete with the acceptance of the ten new member states into the Union. Furthermore, in terms of employment the southern fisheries agreements are by far the most important, accounting for approximately 83% of the total 40,650 jobs depending on fisheries agreements in the period. The financial costs of the external dimension of the CFP amounted to € 276 million in 2000 (after the failure to reach an agreement with Morocco). This can be considered as financial aid to the fleets depending on the southern agreements (European Commission, DG Fish, 2001, p. 9f).

Third country agreements are also important in relation to relocating European excess fleet capacity and thereby reducing the pressure on domestic resources.

There are presently three purely reciprocal northern fisheries agreements, namely agreements with Iceland, the Faeroes and Norway. The one with Norway is most important (the content of the agreement is described in the chapter on Norway) also in relation to territorial impact. The agreement is important because it provides access to fishing in Norwegian waters when this is most profitable and *vice versa*. In other words the reciprocal agreements facilitate more rational fishing behaviour for both of the involved parties. Failure to agree on exchange of quotas in each others' waters will consequently have negative effect in the regions, where the fleet commonly fish in third countries' zones.

The importance of the northern agreements is as described above not comparable to that of the southern agreements. However, in some regions the agreements are important. These regions are most importantly situated in Denmark, United Kingdom and Germany, which are the main beneficiaries of the northern agreements and together accounted for around 80% of the catch value from 1993 to 1997 (IFREMER, 1999, p. 11).

The development of fisheries agreements with developing countries (southern agreements) is territorially particularly important because these agreements are in general utilised by only a few member states, primarily Spain (more than 80% of catch value 1993 to 1997 (IFREMER, 1999, p. 11)), and a large number of jobs depend on them (European Commission, DG Fish, 2000, p. 12).

The fact that the EU has negotiation powers over any international fishing agreement has both negative and positive consequences for the affected regions, which host fleets fishing under the agreements. The positive impact from the arrangement is that the EU as a whole is a much more powerful actor in negotiations with third countries than the individual member states (or regions) would be. This leads logically to better agreements for the affected regions. Anyway, failure to reach agreements can have severe negative implications for the affected regions, which have little to say in these negotiations. The failure to reach an agreement with Morocco is an example of this, which led to support from the FIFG being directed to the affected fleets in Spain and Portugal. Furthermore, the countries, which benefit noticeably from non-reciprocal agreements, are few, which naturally creates some scepticism towards this budgetary post in other member states.

Regional Fisheries Organisations

The Common Fisheries Policy, such as it is presently defined, gives the European Community exclusive power over preservation and administration of fishing resources. The Council made the European Commission responsible for the negotiation of fishing rights and the representation of the Community in international fisheries organizations. The Commission and DG Fish in particular are assisted in this task by member States representatives and the Secretariat of the Council.

The European Union is contracting party in 11 regional fisheries organisations (RFOs), which have been created through international agreements. These are:

- North-West Atlantic Fisheries Organisation (NAFO)
- North-East Atlantic Fisheries Convention (NEAFC)
- Indian Ocean Tuna Commission (IOTC)
- North Atlantic Salmon Conservation Organisation (NASCO)
- International Baltic Sea Fishery Commission (IBSFC)
- Commission for the Conservation of Antarctic Marine Living Resources (CCAMLR)
- International Commission for the Conservation of Atlantic Tuna (ICCAT)
- General Fisheries Council for the Mediterranean (GFCM)
- Western Central Atlantic Fishery Commission (WECAFC)
- Fishery Committee for the Eastern Central Atlantic (CECAF)
- South-East Atlantic Fisheries Organisation (SEAFO)

These organisations provide a framework for cooperation on the management of shared fish stocks and fish stocks in the high seas. The RFOs make recommendations on management and conservation measures, which must then be implemented by the contracting parties, and in some cases, such as the NEAFC and the IBSFC the RFOs, serve as the forums where agreements on the distribution of fishing access are made. Nevertheless, compliance cannot be guaranteed, although some RFOs have joint inspection programmes to ensure that contracting parties abide by the adopted measures.³⁷

The territorial implications of the external policy and RFOs can be illustrated by reference to the current failure to get an international agreement on the fishing of Norwegian spring spawning herring (or Atlanto-Scandian herring). This stock is managed within the remits of the NEAFC and the countries involved in the fishery are Norway, Iceland, the Faeroes, Russia and the EU (Denmark, the UK, Sweden, the Netherlands, Germany, France and Ireland).

Norway decided in 2002, following its dissatisfaction with its negotiated share of the TAC³⁸, to opt out of an agreement from 1996 on the allocation of the TAC. No new agreement has so far been agreed. This has - besides the fact that this in the longer perspective puts the state of the stock at risk with following negative impact for all regions with fleets exploiting the species - had negative impact on the Danish processing industry (especially one enterprise in Skagen) and also to some extent on the Danish purse seiner fleet (located in Hirtshals). Both municipalities (NUTS5) are placed in the Danish NUTS3 region of Nordjyllands Amt, which, as earlier described, is one of the regions with the highest rate of unemployment in Denmark. The situation has affected the purse seiner fleet adversely by denying them access to fishing for Norwegian spring spawning herring in Norwegian zone during the first months of the calendar year, which is when this is interesting for them. The processing industry has been affected negatively by the fact that Norwegian vessels, as a consequence of the missing agreement, have landed their catches of herring in Norway instead of in Skagen.

³⁷ DG Fish website:

http://europa.eu.int/comm/fisheries/doc_et_publ/factsheets/facts/en/pcp4_3.htm (2 December 2004).

³⁸ The total TAC is based on advice from ICES.

The agreements made within the RFOs are consequently of importance for the regions which host fleets that fish in the areas.

3.4.2 The Capture Fisheries Sub-Sector

The capture fisheries sub-sector is in economic terms of limited importance on a common EU or national scale. However, capture fisheries are in some regions very important as it has been stated several times in this report. In the following sections, an introductory description of the overall structural development of EU capture fisheries will be provided based mainly on Eurostat data, which is presented in the following annexes: *landings and catches, the fishing fleet and aquaculture*. This introduction will provide background data for approaching the structural developments, which will enable us to move down to greater levels of regional disaggregation and study the effects of the Common Fisheries Policy there by the means of for instance example studies.

The data in these sections are mainly taken from the Eurostat database, which includes statistics on volume of catches, volume and value of landings; the fishing fleet etc.³⁹ Eurostat obtains data from national statistics and from FAO. The information, which can be obtained from statistics on capture fisheries, is ambiguous. There are various reasons for this. Some of these are: 1) Fishing vessels are not obliged to land in ports of the country, whose flag they are flying. When vessels land in a port of a foreign (EU) country the value of the landing (first sale) will be ascribed to the value of landings in that country, irrespective of the fact that the profit actually ends up benefiting the economy of a region in another country. The spin-off effect of the landing will benefit the country of the landing. 2) The black economy in the capture fisheries sub-sector is generally estimated to be considerable, which means that official statistics underestimate the *de facto* economic importance of the sub-sector (and in biological terms the volume of catches). This is of course also the case for other economic sectors but the capture fisheries are particularly difficult to control.⁴⁰ 3) The data accuracy and compilation routines differ from country to country. One reason is that it is easier to control e.g. landings in a country with a small number of large vessels landing in a small number of ports like for example UK and Denmark than in a country with a large number of small vessels landing in a large number of ports, which is the situation in for instance Greece and Italy.⁴¹

The Fleet

An indicator of the structural changes in the European capture fisheries sub-sector is the development of the fleet. The interesting aspect of the fleet is the development of its fishing power. The fishing power of a fleet is notoriously difficult to measure and the size of the European fleet is therefore presently measured in three units: absolute numbers, tonnage (GT), and engine power (kw). The development in engine power in terms of

³⁹ 'Catches' refers to fish caught by vessels from a certain country (this is the information needed in order to manage quotas), whereas 'landings' refers to fish landed in the ports of a certain country, regardless of the country of origin of the supplying vessel.

⁴⁰ A related problem concerns the fact that the volume of (legal as well as illegal) discards has to be estimated, which creates a distortion of the data on the impact of fishing activities. However, this statistical problem is mostly relevant when making biological research. Discarded fish do not contribute to the economy and the problem is in this way not relevant to this study.

⁴¹ In the context of this project it is furthermore a problem that the statistics are more focused on volume than value. Volume is in the case of fisheries not a suitable indicator for economic importance because the kilo prices for different species can be very, very different, not least because some species are caught for industrial use.

kilowatt is presently considered the best indicator of the development of the actual fishing capacity of the fleet, even though ‘technological creep’⁴² is not taken into consideration.

The development of the EU15 fishing fleet from 1995 to 2003 in terms of absolute numbers, tonnage and engine power is outlined in the table beneath.

Table 3.3 EU15 – indicators on the fleet

	1995	1996	1997	1998	1999	2000	2001	2002	2003
Number	103,633	101,141	102,063	100,133	97,751	95,381	92,328	90,129	88,122
Tonnage⁴³ (1000 GT)	1,998	1,985	2,021	1,996	1,995	2,007	2,006	1,965	1,912
Power (1000 kw)	8,187	7,958	7,973	7,823	7,702	7,601	7,472	7,274	7,107

Source: Eurostat database, 19 November 2004

The size of the European fishing fleet decreased in the period from 1995 to 2003 in terms of absolute numbers (15%) and tonnage (4.3%) as well as the most important indicator: engine power (decrease 13.2%).

The development of the fleets of EU15 member states from 1990 to 2003 in terms of numbers, tonnage and power can be found in the *Annex on the Fishing Fleet*. The tables in the annex show that some member states have contributed more to this decrease than others. The Irish and French fleets increased their capacity, while for instance Denmark, Greece and Spain decreased their capacity significantly in the same period. However, it should be kept in mind that also the scrapping of an inactive (but registered) vessel counts as a decrease. Although in different paces, most member states decreased their capacity in kilowatt over the period. The size of the fleets of the EU15 member states in terms of engine power in 1995 (first year with full EU15 coverage) and 2003 respectively, is gathered in the table beneath (including Iceland and Norway for comparison). The developments of the EU15 fleet can also be examined in the maps beneath.

⁴² Due to so-called technological creep, the fishing power of a fleet will actually increase over time even if the engine power in terms of kilowatt is kept stable. This means that if the fishing power of a fleet should be kept stable, the engine power of the fleet should continuously be decreasing.

⁴³ The registration of the tonnage changed over a period from 1996 from Gross Registered Tonnage (GRT) to Gross Tonnage (GT), which is generally higher. This might partly explain that the tonnage does not seem to have decreased in the same regular pace as engine power.

Table 3.4 Size of fleet in EU15 states and others in 1995 and 2003, kw engine power

	1995	2003
Belgium	65,965	66,869
Denmark	407,760	324,957
Germany	169,182	160,248
Greece	669,272	572,228

Norway	:	1,355,745
Iceland	:	538,442

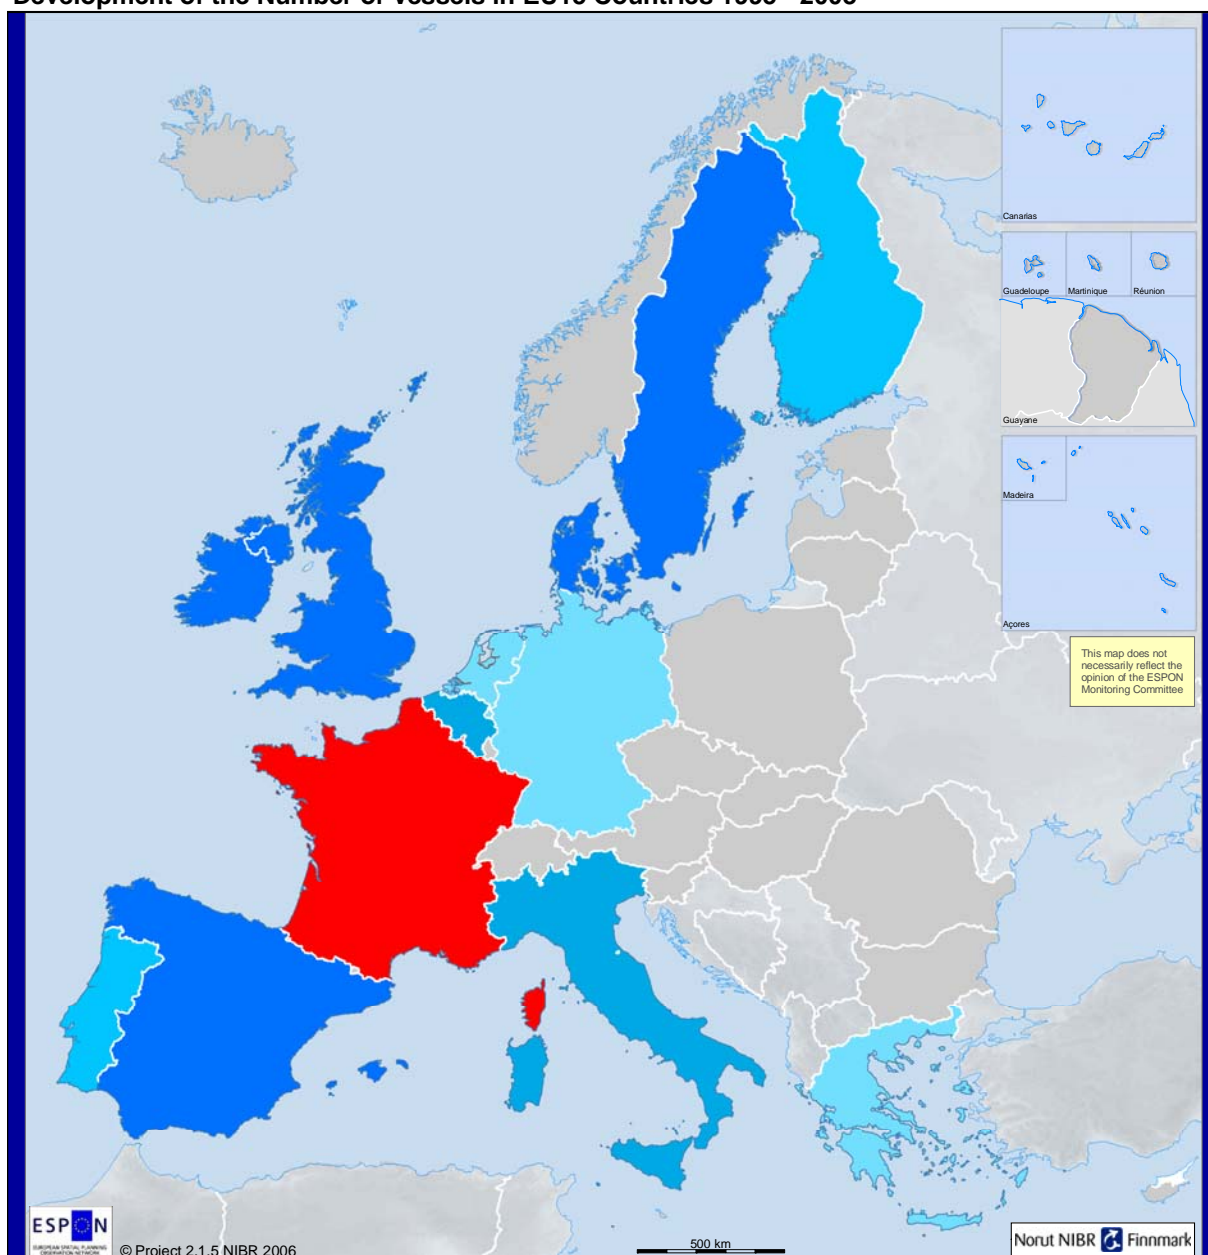

Source: Eurostat database (see *Annex on the Fishing Fleet*)

In the following figures the development of the various EU member states' fleets have been visualised. It is noteworthy that there is large difference between the different member states. France's fleet has grown both in terms of numbers, kW and tonnage, whereas the fleets of most other member states have become smaller in the period. The development in number of vessels is less telling about the development of the actual fishing capacity than factors such as kW and tonnage. This can be exemplified by Ireland where the fleet in terms of number of vessels has decreased significantly. However, in terms of kW and tonnage the Irish fleet has increased substantially.

Generally, most member states' fleets have become smaller over the period from 1995 to 2003. However, it is also clear that the decrease has been more significant in terms of number of vessels than in terms of kW and GRT, which is actually what matters when discussing fishing capacity.

In the context of this study, vessels less than 12 meters of length are defined as engaged in *small-scale coastal fishing*. This definition is similar to the definition applied by the EU in the context of the structural policy under the Common Fisheries Policy (Council Regulation (EC) No 2792/1999, art. 11(1)). As for the composition of the EU fleet more than 80 percent of the vessels are less than 12 meters long. Vessels above the length of 12 meters are per definition not engaged in small-scale coastal fishing but in *offshore fishing*. The proportion of vessels over the length of 30 meters is just above 2 percent (2003 figures). The balance between the different vessel length segments seems to be rather unaffected by the decrease in absolute numbers, indicating that the decrease has taken place in all segments (Eurostat database, 26 November 2004).

The EU15 capacity in terms of kilowatt of vessels under 12 meters was a little more than 2.1 million whereas the capacity of vessels over 12 meters was a little more than 4.9 million in 2003. The difference between the two segments is considerably bigger when calculated in terms of tonnage where the group over 12 meters accounts for more than 10 times the tonnage of the vessels under 12 meters (see *Annex on the Fishing Fleet*).

However, there are great differences between the different EU countries when it comes to the composition of the fleet. Belgium and Finland constitute the extremes. No Belgian vessels are less than 12 meters long and 48 percent of the vessels of the Belgian fleet (numbering only 125 vessels) are more than 30 meters long. In the other end of the spectrum is Finland, where more than 94 percent of the vessels are less than 12 meters long and none over 30 meters long⁴⁴ (Eurostat database, 26 November 2004).

Information on the length composition of the EU15 member states' fleets in 2003 in terms of numbers, tonnage and power can be found in the *Annex on the Fishing Fleet*. A total for respectively vessels under and over 12 meters have been calculated for each member state. The totals in regards to kilowatt engine power are gathered in the table beneath (including Iceland and Norway for comparison).

⁴⁴ However, Finland does not fit very well to the chosen definition because many of the vessels are engaged in the Finnish speciality of inland (not coastal) fisheries, which are also managed under the Common Fisheries Policy. Better examples are the Mediterranean member states' fleets.

Table 3.5 Engine power (kw) in 2003 by vessel lengths, over and under 12 meters⁴⁵

	Total under 12 m	Total 12 m +
Belgium	0	66,869
Denmark	77,328	247,629
Germany	34,779	125,469
Greece	345,294	226,931
Spain	177,851	980,063
France	472,558	635,888
Ireland	34,436	192,608
Italy	301,976	987,740
Netherlands	8,739	461,462
Portugal	130,414	263,194
Finland	131,651	34,648
Sweden	78,465	142,384
UK	333,731	572,955
EU15	2,127,222	4,937,840
Norway ⁴⁶	Total 1,356,000	
Iceland	152,043	386,068

Source: Eurostat database (see *Annex on the Fishing Fleet*)

The small-scale fleet constitutes consequently an important segment in EU15 total as well as in a number of member states.

Employment

Data on employment in the capture fisheries sub-sector is in general scattered and of variable quality making comparison difficult, which makes Eurostat less useful in this area. However, according to the Commission's latest data there were a total of 526,034 persons employed within the *entire* fisheries sector in 1997. It has to be stressed that the definition of 'fisheries sector' employed here is relatively broad, including also ancilliary industries.

⁴⁵ The lengths of some vessels are unknown. These vessels are not included in the figures; see instead *Annex on the Fishing Fleet*.

⁴⁶ The data on engine power for Norway in the Eurostat database is unfortunately not correct. The figure for total engine power is from the Directorate of Fisheries, Norway.

Figure 3.7 Total employment in the fisheries sector by member state in 1997

Source: European Commission, DG Fish (2004, p. 11)

It was in connection with the publication of the Commission's reform proposals in 2002 estimated that 66,000 jobs (a decrease of 22 percent) had been lost in the capture fisheries sub-sector in the period from 1990 to 1998. This suggests an employment figure of approximately 234,000 in the capture fisheries sub-sector in 1998. It was, furthermore, predicted that the reform would lead to the maximum loss of yet another 28,000 jobs over the period from 2003 to 2006 (COM (2002) 181 final, p. 3 and p. 20). It has to be kept in mind that the prediction was based on the Commission's proposals and that the final provisions eventually agreed in the Council were not as far-reaching as the measures proposed. Furthermore, only part of the jobs is lost because of reform; many of the jobs would be lost anyway due to technological advances. It can be concluded that jobs will continue to be lost in this sector and that this process will probably be to some extent accelerated by the ongoing reform.

Catches and Landings

The total catches of the EU25 fleet was approximately 8 million tonnes (live weight) in 1995. This figure had in 2002 dropped to approximately 6.8 million tonnes. (European Communities, Eurostat, 2004, p. 248). Figures indicating the value and volume of landings in 2000 and 2002 for EU15 member states can be found in the *Annex on Landings and Catches*, where also data on the volume of catches for each EU27 country in the period from 1990 to 2003 can be found.

It is possible to get reasonable data on the catches by different countries. Using statistics over catches as an indicator of territorial impact is, as earlier described, not unproblematic because vessels can land in other countries than that of their homeport. Anyway, in the table beneath the catch figures for EU27 in respectively 1990 and 2003 are gathered. Areas with catches below or around 10,000 tonnes pr year in the reference period have been excluded (see *Annex on Landings and Catches* for the full time series for all areas).

Table 3.6 Catches by EU member states and others (tonnes)

	1990	2003
Belgium	41,470	26,324
Denmark	1,475,716	1,031,204
Germany	326,316	260,675
Greece	132,381	74,338
Spain	1,126,318	840,495
France	689,662	694,370
Ireland	215,485	265,604
Italy	371,873	283,218
Sweden	250,985	286,875
Netherlands	404,816	524,125
Portugal	324,776	209,049
Finland	123,024	121,956
UK	766,904	635,938
EU15	6,250,260	5,254,542
Latvia	162,827	114,541
Lithuania	137,598	155,246
Estonia	131,178	79,083
Poland	448,292	163,117
EU25	:	5,778,167
Bulgaria	49,254	12,051
Romania	92,784	:
Norway	:	2,453,699
Iceland	1,521,877	2,002,180

Source: Eurostat database (see *Annex on Landings and Catches*)

Furthermore, the volume of catches includes species of very different value in the same categories. The most extreme example of this is species caught for industrial purposes *versus* those caught for human consumption. Especially Denmark catches a considerable amount of fish for industrial purposes. Consequently, declining catches in terms of volume does not necessarily indicate an equivalent decline in terms of value. Increasing prices because of lower supply to the market will also to some extent compensate for lower catches. This tendency is, however, decreasing in importance because of import of equivalent species from elsewhere in the world. This development towards less compensation through prices will probably be enforced in the years to come as the market for fish product is becoming increasingly global - increasing demand for fish products will work in the opposite direction. The development of the catches of European countries can be examined in the maps beneath.

Figure 3.10 Development in volume (percent) of catches 1993 – 2002

Change in Volume of Catches 1993 - 2002

Data from Eurostat, see Annex on Landings and Catches

The value of the landings in EU15 (by all vessels) increased from approximately € 5,990 million in 1995⁴⁷ to € 6,230 in 2003⁴⁸ (summation on the basis of individual countries' data, Eurostat database, 25 November 2004). This is an increase of approximately 4 percent. However, if we take inflation into account (and calculate with an average annual inflation of just below 2 percent) the increase ought to have been more than 15 percent just to maintain *status quo*. The value of the landed catch in real terms therefore decreased, even though the average kilo price of fisheries products increased over the same period of time (see also *Annex on Landings and Catches*).

However, there are significant differences as to how the development has been in the different member states. Denmark is one of the countries where the difficulties of some segments of the European capture fisheries sub-sector has been felt most. The landings in Denmark in 1995 had a value of € 499 million. In 2003 this figure had dropped to € 390 million. In the other end of the scale is the development of the landings in Ireland, which increased from a value of € 140 million in 1995 to € 253 million in 2003 (see *Annex on Landings and Catches* for full data on the value of landings in EU15 member states in respectively 2000 and 2002).

Challenges to and Potentials of the Capture Fisheries Sub-Sector

That the problems in the capture fisheries sub-sector has been felt differently in the different member states and regions can be explained by reference to structural differences between countries and regions; these differences, which have also been touched upon in the sections on the CFP, concern for instance:

- Differences in the *geographical area* in which the fishing takes place (e.g. the North Sea, the Mediterranean or third countries waters) – the regions are on this point affected unequally by the conservation provisions of the CFP.
- Differences in the *type of fishing carried out*, e.g. *small-scale coastal* or *offshore* (demersal, pelagic or industrial), and the species fished for - the regions are on this point affected unequally by the conservation provisions (and other elements) of the CFP.
- Differences related to the *national implementation* of the Common Fisheries Policy.
- Differences in the impact of provisions of the Common Fisheries Policy, which are not directly linked to the state of the fish stocks, e.g. financial assistance and market regulations.

SWOT Analysis of the Capture Fisheries Sub-Sector

It is clearly difficult to give a diagnosis for something as diversified as the capture fisheries sub-sector of the European Union. However, some common trends for main segments of the sector/fleet are identified in the SWOT table beneath.

Table 3.7 SWOT analysis of the capture fisheries sub-sector in EU

SWOT analysis of the capture fisheries sub-sector			
Strengths	Weaknesses	Opportunities	Threats
Advanced technology and ability to fish	Severe overcapacity in many fleet segments	Further capacity reductions	Increasing competition from third countries beginning to exploit

⁴⁷ Finnish figures for 1997 and French figures for 1999.

⁴⁸ Portuguese figures for 2000 and Spanish figures for 2002.

anywhere			their own resources
High and increasing demand for fish products	Fisheries is increasingly seen as unattractive work	Focusing on branding sustainable fishing when this is possible	Failure to address the issue of overcapacity
Good reputation compared to farmed fish	The bad state of many (demersal) stocks, an increasing resource base has long perspectives	Recovery plans leading to larger more stable catches	Failure to recover stocks
	Some fleets (segments) are ageing due to lack of investments	National experiments with transferable quotas, e.g. Netherlands and Denmark	Competition from third countries, increasing due to tariff reductions
	Some fishing dependent regions far from main markets (ex. Scotland)	Better coordination of supply and demand through the POs	Lack of skilled fishermen due to the perceived unattractiveness of the job
		Introducing new species for human consumption	Competition from aquaculture, also on new species such as cod

3.4.3 The Aquaculture Sub-Sector

Aquaculture is defined as the farming of aquatic organisms, including fish, molluscs, crustaceans and aquatic plants. Farming implies some form of intervention in the rearing process to enhance production, such as regular stocking, feeding, protection from predators, etc. Farming also implies individual or corporate ownership of, or rights resulting from contractual arrangements to, the stock being cultivated. This definition is the one used by Eurostat and in line with the definition developed by FAO and its Coordinating Working Party on Fisheries Statistics (Eurostat database, 15 November 2004).

Products from aquaculture have different forms and different intended end uses. FAO distinguishes for instance in the statistics between finfish, molluscs, aquatic plants, crustaceans and other aquatic animals (e.g. crocodiles, turtles etc.). Of these groups finfish is the dominant followed by molluscs and aquatic plants. The majority of aquaculture products are used for human consumption, but a significant part is, nonetheless, used for non-food uses (e.g. meal, oil, bait, aquarium fish etc.) (FAO; Fisheries department, 2002, p. 29).

Aquaculture Production in Europe

Aquaculture in Europe is becoming increasingly important relative to capture fisheries. This is the case both in terms of production measured in volume and even more so in terms of value because almost all European aquaculture products are intended for human consumption - as opposed to capture fisheries where for instance Danish vessels catch considerable quantities of species destined for industrial use with a low value pr. kg (e.g. sandeel). A noteworthy point is that much of the captured industrial fish actually ends up as fodder for carnivorous farmed fish.

The figure and table beneath show the development of European aquaculture (EU15) since 1995; in terms of volume of production aquaculture represented 13.3% of the total EU15 fish production in 1995 and 17.5% in 2001. In terms of value the production in 2001 was 33% of the value of the EU15 total fish production (European Communities, 2004, p. 16).

Figure 3.11 EU15 aquaculture production (volume)

Source of data: Eurostat database 9 November 2004.

The aquaculture production rose from 1995 to 2002 with 8.8%. Production peaked in 1999 and has been gradually declining since then. The value of the aquaculture production has been rising substantially in the same period, namely 51.7%. The value peaked in 2001. The increase can partly be explained by the scarcity of European fish products, which has driven up prices⁴⁹, but it must also be ascribed to increased farming of more valuable species. The average value of aquaculture products was € 2.29 pr. kg (live weight) in 2002.

The value of the aquaculture production was in EU15 approximately € 7.24 pr. capita in 2002 (2001 population figures). The EU15 aquaculture production represented 2.3% of the world production of which the Chinese production represented remarkable 71.2% (2002 figures) (Eurostat database, 15 November 2004).

The development of the European aquaculture sub-sector can be studied in the *Annex on Aquaculture*, where data on value and volume of production in the period from 1990 to 2003 of respectively freshwater, brackish water and seawater (marine) aquaculture is

⁴⁹ The increase has been from € 1.20 pr. kg to € 1.39 pr. kg in the period from 2000 to 2002 (European Communities, 2004, p. 10).

presented for each EU27 country. In the table beneath the total value of aquaculture (all types) for each member state in 1990 and 2002 respectively, can be examined including Norway and Iceland for comparison.

Table 3.8 Value of aquaculture production, European countries (1000 euros)⁵⁰

	1990	2002
Belgium	2,311	4,600

Iceland	11,734	17,066

Source: Eurostat database, 16 March 2005.

Most countries have experienced an increase in value of aquaculture production in the period. The most notable examples of this development include Greece and the UK.

The aquaculture sub-sector employed in 1998 the equivalent of 57,000 full-time persons (COM (2002) 511 final, p. 4).

Marine Aquaculture

The focus of this study is on aquaculture, which takes place in the coastal zones. This is dominantly marine aquaculture of molluscs, fish and others taking place in sea water, which is defined as “waters where the salinity is high and not subject to significant variation” (Eurostat metadata, 25 November 2004). The development of marine aquaculture defined in this way from 1995 to 2003 in EU15 is shown in the figure beneath.

⁵⁰ Excluding Channel Islands and French overseas territories.

Figure 3.12 EU15 marine aquaculture production

Source of data: Eurostat database, 25 November 2004.

The value of the marine aquaculture has increased with more than 80 percent from 1995 to 2002. Marine aquaculture represented 66% of total aquaculture production by value in 2002, up from 55% in 1995. The development of the marine aquaculture sector for the relevant coastal states with reference years of 1990 and 2002 can be examined in the table beneath, more information is available in the *Annex on Aquaculture*.

Source: Eurostat database (see *Annex on Aquaculture*)

The increase in value of seawater/marine aquaculture production has been significant for most countries. Most impressive is the figures for countries like Malta (increased by factor 15), Greece (increased by factor 10), Portugal and the UK (both increased by approximately factor 4). Denmark and Sweden has experienced a decrease in the same period.

Challenges to and Potentials of European Aquaculture

The Commission's strategy for the aquaculture sub-sector⁵² includes three main aims: 1) "Creating long term secure employment, in particular in fishing dependent areas", 2) "Assuring the availability to consumers of products that are healthy, safe and of good quality, as well as promoting high animal health and welfare standards", and 3) "Ensuring an environmentally sound industry" (COM (2002) 511 final, p. 21).

The overall economic goal of the Commission is continued growth in the aquaculture sub-sector and thereby the creation of 8,000 to 10,000 jobs (full-time equivalents) over the period from 2003 to 2008. These jobs should mainly be created by means of developing mollusc and cage farming in areas dependent on (capture) fisheries, which will be negatively affected by the reformed Common Fisheries Policy. Success in relation to this main target is, again according to the Commission, dependent on the ability to 1) increase the growth rate to 4 % per year, 2) solve conflicts for space, 3) promote market development, and 4) improve governance (COM (2002) 511 final, p. 11).

⁵¹ Excluding Channel Islands and French overseas territories

⁵² The strategy is outlined in a Commission communication: COM (2002) 511 final: "Communication from the Commission to the Council and the European Parliament: A strategy for the Sustainable Development of European Aquaculture". This paper constitutes presently the most important EU policy document directed solely towards the aquaculture sub-sector.

The future economic situation of the aquaculture sub-sector (at EU level as well as regionally) will, consequently, depend on its (or policy-makers) ability to address the abovementioned issues. The statistics from the most recent years (see *Annex on Aquaculture*) show that continuous growth in the aquaculture sub-sector is not self-evident, even though the sub-sector has the potential to supply farmed fish as a substitute to threatened wild fish species in European waters such as e.g. cod.

Table 3.10 SWOT analysis of the aquaculture sub-sector in EU

SWOT analysis of the aquaculture sub-sector			
Strengths	Weaknesses	Opportunities	Threats
Many good spots for aquaculture on a long EU coastline	Fluctuating prices	Diversification and introduction of new species	Competition for space in some areas
High and increasing demand for fish products	Not as good reputation as 'wild fish'	More off-shore farming as technology improves	Competition from third countries and new species, increasing due to tariff reductions
Many producers have high technological level	Reputation in some places damaged due to pollution	Making use of the strong political support for aquaculture in the EU (e.g. through FIFG)	Fish diseases and pollution
Potential for more regular supply to markets than with 'wild fish'			In some places animal protection organisations target aquaculture
			Risk of (periodical) oversupply because of speed of growth of the industry
			Lack of fish meal (used for carnivorous species)

3.4.4 The Fish Processing Sub-Sector

There are over 3,000 processing enterprises in the EU15 with almost 100,000 employees. Most member states have seen a reduction in the number of processing companies in recent years. However, collation of data related to the number of fish processing companies is only undertaken sporadically, making the identification of trends difficult. The criteria defining a fish processor also vary between member states and between surveys within member states, which further complicates comparison. The average number of employees per processing enterprise has increased from 30.4 in 1994 to 37.8 in 2000, an indication of consolidation in the industry.⁵³

⁵³ The description of the processing sub-sector is primarily based on Nautilus Consultants et al. (2003).

The value of the output of the EU15 processing sector amounted to more than € 16 billion in 2000. The main processing countries were Denmark, Italy, Germany, France, Spain and the UK, which together accounted for more than 80% of the value of output.

Figure 3.13 Value of the Output of the Processing Sector in 2001 (1000 euros)

Source: European Commission, DG Fish (2004, p. 28).

The European processing sub-sector remains for the most part in contraction and consolidation due to supply shortages and competition from cheaper imports. This situation may persist for some years to come as trade barriers such as tariffs and import licences are reduced or stopped through international trade agreements. Third country suppliers of raw material are increasingly taking advantage of lower labour costs and process for export as processing units achieve EU quality standards. Some European trading companies are using the comparative advantages of countries outside the EU. In extreme cases EU-sourced raw material is exported out of the EU for low-cost part processing in countries such as China before being returned to the EU for finishing.

Many employment opportunities in the EU fish processing sub-sector remain temporary in nature, often associated with fishing seasons or seasonal peaks in demand, which makes accurate quantification of sector employment difficult. The major employers are the UK, Spain, France, Denmark and Germany. Employment in the fish processing sub-sector is not recorded on an annual basis, making it difficult to define trends. Overall employment in EU fish processing has not changed significantly since the mid-90s. Individual member states such as the Netherlands and Portugal have seen employment reduction between 1994 and 1999 whereas others have seen increase, notably the UK, Spain, Ireland and Sweden.

There has been a significant decrease in EU landings as described above. The EU processing sub-sector has made up this shortfall in supply with more imports. Extra-Community imports of processed seafood rose from € 6.13 billion in 1994 to € 9.55 billion in 2000 (a 36% increase). In addition, the EU processing sub-sector imported approximately € 4 billion worth of unprocessed seafood products (fresh or frozen whole fish) in 1993.

Intra-Community trade in processed products increased by around 39% from 1994 to 2000 where it totalled € 5.7 billion; this brings total EU imports of processed seafood products in 2000 to over € 15 billion. 86% of the value of EU exports which totalled € 6.6 billion in 2000 is derived from intra-Community trade, less than € 900 million of processed seafood products were exported in 2000. Most member states in the European Union have seen increases in demand for seafood products. In conjunction with reduced landings and increased extra-EU competition, this has contributed to an ever-widening seafood trade deficit between the EU and third countries. Only the continued development and increased production of the European aquaculture sector has been such as to counter this trend, creating a source of raw material for processors and new products for consumers from within the EU.

Problems facing the processors are primarily focused on employment, raw material supply and competition from extra-EU imports. To an extent these issues are all interconnected – particularly the costs associated with employment and raw materials leading to processor concerns over their ability to compete with third country imports.

There is general movement in the EU towards added value and away from primary processing, which for the most part can be done more cost-effectively outside the EU in regions with closer access to raw material and / or far lower labour costs. The fish processing sub-sector is becoming less distinct from the wider food processing sector as raw material sourcing is less associated with local landings. Consolidation of the sector results in integration with larger food processing companies and moves towards added value products, such as ready meals where fish is only one of many ingredients used.

A process of consolidation is underway in almost every corner of the EU fish processing sub-sector and is resulting in the formation / evolution of a smaller number of generally larger businesses, with a handful of very large businesses forming in most member states. The corollary of this process is that significant numbers of businesses are failing or being absorbed / bought-out by larger food companies.

The current situation of the processing sub-sector is very much defined by the globalization of the market in fish products. Some general issues are highlighted in the SWOT table beneath.

Table 3.11 SWOT analysis of the processing sub-sector in EU

SWOT analysis of the processing sub-sector			
Strengths	Weaknesses	Opportunities	Threats
High and increasing demand for fish products	High labour costs compared to competitors	Increasing ability to source raw materials from wherever the price and/or quality is best	Competition from third countries with lower wages - also intra-EU, which in fact makes this a temporary opportunity for some EU regions - particularly in the new member states
	Decreasing access to local resources due to the state of the stocks	Concentrating on value-adding rather than primary processing, which can be done cheaper elsewhere	
	Some plants especially in southern Europe have difficulties living	Innovation in terms of new value-added products	

	up to new standards		
	Prices for raw material are sometimes higher than necessary because of protection of domestic suppliers and processors (ex. salmon)		
	Fish processing is increasingly seen as unattractive work		

3.5 The Fisheries Sector in Norway

Norway is one of the world leaders in fisheries and was the tenth largest seafood production nation in the world measured in terms of volume of aquaculture and fishing in 2001 (Ministry of Fisheries, 2003, p. 4). Norway is, moreover, in the absolute top among the worlds largest net exporters of seafood products as around 90 percent of the production is exported. The importance of this export for the country, which is only exceeded by that of crude oil, is significant and makes fisheries an important economic sector in Norway. Norway was, consequently, also the first nation in the world to create a separate Ministry of Fisheries in 1946 (Myrstad, 2000). It is worth noticing that aquaculture is increasing in importance relative to capture fisheries (Ministry of Fisheries, 2003, p. 6).

The main markets for Norwegian seafood are the EU member states (approximately 60 percent of the total export of fish products), among which Denmark, France and the UK are the most important markets. (Myrstad, 2000 and Ministry of Fisheries, 2003, p. 6)

Norway has to some extent a tradition of combining objectives of regional policy with the objectives of fisheries policy. It is, however, questionable whether the link is in reality so strong that it could be said that fisheries policy supports the objectives of the regional policy. Nevertheless, fishing and related businesses are and have always been seen as important elements in maintaining viable settlements along the Norwegian coast. The Norwegian fisheries sector was heavily subsidised from the beginning of the 1960ies until the beginning of the 1990ies. Subsidies in current prices amounted at its highest to approximately 2.7 billion Norwegian kroner (NOK) (approximately € 330 million) in 1987 compared to an export value of seafood products of a little more than NOK 11 billion (a little less than € 1.35 billion) the same year. This policy changed dramatically over a relatively short time span in the beginning of the 1990ies. Since 1995 the subsidies have been less substantial - in the neighbourhood of NOK 100 million (a little more than € 12 million) per year⁵⁴ compared to an export value of between NOK 20 billion (a little under € 2.5 billion) in 1995 and NOK 31 billion (more than € 3.75 billion) at its most in 2000 (Ministry of Fisheries, 2003, p. 7).

⁵⁴ In 2002 subsidies amounted to a little more than NOK 77 million - under € 10 million. Statistics Norway website: http://www.ssb.no/english/subjects/10/05/nos_fiskeri_en/nos_d298_en/tab/54.html (accessed 26 January 2005)

Norway has applied for membership of the European Union twice. On both occasions the Norwegian government has withdrawn the application after negative referendums in 1972 and 1994 respectively. The issues of jurisdiction over fish resources and regional policy implications have played a considerable role in the political debates on the applications, most prominently in 1972.

The most important fish species for the Norwegian fisheries sector were in 2002 herring, mackerel and cod for the capture fisheries sub-sector, and salmon and trout for the aquaculture sub-sector. The export value of these five species amounted to around NOK 22 billion out of a total value of export of a little more than NOK 28.5 billion (around 80 percent) (see sections on capture fisheries and aquaculture).

3.5.1 Policy

The Norwegian fisheries policy has changed a great deal in the last decades. The practice of giving subsidies, which was a characteristic of Norwegian fisheries policy until the beginning of the nineties, has been almost completely abandoned (Ministry of Fisheries, 2003, p. 7). The management of the Norwegian fisheries has in the course of the last decades, furthermore, changed from basically 'free access fisheries' to a management regime, involving (increasingly transferable) quotas and concessions.⁵⁵

The management regime is a rather complicated mixture of systems specific to different fisheries and categories of vessels. The regime has evolved incrementally over the years in response to developments in the sector and the external conditions: "*The Ministry of Fisheries has been - and still is - more of a fire department than a Soviet planning bureau.*" (Mikaelsen og Jentoft, 2003, p. 399). The 'cod crisis' in 1989, when the authorities decided on a drastic reduction in the TAC for cod because of on a critical situation for the stock, can be considered the turning point for Norwegian fisheries management. After 1990 individual quotas of various sorts have spread to almost all fisheries and vessels (Mikaelsen og Jentoft, 2003, p. 399).

Two legal acts regulate *inter alia* the basic features of Norwegian capture fisheries, namely the acts on respectively fishing in saltwater etc. (Lov om saltvannsfiske m.v.) and on the right to participate in the fisheries (Lov om retten til å delta i fiske og fangst (deltakerloven)).⁵⁶

The Norwegian fisheries policy is based on four main objectives: 1) increasing the profitability of the fisheries sector; 2) protecting the resources, which implies a precautionary approach to harvesting; 3) securing employment in coastal communities; and 4) maintaining the settlements along the coast. It is from the two latter points easy to recognise an element - at least in words - of regional policy-objectives in the fisheries policy (Årland and Bjørndal, 2002, p. 309).

Another characteristic of the Norwegian fisheries management system is the (advisory) involvement of the fish processing sub-sector and the fishermen's organisations in the management through the Management Council⁵⁷. This Council, which is part of a long (corporatist) tradition in Norwegian fisheries management, advises on the detailed allocation of quotas among the different fisheries and vessel categories but also on issues

⁵⁵ Ministry of Fisheries and Coastal Affairs website:

<http://odin.dep.no/fkd/norsk/tema/fiskeogfangst/bn.html> (2 December 2004, in Norwegian).

⁵⁶ A full list of the legal acts (in Norwegian), which are administered by the Ministry of Fisheries and Coastal Affairs can be found by following this link: <http://www.lovdatab.no/cgi-wif/wiftdsok?base=nl&titt=&dato=&emne=&button=S%F8k&dep=fkd> (18 January 2005).

⁵⁷ In Norwegian: 'Reguleringsrådet'.

relating to gear, fishing periods and areas etc. The Management Council is relatively influential and its recommendations are most often followed by the Ministry of Fisheries. This has on several occasions been the case also when the advice of the council has been in opposition to the scientific recommendations. (Mikaelsen and Jentoft, 2003, p. 401ff)

The point of departure for the Norwegian fisheries policy is TACs, which are set for individual stocks based on scientific advice. The majority of the Norwegian capture fisheries are, although the majority of the catch is actually taken inside the Norwegian EEZ, based on stocks, which are shared with other countries. The shared nature of the stocks necessitates international agreements on TACs, which are based on ICES' advice. TACs are susceptible to political negotiations between the countries involved, notably Russia in the Barents Sea and the EU in the North Sea (Hoel, 2000 and Mikaelsen and Jentoft, 2003, p. 400f). The national regulations deal in general with distribution (through quotas) of the internationally agreed Norwegian TAC in order to secure a rational pattern of fishing. In this process it is also taken into consideration that there is a need to reduce the capacity of the fishing fleet and that the distribution between fishermen is 'fair' (Hoel, 2000).

The national Norwegian fisheries management system is, as already indicated, rather complicated. It will in this context not be feasible to go into details with all the specific fisheries and vessels categories. Rather, we will in the following elaborate on the overall principles and main elements of the management system and the territorial implications of these.

Licenses and annual fishing permits are used to restrict access to most of the Norwegian fisheries. The three main segments of the fleet are: 1) purse seiners, which catch mostly pelagic species but also more than half of the TAC for cod; 2) trawlers, which catch mostly cod and saithe but also to lesser degree pelagic species; and 3) coastal vessels⁵⁸, which catch mainly herring and cod but also other species. Licenses are used in the purse seiner fleet and the trawler fleet. The licenses are in principle non-transferable and a transfer of a license on the grounds of sale of vessel must be approved by the authorities. Licensed vessels held on average 1.87 licenses in 2002; this figure has been increasing over the years, as the number of licensed vessels has declined from 996 in 1980 over 547 in 1990 to 388 vessels in 2002. Annual fishing permits are increasingly used to restrict access to the coastal fleet fisheries, which have traditionally been subject to open access (Årland and Bjørndal, 2002, p. 309f and Norwegian Fishermen's Association and the Norwegian Ministry of Fisheries, 2003, p. 6). All important coastal fisheries are from 2003 and onwards subject to access restrictions of some sort (Fiskeridepartementet, 2003, p. 29).

The Norwegian TACs for individual species, as agreed internationally (both in relation to demersal and pelagic species), are distributed between the three main segments of the Norwegian fleet as *group quotas*. These quotas set the limit as to how much each segment of the fleet is allowed to catch of certain species. However, the allocation of quotas, which are in general sub-divided into group quotas for smaller groups/fisheries within the different segments, is subject to different practices. The simplest practice, which is utilised in some smaller fisheries, is no sub-allocation of the group quota for the specific fishery. This naturally stimulates competitive, 'race for fish' behaviour among the qualified participants. Restrictive measures, which are more commonly used, include *non-transferable individual vessel quotas* (IVQ) and *maximum quotas*. (Årland and Bjørndal, 2002, p. 308ff)

⁵⁸ The coastal fleet consist of a diverse mix of vessels ranging from small open boats to smaller seiners and conventional vessels more than 28 meters long (Årland and Bjørndal, 2002, p. 308).

The first type of catch restrictions, IVQs, entails that each vessel is awarded a quota, which sets the limit for the annual catch quantity. IVQs are used to a varying degree in the different fleet segments. IVQs are allocated in relation to all fish species targeted by the purse seiner fleet. The formula used to allocate the quotas among the purse seiners favours smaller vessels over bigger ones by giving them a larger IVQ relative to their capacity. The picture is more composed for the trawler fleet, which is subject to IVQs in the main fisheries but managed by means of maximum quotas in the others. The IVQs in the trawler fleet are allocated on the basis of size of vessels (tonnage or length) and the type of trawler license. In the allocation process it is furthermore possible to take into consideration if the vessel is a qualified participant in other fisheries and thereby has 'an alternative source' of income/employment. IVQs are generally not used in the coastal fleet with the exception of the cod fisheries by conventional vessels above 28 meters. (Årland and Bjørndal, 2002, p. 310f)

Connected to the main fisheries, which are managed by IVQs (purse seiner fleet, cod trawling fleet and Greenland shrimp trawling fleet), a unit quota system is (from 2002) in place to address the issue of overcapacity, which is also a problem in Norway, albeit not as acutely as in the EU. The unit quota system introduces some form of transferability into the IVQ system by allowing owners of more licensed vessels to acquire a unit quota (valid for a limited number of years) when permanently withdrawing a vessel and its licence(s) from the fleet. This unit quota can subsequently be harvested by another vessel owned by the unit quota holder and thereby give an economic incentive to reduce fishing capacity. There are some restrictions on the amount of quotas, which can be held by a single vessel owner, in order to prevent inexpedient concentration of quotas. The system of unit quotas is moreover designed to be more attractive for the southern fleet than for the northern fleet because of regional policy considerations (Årland and Bjørndal, 2002, p. 311f).

In terms of economic efficiency IVQs are intuitively favourable because they - by guaranteeing a vessel to have access to catch a fixed amount of fish over the year - terminate the 'race for fish' and allow the vessels to plan their activity and aim at minimising operations costs. Nevertheless, the maximum resource rent (value of catch minus costs) is most probably not realised because IVQs are not only awarded to the most efficient vessels and because they cannot be traded on the market. The unit quota system goes, however, some way in the direction of increasing economic efficiency by enabling the vessel owners to take advantage of the benefits of economies of scale (Årland and Bjørndal, 2002, p. 311f).

The second type of catch restrictions are maximum quotas, which entail that the vessels are allocated a maximum quota, which the vessel may catch during the year. The vessel owner cannot be sure whether he will be allowed to catch the entire quantity because the aggregated sum of the maximum quotas is higher than the total quota for the group of vessels. When the aggregated catch reaches the group's quota the fishery is closed.⁵⁹ This practice, which is used in order to ensure that the entire group quota is actually caught, is referred to as 'overregulation'. Maximum quotas are, as earlier mentioned, not used for the purse seiner fleet. In the coastal fleet fisheries management by maximum quotas dominates.

In terms of economic efficiency maximum quotas and overregulation maintain incentives for a 'race for fish' because of the risk of closure of the fishery in question. The vessel owners will consequently fish heavily in the beginning of the season instead of planning

⁵⁹ Some smaller coastal vessels have a guaranteed quota, which can be harvested even after the overall quota is exhausted (Årland and Bjørndal, 2002, p. 311).

according to resource accessibility and optimal size, quality or price over the year. This problem has been mitigated by dividing the quotas into seasons and in general by minimising the overregulation, which do not, however, alter the dynamics of the maximum quota system (Årland and Bjørndal, 2002, p. 310ff). As of 1 January 2004 a flexible quota arrangement for vessels between 15 and 28 meters was introduced. The justification for the new arrangement is basically the same as for the unit quota system and it aims equally at capacity reduction through a regulated transferability of quotas in the restricted access coastal fisheries.⁶⁰ The impact of this new measure remains to be seen.

In conclusion, the Norwegian management measures for stock conservation consist *inter alia* of input restrictions in the shape of licensing schemes for most fisheries, output restrictions in the shape of quotas allocated to groups of fishermen and on individual vessel level, and, finally, of technical measures related to particular fisheries, for instance minimum mesh sizes, minimum landing sizes, gear type restrictions etc.

According to Årland and Bjørndal (2002, p. 312f) compliance is relatively high in the Norwegian fisheries, even though the system does provide incentives for high-grading of quota species and discarding of non-quota species. The total annual landings are rarely more than marginally above the agreed TACs. Control is among other elements based on random controls at sea, sample controls of landings and increasingly paper-based.

The agreement with Norway is the European Union's most important third party agreement in the fisheries sector. The fisheries agreements between Norway and the EU concern:

- joint management/setting of TACs and subsequent sharing of seven main stocks straddling between the Norwegian and the EU part of the North Sea
- balanced exchange of other fish stocks in each other's waters

The fish stocks, which are managed jointly, are cod, haddock, saithe, whiting, plaice, mackerel and herring. The agreements are negotiated annually and in the agreement for 2004⁶¹ the total TAC for the seven species was set at 889,031 tonnes of which Norway got 297,667 and the EU got 591,364. The TACs for 2005 resulted in an increase of the total TAC to 905,179 tonnes with 622,203 tonnes going to the EU.⁶² The EU share benefits mainly Denmark, Germany, France, the Netherlands and the United Kingdom. The balanced exchange of stocks, which Norway and the EU member states can catch in each others' waters, is in the magnitude of 230,000 to 240,000 tonnes of various species.

Norway and the EU have in recent years disagreed on a number of important issues (especially on the exploitation of pelagic stocks), which has created some tension between the two parties. Trade in fish and marine products is regulated through Protocol

9 of the EEA agreement, which gives preferential treatment of a number of products but imposes taxes on others.⁶³

Norway has, as mentioned above, fisheries agreements with other neighbouring countries. Most important are the agreements on cod, capelin and haddock with Russia.⁶⁴ Norway is also contracting party to a number of RFOs, which manage resources outside the EEZs (Hoel, 2000).

Aquaculture is, as mentioned above, increasing in importance relative to capture fisheries. The basic legal acts, which regulate Norwegian aquaculture, are the acts on the farming of fish, crustaceans etc. (Lov om oppdrett av fisk, skalldyr m.v.) and on sea ranching (Lov om havbeite).⁶⁵ The acts provide that one must seek and acquire acceptance from the authorities before starting an aquaculture business and that the authorities may take regional policy objectives into consideration when deciding on a request.

3.5.2 The Territorial Implications of the Norwegian Fisheries Policy

The Norwegian fisheries sector is of most importance in the northern part of the country. Here fisheries form an important part of a strategy aiming at keeping viable settlements along the coast. Changes in the overall conditions of the fisheries sector will, consequently, be felt most significantly in the northern part of the country. This is e.g. the case as regards the changes in the behaviour of the Russian fleet, which traditionally has landed much of its catch for processing in the northern part of Norway.

When it comes to subsidies, which have arguably been decreasing, it seems - based on an example study on Norway presented elsewhere in this report - to be the case that a few NUTS3 regions receive the majority of the support, and the territorial distribution of the fisheries policy measures in Norway are mainly determined by the regions' ability to develop new structures in the sector. More information on territorial imbalances in the Norwegian economic support to fisheries can be found in the example study.

3.5.3 The Capture Fisheries Sub-Sector

Production

The Norwegian capture fisheries sub-sector is, as already indicated, very important in terms of contribution to GDP and especially income from export. Most of the catch is exported and the value of the export is substantial. Exports have been increasing from the beginning until the end of the 1990ies, after which time it has levelled out somewhat (Ministry of Fisheries, 2003, p. 5).

The most important species in terms of value are herring, mackerel, capelin, blue whiting (pelagic species), cod, saithe, haddock (demersal species) and prawns. Herring, mackerel and cod are the three most important species with an aggregated catch value of

⁶³ DG Fish website:

http://europa.eu.int/comm/fisheries/doc_et_publ/factsheets/facts/en/pcp4_2n07.htm (1 December 2004) and DG Trade website:

http://europa.eu.int/comm/trade/issues/bilateral/countries/norway/index_en.htm (2 December 2004).

⁶⁴ Agreements with other countries include the Faeroe Islands, Iceland and Greenland.

⁶⁵ A full list of the legal acts (in Norwegian), which are administered by the Ministry of Fisheries and Coastal Affairs can be found by following this link: <http://www.lovdato.no/cgi-wif/wiftdsok?base=nl&titt=&dato=&emne=&button=S%F8k&dep=fkd> (18 January 2005).

approximately NOK 6.25 billion (a little over € 760 million) in 2002. This is more than half of the total catch value of approximately NOK 11 billion (a little less than € 1.35 billion) (Ministry of Fisheries, 2003, p. 10, preliminary figures). The export value of these three species amounted in 2002 to around NOK 11 billion - or more than one third of the total value of the export of seafood products including aquaculture, which was a little more than NOK 28.5 billion (Norwegian Fishermen's Association and the Norwegian Ministry of Fisheries, 2003, p. 15 and 18).

Data compiled From Statistics Norway website, 11 March 2005.

Figure 3.15 Regional distribution of volume of landings in 2001

Data compiled From Statistics Norway website, 11 March 2005.

Employment and Fleet

The capture fisheries sub-sector is still an important provider of employment, especially in the northern parts of Norway. Although the overall number of fishermen has been continuously decreasing for several decades, just below 14,000 persons had in 2002 fishing as their sole or main occupation, and a little under 5,000 persons had it as their secondary occupation. The aggregated figure (main and secondary occupation) decreased from 23,653 to 18,648 (more than 20 percent) over the relatively short time span from 1995 to 2002 (Ministry of Fisheries, 2003, p. 10). The explanation cannot be found in declining (value of) catches but is most likely associated with technological change, that makes it possible to catch the fish with a reduced input of manual labour (Norwegian Fishermen's Association and the Norwegian Ministry of Fisheries, 2003, p. 4).

The fleet can, as described above, basically be divided into three main segments, namely purse seiners, trawlers and the coastal fleet, which varies from small open boats to smaller seiners and vessels above 28 meters in length. The number of vessels in the Norwegian fleet has declined alongside with the number of people employed in the sector. The explanation for this is technological developments and the introduction of bigger and more efficient vessels (Årland and Bjørndal, 2002, p. 308f). The total number of registered vessels in the Norwegian fleet was 10,651 in 2002. However, only a fraction of these were fulltime fishing vessels, namely 2206. 1127 of the full-time vessels were under 13 meters in length, 188 were 41 meters or more in length (Ministry of Fisheries, 2003, p. 12f).

The development of the Norwegian fleet is summed up in the table below, which shows the development from 1997 to 2003 in terms of number of vessels, gross tonnage (GT) and kilowatt (kw).

Table 3.12 The Norwegian fleet 1998 to 2003

Year	1997	1998	1999	2000	2001	2002	2003
Number	13,645	13,251	13,196	13,014	11,951	10,651	9,93
1000 GT	359	372	385	392	407	394	39
1000 kw	1202	1238	1286	1321	1362	1351	135

Source: Eurostat database website, 17 January 2005, and Directorate of Fisheries, Norway.

Even though these figures can only give an indication of the development in the Norwegian fleet because a large proportion of the registered vessels are only to a very limited extent active, the fact remains that the decrease in the capacity of the fleet has been much more limited than indicated by the decrease in absolute number of vessels - it actually looks as if there has been an increase in the period from 1997 to 2002. On top of this, technological creep has to be added to give a reasonable idea of the development in effective fishing capacity. However, programmes to reduce capacity were renewed in the summer of 2000 (Myrstad, 2000) and from the table it looks as if they have had some impact.

Perspectives for the Future

The development of the capture fisheries sub-sector depends to a large extent on the developments in the stocks of the most important Norwegian fish species: cod, saithe, herring, mackerel and prawns etc. Norwegian fish stocks are in varying conditions and a number of them are outside what is defined as safe biological limits. This is especially the case for a number of demersal fish stocks in the North Sea, which are, however, not the most important for the Norwegian fleet.

Moreover, Norwegian fisheries are based on exploitation of a relatively high number of different species and stocks, this secures to some extent that fluctuations (natural as well as those caused by the impact of fishing) in the abundance of some stocks do not have detrimental effect on the capture fisheries sub-sector in total although certain fleet segment would suffer. However, it remains a concern that the TACs for a number of stocks, which are exploited by the Norwegian fleet, have consistently been set above the recommendations from ICES during a number of years. This has for instance been the case for Arctic cod, which accounts for most Norwegian cod landings. The biomass of the stock has been increasing in recent years but the fishing mortality was outside safe biological limits in 2002 (Havforskningsinstituttet, 2004, p. 31). This is one side of the challenges faced by the Norwegian capture fisheries sub-sector: making sure that the resources are not - at the very least - overexploited to an extent, where the catches in the longer term will decrease and in extreme cases lead to stock collapses. Ensuring that the regulatory measures are sufficient remains thus a major task in the future. Resources in Norwegian waters are on average in a better condition than many other places in the world - the challenge is to keep it that way.

Another problem is the continuing declining employment within the sub-sector. Although this development is definitely a real problem for the fishermen, who lose their jobs, it might be positive for the sector in general because it is an indication of a move towards increasing competitiveness and economic efficiency in the face of increased competition from other countries getting more efficient and from aquaculture. Even if the development of the stocks turns out to be positive in the future, this is no guarantee that jobs will be created. Technological developments are continuously increasing the efficiency of the vessels and vessel owners can be expected as far as possible to take advantage of economies of scale. Both tendencies tend to diminish the share of manual

labour input as per unit caught. This will lead to fewer employees in the fleet even if catches remain stable or increase.

However, the demand for fish is increasing worldwide and the market situation for the products from the capture fisheries sub-sector seems relatively good. The farming of cod could have a negative effect on the segments of the fleet, which catch cod. The present undersupply of cod could also lead to a situation where consumers get accustomed to cheaper alternatives from other places in the world, for instance hoki etc. Anyway, it must be expected that the capture fisheries sub-sector will continue to be of major importance for Norway, which has access to some of the richest fishing grounds in the world with high quality fish - globalisation will not change this fact.

Table 3.13 SWOT analysis of the Norwegian capture fisheries sub-sector

SWOT analysis of the Norwegian capture fisheries sub-sector			
Strengths	Weaknesses	Opportunities	Threats
Large resource base of high quality	Restricted access to EU markets due to non-membership	Increasing demand for fish products, especially of high quality	Natural fluctuations in fish abundance
Broad spectrum of commercially important species	High wage costs	Utilisation of species not yet recognised as commercially valuable	Competing low price species from other places in the world
		Increasing transferability of quotas leading to higher efficiency	Smaller TACs in the longer term due to management failure (too high TACs)
			Climate changes, see chapter on ICZM

3.5.4 The Aquaculture Sub-Sector

Production and Employment

The Norwegian aquaculture sub-sector, which is almost exclusively situated in seawater, has become increasingly important during the last twenty years and products (processed to a varying degree) from aquaculture amount to around 30 to 40 percent of the export value (Ministry of Fisheries, 2003, p. 5).

The dominating species is Atlantic salmon. The production of salmon has in later years amounted to between 400,000 and 450,000 tonnes per year until actually exceeding 500,000 tonnes in 2003. The farm gate value of the salmon produced was in 2002 a little more than one billion euro (Eurostat database website, 16 January 2005). Norway has also a considerable production of trout with a value of a little under € 180 million in 2002 (Eurostat database website, 16 January 2005). The main export markets are the EU, mostly France and Denmark, and Japan (Ministry of Fisheries, 2003, p. 19). Trout, for which the export value has increased by more than a factor six over the period from 1991 to 2002, is exported mainly to Japan (Ministry of Fisheries, 2003, p. 20). The export value of salmon and trout was in 2002 approximately NOK 11 billion. (Norwegian Fishermen's Association and the Norwegian Ministry of Fisheries, 2003, p. 18)

The economic contributions from other species are so far modest and include farmed cod, Arctic char, halibut, oysters, blue mussels, great scallop etc. Cod and blue mussels are currently the largest contributors besides salmon and trout. (Ministry of Fisheries, 2003, p. 24)

Aquaculture production is a growing source of employment in coastal areas in Norway. More than 4,500 persons are presently employed in the aquaculture sub-sector. Of this figure a little more than 800 persons are employed with aquaculture of other species than Atlantic salmon and trout. The aquaculture production is distributed all the way up the Norwegian west coast and the production in the northernmost county of Finnmark is the greatest in terms of volume per inhabitant. Aquaculture is consequently also very important in regional policy perspectives. (Ministry of Fisheries, 2003, p. 21 and 24)

Figure 3.16 Regional distribution of value of aquaculture in 2002

Data compiled from Statistics Norway website, 28 February 2005⁶⁷

Perspectives for the Future

The development in the EU, which is Norway's main trade partner, is important in relation to the perspectives for the Norwegian aquaculture sub-sector. The enlargement in 2004 was in this respect an important event as it included approximately 75 million persons into the European Union.

The enlargement of the European Union is expected to have adverse as well as positive effects on the Norwegian seafood export, including in relation to the aquaculture sub-sector most notably the export of salmon. On the positive side it can be expected that the enlargement will lead to (continued and perhaps accelerated) increasing GDP per capita in the new member states. This is especially important for the export of salmon, which is considered a 'luxury' food item. The potential here is significant, which is also indicated by the fact that the (so far comparatively small) export value of salmon to the candidate countries doubled from 2000 to 2002 (Næringsforum Nord, 2004, p. 11f).

However, Norway has so far had bilateral free trade agreements with the candidate countries; these agreements disappeared as of May 2004 after which trade with fish is subject to the agreements with the EU. This meant increasing taxes on export of salmon to the new member states (tax: 2 percent). This put Scottish producers of salmon in a better position *vis-à-vis* the Norwegian producers in relation to the new member states, something which must be expected to reduce the positive effects of the increasing demand resulting from increased GDP per capita (Næringsforum Nord, 2004, p. 14ff). Nevertheless, production of salmon and trout in Norway is forecasted to continue to increase to at least the double in 2020 (Brugère and Ridler, 2004, p. 18 and 21) or possibly already in 2010 (Foss, Matthiasson and Ulrichsen (eds.), 2003, p. 63) even though the market perspectives in the EU are ambiguous.

⁶⁷ Sold unrefined fresh or frozen. Including value of fish further processed in own plants.

Cod is probably the species, which is currently most interesting in relation to future growth in the aquaculture sub-sector in Norway. The production of fry for on-growing indicates that the industry is expanding. However, the production of fry is still experiencing problems of diseases and deformities. Research is currently focusing on solving these problems. Farmed cod enjoy so far a good reputation and the perspectives for cod farming are positive (Institute of Marine Research, 2004a, p. 9-10). The success of cod as a farmed product is, however, to a large extent contingent on the development of the wild cod stocks, which are for instance in the EU subject to recovery measures. Projections for the increase in cod farming in Norway vary (up to 400,000 tonnes in 2020!) and the outcome is still to a certain degree dependent on how technical difficulties are overcome. However, considerable expansion can in any case be expected in the years to come (EuroFish, March/April 2003).

Besides the two species dealt with above, a number of other species are expected to contribute to growth in the aquaculture sub-sector in the future; the way forward for Norwegian aquaculture is partly considered to be diversification. Species, which are expected to contribute to the growth in the sector, include most notably (besides cod and salmon): lobsters, scallops, halibut, mussels, Arctic char and spotted ocean catfish (Institute of Marine Research, 2004a, p. 9-11 and Ministry of Fisheries, 2001).

All in all the perspectives for Norwegian aquaculture seem fairly bright. Norway is world leader in salmon farming and the export of trout has increased substantially in recent years. At the same time is the Norwegian aquaculture sub-sector working towards increasing diversification in order to create and supply new markets - the most promising example being cod aquaculture. Nothing suggests that the global market for seafood products is anything close to saturation. Rather, all projections predict that the demand for aquaculture products will increase over the coming years, as wild stocks are unlikely to provide an increased output. Norway is physically well suited for aquaculture with for instance a low population density and comparatively small problems of resource use conflicts in coastal areas. On the other hand the globalisation of the market in food products increases worldwide competition, an example being the Chilean salmon producers, who have utilised the lower wages in the country to win market shares on an expanding global market.

Table 3.15 SWOT analysis of the Norwegian aquaculture

SWOT analysis of the Norwegian aquaculture			
Strengths	Weaknesses	Opportunities	Threats
Favourable conditions for farming of certain species, e.g. cod and salmon	Restricted access to EU markets due to non-membership	Introduction of new species, such as lobsters and halibut	Fish diseases
High technological level		Growth in cod aquaculture	Pollution
		Increasing EU demand for 'luxury' species, such as salmon	

3.5.5 The Processing Sub-Sector

The developments within different segments of the processing sub-sector have showed different tendencies over the last decades. The overall figures for employment in the processing sub-sector have, however, been relatively stable in the period from 1994 to 2001, although with a declining tendency in the second half of the period. The number of processing companies (excluding sole proprietors) has likewise been relatively stable. The aggregated figures were 11,774 employees in a total of 484 companies in 2001.⁶⁸

The general trend has been fewer companies and employees in the processing industry connected to the whitefish sector. This sub-sector consists of approximately 22 larger filleting companies and 180 conventional (for instance salting and drying) companies, where most of the products are exported. There are various reasons for this development. The situation for the filleting companies are characterised by 1) increasing competition from other, cheaper whitefish species, which are now available because of globalisation ; 2) supply shortages due to decreasing landings of cod from Russian vessels, which are increasingly able to carry out some processing onboard and land the products elsewhere; and 3) more frozen raw material landed in Norway is exported for processing in other countries due to increased global competition for raw materials. These tendencies have made the favourable geographical localisation of the Norwegian processing sub-sector *vis-à-vis* the resources less important and the problems of higher wages and transportation costs more important. The problems have, furthermore, been aggravated by the strong Norwegian currency (which has lately stabilised at a more normal level) and high level of interest, which has made high production costs even higher (Fiskeridepartementet, 2003, p. 31f).

Perspectives for the Future

The strength of the Norwegian processing sub-sector continues to be the relatively easy access to high quality raw material be it from capture fisheries or aquaculture. Other strengths include the good reputation enjoyed by Norwegian seafood products, the high hygiene standards etc. and the relatively short distance to the European market. Weaknesses of the Norwegian processing sub-sector include overcapacity and high wage costs. Possible opportunities for the fish processing sub-sector lie in further developing

⁶⁸ Statistics Norway website:
http://www.ssb.no/english/subjects/10/05/nos_fiskeri_en/nos_d298_en/tab/40.html (18 January 2005).

the processing technology to make the input of manual labour as small as possible. Another possibility is to concentrate on added value fresh fish products, since Norway is situated relatively close to major markets for these high-end products. However, a serious threat faces the Norwegian processing sub-sector: as transport gets cheaper and easier, the competitive advantage of being close to the resources is undermined. Competing countries are increasingly able to take advantage of lower production costs; at the same time they are becoming technically more advanced, which makes it attractive to export raw material for processing outside of Norway. Moreover, as a consequence of the introduction of factory trawlers more processing will take place at sea. At the same time the Norwegian processing sub-sector is also very sensitive to the developments in the fish stocks, which are exploited by Norwegian vessels. This means that higher Norwegian TACs could ease the situation for the processing sub-sector to some extent.

In conclusion, the perspectives for the future of the Norwegian processing sub-sector are at best mixed. The one major competitive advantage, which the industry has enjoyed, namely easy access to high quality raw material, is being eroded by the globalisation of the fish market, which increasingly makes it profitable to export the raw material to processing in countries with lower labour and other costs. A way forward is perhaps diversification and reliance on niche products and traditional Norwegian products utilising the good reputation of Norwegian products. However, a feasible prediction for the future is fewer and more technically advanced plants. The result is in any case fewer employees - either because processing is outsourced or because labour is substituted with technology.

Table 3.16 SWOT analysis of the (landbased) Norwegian processing sub-sector

SWOT analysis of the (landbased) Norwegian processing sub-sector			
Strengths	Weaknesses	Opportunities	Threats
Close proximity to raw material of the highest quality	Restricted access to the EU market due to non-membership	Development of competitive, modern, technology based processing plants	Increasing competition from cheaper alternatives (especially) on the frozen filet market
Vertical integration, which secures access to raw material	Low profitability for a number of businesses	Adding value to fresh fish products	Increasing international competition for raw material landed in Norway
	Characterised by geographically dispersed, small and medium sized enterprises		Declining foreign (especially) Russian landings because of onboard freezing and landings elsewhere
	Overcapacity		
	High wages		

3.5.6 In Sum

There is no doubt that the fisheries sector will continue to be of major importance in Norway in the future. However, globalisation will undoubtedly change the structure and relative importance of the various sub-sectors. Aquaculture will most probably be the driver of the main development in the fisheries sector in the future.

- The future of the capture fisheries sub-sector is relatively bright. The state of the resources is acceptable for many of the most important species, even though recommendations from ICES are not always followed, and policy-changes are increasingly making the fleet economically efficient. It cannot, however, be expected that this sub-sector will provide more jobs in the future. On the contrary, technological changes are leading to more and more efficient vessels, which need less manual labour. Anyway, the unknown factor is the development of the fish stocks, which also fluctuate naturally. There is, however, nothing which indicates that the Norwegian capture fisheries sub-sector as such is facing major problems. However, this sub-sector will not in the future be the great provider of jobs as it has been in the past.
- The aquaculture sub-sector is in good shape and the perspectives for the future are bright. Considerable expansion is expected in salmon aquaculture, and cod aquaculture is increasingly looking promising even though it has not taken off yet. New jobs can be expected to be created within this sub-sector in the years to come as it has also been the case in the past years. This is in line with the expected development worldwide; where it is projected that aquaculture will increase dramatically in importance relative to capture fisheries. This will of course increase competition but the global market for fish is growing and Norway is particularly well suited for aquaculture of cod, salmon and other species.
- The processing sub-sector is in a more difficult situation than the other two sub-sectors. This is due mainly to the effects of globalisation, which means that it is becoming increasingly profitable to process the raw material in countries with lower costs. Supply of resources from Russian vessels is also becoming less than in previous years due to the introduction of factory trawlers. Possible solutions are to take advantage of economies of scale and reduce the number of plants, which can then work at a higher technological level. This would to some extent be in contrast with the regional policy objectives in the fisheries policy and would in any case result in fewer jobs.

3.6 The Fisheries Sector in Iceland

The fisheries sector is tremendously important in Iceland, which is - despite its modest population of less than 300,000 - the eleventh largest seafood producing nation in the world measured in terms of volume of catch (Ministry of Fisheries, 2004, p. 2). From the mid-nineties to 2003 fishing and processing represented between approximately 10 and 13 percent of the Icelandic overall GDP - and the value of fisheries products constituted more than 60 percent of the value of exported goods and 40 percent of the value of exported goods and services. Approximately three quarters of the export value of fish products goes to other EEA countries - the biggest importer of Icelandic fish products is the UK (Ministry of Fisheries, 2004, p. 3 and 9). Thus, the state of the Icelandic fisheries sector strongly influences the overall state of the Icelandic economy.

Fisheries policy is, consequently, of national importance to a degree, which is not comparable to any of the 25 EU member states where the fisheries sectors in comparison seem insignificant – with the possible exceptions of the most fisheries dependent regions of the Union: *“Due to the size, scope and importance of fisheries in Iceland, policy formulation and decision-making on marine issues has far-reaching effect on the standard of living”* (Ministry of the Environment et al., 2004, p. 4).

Iceland has never applied for membership of the EU, mostly due to unwillingness to accept the fisheries policy of the Union, which has been perceived as severely flawed.

Sharing the responsibility for managing Icelandic fish stocks with the EU member states has therefore not been considered an attractive option. The Icelandic emphasis on national jurisdiction over resources has long roots and includes dramatic incidents like the so-called Cod War(s) with the UK.

3.6.1 Policy

Iceland has, as a consequence of the fact that fisheries are not part of the EEA agreement (of which Iceland is part), its own fisheries policy, which on important points differs from that of the EU.

The Icelandic fisheries management system, of which the cornerstone is the Fisheries Management Act from 1990 (comparable to the basic regulation of the CFP), is based on an individual transferable quota system (ITQ), in which discarding is illegal - as opposed to the EU management system where discarding is in certain situations mandatory. Quotas cannot be sold out of Icelandic ownership (Intrafish, Feb. 2004, p. 10).

The current ITQ system, which has remained in essence the same since the beginning of the nineties, evolved from an initial individual vessel quota (IVQ) system first agreed on in 1983 to take effect from 1984. The last fleet segment, small boats under 6 GRT, became part of the ITQ system in 2004, which means that all segments are now managed under the ITQ system. Some of the resource rent from the fisheries will from 2004/2005 be collected by means of a fishing fee, which equals 6 percent of the net catch value. This fee will increase by law over the coming years to a level of 9.5 percent in 2009. (Gudmundsson et al., 2004, p. 1-4)

The ITQ system is supported by a number of technical measures designed for conservation purposes in specific fisheries. These include nursery areas, which are permanently closed for fishing; spawning areas, which are closed for fishing at certain times; mesh size limitations and different gear restrictions - including in most areas a 12 nautical mile limit, inside which fishing with large trawlers is not allowed.⁶⁹

The Icelandic ITQ system entails that the minister of fisheries sets a TAC for individual species after having received an advice from the Icelandic Marine Research Institute (MRI). The TAC for each species is subsequently divided among those holding rights to catch a percentage of the species in question. The minister is not obliged to follow the advice from MRI besides on the setting of the TAC for cod, which is subject to a 'catch rule' and under normal circumstances based directly on estimates from MRI (Gudmundsson et al., 2004, p. 3-4). The catch rule for cod was introduced in 1996 following a series of years where the TAC for cod had been set higher than recommended. The same years witnessed a series of declining recommended catches, TACs and actual catches (Ministry of Fisheries, 2004, p. 5).

The individual quotas are divisible and to a wide extent freely tradable and transferable. However, there is an upper limitation on how much of the total quota an individual (or related individuals) or an individual company can hold: firstly, a vessel cannot hold more quotas than it can harvest; secondly, there is an upper limit (ranging from 12 to 35 percent) as to how big a share of a certain fishery's total quota an individual or a legal entity can own (directly or indirectly); and, finally, no individual can own more than 12 percent of the total TAC for all species measured in cod equivalents (Gudmundsson et al., 2004, p. 3). These restrictions aim at reducing or at least slowing down the tendency

⁶⁹ Information Centre of the Icelandic Ministry of Fisheries website: <http://www.fisheries.is/managem/legisl.htm> (13 January 2005)

towards concentration of fishing rights in the hands of very big companies, which is a possibility in ITQ systems.

A major debate regarding ITQs has over the years been on whether the system would eventually result in a concentration of fishing rights, which seems to have been to a certain extent the case in Iceland (Pálsson and Helgason, 1996, p. 58 and Gudmundsson et al., 2004, p. 12). This concentration has, on one hand, to some extent increased the vulnerability of the local (fishing) communities, which rely on sufficient 'locally' owned quotas to stay viable. Locally owned quotas are important, not only because they provide jobs to local fishermen, but also because the landings from 'local' vessels have traditionally provided the raw material for local processing plants. This process of regional concentration of quotas has taken place, even though there are provisions in the Fisheries Management Act (art. 11), which makes transfers of vessels with quotas between municipalities potentially subject to some restrictions. On the other hand, it seems to be a fact that the ITQ system has improved the economic efficiency of the Icelandic capture fisheries sub-sector (Eythorsson, 2000, p. 487).

The politically agreed TACs for the fishing year 2004/2005 in relation to Icelandic stocks corresponded in general very closely to the recommendations of the MRI. The recommendations were followed exactly in relation to 16 of the 20 quota-species, including cod, saithe, haddock and halibut,⁷⁰ which serves as an indication of the relatively strong political commitment to following the scientific advice in Iceland.

Transparency is according to Eythorsson (2000, p. 484) a defining characteristic of Icelandic fisheries. This is the case due to a relatively limited number of vessels (today under 2000) and ports (approximately 60) compared to the significance of the sector. This means that the sector is relatively manageable when it comes to control and reliability of catch statistics. Transparency (and reliability of catch statistics) is also strengthened by the ban on discarding. The basic conditions for fisheries management is consequently somewhat different in Iceland compared to within the European Union, where problems of reliability of statistics and control in general are prominent due to various characteristics of the EU fisheries sector, including its multi-national character.

Iceland has a relatively insignificant bilateral reciprocity agreement with the European Union on redfish for capelin.⁷¹ Iceland is, furthermore, contracting party to a number of RFOs and Iceland has fisheries agreements with a number of countries besides the EU, including Norway.⁷²

The following table contains a selection of the most important Icelandic fisheries policy-developments in the period from 1983 to 2004.

⁷⁰ Information Centre of the Icelandic Ministry of Fisheries website:
<http://www.fisheries.is/managem/tacs.htm> (5 January 2005).

Table 3.17 Important Icelandic fisheries policy-developments 1983 - 2005

1984	A system of IVQs quotas is in function from the year 1984 (decided in 1983). The system is in the following years extended. An alternative, optional system of effort quotas (days-at-sea) exists from 1985.
1991	The catch quotas are made divisible and fully transferable as from 1 January 1991 (decided in 1990) - effectively introducing an ITQ system. Only boats under 10 GRT are still allowed to work under effort limitation.
1995	A catch rule for the Icelandic cod stock stating that the annual TAC shall be set at 25 percent of the fishable biomass is introduced. The setting of the TAC for the commercially most important fish species in Iceland is, consequently, directly based on the scientific (biological) estimates. ⁷³
2004	A resource rent tax in the form of a fishing fee is introduced from the fall of 2004 (decided in 2002). The last segment of boats (under 6 GRT) is changed from optional effort management to the ITQ system.

Sources: Information Centre of the Icelandic Ministry of Fisheries website: <http://www.fisheries.is/managem/legisl.htm> (11 January 2005) and Gudmundsson et al., 2004, p. 1-4.

Legislation regarding aquaculture in Iceland is complicated and involves the Ministry for the Environment and the Ministry of Aquaculture, which have both the right to issue licenses through governmental agencies. A number of other institutions are also involved in relation to issues such as disease control and processing etc.

A number of legal acts, which secures a high standard of quality, safety, hygiene and identity are relevant for the Icelandic processing sub-sector. The main acts are Law No. 55/1998 on the handling, processing and distribution of seafood and Law No. 54/1992 on the processing of all catch onboard fishing vessels. Iceland has, if anything, adopted stricter rules in relation to these issues than the EU, so there is nothing that suggests that Iceland will have problems in this area if rules are tightened in the EU, which is Iceland's main trading partner. (Foss et al., 2003, p. 67f)

3.6.2 The Territorial Implications of the Icelandic Fisheries Policy

The entire country of Iceland constitutes one NUTS3 region, which in the context of this study makes it impossible to analyse differences in fisheries policy impact in different regions on this level. Trends and developments must, consequently, be analysed on lower NUTS levels though examples.

However, a key question in relation to the territorial consequences of the Icelandic fisheries policy is whether the smaller, local fishing communities are worse off with the ITQ system than they would otherwise be.

A major issue for the local fishing communities and in the debate over the ITQ system in Iceland has been the transferability of the quotas, which means that quotas can be 'sold away' from local fishing communities, which then do not have access to the resources anymore with loss of fishermen's jobs and problems in the local processing sub-sector as a result. A result of the ITQ system has according to Eythorsson (2000, p. 488f) been marginalisation of some fishing communities. This has especially been the case for the

⁷³ The catch rule for cod is in 2000 amended so that the total TAC should not vary more than 30,000 tonnes from one fishing year to the next. Information Centre of the Icelandic Ministry of Fisheries website: <http://www.fisheries.is/managem/legisl.htm> (11 January 2005).

smallest communities under 500 inhabitants. These small communities have lost to the larger communities in a competition for quotas.

The ITQ system has supposedly not only led to a consolidation in terms of larger companies but also a relative concentration of activity in larger fishing communities leaving the smaller communities without fewer sources of income as the processing plants lose their source of raw material.

Anyway, an open question is if external trends would have pushed for a similar development simply because of the increased global competition in the market for fish products, something which is increasingly giving rise to similar structural adaptations in other countries, where quotas are not transferable.

Furthermore, some of the coastal regions in Iceland have suffered a rapid depopulation since the beginning of 1990ies. This has been very clear in the Vestfjords, which has suffered the greatest depopulation of all regions in Iceland in this period. The overall population development for this region is around minus 20%, and every municipality but one has a negative development. (Sigursteinsdóttir and Ólafsson, 2004). Between 1990 and 2000 the cod quota for the region declined by 4.8%, which was by far the greatest decline by all regions (Sigursteinsdóttir, 2002). There are conflicting views on whether there exists a correlation between these two variables or not. While some argue that the quota would have gone anyway through mergers of companies, others (most significantly the Liberal Party) argue that the depopulation is due to the transfer of quota.

3.6.3 The Capture Fisheries Sub-Sector

Production

The Icelandic capture fisheries sub-sector is, as already indicated, very important. It is estimated to have accounted for approximately 7 percent of the overall GDP in 2003 (Ministry of Fisheries, 2004, p. 3). The value of the Icelandic catches has been increasing (in current prices) since 1997 from just under 60 billion Icelandic kronur, approximately € 725 million, to 77 billion Icelandic kronur in 2002, approximately € 930 million (up 28 percent) (Ministry of the Environment et al., 2004, p. 4 and Ministry of Fisheries, 2003, p. 4). However, the figures for 2003 show a decline from 2001 and 2002, although still higher than the period from 1998 to 2000 (Ministry of Fisheries, 2004, p. 4).

Demersal fish species (including cod, haddock, saithe, redfish and Greenland halibut), flatfish and shellfish constitute almost 80 percent of the value of catches even though almost 75 percent of the volume of the total catch is constituted by pelagic species (Ministry of Fisheries, 2004, p. 4). Cod, which is mainly caught in the Icelanders' own EEZ, is the economically most important fish species.

Most of the Icelandic fish are caught in own waters but the share, which is caught outside own EEZ, has been increasing in recent years. In 2002 the catch from outside own zone constituted 24.3 percent of the total catch value (Ministry of the Environment et al., 2004, p. 24).

Employment and Fleet

The number of persons employed in the marine capture sub-sector has been gradually declining over the past years. Official estimates indicate that the number employed has dropped from approximately 7000 to 5500 in the period from 1992 to 2002 (Ministry of Fisheries, 2003, p. 4) - this on the background of increasing catches both in terms of value and volume. The trend continued in 2004 where the data indicate that a little more than

5000 persons were employed in the marine capture fisheries sub-sector (Ministry of Fisheries, 2004, p. 4).

The development of the Icelandic fleet is summed up in the table beneath, which shows the development from 1998 to 2003 in terms of number of vessels, gross tonnage (GT) and kilowatt (kw) engine power.

Table 3.18 The Icelandic fleet 1998 to 2003

Year	1998	1999	2000	2001	2002	2003
Number	1932	1970	1997	2015	1938	1876
1000 GT	187	181	180	191	191	184
1000 kw	503	514	529	555	548	538

Source: Eurostat database website, 12 January 2005.

The Icelandic fleet has, according to the figures from Eurostat, decreased in terms of numbers, kilowatt and gross tonnage from 2001 to 2003. The decrease in capacity is at least in part due to an attempt to make the capture fisheries sub-sector more economically efficient.⁷⁴

Anyway, the tendency in the development of the overall fleet is not clear but in the trawler fleet, which catches more than half of Iceland's demersal catch by volume (Ministry of Fisheries, 2004, p. 5), there seems to be an ongoing development where the trawler fleet as such decreases the number of vessels used to catch their quotas - taking advantage of economies of scale - as an adjustment to the incentives in the ITQ management system (Gudmundsson et al., 2004, p. 12). This means higher efficiency but most probably also less persons employed.

Perspectives for the Future

The Icelandic policy on TACs is according to the minister of fisheries that these shall as far as possible reflect the recommendations put forward by the biologists in MRI (Intrafish, Feb. 2004, p. 10), which was also, as described above, in general the case for the fishing year 2004/2005. This commitment to science is especially true for the most important species, cod, which is, as earlier described, subject to a special arrangement where the scientific estimate of the fishable biomass is calculated directly into a TAC. However, the scientists in MRI believe that the catch rule for cod is not restrictive enough and that it should optimally have been set at 22 percent instead of 25 percent. It is, nonetheless, predicted that the biomass for cod will increase *"in next several years"* (Marine Research Institute, 2004, p. 167), which is positive news for the capture fisheries sub-sector. The sub-sector relies heavily on cod, which constitutes almost 40 percent of the value of exports of fish products (Ministry of Fisheries, 2004, p. 10).

The Icelandic fisheries management scheme is rather restrictive in terms of conservation of resources (e.g. the catch rule for cod) and it must be expected that this in the long term will lead to a stable and positive development in relation to availability of resources providing that the Icelanders manage to 'get the science right', which is not uncomplicated. However, Icelandic scientists have better conditions than their EU counterparts due to the transparency of the fisheries sector. The capture fisheries sub-sector will, nevertheless, probably also experience ups and downs in the future due to natural fluctuations in the abundance of fish. This does not, however, change the relatively positive outlook for the future.

⁷⁴ Information Centre of the Icelandic Ministry of Fisheries website: <http://www.fisheries.is/ships/fleet.htm> (12 January 2005).

Furthermore, the demand for fish in the EU, which is Iceland's main trading partner, is growing due to the increasing perception of fish as healthy food and increasing GDP (especially in the new member states) - and the EU is not in a position to increase its own landings considerably in the short or medium term due to the state of the stocks and will continue to import a significant share of fish products. Icelandic fish products have, furthermore, a good reputation and are able to live up to EU standards, which give Iceland an advantage *vis-à-vis* to some of its competitors, which might otherwise be able to utilise lower wage costs.

The perspectives for the Icelandic capture fisheries sub-sector is, consequently, all in all positive. The sub-sector is highly competitive and in a process of further improving its economic efficiency as a result of the ITQ system, which should ideally make the Icelandic capture fisheries sub-sector more competitive *vis-à-vis* competing fleets. There is nothing in the evidence above, which suggests, that the Icelandic capture fisheries should be facing a crisis anytime soon. Also, the resource situation is better and more transparent than for many competitors. Nevertheless, it should be kept in mind that dealing with a natural marine resource involves uncertainties.

Table 3.19 SWOT analysis of the Icelandic capture fisheries sub-sector

SWOT analysis of the Icelandic capture fisheries sub-sector			
Strengths	Weaknesses	Opportunities	Threats
Strong management regime based on science	Restricted access to EU markets due to non-membership	Increasing economic efficiency due to incentives of the ITQs	Natural fluctuations in fish abundance
Efficient fleet	High wage costs	Increasing demand for fish products, especially of high quality	Competing low price species from other places in the world
Large resource base of high quality		Utilisation of species not yet recognised as commercially valuable	Cod aquaculture
Relatively little overcapacity			Climate changes, see chapter on ICZM

3.6.4 The Marine Aquaculture Sub-Sector

Production

Aquaculture production in Iceland started in the beginning of the eighties with high hopes from both investors and authorities (FAO, 1997). Looking back, the sub-sector has so far only turned out to be a modest success. Expansion is, however, feasible in the years to come.

Marine aquaculture (including coastal aquaculture taking place in brackish water) is of relatively modest importance in Iceland. This is especially the case if the magnitude of it is compared with that of capture fisheries. The value of the Icelandic marine and brackish water aquaculture production has been increasing over the years from € 11.7 million in 1990 to € 14.9 million in 2002 (up 27 percent, in current prices), peaking at € 17.4 million in 2001. (Eurostat database website, 6 January 2005)

Half of the production in 2002 took place in brackish water. The dominant species mainly cultured in brackish water is arctic char (€ 7.8 million in 2002) and the dominant species mainly cultured in sea water is salmon (€ 5.9 million in 2002). Aquaculture of cod and halibut amounts to a little under € 1.8 million (2002).⁷⁵ (Eurostat database website, 6 January 2005)

Perspectives for the Future

The future perspectives of Icelandic aquaculture are relatively good although some species are more promising than others. The government does not expect that there will be much growth in salmon aquaculture because the world market is close to or over saturation at the prices Iceland can produce at. However, Icelandic companies are important players on the world market for salmon aquaculture technology. (Intrafish, Feb. 2004, p. 10)

⁷⁵ The total of these three figures amounts to more than € 14.9 million, which was the total marine and brackish water aquaculture production in 2002. The explanation for this is that arctic char is also farmed in fresh water.

Cod farming has for some years been expected to take off commercially, so far the success has been modest. The government expects a modest development of Icelandic cod farming to a level of 10,000 tonnes in 2013. The government does not foresee a dramatic development; on one hand, because of the technical difficulties still experienced in cod farming and, on the other hand, because the relatively sound wild cod stock is expected to remain the most important Icelandic fish stock, wherefore extensive investments in cod farming would resemble competing with oneself (Intrafish, Feb. 2004, p. 10). The development of cod aquaculture is of course dependent on a number of other factors, including the development of the cod stocks currently subject to recovery plans in the waters of the EU, which is the main target of Icelandic export of fish products and more specifically cod.

Iceland has found a niche in farming of arctic char, for which Iceland is world market leader (Eurostat database website, 5 January 2005), and other species, which can be expected to be future candidates for aquaculture in Iceland, include halibut and abalone, which is both farmed commercially already, and turbot, spotted wolf fish and mussels. (Intrafish, Feb. 2004, p. 10-11 and Ministry of the Environment et al., 2004, p. 25)

All in all the perspectives for Icelandic aquaculture seem good. The Ministry of Fisheries has forecasted that the income from export of aquaculture products will increase from approximately € 12 million to approximately € 144 million in 2012 (Ministry of the Environment et al., 2004, p. 25). Anyway, the optimistic figure of € 144 million represents under 10 percent of the total value of exported fish products in 2002.

Compared to capture fisheries, aquaculture will, in conclusion, continue to be of relatively minor importance. Nevertheless, this sub-sector is perhaps the most promising in terms of creation of new jobs in the fisheries sector.

Table 3.20 SWOT analysis of the Icelandic aquaculture sub-sector

SWOT analysis of the Icelandic aquaculture sub-sector			
Strengths	Weaknesses	Opportunities	Threats
Favourable conditions for farming of certain species, e.g. cod	Competes with Icelandic capture fisheries	Introduction of new species such as turbot and mussels etc.	Increasing efficiency of competitors
High technological level	Unfavourable conditions for some species	Worldwide increasing demand for fish products, especially of high quality	More efficient producers producing at lower prices (e.g. salmon)
	Relatively high production costs for e.g. salmon	New technology adapted to Icelandic conditions	Fish diseases
	Restricted access to EU markets due to non-membership	Growth in cod aquaculture	

3.6.5 The Processing Sub-Sector

Production and Employment

Iceland has an important processing sub-sector, which in 2003 is estimated to have contributed with approximately 4 percent of the overall GDP and employed in the

neighbourhood of 6500 persons - down from almost 10,000 at its highest in 1994 (Ministry of Fisheries, 2003, p. 4). The trend continued in 2003, where the data indicates less than 5500 employed in the processing sub-sector and a slightly smaller percentage of the overall GDP (Ministry of Fisheries, 2004, p. 4).

The overall number of licensed fish processing companies has in the period from 1999 to 2003 been declining (Ministry of Fisheries, 2004, p. 8). Their main products are the results of a mix of traditional (salted and cured) and modern (fresh or frozen) processing techniques.⁷⁶

A prominent development during the nineties has been that processing is increasingly carried out at sea, which means that for the local fishing communities important land-based processing is declining relative to at-sea processing. These changes are the result of changes in technology. Changes in the market for fish have also put traditional processing under pressure (Eythorsson, 2000, p. 489). Fresh fish, which involves much less processing than other categories of processed fish products, has increased its share of value of processing output markedly in the period from 1996 to 2003 (Ministry of Fisheries, 2004, p. 10). The development has consequently been negative, especially for the land-based processing sub-sector, which is closely linked to the wellbeing of local fishing communities. However, this development has been reversed somewhat in the past two to three years, most notably one of the largest fishing companies recently sold one of their freezer trawlers and others have been landing fresh fish for processing on land.

Perspectives for the Future

The Icelandic processing sub-sector is to some extent protected by the fact that quotas cannot be sold out of Icelandic ownership, which would otherwise perhaps result in transfer of more catch to processing in other countries. It is, furthermore, a stated objective of the Icelandic government to work *"to retain as much as possible of added value within the country"* (Intrafish, Feb. 2004, p. 10). Nevertheless, the figures for number of persons employed and proportion of overall GDP (as well as the number of licensed fish processors) have been declining in recent years, which suggests that the processing sub-sector is adjusting to the increased competition from countries with for instance lower labour costs resulting from the globalisation of the market in fish products.

The development in the processing sub-sector in the period from 2001 to 2003 has in sum been fewer employees, fewer licensed fish processors and smaller percentage of overall GDP (estimate) (Ministry of Fisheries, 2004). It is an open question if this tendency can reasonably be changed upwards by political initiatives - and if this would in any case be preferable - given the increasing globalisation of the market in (raw) fish and the high wage costs in Iceland. The globalisation of the market in fish products tends to undermine the competitive advantage of being close to where the resources are harvested. The Icelandic processing sub-sector is to some extent protected by its own good reputation, which gives it an advantage over many competitors with less 'good names'. However, this might change in the future if competitors get better at what they do, which is a plausible prediction. While this happens it is necessary for the Icelandic processing sub-sector to find its niche, perhaps in adding value to ultra-fresh fish products, to which Icelanders have good access, or by upgrading the technology used to become more efficient. However, this will probably only be possible on bigger plants and will in any case mean fewer jobs.

⁷⁶ Information Centre of the Icelandic Ministry of Fisheries website: <http://www.fisheries.is/process/index.htm> (12 January 2005).

In sum, there is no doubt that the Icelandic processing sector will increasingly be put under pressure from competitors with smaller processing costs. The most important reason for this is that the competitive advantage of easy access to resources is eroded as transport gets easier and cheaper.

Table 3.21 SWOT analysis of the (landbased) Icelandic processing sub-sector

SWOT analysis of the (landbased) Icelandic processing sub-sector			
Strengths	Weaknesses	Opportunities	Threats
Close proximity to raw materials of the highest quality	Restricted access to EU markets due to non-membership	Concentrate on high value-added products from fresh raw material using Modified Atmosphere Packaging (MAP) technology	Factory trawlers carrying out processing at sea and possibly landing for export
Good reputation for high quality and hygienic standards	Relatively large distances to main markets	Concentration in larger, more technology based units	Increasing competition from low cost countries as trade barriers disappear
Political clout and legal protection	Dispersed industry / small units	Worldwide increasing demand for fish products, especially of high quality	Increasing detachment between quota holders and local communities
	High labour costs		

3.6.6 In Sum

The prospects for the Icelandic fisheries sector are mixed - with variable outlooks for the different sub-sectors:

- The capture fisheries sub-sector is relatively economically healthy and the state of the resources is good compared to other places. Anyway, in terms of employment this sub-sector cannot be expected to provide more jobs in the future as technological developments continuously increase the efficiency of the fishing vessels, which leads to less and less input of manual labour to catch the quotas. This development is, furthermore, supported by the incentives provided by the Icelandic ITQ system, which in itself gives incentives to larger, more efficient vessels.
- The aquaculture sub-sector is in a position to generate new jobs in the future, especially if farming of cod takes off. Iceland is, together with Norway and the UK (Scotland), one of the few places where farming of cod is expected to be possible. The future development of aquaculture in Iceland is, furthermore, dependent on the development in wild fish resources, especially cod, and the outcome of experiments with other potential aquaculture species. The future of the aquaculture sector looks, all in all, positive, given that the global demand for fish products is expected to increase in the years to come.
- The perspectives for the processing sub-sector are less positive. One reason for this is that more processing takes place onboard the vessels as a result of the introduction of factory trawlers. A second reason is the globalisation of the

market in fish products, which makes it easier and increasingly cheaper to export raw material for processing in countries with lower costs. This development is probably reinforced by the Icelandic ITQ system, which must be expected gradually to remove the traditional links between local quota holders and vessel owners, local ports of landing and local processing plants. In other words, the processing sub-sector is facing great challenges and it is probably fair to assume that the development in the future will be negative, at least in terms of jobs.

