Methods: Retrospective observational study of all renal patients who underwent parathyroidectomy under a single surgeon over 6 years (April 2008 to September 2014). Data was collected from the Electronic Patient Record. Data were analysed using Stats direct and Fisher Exact test was used for testing statistical significance.

Results: 72% of our sample ($n = 25$) were male with a mean age of 54. Of the 25 there were 13 transplant, 9 haemodialysis and 3 CKD patients. The mean hospital stay was 5 days shorter than quoted in the literature (5.6 Days). 3 of 25 patients were not preloaded. 40% of our patients needed intravenous calcium replacements which was the main cause for increased LOS ($p=0.0002$). Haemodialysis patients had longer LOS than CKD and Transplant patients ($p=0.0002$), this group were more likely to not have received pre-loading. Those undergoing total parathyroidectomy had increased LOS compared to subtotal parathyroidectomy ($p=0.0009$). There were no surgical complications contributing to a delay in discharge.

Conclusions: Insufficient preloading was identified as a major risk factor for hypocalcaemia, which significantly increased LOS. Further to consensus between renal and surgical teams we have increased the preloading dose of one-alpha-calcidol to 5 mcg for 5 days pre operatively. A follow up study is planned in 12 months to observe the outcome of this change.

PUB537

Links Between Urinary Phosphate Handling, FGF23 and Klotho: An Australian Single-Centre Cross-Sectional Study Sven-Jean Tan,^{1,2} Edward Robert Smith,¹ Stephen G. Holt,^{1,2} Tim Hewitson,^{1,2} Nigel David Toussaint,^{1,2} ¹Nephrology, The Royal Melbourne Hospital, Melbourne, Victoria, Australia; ²Medicine (RMH), The Univ of Melbourne, Melbourne, Victoria, Australia.

Background: Aim: To examine the links between measured phosphate parameters and regulators of phosphate homeostasis (fibroblast growth factor-23 [FGF23] and soluble α -klotho [sKl]). Background: FGF23, via the FGF-Receptor/Klotho complex, reduces expression of sodium-phosphate co-transporters thereby inhibiting tubular phosphate reabsorption. Chronic kidney disease (CKD) leads to FGF23 excess and deficiency of sKl. Elevated serum phosphate (sPi) results as remaining functioning nephrons are unable to compensate for reduction in total phosphate excretion. Complex relationships between these parameters in health and disease, and the impact on phosphate handling, are not fully understood.

Methods: Blood samples and spot and 24-hour urine were collected from patients with CKD (Stages 1-5) and healthy volunteers. Serum and urine biochemistry, intact FGF23 and sKl were analysed. FGF-23 and sKl were log-transformed (Ln). Fractional excretion of phosphate (FEPi) and maximal tubular phosphate reabsorption (TmP) were calculated. Pearson correlation coefficients were used to assess correlation between phosphate handling and regulatory hormones.

Results: 116 participants (77 CKD and 39 controls) were recruited. 74 (63.8%) were male. Median (IQR) age of all participants was 61 (49-71) years. FGF23 and FEPi were higher, while sKl and TmP were lower, in CKD compared to controls (all $p<0.005$). Adjusting for eGFR, LnFGF23 correlated with FEPi ($R=0.222$, $p=0.026$) and sPi ($R=0.268$, $p=0.007$) while LnKlotho displayed robust relationships with TmP ($R=0.336$, $p=0.001$) and sPi ($R=0.309$, $p=0.002$). There was no association between LnFGF23 and LnKlotho.

Conclusions: Disruption of phosphate regulatory mechanisms is characteristic of CKD. In this small cohort, we established that FGF23 contributes to phosphate excretion. However, sKl may provide insight into a greater physiological role of Klotho in regulating TmP at a cellular level. Causal relationships should be explored further *in vitro*.

PUB538

Fibroblast Growth Factor 23 Can Predict the Progress of Aortic Artery Calcification in Dialysis Patients Zijin Chen,¹ Xiaonong Chen,¹ Xiaobo Ma,¹ Bei Ding,² Huawei Ling,² Nan Chen.¹ ¹Nephrology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China; ²Radiology, Ruijin Hospital, Shanghai Jiaotong Univ School of Medicine, Shanghai, China.

Background: To investigate the factors associated with progress of aortic artery calcification in maintenance haemodialysis (MHD) patients and to determine whether plasma FGF23 level is related to progress of aortic artery calcification.

Methods: MHD patients from Ruijin Hospital from July 1st 2011 to July 31st 2011 were involved in our study. Follow up 36 months. Aortic artery calcification (AAC) was detected by a lateral lumbar X-ray plain and read by two radiologists.

Results: 120 MHD patients were enrolled and followed up for 36 months. To July 2014, a total of 67 MHD patients finished the study. Among 67 patients, 32 were male, mean age 53.9±13.1 years old, mean dialysis vintage 44.1±38.1 months, median FGF23 level 48052 (11372-35750.4)Ru/ml, LgFGF23 3.79±0.83. In July 2011, 53.7% of patients had visible calcification in the abdominal aorta and mean involved segment was 1.42 with mean AAC scores(AACS) 3.96. In July 2014, 73.1% had AAC and mean involved segment was 2.34 with mean AACS 10.7. There are significant differences between two AAC involved segments and AACS (both P<0.001). Age, dialysis vintage and FGF23 level had significant difference between AAC progress group and no AAC progress group (P = 0.007, <0.001 and 0.020, separately). Logistic analysis showed that the independent parameters associated with AAC progress were age (OR=1.114, CI:1.045-1.186) and Lg FGF23 (OR=3.848, CI:1.429-10.346) (P<0.001).

Conclusions: The severity of vascular calcification progress yearly in maintain haemodialysis patients. Age and FGF23 are independently associated with the progress of AAC. FGF23 level could predict the progress of AAC in MHD patients.

PUB539

Could FGF23 Be a Regulator of Hecpudin in Liver Cells? Justine Bacchetta, Nathalie Demoncheaux, David Durantel. Hospices Civils de Lyon and INSERM, Univ Claude Bernard Lyon 1, Lyon, France.

Background: Hecpudin is a 25-amino-acid protein synthesized in hepatocytes and macrophages that acts as a post-translational inhibitor of ferroportin, the only receptor known to export iron from intracellular compartments to systemic circulation. Thus, higher hecpudin levels are associated with greater intracellular sequestration of iron, and increased risk of anemia. Vitamin D is an inhibitor of hecpudin expression; the working hypothesis is that FGF23 could be an 'inverse' regulator of iron metabolism in comparison to vitamin D, with a stimulation of hecpudin expression, an increase of intracellular ferritin and an inhibition of ferroportin expression on the cell membrane, leading to a further intracellular sequestration of iron.

Methods: Three different types of liver cells were used: HepG2, HepaRG and primary human hepatocytes (PHH). Cells were exposed to FGF23 (1, 10 et 100ng/mL), at different time points (H6, H24, H48). Cultures were performed in triplicates, and QRT-PCR in duplicates (StepOne Plus Real-Time PCR). Western Blots were also performed (Erk and Akt phosphorylation pathways, FGFR1, FGFR3, ferritin).

Results: In HepG2, even though FGFR-1 expression was found by Western blot analysis, FGF23 did not modify hecpudin expression by QRT-PCR, and Erk/Akt pathways were not activated by FGF23. In HepaRG cells, hecpudin expression was modified with FGF23 by QRT-PCR, i.e. increased at 6 hours and decreased at 24 hours,

Fold change of hecpudin mRNA expression in comparison to PBS	FGF23, 1 ng/mL	FGF23, 10 ng/mL	FGF23, 100 ng/mL
6 hours	1.34±0.22 *	1.53±0.18 *	1.17±0.01*
24 hours	0.68±0.12 *	0.73±0.08*	0.90±0.04

* p<0.05; Western blot analyses demonstrated the presence of FGFR1 and FGFR3, with an activation of the Erk pathway at 30 and 60 minutes with FGF23. However, there was no modification of ferritin by Western blots analysis with FGF23. In the only batch of PHH that was available, hecpudin expression increased at 6 and 24 hours.

Conclusions: FGF23 does not appear to play a crucial role in iron regulation in liver cells, even though its potential role in PHH deserves further studies.

PUB540

Prevalence of Hyperparathyroidism and Its Correlates in a Large Cohort of Hemodialysis Patients Pasquale Esposito,¹ Fabio Malberti,² Elena Caramella,¹ Marta Calatroni,¹ Edoardo La Porta,¹ Marina Foramitti,² Rosanna Coppo,³ Antonio Dal Canton.¹ ¹Nephrology, Fondazione IRCCS, Pavia, Italy; ²Nephrology, Istituti Ospitalieri di Cremona, Cremona, Italy; ³Nephrology, Regina Margherita Children's Hospital, Turin, Italy.

Background: Beyond experimental setting of randomized trials, little is known about the occurrence of mineral bone disorders (MBD) in the real-life clinical practice of hemodialysis (HD). This is the reason why we designed this observational study to define the prevalence of hyperparathyroidism (HPT) and its correlates in a large cohort of HD patients.

Methods: We enrolled HD prevalent patients from 38 Dialysis Units collecting data on: clinical information, dialysis parameters, biochemical and instrumental evaluations and pharmacological therapy. According to the KDIGO guidelines we divided the patients in: patients affected by HPT (i.e. PTH> 9 the upper reference limit of each laboratory) vs patients on target.

Results: Out of 495 patients, 34 (6.8%- 59.9±15.5 years, 53%M) presented HPT with mean PTH of 1064±536 pg/ml, while 461 patients resulted OT (93.2%- 66.9±13.7 years, 66%M), mean PTH 242±151 pg/ml (p<0.0001). HPTs were younger than OT (59.9±15 vs 69.9±13.7 years, p=0.008), with a longer HD history (126.2±125 vs 64.3±69.4 months, p=0.0003). There were not significant differences in both clinical and dialysis parameters. Similarly, there were not differences in laboratory examination except from serum ALP that resulted higher in HPTs (194.8±142 vs 144.1±108 U/l OT, p=0.01). Moreover, there were not differences in the use of phosphate binders, whereas a significantly higher percentage of HPTs was taking paracalcitol and calcimetics and the prescribed vitamin D doses (both as calcitriol and paracalcitol) were significantly higher in HPT patients.

Conclusions: The prevalence of HPT in our population was surprisingly lower, compared to that reported in previous studies. This finding could be due to the general application of KDIGO guidelines, which recommend more permissive PTH levels compared with the previous K-DOQI guidelines, such as to the availability of effective drugs, probably used more appropriately than in the past.

PUB541

Effect of Vitamin D Receptor Activators on Glomerular Filtration Rate: A Meta-Analysis and Systematic Review Qian Zhang, Jing Chen. Div of Nephrology, Huashan Hospital, Fudan Univ, Shanghai, China.

Background: Vitamin D receptor activators (VDRAs) can protect against mineral bone disease, but they may also elevate serum creatinine and reduce glomerular filtration rate (GFR).

Methods: We conducted a systematic review and meta-analysis of randomized clinical trials (RCTs) to evaluate the effect of VDRAs on kidney function and adverse events. MEDLINE, EMBASE, the Cochrane Controlled Trials Register were searched for RCTs that evaluate vitamin D receptor activators (alfacalcidol, calcitriol, doxercalciferol, falecalcitriol, maxacalcitol and paricalcitol) up to March 2015.

Results: We included 31 studies, all of which were performed between 1976 and 2015, which enrolled 2621 patients. Patients receiving VDRAs had lower eGFR (weighted mean difference WMD -1.29 mL/min/1.73 m², 95% CI -2.42--0.17) and elevated serum creatinine (WMD 7.03 μmol/L, 95% CI 0.61-13.46) in sensitivity analysis excluding studies with dropout rate more than 30%. The VDRAs and control groups had no significant differences in all-cause mortality (relative risk RR 1.41, 95% CI 0.58-3.80), cardiovascular disease (RR 0.84, 95% CI 0.42-1.71), and severe adverse events (RR 1.15, 95% CI 0.75-1.77). Episodes of hypercalcemia (RR 3.29, 95% CI 2.02-5.38) were more common in the VDRAs group than in the control group.

Conclusions: Although administration of VDRAs slightly reduced the eGFR, all-cause mortality and severe adverse events were comparable between the groups. Future RCTs with larger sample sizes are needed to assess whether the mild reduction of eGFR is of clinical significance.

PUB542

Low Dose Cholecalciferol Supplementation on Serum Inflammatory Markers in Hemodialysis Patients with Hypovitaminosis D Yeon Joo Lee,¹ Insun Kim,¹ Eunyoung Lee,² Joo-Hark Yi,² Hee Joon Baek,³ Sang-Woong Han,² Sang sun Lee.¹ ¹*Food and Nutrition, Hanyang Univ, Seoul, Korea;* ²*Internal Medicine, Hanyang Univ Guri Hospital, Guri, Korea;* ³*Nutrition, Hanyang Univ Seoul Hospital, Seoul, Korea.*

Background: Vitamin D deficiency is common in hemodialysis(HD) patients and has been reported to be associated with mortality due to cardiovascular disease and an inflammatory response. The aim of this study was to investigate the hypothesis that low dose cholecalciferol supplementation improves serum 25(OH)D and 1,25(OH)₂D levels, and reduces inflammatory markers. Moreover, it was to analyze the association of FGF-23 and 25(OH)D levels.

Methods: This study was an one-year intervention study for hemodialysis patients with hypovitaminosis D (25(OH)D<30 ng/mL). During the first six months, the patients received 3,000 IU of cholecalciferol after each hemodialysis (9,000 IU/week), thereafter, they stopped taking supplements. Serum levels of 25(OH)D, 1,25(OH)₂D, and other biological variables were measured every 3 months for one year. We investigated the effects of cholecalciferol supplementation on the biological variables and inflammatory markers. In addition, the effective factors on the levels of 25(OH)D and 1,25(OH)₂D after cholecalciferol supplementation were assessed by multivariate regression analysis.

Results: Twenty-nine patients with hypovitaminosis D participated in our study. During cholecalciferol supplementation, the 25(OH)D and 1,25(OH)₂D concentration significantly increased from baseline to six months [9.9 to 34.3 ng/mL (p<0.001) and 19.7 to 22.9 pg/mL (p<0.05), respectively]. At 6 months, 65.5% of the patients had 25(OH)D levels within the target range [30 ng/mL] with a low dose of cholecalciferol supplementation. Also serum calcium and phosphorus levels did not increase above the normal range. However, the inflammation markers, hsCRP, e-selectin, VEGF-A, were not shown significant improvements after taking cholecalciferol supplements. The effective factors on serum 25(OH)D levels were BMI, baseline 1,25(OH)₂D and 6 months FGF-23 concentration by multivariate regression analysis.

Conclusions: The low dose cholecalciferol supplementation was effective in correcting serum vitamin D deficiency or insufficiency and safe for hemodialysis patients. However, 6 months of low dose cholecalciferol supplementation in these patients did not improve the levels of inflammatory markers.

PUB543

The Effects of sKlotho on Left Ventricular Mass and Echocardiographic Changes in Patients with Chronic Kidney Disease Marc-Sebastian Baier,¹ Lucie Bauer,¹ Franziska Sandermann,¹ Insa E. Emrich,¹ Kathrin Untersteller,¹ Sarah Seiler,¹ Vincent Brandenburg,² Danilo Fliser,¹ Gunnar H. Heine.¹ ¹*Internal Medicine IV - Nephrology and Hypertension, Saarland Univ Medical Center and Saarland Univ Faculty of Medicine, Homburg, Saarland, Germany;* ²*Dept of Internal Medicine I – Cardiology, Univ Hospital of the RWTH Aachen, Aachen, Nordrhein-Westfalen, Germany.*

Background: Recently experimental data suggest that elevated circulating levels of soluble Klotho (sKlotho), which is the beyond FGF-23, may directly induce myocardial damage. In our prospective CARE FOR HOME study we analyzed the effect of serum sKlotho levels on patients with left ventricular hypertrophy at baseline and on echocardiographic changes during five years of follow-up.

Methods: The ongoing CARE FOR HOME study recruits chronic kidney disease G2-G4 patients. At baseline serum FGF-23 (c-terminal; Immuntopics; San Clemente; CA) and serum sKlotho (Immuno-Biologic Laboratories, Fujiokashi, Gunma, Japan) were measured in all patients. Cardiovascular and renal risk factors were evaluated by a questionnaire. The present analysis includes 398 patients with an echocardiography at baseline. 94 patients received an echocardiography after five years of follow-up according to the American Society of Echocardiography guidelines. Moreover the echocardiography was done by one physician.