3.7 EU, Norway and Iceland compared

The fisheries management systems of the EU, Iceland and Norway differ on several points and the outlooks for the fisheries sectors are in many respects also different, as described above. At the moment the general outlooks are better in Norway and Iceland than in the EU – particularly in relation to capture fisheries because of a better biological state of the commercially important fish stocks in those countries. The adoption of new measures in connection with the recent reform of the CFP may, however, improve the situation in EU waters in the longer term. Aquaculture is an area of optimism in EU, Norway and Iceland. So far Norway has been the success story in this respect but both EU and to a lesser extent Iceland have great hopes for the future - and a lot to have their optimism in. However, in many ways EU, Norway and Iceland are also all subject to some of the same challenges posed particularly by globalisation, increased competition and technical developments, which for instance makes a lot of job functions in the processing sector obsolete. Processing is probably one of the areas where globalisation has the greatest impact. Whereas it is not possible for a Chinese to catch a cod in the North Sea, it is nonetheless possible for him to buy it process it and ship it back to Europe. This puts special stress on the processing industry. However, competition from new species, which impacts both capture fisheries and aquaculture, is also a result of globalisation, which impact EU, Norway and Iceland alike.

The new developments and framework conditions have in all three areas resulted in a tendency towards some regions benefiting from the new situation at the expense of other regions. How to cope with these structural changes is a challenge, which all three fisheries management systems face. In the EU the situation is complicated by the fact that the different regions are situated in different countries. This makes it comparatively difficult to compensate disadvantaged regions in one way or the other. In unitary states like Norway and Iceland these problems are in principle easier to handle. However, also in Norway are the problems felt as particularly the northern part of the country is facing difficulties, which because of the massive importance of fisheries are difficult to solve. In Iceland it is especially the smallest communities that are suffering - not only because of globalisation but also under the side effects of the ITQ management system.

Despite the differences in the situation of the sectors and the way that the management systems work there is, consequently, no doubt that the three parties can benefit from looking at how problems in relation to territorial imbalances etc. are solved or not solved in the other areas; at the moment all three systems are struggling to develop mechanisms to cope with territorial imbalances brought about by fisheries management and globalisation.

Of particular interest when comparing the three systems is the fact that they to a varying degree include private property to and transferability of fishing rights. The Icelandic system is close to being one of the most pure ITQ systems in the world; and the Norwegian system is also increasingly turning towards privatisation of fishing rights -

although not to an extent as the Icelandic. At EU level the allocation of fishing rights is, however, determined by the principle of *relative stability*, which to a large extent rules out a system with transferable, private property rights at this level of management. However, it should be observed that at national level many member states do employ systems with more transferability. This, nonetheless, illustrates that there are differences between basic conditions for fisheries management in a collective of states like the EU and unitary states like Norway and Iceland.

Also when it comes to the use of subsidies can differences be observed. Both Norway and Iceland are now operating close to subsidy-free fisheries, whereas subsidies remain an integral part of fisheries management under the CFP. A thing to observe in this respect is the fact that both the subsidies in the EU and the (limited) subsidies in Norway do not necessarily seem to reduce territorial imbalances, which is often how they are viewed. In fact in some instances the subsidies seem to enforce such a development because of the criteria for eligibility.

In conclusion, all three systems are facing challenges in the coming years - although these challenges to some extent vary in nature and severity. Many of the challenges are brought about by external developments, exemplified by globalisation. Such challenges are basically shared, which makes it useful to look at how well these are met in the different management systems. Moreover, the management systems are also creating challenges in themselves. It is therefore also useful to look and learn from each other to avoid repeating management mistakes that others have made before.

3.8 Conclusion / Revisiting the Hypotheses

The hypotheses outlined in the beginning of this chapter were related to different elements of the CFP (and fisheries politics in general): five hypotheses were related to conservation policy, two to market policy, two to structural policy, and one to external policy. On a general level the hypotheses have been supported by the analysis of the different policy areas. In the following discussion we will go through each hypothesis and sum up the main findings, mainly related to the CFP. However, the discussion and findings below apply in general also to the situation in Norway and Iceland, which are more or less subject to the same situation as the EU countries. However, the two countries are at present in a better situation in regards to the sustainability of stocks and the economic situation of the sector than the EU countries on average, see above.

Conservation Policy Findings

Five hypotheses, which related to conservation policy, were outlined in the beginning of this chapter.

TAC management allows for quantitative allocation of fishing resources (catches) at all territorial levels (EU/international, regional and local) and the establishment of “relative stability” between geographical areas/territories; adopted at international level in the EU (and in some cases at national level, e.g. by the UK - via allocation to Producer Organizations). This implies intentional territorial impact.

The first hypothesis related to the intentional territorial impact of the CFP, which occurs from the allocation of fishing opportunities through quotas. Quotas are not allocated on the basis of need but following a principle of ‘relative stability’. This creates territorial impacts across nations on a very general level. Some nations might be better at matching their allocations to the structure of their sector, which gives them (and their regions) an advantage over other countries.

EAF and precautionary approach management implies that fishing effort will have to be reduced in waters/fish stocks involved and that catches from some stocks may be permanently lower but less fluctuating over time. This implies loss of jobs in the affected communities (onboard fishing vessels and in the related trades). The economic outcome may be positive but will directly benefit fewer people. The less fluctuating catches, which are also expected, will provide improved opportunities for investment planning. Unintentional negative territorial impact in the short and medium term is one result.

The second hypothesis was also supported by the analysis of the future direction of the CFP, which must be expected to move towards EAF. This will - at least in the short or medium term - lead to negative impacts because of lower (or at least not significantly higher) TACs, which are supposed to result in lower fishing pressure.

Applying market principles in the allocation of access rights to fish resources (e.g. ITQs) implies concentration of the fishing industry in territorial terms and fewer, larger and more efficient production units in the fisheries sector. Territorial impacts are not intended and sometimes negative impacts can be counteracted by policy measures.

The third hypothesis has mainly been dealt with in the section on Iceland. The analysis seems to support the assumption that ITQs in some instances lead to (often unintentional) regional redistribution, as well as to the desired restructuring of the sector towards larger, more efficient units. Market based management systems have, however, not yet been applied on a European scale.

Recovery plans for depleted fish stocks (involving closed areas, closed seasons, catch/effort limitations etc.) will in the short and medium term have negative impact on the fishing communities dependent on these resources. The more immobile and inflexible the fishing fleet is and the more species dependent the processing industry is, the more significant will the impact be. Coastal communities dependent on small-scale fishing may be particularly vulnerable. This implies unintentional territorial impacts in the short and medium term.

The fourth hypothesis related to the fact that recovery plans might have unintentional consequences. As discussed, recovery plans are intended to 'punish' or at least restrict the fleets targeting endangered stocks. This might be considered the intentional impact; an unintentional - partly territorial - impact is that the different fleet segments are put in different situations. Larger vessels might be able to utilise resources far from where they have homeport, whereas this possibility does not exist for smaller coastal vessels. This is unfortunate as it is often not the smallest vessels, which constitute a problem for the resources or destroy habitats. Therefore it seems unfortunate that they have to carry the largest burden.

Fishing communities, dependent on the exploitation of fish stocks that are within safe biological limits (e.g. North Sea herring and mackerel), are operating on a more stable resource basis and are thus experiencing less negative territorial impacts from fisheries resource management measures at both political and private business levels.

The fifth hypothesis was general and related to the distribution of negative impacts of the conservation policy. The analysis has to a high degree supported the hypothesis that the most important factor in determining how the negative impacts will be distributed across regions is the state of the stocks the fleets utilise. This is hardly surprising but the most important information related to this is in fact also the varying unintentional impacts; for instance the different possibilities to change gear or sea area.

Market Policy Findings

Fisheries market policies counterbalancing the free market forces have intended territorial impacts that may be on international (EU), national and local levels. Unintended impacts may occur in other territories/territorial levels.

The analysis of the market policy supported the assumption that this policy has serious territorial effects. The effects relate not so much to the direct financial transfers under the price support mechanism, which are relatively insignificant compared to those distributed under the FIG. Rather, the varying territorial impacts are related to the different impacts of tariffs and external trade measures. An example provided in the preceding chapter was the decision to put an extra tax on (especially Norwegian) salmon. This was done in order to protect salmon producers in Scotland and Ireland but the safeguard measures had serious negative impact on salmon processors in Denmark, which depend heavily on Norwegian raw material.

The territorial impact of specific fisheries sector oriented market policies is of decreasing importance compared to the impact of general international and national market and food policies. This especially counts for territories dependent on import or export of fish products (fish as raw material for processing value-added products). The territorial impacts are unintended.

The analysis supports also the assumption that fish products will increasingly be affected by other policies not directly stemming from the fisheries market policy. The policy on traceability is provided as one example of such.

Structural Policy Findings

Two hypotheses were related to the impacts of the structural policy.

Fisheries structural policies have intended territorial impacts that may be on international, national, regional and local levels. Unintended impacts may occur in other territories or on other territorial levels.

The analysis supports the hypothesis that the policy has significant territorial impact; this is actually the whole idea of it. However, more interesting is the fact that some regions are able to get more funding from the EU based on considerations, which are wholly or partly unrelated to the situation of their fisheries sector. This puts unintentionally some regions in a better situation than other regions. Furthermore, the analysis has also shown how some countries and regions receive a very significant part of the total EU support, which in general puts their regions in a favourable situation *vis-à-vis* others. Galicia could be mentioned as one region, which gets a surprisingly large share of the total FIG support. Finally, it is also interesting to see how the structural policy has - until recently - supported modernisation and renewal of the EU fleet in a situation, where overcapacity is considered one of the main problems facing the conservation policy.

Territorial impact in fisheries dependent areas are increasingly determined by global or national agendas, developments and policies rather than by EU sector specific structural policies.

The second hypothesis is related to the fact that the EU structural policies are increasingly becoming less important because of increasing impacts of the surrounding environment, i.e. the global development. Although this might be true, the impact of the direct injections of money through the FIG (whether these are viewed as positive or negative) should not be underestimated. It could be argued that the FIG support is important exactly to tackle a situation where the local markets and fleets are increasingly becoming

part of a world market. In the new member states this is happening simultaneously with a demanding transition towards market economy.

External Policy Findings

The policies relating to fisheries agreements with third countries have territorial impact in regions with fleets, which utilise these agreements. Failures to renegotiate agreements or changes in circumstances around agreements have unintentional negative impact in affected regions. Impact can also be felt in regions not exploiting the agreements because they serve to keep some excess capacity out of Community waters.

The analysis clearly showed that the external policy has territorial impact, which varies across regions. This relates especially to fisheries agreements, which are of most importance for the southern EU member states. The transfer of money through the fisheries agreement could be seen as subsidies for the vessels engaged in these fisheries. However, also bilateral and international agreements or the failure to conclude these could have significant impact, as illustrated with the failure to get agreement with Norway over Atlanto-Scandian herring, which are of importance to a number of Danish ports.

In Sum

The analysis in this chapter has supported the outlined hypotheses and in this way also supported the underlying general hypothesis that the CFP (and fisheries policies in general) potentially has significant territorial impacts – intentional as well as unintentional. It is, consequently, possible to conclude that these hypotheses provide a good basis for the analyses in the following chapters on actual territorial impacts and example studies related to this. The chapter has, furthermore, outlined a number of concrete examples of territorial impacts as well as provided a thorough introduction to the structure of the sector in the EU, Norway and Iceland.

3.9 Policy Recommendations

This chapter sets the scene for the following chapters, which deal specifically with the impact of the fisheries policy, by describing the CFP and the fisheries policies of Norway and Iceland and the overall structure of the sector in Europe. This chapter does not, however, analyse the territorial impact of the fisheries policy, which is the objective of the following chapters. It is therefore not appropriate to use this chapter as the basis of concrete policy recommendations. However, the chapter does describe issues, which might be considered in future discussions over policy reform and territorial impacts. Many could be mentioned and these should only be considered as a selection:

- Introducing market based management systems at EU or national level may serve to increase efficiency but there is also a risk that an unintended result will be territorial restructuring, which has to some extent been seen in especially Iceland. It is important that analyses of the possible results and side-effects of a possible introduction of market based management systems are undertaken.
- Measures to protect stocks may have unintended territorial impact. In case of restrictive measures being taken, the least mobile and flexible fleets are the ones, which are hit the most. These fleets are not necessarily the ones, which have contributed most to the resource problems. Regions with these types of fleets will be hit harder than regions with more mobile and flexible fleets.

- There is a need to consider what role the RACs should play in the future. Are they to continue to be only advisory bodies or should steps be taken towards a true regional management approach?
- The criteria for awarding support and especially the share of support, which the EU can contribute with, are not necessarily fair from a fisheries point of view. Objective 1 areas are defined on the basis of GDP and not on the basis of the specific situation of fishermen.
- Due to the better economic situation (and the possibility to finance for instance 50% themselves) enterprises situated in more developed areas are possibly those, which send in more applications. Poor enterprises in poor areas are in contrast not to the same degree able to cover self-financing and are thus not eligible, which constitutes a problem if the wish is to maintain activities in the poorest areas.
- Protectionist measures aimed at protecting certain parts of the fishing sector in one area may very well have negative effects in other areas of the EU. This has been the case with the safeguard measures imposed against Norwegian salmon. These measures benefit Scottish and Irish Producers but have severe negative effects on Danish processors.

4 Environmental impacts and integrated coastal zone management (ICZM)

4.1 European fisheries and environmental impacts

According to European Environment Agency (EEA) a chronic overexploitation of fishery resources is the greatest current environmental concern of the fishery policy in Europe. Protection of and access to fishery resources are therefore an important and may be the most difficult part of the CFP. The objective of the conservation policy is primarily to protect the fish stocks by limiting the amount of yearly catches and to ensure that this is respected. This is done through a system of TACs for each stock, which ICES gives scientific advises on, and national quotas, which are distributed between the member states on the basis of the core principle of ‘relative stability’). One of the most important new elements in the conservation policy is the obligation or possibility for the Council to adopt multi-annual recovery or management plans for certain fish stocks which are outside safe biological limits or within safe biological limits (see chapter 3 for more details).

EEA has developed an indicator-based approach to assessing the environmental performance of European marine fisheries and aquaculture, based on statistics from ICES, GFCM, FAO, Eurostat, etc. We will primary make use of indicators developed and presented by EEA⁷⁷, such as percentage of stocks outside safe biological limits, catches by major species and areas, impacts on habitats and ecosystems, fishing fleet trends and aquaculture production. Some of these indicators will be supplemented with data and indicators from other sources. However, the majority of the environmental data is on national level or for ocean areas, and it is a general problem with geographical breakdown. In addition, according to EEA data on small-scale fisheries for Mediterranean are often not registered or are very difficult to obtain. The available indicators are nevertheless important to highlight the changes and status for the environment, e.g. fishery and habitat resources.

It must not be forgotten that fishing habitats and ecosystems in the oceans and the coastal zone are subject to a heavy pressure also from other sources than fisheries, like water pollution from agriculture, sewage, manufacturing in urban areas and increasing land use pressure on the seashore. Sustainable and integrated development in form of clean water and viable ecosystems is a framework condition for further growth in aquaculture and other marine businesses and for the fishing industry in general.

⁷⁷ See http://themes.eea.eu.int/Sectors_and_activities/fishery/indicators

In the Fact Sheets of EEAs web-page, information about data quality and methodology concerning the specific issues is given.⁷⁸ The EEA core set of indicators – Guide (http://reports.eea.eu.int/technical_report_2005_1/en) provides information on the quality of the 37 indicators in the EEA core set.

4.1.1 Fishing fleet trends

The size of the fishing fleet (number of vessels, tonnage and power) is an important factor in managing the fishing effort. Fishing capacity is defined in terms of tonnage and engine power, but there are many parameters that determine the fishing mortality exerted by the fleet. The development of engine power in terms of kilowatt is generally considered the best indicator of the development of the actual fishing power of the fleet. It is currently believed that the fleet is too large. In simple terms excess capacity may lead to over-fishing and increased environmental pressure. EU has aimed to restructure the fleet and reduce its capacity. Currently efforts focus on reduction of fishing effort defined as the product of the capacity of a fleet with the days spent at sea by scrapping vessels or keeping them in port. In the MAGP⁷⁹ IV has decided a cut of 30 % in the fishing effort for stocks in the verge of collapse and for 20 % for those that are over-fished (see chapter 3 for more details).

The fishing fleet is regarded as too big for the available resources. According to EEA, the key message on this issue is rather positive because *the EU 15 fishing fleet (1989-2000) has decreased both in numbers of vessels (10 %), in tonnage (6 %) and power (12 %)*. On the negative side, the EFTA fishing fleet (Norway and Iceland) has in the same period dramatically increased in tonnage (31 %) and in power (6 %), despite that the fleet has decreased in number (27 %). However, during the last years the fleet is decreasing also in tonnage and power for these two countries. For Norway and Iceland, the reduction of the fleet came in 2001 in terms of absolute number, and reduction in terms of tonnage and engine power came in 2002. From 2000 to 2005 the Norwegian fleet have a very sharp decrease, with 37.1 % in number and 45.6 % by engine power. By contrast the fleet of the other EFTA country, Iceland changed relatively little over the same period (Eurostat 45/2005).

These reductions do not, however, take into account the so called technological creep.⁸⁰ However, advances in technology may well mean that new vessels exert more fishing pressure than older vessels of equivalent tonnage and power. And not only is the quantity of fish taken from the sea important, but also their species and sizes, and the techniques used in catching them, and the areas in which they are caught. Control must also be exerted on net mesh sizes, landing sizes, by- and incidental catches, use of selective gear and closed areas and seasons. The summary from EEA is after all that the CFP has succeeded in enforcing a decreasing trend in the fisheries fleet. However, MAGPs have proved not to be ambitious enough to address excess fleet capacity; they were not always enforced and were complex to administer.

Despite the overall drop in size and capacity (power and tonnage) experienced by the EU fleet in the past 15 years, according to EEA, no visible improvement in the condition of the fish stocks has so far been observed. Conservation measures according to the CFP have persistently been undermined by fishing activities at levels well beyond the level of pressure that the available fish stocks could safely withstand. As new technology makes

⁷⁸ http://themes.eea.eu.int/indicators/all_factsheets_box

⁷⁹ Multi annual guidance programmes.

⁸⁰ Due to so-called technological creep the fishing power of a fleet will actually increase over time even if the engine power in terms of kilowatt is kept stable. This means that if the fishing power of a fleet should be kept stable, the engine power of the fleet should continuously be decreasing.

fishing vessels ever more efficient, the capacity of the fleet should be reduced to maintain a balance between fishing capacity and the quantities of fish that can safely be taken out of the sea by fishing.⁸¹ EEA (2005) conclude that compared with the indicative policy objectives, only modest reductions in the capacity of the European fleet as a whole have been achieved over the past decades.

4.1.2 Development in catches

Total fish landings of all species in all European sea regions⁸² have increased by 20 % (1.6 million tonnes) between 1990 and 2000, see figure 6.2. This is largely due to an increase in landings by vessels of the EU 15 and EFTA countries, which account for an average of 93 % of total European landings by weight. Landings reached a peak in 1997 of over 12 million tonnes and declined to 11 million tonnes in 2000. From 1995 to 2002 the total catches of the EU25 fleet has dropped from app. 8 million tonnes to app. 6.8 million tonnes (in live weight).

Landings of demersal marine fish, pelagic marine fish and shellfish account for an average of 95 % of all European landings. The landings of these major fish types have increased from 1990 to 2000. Landings of demersal marine fish have increased by 2.4 % (99 786 tonnes) since 1990. Landings of pelagic marine fish have increased by 24.6 % (1.15 million tonnes) since 1990, while landings of shellfish have increased by 1.7 % (12 000 tonnes). Landings of cod and tuna rose significantly between 1992 and 1997, since when they have decreased. Landing of mackerel rose between 1990 and 1994, fell rapidly until 1997, but have since risen again.

Figure 4.1 Total landings by region (tonnes), 1990 - 2000

Source: <http://dataservice.eea.eu.int/atlas/viewdata/viewpub.asp?id=700>

⁸¹ http://themes.eea.eu.int/IMS/IMS/ISpecs/ISpecification20041007132252/IAssessment1116524527114/view_content

⁸² North East Atlantic Ocean (including the Baltic Sea), Mediterranean Sea, Black Sea and Arctic Ocean. The Caspian Sea and Aral Seas are not included, as these are considered to be “inland waters” by FAO.

Notes: All North East Atlantic Ocean (includes Baltic Sea), Mediterranean Sea & Black Sea (including the Azov Sea) and Arctic Ocean catches of all species. Caspian Sea and Aral Sea not included, as these are considered to be "inland waters" by FAO.

The North East Atlantic is the most important fishing region for EU25. 73 % of their catches was taken from this region in 2002. Since 1990 the EU25 catch in this region has fallen by 5.4 %. On the other hand, the combined catch of Iceland and Norway has risen by 57 % in the same period (fishery statistics 2004). However, in 1996 ICES indicated that there was a need for a 40 % reduction in the fishing fleet to avoid over-fishing and match available resources (EEA 2003). In the Mediterranean the EU25 accounted for 33 % of the total catch in 2002, 50 % by Italy. The EU25 total catch decreased by about 16 % in the period from 1990 to 2002. In the same period the total catches in the Mediterranean increased by 13 %. Turkey accounted for 34 % of the total catch in 2002 (ibid.).

Increases or decreases in landing do not, however, alone signal a healthy or unhealthy fishing industry or marine environment. Increases in fish landings may be driven by either increasing amounts of available fish or increasing fishing effort. Similarly, decreasing landings may be the result of a lack of available fish or a change in management measures of fishing patterns. FAO statistics do not take into account those organisms that are caught but not landed (discards). Most discarded species, especially fish and marine mammals, do not survive. Landings statistics, therefore, underestimate the total catch of fishing vessels and, thus, the impact on the marine environment. Also illegal, unregulated and unreported fishing still remains a huge problem.

The seas around Europe contribute to the majority of landings by European countries, i.e. European countries are in general not heavily dependent on landings from distant waters. Since 1990, the dependence on landings from distant waters has declined from 21 % (2.5 million tonnes) to 8 % (0.9 million tonnes).

4.1.3 Percentage of stocks outside safe biological limits

One central indicator in the EEA list of environmental impact indicators in relation to CFP is commercial fish stocks outside safe biological limits (EEA Indicator Fact Sheet: FISH1a in 2002). This is defined as the point where the indicators of the state of a stock predict a low risk for transgressing certain so called 'limit reference point', for instance values of biomass or fishing mortality rate, which are to be avoided (Council Regulation (EC) no 2371/2002, art. 3(j) and (I)). In other words, stocks are characterised as being outside safe biological limits when mortality exceeds recruitment and growth. By comparing trends over time in recruitment (the number of new fish produced each year by the mature part of the stock), spawning stock biomass, landings (estimate of the most likely removal from the stock, sometimes including discards) and fishing mortality, a fairly reliable picture of the stock development can be derived. With the introduction of the precautionary principle, a biomass and a mortality precautionary approach reference points are in addition being made (not for the Mediterranean stocks).

Data for this indicator are only available for the North East Atlantic and the Baltic Sea, and many commercial fish stocks are not assessed (see figure 4.2). In the North East Atlantic, the percentage of non-assessed stocks of economic importance range from a minimum of 13 % (North Sea) and maximum 59 % (West Ireland). The Baltic Sea also has a high percentage of non-assessed stocks at 56 %. In Mediterranean fisheries data on small-scale fishery are not registered or are very difficult to obtain. For the Mediterranean

Sea, stock assessments are based mainly on landings in the absence of complete or independent information on fishing intensity or fishing mortality. The percentage of non-assessed stocks of economic importance here is 80 %, and a range from 65 % (Aegean Sea) to 90 % (South Alboran Sea). Background data exist up to 2002.

Figure 4.2 Commercial fish stocks outside safe biological limits in the North East Atlantic and the Baltic Sea in 2002

Source:

<http://dataservice.eea.eu.int/atlas/viewdata/viewpub.asp?id=190> (blue lines indicate fishing regions)

According to EEA, *most fish stocks of commercial importance in European waters appear to be outside safe biological limits* of the assessed stocks. Following the assessment of stocks 33-60 % of commercial stocks in the North East Atlantic were in 2002 outside safe biological limits. The Baltic and West Ireland are in a better shape (with 33 % of their stocks being outside safe biological limit) and West of Scotland area the worst (with 60 %). For the Mediterranean the percentage of stocks outside safe biological limits range from 10 to 20 %. In the OSPAR area, 40 of the 60 major commercial stocks were assessed outside safe biological limits in 1999 (EEA 2002).

In general, the situation for some central commercial stocks is:

- Herring stocks appear to have recovered since 2001
- Almost all round fish have declined and are currently not sustainable
- Hake stocks dramatic decline caused alarm leading to TAC cuts up to 50 % in 2001
- Deep-sea species show signs of over-exploitation
- Flatfish stocks are heavily exploited but are close to sustainable levels
- In the Mediterranean region, demersal stocks are outside safe biological limits.
- Cod stocks in the North Sea, Skagerrak, Irish Sea and waters west of Scotland are now so depleted that the chance of collapse must be seriously considered. ICES recommend that all fisheries with the target fish cod should be closes in these areas, and should be subject of increasing management measures in EU waters in efforts to rebuild them to biological stable conditions.
- Pelagic species are in better condition but need to be subject to reduced fishing rates

The North Sea cod stock is outside safe biological limits, despite the measures that have been put in place by the Commission over the past years, the most drastic of which was the temporary closure of selected nursery grounds in 2001. There are a number of biologically distinct stocks of cod of Atlantic cod in different areas, and most of them are considered to be outside safe biological limits.

Examining the 'safe' stocks in the North East Atlantic, their percentage ranges between 5 and 33 %, values that correspond to Celtic Sea/Western Channel and the Arctic respectively. In the Mediterranean the range extends from 0 % (S. Alboran and Cretan Seas) to 15 % (Aegean Sea).

One of the main causes of the declining fish stocks is the continuing, significant imbalance between fishing capacity and available resources. According to EEA, the status of the stock indicates that a sustainable CFP still is some distance from its target to achieve sustainable fish resource management. A multi-annual cod recovery scheme was adopted by the Council in December 2002, in a long term effort to help the stocks recover.

4.1.4 Fisheries impact on habitats and ecosystems

Fishing gear is designed to maximise yields of target species and minimise cost of effort but they also trap non-target species and damage the marine environment and habitats. Non-target organisms affected include benthos, birds, marine mammals, marine reptiles (turtles), plants and non-target fish. Capture fisheries tend to target the more valuable larger fish that are at higher trophic levels such as species that eat other fish. However, as over-fishing reduces the populations of these fish, the landings of fish lower down the food web such as those species that eat zooplankton make up a larger proportion of the overall catch. This means a change in the ecosystem composition from fish eating species to plankton eating species. This is generally indicative of a negative impact on the whole ecosystem caused by fishing and has been called 'fishing down marine food webs'. This can be seen on Figure 6.4, which shows that the mean trophic levels in both the north east Atlantic and Mediterranean and Black sea fishing areas have declined since 1950. An ecosystem-based approach for fisheries management has been highlighted to protect the vulnerable marine wildlife and habitats.

There is particular concern about the impact of fishing on marine mammals, turtles and birds. Cetaceans (whales, dolphins and porpoises) are accidentally caught in drift nets and are in competition with fishermen for small pelagic resources. Drift nets and pelagic long lines are the major threats to birds and marine turtles. Even though there are no comparable datasets to properly assess the extent of the problem across Europe, there has been some efforts nationally or regionally to monitor the by-catch of mammals, birds and turtles. Fishing seems to have a significant impact on cetacean, turtle and birds populations, but comparable datasets are not available to properly assess the extent of the problem.

Figure 4.3 Mean trophic level of fisheries landings for the north-east Atlantic Ocean, and the Mediterranean and Black Sea, 1950 to 1998.

Source: <http://dataservice.eea.eu.int/atlas/viewdata/viewpub.asp?id=536>

NB: Trophic level is the position in a food chain or web that an organism occupies and is a way of describing the feeding hierarchy. For example, primary producers such as marine phytoplankton are considered to occupy the lowest trophical level. Herbivorous zooplanktons are considered to occupy the next trophical level. Fish which eat zoo plankton occupy the next trophical level and so on. The assigning of trophical levels is, in fact, a complex process involving modelling the food web and examining the diet of each species.

4.2 Development of aquaculture and environmental impacts

European aquaculture production has continued to increase rapidly during the last 10 – 15 years, due to expansion in the marine sector in the EU and EFTA countries (see Figure 4.4). In 2002, aquaculture represents 17 % of total fishery production in Europe. For EU15 the aquaculture production rose from 1995 to 2002 with 8.8 %. This increase represents, according to EEA,⁸³ a rise in pressure on adjacent water bodies and associated ecosystems in the coastal zone. Aquaculture typically takes place in water of high quality. The principle measurable environmental pressures of aquaculture production are increased local organic matter, nitrogen and phosphorus, which in turn may lead to locally increased eutrophication. Other pressures that may be experienced with some culture systems include escapes and increases in pathogen density which may negatively affect wild populations by genetic dilution and disease transfer. Chemotherapeutants also represent a pressure, some of which may have impacts even below detection level. Increased production also implies increased demand for fish inputs, stimulating increased

⁸³

http://themes.eea.eu.int/Sectors_and_activities/fishery/indicators/FISH03%2C2004.05/tab_factsheets_ILR

pressure on industrial fisheries that supply fishmeal for aquaculture feed. App. 30 % of the fish landings from the North Sea are caught for fish meal and fish oil. Finally, the collection of “seed” from the wild, ranging from larvae, juveniles and even large individuals, may well have serious impacts on community structure dynamics and ecological equilibrium. However, the relationships between many of these pressures and possible impacts are often difficult to establish.

Any localised degradation will lead to production problems of the farms. This provides an additional incentive for producers to protect their adjacent environments. Strict food safety criteria will also encourage producers to maintain high environmental standards and limit their dependence on expensive and persistent chemical treatments. Although the environmental pressure from aquaculture will continue to grow as European aquaculture production expands, the rate of increase may be mitigated substantially by adoption of more sustainable management practices and production techniques.

The precise level of local impacts will vary according to production scale and techniques as well as the hydrodynamics and chemical characteristics of the region. Generally, significant improvements in the efficiency of feed and nutrient utilisation and improvements to environmental management generally have served to partially mitigate the associated increases in environmental pressure. This increase in both production and pressure has not been uniform across countries or across production systems. Only the marine mariculture sector has experienced a significant production increase, while brackish water production has increased at a much slower rate and levels of freshwater production have declined.

Figure 4.4 Annual aquaculture productions by major area, 1990 - 2001

Source: <http://dataservice.eea.eu.int/atlas/viewdata/viewpub.asp?id=704>

Note: The figure includes all environments i.e. marine, brackfish and freshwater aquaculture. Luxemburg, Liechtenstein and Bosnia-Herzegovina are not included due to either no aquaculture production or lack of data.

Europe's fish farms fall into two distinct groups: the fish farms in western Europe grow high-value species such as salmon and rainbow trout, frequently for export, whereas lower-value species such as carp are cultivated in central and eastern Europe, mainly for

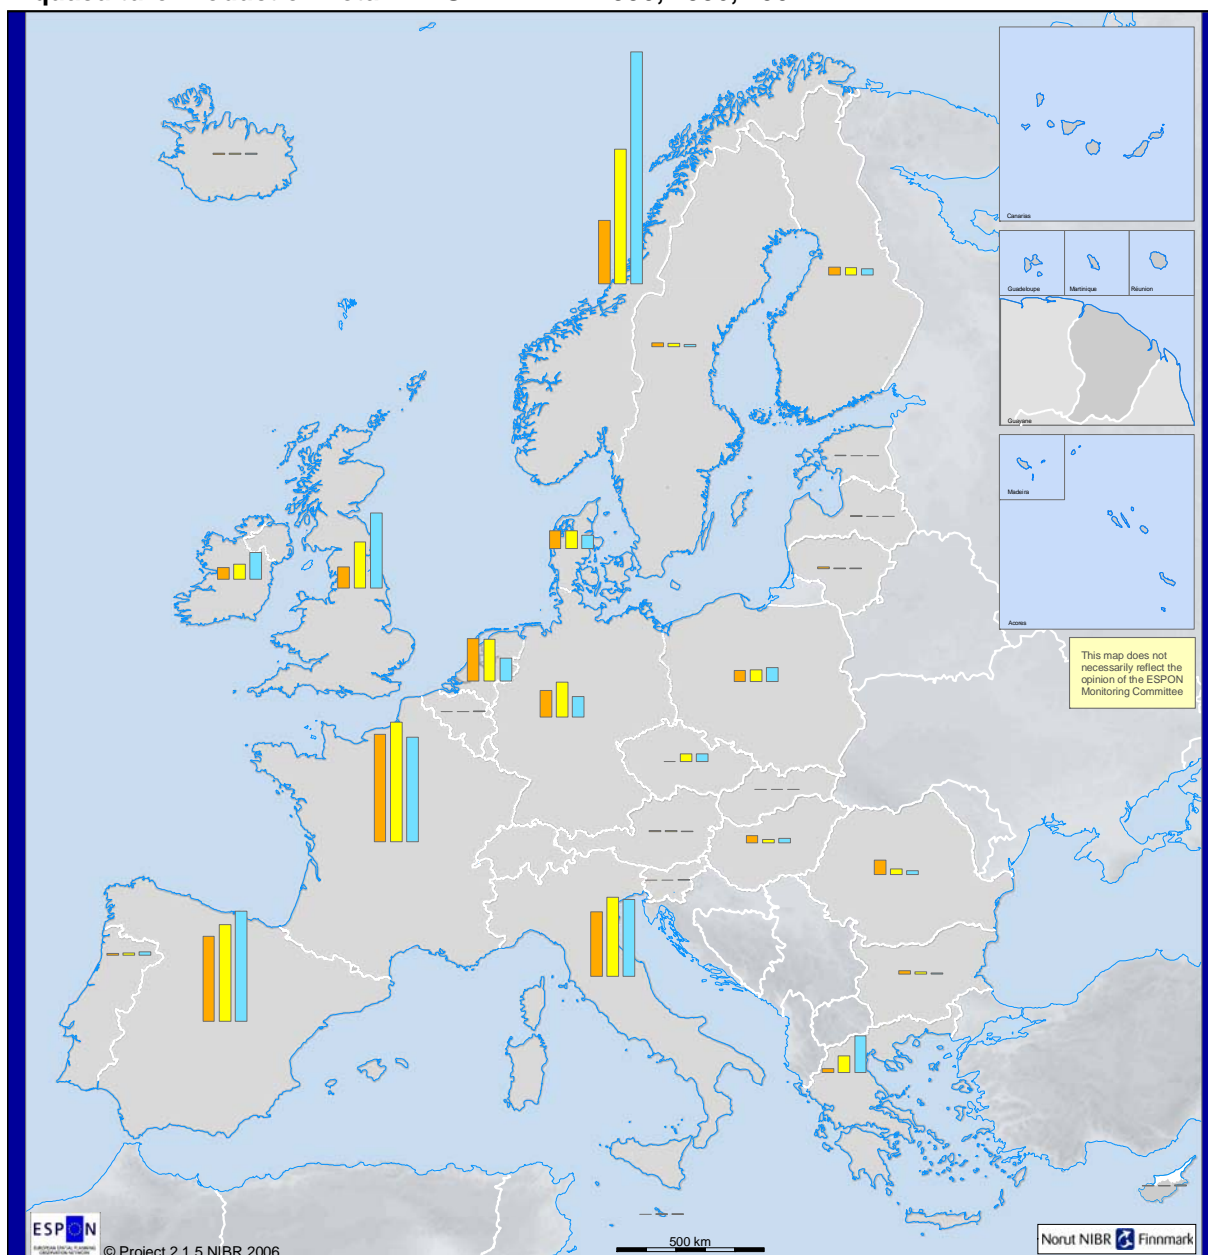

local consumption. Norway has the highest production by far with over 500 thousand tonnes in 2001, followed by Spain, France Italy and UK. These five countries account for 75.5 % of all aquaculture production from all European countries. Norway is dominant of Atlantic salmon production, while Spain is dominant by production of blue mussels. The major part of the increase in aquaculture production has been in marine salmon culture in Northwest Europe, and to lesser extent trout culture (throughout Western Europe and Turkey), sea bass and sea bream cage culture (mainly Greece and Turkey), and mussels and clam cultivation (throughout Western Europe); although the latter exhibits a downward trend since 1999. Inland aquaculture of carps has declined significantly throughout Eastern and Central Europe. The EU25 production increased by about 25 % from 1990 to 2002. In the same period the production in Norway (largely Atlantic salmon) increased by 268 % (fishery statistics 2004).

Marine aquaculture has also shown a large expansion in production in a number of Mediterranean countries over recent decades. This industry increased from 78 000 tonnes in 1984 to 248 500 tonnes in 1996 (freshwater aquaculture not considered). EEA (1999) consider the environmental impacts of the increased aquaculture in Mediterranean as limited, i.a. because the production units are relatively small.

In annex 3 in Interim report 2, seawater, freshwater and brackish water aquaculture production for EU27+EFTA countries from 1990 to 2003 is shown (in tonnes live weight and in 1000 euro), based on Eurostat database. These data show that most countries have experienced an increase in value of aquaculture in the period.

The map for aquaculture production in total for each country shows that Norway has become the leading country on aquaculture in Europe, and have experienced an almost continuous growth since 1990. An annual growth of 10-15 % is expected in the coming years (MoE 2000). Also UK (mainly Scotland) and Ireland with a significant share of finfish production have experienced a great growth in production (figure 6.6). It is seawater production of finfish such as salmon and trout that dominate in Norway, UK and Ireland. In the other countries with high production, like Spain, the Netherlands and France, the production has been more stable during the last years. Italy has experienced a decline since 2001. Italy is the dominating country in brackish water aquaculture production. Greece has experienced a significant growth since 1990, dominating with seawater production.

4.2.1 Aquaculture production relative to coastline length

Aquaculture production relative to coastline length is potentially a better indicator of environmental pressure than a single production value (figure 4.6). It makes it possible to determine a more comparable value of production density. However, there are some difficulties with this indicator; it does not apply to freshwater production; it does not consider the area of coastline that is potentially suitable for production; and the determination of coastline length is problematic and relies upon uniform scale being used for each country's determination.

Figure 4.6 Marine aquaculture productions relative to coastline length, 2001. Source: EEA 2005.

Note: Only marine and brackish waters production. Average production density values for countries with a coastline and with coastline data available. Based on 2001 data, except for Bulgaria (2000), Estonia (1995) and Poland (1993).

The map shows that aquaculture production related to coastline length for each country is highest in the Netherlands, France and Spain. Other countries with high production, like Norway, UK and Ireland, have not the same intensive production related to coastline

length because they have a long and archipelagic coast with many fjords, islands and reefs. The Norwegian coastline is as much as 57 000 km long, including the fjords and islands. The map also shows that Turkey is an important country for aquaculture, with a high production relative to coastline length.

Aquaculture production intensity as measured per unit coastline has reached an average of around 8 tonnes per km of coastline in EU and EFTA countries. In Spain the overwhelming mariculture production is of mussels. Shellfish production also predominates in France (oysters and mussels) and the Netherlands (mussels). The increasing trend observed during the past years appears to be stabilising. However, pressure is likely to continue to increase as production of new species such as cod, halibut and turbot becomes more reliable.

4.2.2 Environmental impacts of aquaculture

Overall production, however, is a simple available indicator on environmental pressure in its various dimensions. As a single indicator, its meaning and relevance is limited because of widely varying production practices and local conditions. An integrated ecosystem approach has only seldom been applied to aquaculture. Most environmental studies have been done at local level, i.e. single farms. The effects on a local scale are better documented whereas the effects at an ecosystem remain unexplored. Assessing effects at ecosystem level are hindered because there is a large difference in sensitivity and assimilation capacity of different ecosystems. Furthermore, general conclusions cannot be easily drawn since the impact of aquaculture depends on species, culture method, stocking density, feed type and hydrography of the site and aquaculture practices (EEA 2006).

In general, the pressure from nutrients from the intensive cultivation of marine and brackish water is becoming significant in the context of total nutrient loadings to coastal environments. Different types of aquaculture generate, however, very different pressures on the environment. Intensive finfish production in marine and freshwater generates the greatest environmental pressures and it is this kind of production which has increased most rapidly in recent years. Marine finfish production (mainly Atlantic salmon) is making a significant contribution to nutrient loads in coastal waters in Ireland, Scotland and Norway (particular phosphorus and nitrogen, see figure 4.7). In Norway (particular the west and north coast were the production mainly take place), phosphorus discharges from aquaculture appear to exceed the total from other sources (see figure 4.7). However, the published data on total nutrient loadings to coastal waters remains poor in quality and inconsistent in coverage. The data on this matter should therefore be treated with caution. Eutrophication is one of the major environmental problems across Europe, also in the coastal and marine areas, but diffuse losses of nutrients is from agricultural lands, other diffuse losses and point source discharges are the main contributors (EEA 2005).

Figure 4.7 Estimated mariculture nutrient as percentage of direct coastal and river nutrient inputs. Source: EEA 2005.

Significant numbers of farmed fish escape from fish cages and may affect wild populations through competition, genetic change and disease transmission. The largest producer of Atlantic salmon, Norway, recorded 276 000 escapes in 2000. This should be seen in relation to the wild stocks numbering about one million wild salmon. In Scotland, total recorded escapes from cages varied between 67 000 in 1998 and 420 000 in 2000. These have been released into an area that probably supports about 60 000 wild salmon. Salmon farming could be contributing, along with other important pressures, to the current poor state of wild Atlantic salmon and sea trout stocks. Direct indicators of competition, genetic change or disease incidence in wild stocks are currently not available or reliable enough to illuminate these issues (EEA 2003). Despite for limited knowledge, escape from fish cages is regarded as one of the most significant environmental impacts of salmon farming in Norway. And it seems to be an increasing problem. In 2004 the escape of salmon and rainbow trout was 450 000, and for 2005 the number was until 24 November as much as 722 000 (the Norwegian Directorate of Fisheries⁸⁴). One countermeasure that is been achieved according to this threat is establishment of temporary national salmon fjords important for wild salmon stocks (close to important rivers for wild salmon possibilities for spawning), where location of new salmon farms should be avoided. Another measure is introducing of more adequate technical standards for aquaculture installations.

Another environmental impact of farmed Atlantic salmon is the increase of fish lice. These parasites may cause problems for wild fish stocks. Sea trout seem to be particularly heavily infected and this may be one reason for the observed decrease in population of sea trout and salmon in Norwegian waters (EEA 2003). But in general, significant improvements in the efficiency of feed and nutrient utilisation as well as environmental management have served to partially mitigate the associated increase in environmental pressure. A major concern is that the increase in the industry faces challenges to other

84

http://www.fiskeridir.no/fiskeridir/aktuelt/fiskets_gang/havbruk/2005/1105/over_700_000_roemt_hittil_i_aar

users and interests in the coastal zone, such as recreation, tourism, nature conservation, etc. A major problem is that aquaculture is an activity that excludes other users close to the actual location. This issue will be further addressed in the example studies on integrated coastal zone management (ICZM).

4.3 Conclusion

Two of the hypotheses regarding environmental impacts of the fishery policy are:

- The changes in CFP from 2002 will contribute to a faster reduction and restructuring of the fishing fleet, both in absolute numbers, tonnage (GT) and engine power (kw).
- Changes in CFP will probably be directed towards improvements of the marine environment and marine resources. In the long run this may lead to higher and more stable fish stocks, but only if the fishing effort is sufficiently reduced.

CFP seems to be successful regarding reduction of the fishing fleet, which is a necessary precondition for a sustainable resource management. The size of the European fishing fleet decreased in the period from 1995 to 2003, both in terms of absolute numbers (15 %) and tonnage (4.3 %) as well as the most important indicator: engine power (13.2 %). However, it is too early to see if the changes in CFP from 2002 have contributed to an even faster reduction in the fishing fleet. The reduction from 2002 to 2003 was approximately of the same quantity than the years before.

From 1995 to 2002 the total catches of the EU25 fleet has dropped from app. 8 million tonnes to app. 6.8 tonnes (in live weight), which seem to have a connection to the decrease in the fishing fleet. However, the total fish landings of all species in all European sea regions⁸⁵ have increased by 20 % (1.6 million tonnes) between 1990 and 2000, but with a small decrease from 1997 to 1999. The indicators on stocks outside biological limits indicate that the changes in CFP, i.a. reducing the fishing fleet capacity, are still not sufficiently for a sustainable marine development. It is still an imbalance between fishing capacity and available resources. However, for a sustainable resource management, EU is also dependent on that other countries outside EU reduce their fishing fleet capacity according to the available resources. In that respect, a major concern is the agreements between EU and other countries regarding fishing.

At the same time, there is a need for a greater emphasise on the whole marine environment and ecosystems, and not only assessments for single species. During the last years there has been a greater focus on ecosystem approach in marine (including fisheries) management. However, it is a challenge to implement these ideas into the management regime. One central element is to move away from the single-species approach characteristic of the existing CFP and to adopt a multi-species and ecosystem-based management approach as indicated in the 2001 Reykjavik Conference on Responsible Fisheries in the Marine Ecosystems.⁸⁶ Ecosystem-based management models are also needed to assess external impacts on fisheries such as accidental and operational discharges from oil exploitation and shipping activities toxic algae blooms, and runoff from land causing eutrophication and contamination (EEA 2002). An ecosystem approach should also be considered in a larger extent regarding development of indicators on this

⁸⁵ North East Atlantic Ocean (including the Baltic Sea), Mediterranean Sea, Black Sea and Arctic Ocean. The Caspian Sea and Aral Seas are not included, as these are considered to be "inland waters" by FAO.

⁸⁶ <http://ftp.fao.org/fi/DOCUMENT/reykjavik/Default.htm>

issue. The EU Water Framework Directive (2000/60/EC) draws up a more ecosystem based development of data and indicators, based on river basins, including coastal waters up to one nautical mile outside the basic line (see chapter x for information about the Directive). Also the EU's proposal Marine Strategy Directive is a step in that direction (European Commission 2005).

The increasing production in aquaculture is important for many countries and coastal regions. Aquaculture development is spread widely over Europe and is often found in rural zones or peripheral areas depending on fisheries, where alternative employment opportunities are lacking. In general, significant improvements in the efficiency of feed and nutrient utilisation as well as environmental management have served to partially mitigate the associated increase in environmental pressure in the coastal zone. Different types of aquaculture, however, generate very different pressures on the environment. Intensive finfish production generates the greatest environmental pressures and it is this kind of production which has increased most rapidly in recent years. The challenges are biggest in countries with high finfish production like Norway, UK and Ireland. The growth in aquaculture is also a challenge for the coastal zone management and planning, particular with regard to adapt the locations to other coastal interests like tourism, recreation, nature and cultural heritage, coastal fishing, etc. Further expansion should be addressed through the concept of integrated coastal zone management (ICZM), which also the EU Strategy for the sustainable development of European aquaculture emphasise (see chapter 4.5).

TIA is mainly a methodology for territorial impacts on the terrestrial environment, and not the marine. The EEA has decided to directly address the issue of fisheries/aquaculture impact on the environment for possible inclusion in the development of a core set of indicators covering the whole driving forces – pressure – state – impact – response (DPSIR) assessment framework. The DPSIR-model does not fit so well to the TIA-model. DPSIR main focus is on the relation between human activities and environmental impacts, and responses to deal with the actual problems.

4.4 Policy Recommendation

There is a need for a greater emphasis on the whole marine environment and ecosystems, and not only assessments for single species in the fishery policy. The efforts according to this should be further stimulated, also in regard to the development of indicators for environmental impacts of fishery and aquaculture. Today most of the indicators focus on the development of single fish species with commercial interest. An ecosystem approach is also demanded in order to trace environmental impacts of the aquaculture industry.

4.5 Integrated coastal zone management (ICZM)

Integrated coastal zone management (ICZM) is developed by EU as a general tool to coordinate different and competing interests in the coastal zone.⁸⁷ Being an integrated approach the ICZM has potential to offer a broader perspective to aquaculture and most of the fishery related activities. Through example studies we highlight how ICZM is implemented and applied in different countries and regions in Europe. A particular

⁸⁷ In annex an overview of the EU initiated ICZM activities through the Demonstration Programme and relevant Interreg-projects are presented.

attention will be drawn to local and regional coastal zone planning. Further we highlight experiences with Norwegian and Danish coastal zone planning. Our data sources are available web-pages, drafts and articles regarding research studies on ICZM processes for different coastal regions. In addition, we draw on finished or ongoing research projects among the TPG-partners IFM (for Denmark) and NIBR (for Norway). In the end we highlight implications for ICZM by implementation of the EU Water Framework Directive.

In the examination of the example studies we have been looking at some common criteria for measuring ICZM. A particular attention has been drawn to management and administrative/ political issues regarded to coastal zone planning. ICZM is characterized as a complex management situation, demanding integration across geographical borders, different policy sectors and levels of government. There is, however, no authoritative definition of integrated coastal zone management, or agreement on one definition among scholars (Sanderson 1999). Most definitions stress that integrated coastal zone management is about *institutional* design for *integrated* management, and the aim is to achieve a *sustainable development*. The goal of ICZM can be defined as “to improve the quality of life of human communities who depend on coastal resources while maintaining the biological diversity and productivity of coastal ecosystems” (GESAMP 1996, quoted by Sanderson 1999:3). In addition most scholars stress the dynamic and adaptive nature of integrated coastal zone management. It can be defined as “a *continuous, adaptive, day-to-day process* that consists of a set of tasks, typically carried out by several or many public and private entities” (Sanderson 1999:3).

Cinsin-Sain and Knecht (1999) highlight that “Integrated coastal zone management can be defined as a continuous and dynamic process by which decisions are made for the sustainable use, development and protection of coastal and marine areas and resources. First and foremost, the process is designed to overcome the fragmentation inherent in both the sectoral management approach and the splits in jurisdiction among levels of government and the land-water inter-face. This is done by ensuring that the decisions of all sectors and all levels of government are harmonised and consistent with the coastal policies of the nation in question. A key part... is the design of institutional processes to accomplish this harmonisation in a politically acceptable manner (Cinsin-Sain and Knecht 1999: 39).

An integrated coastal zone management requires co-ordination along three, not mutually independent dimensions (Bennet 2001:23):

- *Space*, territorial integration, which includes both:
 - o A co-ordination of the activities and development of both terrestrial and marine areas
 - o A co-ordination of different territorial-administrative units
- *Cross-sector integration*, i.e. co-ordination of different sector interests at the same administrative level
- *Vertical integration*, i.e. co-ordination across levels of government

Integrated regional coastal zone management thus requires co-ordination across municipal borders, sector borders and levels of government.

These definitions of ICZM mentioned above will be taken into account in the example studies. We will particularly look at the administrative organisation and integration between different levels of government and sector interests, integration across land and sea boundary and how ICZM is facing the declining of fishing activities and challenges regarding fishing dependent communities. At least, we will look at how the ICZM

activities are able to balance between use and protection in the coastal zone, and in that connection also participation from relevant stakeholders.

4.5.1 Example studies regarding ICZM

Regional coastal zone planning in the North Sea Area (Norcoast)

This chapter summarise experiences with regional coastal zone planning in the North Sea Area, based on the Norcoast project (1998 – 2000) under Interreg IIC (Norcoast 1999; Norcoast 2001). The aim of the project was to investigate and promote good practice in ICZM in the North Sea region and to support transnational regional cooperation on coastal spatial planning. The project was based on the experience and knowledge of practitioners in coastal planning and management with particular focus on the regional level of governance.

There were partners from seven regional authorities from England, Scotland, Germany, Norway, Sweden, the Netherlands and Denmark (project secretariat). The regions of Highland in Scotland and Hordaland in Norway represent the most undeveloped coasts in the project, where the management of fishing and aquaculture are main issues. The regions of North Holland, Lower Saxony in Germany and Suffolk in England are more urbanised, but also with important nature areas as lowland landscapes, heath, marshes and mudflats. However, in Lower Saxony almost the whole coastal area is characterised as a rural area with a lack of economic activities and problems of employment, partly caused by its peripheral location away from the economic centres in Germany. The coast of the Danish region, Nord Jylland, consists primarily of beaches and dunes, while the Swedish region, Västra Götaland, is mostly characterised as an archipelago coast. In Nord Jylland and Västra Götaland, parts of the coast are highly urbanised. The physical character of the coastal zone varies considerably. The problem of depopulation due to i.a. decline in local fishing and development and control of aquaculture and inshore fisheries is common challenges in many of the regions. In Hordaland and Highlands a key question for coastal planning are how to get the appropriate balance between different types of aquaculture development and other interests around the coast, and how to minimise the environmental 'footprints' of the aquaculture industry.

Responsibilities concerning many aspects in ICZM are usually placed at the regional level in the involving countries. The national level normally acts through guidelines and legal acts. The only country in the project where the central government produces a national statutory plan is the Netherlands. In most cases the regional level are responsible for strategic planning concerning landscape, nature and development. Nevertheless, the county role ranges widely from strict statutory planning in Denmark, the Netherlands and Germany to more regional guidelines in England, Scotland, Sweden and Norway. Sectoral planning and management arrangements are in most cases more centralised than the spatial planning system in all the involved countries, and the aim of ensuring integration of sectoral interests is often stated in the laws for spatial planning. However, the general experience is that the sectoral policy in marine areas is somewhat separated from spatial planning, and co-operation between them is not yet well developed.

The Norcoast documents highlight Norway and Sweden with long tradition in integration between land and water interests in the coastal zone planning system. In England, Scotland and Denmark the formal spatial planning system stops at the shoreline – in England and Scotland at the Low Water Mark. Local and regional planning in Germany stop at the High Water Mark, while the federal state planning covers the marine area out to the 12 nautical miles boundary, presently only used for federal waterways and for the protected Wadden Sea. In the Netherlands (regional level), Norway (regional and local

level) and Sweden (local level) the spatial planning system reaches some distances into the sea (see the figure below).

Table 4.1 Statutory spatial planning in the coastal zone

Country:	Shoreline	State boundary, 12 nm
England / Scotland:	Regional plans and local plans	
Germany:	Federal state plan	
Norway:	Regional and local plans	(outmost skerries)
Sweden:	Local plans	
The Netherlands:	Regional plans	(1 km)
Denmark:	Regional and local plans	

England, Scotland and partly the Netherlands have a range of experience in working with voluntary partnership approaches primarily for management plans on designated areas, as the coastal zone. Highland has developed advisory non-statutory frameworks plans for aquaculture along sections of its coastline which have proved fairly cost effective in areas of coastal waters which have come into pressure for this type of development. The overall experience with this planning approach is great successfulness as a sectoral CZM initiative, but it needs to be embraced within a wider strategic context.

Norcoast (2001) recommend combining the best elements of the statutory spatial planning system with the best elements of the voluntary partnership approach. The voluntary partnership approach provides, according to Norcoast, not only cooperation and transference of knowledge between sectors, but also encourages interest groups to take a wider view of their activities. At the same time the compromises required may lead to rather generalised policy statements, which require little real commitment, if not combined with statutory responsibilities. Coastal partnerships may put lesser degree on commitment, as they primarily exist to facilitate better communication between interests in the coastal zone and to stimulate debate on how the coastal zone should be managed.

In most of the involving regions the statutory planning system does not cover many of the most important sectoral interests, especially in the sea area, such as exploitation of marine resources (fishery, raw materials, oil and gas), use of marine area (shipping routes, pipelines, wind power installations), pollution and coastal defence. These sectoral interests should be included in the planning process in the development of real integrated planning.

In light of the experiences with ICZM through spatial planning and voluntary partnership approaches, the general recommendations in the NORCOAST project are regarded to i) process, ii) regulatory framework and iii) planning techniques:

i) Process:

- Aim for an integrated approach to reduce conflicts and build synergy
- Involve all relevant stakeholders and politicians

- Make the process transparent, accountable, open and consultative in all phases of the process
 - Identify a lead agency to initiate and facilitate the ICZM process
 - Develop a clear vision for the coastal zone at both national and regional level. The vision should describe the resources and qualities that should be protected or enhanced and the resources which should be developed or sustainably exploited.
 - Establish a coastal forum or partnership to develop a shared sense of stewardship, which should be integrated with the statutory planning system
- ii) Regulatory framework:
- Legislate for a clear statutory responsibility for spatial planning for land and sea areas
 - Appoint authorities as lead agencies to initiate ICZM (with adequate resources). Norcoast recommends that the regional level in many cases will be the most appropriate level to lead ICZM-processes.
 - Define a national framework for ICZM, which can stimulate policy at national level and allocate responsibilities to the appropriate level
 - EU should provide practical support for the development of ICZM
- iii) Planning techniques for coastal issues:
- Describe possible consequences of the plan
 - Consider different scenarios to find the right balance of interests
 - Accept that the coastal area is an open system by using the “catchment area” or “coastal cell” approach as far as possible and define the boundaries of plans accordingly, but with an open view to external influences
 - Aim for flexible planning

Regarding the aim for flexible planning, Norcoast recommends that planning methods should allow a reasonable degree of flexibility for changing circumstances and new types of development. The rapid development of aquaculture in Norway and Scotland in the 1980s is regarded as a good example of technological and market changes moving too fast for the conventional planning system to keep up. The planning system in the coastal zone therefore has to be flexible, responsive and innovative to deal with the quick changes that may occur. This is a challenge for the prevailing planning practice, with long intervals between revisions of the plans and they are poorly equipped to deal with new issues as quickly as is sometimes necessary when dealing with pressures in the coastal zone, e.g. the impact of new technologies in aquaculture. In that connection, procedures for how to deal with unexpected development or un-planned results should also be included in the plan.

The issue-specific recommendations regarding the decline in traditional fishing culture and/or seaside resorts are: 1) Create local development strategies based on local natural and cultural values and resources – involving local people and other stakeholders. 2) Secure income from tourism to develop the local economy, community and facilities, e.g. by the tax system. In many areas in the North Sea tourism now provides the economic base, but it should be tuned more closely to what the local community and environment can comfortably absorb.

The recommendations regarding inshore fisheries management and aquaculture are:

1. Introduce licensing systems for fishing and for mariculture installations into the coastal zone which are regulated by the regional authorities,
2. Encourage community-based management of semi-enclosed inshore waters (e.g. fjords, estuaries, island groups) via the formation of local coastal partnerships,
3. Identify areas favoured for mariculture activities in regional and local plans,

4. Environmental Impact Assessments should be an integrated part of the licensing procedure for each mariculture project, and should be matched against the strategies and development criteria of the regional plans,
5. Strategies for mariculture development should be prepared at the regional and/or national level to guide investments in support infrastructure to the appropriate areas, to divert pressure for mariculture away from sensitive areas, and to encourage better integration with the other fisheries sectors,
6. European funding should be used to enable local authorities from the main mariculture areas to develop best planning and regulatory practices in this field.

There is, according to Norcoast, a need to define and promote sustainable fishing and aquaculture practices, which lead to effective management, and to harmonise with policies for development and conservation. There is an overall need to integrate aquaculture and commercial fishing better into the spatial planning system, which includes among its concerns the local economy, protection of natural and built heritage, and water quality.

Another issue is the ability of local plans and management initiatives to deal with coastal issues where the impacts often transcend municipal boundaries. Here a regional or even national planning overview is needed to ensure effective coastal management with cooperation between the different stakeholders. Norcoast recommend that the regional level in many cases will be the most appropriate level to lead ICZM-processes, because it has the necessary overview of processes and interests in the coastal zone, a ready awareness of their national and international dimensions. The regional level of government is further assessed as well equipped to translate the claims from different sectors, national plans and policy frameworks, and local level initiatives into regional spatial planning. Regional plans are used in many areas around the North Sea as statutory means to obtain a broad view of processes and interactions at work in the coastal zone. The regional authorities are, however, not always strong enough (in resources and statutory power) to fulfil these responsibilities. In such cases the tasks should, according to Norcoast, be allocated to a higher level of government or the necessary powers should be given to the regional authority.

Municipal coastal zone planning in Norway

Local coastal zone planning in accordance to the Planning and Building Act (PBA) is regarded as the most important tool for ICZM in Norway (Bennett 2001). The municipalities are given responsibility to coordinate the land use, and also the use and protection of sea areas. However, the municipalities are not given responsibility for the coordination of resource extraction, which is responsibility under different state sectors. The possibility to make legally binding plans in the sea is limited to the baseline, which is defined as the straight line between the outer islets and reefs. The PBA is designed to provide the basis for decisions regarding balancing use and conservation. Many coastal municipalities responded rather quickly to the revision to the PBA in 1989, giving them the opportunity (but not an obligation) to produce spatial plans for the coastal areas and the sea. Coastal zone planning is discretionary, and as far as necessary the plans shall indicate: “Areas for special use or conservation at sea and rivers, including areas for *traffic, fishing, aquaculture, nature and recreation*, either separately or in combination with one or several of the use categories mentioned” (PBA § 20-4). By the end of 2003, 192 of Norway’s 283 coastal municipalities had such plans. In addition 20 municipalities had started the planning process (Directorate of Fisheries web page⁸⁸).

⁸⁸ http://www.fiskeridir.no/fiskeridir/aktuelt/fiskets_gang/kytsone/2005/0605/best_i_nord

An increasing pressure on, and competition for space and resources have led to an increasing demand for the planning activity. This is mainly caused by the development within three industries or activities:

1. The recent development in aquaculture (fish and shell farming) and the further expected growth in this industry in the near future
2. The development in the tourist industry
3. A long lasting tendency of building new and extending old second homes (recreational houses) by the coast line (shore) (MoE 2000).

There are, however, major regional variations. In the eastern and southern part of the country the pressure for building on or near the shore is the most crucial question, while further west and north the aquaculture industry demand for more space is dominating the agenda in the planning processes. In the north part it is particularly conflicts between aquaculture and coastal fisheries because of an increasing growth in fish farming the recent years, and coastal fishing activity is still relatively high. A registration of conflicts in the Norwegian coastal zone by the Ministry of fishery and coastal affairs pointed out that the conflicts between aquaculture and coastal fishery will continue to in the near future, e.g. with new forms of mariculture as for example sea ranching (Røsvik, O. & J.H. Sandberg 2002).

The general experiences with local coastal zone planning as tool for ICZM are ambiguous (Hovik & Stokke in prep). Much has been achieved regarding coordination of different local user interests *within* many coast municipalities, also regarding the coordination of sea areas and land areas. One important success factor is active stakeholder participation in the local planning processes (e.g. local fishermen, aquaculture organisations, nature and recreational organisations, etc.) and involvement of the general public, even though it is significant variations between the municipalities regarding this issue. On the other hand, there are great weaknesses regarding coordination across municipal borders, across different public (state) sectors and across levels of government (Bennett 2001). There seems to be a strong agreement that the main problem of coastal zone management in Norway is lack of co-ordination mainly between different public government bodies, and especially between different State sectors with responsible for sea activities (with special legislation) and different levels of governments (Bennett 2001; Sandersen 1999).

A study of local coastal zone planning related to the aquaculture industry by NIBR in 2003 shows a tendency to a more flexible planning practice (Arnesen & Stokke 2003; Stokke & Arnesen 2004). The change toward a more flexible planning regarded to the aquaculture industry has been a result after pressure from the fishery authorities (the regional branch of the Directorate of Fisheries) in the local planning processes. Many of the earliest plans gave specifically allocated localities for aquaculture, and aquaculture could not take place outside those specific areas without dispensation from the plans. The new planning practise focus in a greater extent on areas where aquaculture not can find place out of consideration of other coastal interests as coastal fisheries, recreation, conservation, etc., instead of lay out smaller areas for aquaculture in their plans. The intension is that such strategy shall give the aquaculture industry more space and predictability, and secure sufficient flexibility for further expansion, and thereby secure employment and income to rural coastal communities. Aquaculture is seen as the main way to compensate for the decline in the local employment in many fishery dependent communities. The lack of knowledge about good locations for aquaculture in many municipalities is also an explanation for this shift in planning practice. The National evaluation of suitability of the Norwegian coast and river systems for aquaculture (LENKA) from the 1980s is now in a great extent outdated.

The inverted planning practice in the marine areas seems to have contributed to reduce the level of conflicts among the different state sectors, and become an accepted practice. The regional authorities have made fewer objections in the municipal planning processes (Arnesen & Stokke 2003; Stokke & Arnesen 2004). The study outlines three conditions for the establishment of a sustainable coastal zone management through the inverted planning principles:

1. There is a need for increasing knowledge of marine biological diversity, marine resources etc, in the municipal planning processes
2. The precautionary principle must be made concrete and applicable to the municipal planning process
3. The marine municipal planning process has to be more inclusive and participatory, involving all relevant stakeholders and giving them real influence

However, in Hordaland, the leading aquaculture county in Norway, many municipalities find it necessary with plans that steer the location of aquaculture in a more detailed way because of the lack of available space and because of the many conflict between aquaculture and other interests as nature conservation, recreation etc. The choice of planning strategy will be dependent on the land use pressure and other contextual factors.

Everybody needs a licence from the authorities to start fish and shellfish farming in Norway. To get a licence, the applicant must ensure that the establishment will not pollute or disseminate fish diseases and that installations are not in conflict with local interests. It is the Directorate of Fisheries with their seven regions offices which gives licences/reject applications. This is coordinated with other governmental bodies, i.e. veterinary authority, environmental, harbour and port authority. In that connection, the local plans have an important role as a decision framework.

The local coastal zone plans have also become a more important tool in protecting vital areas for coastal fisheries, such as land-seines (*kastevåger*), areas for spawning and good places for live holdings (*låssettingsplasser*). The increasing pressure from other activities in the coastal zone has led to a bigger need for local fishermen and their organisations in involvement in local coastal zone processes, to secure their land use interests. Their local knowledge is also valuable inputs in the local planning processes.

In Norway planning and management of terrestrial coastal areas has for many years been supported by detailed knowledge and extensive data on habitats and their associated species. In contrast, for undersea areas little focus has so far been drawn to identification and mapping of marine biological resources and the distribution of marine habitats in the coastal zone. However, new electronic topographic maps showing depths, biological resources and marine habitats would be an important tool for the coastal zone planning and management.

Regional coastal zone planning – lessons from three counties in Norway

This illustration is based on the research project “Regional coastal zone planning - a tool for integrated coastal zone management?” The main research question in this project is to study if and how regional coastal zone planning can contribute to ICZM. Further, we wanted to analyse under which conditions the planning processes lead to a successful integration. We are both interested in how different co-ordination problems and different institutional settings, i.e. traditional planning or planning through network governance, affect the possibility for an ICZM. The analysis is limited to the questions regarding use of the coast line (shore), the fish and shell farming industry and the coastal fisheries, leaving other topics for coastal zone planning. The text is mainly from an article from

Hovik & Stokke in prep, with the title “Network Governance and Policy Integration – the Case of Regional Coastal Zone Planning in Norway”.

Regional coastal zone planning in Norway was in the mid 90s introduced to deal with problems municipal coastal zone management so far had not solved: Co-ordination across municipal borders (surprisingly few municipalities cooperate with their neighbours on planning matters, despite the fact that they plan the use of the same fjord systems), across public sector borders and levels of government. The aim of a county plan is to “co-ordinate the state, the county municipal, and the main parts of the municipal physical, economical, social and cultural activities” (Planning and Building Act §19-6). The Cabinet lays emphasis on extensive co-operation between the county municipality, the County Governor’s Office (state representative in the county), - particularly the environmental agency, the regional branch of the Directorate of Fisheries, municipalities and private actors. Through open and democratic planning processes, the aim is to achieve a good balance between land and sea use, production, resource extraction and protection in the coastal zone. The county municipality has, however, no authority to command or order other actors, neither state regional actors nor municipalities, to comply with a regional coastal zone plan, except to raise objections to municipal plans. A county plan is not legally binding for state or municipal government, it only give guidelines for their activity. Due to limited formal authority given to the county municipalities as planning authority, integration must be accomplished through voluntary co-operation and negotiation among different public and private actors. Integration must then be accomplished through creating arenas and building or engaging networks for conflict resolution and co-operation. Regional coastal zone planning can then be interpreted as multi-level governance.

In the research project we study the processes of formulating and implementing the regional coastal zone plans in three counties (and NUTS III regions), Hordaland, Sør Trøndelag and Troms. The counties are placed in different regions of Norway. Hordaland is located at the western coast, Sør Trøndelag in the middle, and Troms in the northern part of the country. They can all be characterised as fisheries regions. Troms is specialised in harvesting, while Sør-Trøndelag in processing (defined as over the national average). Hordaland and Sør-Trøndelag is specialised in aquaculture, with Hordaland as the leading aquaculture region in Norway (mainly production of salmon and trout).

Table 4.2 Hallmarks for the three counties

Hordaland	Sør-Trøndelag	Troms
15 634 km ²	18 832 km ²	25 848 km ²
438 312 inhabitants	264 856 inhabitants	151 637 inhabitants
33 municipalities, Bergen administrative capital	25 municipalities, Trondheim administrative capital	25 municipalities, Tromsø administrative capital

One experience from these three cases is that an open and inclusive decision process does not alone increase the integration capacity of the regional planning. The results rather support the opposite argument of a trade-off between the number of actors participating in the decision process and the ability to agree on and implement a joint action which effectively will deal with the problem. Coastal zone management is described as a complex management situation, with numerous actors, with different interests, world views, values and goals. In addition, there are asymmetric division of power and dependencies between the different actors. In Hordaland they chose to open the network only for the most central regional state agencies (the county governor’s environmental

agency, the fishery authorities, the veterinary authorities, the coastal authority and the military). These public stakeholders are, as holders of important resources and authority, necessary contributors to an integrated coastal zone management. By reducing the number of actors, the perceived transaction costs of negotiating compromises can be limited. To limit the number of actors actually participating in the consensus seeking discussions and negotiations, as was done in Hordaland, might have been an effective strategy. To continue the co-operation through formalized networks engaged in the implementation of the plan does also seem to be an effective strategy.

Another experience from these cases is that the integration potential of network governance seems to rest on actors believing they will gain from co-operation. To gather different actors together to discuss and propose a coastal zone plan might contribute to more positive and close relations between these actors, and as such make co-operation easier when they in the future find it in their interest to do so. It does not in itself contribute to an integrated plan or a formal network engaged to accomplish integration in the implementation phase. The integration capacity of the planning process is greater where the context creates stronger interdependencies probably influencing the actors' interest in co-operation. It does also help with some pressure from central government.

A possible lesson to be drawn from this study is the importance of a balance of independency and interdependency between different actors in network governance. Some central actors, mainly regional state sector agencies, might perceive greater pay off by following the strategies of their own sector policy, than by co-operating with other actors, and at the same time be sufficiently independent of other regional actors to be able to follow such strategy. They are neither interested in, nor forced to involve themselves in negotiating compromises with other actors. Added to this picture is possible constraints given by central state ministries or directorates, forcing them to maximise the policy goals of their own sector. They might not have the necessary independence from central government to involve themselves in negotiations at regional level.

Integration through voluntary co-operation is dependent of all actors perceiving some positive pay offs, i.e. some sort of win - win situation. Powerful actors, neither forced nor interested in co-operation can set conditions other actors can not accept. Symmetry among actors regarding the distribution of independency and interdependency might be an important precondition for voluntary integration and successful governance, in addition to a plus sum game. It were the lack of will among central actors to commit themselves to a co-operative process, rather than the openness of the process and the number of participants, that resulted in less integration capacity in Sør Trøndelag and Troms compared to Hordaland. Whether Hordaland could have increased their integration capacity through a more open process is impossible for us to conclude on. However, the involvement of actors holding important resources and power seems to be crucial. Coastal zone management is facing a situation with a variety of actors with asymmetric distribution of powers and dependencies and with potentially conflicting interests. It is a challenging task to achieve integration through voluntary co-operation in such a situation. For regional and local actors to meet this challenge there is a need for a change in central government policy in the direction of stimulating and facilitating local co-operation.

The conclusion in the paper is that integration through regional coastal zone planning and voluntary co-operation is possible, but also difficult to achieve. One important obstacle towards achieving the goal of integrated coastal zone planning and management is the fact that important public actors perceive a greater pay off from promoting their own goals and values through policy instruments controlled by the authority themselves, than from involving themselves in regional co-operation around an integrated strategy. In regions where the pressure on the areas and the conflicts between different user-interests

are more visible, different actors have joined together in networks established to promote integrated coastal zone management. More emphasis on this matter from central government would probably also help. Due to great regional differences, central government rather than to decide a national integrated policy, should lay stronger pressure on regional and local state and municipal authorities to co-operate in processes of integrated planning and policy making at regional level. Even in Hordaland where the interdependency between the actors is greatest, the relations are fragile because of asymmetric division of power and dependency between actors. There is a significant amount of leeway in terms of how the regional state can relate to the regional coastal zone planning as an integration arena. In such situation there is a need for central government taking action to facilitate regional integration through voluntary co-operation. Clear guidelines with regard to how regional state agencies should participate, as well as an institutional framework facilitating such co-operation is needed. Rewarding actors with a will to co-operate and sanction actors that avoid taking part in co-operation might be necessary to secure an integrated coastal zone management.

Coastal zone management and planning in Denmark

The article summarises the findings of a research project on ICZM in Denmark, in form of case studies in the counties of North Jutland and Viborg. In addition, two cross-county case studies concerning the Limfjord area and the southern Danish Archipelago were included. There were also three separate sub-projects from the Netherlands, Sri Lanka, USA and the trilateral Wadden Sea Co-operation (Anker, Nellemann and Sverdrup-Jensen 2004).

Many interests are at stake in the Danish coastal zone. The majority of the population is resident in urban zones in the coastal areas, and the greater part of the summer cottages and other holiday and recreation facilities are situated here. At the same time, the near-shore waters and the interface between land and sea are the basis for fishing, marine aquaculture, extraction of raw materials, land and sea transport, harbour activities, agriculture, etc. In recent years, the coastal zone, probably more than any other part of society has been exposed to pressure and processes of change. Among these changes are urbanisation and new infrastructure, exploitation for recreation and tourism, acute nature and environmental problems, retreat of coastal occupations, reorganisation of freight traffic between land and sea and changed functional demands and working conditions for harbours.

The legal and regulatory framework for the Danish coastal zone is scattered across a number of different regulatory systems. The most characteristic feature is the fairly split in powers regarding management on land and sea. The land-based activities are characterised by powers vested in the regional and local authorities and by a comprehensive planning system embedded in the Planning Act. The regulatory system that governs sea areas is characterised by a sectoral approach and by powers vested in national State authorities embedded in the State Supremacy over the sea.

The research project identifies several weak points in the legal and regulatory framework and in management practice. One major problem is the regulatory split between land and the sea. This is reflected in the legal framework, in the distribution of powers and in management practices. Because of the lacking land – sea integration, management of fishing, sea transport, raw material extraction, etc. is, by and large, not integrated with the management of other activities in the coastal zone, e.g. recreation and tourism. On the other hand, the Danish Planning Act and the informal cooperation procedures established in Denmark form the basis of a high degree of integration between the authorities dealing with land-based coastal activities. The voluntary collaboration approach between different public authorities and the citizens on urban/regional planning and management

has demonstrated that ICZM has a lot of potential, where the fisheries management plan for the Limfjord and the development plan for the southern Danish Archipelago are good examples.

The studies from the other countries show a development in coastal zone management from an initial rather narrow focus, typically on coast protection, toward a situation characterised by a more holistic approach to management with an understanding of the interdependencies between the many problems in the coastal zone. Even though most cases point out that important coastal zone activities such as fishing and oil extraction are only rarely included in the integrated plans. The authors in this article claim that the tradition for protecting coastal areas may have led to a neglect of the ideas of ICZM as such.

4.5.2 The EU Water Framework Directive (WFD) – impacts for ICZM

Main principles and goals

The EU Water Framework Directive (2000/60/EC) (WFD) draws up a new legal framework for integrated management of the water resources. A basic principle in the WFD is that planning and management of all waters should consider water basins as comprehensive units, ranging from the very source of the watercourses to their outfall into the sea, including transitional waters and coastal waters up to one nautical mile outside the basic line. Primarily through the development and implementation of River Basin Management Plans (RBMP), the WFD requires Member States to take whatever measures may be necessary to achieve the environmental objective of “good status” for all EU waters by 2015. The RBMP will be based on a characterisation of the water bodies within river basin districts, comprising an analysis of the ecological status, an assessment of pressures (user interests, impacts), and an economic analysis of the water uses. Finally, the RBMP will set out the actions required within each river basin and its adjoining coastal area to achieve the goal, and which will be reviewed on a six yearly basis.

The WFD’s ambitious goal of achieving “good status” implies that the chemical, biological and hydro- morphological conditions in the water bodies shall not deviate significantly from the natural state, referring to a pre-industrial situation before the watersheds were affected by human activities. Exceptions can be made for water-bodies classified as “heavily modified”, i.e. water bodies that are influenced by past physical alterations due to major water uses such as industrial development, navigation, and flood control, and where it will be too difficult or costly to bring them back to their natural state. In such cases, the overall goal may be reduced from “good status” to “good ecological potential”, which is the best possible status that can be obtained without removing or terminating the existing activities.

Table 4.3 Connection between ecological status class and goal in the EU Water Framework Directive.

Ecological status classification	Achievement of WFD goal
<ul style="list-style-type: none"> • High status. • Good status. 	WFD goal is achieved.
<ul style="list-style-type: none"> • Moderate status. • Poor status. • Bad status. 	WFD goal not achieved. Actions for improvement will be formulated through River Basin Management Plans.

Implications for ICZM

The WFD can be regarded a significant policy instrument in facilitating ICZM and for coordination of river basin and coastal zone management. The concept of river basin management has been included by the EU Recommendation on the Integrated Coastal Zone Management (ICZM) from 2002 to provide the key for the integrated development of the natural, economic and cultural environment within river basins and coastal areas. There are, however, also significant differences between the two systems. For example, the legal form of the WFD is binding, while the EU Recommendation on Integrated Coastal Zone Management (ICZM) is considered optional. Both the WFD and the ICZM provides for the implementation of integrated management plans pertinent for the coastal areas and resources, but the WFD focuses mainly on the environmental quality in the aquatic ecosystems as a basis for promoting sustainable development, whereas ICZM addresses a broader spectrum of issues aiming at a coordinating and balancing the different user-interests and for prevention of conflicts i.e. between resource utilisation and conservation. ICZM also seeks to integrate terrestrial issues in the “land-ocean nexus” to a larger extent and is more oriented towards spatial (land-use) planning compared to the WFD.

One noticeable implication of the WFD in relation to ICZM is that it will have far-reaching implications for the way in which coastal monitoring is carried out at the regional and national levels. Firstly, the WFD requires evaluation of the ecological characteristics of water bodies as being of prime importance in the assessment of their overall quality. Reporting has to be carried out in a consistent and comparable way. Secondly, the monitoring is more complicated than previous systems; it takes on a more “risk based” approach and it has to be demonstrably statistically robust and must consider the “most sensitive elements” for any given pressure.

A network of monitoring sites need to be established using a combination of surveillance, operational and investigative monitoring of prescribed quality elements to satisfy the information needs. The WFD utilises a complex set of quality elements with strong emphasis on biological communities as long-term indicators of the health of the water bodies at ecosystem level. This will be a particular challenge in transitional and coastal waters due to the complexity in typology and regional and local ecological variability.

Likely, the WFD will contribute to a significant upgrading of the knowledge-base for ICZM and may ensure better coverage and harmonisation of data across national borders. It is, however, important that the monitoring is comprehensive and is designed to cover both the information requirements of the WFD and the ICZM in order to serve their

combined purposes and to avoid unnecessary overlaps. In table xx the various quality elements required in the WFD monitoring are listed. It may be observed that composition and abundance of fish fauna as quality element/indicator in the WFD is only applicable for transitional waters and not included for coastal waters.

Table 4.4 Monitoring – prescribed quality elements. Reference: WFD Annex V 1.1.3 Transitional waters and Annex V 1.1.4 Coastal waters.

TRANSITIONAL WATERS

COASTAL WATERS

Biological elements:

- | | |
|---|--|
| <ul style="list-style-type: none"> • Composition, abundance and biomass of phytoplankton. • Composition and abundance of other aquatic flora. • Composition and abundance of benthic invertebrate fauna. • Composition and abundance of fish fauna. | <ul style="list-style-type: none"> • Composition, abundance and biomass of phytoplankton; composition and abundance of other aquatic flora. • Composition and abundance of benthic invertebrate fauna. |
|---|--|

Hydro-morphological elements supporting the biological elements:

- | | |
|--|---|
| <ul style="list-style-type: none"> • Morphological conditions: depth variation; quantity, structure and substrate of the bed; structure of the inter-tidal zone. • Tidal regime: freshwater flow; wave exposure. | <ul style="list-style-type: none"> • Morphological conditions: depth variation; quantity, structure and substrate of the bed; structure of the inter-tidal zone. • Tidal regime: direction of dominant currents; wave exposure. |
|--|---|

Chemical and physio-chemical elements supporting the biological elements:

- | | |
|--|--|
| <ul style="list-style-type: none"> • General: transparency; thermal conditions; salinity; oxygenation conditions; nutrient conditions. • Specific pollutants: pollution by all priority substances identified as being discharged into the body of water; pollution of other substances identified as being discharged in significant quantities into the body of water. | <ul style="list-style-type: none"> • General: transparency; thermal conditions; salinity; oxygenation conditions; nutrient conditions. • Specific pollutants: pollution by all priority substances identified as being discharged into the body of water; pollution of other substances identified as being discharged in significant quantities into the body of water. |
|--|--|

Another main feature of the WFD is that utilisation of water shall be based on the precautionary principle and be sustainable in the long run. Mapping and characterisation of the different user interests is therefore an important requirement in the WFD. An assessment of pressures on every water body will be carried out as part of the characterisation, and will inform monitoring networks. Assessment of pressures in relation to fisheries and aquaculture in coastal and transitional waters require information on i.e. nutrients, hazardous substances, organic enrichment, morphology, commercial fishing, and alien species, and additionally for transitional waters; water abstraction, industrial intakes and discharges. This information will enable a rational discussion on the cost-effectiveness of the various possible measures that might be required for achieving

“good status”. It is also necessary for the calculation of environmental costs for the operationalisation of the “polluter pays” principle and in order to estimate full cost recovery of water services. According to the WFD, water pricing shall provide for incentives for the optimal use of the water resources and for the achievement of the ecological goal.

The final point of particular significance to be mentioned is the WFDs strong focus on democratic, participative processes during the entire process of its implementation – to ensure transparency and enforceability and in keeping the process open to the scrutiny of those who will be affected. The WFD Article 14 requires Member States to encourage the active involvement of all interested parties in the implementation of the directive, in particular the production, review and updating of the RBMPs. Key documents shall be published made publically available for comments and background documents provided on request. This is further emphasised in preamble 14, which states that the success of the WFD relies on close cooperation and coherent action at Community, Member State and local level, as well as on information, consultation and involvement of the public, including the users.

Public participation and involvement is also an essential ingredient of ICZM. The ICZM principles both point on the statutory rights on access to information as well as open and transparent planning processes with broad stakeholder involvement and local participation. Thus, there is resemblance between the two systems, but adequate coordination is required to prevent parallel processes.

Pilot projects in implementation of the WFD in Norway

Two pilot projects in implementation of the WFD were carried out in selected river basins in Norway covering different characteristics and issues; the Vansjø-Hobøl River Basin in the Eastern part of Norway and the River Suldalslågen with adjoining fjord area on the Western coast. The last project focused primarily on gaining experiences on alternative organisation models at regional level (for river basin districts) and on assessing the availability of data compatible with the WFD requirements (Berge et al 2003). A typology was initially established for the river basin/fjord area and preliminary characterisation of the water bodies was carried out. The coastal part included three types of areas: a fjord area influenced by river regulation (hydro-power); an area with high density of marine aquaculture (arctic salmon); and an area dominated by harbour development and sea transport.

As for the organisation, the WFD requires set-up of administrative units with responsibility for coordination in each river basin district. The results from the pilot project show that the existing administrative structure is not in direct coherence with the WFD and that adaptation to the new requirements are needed. In Norway, water resources management comes under a number of statutory acts, and responsibilities are shared between many institutions as well as different levels of administration. In general, the municipalities are responsible for coordination and integration. The municipalities have the authority to endorse legally binding master plans (the land-use part) anchored in the Planning and Building Act, including river basin and coastal zoning plans. Planning in cross-boundary river basins (across municipal borders) are mostly facilitated by the County Governors (state administrative unit at regional level) and based on inter-municipal collaboration, however actual implementation in most cases requires incorporation of decisions in the municipal plans.

The Ministry of Environment has been selected as the leady ministry in the implementation of the WFD, while the County Governors (state representatives at regional level) will have the responsibility for coordination of the work in the river basin

districts. The experiences from the pilot project emphasises the need for active stakeholder involvement and collaborative approaches during all stages of the planning process, with special attention to the role of the municipalities, as well as the need for efficient information sharing. Establishment of regional “River Basin Committees” and working groups (i.e. involving NGOs, civil society and public institutions) based on previously acknowledged models and best practices in river basin management is recommended. For proper attendance of coastal issues, key institutions such as the (district branches of) the Directorate of Fisheries, the Coastal Administration, and the Norwegian Water Resources and Energy Directorate should be invited to play an active role.

4.5.3 Conclusion

ICZM is a demanding task, which i.a. should have a broad “holistic” and long run perspective, integrating all relevant interests and sectors in the coastal zone. Activities in the coastal zone, particular in the marine part, have traditionally been carried out by different sectoral bodies, and rigid bureaucratic systems. Sectoral policy in marine areas is somewhat separated from spatial planning, and co-operation between them is not yet well developed. ICZM imply a new style of governance, a style that involves partnership between all relevant interests. As the European Commission (2000) emphasise, integrated solutions to concrete problems can only be found and implemented at the local and regional level. Related to integration between fisheries and spatial planning it is a challenge that the EU Fisheries policy is one of the EU policies that are least adaptable to regional needs.

Norcoast (2001) recommend combining the best elements of the statutory spatial planning system with the best elements of the voluntary partnership approach in order to achieve integrated solutions. The Norwegian experiences support this recommendation. Another experience from Norwegian regional coastal zone planning is that an open and inclusive planning process does not alone increase the integration capacity of the regional planning. The results rather support the opposite argument of a trade off between the number of actors participating in the decision process and the ability to agree on and implement a joint action which effectively will deal with the problem. This is of particular importance for the coastal planning efforts, where different, and often competing, state sectors have a tendency to optimise their own strategies and aims instead of go into integrated solutions in regional and local levels through the spatial planning system. A general experience is therefore that integration at regional level is only possible if the higher levels of administration provide an integrated legal and institutional context (Hovik and Stokke in prep).

One lesson from the EU Demonstration programmes is that the spatial planning system alone has some limitations to secure the idea of ICZM. The first is the necessity that the spatial planning system covers both the terrestrial parts and the marine part of the coastal zone. Only few countries have institutionalised such integration today. The EU Water Framework Directive could secure this element because also coastal waters up to one nautical mile outside the basic line should be included in the river basin management plans. Another limitation is that the spatial planning system often focusing narrowly on development control rather than a broader ICZM focus. In that respect, it could be necessary to combine economic instruments to the planning system. The tradition for protecting coastal areas may also have led to a neglect of the ideas of ICZM as such, where a main purpose is to balance protection and development in coastal communities. ICZM strategies in fishery dependence areas should for instance also focus on new forms for development, such as aquaculture, tourism, etc.

The hypothesis regarding aquaculture is that this industry will increase the pressure on the coastal zone, but a management based on ICZM could contribute to a further sustainable growth. The Norwegian experiences with local coastal zone planning indicate that this could be a suitable instrument to balance the increase of aquaculture with other interests. A central challenge is to find a balance between the need for long-term steering and predictability on the one side, and the need for flexibility on the other side. A precondition is broad participation from the relevant local interests and stakeholders, and the relevant sectoral administrative bodies to find an acceptable balance between growth in aquaculture and other interests as protection, recreation, coastal fisheries, etc. However, open and inclusive planning processes do not automatically lead to integrated planning. In the coastal zone there are many strong state sectors, and a will among these actors to find compromises at the regional level seems to be necessary.

It is a need for a regional approach across the municipalities regarding the development of the industry. Regional coastal zone planning and planning in accordance to the Water Framework Directive can contribute to more integration across municipalities and a more ecosystem-based management, also in the case of aquaculture.

4.5.4 Policy recommendations

According to the ICZM example studies, primarily regarding the aquaculture industry, we point out the following policy recommendations:

- a) It is necessary to further develop the integration of the terrestrial and marine environment in coastal planning and other ICZM activities.
- b) It seems to be an effective strategy to combine the best elements of the statutory spatial planning system with the best elements of the voluntary partnership approach in order to achieve integrated solutions at the regional level of government.
- c) To find acceptable balances between further growth in aquaculture and protection and other interests in the coastal zone, it is a precondition with a broad participation from relevant local interests and stakeholders in the planning processes, together with relevant sectoral administrative bodies. Environmental Impact Assessment (EIA) and Strategic Environmental Assessment (SEA) could be useful instruments in the process to find the right balance between protection and use.
- d) The aquaculture industry is in a continuously technological change, i.e. with introduction of new species and in being more offshore based. It is therefore necessary with flexible planning approaches in order to be able to deal with the quick changes that may occur. It is, however, also a need to find suitable combination between the need for long-term steering and predictability on the one side, and the need for flexibility on the other side. The specific choice in this regard will be dependent on the specific context on the ground.
- e) It is a need for a regional approach across the municipalities and other administrative borders regarding the development of the aquaculture industry and other coastal activities. The implementation of the Water Framework Directive may contribute in that direction.

5 Territorial Social Cohesion Impacts

5.1 Introduction

The fisheries project has demonstrated the considerable volume of EU fisheries. European fisheries includes over 88 thousand vessels, over 500 thousand employed persons, harvest 6 millions tonnes of catches and produce over 1 million tonnes of aquaculture fish. Viewed against this background, the position of the European fisheries policies is of importance for the total European development. The European fisheries policy is regarded as one of the sector policies with great territorial implications, by having impact on socio-economic development in the European territories, particularly European coast territories, fisheries territories of different types as “fisheries specialised territories”. Due to the impacts inside the respective European territories, the CFP will also influence on the position and the role of the coastal/fisheries territories in the European territorial system and of specific countries by forcing growing and declining processes that differentiates the development in fisheries territories compared with socio-economic trends in other types of territories. Thereby the CFP also can impact on the territorial policies system of EU by changing the position of the fisheries territories in the policy system and by challenging other types of policies measures in EU territorial policies regimes.

More concretely, the social cohesion analysis will:

- Explain the challenges for organising socio-economic data of relevance for Territorial Impacts Analyses of the common fisheries policies. De facto this is an investigation and an assessment of available and not available socio-economic fisheries data.
- Analyse, exemplify and discuss territorial impacts of CFP by using available statistical data as well as example studies.
- Specify types of fisheries territories that demonstrate the European territorial embedding as well as the huge dependence of fisheries in some territories. Fisheries dependency is analysed by using the Megapesca study from the 1990s.
- Analyse the territorial implementation of the CFP by demonstrating the regional distribution of the Common Financial Instrument for Fisheries Guidance (FIFG).
- Analyse direct impacts of CFP on fisheries employment inside specific territories, mainly by different types of exemplifications.
- Analyse, exemplifying and discuss how CFP interplays with population changes and the income situation of the specific territories. The demographic analysis is based on ESPON project 1.1.4.
- Discuss possible impacts of CFP on the territorial system in Europe.
- Discuss impacts on the Territorial Impacts Assessment system from analysing CFP.
- Discuss policies recommendations.

For conclusions and summing the important part of the analyses of the Work Package 3, we recommend you to read the summary in chapter 1.

5.2 Hypothesis on territorial social cohesion impacts of the CFP

Interim Report no 1 specified several hypotheses on territorial social cohesion impacts of CFP.

According to hypothesis no 1, the position of fisheries, fisheries territories, and fisheries policies varies between the European nations and among the territories inside the countries. This is an evident statement, but still it underlines the territorial dimensions of fisheries: The general historical development of the fisheries is based on access to marine fishing areas; in some territories the access to fish markets could be equally important to resource availabilities. The general picture also demonstrates the importance of market access for the localisation of fisheries activities. Moreover the traditional picture for fisheries territories is that they have been socio-economically as well as politically marginalised. By analysing the geographical aspects of catchings, landings, fisheries employment and the distribution of fisheries policies measures we are able to demonstrate territorial variations of the modern European fisheries in order to identify the geographical centre of gravities of European fisheries as well as marginal fisheries dependent territories.

According to hypothesis no 2, the CFP can have side effects such as declining fisheries employment, increasing unemployment, decreasing average incomes, population decrease and altered age composition due to increased out migrations and decreased immigrations. This statement underlines that the principal objective of CFP is to protect fish resources and to develop fisheries. Saying this we have already stated that CFP will have territorial impacts according to e.g. decreasing catches, landings and structural changes, but that a TIA also will focus on the unintended but not surprising socio-economic side impacts.

According to hypothesis no 3, the fisheries specialised territories mainly in remote areas, have more negative development in population, employment and income than the average European territories. This statement is caused by the relative important position of fisheries in some local economies, as well as an anticipated lack of employment alternatives to local fisheries.

According to hypotheses no 4, the incidence of the CFP on regional level is not consistent with the social and economic cohesion objectives of EU. The statement argues that due to socio-economic side effects of CFP in already marginalised territories, the territorial differences between the European levels will increase due to the development in the fisheries.

We will return to the hypotheses in the final section of the chapter.

5.3 Data on fisheries socio-economics and social cohesion

Data needed to undertake TIA analyses in fisheries

In order to undertake a socio-economic study and analyses of fisheries in a TIA frame, we need regional data and figures on developments of population, total employment, fisheries employment and income (household, disposable). Moreover, in order to analyse

the interconnections between the CFP and the socio-economic development we need regionalised fisheries data on catches and landings as well as data on the territorial distribution of financial measures in the fisheries policies where the Financial Instrument of Fisheries Guidance (FIFG) is the most important.

We have not been able to establish a regional database on catches and landings on NUTS 2 and NUTS 3 levels. In order to clarify the regional implementation of the protection policies we refer to analyses in WP 2 and WP 5 undertaken at NUTS 0 level. The regional distribution of FIFG can be analysed on NUTS 2 level.

It has not been possible to explicitly split between employment in fisheries and aquaculture in most of the countries. Information on employment in the fish processing industry is missing for several countries, also in the ESPON database, unless it has been concealed by a misleading variable label, in line with the employment data for fisheries and aquaculture (called ‘agriculture’ in the present data base). Moreover, it has not been possible to obtain socio-economic data from the same time series in each country, which means that data often are not consistently comparable from year to year.

5.4 The territorial system of European fisheries: “Dependencies”; “employment concentration”; “specialisation”

As far as we know only one socio-economic study on regional fisheries on the European level has been conducted before this ESPON study. The study of Ian Goulding, David Hallam, Lucy Harrison-Mayfeld, Victoria Mackenzie-Hill and Helder da Silva (2000) identified fisheries dependence on municipal/NUTS 5 level (the Megapesca study). This study was based on building a comprehensive data collection network in every EU 15 country, and the project paid for collection of data in the respective countries. Today, data available in the ESPON framework is collected and organised mainly on NUTS 2 level.

From a principal point of view, the development of the TIA for the fisheries therefore can take one of two possible directions: Either to collect data on very low geographical level in order to get detailed information on regional fisheries, or to develop the pictures of the fisheries position in the European systems of territories on higher level. Probably the latter is the most feasible and realistic to develop based on the data status today. Choosing the first direction needs the development of a comprehensive system of data collection, as was done by Goulding et al in the Megapesca study.

We argue that studying the territorial system on a very low level mainly contributes to identifying some very fisheries dependent territories, but will not provide a correct picture of the spatial distribution of the enormous European fisheries. The Megapesca study demonstrated the territorial concentration of the European fisheries, particularly the fisheries employment. For example, fifty-one per cent of the fishermen are living in 56 NUTS 3 territories where the fisheries have more than one per cent of total employment. However if the criteria is raised to two per cent of the total employment the number of NUTS 3 territories decreases to 35. Whether all of these territories should be called fisheries dependent should however be discussed more, in our point of view.

The problem of describing the European territorial fisheries system as collection of real fisheries dependent territories problem was also demonstrated by the Megapesca study where Goulding et al. (2000) selected the most fisheries dependent NUTS 3 territories in Europe in the 1990s. The fisheries dependency was indicated by three dependency ratios: value added, employment and quota ratios. They considered employment as the

most reliable measure of dependency, since it is tangible, clearly defined between territories, and provides a direct measure of the importance of fishing for peoples' livelihood.

The two first columns in table 5.1 below show that only twelve of the 343 NUTS 3 territories fulfilled the criteria for both economic and employment dependency, and additional eleven territories were classified as fisheries dependent territories having either economic or employment dependency. When considering all three dependency ratios defined by the Megapesca study, 43 of the 343 NUTS 3 territories fulfilled some dependency criteria, however, only ITA01 Trapani fulfilled all criteria.

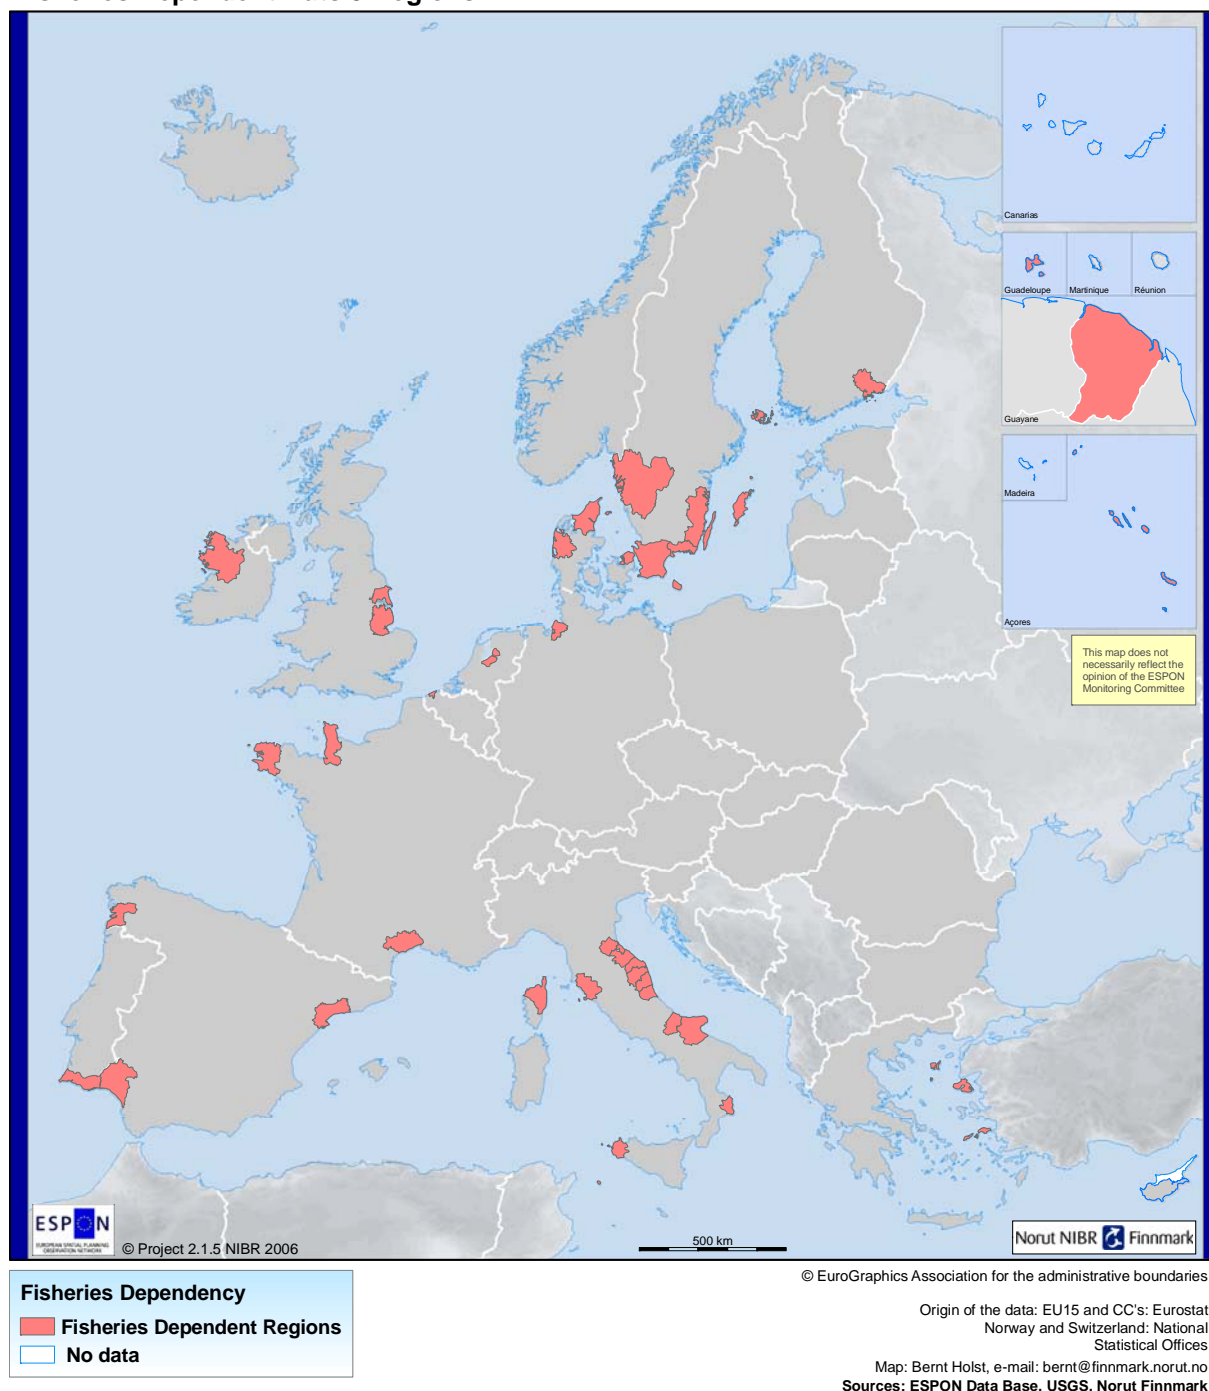

Table 5.1 The 25 fishery dependent territories at NUTS 3 levels, according to MegaPesca (Goulding et al. 2000).

Figure 5.1 Fisheries dependent territories using Megapesca indicators (mapping the 43 European NUTS 3 territories)

Fisheries Dependent Nuts 3 Regions

Based on the first two columns of the table above: According to the Megapesca study, the 12 most fisheries dependent European NUTS 3 territories are distributed between nine European countries:

- Belgium (Ostende region)
- Germany (Cuxhaven, part of the Lüneburg NUTS 2 territory)
- Spain (Pontevedra, part of Galicia NUTS 2 territory)

- France (Manche and Finistère territories)
- Ireland (West)
- Italy (Trapani, part of Sicilia NUTS 2 territory)
- Portugal (Algarve and dos Acores, part of the same NUTS 2 territories)
- Finland (Åland)
- United Kingdom (East Riding and Lincolnshire).

Moreover, still contemplating the first two columns, five territories are fisheries dependent according to economic importance of the fisheries (but not employment dominance). Those are in Greece (Samos, part of Voreio Agio, NUTS 2 territory), France (Haute Corse and Guadeloupe) and Italy (Grosseto, that is part of Toscana NUTS 2 territory and Teramo, that is part of Abruzzo). Seven others are dependent according to employment dominance in fisheries. Those are in Denmark (Bornholm), Greece (Lesvos, as Samos part of the Voreio Agio NUTS 2 territory), Italy (Foggia and Crotone), Spain (Huelva part of Andalucia NUTS 2 territory), France (Hérault and Guyane) and Sweden (Gotland).

The Megapesca study identified the European territories that are most dependent on fisheries, before the enlargement of the EU. However, the most fisheries dependent territories included give an image of a very marginal territorial fisheries sector, where the sector policies only will be of importance for small parts of the European space. Of 387 NUTS 3 territories with a coastline, the fisheries dependent territories only constitute 6.5 percent according to the above criteria. In view of the considerable volume of the European fisheries (conf IR 2), one objective of an assessment of the territorial impacts of CFP is to enlarge the picture of the territorial importance of European fisheries.

ESPON has to discuss how fisheries territories of relevance for the total European fisheries should be identified. We have tried a national path, that is, by classifying fisheries territories according to national averages. Thereby we will be able to identify fisheries territories, not necessarily territories with high dependence of fisheries, but territories with a relative specialisation in fisheries compared with the national position of the fisheries sector. We will also argue that this way harmonises with the central role of the national level in the territorial distribution of the fisheries policies measures. We will also argue that all fisheries dependent territories according to the European level will be included, but may have another role and position than in the Megapesca study.

5.4.1 Fisheries employment in European nations

According to the data from the ESPON database the five European nations where the employment of European fisheries (2002) is most frequent are: (number of employees in the brackets)

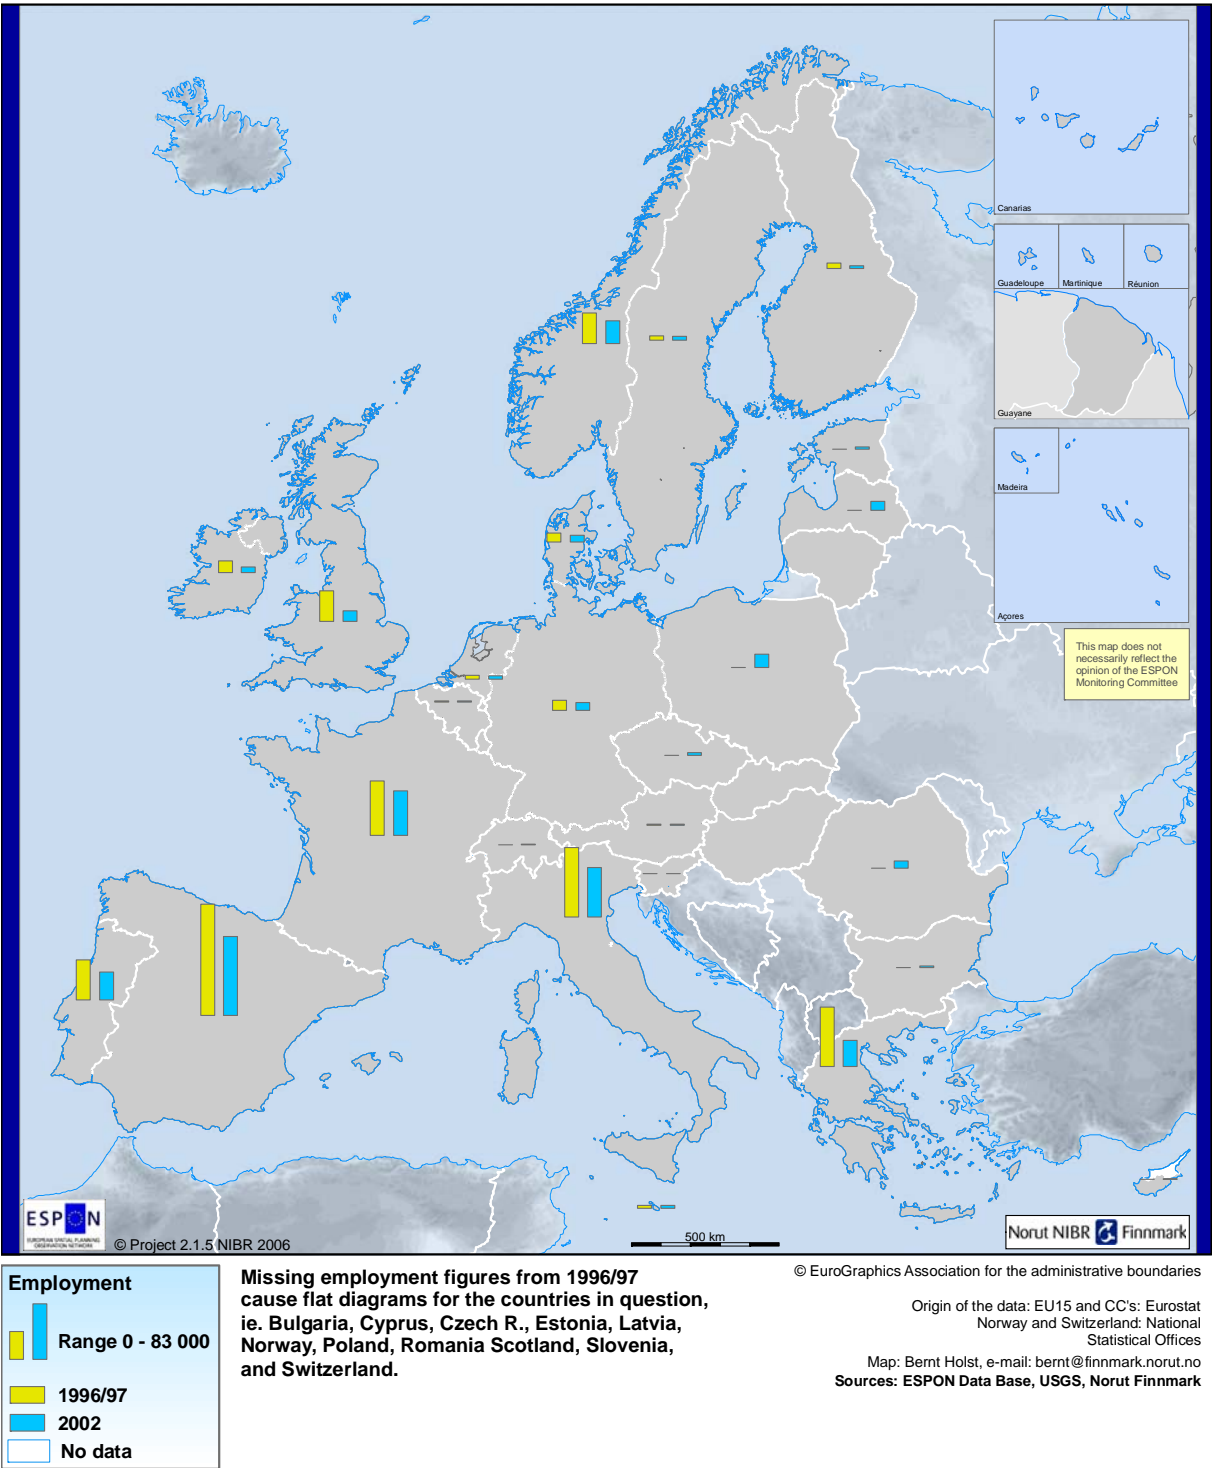

Spain (58820)
Italy (37120)
France (33460)
Portugal (20750)
Greece (19450)

These figures demonstrate the “South” embedding of the European fisheries. In France, however, a large share of fisheries employment is in Northern territories. The map also demonstrates that the decrease of the number of employees has been much stronger in these countries than in most of the other countries. From that point of view we can see a

weakening of the traditional core area for European fisheries employment since mid of the 1990s, but still employment centres of the fisheries in Europe is in south areas in east and west.

Figure 5.2 Fisheries and Aquaculture employment 1996/97 and 2002 on NUTS 0/NUTS1 level

Fisheries and Aquaculture Employment 1996/97 and 2002

5.4.2 Fisheries specialisation in national economies

The starting point for estimating fisheries specialised territories according to the national averages is a comparison of the proportion of employment in each of the territories and the national average of the fisheries employment. This will enable an identification of fisheries specialised territories in a national context. As the implementation of CFP to the specific territories is embedded in national level, the characteristics of the fisheries in the territories can explain aspects with the distribution. By this method, we identify fisheries specialized territories in 13 European countries (12 if we split Scotland from the UK): Denmark, Finland⁸⁹, France⁹⁰, Germany, Greece, Iceland, Italy, Norway, Portugal, Spain, Scotland (UK), Sweden⁹¹, and the UK (minus Scotland)⁹². The extent of data collected varies, for example, for Germany, we lack data from two of the five NUTS 2 territories with a coastline.

The identification of fisheries specialised territories is done by following process:

- (i) Estimating the national fisheries employment averages. Due to the data situation it is today difficult to estimate figures for the same year (conf Table 7.5).
- (ii) Identifying NUTS 2 territories (Denmark NUTS 3, Iceland NUTS 4) with coastline (conf Table 7.6).
- (iii) Estimating the fisheries employment averages in each of the coastal territories (conf Tables 7.7-7.15).
- (iv) Estimating specialisation indexes for each of the territories based on the relations between (iii) and (i), that is the proportion of fisheries employment in the respective territories compared with the national average.
- (v) In “fisheries specialised territories” the relative employment in fisheries is higher than the relative fisheries employment on national level (de facto over 100)

5.4.3 National fisheries employment averages

According to (i) above, we estimated the following fisheries employment share of total national employment, as illustrated in table 5.2. The years differ, as explained above.

⁸⁹ Source Finland: Espon databases

⁹⁰ Source France: Espon databases

⁹¹ Source Sweden: Espon databases

⁹² Source UK: Espon databases

Table 5.2 Fisheries employment as percentage of total employment. NUTS 0

Country, year	Fisheries employment as percentage of total employment
Denmark 1996	0.25 %
Denmark 2001	0.2 %
Finland 2001	0.09 %
France 2001	0.13 %
Germany 1996	0.013 %
Germany 1997	0.008 %
Greece 1995	0.77 %
Greece 2000	0.6 %
Iceland 1997	9.7 %
Iceland 2003	7.5 %
Italy 1995	0.19 %
Italy 2001	0.17 %
Norway 1999	0.94 %
Norway 2001	0.83 %
Portugal 1996	0.53 %
Portugal 2001	0.32 %
Spain 1995	0.52 %
Spain 2001	0.36 %
Sweden 2001	0.08 %
UK 2002 (Scotland)	0.24 %
UK 2004 (Scotland)	0.22 %
UK 2002 ⁹³ (minus Scotland)	0.03%

All countries have had a decrease in fisheries employment's share of total employment. Germany, Italy and the UK have the lowest shares of employed in fisheries, while Iceland and Norway have the highest shares. Iceland is by far the most fisheries dependent country; in 2003, 7.5 per cent of the workforce was employed in the fisheries, while the corresponding figures for the other countries were below one per cent.

⁹³ Total national employment figure from 2001.

5.4.4 Coastal territories included in the sample

Table 5.3 lists the number of coastal territories used for this analysis in the twelve countries with available employment data.

Table 5.3 Territories with coastlines in the sample

Country	Number of territories with coastline		
	NUTS 2	NUTS 3	NUTS 4

Finland	5		
France	15		
Germany	5		
Greece	13		
Iceland			8
Italy	15		
Norway	6		
Portugal	7		
Spain	10		
Sweden	8		
UK	27 ⁹⁴		
Total	111	14	8

5.4.5 Regional fisheries specialisation indexes

Fisheries specialisation indexes are calculated on NUTS 2 level, except for Denmark (NUTS 3 level) and Iceland (NUTS 4 level). The procedures of the calculations are as follows:

- 1) Estimate the fisheries' share of total employment in the country for one or more years and set the country average to 100.
- 2) Estimate the fisheries' share of total employment in each territory for the same years.
- 3) Estimate the level of each country's lower level territory compared to the country's 100.
- 4) The territories with an index above 100 are defined as territories with specialisation in fisheries.
- 5) The results are entered into maps. The coastal territories are plotted with different colours according to their degree of specialisation.

5.4.6 Fisheries specialised territories

According to the above description of fisheries specialisation indexes, the following tables demonstrate the different countries' fisheries specialisation indexes. The fisheries specialised territories, i.e. those with an index above 100, are marked with bold.

Table 5.4 The relative position of fisheries in Danish NUTS 3 coastal territories. Figures above 100 indicate fisheries specialised territories.

2001

⁹⁴ Including Scotland with four NUTS 2 regions and Northern Ireland as a NUTS 2 region.

DK001	København og Frederiksberg kommuner	2,5
DK002	Københavns amt	4,2
DK003	Frederiksborg amt	52
DK004	Roskilde amt	23
DK005	Vestsjællands amt	73
DK006	Storstrøms amt	139
DK007	Bornholms regionskommune	754
DK008	Fyns amt	61
DK009	Sønderjyllands amt	43
DK00A	Ribe amt	263
DK00B	Vejle amt	52
DK00C	Ringkøbing amt	409
DK00D	Århus amt	36
DK00E	Viborg amt	196
DK00F	Nordjyllands amt	232

Denmark has six NUTS 3 territories with different levels of fisheries specialisation: DK006 Storstrøms amt, DK007 Bornholm regionskommune, DK00A Ribe amt, DK00C Ringkøbing amt, DK00E Viborg amt, and DK00F Nordjyllands amt. DK007 Bornholm regionskommune is the most fisheries specialised NUTS 3 territories.

Table 5.5 The relative position of fisheries in 3 German NUTS 2 coastal territories. Figures above 100 indicate fisheries specialised territories.

		1996
DE5	Bremen	374
DE8	Mecklenburg-Vorpommern	2222
DE93	Lüneburg	:
DE94	Weser-Ems	:
DEF	Schleswig-Holstein	923

As explained earlier, the data from Germany is sparse, and displays three NUTS 2 territories with fisheries specialisation, of which Mecklenburg-Vorpommern clearly is the most fisheries specialised.

Table 5.6 The relative position of fisheries in Finnish NUTS 2 coastal territories. Figures above 100 indicate fisheries specialised territories.

		2001
FI13	Itä-Suomi	233,9
FI14	Väli-Suomi	46,4
FI15	Pohjois-Suomi	231,3
FI16	Uusimaa	20,6
FI17	Etelä-Suomi	83,4
FI2	Åland	18,8

In Finland, two out of six coastal NUTS 2 territories are fisheries specialised.

Table 5.7 The relative position of fisheries in French NUTS 2 coastal territories in 2001. Figures above 100 indicate fisheries specialised territories.

		2001
FR22	Picardie	:
FR23	Haute-Normandie	99,7
FR25	Basse-Normandie	282,6
FR3	Nord-Pas-de	95,3
FR51	Pays de la Loire	288,0
FR52	Bretagne	450,4
FR53	Poitou-Charentes	382,1
FR61	Aquitaine	217
FR81	Languedoc-Roussillon	625,1
FR82	Provence-Alpes-Côte d'Azur	35,3
FR83	Corse	:
FR91	Guadeloupe	:
FR92	Martinique	:
FR93	Guyane	:
FR94	Réunion	:

In France, there are six NUTS 2 territories with a specialisation index above 100. Regrettably, we lack information on NUTS 2 territories where fisheries probably have a higher share of the total employment, such as for instance FR83 Corsica, and the overseas French NUTS 2 territories.

Table 5.8 The relative position of fisheries in Greece NUTS 2 coastal territories in 1995 and 2000. Figures above 100 indicate fisheries specialised territories.

		1995	2000
GR11	Anatoliki Makedonia, Thraki	96	97
GR12	Kentriki Makedonia	71	67
GR13	Dytiki Makedonia	13	36
GR14	Thessalia	46	26
GR21	Ipeiros	99	116
GR22	Ionia Nisia	206	310
GR23	Dytiki Ellada	125	78
GR24	Stereia Ellada	282	296
GR25	Peloponnisos	202	223
GR3	Attiki	33	30
GR41	Voreio Aigaio	812	637
GR42	Notio Aigaio	569	650
GR43	Kriti	31	123

For Greece, we are able to compare fisheries specialisation from two years, 1995 and 2000. In 1995 there were six of 13 fisheries specialised NUTS 2 territories, while in 2000 it had increased to seven. GR21 Ipeiros had changed from being a non-specialised territory to a fisheries specialised territory (from index 99 to 116), while the opposite happened for GR23 Dytiki Ellada, which went from being a fisheries specialised territory to a non-specialised territory (from 125 to 78). GR43 Kriti went from the low index of 31 to being a fisheries specialised territory with index of 123. This may indicate that Kriti had a large influx of fishers, however, it may also indicate that the data collection method varied between these two years, which we are not able to verify within the frame of project 2.1.5.

Table 5.9 The relative position of fisheries in Italian NUTS 2 coastal territories min 1995 and 2001. Figures above 100 indicate fisheries specialised territories.

		1995	2001
IT13	Liguria	35	48
IT32	Veneto	72	71
IT33	Friuli-Venezia Giulia	337	259
IT4	Emilia-Romagna	97	102
IT51	Toscana	64	60
IT53	Marche	128	135
IT6	Lazio	29	35
IT71	Abruzzo	230	173
IT72	Molise	0	52
IT8	Campania	77	65
IT91	Puglia	225	244
IT92	Basilicata	30	0
IT93	Calabria	194	176
ITA	<i>5.4.6.1.1.1 Sicilia</i>	431	459
ITB	Sardegna	254	231

For Italy, the years 1995 and 2001 are compared. In 1995, seven of 15 NUTS 2 territories were fisheries specialised, while in 2001, the number of fisheries specialised territories had increased to eight. IT4 Emilia-Romagna had gone from being a non-specialised to a fisheries specialised territory. However, both years, Emilia-Romagna was close to the average index of 100 (97 and 102 respectively).

Table 5.10 The relative position of fisheries in NUTS 2 coastal territories in Portugal. Figures above 100 indicate fisheries specialised territories.

		2001
PT11	Norte	67
PT12	Centro	74

ES61	Andalucia	98	93
ES62	Región de Murcia	71	56
ES7	Canarias	199	161

For Spain, the years 1995 and 2001 are compared. In 1995, five out of ten NUTS 2 territories were fisheries specialised, while in 2001, the number of fisheries specialised territories had decreased to four. ES21 País Vasco went from being a fisheries specialised to a non-specialised territory (from an index of 115 to 95). Galicia and Principado de Asturias both show an increase in the fisheries specialisation indexes, from 586 to 781, and from 112 to 137 respectively.

Table 5.12 The relative position of fisheries in NUTS 2 coastal territories in Sweden.
Figures above 100 indicate fisheries specialised territories.

		2001
SE01	Stockholm	:
SE02	Östra Mellansverige	62,14
SE04	Sydsverige	176,99
SE06	Norra Mellansverige	64,68
SE07	Mellarste Norrland	306
SE08	Övre Norrland	56,99
SE09	Småland med öarne	12,28
SE0A	Västsverige	167,86

There were two fisheries specialised NUTS 2 territories in Sweden in 2001, of total of eight coastal NUTS 2 territories.

Table 5.13 The relative position of fisheries in NUTS 2 coastal territories in Scotland.
Figures above 100 indicate fisheries specialised territories.

		2002	2004
UKM1	North Eastern Scotland	324	281
UKM2	Eastern Scotland	17	18
UKM3	South Western Scotland	25	33
UKM4	5.4.6.1.1.2 Highlands and Islands	606	649

For Scotland (UK), 2002 and 2004 are compared. Two of four NUTS 2 territories are fisheries specialised.

Table 5.14 The relative position of fisheries in NUTS 2 coastal territories in the UK.
Figures above 100 indicate fisheries specialised territories.

		2001
UKC1	Tees Valley and Durham	:
UKC2	Northumberland, Tyne and Wear	:
UKD1	Cumbria	:
UKD2	Cheshire	:
UKD4	Lancashire	:
UKD5	Merseyside	:
UKE1	East Riding and North Lincolnshire	:
UKE2	North Yorkshire	223,98
UKF3	Lincolnshire	:
UKH1	East Anglia	212,75
UKH3	Essex	:
UKI1	Inner London	:
UKI2	Outer London	:
UKJ2	Surrey, East and West Sussex	:
UKJ3	Hampshire and Isle of Wight	224,97
UKJ4	Kent	:
UKK1	Gloucestershire, Wiltshire and North Somerset	:
UKK2	Dorset and Somerset	145,25
UKK3	Cornwall and Isles of Scilly	1072,25
UKK4	Devon	:
UKL1	West Wales and the Valleys	107,36
UKL2	East Wales	:
UKM1	North Eastern Scotland	1969,74
UKM2	Eastern Scotland	222,82
UKM3	South Western Scotland	178,42
UKM4	Highlands and Islands	3542,35
UKN	Northern Ireland	142,54

Both tables 5.13 and 5.14 contain Scotland; in table 5.14, Scotland is seen in the whole UK context. It clearly demonstrates that when the fisheries consist of a very small share of total employment, the indexes are large in areas where there are relatively more fishers.

Table 5.15 The relative position of fisheries in Norwegian NUTS 2 coastal territories.
Figures above 100 indicate fisheries specialised territories.

		1999	2001
NO01	Oslo og Akershus	2	2
NO02	Hedmark og Oppland	:	:
NO03	Sør-Østlandet	13	13
NO04	Agder og Rogaland	55	59
NO05	Vestlandet	197	204
NO06	Trøndelag	66	61
NO07	Nord-Norge	496	487

For Norway, 1999 and 2001 are compared. Two out of seven NUTS 2 territories are fisheries specialised. The fisheries specialisation index for NO05 Vestlandet (from 197 to 204) while it has decreased for NO07 Nord-Norge (from 496 to 487).

Table 5.16 The relative position of fisheries in Icelandic NUTS 4 coastal territories. Figures above 100 indicate fisheries specialised territories.

	1997	2003
Capital region	34	26
South peninsula (Reykjanes area)	251	211
West region	211	223
Westfjords	362	402
North-west regions	185	177
North-east regions	209	191
East region	298	347
South region	145	142

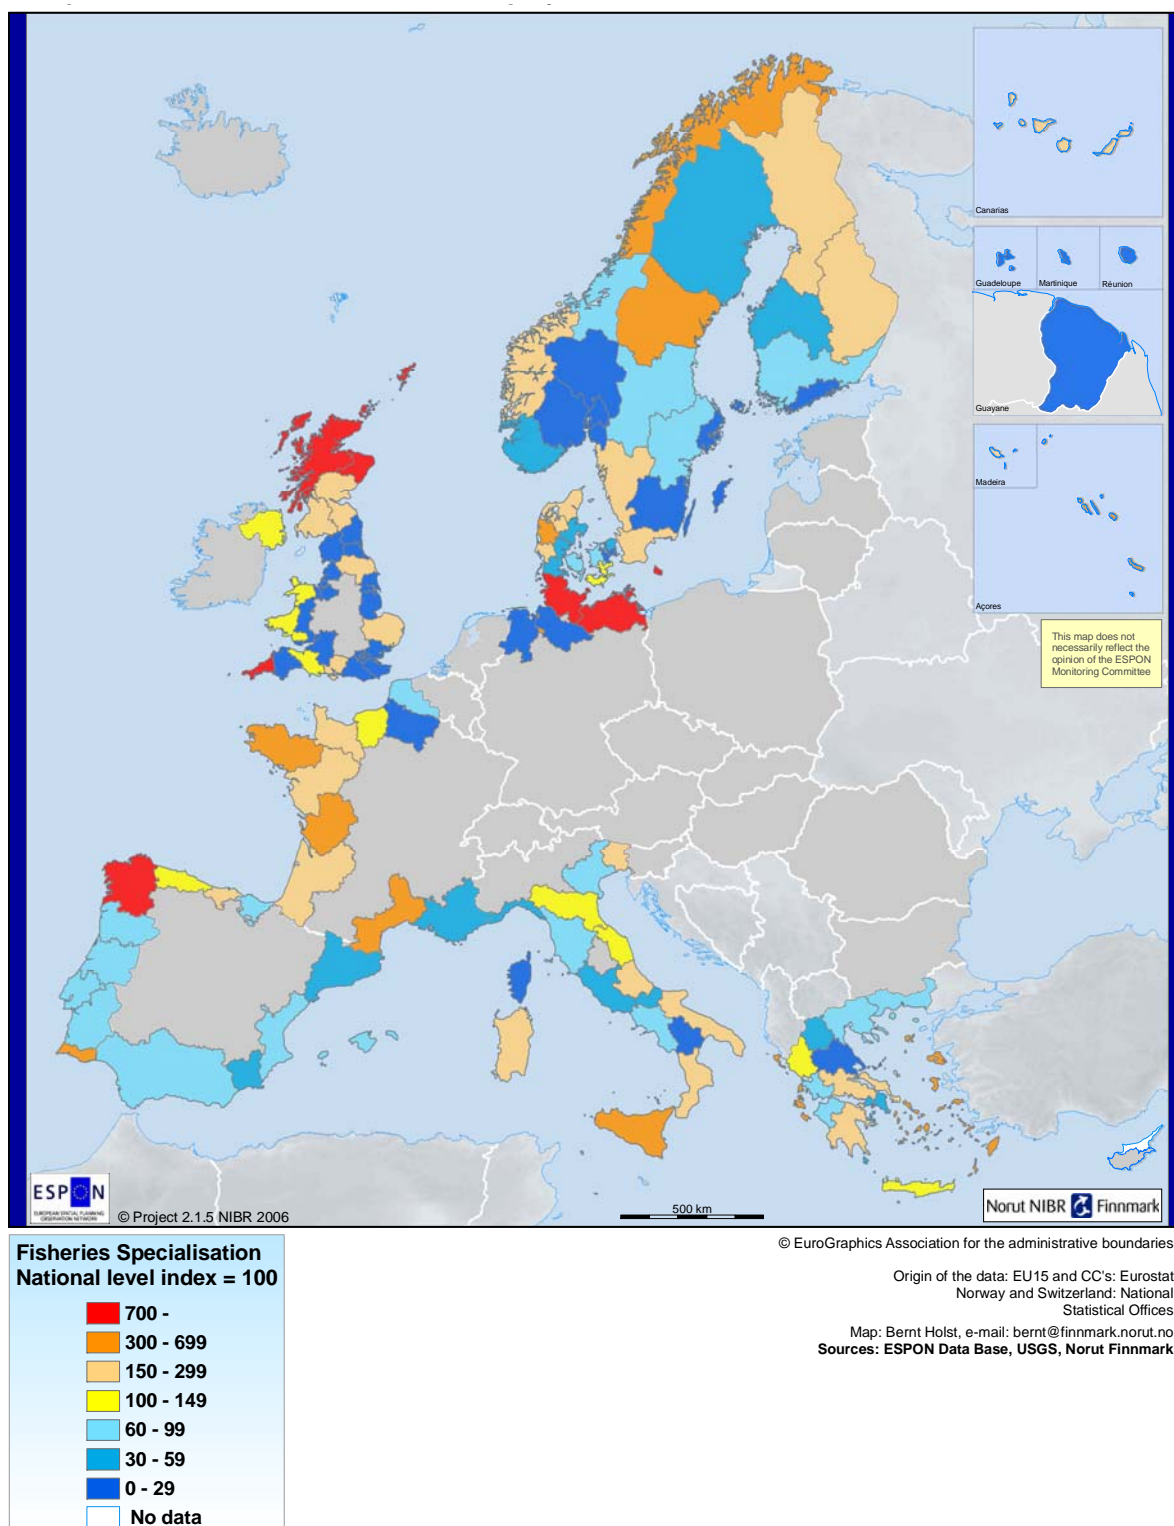

Out of Iceland's eight NUTS 4 territories, all but the Capital region are fisheries specialised. As demonstrated earlier, 7.5 per cent of the Icelandic employees work in the fisheries (2003).

In sum, based on the data WP3 has been able to collect for this section, coastal territories with higher specialisation in fisheries than the national average are:

- Denmark, 40 per cent (six of 15) NUTS 3 territories are fisheries specialised.
- Finland, 33 per cent (two of six) NUTS 2 territories are fisheries specialised.
- France, six territories are fisheries specialised. We cannot estimate shares, as we lack information from certain territories where fisheries may be important.
- Germany, three fisheries specialised NUTS 2 territories were identified, of five coastal NUTS 2 territories.
- Greece 46 per cent (six of 13) of the NUTS 2 territories was identified as fisheries specialised in 1995, and 54 per cent (seven of 13) in 2000.
- Italy 47 per cent (seven of 15) in 1995, 53 per cent (eight of 15) of the NUTS 2 territories were fisheries specialised in 2001.
- Portugal 47 per cent (3 of 7) fisheries specialised NUTS 2 territories was identified.
- Spain 50 per cent in 1995, and 40 per cent (4 of 10) of the NUTS 2 territories were identified in 2001 as fisheries specialised.
- Norway 33 per cent (2 of 6) of the NUTS 2 territories was identified as fisheries specialised.
- Iceland 87.5 per cent (7 of 8) of the NUTS 4 territories was identified as fisheries specialised.
- Scotland 50 per cent (2 of 4) of the NUTS 2 territories was identified as fisheries specialised.
- Sweden, two of eight NUTS 2 territories are fisheries specialised.

In conclusion, the bulk of the countries have a fisheries specialisation of 40-50 per cent, while the fisheries nation Iceland stands out with 87.5 per cent. Below is the fisheries specialised territories mapped on ESPON space.

Figure 5.3 Fisheries specialisation territories: NUTS 2 territories with coastline share of employment in fisheries compared with the share of fisheries employment on national level National level index = 100

The fisheries specialisation indexes (table 5.4-5.16) and their mapping can be analysed on national as well as on European level. The indexes have to identify relative fisheries regions/dependence on national level and European fisheries regions.

On national level the differences between the respective coastal NUTS 2 regions according to position in national fisheries will contribute to knowledge about dependence, specialization, clusters and probably also political processes related with the distribution of fisheries policies measures. In the European countries the figures and the map demonstrates comprehensive differences between the regions in some of the countries, conf. the colours of the map in figure 5.3. The map demonstrates big territorial differences particularly in:

Denmark (Bornholm vs. the urban territories)
Germany (very high specialisation in the Northern territories)
Spain (Galicia vs. the rest of the Spanish NUTS 2 regions)
United Kingdom (Two Scottish regions vs. the other regions)

The analyses on European level should compare the maps in figures 5.1, 5. 2 and 5.3. Comparing figure 5.3 and figure 5.2 demonstrate that importance of including territories in northern Europe in spite of the number of employees in the fisheries in the north are low compared with south (conf chapter 5.4.1) Particularly territories of Scotland, Northern Norway and Northern Norway are important to address in territorial analyses of European fisheries and fisheries policies. Comparing figure 5.1 and figure 5.3 demonstrates the importance of including NUTS 3 regions in the mapping. Many of the fisheries dependent NUTS 3 regions are not included in the fisheries specialised NUTS 2 regions. Many of them are localised in NUTS 2 regions with fisheries employment below the national averages: Among those are:

Spanish NUTS 3 regions outside Galicia
NUTS 3 regions on the eastern coast of UK
Italian NUTS 3 regions on Corsica and on the North West coast of the mainland.
Swedish NUTS 3 regions on Gotland and the Eastern coast
A Finnish NUTS 3 region in the Finnish Gulf

It will be of big importance for European fisheries policies to aware of these regions, particularly if NUTS 2 regions will play the central role in the territorial system of implementation of the CFP.

5.4.7 Changes of the position of the fisheries territories in European territorial system?

Data are only available for Greece (2000), Italy (2001), Norway (2001) and Spain 2001.

Greece: Seven fisheries specialised territories in 2001, six in 1995, of whom two are newcomers (Ipeiros and Kriti), Dytiki Ellada is removed. The newcomers received a high level of FIFG 1995-1999 (indexes of 275 and 119), Dytiki Ellada only 65 (of the nation average level). For the period 2000-2006, there were changes for these territories. Ipeiros' index decreased from 275 to 198, Kriti's index went down from 119 to 69, while Dytiki Ellada went from low 65 to relatively high 151.

Italy: 8 fisheries specialised territories in 2001, 7 in 1995. One new, Emilia Romagna.

Norway: No changes, Nord-Norge and Vestlandet are the fisheries specialised territories in 2001, and the indexes have no dramatic changes.

Spain: Four fisheries specialised territories in 2001, five in 1995. One removed (Pais Vasco). The most important development in Spain is the strengthening of the position of Galicia (from an index of 586 in 1995 to 781 in 2001). Thereby Galicia is, according to our indexes, the most fisheries specialised NUTS 2 territory of Europe.

5.4.8 The fisheries specialised territories and the territorial fisheries system

In the following, there is an outline of the position of the fisheries specialised territories in Norway, Denmark, Greece, Italy, Portugal, Spain, Iceland and Scotland..

Norway has two fisheries specialised NUTS 2 territories: Vestlandet and Nord-Norge. The fisheries of Vestlandet is characterised by pelagic, offshore fisheries, the fleet fishing operates in the North Sea and the Barents Sea (dominated by trawl and purse seine fleet). There are large private fishing enterprises, and the region benefits from an expanding economy, except for the county Sogn og Fjordane. The largest aquaculture farms in Norway are located in Vestlandet, which is the home of the aquaculture pioneers. The main species of the Nord-Norge fisheries is the cod, and the bulk of the fleet is small-scale and inshore, operating in the Barents Sea and in Lofoten. The gear used is predominantly gill net, long line, and hand line. The region has a history of significant state interventions after 1945, also in ownership of fishing companies. The past decades the region has experienced a declining economy (conf the example studies)

Denmark: According to the MegaPesca study, Bornholm is the only fisheries dependent NUTS3 territory in Denmark. While Bornholm by far remains the most fisheries specialised territory in Denmark according to WP3's fisheries specialisation indexes, five additional NUTS 3 territories are fisheries specialised. The island of Bornholm has 43445 inhabitants (2005). In 1996, there were approximately 400 fishers, while there were about 1000 in the mid-1980s. In 2003, 251 persons were registered as full-time fishers. In other words, there has been a significant decline in opportunities to make a living from the fisheries. The fishery takes place in the Baltic Sea, and is dependent on cod, herring, sprat and salmon. Cod is by far the most important, and the development of the fisheries sector depends on the development of the catch and landings of cod. Bornholm is also the focus of the example studies. The other fisheries specialised territories in Denmark are on the west coast of Jutland, from Esbjerg and northwards, and the fleet operates mainly in the North Sea and the Skagerrak sea. The development on the west coast of Jutland in the last decade has been dramatical especially in relation to pelagic fisheries. Esbjerg (Ribe Amt) has traditionally been the centre of Danish herring fisheries (and a major fishing port in other respects, too) but that position belongs now to ports in the Northern part of Jutland, particularly Hirtshals and Skagen (both Nordjyllands Amt). The centres of the demersal fisheries, which are very dependent on cod, plaice and Norwegian lobster, are the ports of Hvide Sande, Thyborøn (both Ringkøbing Amt) and Hanstholm (Viborg Amt). The pelagic species are primarily caught by large purse seine vessels and secondarily by large pelagic trawlers. The demersal fisheries are to a large extent conducted by trawlers but there are also Danish seiners and gill netters.

Greece: According to the Megapesca study, there are two fisheries dependent territories: Lexvos and Samos, which together with the island of Chios are part of the Voreio Aigaio territory. This is the most fisheries specialised territory in Greece. The second most fisheries specialised territory in Greece is also in the Eastern Aegean Sea (Notio Aigaio). The rest of the fisheries specialised territories are in the west, probably based on fishing in the Mediterranean Sea.

Italy: Fisheries specialisation in Italy has a North-East (Adriatic Sea) and South (Mediterranean sea) profile. The most fisheries dependent territory is the island of Sicilia (NUTS 2 territory ITA).

Portugal: The most fisheries specialised NUTS2 territories of Portugal include the South coast of Algarve (NUTS 2 territory PT15) and the Atlantic islands of the Azores and Madeira. The other NUTS 2 territories in Portugal have specialisation indexes way below the average.

Spain: The most fisheries specialised territories of Spain are found in the North, namely Galicia, Cantabria, Principado de Asturias, and País Vasco. The northern fisheries should be divided into two systems: *Galicia* features prominently as a fishing territory, encompassing 40% of the Spanish fleet, most of the marine production, a high degree of fishing-related employment and, above all, big international companies (such as PESCOVA) located worldwide. The exploitation of water resources in Galicia is a strategic sector attracting a great deal of public attention and tourism (according to official surveys, fish and shell-fish cuisine are the second reason why tourists visit the territory), and stimulating the development of rather peculiar international politics. *The Basque Country*, like Galicia, has large fishing companies, although industry continues to be the territory's main source of wealth.

Furthermore, the Canary Islands are fisheries specialised. Curiously enough, the Las Palmas port in the Canary Islands is the one with the largest number of disembarkations, but most of the ships are foreign (Basque and Galician, but also Korean, Russian and Japanese, fishing in the Gulf of Guinea, the Western African coast and the Saharan bank). The local fleet is small and rudimentary.

The not specialised fisheries territories could be characterised by: In spite of the existence of a few well-established ports (Santa Pola, Avilés, Santoña, Tarragona, etc), fishing plays a secondary role in the economy of Catalonia, Valencia, Asturias or Cantabria. Tourism and industry feature prominently in Catalonia and Valencia; tourism and cattle-rearing predominate in Cantabria, mining and base industry in Asturias.

Fishing is rather marginal in the Balearics and Murcia (and also in the Spanish cities in Northern Africa, Ceuta and Melilla). These territories are somehow exceptional within Spain, where fishing is perceived as a crucial economic activity.

Iceland: Iceland is the most fisheries specialised country in Europe. Seven of eight territories are fisheries specialised, the South peninsula and the West region most so.

Scotland: The northernmost NUTS 2 territory of the Highlands and Islands (Orkney islands and Shetland islands) is the most fisheries dependent territory.

5.5 Exemplification of territorial allocation of fisheries policies measures: The territorial distribution of FIFG

5.5.1 The territorial distribution of economic policies measures of CFP (FIFG)

The data on FIFG is from two periods: 1994-1999, and 2000-2006, respectively.

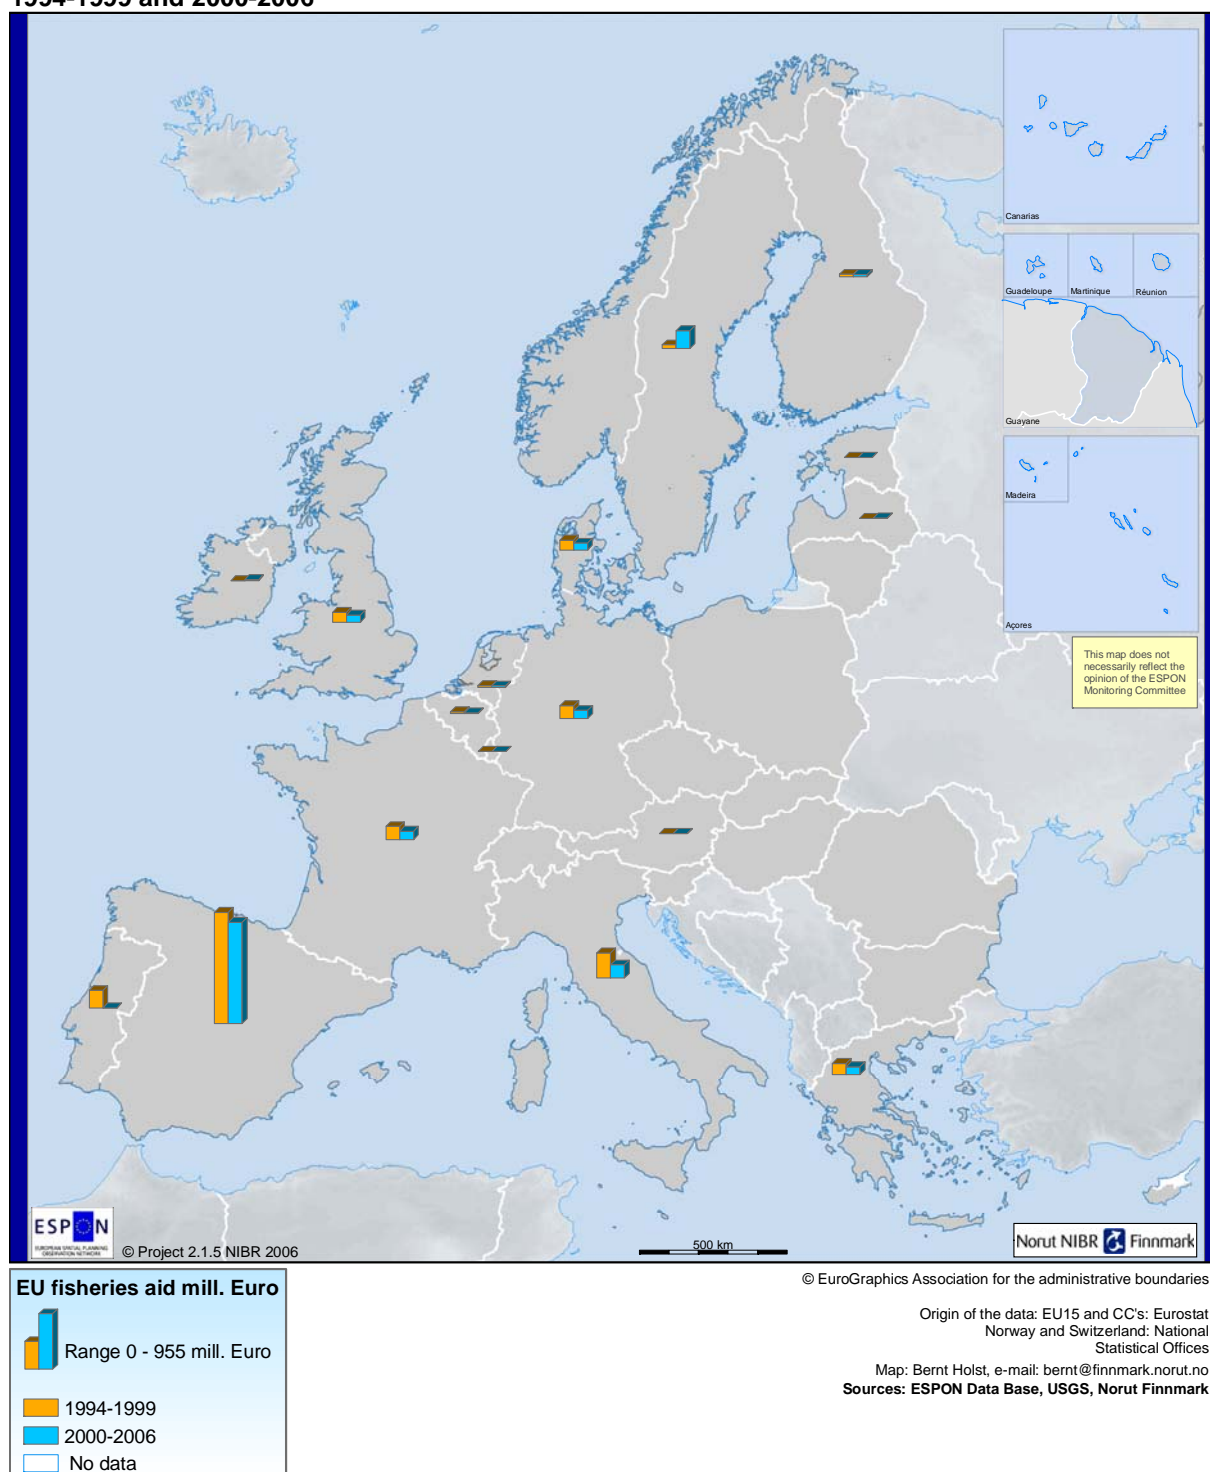

The starting point for estimating the regional distribution of economic policies measures of the CFP (FIFG) at regional level according to the national averages is a comparison of

the proportion of economic policies measures in each of the territories and the national average. As with the fisheries specialisation indexes, this measure will enable an identification of territories with low and high indexes in a national context. The following table shows the absolute figures for EU aid to the fisheries, in Million Euros, for the periods 1994-1999 and 2000-2006 respectively. More details are presented in Annex 4.

The mapping demonstrates that the North-Iberian fisheries system is the most important single target territory for the FIFG, with Galicia as the top recipient of EU fisheries contributions, however, with a decline from 433.49 million Euros in 1994-1999 to 372.48 million Euros in 2000-2006. The support for Galicia is allocated for all four types of actions, a majority however for renewal and upgrading of the fleet and for so called protection and development of aquatic resources.

Figure 5.4 Distribution of FIFG on NUTS 0/NUTS1 level in 1994-1999 and 2000-2006

**Territorial Allocation of the Financial Instrument for Fisheries Guidance (FIFG)
1994-1999 and 2000-2006**

While inland Austria has a relatively small amount of FIFG contribution, it increased by more than 40 per cent from the period 1994-1999 to the period 2000-2006. As a contrast, most other countries have had their EU contribution to the fisheries cut: Belgium by 73

per cent, Germany by 38 per cent, Spain by nine per cent, Finland by 14 per cent, France by 35 per cent, Greece by 30 per cent, Italy by 47 per cent, Netherlands by 17 per cent, and the UK by 28 per cent. Sweden is an exception, with an increase of 382 per cent. The countries' changes are as a rule reflected in the territories, with a few exceptions: For instance, in Spain, ES63 Ceuta is the only NUTS2 territory with an increase (of about 10 million euros) while the other territories have experienced a decline in EU contributions. In France, NUTS2 overseas territory FR94 Réunion is the only one with a mentionable increase, from 1.86 million Euros to 5.35 million Euros. In Italy, NUTS 2 territory ITF3 Campania had an increase from 11.91 million Euros to 22.98 million Euros.

The FIFG distribution at NUTS 3 level in Denmark for 2000-2002 is demonstrated in the following table.

Table 5.17 Denmark: FIFG distribution at NUTS 3-level, DKK

NUTS 3 territory	Name of territory	FIFG subsidy in Danish krone (DKK)	Percentage of total
DK00F	Nordjyllands Amt	48350718	57%
DK00A	Ribe Amt	14212117	17%
DK00B	Vejle Amt	5433798	6%
DK003	Frederiksborg Amt	2475668	3%
DK007	Bornholms Amt	1773086	2%
DK00E	Viborg Amt	3251188	4%
DK00D	Århus Amt	1050308	1%
DK00C	Ringkøbing Amt	736439	1%
DK006	Storstrøms Amt	1365745	2%
DK008	Fyns Amt	2502904	3%
DK009	Sønderjylland Amt	2673219	3%
DK001	København/Frederiksberg Kommuner	382126	1%
DK005	Vestsjællands Amt	675000	1%
Total		84882316	100%

DK00F Nordjyllands Amt is the territory that receives the bulk of the EU contribution, while fisheries dependent island DK007 Bornholms Amt receives a rather small share of only two per cent of Denmark's total FIFG.

Ideally, we would like to relate the FIFG figures to figures on fisheries employment for all countries, but that has not been feasible. However, we have been able to relate data on FIFG for lower level territories in Denmark, Germany, Greece, Italy, Norway, Portugal, and Spain. In order to clarify the "real" importance of FIFG we have developed territorial indexes taking into consideration the position of the fisheries in the respective territories, based on fisheries employment.

5.5.2 FIFG Territorial distribution indexes

FIFG Territorial distribution indexes are calculated on NUTS2 and NUTS3 levels. The procedures of the calculations are as follows:

- 1) Calculation of EURO per year per employee in the fisheries at country level.
- 2) Calculation of EURO per year per employee in the fisheries in the respective territories.
- 3) Calculate the level of each country's lower level territory compared to the country's 100.

- 4) The territories with an index above 100 are defined as territories with FIFG distribution above the country average.
- 5) The results are entered into maps. The coastal territories are plotted with colours according to the index indicating their share of the FIFG.

5.5.3 FIFG Territorial distribution indexes per territories

According to the above description, 7.18 demonstrates indexes of different territories' territorial distribution. While the FIFG-figures are from 1994-1999 and 2000-2006, we are forced to relate them to different years for employment, due to the methodological problems described earlier. The year of employment is indicated in footnotes for each country.

Table 5.18 Indexes of FIFG territorial distribution NUTS 2 level for Finland, France, Germany, Greece, Italy, Portugal, Spain, Sweden and the U.K. (Number of employees in parenthesis)

Financial Instrument for Fisheries Guidance Indicator (FIFG) 1994 - 1999

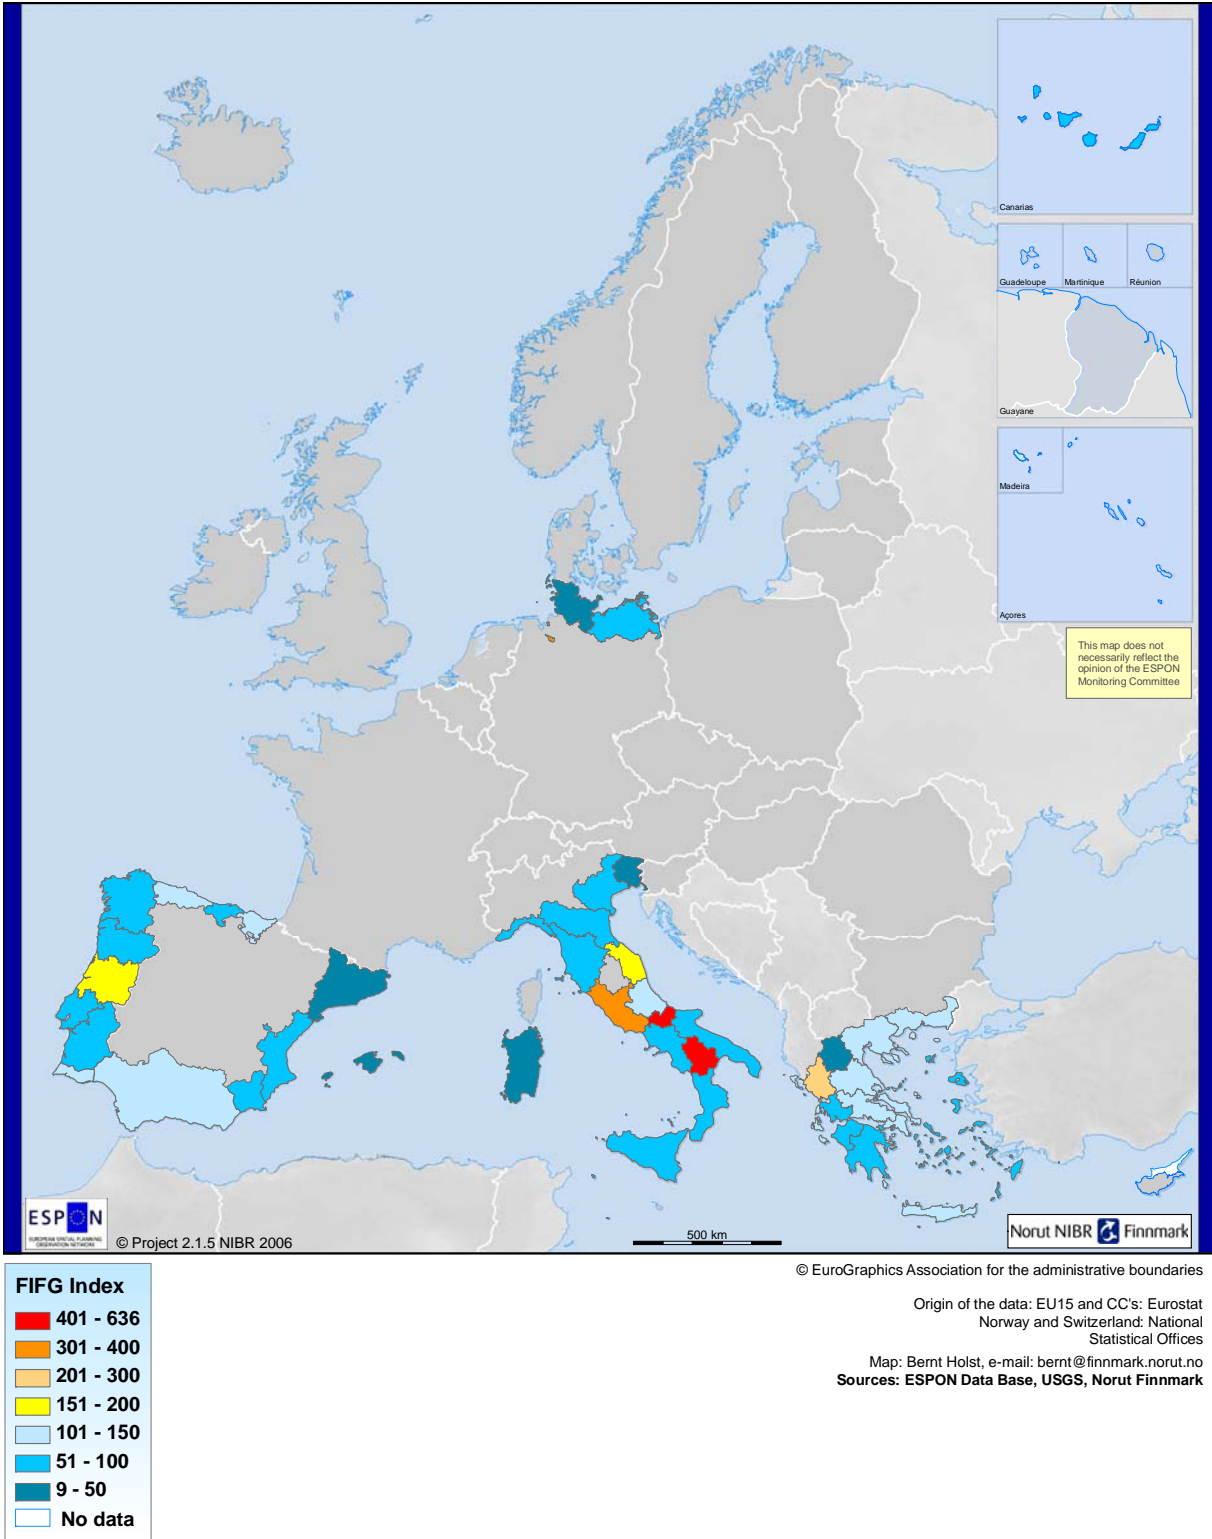

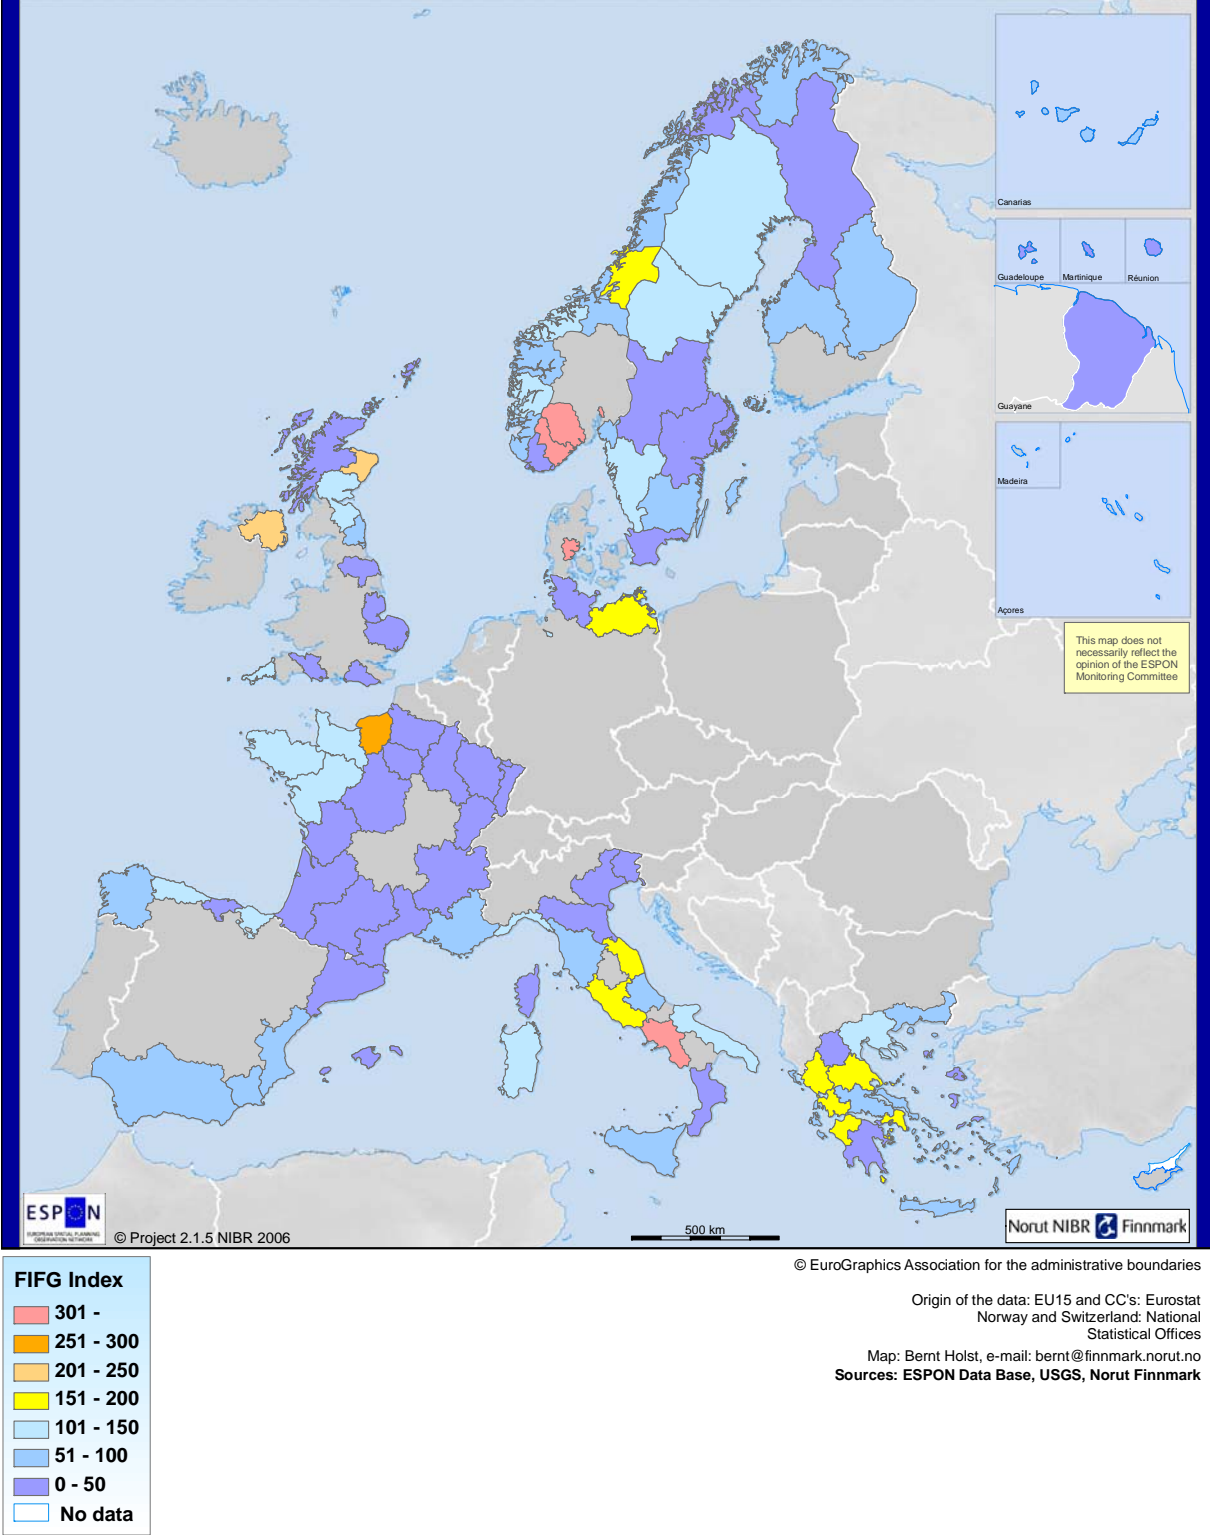

Figure 5.6 Territorial distribution of FIFG 2000-2006: FIFG per employee in fisheries sector at NUTS 2 level compared to FIFG per employee in fisheries sector at national level (Norway 2000, Danish NUTS 3 regions 2000-2002)

Financial Instrument for Fisheries Guidance (FIFG) indicator 2000 - 2006

The analyses of figure 5.6 and figure 5.5 could be based on comparing the figures with 5.1, 5.2 and 5.3 respectively. The main findings of these analyses are that fisheries specialised regions have targeted less support from FIFG than their “fair share” based on the importance of the fisheries in the respective regions. We don’t exactly know why, such knowledge needs to be based on territorial analyses of the distribution processes of FIFG. This should be an issue for further research. De facto the fisheries regions (specialised or dependent) receive much less per fisheries employed than marginal fisheries regions do.

5.5.4 FIFG and the territorial fisheries systems

In Norway, the indexes demonstrate that NO05 Vestlandet (including NO051 Hordaland, NO052 Sogn og Fjordane and NO053 Møre og Romsdal) is favoured in terms of economic measures, and NO07 Nord-Norge (including NO071 Nordland, NO072 Troms and NO073 Finnmark) is discriminated. This is especially evident when held against the fisheries specialisation indexes, which were 204 for NO05 Vestlandet and 487 for NO07 Nord-Norge in 2001.

For Denmark, it is not surprising that DKK00F Nordjyllands Amt has a high FIFG index of 250. However, it is somewhat unexpected that DKK00E Viborg Amt has a low FIFG index of 45, considering that one of Denmark’s largest fishing harbours, Hanstholm, is here. While DKK00C Ringkøbing Amt has as much as 1104 fishers, it has an index of only 4, and the opposite is the case for DKK00B Vejle, which has only 31 fisher employees, but a high index of 952. DKK007 Bornholms Amt has a low FIFG index of 33, even though it is a fisheries dependent territory.

For Greece, according to the estimated indexes, there is no favouring of the fisheries specialised territories. The east territories Voreio Aigaio and Notio Aigaio receive only 51 and 66 per cent of national average per capita level, while the fisheries specialisation indexes for the same territories for 1995 were 812 and 569 respectively. The major trend seems to be favouring of not fisheries specialised territories. There are some changes from the FIFG-period 1994-1999 to 2000-2006. NUTS2 territories GR11, GR22, GR24 and GR43 have all gone from having a FIFG-index above 100, to a rather significant drop. Only one territory that has gone from below to above 100: GR23 (from 65 to 151).

For Italy, as for Greece, there is no favouring of fisheries specialised territories. FIFG period 1994-1999: Sicilia 72 (compared to its fisheries specialisation index of 435 in 1995), Friuli-Venezia Giulia 9 (fisheries specialisation index 337 for 1995), Sardegna 34 (fisheries specialisation index of 254 in 1995), Puglia 80 (fisheries specialisation index of 225 in 1995) of the national per capita average. There is a clear pattern of favouring the central, not fisheries specialised territories as Lazio (320) which has a fisheries specialisation index of only 77 in 1995, and Molise (429), with a fisheries specialisation index of 0 in 1995. Compared with 2000-2006, there has been a significant drop in the FIFG index for many territories. IT71 Abruzzo has gone from 141 to 80. IT8 Campania has gained, gone from 96 to 351, and IT91 Puglia from 80 to 102. ITB Sardegna has gone from a low index of 34 to just above average to 109.

For Portugal, there is favouring of the fisheries specialised islands (the Azores 135, and Madeira 116). However the most important target territory is the Centro territory (196), which is not a fisheries specialised territory.

For Spain, we do not detect a specific pattern. Two of the northern territories are favoured: Principado de Asturias with an index of 132 and a fisheries specialisation index of 112 in 1995, and Pais Vasco with a 118 and a fisheries specialisation index of 115 in

1995. The other two territories are not favoured; Galicia has an index of 80, held against its fisheries specialisation index of 586 in 1995, and Cantabria with an index of 86, and a fisheries specialisation index of 333. The Canary Islands and its type of fishing is definitively not favoured. As opposed to Italy and Portugal, there is not favouring of central areas

In conclusion, most of the fisheries specialised territories are discriminated, or at least not favoured, in the distribution of the FIFG. And vice versa: Central areas are favoured, which is probably a result of the national implementation processes. In other words, the CFP demonstrates a higher level of support per employed in economies where labour has higher alternative value than in the fisheries specialised territories. This situation has not changed much from 1994-1999 to 2000-2006.

5.5.5 The territorial dimension of the fisheries conservation policies of CFP

As one of the two major parts of CFP the territorial distribution of variables as fish quotas, harvesting, landings and capacities to put into catching is a central part of a territorial impact analysis of CFP. IR 2 demonstrated however the lack of data on regional levels on these topics. The mapping in IR3 organised under WP 2 is also based on distribution between NUTS 0 territories (the respective countries). The impression is however that these types of data are available for NUTS 2 territories in some very few countries. We have received data only from Italy and Greece. These data demonstrate, among other things, that some territories in a very dramatic way are targeted by the declining harvesting opportunities; and how specific territories are targeted vary very much. The infrastructure for carrying out these types of analyses has to be developed as part of TIA, but will not be completed through this project.

5.6 Exemplification of the direct impacts on social cohesion: Changes in fisheries employment after 1995

The mapping of the fisheries employment based on the ESPON database on NUTS0/NUTS1 level demonstrated a strong decrease of the fisheries employment in the southern areas in west and east, but the map also confirmed that south of Europe still is the core territories for fisheries employment in Europe.

We suggest estimating the *direct* impacts on the fisheries by analysing the fisheries employment development. In this exemplification only territories where we have time serial data on fisheries employment are included.

Table 5.21 Employment change in fisheries in absolute figures for Greece, Italy, Norway, Portugal and Spain.

Figure 5.7 Changes in fisheries employment changes at NUTS 2 level according to national average employment changes in fisheries. National average employment changes in fisheries = 100.

Shift-Share Employment

Fisheries employment changes in the coastal territories in more detail:

Greece: 13 coastal NUTS 2 territories, where six of them were fisheries specialised in 1995. Three territories have increased their fisheries employment in absolute figures: GR13 Dytiki Makedonia, GR22 Ionia Nisia, and GR43 Kriti, only Ionia Nisia was fisheries specialised in 1995. In Kriti and Dytiki Makedonia the fisheries had a very modest position in 1995 (index of 31 and 13, respectively). The growth in Kriti fisheries is so strong that the territory became a specialised fisheries territory in 2000 (index of 123). Both of the growth territories are favoured in the distribution of the FIG 1995-1999. The most fisheries dependent territory of Greece (GR410Voreio Aigaio) has a strong drop in fisheries employment (from 3400 in 1995 to 211 in 2000), and in 2000 GR42 Notio Aigaio has become the most fisheries specialised territory.

Italy: 15 coastal NUTS 2 territories, where seven of them were fisheries specialised in 1995. Four territories have an absolute increase in fisheries employment from 1995 to 2002 (IT13 Liguria, IT4 Emilia-Romagna, IT6 Laxio and IT91 Puglia), and seven territories have an increase compared with the national average; the four already mentioned, and IT51 Toscana, IT53 Marche, and ITA Sicilia. Only one of the fisheries specialised territories has increased the fisheries employment (the south territory Puglia). The most dramatic increasing is in Liguria in the north, which has a very low specialisation in fisheries (index 35 in 1995). The most fisheries specialised territory (Sicilia with an index of 431 in 1995) has modest absolute decreasing, but a better development than the national average. Lazio is favoured in the FIG-distribution and is a winner in the growth processes. However it has still a very low representation of fisheries (35 in 2002, 29 in 1995)

Norway: Six coastal NUTS 2 territories, of which two are fisheries specialised. All territories but NO01 Oslo og Akershus have had an absolute decline of fisheries employment; NO01 Oslo og Akershus has had an increase from 93 to 99 from 1997 to 2001. NO07 Nord-Norge has had a decline of 2281 fishers employed, while NO05 has had a decrease of 1206. However, when looking at the indexes, the picture is different, then Vestlandet has had a growth compared to the decrease on national level (index 102). Vestlandet is also the winner territory of the battle for the economic support distribution.

Portugal: Seven coastal territories where three of them are fisheries specialised in 2001, of which two have a high fisheries specialisation (Algarve and Azores with 2001 indexes of 593 and 431, respectively). Portugal has an enormous decrease in the fisheries employment after 1995 (40%). Thus all territories have an employment decline, but relative to the national average two territories (Norte and the Azores) have an employment increase. Azores (and Centro) is also favoured in FIG-distribution.

Spain: Ten coastal NUTS 2 territories, of which five were fisheries specialised in 1995. One of the territories has increased the fisheries employment (Galicia). Galicia and Principado de Asturias are the only two territories with increasing indexes compared to the national average. Both of them are part of the northern fisheries system of Spain. The rest of the territories have a strong employment decline, this development also include the fisheries on the Canary Islands. Principado de Asturias is also the “winner” in Spain for the FIG.

In more detail the changes of the employment in the Spanish fisheries can be described as: Since 1987 –when Spain adhered to the EU- the number of fishers has decreased, being such decrease more or less accelerated according to the Autonomous Community. There has been a reduction of working population in the fishing sector since 1987 in all Spanish coastal territories except for Asturias -where the labour employed in fishing remained stable throughout the whole decade- and Galicia. In this community, the

population employed in this sector did not stop increasing until 1999, when there was a slight point of inflection, but the upward trend recovered during the following years.

The number of young people who choose to work on the sea is much lower than that of people over 60 or 65 who decide to come into retirement. There is a self-regulation in the access to this sector, which reflects on the fact that the percentage of unemployed has not increased since fishers –who have difficulties to keep on working- either prefer to look for a new way to earn a living in their locality (to run a business, to become an intermediary between fish distribution networks, to benefit from the tourist boom on the coasts, etc.) or decide to emigrate before becoming part of the fisheries unemployment statistics.

The decrease in the number of fishers is due to several interconnected facts, being the most outstanding:

The crisis of the artisanal and estuary fishing -linked to self-consumption and traditional systems of near sea management-, caused by both the exhaustion of the fishing grounds (quite apparent in some areas of the Mediterranean Sea) and the successful competition of other activities (tourism, employment in services or industries), as well as by the unfeasibility of low profitable models of work in vessels. Artisanal fishing is moving backwards but, at the same time, *fishing as a sport or a hobby* is increasing among the locals who have already retired or who are engaged in another remunerated activity. The cutback in the number of licenses to fish in EU and third country waters. The fleet fishing in near seas (e.g. Saharan, Gran Sol and Irish fishing grounds) had to reduce their capacity and, of course, their staff. The same happened to the fleet operating in NAFO (northwest Atlantic fishing grounds), Southern Africa, Falklands, Chile or Seychelles waters, among many examples of far-away fishing areas. However, this situation -which always results in the decrease of the workforce- hides the evidence that a number of Galician, Andalucian or Basque fishers that is difficult to calculate have settled in Ireland, Guinea-Bissau, Namibia, Saint Pierre et Miquelon, Chile, Argentina and many other places.

On the other hand, the data on the active and working population in fisheries have seldom included shellfish fishers, who make possible that thousands of tons of molluscs and crustaceans come into the market, but who are undergoing a professionalization process in many cases not yet completed.

From these descriptions, it can be concluded that:

- It looks like the level FIGF targeted the respective territories are more important for the employment development in the territories than level of fisheries specialisation.
- Therefore positive employment development is more frequent in territories that are not fisheries specialised than in territories with high representation of fisheries.
- The importance of separating between factors as fisheries structures in the respective territories, position in the FIGF-distribution and level of decreasing of fish quotas and landings.

5.7 Exemplification: Indirect Socio-economic Impacts of CFP

While we demonstrated the direct impacts of CFP on fisheries employment in 5.6, we will in 5.7 exemplify indirect impacts. Those can be on demographic figures, and figures

indicating changes in living conditions. According to the hypotheses the direct impacts can have unintended side effects which will influence the fisheries specialised or/and fisheries dependent territories position in the European regional system. We analyse these dynamics from two starting points.

The first is that changes of the fisheries employment can influence on migration processes. While employment declining can cause out-migration of households, lower birth rates and population declining, employment increasing can cause immigration, growing birth rates and population growth. These impacts are demonstrated by using analyses from the ESPON-project 1.1.4., which have included more data than the ESPON databases.

The second is that employment changes in the fisheries can influence on incomes and consumption. These relations can take different forms. Unemployment impacts of the development in the fisheries can cause declining incomes, while successful structural changes in the regional economy can cause income and consumption growth. These exemplifications are based on data from the ESPON databases, but there are a lot of loopholes in these data. However such data is probably the best way to analyse changes of social issues.

The result of the indirect impacts is changes of the position of the fisheries regions in the European territorial system. By these analyses we can discuss the role of fisheries regions in forming economic centres of gravity in the European economy and developing, and in the exploring of new types imbalance shaping processes.

5.7.1 Population changes in fisheries specialised territories (1995), coastal territories and all territories (NUTS 2), ESPON space (e.g. total number of population)

This part of the study is based on comparing aging and migration variables (from ESPON project 1.1.4) and income and consumption figures. Indicators used in the 1.1.4 project that can elucidate the development in the fisheries territories are:

- 1) Annual population change
- 2) Score on indirect depopulation indicators
- 3) Number of children per women
- 4) Part of people over 65 years in the population
- 5) Different types of population dependency rates
- 6) Migratory balances
- 7) Exterior migration rates
- 8) Depopulation trends (2000-2050)
- 9) Depopulation indicators

The maps of 1.1.4 demonstrated that also territories which have experienced demographic growth the previous years can face ageing and depopulation problems in the near future. These challenges do of cause differ between the territories within and between countries, and between the countries as well.

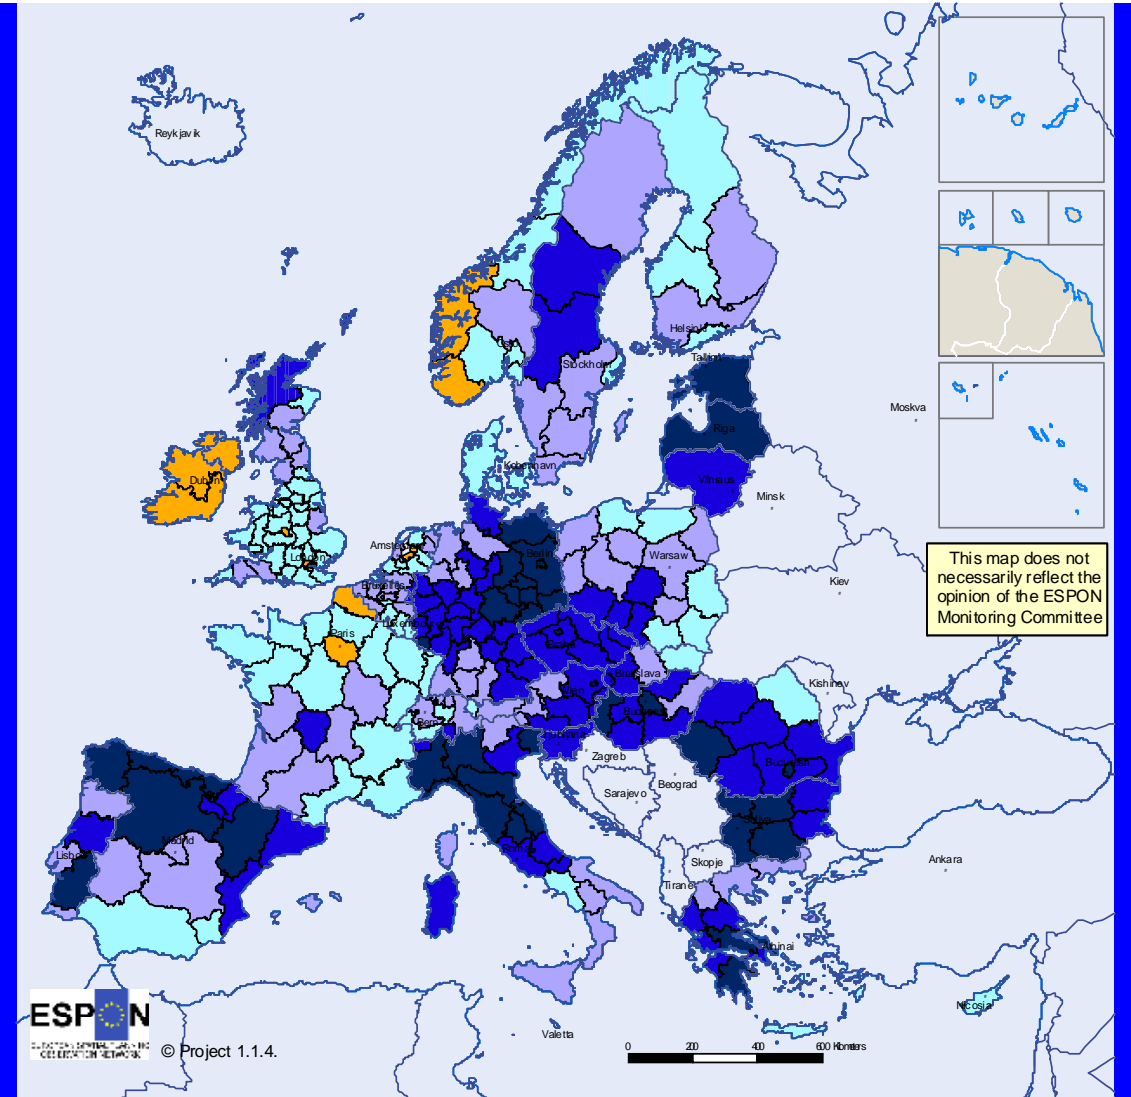

In order to analyse the particular development in fisheries regions and between those regions and other regions we compare the mapping in figure 5.3 and the demographic mapping in 5.8, 5.9 and 5.10. These comparing demonstrate that while fisheries territories

in Portugal, Greece and Spain have to concern with different types of aging problems, Danish, Norwegian and Italian fisheries territories are affected by migration imbalances.

Most of the analyses from ESPON project 1.1.4 is based on data and mapping on NUTS 3 level. Since most of the fisheries data are on NUTS 2 level we have used two of the NUTS 2 level maps from the final report of 1.1.4 in this part of the report. These tables are followed by exemplifications where population changes is analysed against collected data on fisheries employment changes. Maps from 1.1.4 analysing NUTS 3 level is in the annex.

Figure 5.8 Depopulation trends in NUTS 2 territories. (page 153 of final report of 1.1.4)

Depopulation trends by NUT2

Variation of population, 2000-2050 (%)
Model A

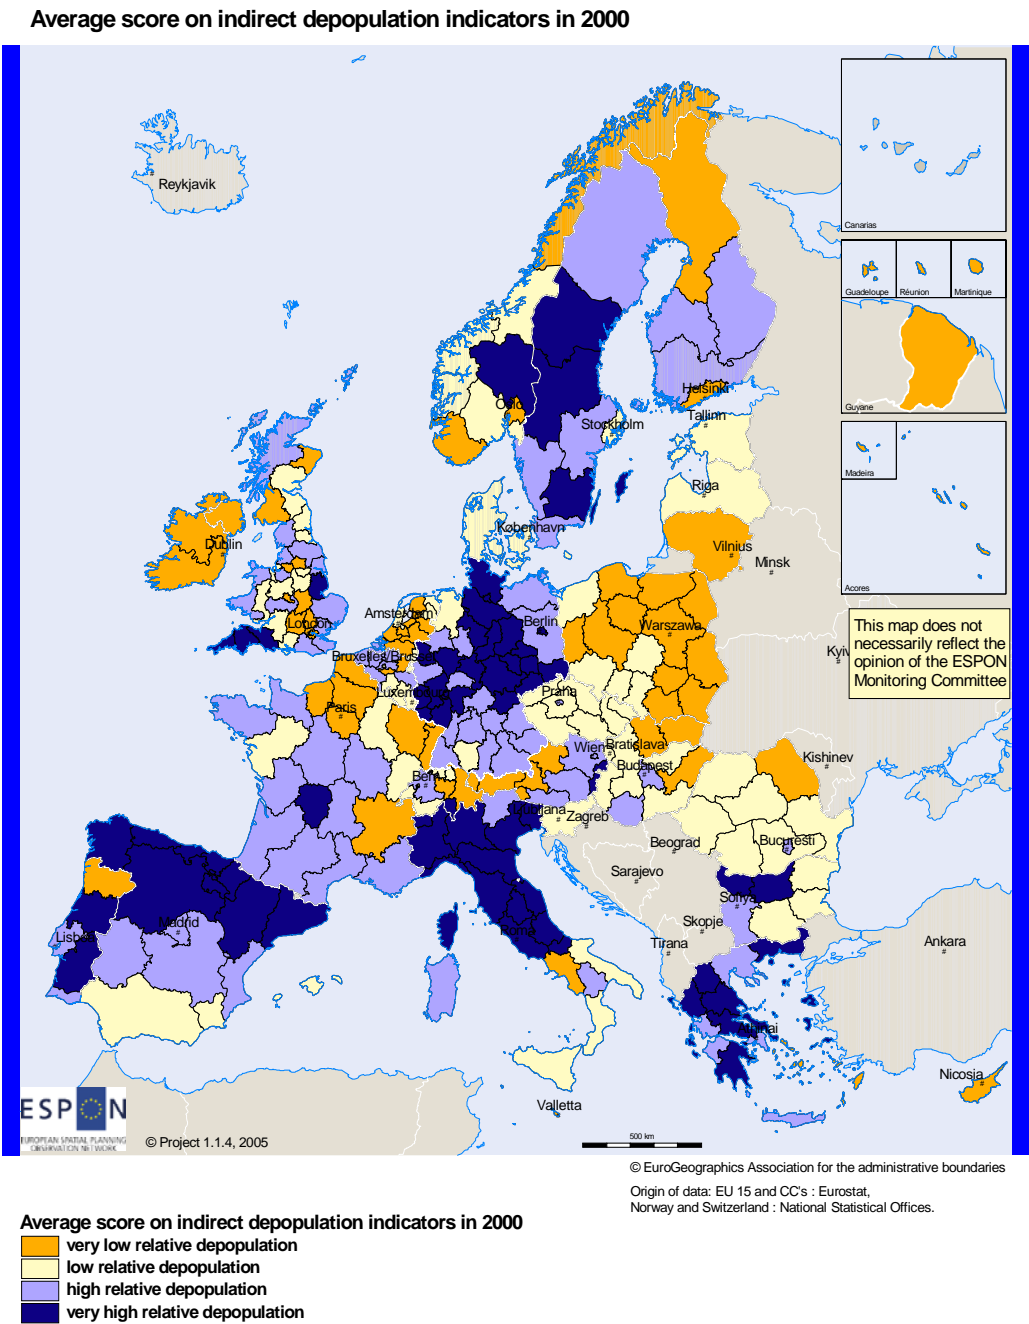

© EuroGeographics Association for the administrative boundaries
Origin of the data: Eurostat and others
Source: ESPON Data Base and others

The main finding based on comparing of the mapping in 5.3 and 5.8 is the negative forecasts in the South European fisheries territories and territorial fisheries systems compared with the Northern regions.

These tendencies are confirmed by the mapping depopulation indicators in 2000.

Figure 5.9 Structural depopulation scores 2000. NUTS 2 level.

The *main* challenge of the TIA of CFP is to integrate the fisheries territories into the demographic trend analyses. We have not been able to finalise this typologisation in this project, however one starting point is analyses of population changes in fisheries regions. These is exemplified in the 5.22, such analyses should also include changes of fisheries employment and the level of fisheries specialisation.

Below is an exemplification where the population development in fisheries specialised territories (based on the collected data in 2.1.5) are demonstrated

Figure 5.10 Population changes in fisheries specialised territories. 1995-1999. Percent.
NUTS 2 territories. For Denmark: NUTS 3

Population changes in fisheries specialised territories 1995 - 1999

Denmark: From 1995 to 1999, Denmark had a population growth of 1.80, and in the period 1996-1999 the coastal territories experienced a population change in the range from -0.45 to 1.02 per cent. Bornholm as the most fisheries specialised territory with an

index of 754 in 2001, had a population decrease of 0.45 per cent. The rest of fisheries specialised territories have an increase of about 0.20. Six of the coastal territories have a much higher increase, and only one has a lower.

Conclusion: Danish fisheries specialised territories have a more negative population development than most of the other coastal territories. This could be related to the decline of fisheries but it is probably also partly related to the fact that most of the fisheries specialised territories are coastal territories, which are placed comparatively far from the urban growth centres of Denmark due to location of the sea areas where Danish fisheries takes place. The non-specialised territories are generally located in a better position to hook up to the urban growth centres of Denmark as commuting communities.

Greece: There is a marked difference in population change among the territories, and also among fisheries specialised territories. The data material demonstrates that the average population development in the fisheries specialised territories is more positive than in the other coastal territories.

Italy: As many as six coastal NUTS 2 territories in Italy experienced a population decrease from 1995 to 1999, and four of them are fisheries specialised. Thus it can look like the fisheries specialised territories are more vulnerable for population declining processes than the other coast territories.

Norway has a very uneven population development among the territories (from a 5.50 per cent increase in Oslo/Akershus to -1.60 in Nord Norge). Vestlandet has a population growth of 1.60, which is far below the other coast territories in the south.

Portugal: A very strange situation where the differences between particularly the fisheries specialised territories are significant. While the population growth in the Algarve territories is over seven per cent, the population decrease in Madeira is more than three per cent. The third fisheries specialised region (Azores) has also population decline. All of the others (except for Alentejo) have population growth. If we suppose that the growth in Algarve is generated by the tourism, the conclusion is that the population is decreasing in Portugal in fisheries dependent territories.

Spain: It looks like the picture is very clear: The only territories with declining population are the fisheries specialised territories in the north. However it is very difficult to establish a cause-effect relationship between the deep changes experienced in fisheries in Spain during the last 20 years -a sector in continuous restructuring- and the demographic evolution of the coastal territories deeply dependent on fishing, since many of such territories have seen tourism as strong trigger of endogenic development, an activity which has created employment and encouraged the settlement of population in the territory

Substantial conclusions:

- The fisheries specialised territories have more frequent than other coastal territories population declining processes.
- Therefore these territories have less favourable positions in the national territorial systems since 1995 (measured by population changes which is a “good” indicator in the north of Europe, but we are not sure in the south).

5.7.2 Exemplification: Changes in living conditions in Fisheries territories compared with the the European development

Developing of similarities between territories in living conditions is an important of the developing of territorial social cohesion. We have exemplified these types of analyses by using indicators on average income changes and consumptions. The databases lack data from many countries, but the should be a potential for building a sustainable monitoring datarecording system. As in 5.7.1, these tables and mapping should be compared with the map in figure 5.3 and the tables 5.4 to 5.16.

Figure 5.11 Income changes, different periods. Per cent. NUTS 2 level. NUTS 3 level for Denmark.

Income changes in percent, Nuts 2. Denmark Nuts 3.

Based on comparing with figure 5.3, we can very preliminary conclude for the countries we have data that:

Greece: There are very strong differences in income growth between the coastal territories, from 19 % on Kriti to over 54 % in Ipeirios and Notio Aigio. This is also the situation among the fisheries specialised territories, very strong differences between the two most fisheries specialised territories (Voreio Aigaio +30 % and Notio Aigaio + 54%).

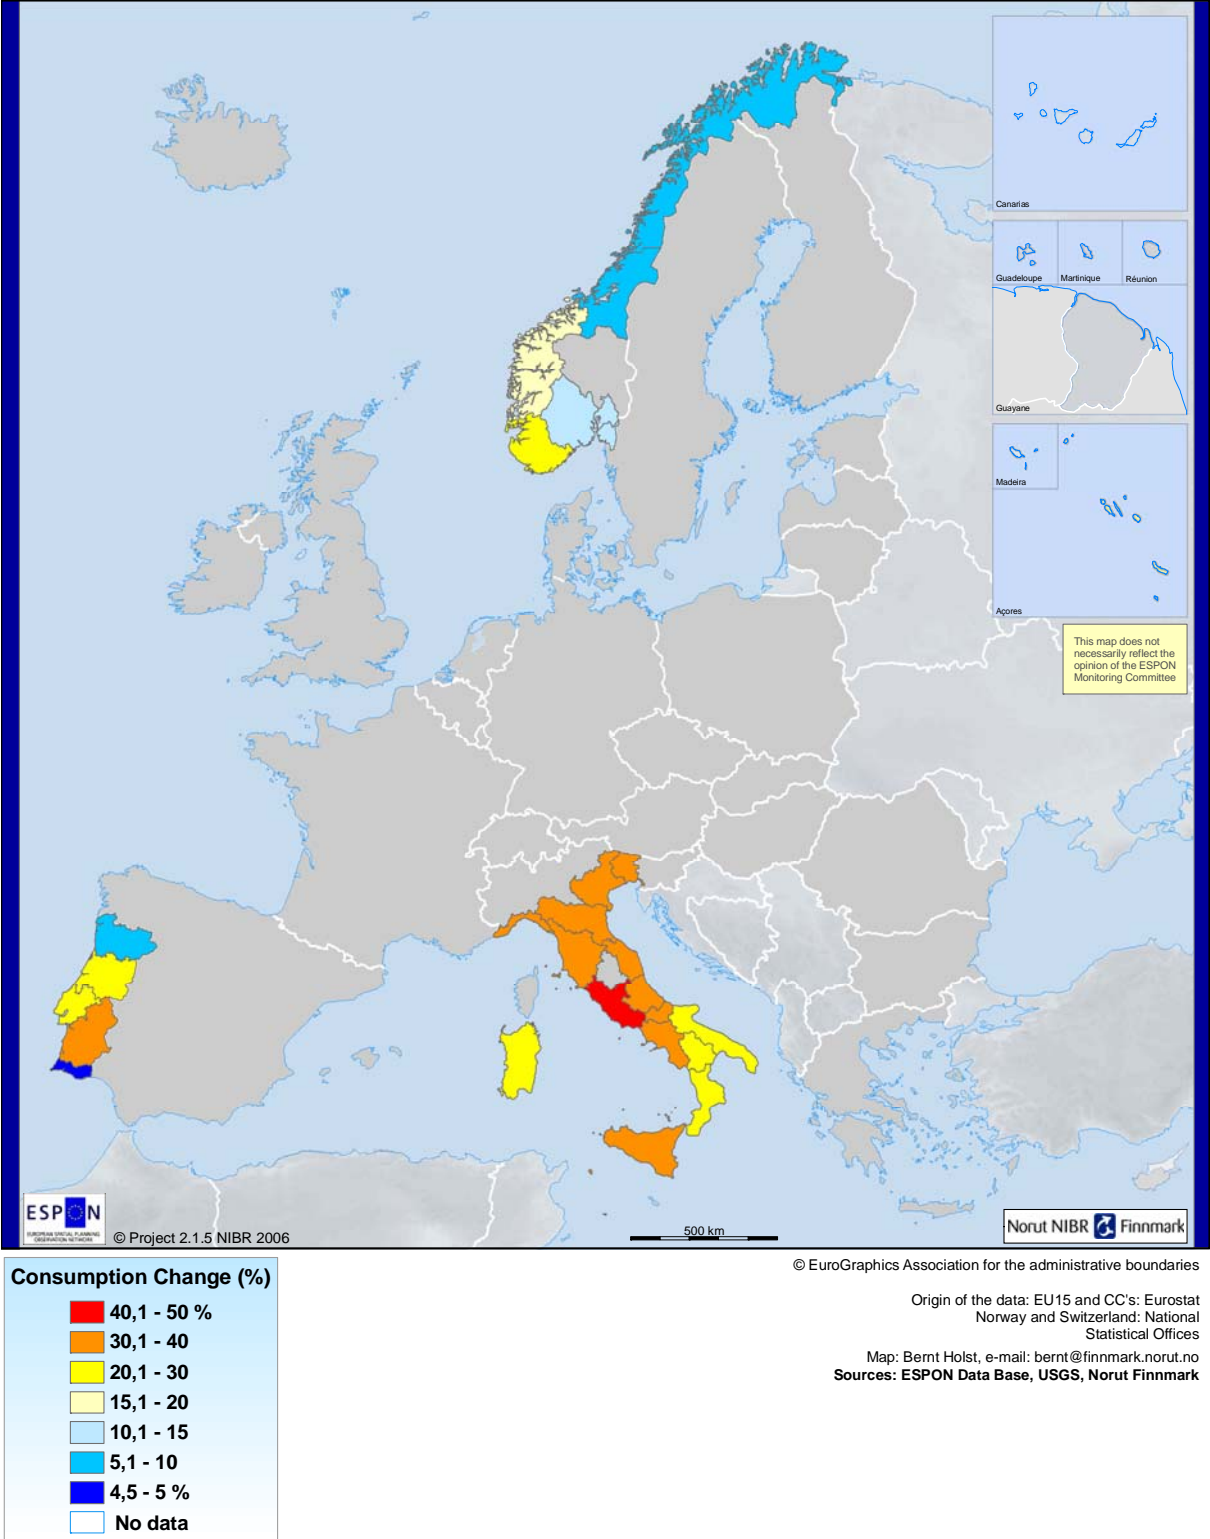

Italy: The incomes development differences among the territories are very small. The impression is however that the income growth in the fisheries specialised regions (except for Sardegna) is lower than in most of the coastal territories.

Norway: As in Italy there are small income development differences among the coastal territories. But Northern Norway has the lowest incomes growth.

These types of living conditions analyses can be enlarged by analyses of household consumption. We have no advice concerning this question. It looks however like the data condition is even worse regarding the consumption figures than the incomes data. Figure 5.12 demonstrates a mapping based on available data today.

Figure 5.12 Household consumption growth (different periods). Per cent changes. NUTS 2 level.

Household Consumption Change Nuts 2

This mapping should also be compared with the mapping of figure 5.3. The preliminary results (regarding respective countries) are:

Italy: Lowest level of growth in the fisheries specialised territories of the south (Puglia, Calabria and Sardegna)

Norway: Very strong development differences, with a minor change in Northern Norway compared with the southern territories.