Results: At baseline 155 patients (40%) had a normal ventricular geometry, 134 patients (34%) had an apparently concentric remodelling, 61 patients (16%) had a concentric hypertrophy and 39 patients (10%) had an eccentric hypertrophy. At the beginning of our study, left ventricular mass (LVMI) correlated with the following parameters: glomerular filtration rate (eGFR; r = -0.19; p < 0.001), serum FGF-23 (r = 0.18; p < 0.001), age (r = 0.18; p < 0.001) and pulse pressure (r = 0.15; p < 0.001). LVMI was not correlated with sKlotho (r = -0.07; p = 0.183) and mean blood pressure (r = 0.10; p = 0.052).

Conclusions: In contrast to recent animal data our results show neither an association of sKlotho with prevalent left ventricular hypertrophy nor with LVMI changes in patients with chronic kidney disease.

PUB544

Cost-Minimization Analysis of Sucroferic Oxhydroxide and Sevelamer Carbonate in Patients on Dialysis with Secondary Hyperparathyroidism in Germany Joris Van Stiphout,¹ Matthias Schwenkglenks,¹ Peter Braunhofer,² Thomas Szucs,¹ Viatcheslav Rakov,² Patricia R. Blank.¹ ¹*Univ of Basel, European Center of Pharmaceutical Medicine, Univ of Basel, Basel, Switzerland;* ²*Vifor Pharma, Glatbrugg, Zurich, Switzerland.*

Background: Many patients with chronic kidney disease (CKD) on dialysis require vitamin D (Vit.D) agents for managing secondary hyperparathyroidism (SHPT). It has been shown that the concomitant administration of oral phosphate binders (sucroferic oxhydroxide, SFOH or sevelamer carbonate, SEV) and Vit.D therapies might impair the therapeutic effect of the Vit.D due to drug-drug interaction. Based on clinical trials (NCT01324128/ NCT01464190), this cost-minimization analysis assessed the economic impact of using SFOH compared to SEV treatment with Vit.D agents from a German third-party payer perspective.

Methods: Costs of patients with serum phosphate concentrations ≥ 6.0 mg/dL receiving either SFOH (1.5g/day [3 tablets/day]) or SEV (6.4g/day [8 tablets/day]) were assessed. Due to lack of interaction, it was assumed that patients on SFOH were treated exclusively with oral Vit.D (calcitriol, 0.28mg/day), whereas SEV patients received intra-venous Vit.D agents (paricalcitol, 1.84mg/day). Costs for the administration of paricalcitol and for adverse events were not included. Drug acquisition costs were calculated on the basis of the German standard pharmacy prices (Rote Liste 2015). Uncertainties were addressed in one-way sensitivity analyses.

Results: Over an observation period of one year, costs for SFOH or SEV resulted in EUR 3'416 or EUR 3'592, respectively. Annual Vit.D therapy costs yielded in EUR 209 for calcitriol and EUR 3'306 for paricalcitol, respectively. SFOH treatment with calcitriol versus SEV with paricalcitol resulted in an annual cost-saving of EUR 3'273 per patient. The variation of drug prices by $\pm 25\%$ did not change the conclusion of the base-case.

Conclusions: This study provide evidence that SFOH treatment with calcitriol has an economic benefit compared to SEV with paricalcitol to treat German CKD patients with SHPT. Economicsavings might be substantial for the German health care system, but real world data will be needed to confirm these findings.

Funding: Pharmaceutical Company Support - Vifor Pharma. Research funding by Vifor Pharma via employment institution.

PUB545

Effect of Intravenous Saccharated Ferric Oxide on FGF23 Metabolism in Dialysis Patients Masahiro Koizumi,¹ Hirotaka Komaba,¹ Yoko Takeda,² Masafumi Fukagawa.¹ ¹*Div of Nephrology, Endocrinology and Metabolism, Tokai Univ School of Medicine, Isehara, Kanagawa, Japan;* ²*Div of Nephrology and Kidney Center, Kobe Univ Graduate School of Medicine.*

Background: Fibroblast growth factor 23 (FGF23) is a phosphaturic hormone, secreted from the bone. It has been well known that the reduction in serum phosphate occurs following intravenous administration of saccharated ferric oxide. A recent clinical study showed that both production and degradation of FGF23 is enhanced in the setting of iron deficiency (M Wolf. *J Bone Miner Res* 2013). These findings suggest that iron may be a key regulator of FGF23. However, its precise mechanism remains to be elucidated.

Methods: We previously reported that intravenous saccharated ferric oxide further increase in elevated serum FGF23 levels in hemodialysis patients with iron deficiency anemia, using the intact FGF23 assay that only detects the full-length protein (*Am J Nephrol* 2011). In this study, we additionally examined the FGF23 levels by the C-terminal FGF 23 assay which detects both the full-length protein and C-terminal fragments, and compared the results of these two assays (N = 27).

Results: We previously reported that intravenous saccharated ferric oxide further increase in elevated serum FGF23 levels in hemodialysis patients with iron deficiency anemia, using the intact FGF23 assay that only detects the full-length protein (*Am J Nephrol* 2011). In this study, we additionally examined the FGF23 levels by the C-terminal FGF 23 assay which detects both the full-length protein and C-terminal fragments, and compared the results of these two assays (N = 27).

Conclusions: Collectively, in hemodialysis patients with iron deficiency anemia, substantial amounts of C-terminal fragments of FGF23 accumulate by increase in both the production and the degradation. The administration of saccharated ferric oxide suppresses both the production and degradation, leading to increase in values by Intact FGF23 assay and decrease in those by C-terminal assay. Specific preparations of iron for intravenous use may regulate both the production and degradation of FGF23.

PUB546

Serum Levels of Sclerostin (SOST) in Renal Transplantation (Tx) Marzia Pasquali, Lida Tartaglione, Silverio Rotondi, Maria Luisa Muci, Sandro Mazzaferro. *Cardiovascular, Respiratory, Nephrologic, Anesthesiologic and Geriatric Sciences, Sapienza Univ, Rome, Italy.*

Background: SOST, by inhibiting the Wnt pathway, suppresses osteoblasts activity and stimulates their apoptosis. Recent evidence has shown a role of SOST in alterations of bone metabolism in CKD. In CKD patients SOST serum levels are higher than in the general population and in HD patients SOST correlate negatively with histomorphometric parameters of bone turnover. Little is known about serum levels of SOST in Tx. Aim of our study was to evaluate serum SOST levels in Tx in whom few data are available.

Methods: We performed a cross sectional study in 80 Tx (55±10 y.o.;49M/31W) with CKD stage 2-4 (eGFR 47±16 ml/min). 30 healthy subjects (34±12y.o.;eGFR95±19 ml/min) were the control group. We evaluated in all patients SOST, Ca, Pi, PTH, FGF23 and Alkaline Phosphatase (AP).

Results: SOST was not different between Tx and controls (27,6±10.3vs31,0±6,0 pmol/l, p: n.s). The table shows the mean values of the parameters evaluated With mild vitamin D insufficiency (25D:26±11ng/ml), TX had normal 1,25D values, mild increment of PTH and Ca, and normal values of P.

Sclerostin, pmol/l	Cas, mg/dl	Ps, mg/dl	A.P, U/l (80-275)	PTH, pg/ml	25D, ng/ml	1,25D, pg/ml	FGF23, pg/ml
27.6± 10.3	10.1± 0.8	3.0± 0.7	178± 65	59± 51	26± 11	42± 15	47.3± 28.8

Serum levels of FGF23 were increased compared to controls (47,3±28,8 vs 30,0±19,0 pg/ml, p<.05). SOST showed a negative correlation with AP (r=-.375; p<.05) and a positive correlation with FGF23 (r=.236; p<.05) and 25D (r=.238; p<.05). No correlation existed with others parameters

Conclusions: eGFR does not seem to affect serum levels of SOST in Tx. The negative correlation whit AP indicates that SOST maintains its modulatory role of osteoblastic activity in this population. The correlation with FGF23, which is in agreement with low FGF23 in SOST null mice, suggests modulatory effects of both proteins on osteoblasts: direct, through Wnt inhibition, for SOST; indirect, through effects on 1,25D levels, for FGF23. Serum SOST may be an additional marker of bone metabolism, useful to understand metabolic pathways in normal subjects and in CRF.

PUB547

Comparison of Cholecalciferol Supplementation Dosing with a Bolus Dose Versus Daily Administration in Chronic Hemodialysis Patients
Pablo Molina, Belen Vizcaino, Mercedes Gonzalez Moya, Sandra Beltrán, Marco Montomoli, Cristina Castro, Jose L. Gorriz, Luis M. Pallardo. *Nephrology, Dr Peset Univ Hospital, Valencia, Spain.*

Background: The aims of this study were to assess the safety profile of bolus cholecalciferol supplementation and compare its effectiveness to daily oral administration in hemodialysis (HD) patients.

Methods: This 6-month prospective, intervention study enrolled 60 stable HD patients with 25-hydroxyvitamin D [25(OH)D levels] <30ng/ml, who received cholecalciferol 25,000 IU once or twice monthly (n=30) or 700 IU daily (n=30). Differences in biochemical parameters, including 25(OH)D, calcium, phosphorous, parathyroid hormone(PTH), alkaline phosphatase and C-reactive protein levels, were analyzed monthly. Primary outcome was 25OH(D) level at 6 months. For safety purposes, in the subgroup of patients receiving the bolus regimen, biochemical parameters were also assessed on days 2,4 and 7 after the first bolus dose.

Results: At baseline, patient and biochemical characteristics were similar in both groups. No changes were observed in calcium, phosphorus and 25OH(D) levels in the first week after the first bolus dose. Throughout the 6-month follow-up, similar responses in 25OH(D) levels and other biochemical parameters were observed in both groups.

Parameter	Fortnightly 25,000 IU cholecalciferol (n=30)			Daily 700 IU cholecalciferol (n=30)			p-value between groups at month 6
	Baseline	Month 6	Pre-post p-value	Baseline	Month 6	Pre-post p-value	
25(OH)D (ng/ml)	10.5 ± 6.5	22.0 ± 6.5	<0.001	11.4 ± 5.2	24.8 ± 10.0	<0.001	0.195
25(OH)D status (n,%)							
Sufficiency (≥20ng/ml)	4 (13%)	18 (60%)	0.001	4 (13%)	20 (67%)	<0.001	0.395
Deficiency (<10ng/ml)	15 (50%)	30 (100%)	<0.001	13 (43%)	29 (97%)	<0.001	0.500
iPTH (pg/ml)	257 (128-318)	281 (151-354)	0.107	193 (130-266)	187 (132-315)	0.778	0.176
Ca _{adj} (mg/dl)	9.1 ± 0.6	9.1 ± 0.5	0.571	9.0 ± 0.6	8.9 ± 0.6	0.943	0.199
Phosphorous (mg/dl)	4.0 ± 1.4	3.8 ± 1.2	0.465	4.0 ± 1.3	3.8 ± 0.6	0.031	0.417

Conclusions: Supplementation of 25,000 IU fortnightly or monthly oral cholecalciferol seems to be safe, being equally effective for raising 25(OH)D levels than 700 IU daily cholecalciferol administration.

PUB548

The Prevalence of Vitamin D Deficiency Among IgA Nephropathy: A Cross-Section Study from One Center
Minxia Li,¹ Li Yuehong,¹ Guangyan Cai,² Xueying Cao,² Xiang-Mei Chen.² ¹*Dept of Nephrology, Beijing Tsinghua Changgung Hospital Medical Center, Tsinghua Univ, Beijing, China;* ²*Dept of Nephrology, Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases, Beijing, China.*

Background: Low serum vitamin D concentrations have been reported in chronic kidney disease (CKD). Very few studies concerns vitamin D deficiency of IgA nephrology (IgAN) in Chinese patients. Our aim is to assess the deficiency of serum 25(OH)D concentrations in patients with IgAN, and to explore the possible correlated factors contributing to Vitamin D deficiency.

Methods: 283 patients who were come from north China and were not receiving vitamin D supplementation were included in this study from February 2013 and April 2014. We collected blood samples to determine levels of Scr, BUN, UA, serum phosphate (P) and calcium (Ca), iPTH, albumin, as well as urinary excretion of creatinine, protein, P and Ca within 24h. Electrochemiluminescence immunoassay measured total 25-hydroxyvitamin D. Vitamin D deficiency should be defined as a 25(OH) D of < 15 ng/ml.

Results: All of the 283 patients, 25(OH)D concentration was 10.25±6.94 ng/ml. Only 18.82% of the patients had a circulating 25(OH) D level greater than 15ng/ml. The prevalence of deficiency(<15ng/ml) were 87.2%, 72.9%, 75.0%, 85.45%, 93.1%(P=0.000) at different CKD stages.All the 120 IgAN patients were divided into 4 groups according to eGFR. The prevalence of vitamin D deficiency were higher in CKD stage 1 and 4-5(P=0.000), but there is no difference of average 25(OH) D concentration according to eGFR(P=0.059). The 25(OH)D concentration was higher in IgAN patients than MN and DN patients. But, 24UPR in IgAN patients was lower than MN and DN patients. In different age, gender, season, BMI or iPTH group, 25(OH)D levels were not affected, but 25(OH)D level was lower in ³.5g/24h group.

Conclusions: For the IgAN patients in north China, kidney function might be related to vitamin D deficiency, and 24UPR may play a very important role in maintaining 25(OH) D serum concentrations.

PUB549

Utility of Whole Exome Sequencing in the Diagnosis of a Family with Apparent Mineralocorticoid Excess
Ranjit Narayanan. *Nephrology, KMCT Medical College, Calicut, Kerala, India.*

Background: Apparent Mineralocorticoid Excess (AME) is a rare familial disorder with hypertension, hypokalemia, metabolic alkalosis and low plasma renin and aldosterone due to mutations in the 11-β-hydroxysteroid dehydrogenase-2 (HSD11B2) gene. Five siblings of a third degree consanguineous family with unaffected parents were evaluated for hypertension of juvenile onset. They had varying degrees of hypokalemia, medullary nephrocalcinosis, concentric left ventricular hypertrophy and renal dysfunction. Plasma renin and aldosterone levels were low. Given the clinical picture and autosomal recessive inheritance pattern, a provisional diagnosis of AME was made. 24 hour urinary cortisol and cortisone estimation was unavailable. We decided to confirm the diagnosis using next generation gene sequencing.

Methods: Whole blood was collected from the parents and the affected members after informed consent. 50 ng of the isolated high quality DNA was used to prepare library and exome capture. Sequencing was performed using v3 reagents to generate over 49.48 million paired end reads of 101bp. The reads were aligned to the Human genome (hg19 build, UCSC) and was further filtered for read duplicates, recalibrated and realignment was performed around well-annotated Indels from the 1000 genome project using GATK and Picard tools. Variations were called using the GATK Unified Genotyper and analysed using ANNOVAR and annotated ClinVar.

Results: Analysis revealed the presence of homozygous variation p.R337C in HSD11B2 gene annotated to be pathogenic in ClinVar and predicted to be deleterious using PROVEAN in the affected siblings. The variant was further validated using Sanger sequencing of the amplicons, confirming the diagnosis. Both parents were heterozygous for the variation. This variation has been reported to be associated with the similar phenotype in two independent studies on native American populations.

Conclusions: A homozygous mutation (p.R337C variation) in the 11HSDB2 gene was demonstrated in the family using whole-exome sequencing. This is the first genetically characterized report of AME from Indian population. Our study underscores the utility of using next generation sequencing in the diagnosis of rare inherited diseases.

Genetics of Thrombotic Microangiopathies – The Viennese TMA Cohort
Christof Aigner,¹ Martina M. Gaggl,¹ Zoltan Prohaszka,² Raute Sunder-Plassmann,³ Gere Sunder-Plassmann,¹ Alice Schmidt.¹ ¹*Dept of Medicine III, Div of Nephrology and Dialysis, Medical Univ of Vienna, Vienna, Austria;* ²*IIrd Dept of Internal Medicine, Research Laboratory, Semmelweis Univ, Budapest, Hungary;* ³*Dept of Laboratory Medicine, Laboratory for Molecular Diagnostics, Medical Univ of Vienna, Vienna, Austria.*

Background: Thrombotic microangiopathies (TMA) classified as hemolytic uremic syndrome (HUS) are characterized by acute kidney injury (AKI), mechanical hemolysis and thrombocytopenia, caused by an excessively activated alternative pathway of the

complement system. This is a result of either genetic alterations within complement factors and regulatory proteins or secondary causes. The aim of this study was to systematically investigate our cohort of patients with TMA regarding genotype and triggers of disease episodes.