Portugal: As in Norway very strong differences among the territories, but systematic according to the positions of the fisheries specialised territories.

Conclusion of analysing changes in living conditions indicators:

- It looks like the living conditions in fisheries regions have not followed the pace of income growth and consumption in most of the other European countries which can reflect a marginalisation of the fisheries regions (opposite the aims of cohesion)
- ESPON should assess the possibility for developing an analysis system monitoring the changes in living conditions in fisheries regions and its impacts for these regions position in the overall territorial system.

5.8 Revisiting the cohesion hypotheses

As mentioned in the beginning of the analysis, IR 1 specified several hypotheses on social cohesion impacts of CFP. Below we discuss how the analysis can contribute to developing these hypotheses.

1) The position of fisheries, fisheries policies and fisheries territories vary between the European nations and among the territories inside the countries.

The typologies of fisheries territories confirms the variations of the position of the fisheries in the European regions as the specialisation indexes varies from 2 to over 800 (compared with national average of 100). The figures also demonstrate the differences regarding the position of the fisheries in the European countries, and identify national and transnational fisheries specialised territories with wide extension.

Based on the mappings we can identify at least:

- a. An East Aegean and East Mediterranean (small scale fishing), embedded on the Greek and Italian islands;
- b. The global North Iberian fisheries, including territories in Spain, Portugal and France.
- c. The North Sea/Atlantic fisheries of Denmark, UK, France
- d. The Barents Sea fisheries of mainly of Norway.

These territories have a stable position as fisheries territories in the European territorial system.

Concerning the CFP impacts the relations and the balance between these territory it looks like the economic efforts of CFP mainly has strengthen the global Northern Iberian system, but may be not so much after 2000 as in the 1990s.

2) While the principal objective of the CFP is to develop the fisheries and protect the fisheries resources, the CFP can have side effects as declining fisheries employment, increasing unemployment, decreasing average incomes, population decreasing due to increasing out migrations and decreasing immigrations, altered age composition.

The hypotheses are probably confirmed in the very restricted analyses we have been able to carry out, due to lack of data. We can confirm fisheries employment decreasing and can probably also relate this to parts of CFP, and the population figures are more negative in fisheries territories than in other coastal territories. The average incomes in all territories have increased much, but more in not fisheries specialised territories than in others.

In our examples (comparing the fisheries specialised territories with the mapping of ESPON project 1.1.4.), all types of fisheries territories will experience impacts due to actual demographic trends as aging processes and negative migration balances. These challenges will appear also in territories which have experienced demographic growth the previous years. These challenges seems however to differ between the territories and the countries. While fisheries territories in Portugal, Greece and Spain have to concern with different types of aging problems, Danish, Norwegian and Italian fisheries territories are affected by migration imbalances.

3) The fisheries specialised territories, mainly in remote areas, have more negative development in population, employment and income than the average European territories.

In order to carry out such analyses we need to include fisheries data and typologies into typologies covering the EU territorial system, mainly the polycentric system. Unfortunately the results of that work is not finished yet (see chapter 1)..

4) The incidence of the CFP on regional level is not consistent with the social and economic cohesion objectives of EU.

This hypothesis is confirmed by analyses of FIFG data 1994-1999, and 2000-2006. The biggest analyses and also political challenge is however to include fisheries harvesting (quotas, landings) in these types of evaluations, these will need building an extensive data recording infrastructure.

5.9 Territorial Impact Assessment (TIA) and the assessment of CFP

Due to the challenge explained earlier, in terms of lack of relevant data, we have carried this TIA as an “experiment” which major result is to make inputs to a recipe for how to use TIA as a tool in CFP assessment. Thereby the main objective will be to specify the preconditions that have to be available for assessing impacts on CFP for the European territorial system. In spite of that the most of the preconditions is not available in most of the European countries today, we will present the results of the analyses in order to elucidate what types of knowledge an impact analysis can bring.

General experiences

1. CFP is a small and “narrow” policy area probably having *significant direct impacts on a very low territorial level*. The example studies as the Norwegian analyses from Norut demonstrated that the fisheries policies are present in only five per cent of the coastal municipalities.
2. There is a dramatic *lack of data* on territorial differentiation in the policy implementation. This experience includes data on the territorial distribution of the fisheries policies measures and socio-economic data of relevance in the territories. The previous consists of key data sources as employment status in the fisheries and its sectors, and relevant time serial data. We therefore experience

enormous challenges at the moment in order to be able to realise the TIA in a traditional “unorganised” policy area as the fisheries.

General experiences from using fisheries data on NUTS 2 level from specific European countries

1. In developing TIA for the CFP and the fisheries it is important to develop fisheries territories typologies that do not marginalise the territorial importance of the European fisheries. We have demonstrated that identifying typologies by taking the nation level as a reference can be a possibility. In any case it is important to extend the “fisheries dependence perspective” which often not cover the wider territorial position of European fisheries.
2. Our examples, using the national level as a reference, demonstrate that the fisheries have a relative important position in about 30-50 per cent of NUTS 2 European territories with coast lines. That can be one path leading to the territories that can be focused in TIA of CFP.
3. TIA of CFP should also show attention to that the European fisheries probably can be divided into several different territorial fisheries systems including also transnational areas, and that TIA should be aware of including all of them. We can identify at least: (i) An East Aegean and East Mediterranean (probably small scale), embedded on the Greek and Italian islands; (ii) The global North Iberian fisheries; (iii) The North Sea/Atlantic fisheries and (iv) The Barents Sea fisheries of mainly Northern Norway.
4. The territories related with the fisheries in 3) have a stable position as fisheries territories in the European territorial system, but the development inside the territories vary.
5. In general the socio-economic development in the fisheries specialised territories are more negative than the changes in most of the other European coastal territories.
6. The fisheries territories were not favoured in the distribution of economic support in the fisheries. In contrast growth territories, often surrounding the capitals, became the relative winners.
7. And finally: In order to build a systematic data registration system for TIA for CFP it will be of extremely importance to:
 - Be able to register harvesting figures in different fisheries (quotas, landings) and relate them with the specific territorial fisheries systems.
 - Be able to register the territorial distribution for FIFG on lower level than NUTS 2.
 - Be able to register changes in the socio-economic systems of the fisheries in more detail than today.
 - Be able to correlate the socio-economic development in the fisheries territories in a systematic way to the development of the other territorial systems in Europe. One tool, that probably can be fulfilled today, is to correlate data on fisheries, polycentrism (availability) and economic modernisation (the emergence of the knowledge economy).

Specific experiences from CFP in NUTS 2 territories

Scoping

1) The importance of *specifying the policy interventions*. In the CFP they are of two major and very different types. One is the *economic incentives* (FIFG) and their impacts (giving *growth* in fisheries, in the regional economy etc); another is the effort regulation or the *conservation policies* (giving *declining* processes). The experiences here are that information about the territorial distribution of the interventions are insufficient, the target areas are very different according to geographical areas and their extent and the possible impacts can be of very different types.

2) Hypothesis on the *cause-effect-relations*. In analysing policies targeting traditional outlying territories we are used to look at how they compensate for or turn around declining processes. In the case of analysing coast territories this starting point may need a revision. Probably the fisheries policies rather go into growth processes than declining processes, but may be not in the most fisheries specialised territories. A challenge is to put this experience into the TIA design.

3) The *spatial level of observation and analysis*. The major experience so far is the possible mismatch between the extent and the dimensions of the fisheries and fisheries policies and the regional level of observations. From our point of view it is an overwhelming danger that the policies interventions will “disappear” in most of the coast territories.

4) Reference to past and future. So far our experience is that past analyses in fisheries can contribute to future predictions. One of the results of our analyses is the stable positions of the fisheries specialised territories in the respective nations as well as in the European space.

Analysing

1) Interventions and effects measures. Data on demography, employment specific data on fisheries, socio-economic indicators, relation area/population, either time series or for one year only. It looks like there is no system specifying when to register data and how to do it.

2) The data referring to NUTS 2 and 3-levels are useful. However, in the ESPON database there is a shortage of such data, also on NUTS 2 level. The database has been expanded and supplemented as part of IR 3, but still probably only a few European countries have a system for collecting relevant data, and ESPON lacks a strategy for systematically collecting the data that exist.

3) Quantitative / qualitative appraisals. Most of the indicators are of quantitative character. Qualitative appraisals are more easily undertaken by example studies, but there is still need for developing relevant design for example studies in CFP assessment.

4) Technique of analysis. The analysis so far is performed in terms of compiling data from different databases, enlisting the data in tables and analysing them according to the TOR / hypotheses. With respect to reliability, we are obliged to depend on the reliability of the data in public data bases and cannot go to further means to confirm the reliability.

Assessing

1) *Polycentric spatial development*:

- A danger in the analyses is that the CFP is too marginal, and has no meaning according to the changing of the polycentric spatial development on European, transnational and national level.
- The mapping of fisheries specialised territories on higher level (NUTS 2) demonstrates the importance of analysing huge dominating territorial fisheries system in Europe as transnational systems.

- There is a general need for correlating fisheries territory typologies and polycentric typologies.

2) *Cohesion:*

- It looks like the TIA on fisheries mainly will give results on economic and social cohesion.
- According to social cohesion it looks like the fisheries and CFP contribute to enlarging territorial social differentiation, and contribute to territorial cohesion on very low level..

3) *Applied meaning of “spatial/territorial”*

- Fisheries and CFP are included in general and quite strong differentiation processes in coastal areas, and therefore may contribute to increasing differences between coast territories and between fisheries coast territories more central territories
- Significant socio-economic impacts of CFP are found on very low territorial levels.

5.10 Conclusion

The chapter is written as an examination of the opportunity to carry out social cohesion impacts analyses of the Common fisheries policy in the framework of territorial impact analysis. The most important part of the examination has been concerned with building analytical bridges between: the territorial dimensions and systems of European fisheries; the two major types of CFP (the specific economic measures (FIFG) and the “conservation” policies); the direct impacts of the CFP on the socio-economic systems of the fisheries; and the impacts on the position of the fisheries territories in the general European territorial systems. The main conclusion is that the attempt presented in the work package is a way that is possible to use in order to carry out relevant territorial impact studies of CFP. However there are several conditions that are not established yet, most of them related with building a valid systems for data registration, collection and analyses. Moreover there are also other more analytical challenges as:

- The need for building a valid idea about the territorial dimension of the European fisheries. From our point of view there is a contradiction between the enormous dimension of European fisheries and its minor territorial impacts when measuring those by using strict fisheries dependencies indicators. We have tried out a solution by using NUTS 2 territories, and from our point of view we have identified relevant territorial fisheries systems by these analyses. However we think that that establishing more permanent analytical systems of TIA in CFP should be able to use data on NUTS 3 level (conf chapter 1).
- The need for establishing a system for territorial distribution analyses of FIFG as well as the regulation policies which integrate these dimension to the territorial systems of the fisheries.
- The need for integrating analyses on fisheries territories and territories into the general analyses of European territorial development and changes. Here are at least two challenges: The first is to establish typologies that integrate fisheries territories characteristics with other ESPON typologies as information about polycentrism, functional/urban and variables registering the emergence of new types of economics. The other is to build valid indicators for comparing territorial development. In the examination we have used indicators on population changes, income changes and consumption changes. We are not sure that these indicators

are the most valid for analysing all types of European territories. The finding in the chapter is that it looks like the fisheries specialised territories in systematic way have experienced more negative trends than the average European territories in the period around 2000 is an argue for building such systems.

5.11 Summary

The more specific content of the chapter is:

- An examination of the availability of relevant data in the ESPON-databases as well as in national sources. For the moment bases on both of these levels lack a lot of data and we have not identified data registering systems which for the moment will make such data available.
- An attempt on revising and building new ideas of the territorial dimensions of European fisheries which can substitute or complete the traditional fisheries dependency perspective.
- An attempt to analyse the territorial distribution of the CFP policies measures (FIFG and the fisheries resource regulations)
- An analysis of the direct impacts on fisheries from CFP, analysed by using data on fisheries employment.
- Analysis of socioeconomic changes in European fisheries specialised territories compared with the development in other European coast territories. In these analyses we have used variable on three indicators: Population changes, income changes and household consumption changes.
-

All analyses are based on mapping indexes developed in the analyses. The chapter discusses the experiences from the analyses regarding using TIA in CFP-analyses, giving three types of policies recommendations based on the conclusions from the mapping as well as the example studies.

5.12 Policy recommendation

Based on the examination we recommend four main types focusing on the policies development. All four are about the question of the need of integrating if integration should take place, and are elaborated in the summary:

- (i) The co-ordination of the implementation of the economic measures in CFP (the FIFG) and the fish resource regulation policy. Most of data on the latter territory level is not available, but the impression is that there is no co-ordination, and that FIFG in some countries rather targeting new types fisheries models than the specialised territories. Thereby the structure in the latter territories is in danger of being conserved (becoming rawfish satellites) and territorial differential processes are increased.
- (ii) The question of the interplay between fisheries policies implemented on national and European level. The national level has a central role in the implementation of the part of CFP focusing of economic support for the fisheries. The distribution analyses as well as the example studies demonstrate that the national implementation processes probably in many occasions vary between the nations, and

that these variations can have territorial as well as social cohesion impacts in the respective countries as well as in the European space.

- (iii) The relations between the European sector policies of the fisheries and the European territorial policies on reduction social cohesion differences on the European territory. Despite the restriction of the actual data, the conclusion can be that these two types of policies do not pull the European territorial development in the area of social cohesion in the same direction.
- (iv) The need to integrate territorial characteristics and development trends in to the market policies.

6 Territorial Economic Cohesion Impact

6.1 Introduction

Fisheries and aquaculture play a varying role in the economy of the different European countries and regions. If on one hand there are few countries in Europe – Iceland, the Faeroes and north Norway – where fishing and related activities account for a significant share of total employment and gross domestic product, on the other hand there are a lot of European regions where the fishing industry makes an important contribution to income and employment in an otherwise underdeveloped rural economy. The importance of the sector becomes clearer when analysed at lower regional level or at the local level. In these cases, indeed, dependency rates are higher at greater level of regional disaggregation (Goulding *et al.*, 2000).

All around Europe (both in EU and EFTA countries) the fishery sector has been involved in significant structural changes in the past decades and it is expected to undergo a number of changes also in the near future. Undoubtedly the fisheries policies have important territorial impacts in several European regions, where fishing and related activities take place. This is usually coastal regions and areas where there often is little prospect of growth in alternative economic sectors, and this makes the CFP and the fishery policy of countries like Norway and Iceland important for coastal regions throughout Europe. *The situation is most outspoken in the areas most dependent on fisheries and related activities. Such areas can – depending on the level of disaggregation be identified in many European countries.* Furthermore, the territorial impact of the fishery policy varies among the regions, as not all of them are equally dependent on fisheries or are suited to face the processes of restructuring, reduction and expansion. This means that some regions might benefit from the measures agreed while others might not.

The purpose of this chapter is to evaluate the effects of the present EU cohesion policy in terms of regional growth and access to economic resources in a sector which is very complex to analyse for a series of different factors. The main difficulty refers to the structural and social differences existing between the North European fishery and the Mediterranean fishery which means that the CFP does not not apply in the same way in all the Union. Compared with other EU regions, the main features of the Mediterranean fishery can be synthesized in its prevailing artisanal nature and extreme heterogeneity in terms of gears used, number of landing sites, impact on the marine environment. However, also along the Mediterranean shores, there are significant differences between highly specialised fleets and small scale fisheries.

The minimum regional level of the analysis was NUTS2, as this is the level at which EU structural policies are designed and evaluated. The major problem experienced in this study is the lack of information that has heavily limited the possibility of comparison of the main economic indicators and from year to year. Some important variables, as those related to the fleet segmentation, were completely missing while others as landings were accessible only for a limited number of NUTS2 regions and years. Data on composition

of fleets by vessel gears and data on the value of the landings were available only at the NUTS0 level.

6.2 Hypothesis related to economic cohesion

Before presenting the hypotheses to be tested within the present WP4, it should be noted that, within the context of this study, there is more than one level of policy objectives against which the territorial impact of the European Fisheries Policies can be assessed. In particular, these policies may be shown to be either consistent or inconsistent with the “high-level” or strategic EU objectives of social and economic cohesion and environmental sustainability in the regions.

Below these high-level/strategic EU objectives, one may identify the European Fisheries Policies specific objectives such as a more sustainable balance between fisheries resources and their exploitation, an improvement of the fishery sector competitiveness, a reducing of the fish stocks overexploitation and the revitalisation of the fisheries dependent areas.

One should not forget that also interventions in other fields are likely to produce effects in the field of fisheries and aquaculture. For example, an intervention in the environmental field, like a treatment plant that brings an end to direct discharges of human waste in coastal waters will contribute to the quality of beaches and therefore facilitate efforts to diversify the local economy towards tourism. It may also contribute to the diversification of economic activities by allowing the development of aquaculture (mussel farms, etc.). Finally, an intervention in the transport and infrastructure sectors, as the construction of a new road link to the national motorway system, could have an impact on the transport costs of local firms which process locally landed fish, or improve tourist access to a previously poorly connected region. However, there is usually room to argue that the specific CFP objectives and/or the effect of intervention in other fields can or cannot be consistent with the high-level/ strategic EU objectives (social and economic cohesion) and among them.

In WP4 the following hypotheses, have been tested:

General impact hypotheses:

- Hp.1: The CFP will have different impacts between coastal regions, and within regions. Processes on restructuring, reduction and expansion will occur side by side and in various combinations. Impacts of CFP will be more significant the lower the geographical levels.

The cluster analysis has individuated three main groups of NUTS2 regions, which differ for degree of fishery specialization (in terms of value added and employment), amount of public support received, fleet characteristics and productivity. A first group, composed by Denmark, Galicia and Andalusia, exhibits the highest shares in terms of fishery employment and value added, landings, fleet’s capacity and FIFG funds. A second cluster, mostly located in the southern regions, exhibits lower levels of FIFG assistance and fishery value added compared to the first group. This second group of Mediterranean regions also shows the lowest average productivity per vessel. Finally, there is a third group of Northern regions that has benefited from less support than the average European region. It exhibits the lowest fishery specialization indexes while as a whole it seems to have performed better in GDP change and productivity terms.

- Hp.3: Territorial impacts of CFP will vary with different structures of the fishing and aquaculture industries of the regions. Impacts will differ in accordance with

the extent the regions are dominated by coast fishing and small vessels, etc.

In order to test this hypothesis we used the average engine power and gross tonnage per vessel (respectively expressed by the ratios engine power on vessel's number and the gross tonnage on vessel's number) as proxy variables of fleet capacity. The evolution of these indicators between 1997 and 2005 didn't highlight any significant differences between large and small fleets in terms of average capacity. Furthermore, the Pearson correlation coefficient between the average capacities is not significative. This could indicate that European funds have been allocated in an undifferentiated way between small and large vessels.

- Hp.4: Territorial impacts of the CFP may contradict with the aims of cohesion, territorial balanced development and polycentrism.

The relationship between the FIFG 1994-99 per capita and the growth 1995-99 of the Agriculture, Forestry and Fishery Value added is positively significant only for the regions with high Fishery Value added. This could indicate that in general CFP tends to favour regions specialized in fisheries.

Social and economic impact hypotheses:

- Hp.1: The CFP has unintended side effects in coastal regions.

The trend of some structural indicators put in evidence that most specialized regions (according to the share of the fishery value added and employment) exhibit a marked decline in fleet capacity. In most cases, the percentage reduction in the number of vessels has been larger than the reduction in capacity, causing unintended effects in terms of composition of fleet and unemployment.

Fishery hypotheses:

- Hp. 3: Territorial impacts of the CFP measures are dependent on how the measures in use are implemented in the various regions.

In four countries (Germany, Greece, Netherlands and Sweden), the relationship between FIFG 1994-99 per capita and the growth 1995-99 of the Agriculture, Forestry and Fishery Value added reveals that most recipient NUTS2 regions have grown relatively faster. The relationship is not verified for Spain and Italy. The reason of such negative trend should be in part related to the region's initial economic conditions and to the different way funds have been invested and administered.

- Hp.4: Less prosperous regions receive more CFP support though the FIFG than the more prosperous regions.

The relationship between the amount FIFG funds per head and the (log) GDP per capita reveals that, in general, funds have been distributed progressively between EU regions, even if the progressiveness decreased from one programming period to the next.

The aforementioned hypotheses include both social and economic issues as well as general impacts subjects. Thus, a more detailed description of them, in the light of the solely economic issues will follow in the description of the methodology.

6.3 CFP measures and impacts in the light of economic cohesion¹⁰⁴

As stated in the previous interim reports, the planned reference period for ESPON Project 2.1.5 is from 1990 –2004. However, changes in CFP did not take place before late 2002 and many measures are just or about to be implemented. As a consequence, it would be difficult to carry out an impact assessment analysis based on the future changes of the CFP. In order to face the problem it has been taken into account the policy measures carried out during the past years in many European countries.

The main instruments of the past CFP have been fleet reduction and quota, while the most important elements of the future resource policy are the multi-annual recovery or management plans for certain fish stocks, which are “outside safe biological limits”¹⁰⁵ or “at/or within safe biological limits. They are structured so to include both input (fleet reduction, effort quota) and output (quotas, TACs) measures. A catch/landing quota-system for the most depleted stocks will be accompanied by effort measures (effort quotas) and further capacity adjustment measures. Taking this into account it can be stated that the most important changes that will have an impact on the economy of coastal regions will concern the:

8. size of fishing fleets;
9. production in weight and value of fish catching activities;
10. share of the fishery sector on total GDP (value added);
11. employment in fish catching activities and in fish related activities (processing, marketing, etc.).

It is also expected that recovery plans will be applied for those fishing fleets exploiting the most depleted stocks such as most cod stocks, some sole and Nephrops stocks and hake of the North Sea. This can have important territorial consequences, as fleets from different regions traditionally exploit different stocks. Vessels from those regions, which exploit the most threatened stocks, can consequently expect to be worse off than vessels from the regions which traditionally exploit less threatened stocks.

The evaluation process carried out in the present study consisted in both analysing data and in providing judgements/conclusions.

The first section is aimed to analyse the main characteristics of the EU fishery sector. The purpose is to highlight the heterogeneities existing within the EU coastal regions on the basis of the evolution of the main macroeconomic indicators, as the GDP per capita, the share of the fishing value added the fleet and the landings.

In the second section, related to an ex post evaluation of the CFP, the most common quantitative techniques based on econometric models and regression analyses have been applied. Unfortunately, the narrowness of the information/data available has heavily limited the applicability of more sophisticated econometric models.

¹⁰⁴ Most of what said in this paragraph referring to the CFP has to be considered valid also for the Norway and Iceland fishery policies.

¹⁰⁵ ‘Safe biological limits’ is defined as the point where the indicators of the state of a stock predict a low risk of transgressing certain ‘limit reference points’, for instance values of biomass or fishing mortality rate, which are to be avoided (Council Regulation (EC) No. 2371/2002, art. 3(j) and (l)).

6.4 Characteristics of the EU fishery sector

6.4.1 Regional Inequality

Within the EU it is well known that the existence of large economic and social disparities have narrowed over the past decade although large differences still remain. Looking at the GDP per capita measured in Purchasing Power Standard (sourced from the ESPON database), in 1995 the ratio between the two border coastal regions of *Inner London* and *Latvia* was 1:9. In the 2000, the gap was reduced to 1:7.

On average, the GDP per capita has increased of 0.29% from € 14, 8 millions in 1995 to 19,1 in 2000. In some cases, as (LV) *Latvija*, (IE02) *Southern and Eastern*, (IE01) *Border, Midlands and Western*, (EE) *Eesti*, (FI2) *Åland*, (PL0B) *Pomorskie*, (PT3) *Madeira*, (UKJ3) *Hampshire and Isle of Wight*, (FI16) *Uusimaa*, (PL0G) *Zachodniopomorskie*, (PL0E) *Warmińsko-Mazurskie*, (LT) *Lietuva*, (GR25) *Peloponnisos*, (UKJ2) *Surrey*, *East and West Sussex* and (GR41) *Voreio Aigaio* the GDP rose by around 50% between 1995 and 2000. In other seventy-nine regions (over 139 coastal regions), the growth has been much lower than the EU average.

Figure 6.1 depicts the GDP per capita in PPS 2000 on NUTS2 level for the entire ESPON space. From this picture, it's evident that disparities exist both between countries and between regions. Among the 139 NUTS2 coastal regions, sixty exhibits a GDP above the respective average national for both years considered. During these five years, five regions (*the Bulgarian Yugoiztochen* - BG06, the French *Bretagne* - FR25, the Norwegian *Vestlandet* - NO05, the Greek *Voreio Ai gaio* - GR41 and the Portuguese *Madeira* -PT3) increased in GDP per capita while six (*Basse-Normandie* - FR25, *Zeeland* - NL34, *Sør-Østlandet* - NO03, *Mellersta Norrland* - SE07, *Övre Norrland* - SE08, *Cumbria* - UKD1) decreased. In terms of Gross Domestic Product per person employed, disparities across countries seem to be more marked than across regions (cf. figure 6.2). In this case, the less favoured regions are located in Romania, Slovenia, Estonia, Latvia, Lithuania and in some Portuguese regions as *Algrave*, *Madeira* and *Ancores*.

Focusing the discussion on the importance of the fishery sector, in 1995 the average European share of fishing in the value added of the area was equal to 0.3 and only 19 NUTS2 regions exhibited a ratio above this overall average. In 2002, the average ratio was reduced to 20% and the regions above this value were 22. The regions most specialized in terms of fishing value added have almost remained the same over the period considered. In most specialized regions, as the British *Cornwall and Highlands* or the Spanish *Galicia*, *Cantabria* and *Canaries* this share has heavily fallen.

Comparing data on GDP per capita with the fishing share in the value added of the area, few specialized regions as the Finnish *Aland*, the *North Eastern Scotland* and the Italian *Friuli Venezia Giulia* show high GDP per capita. The other most specialized NUTS2 regions, as *Canarias*, *Cantabria Galicia and Ceuta y Melilla (ES)*, *Highlands and Islands (UK)*, *Algarve and Madeira (PT)*, *Puglia (IT)* and *Martinique (FR)* exhibit a GDP lower than the EU average.

Looking to the employment in fishing and fish farming¹⁰⁶ (ESPON database) as alternative indicator of the sector importance, the results don't seem to change much. Among the 37 NUTS2 regions with a fishery employment ratio higher than 0.34 (the overall European average in 2001), only ten regions - *Nord-Norge*, *Vestlandet*,

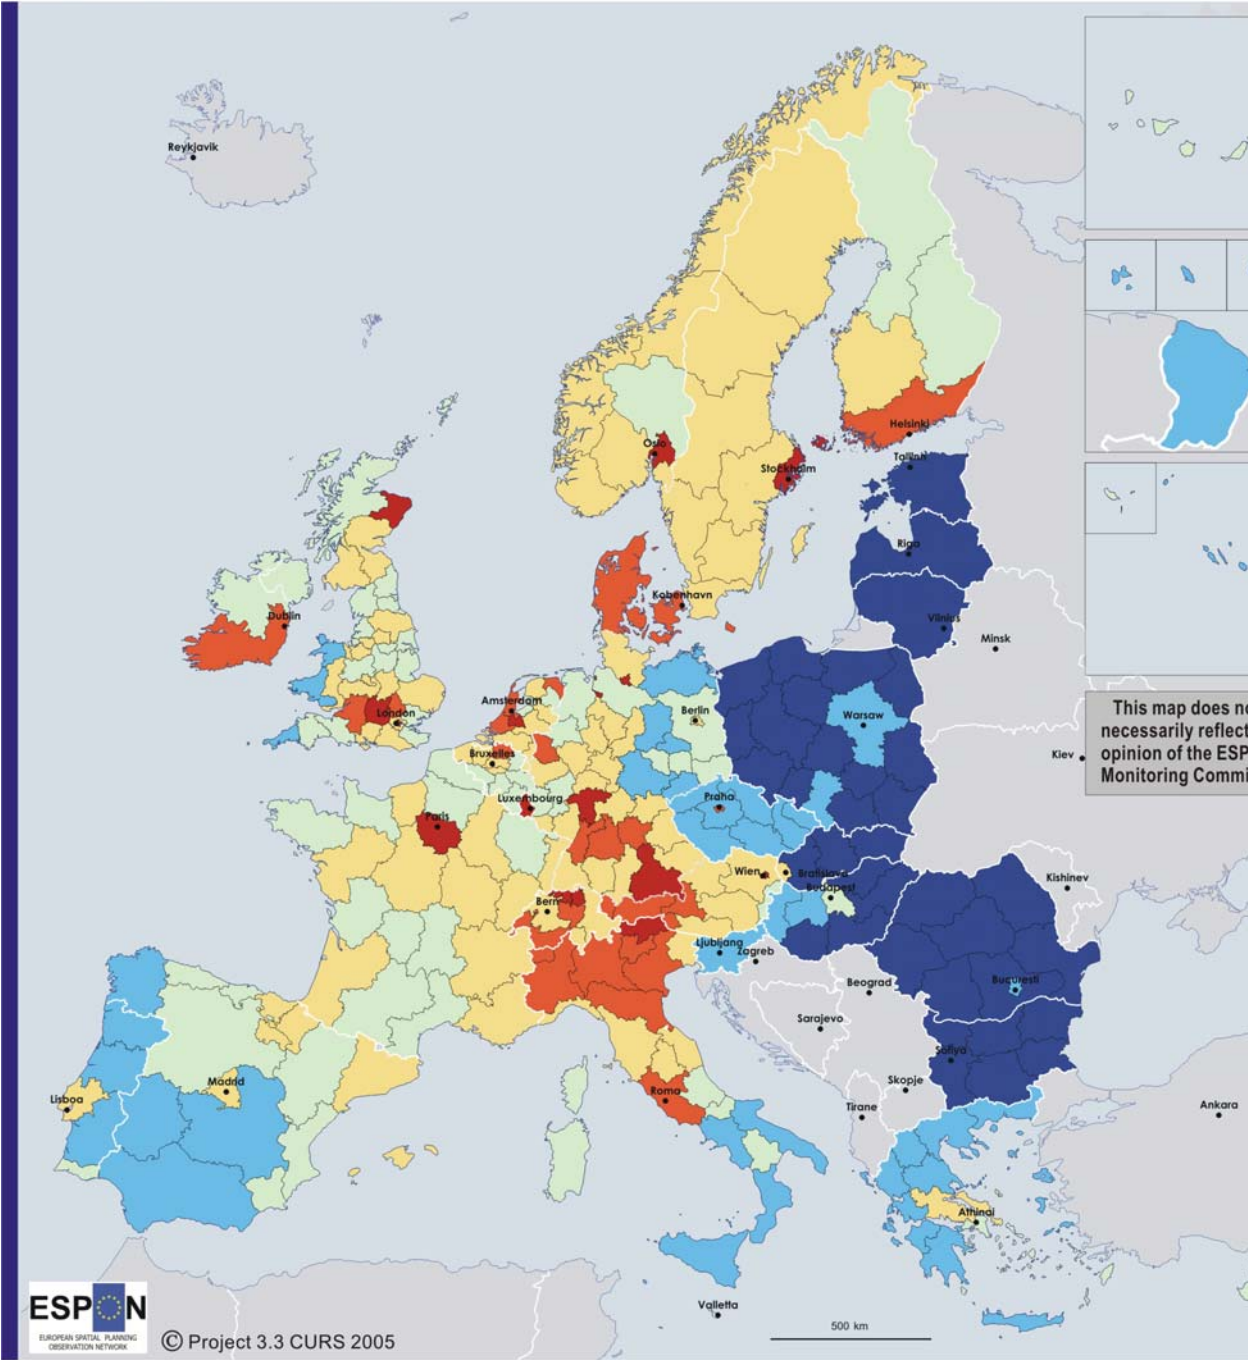

¹⁰⁶ The limited temporal extension of this variable in the ESPON did not allow comparisons over the time.

Trøndelag (NO), *Åland* (FI), *North Eastern Scotland* (UK), *Marche* (IT), *Bretagne*, *Pays de la Loire* (FR), *Pais Vasco* (ES), *Lisboa e Vale do Tejo* (PT) - have GDP per capita levels higher than the overall European average.

This first overview of the fishery sector seems to confirm some findings highlighted in the previous chapter related to the Social Cohesion Impact analysis with reference to the relative stable positions of most fisheries specialised regions and to their slow socio-economic development in relation to the other European regions.

6.4.2 A cluster analysis

In this paragraph, the results of a cluster analysis are shown. The aim is to identify homogenous groups of NUTS2 regions in relation with the 20 indicators depicted in Annex 6.1. Even if it doesn't add much in terms of economic impact evaluation of the CFP, this kind of analysis is particularly useful to find similarities and differences on the basis of some important social and economic indicators. It can be defined as an exploratory data analysis tool, which aims at sorting different objects into groups in a way that the degree of association between two objects is maximal if they belong to the same group and minimal otherwise. In other words, it helps to identify a set of groups which both minimize within-group variation and maximize between-group variation.

The approach used was the K-means clustering with Euclidean distance and Ward's method. Since K-means assumes that the K number of cluster is known, in a preliminary phase the appropriate number of clusters of the standardized data have been found on the basis of the hierarchical clustering. Respect to the K-means method, the hierarchical clustering generates a nested solution by successively grouping two closest cases or clusters in a sequential process.

The K-means algorithm assigns each point to the cluster whose center (also called centroid) is nearest. The center is the average of all the points in the cluster that is, its coordinates are the arithmetic mean for each dimension separately over all the points in the cluster (Everitt 1980, Gnanadesikan et al. 1977). As distance measure was chosen the Euclidean distance that is the geometric distance in the multidimensional space. As linkage or amalgamation rule to determine when two clusters are sufficiently similar to be linked together, we used the Wards' method (1963) that uses an analysis of variance to evaluate the distances between clusters. In short, this method attempts to minimize the Sum of Squares (SS) of any two (hypothetical) clusters that can be formed at each step. In general, this method is regarded as very efficient; however, it tends to create clusters of small size.

The results refer to 124 observations. Since the variable landings were available only for 101 NUTS2 regions, we used the mean substitution for the missing values. It should be noted that missing values affect different countries unequally. For Norway and Poland, no data on landings were available in international databases¹⁰⁷. For Greece, Portugal, Netherlands, Sweden and Germany the only data available refer to 1997 and 1998.

¹⁰⁷ Actually for Norway landing data has been made available in May 2006, after the cluster analysis was already performed for the final report.

Table 6.3 reports the means for each cluster on each dimension (not standardized) in order to assess how distinct clusters are. Ideally, we would obtain very different means for most, if not all dimensions, used in the analysis. Three partitions have been identified: only 3 regions belong to the first and 56 to the second. The former third cluster sharply distinguished 65 regions. The 3 clusters are:

12. Cluster 1 - **Fishing specialized regions**: 3 NUTS2 regions Denmark, Galicia and Andalusia. The main distinguishing feature of this group is the high dependency on fishery in terms of employment, fishing value added, production, fleet's dimension and, consequently, shares of FIFG funding in both 1994-99 and 2000-06. However, deep differences in terms of GDP per capita and unemployment rates distinguish the rich Denmark from the other two Spanish regions.
13. Cluster 2 - **Mediterranean regions**: 56 NUTS2 regions, many of which are in Spain, Portugal, Italy, Greece and Malta. Respect to the first cluster, they exhibit lower levels of GDP/head, fishery employment, fishery value added. These regions have also the lowest fleet dimensions and capacities.
14. Cluster 3 – **Northern regions**: 65 NUTS2 regions, most in France, United Kingdom, Germany, Sweden, Slovenia, Netherlands, Finland and Belgium. The

highest GDP/head level and fishing productivity (measured in terms of kW/No of vessels and GT/No of vessels) are the distinguishing factors in this cluster. In terms of fishery employment and value added, the importance of the sector seems to be secondary in these regions, which also have the lowest unemployment rates and the lowest average share of FIFG funding.

Table 6.3 Cluster means

15.

The composition of each cluster is listed in Table 6.4.

This first attempt to provide a categorization of the coastal regions indicates how the NUTS2 European regions can be broadly subdivided into three groups (cf. figure 6.3). A first restricted group of regions heavily specialized in fisheries activity and located in Denmark, Galicia and Andalusia. A second larger group mostly located in Mediterranean regions with lower level of specialization in terms of fishery value added and employment and characterized by small fleets. Finally, there is a third group mostly located in the Northern regions, that exhibits larger regional fleets and higher productivity levels but that also has lowest specialisation fishery degrees and has been less supported by the EU Funds.

Figure 6.3 Clusters by NUTS2 regions

Fisheries Cluster Nuts 2

6.4.3 Trends in European fishery sector

The picture of the European fleet is a fundamental starting point in order to provide a snapshot characterization of the fishing sector and its tendencies. In 2005, the European fleet amounted at 88846 vessels spread out among 320 NUTS3 regions (cf. figure 6.4). The majority of fleets are concentrated in the Spanish regions of *Pontevedra* and *La Coruña* with 3542 and 2874 vessels respectively. *Attiki* (Greece) is the third region with 2086 vessels, followed by *Ancoras* (1587 vessels) and *Alentejo Central* (1444 vessels) in

Portugal. Almost the 30% of the total fleet is concentrated in 18 NUTS3 regions, belonging to Malta, Cyprus, Greece (with 7 regions), Portugal (with 5 regions), Finland and Spain (respectively with 2 regions).

Looking at the capacity, 27 NUTS 3 regions hold over the 50% of the total gross tonnage (GT) (cf. figure 6.5). Also in this case the larger fleet is in *Pontevedra*, followed by *Aberdeen City* (UK), *Finistere* (FR), *Agglomeratie's –Gravenhage* (NL) and *Vizcaya* (ES). The nations included in this list are the Spain with 7 NUTS3 regions, Netherlands with 5 regions, Denmark, United Kingdom and Ireland with two regions respectively. Finally, Belgium, Germany, France, Greece, Italy, Lithuania, Latvia, Portugal and Sweden have respectively one region.

Respect to the engine power (kW) even if the Northern European fleets present an average power higher than the Mediterranean fleets, it is interesting to notice that over 320 NUTS3 regions, the 30% of the overall engine power is concentrated in only 20 regions. Among these 20 regions, three are located in Italy (*Trapani*, *Bari* and *Venezia*), in Spain (*Pontevedra*, *La Coruña* and *Vizcaya*), in France (*Finistère*, *Guadalupe* and *Martinique*) and in Netherlands (*Overig Zeeland*, *Flevoland* and *Agglomeratie's Gravenhage*). Two NUTS3 regions with highest kW are in Denmark (*Nordjyllands amt* and *Ringkøbing amt*) and in United Kingdom (*Aberdeen City* and *Cornwall* and *Isles of Scilly*). Portugal (*Algarve*), Greece (*Attiki*), Malta and Sweden (*Västra Götalands län*) have respectively one region with the highest EU engine power (cf. figure 6.6).

Figure 6.4 Number of vessels by NUTS3 regions

Number of Vessels by NUTS 3 Regions

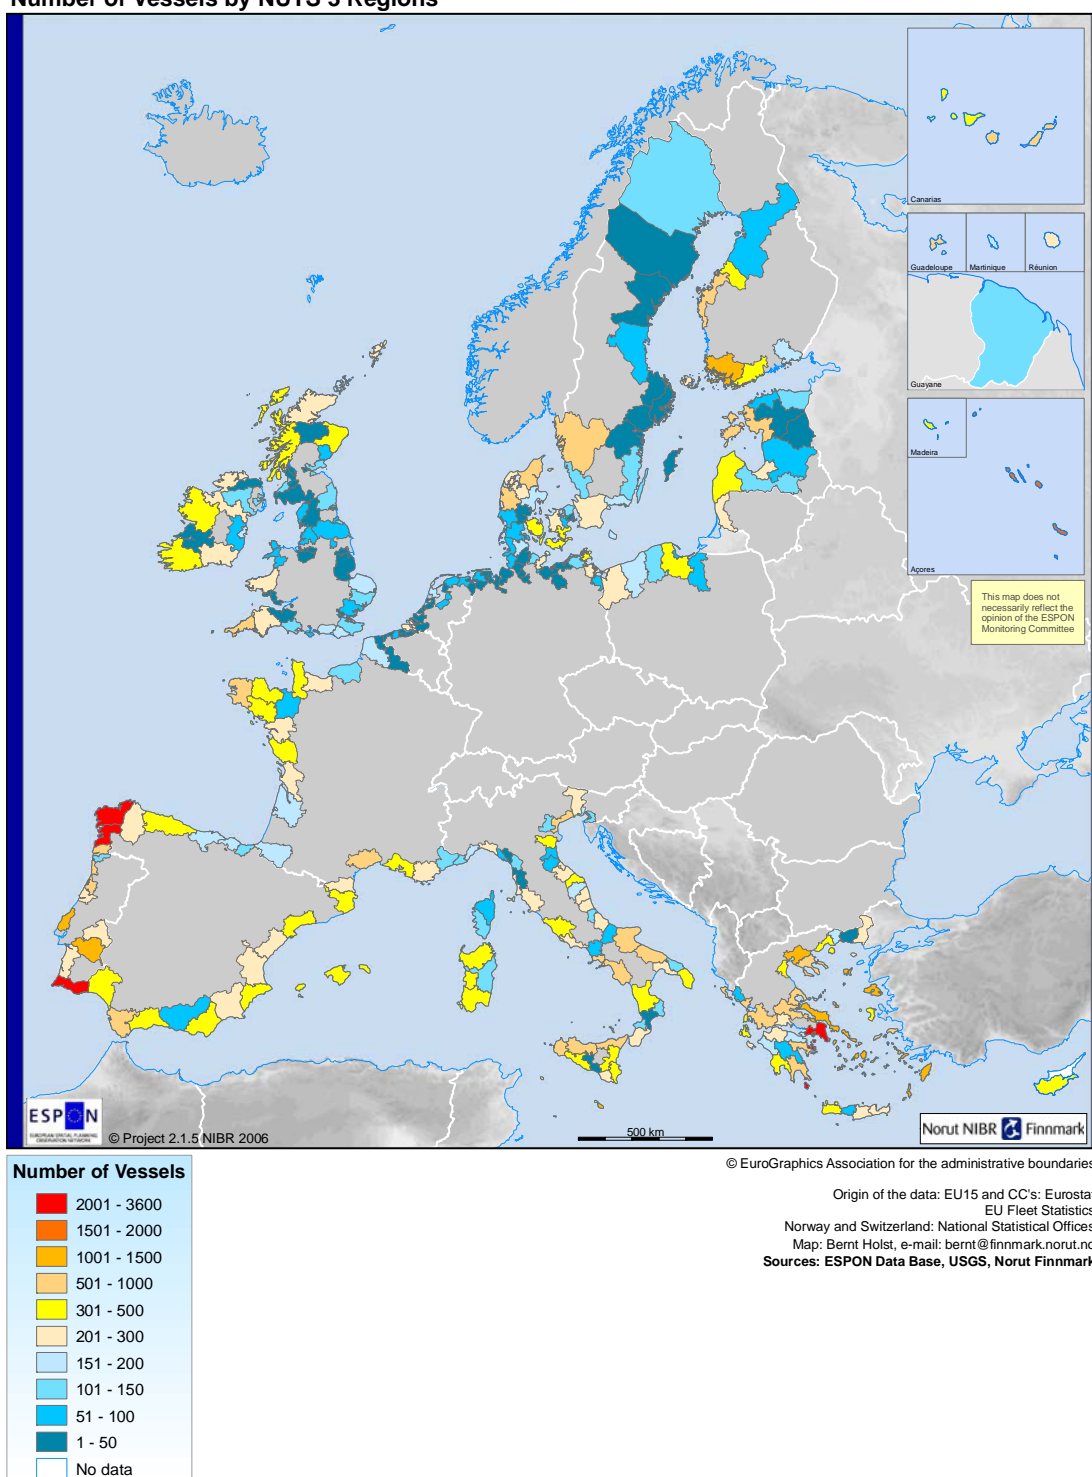

Figure 6.5 Gross tonnage (GT) by NUTS3 regions

Gross Tonnage (GT) by NUTS 3 Regions

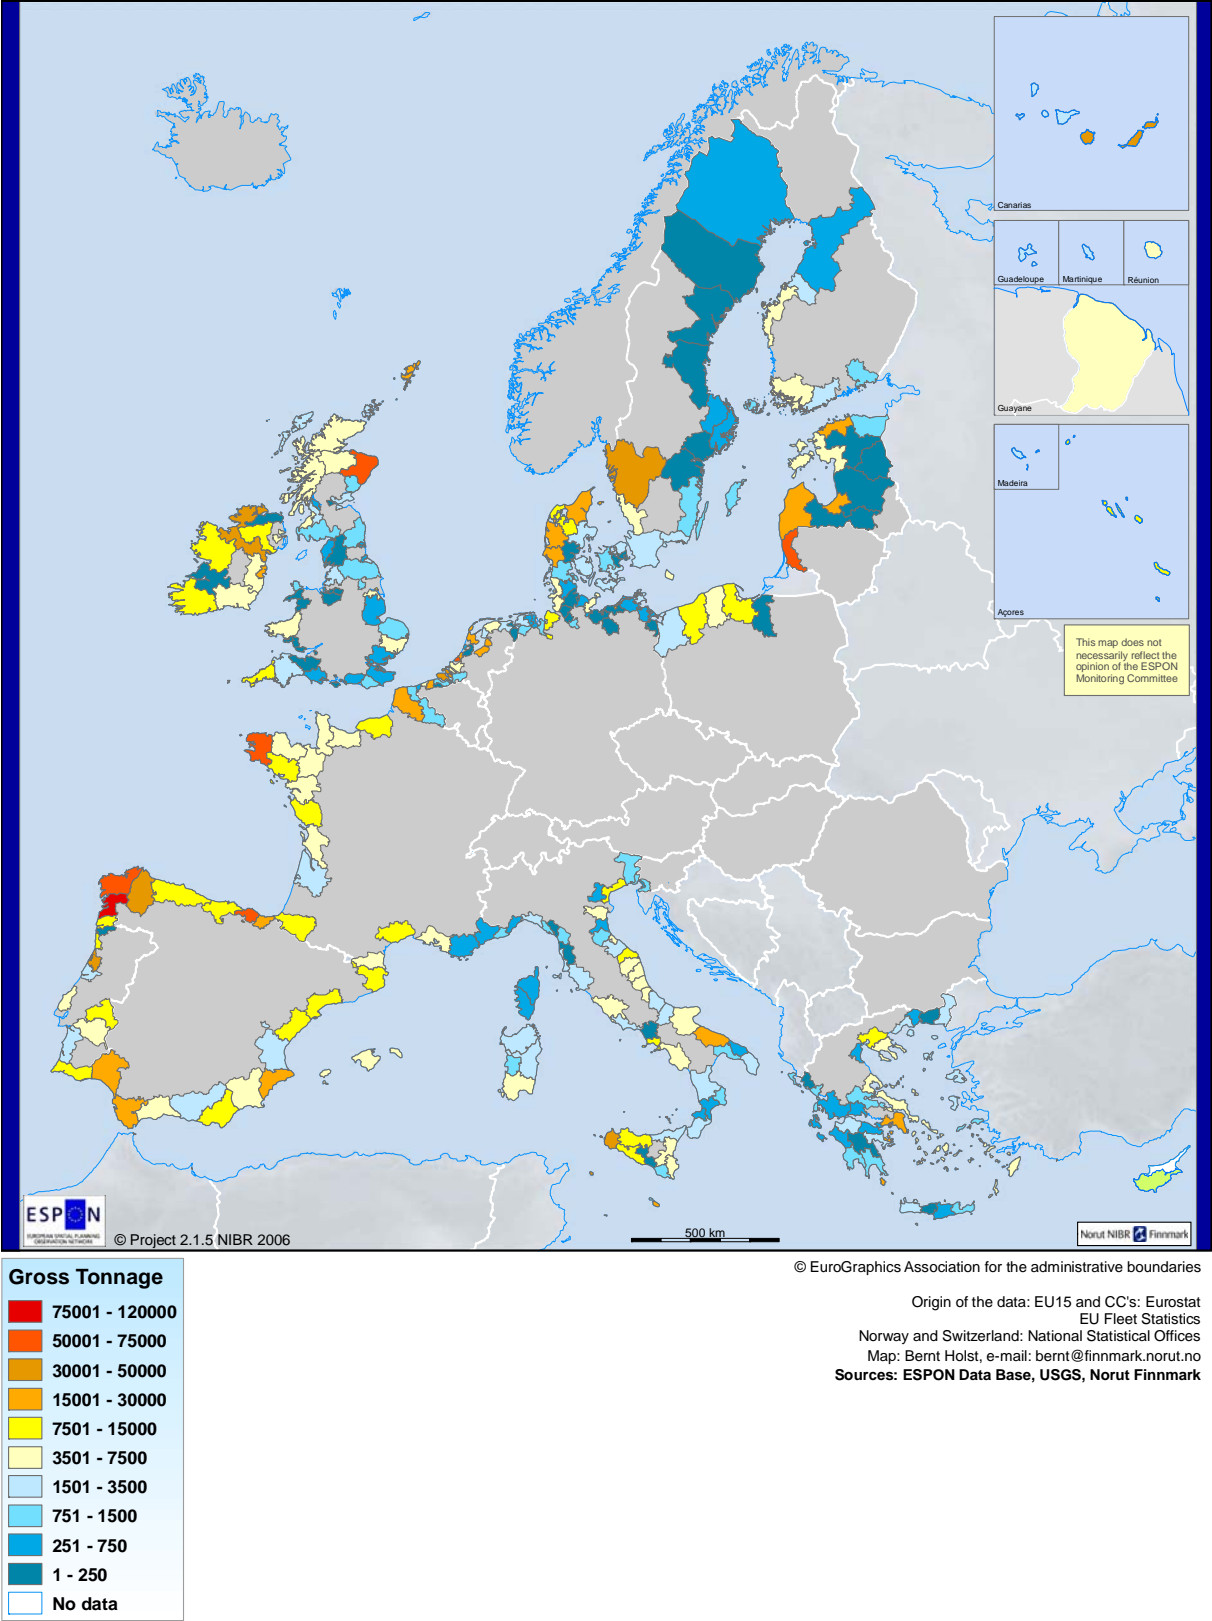

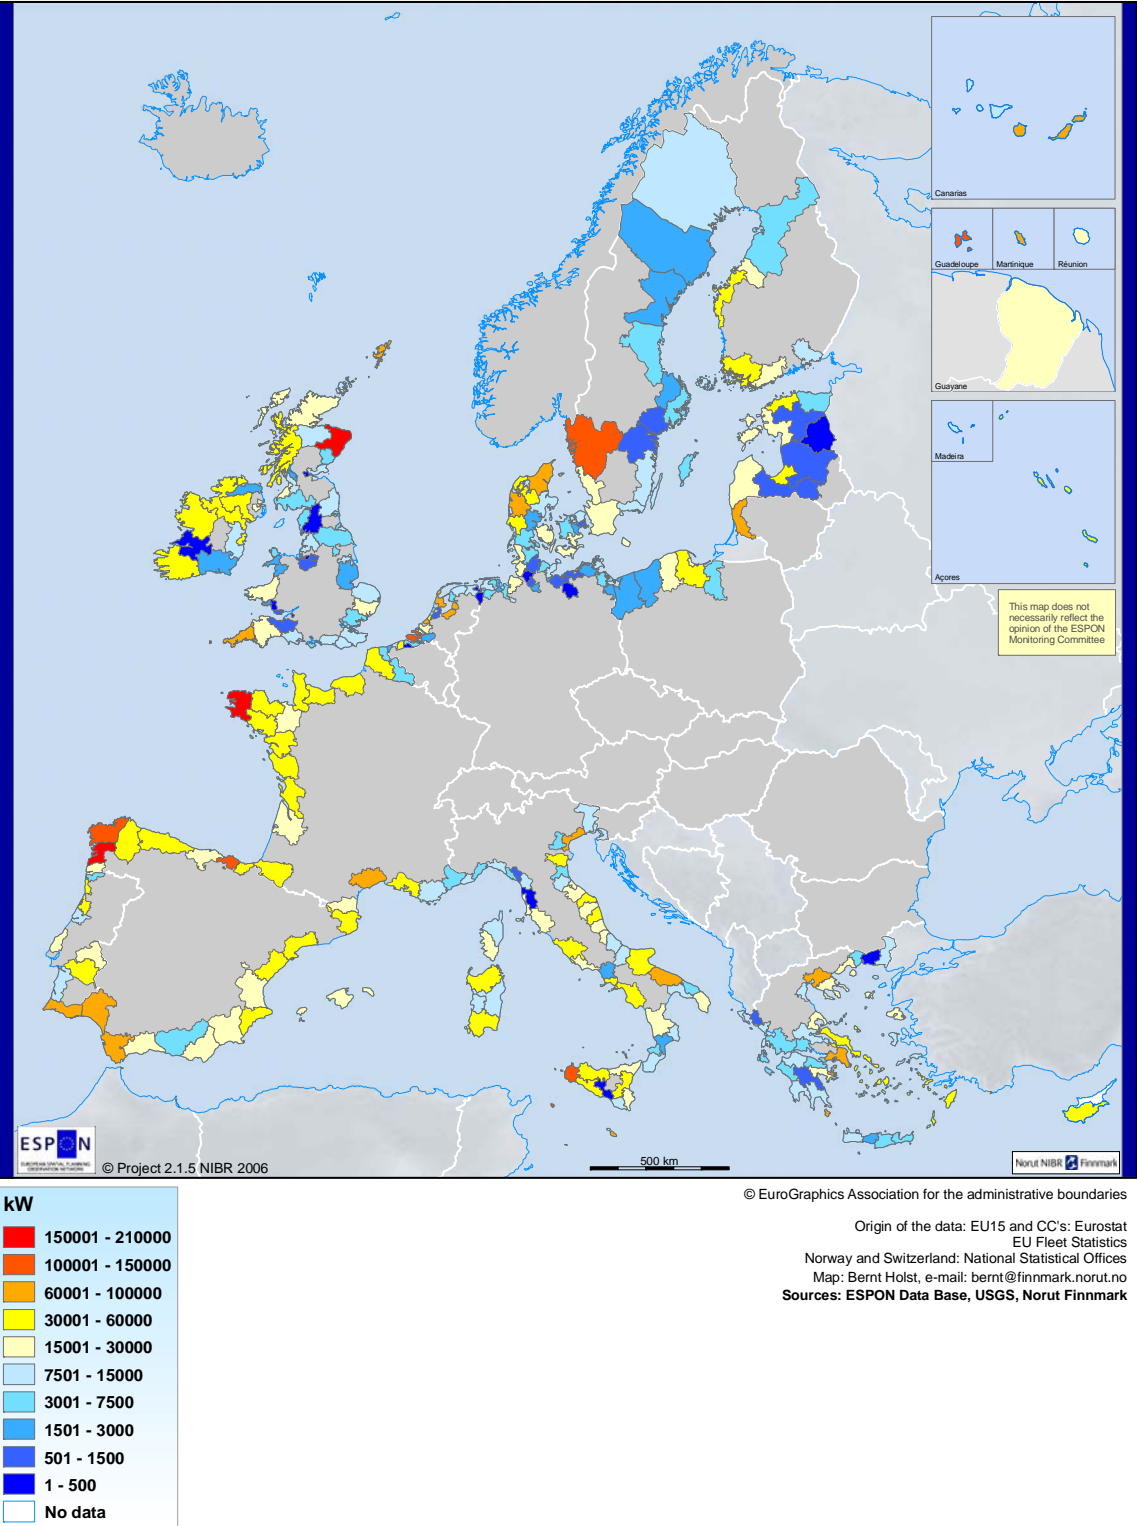

Figure 6.6 Engine power (kW) by NUTS3 regions

Engine Power (kW) by Nuts 3 Regions

From this first overview of the EU fishery, it is clear that the importance of the fishery sector differs considerably not only from one country to another but also within each country. As no official data on volume of landings are available at NUTS3 level, we have collected data only for 101 NUTS2 regions of the 137 coastal regions considered in the ESPON space. From these data, it emerges that over the 50% of total landings are concentrated in 5 NUTS2 regions, such as *Denmark*, *South Western Scotland* (UK), *Zuid-Holland* (NL), *Galicia* (ES) and *Border, Midlands and Western Ireland*.

Aggregating the NUTS3 data of fleet, it's possible to compare the productivity per vessel or kW. The average volume of landings per vessel of the 99 NUTS2 regions considered is equal to 176 tonnes. This value is 31 times higher than the overall mean in the German region of *Bremen* and 17 times in the Dutch region of *Zuid-Holland*. On the contrary, the low average productivity in terms of tonnes per vessel is concentrated in those Mediterranean regions, which compose the second cluster previously described. The situation doesn't change much if we consider the average tonnes per kW. In this case only 17 NUTS2 regions present levels of productivity above the overall average, which is equal to 0.62 tonnes per kilowatt.

Since no data on the value of landings were available at NUTS2 level, we have considered the information of the "Annual report 2004" on Economic performance of selected European fishing fleets, which contains economic indicators regarding fisheries in sixteen European countries (Commission of the European Communities, 2004). These data confirm the importance of the Mediterranean areas and of Spain and Italy in particular, where are concentrated the 23% and 18% of the total European revenues (cf. figure 6.7).

Figure 6.7 Distribution of value and volume of landings of some European fishing fleets (NUTS0 level).

Source: *Commission of the European Communities, 2004*

If we look at the composition of the fleets by vessel gears, the most part of the EU fleet is composed by passive gears vessels with an average length of 19 metres and an average age of 24 years (cf. figure 6.8). Some 70059 EU vessels are non trawlers under 12 meters in length. Passive gears include mostly set gillnets (anchored), trammel nets and pots. Beam trawling is the most important segment of the towed gears fleet. Unfortunately no data about the composition of the fleet and its evolution are available at a lower geographical level.

Figure 6.8 Composition of the EU fleets by vessel gears (NUTS0 level).

(<http://europa.eu.int/comm/fisheries/fleetstatistics/index.cfm>)

In this context, a first preliminary analysis on the territorial effects of the CFP might consider the development of the fleets in terms of capacity expressed in number of vessels and engine power (kW). The aim was to test if **territorial impacts of CFP will vary with different structures of the fishing industry of the regions** (cf. general impact hypotheses, HP3).

In order to test this hypothesis and taking into account data availability, it has been tested if the fleet's dimension has an influence on the FIG allocation. The average capacity per vessel (total kW/ vessels' number), giving a measure of the predominance of small, medium or large vessels in the regional fleets, has been used as a proxy of the structure of the fish harvesting sector. For this purpose, we compared data taken from EC shortcuts updated to 2005 with data taken from Megapesca updated to 1997. The two sources have in common only 56 NUTS2 regions belonging to Belgium, Germany, Denmark, Greece, Italy, Netherlands, Sweden, Portugal and United Kingdom. Over 56 regions, 21 registered an increase in the average capacity between 1997 and 2005. We also distinguished regions having average capacity above and below the overall average of the data set (187 kW/N in both years considered). From Figure 6.9 and 6.10 it's evident that there aren't substantial differences between them. In Figure 6.9, is depicted the average capacity in 1997 and 2005 of the eleven NUTS2 regions above the overall average. They all belong

to Northern EU countries and five of them increased their average capacity during the two FIG programmes.

Figure 6.9 Average capacity expresses in kW/number of vessels in NUTS2 regions above the overall average

The following Figure 6.10 shows the evolution in capacity of the forty-fives NUTS2 regions below the overall average. In this case, the most part is located in the Mediterranean area and eighteen of them exhibit an increase between 1997 and 2005.

Figure 6.10 Average capacity expresses in kW/number of vessels in NUTS2 regions below the overall average

In addition, the correlation coefficient did not highlight any significant relation between the average vessel capacity (expressed by the ratios GT/Number of vessels and kW/Number of vessels) and the FIFG funds (cf. table 6.1). Among the top financed NUTS2 regions, only the Spanish Pais Vasco and Cantabria and West-Vlaanderen (BE), Nord - Pas-de-Calais (FR), Highlands and Islands (UK) and Bremen (DE) show large fleets in terms of average dimensions. In all the cases under analysis, the FIFG funds have been allocated in an undifferentiated way between small and large vessels.

Table 6.5 Correlations matrix between FIFG allocations and average vessel capacity(GT/N and kW/N). (Marked correlations are significant at $p < .05000$)

	FIFG allocations 94/99	FIFG allocations 94/99	GT/N	kW/N
FIFG allocations 94/99	1.00	0.98	0.03	0.01
FIFG allocations 00/06	0.98	1.00	-0.02	-0.04
GT/N	0.03	-0.02	1.00	0.96
kW/N	0.01	-0.04	0.96	1.00

Finally, in most of the NUTS2 regions considered the percentage reduction in the number of vessels has been much larger than the reduction in capacity (kW and GT) causing a general increasing in the average dimensions of the fleets. This consideration could be interpreted as an unintended effect of the fleet restructuring process undertaken by the European Union over the last decades (cf. social and economic impact hypothesis HP1).

6.5 Ex-post assessment of the territorial impacts of European fishery policies

In this paragraph we will present an interpretation of the spending information and its territorial effects in the coastal NUT2 regions of the ESPON space. With this scope in mind, the impact of CFP is considered through what has been the incidence, at territorial level, of the financial interventions in the fishery via the expenditures of the main financial instrument for the fishery sector, the Financial Instruments for Fisheries Guidance (FIFG), introduced in 1993.

The rationale for Structural Fund interventions in the area of fisheries (in other words, its specific objectives) is based on:

- The need for a more sustainable balance between fisheries resources and their exploitation
- Increasing the competitiveness of the fisheries sector
- Creating viable enterprises in the sector
- Strengthening the sector, which is going through a prolonged period of restructuring resulting from the increasing need to reduce over-fishing of limited natural stocks
- Revitalising those areas that are dependent on fisheries and related activity.

The FIFG was conceived with the aim of bringing together all fisheries oriented structural measures, in particular those concerning the promotion and marketing of fisheries and aquaculture products. Interventions in this field have been directed towards:

- Financial support for fleet renewal
- Adjustment of fishing capacity and protection of marine resources
- Socio-economic measures
- Processing and development of new market outlets.

The database¹⁰⁹ concerning this indicator is composed as follows:

- FIG allocations in total 1994-1999 on NUTS2 divided on targeted area of assistance (e.g. demolition) (EU15)
- Projected FIG allocations in total 2000-2006 on NUTS2 divided on targeted area of assistance (EU15)

In the 1994-99 programming period, the FIG contributed an estimated € 4,7 billion to regional economic development, covering a territory of 190 NUTS2 regions. The following 2000-06 FIG contribution was estimated around € 4.4 billion with a reduction of the 6.6% respect to the previous FIG programme. In this current FIG programme, the national and the Community contributions reduced respectively of the 3.5% and 14.3%. The number of financed NUT2 regions decreased to 181, while the number of the projects increased from 27419 to 39079 (+42.5%). Between the two programs, the NUTS 2 regions that have received most funding are broadly the same (cf. table 6.2).

Table 6.6 NUTS2 regions receiving most funding

NUTS2	REGION	FIG 1994-99		FIG 2000-06	
		Total cost	% FIG 94/99	Total cost	% FIG 00/06
ES11	Galicia	794.38	16.7	786.56	17.7
ES61	Andalucia	337.66	7.1	254.8	5.7
DK	Danmark	305.57	6.4	266.35	6.0
ES21	Pais Vasco	220.22	4.6	235.55	5.3
FR52	Bretagne	157.45	3.3	104.82	2.4
DE8	Mecklenburg-Vorpommern	125.72	2.6	117.61	2.6
ES13	Cantabria	117.76	2.5	93.16	2.1
ES7	Canarias (ES)	114.4	2.4	94.88	2.1
ES52	Comunidad Valenciana	110.24	2.3	112.87	2.5
ITA	Sicilia	94.39	2.0	71.13	1.6

Figure 6.11 shows the flow per head of the FIG funds in current prices to EU 14 countries. Inspections of this figure permit us to remark two features. First: the lion's share went to Spain even if there are some regions in Germany (Mecklenburg-Vorpommern), France (Bretagne), Finland (Åland), Denmark, United Kingdom (North Eastern Scotland and Highlands and Islands), Sweden (Västergötland, Sydsvenska), Greece (Ionia Nisia, Voreio Aigaio, Ipeiros), Portugal (Notio Aigaio) and Italy (Sicilia, Marche) that have been largely supported in both periods. Second the amounts of funds per head have decreased in the second period in all countries, with the exception of France, Sweden and United Kingdom. In particular in 112 NUTS2 regions over 171 the assistance decreased. The assistance increased in the remaining 59 regions, spread over France, Spain, Italy, Greece, Germany, Netherland and Sweden.

¹⁰⁹ Source: DG Fish website.

This extreme disparity existing between regions and within regions seems to confirm the general hypothesis that **impacts of CFP will be more significant the lower the geographical levels** (cf. general impact hypotheses Hp.1).

Figure 6.11 FIFG distribution per inhabitant. Programming period 1994-99 and 2000-06

It seems interesting also to analyse whether Structural expenditure have or not have a progressive effect from the fiscal point of view. The fiscal progressiveness is frequently interpreted as a symptom of social and economic cohesion or even a necessary condition for economic convergence between the member countries (Solanes and Ramon, 2002). For that purpose, in Figures 6.12 and 6.13 we represent for each NUTS2 region covered by the FIFG programmes, the relationship between the log of the GDP per capita and the amount of FIFG funds per head received in the two programming periods. In particular, Figure 6.12 relates to GDP per inhabitant 1999 with FIFG funds 1994-99 per head and Figure 6.13 to GDP per inhabitant 2002 with FIFG 2000-06. In each Figure, the set of points may be adjusted by a negatively sloped straight line, which reveals that, in general, funds distribution is inversely related to the countries' degree of development (measured by the level of GDP per head). However, the fact that the line of the second period is steeper than that of the first period indicates that the progressiveness has decreased during the last period.

Furthermore, the information of these figures allows us to make judgments about the financial treatment that regions have received in comparisons with their wealth levels. Thus, taking as a benchmark the adjusted relationship, the best relative positions is that represented by the horizontal distances between the region points and the adjusted line. In Figure 6.12, the best position corresponds to Åland (FI2) and Canaries (ES7) and the worst position to Galicia (ES11). With the FIFG program 2000-06 (Fig.6.12), new regions were financed and improved their economic conditions as North Eastern Scotland (UKM1), Pais Vasco (ES21) and Västsverige (SE0A).

Finally the distances in terms of GDP confirm the initial disparities existing among EU regions. For example in Figure 6.13 the best position corresponds to Trentino Alto Adige (IT31) and Bruxelles (BE). The worst positions are covered by the less favoured Estonia (EE) and Latvia (LV).

Figure 6.12 FIFG funds and relative GDP in NUTS2 regions. Period 1994-99

Figure 6.13 FIFG funds and relative GDP in NUTS2 regions. Period 2000-06

From the above general analysis it seems clear that FIFG funds have been distributed progressively among EU regions, even if the relative positions and the slope of the adjusted line indicate that progressiveness decreased from one programming period to the next. These findings agree with **the hypothesis that less prosperous regions receive more CFP support though the FIFG than the more prosperous regions** (cf. general

impact hypotheses Hp. 4). Consequently, an important condition has been fulfilled for the Structural Funds to enhance regional economic convergence in the EU during the last years.

Moreover, the Pearson correlation coefficients between the FIFG funds 1994-99 and the main indicators of the fleet capacity (vessels number, GT and kW) demonstrate that funds were distributed proportionally to the dimension of fleets, to the fishery employment but not to the level of landings (Tab.6.3).

Table 6.7 Correlation matrix. (Marked correlations are significant at $p < .05$)

	Fishempl	vessels N	kW	GT	Landings
Fishempl	1,00	0,87	0,80	0,84	-0,01
vessels N	0,87	1,00	0,76	0,70	0,29
kW	0,80	0,76	1,00	0,86	-0,14
GT	0,84	0,70	0,86	1,00	-0,05
Landings	-0,01	0,29	-0,14	-0,05	1,00
FIFG 94/99	0,86	0,84	0,64	0,80	0,25
FIFG 00/06	0,87	0,83	0,64	0,81	0,22

A way to test whether regions who benefits from a relatively larger increase in allocated funds have grown faster than the other regions is by plotting the growth rate 1995-99 of Value added from Agriculture, Forestry and Fishery (AFF)¹¹⁰ against the FIFG 1994-99 per capita (Bouvet, 2005). In this case a positively sloped fitted line in the scatter plot indicates that regions receiving largely amounts of funding tend to outperform other regions.

The test performed for 66¹¹¹ NUTS2 regions gives no evidence of a positive relationship between support and AFF Value added growth. (cf. figure 6.14). However, if performed only on the 27 NUTS2 regions with an AFF Value added higher than the 1995 overall average, the relation turns out to be positive (cf. figure 6.15). These results confute the **general impact hypothesis that the territorial impacts of the CFP may contradict with the aims of cohesion, territorial balanced development and polycentrism – Hp. 4**. On the contrary, the CFP seems to favour regions particularly specialized in fisheries.

¹¹⁰ In the ESPON databank, the value added indicator was available only for the entire Agriculture, Forestry and Fishing sector from 1995 to 1999.

¹¹¹ The only regions in common for both the indicators considered.

Figure 6.14 FIFG funds 1994-99 and AFF Value Added growth 1995-99 in 66 NUTS2 regions.

Figure 6.15 FIFG funds 1994-99 and AFF Value Added growth 1995-99 in 27 NUTS2 regions with higher AFF Value added ratios.

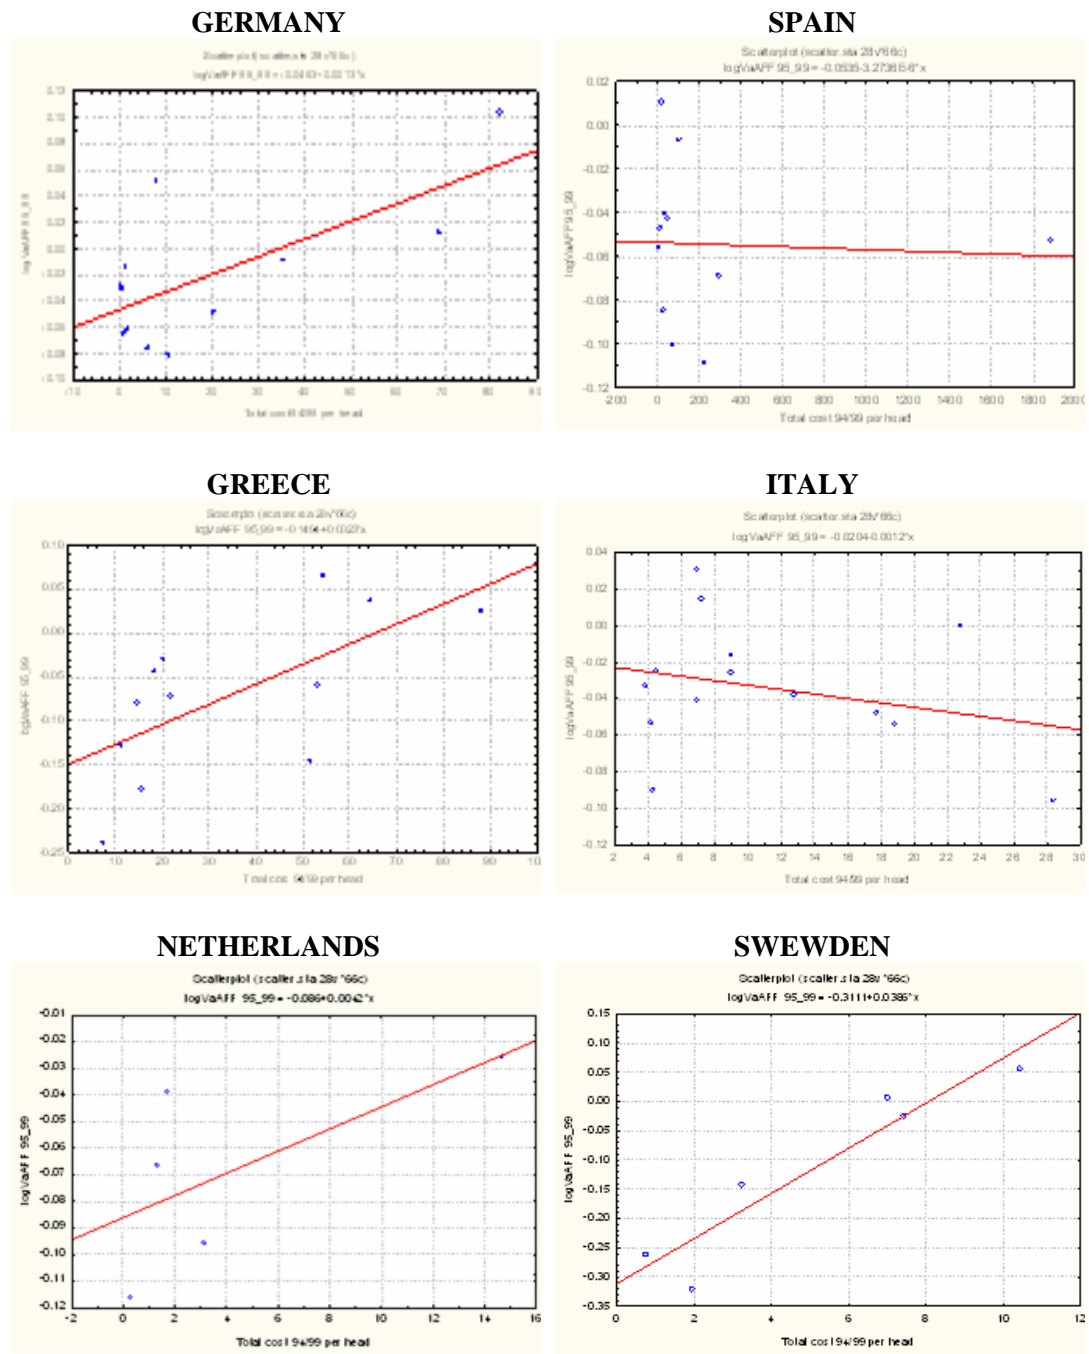

Figure 6.16 reports the same test distinct for six countries (that have a number of observations higher than three). In four countries (Germany, Greece, Netherlands and Sweden), NUTS2 regions that have received more support growth relatively faster. The

relationship is not verified for Spain and Italy. The reason of such negative slop could in part be related to the region's initial economic conditions. In any case the results seem to verify the fishery hypothesis that **Territorial impacts of the CFP measures are dependent on how the measures in use are implemented in the various regions** (cf. fisheries hypotheses Hp. 3), and in particular on the quality of national and regional administrations. As it was also underlined in the previous chapter, the Italian case appears emblematic. In the FIG allocation, it emerges a tendency to favour the central not specialised Italian regions to the detriment of the more fishery specialized regions mainly located in the south of the country. Such disparity is mainly to refer to the regional administrative decentralization realized in Italy, with the results that the more administrative skilful regions are able to obtain more public aids.

Figure 6.16 FIFG funds 1994-99 and AFF Value Added growth 1999-95 for some countries.

6.6 Conclusions

Our main concern in this study has been the lack of sufficient information in order to assess the economic impact of the CFP in the ESPON area. The relatively short period of our analysis allowed capturing part of the impact of the European CFP. In fact, many of the programmes and measures introduced are of a long term nature and produce their effect after a long number of years. Furthermore, the NUTS2 geographical level didn't allow for comparisons across regions. This geographical level comprises both states (as Denmark, Cyprus, Malta) and lower administrative areas of a same state. In the context of this analysis, it would be more appropriate to consider the NUTS3 regions. Unfortunately fishery information at NUTS3 level is very limited.

The improvement of the quality and homogeneity of statistics necessary represents an important priority. Even if several committees within the scientific community provide fishery information, there is yet a lack of consistency in the type and extension of data collected. For example, it has been underlined how the lack of data on the classification of fleet by fishing metier or system didn't allow for further differentiations among regions. In this perspective, a policy option could be aimed to strengthen the cooperation also through the development and diffusion of guidelines in order to support scientists in the application of good publication practices, to verify the source data and to improve quality in research.

In the present work we followed the approach of many scholars that have studied the impact of the European policy on the economic on the basis of the allocations of the Structural funds (for instance Boldrin and Canova, 2001; Barro and Sala i Martin, 1991; Cappelen *et al.*, 2003). These authors examined changes in the statistical distribution of several factors productivity and income per head of the EU regions during long period of time. Bearing in mind the narrowness of the information available, we verified that in general FIFG funds have been distributed progressively among regions, even if the progressiveness decreased from the 1994-99 programming period to the 2000-06 one. As expected, the main recipients are regions with larger fleets (in terms of number of vessels, engine power and gross tonnage) and higher level of fishery employment. It has also been noticed that even if the 2000-06 FIFG contribution was reduced of the 6.6% respect to the previous FIFG programme, in some 59 regions the assistance increased without any specific reason. On the contrary, it has been observed that institutional obstacles and existing policies can severely limit opportunities of effective utilization of FIFG funds. In fact, the study has demonstrated how effectiveness of FIFG programmes depends heavily on the region's initial economic conditions and on the quality of national and regional administrations.

Finally, the EU enlargement raises another challenge for the cohesion policy. The budgetary proposals of the new European Fisheries Fund for the 2007–2013 period anticipate that the share of funding allocated to the management of 'natural resources' (agriculture, rural development and fisheries) is expected to fall of around 36%. As envisaged by Symes (2005), enlargement threatens the achievement of cohesion goals for disadvantaged regions within the EU 15. "Although regional disparities have narrowed, they still persist especially in peripheral Europe. Several less developed regions are certain to fall outside any new thresholds for defining problem regions in the enlarged EU, including a number of fisheries dependent areas". In this perspective, the expected restriction of the future fishery funding will further sharpen the disparities among regions in relation to their capacity of utilization of economic support.

6.7 Policy recommendation

- A better specification of the concept related to fishery dependency and improvement in the quality of data collected.

The fishery dependency, mainly based on the relative importance of fishery employment and Value Added in the area, is also affected by the characteristics of the fishing activities (artisanal or industrial) and by the unemployment rate existing in those areas. In this perspective, restrictive policies could be better calibrated to the different local demands, especially in terms of socio-economic alternatives. For this reason, it is indispensable to improve the quality of economic and biological information collected at low geographical levels in order to integrate the different statistical sources and to improve homogeneity and comparability.

- The economic cohesions should be evaluated both in quantitative and qualitative terms.

CFP affects differently the local economies. This is confirmed by the fact that regions that are in the same initial conditions take different advantages of the resources received. At a lower geographical level, the impact assessment analysis should be better focused on disparities existing also in terms of proximity to resources, economic alternatives, administrative efficiency. In this sense, the example of the more dynamic regions could be deeply investigated in order to furnish a guide for the best practice.

7 Conclusions and policy recommendations

7.1 Conclusions

7.1.1 NUTS territories as territorial units for analysis, classification and typologisation

Typologisation and analysis based on NUTS territories is a challenge due to the heterogeneity of the NUTS units. One of the consequences of basing analysis on heterogeneous geographical units is a loss of differentiation between territories compared to what is found when more homogenous geographical territories are the analytical geographical units. NUTS territories will in comparison bring results that can be viewed as average scores for the homogenous territories within each NUTS territory (average in the meaning that it is the aggregate of statistics for smaller territories that is not available for the analysis). The typologisation effort has therefore included information on the heterogeneity of the territories by using a criterion for functional regions in the main typology. This does not change the basic limitations of heterogeneous territories as territories for regional comparison.

Due to the heterogeneity of the NUTS regions, and as the regions highly dependent on the fisheries will generally be smaller regions located *within* NUTS 3 territories, there has been a need for impact analysis (example studies) on LAU levels in the project. This has also been necessary in the project in order to be able to look into for example tendencies of concentration of activity within fishing to urban centres (even though in many cases seafood industries are still located in areas outside commuting distance to cities and with few alternative income sources). In some parts of Europe, the fishing industry still plays an important role in an otherwise underdeveloped rural economy. Many of our hypotheses require example studies. These example studies can be conducted in a way that takes into consideration the ESPON requirements of an analysis and policy recommendations on the macro, meso and micro scales.

The macro, meso and micro scales

The macro, meso and micro scale is integrated in the project by supplementing the mapping for the entire ESPON space with a set of example studies. We have:

- used information from evaluations of Interreg IIIB projects
- used relevant research projects already completed
- made analyses based on statistics from countries with relevant data on lower geographical levels

While the mapping involves the macro scale, the use of Interreg projects and to some extent of relevant research projects already completed involves the meso scale. For an impacts study of the CFP, the meso scale is not really very relevant, the CFP being related to the EU level and to national implementation. The relevance of the meso scale is primarily within aqua culture, where research projects conducted within Interreg have been of importance for the development within this sector. Research projects already completed and analysis based on statistics from countries with relevant data on lower geographical levels constitute our research on the micro level.

Indicators

There has been, as seen also in other ESPON projects, difficulties concerning both the availability of and the regional level of the data and indicators for this impact study. One result of this situation has been the necessity of making a differentiation of analysis between countries according to the availability of statistics. To some extent this has just implied a reduction in the number of countries in specific parts of the analysis, while in other instances an example study has been carried out instead.

Methodology for the impact analysis

The different WPs of the project have developed in different directions, the methodological work being quite different, but all of them working from a position where TIA as check list and within the agreement of making the analysis into an *ex post* study. The selected methodologies have been influenced by the geographical levels of analysis, matters concerning data availability and by the different subjects to be looked into.

The coastal typology

A territorial typology like the coastal typology represent a special kind of mapping of ESPON Space, giving an accurate picture of certain characteristics on the chosen geographical level. The territorial typologies will in most cases show a concentration of certain types in specific countries or in larger regions within Europe. This means that the typologies should be used with great care in territorial analysis covering ESPON Space, as national differences can be the more important factor, even though results on type of region can be interesting. This is a situation that research strategies will have to take into consideration, combining national context and ESPON Space.

7.1.2 Conclusion chapter 3 - Diagnosis of the Fishery Sector

The hypotheses outlined in the beginning of this chapter were related to different elements of the CFP (and fisheries politics in general): five hypotheses were related to conservation policy, two to market policy, two to structural policy, and one to external policy. On a general level the hypotheses have been supported by the analysis of the different policy areas. In the following discussion we will go through each hypothesis and sum up the main findings, mainly related to the CFP. However, the discussion and findings below apply in general also to the situation in Norway and Iceland, which are more or less subject to the same situation as the EU countries. However, the two countries are at present in a better situation in regards to the sustainability of stocks and the economic situation of the sector than the EU countries on average.

Conservation Policy Findings

Five hypotheses, which related to conservation policy, were outlined in the beginning of this chapter.

TAC management allows for quantitative allocation of fishing resources (catches) at all territorial levels (EU/international, regional and local) and the establishment of “relative stability” between geographical areas/territories; adopted at international level in the EU (and in some cases at national level, e.g. by the UK - via allocation to Producer Organizations). This implies intentional territorial impact.

The first hypothesis related to the intentional territorial impact of the CFP, which occurs from the allocation of fishing opportunities through quotas. Quotas are not allocated on the basis of need but following a principle of ‘relative stability’. This creates territorial impacts across nations on a very general level. Some nations might be better at matching their allocations to the structure of their sector, which gives them (and their regions) an advantage over other countries.

EAF and precautionary approach management implies that fishing effort will have to be reduced in waters/fish stocks involved and that catches from some stocks may be permanently lower but less fluctuating over time. This implies loss of jobs in the affected communities (onboard fishing vessels and in the related trades). The economic outcome may be positive but will directly benefit fewer people. The less fluctuating catches, which are also expected, will provide improved opportunities for investment planning. Unintentional negative territorial impact in the short and medium term is one result.

The second hypothesis was also supported by the analysis of the future direction of the CFP, which must be expected to move towards EAF. This will - at least in the short or medium term - lead to negative impacts because of lower (or at least not significantly higher) TACs, which are supposed to result in lower fishing pressure.

Applying market principles in the allocation of access rights to fish resources (e.g. ITQs) implies concentration of the fishing industry in territorial terms and fewer, larger and more efficient production units in the fisheries sector. Territorial impacts are not intended and sometimes negative impacts can be counteracted by policy measures.

The third hypothesis has mainly been dealt with in the section on Iceland. The analysis seems to support the assumption that ITQs in some instances lead to (often unintentional) regional redistribution, as well as to the desired restructuring of the sector towards larger, more efficient units. Market based management systems have, however, not yet been applied on a European scale.

Recovery plans for depleted fish stocks (involving closed areas, closed seasons, catch/effort limitations etc.) will in the short and medium term have negative impact on the fishing communities dependent on these resources. The more immobile and inflexible the fishing fleet is and the more species dependent the processing industry is, the more significant will the impact be. Coastal communities dependent on small-scale fishing may be particularly vulnerable. This implies unintentional territorial impacts in the short and medium term.

The fourth hypothesis related to the fact that recovery plans might have unintentional consequences. As discussed, recovery plans are intended to ‘punish’ or at least restrict the fleets targeting endangered stocks. This might be considered the intentional impact; an unintentional - partly territorial - impact is that the different fleet segments are put in different situations. Larger vessels might be able to utilise resources far from where they have homeport, whereas this possibility does not exist for smaller coastal vessels. This is unfortunate as it is often not the smallest vessels, which constitute a problem for the resources or destroy habitats. Therefore it seems unfortunate that they have to carry the largest burden.

Fishing communities, dependent on the exploitation of fish stocks that are within safe biological limits (e.g. North Sea herring and mackerel), are operating on a more stable resource basis and are thus experiencing less negative territorial impacts from fisheries resource management measures at both political and private business levels.

The fifth hypothesis was general and related to the distribution of negative impacts of the conservation policy. The analysis has to a high degree supported the hypothesis that the most important factor in determining how the negative impacts will be distributed across regions is the state of the stocks the fleets utilise. This is hardly surprising but the most important information related to this is in fact also the varying unintentional impacts; for instance the different possibilities to change gear or sea area.

Market Policy Findings

Fisheries market policies counterbalancing the free market forces have intended territorial impacts that may be on international (EU), national and local levels. Unintended impacts may occur in other territories/territorial levels.

The analysis of the market policy supported the assumption that this policy has serious territorial effects. The effects relate not so much to the direct financial transfers under the price support mechanism, which are relatively insignificant compared to those distributed under the FIGG. Rather, the varying territorial impacts are related to the different impacts of tariffs and external trade measures. An example provided in the preceding chapter was the decision to put an extra tax on (especially Norwegian) salmon. This was done in order to protect salmon producers in Scotland and Ireland but the safeguard measures had serious negative impact on salmon processors in Denmark, which depend heavily on Norwegian raw material.

The territorial impact of specific fisheries sector oriented market policies is of decreasing importance compared to the impact of general international and national market and food policies. This especially counts for territories dependent on import or export of fish products (fish as raw material for processing value-added products). The territorial impacts are unintended.

The analysis supports also the assumption that fish products will increasingly be affected by other policies not directly stemming from the fisheries market policy. The policy on traceability is provided as one example of such.

Structural Policy Findings

Two hypotheses were related to the impacts of the structural policy.

Fisheries structural policies have intended territorial impacts that may be on international, national, regional and local levels. Unintended impacts may occur in other territories or on other territorial levels.

The analysis supports the hypothesis that the policy has significant territorial impact; this is actually the whole idea of it. However, more interesting is the fact that some regions are able to get more funding from the EU based on considerations, which are wholly or partly unrelated to the situation of their fisheries sector. This puts unintentionally some regions in a better situation than other regions. Furthermore, the analysis has also shown how some countries and regions receive a very significant part of the total EU support, which in general puts their regions in a favourable situation *vis-à-vis* others. Galicia could be mentioned as one region, which gets a surprisingly large share of the total FIGG support. Finally, it is also interesting to see how the structural policy has - until recently - supported modernisation and renewal of the EU fleet in a situation, where overcapacity is considered one of the main problems facing the conservation policy.

Territorial impact in fisheries dependent areas are increasingly determined by global or national agendas, developments and policies rather than by EU sector specific structural policies.

The second hypothesis is related to the fact that the EU structural policies are increasingly becoming less important because of increasing impacts of the surrounding environment, i.e. the global development. Although this might be true, the impact of the direct injections of money through the FIFG (whether these are viewed as positive or negative) should not be underestimated. It could be argued that the FIFG support is important exactly to tackle a situation where the local markets and fleets are increasingly becoming part of a world market. In the new member states this is happening simultaneously with a demanding transition towards market economy.

External Policy Findings

The policies relating to fisheries agreements with third countries have territorial impact in regions with fleets, which utilise these agreements. Failures to renegotiate agreements or changes in circumstances around agreements have unintentional negative impact in affected regions. Impact can also be felt in regions not exploiting the agreements because they serve to keep some excess capacity out of Community waters.

The analysis clearly showed that the external policy has territorial impact, which varies across regions. This relates especially to fisheries agreements, which are of most importance for the southern EU member states. The transfer of money through the fisheries agreement could be seen as subsidies for the vessels engaged in these fisheries. However, also bilateral and international agreements or the failure to conclude these could have significant impact, as illustrated with the failure to get agreement with Norway over Atlanto-Scandian herring, which are of importance to a number of Danish ports.

In Sum

The analysis in this chapter has supported the outlined hypotheses and in this way also supported the underlying general hypothesis that the CFP (and fisheries policies in general) potentially has significant territorial impacts – intentional as well as unintentional. It is, consequently, possible to conclude that these hypotheses provide a good basis for the analyses in the following chapters on actual territorial impacts and example studies related to this. The chapter has, furthermore, outlined a number of concrete examples of territorial impacts as well as provided a thorough introduction to the structure of the sector in the EU, Norway and Iceland.

7.1.3 Conclusion chapter 4 - Environmental impacts and ICZM

Environmental impacts

Two of the hypotheses regarding environmental impacts of the fishery policy are:

- The changes in CFP from 2002 will contribute to a faster reduction and restructuring of the fishing fleet, both in absolute numbers, tonnage (GT) and engine power (kw).
- Changes in CFP will probably be directed towards improvements of the marine environment and marine resources. In the long run this may lead to higher and more stable fish stocks, but only if the fishing effort is sufficiently reduced.

CFP seems to be successful regarding reduction of the fishing fleet, which is a necessary precondition for a sustainable resource management. The size of the European fishing fleet decreased in the period from 1995 to 2003, both in terms of absolute numbers (15 %) and tonnage (4.3 %) as well as the most important indicator: engine power (13.2 %). However, it is too early to see if the changes in CFP from 2002 have contributed to an even faster reduction in the fishing fleet. The reduction from 2002 to 2003 was approximately of the same quantity than the years before.

From 1995 to 2002 the total catches of the EU25 fleet has dropped from app. 8 million tonnes to app. 6.8 million tonnes (in live weight), which seem to have a connection to the decrease in the fishing fleet. However, the total fish landings of all species in all European sea regions¹¹² have increased by 20 % (1.6 million tonnes) between 1990 and 2000, but with a small decrease from 1997 to 1999. The indicators on stocks outside biological limits indicate that the changes in CFP, i.e. reducing the fishing fleet capacity, are still not sufficient for a sustainable marine development. It is still an imbalance between fishing capacity and available resources. However, for a sustainable resource management, EU is also dependent on that other countries outside EU reduce their fishing fleet capacity according to the available resources. In that respect, a major concern is the agreements between EU and other countries regarding fishing.

At the same time, there is a need for a greater emphasis on the whole marine environment and ecosystems, and not only assessments for single species. During the last years there has been a greater focus on ecosystem approach in marine (including fisheries) management. However, it is a challenge to implement these ideas into the management regime. One central element is to move away from the single-species approach characteristic of the existing CFP and to adopt a multi-species and ecosystem-based management approach as indicated in the 2001 Reykjavik Conference on Responsible Fisheries in the Marine Ecosystems.¹¹³ Ecosystem-based management models are also needed to assess external impacts on fisheries such as accidental and operational discharges from oil exploitation and shipping activities toxic algae blooms, and runoff from land causing eutrophication and contamination (EEA 2002). An ecosystem approach should also be considered in a larger extent regarding development of indicators on this issue. The EU Water Framework Directive (2000/60/EC) draws up a more ecosystem based development of data and indicators, based on river basins, including coastal waters up to one nautical mile outside the basic line (see chapter x for information about the Directive). Also the EU's proposal Marine Strategy Directive is a step in that direction (European Commission 2005).

The increasing production in aquaculture is important for many countries and coastal regions. Aquaculture development is spread widely over Europe and is often found in rural zones or peripheral areas depending on fisheries, where alternative employment opportunities are lacking. In general, significant improvements in the efficiency of feed and nutrient utilisation as well as environmental management have served to partially mitigate the associated increase in environmental pressure in the coastal zone. Different types of aquaculture, however, generate very different pressures on the environment. Intensive finfish production generates the greatest environmental pressures and it is this kind of production which has increased most rapidly in recent years. The challenges are biggest in countries with high finfish production like Norway, UK and Ireland. The growth in aquaculture is also a challenge for the coastal zone management and planning,

¹¹² North East Atlantic Ocean (including the Baltic Sea), Mediterranean Sea, Black Sea and Arctic Ocean. The Caspian Sea and Aral Seas are not included, as these are considered to be "inland waters" by FAO.

¹¹³ <ftp://ftp.fao.org/fi/DOCUMENT/reykjavik/Default.htm>

particular with regard to adapt the locations to other coastal interests like tourism, recreation, nature and cultural heritage, coastal fishing, etc. Further expansion should be addressed through the concept of integrated coastal zone management (ICZM), which also the EU Strategy for the sustainable development of European aquaculture emphasise (see chapter 4.5).

TIA is mainly a methodology for territorial impacts on the terrestrial environment, and not the marine. The EEA has decided to directly address the issue of fisheries/aquaculture impact on the environment for possible inclusion in the development of a core set of indicators covering the whole driving forces – pressure – state – impact –response (DPSIR) assessment framework. The DPSIR-model does not fit so well to the TIA-model. DPSIR main focus is on the relation between human activities and environmental impacts, and responses to deal with the actual problems.

Integrated coastal zone management (ICZM)

Integrated coastal zone management (ICZM) is developed as a general tool to coordinate different and competing interests in the coastal zone. Being an integrated approach the ICZM has potential to offer a broader perspective to aquaculture and most of the fishery related activities. ICZM is a demanding task, which i.a. should have a broad “holistic” and long run perspective, integrating all relevant interests and sectors in the coastal zone. Activities in the coastal zone have traditionally been carried out by different sectoral bodies, and rigid bureaucratic systems. Sectoral policy in marine areas is also somewhat separated from the spatial planning system, and co-operation between them is not yet well developed. The definition of ICZM is still unclear. However, there is broad agreement that coordination and harmonisation of policies and activities across geographical and sectoral dividing lines and management levels are key elements. There is also considerable emphasis on the idea that such coordination should be based on an integrated overall approach and have sustainable development as its goal.

Some experiences with ICZM have been drawn from the EU Demonstration programme from 1996 to 1999, which included 35 demonstration projects and 6 thematic studies in different European regions. One lesson is that integrated solutions can only be found at the local and regional level. Particular the regional level, where it exists, has a key role to play in integrated planning and management of the coastal zone. This level of government is still closely aware of the specific context on the ground, but has a broad enough remit to take a strategic outlook. From the early 1990s there has been an increasing focus on the regional level concerning management and planning for the public sector, and EU has been a pusher in that direction. However, still it is a lot of differences among the European countries concerning the strength on regional management and planning. Related to integration between fisheries and spatial planning it is a challenge that the EU Fisheries policy is one of the EU policies that are least adaptable to regional needs, but there is a pressure for a greater regionalisation. One of the suggestions is to integrate the FIFG allocations with other structural policies, with a cohesion perspective.

Another lesson from the EU Demonstration programme is that the spatial planning system alone has some limitations to secure the idea of ICZM. The first is the necessity that the spatial planning system covers both the terrestrial parts and the marine part of the coastal zone. Only few countries have such integration today. The EU Water Framework Directive could secure this element because also coastal waters up to one nautical mile outside the basic line should be included in the river basin management plans. Another limitation is that the spatial planning system often focusing narrowly on development control rather than a broader ICZM focus. In that respect, it could be necessary to combine economic instruments to the spatial planning system. The tradition for protecting

coastal areas may also have led to a neglect of the ideas of ICZM as such, where a main purpose is to balance protection and development in coastal communities. ICZM strategies in fishery dependence areas should for instance also focus on new forms for development, such as aquaculture, tourism, etc.

The Interreg IIC project Norcoast emphasises Norway and Sweden with long tradition in integration between land and water interests in the spatial planning system for the coastal zone. While the regional and local spatial planning system for Norway reach to the baseline (e.g. the straight line between the outer islets and reefs), the local authorities in Sweden can include the sea in their spatial plans to the state boundary (12 nm). England, Scotland and partly the Netherlands have a range of experience in working with voluntary partnership approaches on regional level for management plans in the coastal zone. The Highland region in the west part of Scotland has for instance developed advisory management plans for aquaculture along sections of its coastline, which have proved fairly cost effective in areas of coastal waters which have come into pressure for this type of development.

One recommendation from the Norcoast project is to combine the best elements of the statutory spatial planning system with the best elements of the voluntary partnership approach in order to achieve integrated solutions. The voluntary partnership approach provides not only cooperation and transference of knowledge between sectors, but also encourages interest groups to take a wider view of their activities. At the same time the compromises required may lead to rather generalised policy statements, which require little real commitments, if not combined with statutory responsibilities. One solution is then to establish a coastal forum or partnership to develop a shared sense of stewardship, which should be integrated with the statutory planning system. It should, according to Norcoast, also be identified a lead partner to initiate and facilitate the ICZM-process. Coastal countries in Europe should also legislate for a clear statutory responsibility for spatial plans for land and sea areas. Norcoast recommends that planning methods for the coastal zone should allow a reasonable degree of flexibility for changing circumstances and new types of development. The rapid development of aquaculture is also regarded as a good example of technological and marked changes moving too fast for the conventional planning system to keep up. The planning system for the coastal zone has to be flexible to deal with the quick changes that occur in the coastal zone.

NIBR has studied experiences with regional and municipal coastal zone planning in Norway the recent years. Norway's long tradition of integrated sea-land planning and the major importance of the aquaculture industry for the Norwegian economy and its significant contribution to the pressure on the coast make the country an appropriate case for a study of the factors necessary for achieving integration between the interests of this industry and those of other interests. In Norway, integrated management of coastal areas is primarily ensured through municipal coastal zone planning in accordance to the Planning and Building Act. This planning is seen as an important tool for a balanced and sustainable development of the aquaculture industry and for ICZM more generally. The strong growth in the industry is the most important single reason why municipalities integrate the sea areas into their spatial master plans. By the end of 2003, 192 of Norway's 280 municipalities had such plans. In addition, 20 municipalities had started the planning process. Municipal coastal zone planning is based on two premises: that it enables adjacent sea and land areas to be considered as a whole, and that the planning takes place in an arena where all the relevant actors can meet. The plans shall as far as necessary indicate areas for special use or conservation at sea, including areas for traffic, fishing, aquaculture, nature and recreation, either separately or in combination with one or several of the area categories mentioned.

The studies show a tendency to a more flexible planning practice. Many of the earliest plans gave specifically allocated localities for aquaculture, and aquaculture could not take place outside those specific areas without dispensation from the plans. The new planning practise focus in a greater extent on areas where aquaculture not can find place out of consideration of other coastal interests as coastal fisheries, recreation, conservation, etc. The intension is that such strategy shall give the aquaculture industry more space and predictability, and secure sufficient flexibility for further expansion, and thereby secure employment and income to rural coastal communities. Aquaculture is seen as the main way to compensate for the decline in the local employment in many fishery dependent communities in Norway. The lack of knowledge about good locations for aquaculture in many municipalities is also an explanation for this shift in planning practice. The National evaluation of suitability of the Norwegian coast and river systems for aquaculture (LENKA) from the 1980s is now in a great extent outdated.

The experiences with municipal coastal zone planning in Norway are ambiguous. Much has been achieved with regard to the coordination of different local user interests within the municipality, also with regard to the coordination of coastal water and land areas. One important success factor is active stakeholder participation in the planning process and involvement of the general public, even though it is significant variations between the municipalities regarding this issue. On the other hand, there are great weaknesses in coordination across county and municipal borders, across different public (state) sectors and across levels of government. Regional coastal zone planning has been introduced to deal with these problems municipal planning so far had not solved. It is the county municipalities which have the overall responsibility with regional coastal zone planning, with close collaboration with the County Governor's Office (state representative in the county), the regional branch of the Directorate of Fisheries, local municipalities and private actors. The county municipality has, however, no jurisdiction over other actors. A county plan is not legally binding for either state or local municipal governments; it only gives guidelines for their activity. Since the county municipality has few legal means to enforce compliance with the plan, the establishment of networks or arenas where relevant actors meet, discuss their common challenges and try to agree upon a plan, might be an effective way to promote ICZM.

An experience from Norwegian regional coastal zone planning is that an open and inclusive decision process does not alone increase the integration capacity of the regional planning. The results rather support the opposite argument of a trade off between the number of actors participating in the decision process and the ability to agree on and implement a joint action which effectively will deal with the problem. Another experience from regional coastal zone planning is that the integration potential of network governance seems to rest on actors believing they will gain from co-operation. To gather different actors together to discuss and propose a coastal zone plan might contribute to more positive and close relations between these actors, and as such make co-operation easier when they in the future find it in their interest to do so. It does not in itself contribute to an integrated plan or a formal network engaged to accomplish integration in the implementation phase. The integration capacity of the planning process is greater were the context creates stronger interdependencies probably influencing the actors interest in co-operation. It does also help with some pressure from central government.

One conclusion is that integration through regional coastal zone planning and voluntary co-operation is possible, but also difficult to achieve. One important obstacle towards achieving the goal of integrated coastal zone planning and management is the fact that important public actors perceive a greater pay off from promoting their own goals and values through policy instruments controlled by the authority themselves, than from involving themselves in regional co-operation around an integrated strategy. In regions

where the pressure on the areas and the conflicts between different user-interests are more visible, different actors have joined together in networks established to promote integrated coastal zone management. More emphasis on this matter from central government would probably also help. Due to great regional differences, central government rather than to decide a national integrated policy, should lay stronger pressure on regional and local state and municipal authorities to co-operate in processes of integrated planning and policy making at regional level. Clear guidelines with regard to how regional state agencies should participate, as well as an institutional framework facilitating such co-operation is needed. Rewarding actors with a will to co-operate and sanction actors that avoid taking part in co-operation might be necessary to secure an integrated coastal zone management.

The hypothesis regarding aquaculture in IR2 is that this industry will increase the pressure on the coastal zone, but a management bases on ICZM could contribute to a further sustainable growth. The Norwegian experiences indicate that regional and local coastal zone planning could be a suitable instrument to balance the increase of aquaculture with other coastal interests. A central challenge is to find a balance between the need for long-term steering on the one side, and the need for flexibility on the other side. Greater pressure on the coastal zone could make it necessary with stronger governance and more detailed plans for aquaculture. In any case one precondition is broad participation from the relevant local interests and stakeholders, and the relevant sectoral administrative bodies to find an acceptable balance between growth in aquaculture and other interests as protection, recreation, coastal fisheries, etc. It is, however, a need for a regional approach across the municipalities regarding the development of the industry. Regional coastal zone planning and eco system based planning in accordance to the Water Framework Directive in the future may contribute to more integration across municipalities and a more ecosystem-based management, also in the case of aquaculture.

7.1.4 Conclusion chapter 5 - Social cohesion

The chapter is written as an examination of the opportunity to carry out social cohesion impacts analyses of the Common fisheries policy in the framework of territorial impact analysis. The most important part of the examination has been concerned with building analytical bridges between: the territorial dimensions and systems of European fisheries; the two major types of CFP (the specific economic measures (FIFG) and the “conservation” policies); the direct impacts of the CFP on the socio-economic systems of the fisheries; and the impacts on the position of the fisheries territories in the general European territorial systems. The main conclusion is that the attempt presented in the work package is a way that is possible to use in order to carry out relevant territorial impact studies of CFP. However there are several conditions that are not established yet, most of them related with building a valid systems for data registration, collection and analyses. Moreover there are also other more analytical challenges as:

- The need for building a valid idea about the territorial dimension of the European fisheries. From our point of view there is a contradiction between the enormous dimension of European fisheries and its minor territorial impacts when measuring those by using strict fisheries dependencies indicators. We have tried out a solution by using NUTS 2 territories, and from our point of view we have identified relevant territorial fisheries systems by these analyses. However we think that that establishing more permanent analytical systems of TIA in CFP should be able to use data on NUTS 3 level (conf chapter 1).

- The need for establishing a system for territorial distribution analyses of FIFG as well as the regulation policies which integrate these dimension to the territorial systems of the fisheries.
- The need for integrating analyses on fisheries territories and territories into the general analyses of European territorial development and changes. Here are at least two challenges: The first is to establish typologies that integrate fisheries territories characteristics with other ESPON typologies as information about polycentrism, functional/urban and variables registering the emergence of new types of economics. The other is to build valid indicators for comparing territorial development. In the examination we have used indicators on population changes, income changes and consumption changes. We are not sure that these indicators are the most valid for analysing all types of European territories. The finding in the chapter is that it looks like the fisheries specialised territories in systematic way have experienced more negative trends than the average European territories in the period around 2000 is an argue for building such systems.

The more specific content of the chapter is:

- An examination of the availability of relevant data in the ESPON-databases as well as in national sources. For the moment bases on both of these levels lack a lot of data and we have not identified data registering systems which for the moment will make such data available.
- An attempt on revising and building new ideas of the territorial dimensions of European fisheries which can substitute or complete the traditional fisheries dependency perspective.
- An attempt to analyse the territorial distribution of the CFP policies measures (FIFG and the fisheries resource regulations)
- An analysis of the direct impacts on fisheries from CFP, analysed by using data on fisheries employment.
- Analysis of socioeconomic changes in European fisheries specialised territories compared with the development in other European coast territories. In these analyses we have used variable on three indicators: Population changes, income changes and household consumption changes.

All analyses are based on mapping indexes developed in the analyses. The chapter discusses the experiences from the analyses regarding using TIA in CFP-analyses, giving three types of policies recommendations based on the conclusions from the mapping as well as the example studies.

7.1.5 Conclusion chapter 6 - economic cohesion

Our main concern in this study has been the lack of sufficient information in order to assess the economic impact of the CFP in the ESPON area. The relatively short period of our analysis allowed capturing part of the impact of the European CFP. In fact, many of the programmes and measures introduced are of a long term nature and produce their effect after a long number of years. Furthermore, the NUTS2 geographical level didn't allow for comparisons across regions. This geographical level comprises both states (as Denmark, Cyprus, Malta) and lower administrative areas of a same state. In the context of this analysis, it would be more appropriate to consider the NUTS3 regions. Unfortunately fishery information at NUTS3 level is very limited.

The improvement of the quality and homogeneity of statistics necessary represents an important priority. Even if several committees within the scientific community provide fishery information, there is yet a lack of consistency in the type and extension of data collected. For example, it has been underlined how the lack of data on the classification of fleet by fishing metier or system didn't allow for further differentiations among regions. In this perspective, a policy option could be aimed to strengthen the cooperation also through the development and diffusion of guidelines in order to support scientists in the application of good publication practices, to verify the source data and to improve quality in research.

In the present work we followed the approach of many scholars that have studied the impact of the European policy on the economic on the basis of the allocations of the Structural funds (for instance Boldrin and Canova, 2001; Barro and Sala i Martin, 1991; Cappelen *et al.*, 2003). These authors examined changes in the statistical distribution of several factors productivity and income per head of the EU regions during long period of time. Bearing in mind the narrowness of the information available, we verified that in general FIFG funds have been distributed progressively among regions, even if the progressiveness decreased from the 1994-99 programming period to the 2000-06 one. As expected, the main recipients are regions with larger fleets (in terms of number of vessels, engine power and gross tonnage) and higher level of fishery employment. It has also been noticed that even if the 2000-06 FIFG contribution was reduced of the 6.6% respect to the previous FIFG programme, in some 59 regions the assistance increased without any specific reason. On the contrary, it has been observed that institutional obstacles and existing policies can severely limit opportunities of effective utilization of FIFG funds. In fact, the study has demonstrated how effectiveness of FIFG programmes depends heavily on the region's initial economic conditions and on the quality of national and regional administrations.

Finally, the EU enlargement raises another challenge for the cohesion policy. The budgetary proposals of the new European Fisheries Fund for the 2007–2013 period anticipate that the share of funding allocated to the management of 'natural resources' (agriculture, rural development and fisheries) is expected to fall of around 36%. As envisaged by Symes (2005), enlargement threatens the achievement of cohesion goals for disadvantaged regions within the EU 15. "Although regional disparities have narrowed, they still persist especially in peripheral Europe. Several less developed regions are certain to fall outside any new thresholds for defining problem regions in the enlarged EU, including a number of fisheries dependent areas". In this perspective, the expected restriction of the future fishery funding will further sharpen the disparities among regions in relation to their capacity of utilization of economic support.

7.2 Hypotheses on territorial impacts of CFP

The second and third interim report presented a list of hypotheses of territorial impacts related to European fisheries policy. The hypotheses referred mainly to CFP and their respective measures and to some extent also to the development of aquaculture. The fishery policy in Iceland and Norway is also included in this analysis. Related territorial impacts projects within the ESPON program was taken into consideration in the development of the hypotheses. The time period between the third interim report and the final report, therefore, has mainly been used to sharpen and highlight the hypotheses based on the overall results from the project. This section summarise possible territorial impacts of CFP in the light of the hypotheses in the project based on both analyses from mapping and example studies.

General impact hypotheses:

1. *The CFP will have different impacts between coastal regions, and within regions.*

In order to identify territorial impacts of the fisheries policy, both NUTS3 and NUTS2 level often constitute a too high level of analysis. However, on a lower geographical level impacts of CFP may be significant. This is verified in the example studies which also show that processes on restructuring, reduction and expansion occur side by side and in various combinations, both between coastal regions and within regions. The example studies clearly indicate that CFP will have different impacts within regions.

2. *Socio-economic effects related to employment, migration, age structure of the labour force etc., may be less devastating in urban regions than in fisheries dependent regions and areas.*

Economic, social and demographic impacts of the CFP seem to vary between urban and remote areas according to these elements. However, to what extent this is a product of the fisheries policy or other changing forces is rather uncertain according to our studies. A crucial point in remote areas is the problem with accessibility to the market (as export nodes) and lack of a sufficient infrastructure.

3. *Territorial impacts of CFP will vary with different structures of the fishing and aquaculture industries of the regions.*

Impacts of CFP seem to differ in accordance with the extent the regions are dominated by coast fishing and small vessels, fishing in distant waters with greater vessels, landings, fishing processes or aquaculture. In Bornholm, for instance, the landings of cod have been lower than they needed to be just because the fleet, which to a large extent consists of small vessels, has had difficulties in fully utilising the quota available. Furthermore, even though there has been a general decline in fish landings, the powerful fish processing sector in Bornholm has managed to detach itself, at least partly, from the local landings.

4. *Territorial impacts of the CFP may contradict with the aims of cohesion, territorial balanced development and polycentrism.*

There is no unambiguous tendency that CFP contradict aims of territorial cohesion. Generally it is very difficult to separate impacts of CFP from other sector policies, and our findings indicate that different measures have different impacts in different regions due to the structure in the fisheries, accessibility, political and administrative capacities and so on.

Social and economic impact hypotheses:

5. *The CFP has unintended side effects in coastal regions or fishery dependent regions. Significant territorial impacts may be:*

- Economic effects such as increasing unemployment
- Decreasing regional economic productions (GDP)
- Population decreasing due to out-migration particularly in fisheries regions
- Altered age composition in fisheries dependent regions, with an increasing share of elderly
- Population. Indication of gender and age biases in fishing dependent regions
- Change in population density in fisheries regions

The example studies illustrate different development trends in different fishing dependent regions in Europe according to these characteristics. For instance, Ría

de Arousa in Galicia (Spain) is a fishery dependent area that shows a positive demographic evolution compared to Galicia as a whole and constitutes a fast growing economy. However, several of the other example studies show a tendency of declining population and unbalanced age-structure (ageing), decrease in the employment in the fisheries sector, particularly in capture and processing industry, and reduction in income in relation to national average. A common challenge is to allure young people to the fishery sector. The link between the CFP and the described socio-economic changes is usually not straightforward because it is difficult to distinguish the effects of general social and economic development from the CFP-effects.

6. *As the restrictions on harvesting activities mainly target the fishing fleet these measures have strongest negative impacts in remote, coastal region, while the more urban regions involved in fish processing still are able to source raw fish through e.g. import from 3rd countries .*

The Borholm example study elucidates the importance of the impacts of the conservation policies of CFP, probably due to this region dependency of very few and quota regulated species. However, The Bornholm case also highlight that a relatively remote, non-urban region can source raw-material from 3rd countries when they have the economic strength and the technological and human expertise to be international competitive.

7. *More favourable regions are able to take greater advantage of the measures included in the FIFG due to closer access to products and markets.*

Some of the example studies support this hypothesis. For instance Galicia is the European region which has most benefited from FIFG funds. The Ría de Arousa case shows that FIFG funds help adapt to the new conditions of access to European and international fishing grounds and favours the restructuring, modernisation and improvement of the fishing sector. The fishing sector has been more competitive. The study of the territorial distribution of the Norwegian fisheries measures indicates that the system favouring the already growing West coast and discriminate less prosperous regions in the North coast. The major reason is not, as stated in the hypothesis, that the West coast has closer access to products and markets, but rather that the national policies target shipbuilding factories and renewal of vessels.

CZM/environment hypotheses:

8. *Subsidies to support incomes or costs reduction in the fisheries sectors result in an increase of the fishing effort which has undesirable effects on social and environmental sustainability.*

Industrialised countries are particularly concerned with overexploitation aspects, and due to biological constraints, fishing subsidies mainly aim at capacity reduction. However, we have no certain evidence in our project which could either weaken or strengthen this hypothesis.

9. *The changes in CFP from 2002 will contribute to a faster reduction and restructuring of the fishing fleet, both in absolute numbers, tonnage (GT) and engine power (kw).*

The study supports this hypothesis. CFP seem to be successful regarding reduction of the fishing fleet, both in absolute number, tonnage (GT) and engine power (kw) from 2002. However, some countries and regions have contributed more to the decrease than others.

10. Changes in CFP will probably be directed towards improvement of the marine environment and marine resources.

Despite the overall drop in the fishing fleet, no visible improvements in the conditions of the fish stocks has so far been observed. As new technologies makes fishing vessels ever more efficient, the capacity of the fleet should be reduced to maintain a balance between fishing capacity and the quantities of fish that can safely be taken out of the by fishing. Compared by the indicative policy objectives, only modest reductions in the capacity of the European fleet as a whole have been achieved. Most of fish stocks of commercial importance in European waters still appear to be outside safe biological limits. However, there is a need for a greater emphasise on the whole marine environment and ecosystems, and not only assessments for single species to get a more comprehensive understanding.

11. Aquaculture will continue to expand, but the further development may be more regional concentrated both with regard to value added and employment.

Aquaculture is in many cases localised on the basis of availability of suitable production sites. On the other hand, the development of the salmon industry in Norway shows a tendency that the industry is becoming more regional concentrated both with regard to value added and employment during the latest years. Arousa, which is the top world mussel producer, is still characterised by many small farms, but perhaps in the next few years a property concentration will take place in order to attain a more rational exploitation of the well barge areas.

12. A management based on ICZM principals will contribute to a further sustainable growth in aquaculture.

Coastal zone planning based on the ICZM principles in Scotland and Norway, two of the countries with the biggest growth in aquaculture production from 1990 to 2002, show that this instrument have potential to be a useful contribution in order to secure further sustainable growth in aquaculture. This is particularly the case when it comes to balance the growth in the industry with other coastal interests. A major challenge is the competition for space in the coastal zone.

Fishery hypotheses:

13. Changes in CFP may contribute to increased concentration and centralisation of the seafood industry.

The Norwegian example study demonstrates a weak urbanisation of the fisheries, mainly due to lower decline of the fisheries employment in the FUA-centres than in areas outside the FUA-centres. These tendencies can demonstrate a potential new pattern where the fisheries increase in areas where there are several economic favourable alternative labour opportunities for the fishermen.

14. The potential and the preconditions for innovation and restructuring in this sector are probably highest in regions with larger cities or in close distance to larger cities (FUA).

There is not much evidence in the project related to this hypothesis but findings in the example studies from Iceland and Denmark suggest that innovation also is taking place in more remote and non-urban areas.

15. Territorial impacts of the CFP measures are dependent on how the measures in use are implemented in the various regions.

Impacts will also vary by the structure of the fisheries in the respective regions and the access to alternatives, such as fishing opportunities, sources of fish raw material for processing, alternative job opportunities etc.

16. Less prosperous regions of the EU receive more CFP support through the FIG (Financial Instrument for Fisheries Guidance) than the more prosperous regions.

The analysis does not verify this hypothesis but show that in general FIG funds have been distributed progressively among regions. Regions with larger fleets and higher level of fishery employment are the main recipients. However, the effectiveness of support programmes (FIG) depends heavily on the region's initial economic conditions and on the quality of national and regional administrations.

7.3 Policy recommendations

The policy recommendations take the set of hypotheses which has directed the analyses in mapping and example studies as their point of departure.

General policy recommendations

- As the CFP is likely to have different impacts in different regions, and in different types of regions, the policy should be directed towards (possibly by use of best practises) social, economic and territorial cohesion. Special care should be taken to counteract negative development in lagging regions.
- As the CFP is likely to have unintended side effects in coastal/fishery dependent regions, there is a need to develop policies that can counterbalance the non-fishery aspects of these side effects (as listed in hypothesis 5). The same is the situation if impacts of the CFP should be shown to contradict aims of cohesion, territorially balanced development and polycentrism.
- The development in urban-rural relations in the fisheries should be governed by thoughts about polycentric development, and the assumption that such a development is especially advantageous in countries and territories with lower population densities (which is the situation in many fisheries dependent regions)
- The relation between territorial impacts and the structure of the fishing and aquaculture industries of different regions should be a basis for policy recommendations

Policy recommendations related to environmental impacts and ICZM

- There is a need for a greater emphasise on the whole marine environment and ecosystems, and not only assessments for single species in the fishery policy. The efforts according to this should be further stimulated, also in regard to the development of indicators for environmental impacts of fishery and aquaculture. Today most of the indicators focus on the development of single fish species with commercial interest. An ecosystem approach is also demanded in order to trace environmental impacts of the aquaculture industry.

According to the ICZM example studies, primarily regarding the aquaculture industry, we point out the following policy recommendations:

- It is necessary to further develop the integration of the terrestrial and marine environment in coastal planning and other ICZM activities.

- It seems to be an effective strategy to combine the best elements of the statutory spatial planning system with the best elements of the voluntary partnership approach in order to achieve integrated solutions at the regional level of government.
- To find acceptable balances between further growth in aquaculture and protection and other interests in the coastal zone, it is a precondition with a broad participation from relevant local interests and stakeholders in the planning processes, together with relevant sectoral administrative bodies. Environmental Impact Assessment (EIA) and Strategic Environmental Assessment (SEA) could be useful instruments in the process to find the right balance between protection and use.
- The aquaculture industry is in a continuously technological change, i.e. with introduction of new species and in being more offshore based. It is, therefore necessary with flexible planning approaches in order to be able to deal with the quick changes that may occur. It is, however, also a need to find suitable combination between the need for long-term steering and predictability on the one side, and the need for flexibility on the other side. The specific choice in this regard will be dependent on the specific context on the ground.
- It is a need for a regional approach across the municipalities and other administrative borders regarding the development of the aquaculture industry and other coastal activities. The implementation of the Water Framework Directive may contribute in that direction.

Policy recommendations related to social cohesion

Based on the examination we recommend four main types of recommendations focusing on the policies development. All four are about the question of the need of integrating if integration should take place, and are elaborated in the summary:

- There should be a better co-ordination of the implementation of the economic measures in CFP (the FIGF) and the fish resource regulation policy. Most of data on the latter territory level is not available, but the impression is that there is no co-ordination, and that FIGF in some countries rather targeting new types fisheries models than the specialised territories. Thereby the structure in the latter territories is in danger of being conserved (becoming rawfish satellites) and territorial differential processes are increased.
- The interplay between fisheries policies implemented on national and European level should be better integrated. The national level has a central role in the implementation of the part of CFP focusing of economic support for the fisheries. The distribution analyses as well as the example studies demonstrate that the national implementation processes probably in many occasions vary between the nations, and that these variations can have territorial as well as social cohesion impacts in the respective countries as well as in the European space.
- European sector policies of the fisheries should be adjusted in accordance with the European territorial policies on reduction of social cohesion differences on the European territory. Despite the restriction of the actual data, the conclusion can be that these two types of policies do not pull the European territorial development in the area of social cohesion in the same direction.
- There is a need for integrating territorial characteristics and development trends in to the market policies.

Policy recommendations related to economic cohesion

- A better specification of the concept related to fishery dependency and improvement in the quality of data collected.

The fishery dependency, mainly based on the relative importance of fishery employment and Value Added in the area, is also affected by the characteristics of the fishing activities (artisan or industrial) and by the unemployment rate existing in those areas. In this perspective, restrictive policies could be better calibrated to the different local demands, especially in terms of socio-economic alternatives. For this reason, it is indispensable to improve the quality of economic and biological information collected at low geographical levels in order to integrate the different statistical sources and to improve homogeneity and comparability.

- The economic cohesions should be evaluated both in quantitative and qualitative terms.

CFP affects differently the local economies. This is confirmed by the fact that regions that are in the same initial conditions take different advantages of the resources received. At a lower geographical level, the impact assessment analysis should be better focused on disparities existing also in terms of proximity to resources, economic alternatives, administrative efficiency. In this sense, the example of the more dynamic regions could be deeply investigated in order to furnish a guide for the best practice.

Summary policies recommendation

The policies recommendation can be summarised according to that the CFP categories correspond to the three types of EU objectives (sustainability, competitiveness and territorial and social cohesion); and can be implemented on three different levels (micro, meso and macro). Moreover the fisheries policies can be separated into the conservation policies and the distribution of the economic measures. The present CFP are italicised in the figures:

Table 7.1 The conservation policies

	Micro (enterprises, local, regional)	Meso (nation, bilateral agreements)	Macro (European)
Sustainability (Conservation objectives)	Alternatives: Implementation of local/regional co-management based systems	CFP today by the role of the national level in implementation of CFP	Alternatives: More of the implementation from the main territorial fisheries systems
Competitiveness (Market objectives)	CFP today and in the future by forcing winner regions in the national battles for quotas.	Alternatives: Implement the knowledge of the specific regional characteristics of fisheries in the conservation policies (gear types, species dependence ...) in order to give all regions the same starting point in the quota distribution	Alternatives: Implementation of a common quota distribution policies which give all actors real similar opportunities to get access to the fish resources.
Territorial and social cohesion (structural objectives)	CFP today by forcing territorial cohesion on low level in winner regions in the national battles for quotas. Alternatives: Helping the loser regions by “buying back” quotas	Alternatives: Improve the co-ordination between the conservation policies and the national territorial policies	Alternatives: Improve the co-ordination between the conservation policies and the common policies e.g. the structural funds.

Table 7.2 The economic measures

	Micro (enterprises, local, regional)	Meso (nation, transnation)	Macro (European)
Sustainability (conservation objectives)	CFP today by “buying out” programmes	Alternatives. Co-ordination with ecosystem based management systems	Alternatives: Co-ordination with eventual systems targeting the major European territorial fisheries systems
Competitiveness (market objectives)	Alternatives: Strategic priorities of selected communities	CFP today by the national opportunity for co-ordination of the economic policies measures	Alternatives: Co-ordination according to strengthen of particularly parts of the territorial

Territorial and social cohesion (structural objectives)

CFP today by de facto favouring selected locals and regions.

Alternatives: Specific support of “buy back programmes” of quotas in regions which have lost in market based allocation regimes as some Icelandic communities and the northern Norwegian counties

Alternatives: Coordination with national policies and programmes

systems of the fisheries

Alternatives: Coordination with EU-policies and programmes

PART 3 Results of the project: Example studies

1 Introduction

This part of the final report presents the example studies in the ESPON Action 2.1.5: Territorial Impacts of European Fisheries Policy.

The example studies have from the start of the project been planned as a way of getting to grips with the micro level in the project. Originally we looked at the micro level as a geographical level where we could analyse processes that could not be studied properly on the NUTS levels. They were in other words looked at as studies on LAU levels.

As the project has matured, it has appeared that the micro level should be regarded also as a perspective, where the micro level becomes the level for analysing ESPON results from a national standpoint. This means that the micro level example studies have primarily become the part of the fisheries project for analysis of *national implementation* of the CFP. The example studies have thus become more important for the project than originally conceived. When it comes to implementation, a distinction must be made between EU member countries and non members, where the micro level to a greater extent shows the impact of a country's national policy for the latter. To a large extent, also the impacts in the new member states will be related to older impacts from national policies.

From the start of the project, we needed to conduct example studies to make distinctions according to an urban-rural dimension, as locational aspects for this dimension cannot be properly analysed on any NUTS level. The example studies therefore become very central for the impacts hypotheses on urban-rural aspect of CFP since only example studies makes it possible to analyse impacts on LAU levels.

The LAU levels are also vital for the delimitation of fisheries dependent territories within selected nations, as only LAU areas can be called fishery dependent in the true sense of the word in most ESPON nations. Only by using LAU areas can a comparison on dependency between countries be achieved. This has to do with the problem of differing size for the NUTS 3 territories, which means, as stated in the final report of MegaPesca on employment and dependency in fishing (Commission of the European Communities 2000) "... the area and population size of the NUTS 3 areas can vary considerably between member states which can significantly affect the ratio." We do in other words need a finer geographical sub division for some geographical areas to be able to make more accurate comparisons. Information on such levels is, however, only available for selected countries, which means that it will be impossible to cover ESPON Space. It is therefore important to see the territorial impacts of the policies in a perspective where we can make distinctions according to level of fisheries dependency. Example areas have been selected from a number of countries, covering important nations within ESPON Space in fisheries terms, and geographical areas within these countries that are important fishing communities in these countries.

There are three different possible sources for the example studies on the fisheries in the selected geographical territories:

- Information from evaluations of Interreg projects
- Relevant research projects already completed
- Statistics on LAU levels

As the example studies consider national implementation, the relevance of typologisations based on ESPON Space has changed. Some of them are quite simply not relevant for studies on national implementation, as the nationally important regional patterns behind the implementation are not visible on a European scale. To some extent, selected national classifications could supplement ESPON territorial typologies to clarify the national context. The example studies have been carried out by the different national TGP partners in the project, as they have first hand knowledge of the national development in their own countries.¹¹⁴

1.1 Classification of example studies in relation to typology

In order to place the example studies in a European context the studies are classified and related to the coastal typology for ESPON space. The purpose of the typology is to contribute to studies of regional variation in coastal territories, where it aims at providing a useful basis for analysing differences between regions according to their relation to Functional Urban Areas and population density. The typology covers all NUTS 3 territories with a coastline, and has been based on the FUA typology, population density, and share of the population living in FUAs.

As can be seen from table 1.1 the example studies presented here falls into 5 different categories ranging from Hinterland to Transnational/national 1. This indicates that the example studies represent very different geographical territories with regard to population density and the level of urbanisation. The majority of the studies are located in what must be characterised as peripheral territories, whereas three of the studies are in NUTS territories with mid size centres. The study areas in the hinterland type can be linked with what is generally called “the Nordic periphery”, consisting of thinly populated areas with small centres, and where this strongly influences job opportunities locally. There are no FUAs within these territories, which mean that the centre – periphery dimension locally will have to relate to small towns at best.

¹¹⁴ There are two studies from Norway. NIBR has produced the one presented in chapter 3 *Territorial variations in the fishery sector in Norway*, whereas the NORUT Group has produced the one in chapter 4 *Forcing territorial differentiation: The Norwegian Example - Fisheries policies allocated by market models*.

Table 1.1 Classification of example studies in relation to typology

Hinterland	Regional/local 1	Regional/local 2	Regional/local 4	Transnational/ national 1
Westfjords (Iceland)	Troms (NO)	Oeste (Nazaré and Peniche) (PT)	Bornholm (DK)	Møre og Romsdal (NO)
Finnmark (NO)	Hiiumaa (EE)			Rio de Arousa
Sogn og Fjordane, (NO)				Salerno (ES)

The three types of regional/local example studies constitute different territorial distributions between FUA/non FUA population and densities within NUTS 3-territories with only small centres. This also means that they are differently integrated into urban regions. The regional/local 1 studies are in Northern Norway and Estonia. The territories in this coastal type have a low population density combined with a low share of the population living within FUAs. This means that for results based on the NUTS 3 level, the rural population will influence the findings to a large degree. Like the hinterland examples, these can also be described as within the term “Nordic periphery”. In cases where such a periphery include centres (as is the case here), this often mean that these centres have a strong influence on regional development.

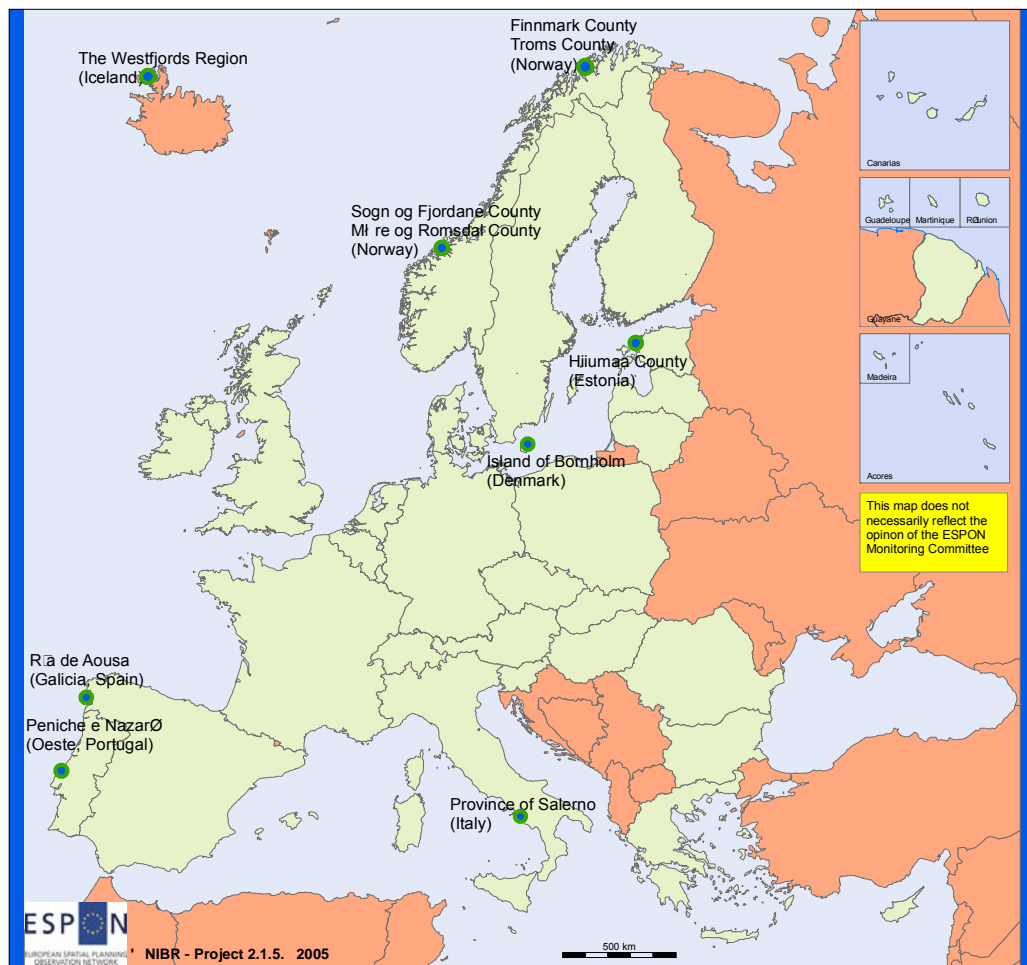

The Portuguese example, falling within the Regional/local 2 type differs from the type discussed above in that the population density is higher. It is however still a type where the FUA population is a minority within the territory. This is a more continental type of territory. The selected example area is located relatively close to a capital, Lisbon. This however is not revealed by the typology, but from comparisons with proximity/accessibility indicators.

The Danish example area, falling into the regional/local 4 type, is one where a large share of the population lives within a smaller FUA, and the population densities are relatively high. In this territory, there is a larger share living within FUAs. The population is in other words more urbanised than in the other example studies within the regional/local types.

There are also three example studies where the NUTS 3 territories the example studies fall within is in the transnational/national 1 type. They are found in Italy, Norway and Spain. Even though these territories have larger towns within their borders than the other NUTS 3 territories listed in table 1.1, the population living outside FUAs still outnumber the population living within them. This means that the economy is not as urbanised as the heading transnational/national might indicate at first glance.

Figure 1.1 shows where the different example studies are located. They include coastal communities of the Baltic Sea and the Mediterranean as well as communities along the Atlantic coast. The two largest fisheries nations within EU/EEA, Norway and Iceland are included, as well as the most important southern European fishing nations. By including Estonia, we get information on conditions in one of the new member states formerly under Soviet regulations. By including Denmark, we can look at conditions for a community in one of the most important fisheries nations in Western Europe.

Figure 1.1 Example study regions ESPON 2.1.5

2 The Westfjords region in Iceland: An Icelandic fisheries region in times of depopulation

2.1 The region

The Westfjords region¹¹⁵ is a remote and mountainous peninsula of 9,200 km² located close to some of Iceland's richest fishing grounds. The Westfjords is a LAU 1 region. Traditionally the Westfjords has been one of Iceland's main fishing regions. However, during the past few decades the region's strong position has been eroding in times where the general development has been towards larger companies with large and diverse fishing ships. These companies have a particularly strong position in the northeast and in the capital region. The development of the Westfjords in recent years is in the political debate sometimes linked to the individual transferable quota system based on the Fisheries Management Act from 1990. The development in the Westfjords does not describe the development in other LAU 1 regions in Iceland.

Figure 2.1 The Westfjords region

¹¹⁵ Vestfirðir in Icelandic

2.2 Population development

The Westfjords region is one of the most sparsely populated regions in Iceland with only 0.83 persons per km². It experienced much decline in population during the last century and the process is still going on. In 1901 there lived 12,481 in the region but in 2004 there were only 7,698 persons, a decline of 38%. During the same period the Icelandic population grew from 79,000 to 294,000 and 63% of the population lives in the capital region. In the capital region and an area within 45 minutes driving distance, there lives approximately 75% of the Icelandic population. There has been heavy out-migration from the Westfjords as is the case with many other regions, to the capital region. In 1997, of those persons born in the Westfjords region, no less than 46.3% lived in the capital region!

Figure 2.2 Population development in the Westfjords region 1990-2004

Source: Statistics Iceland (2005)

The out migration is still an important fact in the demographic development of the region. According to a survey carried out by the Icelandic Institute of Regional Research some 27% of the inhabitants state that it is likely or rather likely that they will migrate out of the region during the next 2-3 years (Sigursteinsdóttir and Ólafsson, 2004). According to data on unemployment, a lack of jobs in general is not the main reason for this trend. According to a large research on migration in Iceland carried out in 1997 factors associated with modern urban lifestyle are very important. Examples of these factors influencing migration decisions are varied jobs in the tertiary sector and a wide variety of services only found in larger urban settings (Ólafsson, 1997). Other general explanations to increasing depopulation of the rural areas are believed to be: firstly, number of jobs within the agricultural sector has been reduced due to less need for manpower, caused by rationalization and increased technology. Secondly, fish can be transported longer distances still being kept fresh, at the same time many of the functions of the fish processing plants are now on board larger fishing vessels. This of course has threatened the jobs ashore and therefore the existence of the fishing villages around the country.

Thirdly, the share and importance of knowledge in the fish production has increased, which has led to a general rationalization in the fish processing plants. The new knowledge-based jobs in the fishing industry have mostly been established in the capital region and to much less extent in the remote regions. Fourth, change of values, especially the young people, could be a driving force in this development. Increased importance of education, mass media and travelling are reasons why the young people have chosen a future in the capital region instead of the periphery which has much less supply of these opportunities. A fifth factor in this is believed to be the municipal structure¹¹⁶. (Jóhannesson 2001, Hovgaard, Eythórsson, Fellman 2004).

The sex and age structure of the Westfjords shows the signs of out migration. Young adults are relatively fewer in the region than in Iceland in general. Young people generally migrate out of the region for work and/or studies in the capital area or abroad. In many cases, return migration does not take place, e.g. due to a lack of various opportunities. In certain age groups, especially among young adults and middle aged, there live relatively more men than females in the region which in another sign of the out migration.

Figure 2.3 The Westfjords region, sex and age structure 1 December 2004

Source: Statistics Iceland (2005)

People of foreign background have to a certain degree migrated to the Westfjords region (counter migration) and e.g. work in the fisheries sector. The ratio of foreign nationals was 3.6% in Iceland in general compared with 5.8% in the Westfjords region December 1 2004 (Statistics Iceland, 2006). The nationality which is most common among these new residents of the region is Polish (55,6%), followed by Thailand (8,2%). This development is most pronounced in the municipality Tálknafjarðarhreppur with 325 inhabitants, of whom 12,5% have foreign citizenship.

¹¹⁶ One of the main characteristics of the Icelandic municipal structure has been the high number of small municipalities, but due to amalgamations the number of municipalities has been decreasing rapidly during the past few years. The number of municipalities in the spring 2006 is 79 but they were most numerous 229 in 1950. The smallest municipalities only have 50-60 inhabitants while Reykjavík has over 114,000 (Samband íslenskra sveitarfélaga, 2006).

2.3 Employment structure and income

The Westfjords region has traditionally been dependent on fisheries and this is one of the reasons for the decline as the number of persons working in the fisheries sector has been shrinking. In the regions outside the capital region the number of persons working in fishing and fish processing has shrunk by 33% and 30% respectively since 1991. In 2003 fishing accounted for 11.1% of the work force in the Westfjords region and fish processing 19.3%. The national average was 3.5% and 4.0% respectively. This indicates the dependency of the region on the fisheries sector.

Figure 2.4 Iceland, share of employed persons by regions and primary occupation 2003

Source: Statistics Iceland (2005)

The wage level in the Westfjords region has furthermore been declining relatively during the past years. Traditionally, wages in fisheries were relatively high in the region, but this has been changing. In 1998 the average income in the Westfjords was close to the national average but in 2004 the income level was around 10 percentage points below the average. The income level is highest in the capital region (Director of Internal Revenue, 2005).

In spite of (or because) out migration from the region there has not been much unemployment in the Westfjords region compared with other regions in Iceland (see figure).

Figure 2.5 Unemployment ratio by regions

Source: Directorate of Labor (2005)

2.4 Quota and its relative development in the Icelandic regions

The eight Icelandic regions have experienced different development as regards the amount of fishing quota since the transferable quota system was introduced (see figure). The quota is registered to individual vessels so that the location of quota is the homeport of the particular vessel. During the period 1991-2004 the Westfjords experienced a relative decline in their share of the total allowable catch, especially during the first half of the period (see the figure below). How well other regions have been doing in this sense is rather different. During the first half of the period the Northeast region was clearly a winner and during most of the latter half it was the East region. This however seems to be rapidly changing. At the end of the period there is a clear gain by regions in the western part of the country, including the Westfjords at the cost of regions in the eastern part of the country. If this is a short term development or a beginning of a new era is not clear. However, there are indications that a long term development could be occurring due to e.g. recent purchases of large companies in the northern and eastern part of the countries by companies in the western part.

Figure 2.6 The relative quota by harbors and regions 1991-2004 by homeport of vessels (cod equivalences)

Source: Directorate of Fisheries (2005)

This geographical division of quota does only to a certain degree reflect the relevance of fisheries or the size of the business in the respective regions. In spite of a fishing vessel being registered in a particular harbour it may unship the catch in a different harbour. This is indeed often the case in Iceland. This applies e.g. to large fishing vessels with freezing capacity which often unship the product in locations close to the export harbours. Most of these export harbours are located in the Reykjavík (capital) region. This type of fishery is much practiced among fishing companies in North Iceland. Even for the small boat fisheries, landings in their homeport does not necessarily result in job creation in fish processing in that particular location. The fish is often transported to other locations for processing or sold on fish markets.

As far as the amount of quota in absolute tonnage is concerned (cod equivalences), the Westfjords have lost more than in relative terms due to a general downturn in the allowable catch. Compared to the quota year 1991/1992, the Westfjords have only around 58% of the allowable catch in 2004/2005 compared to 98% in Iceland as a whole in the same period (Directorate of Fisheries, 2006). This is of course a more serious downturn than if the allowable catch is measured in relative terms.

2.5 Catch and catch value

The Westfjords region had the second lowest catch value in 2004 (see the pie chart). This is in line with the picture (above) showing the relative quota in 1991-2004.

Figure 2.7 Catch value by home port of vessels in 2004 (source: Statistics Iceland)

Source: Statistics Iceland

It appears that the structure of the fishing fleet is changing in the Westfjords region. The emphasis on smaller vessels has been increasing in the region which seems rational bearing in mind the region's location close to rich fishing grounds (see figure). The share of small boats with limited fishing days and hook and line boats with catch quota has been increasing.

Figure 2.8 The structure of the fishing fleet by number in 2004 (source: Statistics Iceland)

Source: Statistics Iceland (2005)

There has been much development in the design of smaller fishing vessels in Iceland, resulting in a much faster and better equipped fleet having more fishing power, often with engines of 250-350 hp. and a top speed of 30 nm. (The Federation of Icelandic Fishing Vessel Owners, 2006). Therefore, the number of boats does not necessarily reflect their fishing power. This development may to some degree have compensated for loss of quota from the Westfjords region since these boats have e.g. been able to use limited fishing days more effectively.

As a final remark on this, it appears that the region has to a certain degree been able to compensate for the loss of quota through the use of efficient, smaller boats.

Source: Statistics Iceland (2005)

2.6 Regional development and infrastructure

Due to the development of the region, there have been carried out at least four regional development plans for the Westfjords. As early as 1965, there was emphasis on growth centre policy for the region, with an emphasis on its regional centre; the town Ísafjörður (Efnahagsstofnunin, 1969). However, not much was implemented and this strategy was mostly abandoned by Icelandic governments in the 1970's and 1980's. A change of course took place in the 1990's and this growth centre strategy was again adopted by the Icelandic government. In 2005 there was signed a growth agreement for the Westfjords region¹¹⁷. The main task of the growth agreement is to support the formation and development of clusters in the following sectors: fisheries and food production (e.g. aquaculture and research on fishing gear), education and research and culture and tourism. In a report on the growth agreement it is stated that the experience and proximity of the fisheries sector, manufacturing and research has led to innovation in the region. Therefore increased emphasis on research and education in these fields is appropriate in the region and favourable results can be expected (Verkefnisstjórn um byggðaaætlun fyrir Vestfirði, 2005, 39).

The infrastructure, especially the road system has been one of the region's major shortcomings. Due to topography, developing a modern road system is very costly. To interconnect the region with a better road system has however always been in the forefront of regional plans for the Westfjords. Still today there is much unaccomplished in that field and the regional centre Ísafjörður is not accessible for 17% of the total population of the southern part of the region due to closure of mountain roads during extended periods of the winter time (Jóhannesson and Heidarsson, 2005). For some inhabitants, during the wintertime, Reykjavík has at times been more accessible by air transportation than is the regional centre, Ísafjörður.

2.7 Future prospects

Even if the development of the region can to a great extent be traced to its heavy dependency on fisheries, its remoteness and lack of road infrastructure is a major shortcoming of the region.

The Westfjords share with other remote regions in Iceland the development that for the younger generation, the region does not seem to provide enough opportunities e.g. jobs demanding a university degree, leisure opportunities, diverse services and those varied amenities generally only found in (larger) urban centres or their immediate vicinity. There are in fact regions in Iceland that have been able to be very successful in fisheries during the same period as is described here, especially Akureyri in central north Iceland with some 16.500 inhabitants and the largest municipality outside the capital region.

It is clear that since the introduction of the individual transferable quota system, the region has lost a large share of quota. At the same time the region has lost people. However regions in Iceland that have suffered depopulation to a similar degree seem not to have lost as much quota at the same time. It is difficult to state that the quota transfer system is the only reason for the massive depopulation in the Westfjords region since the early 1990's. According to a report carried out for the Icelandic Institution of Regional Development the regional development in Iceland *can* however be linked to the

¹¹⁷ As a part of the regional development policy for Iceland 2002-2005 there were designated three growth centres outside the capital region, i.e. the Westfjords, Eyjafjörður in north Iceland and central east Iceland.

individual transferable quota system causing movement of quota between regions (Haraldsson, 2001). The authors of this present study however suggest that further research is needed to study this relationship and its various aspects.

2.8 The Westfjords example study and its relation to the main hypotheses of the project

The Westfjords example study can be related to some of the hypotheses of the ESPON 2.1.5. project. Of course Iceland has a special position in the study. Firstly, since the country is not a member of the European Union and thus not appertaining to the CFP, secondly few studies have been carried out on the causality between regional development and the fisheries policy in the country and thirdly that comparable data for Iceland and the ESPON countries is rather limited (e.g. since it has not previously been involved in ESPON projects).

General impact hypotheses:

“1. The CFP will have different impacts between coastal regions, and within regions. Processes on restructuring, reduction and expansion will occur side by side and in various combinations. Impacts of CFP will be more significant the lower the geographical levels.”

It is apparent that impacts of the Icelandic fisheries policy are being noticed to a greater extent at lower geographical levels and the Westfjords case supports that. There have been considerable changes in the fisheries sector in this fisheries dependent region.

“2. Economic, social and demographic impacts of the CFP will vary between urban and remote areas. Socio-economic effects related to employment, migration, age structure of the labour force etc., may be less devastating in urban regions than in fisheries dependent regions and areas.”

There has been heavy out migration from the Westfjords region and the age structure has become unbalanced, as is the case with many regions in Iceland outside the growth region of the capital Reykjavik. To what extent this is a product of the fisheries policy or other forces is however rather uncertain. In the same period some agricultural regions have experienced a similar population development. This seems to relate to a mixture of several factors concerning the development of Icelandic society and an uneven development of regions. However it is clear that in the Westfjords region there has been more downturn in allowable catch than in Iceland as a whole.

“3. Territorial impacts of CFP will vary with different structures of the fishing and aquaculture industries of the regions. Impacts will differ in accordance with the extent the regions are dominated by small scale coastal fishing or fishing in distant waters with greater vessels, landings, fishing processes or aquaculture.”

As described in the example there has e.g. been development of moving fish processing onboard vessels with freezing capacity. More recently fish has to a larger degree been exported fresh and either processed ashore on the landing place or in other regions e.g. close to an international airport or an export harbour. To what extent the Westfjords differs from this general development is unclear, since evidence from data is lacking.

Social and economic impact hypotheses:

“1. The CFP has unintended side effects in coastal regions or fishery dependent regions. Significant territorial impacts may be:

- Economic effects such as increasing unemployment
- Decreasing regional economic productions (GDP)
- Population decreasing due to out-migration particularly in fisheries regions
- Altered age composition in fisheries dependent regions, with an increasing share of elderly population. Indication of gender and age biases in fishing dependent regions
- Change in population density in fisheries regions.”

The Westfjords have many of these characteristics. However, the causality between the fisheries policy and this socio-economic change is not certain. The remoteness of the region, the lack of road investment in the region and the lack of diversity of jobs and services are among the factors contributing to the negative development of the region. Furthermore the growth region of the capital city, Reykjavik has had much pull effect on all other regions in Iceland. There is similar out-migration from fisheries regions as from declining agricultural regions.

“2. As the restrictions on harvesting activities mainly target the fishing fleet these measures have strongest negative impacts in remote, coastal regions, while the more urban regions involved in fish processing still are able to source raw fish through e.g. import from 3rd countries.”

Regions close to an international airport and export harbours have some advantage when it comes to compete on processing, especially fresh fish, for export. The Westfjords do not at all have this easy access to export nodes.

“3. It follows from hypothesis 6 and 16 that the incidence of the CFP on the regional level is not consistent with the social and economic cohesion objectives of the EU due to the unintended territorial effects of CFP. More favourable regions are able to take greater advantage of the measures included in the FIFG due to closer access to products and markets.”

As said previously other factors such as market access and access to transportation network is one of the greatest shortcomings of the Westfjords region.

Fishery hypotheses:

“1. Changes in CFP may contribute to increased concentration and centralisation of the seafood industry. This will be a particular disadvantage for the most fishery dependent and remote areas, which are often underperforming regions in an accessibility perspective.”

As stated previously, it is uncertain to what extent shrinkage of the seafood industry in regions is related to fisheries policy and to what extent it is related to other factors such as location and accessibility.

“2. Innovation is generally concentrated in cities and urban areas. If the same tendency occurs in the marine sector, the potential and the preconditions for innovation and restructuring in this sector are probably highest in regions with larger cities or in close distance to larger cities (FUA).”

In fact, there has been considerable innovation in the fisheries sector in the Westfjords, e.g. in fishing gear and processing equipment. In a report from 2002 on knowledge based jobs in the fisheries, the Westfjords are pointed out as second best suitable region outside the capital region in which to locate such jobs.

“3. Territorial impacts of the CFP measures are dependent on how the measures in use are implemented in the various regions. Impacts will also vary by the structure of the fisheries in the respective regions and the access to alternatives, such as fishing opportunities, sources of fish raw material for processing, alternative job opportunities etc.”

The above hypothesis appears to a large extent to be in line with the development of the fisheries sector in the Westfjords.

3 Territorial variations in the fishery sector in Norway

3.1 Introduction

Norway has always been a fishery nation. A long coast with many fjords and closeness to good fishing grounds gives Norway natural advantages to harvest from the sea. The most important challenge has been and will be to manage the stock of fish in favour of both nature and man. Norwegian fisheries and aquaculture have gone through extensive changes the past years and has developed into a modern industry with high export value. Today fish is the third most important export product after oil/gas and metal, and it constitutes 5.2 per cent of the total Norwegian export value. Most of the export is for Denmark, Russia, France and Japan.

The fishery in Norwegian waters has varied a lot over time. Overfishing and natural variation of stocks explain much of this variation. After a historical minimum in 1990 the Norwegian catch has been almost doubled up to now. In the same period both the numbers of fishermen and vessels have been reduced with more than one third. Today 13 240 persons have fishery as their main occupation whereas the number in 1950 was more 68 000. Aquaculture production started for real in the early 1980s when one succeeded to produce salmon at a large scale. Today salmon constitutes 85 per cent of the total sale of Norwegian farmed fish. Rainbow trout dominates among other species.

3.1.1 The importance of fisheries and aquaculture in Norway

In order to evaluate the total impact of fisheries and aquaculture on economic strength, employment and settlements in coastal regions, one has to include the fish processing industry and wholesale and multiplier effects in other businesses and industries. A Norwegian analysis from 2004 shows that employment in the core activity in fisheries and aquaculture (catches, aqua, and fish processing and wholesale) constituted 25 000 man-labour year. The contribution to GNP was 15, 7 billion NOK, whereas the turnover was 49, 6 billion NOK. In addition fisheries and aquaculture had multiplier effects in other businesses and

Figure 3.1 Total effects of the Norwegian Fisheries- and Aquaculture industry. Employment (man-year) contribution to gross national product (GNP) and turnover in year 1999, 2002, 2003 and 2004 (current prices).

Source SINTEF 2005

Industries corresponding to 22 900 man-labour years, contribution to GNP 14, 5 billion NOK, and turnover 36, 2 billion NOK. The total impact of fisheries and aquaculture then summarises to 48 000 man-labour years, contribution to GNP 30 billion NOK, and turnover 86 billion NOK (SINTEF 2005).

Figure 1 show the development in fisheries and aquaculture in the period 1999-2004, and the main tendencies can be summarised as follows:

- decreasing employment (- 17 % man-labour years)
- increasing contribution to GNP (3 %)
- increasing turnover (3 %)

The multiplier effects in other businesses and industries increased both with regard to employment (2 % man-labour years), contribution to GNP (25 %) and turnover (26 %).

3.1.2 Regional employment in the fishery sector

Fisheries are concentrated in the Northern and Western part of Norway, particularly in the counties of Finnmark, Troms, Nordland, Møre og Romsdal and Sogn og Fjordane. However, the share of employment is relatively low also in these parts of the country when measured on NUTS 3 level. When measured on lower geographical levels (LAU 2), one is able to trace the so called fisheries dependent areas in which fisheries are rather important and the employment share are correspondingly high. We come back to this in the further analysis.

Table 3.1 Share of employment in the fishery sector by counties (NUTS 3). 2006.

	Fisheries		Aquaculture		Wholesale of fish and crustaceans		Processing and preserving of fish products	
	Employees	Share of employees	Employees	Share of employees	Employees	Share of employees	Employees	Share of employees

20 Finnmark	920	2,85	245	0,76	81	0,25	793	2,45

Source: Statistics Norway, s Business Register

* The figures include only employees in registered firms. This implies that figures are too low for fisheries since many persons with fisheries as their main occupation are not registered as firms. The figures are therefore estimated in accordance to information about employees intervals in the enterprises, but still the figures are slightly underestimated. Some fishermen have also fisheries as secondary occupation. For aquaculture, wholesale and processing the figures are fairly accurate.

As can be seen in table 1, only in Finnmark does the share of employment in the fishery capture sector exceeds 2 (2, 85) per cent. This figure, however, slightly underestimate the employment in fisheries so the correct share in Finnmark is probably closer to four per cent (see explanation in table 1*). For aquaculture, wholesale and processing the employment figures are fairly accurate.

3.1.3 The industrial structure in counties with the largest fishery sectors

Services dominate in all parts of the country and particularly in the Northern counties. Manufacturing industry on the other hand is far stronger in the two Western counties (Sogn og Fjordane and Møre og Romsdal) than in the two Northern counties (Troms and Finnmark). The share of employees in manufacturing industry is far above the national

average in the Western counties whereas it is far below in the Northern counties. The primary industries (agriculture, forestry and fishing) are more widespread in all four counties in West and North than the national average, and particularly in the Western county Sogn og Fjordane.

Figure 3.2 Share of employees by industries in Norway and four of its counties. 2006. Per cent.

3.1.4 Demographic structure and population development

The population has developed somewhat differently in the counties with the largest fishery sectors in the past decade (1996-2005). In the North Finnmark has experienced a relatively strong reduction in population (-3387), whereas population has increased in Troms (+ 1581). The same tendency occurs in West with population growth in Møre og Romsdal (+ 3657) and population decrease in Sogn og Fjordane (- 706). Depopulation was strongest in Finnmark which is the most scarcely populated county in Norway. Population decreased from 76 461 in 1996 to 73 074 inhabitants in 2005.

The demographic structure by sex and age in the four counties compared to the national share is presented in figure 3. The share of population in counties are coloured whereas the national share is marked with black lines. The figure reveals some interesting differences between the counties. The two counties in the Western part of Norway are underrepresented among young and medium aged adults (25-29, 30-34, 35-39 and 40-44) for both men and women. In the North this is only the case for the age-group 25-29 in the county of Finnmark, which on the other hand has an overrepresentation of women in the age-group 30-39. Troms is more or less on the national average for all age-groups for both men and women. In certain age groups there are more men than women in all four counties. This is particularly the case for the age groups from 45-60 year.

Figure 3.3 Share of population by sex and age in four counties in Norway compared to national share. 2006. Per cent of population.

3.2 Data and methodology

Using data from Statistics Norway's Business Register, we can make an overview of employees in both fisheries and aquaculture, on different geographical levels. In this analysis we concentrate on NUTS 3 (the Norwegian counties) and the LAU level 2 (the Norwegian municipality level). The main purpose is to show the territorial variations in fisheries and fish farming employment, and particular to give an illustration of the differences on NUTS 3 and the municipality level, and the territorial variations within NUTS 3 regions. Using Functional Urban Areas (FUA) classification in Norway we are also able to indicate urban-rural dimensions in aquaculture and fisheries.

The Business Register covers all enterprises and local kind of activity units (local KAU) in private and public sector in Norway, both structural data and employment. For geographical analyses, local KAU is used, since they are unambiguous, both geographically and by industry. Industry is given by 5-digital level NACE-code. Fishing

includes coast and ocean fishing. Aquaculture includes production of fish and shellfish, spawns and young fish, and services connected with aquaculture.

In this analysis, we mainly use relative numbers, as share or per cent, due to the great variation in size of our geographical units. Using relative numbers means that we can easily compare units with different sizes, but it also means that changes in employments in other sectors can alter the shares of employees in fisheries or aquaculture. If a relatively big enterprise in an industry disappears, then the shares of employees working in other industries will “artificial” increase.

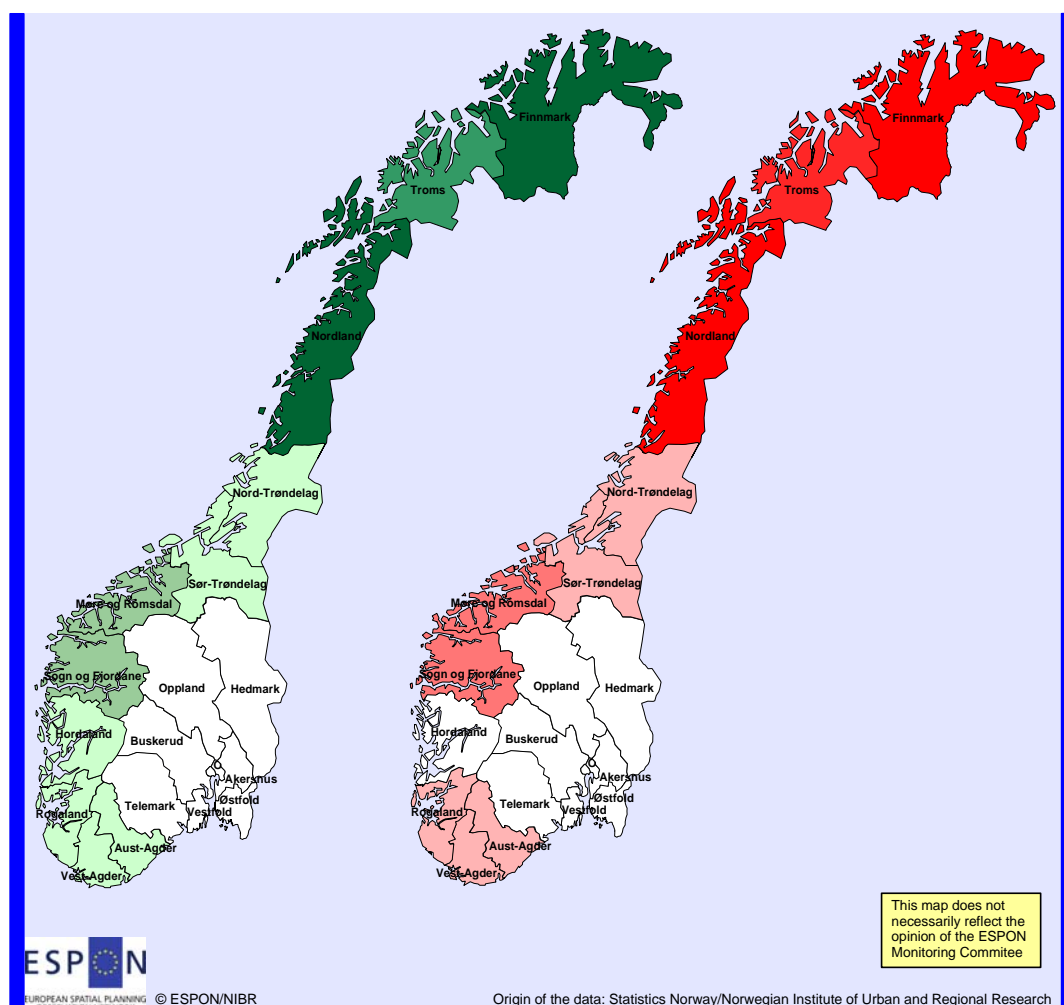

The numbers of employments are estimates based on size-classes in the Business Register. This means that people working as fishermen, without register as an enterprise, will not be covered by the register. At the same time, lots of enterprises or local KAUs have none employees in the register, because self-employment without an employment-contract is not registered. NIBR has done some estimation for these lacking employees, but still the absolute numbers is somewhat low. For comparison of geographical units, and development over time, it is, however, of minor significance.

3.3 Employment in Fisheries – analysis on NUTS 3 level

Focusing on fisheries on NUTS 3 level (the Norwegian counties), a geographical uneven employment patterns appears within this sector in Norway (figure 4). The share of employees working in fisheries in NUTS 3 regions is not particularly high. Only Finnmark county has a share over 2 per cent in fisheries in 2006 (2.85 per cent, see table 1). The share of employees working in fisheries is highest in northern Norway (in addition to Finnmark, Troms with 1.76 percent and Nordland with 1.97 per cent) and two counties in the western Norway (Sogn og Fjordane with 0.95 per cent and Møre og Romsdal with 0.93 per cent). These are the counties that historically have been most dependent on fisheries and which have long traditions in this sector.

Looking back eight years, the picture has not changed much. It is the same counties which had the highest shares of employees in fisheries in 1998 as in 2006, but in general the shares were a bit higher in most of the counties in 1998. Looking more specifically on the differences between 1998 and 2006, we see that those counties with the highest shares in 1998, even though they also are on the top in 2006, have lost relatively most of the employment in fisheries during the period, namely Finnmark and Nordland (figure 4). Correspondingly for the west part of Norway, Sogn og Fjordane and Møre og Romsdal have lost relatively most of the employees in fisheries since 1998.

Figure 3.4 Share of employees and changes in the share of employees in fisheries.

Left map: Share of employees in fisheries. NUTS3. 2006

Right map: Changes in share of employees in fisheries from 1998 to 2006. NUTS3. Per cent points

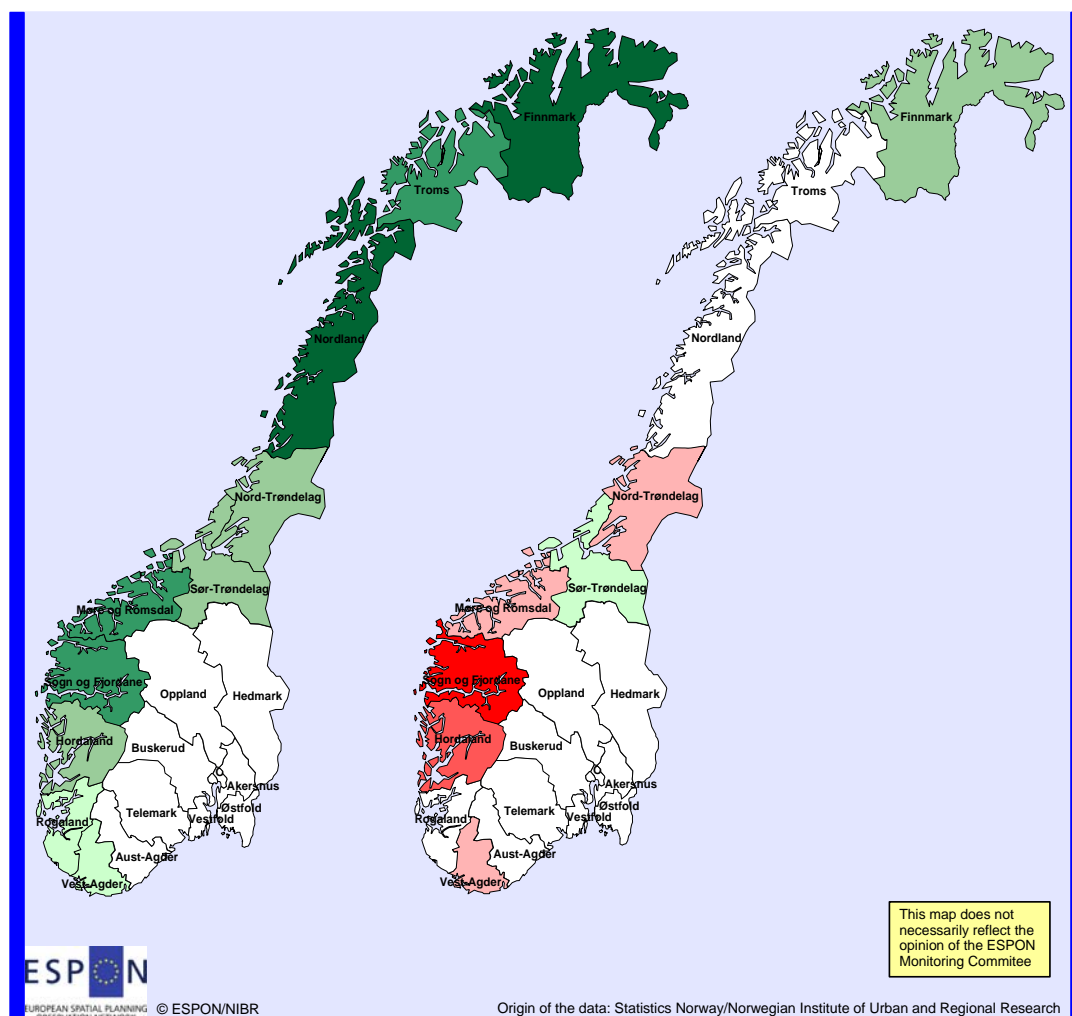

3.4 Employment in aquaculture – analysis on NUTS 3 level

The share of employment in the aquaculture sector is also low on NUTS 3 level, and even lower than for the fishery sector. It is more or less the same counties that have many employees in fisheries which also have the highest share of employees in aquaculture, namely Finnmark, Nordland, Troms, Sogn og Fjordane and Møre og Romsdal in 2006 (figure 5 and table 1). In 1998 Sogn og Fjordane was on the top with a share of the

employees in the aquaculture sector at almost one per cent. In 2006 the share is reduced to 0.53 per cent.

Figure 3.5 Share of employees and changes in the share of employees in aquaculture. NUTS3. 1998-2006

Left map: Share of employees in aquaculture NUTS3. 2006

Right map: Changes in share of employees in aquaculture from 1998 to 2006. NUTS3. Per cent points

In contrast to the employment development in fisheries (with a relative decrease in all counties), three counties have had a relative increase in employment in aquaculture (Finnmark, Sør-Trøndelag and Rogaland). Finnmark has the highest increase in the period from 1998 to 2006 (figure 5), with a share of employment with 0.76 per cent in 2006 (table 1). But as for fisheries, the county which had the highest rate of employees in 1998 has also experienced the largest decrease in employment in the aquaculture sector. While

Finnmark has experienced the biggest employment losses in fisheries, Sogn og Fjordane has experienced the biggest losses in aquaculture.

3.5 Employment in fisheries - analysis on LAU 2 level

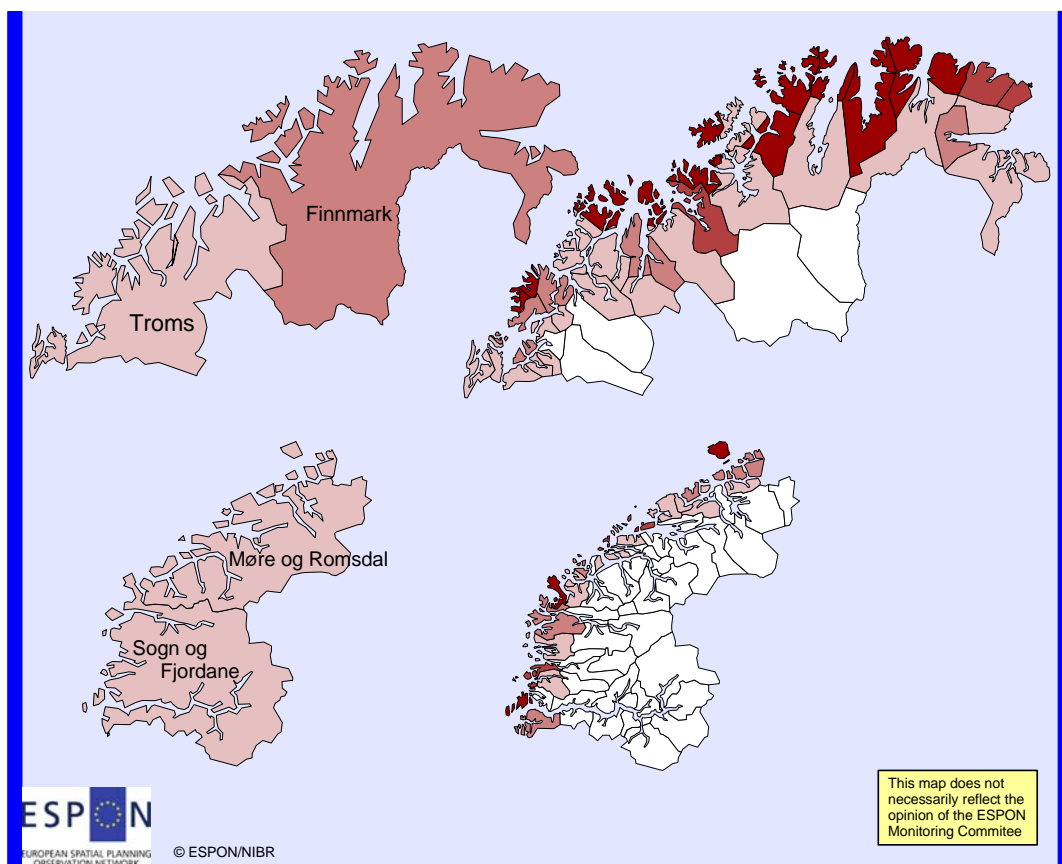

NUTS3 regions in Norway are in many cases too aggregated and heterogeneous units for analysing economic processes or policy impacts, and particularly in relation to fisheries and aquaculture. Naturally these activities are tied to the coastline (with some exceptions for fishing and aquaculture in fresh water), but many counties in Norway cover large areas from the coast and up to the watershed, or in some cases to the boarder of the neighbouring countries Sweden, Finland or Russia. In order to trace territorial impacts of the fisheries policy one has to examine the development on lower geographical levels, and here we look into to municipality level, i.e. LAU 2 level.

As showed in figure 4 fisheries are concentrated to the Western and Northern part of Norway, and in these parts of the country one also find the municipalities most dependent on fisheries. But there is a strong concentration of fishery employment to some municipalities within these counties, whereas some municipalities have little or no employment in this sector (figure 6). As expected it is the most outward coastal municipalities that have highest shares of employees in fisheries.

The overall picture within fisheries employment seems to be quite stable also on LAU level, some major transformations has taken place within some counties in the period 1998 -2006. This is particularly the case in Finnmark and Northern Troms where some municipalities have experienced a major decrease in the rate of employment in fisheries while others have experienced an increase in the same period (figure 7). Finnmark is the county which has experienced both the strongest growth and decline within fisheries employment in the period 1998 - 2006. These findings which are not visible on NUTS 3 level and clearly demonstrate the importance of geographical breakdown in the analysis of territorial impacts with regard to fisheries. Despite the fact that all counties have experienced a decrease in the rate of employment, there are major differences *within* some counties. Processes of decline and growth in employment occur side by side. The analysis on LAU 2 level also indicates that fisheries employment has become more concentrated to a few municipalities in the past decade. This tendency is especially clear in Finnmark, which is the county that have lost relatively most of employees in fisheries from 1998 to 2006.

In order to highlight the heterogeneity of NUTS 3 regions and the necessity to analyse territorial impacts on lower geographical levels, figure shows the fisheries employment in 2006 at both NUTS 3 level and LAU 2 level for the two selected counties in the Western and Northern part of Norway respectively. This map clearly shows how fisheries are unevenly distributed within the counties, and it also reveals that this particular kind of activity is tied to the outermost coastal municipalities within the counties. This also indicates that although policy impacts could be unimportant on NUTS 3 level they may be significant on LAU 2 level for the municipalities that experiences relative decline or growth within fisheries.

Figure 3.6 Share of employees in fisheries at two geographical levels – NUTS 3 and LAU 2. 2006

Share of employees in fisheries. Four counties (left maps) and their municipalities (right maps). 2006

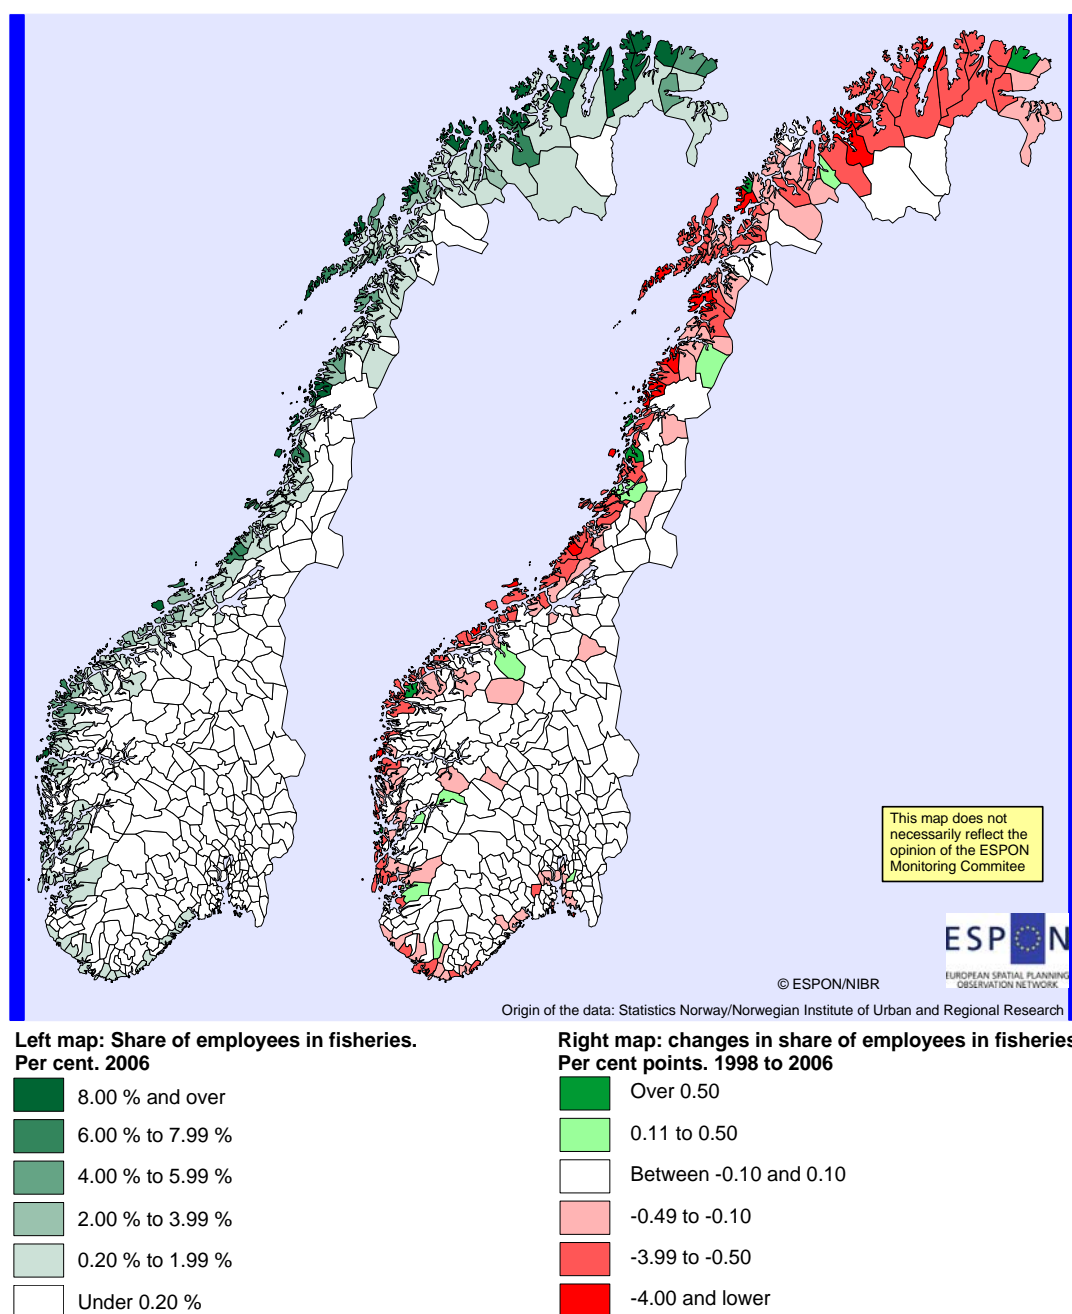

Figure 3.7 Share of employees and changes in the share of employees in fisheries in Norwegian municipalities. 1998-2006

3.6 Employment in aquaculture – analysis on LAU 2 level

For aquaculture the situation is slightly different than for fisheries. The development from 1998 to 2006 has also been somewhat different within the two sectors. Today most municipalities along the western and northern coast are involved in aquaculture and this type of activity is almost as widespread as traditional fisheries. However, the geographical employment pattern is somewhat different in these two sectors. Whereas fisheries employment primarily is concentrated to the most outward coastal

municipalities, aquaculture employment is to a larger extent located to municipalities in the fjords, cf. figure 8. This picture has not changed much the past decade. Unlike fisheries, however, more municipalities have experienced employment growth in the aquaculture sector (figure 9). As for fisheries there also is a tendency of employment concentration in the aquaculture sector within the counties. This is clearly illustrated in the maps for the counties in West and North Norway (figure 8).

Figure 3.8 Share of employees in aquaculture at two geographical levels – NUTS 3 and LAU 2. 2006

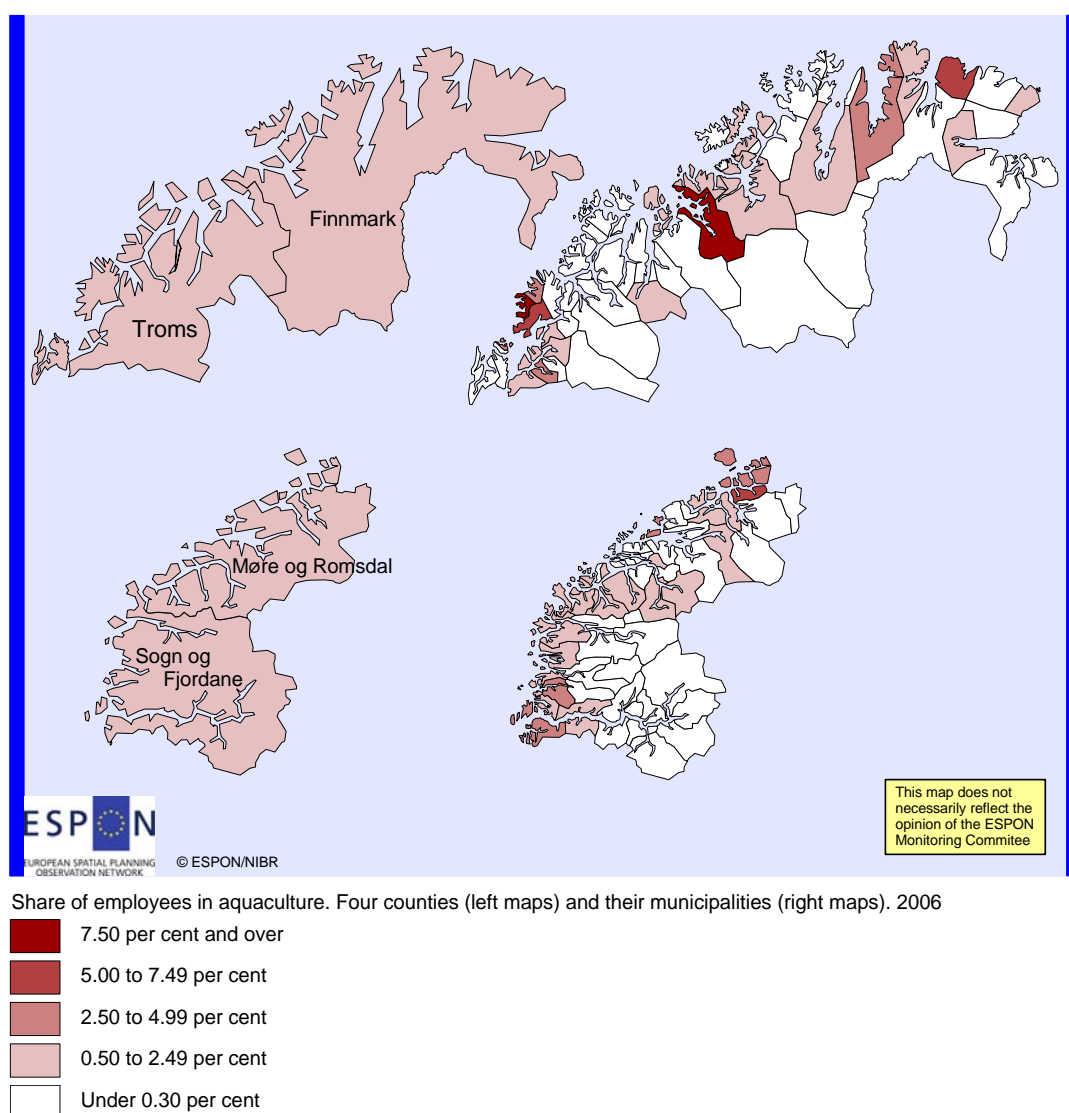

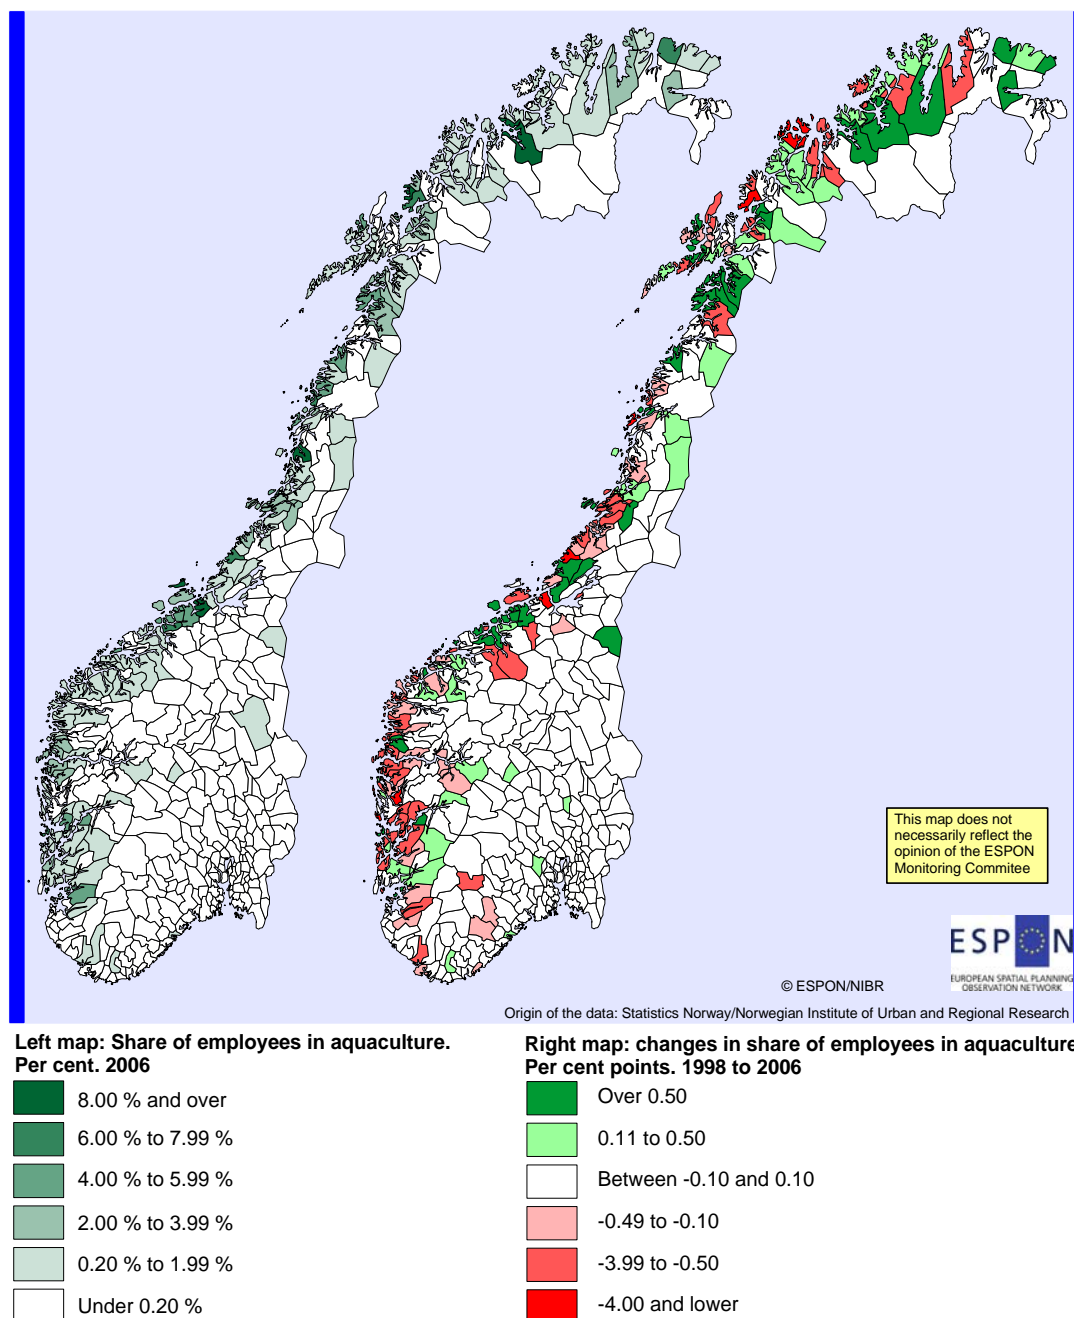

Figure 3.9 Share of employees and changes in the share of employees in aquaculture in Norwegian municipalities. 1998-2006.

In most counties, the employment share is higher in fisheries than in aquaculture. However, this is certainly not the case at the municipality level (figure 9). In northern Norway, fisheries are in general more important than aquaculture, but aquaculture have gained importance since 1998 also in this part of the country. At the West coast, the picture is more mixed. Aquaculture is, for most municipalities, not taking new shares of the employment, and for some municipalities fisheries have gained importance compared to aquaculture. The general picture, however, is that the share of employees in aquaculture has caught up or surpasses the share of employees in fisheries in many municipalities, particularly in the northern part.

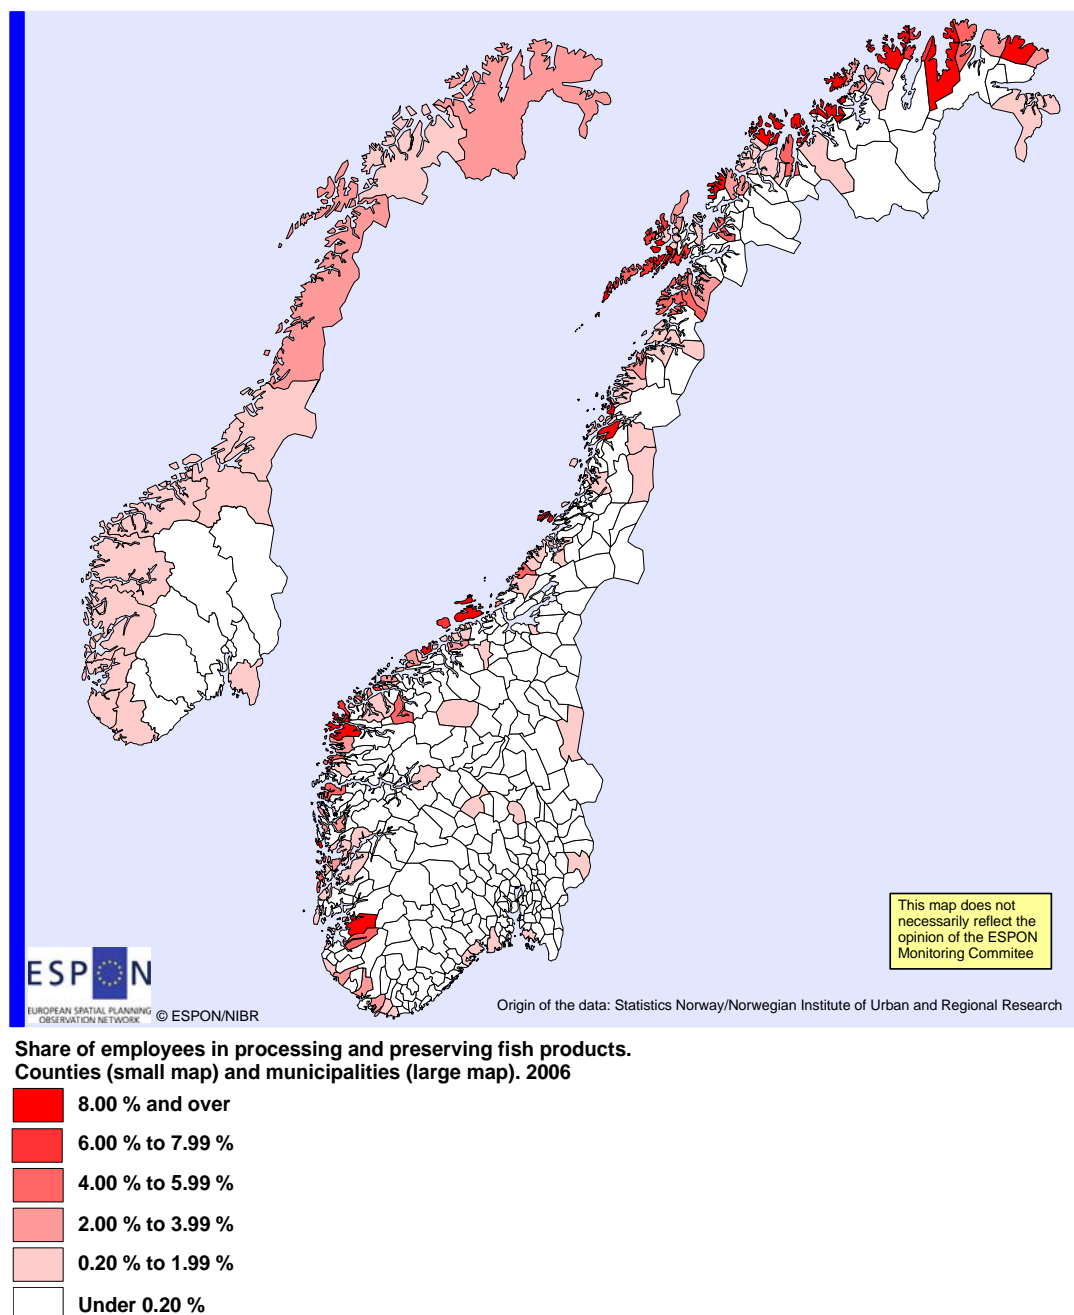

3.7 Employment in the fish processing industry

Figure 10 shows the share of employees in processing and preserving of fish products in Norwegian counties (NUTS 3) and municipalities (LAU 2) in 2006. The relative employment share in this industry is highest in two of the Northern counties – Nordland and Finnmark – in which the share is between 4 and 6 per cent. The map for the municipalities shows that the fish processing industry is scattered along the coast, but as for fisheries and aquaculture also this industry is concentrated to some municipalities within the counties.

The total employment in the fish processing industry in Norway has decreased with almost 30 per cent from 1998 to 2006, from 13 933 to 9895. The Northern part of the country (Nordland, Troms and Finnmark) have experienced the strongest decline with approximately 40 per cent (more than 4000 employees), while the reduction in the Western part of the country (Hordaland, Sogn og Fjordane and Møre og Romsdal) is on the national average. In the North Finnmark has experienced the most dramatic decline in this industry with a decrease from 2196 employees in 1998 to 793 in 2006, i.e. 64 per cent. Almost all municipalities in Finnmark have had a decrease in employment in the fish processing industry in this period. The decline has been particularly strong in Båtsfjord and Vardø, two municipalities in which fisheries and fish processing industry have been very important for a long time. The dramatic fall in employment in the fish processing can explain why these two municipalities experienced an increase in the share of employment in fisheries and/or in aquaculture in the same period (figure 7 and 9) since employment changes in the processing industry will alter the shares of employment in other sectors such as fisheries and aquaculture. The employment decline has also been markedly strong in Troms which lost half of the employees in this industry in from 1998 to 2006 (1545 to 876). The development has been less harsh in Nordland where the number of employees has been reduced from 2507 to 2117 in the same period.

In the Western part of the country, Sogn og Fjordane has experienced the strongest decrease in employment in the fish processing industry. Almost half of the employees disappeared from 1998 to 2006, from 1291 to 651. Møre og Romsdal also had a substantial reduction from 2335 to 1759 employees in this period, while the decline in Hordaland was somewhat less, from 1327 to 1055. This illustrate that many municipalities are very fragile in a more global marked. Closure of the factory in one fishery dependent municipality will have great negative impacts in employment.

Figure 3.10 Share of employees in processing and preserving of fish products in Norwegian counties (NUTS 3) and municipalities (LAU 2). 2006

3.8 Employment in relation to Functional Urban Areas (FUAs) in Norway

For this example study the municipalities have been typologised as being within or outside a Functional Urban Area (FUA) as defined by ESPON project 1.1.1 (see figure 11). The FUAs are among the labour market regions defined by Juvkam (2002). Within each FUA we distinguish between FUA centre and other municipalities. The typologisation differentiates between centres, intermediary municipalities (municipalities

within a FUA, but not a FUA centre) and peripheral municipalities (municipalities outside the FUAs) to make possible an analysis according to urban-rural patterns.

A study based on a grouping of municipalities is important for answering some of our hypotheses. Already in hypothesis no. 1 it is stated that the impacts of CFP will be more significant the lower the geographical level. We also state in hypothesis no. 2 that economic, social and demographic impacts vary between urban and remote areas. The typologisation makes it possible to make further distinctions in an analysis between fishery dependent municipalities and other municipalities.

Figure 3.11 Functional Urban Areas (FUAs) in Norway. 2005

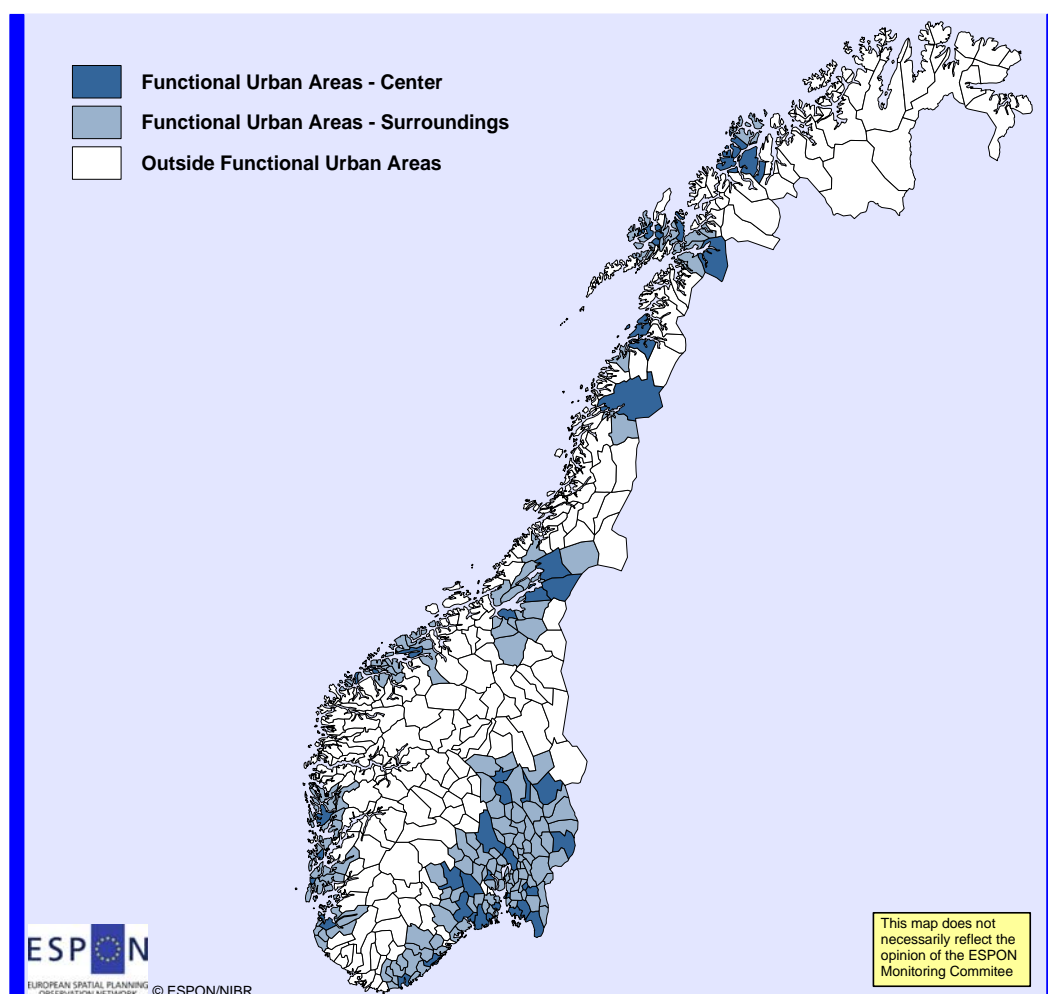

Table 3.2 Share of employees in fisheries and aquaculture in Functional Urban Areas (FUA). 1998 and 2005

	Fisheries		Aquaculture		Per cent points changes 1998-2006	
	1998	2006	1998	2006	Fisheries	Aquaculture
FUA - Centres	0,12	0,08	0,04	0,04	-0,04	0,00
FUA - Surroundings	0,61	0,31	0,25	0,15	-0,30	-0,10
Outside FUA	2,03	1,36	0,79	0,73	-0,67	-0,06

The share of employees in fisheries and aquaculture is very low for FUA centres, since most of the FUAs are located in the south-eastern Norway, cf. figure 11. Fisheries and aquaculture is also an important business and employment base for coastal municipalities and regions outside the FUAs. The relative decrease is highest outside FUA for fisheries from 1998 to 2006, with a decrease with 0.67 per cent, and smallest for FUA centres (with a decrease in only 0.04 per cent), leaving FUA-Surrounding in between with a decrease with 0.3 per cent (table 2).