Methods: Data were analyzed by means of patient records: Demographic and laboratory data, results of kidney biopsies, results of genetic sequencing of complement regulatory proteins, CFB, thrombomodulin (THBD) and C3, and medical history for triggering factors were analyzed.

Results: Out of 92 patients with TMA we classified 30 as atypical HUS (aHUS), 1 as typical HUS, and 61 as secondary HUS. At onset of disease patients with aHUS had a mean age of 25 years (range: 1-47), 20 were female (67%), and 13 (43%) were kidney transplant recipients. First presentation of 24 patients was AKI, 3 showed hemolysis, 2 had pre-eclampsia and 1 HELLP-syndrome. Distinct triggering factors in 20 patients were: infection (n=10), pregnancy (n=5), hypertension (n=2), surgery, diarrhea and renal transplantation (each n=1). Thirteen and 3 showed a CFH-H3 and a MCPggaac risk haplotype, respectively; potentially disease-causing mutations were identified in 22 patients (7 CFH, 6 CD46, 5 CFI, 4 C3, 2 CFB, 1 THBD; 4 of them with more than 1 mutation); 7 showed wild-types and no data existed for 1 patient.

Conclusions: In our cohort of TMA patients we identified 30 cases of aHUS. In 22 patients (74%) we identified a mutation within genes of the complement regulatory proteins or C3, whereas 7 subjects showed wild-type sequences despite presenting with a classic phenotype of aHUS.

PUB551

Under-Diagnosis of Alport Syndrome in First-Degree Relatives of Affected Individuals Clifford E. Kashtan,^{1,2} Theresa F. Cassidy,^{1,2} Michelle N. Rheault,^{1,2} ¹*Pediatrics, Univ of Minnesota, Minneapolis, MN;* ²*Alport Syndrome Treatments and Outcomes Registry (ASTOR).*

Background: Alport syndrome (AS) is an important inherited cause of progressive renal disease. Hematuria, the cardinal feature of AS, is highly penetrant in affected individuals. Urinalysis is a sensitive method for detecting AS in relatives of AS patients. This report describes a cohort of at-risk individuals (first-degree relatives of known AS patients) who underwent a first urinalysis as part of a clinical trial feasibility study.

Methods: For a study entitled “Multi-center Controlled Clinical Trials in Alport Syndrome - A Feasibility Study” (R21 DK91480, Clinicaltrials.gov #NCT01696253) conducted during 2013-14, first morning urine collection kits were sent to 104 people registered with ASTOR who carried a diagnosis of AS or were first-degree relatives of people known to have AS. 45/104 participants (43%) had been classified as unknown because a urinalysis had not been performed previously.

Results: 17/45 unknowns did not return the urine kit. Of the 28 who returned a urine kit, 11 had hematuria and 17 had normal urinalyses. Of the 11 who were reclassified from unknown to affected, 6 were siblings of a known affected child, 3 were sons of a known affected mother and 2 were mothers of known affected children. 3/11 had microalbuminuria (urine microalbumin:creatinine ratio > 30 mg/g); none had overt proteinuria.

Conclusions: The results are consistent with the following conclusions: 1) it is not unusual for first-degree relatives of known AS patients to have never been screened by urinalysis; 2) screening of first-degree relatives of known AS patients frequently identifies affected individuals (39% [11/28] of those who returned urine kits) who may benefit from early intervention. Early initiation of ACE-inhibitor therapy appears to slow renal disease progression in AS (Gross et al, Kidney Int 2012). It is recommended that treatment be initiated in AS patients as soon as they develop overt proteinuria (Kashtan et al, *Pediatr Nephrol* 2013; Savige et al, *JASN* 2013). Screening urinalyses should be performed in all first-degree relatives of AS patients in order to identify those who are or may become candidates for treatment.

PUB552

Urinary Biomarkers (UBio) Predict Renal Damage in Primary Hyperoxaluria (PH) Gauri Bhutani,¹ Lisa E. Vaughan,² Felicity T. Enders,² Samuel Edeh,¹ Andrea G. Cogal,¹ Nick Voskoboev,¹ Dawn S. Milliner,¹ John C. Lieske.¹ ¹*Nephrology, Mayo Clinic, Rochester, MN;* ²*Biostatistics, Mayo Clinic, Rochester, MN.*

Background: PH often results in kidney stones and CKD/ESRD. We investigated diverse UBio for correlations with urinary chemistries (UChem) and as predictors of GFR decline.

Methods: UBio (Table1) were measured in biobanked urine from PH cases and healthy controls. Clinical details and outcomes for PH cases were obtained from the Rare Kidney Stone Consortium Registry, including 24 hour UChems oxalate (Uox), calcium (UCa), citrate (UCit) and calculated CaOx supersaturation (CaOx SS) and proximal tubular Ox (PTOx= (UOx* serum Cr⁴/ UCr). Univariate and multivariate models were used to compare UBio with UChem and outcomes.

Results: Urine was available from 30 cases (114 samples) and 47 controls (47 samples). Significant correlations were present between UChem and UBio including: U RBP, NGAL, MCP1, L-FABP with U Ca; U MCP1, L-FABP with U CaOx SS; L-FABP, H-FABP with PTOx (all P<0.05). Compared to controls NGAL was increased and OPN decreased in PH cases. Both NGAL and OPN independently predicted subsequent eGFR (P<0.001).

Log (n) of Cr-corrected Urinary Biomarker	Cases v/s Controls		eGFR prediction for cases (coefficient [95% CI; p-value])	
	Odds Ratio (95% CI)	P-value (c-statistic)	Univariate	Multivariate
Retinol Binding Protein [RBP], ug/g	1.01 (0.62-1.64)	.97 (0.47)	2.96 (-1.16,7.08; 0.16)	
Clusterin, ug/g	0.63 (0.49-0.81)	<.001 (0.68)	1.38(-0.41,3.16; 0.13)	
Neutrophil Gelatinase-Associated Lipocalin [NGAL], ug/g	4.70 (2.76-8.00)	<.001 (0.90)	1.85 (0.3,3.4; 0.02)	2.94 (1.47,4.41; <0.001)
8 isoprostane [8 IP], ng/g	3.33 (1.44-7.69)	.005 (0.64)	2.93 (-2.01, 7.86; 0.25)	
Monocyte Chemoattractant Protein [MCP1], ng/g	0.59 (0.40-0.87)	.007 (0.61)	1.55 (-0.47, 3.58; 0.13)	
Liver-type fatty acid binding protein [L-FABP], ug/g	1.11 (0.69-1.81)	.66 (0.57)	-3.53 (-7.61,0.54; 0.09)	
Osteopontin [OPN], ug/g	0.38 (0.22-0.66)	.001 (0.84)	2.20 (0.79,3.6; 0.002)	2.82 (1.25, 4.40; <0.001)
Heart-type fatty chain binding protein [H-FABP], ng/g	0.33 (0.18-0.59)	<.001 (0.74)	0.85 (-3.13,4.83; 0.68)	

Conclusions: In PH, specific UBio correlate with UChem and provide renal prognostic information. These likely reflect ongoing intrarenal pathology.

PUB553

Whole Exome Sequencing Identifies Advillin Mutation as a Novel Single-Gene Cause of Nephrotic Syndrome Jia Rao,¹ Shazia Ashraf,¹ Svetlana Lovric,¹ Weizhen Tan,¹ Merlin Airik,¹ Eugen Widmeier,¹ Heon Yung Gee,¹ Richard P. Lifton,^{3,4} Friedhelm Hildebrandt.^{1,4} ¹*Div of Nephrology, Boston Children’s Hospital, Harvard Medical School, Boston, MA;* ²*Dept of Pediatric Nephrology, Faculty of Medicine Univ of Istanbul, Istanbul, Turkey;* ³*Dept of Genetics, Yale Univ School of Medicine, New Haven, CT;* ⁴*Howard Hughes Medical Inst, Chevy Chase, MD.*

Background: Identification of single-gene causes of steroid resistant nephrotic syndrome (SRNS) has furthered the understanding of its pathogenesis. However, many genes and disease mechanisms remain unknown. To identify additional genes that if mutated cause SRNS, we combined homozygosity mapping (HM) and whole human exome sequencing (WES) in a consanguineous families with NS.

Methods: An individual of consanguineous parents from Turkey with SRNS, deafness, cataract, microcephaly, and mental retardation histologically exhibited diffuse mesangial sclerosis. HM yielded >11 segments of homozygosity by descent with cumulative homozygous segments of ~200 Mb. We performed WES in this individual to identify the underlying single-gene disease-causing mutation.

Results: We identified a homozygous missense mutation (p.Leu425Met) in the AVIL (advillin) gene in an amino acid residue conserved since *Ciona intestinalis*. The mutation segregated with the affected status in this family and was absent from >6,500 European controls in the Exome Variant Server. AVIL (advillin) is a member of the gesolin superfamily of actin binding protein. AVIL (advillin) is known to be involved in neurite outgrowth and morphogenesis via interaction with the cytoplasmic domain of the Type F scavenger receptor, SREC-I.

Conclusions: We identified mutation of AVIL (advillin) as a novel single-gene cause of SRNS. Further genetic and functional studies will shed light on the gesolin superfamily of actin binding proteins in the pathogenesis of NS and will provide further understanding of the disease mechanism.

PUB554

Adult-Onset Familial Thrombotic Microangiopathy and Pulmonary Arterial Hypertension Related to Cobalamin C Deficiency Steven Grange,¹ Elise Artaud-Macari,¹ Soumeiya Bekri,³ Arnaud Francois,⁴ Christophe Girault,¹ Fabienne Tamion,¹ Dominique Guerrot.² ¹*Intensive Care Unit, Rouen Univ Hospital, France;* ²*Nephrology Dept, Rouen Univ Hospital, France;* ³*Dept of Metabolic Biochemistry, Rouen Univ Hospital, France;* ⁴*Dept of Pathology, Rouen Univ Hospital, France.*

Background: Cobalamin C (cblC) deficiency is the most frequent inherited disease of vitamin B12 metabolism, related to mutations in the MMACHC gene. The presentation in adults is dominated by neuro-psychiatric symptoms, and usually constitutes a diagnostic conundrum. We describe a unique presentation of cblC deficiency in 2 brothers, with the association of renal thrombotic microangiopathy (rTMA), atypical glomerulopathy, and pulmonary arterial hypertension (PAH).

Methods: An 18 year-old patient was referred for dyspnea. The investigations revealed stage 5 CKD, nephrotic syndrome, haemolytic anemia, and PAH. Renal histology showed major stenosing fibroproliferative myxoid lesions in the interlobular arteries. The glomeruli presented an ischemic appearance, with thickened and ribbon-like glomerular basement membranes. Immunofluorescence showed granular glomerular deposits of IgM,

without IgG or C3. Metabolic analyses showed an elevation of plasma homocysteine, methylmalonic acid, and propionylcarnitine concentrations. Genetic analyses found a compound heterozygosity in MMACHC gene, with c.271dupA and c.82-9delTTC mutations. The patient's brother died at the age of 17. Autopsy revealed pulmonary capillary hemangiomatosis, while the kidney histology showed similar lesions to those of his brother.

Conclusions: This is the first report of late-onset rTMA, atypical glomerulopathy, and PAH associated with cblC deficiency. We suggest that the association of rTMA and/or glomerular proteinuria with PAH in children and young adults should prompt metabolic investigations to identify cblC deficiency, and provide early specific management including hydroxycobalamin, folic acid, and betaine.

PUB555

The DS3 Scores and Quality of Life in Japanese Patients with Fabry Disease Nobuhito Hirawa,¹ Keisuke Yatsu,² Sanae Saka,¹ Gen Yasuda,¹ Satoshi Umemura.² ¹Dept of Nephrology and Hypertension, Yokohama City Univ Medical Center, Yokohama, Kanagawa, Japan; ²Dept of Medical Science and Cardiorenal Medicine, Yokohama City Univ Graduate School of Medicine, Yokohama, Kanagawa, Japan.

Background: Fabry disease (FD) is the lysosomal storage disorder, caused by the deficiency of lysosomal hydrolase α -galactosidase A activity. Various symptoms associated with renal disease, heart lesion and cerebrovascular disease occur in Fabry disease patients. Thus, the quality of life (QoL) would be altered with the disease progressed. We evaluated the clinical severity and the QoL in a sample of Japanese patients with Fabry (FD) disease using the Disease Severity Scoring System (DS3) and the SF-36 survey in male and in female.

Methods: Observational cross-sectional study. The DS3 and SF-36 survey was administered to the patients of the hospitals, which belong to the research group of Kanagawa enzyme replacement therapy. Participants were treated with agalsidase- α or agalsidase- β . Disease activity was assessed by the Disease Severity Scoring System (DS3). The QoL was measured by Short form-36 (SF-36) and the Kidney Disease QoL Short Forum version 1.3 (KDQoL).

Results: Fifteen patients were included in the study. Mean age was 45 years (M/F=10/5), and all patients were receiving ERT. The mean serum Cr was 2.9 mg/dl. The DS3 scores were follows; mean assessment score: 26.5 \pm 10.1, average domains: 10.5 \pm 0.9. The renal domain and the cardiac domain showed relatively high score compared to PNS and CNS scores. The QoL scores of the FD patients were lower than those of general population, but the scores were better than the previous reports of FD from U.S. or EU. The mental component summaries of women were similar to those of the general population. The physical component summaries of QoL were negatively associated with the assessment score of DS3 ($r=-0.545$, $p<0.05$).

Conclusions: Japanese patients with FD receiving ERT had a relatively good QoL beyond anticipation. DS3 score is useful for assessing disease severity, and may predict some components of QoL.

PUB556

Two Cases of Fabry Disease in Women with Proteinuria Diagnosed by Molecular Analysis of α -Galactosidase A Gene and Kidney Biopsy Jong Oh Yang,¹ Eun-Young Lee.² ¹Internal Medicine, Soonchunhyang Univ, Cheonan, Chungcheongnam-do, Korea; ²Internal Medicine, Soonchunhyang Univ, Cheonan, Chungcheongnam-do, Korea.

Background: Fabry disease is a X-linked lysosomal storage disorder caused by deficiency of α -galactosidase A. This abnormality in enzyme results intracellular accumulation of globotriaosylceramide and leads to severe painful neuropathy with progressive renal, cardiovascular, and cerebrovascular dysfunction and early death. We report 52 and 55 year-old women with proteinuria and hematuria, which were proven to be due to Fabry disease.

Methods: A 52 and 55 year-old women was admitted to the hospital due to proteinuria. They denied previous histories of hypertension, diabetes mellitus, pulmonary tuberculosis, and hepatitis. Their sister and cousin diagnosed fabry disease. Physical examination revealed nonspecific findings. On admission, blood pressure 110/60 mmHg, heart rate 64/min, respiratory rate 16/min, body temperature 36.5°. Lungs were clear and heart was normal. The extremities showed no edema, cyanosis or skin rashes. The laboratory data showed the WBC 5650/mm³, Hb 13.2 g/dL, Platelet 212,000/mm³, BUN 10.2 mg/dL, serum creatinine 0.7 mg/dL. Urinalysis showed pH 5.0 SG 1.023 protein 2+ RBC 5-9/HPF WBC 5-9/HPF. 24-hour urine protein was 533 mg. Abdomen & Pelvic CT and echocardiography were normal. The serologic study was normal. The kidney biopsy showed expansion of mesangial matrix and glomerular hypertrophy. The cytoplasm of podocytes was vacuolated, which consisted of multiple, variable-sized, concentric electron-dense lamellated structures, by electron microscopy.

The enzyme activity for α -galactosidase in serum was 0.59 nmol/min/mg protein.

Conclusions: The patients received enzyme replacement therapy every other week. They had reduction in proteinuria and normal renal function.

PUB557

Intradialysis Partial Parenteral Nutrition (IDPN) in Hemodialysis Patients (HDP) with Protein Caloric Malnutrition (PCM): Preliminary Results Susana Beatriz Asia,¹ Marcela Fabiana Munizaga.¹ ¹Servicio de Nefrologia, Hospital Nacional de Clinicas, Cordoba, Argentina; ²Servicio de Nefrologia, Hospital Nacional de Clinicas, Cordoba, Argentina.