For aquaculture the decrease in employment is not that significant outside FUAs as for fisheries, with a decrease in only 0.06 per cent during the period. However, also here there has been a decrease outside FUAs and in FUA surroundings, while the development in FUA-Centres is stable. Generally spoken, we can conclude that there have not only found place a concentration of employment in fisheries during the latest years, but also an urbanisation. For aquaculture the decrease has been greatest in the FUA-Surroundings.

If we distinguish between Western Norway and Middle/Northern Norway (see table 3), we see that the urbanisation for fisheries is most significant for the Middle and Northern part of Norway. For the Western part the decrease has been greatest in the FUA surroundings. Here, the decrease in fisheries outside FUA is only 0.23 per cent. This is also the case for aquaculture, where the decrease in the share of employment has been highest in FUA surroundings (0.46 per cent), less outside FUA (0.19 per cent) and stable within FUA centres. The share of employment in aquaculture has increased for all types of regions in the Middle and Northern part of Norway. Here, the increase has been most significant in FUA surroundings with 0.13 per cent.

This indicates that there has been an urbanisation within fisheries in Middle and Northern Norway, i.e. the decrease in employment has hit the areas outside FUAs in a far greater extent than the FUA centres, leaving the FUA surroundings in between. However, for the aquaculture there has been an increase in the share of employment in all these types of regions in the Middle and Northern Norway, but with the greatest increase in FUA surroundings. For Western Norway the decrease in both fisheries and aquaculture has been biggest the FUA surroundings. To conclude, looking more specific on the different parts of Norway, the urbanisation is only valid for fisheries in the Middle and Northern Norway.

Table 3.3 Share of employees in fisheries and aquaculture in FUA 1998 and 2005, in Western Norway and Middle and Northern Norway

	Fisheries		Aquaculture		Per cent points changes 1998-2006	
	1998	2006	1998	2006	Fisheries	Aquaculture
<i>Western Norway</i>						
FUA – Centre	0,13	0,08	0,11	0,11	-0,05	0,00
FUA - Surroundings	1,64	0,82	0,90	0,44	-0,82	-0,46
Outside FUA	1,01	0,78	0,90	0,71	-0,23	-0,19
<i>Middle and Northern Norway</i>						
FUA – Centre	0,45	0,27	0,07	0,09	-0,18	0,02
FUA - Surroundings	2,01	1,19	0,45	0,58	-0,82	0,13
Outside FUA	3,95	2,57	1,09	1,16	-1,38	0,07

3.9 Conclusions related to the hypotheses

The Norwegian example studies on territorial variations in fisheries and aquaculture highlight the need for geographical breakdown in analysing territorial changes and impacts of the fishery policy (highlighting the general **hypothesis 1**). The example study illustrates the heterogeneity and the great differences between different municipalities within NUTS3 regions (the Norwegian county levels), and that impacts are more significant the lower the geographical level. In order to identify impacts, the NUTS3 seems to constitute too high level of analysis.

The analysis elaborates the **hypothesis 11**, regional concentrations regard to employment in the aquaculture industry. In addition, the analysis also indicates that employment in fisheries has the same concentration tendencies than in aquaculture. The analysis on municipality level indicates that there has been a concentration regarding employment in fisheries and aquaculture to a rather few municipalities within the counties. The structural changes in the aquaculture industry, i.a. the development from small to big companies are possibly one important driving force in that direction.

Using FUA classification in Norway, we are also able to indicate urban-rural dimensions in aquaculture and fisheries, which highlight the general **hypothesis 2** and in some extent **hypothesis 4**. The typologisation makes it possible to make distinctions in an analysis between fishery dependent municipalities and other municipalities. In general, the analysis shows that there have find place both a concentration and an urbanisation of employment in fishery in the Middle and North Norway. In West Norway, however, the biggest decrease have find place in the FUA surroundings.

There has been a dramatic decline in employment in the fish processing industry in some fishery dependent municipalities. The municipalities with most decrease in employment is located outside FUA areas, which support **hypothesis 13** that the most important driving forces (but not necessarily only the fishery policy) contribute to increased concentration and centralisation of the seafood industry, and that this will be a particular disadvantage for the most fishery dependent and remote areas, which are often underperforming regions in an accessibility perspective.

4 Forcing territorial differentiation? The Norwegian Example - Fisheries policies allocated by market models

4.1 Introduction

The example studies of project 2.1.5 are carried out with reference to aims of cohesion and territorial balanced development in particular areas of the European territory. This presentation demonstrates territorial impacts of Norwegian fisheries policies by focusing on the role of the national level in the distribution of the Norwegian fisheries policy measures around 2000, and its impacts for the Norwegian territorial fisheries system.

The Norwegian example, as all examples of national fisheries policy implementation, takes its starting point in the particular historical context of the Norwegian fisheries. Compared to almost all of the other European countries the Norwegian fisheries have several distinguished characteristics:

- *Historical:* The export basis dominates Norwegian fisheries. The domestic markets for fish products in Norway have been of no importance for the development of Norwegian fisheries.
- *Socio-economical:* The traditional co-ordination of fisheries and agriculture in the coastal households, which constituted the Norwegian characteristic small-scale low capitalised seasonal fisheries.
- *Biological:* The big fish stocks, mainly Cod and different pelagic species, combined with a developed resource management system, have secured historical high catches and increasing catches the last 10-15 years while the CFP had to reduce the quotas. One impact is however that the Norwegian fisheries (the fleet as well as the processing) have been concerned with high volume landings rather than high economic values.
- *Political:* A strong state intervention 1945-1985 caused by, among other aspects, objectives related to the rebuilding of the northern Norwegian regions. The state substituted these policies by market governing principles after the 1980s and disconnected fisheries policies from regional development policies. Today the level of economic support to the fisheries is very low compared to the CFP.

While the number of fishermen in Norway 1945 was as high as 114 000, the number today is only 13 000. The last 20 years 40 per cent of the fishermen have left the fisheries. Still 63 Norwegian municipalities have more than 10 per cent of their labour force in the fisheries.

4.2 Analyses themes and hypotheses

The Norwegian example will relate to the overall themes of CFP territorial impact study by examining:

- The position of Norwegian fisheries regions inside the Norwegian territorial system
- The position of Norwegian fisheries regions in the Norwegian policies systems, particularly in the Norwegian regional policies measures.
- Aspects of the territorial development inside the fisheries regions.

These research themes will concretely be related to five hypotheses, specifying territorial impacts of the Norwegian fisheries policies:

- 1) According to hypothesis no 1, the position of fisheries and aspects of the fisheries policy vary between the Norwegian regions. According to the historical context presented above we observe one important contradiction in the Norwegian fisheries with impacts for the territorial organisation: The low capitalised fisheries based on household combining fisheries and subsistence agriculture, which forces the embedment of fisheries activities close to fishing grounds and available agricultural resources, and the dependence on the European and global markets for fish products. This, in turn, generated a dependence on local middlemen (Norwegian. “Nessekonger”).
- 2) According to hypothesis no 2, the Norwegian fisheries policy has side effects as declining fisheries employment, increasing unemployment, decreasing incomes, and population decreases. Again with reference to the introduction: The increase of catches and landings, a very low level of economic measures, combined with the dependence on international markets, can reduce the importance of fisheries policy changes for socio-economic changes inside the Norwegian fisheries regions.
- 3) Therefore, hypothesis no 3 is that changes in the Norwegian territorial system of fisheries is caused by different types of regional adaptation to market changes rather than national policy implementation.
- 4) According to hypothesis no 4, the fisheries specialised regions mainly in the Norwegian remote areas, have more negative development in population, employment and income than the average Norwegian regions. It is difficult to give an exact definition of remote fisheries areas (conf hyp no 1). For example, the Norwegian areas that are close to the fish resources can be far from the markets. We categorise regions far from the international fish product markets as remote, however these regions can have a close localisation to fishing grounds as well a central position in the global markets for raw fish.

These development trends can be examined by using the analyses of ESPON project 1.1.4 (The Spatial Effects of Demographic Trends and Migration). By using this analysis processes related with aging and migration in the fisheries regions can be studied. These studies also include Norwegian regions, and the main conclusions (compared with the situation in European regions) are that Norwegian regions have to handle migration imbalances rather than aging the problems which target many European fisheries regions. Moreover, the migration

imbalances is a bigger problem in North Norwegian regions than in the regions at the southwest coast.

- 5) According to hypothesis no 5, the incidence of the Norwegian fisheries policies is not consistent with the objectives of the Norwegian policies of social and economic cohesion. A problem is that it is probably not only one picture of the general objectives for the territorial development in Norway. It is of course an aim to offer equal living conditions in all parts of the country; at the same time, the target areas for new types of regional and industrial policies measures are the big cities.

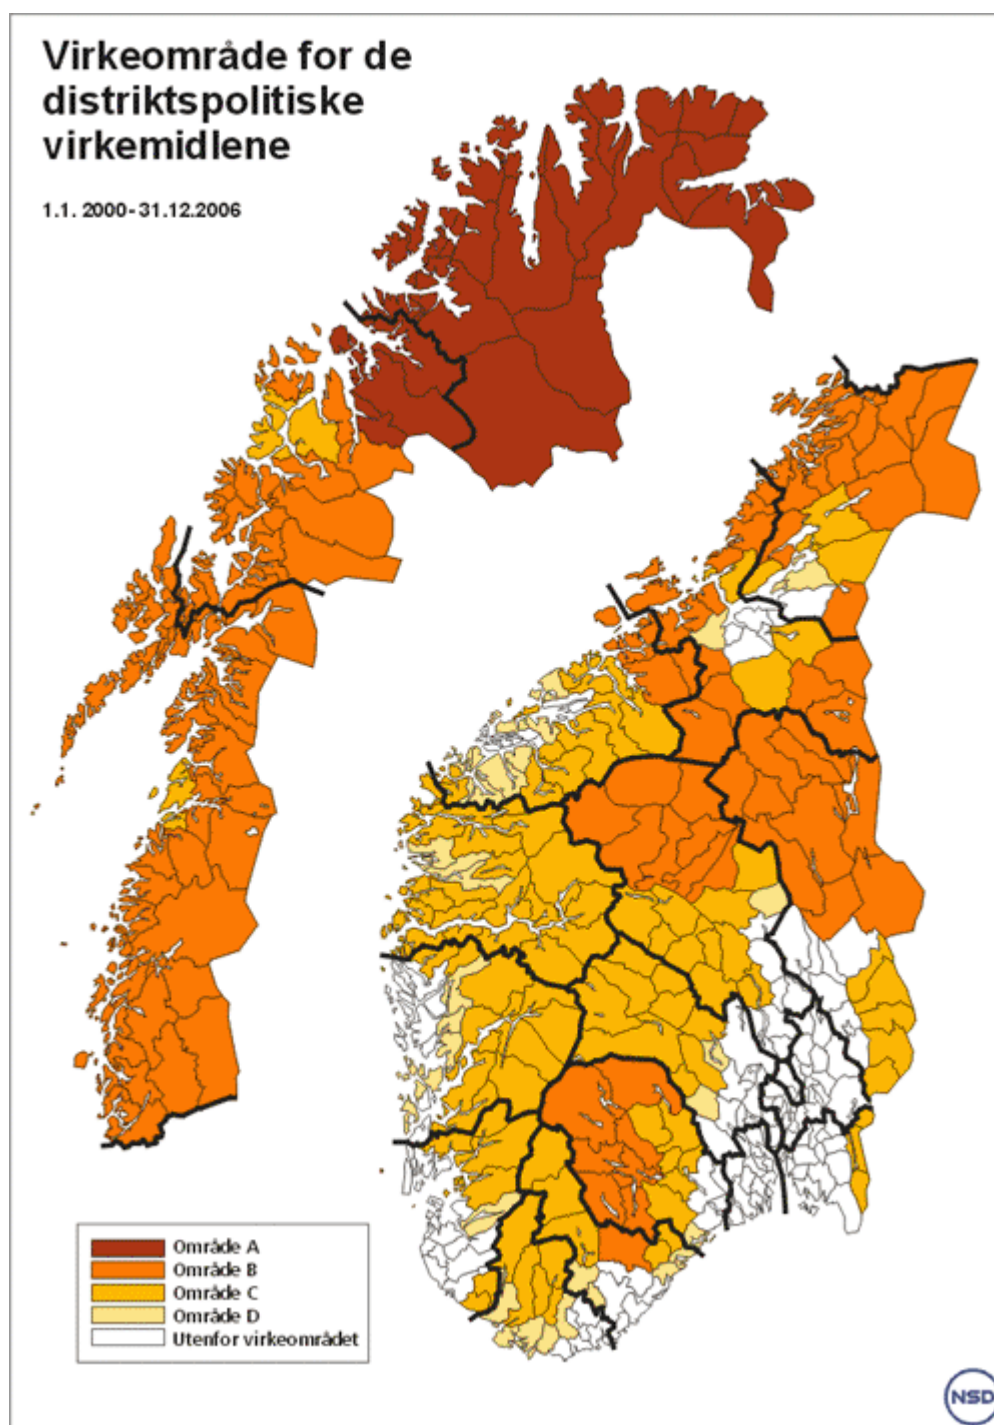

4.3 Norwegian territorial organisation and the territorial level of analyses

In Norway, the counties that are the political-administrative units on the level between the state and the municipalities are defined as NUTS3 regions. Norway has 19 counties and hence 19 NUTS3 regions, and as many as 17 of them have a coastline. However, from our point of view, in only 8-9 of them the fisheries have some representation. In the example study we have included nine, starting with Rogaland in the southwest and ending in Finnmark, the northernmost county. These regions landed over 99 per cent of the Norwegian catches in 2000. All of the selected counties (except Nord-Trøndelag) had over 1000 employed in the fisheries in 2000.

The lower level units in Norway (political- and administrative organisations as well as data units) are the municipalities. Norway has 434 municipalities, of which 384 are located in the 17 counties with coastlines. The nine counties that are selected for the main analyses in this example study have a total of 262 municipalities. Outside the fisheries regions the fisheries have some degree of importance in only four municipalities.

Moreover, Norway has a specific territorial organisation of the regional policies measures by separating between target areas for specific territorial policies measures and areas that not have this status. The map, developed by the Norwegian Ministry for Local Government and Regional Development – unfortunately only in Norwegian, demonstrates de different zones where A-areas target the strongest measures and economic incentives and D the weakest. The white areas on the map are outside the target areas.

Figure 4.1 Target areas for specific territorial policy measures in Norway

Source: Norwegian Ministry for Local Government and Regional Development. 2006

In 2000, twenty-nine per cent (615 000) of the total Norwegian employment was in the specific target areas (A, B, C, D), the proportion had decreased from 31 per cent in 1990, in spite of that the employment in these regions increased by 35 000 employees from 1990 to 2000. Only minor parts of south-west coast are localised outside the target territories (parts of Rogaland and Hordaland)

4.4 Territorial distribution of the Norwegian fisheries measures

As was demonstrated by the map above, almost all parts of the Norwegian coast with fisheries are “districts”. Therefore the state regulations of the fisheries sector have districts or territorial impacts. In Norwegian fisheries a lot of types of regulations have played central roles during different periods. The legislation and rules of most importance are: The annual fisheries agreement between the state and the fisheries organisations; regulation of the availability to participate in the fisheries; regulation of the ability to own vessels; regulation of the ability to process offshore; subsidising of fish export and export organisations; direct ownership of fisheries factories; regulation of the availability to import raw fish; and different types regulation of the aquaculture industry. Most of these regulations have been built down or removed, due to political ideological changes and the European competitions policies.

Today the Norwegian fisheries policy distributes the state economic support for the fisheries, and allocates the allowable catches, mainly in form of vessel quotas. The territorial implementation of the fisheries policies can, according to available data, be measured by analysing the territorial distribution of the landings and the economic measures, the level of economic support (only possible in 2000) and development of the landings (2000 compared with 1995).

An important background for understanding the Norwegian figures is that while the objective of the CFP the last decades has been effort reduction, it is not obvious that this has been of priority in Norway. 1989/1990 was a period of crisis in Norwegian fisheries particularly in the important Cod fisheries. After 1995 the landings as well as the capacity probably have increased. The total landings in 2000 had increased by four per cent and the number of vessels with a length over ten meters increased from 3319 in 1996 to 5563 in 2002, i.e. by 68 per cent. These figures demonstrate a capacity increase as well as growing catches in the period of the analyses.

In 2000, the Norwegian fisheries policies measures amounted to 109 million NOK (13,2 million EUR). The measures were divided into two types:

- (iii) State support for modernising the fishing fleet (66 million NOK, 8 mill EUR, 61 per cent of the amount).
- (iv) Funding of the annual fisheries “agreement” concerning economic support between state and the fisheries (43 mill NOK, 5,2 mill EUR, 39 per cent). The “agreement” today consists of support to condemning fisheries vessels, transport subsidies and welfare policies (guaranteeing fishermen a minimum income level).

100 mill NOK (12,1 mill. EUR) were distributed to the nine fisheries regions by the fisheries policies measures, which equals 92 per cent of the total amount. The highest amount (36 mill NOK/3,4 mill EUR) was allocated to NUTS3 region NO53 Møre og Romsdal and the lowest (3 mill NOK/364 000 EUR) to the counties of NO061 Sør-Trøndelag and NO053 Troms, respectively.

Table 4.1 demonstrates the territorial distribution of the types of the Norwegian fisheries policies measures. The two columns on the right hand side of the table is based on indexes that should be useful for developing of a TIA methodology for the fisheries sector policies cf. Draft Final Report, Results Part A.

Table 4.1 The territorial allocation of Norwegian fisheries policies according to part of landings and economic measures; level of economic support and development of landings, nine Norwegian NUTS 3 regions

Coastal territories ranged from South to North	Parts of landings 2000	Parts of economic support 2000	Level of economic support 2000*	Landings 2000 compared with 1995**
Rogaland	20	5	86	107
Hordaland	7	9	89	86
Sogn og Fjordane	15	6	91	101
Møre og Romsdal	26	33	199	95
Sør-Trøndelag	.1	5	40	50
Nord-Trøndelag	.1	4	138	89
Nordland	13	21	99	102
Troms	10	3	23	123
Finnmark	8	8	67	167
Other regions	1	8		
Norway	99	100	100	104

* Indexes compared with national level (100)

** Indexes compared with territorial level 1995 (100)

The *economic measures* favour two regions: Møre og Romsdal (per capita of the fisheries population: 199 compared with the national level of 100) and Nord-Trøndelag (138)), all the other regions target below the national average. More important is however that the measures de facto are targeting a very few number of municipalities. Fifty per cent of the total economic measures in the fisheries agreement were distributed to ten municipalities, almost all of them on the south-west coast dominated by pelagic fisheries. The economic measures are important for the modernisation of these fleets. Of a total amount of 8 million EUR, fifty per cent were allocated for four municipalities (Ålesund, Herøy, Smøla and Lurøy). As much as 93 per cent were distributed to 15 municipalities.

Thus, the figures demonstrate that only two of the regions (Møre og Romsdal and Nord-Trøndelag) receive more from the fisheries policies measures than the national average. There are different reasons for that. Møre og Romsdal receives 48 per cent of the national support for modernisation of the fleet. This support constitutes as much as 89 per cent of the amount given to the region. Almost all parts of these measures are targeting the clusters of shipyards and ship owners in the four municipalities surrounding Ålesund (Ålesund, Herøy, Haram and Giske) and the municipality of Smøla (an island commune in the north of Møre and Romsdal). These areas are the centre, and probably the only centre, of the integration of a modern offshore fleet and shipyard industry. The figures demonstrate the importance of the state for developing and maintaining these structures. The relative high level of support for Nord-Trøndelag is caused by the comprehensive state contribution for developing aquaculture in one rural municipality, Vikna.

The more traditional Norwegian fisheries structures in the three Northernmost counties Nordland, Troms and Finnmark, and Sogn og Fjordane were not able to secure the regions high level of support from the fisheries policies incentives in 2000. Thus, the territorial distribution of the fisheries policy measures in Norway is mainly determined by the regions ability to develop new structures in the sector. In Finnmark and Hordaland the part of public resources received corresponds with their proportion of landings.

Most important is maybe that the fisheries policy looks like being related with growth processes in the fisheries. Møre og Romsdal (probably represented by five municipalities) is the winner in the battle for fisheries resources as well as for economic resources. The losers are Rogaland and Troms, we are not able to explain why at the moment. The figures also indicate that the fisheries policies have not been of importance in the rebuilding of the Cod fisheries in the northern counties.

Finally: Twenty-four per cent of the economic measures of the fisheries policies in 2000 were allocated to territories outside the specific target areas for Norwegian territorial policies measures.

4.5 Impacts for the territorial systems of Norwegian fisheries

The fact that 17 out of 19 NUTS 3 regions in Norway are coastal regions demonstrates the central position of coastal territories in Norway. Due to the historical distinctiveness of the Norwegian fisheries it has its embedding in coast regions in the west and north. Today only nine NUTS 3 regions, starting with Rogaland in the southwest and ending in Finnmark, can be characterised as fisheries regions. However, only some of the nine regions are specialised in the fisheries, and the specialisation varies by the different fisheries sectors.

In the mapping in Draft Final Report, Results Part A as well as in this example study we have used the concept “*fisheries specialisation*” in order to identify a region’s position in systems of fisheries regions on higher geographical level. In this Norwegian study the reference is the national averages of employment in harvesting, aquaculture and fish processing in 2000.

Figure 4.2 Nine Norwegian coastal NUTS 3 regions and their 2000 position in the Norwegian fisheries indicated by their fisheries specialisation 2000 (compared with the national average in the respective sectors).

Fisheries Specialisation in Norwegian Coastal Regions

In the red and yellow coloured regions the respective fisheries sectors have a higher representation than the national average. In the red coloured regions these representations are of more than 10 per cent.

The figures demonstrate important characteristics of modern territorial system of Norwegian fisheries in 2000:

- (i) The dominance of traditional Cod fishing (harvesting) in the Northern NUTS 3 regions, i.e. Troms, Nordland and Finnmark. Moreover, during the pelagic fisheries Møre og Romsdal are represented just over the national average. Thereby the harvesting sector had its territorial centres in those four regions.
- (ii) The dominance of “value adding” processes in southern west coast; i.e. in Sør-Trøndelag, Sogn og Fjordane and Rogaland. Furthermore Møre og Romsdal and Finnmark, the previous is the only northern region with some representation in fish processing.
- (iii) A relative concentration of the aquaculture to Nord- and Sør-Trøndelag, and Hordaland.

The development of the fisheries employment is probably the best and easiest available indicator on the fisheries policies contribution to territorial cohesion. According to the ESPON-project 3.2 territorial cohesion is, among other aspects, related with balanced territorial systems, employment performance and general improvement of living

conditions. From our understanding measuring fisheries employment is a realistic method for assessing the status of cohesion.

From that point of view we have compared the fisheries employment in 2003 with the level in 1990 in the respective NUTS 2 regions. The total employment in the fisheries increased by 28 per cent in Hordaland, 21 per cent Møre og Romsdal as well as in Sør-Trøndelag in the period 1990-2003, the corresponding figures decreased by 29 per cent in Finnmark and seven per cent in Troms. Møre og Romsdal was the only region that increased employment in harvesting. Moreover, while this region increased the employment in the processing industry by 44 per cent, Finnmark reduced its employment by as much as 49 per cent.

Figure 4.3 Changes of employment in the 3 fisheries sectors (harvesting, processing and aquaculture) 1990-2003 (source: PANDA), the level in the respective NUTS 3 regions 1990 =100.

Employment Changes in Norwegian Fisheries 1990-2003

The red coloured regions are the only ones that have increased the employment figures after 1990. In the harvesting that is Møre og Romsdal, the Pelagic specialised region, which also content low level regions which are winners in the Norwegian battles for quotas (conf the description of the Ålesund region below). In the processing industry it is Møre og Romsdal, Sør- og Nord Trøndelag and Hordaland. Sør-Trøndelag and Møre og Romsdal are specialised regions in processing. The development in aquaculture differ from the other sectors because of the high growth in Finnmark where the aquaculture we least represented in 2000. One of the reasons for the increase in this type of region is probably that expansion in aquaculture is caused by the availability of coast surface area.

One of the main conclusions is that several of the regions with high level of employment increase did not benefit from Norwegian regulation policies in terms of landings. Regions

with decreased employment in harvesting as well as processing like Finnmark increased its landing by 67 per cent 1995-2000, Troms by 23 per cent. In the same period the southern regions Hordaland and Møre og Romsdal decreased the landings by approx ten per cent. Probably therefore Norwegian winner regions in the battle for landings or competition for raw fish are so-called raw fish satellites, which are not able to use the raw fish in the industrial development of the region or strength their own fleet.

The relation between the Norwegian fisheries policy and the territorial specialisation in the fisheries are the favouring of specific types of new structures (particularly those developed by the integration of a modern fleet and ship building). The only Norwegian cluster, which is the region of Ålesund, received 28 per cent of the policies measures. The most dramatic territorial impact in Norway is the favouring of the southwest regions, and the discrimination of the harvesting specialised northern regions where Finnmark is most dramatically affected. Thereby the Norwegian fisheries policy is well integrated with the “normal” territorial growth processes in Norway after 1990, favouring the already growing west coast regions, failing to contribute to new growth in less prosperous regions in the north. At the same time the policy measures do not favour the real urban parts of Norway, cf. the allocation for the specific target areas for Norwegian regional policies measures as 75 percent of the measures are targeting areas with different types of problems related with industrial development (region A-D).

4.6 The Ålesund region

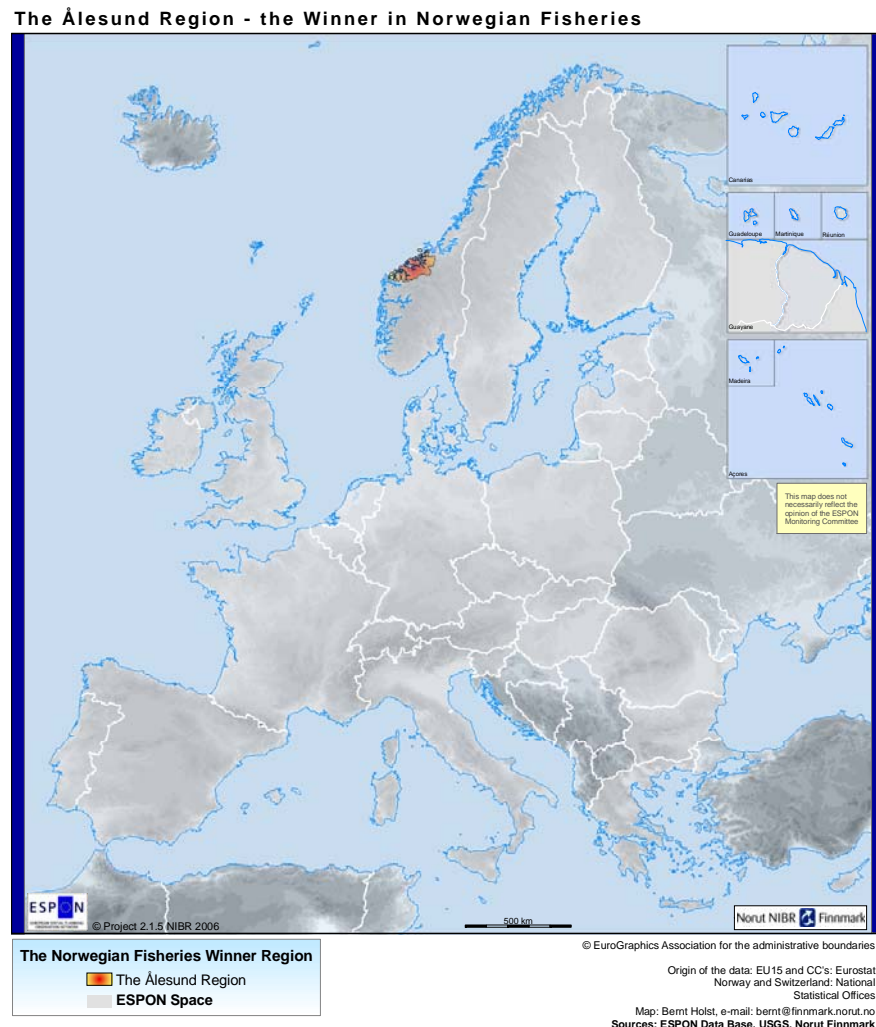

The city of Ålesund has a population of 45 000 in the core city and 88 000 in the city region. Ålesund is the biggest city of the NUTS 3 region Møre og Romsdal which is a transnational/national coast region of type 2. The emergence of the fisheries in this region has been studied, mainly by the associated professor Knut Bjørn Lindkvist at the University of Bergen (Lundkvist 1993, 2004). Based on his findings we can conclude that its position in the Norwegian fisheries has many reasons, where the most important are:

- The region is a winner of the Norwegian competition for quotas, mainly due to its traditional position in the pelagic fisheries.
- The region is a winner of the Norwegian Cod fisheries due to its local cluster of salt fish industries. While the traditional frozen filet processing has experienced big problems since 1980s, the salt fish sector has benefited from stable European markets.
- The well established position of the regional fisheries in the developed marine cluster, where the regional vessels for decades have been an important mean in the development of the shipbuilding industries.
- The position of the Ålesund fisheries in the marine cluster has strengthen the region's ability to reduce the disadvantages of distances to fishing areas as well as strengthen it's opportunity for rapid moving from one fishing area to another (strengthening of the geographical flexibility). Thereby the fisheries of the region have succeeded in developing the role as a modern free rider in classical tragedy of the commons by rapid moving from overfished areas to areas where resources still are available.

As stated by Lindkvist; the Norwegian state has by using the fisheries policies measures forced activities in the regions that strengthen the role as a free rider in the Norwegian fisheries system. However, Lindkvist also exemplifies that the regions in some situations have developed these skills too far. In developing the mussel trawling in 1980s the region

went to far according to lobbying the state, and the exposing of how state measures were lobbied as well as environmental impacts in fact threatened the region's position. In a way the region was captured by its own success.

Figure 4.4 The winner of the Norwegian market based fisheries policies (the Ålesund region)

4.7 The loser region's resistance

Except for the increasing of the employment in aquaculture, the northernmost counties – and particularly Finnmark, are the losers regions in the battle for obtaining benefits from the Norwegian fisheries policies. Therefore Finnmark around 2000 started to develop a new fisheries strategy. By attempting to fight for the property rights for the fish resources, the region challenged the state position in Norwegian fisheries. The strategy was planned to be implemented in the following way:

- The Finnmark county administration sold their properties of the transport company ("Finnmark fylkesrederi") to the global French transport organisation "Connex". The sale sum should be used for buying back quotas from the state. The situation was quite strange since the county

administration did not accept the state's legal base for the gratis obtaining of the quotas 10-20 years earlier, but they accepted the state position if they were allowed to buy some of the quotas back.

- The quotas should then be rented to local fishermen and fisheries enterprises for a period on the condition that the tenants should deliver all the catches to enterprises that processed the raw fish inside the region of Finnmark.

The Norwegian state has not yet accepted the Finnmark strategy. They argue that the fish stocks are a national resource that cannot be transferred to the regions. When the former Bondevik-government allocated a crisis grant for the Finnmark fisheries in 2004 they forbid the regional administration to use any of the funding for buying quotas. After the red-green Stoltenberg-government team came in office in 2005, the situation is more unclear. The architect of the Finnmark strategy, the former mayor of the county administration Helga Pedersen, has become the minister of Fisheries. The Finnmark bidding lies on her office table and still waits for a solution.

4.8 Summing up results and revisiting the hypotheses

The first impact of this example is that when analysing sector policies impacts it is of importance to specify the policy areas of relevance. The actual Norwegian fisheries policy mainly includes the economic support, and the Norwegian landings and capacity building. Moreover, it is important to substantiate that the status and position of these measures have had a special development in Norway. The economic policies measures have probably low importance compared to CFP, while the development of capacities and quotas take different direction in Norway compared to the European countries. These findings stress the need of specifying policy types of relevance according to territorial impacts in different countries or regions.

This is also an input to the discussion related to hypotheses no 3, saying that what we can observe that territorial changes are a result of regional adaptation rather than fisheries policies measures. While the growth of landing figures in the north of Norway can be caused by adaptation to the global markets for raw fish (e.g. Russian offers), the employment growth in the south reflects the ability to benefit from changes in the European markets for fish products (incl. aquaculture production).

The second impact emphasises the need for selecting fisheries ("dependent" or "specialised") regions from the coastal regions. In the Norwegian example 17 of 19 NUTS 3 regions have a coastline, but only nine (about 50 per cent) of the regions with a coastline have fisheries activities. By arguing that the fisheries policy targets a low number of municipalities (small scale territories), studies of direct policies impacts on economic development should be carried out in a very few regions. In 2000, thirty per cent of the Norwegian fisheries policy measures targeted four municipalities, of whom three were located in one NUTS 3 region.

Related to the fourth hypotheses the example study demonstrates that the Norwegian fishery policies are integrated with the "normal" territorial growth processes in Norway after 1990, mainly due that it is not contributing to new growth in less prosperous regions in the north. We can however also argue that the favouring of the target areas for the Norwegian regional policies measures means that the territorial allocation of the fisheries policies follows the objectives of Norwegian regional policies. The reason is probably that territories developing specific types of new structures (particularly those developed by the integration of a modern fleet and ship building) are the winners in the battle for

state economic support as well for landing. The only Norwegian cluster (the region of Ålesund) receiving 28 per cent of the policies measures, and most of these communes are included in the target areas. These findings generate a new hypothesis arguing that some of the regions that benefit from the fisheries policies measures do so due to ability to influence on the policies making and by adapting to the system of policy measures.

4.9 Policy recommendations

These recommendations are elaborated with the aims of securing a relative broad territorial representation of Norwegian fisheries. Moreover as the Norwegian fisheries will continue to be almost free of subsidizes, the opportunities for compensation of the remote regions disadvantages will still be absent. The markets demands for quality and continuity will be stronger than the demand for big amounts of raw fish.

Recommendations:

- Reassessment of the need for formal agreements between vessels and fish product producers and sellers in order to secure quality and stability (such agreements are not allowed today)
- Fisheries management that secure flexibilities in the sector, as well as aims of regional development. A closer adaptation to regional challenges can be implemented by co-ordination with other types of regional policies measures.
- The regional authorities should have the abilities for using resources for buying quotas and rent them to local fisheries.
- Assessing the ability for introducing different types of regional management regimes based on secured and predictable amounts of fish resources or quotas.
- Introduction of obligatory TIA for all planned changes of the conservation policies and other important fisheries legislations.

5 Example study: Island of Bornholm, Denmark

5.1 Introduction

Bornholm is a small Danish island situated in the Baltic Sea between Sweden and Poland - relatively far from the mainland of Denmark, see Figure 5.1 beneath. The island is the only place in Denmark where mountainous areas are found – although the height of these mountains (max. 162 meters) would hardly impress anyone except Danes. Capture fisheries has since ancient times been an important activity for the people of Bornholm, for subsistence as well as for commerce/export of processed products. Fisheries in the waters around Bornholm have also traditionally attracted fishers from other parts of Denmark and from other countries bordering the Baltic Sea to land their catches in Bornholm on a seasonal basis. The island's geography has until recently not been considered particularly well suited for any type of aquaculture and the production has as a result hereof so far been negligible. There are no suitable freshwater streams on the island and marine aquaculture is complicated by several natural factors, i.e. the fact that there are hardly any places, which are sheltered from wind and waves. Partly because of its geographical location and partly because of the remoteness of the island a more diversified development of the economy has been difficult. Tourism is one of the few other sectors, which has benefited from the remoteness and natural conditions of the island.

Figure 5.1 Bornholm *vis-à-vis* the mainland of Denmark

Source of raw map: European Commission

The remoteness of the island must be considered a defining characteristic and discussions over the quality of the routes of transportation from the island to especially Copenhagen are often heated. The main mode of transportation is by ferry from Rønne, the largest city in Bornholm and administrative centre of Bornholms Regionskommune (region-municipality), to Ystad in Sweden. Other routes go from Rønne to Køge just outside Copenhagen, the capital of Denmark, and to Sassnitz and Swinoujscie in Poland. There are, however, also several daily flights back and forth between Copenhagen and Rønne.

5.2 NUTS in Bornholm

Bornholms Regionskommune (until 31.12.2002 called Bornholms Amt (county), NUTS3 level code: DK007) is currently the smallest NUTS3 region in Denmark in terms of population with 43,445 inhabitants in 2005. The administrative structures in Denmark are currently undergoing reform and as from 1 January 2007 the number of administrative units at the level under the state of Denmark will be reduced from 16 (13 counties, 1 region-municipality, and 2 municipalities outside the counties) to 5 larger regions. The number of municipalities will likewise be reduced significantly from 271 to 98. Bornholm got a head start on this process by joining together the five municipalities (previously LAU2 areas of Nexø, Hasle, Allinge-Gudhjem, Rønne and Aakirkeby, see Figure 5.2 on the island to form Bornholms Regionskommune on 1 January 2003. This means that statistics for these areas ceased to be collected as from 2003 and it is therefore in general not possible to analyse the most recent development by these areas. Nonetheless, Bornholm Regionskommune remains smaller, at least in terms of population, than many Danish municipalities, which are currently defined as LAU2 areas. Bornholm will, after the national reform of the administrative structures enters into force on 1 January 2007, become a municipality within a region otherwise comprising of Copenhagen and its

surroundings. In general, the reform will in important ways change the NUTS and LAU maps of Denmark.¹¹⁸

Figure 5.2 Main fishing ports and old LAU areas

Statistics related to capture fisheries continue to be registered on port level, which allows for some regionalisation even beneath the level of the NUTS3 region. However, rather than analysing differences in the development in various parts of the island of Bornholm, this case study will analyse the overall development in Bornholm, particularly in the fisheries sector. Bornholm's limited size means that it is considered as one labour market. Taxes are, furthermore, paid to Bornholms Regionskommune (as well as to the state). A job created or lost in Bornholm will therefore impact the entire island. The primary aim is to - as far as possible - relate the development to impacts of and changes in the Common Fisheries Policy and provide policy recommendations based on the findings. Figure 5.2 shows where the main ports in Bornholm are situated. The port of Nexø is by far the most important in relation to fishing. Rønne is the most important port in relation to transport of goods as well as persons.

5.3 Overall Development of Bornholm

Bornholm has experienced a negative development in terms of population. The population of Bornholm has been continuously decreasing over last decades as shown in Figure 5.3 beneath.

¹¹⁸ The tiny island of Christiansø (population of 98) just east of Bornholm employs a special position within the Danish administrative system, which means that Christiansø is not included in any municipality. Consequently, statistics for Bornholm does not always automatically include this island. Christiansø will as far as possible be included in the present case-study of Bornholm. The small size of Christiansø means, however, that it makes little difference whether it is included or not; overall conclusions will not change in any case.

Figure 5.3 Population development

Source of data: Statistics Denmark

The population of Bornholm has decreased by approximately 9 percent over the period from 1980 to 2005. Over the latest 10 years the decrease has been 3.3 percent. The development in Denmark over the last 10 years has in contrast been an increase in the population of 3.8 percent. The negative development on Bornholm in terms of population can probably not be ascribed to a single factor like the decline in the fisheries sector, see beneath. Although the decline in the fisheries sector might be considered a contributing factor, other factors are probably important, too. One such factor could be that the possibilities of getting higher education on Bornholm are limited or lacking. There is for instance no university on Bornholm. Education is generally considered increasingly important and chances are that people who move away from Bornholm to get a higher education will not always return not least because of the limited diversification of the economy. The job market for people with higher education is more promising in other areas of Denmark, particularly around the largest cities. Significantly, Bornholm is one of the few regions of Denmark (perhaps the only), which is definitely outside commuting distance of any of the largest cities; the only exception being by aeroplane to Copenhagen, which would only be economically feasible for the very few.

Another important indicator of the overall development of Bornholm is the unemployment rate. The development has, as it can be seen in Figure 5.4 beneath, not been particularly favourable in Bornholm in the later years compared to the development on national level.

Figure 5.4 Unemployment

Source of data: Statistics Denmark

Although it is clear that Bornholm's unemployment rate to a large extent fluctuates along with the national rate according to the overall economic climate, it is equally clear that Bornholm has not been able to benefit as much from the favourable economic climate in the second half of the nineties as Denmark in general. As we shall see in the following sections, the period of favourable economic climate in the country as a whole coincided with a period of increasing difficulties related to fisheries, which at least partly explain the different developments in Bornholm and in Denmark as a whole.

A final overall indicator, which highlights the situation of Bornholm, is the development of the average (disposable) family income. In general the average family income has increased since the beginning of the nineties both in Bornholm and in Denmark in general. However, the average family income in Bornholm was already in 1991 approximately 5 percent lower than the national average. Figure 5.5 shows the development from 1991 until 2003.

Figure 5.5 Development of average family income

Source of data: Own calculations based on data from Statistics Denmark

Figure 5.5 shows clearly that the increase in the average family income in Bornholm has not been able to keep up with the increase of the average family income in the country as a whole. The average family income in Bornholm was in 2003 approximately 10 percent lower than the national average.

This section has painted a picture of a region with some clear problems and challenges ahead. Bornholm suffers from depopulation as well as from higher unemployment and lower average family income than the rest of Denmark. The development in the fisheries sector is one of the explanations of Bornholm's situation. This will be the topic of the following section.

5.4 Fisheries Sector

The fisheries sector is important for Bornholm. The regional socio-economic studies on employment and the level of dependency on fishing calculated that Bornholm was the most dependent NUTS3 region in Denmark in 1997 [1]. Although the dependency is not that impressive compared to dependent regions in other parts of Europe, the development of the sector is, nonetheless, linked to the overall development of Bornholm. In the following sections the development of each of the sub-sectors of the fisheries sector will be described.

5.4.1 Past Fisheries Studies

Bornholm was chosen as one of two Danish case studies in connection with the Europe-wide regional socio-economic studies on employment and the level of dependency on fishing [2]. The study was finalised in November 1999 and the most recent numbers in the study in Bornholm are from 1997. That study draws to some extent on survey data gathered by the Institute for Fisheries Management (IFM) in 1997 and published in 1998 as part of an evaluation of the development possibilities of the fisheries sector of Bornholm in the period from 1998 to 2003 [3].

In 2004 the Centre for Regional and Tourism Research (CRTR) in Bornholm published a study on the development possibilities of Bornholm [4]. A report containing the background material for the study contains a section on the current situation of the fisheries sector with particular emphasis on the processing sub-sector [5].

Moreover, the Danish Technological Institute in collaboration with IFM carried out the Danish evaluations of the FIFG programme 1994-1999 [6] and the PESCA programme from 1994-1999 [7] as well as the mid-term evaluation of the FIFG programme 2000-2006 [8]. However, as these were national studies detailed information on Bornholm is limited. Some information can nevertheless be derived on the impact of the structural measures under the CFP.

5.4.2 Capture Fishing

The fisheries sector of Bornholm has traditionally been dependent on a relatively limited number of species, namely cod, herring, sprat and salmon. Cod is by far the most important of these and the development of the sector is therefore particularly sensitive to the development of the catch and landings of cod. The regional socio-economic study on employment and the level of dependency on fishing calculated the quota dependency of Bornholm to be 95 percent - meaning that only 5 percent of the landings (by value of

species destined for human consumption) in Bornholm were not subject to quotas. Bornholm is as a result very sensitive to the conservation policy of the CFP [1].

The TACs for cod in the Baltic (eastern and western stocks) were reduced significantly from 220,000 tonnes in 1989 to 40,000 tonnes in 1993 after which it went up to 180,000 tonnes in 1997. From 1997 and onwards the TAC for Baltic cod has declined to 61,600 tonnes in 2004 (International Baltic Sea Fisheries Commission). The recent and continuing decline in the TAC for cod is clearly reflected in the development of landings in Bornholm. Figure 5.6 shows the volume of landings from 1996 and onwards by cod and other species.

Figure 5.6 Volume of landings in Bornholm

Source of data: Directorate of Fisheries' dynamic landing and catch statistics

Over the period from 1996 to 2004 the landings of cod declined from just below 39,000 tonnes to only a little more than 10,000 tonnes. In 1994 more than 40,000 tonnes of cod were landed in Bornholm [3]. The majority of the volume of landings of other species consists of the low-value species sprat, which is not used for human consumption. The fact that a large proportion of the landings of other species consists of sprat is reflected in the contribution of cod in terms of value of landings. Figure 5.7 shows the value of cod and the value of other species landed in Bornholm.

Figure 5.7 Value of landings in Bornholm

Source of data: Directorate of Fisheries' dynamic landing and catch statistics

Figure 5.7 shows that cod remains by far the most important species in terms of value. However, the relative share of the value of other species has been increasing from 1999 when the share was under 10 percent to 2004 when the share approached 25 percent. However, the increase in relative importance is mostly related to the decline in the volume and value of landings of cod. The total value of landings in Bornholm in 2004 was less than half the value in 1999 (inflation not taken into consideration).

However, the size of the TAC is not the only factor, which determines the volume of cod landings in Bornholm. The Danish quotas for cod have not always been fully utilised due to the fishing conditions in the Baltic Sea for a fleet consisting to a large extent of smaller vessels. Furthermore, landings by foreign vessels have traditionally been an important source of cod for the processing industry of Bornholm. Figure 5.8 shows the volume of landings of cod by origin of vessel in the period from 1996 to 2004.

Figure 5.8 Cod landings in Bornholm by origin of vessel

Source of data: Directorate of Fisheries' dynamic landing and catch statistics

Landings of cod by foreign vessels accounted for more than 30,000 tonnes in 1994, approximately 75 percent of the total that year [3]. The share of cod landed by foreign vessels relative to Danish vessels has since then been declining. In the period from 2002 to 2004 cod landed by foreign vessels represented approximately 25 to 30 percent of the total volume. Bornholm has not in the period from 1997, when the TACs started to go down again, been able to attract more foreign landings to compensate for the negative development of the national quota. IFM calculated in 1998 that Bornholm's share of the aggregated landings of Baltic cod in all the countries around the sea was reduced from 42 percent in 1992, when Bornholm could rightly be considered the centre of Baltic landings, to only between 13 and 15 percent in 1997 [3]. The data does not suggest that Bornholm has been able to reverse this development and regain its previous position. The foreign landings are as indicated above important because the processing industry otherwise has to source raw material from elsewhere. Foreign vessels are also important for the companies servicing the fishing fleet. IFM reported in 1998 that the employment depending on servicing the fleet in these companies had decreased from 246 in 1993 to 148 in 1997 [3]. According to the companies themselves the decline was directly related to the decline in landings as it is not possible to attract vessels for servicing only. In the same report the institute listed the following reasons for the declining share of landings of especially cod (before the 2004 EU-accession of several states around the Baltic):

- increase in demand in especially Poland and Germany as well as in the Baltic countries and Russia;
- increasing capabilities in the sector servicing the fishing vessels in the other states around the Baltic Sea;
- complications of having to notify foreign landings in an EU member state in advance; and stricter enforcement of hygiene regulations and control in general than elsewhere in the area.

The reduced TACs have resulted in reduced employment as well. There was in 1996 approximately 400 fishermen in Bornholm, as opposed to 1,000 in the mid-80s [3]. Only 251 persons were in 2003 registered as full-time fishermen (7 part-time) in Bornholm (Directorate of Fisheries' static employment tables).

In the study on employment and the level of dependency on fishing it was calculated that approximately 1.72 percent (as opposed to 0.29 percent nationally) of the total employment of Bornholm was in capture fishing in 1997 [1]. In comparison, the figure for 2003 is approximately 1.26 percent if the part-time fishermen are not included (own calculation based on Directorate of Fisheries' static employment tables and Statistics Denmark's register based labour force statistics, RAS). The development of the fleet can be examined in Figure 5.9.

Figure 5.9 Vessels with homeport in Bornholm

Source of data: Directorate of Fisheries' dynamic fleet statistics

Although there has been a significant reduction in the number of vessels in Bornholm the total tonnage has only been marginally reduced from 1995 to 2004. However, after having peaked in 1997 the tonnage has actually decreased with more than 15 percent. The peak in 1997 probably reflects the fact that this year marked the beginning of a substantial fishery of sprat. This fishery usually takes place from larger boats, which might explain that the total tonnage of the boats indicating to have homeport in Bornholm was particularly large that and the following years.

It seems clear that the capture fishing sector has been negatively affected by especially the declining quotas for cod in the later years. This is also reflected in the economy of the concerned businesses, which is evaluated each year by the Danish Food and Resource Economic Institute based on a sample survey of businesses' annual accounts. The surveyed businesses have seen a serious decline in the average gross output from cod in the period from 2000 to 2004, see Figure 5.10 (earlier figures are not available for NUTS3 regions in a comparable format).

Figure 5.10 Average gross output from cod per capture fishing business

Source of data: Food and Resource Economic Institute's fisheries accounts statistics

Consequently, average operating profits of the businesses have been declining, too. This has over the period resulted in a severely declining solvency ratio (net capital / total liabilities), which is now well under 30 percent – the figure considered as a rule of thumb the lower limit on sound solvency, see Figure 5.11. The declining solvency ratio clearly indicates that the capture fishing sector of Bornholm is in a difficult situation.

Figure 5.11 Average solvency ratio for capture fishing businesses

Source of data: Food and Resource Economic Institute's fisheries accounts statistics

The TACs and quotas decided under the conservation pillar of the CFP are, as documented in the section above, closely linked to the situation of the capture fishing

sector of Bornholm. Declining quotas - especially for cod - in later years have affected the fleet negatively and led to a decline in employment, a decline in the number of vessels, and a worsening of the economic situation of the businesses. However, declining TACs and quotas are not the only elements, which have contributed to this development: the capture fishing sector has also been affected by the dioxin pollution in the Baltic, which have affected mainly salmon, and the declining employment must also partly be ascribed to increases in effectivity, which means that the same amount of fish can be caught with less input of labour.

Although the conservation measures of the CFP have affected the fleet negatively it should be remembered that these measures have not been applied without reason. The TACs and quotas are applied to protect fish stocks, which are, if no measures were adopted, in a risk of collapse - as the worst case scenario. Whereas these measures have resulted in lower quotas in the past and will probably not result in significantly higher quotas in the short or medium term, the longer term objective is to restore stocks to a level where they can support a higher overall yield to the benefit of the sector currently suffering. In regards to cod, there is, furthermore, the risk that progress in relation to farming of cod (especially in Norway) will change the situation by making capture fishing for cod unprofitable even with stocks in better condition. However, cod farming has been long underway and it is hard to say if and when farming of cod will make fishing for cod unprofitable – but when or if this happens it will surely impact the fishing fleet of Bornholm significantly.

As regards the decline in foreign landings, the main reason seems not to be the conservation measures, but rather that the new EU member states in Eastern Europe are increasingly able to attract landings. This is related to the fact that their economies have been undergoing serious restructuring as a result of the fall of the Soviet Union and also that transition funds have been available from the EU in the years prior to accession. The development in the foreign landings is thus related to the enlargement of the European Union and macro-economic developments in the accession states; however, the declining quotas are probably not without importance, either. The declining number of foreign landings has affected companies servicing the fishing fleet and other related businesses negatively. As a consequence some financial support (1.45 million Danish kroner) under the PESCA programme was directed towards providing these businesses with support to build new markets and export their services – as a first step to the rest of Denmark, but also to other countries. It was estimated that these efforts in Bornholm saved a little less than 100 jobs, which would otherwise have been lost [7].

How the Danish quotas are managed at the national level is going to be particularly important in a regional perspective in the future. The Danish government and the Danish Peoples Party have recently decided to adopt a system of vessel quota shares (VQS) to be introduced from 1 January 2007. The VQS system introduces an element of transferability of quotas in the demersal fisheries. The introduction of an ITQ-type system in most herring fisheries some years ago led to great displacements in quota-shares between different ports in Denmark, which did not, however, affect Bornholm significantly because the Baltic Sea was not included. The fishermen's organisation in Bornholm has been a fierce opponent of the VQS system, which - it is feared - might result in quota concentration in some ports. It is, however, difficult to predict how this arrangement, which is meant to improve the economic situation of the sector, is going to affect Bornholm. Unlike in the Icelandic ITQ system there are no rules in the Danish system, which prohibits selling quotas out of a region. However, quota shares are linked to specific sea areas, which might protect Bornholm a little, since its ports are situated relatively far from other major fishing ports in Denmark and mainly oriented towards the Baltic Sea. Anyhow, it does not seem unlikely that the VQS system will to some extent

result in more fish being caught around Bornholm by vessels owned and operated by non-locals. This could lead to further decline in capture fishing on Bornholm.

5.4.3 Aquaculture

Aquaculture has traditionally not been part of the profile of Bornholm. The natural conditions have, as described in the introduction, been unfavourable. However, as technologies change so do the possibilities for aquaculture in Bornholm. Bornholm is, according to a presentation by Bovbjerg Pedersen from the Danish Institute for Fisheries Research, suitable for several types of aquaculture [9]. Bovbjerg Pedersen lists the following aquaculture possibilities for Bornholm: farming of salmon type species in sea cages, farming of various brackish water species in sea cages, possibly shellfish, juvenile cod, juvenile brackish water species for restocking and aquaculture, farming of fish for put-and-take and farming of various species in recirculation installations.

Besides the fact that the technologies are available Bovbjerg Pedersen points to the fact that Bornholm has some competitive advantages compared to other areas. These advantages relate to the fact that Bornholm is an area, which is used to fisheries related businesses: there is local experience with the product (fish), the infrastructure is well developed and there is a processing industry to handle the products. Furthermore, the areas for sea cages are available as opposed to other places where there are significant conflicts over this issue.

In other words, aquaculture is insignificant at present but has growth potential. FIFG support in Bornholm has already been targeted towards aquaculture development and related activities. Bornholms Lakseklækkeri (Bornholm's Salmon Hatchery) has for instance been involved in a FIFG supported project with a total budget of 4 million Danish kroner on the development of methods to farm perch. This is the first experiments with farming of this species in Denmark. Perch are farmed in countries such as France and Switzerland [8]. The same institution has also been involved in a project to breed salmon smolt to release in the wild to increase the amount of salmon, which can be caught by the coastal fleet in Bornholm. The project was a success in the sense that many of the released salmon were caught by Danish fishermen. However, Swedish fishermen have raised concerns about the possible genetic pollution of wild salmon. FIFG support has as a consequence also been directed towards research into this issue [6].

FIFG support under the CFP has contributed to raising the profile of aquaculture in Bornholm and Bornholms Lakseklækkeri is today one of the knowledge centres of Danish aquaculture. However, aquaculture has not yet taken off as a production industry in Bornholm and this is an area where FIFG support would be in a position to facilitate a development, which according to Bovbjerg Pedersen [9] is fully possible in Bornholm.

5.4.4 Processing

The processing industry is particularly important for Bornholm. This is especially the case for the industry engaged in processing of cod. The study on employment and the level of dependency on fishing calculated that 4.35 percent of the total employment of Bornholm was within the processing industry in 1997 [1]. According to IFM 654 (not counting 12 employed in trading firms) were employed in the processing industry that year. The equivalent figure for 1992 was approximately 1000 [3]. Comparability between the figures in the IFM report and those in the Directorate of Fisheries' static employment tables is not good because of differences in definitions of the processing industry; basically the Directorate's statistics include a broader spectrum of companies. However,

CRTR gathered data in 2004, which are comparable to that of 1997. These figures indicate that the employment decreased with approximately 200 to 447 [5]. Figure 5.12 includes - besides the three (statistically defined) sub-sectors of the processing industry - also the employment in retail and wholesale of fish.

Figure 5.12 Employment in processing etc. in Bornholm

Source of data: Directorate of Fisheries' static employment tables

From 2001 to 2003 the employment in the sector decreased significantly. The negative development is due to a drastic decline in the employment in fish processing and preservation. Employment has on the other hand increased in especially smoking, curing and salting of fish over the same period. The total employment in the processing industry was 647 (incl. full time and part-time) in 2003. The majority of those employed in fish processing and preservation are employed by only two firms. The largest firm has 400 employees in Bornholm - and 800 employees on factories in Poland, Lithuania and Poland [5]. Although the outsourcing of some of the labour-intensive processes to low wage countries might be perceived as a threat to the processing industry in Bornholm it might, however, alternatively be seen as a survival strategy, which secures that at least some of the more specialised processes can be upheld in Bornholm. The Danish processing industry is increasingly dependent on imports of raw materials because of decreasing landings. This is also the case for the processing industry of Bornholm. Anyhow, Bornholm has in spite of fierce competition from other actors managed to keep a significant and viable processing industry in the island. According to CRTR the industry continues to have a strong position on the international market for processed whitefish [5].

CRTR lists the strengths, weaknesses, opportunities and threats of Bornholm's processing industry. Some of the points, which are mentioned, are summed up in the following [5]: Strengths: stable, qualified and loyal labour force; local raw material from local landings or import from nearby countries; high and uniform quality of products; and good contacts with customers, i.e. retail and fast-food chains. Weaknesses: local raw material is limited and highly sensitive to regulations; relatively high level of costs (due to wages) on standard products, i.e. fillets; and a need to develop technology to cut costs. Opportunities: higher quotas on and consequently easier access to cod if stocks improve; increased import of frozen fish and new species; industrial development to become able

to produce the local artisan seafood specialties at larger scale; and develop new products for high-end market. Threats: pollution, i.e. dioxin; lower quotas; increased competition especially on standard products from low-cost areas such as China and Eastern Europe; and employees finding more attractive jobs.

As suggested by CRTR the processing sector is affected negatively by the low quotas on cod. However, the main challenge for the processing sector of Bornholm is not related to the CFP but rather to the globalisation of the market economy, which means that the sector is increasingly competing with low-cost countries. The enlargement of the EU has increased competition as well as made it easier to import raw material from nearby countries. Some companies in Bornholm have been able to take advantage of the new situation by means of outsourcing. FIG support could with advantage continue to be directed towards developing some of the points mentioned as opportunities by CRTR, e.g. industrial development to become able to produce the local artisan seafood specialties at larger scale and developing new products for the high-end market. These are areas where Bornholm has a competitive advantage compared to many low-cost countries.

5.5 Impact of the CFP

It is difficult to link the overall development in Bornholm directly to impacts of the CFP. Bornholm is as an island facing particular difficulties, which have little to do with fisheries. However, the negative development, which the fisheries sector has experienced from the mid-90s (see for instance Figure 5.7 and Figure 5.8), corresponds to the period where the unemployment in Bornholm increased to become significantly higher than the national average (Figure 5.4). Furthermore, in the same period the average family income in Bornholm declined from around 94 or 95 percent of the national average up to 1994 to 90 percent in 2003 (Figure 5.5). Whereas this is not a proof that the development is directly linked to the fisheries sector it is nonetheless a good indication.

As described, the difficulties of the fisheries sector of Bornholm can partly be ascribed to the measures adopted under the conservation pillar of the CFP. However, globalization and the enlargement of the European Union have also changed the situation for the sector. These developments have for instance increased the competition, which the processing sector is facing and redirected landings from foreign vessels to ports not situated in Bornholm.

In the longer term the conservation policy of the EU should result in better conditions for the fisheries sector but this can not be expected in the short term. FIG support should be directed towards the areas where there is growth potential, for instance aquaculture or processing of special products. In regards to the capture fishing sector FIG support should not be used to increase the fishing capacity of the fleet of Bornholm; rather it should be aimed at bringing the capacity in line with the fishing opportunities to improve the economic situation of the sector. This is also the approach, which has been taken by the EU since the end of 2004; since then it has not been possible to get FIG support for renewal and modernisation. It is expected that this line will be followed in the EFF (successor to the FIG 2000 to 2006) but this cannot be taken for granted. Several member states opposed the decision to abolish aid for renewal and modernisation when this was taken in 2002 and since then 10 new member states have entered the EU; a majority of these has a more favourable view on aid in general. Anyway, it is hard to believe that a Danish government would support applications in this category given the change to a more market based national management system and a general recognition of a need to reduce capacity.

In general any support should take into consideration that a diversification of the economy of Bornholm would be preferable. The fisheries sector will probably continue to play an important role in Bornholm's economy but it cannot be expected that this sector will be the backbone of the economy in the future. Tourism has traditionally been important for Bornholm and it can be expected that this will continue to be the case in the future. As described above, aquaculture may also be considered an area with potential for expansion.

5.6 Revisiting the Main Hypotheses

The case study in Bornholm sheds light on several of the project's 16 main hypotheses. We will briefly go through each hypothesis and discuss if and how the Bornholm case supports/falsifies the specific hypothesis.

General impact hypotheses relates to all work packages analysing territorial impacts, i.e. WP3, WP4 and WP5:

1. The CFP will have different impacts between coastal regions, and within regions. Processes on restructuring, reduction and expansion will occur side by side and in various combinations. Impacts of CFP will be more significant the lower the geographical levels.

The Bornholm case shows that processes of reduction and expansion do occur side by side. The fishing of cod has declined in response to the negative development of the fish stocks and TACs but at the same time aquaculture is on the move forward and fishing for other species than cod has increased.

2. Economic, social and demographic impacts of the CFP will vary between urban and remote areas. Socio-economic effects related to employment, migration, age structure of the labour force etc., may be less devastating in urban regions than in fisheries dependent regions and areas.

The Bornholm case shows that the island has had difficulties compensating for the lost jobs in the fisheries sector. Bornholm now has significantly higher unemployment than Denmark in general, something which was not the case 10 years ago. This is very likely due to the remoteness of the island, which was not a problem when fishing in the Baltic was of greater importance also to fishermen from other parts of Denmark undertaking seasonal fishing for cod.

3. Territorial impacts of CFP will vary with different structures of the fishing and aquaculture industries of the regions. Impacts will differ in accordance with the extent to which the regions are dominated by small scale coastal fishing or fishing in distant waters with greater vessels, landings, fishing processes or aquaculture.

The Bornholm case supports that these things matter. In Bornholm the landings of cod have been lower than they needed to be just because the fleet, which to a large extent consists of small vessels, has had difficulties in fully utilising the quota available. Furthermore, even though there has been a general decline in fish landings, the powerful fish processing sector in Bornholm has managed to detach itself, at least partly, from the local landings.

4. Territorial impacts of the CFP may contradict with the aims of cohesion, territorial balanced development and polycentrism. The CFP may favour the prosperous regions and disfavour the most remote regions, i.e. favour regions which are not particularly fisheries dependent at the cost of regions which are strongly dependent on fisheries.

Unfortunately, Bornholm cannot be convincingly compared to other EU regions when it comes to financial transfers because the Commission's FIG data sheets only go to NUTS2, which covers all of Denmark.

Social and economic impact hypotheses relate to WP3 and WP4:

5. The CFP has unintended side effects on coastal regions or fishery dependent regions. Significant territorial impacts may be:

- *Economic effects such as increasing unemployment*
- *Decreasing regional economic productions (GDP)*
- *Population decreasing due to out-migration particularly in fisheries regions*
- *Altered age composition in fisheries dependent regions, with an increasing share of elderly population.*
- *Indication of gender and age biases in fishing dependent regions*
- *Change in population density in fisheries regions*

The Bornholm case bears evidence of some of these unintended effects, but it is difficult to isolate what is due to fisheries policy. However, there are indications that unemployment increases and out-migrations and changes in age composition in fishing communities can to some extent be related to the impact of the conservation measures (in response to overfishing). This is probably also one reason for the lower average income in Bornholm compared to the rest of Denmark.

6. As the restrictions on harvesting activities mainly target the fishing fleet these measures have strongest negative impacts in remote, coastal regions, while the more urban regions involved in fish processing still are able to source raw fish through e.g. import from 3rd countries.

The Bornholm case highlights that also a relatively remote, non-urban region can source raw-material from 3rd countries when they have the economic strength and the technological and human (innovative) expertise to be internationally competitive.

7. It appears from hypothesis 6 and 16 that the incidence of the CFP on the regional level is not consistent with the social and economic cohesion objectives of the EU due to the unintended territorial effects of CFP. More favourable regions are able to take greater advantage of the measures included in the FIG due to closer access to products and markets.

This – at least in the case of the FIG - is difficult because the Commission's data sheets only exist at NUTS2 level, which is all Denmark.

ICZM/environment hypotheses relates to WP5:

8. Subsidies to support incomes or costs reduction in the fisheries sectors result in an increase of the fishing effort which has undesirable effects on social and environmental sustainability. Industrialised countries are particularly concerned with overexploitation aspects, and due to biological constraints, fishing subsidies mainly aim at capacity reduction.

The Bornholm case does not have the data needed to test the hypothesis.

9. Increasing awareness of the need to assure resource sustainability and to preserve the whole marine environment, CFP measures aim at reduction of quotas and/or to the reduction of fishing effort. The changes in CFP from 2002 will contribute to a faster

reduction and restructuring of the fishing fleet, both in absolute numbers, tonnage (GT) and engine power (kw).

The Bornholm case does not have the data needed to test the hypothesis.

10. Changes in CFP will probably be directed towards improvement of the marine environment and marine resources. In the long run this may lead to higher and more stable fish stocks but only if the fishing effort is sufficiently reduced.

The Bornholm case does not have the data needed to test the hypothesis.

11. Aquaculture will continue to expand, but the further development may be more regionally concentrated both with regard to value added and employment.

The Bornholm case shows that aquaculture might spread to new regions rather than just concentrating. This is mainly due to new technology but also because the decline in capture fishing results in idle expertise within the area of fish and fish handling in many coastal areas. The Bornholm case also suggests that aquaculture will be localized on the basis of availability of suitable production sites.

12. A management based on ICZM principals will contribute to a further sustainable growth in aquaculture.

The Bornholm case does not have the data needed to test the hypothesis.

The description and diagnosis of fisheries policy lay down the basis for the territorial impact studies. The fishery hypotheses deal with questions of structural changes in the seafood industry, innovation in marine sectors, financial instruments etc., and relates to WP2:

13. Changes in CFP may contribute to increased concentration and centralisation of the seafood industry. This will be a particular disadvantage for the most fishery dependent and remote areas, which are often underperforming regions in an accessibility perspective.

The Bornholm case shows that it is possible to continue a viable seafood industry in a remote region. Bornholm faces big challenges in terms of logistic services and other but has so far been able to keep a rather significant fish processing industry. The decrease in employment is partly due to new technologies. In those sub-sectors of fish processing that are producing local, traditional products, employment has actually increased. This is possible when a region can find a “niche”.

14. Innovation is generally concentrated in cities and urban areas. If the same tendency occurs in the marine sector, the potential and the preconditions for innovation and restructuring in this sector are probably highest in regions with larger cities or in close distance to larger cities (FUA).

The Bornholm case shows that innovation in the fisheries sector does not happen exclusively in urban centres. Local and artisan food production, including fish food, has been expanding in Bornholm. At the same time the processing industry has taken advantage of the new possibilities brought about by globalisation. Tasks, in which the Bornholm workforce is not competitive due e.g. to high labour (wage) costs have been outsourced.

15. Territorial impacts of the CFP measures are dependent on how the measures in use are implemented in the various regions. Impacts will also vary by the structure of the fisheries in the respective regions and the access to alternatives, such as fishing

opportunities, sources of fish raw material for processing, alternative job opportunities etc.

The Bornholm case shows the vulnerability of a region, which is highly dependent on one fish species, in this case cod. The case also illustrates the effect of a general lack of diversification in the island economy, which has probably also led to the higher unemployment rate than the rest of Denmark - besides what can be related to the fisheries sector.

16. Less prosperous regions of the EU receive more CFP support through the FIFG (Financial Instrument for Fisheries Guidance) than the more prosperous regions.

The Bornholm case does not provide the data needed to test the hypothesis.

6 Example study of the West-Estonian Hiiu county. The transition from Soviet system to market economy: the cause of “end of fisheries” on Estonian islands

6.1 Introduction

If fisheries of the new Baltic European Union Member States (MS) are compared to the old MS situated in the Baltic Sea region, then it appears that in the new MS the fisheries sector is more important. The number of fishermen is relatively high, both as a share from the total active population, or if expressed as the average number of fishermen per length of coastal strip or territory of the Economic Zone. Partly this is an heritage from the Soviet period. However, during the beginning of the post-soviet period number of employees and importance of the fishery in new MS even increased.

From the four new Baltic Sea MS – Poland, Lithuania, Latvia and Estonia – only the last one has inhabited islands. It has been pointed out by the previous interim reports of the ESPON project 2.1.5 that the impact of fishery is best visible on the lowest administrative/geographical level (municipalities) and at higher levels fisheries impacts to economic strength, employment and settlements start to be overshadowed by other more important sectors. At the same time it also appeared that the relevant statistical data from municipality level is usually scarce or even absent. Fishery has importance in all new Baltic MS. However, due to its big islands (separate counties) only in Estonia this importance can be visible on county level. In Estonian mainland counties fishery can be very important in coastal settlements, but as these form usually only a small part of the total territory, the county statistics is unsuitable to analyse the impact of fisheries policy.

The Megapesca study [1] demonstrated the territorial concentration of the European fisheries, particularly the fisheries employment. It revealed that 51 per cent of the fishermen are living in 56 NUTS 3 regions where the fisheries have more than 1 per cent of total employment. However if the criteria is 2 per cent of the total employment the number of NUTS 3 regions decreased to 35. Estonian western counties Hiiu and Saare are just a part of NUTS 3 region. However, since more than 7 per cent are employed by fisheries (fishing + processing) on Saare and above 12 per cent in Hiiu counties, they can certainly be classified as areas strongly depending on fisheries.

The aim of the present example study is to analyse how overall changes in the political and economic life in general and in the fisheries policy in particular has affected the life on islands belonging to the Estonian western archipelago. This archipelago consists of

four main (big) permanently populated islands and hundreds of smaller islands and islets, from which the bulk are inhabited at least during winters.

6.2 Study area

Numerous islands in the West-Estonian archipelago area are divided between three counties. While some smaller eastern islands belong to the counties situated mainly on the West-Estonian mainland, the three biggest islands – Saaremaa, Hiiumaa and Muhu – form separate counties situated only on islands. Saare county consists of islands Saaremaa and Muhu (separated only by narrow strait) and Hiiumaa county is Hiiumaa island (Fig 1). Saare county is bigger than Hiiumaa county both by territory and number of inhabitants. Respective number of inhabitants is around 39 and 11 thousand.

In order to evaluate the total impact of fisheries and aquaculture on economic strength, employment and settlements in coastal regions, it is useful to look for areas which depend heavily on these sectors. Since Saare county has also some small-scale industries it is less suitable. Moreover, most of the Saaremaa island's territory can be used for agriculture. Besides, it is important tourist destination, at least in Estonia and neighbouring countries (e.g. thousands of Finnish citizens visit this area every year). Therefore its dependence on fisheries is not so evident if compared to Hiiumaa island. In conclusion, Hiiumaa county situated on the Hiiumaa island seems to be the most suitable area to study the impact of fisheries and fishery-related politics in Estonia, as well as in all new Baltic Sea MS.

Figure 6.1 Hiiumaa (county centre Kärdla indicated) and Saaremaa counties.

Hiiumaa (Fig 1) is much smaller than Saaremaa, both by territory and population size. While ferries to Saaremaa depart after every hour and travel time is only 25 minutes, then there are only 4-5 ferries to Hiiumaa daily and the steaming time is 1.5 hours under normal conditions. During bad ice conditions which appear regularly at winter, however, ferry trip might take 10 hours or more. This makes the island not attractive even to developers of small-scale industries.

Human inhabitation of Hiiumaa can be traced back to the 5th millennium BC. Mesolithic sites in Kõpu peninsula are presented by the seal-hunters' and fishermen settlements. Due to its isolation fisheries have historically played very important role on the Hiiumaa island. Most of the villages are situated by the sea, and fishery has always provided main or at least important additional food for households, because good agricultural lands lie only on the minor part of the island. During the rapidly changing economic situation in two last decades, however, the life-style of the islanders has started to change.

Table 6.1 Main data about Hiiumaa county and Estonia in total (2002). [1, 2]

	Hiiumaa county	Estonia total
Territory	1 019 km ²	43 432 km ²
Inhabitants	10246	1 356 045
Population density	10.1 pers./km ²	31.3 pers./km ²
Births	84	13 001
Births-deaths	-46	-5 354
Capital	Kärdla	Tallinn
Administrative distribution	5 municipalities	15 counties, 241 municipalities

6.3 Administrative distribution and economic overview

There are five local municipalities on Hiiumaa (number of inhabitants in 2005 in parentheses): Emmaste Municipality (1276), Kõrgessaare municipality (1331), Pühalepa Municipality (1725), Käina Municipality (2190) and Kärdla Town (3724) [2]. (Fig 6.2)

Figure 6.2 Administrative distribution of the Hiiumaa county.

In most northern European countries, coastal small-scale fisheries is often just a part-time activity. For example, in Sweden and Finland the bulk of commercial fishermen receive more than half of their income from other activities. During the soviet period most of the Estonian commercial fishermen received all of their income from fishing [4]. Nowadays, the importance of fishery in their households is, however, steadily declining and soon the situation is similar as in Sweden and Finland.

Since in the Hiiu county statistics coastal fishermen are often registered as employed by other sectors of economy (i.e. they receive bigger income from e.g. forestry, industry, agriculture) it is not possible to present exact data reflecting the share of fisheries in the total employment. Figure 3 presents the distribution of employment between different sectors [3]. Under „fishing” only work-force employed by open-sea fishing, distant (Atlantic) fishing and aquaculture is classified (i.e. coastal fishermen not included). If all persons receiving income from the coastal fisheries sector are also included, then the employment in fisheries would increase to approximately 15% from the total in the county.

Figure 6.3 Employment in the Hiiu county [3].

The collapse of the Soviet system created heavy problems both in Estonian fisheries and agriculture sectors [4]. However, during the last few years agriculture has started to develop quickly (in the last two years supported by the EU Common Agricultural Policy). There are many supporting systems designed for agriculture. In 2004 the total netto value added generated by the whole Estonian agricultural sector totalled 203 million Euro, while 74 million of it (36%) was made by different supporting systems [7]. In the fisheries sector, the share of supporting funds is still much smaller and therefore the signs of improvement are not visible (Fig 6.4). Financial support to Hiiu County fisheries in 2004-2006 are presented in the Table 6.4 [8].

Figure 6.4 Turnover in fisheries and agriculture in the Hiiu county 2000 – 2005 [3].

6.4 Demography and salaries

During the soviet period the number of inhabitants was on the Hiiumaa island was rather stable. During the last decade, however, it has started to decline; from 11554 in 1993 to 10289 in 2004 (Figure 5) [2]. Moreover, as the share of older people (more than 60 years) has increased from 16 to 20% [2,3], a further decline in population size is expected to take place in future.

Figure 6.5 Number of inhabitants in the Hiiu county (Hiiumaa island) and the share of elderly people (> 60 years old).

One of the reasons for the population decline is the decrease of employment possibilities in the fisheries sector. Secondly, Estonian fisheries sector (fishing + processing) offers the lowest salaries in the state, only 57% from the average brutto salary (16 sectors compared, data from 2004) [2]. So, employment in this sector is not very attractive. Average monthly salaries in Hiiu county (5975 EEK) in 2004 were close to the average of Estonian counties. However, they still form only 67% from the average salary in capital Tallinn (8800 EEK) [2]. In conclusion, out migration (mainly to the capital area) is permanent problem in the Hiiu county.

6.5 Overview of fisheries

6.5.1 Coastal fishery

Traditionally, during the past centuries, fishery has been small-scale activity. Boats were open and small in size and they employed only passive gears: gill nets, trap nets and long lines.

During the last decades of the soviet period the number of coastal fishermen on Hiiumaa Island was around 200 and they were almost all full-time employed. Coastal fishery used 10-15 bigger harbours which were well-equipped according to standards of that period [4]. For many reasons, such as restrictions on fishing connected to the border regime, the low value of fish, and the moderate number of fishermen, the stocks were relatively healthy at the end of the eighties. After the re-establishment of the independent Estonian Republic western markets were opened. Trade liberalization enabled unlimited exports of fish. First-buyer prices of high-value species such as perch, pikeperch and pike increased rapidly almost up to the Western European level. Due to the high profitability of fishery the pressure on the fish resources increased substantially, both in terms of the total number of fishermen and in fishing effort. Since fishery costs were low and catches and fish buyer prices high, the incomes of fishermen were good. The relative wealth of the people engaged in coastal fishery was also due to the fact that, at that time, most Estonians worked in sectors of the economy that were unable to export to Western Europe. Therefore the earnings of most people at that time were very low [4].

However, after the first prosperous years the incomes of fishermen started to decline both in the absolute and the relative sense. The first reason was that the first-buyer prices had already reached levels comparable to Western Europe and could rise no further. Soon stocks started to decline. Fishermen who were already used to high incomes increased their fishing effort, which in turn accelerated the decline of stocks. For example, value of the catch of the coastal fisheries declined between 1996 (when the collection of first buyer prices of fish was started in the Ministry of Environment) and 1999 more than two times (Figure 6.6). At the same time, dynamic development of the Estonian economy caused a steady increase in all costs connected to fishery. And finally, increases in earnings in other sectors of the economy have increased the average gross wage in the country to a level more than ten times as high as that during the first years of independence.

The described developments have resulted in a decline in the importance of coastal fishery during recent years and, as there are few alternative employment possibilities in many coastal areas, increasing social problems have hit households dependent on fishery [4].

Figure 6.6 The value of the catch in coastal fisheries (Hiiu County and Estonia in total, in thousands Euros)

The changes in the profitability of the coastal fishing are presented in Table 6.2. The very clear pattern is that while raw fish prices have remained on the same level, the average salary in the country has increased rapidly and steadily. As a result, comparative profitability of this sector has declined. Since the equilibrium between raw fish prices and average salaries is even worse in neighbouring (and much more developed) Finland, future decrease can be prognosticated also in the profitability of Estonian coastal fisheries sector.

Table 6.2 Decrease of profitability in Estonian coastal fishing: example with pikeperch prices and average salaries.

	Estonia					Finland
	1993	1996	1999	2001	2004	2004
first buyer price of pikeperch (Euro/kg)	1.60	1.98	1.21	1.85	1.53	2.90
average monthly brutto salary, Euro	68	191	291	352	451	2322
amount of pikeperch equalling salary, kg	43	96	240	190	294	801

6.6 Open-sea fishery

In the Soviet period (1950s-1960s) large trawling in the Baltic Sea targeting herring and sprat was started. While the first trawlers were wooden and engines small, at the end of soviet period (1980s) there was already big and powerful steel trawler fleet. The number of fishermen was 100-150 and the bulk of them was full-time employed. Most of the vessels (length ca 24 m, engine power ca 220 kW) targeted herring and sprat [4]. Most of

the catch was processed on the Hiiumaa island by state owned enterprise Hiiu Kalur. Salaries were comparatively high (i.e. in comparison with other sectors of economy) both in fishing and processing sector.

During the Soviet period the fisheries in Estonia were a part of the Soviet type planned economy, and fishing activities were carried out by collective farms. Fishermen were employees of the collective farms without any rights to the fish resources. Open-sea fishing enterprises were one of the most important employers on the Hiiumaa island. Most important segment was Baltic Sea trawling, but also distant (Atlantic) fisheries targeting many different species. Easily comparable exact data from soviet period is not available (different accounting systems), but it seems that open-sea fishing was responsible to around 25% of Hiiumaa islands turnover.

The re-establishment of independence in Estonia in 1991 was followed by a rapid transition to a market economy, and the fishery was privatised. During the soviet period the trawling sector used cheap fuel and machines produced in the Soviet Union, which were uneconomic in terms of fuel use. The disintegration of the centrally planned economy resulted in the discontinuation of subsidies. Furthermore, the profitability was reduced due to increased fishing costs, and low prices in Eastern Europe where the Estonian trawl fishery had its traditional market. As a result, catches decreased and national quotas were not fully utilised. While small-scale fisheries found new markets in the west, it was still only possible to export products made from herring and sprat to the eastern markets (Russia, Ukraine). Price levels in those markets were low, and Russia tried to enforce several trade barriers both to “punish” the Baltic states for their independence and to force them into a closer alliance with the Russian Federation. As a result, the profitability of Baltic trawling decreased sharply and the volume of catches fell [5,6].

In the middle of the 90s, however, the trawl fisheries started to grow again. The most important reason for this was the increasing purchasing power in the eastern markets. As those markets were known to Estonian fish processors from the soviet time, exports started to grow quickly. As a result, fish processors were interested in raw material and the prices for raw fish rose. In 1996 open-sea fishing created 15% (68 mill. EEK) of Hiiumaa islands turnover and in 1999 the figure was even 19% (143 mill. EEK) (Figure 6.7) [3].

However, the Russian financial crisis which broke out at the end of 1998 decreased drastically marketing possibilities in the eastern markets during 1998-99. Export volumes fell almost to zero and as a result many fishing and processing enterprises, oriented almost exclusively towards the eastern markets, went bankrupt in Estonia. Even if the situation stabilised after 2000, the economical situation (increasing labour costs etc.) for fisheries enterprises has not allowed to win back lost markets in Russia and Ukraine. In 2004 the turnover of the open-sea fishery (73 mill. EEK) was responsible for only 5% of islands total (Figure 6.7) [3].

The number of people employed in connection to the open-sea fishery sector (fishermen + other land-based employees of the enterprises) has fallen dramatically. During the soviet period the statistics was counted differently, so it is not easy to draw parallels to today's figures. However, employment was 50-80% bigger than in 1998, when this sector responded to roughly 16% from the total employment on island. In 2001 the respective number was 8%. The data from 2004 is not yet clear, but it is only around 5%.

Figure 6.7 The turnover of open-sea fishing enterprises based on Hiiumaa island (sprat and herring trawling in the Baltic Sea) and total turnover of Hiiumaa island economy (in million Estonian kroons; 1 Euro = 15.6466 EEK).

6.7 Conclusion, main trends in Hiiu county fisheries

Due to the differences in the accounting principles used in the soviet period and today it is not possible to present exact statistics reflecting the developments in the fisheries sector. However, approximate figures presented in the Table 6.3 give rough overview of the changes.

Table 6.3 Developments in the fisheries sector of the Hiiu county

Year	1985	1995	2005
Role of fishery in county GDP (%)	25	15	5
Number of fishermen in the coastal fishery sector	200	200	180
Share of fisheries income in the coastal fishermen's income (%)	100	100	20
Number of fishermen, trawling fishery	500	200	100
Share of fisheries income in total, trawling (%)	100	100	75
Approximate employment in the fish processing	300	200	100

6.8 Future prospects

Estonia has comparatively limited fish resources. This is in some contradiction with the traditional importance of the fisheries. As it is typical, number of fishermen is high in less-developed countries, while in parallel to the rising living standard the importance of fishing revenues as source of income decreases. It is normal that if a country develops then the average salaries increase more than first-buyer prices of fish. Inevitably, number

of full-time fishermen and relative importance of fisheries must in conclusion decline. For example, the number of professional fishermen using the resources of the Baltic Sea in Estonia is rather equal to Sweden (2000-2500). At the same time the size of the economic zone and length of coastline in Sweden surpasses Estonian ones 5-10 times. Rather analogous is comparison with Finland. Therefore, the decreasing importance of fishing sector can be prognosticated also for the future.

Common Fisheries Policy has set a target to guarantee at least relative stability to people employed in fisheries. Also, it aims to keep incomes of fishermen on decent level. However, if for example the revenues created per fishermen are compared between Estonia and Norway, then it appears that in Estonia an average fishermen creates value that responds to only 10% of value created in Norway. So, it seems quite clear that CFP cannot support such a low efficiency of work. Therefore, in future the decrease in the importance of the fisheries sector as an employer is inevitable and can be foreseen already now. If we take into consideration the general over-exploitation pattern of the Baltic Sea resources and remarkably increased labour efficiency, then it is of no surprise. In conclusion, the emphasis of the CFP structural support as well as other assisting funds should be rather in finding alternative employment possibilities than in maintaining the existing structure of the fisheries.

6.9 Developments related to CFP, national implementation of CFP

Estonia became a member of European Union in May 2004. Since the national statistics is collected on a yearly basis there is no data available, not even about one entire year as a member state of EU yet. Therefore, there is not much numerical information available, which could reflect the territorial impacts of CFP in Estonia.

However, it is still possible to analyse how CFP can impact the fisheries sector of Hiiu County. First of all, it is important to keep in mind that since January 2003 the EU has had a new fisheries policy. It needed to be reformed as it was not effective enough in doing what it had been created to do, that is to conserve fish stocks, protect the marine environment, ensure the economic viability of the European fleets and provide good quality food to consumers. The main reason, as it is put out by EU fisheries administration was that far too many fish had been taken from the sea by fishing, leaving too few adult fish to reproduce and rebuild the stocks. Based on that, the principles for financial support to fisheries sector have also changed. While it is still possible to apply for support to modernise fishing vessels (e.g. to improve security and working conditions on board), the main emphasis has changed to reduce the overcapacity in European fisheries.

In Estonia support to fishing sector can be received for following activities: reducing of fishing capacity (i.e. for utilising vessels); modernisation of harbours and for projects connected to marketing. If these measures are weighted against the main problems of the sector (increasing labour costs, low price of the main fish species, problems on traditional markets), then it is not likely that CFP can stop the “decline of the fisheries” in West-Estonian archipelago. Based on that it can be summarised that while CFP measures can mitigate the problems appeared during the last years, it is not realistic that fishery will once again receive such a high role in the economy of the Hiiu county as it had during the soviet period.

Table 6.4 Financial support to Hiiu County fisheries in 2004-2006. (Data by: Estonian Agricultural Registers and Information Board)

	2004			2005			2006			Total		
	Number of objects	Total Investment	Support	Number of objects	Total Investment	Support	Number of objects	Total Investment	Support	Number of objects	Total Investment	Support
Measure 3.9. Adjustment of the fishing capacity of the fleet				1	531 873	531 873				1	531 873	531 873
Measure 3.10. Modernisation and renewal of fleet	7	1 010 378	404 151	2	153 130	61 252				9	1 163 508	465 403

Total										13	1 725 381	1 027 276

6.10 CFP impact analysis

6.10.1 General impact hypotheses:

“The CFP will have different impacts between coastal regions, and within regions. Processes on restructuring, reduction and expansion will occur side by side and in various combinations. Impacts of CFP will be more significant the lower the geographical levels.”

The Hiiu case supports this hypothesis. However, in strict sense Estonia is not suitable to evaluate effects of CFP, as this policy was adopted comparatively recently, after the accession to EU, and its possible effects are not yet visible. However, it is clear that the effect of all fisheries related policies are much more visible in Hiiu County than in mainland Estonia. Also, it is evident that there have been considerable changes in the fisheries sector in this fisheries dependent region in the last decade.

“Economic, social and demographic impacts of the CFP will vary between urban and remote areas. Socio-economic effects related to employment, migration, age structure of the labour force etc., may be less devastating in urban regions than in fisheries dependent regions and areas.”

Hiiu county do not have urban areas of remarkable size. The only town, county centre Kärkla, is just a “village” than town by European standard (3724 inhabitants). There has been and still is out migration from the Hiiumaa island to the mainland. To what extent this is a product of the fisheries policy or other forces is not fully clear. However, if fisheries sector has been shrinking in terms of turnover, then the agriculture has been clearly growing in the last years (Figure 6.4). This may indicate that the agricultural policy has been more successful than the fisheries policy.

“Territorial impacts of CFP will vary with different structures of the fishing and aquaculture industries of the regions. Impacts will differ in accordance with the extent the regions are dominated by small scale coastal fishing or fishing in distant waters with greater vessels, landings, fishing processes or aquaculture.”

Hiiu county has both coastal small scale vessels as well as big vessels harvesting open-sea resources. However, concerning that hypotheses, the Hiiu county case is not a good example, because in this region both segments of fisheries have been declining rather equally.

“Territorial impacts of the CFP may contradict with the aims of cohesion, territorial balanced development and polycentrism. The CFP may favour the prosperous regions and disfavour the most remote regions, i.e. favour regions which are not particularly fisheries dependent at the cost of regions which are strongly dependent on fisheries.”

In Estonia fisheries enterprises are situated both in urban areas (like the capital Tallinn area) and in very remote coastal areas (like example the study area, Hiiu county). Since the share of the EU fisheries support funds co-financing cannot typically exceed 50% (which leaves another 50% to the developer), more prosperous urban-area enterprises are in better shape to receive structural funds, which may even more increase the difference in the economic situation between prosperous urban and less prosperous provincial areas.

6.10.2 Social and economic impact hypotheses:

“The CFP has unintended side effects in coastal regions or fishery dependent regions. Significant territorial impacts may be:

- *Economic effects such as increasing unemployment*
- *Decreasing regional economic productions (GDP)*
- *Population decreasing due to out-migration particularly in fisheries regions*
- *Altered age composition in fisheries dependent regions, with an increasing share of elderly population. Indication of gender and age biases in fishing dependent regions*
- *Change in population density in fisheries regions.”*

It must be noticed that the link between the fisheries policy and described socio-economic change is usually not straightforward. However, Hiiu county seem to have many of these characteristics. It is a fisheries dependent region where unemployment in fisheries has increased. This can be clearly seen both in the decline of the total number of people engaged in the trawling fishing sector and in the coastal fishing sector. In coastal fishing sector, additionally, the share of income received from fishery has seriously declined – in other words, other income sources have more and more important for the people still engaged in this sector.

In the Hiiu county the welfare situation is lower than the country average. Still, there are no data that this gap is increasing; rather, it has been stable. In Estonia ca 40% live in the capital Tallinn area, and the share of people living in or in the close vicinity of 3 biggest towns (incl. capital) is well above 50%. In these urban areas salaries are higher because of many profitable jobs. However, salaries in the Hiiu county are not lower than in other Estonian remote areas. Rather vice versa, since coastal areas are increasingly more attractive to tourism, Hiiu county might be in better situation than other remote non-urban areas far from the sea coast. At the same time the importance of tourism should not be over-estimated. While in the southern Europe coastal areas are attractive for tourists, in northern MS (like Estonia), however, due to the cold and rainy climate tourist season lasts only two months (July-August). So, increasing employment in the tourism sector can not fully compensate the jobs lost in the fishery.

In the Hiiu county the population is slightly decreasing due to the out migration mainly to the capital area. In migration is small, because there are no attractive jobs. The data also shows clearly that while total population has been slightly decreasing during the last 15 years, the share of elderly people has increased.

In Estonia, fisheries dependent regions (incl. Hiiu county) have lower population density than the national average. However, this is just because most of the people live in few big towns e.g. capital area. Fisheries dependent regions do not have lower population in Estonia than other remote “provincial” non-urban areas. In contrary, coastal areas have been more densely populated than many inland areas which have often low agricultural value (bogs, marshlands). This pattern is analogous to other northern countries e.g. Norway, Sweden and Finland – people live mostly in coastal areas, not inland.

“As the restrictions on harvesting activities mainly target the fishing fleet, these measures have strongest negative impacts in remote, coastal regions, while the more urban regions involved in fish processing still are able to source raw fish through e.g. import from 3rd countries.”

Hiiu county case supports this hypotheses fully. In whole Estonia fish processing has been more and more depending on imported fish. While during the soviet period Hiiu had an advantage to be close to the fishing grounds, this situation is now changing. It is as easy to import frozen raw fish in Hiiu as in the capital Tallinn. However, export of production to main markets (Ukraine, Russia etc.) is cheaper from the capital area. In conclusion, number of employees in fish processing plants (measured as relative importance in the area as an employer) has decreased more in Hiiu county than e.g. in the capital Tallinn area.

6.10.3 Fishery hypotheses:

“Changes in CFP may contribute to increased concentration and centralisation of the seafood industry. This will be a particular disadvantage for the most fishery dependent and remote areas, which are often underperforming regions in an accessibility perspective.”

As stated previously, it is not fully clear to what extent shrinkage of the seafood industry in regions is related to fisheries policy (both Estonian fisheries policy before the accession and CFP) and to what extent it is related to other factors such as location and accessibility. However, in general the Hiiu county example seems to support this statement.

“Innovation is generally concentrated in cities and urban areas. If the same tendency occurs in the marine sector, the potential and the preconditions for innovation and

restructuring in this sector are probably highest in regions with larger cities or in close distance to larger cities (FUA)."

Hiiu county case supports partly this hypothesis – there really is more innovation in the capital area fisheries. However, main disadvantage in Hiiumaa still is the decline of stocks in local fishing grounds, and hard accessibility (geographical remoteness) of the island.

"Territorial impacts of the CFP measures are dependent on how the measures in use are implemented in the various regions. Impacts will also vary by the structure of the fisheries in the respective regions and the access to alternatives, such as fishing opportunities, sources of fish raw material for processing, alternative job opportunities etc."

This hypothesis appears to a large extent be supported by the Estonian Hiiu county fisheries analyses. As it is noted above, other alternative job opportunities are scarce in the county. While the Salerno (Italy) case study presented data that big number of fisheries boats are transporting tourists during the summer season, such a development is not realistic in the northern Baltic Sea.

6.10.4 Specific hypothesis related to post-soviet Member States of the Baltic Sea:

"Importance of fishery is inevitably declining as a result of change of the general economic framework"

As it is typical, number of fishermen is high in less-developed countries, while in parallel to the rising living standard the importance of fishing revenues as source of income decreases. It is normal that if a country develops then the average salaries increase more than first-buyer prices of fish. Inevitably, number of full-time fishermen and relative importance of fisheries must in conclusion decline – even if the fish stocks are stable and in good shape. This process can not be stopped by the CFP. Hiiu county example study reflects this reality.

7 Example study: Ría de Arousa (Galicia, Spain)

7.1 Introduction

Galicia is an Objective 1 region and so eligible for subsidies within the European Union, and the Ría de Arousa is one of the most prosperous territories in Galicia (see figure 1). According to data of the autonomous Administration (Xunta de Galicia), fishing –the extractive sector and the processing industry- amounted to 4.6% of the Galician GDP in 2004.

The Galician fishing fleet is one of the most important of the European regions and the biggest of a country having one of the most powerful fishing sectors in the European Union, Spain. In 2000 Galicia owned almost half of the fishing vessels registered in Spain and 40% of the total carried tonnage. As to employment, despite the reduction in the number of jobs in fishing in Spain and Galicia in recent years, the Galician quota in the total Spanish fishing remained around 40%.

Galicia depends deeply on the respect of the sea environment, the employment and production numbers directly related to fishing activities show this. But this relevance is notably higher if we consider its multiplying effect on the economy of sea resources: ship building and repair, fabrication of fishing devices, transport and a long etcetera of activities which create lots of jobs and a high economic production. As an example, 20 out of the 100 most important companies located in Galicia operate in sectors that are closely related to the sea environment.

Fishing and aquaculture are the main productive activities of the sea environment, where Galician companies have shown an outstanding dynamism both in the extractive process and the marketing of end products. Galicia has managed to associate its sea products with an a renowned image of quality, which makes them have an excelent reputation.

The number of direct jobs in extractive fishing in Galicia is approximately 29.400, which amounts to 11.6% of the total EU employment; and the production from extrative fishing (estuary, coastal, distant-water and deep-sea fishing) unloaded at Galician ports in 2000 increased to 128,035 tons and 329,148,357 €, which represents 2.9% and 10.10% of the EU production respectively.