Background: PCD is highly prevalence in HDP and predicts morbi-mortality. NPID is according Espen Guides (march2012) and the SMOFF formule(soja,TG,olive oil and fish oil), improve inflammation and lipid status.Our goal is to define the evolution of nutritional parameters in HDP and caracterize them for future interventions. **OBJECTIVE:** To evaluate if severe PCD in HDP, improve malnutrition and inflammation markers such as albumine,(Alb),cholesterol (Ch), reactive C protein(RCP).

Methods: Prospective and observational study that included 14 patients up this time,both sexes,age27-80 years old, in maintenance HD from a University Hospital and Army Hospital.Patients signed informed consent. Patients received each HD session and during six months,SMOF lipids 4 grs/kg/d,by IV continuous infusion. We analyzed weight, Hematocrit,Alb,Ch,TG,creatinine,RCP and Global Subjetive Valoration(GSV) in pre HD blood samples at the beginnig,three and six months.Cuantitative demographic variables(age,sex,biochemic parameters)were expressed as medium ,SD and applied Student Wilcoxon Test and Chi Test ($p<0.010$).

Results: fourteen patients improved weight(63,1 \pm 3.3vs64,9 \pm 3.5, $p:0.351$),alb(gr/dl)(3,7 \pm 0.4vs3,9 \pm 0.1, $p:0.016$),TG(mg/dl)(190,1 \pm 26.9vs179,4 \pm 30,8, $p:0.03$)and RCP(mg)(28,9 \pm 6.7vs10,1 \pm 2.5, $p:0.009$),there were not statical significance inHto(gr/dl)(33,3 \pm 1.9vs33,7 \pm 1.9vs33,7 \pm 1.7, $p:0.856$)CH(mg/dl)(163.9 \pm 15.9vs165.6 \pm 13, $p:0.846$),creatinine(mg/dl)(7.7 \pm 0.7vs7.4 \pm 0.5, $p:0.233$).

Conclusions: 1- NPID is a successfull tool as partial supplementation in HDP with oral dietary intake.2-In spite of our sample is small,the improvement of Nutritional and inflammatory status, applying Internatinal Guides was observed after three months of treatment.3- Medical awareness about nutritional risks in HDP, is the best tool to prevent alteration of nutritional status 4-We'll expand the sample.

PUB558

Association of Protein Energy Wasting with Income in Chronic Kidney Disease Stage 3 Patients Anita Saxena, Amit Gupta. Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, Uttar Pradesh, India.

Background: Protein energy wasting (PEW) is a major challenge in CKD. Purpose: Assessment of PEW in predialysis patients at first visit to a nephrologist.

Methods: Three day dietary intake of 484 CKD stage 3 patients. Patients were divided in to groups based on appetite and BMI.

Results: Male and female parameters: Serum albumin 3.7 \pm 0.84/3.68 \pm 0.81g/dL, total protein 7.02 \pm 1.27/6.94 \pm 1.26 g/dL, creatinine 4.68 \pm 4.19 / 3.74 \pm 3.36 mg% creatinine clearance 33.22 \pm 30.48/ 37.55 \pm 33.87 ml/minute, BMI 22.60 \pm 4.29/23.43 \pm 4.77kg/m² energy/kg 16.97 \pm 0.65/16.8 \pm 0.64, protein g/kg 0.65 \pm 0.28/0.64 \pm 0.30, carbohydrate g/kg 2.98 \pm 1.54/2.98 \pm 1.36, fat g/kg 2.98 \pm 0.23/2.79 \pm 0.22, respectively. As appetite decreased dietary protein and energy intake decreased significantly.

Variable/Sex	Normal N 1/126	Average N 70/20	Poor N 88/47	Anorexic N 64/36
Protein g/kg /Male	0.79±.23	0.58 ± .17	0.50 ± .20	0.27 ±.17
Protein g/kg / Female	0.79±.23	0.56 ±.16	0.48 ±.15	0.29 ±.20
Energy cal/kg / Male	21.57 ± 7.85	25± 3.70	12.36±4.26	6.92 ±4.36
Energy cal/kg / Female	21.19 ±5.81	14.67 ±3.09	12.79±3.92	7.25± 3.95

Appetite was average 14.46%/4.13% poor 9.7%/18.18%, anorexic 13.2%/ 7.4% in males and females. Income correlated with BMI (p.000), dietary protein (p.000) energy (p.000) and carbohydrate (p.000). Appetite correlated with creatinine (p 0.019), dietary energy, protein, carbohydrate and fat (p.000) intake. BMI correlated (p.000) with fat, carbohydrate, energy and creatinine clearance. Anova showed significant difference between appetite groups in energy, protein, fat, carbohydrate, creatinine clearance (p.000) and serum albumin (p 0.025). There was significant difference in protein (p.026) energy intake (p 0.000) and creatinine clearance (p.038) between BMI groups. Based on income there was significant difference between groups in BMI (0.000), energy (p.019), protein (p 0.031), albumin (0.001).

Conclusions: With decline in renal function, appetite worsened and nutritional intake decreased. Energy intake was significantly deficient. 84% patients had reduced appetite and 69.2% had PEW. Low income is a risk factor for PEW in CKD.

PUB559

Study on Correlation Between Serum Creatinine, Cystatin-C, Urinary Albumin Creatinine Ratio and Body Composition Xuemei Li, Jie Ma. Nephrology, Peking Union Medical College Hospital, Beijing, China.

Background: Based on an epidemiological survey in Peking, China, to study the correlation between serum creatinine, Cystatin-C and urinary albumin creatinine ratio (ACR)and body composition.

Methods: Rresidents over the age of 35 of the Beijing Pinggu District by random sampling method. Laboratory test: take morning ACR, blood samples were taken for blood routine, kidney function. Test body composition after emptying the bladder by using INBODY-720 machine. Use SPSS 17.0 software for data statistical analysis, count datas were analysed by using multivariate linear regression .

Results: A total of 9283 people participated in the survey, which 4324 males, age 54.7±10.7 years, 4959 females, age 53.4±11.2 years. Male: 1) Human body cell mass (BCM) and ACR, Cystatin-C, no correlation, was positively correlated with height (B=0.43, P<0.01), and serum creatinine was that positive correlation (B=.01, P<0.01) . 2) Lean body mass (FFM) and ACR, serum creatinine, Cystatin-C, no correlation. 3) Skeletal muscle content and ACR, serum creatinine, Cystatin-C, no correlation. 4) Body fat mass and ACR, no correlation, and Cystatin-C was positively correlated with (B=7.09, P< 0.01). Female: 1) Human body cell mass (BCM) with height and cystatin-C, no correlation, but positively correlated with serum creatinine (B=0.035, P<0.01), and ACR was negative correlation (B=-0.005, P<0.05). 2) Lean body mass (FFM) and ACR, Cystatin-C, no correlation, and serum creatinine were positively related (B=0.035, P<0.01). 3) Skeletal muscle content and ACR, Cystatin-C, no correlation, and was positively correlated with height (B=0.031, P<0.01), and serum creatinine were positively related (B=0.035, P<0.01). 4) Body fat mass and ACR was negative correlation (B=-0.01, P<0.05) ,Cystatin-C were positively correlated (B=12.3, P<0.01), and age were negatively correlated (B=-0.13, P<0.01), and serum creatinine was negative correlation (B=-0.092, P<0.01).

Conclusions: There was a positive correlation between serum creatinine and the human body cell mass (BCM), lean body mass (FFM) in men, and skeletal muscle content, body fat weight in women, but the correlation is not strong. The blood cystatin-C and body fat weight was positively correlated.

PUB560

Worsening Nutritional Status Assessed Is an Independent Predictor of All-Cause Mortality in Incident Dialysis Patients Jong Hyun Jhee, Young Eun Kwon, Tae-Hyun Yoo, Shin-Wook Kang. Dept of Internal Medicine, Yonsei Univ College of Medicine, Seoul, Korea.

Background: Malnutrition is closely associated with mortality in end-stage renal disease (ESRD) patients. However, little is known whether improvement or deterioration of nutritional status after dialysis initiation affects clinical outcome. This study was aimed to elucidate the association between the changes of subjective global assessment (SGA) after dialysis initiation and mortality in ESRD patients.

Methods: Data were recruited from the Clinical Research Center for ESRD cohort. SGA score was measured by trained investigators at the time of dialysis initiation and after 12 months. Nutritional status was defined as well-nourished (SGA 6-7, A), mildly to moderately malnourished (SGA 3-5, B), or severely malnourished (SGA 1-2, C). Severely malnourished patients (SGA C) were excluded due to small sample size. The patients were divided into four groups according to the change of SGA; group 1, A to A; group 2, B to A; group 3, A to B; and, group 4, B to B.

Results: A total of 911 patients were enrolled. The mean age was 54.6±14.1 years, 554 patients (60.0%) were male. During a median follow-up duration of 30 months, 109 patients (12.0%) died. Survival rate of group 1 was the highest, and that of group 4 was the lowest (group 1, 91.2%; group 4, 71.4%; P<0.001). Worsening nutritional status was

a significant risk factor for mortality (group 3 vs. 1, HR=3.15, CI=1.51-6.54, P=0.002), while baseline nutritional status at dialysis initiation was not (group 1 vs. 2, P=0.063; group 3 vs. 4, P=0.107).

Conclusions: Improvement of nutritional status after dialysis initiation could be beneficial for patient outcomes regardless of baseline status, suggesting that intervention to improve nutritional status after dialysis initiation might be a strategy to reduce mortality in ESRD patients.

PUB561

Prophylactic Effect of Erythropoietin Injection to Prevent Acute Mountain Sickness: An Open-Label Randomized Controlled Trial Hyungjin Cho, Soon Bae Kim. Div of Nephrology, Dept of Internal Medicine, Univ of Ulsan, College of Medicine, Asan Medical Center, Seoul, Republic of Korea.

Background: This study was performed to evaluate whether increasing hemoglobin before ascent by prophylactic erythropoietin injections prevents acute mountain sickness (AMS).

Methods: This open label, randomized, controlled trial involved 39 healthy volunteers with hemoglobin £15.5g/dL who were divided randomly into erythropoietin (n = 20) and control (n = 19) groups. Epoetin alpha 10,000 IU injections were given weekly for four consecutive weeks. On day1, and 7 days after the last injection (day 29), oxygen saturation (SaO2), and hemoglobin were measured. The subjects departed Seoul on day 30 and arrived at Annapura base camp (ABC, 4,130 m) on day 34. AMS was diagnosed when headache and Lake Louise score (LLS) of ≥ 3 were present. Immediate descent criteria followed US Army recommendations.

Results: Two groups differ in hemoglobin levels on day 29 (15.4 ± 1.1 vs 14.2 ± 1.0 g/dL, P = 0.001). At ABC, erythropoietin group had a significantly lower mean LLS, AMS incidence, and number of subjects who met immediate descent criteria. Multiple logistic regression analysis showed that SaO2 < 87% and control group, but not hemoglobin < 15.0 g/dL, independently predicted satisfaction of immediate descent criteria.

Criteria	EPO (n=20)	Control (n=19)
HACE(ataxia) plus HAPE (PR>110)		1
HACE(ataxia)	1	0
HACE(severe lassitude)		1
Severe AMS plus HAPE (PR>110)	1	1
Severe AMS alone		4
HAPE(PR>110)	1	3
Total	3	10
*p=0.019. HACE, high altitude cerebral edema; HAPE, high altitude pulmonary edema; AMS, acute mountaine sickness; PR, pulse rate		

Erythropoietin-related adverse effects were not observed.

Conclusions: Erythropoietin-related adverse effects were not observed. In conclusion, erythropoietin may be an effective prophylaxis for AMS.

Nutritional Assessment for the Chronic Dialysis Patients with/without Sarcopenia Miho Suzuki, Yuya Sakai, Ikuto Masakane. Yabuki Hospital.

Background: A recent arising problem of chronic dialysis patients is sarcopenia closely related to malnutrition. Muscle loss deteriorates daily activities of dialysis patients and ultimately worsens the QOL and prognosis of the patients. The aim of this study was to clarify the relationship between the nutritional status and sarcopenia and to analyze the status of nutrient intake in these patients.

Methods: 90 chronic hemodialysis patients were enrolled to the current study. (age 62.8yrs. Men were 76%, DM 41%).Skeletal muscle mass (SMM) was estimated by bioelectrical impedance analysis and a low muscle mass was defined by the SMM index (SMI: SMM [kg] / height [m²] as > men: 7.0kg, women: 5.7kg).Muscle function was estimated by grip strength and walking speed as the Timed up and go test (TUG).A low grip strength was defined as less than 26 kg (men) or 18 kg (women). TUG less than 11 second was diagnosed as a low walking speed. Malnutrition was defined as by the Malnutrition-Inflammation Score(MIS)(≥6point) , GNRI(<92) and the criteria of protein energy wasting (PEW).The dietary assessment was performed by the food frequency questionnaire.

Results: Sarcopenia was identified in 22% of the subjects. The sensitivity to detect sarcopenia was not sufficient as 35% in MIS, 50% in GNRI and 10% in PEW. In the patients with sarcopenia, the average of total energy intake and protein was significantly lower than those in non-sarcopenia, 1618±122kcal vs 2041±65kcal in energy; 52±4g vs 68±2g in protein. The intake of fishes and meats (110±15g vs 153±8g),beans (31±11g vs 61±6g),confectionery, beverages and sugar (126±77g vs 306±41g) were significantly lower in sarcopenia than non-sarcopenia.

Conclusions: Malnutrition-related sarcopenia was only 10-50% among sarcopenia. It is important to measure muscle mass and muscle function regularly for dialysis patients because it is not enough to screen sarcopenia only by nutritional measurements. Sufficient protein and energy intake are essential for the prevention of sarcopenia. If patients don't have appetite,confectionery or a beverage or sugar may beacceptable for the prevention of muscle loss.

PUB563

Stomach Acid Reducers May Predict Nutritional Deficiency in Dialysis Patients Klara Berta, Mihaly B. Tapolyai, Maria Faludi, Melinda Forró, Ákos Géza Peth?. *Dialysis, Fresenius Medical Care Semmelweis Univ, Budapest, Hungary.*

Background: Malnutrition is a major predictor of mortality among dialysis patients. Malnutrition markers are thus regularly monitored in order to intervene when the nutritional status may decline. We investigated whether taking stomach acid reducing medications may indicate nutritional risk.

Methods: This is a cross sectional study of 103 patients undergoing chronic hemodialysis in Budapest, Hungary at a university hospital based dialysis unit. The patients' nutritional indicators such as serum albumin, phosphorus, nPCR and whether they were receiving cholecalciferol replacement were examined among those who did and those who did not take an acid reducing agent, such as a Proton Pump Inhibitor (PPI) or H2 blocker.

Results: Six patients were excluded because data were incomplete or the patients had not been on dialysis for more than 2 months. Of the 96 patients 44.9% took an acid reducer on a regular basis. The serum albumin (3.78 ± 0.02 mg/dL vs. 3.56 ± 0.01 p:0.008), phosphate (1.88 ± 0.49 mmol/L vs. 1.64 ± 0.54 p:0.04) and nPCR (1.00 ± 0.20 vs. 0.91 ± 0.25 p: 0.06) were lower among PPI takers. PPI takers were much more likely to be taking cholecalciferol for measured 25-OH-vitamin-D deficiency (1.8% vs. 18.1% p:0.01). While PPI takers were older (59.7 ± 16.2 years vs. 65.7 ± 13.3 p:0.04), there was no difference in the two populations in the presence of an AV Fistula, delivered Kt/V, calcium or serum bicarbonate.

Conclusions: We conclude that taking PPI's or H2 Blockers in dialysis patients may be an indicator of being at risk for malnutrition.

PUB564

Impact of the Potassium Additives on the Total Content of This Element in Processed Foods Margareth Lage L. de Fornasari,^{1,2} Maria raquel Manhani,² Yvoty As Sens.^{1,2} *¹Post Graduation, Santa Casa of Sao Paulo School of Medical Sciences, Sao Paulo, SP, Brazil; ²Nutrition, Sao Judas Tadeu Univ, Sao Paulo, SP, Brazil.*

Background: The additives of potassium salts are allowed in processed foods to preserve, to inhibit mold, to emulsify products. Patients with chronic kidney disease need to control the intake of potassium, and are advised for doctors and dietitians to restrict fresh foods and those rich in potassium. The addition of potassium to processed foods is permitted but frequently not specified on food labels in Brazil. The purpose of this study was to determine the actual potassium content of a number of products often consumed by end-stage renal disease patients and to compare the actual content with that estimated in a reference source.

Methods: Twenty-five frequently processed products consumed in the diet of end-stage renal patients treated at the hemodialysis unit were analyzed. The processed foods were milk beverages, yogurt, a type of cream cheese, margarine, tomato sauce, salad dressing, powdered juices, and had potassium sorbate or others potassium salts. The concentration of potassium (mg K/100g of food) was determined by flame photometry according to the Adolfo Lutz Institute methodology, and in triplicate. The comparison of the potassium obtained with the expected potassium was based on two national reference tables.

Results: All products had potassium-containing additives listed among their ingredients. The medium values of potassium (mg for 100 g or mL) for the different foods were: milk beverages 102.6 to 125.3; type of cream cheese 80.3 to 194.4; margarine 21.6 to 37.3; tomato sauce 253.3 to 258.2; salad dressing 78.5 to 128.4; powdered juices 33 to 240.8. Processed food that had higher potassium values than the content expected from the food label were, milk beverages (1.6 to 2 times); type of cream cheese (0.9 to 2.1 times); salad dressing (1.6 to 2.6 times); margarine (1.4 to 2.5 times) and powdered juices (376 to 726 times). Tomato sauce had less potassium values than expected levels (0.6 times).

Conclusions: Processed foods with potassium additives contain higher levels of potassium than those listed in reference tables.

PUB565

Differences in Eating Patterns Between Maintenance Hemodialysis Patients from the U.S. and the UK Annabel Biruete,¹ Brandon Kistler,¹ Patrick Highton,² Kristin P. Wiens,³ Peter J. Fitschen,¹ Alice C. Smith,² Ken Wilund.¹ *¹Univ of Illinois; ²Leicester Kidney Exercise Team, Univ of Leicester, United Kingdom; ³Univ of Delaware.*

Background: Maintenance hemodialysis (HD) patients in the United States (US) have poorer nutritional status and higher mortality than European patients. Patient characteristics and clinical practices are hypothesized to contribute to these differences. Therefore, our aim was to compare eating patterns between HD patients from the US and the United Kingdom (UK).

Methods: HD patients (US=60, UK=29) were recruited. Four 24-hour diet recalls were collected, two dialysis days (DD) and two on non-dialysis days (NDD) using the USDA 5-pass method. Dietary information was entered and analyzed using diet analysis software and then grouped into eight food categories according to NHANES. Food security was assessed by the USDA 10-item survey. Statistical analysis was performed using independent samples t-test and Pearson's correlations.

Results: Patients from the UK consumed more energy on DD (24.9 ± 2.1 vs. 18.5 ± 1.1 kcal/kg/d; p=0.004) and NDD (24.5 ± 1.5 vs. 20.5 ± 1.2 kcal/kg/d; p=0.048) than US patients. Additionally, US patients had lower energy intake on DD than NDD (p=0.007), while there were no differences in UK patients (p=0.85). UK patients consumed more baked goods/breads, whereas US patients consumed more energy from beverages, entrees, and deli

(p=<0.05 for all). Moreover, some degree of food insecurity was more frequently observed in the US (54.2% vs. 10.3) and was associated with younger age ($r^2=-0.29$, p=0.033), higher BMI ($r^2=0.41$, p=0.005), higher dietary sodium ($r^2=0.29$, p=0.03) and sugar ($r^2=0.27$, p=0.05).

Conclusions: HD patients from the US had lower energy intake on DD and NDD compared to UK patients. Furthermore, US patients had lower dietary intake on DD. This may be in part due to US clinics' restrictive policy on eating during dialysis. Furthermore, there were differences in food pattern consumption and food insecurity. These differences may help explain global differences in nutritional status and outcomes. Further studies are needed to assess the contribution of eating patterns and socioeconomic status on clinical outcomes in HD patients.

PUB566

Is Reverse Epidemiology in BMI of Maintenance Hemodialysis Patients Adaptable to the Patients without PEW? Yuya Sakai, Miho Suzuki, Ikuto Masakane. *Yabuki Hospital.*

Background: Reverse epidemiology has been addressed in Body mass index (BMI) of chronic hemodialysis patients; the lowest mortality rate in BMI 24-26 as reported by the Japanese Society for Dialysis Therapy. The higher BMI the lower mortality as stated by the Dialysis Outcomes and Practice Patterns Study. However, because these survey subjects included lower BMI patients with malnutrition and chronic inflammation, the high BMI patients' mortality risk might have been relatively low. The optimal BMI derived from these epidemiological analysis may not be well indicated for the patients' who do not have malnutrition and inflammation. So, we aim to study the optimal BMI of maintenance hemodialysis patients without Protein Energy Wasting (PEW).

Methods: 183 patients on maintenance hemodialysis patients were enrolled in the current study. All subjects have over 2 years of dialysis vintage and are not applicable to PEW and don't have inflammation which was defined as CRP less than 0.3 mg/dL as of December 2009. The observation period is from December 2009 to December 2014. The subjects were classified into 4 groups on a BMI scale (n(<18.5 (13), 18.5<=22 (81), 22<=25 (47), 25<= (42)). The 5-year cumulative survival rate, the death risk factor, and each BMI groups' relative mortality risk for BMI 22<=25 group were examined.

Results: During the observation period, clinical deaths resulted in 19 patients, changing hospital or accidental death resulted in 22 patients. There was no significant difference in the crude 5-year cumulative survival rate of BMI groups. Age, diabetes mellitus, albumin were dependent risk factors for death. When the mortality risks were adjusted by these 3 parameters, the mortality risk of BMI <18.5 was significantly higher than each of the 3 BMI groups (HR 6.97, P=0.0417). The mortality risk of BMI <25 was relatively higher than BMI 22<=25 group but not significant.

Conclusions: In the maintenance hemodialysis patient without PEW syndrome and inflammation, the patients of BMI <18.5 have a higher risk of death so they require nutritional management to maintain and/or achieve a BMI ≥ 18.5 . Reverse epidemiology in BMI was not adaptable to the Japanese dialysis patients without PEW and inflammation.

PUB567

Body Weight and Proteinuria Determine Plasma Triglycerides via Hepatic Syndecan-1/Heparan Sulfate in Experimental Nephrosis Saritha Adepu,¹ Harry Van Goor,² Gerjan Navis,¹ Stephan J.L. Bakker,¹ Jacob van den Born.¹ *¹Nephrology, Univ Med Center, Groningen, Netherlands; ²Pathology, Univ Med Center, Groningen, Netherlands.*

Background: Dyslipidemia contributes to a high cardiovascular risk profile of proteinuric patients. Via its heparan sulphate (HS) side chains, hepatic syndecan-1 (syn-1) is a major uptake receptor of remnant lipoproteins. We hypothesized that proteinuria induces changes in hepatic syn-1/HS metabolism leading to dyslipidemia, which is reversed by caloric restriction (CR).

Methods: We used the hypertensive rat MWF proteinuria model. Male rats (22 wks) were uni-nephrectomized and fed ad libitum (AL) food (MWF-AL; n=14), or CR (MWF-CR; n=13, 60% of MWF-AL food intake). Wistar rats matched for sex, age, nephrectomy on AL food intake served as controls (W-AL; n=13). Sacrification is at 48 wks. Wistar control rats were sacrificed at 22 wks (Young W-AL; n=6). Body weight, blood pressure, plasma creatinine, cholesterol, triglycerides, and proteinuria were measured at 22 and 48 wks. Livers were used for qRT-PCR and immunostaining. Correlation analysis was done by linear regression analysis.

Results: Renal aging (W-AL vs Young W-AL) was associated by mild proteinuria and dyslipidemia (both p<0.05). Compared to W-AL rats, at 48 wks MWF-AL rats developed hypertension, proteinuria, reduced creatinine clearance (all p<0.05) and comparable dyslipidemia. CR reversed all these parameters in MWF-CR comparable to W-AL rats (p<0.05). Hepatic syn-1/HS profiling revealed striking increase in syn-1 protein and altered HS sulfation pattern in proteinuric W-AL and MWF-AL. CR normalized syn-1 protein levels and increased HS sulfation. Syn-1 appeared positively ($r=0.366$, p<0.02) and HS sulfation inversely ($r=-0.450$, p<0.005) associated with plasma triglyceride concentrations. Both associations were lost after adjustment for body weight or proteinuria.

Conclusions: CR normalized hypertension, renal function, proteinuria, dyslipidemia and synd-1/HS in MWF rats. Regression analysis suggests that body weight and proteinuria reduce hepatic HS sulfation, leading to hampered TRL binding and uptake and increased TG values.

PUB568

Obese Donors: The Multidisciplinary Approach in Improving Outcomes Giselle Guerra,¹ Ian Thomas,¹ Panagiotis Tryphonopoulos,² Linda J. Chen,² Gaetano Ciancio.² ¹*Dept of Medicine, Miami Transplant Inst, Miami, FL;* ²*Dept of Surgery, Miami Transplant Inst, Miami, FL.*

Background: Living donation appears safe over the years but concerns still exists long-term. Small analyses after unilateral nephrectomies have resulted in proteinuria and slight decrease in renal function (eGFR) if patient tended to be obese; thus raising a concern for accepting living kidney donors (LKD) with body mass index (BMI) greater than 30 but less than 35 Aim: Determine the outcomes of obese LKD with BMI greater than 30 but less than 35.

Methods: A single center retrospective analysis was performed at out transplant center from January 1, 2013 - November 30, 2014. LKD ages 18-65 were assessed: 1. Study Arm (SA): obese LKD with BMI>30 who were enrolled into a nutritional program and 2. Control arm (CA): non-obese living kidney donor candidates at the time of referral. Weight loss prior to surgery and afterwards, surgical complications, loss of kidney function (eGFR), and proteinuria (spot urine protein/spot urine creatinine ratio) after 6 months from donation were reviewed.

Results: Patient demographics - SA: 15 African Americans (AA), 13 Hispanics (H), 7 White, 1 Other, 3 Unknown versus CA: 55 H; 49 Whites; 20 AA; 5 Other [figure 1]. In the SA: 24/40 had BMI >35 at time of referral and placed in nutritional program; 8/24 dropped BMI to less than 35 prior to surgery and 3/24 pending surgery now; 4/24 ruled out due to medical issues & (9/24) were non-compliant. Surgical complications 1/8: Parasthesia. After donation in SA, blood pressure remained stable, 2/8 gained weight, kidney function at 6 months: 47% of obese donors had a decrease in eGFR at 6 months of 40% or greater. The mean decrease in eGFR was 33.9% in the study arm. In the control arm: 55 Hispanics; 49 Whites; 20 AA; 5 Other. 15% had a decrease in eGFR at 6 months 40% or greater and the mean decrease in eGFR was 28.9.

Conclusions: Obesity in living donors needs careful analysis especially in minority populations since there is a trend to have a greater loss in kidney function after donor nephrectomy. Donation is possible but strict nutritional and guidelines and medical evaluation need to persist for the wellness of these patients long-term.

PUB569

The Role of Renal Pharmacist in Prescribing Immunosuppressant Medication for Renal Transplant Patients to Improve Safety Israr Baig, Preetham Boddana. *Pharmacy Dept, Gloucestershire Hospitals NHS Foundation Trust, Gloucester, Gloucestershire, United Kingdom.*

Background: This paper describes the safe and efficient repatriation of renal immunosuppressant prescribing from General Practitioners (GPs) to secondary care using hospital Pharmacist Independent Prescribers (PIPs).

Methods: From March 2015 the UK commissioner NHS England required all renal immunosuppressant medication, which was traditionally prescribed by GPs following nephrologists' advice, to be prescribed by hospital renal prescribers. Gloucestershire hospitals NHS Foundation Trust decided to use Pharmacist Independent Prescribers to implement this change and provide the ongoing service using commercial Homecare Companies. All Patients were initially sent detailed information about the changes and asked to consent. On receipt of the completed consent form the PIP wrote the initial homecare prescription which was then processed by the pharmacy homecare team. Patients continued to be reviewed at regular intervals by their nephrologists. Details of these consultations were documented using a central renal database which included graft function, drug levels and communication with GPs. The Pharmacist Prescribers subsequently reviewed the renal database prior to generating ongoing homecare prescriptions and, when necessary, contacted the nephrologist for clarification and interventions.

Results: This service reconfiguration has resulted in safe and robust pathway. The use of Pharmacist Independent Prescribers has insured the whole pathway is efficient and closely monitored. Patients are satisfied with the new homecare service and clinicians value the pharmacists' input. Pharmacist prescribers have made a number of interventions which have included patient compliance issues, changes to doses in response to serum drug levels and appropriate brand changes to improve cost effectiveness.

Conclusions: The use of Pharmacist Independent Prescribers to prescribe and manage the renal immunosuppressant homecare service at Gloucestershire Hospitals NHS Foundation Trust has been shown to be safe and efficient.

PUB570

Tools for Adverse Events Prevention in a Hemodialysis Facility: A Local Experience Cinthia Sobral Vieira,¹ Cassiana G. Prates.² ¹*Nephrology Service, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil;* ²*Hospital Epidemiology and Manager Risks Service, Hospital Ernesto Dornelles, Porto Alegre, RS, Brazil.*

Background: After the publication "To err is human" there has been a new approach to prevent risks in health system. According to the International Patient Safety Goals there are six steps to be followed like patient identification, proper communication, right surgery in the right side, fall prevention, high alert medication and infection prevention. The goal is to show how a hemodialysis unit, for ambulatory and hospitalized patients leads with adverse event prevention.

Methods: This experience happens in a hemodialysis unit with 101 patients, 3 shifts of 4 hours. It is located in a general hospital in Porto Alegre, south Brazil.

Results: Every patient has an id badge with colored marks according to the risk possibilities (falls, allergies, multi resistant germ, no access condition, hypoglycemic risk). There are no medication facilities. There are checklists for dialysis. The staff has continued medical education for patient safety. There is a map risk (adverse events possibilities) and its approach. If it happens, a notification formulary is filled and reported to the Hospital Epidemiology and Manager Risks Service, that analysis the root causes. The chosen tool is Ishikawa diagram resulting in a plan of action. Every month, one case (not only hemodialysis) is discussed together with a multidisciplinary group and the hospital high direction. The quality patient safety indicators are evaluated, as mortality incidence (21,33 % y); sera conversion to hepatitis C and B (0) and catheter infection (5,24% y).

Conclusions: Chronic renal patient is at high risk of advent events because of frequent treatment, comorbidities, many medication and the pathology consequences. Needle dislodgment, hematomas, lack of registration of weight and arterial pressure at the beginning of dialysis, more than 2 vascular access needle insertion attempts, dialysis interruption may occur, so the unit must be prepared to intervention. Health staff rarely reveals mistakes afraid of consequences and blame. It is necessary to promote the Safety Culture, stimulating to talk about bad events or even near miss to prevent other ones.

PUB571

Zinc Deficiency Correction and Phosphaturia in Children with CKD – A Pilot Study Vladimir Belostotsky,¹ Stephanie A. Atkinson,¹ Michelle N. Rasiah,¹ Steven Arora,¹ Ji Cheng,¹ Joanne Grimmer,² Guido Filler.² ¹*Pediatrics, McMaster Children's Hospital, Hamilton, ON, Canada;* ²*Pediatrics, Children's Hospital, London Health Sciences Centre, London, ON, Canada.*

Background: There are no guidelines for correction of Zinc (Zn) deficiency in Chronic Kidney Disease (CKD). Experimental data (Morishita 2001) suggests that Zn modulates the phenotype of Klotho deficient mice and this can potentially increase phosphaturia. Aims: To identify Zn deficiency and determine whether 3 months of oral Zn therapy normalizes Zn status in children with CKD. To assess feasibility of conducting a clinical trial similar to Morishita's in mice and gather information on clinical outcomes and relationship between Zn status and correction of Zn deficiency and phosphate (P) excretion.

Methods: 40 patients (pt) 4-18 yr with primary CKD and CKD due to declining graft function were enrolled from 2 tertiary pediatric nephrology centers. Plasma Zn was measured by High Resolution Magnetic Sector Inductively Coupled Plasma Mass Spectrometry at baseline and 3 months with routine blood and urine parameters. Pt with Zn<11.5 mmol/L were treated for 3 months with Zn citrate tablets (10mg Zn/day for 4-8 yr and 20 mg/day for 9-18 yr). Statistical analysis was done using nonparametric methods and relative risk ratio.