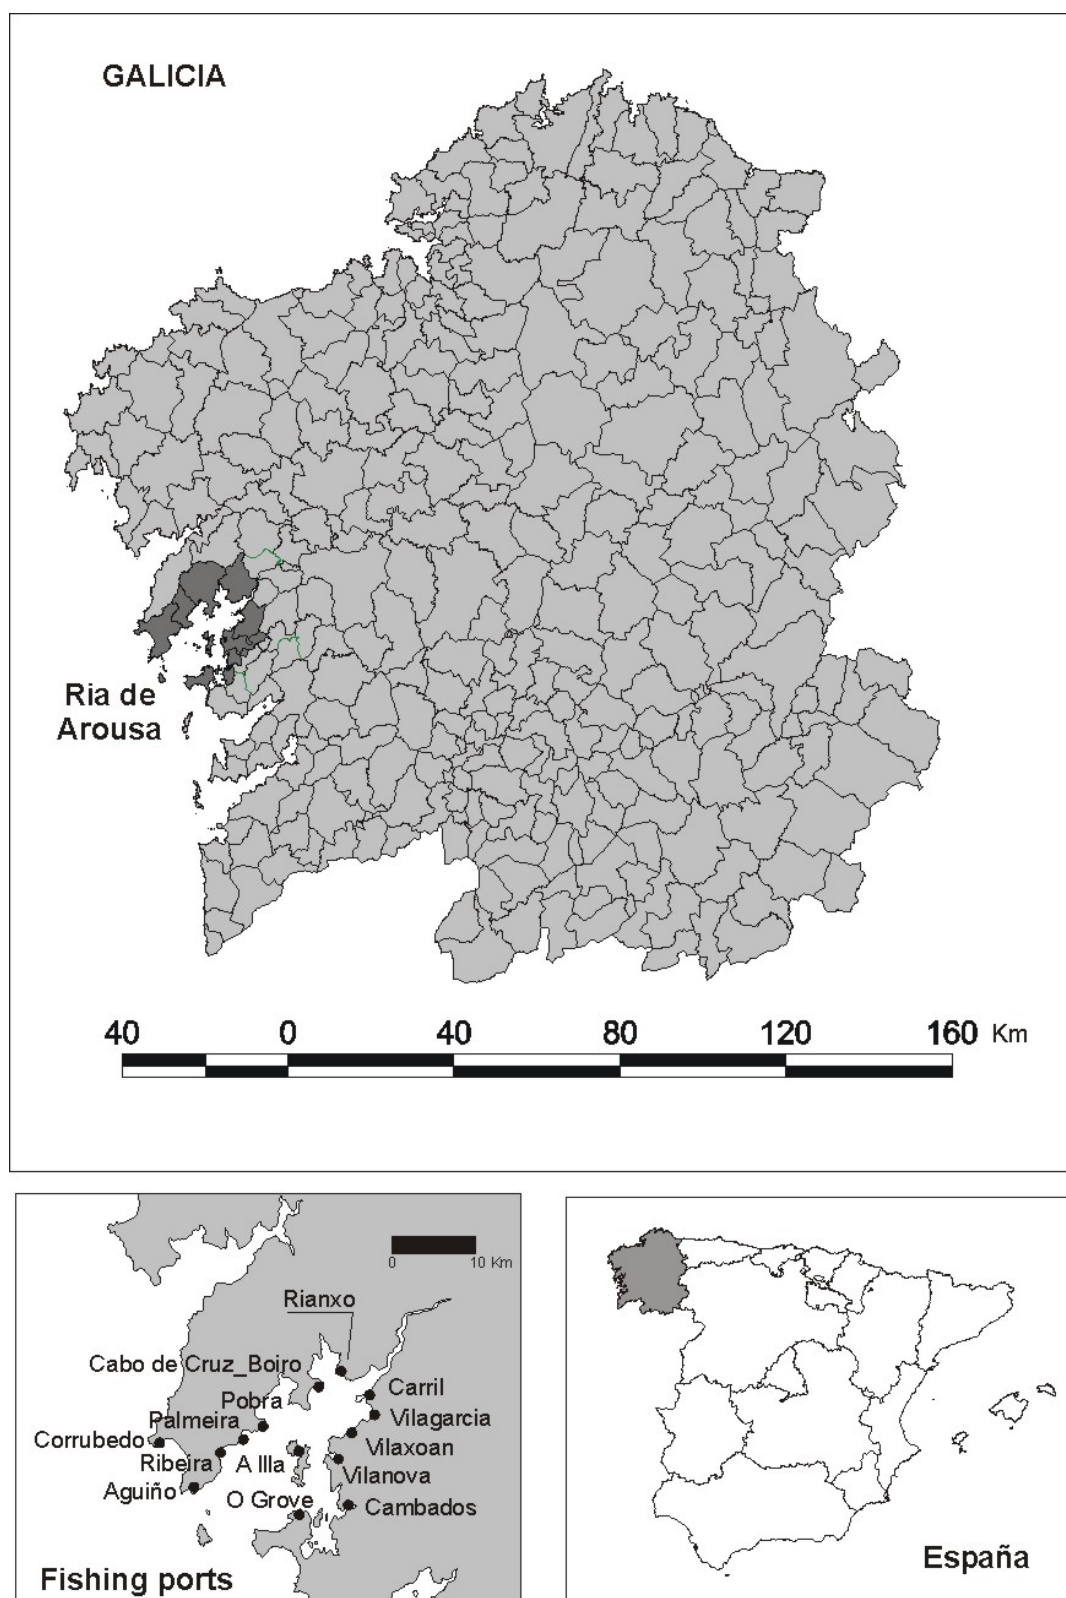

The extractive fishing is made up by fishing units that are mostly dedicated to small-scale fishing in the “rías” and the coast. In 2002 the Galician fleet came to 7.27% of the number of vessels, 6.47% of GRTs and 7.69% of the EU fleet power. We should also mention the presence of Galician capital and crew working in vessels attached to joint ventures in 26 countries, a total close to 265 vessels and more than 7,898 jobs created

both on the sea and on land in the European Union and third countries, with an approximate annual production of 250,000 tons.

Taking into account the economic weight of the Galician fishing on the Spanish trade balance of sea products, the importance of joint ventures in the value of Galician imports is significant: in 2002 21% of fresh fish imports, over 55% of frozen fish imports and 50% of frozen mollusc and crustacean imports came from joint ventures, having the EU market as their first destination.

A simple quantification of the fleet and the jobs at Galician ports would not reflect the reality so as to understand the importance of fishing as an economic activity. The changes of the base port of vessels to other regions of the country or even abroad, the changes in the crew or in the presence of Spanish capital in foreign markets make us go beyond the premise of the mere localization of production means. Due to this, we should consider such data as the minimum for comparative purposes.

Figure 7.1 The Galicia province and Ria de Arousa

As to exports, and excluding the automobile sector, the fishing sector is the main Galician export sector. In 2001, 90% of fresh fish exports, 81% of frozen fish exports, 90.5% of crustacean and mollusc exports and 84.5% of canned products made with fish, seafood and other crustaceans had one of the EU member countries as its destination.

Shellfish fishing and aquaculture – especially the mussel production – created over 22,600 direct jobs, amounting to 40% of the employment in both sectors in Europe. The shellfish-fishing activity employs directly more than 9,000 people, most of them women. The direct jobs created on the 3,337 barges located in Galicia exceed the 13,500, being this region the first EU and the second world producer of mussel, with a production which varies between 250,000 and 300,000 tons.

The canning sector comprises the canning of fish, crustaceans and molluscs in different forms: canned, brine, salted, dried... which employs directly about 4,407 people; and the subsector of the new processed products -such as pre-cooked fish, crustaceans and molluscs-, which employs over 2,130 people. Both sectors are the most important ones in Spain, with pioneering companies in the production of food from fishing and in the labelling with the Galician trademark label.

7.2 Ría de Arousa

The Ría de Arousa is the most extensive of the Rías Baixas, with its mouth opening between the end of Covasa, on the north, and San Vicente, on the south. It clearly borders on the Barbanza range, to the south, and is bounded by the smooth plains of Salnés. There are numerous islands and islets in this "ría", being the most remarkable ones the island of Sálvora, in its entrance; the island of Arousa, in the centre; and the island of Cortegada, to the back, which touches the mouth of the river Ulla.

The winding profile of Arousa favors the existence of many coves and peninsulae that helped the settling of numerous sailor villages such as Aguiño, Ribeira, A Pobra do Caramiñal, Boiro and Rianxo, on the north; and Carril, Vilagarcía, Vilaxoán, Vilanova, Cambados and O Grove, on the south. Catoira, in the confluence with the river Ulla, in the center of the "ría", is the village of the island of Arousa.

From the economical point of view, we must point out that the richness of Arousa is not limited to the sellfish sector, fishing, aquaculture or the canning industry. The wine sector is also of great importance, being the Albariño the most outstanding wine of Arousa.

From the administrative point of view, the Ría de Arousa is part of nine municipalities: Ribeira, a Pobra do Caramiñal, Boiro and Rianxo in the province of Coruña (ES111), and Vilagarcía de Arousa, Vilanova de Arousa, A Illa de Arousa¹¹⁹, Cambados, and O Grove in the province of Pontevedra (ES114). In this territory there are 14 ports, 13 fish markets and 11 fisher guilds.

7.2.1 Demography

Galicia is currently experiencing a negative vegetative growth, with a balance of 7,682 people (provisional data of 2004). This region is characterized by its low birth rate and the ageing of the population. In recent years, the migration movements have compensated the negative vegetative growth of the Galician population.

¹¹⁹ This municipality was created in 1997 from a split of the municipality of Vilanova de Arousa. Due to this, there are no municipal statistical data before that year.

The demographical evolution in the municipalities of Ría de Arousa is similar. The population grew in the 80's: from 133,407 inhabitants in 1981 to 145,823 in 1991. These numbers decrease in the 90's, down to 140,347 inhabitants in 2001. During this decade there were important migration flows of young people to the Canary Islands to work in the building industry and the hotel and catering trade. In the last few years the population became stable, with 140,904 inhabitants in 2004. Not all municipalities show the same trend as immigration is concentrated in two municipalities: Ribeira (labour employed in fishing and in vessels that operate in international fishing grounds) and Vilagarcía de Arousa (having an important trade port and a diversified economy, this is the least dependent on fishing municipality in the Ría de Arousa).

The population of Arousa shows a slower ageing when compared to Galicia. The percentage of the population under 20 in 2004 is 19.8% and 17.5% of the population is over 65. The average age is also around 3 years lower than that of Galicia, 40.8, and the ageing index is slightly lower.

The population density of Galicia in 2003 was 93.02 people per square kilometer, which means that there was a decrease compared to 1981 (95.97). On the contrary, the Ría de Arousa shows a much higher density: 441.6 people per square kilometer, standing out the 780 people per square kilometer in Vilagarcía de Arousa. The previous data clearly reflect the Galician reality, where the population tends to concentrate on the coastal areas (58% of the population is settled here), while the inland of this autonomous community is becoming inhabited.

The municipalities of Arousa show a similar evolution, though more marked: 1,619 people emigrated in 1990, compared to 1,885 immigrants, with a positive balance of 266 people; in 2004 there were 3,048 registered emigrations and 4,032 immigrations, thus increasing the migration balance up to 984 people.

Figure 7.2 Population pyramid for Ría de Arousa in 1991 and 2001

The drop of the birth rate in the last decades deepens a situation which was already worrying since 1990. However, this is the area of Galicia where the population's ageing is less pronounced.

Figure 7.3 Population density: Ría de Arousa and Galicia

Figure 7.4 Evolution of the population in Ría de Arousa and Galicia

7.2.2 Employment

The Galician unemployment rate in 2004 was 13.6%, the activity rate was 53.2% and the occupation rate 45.96%. These data show a general increase compared to the occupation levels of the 90's. The numbers in the Ría de Arousa are similar but there are more marked changes and a more positive evolution. While in 1991 the working population was 51.64%, the occupation rate 41.03% and unemployment 20.5%; in 2001 the working population increases up to 55.84% and the occupation rate to 48.35%, whereas the unemployment rate goes down to 13.28%. These numbers show a higher employment growth in the Arousa area than in the rest of Galicia, which clearly reflects the economic dynamism of the coastal area.

By municipalities, O Grove has the worst results. Here the unemployment rate in 2001 increased to 16.66%, though this is a considerable decrease compared to 28.95% in 1991. On the contrary, the municipality which has the best results is Illa de Arousa, with unemployment down to 7.66% in the same year. This municipality has the highest occupation rates in fishing, as the small-scale fleet is concentrated here.

Before analyzing the occupation levels in fishing, we should note that when talking about the fishing sector we do it according to the National Classification of Economic Activities

(CNAE): 050 Fishing, aquaculture and services related to them (including: 0501, Fishing; 0502, Aquaculture).

Fishing is a fundamental sector for the development of the Ría de Arousa, currently employing almost 10,000 workers (mostly men, over 7,000). The activity rate reflects the importance of this sector, remaining since the 90's up to now around 20%. By municipalities, the numbers of the Illa de Arousa show a very high dependency on fishing, with an employment rate of 60% in this sector (and a remarkable participation of women); Ribeira, with 30%, is in the second place. The lowest fishing employment numbers correspond to Vilagarcía de Arousa, with a rate of only 4.7%.

Table 7.1 Percentage of population employed in fishing compared to the total employed population

Municipalities	Total		
	1991	1996	2001
Boiro	17,3	20,7	17,2
A Pobra do Caramiñal	11,8	15,6	11,6
Rianxo	12,9	15,3	12,5
Ribeira	35,2	36,8	30,1
Vilagarcía de Arousa	4,5	5,02	4,7
Vilanova de Arousa	21,1	29,4	13,4
A Illa de Arousa	60,3
Cambados	18,6	21,5	20,8
O Grove	20,0	21,01	16,1
Ría de Arousa	17,6	20,6	20,7

Source: IGE- Xunta de Galicia

As we can see, all municipalities experienced a growth in the population employed in fishing between 1991 and 1996, which may be due to the economical take-off of Galicia and particularly that of its coastal area (helped by the EU cohesion funds) and to the boom of miticulture, an activity which has its main productive focus in this region.

During the second half of the 90's, employment in this sector decreased substantially and occupation levels dropped below those of 1991.

7.3 Fisheries sector

Since the 60's the fishing sector of Arousa passed from a family and artisanal organizative structure to a semi-industrial one oriented to specialized working processes (bottom trawling, long-line and seining). Industrial fishing provides the most important part of catches, but it is very important to point out the fact that the artisanal fishing gives a good quality image to Galician fishing products.

7.3.1 Fishing fleet

The number of vessels with base port in the Ría de Arousa amounts to 14.6% of the national total in 2004, but only 7.6% of its power. This just shows the proliferation of small vessels dedicated to small-scale fishing.

Table 7.2 Fishing fleet, 2004

	Nº of vessels	GRT	KW
Spain	14.627	498.988	1 210.106
Galicia	5.422	123.271	344.801
Arousa	2.139	21.491	92.911

Source: Pesca de Galicia, Xunta de Galicia.

In 1986 the distribution of the fishing fleet of Arousa –according to the tonnage- showed a strong relevance of smaller units, as vessels with a GRT under 10 added to over 70% of the total. If we look at the current data (November 2005), we can see that the weight of these vessels has not changed much. But the effort compliance schemes and the subsidized scrapping of big units which operated in Gran Sol and other deep-sea fishing grounds resulted in a sensible reduction of the percentage of vessels with a GRT over 100 because the size of new vessels was more adapted to the new conditions of resource reduction and limited access to fishing grounds.

Table 7.3 Evolution of the fleet size (GRT) in the Ría de Arousa

Ría de Arousa	1986	2005
1-10 GRT	75,4	70,2
11-100 GRT	17,7	26,9
Over 100 GRT	6,8	2,6

Source: 1986: Cofradías de pescadores; 2005: Pesca de Galicia

Since 1986 the fleet went through a redimensioning process. The small-scale sector lost weight in favour of the semi-industrial one.

The high participation of small coastal companies hides considerable differences depending on the ports in question. By fishing types, the deep size contrast between semi-industrial fleets –dedicated to coastal seining, trawling and long-line- and the small-scale fleet –which alternate fishing and shellfish fishing depending on the time of the year.

There is a big disparity in the inner structure of the fishing fleet: while the artisanal sector survives and is resistant to changes, the semi-industrial sector is experiencing a strong expansion.

The analysis of the size of the fishing fleet based at the Ría de Arousa ports is further evidence of the strong predominance of smaller vessels. According to the vessels registry of November 2005, 94.8% of vessels are dedicated to coastal fishing with minor gears despite amounting to only 16.8% of the GRT of the total. Almost 43% of the vessels that use minor gears in Galicia have their base port in the Ría de Arousa.

A detailed analysis of the data referred to the fleet in the Ría de Arousa shows a duality with respect to the kinds of fishing practised here: on the one hand, a strong presence of small-power vessels dedicated to inshore fishing, quite spread among all the ports of the “ría” (being Illa de Arousa an outstanding case, with 22% of this kind of vessels); on the other hand, an industrial or semi-industrial fleet that operates in EU and international waters -including seiners of the national fishing ground- and is concentrated at the port of Ribeira, as can be seen in the following numbers:

- Vessels operating in deep-sea international fishing grounds, in distant-water EU fishing grounds and NEAFC long liners have their base at the Ribeira

port. Over 70% of these vessels were built after Spain joined the EU with community funds.

- As to the national fishing ground, all seining vessels of the Ría de Arousa have their base at the port of Ribeira.

When considering the other categories, we can see that they are distributed among the ports of the “Ría” as follows:

- Bottom set longline: 1 vessel in Ribeira and 1 in Aguiño
- Seining: 32 in Cambados, 5 in Ribeira, 3 in Aguiño, 2 in the Illa de Arousa and 1 in Rianxo
- Minor gears: 463 vessels in the Illa de Arousa, 240 in Cambados, 180 in O Grove, 145 in Pobra do Caramiñal, 132 in Boiro, 127 in Aguiño, 114 in Vilanova de Arousa and the remaining 120 at the ports of Vilagarcía, Vilaxoán, Palmeira, Carril and Corrubedo.

Table 7.4 Ría de Arousa description

RÍA DE AROUSA – DESCRIPTION (November 2005)			Nº VESSELS	GRT	GT
International fishing	Ground yarding	Freezers	4	3.486,79	4.972,01
(Deep-sea)	Seine		2	3.983,19	5.920,00

Totals (except aquaculture auxiliary vessels)			2,153	21.214,58	28.814,24

Source: Pesca de Galicia, Xunta de Galicia

The Xunta de Galicia set up an empowerment plan aimed at this artisanal fleet to increase their competitiveness. Over 58,465,000 € are going to be invested on this plan until 2006, to a great extent to modernize vessels and the fish trade structures. The final goal is to adapt the estuary fleet to the new trade and social conditions.

The technical equipment level of the fleet makes it possible to distinguish between a widely spread artisanal sector -with old, smaller and less powerful vessels- and a semi-industrial sector concentrated at the ports of Aguiño, Ribeira and Cambados –with bigger and well-equipped vessels dedicated to seine, long lining and bottom trawl fishing.

7.3.2 Catches by fish markets

During the second half of the 90’s catches remained stable in the fish markets of the “Ría” and even increased 9% until 1999, when a major change occurred: unloading

decreased 33% in 2001 and kept on dropping in the following years¹²⁰ until 2004, when a slight recovery took place.

Table 7.5 Catches in Ria de Arousa

Source: Pesca de Galicia, Xunta de Galicia

The most important fish market of the thirteen which operate in the Ría de Arousa is that of Ribeira, due to its production volume and its turnover (it is, in fact, the second fish market of Galicia with respect to unloadings after Vigo). Fish catches are particularly high, being also quite important cephalopod, crustacean and bivalve catches.

The most representative and valuable product in all fish markets is certainly the group of bivalves (clams), which has the highest catches (800 tons) and sales (6 million euros) in the Illa de Arousa, having also the best numbers in the other fish markets.

The most profitable product of these fish markets are crustaceans. Particularly relevant are the results attained in Aguiño, where 62 tons of crustaceans added to 2.2 million euros. The fish markets of Aguiño, O Grove and the Illa de Arousa stand out in catch volume. Cephalopods obtain far better results in Ribeira than in the other fish markets, where this product is not especially important.

Fish –except in the aforementioned case of Ribeira- does not have significant numbers in the total sea catches. The best results correspond to O Grove, Ribeira and Cambados.

In the fish markets of Arousa there is a clear trend to specializing sea products. Normally, a certain product stands out in each of them, taking up most of the catches and, above all, most of the turnover. Thus, in the biggest fish market, the Ribeira one, two species of fish –blue whiting and blue jack mackerel- account for the highest numbers in catches and turnover. Octopus is also very important.

¹²⁰ We should take into account that the sinking of the tanker Prestige on 13 November 2002 brought all kinds of fishing and shellfish fishing to a standstill in most of the coast.

7.3.3 Shellfish fishing and Aquaculture

Shellfish fishing is defined as an activity aimed at taking out bivalve molluscs from sandy bottoms (clams, cockles, raxon clams...) and it is carried out by shellfishers on foot and with vessels. This is a traditionally undervalued activity which went through a deep transformation in recent years towards the professionalization of the sector, considered until now as a complement to the "family economy".

The Galician Administration organizes every year the intertidal areas by means of exploitation plans which specify dates, places, species, number of authorized professionals and maximum catches. In order to attain the full professionalization, the increase in the profitability of this occupation must be consolidated, investing in semi-farming to increase production. Arousa is well-known around the world for being the most important mussel producer. Nowadays there are 3,500 mussel barges with an approximate annual production of 250,000 tons and the number of jobs created exceeds 11,500.

Most of the Galician canning industry is concentrated here as well. In 1945 the first well barge was placed in the "ría" and in 2004 there were already 36 ranges, where 68.8% of Galician well barges are. This sector is characterized by smallholdings. There are 235 owners in this region, being the average close to 2 platforms per owner.

One of the main problems of farming is the "marea vermella" (red tide) -the presence of diarrhetic (DSP) and amnesic (ASP) toxins-, which lashes Galicia intensely and frequently and forces to close almost 100% of the well-barge areas and the shellfish grounds of this autonomous community. Such a situation -which has to do with the prevailing climate and, mostly, with the temperature of the water and the strong blowing winds that introduce in the "ría" the phitoplankton carrying biotoxins from the continental platform- is specially serious in the Ría de Arousa, considering that it is a world phitoplankton reserve and the most productive one.

The high density of floating crops in Galician inland waters makes it essential to promulgate regulations to guarantee that these crops will not prove damaging for other activities, but particularly for themselves.

7.3.4 Canning industry

Galician canning companies are the most numerous in the Spanish sector and the most important referent in the European Union. Thus, out of the almost 145 Spanish companies dedicated to the production of canned products made with sea products, 76 are located in Galicia. They account for more than 70% of the Spanish turnover of this sector and have a great export vocation.

Galician canning companies are nowadays confronted with new challenges because there is a worldwide competitiveness in the market and less duties. A gradual process of business concentration took place in Galicia -due to globalization- in this sector with over a century of tradition in business associationism. At the same time, investments are increasing in order to gain new markets and the access to raw materials. The average growth of this sector was 7.25% from 1999 to 2002. These companies are making investments to modernize themselves technologically and to produce new and higher-quality canned products. Besides, many companies are making alterations to their installations in order to adapt themselves to the new health and environmental regulations.

The role played by canning companies in the Galician economy is vital. On the one hand, they demand lots of raw material from the fishing and shellfish fishing sector; for instance, about half of the Galician mussel production is processed through canning. On the other hand, this industry also needs to be supplied with additional high-value goods such as machinery or control laboratories. The number of direct jobs created by these companies exceeds 8,000, but indirect employment is much higher.

These canning factories are mostly located in the “Rías Baixas”, exactly 46% in the Ría de Arousa and 28% in the Ría de Vigo, causing various problems due to the high volume of unloaded sewage waters and to the low water renewal of their surroundings.

As to business structure, there is a great number of small factories: 55% of the total turnover 9%, being 59% of the turnover shared only by 5 companies.

7.3.5 Research and development

In Galicia there are many research and initiative centres oriented directly and indirectly to the development of technologies which can be applied to the sea and, in particular, to the aquaculture sector. Most of them are located in the town councils which skirt the margins of the Ría de Arousa:

- Centro de Investigacións Mariñas (‘Sea Research Center’, Vilanova de Arousa)
- Instituto Tecnolóxico para o Control do Medio Mariño (‘Technological Institute for the Control of the Sea Environment’, Vilagarcía de Arousa)
- Centro de Experimentación en Acuicultura (‘Aquaculture Experimentation Centre’, Ribeira)
- Cluster de la Acuicultura de Galicia (‘Aquaculture Cluster of Galicia’, Ribeira)
- Instituto Galego de Formación en Acuicultura (‘Galician Institute of Training in Aquaculture’, Vilanova de Arousa)
- Consello Regulador do Mexillón de Galicia (‘Galician Mussel Regulatory Council’, Vilagarcía de Arousa)
- Escola Oficial Náutico-Pesqueira (‘Official Nautical-Fishing School’, Ribeira)

7.4 Impact of CFP

Some aspects of the CFP pose quite a few problems, especially from the point of view of Spain. When Spain joined the EU, it was confronted with some barriers or restrictions like the existence of boxes and previously established resource access system and resource distribution. Another source of problems is the Galician and Spanish experience in international relations, with the setting up of joint ventures in third countries, a matter which was a cause of conflict due to the non-compliance with the EU common practices.

The implementation of the CFP resulted in the gradual reduction of vessel and employment numbers, while the extractive capacity remained stable through the renewal of vessels and the search for new species.

The evolution of the Galician fishing sector from 1980 to 2005 shows some changes:

- Reduction of the fishing sector quota in the total GBA.

- Loss of working population in the sector. The participation of the elderly is gradually smaller and there are less employees.
- Reduction of the productive units due to the existing unbalance between fishing power and catch possibilities.
- Technical development of the fleet, with bigger size with respect to the crew and more power with respect to tonnage. Vessels are more powerful, more efficient, they offer more possibilities of fishing in different areas and with different fishing gears and allow a more efficient use of the invested capital.
- Reduction of production levels: the quota cuts and the deterioration levels of stocks reduce catches.
- Higher productive specialization; sensible emergence of aquaculture.
- Recent process of increase in the value of fishing products, which makes it possible for fleets and business associations to obtain better results.
- Growth of fishing trade deficits due to changes in the international marine ordenation and the trade liberalization processes. Spain passed from being a mainly exporter country in the 70's to having a position strongly dependent on external supplies, thus losing its relative weight in world exports and increasing it dramatically in imports. Spain was the third fishing importer in 2000 after Japan and the EE UU, and the ninth world exporter. In the same year, 50% of fishing exports and almost a third of imports took place from Galicia.
- Higher market quotas as a result of product specialization, specification and diversification, and positive exploitation of the trademark image both in territory and business. Some countries managed to associate their industrial or food products with a certain trademark image which makes them stand out with respect to other countries. Galicia was able to do so with sea products that enjoy an excellent reputation, which is an advantage to exploit.
- Gradual increase of efficient companies with the appropriate size, organization and relations to face the challenges of globalization.

7.4.1 FIFG Funds

The Xunta de Galicia, through the Ministry of Fisheries, manages the Structural Funds and, of course, distributes and finances the FIFG funds. Between 1986 and 1988, the Galician fishing sector benefited from the FEOGA-Guarantee Funds, as 9,910.1 million pesetas were obtained during these three years, allocating 1,524.5 million pesetas for the building of fishing vessels and 3,854.6 million pesetas for aquaculture. After the 1998 reform of the structural funds, Galicia became a target 1 region.

Table 7.6 FIFG's incidence on the Galician Fishing sector. Period January 1994-May 1999 (million €)

7.4.2 Problems of the implementation of the CFP in Galicia

Since 1986 Galicia benefited from substantial structural subsidies. In fact, the fishing and aquaculture sector was one of the best to take advantage of EU's financing. However, this considerable financing lacked selectivity. The tendency was to finance as much as possible but, in general, in a very indiscriminate way. This resulted in the proliferation of low-quality projects due to the large non-refundable aids offered and to the creation of a "subsidy culture" which did not help improve the business tissue. For instance, some of the problems derived from the excessive density of mussel farming by the end of the 80's can be related to many subsidized changes of farming devices which led many farmers to increase dramatically the number of ropes when making more modern and bigger devices.

In Galicia, structural financing was concentrated on particular private projects which did not help achieve the global objectives. No public project of coastal or marine coastal areas planning was financed. The same happens in France, where public financing from EU funds is more directed to public projects of reorganization and restructuration of aquaculture areas and to the creation of favourable conditions for the private projects, than to private projects themselves.

7.4.3 Position of the Autonomous Government on the CFP

The Galician autonomous government is in favour of the development of market instruments and doubts the current relative stability as it is limited to the EU principle of free movement of people and capital, thus restricting economic efficiency.

One of the main demands of the Galician fishing sector –which was not considered in the 1992 and 2002 CFP reforms- was the recognition of Galicia as a highly fishing-dependent region. The autonomous government considers that the market instruments (individual transferable quotas, fishing days, licences, etc.) are the best to attain a gradual reduction of fishing capital and to adapt to the state of natural resources, so that the most efficient companies are able to stay on the sea by financing the withdrawal of the least efficient companies.

The proposal of fishing decentralization towards fishers associations can boost fishing activities in all regions. The co-management alternative allows cooperatives, fisher guilds, producers' organizations, etc. to take decisions which nowadays are taken on EU, national or autonomic level. But in the end they appear to be abstract entities without a social base, boosted from governmental institutions of local groups to get the financial aids and benefits from the fishing administration.

To sum up, the autonomous government thinks that the current EU system of fishing resources management limits and reduces the strategies which the Galician fleet could use to face the weather, technological and economic variability of fishing grounds. But, most of all, it distorts the biological perception of resource scarcity or abundance through the quota allocation framework, thus reducing the productivity of the fleet and its ability to generate income.

7.4.4 ICZM

Presently there is no integral planning instrument of coastal areas in the Galician spatial planning. On spatial planning matters, the autonomous administration has gives priority to correcting and redirecting the spatial unbalance process, marked by the use congestion of the western coast uses due to the passing of Integral Management Plan of Galician Coastal Areas (PILGA), which will be put in motion by the end of 2006 and will include measures on management, regulation, preservation and maintenance, while establishing sustainable development actions.

Several regulations and plans of coastal areas management have been passed: on certain sectors, on aquaculture, on port activity, on fishing, on industry, etc. In other words: plans and regulations which cannot solve those problems that require an integral approach, but which are a fundamental foundation and reference to consider when approaching and formulating the integral spatial planning. The 1993 fishing law of Galicia is particularly relevant, being its main goal the regulation and management of fishing, shellfish fishing and aquaculture. On the other hand, the regulations on marine living resources management -which make reference to partial aspects- divide the sea environment into zones that have an obvious impact on the spatial distribution of coastal uses and activities.

The regulations on marine-fishing matters are so numerous and diversified that professionals and agents of this sector have difficulty in consulting and getting to know them. This problem becomes worse if we consider the diversity of administrations of the Galician coastal areas and in Ría de Arousa in particular (the Central Administration is responsible for the protection and management of the marine and land environment, while the Autonomous Community is competent on coastal areas planning. Town councils also have competences on urbanism).

Since Spain joined the EU there was significant progress on the programming of regional development policies. In the case of Galicia, one of such proposals is the Strategic Economical Development Plan of Galicia 2000-2006 (PEDEGA). Two priority actions referred to the fishing sector are mentioned in it: boosting the competitiveness of the Galician productive core and protecting the environment. The former is aimed at creating and developing integrated multisector production networks that set up mixed activity conglomerates functionally and spatially linked. The latter action is aimed at overcoming conservationism and raising concern and awareness about these matters as an special long-term development strategy for Galicia.

Two EU programmes are currently in motion in Ría de Arousa. Their goal is the financing and promotion of all actions and projects directed to developing and activating the implementation of the EU's environmental policy:

- The AQUAREG Co-operation Programme through the Community Initiative Interreg IIIC, which is represented by the CETMAR Foundation (Centro Tecnológico del Mar, "Sea Technological Centre").
- The ECOPORT project in the municipalities of the Association of O Salnés (having its head office in the town council of Cambados) was presented to the

European Community through the LIFE project, as a pilot experience, for the integral management of fishing waste material in this Arousa coastal area.

7.5 Revisiting the Hypotheses

7.5.1 General impact hypotheses

1. The CFP will have different impacts between coastal regions, and within regions. Processes on restructuring, reduction and expansion will occur side by side and in various combinations. Impacts of CFP will be more significant the lower the geographical levels.

The Ría de Arousa case seems to support this hypothesis. Some ports were more affected than others by the adaptation to the European legislation. But such changes were more due to the type of fishing which prevailed in each of them (artisanal, coastal, distant-water and deep-sea fishing) or to the level of modernization and efficiency of their fish-product processing companies than to their location, as the Ría de Arousa is located in the most dynamic area of Galicia, both from the demographical and the economical point of view.

2. Economic, social and demographic impacts of the CFP will vary between urban and remote areas. Socio-economic effects related to employment, migration, age structure of the labour force etc., may be less devastating in urban regions than in fisheries dependent regions and areas.

As for the actual effects of CFP on the Ría de Arousa's economy, the fact that multiple factors coexist in this area makes it difficult to determine what its real impact is. It may perhaps be pointed out that the CFP worked as a general revulsive for the region's economy, favouring the professionalization and modernization of the fishing sector.

3. Territorial impacts of CFP will vary with different structures of the fishing and aquaculture industries of the regions. Impacts will differ in accordance with the extent the regions are dominated by coast fishing and small vessels, fishing in distant waters with greater vessels, landings, fishing processes or aquaculture.

There is a notable diversification of activities linked to the sea in the Ría de Arousa. Thus, distant-water and deep-sea fishing are especially important at the port of Ribeira – where all vessels fishing in European and international fishing grounds have their base –, but also coastal fishing –mainly trawling– and artisanal fishing in small vessels –the most common at ports such as that of Illa de Arousa. Furthermore, bivalves farming on mussel-farming platforms and the canning industry linked to fishing have a deep relevance in the local economy as well. So, in the case of the Ría de Arousa, it cannot be said that there is a clear prevalence of a certain fishing modality or the extractive sector over aquaculture or the processing industry of the products of the sea. The structures of the fishing sector were modified at several levels:

- Higher productive specialization, notable emergence of aquaculture
- Recent process of appreciation of fishing products, which allows fleets and integrated business groups to obtain high results.
- Gradual increase in the number of efficient companies: companies which reach a size, organization and relations circuit appropriate to face the challenges posed by globalization.

- Growth of fisheries trade deficits due to changes in the international maritime order and the processes of trade liberalization. In 2000, 50% of the Spanish fishing exports and almost a third of imports took place from Galicia.
- Higher international market shares due to specialization, specification and diversification of products. Positive use of the development of the territorial and business trademark image.

4. Territorial impacts of the CFP may contradict with the aims of cohesion, territorial balanced development and polycentrism. The CFP may favour the prosperous regions and disfavour the most remote regions, i.e. favour regions which are not particularly fisheries dependent at the cost of regions which are strongly dependent on fisheries.

This is not applicable to the Ría de Arousa case. The CFP's implementation affects an area that shows a positive demographic evolution (here lives 58% of the population) and concentrates the most fast growing economy sectors as well as the R+D centres.

7.5.2 Social and economic impact hypotheses

5. The CFP has unintended side effects in coastal regions or fishery dependent regions. Significant territorial impacts may be:

- Economic effects such as increasing unemployment*
- Decreasing regional economic productions (GDP)*
- Population decreasing due to out-migration particularly in fisheries regions*
- Altered age composition in fisheries dependent regions, with an increasing share of elderly population.*
- Indication of gender and age biases in fishing dependent regions*
- Change in population density in fisheries regions.*

Galicia is a region strongly linked to, and dependent on, fishing. But it is also affected by numerous synergies and economical processes –the thrive in tourism among them– which nuance or even distort the impacts of the Common Fisheries Policy.

- Increasing occupation rates in the Ría de Arousa since the 90's. Entre 1991 e 2001 a porcentaxe de poboación empregada na pesca medrou entre un 17,6% e un 20,7%. In the same unemployment decreased substantially.
- According to data of the Xunta de Galicia, fisheries –the extractive sector and the processing industry– amounted to 4.6% of the Galician GDP in 2004. As to the Gross Added Value of fisheries and aquaculture: such values increased gradually from 1995 to 1997 and then decreased slightly up to the present.

We only have data at the NUT3 level. The GDP increased progressively in the province of Pontevedra but at a lower pace in the last considered years: it increased 25.24% between 1985 and 1995 and 22.88% between 1995 and 2000.

- The total population of the country has been diminishing during the last decade, although this trend recently came to a standstill thanks to immigration. In the municipalities of the Ría de Arousa the population grew along the 80's: from 133,407 inhabitants in 1981 up to 145.823 in 1991; these numbers came down in the 90's, stabilizing then in 140,904 inhabitants in 2004. During the last few years the migratory movements allowed Galicia to compensate the negative vegetative growth

of its population. The Arousa municipalities show a similar but more marked evolution. In the 90's significant migratory movements took place in this land to the Canary Islands to work in building and the hotel and catering business. In 2004 there were 3,048 emigrants registered per 4,032 immigrants, so increasing the migratory balance to 984. Not all municipalities show the same trend; immigration is concentrated in two municipalities: Ribeira (labour employed in fisheries and in vessels working in international fishing grounds) and Vilagarcía de Arousa (having an important trade port and a highly diversified economy, the least dependent on fisheries in the whole of the estuary).

- d) The strong emigration of the local population in the 90's of the previous century, specially young people. See population pyramids.
- e) The population of Arousa –as a whole– shows a minor ageing compared to Galicia. The percentage of the population under 20 was 19.8% in 2004, while the population over 65 was 17.5%. Also, the average age is almost 3 years lower than the Galician one, 40.8, and the ageing index is notably lower.
- f) In general, the Ría de Arousa has demographic densities which are higher than the Galician average. The demographic density of Galicia in 2003 was 93.02 people/km², which amounts to a decrease with respect to 1981 (95.07). In contrast, the Ría de Arousa registers a much higher density, 441.6 people/km²; being the highest density that of Vilagarcía de Arousa with 780 people/km². Between 1991 and 2001, the population density in the Ría de Arousa increased from 362.9 to 443.31 people/km². On the other hand, the settlement in Galicia is generally characterized by scattering, while the coast is organized as an urban continuum, which minimizes the problems derived from isolation.

6. As the restrictions on harvesting activities mainly target the fishing fleet these measures have strongest negative impacts in remote, coastal regions while the more urban regions involved in fish processing still are able to source raw fish through e.g. import from 3er countries.

This is not applicable to the Ría de Arousa case

7. It follows from hypothesis 6 and 16 that the incidence of the CFP on the regional level is not consistent with the social and economic cohesion objectives of the EU due to the unintended territorial effects of CFP. More favourable regions are able to take greater advantage of the measures included in the FIFG due to closer access to products and markets.

Being so dependent on fishing, Galicia is the European region which has most benefited from FIFG funds. The Ría de Arousa presents two determining features within the Galician context: being the most dynamic region both economically and demographically and, also, the most dependent on fishing. FIFG funds help adapt to the new conditions of access to European and international fishing grounds and favours the restructuring, modernization and improvement of the fishing sector.

7.5.3 ICZM/environment hypotheses

8. Subsidies to support incomes or costs reduction in the fisheries sector results in a increase of the fishing effort which has undesirable effects on social and environmental sustainability.

The implementation of the CFP resulted in the gradual reduction of vessel and employment numbers, while the extractive capacity remained stable through the renewal of vessels and the search for new species.

In 1986, the Arousa fishing fleet showed a strong prevalence of smaller units (vessels less than 10 GRT amounted to over 70% of the total). Nowadays the proportion small vessels remain stable. However, programmes to ensure compliance with the fishing effort and the subsidized scrapping of big units fishing in Gran Sol and deep-sea fishing grounds made the percentage of vessels over 100 GRT decrease sensibly as the size of new vessels was more appropriate to the new conditions of reduction of the resource and the limited access to fishing grounds.

9. Increasing awareness of the need to assure resource sustainability and to preserve the whole marine environment, CFP measures aim at reduction of quotas and/or to the reduction of fishing effort. The changes in CFP from 2002 will contribute to a faster reduction and restructuring of the fishing fleet, both in absolute numbers, tonnage (GT) and engine power (kw).

The changes introduced in the CFP since 2002 will contribute to the reduction and restructuring of the distant-water and deep-sea fishing fleet. The artisanal and coastal fleet, both quite important in the Ría de Arousa, will be affected particularly by the implementation of the autonomous government policy.

Changes in CFP will probably be directed towards the improvement of the marine environment and resources. In the long run this may lead to higher and more stable fish stocks but only if the fishing efforts are sufficiently reduced.

Changes in the CFP are motivated by other kind of interests which are far less altruist than the achievement of more stable fish stocks.

Aquaculture will continue to expand, but the further development may be more regionally concentrated both with regard to added value and employment.

Arousa is the top world mussel producer. In 2004 there already were 36 production areas concentrating 68.8% of the Galician well barges. This sector is characterized by small farms –235 owners with an average of two platforms per person. Perhaps in the next few years a property concentration will take place in order to attain a more rational exploitation of the well barge areas.

10. The growth of aquaculture and tourism will increase the pressure on the coastal zone, but a management based on ICZM could contribute to a further sustainable growth.

The growth of aquaculture and tourism will increase the pressure on the coastal zone, but a management based on ICZM could contribute to a further sustainable growth. The Strategic Development Plan of Galicia promotes two main actions in the fisheries sector: boosting competitiveness and protecting the environment. The first one is aimed at the shaping and development of integrated multisectorial production networks to create conglomerates of activities which are functionally and territorially articulated. The second one tries to overcome the conservative vision to introduce awareness and concern about these questions within a long-term development strategy.

The canning industries are concentrated in the Rías Baixas, 46% in the Ría de Arousa and 28% in the Ría de Vigo. This fact causes several problems due to the high volume of waste waters produced and to the scarce number of recycling plants existing in these surroundings; lots of canning companies are adapting their facilities to the new health and environmental regulations. On the other hand, the significant number of well barges located in the Arousa area increases the danger of pollution. The high density of the

floating crop beds existing in the inner waters of Galicia makes it essential to dictate rules which guarantee that these crops do not become damaging both for other activities and for themselves. In the Ría de Arousa two EU programmes aim at supporting the implementation of the EU environmental policy:

- The Co-operation Programme called AQUAREG (Interreg IIIC), administered by the CETMAR Foundation (Technological Centre of the Sea).
- The ECOPORT project of the municipalities belonging to the Salnés Association (being its headquarters in the municipality of Cambados) was presented to the European Commission through the LIFE project –as a pilot experience– for the integral management of fisheries waste in this Arousa coastal area.

7.5.4 Fishery hypotheses

13. Changes in CFP may contribute to increased concentration and centralisation of the seafood industry. This will be a particular disadvantage for the most fishery dependent and remote areas, which are often underperforming regions in an accessibility perspective.

This is not applicable to the Ría de Arousa case

14. Innovation is generally concentrated in cities and urban areas. If the same tendency occurs in the marine sector, the potential and the preconditions for innovation and restructuring in this sector are probably highest in regions with larger cities or in close distance to larger cities (FUA).

A significant number of technological research and development centres –linked to the sea and to aquaculture in particular– are concentrated in the Arousa area: Centro de Investigacións Mariñas ('Sea Research Center', Vilanova de Arousa), Instituto Tecnolóxico para o Control do Medio Mariño ('Technological Institute for the Control of the Sea Environment', Vilagarcía de Arousa), Centro de Experimentación en Acuicultura ('Aquaculture Experimentation Centre', Ribeira), Cluster de la Acuicultura de Galicia ('Aquaculture Cluster of Galicia', Ribeira), Instituto Galego de Formación en Acuicultura ('Galician Institute of Training in Aquaculture', Vilanova de Arousa), Consello Regulador do Mexillón de Galicia ('Galician Mussel Regulatory Council', Vilagarcía de Arousa), Escola Oficial Náutico-Pesqueira ('Official Nautical-Fishing School', Ribeira).

15. Territorial impacts of the CFP measures are dependent on how the measures in use are implemented in the various regions. Impacts will also vary by the structure of the fisheries in the respective regions and the access to alternatives, such as fishing opportunities, sources of fish raw material for processing, alternative job opportunities, etc.

It is difficult to test this hypotheses in a space which is so dynamic from the economical point of view as the Ría de Arousa.

16. Less prosperous regions of the EU receive more CFP support through the FIG (Financial Instrument for Fisheries Guidance) than the more prosperous regions.

However, this thesis does not apply in the case of the Ría de Arousa because it is, as already mentioned, one of the most prosperous regions in Galicia (objective 1 region) and, thus, one of the most dependent on fishing, reason why it receives significant allocations from the FIG funds.

7.6 Perspectives and policy recommendations

Fishing is not an strategic sector for the European Union and, thus, the CFP has supported the principle of **relative stability based on a progressive reduction of the fleet**. This system is damaging to countries of late accession to the Community and specially to regions of strong dependence on the fishing activities.

The European Union set up **Areas Dependent on Fishing** (ADFs) and recognized the need to give them special attention, but Galicia is not considered one of them in spite of the 1992 and 2000 CPF Reforms.

The Ría de Arousa is one of the most prosperous regions in Galicia and one of the most dependent on fishing. Galicia (objective 1 region) is the European region which has most benefited from FIG funds. The Ría de Arousa presents two determining features within the Galician context: being the most **dynamic region** both economically and demographically and, also, the most **dependent on fishing**. FIG funds help adapt to the new conditions of access to European and international fishing grounds and favours the restructuring, modernization and improvement of the fishing sector.

Difficulties:

- Strong **dependence on fishing**.
- The current management system of fishing resources (**relative stability**) limits the market instruments.
- **Decrease in the catches** because of the cuts in the quota allocation and the deterioration levels of stocks.
- Disadjustments between the **fishing capacities** and the possibilities of catches.
- Imbalance between a modern and efficient fleet –world market leader–, and a traditional fleet made up of many small units.
- Most of the enterprises in **canning industry** are too **small**.
- The detachment of the younger generations for the sector because of the **low social consideration** of the fishing activities.

Recommendations:

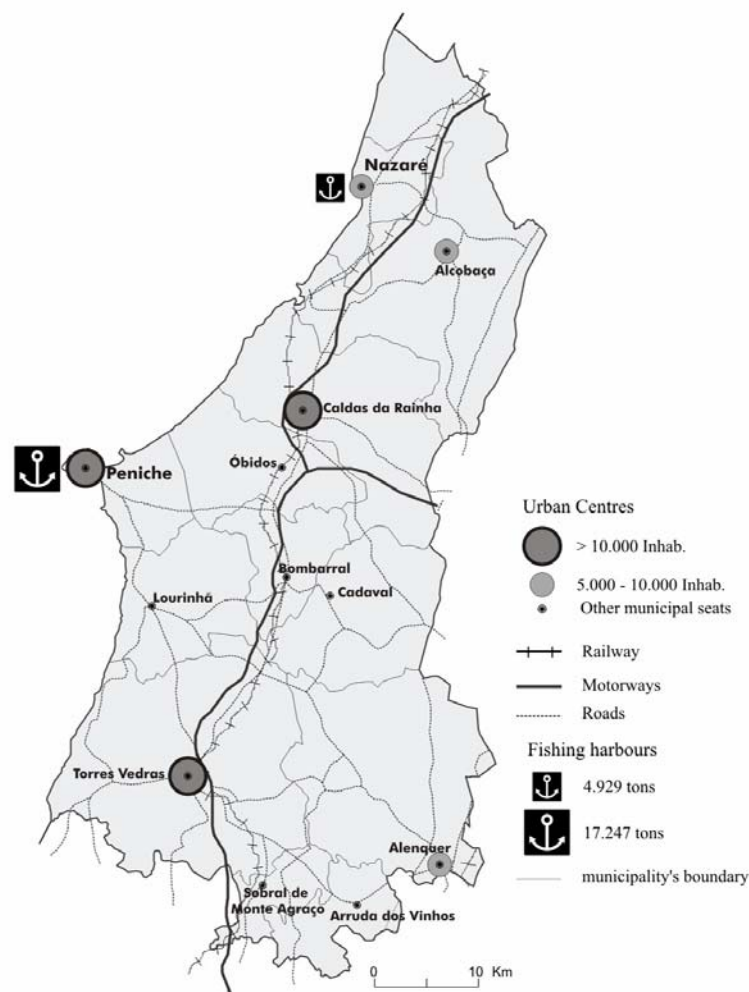

- **Diversification** of the economic activities.
- Looking for **new species** and **fishing grounds**.
- **Business concentration** in order to Galician fishing companies can invest abroad.
- To attract the **young people** towards the fishing activities.
- Improvement of the **living conditions** of the labour force.
- Professionalisation of **on-foot shellfish fishing** (basically shellfish fisherwomen)

8 Example studies: Nazaré and Peniche. (NUTS 3 Oeste, Portugal)

8.1 Introduction

The NUTS 3 Oeste, in central Portugal (NUTS 2), north of the Lisbon Metropolitan Area, has 340.000 inhabitants (156 inh/Km²) and a diversified economy; it comprises three FUA - Functional Urban Areas (Torres Vedras, Peniche and Caldas da Rainha) with population below 50.000 inhabitants (cf. Nordregio, ESPON 1.1.1., 2003). Including 12 municipalities (Alcobaça, Bombarral, Caldas da Rainha, Nazaré, Óbidos, Peniche, Alenquer, Arruda dos Vinhos, Cadaval, Lourinhã, Sobral de Monte Agraço e Torres Vedras) - Map 1 - the sub-region Oeste presents a smooth relief and a landscape that oscillates between a rough coast line and a agro-forest interior, where the vine is the main culture.

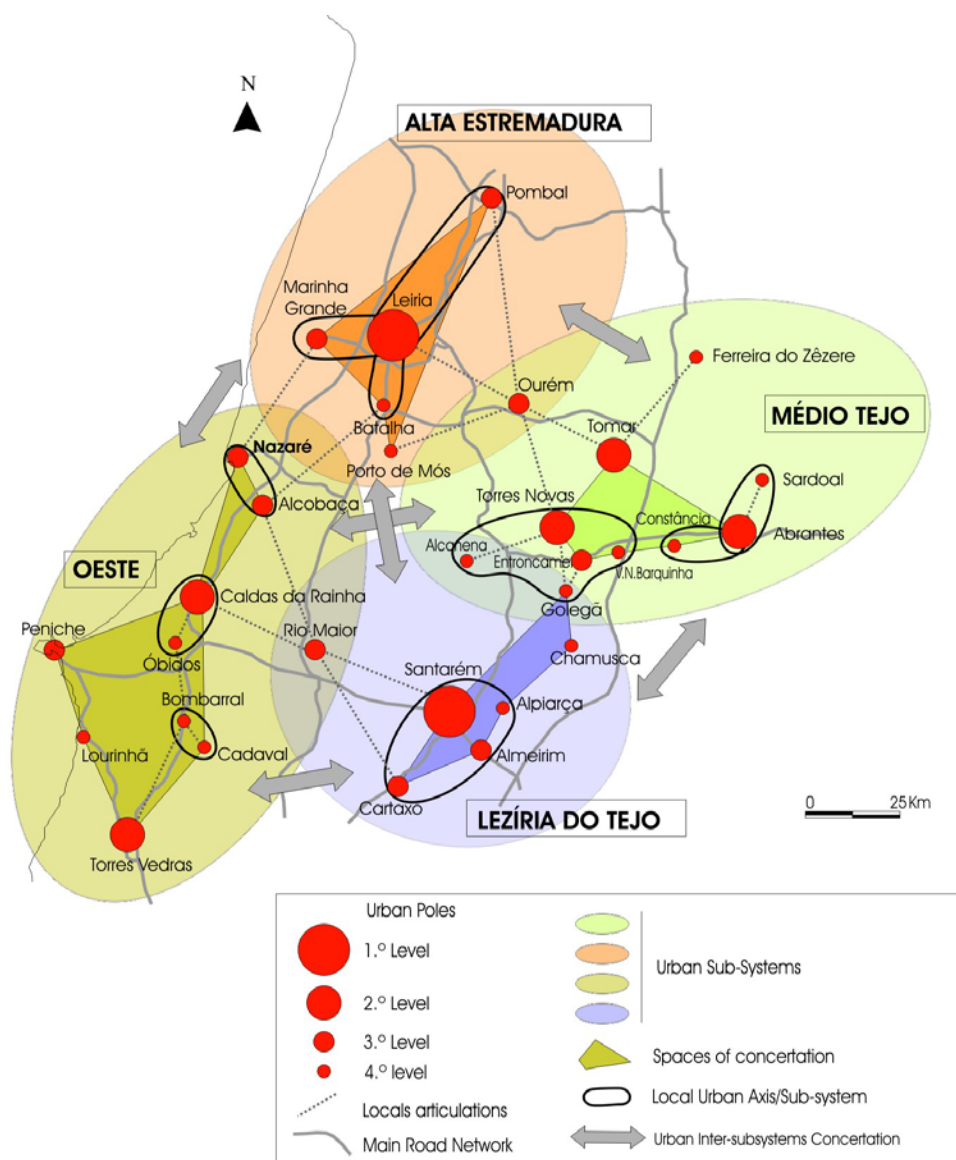

Figure 8.1 NUTS 3 Oeste

It is one of the Portuguese sub-regions where one can feel better the existence of a territorial cohesion, evidenced for the strong mobilization of its economic agents and the civil society in general. With a policentric urban system, four main urban poles are identified (Caldas da Rainha, Torres Vedras, Alcobaça and Peniche) – Map 2 - presenting not only higher level functionalities, but also a relevant polarizing capacity. Thus, in this urban system, the two case studies meet in differentiated positions. Peniche, in an eccentric position between Lisbon and Leiria regions, even though it has an economic base

very concentrated in the fishing industries, simultaneously, benefits from the existing road network, setting privileged relations with some middle sized cities of the region. Nazaré, instead, integrates an axe polarized by Leiria and Marinha Grande, an urban axis characterized for a strong industrial dynamism, potentiated by the recent improvements in accessibilities. In accordance with recent studies, in a circumscribed reading of the urban system of the sub-region Oeste, Nazaré and Peniche are considered to be same level urban poles. The population settlement structure of the sub-region Oeste is mainly dispersed, resulting from the process of diffuse urbanization along the main communication axes throughout the last years.

Figure 8.2 Urban Regional System

In the last intercensus period (1991-2001), the sub-region Oeste has registered a significant population variation (7,7%), due to increasing immigration flows and a relatively low birth rate (11%). In 2001, the population's age structure of this sub-region denoted an aging trend: the aged (over 65 years) corresponded to 17,9% of the total population, while the young (less than 15 years) only represented 15,5%.

With a past strong marked by the agricultural and industrial dynamism, the fishing activity equally constitutes one of the most characteristic marks of this territory, in which we find two of the most important ports of the Country (Nazaré and Peniche), as well as a notable variety of activities associates to fishery. Currently, in what concerns to the job structure, the tertiary sector is presented as the most relevant in the sub-region Oeste, with 54,1% of the employed resident population. Even though less important, the secondary sector, continues to enclose a significant parcel of the population (36,7%), while the primary sector does not go beyond 9,2%.

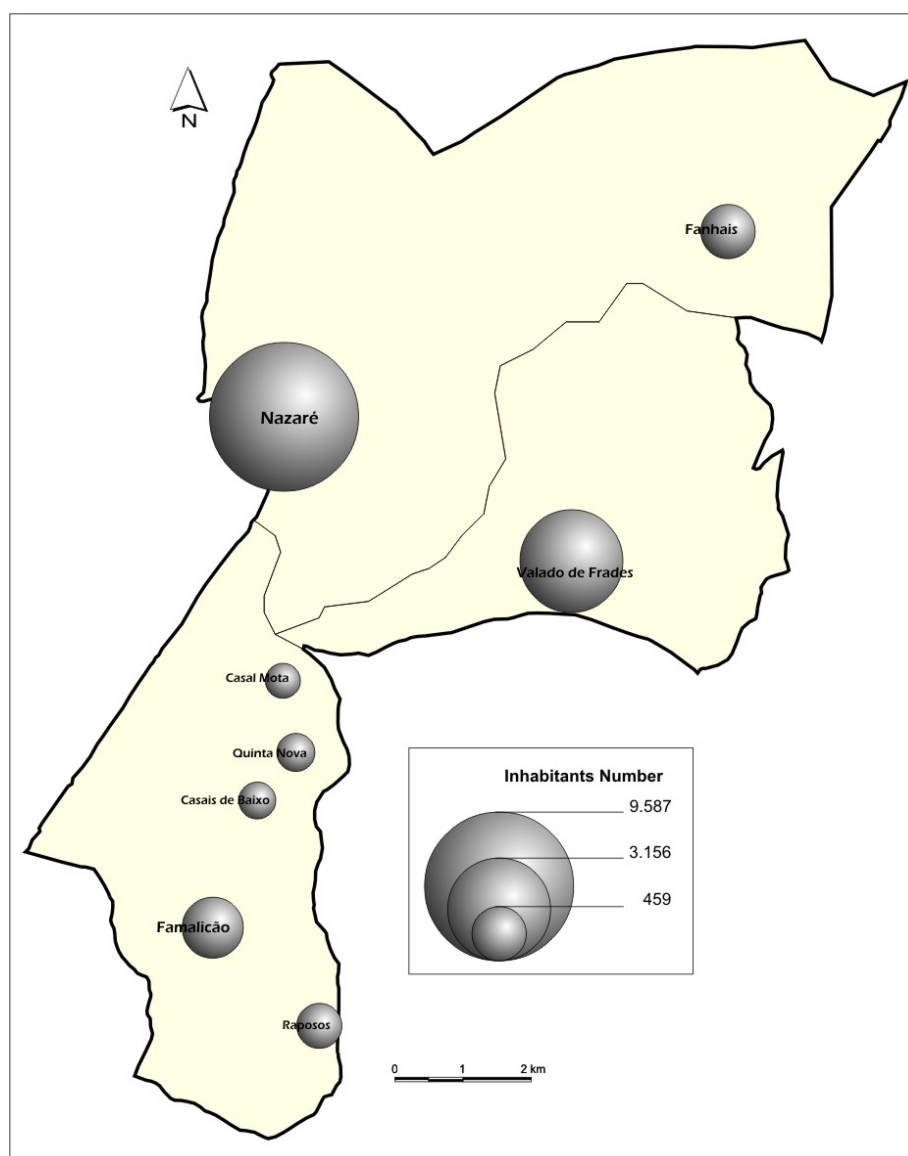

8.2 Example study: Nazaré

8.2.1 The Geography

Nazaré, a municipality located in the Northern sub-region of the West, is composed by three civil parishes (Nazaré, Famalicão and Valado dos Frades). With a total area of 85.1 Km² and a population density of 184,2 hab/ Km² in 2001, it is one of the ancient Portuguese fishing towns, although throughout the years it has lost some of its fishing importance and related traditions. In the past few years, the municipality of Nazaré has clearly taken advantage of its favorable location related to the proximity to some of the country's urban-industrial centers, namely, Caldas da Rainha and the axis Leiria/Marinha Grande, empowered by the recent improvement in the accessibility rates.

At large, Nazaré followed the pattern of the social and economical transformations registered in Portugal in the last decades, including the changes in the population structure. The settlement also evolved, to a more concentrated pattern – Map 3 - particularly with an increase of the municipal seat, which represents now some 64% of the total municipality population. Opposite to the population structure of the sub-region to which it belongs, Nazaré presents a concentrated population pattern, which is one of the competitive advantages of the municipality, even though in the last few years there has been a relative increase of the importance of the dispersion phenomena.

Figure 8.3 Population living in places over 100 inhabitants

8.2.2 Demographic structure

At the end of the twentieth century the population of the municipality of Nazaré kept on increasing, from 10.148 inhabitants in 1981 to 15.060 in 2001. The 80ies decade has been, however, a turning point from which the population tends to stabilize, as a result of a decreasing birth rate and a decline of migratory movements.

In what concerns the age structure, in the last twenty years, there is a progressive population ageing: the proportion of young people, with less than 15 years old, has decreased from 25,3% in 1981 to 15,1% in 2001, while the population over 65 years has considerably increased in the same period (from 11,7% to 16,7%) - Figure 4. There was a significant increase on the dependencies rates, reproducing the fast ageing of the population.

Figure 8.4 Age Pyramid of the Municipality of Nazaré

8.2.3 Economic overview

The analysis of the municipal economic base shows a progressive tertiarization and a clear decrease of the share in the product by the primary sector, which is a consequence of the incapacity of modernization and reorientation of the agricultural productive structures and the decline of the fishing activities, partly as a result of an ageing of the fleet and of the human resources related to this activity.

On the other hand, the secondary sector has played a determinant role in the municipal economy, granting employment to 36% of the active population (2001), even though a significant part of this population is employed out of the municipality seat, namely in Valado dos Frades and Alcobaça, Caldas da Rainha and Marinha Grande. In the industrial structure of the municipality, the industries of porcelain manufacture and faience stand out. The tertiary sector has a higher economic relevance, covering 55.1% of the municipality's active population. In 2001, the employment's structure in the tertiary sector was relatively diversified, although the branches of retail trade and social services are the ones that absorb larger quantitatives of active population: 23,5% and 22,0%.

Within the tertiary sector, it is important to point out the increasing relevance that tourism has gained throughout the second half of 20th century. The increase on the number of tourists, as well as the premises for tourism purposes and the support services to this activity in the municipality of Nazaré are not only associated to the natural conditions that promote the Sea, Sun and Sand tourism, but also the complementarities that have been developed between tourism and the fishing activity.

8.2.4 The fishery sector

In a recent past, fishing (mainly hook fishing) was vital in the municipal economy. Although in the context of the post April 25th 1974, articulated with the returning migration of the ex-colonies great investments took place in the fishing activity, which

was specially translated by the acquisition of more modern ships and with a higher capacity, in the last few years, this activity has suffered a serious crisis. The fact that fishing lost its importance stands out, among the aspects, by the rough decrease of the active population which is employed in this activity at a municipality level, once that it went from 54% in 1960 to 9% four decades later. In fact, an interpretation of the partition of the resident population employed shows the weak importance of fishing, aquaculture and related activities and services (only 201 jobs in 2001).

In what concerns the number of fishermen registered in the Port of Nazaré - Figure 5 - only in the period between 1996 and 2002, there was a quite significant decrease (-17.8%). However, important fluctuations occurred concerning the kind of fishing. While in *tuna fishing and others related* there was a rather significant decrease in the number of fishermen (21,3%), in *trawling* the decrease was substantially lower (-4,9%).

Figure 8.5 Registered Fishermen in the Port of Nazaré

Source: Statistics Portugal, 1996 and 2002.

Simultaneously, the analysis of the number of vessels, Figure 6, is also an indicative of the loss of relevance of this activity in Nazaré. In fact, since the middle of the 20th century, the number of vessels has been decreasing, for only between 1954 and 1985 there was a decline of 44,4%. Nevertheless, from the end of the 1980ies onward, this decrease is even higher, because in less than two decades (between 1985 and 2001) there was a negative variation of 43,6%. This significant decrease of the number of vessels in recent years is mainly explained by the systematic European policy of incentive/support to the destruction of vessels.

Figure 8.6 Evolution of the Number of Vessels in the Port of Nazaré

Source: Oliveira, 1955; *Statistics Portugal* (between 1969 and 1995),

In the course of the 90ies, the fishery tonnage of the Port of Nazaré had an increase of 24,6% (went from 3.541 tons in 1990 to 4.411 tons in 2000), although there is some fluctuation. In terms of the main species caught, in the beginning of the 90ies decade the sea fish was the one who held the more privileged position (92% of the total of unloaded catch in the Port of Nazaré) and among these, o horse mackerel was the major specie, corresponding to 23% of the total. After a decade, and although sea fishes are still the most important in this Port, the dominant specie in terms of tonnage, is now the sardine (34% of the total) followed by horse mackerel (20,1% of the total).

8.2.5 Perspectives

Although this is a municipality and a port with an ancient tradition of fishing, Nazaré hasn't been able to stand up has a fishing centre. However, complementarities and undeniable synergies between the more traditional fishing activity and tourism are established. This fact is validated, for instance, by the transformation of part of the fishing port into a Marina with success to an extent that there are plans to expand it. Consequently, it is considered in recent planning instruments that the future of Nazaré is in the interconnection of these activities, which might constitute a factor of development in the municipality.

8.2.6 General Impact Hypothesis

In Nazaré's case study, a few impacts resulting from the Common Fisheries Policy can be found. As it is a territory where fisheries assumed a traditional character, the implementation of the Common Fisheries Policy has lead to deep restructuring and remarkable impacts, namely, within an economic, social and territorial scope. Nevertheless the fact that it allowed the introduction of improvements on the sector, it has simultaneously contributed to display the vulnerability of the fisheries sector in this territory and, ultimately, has failed to promote the necessary economic and social cohesion.

8.2.7 Social and Economic Impact Hypothesis

I. In Nazaré's case study, the crisis that fisheries have been going through in the last few years, as a result of the quota policy, of the necessary modernization of the ships, among other aspects arising from the Common Fisheries Policy, has contributed for the unemployment increase on the sector. However, this issue is particularly relevant, given that this is a population with low education levels and mostly old aged, making its re-integration on the labor market a difficult task. Thus, the increase in long-term unemployment in Nazaré and the subsequent upsurge of a few areas of poverty is partially explained.

II. Notwithstanding the improvements and transformations on the fisheries activity, it still does not provide the population with living standards as high as in other activities and it is, in general, associated to a very hard working life. In the past few years, this reality has contributed to a continuous decrease of the population working in the sector, as well as a decrease of the municipality's population quantitatives. Although not very significant, there have been some output migratory flows of the Nazaré's municipality population to some of the main urban and industrial centers, either in the West sub-region (such as Caldas da Rainha), the Center NUTS 2 (such as Leiria and Marinha Grande) and Lisbon and Vale do Tejo NUT II (Lisbon and its metropolitan territory).

III. Tightly articulated with the output migratory flows of Nazaré's municipality population, over the last decade there have been a few relevant demographic behaviors, namely: a progressive decrease of the birth rate and the substantial ageing of the population.

IV. The loss of importance of the fisheries activity in Nazaré's case study has also introduced relevant changes in settlement, because while the population living in small fishing villages tends to decrease, on the other hand, there is a concentration of the population in more numerous populated settlements (urban centers with more than 5 thousand inhabitants).

V. The Common Fisheries Policy has also greatly contributed to an improvement of the active population living conditions on this sector, given the vast support and welfare cover measures. Thus, notwithstanding the crisis the sector has been through, it has acquired an enhancement of its image.

VI. In the last decades there has been a increasing expertise in Nazaré's port authority in what concerns sardine and horse mackerel's catches, which are the main species unloaded (in tons), for in 2002 it corresponded to 55% of the total unloaded catches. This fact might come as a weakness, in case productive expertise is intensified, once it can lead to an overexploitation of those species and thus obstruct this activity in the medium/long term.

8.2.8 Environment Hypothesis

I. The adoption of measures aiming at the control of the overexploit species, as well as the promotion of the destruction of obsolete fishing boats and its replacement for technologically advanced equipped boats, but simultaneously more environmental friendly, has lead to a greater protection of the ecosystems.

II. The increasing articulation between fisheries and Nazaré's tourism has generated diversified synergies and has lead to the re-use of certain municipal infrastructures and equipments that were abandoned. An evidence of such rehabilitation is the transformation

of part of the Fishing Harbor into a Marina for leisure boats. This allows the environmental preservation of certain spaces and infrastructures that had been abandoned as a result of the fisheries loss of importance in Nazaré.

8.2.9 Fishery Hypothesis

I. In the last few years, the incentive of the Common Fisheries Policy measures for the destruction of obsolete boats has promoted a renewal in the fishing fleet, although not very significant when compared to other harbors. However, though there was some innovation in the sector, it comes across with a few obstacles, namely: human resources with low education levels; reduced or null professional education; non-existence of basic skills within the scope of technological innovation and knowledge society. Besides these factors, the progressive abandonment and detachment of the younger generations for fishing activities, do not contribute to the improvement and restructuring of this sector in Nazaré.

II. According to what was gathered from local actors connected to fisheries, the application of the Common Fisheries Policy measures, while promoting a free competition, in a territory where competitive factors were reduced, ended up not stimulating the adhesion of young population to this activity. In fact, not even the Common Fisheries Policy subsidies were enough to compensate the negative impacts of these measures.

III. In Nazaré's municipality, besides the decrease in the unloaded fish, it appears that the fishing manufacturing is not very significant, which can be perceived, for instance, in the small proportion of employed population in the fishing manufacturing and aquaculture (0,3%), in 2001. This is an evidence of the loss of importance that the sector has been going through in the past few years, in this territory.

IV. In what concerns investments in the sector, approximately two years ago, a porch was built, with a parking lot for boats, which enables ship repairing. Considered one of the most important investments in the sector, it allows a whole group of work to fishermen, besides diminishing some of the tasks they had to do while repairing their boats up until that moment. However, a few investments remain to be carried out, namely the harbor's recovery and remodelling, that show considerable signs of degradation.

V. In more recent years, Nazaré has assumed itself especially as an important fisheries marketing center. According to what was scrutinized, the main portion of the catch is unloaded in Peniche and subsequently transported to Nazaré's municipality, where it is sold, mainly to catering activities.

VI. Nevertheless, within the whole group of identified problems that deeply contributed for the crisis that the sector has gone through in Nazaré, the most alarming question for the local fishermen is the decrease of the sector's labor work. In fact, the future reforms laid down by the CFP shall be specially oriented towards the stimulation of the younger population for the fishing activity.

8.3 Example study: Peniche – a major fishing pole

8.3.1 The Geography

The municipality of Peniche, which is located in the most western area of the West sub-region, is in a peninsula of about 10 km of perimeter, being the Cabo Carvoeiro its

western edge - Figure 7. With a total area of 77 km², the municipality of has six civil parishes (Ajuda, São Pedro, Conceição, Ferrel, Atouguia da Baleia e Serra d'El Rei) and has a population density of 360,2 inhab/ km².

Its geo-morphologic specificity has shaped and conditioned its population, throughout the years, from the cultural and socio-economic point of view. In fact, since ancient times, the populations which have stayed in this municipality has always seen fishing as an important economic resource, that can be proved by its several vestiges of the Roman Era, and took this municipality to be seen as one of the most important fishing centers of the Country.

Figure 8.7 Figure 7. An Overview of Peniche

Like Nazaré, Peniche has a concentrated peopling and a strong tendency for concentration in towns of average dimension, once 57% of the population lives in places among 10.000 and 19.000 inhabitants, while only 27% of the population lives in places with less than 2.000 inhabitants. As it has happened in in the whole of the national urban network, also in Peniche there is a strong tendency for the population concentration in the city of Peniche, which tends to play a remarkable effect of population suction on the population of the remaining civil parishes. Thus, it is explained that 57% of the municipality population is concentrated in the civil parishes that form the city (Ajuda, Conceição and São Pedro), while in the rural civil parishes, that correspond to 90% of the municipality area, live only 43% of the population. This concentrated peopling is one of Peniche's competitive advantages.

8.3.2 Demographic structure

Throughout the XXth century, the population of Peniche increased substantially, from 9.814 inhabitants in 1911 to 27.315 in 2001 - Figure 8. However, the 60's constitute a

turning period, since population growth from now on occurred in a substantially more moderate rhythm.

Figure 8.8 Population change in the municipality of Peniche

Source: *Statistics Portugal* (between 1911 and 2001).

The recent evolution of the age structure of the municipality of Peniche copies thick way the current standards of the Portuguese and European demography. In the intercensus period 1991-2001, it registered an accented and double aging population, resulting in a well-known loss of relevance of the population under 14 years - 20.9% of the population in 1991 and 15.9% in 2001 - while the population over 65 or more years increased very significantly - in 1991 was only 12.6% of the population of Peniche, and in 2001 its proportion surpassed the one of the young population (16.7%) - Figure 9. Although these factors are clearly indicative of a population aging, it should be pointed out that Peniche, comparing to other municipalities, still has an important segment of young population the aged are still not accented.

Although in the most recent years important improvements in the instruction level of the resident population in Peniche has registered, diverse weaknesses continue to be identified. In fact, in 2001, a part of this population still did not have any level of education (13.1%), the illiteracy rate, similarly to the sub-region Oeste, was still considerably high (10.6% and 11.1%, respectively) and only 3.3% of this had complete higher education.

Figure 8.9 Age Pyramid of the Population in the Municipality, in 2001

Source: *Statistics Portugal*, 2001

Although in more recent years there have been important improvements at the level of the population's education living in Peniche, there are still many weaknesses. In fact, in 2001, a proportion of this population still hasn't a single level of education (13.1%), the illiteracy rate, like the West sub-region, is considerably high (10.6% and 11.1%,) and still 3.3% had university qualifications.

8.3.3 Economy and Employment

Peniche's economic base - Figure 10 - although with a structure similar to the West sub-region and for the municipality of Nazaré, presents important specificities. The most remarkable feature is in the relevance that the primary sector still in the beginning of the 20th century (covers 13.1% of the employed population) and which is, in part, a consequence of the fundamental role that the fishing activity still plays in the municipal economy, being inclusively its main economic activity. The rural activity has also some importance, mainly in the municipality rural interior where the presence of several courses of water has conferred this municipality the needed fertility for the development of an important horticultural and fruit production destined for the regional and local consumption, although there are several conditionalisms to a new rural practice, mainly, the shore proximity.

The secondary sector covers 33.2% of the employed resident population, being the construction the most relevant sub-sector in terms of labor; the second and third place being fishing related activities, namely the fishing and aquaculture manufacturing and shipbuilding.

Finally, in what concerns the tertiary sector, it is possible to see that this is the economic sector that covers the larger segment of the employed resident population (53.8%), which shows the tertiary nature of Peniche's economy. Within the scope of the tertiary sector, the most relevant activity branches are retailing and public administration and social

services. However, there has been an increase of the tourism activities associated to fishing activities, although less relevant than in Nazaré.

Figure 8.10 Employed Resident Population by Activity Sectors, em 2001

Suource: *Statistics Portugal, 2001*

8.3.4 The fishery sector

Peniche it is not only the Portuguese harbor with the most significant capacity, but also the one with major induced effects, downstream and upstream of fishing activities.

Once a major fish cannery centre, Peniche still plays an important role in caning, freezing and filleting. In 2001, activities directly related with fisheries employed around 1500 workers (13% of the municipality active population) and only 48 workers were enrolled at the unemployment centre (5.8% of total unemployment rate). Transformation industries related with fishing employed 913 active residents, that is, 8% of total active population of the municipality; within the same scope, there were 148 unemployed workers (18% of total unemployed workers in 31/12/2001).

Associated with fishing activities one must also consider a construction and repairing wharf (fishing boats and, less important, recreation boats), land transportation and logistics, Forpescas training centre and the new Graduate School of Sea Technologies.

As a whole, employment directly generated by fishing activities almost reaches 30% of active population at the Peniche municipality, which due to its highly induced potential turns this into a crucial sector to local economy and social well-being.

The evaluation fishing representatives make of local projects within the last CSF as well within CI PESCA is positive – they consider it “well structured” and with an “efficient application of financial supports” – allowing the renewal of the fleet as well as a diversification of captures (both in species captured and geographical areas for capture).

Relatively to the fish unloaded in the Port of Peniche, the last decade has registered a significant reduction – from 34.318 tons in 1992 to 17.247 tons in 2002 - representing a negative variation of 50%. However, in 2002, the Port of Peniche was, in terms of

tonnage of fish unloaded, the second most important one of the country, only surpassed for the Port of Matosinhos, situated in NUT II Norte, with 28,254 tons - Figure 11.

Figure 8.11 Tonnage of fish unloaded, by ports, in 2003

Source: Statistics Portugal, 2003

In the Port of Peniche, marine fish has been the main type captured in the last decade, representing 91.4% of the fish unloaded. Within it, one can distinguish sardine - in 1992 it corresponded to 54% of the total and in 2002 to 64%. Clams constitute the second major group of species captured and registered a fast increase between 1992 and 2002 (+27%). This corresponds to a reality quite similar to the one observed in Nazaré, even so the quantitative of fish is in Peniche substantially higher, as presented in the following table - Figure 12.

Table 8.1 Catches by major species and areas, 2002

Species	Nazaré		Peniche		Total NUT III Oeste	
	t	Million (Euros)	t	Million (Euros)	t	Million (Euros)

8.3.5 Perspectives

Peniche has the conditions for its development as one of the major fishing harbours of the Iberian Peninsula – for its tradition, infra-structures, local entrepreneurship, graduate educational and training equipments. Recent improvements in surface accessibilities and the upgrade in logistics have reinforced such conditions. Local responsables of fishery activities have the ambition to broaden the fisheries “*fillière*”/cluster, namely, through the expansion, qualification and diversification of captures transformation and commercialization – it is in such realms that the support from public policies can be most effective.

With this conditions Peniche can not only became a major development pole of NUTS 3 Oeste economy, but also reduce the constraints derived from the closure of the Lisbon fishing port. Tourism is being developed likewise along the Western coast, but in a controlled way; it brings up more synergies and complementarities rather than conflicts with fishing activities turning into the utmost alternative.

8.3.6 General Impact Hypothesis

Like Nazaré, fishing is an ancient activity in Peniche. However, unlike the previous case study Nazaré, in the past few years, Peniche has emerged as one of the most important fishing harbors at a national level and even within the context of the Iberian Peninsula. This has been a result of the contribution of the measures and support granted by the Common Fisheries Policy, that has not only allowed the modernization of the fleet, equipments and techniques used in fishing and on board conservation, as well as new and more efficient methodologies and techniques of fish processing, but also significant improvements concerning the fishermen and fish processing industry workers living conditions, contributing thus for the promotion of a new image for the sector.

8.3.7 Social and Economic Impact Hypothesis

I. Notwithstanding the investments on the sector, it is still associated to living and working conditions that fail to allure young people at an active age, causing migratory movements of these out of the municipality. To a certain extent, as a consequence of this migratory phenomenon, there has been a slight decrease of the municipality’s population quantitatives, to which the decline of the birth rates and the increase of the proportion of the population with 65 or more years old is associated, once most of the times, it is the younger population that moves abroad. Indeed, there is an ongoing change on the municipality’s age structure of the population evidencing a double ageing process.

II. The measures carried out by the Common Fisheries Policy, supporting small-scale fishing, have manifested positive impacts which are important to point out: it has allowed to keep active a population with no individual economic capacity and lacking a group of skills that allow them to set in other professional activities, given their quite poor education levels and the fact that they have never worked in a different area other than fishing. Without those measures, it would be almost impossible to maintain part of this population economically active, which would create long term unemployment situations with a whole group of attached social problems.

8.3.8 Environment Hypothesis

I. Within the scope of the resources management, CFP's measures have had a modest impact in Peniche, since they fall upon species with small relevance (in terms of catches), in Peniche's harbor. However, the attempts to introduce mechanisms of community management - for instance, concerning sardine (the most important species in terms of unloaded catch at Peniche's harbor) - in the 90ies, have displayed the local fishermen's apprehension on the adoption of this kind of measure, once it might seriously compromise their financial resources.

II. The fleet's renewal, which was allowed by CFP, is a measure with important environmental impacts, for not only it allows the use of environmental friendly ships, but also the use of equipment and technology incorporated in the ships, which promotes fish storage for a longer period of time and thus avoids wasting, as well as the possibility of guarantee for a greater quality of the food.

III. Obviously, some of the limitations concerning the preservation of halieutic resources create negative economic impacts in this case study, such as, for instance, the limitation of the number of days at sea, once the consequence is the reduction of the ships' owners and crew profits. Therefore, rather than granting compensation subsidies, it is important to encourage the diversification of the fishermen's activities, that might be able to combine fishing with other economic activities, particularly, those oriented towards tourism, given the several synergies that have been established between both sectors.

8.3.9 Fishery Hypothesis

I. The adoption of some of CFP's measures had a few negative impacts on the international relationship's framework, for if up until Portugal's accession to the Community it was possible to establish bilateral agreements with any of the Members States, after such commitment, it became unfeasible. The impacts of these strategies reached a considerable extent in Peniche, since, as an international scale harbor, it has witnessed the decrease of the tonnage and diversity of the unloaded catches.

II. The impacts of CFP at a structural policy level in Peniche have been mostly negative, since although many of the obsolete ships have been destroyed, the suspension of the support for the purchase of new ships has prevented the necessary renewal of the fleet.

III. Peniche presents a group of conditions which are suitable to its consolidation as one of the most prominent harbors of the Iberian Peninsula. These conditions are a result of its excellent geographic and port location, as well as the fact that it is not just a mere port of unloading, since it is quite important in terms of shipbuilding and specially in terms of fish processing and cold storage industry (it has nowadays the country's larger cold storage network and it is

IV. the greatest producer of canned fish, specially sardines and tuna), that has been enhanced. The awareness of such potentialities has lead to the materialization of several investments on the fleet, shipbuilding and fish processing and cold storage industry, as well as the making of several sectorial diagnosis and strategic plans for the sector, by various municipal organizations.

V. The territorial concentration of both a major fishing harbor, and industrial units of fish processing and cold storage on the municipality of Peniche, is an advantage, because the transport by land of these raw-materials is expensive, which allows to reduce the production costs and turn local industry into a more competitive one. Consequently, the

synergies resulting from the territorial concentration of these two activities in fisheries are an advantage for the municipal economy that is important to strengthen, either through the several municipal and regional planning instruments and the management and planning of infrastructures and logistics of support.

VI. Nowadays, the main problem of the fisheries sector in Peniche is the decline of the available labor work, since the workers are ageing and, for that reason, retiring. Furthermore, there is no compensation from the younger people, since the hard working and reduced expectations do not seem to allure them. Seeking to change this negative trend scenario, there have been developed several projects whose main goal is to stimulate the renovation of generations of fishermen.

- a. In this context, it is worth pointing out the ISTMO Project, which, among other aspects, has tried to turn fisheries into a more attractive sector for young people, through promotional actions of jobs associated to the fishery cluster next to younger people (marketing campaigns, visits to companies and training centers), creation of better working conditions and ongoing training actions for actives in fisheries.
- b. Another answer for this problem would be the creation of extra job opportunities on the sector for the immigrant population living in Peniche. Like stated in some of the recent studies carried out within the municipal scope, it was confirmed that part of this population, particularly those coming from Official Portuguese Language African Countries, had experience in activities connected to fisheries, since in their home countries, they were mostly fishermen and their main motive to settle in Peniche was precisely the fact that it was a coastal city and had an important fishing harbor. According to the above mentioned studies, the immigrants living in Peniche are already working on the sector, mainly, in fish processing factories (an activity developed mostly by immigrant women), followed by the fishing activity itself and, though at a lower scale, working in shipbuilding areas. Given the articulation of these factors, it is important to promote and turn a few aspects easier, such as the decrease of the bureaucracy demanded to obtain the fishing license.

9 CFP impacts on the province of Salerno, ITF35

9.1 Introduction

The province of Salerno (NUTS 3 level) extends for a surface area of around 5000 square kilometres and it is one of the largest NUTS 3 regions in Italy. It is made up of 158 municipalities or local administrative units, identified as LAU 2 levels. The Salerno province is located in the south of Italy and it is one of the five provinces of the Campania (NUTS 2) region. The extension of the province, with the localisation of the 15 enrolment offices¹²¹ of the province, is reported in figure 1.

Figure 9.1 The Salerno province and the overall Italian territory

According to typologies created within other ESPON projects and in particular used within projects 2.1.1 and 3.1, the Salerno province can be classified as a lagging region. This classification takes into account the GDP per inhabitant, in Euro, and the unemployment rate. It falls under the Objective 1 regions.

¹²¹ Administrative districts, distributed along the coastline, where vessels have to be registered.

Concerning the rural-area typology, created within ESPON project 1.1.2, Salerno has a value of 1, that means that is a densely populated area. The same results can be found if considering the settlement structure typology; this typology is based on nine basic types defined by population density and situation regarding centres. Salerno has a value of 3 that again means a densely populated region. Finally, if considering the depopulation category, Salerno has a value of 1, in other words it falls into the “very low relative depopulation category”.

In terms of fisheries dependency, the Salerno province presents levels slightly above the national average. In 1997 the share of fisheries in the value added of the area was equal to 0.13 for fisheries activity and to 0.14 for the other related activities. In terms of fisheries employment, the share was equal to 0.38 for fishing and to 0.27 for the other related activities (Megapesca study).

9.2 The geography

The territory of Salerno is varied and presents a good percentage of hilly and mountainous areas, while the level area is only 11%, but constitutes one of the most important agricultural areas thanks to its extraordinary fertility. The littoral is characterized by both high and rocky coasts, as in the first stretch of coast from north, along the renown Costiera Amalfitana, and by long and sandy beaches, flanked by large plains, as it happens in the more southern “piana del Sele. The southern part is also an area of high naturalistic importance, where is located one of the largest European national parks, the Cilento National Park. Moreover, two marine reserve areas (Costa degli Infreschi and S. Maria di Castellabate) will be established in the near future (Law 979/82). While the southern Cilento coast is characterized by the presence of a number of little fishing communities, the northern one, thanks to the beauty of the coast is strongly vocated to tourism. It should be taken into account that considering that the Costiera Amalfitana is an outstanding example of a Mediterranean landscape, with exceptional cultural and natural scenic values, the UNESCO committee inscribed it in the World Heritage list.

9.3 Demographic structure

In 2003 the Salerno province had a population of about 1.100.000 inhabitants. In the following graph the trend of the yearly average population for the period 1990-2003 is shown.

Figure 9.2 Population trend of the Salerno province for the period 1990-2003 (yearly average x1000, ESPON 3.2 indicator)

After a noticeable increase in the period 1990-1997, the population has slightly decreased until 2002. In the overall period 1990-2003 an increase of 2% is registered. In 2002 the population density was equal to 218.4 inhabitants for a square km above the Italian average, 194, but less than the Campania average, 416 (ESPON 3.2 indicator). If compared to the EU average (fixed equal to 100), the population density of the Salerno province was equal to 188 (ESPON 1.3.1 indicator referred to 1999).

The provincial capital, the city of Salerno, is the largest in terms of population (294,220 inhabitants) and the third largest in terms of geographical size. The city of Salerno can be considered to be the metropolitan area of the province, given that it is the main geographical pole and that 15 municipalities in the metropolitan area gravitate towards it.

The demographic structure of the Salerno province reflects the great heterogeneity of its territory. During the last century, the overall demographic dynamic has been characterized by a growth lower than the national one and by an internal re-composition of the population. In fact, while the population of the coastal areas has grown more than the national average, the internal areas have progressively depopulated. Some figures related to the population density of the coastal and internal areas of the provinces and of its trend during the decade 1991-2001 can give a measure of the phenomenon. The coastal areas had a population density, in 2001 (the year of the latest population census) of about 378 inhabitants per square kilometer against 94 of the internal areas – table 1. Furthermore, while in the decade 1991-2001 the population of the coastal areas has faced an increase of 1.7%, in the internal areas a depopulation trend can be observed (-2.5%) -

Table 9.1 Main population figures of the coastal and internal areas of the Salerno province, 1991-2001.

Areas	Square km	Population			
		1991	2001	diff. 2001-1991	Density 2001
Coastal	2,157	801,019	814,678	1.71	377.8
Internal	2,766	265,582	258,965	- 2.49	93.6
Total Province	4,922	1,066,601	1,073,643	0.66	218.1

Source: Irepa elaboration on data from the II Interim Report of the COMMENT project, Base analysis of the supply and demand of the local employment, CELPE.

The effect of this process has been a distribution of the population different over the province territory and different demographic structure among municipalities. This has had relevant effects also on the labour market indicators and on the activity rates. For instance, the old age indicator is very higher in the internal areas than in the coastal ones or in recent urban settlements. The demographic dynamic of the Salerno province has also been influenced, in the last fifteen years, by migratory flows from the internal areas towards the coast and the urban areas.

As far as the migratory phenomenon, in the period 1996-99, the migratory balance has been negative, equal to -0.47 for 1000 inhabitants (ESPON 1.1.4 indicator).. In 2000, the total number of immigrants in the Salerno province was equal to 2720 persons, of which the 64% was represented by people coming from non-EU countries (ESPON 1.1.2 indicator).

9.4 Economic overview

In 2002 the total GDP of the Salerno province was equal to 16632 millions Euro. In the period 1998-2002 it shows an increase of about 21% against an increase of 18% of the GDP at national level. In the same year, the GDP per inhabitant in PPS was equal to 16200.7, against a national level of 23082.7.

The value added (V.A.) per inhabitant presents high differences among the areas of the province. In the internal areas the value added per inhabitant is, in some cases equal, to 1/3 than that of the urban areas. A second element that emerges from the analysis is the different productive structure.

As far as the primary sector, even if this region has traditionally been devoted to marine economic activities, fishery has a secondary importance in the local economy. The agriculture still covers a fundamental importance in the regional economy, with an occupational rate of about 10% - figure 3 - and an incidence on the total regional V.A. of 5.7% (ESPON 2.1.3 indicator). The importance of the agriculture derives also by its strict connection with the industrial and tertiary sectors. In this area there is also one of the most important zoo technical buffalo patrimonies, where it is born and developed the famous *mozzarella* cheese.

Figure 9.3 Distribution of the Salerno province employment by sector, 2000 (Source: Irepa elaboration on data from Istituto Tagliacarne databank)

The industries are scarcely present on this territory, since the most part of the industries did not survive to the industrial crisis of 70s. Among the manufacturing, the most important sectors are those related to ceramic and to the production of the paper and pasta. The industrial occupational rate, including the manufacturing and construction sectors, is equal to 21%.

About 69% of people is employed in the tertiary sector, in particular in the activities connected with trade (wholesale and retail), tourism and transports. Commercial exchanges are particularly favoured by the port, which is one of the most important in Tyrrhenian Sea. During 2003, the goods traffic amounted at 7 million tons, of which the 60% are containers. In the same year, the passenger traffic has increased to 331000 units (ISTAT, 2004). Furthermore, thanks to the natural features of the landscape, the Salerno province, especially in its northern part, shows a discrete presence of facilities and structures for tourism. In 2000, the number of tourists arrivals at the tourist facilities of the province was equal to 1424786, with an increase, since 1995, of 24% (ESPON 1.1.2 indicator). About the same increase (25%) shows the number of overnight stays in tourist facilities that, in the period 1995-2000 increased from 6643709 to 8318957.

Finally, the Salerno province is characterized by a local labour market where the internal areas serve as basin for the coastal ones. In 2003, the unemployment rate was equal to 11.7% (ESPON 3.2 indicator), almost twice the national average. Unemployment is higher for females (16%) than for males (9%).

As far as economic benefits received through accession to structural funds, table 2 reports the amount of structural funds by destination obtained by the Salerno province in the period 1994-1999. The 75% of the total funds have been invested in development and productive infrastructures.

Table 9.2 Structural funds by destination obtained by the Salerno province in the period 1994-1999.

Structural Fund and Cohesion Fund expenditure - All funds included in Operational Programmes and SPDs (Objectives 1, 2, 3, 5b and 6) 1994-1999	709.236.910
Structural Fund expenditure related to Regional Development and Productive Infrastructure (Obj. 1, 2 and 6 ERDF) 1994-1999	532.256.908

9.5 The fishery sector

9.5.1 Fleet

The great part of the fleet (made up, in 2003, of 568 with vessels a total capacity of 6210 GRT and 38666 kW) consists of small boats exercising small-scale fishery whose landings are mostly made up of high valued fishes – table 3.

Depending on the small size of the vessels, the majority of the fleet enrolled in the Salerno province performs its fishing activities in regional waters, i.e. not outside the province's waters. The great bulk of the fleet is, in fact, made up of small boats devoted to small-scale fishery near to the coastal zone. In 2003, 78% of the vessels were shorter than 10m. and the 64% had an average GRT lower than 2,9.

Table 9.3 Salerno fishing fleet by fleet segment. Effort data, 2003

Fleet segments	Number of vessels	GRT		kW		Average days at sea
		Total	Average	Total	Average	
Demersal trawl	45	1266.56	28.15	8837.39	196.39	207
Purse seine	9	160.58	17.84	1530.98	170.11	83

The only vessels operating in EU waters, that mean, in this case, outside the waters of the Salerno province, are those vessels associated to the local tuna fleet, named “Associazione dei Produttori Tonnieri del Tirreno”. The Tuna Fleet Association of Salerno is the most important Italian reality in the tuna fishery. It consists of vessels not all enrolled in the administrative district of Salerno as they fish in other zones, but delivering their captures to the tuna association of Salerno. In 2003, they were 23 vessels with an average tonnage of 204 GRT and an average power of 826 kW. These vessels operate with great seines for tuna and fish in the Tyrrhenian, in the Ionic and in the Adriatic seas. Even if bluefin tuna is the target specie, the vessels also catch other large pelagics, like albacore and swordfish. The tuna fishery is a seasonal activity and is performed from April to October. Apart of these vessels, there are around three great purse seines in the Salerno fleet that fish inside and outside the province's waters. Only one vessel fishes in Third country waters as it is registered as vessel for “oceanic fishery”.

By the analysis of the historic series of the fleet by age classes, it emerges the increasing age of the fleet. While in the first three years of the analyzed period (1992-1994) most of the vessels had an age between 5 and 10 years, since 1995 the most abundant age classes are 10-15 and 15-20 years. Furthermore, since 1998, a consistent number of the vessels have an age between 25 and 30 years and over 40 years. The explanation of this is the increasing tendency to leave the fishery sector that, in most recent years, has also been enhanced by economic subsidies for final withdrawal and re-conversion.

Another interesting thing is the fact that most of the fleet (95%) entered the sector before 1994. Since 2001 there have not been new entrances. This is an evidence of what said above, in terms of obsolescence of the fleet and on the influence to leave the sector played by incentives to withdrawal and re-conversion.

It has also to be outlined that in recent years the Salerno fishing fleet has reduced in number also due to the increasing level of intermediate costs. The last period has in particular been interested by an increase of the fuel cost. The difficulty to charge the fuel cost on the fish prices and, hence, on revenues, has been in particular faced by the small boats, i.e. by artisanal fishery. The direct effect of this has been a wide exit from the sector especially by small scale vessels (see tables 4, 6 and 7).

9.5.2 Production

Landings are almost totally destined to the fresh fish consumption. The local demand for fresh fish products, as in the whole Campania region, is, in fact, very high (in 2003 the monthly pro-capita consumption for consumers of the Campania region was equal, in value, to €16 whereas, at national level, it was equal to €14.64). For this reason, the regional fishing production is not sufficient to cover local demand and the fish market has to face the high demand for fresh fish asking supply to outside markets (especially in other Italian regions).

The province of Salerno accounts for more than 50% of the Campania (NUTS 2 level) fish production both in terms of weight and values. In 2003, total fish catch production amounted to around 8000 tons, worthing for around 44.4 million Euro. The great part of the captures, both in quantity and in value terms, realized by the fleet of the Salerno province was made up of “other fishes” – figure 9.4.

Figure 9.4 Distribution of landings by group of species of the Salerno fishing fleet production. % in weight and value. (MIPAF – IREPA, 2003)

This group, basically made up of high value species, amounts to 3440 tons for around 19.5 million Euro, equal to 45% in weight and 43% in value terms on the total landings. As for the whole Italian fishery production, quotas on fish captures exist only for bluefin tuna (*Thunnus thynnus*). As a consequence of the adhesion of EU to the ICCAT, quotas on bluefin tuna are set for Member countries since 1999. Captures of bluefin tuna allowed to vessels of the tuna fleet association amounted, in 1999, to 1413 tons. The quota increased in the following years, reaching 2909 tons.

In the last decade (1993-2003) production has largely increased, passing from 3471 to 8003 tons (+130%). The increase of catches has not been a negative influence on prices that have increased, in the same period, of about 52%. The consequence has been a progressive upward trend of revenues that, in 2003, were more or less 3.5 times those of 1993 (figure 9.5).

Figure 9.5 Trend of the gross revenues of the Salerno fishery sector (1993-2003, million Euro (MIPAF - IREPA, 2003).

9.5.3 Processing

The fish processing industry is made up of very different realities, from very modern and innovative plants to small and artisanal ones. The prevailing products are preserved in oil, salted and, for a smallest part, marinade anchovies. In a second position we can find preserved tuna. Only a small part of the production is made up of products that are more and more becoming important in the local demand for fish products as salad of sea products (mainly mollusks and crustaceans). Chilling of fish products is totally absent in the area under consideration. Production of salted fish products is limited and has lost importance in the last years; the specializing process that involved this type of production gave gradually to it the features of an artisanal sector.

For the most part, fish processing plants realize combined production of fish fillets preserved in oil and vegetables preserved in oil and vinegar. The combination is due to the similarity of the production process, simple and partly hand made. The combined productions also foster the combined commercialization of both products.

The fish processing sector is supplied by different markets: Medium and Lower Tyrrhenian, Adriatic Sea, Sicily and Sardinia. In particular, anchovies come from the Adriatic Sea and from the Upper Tyrrhenian Sea (Piombino, an important fishing base of Tuscany). For preserved tuna, supply, made up mainly of yellowfin tuna, comes for a 50% from other sides of Italy and for a 50% from countries outside EU. All the landings are destined to fresh consumption in local and foreign markets (France, Spain, Malta, Korea and Japan).

The most important fish processing plants are based in places located near to the coast. This is due more to historical and traditional reasons than to the need of links to fishing areas as supply sources. In fact, tuna destined to processing (mostly yellowfin) comes mainly from abroad and only a small part of anchovies destined to processing comes from local landings: the small size of local anchovies is, in fact, not good for processing. The creation of a processing “district” in this area has its origin in the anchovies processing that developed in Cetara, a little village of the coast of Amalfi, traditionally vocated to fishing activities and an ancient base of the fishing industry of the province of Salerno where, even today, there is a well developed and modern fishing industry.

9.5.4 Employment in the fisheries sector

The great part of employment in the fishing sector consists of people employed on board of the vessels. Total employment amounted, in 2001, to 1580 units (Tab.4). In the fish catching sector work only male. The percentage of self-employment is equal to 71%. The areas with the large number of employees are: Salerno, Cetara, Pollica and Castellabate with, respectively, 550, 138, 167 and 137 people employed in the sector. The last two municipalities are located in the Cilento area.

Most people working on board have a primary degree of scholar education; another large part (40%) has a secondary level of education while only 17% of the employments on board have a further level of education (figure 9.6).

Figure 9.6 Distribution of people employed in the Salerno fishing fleet by educational level and age classes, IREPA 2001

Figure 9.6 shows also the distribution of employment in the fish catching sector among age class. The most evident thing is the old age of the crews employed on board of the vessels of the fleet of the Salerno province. The greatest part (47%) of it falls into the

medium age class: between 24 and 54 years. Another large part is made up of people aged more than 54 whereas young people (less than 24 years) represent a very small part of total employment. Whereas people employed on board of fishing vessels are predominantly male, in the fish processing employment the female component is very important. Females have an important role also in the commercialization sector.

Table 4 shows figures on employment in the fish industry in the province of Salerno. The units employed in the fish processing plants amounted to 123. The greater part (87%) is constituted of female units. Full time units are equal to 105 units where part time is only a smaller part of the total employment (15%).

The total employment in the construction and repair industry was 53 in 1996. In relation to the construction industry, we must mention that in this area is placed one of the most important Italian shipyards specialized in the construction of typical wood boats.

Employment in the commercialization of fish products, related to wholesalers, amounts to 661 units, almost equally distributed between the female and male component. The great bulk of the wholesalers operate in the city of Salerno.

Finally, people employed as retailers in the commercialization of fish products are 296 units, almost equally distributed between the female and male component. The 15% of the retailers operate in the city of Salerno.

Table 9.4 Employment in Fishery sector, 1996

Note: FT: full time employment; PT: part time employment; T: total employment; SE: self-employment

As far as the aquaculture sector, along the coastline of the province of Salerno there are two mariculture plants. In both cases, they are managed by local fishing co-operatives and they constitute an alternative way to diversify fishing activity and hence to integrate income coming from fish catching activity.

9.6 CFP impact analysis

Before going further into the analysis of the CFP impacts on the Salerno province, it should be taken in due account that the Italian fishery has been interested by the CFP policy in a different way respect to the other European countries. Within the conservation policy, that represents the most important plank of the CFP, the Mediterranean Sea constitutes a special case. The specific features of fisheries of the European countries

bordering the Mediterranean Sea have not allowed the practical applicability of quotas in the area. Bluefin tuna (*Thunnus Thynnus*) is the only specie in the Mediterranean where a TAC has been enforced since 1998.

In addition it must be considered that the most fishing activities take place near to the coast within the territorial waters of the member states. The EEZs in the Mediterranean Sea is generally not extended beyond the 12 nautical miles territorial. As a consequence, the average size of the vessels in the Mediterranean Sea is smaller than in the rest of the European Union. The landings constitute a modest share of EU landings in terms of volume but a significantly higher share in terms of value. This is due to the fact that the fishing techniques used are generally less selective than, for instance, in the North Sea and also because most of the catches are used for human consumption. The Mediterranean fishery is also characterized by a high average number of crewmembers. 42% of the jobs in the capture fisheries sector in the EU15 are found in the four member states bordering the Mediterranean Sea.

Anyway, as for many of the North Sea resources, the state of the resources in the Mediterranean Sea is sometime considered problematic as most species are considered to be overexploited. Estimates by ICCAT and GFCM suggest that fishing effort in fisheries targeting overexploited stocks should be reduced by 15 to 30%¹²². Until now the main instruments for the achievement of conservation objectives in the Mediterranean Sea has been:

- the buy-back programmes, whose main objective is the control of the fishing capacity and effort. These measures come under the jurisdiction of the EC regulations and are governed by the Multi-Annual Guidance Programmes (MAGPs);
- the EC Regulation No. 1626/94 providing technical measures for fishing in Mediterranean waters.

The EU Rule 1626/94 establishes technical limits and minimum fish sizes for the conservation of fishery resources in the Mediterranean. Restrictions apply to the following gears:

- Dredges: the maximum breadth of dredges is 4 m
- Encircling nets (seines and lampara nets): the length of netting is restricted to 800 m and the drop to 120 m, except in the case of tuna seiners
- Bottom-set nets (gillnets and entangling nets) and trammel nets: the maximum drop of bottom-set nets is 4 m, and it is prohibited to have on board and set more than 5000 m of bottom-set nets per vessel
- Bottom-set longline: it is prohibited to have on board and set more than 7000 m of longline per vessel
- Surface-set longline (floating): it is prohibited to have on board and set more than 60 km of longline per vessel.

In case of towed nets, the mesh size is limited to 40 mm. And for the encircling nets the limit is fixed to 14 mm.

¹²² COM (2002) 535 final: "Communication from the Commission to the Council and the European Parliament laying down a Community Action Plan for the conservation and sustainable exploitation of fisheries resources in the Mediterranean Sea under the Common Fisheries Policy", Brussels: Commission of the European Communities, 9.10.2004. http://europa.eu.int/eur-lex/en/com/cnc/2002/com2002_0535en01.pdf

The use of trawls, seines or similar nets is prohibited within three nautical miles of the coast except where a derogation is provided for in national legislation. This is the case of the “Bianchetto” (*Sardina pilchardus fry*) and “Rossetto” (*Aphia minuta mediterranea*) fisheries, that are codified as “special fisheries”. These fisheries are carried out during wintertime (15 January - 15 March as a rule) for a period of 60 days. These fisheries have a long history and represent one the most important small-scale activity. The socio-economic impact of the “Bianchetto” and “Rossetto” fishery is very high at local level.

In case of fish size, a specific national legislation has been in place from 1963 and a minimum size has been attached to each single species. The EU Rule 1626/94 establishes a new set of fish sizes, which are lower than those being fished by the allowed mesh size. Moreover, compliance on limits on fish size from fishers is difficult to achieve for a number of reasons. In particular, when the catch is made of many species at the same time and they are taken on board when they are already dead, it is useless to throw them away, given that in most case there is a market. The enforcement costs to control the respect of such restrictions are also extremely high. This is due to the dimension of the vessels and to their number which is widespread over 250 km of coast.

9.6.1 General impact hypotheses:

1. The CFP will have different impacts between coastal regions, and within regions. Processes on restructuring, reduction and expansion will occur side by side and in various combinations. Impacts of CFP will be more significant the lower the geographical levels.

The Salerno case seems to support this hypothesis. In fact, the CFP has mainly affected the coastal communities where the fishing activities represent an important, and sometime, the unique income source for households.

2. Economic, social and demographic impacts of the CFP will vary between urban and remote areas.

The Salerno case shows different population and economic dynamics among coastal and internal areas. The most remote areas of the Salerno's province are located in a vast territory called Cilento. The Cilento is characterized by many, little and depopulated municipalities. In the last 20 years this area has been interested by consistent migratory flows towards the urban and coastal areas. The main factors in this process are linked to the socio-economic development of coastal areas with the growth of the tourism industry. During the last ten years traditional fishing activities in the coastal zone have been partially replaced by new activities, such as aquaculture, fishing-tourism and tourist pleasure-boating along the coasts. The creation of Marine Reserves and of the National Park of Cilento and Vallo del Diano has accelerated these changes.

3. Territorial impacts of CFP will vary with different structures of the fishing and aquaculture industries of the regions. Impacts will differ in accordance with the extent the regions are dominated by coast fishing and small vessels, fishing in distant waters with greater vessels, landings, fishing processes or aquaculture.

The Salerno case demonstrated that some highly specialized and capitalized fishing activity, as the red tuna fishery, seems to be scarcely influenced by the implementation of quotas since 1999. In the decade 1993-2003, tuna catches have, indeed, increased from 1596 to 2909 tons (+92%) and prices from 2.01 to 5.28 (+163%). On the contrary, the importance of the artisanal fishery is gradually decreasing both under an economic and socio-cultural point of view. In fact it has been more affected by the EU by-back programmes.

The analysis of the trends in fishing capacity and effort represents an interesting starting point in order to evaluate the impact of the buy-back program on productivity and economic rents of the fishing sector of the Salerno province. Between 1998 and 2003, the total number of boats has decreased by 24%, in particular after the adoption of the fourth generation of MAGP's (period 1997-2001). This re-assessment has largely regarded small vessels (table 5). In the same period, GRT increased by 59% and power by 14%. Activity, expressed in terms of average days at sea, decreased by 76%.

Table 9.5 Capacity and activity levels of the Salerno province fishing fleet (1998 and 2003)

	Number of vessels			GRT			kW			Average days at sea		
	2003	1998	Var. %	2003	1998	Var. %	2003	1998	Var. %	2003	1998	Var. %

Source: Mipaf - Irepa

These conclusions are supported by data on fleet permanent withdrawal. During 2003 and 2004, the number of vessels which applied for the permanent withdrawal was in number of 15 (table 6). Among these, only three vessels did not require the Community aids.

Table 9.6 Fleet permanent withdrawal in the Salerno province

DESCRIPTION	2003	2004	Total
Withdrawal without Community aid	1	2	3
Withdrawal with public aid	3	9	12
Change of enrolment office	1	3	4
Non renewed license	10	3	13
Replacement without public aid	10	3	13
Other	1	6	7
Total	26	26	52

Source: Mipaf

Over the same period (2003-2004), the fleet registered a reduction of 52 units in terms of number and 400.26 GRT in terms of capacity (table 7). With reference to the segments, the higher number of withdrawal was recorded within the small scale fishery (31), followed by the purse seine segment (16), demersal trawl (3) and polyvalent (2).

Table 9.7 Numbers of permanent withdrawal in Salerno province, 2003-2004

Fleet segment	No. Vessels	Total GRT	Average GRT	Average LOA
Small Scale fishery < 12m	31	67.97	2.1926	6.2423
Demersal trawl	3	97.54	32.513	18.123
Purse seine	16	218.68	13.668	8.8056
Polyvalent	2	16.07	8.035	11.95
Total	52	400.26	7.6973	7.9692

Source: Mipaf

Small scale fishery, with 6 vessels asking for Community aids (table 7), was most affected by the EU buy-back program. Purse seine and demersal trawl follow with respectively 4 and 2 units.

Table 9.8 Number of withdrawals with Community aid, 2003-2004

	No. Vessels	Total GRT	Average GRT	Average LOA
Small Scale fishery < 12m	6	10.62	1.77	5.43
Demersal trawl	2	73.3	36.65	18.56
Purse seine	4	16.76	4.19	8.02
Total	12	100.68	8.39	8.48

Source: Mipaf

As table 7 and 8 show, the higher number of vessels asking for permanent withdrawal was recorded, in the period 2003-2004, within the small scale fishery (31), followed by the purse seine segment (16), demersal trawl (3) and polyvalent (2). Beside the buy-back programme enforced through the MAGPs, the CFP can have further effects on the fishery of the Salerno province.

The artisanal structure of the fishing sector of the Salerno province can represent a further cause of impact of the CFP having, in this case, origin in the EC Reg. No. 1626/94. Among the number of technical restrictions, this regulation provides for mesh size limits of 14 mm for seine nets and 40 mm for trawl nets¹²³. These provisions represent a great constraint for some artisanal fishery, first of the entire one based on the juveniles of anchovies and sardines (in Italy called “bianchetto”), and widely settled along the Italian coasts.¹²⁴ This is also the case of the Salerno province.

Even if the “bianchetto” fishery does not have a great incidence on the national fishery production, both in economic and physical terms, at local level it has a great importance if considering the role that it plays in social, economic and employment terms for some little fishing communities. It should be considered, indeed, that the high market value of “bianchetto” (it generally reaches 20 €/kg) allows fishermen to realize good revenues in a season characterized by bad climatic conditions that negatively influence the production levels of the fishing sector. The “bianchetto” fishery is indeed exerted during the winter season, more or less, depending on the year and on the areas, the period between January and March. In order to contrast an overexploitation of juveniles in this period, the national Authority yearly issues a decree setting the period when this fishery is authorized. Generally it allows for fishing over a period of 60 consecutive days.

Anyway, as said above, at now these provisions do not have a real impact on the economy of the local fishing sector because of the subsequent amendments that until now has delayed the enforcement of the EC Reg. No. 1626/94. It is a consequence of the Commission acknowledgment that these “special” fisheries give an important socio-economic contribute to the economy of many coastal communities.

4. Territorial impacts of the CFP may contradict with the aims of cohesion, territorial balanced development and polycentrism. The CFP may favour the prosperous regions and disfavour the most remote regions.

In the Salerno case the reduction of the fleet has in large part interested the artisanal fleets located in remote villages, strongly dependent on fisheries.

As stated for hypothesis 3, the major impacts that the CFP has had and can have concern the economy of little coastal communities dependent on artisanal fishery (for details see

¹²³ An exception is provided for the surface trawling for pilchards and anchovies. In this case the minimum mesh size is set at 20 mm when pilchards and anchovies represent not less than 70% of catches (at sorting already done).

¹²⁴ At now, the mesh limits are set at 5 mm.

hypothesis 3). Nevertheless, the parallel increase of tourism-based activities seems to indicate a positive feedback to fishing effort which adjusts itself to the dimensions of resources. Low investment for vessels and gears and the chance to convert towards tourism-based activities may help artisanal fleets to reduce their fishing effort on traditional resources.

9.6.2 Social and economic impact hypotheses:

1. The CFP has unintended side effects in coastal regions or fishery dependent regions

In the Salerno case it is difficult to isolate the impacts of CFP on other socio-economic dynamics related to employment and demography. In any case, from the analysis it emerges the increasing age of the fleet and of the people working on board.

2. As the restrictions on harvesting activities mainly target the fishing fleet these measures have strongest negative impacts in remote, coastal regions, while the more urban regions involved in fish processing still are able to source raw fish through e.g. import from 3rd countries.

The specific features of the Mediterranean fisheries have not allowed the practical applicability of restrictions on harvests, like quotas. Bluefin tuna (*Thunnus Thynnus*) is the only specie in the Mediterranean where a TAC has been enforced since 1998.

Furthermore, it should be outlined that the fish processing sector, especially for tuna-based processing activities, is not supplied by local landings that are exclusively destined to the consumption. Even if the most important fish processing plants are located near to the coast, this is due more to historical and traditional reasons than to the need of links to fishing areas as supply sources. In fact, tuna destined to processing (mostly yellowfin) comes mainly from abroad and only a small part of anchovies destined to processing comes from local landings: the small size of local anchovies is, in fact, not good for processing.

9.6.3 ICZM/environment hypotheses:

2. Increasing awareness of the need to assure resource sustainability and to preserve the whole marine environment, CFP measures aim at reduction of quotas and/or to the reduction of fishing effort. The changes in CFP from 2002 will contribute to a faster reduction and restructuring of the fishing fleet, both in absolute numbers, tonnage (GT) and engine power (kW).

In a region, as Salerno, dominated by old and small vessels, the economic subsidies offered by the EU by-back program have a very limited impact in terms of capacity reduction and ecological impact, while it seems to have a strong impact in terms of social effects. In fact, the analysis of the trends in fishing capacity and effort highlights that the total number of boats of the Salerno fleet has remained constant in the last decade in contrast the tonnage and the power have strongly reduced since 1997, following the adoption of the fourth generation of MAGP's (period 1997-2001). This re-assessment has largely regarded small vessels, while demersal trawlers have increased.

3. Changes in CFP will probably be directed towards improvement of the marine environment and marine resources. In the long run this may lead to higher and more stable fish stocks but only if the fishing effort is sufficiently reduced.

The actual legislation is completely directed towards the achievement of a higher environmental sustainability of the fishing activities and the rebuilding of fishing stocks.

It should be also stressed that in the Salerno province two marine reserves, Costa degli Infreschi and S. Maria di Castellabate, both in the Cilento area, are going to be established in the near future (Law 979/82). Anyway, it should be taken in due account that in future, further reduction of capacity can be foreseen, but it will be difficult to have the previous rate of reduction. In the case of strong multispecies, multigear fisheries, as the Salerno (and the overall Mediterranean) is, measures based on control of activity can be considered most appropriate since these measures do not alter the structure of existing mixed populations and their growth pattern.

4. Aquaculture will continue to expand, but the further development may be more regional concentrated both with regard to value added and employment.

Aquaculture activities are becoming more and more important in the Salerno province both from an economic and from an employment point of view. Along the coastline of the province of Salerno there are few mariculture plants. In most cases, they are managed by local fishing co-operatives and constitute an alternative way to diversify fishing activity and hence to integrate income coming from fish catching activity. Anyway, in recent years the aquaculture sector is facing many difficulties because of the growing competition of the cheaper aquaculture products coming from abroad, mainly from Greece and Turkey.

9.6.4 Fishery hypotheses:

3. Territorial impacts of the CFP measures are dependent on how the measures in use are implemented in the various regions. Impacts will also vary by the structure of the fisheries in the respective regions and the access to alternatives, such as fishing opportunities, sources of fish raw material for processing, alternative job opportunities etc.

Over the last ten years, fishing-tourism has increased and new vessels licensed for traffic have been built. In the ports of Palinuro, Marina di Camerota and Scario (in the Cilento Park) most of the fishing vessels interrupt fishing activities from June-July to September. Gears are landed and vessels are fitted out to host tourists. The main activity is taking tourists along the shore towards those beaches and rocky caves accessible only from the sea (FAO, 2003). In this light, the effects that the CFP has had to some extent on local communities have been contrasted by a natural re-conversion process of the fishery sector towards alternative job opportunities.

9.7 General conclusions and recommendations

Even if the Salerno province has traditionally been devoted to marine economic activities, the importance of fishery has been decreasing during the last 40 years. The number of young unemployed entering the fishing sector is continuously decreasing, despite the very high level of unemployment in some rural areas. Similarly, the average age of fishermen is increasing and a high percentage of fishermen are currently retired people.

Development of tourism-based activities and general social progress at the beginning of the 1970s can be viewed as the main factors influencing this process. In most recent years, as it is happening at national level, the Salerno fishery sector is also facing a crisis due to the increase of the production costs, especially of the fuel costs. If this type of problems can be overcome by more industrialized segments (as the trawlers or the tuna fleet) this is not the case of the artisanal fishery. This is one of the reasons that caused a mass exit from the sector of small boats.

A possible solution for the crisis that is involving especially the artisanal fishery could be a more appropriate management system. It is, indeed, gradually emerging, at national level, the need for a co-management between the central and local Authority and the fishermen, following the positive experience the consortia created for the management of the mollusks fishery along the Italian Adriatic coast. In this perspective, a recent Italian regulation¹²⁵ has allocated about 8 millions Euro to the cooperatives operating in the small scale fishery in order to finance the renovation of the vessels and other related activities performed on land.

Annex 4

Summary Common Fisheries Policy

Chapter 3

Box 1

Scope of the Common Fisheries Policy:

1. *The Common Fisheries Policy shall cover conservation, management and exploitation of living aquatic resources, aquaculture, and the processing and marketing of fishery and aquaculture products where such activities are practised on the territory of Member States or in Community waters or by Community fishing vessels or, without prejudice to the primary responsibility of the flag State, nationals of Member States.*
2. *The Common Fisheries Policy shall provide for coherent measures concerning:*
 - (a) *conservation, management and exploitation of living aquatic resources,*
 - (b) *limitation of the environmental impact of fishing,*
 - (c) *conditions of access to waters and resources,*
 - (d) *structural policy and the management of the fleet capacity,*
 - (e) *control and enforcement,*
 - (f) *aquaculture,*
 - (g) *common organisation of the markets, and*
 - (h) *international relations.*

(Council Regulation (EC) No 2371/2002, art. 2, para. 1)

Box 2

Objectives of the Common Fisheries Policy:

The Common Fisheries Policy shall ensure exploitation of living aquatic resources that provides sustainable economic, environmental and social conditions. For this purpose, the Community shall apply the precautionary approach in taking measures designed to protect and conserve living aquatic resources, to provide for their sustainable exploitation and to minimise the impact of fishing activities on marine eco-systems. It shall aim at a progressive implementation of an eco-system-based approach to fisheries management. It shall aim to contribute to efficient fishing activities within an economically viable and competitive fisheries and aquaculture industry, providing a fair standard of living for those who depend on fishing activities and taking into account the interests of consumers.

(Council Regulation (EC) No 2371/2002, art. 2, para. 1)

Box 3

Allocation of fishing opportunities between the member states:

- (i) The Council, acting by qualified majority on a proposal from the Commission, shall decide on catch and/or fishing effort limits and on the allocation of fishing opportunities among Member States as well as the conditions associated with those limits. Fishing opportunities shall be distributed among Member States in such a way as to assure each Member State relative stability of fishing activities for

each stock or fishery.

- (ii) When the Community establishes new fishing opportunities the Council shall decide on the allocation for those opportunities, taking into account the interests of each Member State.
- (iii) Each Member State shall decide, for vessels flying its flag, on the method of allocating the fishing opportunities assigned to that Member State in accordance with Community law. It shall inform the Commission of the allocation method.
- (iv) The Council shall establish the fishing opportunities available to third countries in Community waters and allocate those opportunities to each third country.
- (v) Member States may, after notifying the Commission, exchange all or part of the fishing opportunities allocated to them.

(Council Regulation (EC) No 2371/2002, art. 20)

Box 4

Measures governing access to waters and resources and the sustainable pursuit of fishing activities:

- (a) *adopting recovery plans under article 5;*
- (b) *adopting management plans under article 6;*
- (c) *establishing targets for the sustainable exploitation of stocks;*
- (d) *limiting catches;*
- (e) *fixing the number and type of fishing vessels authorised to fish;*
- (f) *limiting fishing effort;*
- (g) *adopting technical measures, including:*
 - (i) *measures regarding the structure of fishing gear, the number and size of fishing gear on board, their methods of use and the composition of catches that may be retained on board when fishing with such gear;*
 - (ii) *zones and/or periods in which fishing activities are prohibited or restricted including for the protection of spawning and nursery areas;*
 - (iii) *minimum size of individuals that may be retained on board and/or landed;*
 - (iv) *specific measures to reduce the impact of fishing activities on marine eco-systems and non target species;*
- (h) *establishing incentives, including those of an economic nature, to promote more selective or low impact fishing;*
- (i) *conducting pilot projects on alternative types of fishing management techniques.*

(Council Regulation (EC) No 2371/2002, art. 4, para. 2)

Box 5

Provisions for recovery plans:

1. *The Council shall adopt, as a priority, recovery plans for fisheries exploiting stocks which are outside safe biological limits.*
2. *The objective of recovery plans shall be to ensure the recovery of stocks to within safe biological limits.*

They shall include conservation reference points such as targets against which the recovery of the stocks to within safe biological limits shall be assessed.

Targets shall be expressed in terms of:

- (a) *population size and/or*
- (b) *long-term yields and/or*
- (c) *fishing mortality rate and/or*
- (d) *stability of catches.*

Recovery plans may include targets relating to other living aquatic resources and the maintenance or improvement of the conservation status of marine eco-systems.

Where more than one target is set, recovery plans shall specify the order of priority of these targets.

- 3 *Recovery plans shall be drawn up on the basis of the precautionary approach to fisheries management and take account of limit reference points recommended by relevant scientific bodies. They shall ensure the sustainable exploitation of stocks and that the impact of fishing activities on marine eco-systems is kept at sustainable levels.*

They may cover either fisheries for single stocks or fisheries exploiting a mixture of stocks, and shall take due account of interactions between stocks and fisheries.

The recovery plans shall be multi-annual and indicate the expected time frame for reaching the targets established.

4. *Recovery plans may include any measure referred to in points (c) to (h) of Article 4(2) as well as harvesting rules which consist of a predetermined set of biological parameters to govern catch limits. Recovery plans shall include limitations on fishing effort unless this is not necessary to achieve the objective of the plan. The measures to be included in the recovery plans shall be proportionate to the objectives, the targets and the expected time frame, and shall be decided by the Council having regard to:*
- (a) the conservation status of the stock or stocks;*
 - (b) the biological characteristics of the stock or stocks;*
 - (c) the characteristics of the fisheries in which the stocks are caught;*
 - (d) the economic impact of the measures on the fisheries concerned.*

5. *The Commission shall report on the effectiveness of the recovery plans in achieving the targets.*
(Council Regulation (EC) No 2371/2002, art. 5)

Box 6

Provisions for a capacity ceiling:

Entry/Exit scheme and overall capacity reduction

1. *Member States shall manage entries into the fleet and exits from the fleet in such a way that, from 1 January 2003:*
 - (a) the entry of new capacity into the fleet without public aid is compensated by the previous withdrawal without public aid of at least the same amount of capacity,*
 - (b) the entry of new capacity into the fleet with public aid granted after 1 January 2003 is compensated by the previous withdrawal without public aid of:*
 - (i) at least the same amount of capacity, for the entry of new vessels equal or less than 100 GT, or*
 - (ii) at least 1,35 times that amount of capacity, for the entry of new vessels of more than 100 GT.*
2. *From 1 January 2003 until 31 December 2004 each Member State which chooses to enter into new public aid commitments for fleet renewal after 31 December 2002 shall achieve a reduction in the overall capacity of its fleet of 3 % for the whole period in comparison to the reference levels referred to in Article 12.*
3. *Implementing rules for the application of this Article may be adopted in accordance with the procedure laid down in Article 30(2).*

(Council Regulation (EC) No 2371/2002, art. 13)

Box 7

Regional Advisory Councils, basic setup and mandate:

1. *Regional Advisory Councils shall be established to contribute to the achievement of the objectives of Article 2(1) and in particular to advise the Commission on matters of fisheries management in respect of certain sea areas or fishing zones.*
2. *Regional Advisory Councils shall be composed principally of fishermen and other representatives of interests affected by the Common Fisheries Policy, such as representatives of the fisheries and aquaculture sectors, environment and consumer interests and scientific experts from all Member States having fisheries interests in the sea area or fishing zone concerned.*
3. *Representatives of national and regional administrations having fisheries interests in the sea area or fishing zone concerned shall have the right to participate in the Regional Advisory Councils as members or observers. The Commission may be present at their meetings.*
4. *Regional Advisory Councils may be consulted by the Commission in respect of proposals for measures, such as multi-annual recovery or management plans, to be adopted on the basis of Article 37 of the Treaty that it intends to present and that relate specifically to fisheries in the area concerned. They may also be consulted by the Commission and by the Member States in respect of other measures. These consultations shall be without prejudice to the consultation of the STECF and of the Committee for Fisheries and Aquaculture.*

5. Regional Advisory Councils may:

- (a) *submit recommendations and suggestions, of their own accord or at the request of the Commission or a Member State, on matters relating to fisheries management to the Commission or the Member State concerned;*
- (b) *inform the Commission or the Member State concerned of problems relating to the implementation of Community rules and submit recommendations and suggestions addressing such problems to the Commission or the Member State concerned;*
- (c) *conduct any other activities necessary to fulfil their functions.*

Regional Advisory Councils shall inform the Committee for Fisheries and Aquaculture of their activities.
(Council Regulation (EC) No 2371/2002, art. 31)

Box 8

Objectives of the EU FIG:

- (a) *to contribute to achieving a sustainable balance between fishery resources and their exploitation;*
- (b) *to strengthen the competitiveness of structures and the development of economically viable enterprises in the sector;*
- (c) *to improve market supply and the value added to fishery and aquaculture products;*
- (d) *to contribute to revitalising areas dependent on fisheries and aquaculture.*

(Council Regulation (EC) No 1263/1999, art. 1, para. 2)

Box 9

The Pesca initiative 1994 to 1999:

To cushion the worst effects of restructuring on regions dependent on fisheries, a special Pesca Community initiative was introduced in addition to the FIG. Pesca combined several elements and sought to help the fisheries sector make a successful transition by diversifying fishermen's activities away from fishing and contributing to the diversification of coastal regions by developing new employment opportunities.

The Community contribution to Pesca was approximately ECU 260 million for the period 1994-1999. Pesca, as with all Structural Fund interventions, requires joint financing by the Member State and, in some cases, by the private beneficiaries.

The Pesca initiative has ended but similar measures, such as aid to fishermen to help them retrain and diversify their activities outside marine fisheries and aid for the organisation of electronic trade and other information technologies to disseminate technical and commercial information, are now available under the FIG.¹²⁶

The total budget of the Pesca initiative was rather small compared to that of the FIG for the period. The main beneficiaries (in absolute terms) were Spain, Italy, Greece, Portugal, France and the UK.¹²⁷

Box 10

New arrangement on aid decided as part of the CFP reform in December 2002:

Public aid for fleet renewal and for the equipment of fishing vessels, including for the use of more selective fishing techniques and of Vessel Monitoring Systems or for the modernisation of fishing vessels may be granted only on the following conditions and those set out in the second subparagraph of Article 3(3) and in Annex III:

- (a) *public aid for the renewal of fishing vessels may be granted until 31 December 2004;*
- (b) *public aid for the renewal of fishing vessels may be granted only for vessels under 400 GT;*
- (c) *public aid for the equipment of fishing vessels, including for the use of more selective fishing techniques and of Vessel Monitoring Systems, or for the modernisation of fishing vessels may be*

¹²⁶ From DG Fish website: http://europa.eu.int/comm/fisheries/pcp/faq3_en.htm (3 March 2005)

¹²⁷ Information on the regional distribution of the EU structural funds allocated through the Pesca can be found on NUTS2 on DG Fish's website: http://europa.eu.int/comm/fisheries/doc_et_publ/liste_publi/ifop/ifop_en.htm

granted provided that:

- (i) the aid does not concern capacity in terms of tonnage or of power;
- (ii) the aid does not serve to increase the effectiveness of the fishing gear;
- (d) by derogation from point (c)(i), public aid for the modernisation of fishing vessels may be granted subject to the provisions of Article 11(5) of Regulation (EC) No 2371/2002.

(Council Regulation (EC) No 2792/1999, art. 9 para. 1, consolidated version)

Box 11

Suggested priority-areas of the EFF

The five priority axes/areas are: 1) measures for the adjustment of Community fishing fleet, 2) aquaculture, processing and trade of fisheries and aquaculture products, 3) measures of collective interest, 4) sustainable development of fishing coastal zones, and 5) technical assistance (COM (2004) 0497 final, art. 4, explanatory memorandum, point 17). Under each of the priorities different measures can be supported:

- Ad.1: *Financial assistance will be available to fishermen and fishing vessel owners affected by the measures taken to combat overfishing. In particular, this will include aid for the temporary or permanent laying up of fishing vessels and for training, reskilling and early retirement of fishermen;*
- Ad. 2: *The EFF will promote the acquisition and use of gear and methods that reduce the impact of fishing on the environment. The aid will be concentrated on small and micro enterprises;*
- Ad. 3: *The following projects will be eligible for the aid: those which contribute to the sustainable development or conservation of resources, the strengthening of markets in fishery products or the promotion of partnerships between scientists and operators in the fisheries sector;*
- Ad. 4: *The EFF will support measures and initiatives aimed at diversifying and strengthening economic development in areas affected by the decline in fishing activities;*
- Ad. 5: *The Fund may finance action relating to preparation, monitoring, administrative and technical support, evaluation, audit and control necessary for implementing the proposed Regulation.*¹²⁸

Box 12

Provisions for safeguard measures:

Where, by reason of imports or exports, the Community market in one or more of the products listed in Article 1 is affected by, or is threatened with, serious disturbance likely to jeopardise the achievement of the objectives set out in Article 33 of the Treaty, appropriate measures may be applied in trade with third countries until such disturbance or threat of disturbance has ceased.

(Council Regulation (EC) No 104/2000, art. 30, para. 1)

Box 13

The southern and northern agreements can be divided into three generations:

Firstly, *first generation or "classical" agreements* based on financial compensations in exchange for allowing access to fishing grounds. Such agreements are quite diverse and a distinction could be made

¹²⁸ From European Union website: <http://europa.eu.int/scadplus/leg/en/lvb/l66004.htm> (4 March 2005).

between:

- Reciprocal agreements: The European Community allows fishing in the waters of EU member states in exchange for equivalent quantities in the waters of the third country in question. In general, these are states located geographically close to the EU, which exploit shared stocks. This is the case for most non-EU countries of the North Atlantic such as Norway, the Faeroe Islands or Iceland, as well as the Baltic countries that have recently entered the EU, such as Estonia, Latvia, Lithuania and Poland.
- Agreements allowing access to surplus stocks: Community fishing vessels are authorized to fish in the waters of the third country on the surplus stock of certain fish populations. The agreement with the USA, which expired at the end of 1993, and the agreement negotiated and signed with Canada in 1992 but not ratified by this country fall into this category.
- Agreements allowing access to resources in exchange for access to markets: In this case a third country provides fishing opportunities for Community vessels in exchange for tariff concessions.
- Agreements to exchange access rights to resources for economic compensations: In this kind of agreement the Community acquires fishing rights (fishing licences) in exchange for an economical compensation, which is mainly financed by the EU budget but also by vessel owners' contributions. Most fishing agreements with African countries – both bordering the Atlantic and the Indic Ocean - are of this type. A significant example was the agreement with Morocco
- Agreements establishing the access to resources through an economical compensation together with the application of tariff concessions: This is the case of the fisheries agreement with Greenland.

Secondly, *second generation agreements based on the creation of joint ventures* between the Community industry and that of the third signing country. This kind of agreement requires the third country to have a well-developed fishing industry. A typical example of this would be the agreement with Argentina.

At the end of the 80's the Community had concluded several fishing agreements based either on reciprocal access to resources (mostly agreements with North Atlantic countries) or on the payment of financial compensations in exchange for the access to living marine resources (agreements with African countries). Each of these models had its reason and could be explained by the historical rights and the agreements previously made and based on bilateral relations between sovereign states or on the fact that there were shared fish populations in the EU fishing zones and those of the third countries which took part in the agreement.

However, it was acknowledged that it was necessary to broaden the spectrum of Community fisheries agreements in order to be able to offer additional fishing opportunities, which met the goal of maintaining the operational capacity of the Community fleets and, at the same time, contributed to the modernization of third country fleets and to the development of their fishing sectors.

The most innovative result of this reflection was the definition and conclusion of second generation agreements. According to these agreements, the fishing opportunities in third country waters would be based on the creation of joint ventures by Community vessel owners as well as on the fishing interests of third countries.

In later discussions it was planned that those Community fishing vessels, which took part in the agreement (mostly deep-sea trawlers), would be permanently (that is the case for joint ventures) or temporarily (time-limited joint ventures) transferred to third country waters. This implied the "export" of the fishing effort, which has been strongly criticized in international forums.

In the framework of these agreements, it is laid down that there should be cuts on differential tariffs on exports of certain fishing products for the third country. In other words, these products should "enter" the EU market with reduced and preferential tariffs (under the market policy). Obviously, this is subject to precondition that a trade agreement between the European Community as a whole and the signing country exists.

¹²⁹ These development initiatives do not imply the suspension of the aids financed under the epigraph of the European Development Fund (EDF) or those measures planned by the Centre for Industrial Development (CID), nor all of the other aids and grants laid down in other programs of development aid.

This type of agreement also establishes scientific and technical cooperation programs aimed at developing the fishing sector of the third country.

Finally, *third generation agreements based on the combination of the two previous types* but focusing on the development cooperation with the third country and the Community interests on fishing. This could be a kind of agreement of interest to Morocco. These agreements include the whole fishing sector - not only catches (as it happens with second generation agreements) - as well as the processing sector (canned products) and the marketing sector (product distribution and commercialization).

Third generation agreements entail a financial compensation granted to the authorities of the third country, which should try to create the suitable environment for the cooperation between sectors (vessel owners, processors, traders), Community and third country interests. Such financial compensation granted by the Community can be used by the third signing country to develop its fishing sector or to finance certain classical measures in different fields (technical training of staff, research, port or distribution infrastructure etc.), which help meet the cooperation goals.¹²⁹

Annex 5

FIFG implementation NUTS2 1994-1999

Each year since the programmes have been set in motion, the management authorities have been sending the Commission implementation reports, i.e. information on the actual execution of each project, in a strictly standardised form.

For each country, the data are grouped by area of assistance and, within each area, by measure, as well as by administrative unit (level II of the Nomenclature of statistical territorial units or NUTS 2).¹³⁰

Some projects are not actually sited in a particular region (e.g. generic promotion campaigns and technical assistance relating to the programme as a whole). In such cases, the corresponding expenditure is shown against the capital of the country (since that is where the beneficiary has its address) or the country or region, without any further details.

The implementation reports shown here are in French and give information on NUTS 2 on: area of assistance ('Domaine'), the region's share of the EU aid given to the member state ('Répartition Aide UE'), total costs in million € ('Côté total M€'), the national financial aid in million € ('Aide État membre M€'), EU financial aid in million € ('Aide UE M€') and finally the number of projects ('Nombre de projets').

The source of the information is DG Fish's website on community structural assistance in the fisheries and aquaculture sector (1994-99):

http://europa.eu.int/comm/fisheries/structures/index_en.htm

The reports are shown in the following order:

- Austria
- Belgium
- Finland
- France
- Germany
- Greece
- Italy
- Luxemburg
- Netherlands
- Portugal
- Spain
- Sweden
- United Kingdom

There are no regional reports on Denmark and Ireland.

¹³⁰ There has been changes with regards to the NUTS regions in certain countries since these reports were drafted. An overview of the changes can be found on the following website:
http://europa.eu.int/comm/eurostat/ramon/nuts/changes_1999_en.html (3 March 2005)

Annex 6

FIFG implementation NUTS2 2000-2004

Each year since the programmes have been set in motion, the management authorities have been sending the Commission implementation reports, i.e. information on the actual execution of each project, in a strictly standardised form.

For each country, the data are grouped by area of assistance and, within each area, by measure, as well as by administrative unit (level II of the Nomenclature of statistical territorial units or NUTS 2).

Some projects are not actually sited in a particular region (e.g. generic promotion campaigns and technical assistance relating to the programme as a whole). In such cases, the corresponding expenditure is shown against the capital of the country (since that is where the beneficiary has its address) or the country or region, without any further details.

The summary sheets, which contain the **cumulated data from the 1st January 2000 to 31st December 2004**, were kindly provided by the European Commission, DG Fisheries.

The priorities referred to in the sheets are the following (based on Commission Regulation (EC) No 366/2001 of 22 February 2001 laying down detailed rules for implementing the measures provided for in Council Regulation (EC) No 2792/1999, in Official Journal, L 55, 24.02.2001, p. 3-15.):

- Priority 1: Adjustment of fishing effort
- Priority 2: Fleet renewal and modernisation
- Priority 3: Protection and development of aquatic resources, aquaculture, fishing port facilities, processing and marketing and inland fishing
- Priority 4: Other measures
- Priority 5: Technical assistance
- Priority 6: Measures financed by other structural funds under this programme (only in Objective 1 regions)

The sheets are presented in the following order:

Belgium

Italy

United Kingdom

Sweden

Slovenia

Poland

The Netherlands

Malta

Lithuania

Latvia

Ireland

Greece

France

Finland

Estonia

Spain

Denmark

Austria

Germany

No sheets are provided for the remaining member states.

Annex 7

FIFG 1994 to 1999

Overview of areas of assistance and connected measures of FIFG programme 1994 to 1999

AREA OF ASSISTANCE	MEASURE
1. ADJUSTMENT OF FISHING EFFORT	1. Scrapping of vessels
	2. Export of vessels/assignment to other use
	3. Joint enterprises
	4. Temporary joint ventures
2. RENEWAL AND MODERNISATION OF FISHING FLEET	1. Construction of new vessels
	2. Fitting new engines, improving safety and working conditions on board vessels, improving hygiene conditions for products, introducing new, more highly selective fishing techniques, installing equipment for monitoring fishing activities on board vessels, other investments on existing vessels
3. AQUACULTURE	1. Increasing aquaculture capacity (new production units and/or extension of existing production units)
	2. Modernisation of existing aquaculture units without increasing production capacity
4. PROTECTED MARINE AREAS	1. Development of enclosed seawater areas
5. FISHING PORT FACILITIES	1. Construction of new facilities/extension of existing facilities
	2. Modernisation of existing facilities without increasing physical capacity
6. PROCESSING/MARKETING OF PRODUCTS	1. Increasing processing capacity (new production units and/or extension of existing production units)
	2. Modernisation of existing processing units without increasing production capacity
	3. Modernisation of existing marketing establishments
	4. Construction of new marketing establishments
7. PROMOTION	1. Promotion campaigns
	2. Participation in trade fairs
	3. Market studies and consumer surveys
	4. Sales advice and aid and other services to wholesalers and retailers
	5. Operations associated with quality certification and product labelling
8. OTHER MEASURES	1. Studies, pilot projects, technical assistance and other specific measures
	2. Operations by members of the trade
	3. Temporary cessation of fishing activities

	4. Specific compensation measures for fishermen (ad hoc Council decisions)
	5. Other
9. SOCIO-ECONOMIC MEASURES	1. Early retirement
	2. Flat-rate individual cessation premium
10. ERDF	1. Projects
11. ESF	1. Training
	2. Other projects

Annex 13

Fisheries and fisheries policy in the Baltic States

The fall of the Soviet Union and the Transition to Market Economy

Baltic new EU Member States Estonia, Latvia, Lithuania and Poland accessed EU around two years ago, in May 2004. Since there is a certain time lag in processing national statistics, only little amount of data is available to compare the socio-economic situation after the accession to the pre-accession situation. Therefore it is too early to draw solidly based conclusions of CFP in general or its territorial impacts to these countries.

The life in the Baltic republics and Poland has been very dynamic during the last 15 years. Deep changes in legal, economic and social issues have impacted all sectors of the national economy. Quick rise in the profitability of small-scale coastal fisheries and its later gradual fall has had its deep impact to living standard in coastal villages. Rather analogous development took place in trawling fisheries, which peaked in profitability and importance around 1997. So, due to the very dynamic economic life it is very hard to separate impacts from CFP and other relevant factors.

National Importance of Fisheries

If fisheries of the new Baltic member states are compared to the old member states situated in the Baltic Sea region, then it appears that in new member states the fisheries sector is more important. The number of fishermen is relatively high, both as a share from the total active population, or if expressed as a number of fishermen per length of the coastal strip or territory of Economic Zone. Basically, this is a heritage from the Soviet period, and during the last 15 years the importance of fisheries have decreased.

Figure 1 Share of fisheries in Estonian GDP (%)

The share of fisheries in the total GDP in the Baltic member states is also very high in comparison with e.g. Sweden or Finland. A few years ago in Latvia the share of overall fishery production was around 1.5% of GDP, and the fisheries sector played a significant role in the national economy, especially in the remote coastal areas. It employed around 13900 people (1.2 % of active population). In Estonia the employment was around 10000 people. However, during the last years the fisheries sector has gradually been losing its importance in all new Baltic member states. This has been taking place during the period when some EU pre-accession funds have already been available. Nevertheless, this development cannot be associated to low possible efficiency of the structural funds. Rather, the decreasing importance of the fisheries is just a logical response to the new economic framework and structural funds have not been able to stop it. The dramatically decreasing importance of Estonian fisheries in relation to the national GDP is illustrated in the figure above.

Developments in the Baltic Coastal Fishery

Overall changes in the political and economic life in the Baltic Republics during the last 15 years have affected very deeply the coastal fishing sector. For many reasons, such as restrictions on fishing connected to the border regime, the low value of fish, and the moderate number of fishermen during the Soviet period, the stocks were relatively healthy at the end of the 1980's. Opening of the western markets that followed trade liberalization enabled unlimited exports of Estonian fish. First-buyer prices of high-value species such as perch, pikeperch and pike increased rapidly almost up to the Western European level.

Figure 2 The development of raw prices of most important species targeted by coastal fishermen and average salaries in Estonia (indices, 1996=100%)

Due to the high profitability of fishery the pressure on the fish resources increased substantially, both in terms of the total number of fishermen and in fishing effort. Since fishery costs were low and catches and fish buyer prices high, the incomes of fishermen were good. The relative wealth of the people engaged in coastal fishery was also due to the fact that, at that time, most Estonians worked in sectors of the economy that were unable to export to Western Europe. Therefore the earnings of most people at that time were very low.

However, after the first prosperous years the incomes of fishermen started to decline, at least in relative sense. The main reason is that the first-buyer prices had already reached levels comparable to Western Europe and could rise no further (see figure above). So, while fishing costs and average salaries in the country increased year-by-year, the total revenue in coastal fishing remained the same (see figure beneath) Soon stocks started to decline. Fishermen who were already used to high incomes increased their fishing effort, which in turn accelerated the decline of stocks.

Figure 3 Value of the catch in Estonian coastal fishing and trawling (million euros)

At the same time, dynamic development of the Estonian economy caused a steady increase in all costs connected to fishery. And finally, increases in earnings in other sectors of the economy have increased the average gross wage in the country to a level around ten times as high as that during the first years of independence (see figure beneath). So, if the absolute income of fishermen remained largely the same, then the relative income deteriorated year by year. This has had clear negative impact to coastal areas and there are no signs that CFP has been able to stop this process.

Figure 4 The average gross monthly salary in Estonia (euro)

The described developments have resulted in a decline in the importance of coastal fishery during recent years and, as there are few alternative employment possibilities in many coastal areas, increasing social problems have hit households dependent on fishery. In some areas (like Vainameri) over-fished stocks have still not reached the levels of the first post-Soviet years.

The final conclusion is that countries in transition (e.g. future EU members like Romania, Bulgaria etc.) may encounter serious difficulties in the coastal fishing sector arising from privatization and reforms in the financial system and trade. The new economic framework may give rise to high short-term profits, and help communities survive during the difficult years of reorganization. However, there may be a substantial backlash in later years, since the depleted stocks do not enable a normal fishery pattern to be established even years after the establishment of new ruling principles. Needless to say, such a situation will have very negative impacts to coastal communities as a whole.

Developments in the Baltic Trawling

In Baltic trawling targeting herring and sprat the development was different from the coastal fishing sector. During the soviet period the trawling fleet used cheap fuel and machines produced in the Soviet Union, which were uneconomic in terms of fuel use. The disintegration of the centrally planned economy resulted in the discontinuation of subsidies. Furthermore, while small-scale fishing found new markets in the west, it was still only possible to export products made from herring and sprat to the eastern markets (Russia, Ukraine). Price levels in those markets were low, and Russia tried to enforce several trade barriers both to “punish” the Baltic states for their independence and to force them into a closer alliance with the Russian Federation. As a result, the profitability of Baltic trawling decreased sharply and the volume of catches fell during the first years of new independency, 1991-1994 (see figure beneath).

Figure 5 Catch (tonnes) of herring and sprat (in total) in Estonian waters taken by Estonian vessels

In the middle of the 90s, however, the trawl fisheries started to grow again. The most important reason for this was the increasing purchasing power in the eastern markets. As those markets were known to Estonian fish processors from the soviet time, exports started to grow quickly. As a result, fish processors were interested in raw material and the prices for raw fish rose. Hence the fishing volume and the degree of utilisation of the national quotas started to grow (see figure above). The national quota or the TAC (a constant part of the TAC for the Baltic Sea) allocated to Estonia by the IBSFC was not used fully in the period 1992-1996. Since a part of the Estonian herring and sprat quota was exchanged with the EU against cod quota, the Estonian national quotas were used up for the first time in 1997. Hence it was expected that in 1998 the first serious conflict between competing interests of different fishing enterprises would appear. However, the Russian financial crisis that broke out in August 1998 decreased drastically marketing possibilities in the eastern markets during 1998-99. Export volumes fell almost to zero and as a result many fishing and processing enterprises, oriented almost exclusively towards the eastern markets, went bankrupt in Estonia.

Estonian trawling sector has not fully recovered until today. Of course, the Russian crisis is over long time ago, but due to the other unfavourable factors (increasing wages in the Baltic member states lower profitability, quotas have been decreasing due to the bad state of the stocks) the profitability and prosperous level of 1997 has never reached again. The value of the catch has fluctuated much, but remained rather same in the very general scale (see figure above on the value of the catch in Estonian coastal fishing and trawling 1996-2004), which mean it has steadily decreased in the relative scale.

Developments in the Fish Processing Sector

Estonian fish processing sector has historically been tightly connected to the catching sector. Some of the biggest processing plants have been owned by enterprises, which have also had own fishing fleets. During the last decade most important source of the raw material for processing industry in the Baltic states has been own fish resources. However, due to the changing markets the importance of imported fish is growing.

During the soviet period the bulk of the fish products were marketed in the Soviet Union. After the fall of the soviet system the most important market for fish processors of the Baltic states has been Ukraine and Russia. However, production costs (salaries etc.) have been growing in the Baltic States more rapidly than the purchasing power of the main markets. Therefore the profitability of the fish processing sector has declined. Several big enterprises have bankrupted. In Estonia, for example, most important processors on the islands Hiiumaa and Saaremaa (two biggest islands in Estonia, fisheries was one of the most important employers during the soviet period) are today offering only fraction of jobs in comparison with the period a decade ago.

The number of fish processing enterprises is not very good indicator of the situation of the industry, because the size and number of employees can vary much. Very largely, it has been fluctuating around 100 (peaked

135 in 2000). However, their total importance in the country's economy has steadily declined. While the share of fish processing in food industry was around 18% in 1998, then in 2004 it was roughly 11%.

Much more sensitive indicator is the number of employees. Before the Russian financial crisis in 1998 the total number of people working in Estonian fish processing sector was around 7500. This number has now declined around three times (see figure beneath).

The possibility to export fish products to Russia has granted (by Russian veterinary authority) to only 26 enterprises. At the same time, more than 50 enterprises have fulfilled normative to export to the EU market. This is good example how Russian administration seeks possibilities to hinder export of Estonian fish processing products.

Figure 6 The number of employees in the Estonian fish processing sector¹³⁵

Developments in Aquaculture

The natural conditions for aquaculture are not ideal in the Baltic MS. Two most important species reared are rainbow trout and carp. The number of freshwater water bodies suitable for salmonid rearing is small, especially in the Latvia and Lithuania. In most of the rivers summer peak water temperatures are well over 20°C, which is too high even for the rainbow trout. So, only some cold-water springs can be used for aquaculture plants. In the Baltic Sea the situation is far from ideal too (if compared to e.g. Norwegian conditions) with unfavourably high summer temperatures and too cold winters. Gulf of Riga and Gulf of Finland are usually ice-covered during winters, which is another hindrance. Furthermore, coastal areas are shallow (especially in Estonia) and since coastlines are rather straight they are opened to storms. Deep sheltered cold-water bays like in Norway or northern UK are totally lacking. Finally, in the Baltic Sea there are often problems with toxic blue algae. Since the nutrient loading in the Baltic Sea is already very high, massive aquaculture production is also not very wished scenario.

Natural conditions for the cyprinid (carp) rearing are much better if compared to the possibilities for salmon farming. Especially suitable are Poland and Lithuania, somewhat less Latvia. However, also this sector has not been very profitable and is still small both in sense of employment and value of production. The main problem has been rather low price of carp in Baltic MS due to the small domestic consumption. Big potential markets are situated in the central Europe, but high transport costs are still limiting the usage of these markets.

In general, however, the possibilities for aquaculture have been used in much smaller extent in all Baltic MS than fish resources of the sea and freshwaters. So, the general declining trend of importance typical for catching and processing sector is not shared by the aquaculture sector. The volume and value of aquaculture products in Estonia has been slightly rising in Estonia (see table beneath).

¹³⁵ 2004 is expert estimation by Eesti Kalaliit.

Table 1 The volume and value of aquaculture production in Estonia¹³⁶

	1993	1994	1995	1996	1997	1998	1999	2000	2001	2002	2003

Profitability - Outlook for the Future

All Baltic MS have comparatively limited fish resources. This is in some contradiction with the traditional importance of the fisheries, and means that the usage of national fish resources can not grow in absolute value. Moreover, as other sectors of economic life are growing, the fisheries role in relative scale (share in the national GDP etc.) is doomed to fall. As it is typical, number of fishermen is high in less-developed countries, while in parallel to the rising living standard the importance of fishing revenues as source of income decreases. The reason for this development can be illustrated by the figures showing the profitability of pikeperch fishing in Estonia. During the beginning of the 1990s the value of only few tens of kilograms equalled to the average month salary in the country. Today 7-8 times more should be fished. However, if all costs, earnings and salaries will reach the level of Finland, then the profitability decreases even more. Naturally, such an illustration can not include all aspects of the profitability, but the general trend is still clear: the same fish resource can employ at least 10 times less fishermen in today's Finland if compared to the situation which ruled in Estonia at the beginning of 1990s (see table beneath). Therefore the decreasing importance of fishing sector can be prognosticated also for future. It is important that national governments are aware of the situation and make necessary preparations (promote alternative sources of employment in coastal areas etc.).

Table 2 Decrease of profitability in Estonian fishing: ex. pikeperch prices and average salaries

	Estonia					Finland
	1993	1996	1999	2001	2004	2004
First buyer price of pikeperch, euro	1.60	1.98	1.21	1.85	1.53	2.90
Average monthly brutto salary, euro	68	191	291	352	451	2322
Amount pikeperch equalling salary, kg	43	96	240	190	294	801

The number of professional fishermen using the resources of the Baltic Sea in Estonia is rather equal to Sweden, 2000-2500. At the same time the size of the economic zone and length of coastline in Sweden surpasses Estonia 5-10 times. Very descriptive is also the comparison with Norway. When the number of fishermen is less than 10 times higher in Norway, their revenues surpass Estonia more than 100 times. Even if Estonian fishermen work mostly only part-time, it is still clear that CFP cannot support such a low efficiency of work. So, in future the decrease in the importance of the fisheries sector as an employer is inevitable and can be foreseen already now. If we take into consideration the general over-exploitation pattern of the Baltic Sea resources and remarkably increased labour efficiency, then it is of no surprise.

¹³⁶ Official prices for 1993-96 are lacking.

Therefore, emphasis of the CFP structural support as well as other assisting funds should be rather in finding alternative employment possibilities than in maintaining the existing structure of the fisheries.

Fishing possibilities in Estonia are fully utilised. If price of the fishes is not growing, then also the value generated by the fishing sector cannot grow. In aquaculture, however, maximum possible value can be tens of times higher and therefore the employment in aquaculture can rise remarkably. Recent technical improvements facilitate farming even in such natural conditions, which are not ideal. EU trade barriers can improve profitability, especially in Estonia where the main reared species is rainbow trout, which competes at the market with Norwegian salmon (before the EU accession salmon had free entrance into Estonia).

As mentioned, the importance of the fisheries sector becomes clearer when analysed at lower regional level or at the local level. This is especially relevant to the new Baltic member states. For one thing, three old Soviet republics are small in size, which means that there are no big remote regions strongly dependent on fishery situated far from the main urban centres as e.g. in Norway. Secondly, only Estonia has islands. Latvia, Lithuania and Poland are without islands, which mean that fishery is carried out only from the mainland. In mainland counties there might be only some municipalities depending on fisheries whereas NUTS3 level statistics is not reflecting such dependence or territorial impacts of CFP. However, the general decline in employment as well as share in GDP does not give much ground for optimism.

In conclusion, there is not much data existing, which can in detail reflect the territorial impacts of CFP in Estonia until today. Also, the statistics as it is gathered now in Estonia or in the other Baltic member states is not enabling to follow this development in a very detailed manner. Therefore, there is a need to gather relevant data by key indicators using all possible sources, not only the statistics available on national or EU level.

Annex 14

EU initiatives on ICZM

Chapter 4 (WP5)

The EU ICZM Demonstration Programme

The Demonstration Programme, running from 1996 to 1999, is based upon 35 local and regional projects to demonstrate the application of ICZM. Six cross cutting thematic studies have also been achieved, based primarily on the demonstration projects. The results from these projects are compiled in the document “Towards a European Integrated Coastal Zone Management (ICZM) Strategy – General principles and Policy Options” (European Commission 1999¹³⁷). In the executive summary of this report, the results “confirm the hypothesis that the continued degradation and mismanagement of many of Europe’s coastal areas can be traced to problems related to:

- Insufficient or inappropriate information, both about the state of the coastal zones and also about the impact of human activities
- Insufficient coordination between different levels and sectors of administration, and their policies
- Insufficient participation and consultation of the relevant stakeholders”

As the areas of work where for the most part on a scale corresponding to local and regional competence, these were supplemented by Interreg IIC programmes. Each of the projects has studied the operation of integrated management and cooperation procedures. The projects follow the conventional pattern of description, analysis, planning and implementation.

Baltic Sea Region

This programme concerns 8 countries, some twenty regions, a population of 70 million and an area of around a million km². It covers the coastal zones of the Baltic, as well as a number of large cities in the hinterland. The project for the *southern part of Finland*, the focus was to prepare for efficient land use plans for the 7 municipalities involved. One characteristic of the Finnish project was the promulgation of the law on nature conservation which requires land use plans for the coastal strip. Implementation of existing regional plan is also a part of the project, where environmental impacts assessment and broad participation should be a part of the planning practice. The project proposes that integrated planning should take place at the regional and local level. *The Latvian and Lithuanian coasts* in the project are primarily rural and forested. In both countries it has been taking time to establish and put into operation the new administrative structures to deal with ICZM. In Latvia the government decided in 1990 to establish a 600 metre-wide protection belt (300 m of land and 300 m offshore) to protect the natural and recreational resources, which has to be integrated into land use plan for the various levels (national, regional and local). One important issue in both countries was the contribution to the implementation of the Baltic Sea environmental programme to ensure the ecological restoration and the preservation of its ecological balance. In *Storsørom County*, which is a part of the Southern Danish archipelago, the focus was on sustainable tourism. This is seen as the key to the regions future

¹³⁷ The document has been compiled by the Demonstration Programme’s team of thematic experts, and it was intended to stimulate a broad debate.

prosperity, helping to compensate for declining employment in fishing, agriculture, industry and – to some extent – shipping.

North Sea Region

The Interreg IIC programme for the North Sea region concerns of 6 countries, some 20 regions, a population of 36 million and land area of around 390 000 km². One of the areas in the programme, *the Wadden Sea*, covers almost 10 000 km² along the Danish, German and Dutch coasts, corresponding to the regions of Ribe, Sønderjyllands, Schleswig-Holstein, Groningen, Friesland and Noord-Holland. It is the largest wetland of importance for nature conservation in the EU. The resident population is relatively low, but increases considerably in the high season with tourists, who make a substantial contribution to the regional economy. The national authorities of the 3 countries have been cooperating actively since 1978 on the protection. The project aimed to contribute to develop interregional cooperation and public involvement, and address the promotion of environmentally-friendly tourism to create jobs and generate local income. Also *Norcoast*, which had focus on good practice in ICZM and involved a coastal region in Norway, Denmark, Sweden, Germany, the Netherlands, England and Scotland respectively (see chapter x).

The Forth Estuary in UK is 100 km long and has a catchment of 4500 km². It supports 5 bird populations of European importance for nature conservation. At the same, 1, 25 million people live around its perimeter and the area is heavily urbanised and industrialised. To encourage partnership management that takes as much account as possible of the different interests involved, the Forth Estuary Forum was established in 1993. One important focus for the project was assessment of the effectiveness for this non-statutory voluntary partnership approach in developing integrated management of a large estuarine area.

A pilot experiment for implementing coastal management plans was conducted in 18 municipalities on the *northern coast of Norway*. The aim for the project was to learn from the experience of local management, particularly as regards use and protection of the coastal and marine zones. As the project advanced, a disagreement between the authorities responsible for the environment and those responsible for fisheries and aquaculture caused many problems for the local planning processes. The problem would have, in their opinion, been considerably less serious if there had been prior agreement between the relevant authorities at national level. The experiment demonstrated the need for consultations between local, regional and national interests at an early stage of the planning process (see also the Norwegian example studies on local and regional coastal zone planning in chapter x).

North West Europe Metropolitan Region

The programme concerns 7 countries, some 40 regions, a population of 137 million and a land area of about 610 000 km². The coasts of the English Channel and the southern North Sea are interesting for nature and recreation, industrial and port activities, and intense maritime, road and railway traffic. This transnational area faces the difficulty of preserving landscapes and natural environments. In *the Belgian coast* is entirely situated in the Flemish region. Approx. 2/3 of this coast is erosive. The most important dune- and salt marsh-areas along the Flemish coast are formally designated in terms of nature conservation or scenic interests. The main pressures are general urbanisation, recreation, intensification of fishery and agriculture, etc. Action is being taken to overcome these pressures, as removing camping sites from sensitive dune areas, restricting further urban development, etc. An important effort made by the federal Belgian and regional Flemish environment administrations, together with the most important NGO's, for the restoration and management of the remaining coastal natural habitats. *Côte d'Opale* in the French coast have established an association of 243 municipalities and a lot of regional and national authorities. The area has 3 harbour towns, dense maritime traffic and highly valuable natural assets. The authorities of the project wish to repair the environmental damage of certain hasty sectoral developments carried out in the 1960-70s and before. One of the results anticipated was preparation of an ICZM plan for the area, reflecting the principles and criteria of sustainable development. In UK, the programme involved 3 projects about integrated management; 1) *the Kent coast*, 2) *Isle of Wight*, 3) *Dorset Coast*.

Atlantic Area

This programme concerns 4 countries and some 30 regions. *Irish Dunes* in the Northern Ireland involved a dozen coastal dunes sites in the Counties of Down (UK) and Donegal (IRL). In recent years, tourism and rural development have increased pressure on these sites. One of the tasks is to develop management plan for

each site. For *the Bantry Bay* in Ireland the aim is to develop a consensus based integrated coastal zone management strategy. The bay is an area of outstanding scenic landscapes, housing Ireland's state oil transshipment terminal, one of the largest fishing ports in Ireland, the highest density of aquaculture units and one of our busiest tourist areas. The coast of *Devon and Cornwall* is the UK's major tourist destination, and is regarded as one of the finest coastlines in Europe. There are a number of plans and actions for this area, and the task is to bring these together into a single coherent framework. There are 2 regions in France, *Bay of Brest* and *Arcachon*. In Portugal 3 projects are involved; *The Lima valley* in the north, *Aveiro* and the coast of *Algarve* in the south. Tourism is a major concern in these regions, particular Aveiro and Algarve.

The Mediterranean

The Mediterranean region consists of two programmes; The Mediterranean and the French and Italian Alps, and central and eastern Mediterranean. For the first, the web-page gives information about *La Costera-Canal* and *Barcelona* in Spain and *the Gulf of Naples* and the *Abruzzi Coast* in Italy. For the central and eastern Mediterranean, Italy and Greece with together 10 regions are involved. In La Costera-Canal the project aims to face environmental problems due to intensive development of human activities in the coastal zone and secondly to demographic and economic desertification inland. These processes lead directly to the loss of ecosystems, reduction of natural species, surface and underground water pollution, forest fires and erosion. The project aims to solve these problems through comprehensive land use planning based on the principles of economic and social cohesion and sustainable development. The Gulf of Naples is an urban centre where all the activities and problems that can exist in coastal zones are concentrated: congestion, industrial decline, intensive tourism, pollution, abandonment and deterioration of the natural and cultural heritage, potential with jobs and wealth. The objective is to implement a "cohesion plan" for the Naples coast, as part of the "Territorial Coordination Plan (which is the most important planning document for the metropolitan area). The aim is to draw up the Plan following the procedure and regulations governing cooperation between public and private operators, with a view to harmonising the public bodies' territorial programmes and sectoral strategies, and at the same time encouraging all private projects to adopt policies of sustainable development.

For the central and eastern Mediterranean, *Palermo* and *Taranto* are the Italian regions, and *Attica*, *Ipiros*, *Cyclades*, *Magnesia*, *Strymonikos* and *Kavala* are the Greece regions. In the Attical region the project aims to establish a balance between the protection of the natural areas and archaeological sites and the introduction of moderate leisure activities or tourist activities. In the Cyclades archipelago, tourism is growing very fast and affecting both the natural and build-up environments. The project intends to promote cooperation between the various island communities on matters of immediate concern, as water resources, energy, waste management, regional and environmental planning, conservation of nature and the countryside. For the Prefecture of Magnesia, the coastal zone is subject to pressure from tourism, urbanisation, agriculture and transport. The aim of this project is a consist approach to physical planning economic development projects. In the Stymonikos Gulf, which is rich in natural resources, landscapes and cultural features, the pressures is from tourism, fisheries, aquaculture, forestry and mining. Pollution and environmental damage have increased in recent years and tourism is expected to grow. Authorities are therefore aware of the need for forward planning and implementation of sustainable principles.

General experiences and recommendations from the programme

The general recommendations from the programme were adopted by Council and Parliament on 30 May 2002. The programme was aimed at applying the principles of subsidiarity and integration, which underlie European environment and regional planning activities. Seven key principles were identified by the programme in order to improve the status for European coastal zones (European Commission 1999):¹³⁸

- Take a wide-ranging perspective (both thematic and geographic, i.e. an ecosystem approach and include both the seaward and landward portions of the coastal zone)
- Building on an understanding of specific conditions in the area of interest (which implies a need for collection of appropriate data, production of relevant information and indicators and good flows of information)

¹³⁸ European Commission (1999): Towards a European Integrated Coastal Zone Management (ICZM) Strategy: General Principles and Policy Options.

- Work with natural processes, and not against them
- Ensure that decisions taken today do not foreclose options for the future (which must be secured by sufficiently flexible management, and at the same time take the precautionary principle into account)
- Use participatory planning to develop consensus (the idea is that early involvement builds commitment and shared responsibility, harden local knowledge, helps to ensure identification of real issues and tends to lead to more implementable solutions. Further, it may reduce conflicts and develop consensus).
- Ensure the support and involvement of all relevant administrative bodies (almost all of the Demonstration Programme projects leaders have affirmed that coastal zone management is not effective if it is not supported by all levels of administration, as well as by all the relevant sectoral branches of administration concerned with the target coastal area).
- Use a combination of instruments (including a mix of law, economic instruments, voluntary agreements, information provision, technological solutions, research and education).

The Demonstration Programme point out that the regional level of government, where it exist, has a key role to play in integrated planning and management of the coastal zone. This level of government is still closely aware of the specific context on the ground, but has a broad enough remit to take a strategic outlook.¹³⁹ From the early 1990s there has been an increasing focus on the regional level concerning management and planning for the public sector, and EU has been a pusher in that direction (Albrechts et al. 2003)¹⁴⁰. However, still it is a lot of differences among the European countries concerning the strength on regional management and planning (European Commission 1997)¹⁴¹. The fishery policy is on the other side highly centralised with a low degree of regional control over fisheries management. According to European Commission (2000), the EU fisheries policy is one of the EU policies that are least adaptable to regional needs, but there is a pressure for a greater regionalisation also within this sector. One of the suggestions in Lessons from the Demonstration Programme is to integrate the FIFG allocations with other structural policies with a socio-economic cohesion perspective.

ICZM projects in Interreg III

In the Second and Third Interim reports we listed the most relevant ICZM projects in Interreg III. These projects are not complete before the end of 2006, and therefore it is too early to conclude regarding to experiences and recommendations.

*Forum Skagerak II*¹⁴²

The aim is to widen the knowledge of and deliver concrete actions for a cleaner and more attractive sea and coasts. The project work involves governmental and regional organisations as well as other interested parties. The project includes work in six areas: 1) Eutrophication, 2) Hazardous substances, marine litter and oil spills, 3) Fish and shellfish issues, 4) Integrated coastal zone management and planning, 5) Coordinated environmental monitoring and 6) Mapping for increased knowledge on sensitive deep sea beds. The work in the area of integrated coastal zone management and planning intends to:

- create “marine plans” for a well structured spatial development of the sea areas
- downsize the outcome from the Norcoast project and implement best practice guidelines to Skagerrak and its coastal zone
- Describe and suggest concrete improvements in the “Common rights to access” in the coastal zone
- Participate actively from the regional level in the ongoing international and national work to identify marine protected areas in the Skagerrak
- Spreading knowledge about the high and unique values of the sea and the coastal zone to management, planning actors and the public

Integrated Coastal Zone Development in the Baltic Sea Region – BALTCOAST¹⁴³

The project includes both off-shore and land-side coastal areas; deals with all types of coastal areas, e.g. intensive tourism areas, urban expansion areas, infrastructure development etc. The project is divided into five work packages: 1) Coordinated economic use of water areas through extensions of spatial planning to off-shore regions, 2) Conflict management between economic activities and nature protection in lagoon and wetland areas, 3) Conflict management between urban expansion and nature protection, 4) Preparation of measures for regional development in wider coastal areas and 5) Common recommendations for ICZM.

After more than two years of project implementation, the Interreg III B BaltCoast project has reached such a stage that it was possible to start with the development of common recommendations for the following two major project components: “Expansion of Spatial Planning into offshore water areas“ and “The role of Spatial Planning within ICZM“. The recommendations at a glance are formulated in the following way:¹⁴⁴

- A. Use the strengths of spatial planning for cross-sector co-ordination in offshore development
 - A.1 Prepare spatial plans for offshore areas
The aim: More effective and transparent co-ordination of different use interests; no transfer of unsolved onshore problems to offshore; sea area reservation for unknown future needs.
 - A.2 Base new offshore projects - their location, dimension, technical character - on a systematic cross-sector impact assessment
The aim: Comprehensive balancing of interests with sufficiently detailed consideration of all relevant impacts - environmental, social and economical.
- B. Introduce adequate tools and methods for spatial use coordination in offshore areas
 - B.1 Improve the availability and accessibility of mapped information
The aim: A GIS-based fact-bank on offshore uses with secured updating routines and easy access across borders.
 - B.2 Define basic national policies for offshore development which are coordinated cross-sectorally
The aim: Strategic offshore development guidelines and prioritisation rules for use conflicts.
 - B.3 Improve the effectiveness of cross-border consultation for offshore development plans and projects
The aim: Effective cross-border consultation with clear contact points and consultation procedures and complete, reliable, easy-to-obtain information across borders.
 - B.4 Prepare indicative guidelines for content and procedures of offshore spatial planning
The aim: A tool box for countries wishing to introduce spatial planning for offshore areas; harmonised standards for spatial plans which facilitate cross-border concertation.
 - B.5 Apply ICZM principles in the offshore planning
The aim: Observance of ICZM principles in the offshore spatial planning process.
 - B.6 Ensure wide involvement of stakeholders in planning for offshore development
The aim: Adequate involvement of offshore and onshore stakeholders at all stages of spatial planning. Complete, reliable, easy-to-obtain information across borders
- C. Maintain the transnational discussion and development process
 - C.1 Continued dialogue with international bodies (Helcom, Baltic 21, VASAB and EU Commission) on principles for offshore spatial planning
The aim: Coherent offshore development principles; accelerated implementation of recommendations A to C.
 - C.2 Consultation with the EU EU regarding recommendation on ICZM, EIA and SEA Directive
The aim: a high degree of synchronisation of different organisations' approaches in overlapping themes.
 - C.3 Develop transnationally concerted plans for offshore infrastructure corridors
The aim: Coherent vision of transnational corridors for international shipping and utility networks (pipelines, cables)
 - C.4 Promote transnational research and pilot projects

¹⁴³ <http://www.baltcoast.org/>

¹⁴⁴ http://www.baltcoast.org/Main/News/Recommendations_BaltCoast/recommendations_baltcoat.html

The aim: Enhanced knowledge on present and future use demands and their potential impacts.

C.5 Promote experience exchange with other regions

The aim: Broad knowledge exchange.

Integrated Coastal zone management: towards an Atlantic Vision¹⁴⁵

The transnational Atlantic Area is made up of regions (mainly NUTS 2) in Spain, France, Ireland, Portugal and the UK. The project aims to stimulate the sustainable development of the coastal zone of the Atlantic Area from an environmental, social and economic point of view, by encouraging integrated regional development implementation and management. Given the fact that there is not a homogenous perception of this territory, the project intends to make recommendations to create a common vision based on ICZM. The partners will test together the implementation of ICZM, particularly in the context of spatial planning and achieving sustainable development. The results from the project will contribute towards the development of National Strategies on ICZM. A range of transnational challenges are addressed: a) Coastal access, b) Cultural heritage, c) Natural and environmental heritage, d) Inter-dependency between rural and urban environments, e) GIS and f) Stakeholder involvement. In particular, the expected results of the project are:

- Better knowledge and awareness of the problems affecting the Atlantic Coast and the development of spatial planning and management tools available at different levels
- Better knowledge and awareness of the elements that constitute the natural, environmental and cultural heritage of the Atlantic Area, the relationship between them and acknowledgement of this heritage at the local and wider regional and EU level
- More sustainable spatial planning and delivery of access to different coastal locations
- Improving the environmental conditions of certain areas
- Enhancing coordination between the different stakeholders and among the different administrative levels
- Better understanding of the dynamics of rural communities and urban developments on the coast
- Identification of potential of coastal resources and development of sustainable uses

Integrated Coastal Zone Management in the southern North Sea¹⁴⁶

The aim of the project is to encourage greater participation in joint policy formulation and harmonising informational resources, in order to improve common understanding and provide more effective tools for decision-makers. The project embodies the concept of trans-nationality by bringing together all the relevant regional authorities to find innovative solutions to common maritime problems, recognising the fact that the sustainability of coastlines in the lower North Sea depends on coordinated approaches between all parties directly concerned.

The partnership was formed to help manage the issues affecting the coastlines and communities bordering the Southern North Sea Area. The partnership has representatives from the regions Essex, Kent, Nord-Pas de Calais, West Flanders and Zeeland, and has developed a series of local projects that form an ICZM approach to the issues that impact across the regions. The Final Report of stage one of the project concluded that there were a number of structural, administrative, procedural and informational deficits which together contribute to the polarisation of relatively deprived coastal communities vis-a-vis the prosperous hinterland, and to the continuing degradation of the natural environment in the coastal zone bordering the Southern North Sea. The visions for the project are:

A place where we work with nature rather than against it, where natural and cultural diversity is enhanced and celebrated and where residents and visitors alike can enjoy clean beaches and unpolluted waters, outstanding recreational opportunities and vibrant, prosperous coastal communities.

- Beaches and bathing waters free from human effluent, litter and oil
- A prosperous inshore fishing industry which does not threaten the viability of fish and shellfish populations
- A dynamic and sustainable maritime economy based on local resources

¹⁴⁵ <http://www.coastatlantic.org/>

¹⁴⁶ <http://www.sailcoast.org>

- Degraded coastal and marine habitats restored and new ones created
- Access for all to a wide range of recreational opportunities
- 'best of class' facilities for holiday makers and tourists
- efficient transport networks which give priority to pedestrians, cyclists and public transport

Water management in the coastal zone (CYCLEAU)¹⁴⁷

The project has partners from Ireland, France and UK. Their aim is to develop a common, transferable and integrated approach to planning and management of natural water resources in the coastal zone by looking at the whole catchment area. The project partners will carry out a number of pilot test actions and small investments at demonstration sites to explore new ways of managing and planning, ranging from implementing new techniques for water de-contamination, dredging and dealing with sedimentation, to securing the participation of farmers in addressing diffuse pollution, and developing a technical resource centre.

The Cycleau project aims to:

- Develop models of best practice for the environmental management of coastal/ estuary catchments in selected areas of England, Ireland and France.
- Provide transferable and adaptable ways of dealing with common yet complex coastal environmental problems.
- Provide demonstration sites of monitored catchment management for adoption elsewhere
- Compare, develop and implement different techniques for raising public awareness and involvement. Contribute to territorial planning of regional development.
- Eradicate or reduce diffuse pollution problems in river basins.

AquaReg

The only ICZM-related project in Interreg IIIC is AquaReg¹⁴⁸ (Aquaculture and other coastal economic activities: towards the consensus and the agreement in coastal zone management). AquaReg is a co-operation between the regions of Galicia in Spain represented by the CETMAR Foundation, Border, Midland and Western (BMW) in Ireland represented by The Marine Institute and Trøndelag in Norway represented by joint forces of the South Trøndelag and North Trøndelag counties. The overall objective of AquaReg is to provide opportunities and design strategies for sustainable development of peripheral coastal communities by promotion of interregional co-operation in aquaculture and fisheries.

The rationale behind AquaReg is to make more efficient use of the experience and knowledge of aquaculturists, fishermen and scientists, across regional and national borders. All three regions have strong marine research environments, which reflect the regional resource base and industrial traditions. The AquaReg approach and ambition is concrete co-operation at operational level, involving marine industries, marine researchers, marine schools and coastal zone planners in RFO-internal projects. These groups have also been involved in goal definition in regional RFO-partnerships. Target groups are local and regional coastal zone planners, aquaculture/fishing management authorities, researchers, and representatives from the aquaculture and fishing industries.

AquaReg aims at improving the quality of life in the coastal communities by: 1) Contribute to a coherent and sustainable development in aquaculture and fisheries in the regions.

2) Promote innovative actions and business development in the relevant marine industries

3) Increase employment in the marine sector. The interregional partnership has outlined three strategies for achieving the objectives of AquaReg:

- **AquaLink:** Linking aquaculture/fisheries business and research.
- **AquaEd:** Education and training.
- **AquaPlan:** Coastal zone planning and management.

¹⁴⁷ <http://www.cycleau.com>

¹⁴⁸ <http://www.aquareg.com/AquaReg/AquaWeb.nsf/Firstpage?OpenForm&L=E>

AquaPlan comprises exchange of experience and best practice between planning authorities at local and regional level, to achieve positive interactions amongst coastline users. Exchange of experiences and best practice between groups who have put in place plans to enhance the local fishery resources, such as bay closures, stock enhancements and integrate local developments of fishery and aquaculture activities, assigning the specific aquaculture activities to the best available locations, are critical to the maintenance of coastal communities in the future. There is a strong need for knowledge about nutrition, wave measurement, temperature, salinity, algae production, pollution etc. AquaReg will also focus on restocking and recovery of marine species. The development of aquaculture and fisheries must take other interests into consideration; the environment, traditional fisheries, other industry, tourism and recreation. It is a main objective of AquaPlan to create a basis for a biological and commercially sustainable industry. Possible AquaPlan activities are:

- 1) Delimiting of zones that are adequate for carrying out the different activities and the identification of compatible uses and activities. Determination of areas suitable for developing aquaculture and polyculture
- 2) Development of methodology and exchange of best practise regarding restocking and recovery of marine species.
- 3) The application of norms in coastal areas, with special reference to those regulating aquaculture.
- 4) Exchange of information for establishing databases on the coastal zones and establishing database maps of coastal areas. Including computerised decision tools on the basis of data based maps, numerical simulations and measurements of waves, current, temperature, salinity, algae, pollution, and optimise use of areas for sustainable aquaculture development.

Annex 16

Dissimilarity, specialisation and concentration indexes

Chapter 6 (WP4)

Indexes used in the specialisation and concentration analysis are of three types:

- 1) dissimilarity index (IDS);
- 2) specialisation index (ISP);
- 3) concentration index (ICO).

IDS satisfies the need to assess the similarity of a given phenomenon observed in a set **I** of n elements. The dissimilarity index used in the present analysis is based on composition ratios which define the localization coefficients. The latter give the possibility to make a comparison between the percentage of vessels, for each enrolment office (or another administrative area), having the license for a certain type of fishing gear and the whole set of elements (in this case, the enrolment offices considered as a whole). Thus, the IDS is defined as follows:

$$IDS = \frac{1}{2} \sum_{a=1}^h \left| \frac{B_{au}}{\sum_{a=1}^h B_{au}} - \frac{\sum_{u=1}^s B_{ua}}{\sum_{a=1}^h \sum_{u=1}^s B_{au}} \right|$$

where:

B_{au} = number of vessels having gear a in the enrollment office u

$\sum_{a=1}^h B_{au}$ = total number of vessels in the enrollment office u

$\sum_{u=1}^s B_{ua}$ = total number of vessels having gear a for all the enrollment offices

$\sum_{a=1}^h \sum_{u=1}^s B_{ua}$ = total number of vessels for all the enrollment offices

On the other hand, the ISP is based on a matrix whose data are order so to have the enrolment offices in rows and gears in columns.

$$M_1 = \begin{bmatrix} B_{11} & B_{1a} & B_{1h} \\ B_{u1} & B_{ua} & B_{uh} \\ B_{s1} & B_{sa} & B_{sh} \end{bmatrix},$$

where the generic element B_{ua} represents the number of vessels in the enrolment office u having the fishing gear a . Moreover, given that:

$$q_x = \frac{B_{ua}}{\sum_{a=1}^h B_{ua}}, \text{ and } q_y = \frac{\sum_{u=1}^s B_{ua}}{\sum_{u=1}^s \sum_{a=1}^h B_{ua}}$$

we obtain another matrix, M_2 defined as follow:

$$M_2 = \begin{bmatrix} ISP_{11} & ISP_{1a} & ISP_{1h} \\ ISP_{u1} & ISP_{ua} & ISP_{uh} \\ ISP_{s1} & ISP_{sa} & ISP_{sh} \end{bmatrix},$$

where the generic element ISP_{ua} represents the specialisation index of the enrolment office u for the fishing gear a . This is because:

q_x = the share of vessels having the license for fishing gear a on total vessels enrolled in the office u .

q_y = the share of vessels having the license for fishing gear a on total vessels.

Thus, the specialisation index is defined as follow:

$$ISP = \frac{q_x - q_y}{(1 - q_y)q_x + (1 - q_x)q_y}.$$

The concentration index is obtained by the same procedure used for the specialisation index but the matrix M_2 must be read not by rows but by columns. Thus, the generic element ICO_{ua} represents the concentration index of the fishing gear a for the enrolment office u . Moreover, the meaning of q_x and q_y is different as follow:

q_x = the share of vessels having the license for fishing gear a in the enrolment office u on total vessels having this fishing gear;

q_y = the share of vessels enrolled in the office u on total vessels.

As a consequence, the concentration index is defined as follow:

$$ICO = \frac{q_x - q_y}{(1 - q_y)q_x + (1 - q_x)q_y}.$$

Missing data

The following matrixes provide details over what kind data WP3 sought from different countries. The “:” indicates that data for some reason was not available within the conditions and restrictions of the 2.1.5 project.

Table3: Matrix of data obtained for Belgium, Bulgaria, Cyprus, Denmark, Estonia, Finland, France, Germany and Greece.

Indicator	Belgium	Bulgaria	Cyprus	Denmark *	Estonia	Finland	France	Germany **	Greece
Fishery employment	NUTS 1 1996-1997, 1997-2000	NUTS 1 1991-2003	:	NUTS 1 NUTS 3 2000-2003	NUTS 2 1993-1998 1998-2000	NUTS 1 1980-2004	NUTS 1 1996/97 2001, 2002	NUTS 2 1996, 1997	NUTS 1 1990-2003

Annual household consumption	:	:	:	:	NUTS 3 1996-2004	:	:	:	NUTS 2 1990-2004

* Denmark:

- Data on age structure in the fishery industry can be obtained from Statistics Denmark, but for a fee. With the limited funding of project 2.1.5, we have chosen to channel funds to prioritise analyses of the data available.
- There is no information on unemployment in fisheries, aquaculture, or the fishery industry; the data can possibly be created through different registers but only rough estimates and for a fee.
- Data on distribution of income (median, upper and lower quartiles) exists on NUTS3 level. Longer time series, with upper and lower 20 per cent, can be provided by Statistics Denmark, but for a fee.
- Data on household consumption cannot be obtained on NUTS3 level in Denmark. The sample used to estimate consumption is not big enough to break down to regional level.

** Germany:

- According to the contact person in Regionalstatistiken im Statistischen Bundesamt (e-mail on 25th of November 2005), more data *may* be available, however, the contact person is waiting for response from other institutions, such as the Bundesforschungsanstalt für Fischerei in Hamburg.
- Fisheries related data in Germany is often merged with data on agriculture, since the fisheries comprise a relatively modest activity in Germany. Some data are published in reports in the form of time-series. In order to get access to these time-series, we have to buy a collection of publications, and then search for relevant information here within. This is both too costly and too time-consuming within the frames of project 2.1.5.

Table 4: Matrix of data obtained for Iceland, Ireland, Italy, Latvia, Lithuania, Malta, Netherlands, Norway and Poland.

*** Ireland: For Ireland, it is possible to get regionalised statistics on aquaculture employment. We are waiting for data, and will elaborate on Ireland for the final report of project 2.1.5.

**** Norway: The institution “Garantikassen for fiskere” has been approached several times, as they have data on unemployment in the fisheries. The institution confirms that it can generate the data, and that it will do it, but has failed to do so. WP3 assumes that the

data needed for unemployment purposes have been provided by Arbeidsmarkedsstaten. Anyway, “Garantikassen for fiskere” is a future source of information for ESPON in case of initiation of a data collection regime as suggested by WP3 introductorily.

Table 7.5: Matrix of data obtained from Portugal, Romania, Slovenia, Spain, Sweden and Scotland.

Indicator	Portugal	Romania	Slovenia	Spain	Sweden *****	UK (Scotland) *****

Distribution of income	:	NUTS 1 2000-2002	:	:	:	:
Annual household consumption	:	:	:	NUTS 2 1995-2002	:	:

***** Sweden: After repetitively being in contact with Fiskeriverket in Sweden, the message is that apparently, there is no data on NUTS 2 level (e-mail 16th of November 2005), apart from what was found in the ESPON data base.

***** UK: There is fisheries employment data for England and Wales at NUTS 1 level for 2004. According to the contact person in the Marine Fisheries Agency in London (e-mail on 7th of December 2005), the figures can be broken down into finer levels, however, accuracy will then be compromised. This is due to the data being compiled from the results of a stratified sampling survey.

Annex 21

Glossary

Active Population - <i>População Activa</i>	Group of individuals with specified minimum age which, in the period under review, constitute the available labour work for the production of goods and services that get in the economic circuit (employed and unemployed). www.ine.pt
Analysis of variance (ANOVA)	A statistical procedure for analyzing experimental data (http://stats.oecd.org/glossary/)
Aquaculture Establishment - Aquaculture	The controlled cultivation and harvest of aquatic plants or animals (eg, edible marine algae, clams, oysters, and salmon). (www.streamnet.org/pub-ed/ff/Glossary/glossaryfish.html)
Artisanal	Term used to describe small-scale, traditional fisheries. (www.fishonline.org/information/glossary/)
Average	“Average” value purports to represent or to summarise the relevant features of a set of values; and in this sense the term would include the median and the mode. In a more limited sense an average compounds all the values of the set, e.g. in the case of the arithmetic or geometric means. In ordinary usage “the average” is often understood to refer to the arithmetic mean. (http://stats.oecd.org/glossary/)
Baseline	The straight line in the sea between the outer islets and reefs.
Batea	The traditional mussel production method in Galicia is farming on <i>bateas</i> (platforms). In this system, the mussel seed is placed on ropes hanging from floating platforms located within the “ría”, where they remain completely submerged until its commercial weight is reached. The platform basically

Beam trawl	<p>consists of some floats which support a series of rectangular eucalyptus wood dunnage with a surface of no more than 500 m². The ropes used for mussel farming are normally from 19 to 12 m long. They are submerged into the sea with the seed on and hanging from the platform. The food for this filtering mollusc is the fragmented organic matter.</p> <p>In this type of trawl the mouth of the net is kept open by a beam which is mounted at each end on guides or skids which travel along the seabed.</p>
Biomass	<p>(www.fishonline.org/information/glossary/)</p> <p>The total weight of living organisms or total weight of a resource or stock.</p>
Catch	<p>(www.fishonline.org/information/glossary/)</p> <p>The volume of fish harvested over a certain amount of time or effort. (216.168.47.67/cis-fishnet/Crest/CRD.htm)</p>
Cluster Analysis	<p>A general approach to multivariate problems in which the aim is to see whether the individuals fall into groups or clusters. There are several methods of procedure; most depend on setting up a metric to define the “closeness” of individuals.</p>
Coast Fishery – <i>Pesca Costeira</i>	<p>(http://stats.oecd.org/glossary/)</p> <p>Occurs in well defined areas with boats with an overall length higher than 9 meters, motor’s tonnage higher than 35CV or 25KW and established autonomy according to the operational area predetermined for the ship.</p>
Coastal	<p>www.ine.pt</p> <p>The extractive fishing is made up by fishing units that are mostly dedicated to small-scale fishing in the “rías” and the coast.</p>
Correlation coefficient	<p>It is a measure of the degree to which two variables tend to move together. The coefficient has a value between plus and minus 1, which indicates the strength and direction of association.</p>
Demersal fish	<p>(http://stats.oecd.org/glossary/)</p> <p>Refers to fish such as cod, haddock and plaice which live primarily on or near the seabed.</p>
Discards	<p>(www.fishonline.org/information/glossary/)</p> <p>Fish and other organisms caught by fishing gear and then thrown back into the sea for legal, economic or other reasons.</p>
Ecosystem Approach to Fisheries	<p>(www.fishonline.org/information/glossary/)</p> <p>The ecosystem approach to fisheries management involves a consideration of all the physical, chemical and biological</p>

Effort measures	<p>variables within an ecosystem, taking account of their complex interactions. (www.fishonline.org/information/glossary/)</p> <p>Fisheries management measures involving restrictions on the amount of effort that may be expended in harvesting a fish stock (http://stats.oecd.org/glossary/)</p>
Engine power (kW)	<p>Mechanical force developed by the motive power installation in a vessel. This power should be measured in effective kilowatts (power transmitted to the propeller). (http://stats.oecd.org/glossary/)</p>
Estabelecimento de Aquicultura	<p>Unit where breeding of aquatic organisms is made, implying human intervention on the production process (restocking, feeding and protection against predators) and the existence of private or joint property of production outputs. www.ine.pt</p>
Eutrophication	<p>The enrichment of an ecosystem with chemical nutrients, typically compounds containing nitrogen, phosphorus, or both. (http://en.wikipedia.org/wiki/Eutrophication).</p>
Exclusive Economic Zone (EEZ)	<p>An area in which a coastal state has sovereign rights over all the economic resources of the sea, seabed and subsoil. (www.fishonline.org/information/glossary/)</p>
Fish Market - <i>Lota</i>	<p>On land, infra-structure, near by a fishing port or in a shore line area of influence, that integrates the place for marketing operations and other procedures which are inherent or complementary. www.ine.pt</p>
Fisheries employment volume - Fisheries Protected Zone	<p>An area in which a coastal state has sovereign rights over all the fisheries resources of the sea, seabed and subsoil.</p>
Fishing (harvesting) capacity	<p>It is the capacity of the fishing vessel or fleet of vessels to harvest fish, usually expressed in terms of some measure of vessel size, such as gross tonnage, hold capacity, or power.</p>
Fishing effort	<p>The amount of fishing gear of a specific type used over a given unit of time, e.g. hours trawled per day; the overall amount of fishing expressed in units of time e.g. number of hauls per boat per day. (www.fishonline.org/information/glossary/)</p>
Fishing	<p>Any activity that involves the catching, taking or harvesting of fish. (www.fishonline.org/information/glossary/)</p>
Gear	<p>Any tools used to catch fish, such as hook and line, trawls, traps etc. (www.fishonline.org/information/glossary/)</p>

Gill net	A loosely set and near invisible wall of fine netting (mono or multi-filament nylon) that traps fish by the gill covers (www.fishonline.org/information/glossary/)
Gran Sol	Great Sole (en), Grande Sole (fr)
Gross Register Tonnage	Represents the total internal volume of a vessel, ... 1 gross register ton is equal to a volume of 100 cubic feet (2.83 m ³). ...
Gross tonnage (GT)	It is a measurement of ship volume. With fishing vessels often used together with engine power (kW) as a measure of fishing capacity, especially since the London Convention took effect in 1994. The gross tonnage is a function of the moulded volume of all enclosed spaces of the ship. (http://stats.oecd.org/glossary/)
Gross value added	It is the value of output less the value of intermediate consumption; it is a measure of the contribution to GDP made by an individual producer, industry or sector; gross value added is the source from which the primary incomes of the SNA are generated and is therefore carried forward into the primary distribution of income account. (http://stats.oecd.org/glossary/)
Growth rate (Rates of change)	They are ratios of total change in a specified time reference period to values at the beginning of the period or at a specified earlier time reference. When changes over a period of more than one calendar year are studied, the mean annual rate of change may be computed. (http://stats.oecd.org/glossary/)
Individual Transferable Quota	A catch limit or quota allocated to an individual fisher, who then has a guaranteed share (which may be either harvested or traded) of the Total Allowable Catch of a particular resource species (King 1995). (www.lobsterconservation.com/glossary/)
Individual Vessel Quota	A catch limit or quota allocated to an individual vessel, which then has a guaranteed share (which may be either harvested or traded along with the vessel) of the Total Allowable Catch of a particular resource species.
Integrated coastal zone management	Developed general tool to coordinate different competing interests in the coastal zone, i.e. to integrate the marine and terrestrial environment.
Joint Ventures	A joint venture is an association of two or more entities that undertake an economic activity under their joint control to get individual benefits in the form of a share of

Landings	<p>the product rather than joint or collective profits..</p> <p>Landings of fish are the quantities of fish landed (caught and brought to land) by fishers. (www.reefed.edu.au/glossary/l.html)</p>
Licensed Fisherman – <i>Pescador Matriculado</i>	Professional working in fisheries for which it is licensed by a Port Authority or a Maritime Delegation. www.ine.pt
Local Fishery – <i>Pesca Local</i>	Carried out by boats for local fishing, in rivers, estuaries, backwaters and maritime edges where it beaches, anchors or lands. www.ine.pt
Mariculture	Cultivation of marine organisms for food , either in their "natural environment", or in seawater in ponds or raceways. An example of the latter is the farming of marine fish , prawns , or oysters in saltwater ponds. By definition, mariculture is a specialized branch of aquaculture .
Marine Protected Area	Any coastal or open ocean area in which certain uses are regulated to protect natural resources, biodiversity, or human livelihoods. The level of protection between MPAs varies considerably; most allow some extractive activities such as fishing, while prohibiting others such as drilling for oil or gas. (research.amnh.org/biodiversity/symposia/archives/seascapes/glossary.html)
Minor Gears	A very large number of minor fishing gear typologies are included in this group. The diversity depends on factors such as coastal resources, social traditions, market proximity, geographical configuration, etc. Drift nets and pelagic trawling are banned in Spain. Management is based on fishing effort control and technical measures. Each geographical area has its own census. Most of them are small vessels employing one or two people. Production is for internal market
Offshore Fishery – <i>Pesca do Largo</i>	Carried out in fishing boats with tonnage higher than 100 TAB and with the minimum of 15 days of autonomy. They can operate anywhere, except beyond 12 miles between the Portuguese coast line or the ranging of Roca, Espichel and Sines Capes. www.ine.pt
Overall	A term used to denote an estimate for a whole population, as distinct, for example, from one for a stratum or other sub-section of it. The expression is also used for an estimate derived from the whole of a sample instead

	of only from a part of it. (http://stats.oecd.org/glossary/)
Passive gears	Static or fixed gears refers to fishing gears that are fixed to or on the seabed e.g pots, traps or nets. These types of gears are passive as opposed to mobile gears, e.g. trawl nets, which are referred to as active gears. (www.fishonline.org/information/glossary/)
Pelagic	Refers to fish and animals that live in the open sea, away from the sea bottom. (www.ncfisheries.net/stocks/defso_r.htm)
Per capita	For each person. (http://stats.oecd.org/glossary/)
Percentage change	The change in an index [or other] series from one period to another expressed as a percentage of its value in the first of the two periods. . (http://stats.oecd.org/glossary/)
Pots	Traps, designed to catch fish or crustaceans, are in the form of cages or baskets various materials (wood, wicker, metal rods, wire netting, etc.) and have one or more openings or entrances. Usually set on the bottom, with or without bait, singly or in rows, connected by ropes (buoy-lines) to buoys on the surface showing their position made with. (www.fao.org/fi/glossary)
Precautionary approach	Application of a 'precautionary approach' to fisheries management " <i>means that the absence of adequate scientific information should not be used as a reason for postponing or failing to take management measures to conserve target species, associated or dependent species and non-target species and their environment</i> " (Council Regulation (EC) No 2371/2002, art. 3(i)).
Producer Organisation	Producers' Organisations are set up by fishermen or fish farmers associating freely to take measures in order to ensure the best marketing conditions for their products. They are strategically placed between production and market. Because of their key position, they can implement measures relating to rational resource management, add value to fisheries products and contribute to the stabilisation of the market. (http://europa.eu.int/comm/fisheries/news_cerner/doss_inf/info76_en.htm)
Productivity	It is commonly defined as a ratio of a volume measure of output to a volume measure of input use. (http://stats.oecd.org/glossary/)

Purchasing power parity (PPPs)	It is a price relative which measures the number of units of country B's currency that are needed in country B to purchase the same quantity of an individual good or service as 1 unit of country A's currency will purchase in country. (http://stats.oecd.org/glossary/)
Quota:	Amount of catch or harvest allocated in a time period by a governmental authority; could refer to a fishery as a whole; or to that amount allocated to an individual (individual quota) or company of the total allowable catch from a stock. Can be used also to allocate fishing effort or biomass. (http://filaman.ifm-geomar.de/larvalbase/Glossary)
Regional Advisory Council	The Regional Advisory Councils prepare recommendations and suggestions on fisheries aspects in the area they cover and transmit them to the Commission or to the relevant national authorities. Submissions may be in response to a request from these bodies or on the Regional Advisory Council's own initiative. The Regional Advisory Councils are made up of representatives of the fisheries sector and other groups affected by the CFP while scientists are invited to participate in the meetings of the Regional Advisory Councils as experts. The Commission and regional and national representatives of Member States may be present at the meetings as observers. (http://europa.eu.int/comm/fisheries/dialogue/rac_en.htm)
Regional Fisheries Organisation	Regional Fisheries Organisations are created by international agreements. They provide a framework within which the representatives of governments agree on ways of managing the fish resources of the open seas and overlapping stocks. They aim to strengthen regional co-operation as a way of guaranteeing both conservation and the sustainable exploitation of fish resources. These organisations issue recommendations on management and conservation measures based on the best scientific advice available. The recommendations must then be implemented by all the contracting parties. (http://europa.eu.int/comm/fisheries/doc_et_publ/factsheets/facts/en/pcp4_3.htm)
Resource rent	Resource rent is an economic term of abnormal or supernormal profit which derives from the exploitation of natural

Safe biological limit	<p>resources. en.wikipedia.org/wiki/Resource_rent</p> <p>The point where the indicators of the state of a stock predict a low risk of transgressing certain 'limit reference points', for instance values of biomass or fishing mortality rate, which are to be avoided (Council Regulation (EC) No 2371/2002, art. 3(j) and (l)).</p>
Scatter plot (diagram)	<p>www.fishonline.org/information/glossary/</p> <p>A diagram showing the joint variation of two variates x and y. each member is represented by a point whose coordinates on ordinary rectangular axes are the values of the variates which it bears. A set of n observations thus provides n points on the diagram and the scatter or clustering of the points exhibits the relationship between x and y.</p>
Shellfish fishing	<p>http://stats.oecd.org/glossary/</p> <p>An activity aimed at taking out bivalve molluscs from sandy bottoms (clams, cockles, razor clams...) and it is carried out by shellfishers on foot and with vessels. This is a traditionally undervalued activity which went through a deep transformation in recent years towards the professionalization of the sector, considered until now as a complement to the "family economy".</p>
Small Scale Fishing - <i>Pesca Artesanal</i>	<p>Traditional fishing characterized by small boats, typically <i>open boats</i>; carried out by one or two fishermen, hardly ever more; casual materials are often used; adapted to take place in restricted local areas. This sort of fishing includes local and coastal fishing in ships with less than 12m of overall length.</p>
Specialisation ratio	<p>www.ine.pt</p> <p>It measures the extent to which observations contained within a category are representatives of the population of those observations as a whole (e.g. in industry statistics, the specialisation ratio is the output by an industry of goods and services characteristic to that industry in proportion to its total output).</p>
Sport Fishing - <i>Pesca Desportiva</i>	<p>http://stats.oecd.org/glossary/</p> <p>Leisure activity, in which the catch cannot be commercialized. www.ine.pt</p>
Total Allowable Catch	<p>The total amount of fish allowed to be caught from a particular stock by all resource users over a particular period of time.</p> <p>www.mar.dfo-</p>

Towed or Mobile gears	mpo.gc.ca/communications/maritimes/Factsheets04E/GlossaryE.html Towed or encircling active fishing gears e.g. trawl, dredges or seine.
Trammel net	(www.fishonline.org/information/glossary/) Bottom-set net made with three walls of netting, the two outer walls being of a larger mesh size than the loosely hung inner netting panel. The fish get entangled in the inner small meshed wall after passing through the outer wall. Gillnets and Trammelnets can be combined. www.fao.org/fi/glossary
Unloaded Catch – <i>Pesca Descarregada</i>	Weight of the catch and fishing products unloaded. It represents the net weight at the moment of unloading the fish and other products related to fisheries (interior or gutted, sliced in fillets, frozen, cured/salted, etc...). www.ine.pt
Value added (Gross)	It is the value of output less the value of intermediate consumption; it is a measure of the contribution to GDP made by an individual producer, industry or sector; gross value added is the source from which the primary incomes of the SNA are generated and is therefore carried forward into the primary distribution of income account
<i>Volume de emprego da pesca</i>	Work on the manufacture of fishing products and non-fishing activities inseparable from the fishing productive units which compose the Branch. By definition, it can be divided into payed and non-payd, expressed in Full-time Equivalent Employment which corresponds to a person's fishing activity in a fisheries productive unit – measured in work time – carried out full-time and throughout the year. www.ine.pt

Annex 22

Performance indicators

No of spatial indicators developed:	
- in total	5
covering	
- the EU territory	5
- more than the EU territory	5
No of spatial indicators applied:	
- in total	42
covering	
- the EU territory	42
- more than the EU territory	42
No of sector policies fully addressed	1
No of EU maps produced	26
No of charts on the institutional structure of sector policies	1
No of policy aims mentioned in the ESDP addressed	All relevant