Results: Of 21 pt (M-13, F-8) with completed data, Zn deficiency was found in 10. Stages of CKD were: 2-11 pt, 3-5 pt, 4-5 pt. One pt was hyperphosphatemic. 2 Zn deficient pt had abdominal discomfort whilst taking Zn. Plasma Zn improved in 8 out of the 10 treatment pt (4.4 times more frequently than in control pt) after 3 months of Zn therapy. Zn therapy over 3 months did not change serum P (median 1.23 mmol/L to 1.25 mmol/L) or its fractional excretion (median 24.08% and 21.71%).

Conclusions: Zn deficiency occurred in about 50% of CKD pt. Preliminary analysis indicates that 3 months of oral Zn supplementation is likely beneficial in Zn deficient pt but a larger sample size is required to evaluate the impact of correction of Zn deficiency on other metabolic parameters. Correction of Zn deficiency does not alter P excretion in pt with normal blood P. Similar studies are feasible to perform in hyperphosphatemic pt.

PUB572

Proteinuria as a Marker of Severe Unilateral Ureteral Obstruction in Infants Mariselis Rosa-Sanchez, Jayanthi Chandar, Wacharee Secherunvong, Chryso P. Katsoufis, George N. Sfakianakis, Rafael Gosalbez, Andrew Labbie, Gaston E. Zilleruelo, Carolyn L. Abitbol. *Pediatric Nephrology, Nuclear Medicine, Pediatric Urology, Holtz Children's Hospital/Univ of Miami, Miami, FL.*

Background: Unilateral ureteral obstruction (UO) is a common congenital anomaly in infants. Controversies remain regarding clinical indications for timely surgery. The objective was to compare the radiologic and laboratory parameters of a cohort presenting with significant unilateral hydronephrosis that were managed either conservatively or surgically.

Methods: This retrospective analysis included 81 infants during a 10 year period with high grade hydronephrosis designated by renal ultrasound. Further assessment included renal function by nuclear scintigraphy and proteinuria. Proteinuria was determined by random urine total protein to creatinine ratio (Upr/cr) and albuminuria by random urine albumin to creatinine ratio (Ualb/cr). Receiver operator characteristic (ROC) area under the curve (AUC) statistics were applied to Upr/cr and Ualb/cr ratios with determination of likelihood ratios (LR) for requiring surgery.

Results: In this cohort, 22/81 (27%) were operated, including 21 pyeloplasties and 1 nephrectomy for severe UO. Initial proteinuria was significantly greater in UO patients who underwent surgery compared to those without surgery (p=0.02). ROC-AUC demonstrated that both Upr/cr and Ualb/cr predicted the presence of severe UO requiring surgery (Upr/cr: AUC=0.71; p=0.01 and Ualb/cr: AUC=0.75; p=0.02). Upr/cr and Ualb/cr was similar in normal control infants and those with non-surgical UO.

Conclusions: Proteinuria and albuminuria were significantly elevated in UUO infants who required surgery compared to normal term infants and those with non-surgical UUO. Although both were sensitive markers of renal injury, albuminuria was superior in predicting the need for surgery in patients with UUO.

PUB573

High Prevalence of Glomerular Hyperfiltration in Obese Adolescents
Anitha Ezekiel, Jennifer Therese Potonia, Pedro Anis Rahnemaye rabbani nourani, Samhar I. Al-Akash. *Driscoll Children's Hospital - Kidney Center, Corpus Christi, TX.*

Background: Glomerular hyperfiltration (GHF) has been described in diabetic and obese (O) adults, and usually precedes proteinuria or clinical disease, and may indicate underlying renal damage and chronic kidney disease (CKD). GHF is poorly studied in adolescent children (AC). We hypothesized that GHF is present in AC and that GFR correlates with the BMI.

Methods: We queried the electronic medical records from 6/2010 to 12/2013 to include AC 12-21 years of age with at least one serum creatinine (SCr) and BMI in the same encounter, and excluded pts with CKD, HTN, DM, proteinuria, or renal transplant. Pts were separated into 2 groups; Control (C) - BMI < 30 and O - BMI ≥ 30 kg/m². We used the original Schwartz formula (OSF) to calculate GFR as our lab uses the Jaffe method to measure SCr. We defined GHF as GFR > 150 ml/min/1.73m².

Results: Demographic data and results are shown in table 1.

	C (control) BMI < 30	O (obese) BMI ≥ 30	P-value
N (encounters)	730	246	
Mean age - years	18.5±0.8	15.5±2.0	<0.0001
Mean BMI - kg/m ²	21.7±4.1	38.4±6.8	<0.0001
Male	48%	49%	NS
Prevalence of GHF (GFR > 150)	3%	16%	0.0001 (OR 6.2)
- Male	0	28%	0.0001
- Female	4%		NS
Mean GFR	A 89.6 (85-95)	B 128.2 (114-141) (BMI ≥ 30)	<0.0001
		C 120 (114-127) (BMI 30-34.9)	<0.0001 (A vs. B, C, D, E) 0.01 (C vs. E)
		D 130 (124-136) (BMI 35-39.9)	
		E 134 (128-141) (BMI ≥ 40)	
Prevalence of GFR > 130	20%	43%	<0.0001 (OR 6.9)
- Male	14%	62%	<0.0001 (OR 19.1)
- Female	12%	25%	<0.0291 (OR 2.5)

Conclusions: Using the OSF, we showed a higher prevalence of GHF in obese AC, and a showed that GFR correlated with BMI. Males have a greater risk of GHF. Due to the increased incidence of obesity in AC, special attention needs to be paid to renal function. In the absence of proteinuria or signs of clinical disease, GHF may be the earliest sign of renal disease, and should be assessed in obese AC. The choice of GFR estimation formula

specifically in the obese has not been well established. This study provides preliminary data for a prospective trial for comparison of standard GFR measurement with existing GFR estimation formulas to allow the use of the most appropriate formula in obese pts.

PUB574

Familial Lecithin-Cholesterol Acetyltransferase Deficiency Masquerading as Membranous Nephropathy in Childhood
Ania B. Koziell, Katrina Soderquest. *Experimental Immunobiology, King's College London, London, United Kingdom.*

Background: Familial Lecithin-cholesterol acetyltransferase (LCAT) deficiency is a rare autosomal recessive disorder of lipid metabolism characterised by severely reduced HDL concentrations and impaired esterification of cholesterol. It is characterised clinically by glomerulopathy and mild haemolytic anaemia presenting in adulthood leading to ESRD by the fourth decade of life through the deposition of abnormal lipoproteins in the renal stroma. Paediatric cases are rarely described.

Methods: 2 siblings aged 8 and 11 years presented with asymptomatic non-nephrotic range proteinuria detected on routine testing. There was no family history of renal disease, although parents were consanguineous. Initial screens revealed normal renal function and normal serum albumin. Other investigations demonstrated raised lipid profiles but in keeping with nephrotic syndrome. A renal biopsy was performed in view of escalating protein and albumin creatinine ratios.

Results: Renal biopsy initially demonstrated light microscopic features of membranous nephropathy. However, electron microscopy demonstrated inclusions that were not typical of the adult form of the disease but clearly lipid filled (Figure 1). Confirmation of the diagnosis was by demonstration of significantly reduced HDL-cholesterol, and detection of a novel LCAT gene missense mutation G54V as well as reduced LCAT enzyme activity on assay.

Conclusions: LCAT deficiency may present with mild symptomatic proteinuria in childhood. Although rare, it should be considered in a differential in paediatric membranous nephropathy. The diagnosis was made on characteristic EM appearances, genetics and reduced enzyme activity. A trial of enzyme replacement is planned. Interestingly, the older sibling has higher lipids yet the younger worse renal disease opening up new hypotheses for how LCAT deficiency might cause renal pathology.

PUB575

Umbilical Artery Histomorphometry: Linking the Intrauterine Environment and Nephrogenesis
Marissa J. Defreitas, Deepan Mathur, Wacharee Seeherunvong, Shahnaz Duara, Salih Y. Yasin, Maria Matilde Rodriguez, Carolyn L. Abitbol. *Pediatric Nephrology, Pediatric Pathology, Neonatology, Perinatology, Univ of Miami/Holtz Children's Hospital, Miami, FL.*

Background: An adverse intrauterine environment is linked to the developmental origins of aortic stiffness, nephron deficit, and adult onset cardiovascular and renal disease. We hypothesized that umbilical artery histomorphometry(UAH), a direct extension of the central vascular tree, would provide insight into nephrogenesis across gestational age (GA)groups.

Methods: From 156 newborns enrolled in the Gerber Infant Kidney Study, a subcohort of 32 had umbilical cord specimens evaluated (7 term(T-S), 15 preterm singletons(PT-S) and 10 preterm twins(PT-T)).The umbilical cord was sectioned, stained with Trichrome and digitalized.Muscular(MA) and collagenous areas(CA) of the umbilical arteries were measured in pixels using the ImageJ1.48q software and converted to mm². The combined total kidney volume(TKV) was measured by ultrasound and factored by the infants' ponderal indices and BSAs.

Results: TKV/PI of T-S (6.9±1.8) and PT-S(7.5±1.9) were similar; while TKV/PI of PT-T was significantly less than either of the singleton groups (4.5±0.8;p<0.001). Among PT-S, 6(40%) were from pre-eclamptic (PE) mothers. When paired by GA to other PT-S not from PE mothers, they demonstrated stunted TKV/BSA (93±28 versus 122±19µm²/m²;p=0.02). Among twin pairs, there was also a discordance in TKV/BSA (68±10 versus 81±15 µm²/m²;p=0.04). UAH demonstrated a positive correlation with increasing %MA and a negative correlation with increasing %CA.

Conclusions: UAH links an adverse and/or competitive intrauterine environment with nephrogenesis independent of GA. An enhanced umbilical artery musculature area reflects an increased renal mass while increased vascular collagen parallels decreased renal mass in discordant twins and singletons of PE mothers.

PUB576

Insulin-Like Growth Factor/Growth Hormone and Insulin-Like Growth Factor Binding Proteins in Normal Heighted and Short Children with CKD John D. Mahan,¹ Rose M. Ayoub,¹ Larry A. Greenbaum,² Amira Al-Uzri,³ Frederick J. Kaskel,⁴ Susan L. Furth,⁵ Bradley Warady,⁶ ¹Pediatrics, Nationwide Children's/OSU, Columbus, OH; ²Pediatrics, Emory Univ, Atlanta, GA; ³Pediatrics, Oregon Health & Science Univ, Portland, OR; ⁴Pediatrics, Albert Einstein COM, New York, NY; ⁵Pediatrics, Univ of Pennsylvania, Philadelphia, PA; ⁶Pediatrics, Children's Mercy Hospital, Kansas City, MO.

Background: Earlier reports indicated that children with chronic kidney disease (CKD) have 'normal' Growth Hormone (GH) and Insulin-Like Growth Factor-1 (IGF-1) levels, suggesting that intracellular resistance and increased IGF-1 Binding Proteins (BPs) account for the poor growth seen in 35% of these children. We explored key growth mediators in subjects with CKD enrolled in the Chronic Kidney Disease in Children (CKiD) study with either normal height or short stature to explore potential explanatory differences in these two subsets.

Methods: 232 children in CKiD (206 normal height; 26 short stature; none on GH therapy) were matched by gender, age and GFR. Short stature = Height Standard Deviation Score (SDS) < -1.88. GH, IGF-1, and IGFBP-1 and 3 were determined by chemiluminometer and ELISA.

Results: Normal height CKD children had higher serum IGF-1/GH, higher IGF-1/IGF-1 BP1 and similar IGF-1/IGF-1 BP3 compared to short CKD children.

	IGF-1/GH*	IGF-1/IGF-1 BP1*	IGF-1/IGF-1 BP 3*
Children height SDS < -1.88	356.7 [152.3, 1017.2]	0.0056 [0.0012, 0.0161]	37.91 [22.62, 56.97]
Children height SDS > -1.88	811.8 [168.2, 2360.0]	0.0136 [0.0055, 0.0582]	53.44 [35.34, 77.50]
P-value (Kruskal-Wallis ANOVA)	0.0002	0.02	0.07

* = (median [IQR])

Height SDS correlated with IGF-1 in normal height children (r = 0.323), but not well in short children not on GH RX (r=0.046).

Conclusions: Differences in IGF-1, IGF-1/GH, and IGF-1/IGF-1BP1 may explain some variance in growth in CKD children. Height is more highly correlated to IGF-1 in normal height than short CKD children. Analyses in paired subjects may provide further insights in children naïve to and those on rGH to allow detection of critical thresholds that explain and/or predict growth in children with CKD.

Assessment of Cochlear Sensitivity of the Pediatric Chronic Kidney Disease and Hemodialysis Patients Rahime Renda,¹ Levent Renda,² Omer Tark Selçuk,² ¹Antalya Research and Training Hospital Pediatric Nephrology; ²Antalya Research and Training Hospital Otorhinolaryngology Dept.

Background: Abnormalities in auditory system are frequent in patients with chronic renal disease and hemodialysis. The aim of this study was to throw light on the relationship between cochlear sensitivity and chronic kidney disease with or without hemodialysis.

Methods: Children aged 6-18 years were evaluated in three groups; 36 nondialytic patients with chronic kidney disease, 16 end stage renal disease patients undergoing hemodialysis, and 30 age and sex-matched control subjects. Hearing outcomes were obtained by pure-tone audiometry and distortion product otoacoustic emissions measurements.

Results: No significant difference was found except in the both ears at 500 Hz frequencies between the study group and the control group. The signal/noise ratio levels and distortion product levels were significantly lower in the nondialytic and dialytic group at all frequencies. Patients with normal hearing were found to have significantly lower signal/noise ratios and distortion product levels than those observed in the healthy controls.

Conclusions: These results showed lower cochlear functions in the dialytic and non-dialytic group regardless of hearing loss than in the control group. Patients with chronic renal disease with or without hemodialysis should be monitored periodically even if the hearing thresholds seem to be within normal limits.

PUB578

Percutaneous Renal Biopsy at OPD Level Byoung-Soo Cho,¹ Yumi Choi,² Jin-Soon Suh,³ ¹TheAll Medical Hub Kidney Center, MIRAE ING Research Inst, Seoul, Republic of Korea; ²Dept of Pediatrics, Gwangmyeong Sung-Ae Hospital, Gwangmyeong-si, Gyeonggi-do, Republic of Korea; ³Dept of Pediatrics, College of Medicine, The Catholic Univ of Korea, Bucheon-si, Gyeonggi-do, Republic of Korea.

Background: Renal biopsy is a prerequisite procedure for the final diagnosis and to evaluate the treatment effect or to determine the prognosis, however due to serious complication of the procedure, should be done by nephrologist and has been performed at admission state.

Methods: Our center performed percutaneous renal biopsy 3,000 cases without major complications during last 30 years, when patients were admitted for 3days. During last 18 months, we performed percutaneous renal biopsy at OPD level under the ultrasound guide (LOGIQ E9).

Results: The youngest one is 1 year old male and the oldest was 64 years old. Mean age was 26 years old. Male to female ratio was 3:2 Mean glomeruli numbers were 31. We used disposable kidney biopsy needle (TSK ACECUT). We checked ultrasound 3 times after renal biopsy for checking AV fistula, hematoma formation during 6 hours hospital stay. Of the 100 case 8 cases received follow up biopsies. Among 100 samples renal medulla was not detected. Two patients(2%) among 100 biopsies showed small(less than 1cm) hematomas. No AV fistula were detected. All patients went home 6hours after renal biopsy without any problems. Renal biopsy results showed IgAN(23%), Nonspecific GN(21%), Diffuse mesangial proliferative GN (17%),HSPN (6.7%), MGN(5.6%),FSGS (5.6%),Others were Alport,Lupus nephritis,DM nephropathy,MPGN type I,Thin GBM nephropathy.

Conclusions: In conclusion, percutaneous renal biopsy under the ultra-sound guide at OPD level with 6 hour ABR is safe and effective if performed at renal cortex level.

PUB579

Acute Lymphocytic Leukemia with Bilateral Renal Masses Masquerading as Nephroblastomatosis Salim Aljabari, Poonam Thakore, Curtis W. Turner, Tetyana L. Vasylyeva. ¹Pediatrics, Texas Tech Univ Health Sciences Center, Amarillo, TX.

Background: While leukemia has a wide spectrum of presenting features, renal involvement at presentation of the disease is rarely seen. We are reporting a child with bilateral renal lesions resembling nephroblastic rests as the first and the only finding subsequently developing classic features of acute lymphocytic leukemia (ALL).

Methods: A 4 year old boy was presented with low grade fever and abdominal pain for few days. A complete blood count (CBC) and abdominal CT scan were done to rule out appendicitis. WBC of 8.1 K/UL,hemoglobin of 13.3 g/dL,Platelets of 170 K/UL, neutrophils 22%,Lymphocyte of 68.9% and absolute neutrophil count of 1.8 K/UL.CT scan showed bilateral renal enlargement with multiple hypodense lesions in the cortical and subcortical regions. Blood urea nitrogen of 7 mg/dl and creatinine of 0.38 mg/dl. The patient was diagnosed with viral gastritis and sent home on supportive treatment. CT scan was later interpreted as nephroblastomatosis by pediatric radiologist as an incidental finding advised to follow up with the pediatric nephrologist. After 14 days he again had low grade fever with abdominal pain. CBC showed WBC of 3.5 k/UL,Hemoglobin of 11.1 G/DL,platelets count of 21 K/UL,neutrophils 6 % and lymphocyte 85%,absolute neutrophilic count was 351 and ESR of 71 mm/hr. The pediatric oncology service was consulted for possible malignancy. Peripheral blood smear showed the presence of abundant immature lymphoid cells representing 90 % of the total white cells. Bone marrow aspirate and biopsy,flow cytometry and cytogenetic studies showed early B cell leukemia. Treatment was initiated following the guidelines of COG AALL0932. After one week of induction therapy,the CT scan showed a complete interval resolution of all renal hypodense lesions.

Conclusions: Renal involvement in leukemia is challenging to diagnose due to its variable presentation on imaging. On CT scan, it may present as enlargement of kidneys (unilateral or bilateral), or a low-attenuation focal parenchymal. These focal lesions can be difficult to distinguish from nephroblastomatosis which has a similar radiological picture on CT scan.

PUB580

Modality of Treatment of Pediatric Patients with Diarrheal HUS in Acute Renal Failure Does Not Affect Long Term Outcome and Survival

Sonia Solomon, Julia W. Tzeng. *Pediatrics, Valley Children's Hospital, Madera, CA; Pediatrics, Univ of California, San Francisco - Fresno, Fresno, CA.*

Background: Diarrheal HUS is a disease process usually resulting from infection by *E. coli* H7:0157 and leading to the development of microangiopathic hemolytic anemia, thrombocytopenia, and acute renal failure. Acute renal failure typically follows in five days from presentation, with about two-third of the patients requiring renal replacement therapy. Studies have demonstrated that these patients are at risk for long term renal insufficiency and end-stage renal disease. Indications to start dialysis and the mode of dialysis vary from institution to institution. There is no current study comparing which mode of dialysis, hemodialysis or peritoneal dialysis, has greater benefit and less complications. The aim of this study is to compare dialysis modalities and determine whether one modality will result in less complications and better outcomes.

Methods: This is single center, retrospective review. We studied a total of 102 patients from 1999 to 2014. We compared patients with dHUS started on PD or HD. We compared the number of complications and the types of complications from each modality. Long term outcomes were measured by each patient's CKD staging at least one year after diagnosis. EGRF was calculated using the Schwartz formula. Fisher's exact statistical test was used to assess statistical significance.

Results: No statistical significance was found between the modality of dialysis and associated complications ($p=0.4$). There was also no statistical significance between modality of dialysis and long term outcome ($p=0.9$). Complications of PD were catheter malfunction ($n=6$), peritonitis ($n=5$), and the need to switch to HD or CVVHDF ($n=3$). Complications of HD included central line infections ($n=1$).

Conclusions: PD and HD are equally effective in treating patients with dHUS in renal failure and have comparable long term outcome and risks for complications. An important complication to consider for patients on PD is the potential need to switch to HD or CVVHDF; this exposes the patient to an additional surgical procedure that may result in further complications.

PUB581

Self-Reported Health Care Transition Readiness Among Mexican Adolescents with Chronic or End-Stage Kidney Disease

Guillermo Cantu,¹ Ana Catalina Alvarez-Elias,² Saul Valverde,² Maria E. Ferris,³ Mara Medeiros.²
¹Univ Panamericana, Mexico, DF, Mexico; ²Univ of North Carolina at Chapel Hill, NC; ³Hospital Infantil de México Federico Gómez, Mexico, DF, Mexico.

Background: 90% of pediatric patients with chronic disease live more than 20 years after being diagnosed. When pediatric patients are transferred to adult-focused health services, generally they do not have the skills and abilities to manage their disease. Adolescents tend to have poor adherence to treatment, and there is a period when there may be complications and increased morbi-mortality. Performance on self-reported health care transition readiness (HCTR) needs to be assessed in patients with chronic or end-stage kidney disease. The aim of the study was to measure self-reported HCTR using the STARx (Self-management and Transition to Adulthood with Rx= Treatment) Questionnaire1, among adolescents in the Nephrology Service at Hospital Infantil de México Federico Gomez.

Methods: The Spanish version of the STARx Questionnaire was translated and back translated and applied to adolescents with chronic or end-stage kidney disease, in the outpatient nephrology department over a 9-month period. The 18-question tool diagnoses actions, knowledge and skills on chronic disease self-management, medications adherence and ability to find new health providers. Age was divided at 16 years. Student's T-tests were performed and p-values of <0.05 were considered significant.

Results: We enrolled 68 adolescents (53% males) who had a mean age of 15.75 years (± 1.87). Patients who received hemodialysis in the past were 22 (34%). Females had significantly greater scores than males in the "action" category. Those who received hemodialysis in the past had greater knowledge about the disease ($p 0.013$).

Conclusions: The self-reported HCTR among Mexican adolescents with chronic or end-stage kidney disease differs by sex and treatment modality.

Italian Survey on Patients on Peritoneal Dialysis Treatment: ATENA

Alessandro Possidoni,¹ Sara Di fino,¹ Flavia Caputo,² Carlo Crepaldi,³ Roberto Dell'Aquila,⁴ Emilio Giulio Galli,⁵ Anna Maria Costanzo,¹ Umberto Di Iuzio paparatti,¹ Roberto Russo.⁶ ¹AbbVie Italy; ²H. Civico di Palermo; ³H. Civile San Bartolo; ⁴Bassano del Grappa; ⁵H. of Treviglio; ⁶H. of Bari.

Background: in Italy, there are few epidemiological data concerning the clinical management of patients (pt) on Peritoneal Dialysis (PD) and the impact of PD on clinical outcomes.

Methods: epidemiological, multicenter study with a retrospective phase (12 months) and a prospective phase (6 months) of subjects on PD. Primary objective: evaluate anaemia, hypertension and mineral metabolism compared to K-DIGO and K-DOQI guidelines (GL). Secondary objectives: comorbidities, hospitalizations, therapeutic strategies, mortality and quality of life (QoL).

Results: 377 consecutive pt. were enrolled (at baseline, CAPD 50.4%/APD 49.6%; Male 59%; mean age: 67 years; dialysis duration: 39.7 months). The most frequent comorbidities were hypertension (88%), cardiovascular diseases (CVD=56%), vascular diseases (25%), dyslipidaemia (25%) and diabetes II (20%). The main cause of hospitalization

was peritonitis (27%; no death associated), followed by CVD (20%). At 6 months, anaemia—not corrected or not adequately corrected (Hb<11g/dl)—occurred in 30% of pt. 73% received ESA. Systolic value>130 mmHg and diastolic value>80 mmHg occurred in 50% and 30% of pt, respectively. Left ventricular hypertrophy was observed in about 60% of echocardiograms. 25(OH)D levels were <10 ng/mL in 30% of executed tests. Secondary hyperparathyroidism (SHPT) occurred in 30% of pt. The drugs used to manage SHPT were calcitriol (36.3%), paricalcitol (29.2%), colecalciferol (23.6%) and cinacalcet (21.5%). Considering a group of pt under therapy for a year with similar basal PTH levels, a significant reduction of iPTH occurred with paricalcitol (1.05 mcg/day), but not with cinacalcet (39.4 mg/day) ($p<0.001$ vs $p=0.626$). No effect on Ca and P occurred in the paricalcitol group. At the end of the study, PD didn't modify the QoL significantly.

Conclusions: hypertension and CVD are the most common comorbidities of PD. Peritonitis is the main cause of hospitalization. Anaemia and SHPT are frequent and have to be treated and monitored carefully. There are significant differences in efficacy between different treatment options to treat SHPT.

PUB583

Advancements in Automated Peritoneal Dialysis Cyclers Technology Driving Improved Quality of Care

Catherine Firanek, James A. Sloand. *Global Medical Affairs, Baxter Healthcare, Deerfield, IL.*

Background: Enhancements to APD technology directed at greater ease of use and health care professionals' (HCPs) oversight of patient status may help overcome barriers to home dialysis. Use of connectivity to enable remote patient monitoring (RPM) and prescription modification may facilitate patient management, increase HCP and patient communication, and improve outcomes. Advancements in design may also help simplify APD for patients. Objective is to understand and qualify importance of enhanced graphical user-interfaces (GUI), voice-guided instruction, and RPM embedded into APD cycler for HCPs and patients.

Methods: Forty-minute telephone interviews and web-based surveys, including cycler videos, were conducted with 214 nephrologists, 138 renal nurses, and 193 CKD patients from UK and US. HCPs included those in practice for >3 yrs, spending >75% of their time treating patients, and experience with use of conventional cyclers. Patients included those considered candidates for PD or those currently on dialysis, including incenter HD, home HD or PD. In double-blinded study, participants compared 2 conventional cyclers and a cycler with new technology with information screen, enhanced GUI and clinic connectivity.

Results: On a scale of 1-7 (7 the most important), cycler features rated most important to nephrologists, nurses, and patients include size and portability, GUI with voice-guided instructions, and data connectivity/RPM. When rating each cycler on favorability of attributes, the cycler with new technology scored highest. Attributes of 1st conventional cycler scored an average of 0.5 (on a scale of -3 to 3), while attributes of the cycler with new technology from the same manufacturer scored an average of 2.6 ($p<0.0005$). The attributes of the 2nd conventional cycler compared to the cycler with new technology scored on average 1.15 and 2.3 ($p<0.0005$), respectively.

Conclusions: HCPs and patients identified enhanced GUI, voice guidance, and data connectivity allowing RPM as favorable attributes to cycler usability and patient management. Technological enhancements that facilitate ease of cycler use and connectivity may increase PD acceptance by patients and HCPs.

PUB584

A Single Center Ten-Year Experience in PD Catheter Placement

Yorg Al Azzi, Etti Deborah Zeldis, Girish N. Nadkarni, Harry Schanzer, Jaime Uribarri. *Nephrology, Mount Sinai Hospital - Icahn School of Medicine, New York, NY.*

Background: In our early implantation practice, curly tip catheters had better function and less migration when compared with straight catheters and as such, we for the past 10 years have implanted almost exclusively the curly catheters. This is in disagreement with some current literature that favors straight catheters. Due to this discrepancy, we decided to review our single center experience with PD catheters over the past 10 years.

Methods: PD catheters placed over the period of 2004–2014 at our hospital were reviewed. Demographics, comorbidities, operative note, type of catheter, surgical approach, complications and overall survival were collected.

Results: 170 PD catheters were inserted during 10 years (49.7% men, mean age 54.7 years, 167 curly catheters vs 1 straight intra-peritoneal, 63% placed by open surgical technique vs 37% by Y-Teck peritoneoscopy). Diabetes mellitus was the most common cause of ESRD. 60 peritonitis cases occurred during the period of observation (24 lost their catheter). 30 had exit site infection, 9 had a leak out of which 4 lost their catheter, 3 had primary non-function of their catheter, 4 had hernias (1 taken off PD). There was no difference in hazard ratios in catheter survival after adjusting for demographics; diabetes status and number of previous catheter placement for overall follow up. But, looking at 2-year catheter survival, open placement of catheters had a higher adjusted hazard ratio for catheter loss compared to peritoneoscopic placement (aHR 2.61; 95% CI 1.02–6.71; $p=0.04$)

PD catheter cumulative survival stratified by placement technique

Conclusions: Our single-center experience demonstrated similar PD catheter survival rate and a better 2-year survival for catheters placed by peritoneoscopy. Our predominant use of the curly PD catheters suggests no significant difference in outcome compared to the straight catheters.

PUB585

Peritoneal Dialysis Patients Who Switch Phosphate Binders from Sevelamer to Sucroferric Oxyhydroxide as Part of Routine Clinical Practice: A Retrospective Database Study Linda H. Ficociello, Vidhya Parameswaran, Phaneth Keo, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America (FMCNA), Waltham, MA.*

Background: A retrospective database study on the real-world effectiveness of sucroferric oxyhydroxide (SO), an iron-based phosphate binder (PB), in a cohort of adult peritoneal dialysis (PD) patients (pts) was conducted. This analysis examines PD pts from that cohort who switched from sevelamer (SEV) to SO (n=183).

Methods: All pts were prescribed SO as part of routine clinical practice at FMCNA clinics. Pts eligible for analysis had ³¹P serum phosphorus (sPhos) during SO and the most recent PB used during the 3 months before SO was SEV. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), transferrin saturation (TSAT), ferritin (FER), and PB pills per day were assessed 3-months before starting SO (baseline) and 3-months during SO treatment (follow-up).

Results: Pts (n=183) were, on average, 53 years old with a dialysis vintage of 3.9 years. Pts with in-range sPhos increased from 14.8% to 25.7% (74% increase). There was a significant reduction in sPhos (6.8 to 6.5 mg/dL, p=0.005), sCa (9.2 to 9.1 mg/dL, p=0.02), and PB pills per day (8.4 to 3.8 pills, p<0.001). iPTH changed minimally (544.6 to 559.8 pg/mL, p=0.5). TSAT increased significantly (35.0 to 37.5%, p=0.02) but not FER (782.1 to 840.3 ng/mL) when pts treated with IV iron were included; there was minimal TSAT change (35.2 to 36.3%) and no increase in FER (823.2 to 732.9) in pts not treated with IV iron (n=77).

Distribution of serum phosphorus during baseline compared to sucroferric oxyhydroxide (SO)-treated follow-up for PD patients who switched from sevelamer (N=183)

*Change in %in-range and %out of range baseline compared to SO Follow-up, p=0.003.

Conclusions: In a cohort of PD patients who switched from sevelamer to sucroferric oxyhydroxide as part of routine clinic practice, an increase in patients with in-range serum phosphorus (74%, p=0.003) and significant decreases in serum phosphorus and calcium were observed. Phosphate pill burden was decreased by 4.6 pills (8.4 to 3.8 pills per day, p<0.001).

PUB586

Improved Serum Phosphorus Control and Decreased Phosphate Binder Pill Burden Amongst African American Peritoneal Dialysis Patients Taking Sucroferric Oxyhydroxide Vidhya Parameswaran, Linda H. Ficociello, Claudy Mullon, Franklin W. Maddux, Robert J. Kossmann. *Fresenius Medical Care North America, Waltham, MA.*

Background: This study evaluated the real world effectiveness of sucroferric oxyhydroxide (SO) use among peritoneal dialysis (PD) patients (pts) who self-reported race as Black or African American (AA).

Methods: A retrospective database analysis was conducted on a cohort of AA PD pts who were prescribed SO as part of standard care at FMCNA clinics. Pts had ³¹P serum phosphorus (sPhos) measured while using SO and had been on sevelamer, calcium-based phosphate binders or had no phosphate binder specified prior to SO treatment. Differences in sPhos, pill burden (PB), serum calcium (sCa), ferritin, transferrin saturation (TSAT), and intact parathyroid hormone (iPTH) were noted between baseline (BL; 3 months prior to SO) and follow-up (SO-TX; 3 months during SO).

Results: 117 AA PD pts (mean age=50 years, dialysis vintage=4.2 years) were included. At BL, 37% were on sevelamer, 31% on calcium-based phosphate binders, 2% on dual therapy and 31% had no phosphate binder specified. Figure shows increase in pts who have in-range sPhos (20% to 31.6%; 58% increase). Mean sPhos decreased from 6.55-6.38 mg/dL (p=0.06). A significant decrease in PB was observed (4.5 pills/day, p<0.001) between BL (8.8 pills) and SO-TX (4.3 pills). No significant differences were observed between BL and SO-TX for sCa (BL=9.1 mg/dL, SO-TX=9.1 mg/dL), ferritin (BL=861.9 ng/mL, SO-TX=870 ng/mL), TSATs (BL=34.7%, SO-TX=36.8%) and iPTH (BL=729.5 pg/mL, SO-TX=696.4 pg/mL).

Distribution of serum phosphorus during baseline compared to sucroferric oxyhydroxide (SO)-treated follow-up among African American PD patients (N=117)

*Change in %in-range and %out of range baseline compared to SO-TX, p=0.006.

Conclusions: In a cohort of African American peritoneal dialysis patients who were prescribed sucroferric oxyhydroxide as part of routine clinical care, there was a 58% increase in the number of patients with serum phosphorus levels in-range (p=0.006). Furthermore, there was a significant reduction in pill burden (4.5 fewer pills, p<0.001).

PUB587

Peritoneal Dialysis for Management of Refractory Heart Failure Girish Singhania, Abhilash Koratala, Amir Kazory. *Nephrology, Univ of Florida, Gainesville, FL.*

Background: Refractory heart failure (RHF) is associated with significant morbidity and mortality. There is growing interest in the use of peritoneal dialysis (PD) for management of patients with RHF. In this study, we explored the currently available data on the safety and efficacy of PD in this setting.

Methods: A search of PubMed database using key words "peritoneal dialysis" and "heart failure" from 1985 to 2015 was performed by two of the authors independently and found 763 articles, from which those including at least 20 patients who had initiated PD for cardiac indication were selected. Relevant data on efficacy and safety such as changes in the quality of life and cardiac function as well as the rate of hospitalization were extracted and compared.

Results: Seven studies (4 prospective and 3 retrospective) met the inclusion criteria with a total of 398 patients and a mean age of 70.4 years. PD was associated with improvement in functional status (1 to 2 NYHA class reductions) in 5 of the 7 studies (not reported in 2) as well as an increase in the ejection fraction in 6 studies. A variety of PD regimens were used that in general showed efficacy in removal of fluid as suggested by notable reduction in patients' weight in 6 studies by up to 8.3 kg (unavailable in 1). It was also shown to significantly reduce the number of days of hospitalization for acute HF in 6 studies by up to 90%. Five studies reported increase in responsiveness to diuretics as well as perceived improvement in the quality of life. The PD-related complications were found to be minimal in 6 studies while one reported 0.75 episode/patient/year of peritonitis.

Conclusions: Currently available evidence suggests that PD is an efficacious option for management of patients with RHF that can result in significant improvement in their functional status, hospitalization rate, and the quality of life. Based on the findings of these studies PD is safe in this population and its related morbidity does not replace HF-

associated morbidity. Larger controlled trials are warranted to explore the potential impact of PD on the mortality of patients with RHF and to define those subgroups most likely to benefit from this therapy.

PUB588

Procalcitonin, Is It a Useful Biomarker for Peritoneal Dialysis Peritonitis?
Shinhan Song, Hyeon-Cheol Park, Jae Seok Kim, Jae Won Yang, Byoung Geun Han, Seung-Ok Choi. *Internal Medicine, Yonsei Wonju College of Medicine, Wonju, Korea.*

Background: Peritonitis is a common complication in peritoneal dialysis (PD). Procalcitonin is a peptide hormone which has been used as a biomarker for the diagnosis of bacterial infection. We aimed to investigate the usefulness of procalcitonin in the patients with PD peritonitis.

Methods: This study included 33 episodes of peritonitis in 27 patients for follow-up period of 450 days. In addition, we collected samples of PD effluents from 7 PD patients without peritonitis to compare with those of peritonitis. We investigated clinical characteristics, serum and PD effluent levels of procalcitonin at the time of initial visit and discharge.

Results: The mean value of dialysis vintage of patients with peritonitis was 1774 days, incidence of total peritonitis for period of PD maintenance; 4.3 times, interval from symptom onset to visit; 13.6 hours, duration of intraperitoneal antibiotic treatment; 8.2 days, and interval from clinical improvement to recurrence; 80.7 days. Initial serum procalcitonin increased to 0.97 ± 3.67 ng/mL (mean \pm standard deviation) compared with reference values (healthy <0.05, PD patients <0.30, PD peritonitis >0.50 ng/mL), and PD effluent procalcitonin also increased compared with in the subjects without peritonitis, but not significantly (0.07 ± 0.19 vs. 0.01 ± 0.01 ng/mL, $p=0.503$). The serum procalcitonin decreased to 0.33 ± 0.54 ng/mL with clinical improvement but not significantly ($p=0.308$), and the PD effluent procalcitonin also showed the decreased level of 0.03 ± 0.08 ng/mL but not the statistical significance ($p=0.360$). Pearson's correlation analysis showed that the serum and PD effluent procalcitonin did not have relationships with existing inflammatory markers such as ESR, CRP. Lastly, procalcitonin could not predict recurrence and mortality of peritonitis.

Conclusions: Collectively, procalcitonin showed the tendencies corresponding to the clinical course of PD peritonitis, but not statistical significance. We believe that procalcitonin is not superior biomarker in PD peritonitis compared with other existing markers.

PUB589

Epidemiological Survey of Maintenance Peritoneal Dialysis in China
Xiang-Mei Chen, Xueying Cao, Delong Zhao, Guangyan Cai. *Chinese PLA General Hospital, Chinese PLA Inst of Nephrology, State Key Laboratory of Kidney Diseases, National Clinical Research Center for Kidney Diseases.*

Background: To analysis epidemiology and trend of peritoneal dialysis during 2011 - 2014 in China.

Methods: Patient-reported outcome data from the peritoneal dialysis centers were collected online during the study.

Results: (1) By the end of 2014, there were 55373 cases of maintenance peritoneal dialysis patients in China, had increased by 17% per year over this time period. The annual incidence rate was 5.81/100 million people. The prevalence was 34.3/100 million. (2) The average age was 53 years. Male to female ratio was 1.2:1. The average age at initiation of dialysis was about 50 years old. The average residual renal function was 3ml/min. The average dialysis time was 2 years. The primary causes were primary glomerular disease 54%, diabetic nephropathy 16%, hypertensive renal damage 14%. (3) In 2014, DOR fell to 6.6%. TOT was 27.2 months. The death patients accounted for about 51.3% of exit patients. The average death age was 64.8 years. The average therapy time was more than 28.6 months. The cause of death was the cardiovascular and cerebrovascular events. (4) Peritoneal dialysis access was the two cuffs, no gooseneck, straight. 78% patients were the continuous ambulatory peritoneal dialysis patients. The therapeutic dose was 6L to 8L. High peritoneal transport type was the largest. (5) PD patients with hemoglobin 100g/L ratio was raised every year. The albumin level in plasma was greater than or equal to 35g/L with more than 50% patients. Serum calcium, phosphorus, parathyroid hormone level was improved year by year. The average Kt/V was maintained at 2.1/ weeks. Ccr could reach 62 L/1.73m²/ weeks.

Conclusions: There is a 17% annual increase in peritoneal dialysis patients. The incidence and prevalence was stable. DOR and TOT improved year by year. Anemia, plasma albumin, calcium, phosphorus metabolism and dialysis adequacy control were better than before.

Peritoneal Dialysis Patients Who Switch from Calcium-Based Binders to Suroferic Oxyhydroxide as Part of Routine Clinical Practice: A Retrospective Database Study
Linda H. Ficociello, Vidhya Parameswaran, Phaneth Keo, Claudy Mullon, Franklin W. Maddux, Robert J. Kossman. *Fresenius Medical Care North America (FMCNA), Waltham, MA.*

Background: A retrospective database study on the real-world effectiveness of suroferic oxyhydroxide (SO), an iron-based phosphate binder (PB), was conducted in a cohort of adult peritoneal dialysis (PD) patients (pts). This analysis examines pts who switched from a calcium-based phosphate binder (CaPB); either calcium acetate (n=95) or calcium carbonate (n=35) to SO.

Methods: All pts were prescribed SO as part of routine clinical practice at FMCNA clinics, had ³¹P serum phosphorus (sPhos) measured during SO, and the most recent PB used was a CaPB. Changes in sPhos, serum calcium (sCa), intact parathyroid hormone (iPTH), % transferrin saturation (TSAT), ferritin (FER), and PB pills per day were assessed 3-months before starting SO (baseline) and 3-months during SO treatment (follow-up).

Results: Pts who had in-range sPhos increased from 12.5% to 22.3% (78% increase) between baseline and follow-up (Figure). There were significant reductions in sPhos (7.1 to 6.8 mg/dL, $p=0.004$) and PB pills per day (7.4 to 3.6 pills, $p<0.001$). Minimal change in sCa (8.99 to 8.95 mg/dL, $p=0.5$) and iPTH (519.2 to 544.4 pg/mL, $p=0.4$) was observed. There was significant change in FER (708.5 to 788.3 ng/mL, $p=0.008$, but not TSAT (35.8 to 35.5%, $p=0.8$) when pts treated with IV iron were included. There was minimal increase in FER (733.6 to 735.0 ng/mL, $p=0.98$) or TSAT (38.0 to 39.1%, $p=0.6$) in pts not administered IV iron (n=43).

Serum phosphorus during baseline compared to suroferic oxyhydroxide (SO)-treated follow-up for patients who switched from calcium-based binders to SO (N=130)

*Change in %in-range and %out of range baseline compared to SO Follow-up, $p=0.003$.

Conclusions: In a cohort of PD patients who switch from calcium-based binders to suroferic oxyhydroxide as part of regular clinic practice, there was a 78% increase in patients achieving in-range serum phosphorus ($p=0.003$). Additionally, phosphate binder pill burden was lessened from 7.4 to 3.6 pills per day (3.7 fewer pills, $p<0.001$).

PUB591

Effects of Chlorhexidine-Impregnated Patches on Catheter Exit Site and Tunnel Infections in Peritoneal Dialysis Patients
Chiaki Kawabata. *General Internal Medicine, Japanese Red Cross Kumamoto Hospital, Kumamoto, Japan.*

Background: Exit-site infections and tunnel infections are major causes of catheter loss in peritoneal dialysis (PD) patients. We studied the effects of chlorhexidine-impregnated patches (Biopatch), which are used as central-line dressings or drain site dressings, on PD catheter exit site infection and tunnel infections.

Methods: A retrospective review was conducted of 45 patients whose PD catheter exit site was made between January 2007 and December 2014. We compared acute exit site infections, chronic exit site infections, and tunnel infections of the two groups, (the Biopatch Group and the Non-Biopatch Group), 6 months after the exit site was created.

Results: The Biopatch was used until the exit site had healed perfectly. The mean time of using the Biopatch was 63 ± 26 days. The two groups had no significant differences in age [49.4 ± 12.0 years vs 52.3 ± 16.3 years], diabetes mellitus co-morbidity or pattern of peritoneal dialysis. There were no statistical differences in acute exit site infections [15.4% vs 6.1% ($p=0.27$)], chronic exit site infections [0% vs 9.1% ($p=0.28$)] or tunnel infections [15.4% vs 15.2% ($p=0.90$)] during the 6 months.

Conclusions: Using the Biopatch until the exit site has healed perfectly does not reduce either exit site infections or tunnel infections.

PUB592

The UK Peritoneal Dialysis Catheter Study (UK Cath): An Ancillary Study to the Peritoneal Dialysis Outcomes and Practice Patterns Study Martin E. Wilkie,¹ Simon J. Davies,² Mark Lambie,² Francesca Tentori,³ Jeffrey Perl,⁴ ¹Sheffield Kidney Inst, Sheffield Teaching Hospitals NHS FT, Sheffield, United Kingdom; ²Keele Univ, Keele, United Kingdom; ³Arbor Research Collaborative for Health, Ann Arbor, MI; ⁴St. Michael's Hospital, Toronto, ON, Canada.

Background: Delivering high quality peritoneal dialysis (PD) access placement and outcomes is limited by lack of standardization of PD access definitions and events, variable reporting of outcomes, and a paucity of robust evidence regarding optimal PD catheter insertion pathway(s). The UK Renal Registry PD access audit (2013) demonstrated 82% catheter survival at 1 year, with considerable variation between centres. Moreover, catheter function at 3 months was poorer for a medical (percutaneous) compared to a surgical (open surgical) insertion pathway.

Methods: UK-Cath, a multi-centre prospective cohort study (1350 patients, 45 dialysis centres, 18 month recruitment window) will assess the outcomes associated with different pathways of catheter insertion, dialysis unit-level policy associated with pathway use, and patient-level factors (e.g. case-mix, urgent start). Health economic benefits of these pathways will be determined using the cohort data, enriched by additional information obtained from more long-term follow-up study in a subset of patients using Hospital Episode Summary (HES) data linkage. The study has received funding from the UK NIHR Research for Patient Benefit Programme, NIHR PB-PG-0613-31028. A subset of study 20 centres will contribute to International Peritoneal Dialysis Outcomes & Practice Patterns Study (PDOPPS) with the primary objective of understanding variations in PD technique failure.

Results: We will present information on study design, instrument development, governance mechanisms, and recruitment plan. We will discuss the impact of patient engagement on study design.

Conclusions: The UK Peritoneal Dialysis Catheter Study will inform dialysis units' decision to either focus their efforts on improving a single surgical pathway or to practise a mixture of surgical and medical insertions, with the ultimate goal to improve PD catheter survival, patient experience and optimise health economic efficiency.

PUB593

Preparedness for Telemedicine in Outpatient Peritoneal Dialysis Kana N. Miyata, Panida Ditsawanon, Tiane Dai, Sharon G. Adler, Ramanath B. Dukkkipati, Anuja P. Shah, Lili Tong, Anne A. Ugalde, Jenny I. Shen. *Nephrology, Harbor UCLA Medical Center, Torrance, CA.*

Background: Peritoneal dialysis (PD) is generally performed daily by patients at home, where questions may arise. Telemedicine has the potential to improve the delivery of healthcare services and outcomes for PD patients. We studied the preparedness for telemedicine of a PD clinic run by a large dialysis organization (LDO) serving an urban under-resourced population.

Methods: Adult PD patients cared for by the clinic were asked about their interest and ability to use VSEE® (HIPAA-compliant tool for video calls) to remotely manage clinical concerns about PD. We compared patient characteristics between interested and non-interested groups. We also assessed the clinic's ability to implement VSEE®.

Results: Initial barriers encountered were with the LDO. These included a firewall that prevented video products from being loaded onto clinic computers, consent issues, concerns regarding unequal care potentially being provided to patients with and without internet access, and lack of video equipment for on-call nurses. All of these barriers were overcome. We then assessed interest in 56 patients. Their age (mean±standard deviation) was 43±13 years, 63% were male, English was the primary language for 66%, and they had been on PD for 3.0±3.2 years. 34 patients (61%) showed some interest in telemedicine, 16 (29%) downloaded the software to their laptop, tablet, or cell phone, and downloading in process for the remaining 18 (32%). The most common reason for not being interested was "no device" or "no internet access at home", which was reported by 15 patients (27%). The only additional difference in characteristics between the interested and non-interested groups was that those interested lived further away from the clinic (12.9 vs 9.3 miles, p=0.03).

Conclusions: Multiple barriers to delivering telemedicine to PD patients exist, both on the clinic and patient side. 61% of patients were telemedicine-ready. Future evaluations will determine the impact on clinically significant outcome, patient satisfaction, and clinic workflow in this population.

PUB594

When to Remove the Peritoneal Dialysis (PD) Catheter After Renal Transplantation? (RT) Saul Enrique Yampa,¹ Maité Rivera,¹ Víctor Burguera,¹ Fernando Caravaca-Fontan,¹ Estefanía Yero,¹ Nuria Rodríguez mendiola,¹ Sara Jimenez alvaro,¹ Cristina Galeano,¹ Fernando Liano.¹ ¹Nephrology, Hospital Univ Ramón y Cajal, Madrid, Spain; ²Urology, Hospital Univ Ramón y Cajal, Madrid, Spain.

Background: There seems to be consensus that the time of removal of the peritoneal catheter after RT may be delayed until renal function and the patient is stabilized, but there are few publications about it.

Methods: We analyzed retrospectively patients on Peritoneal Dialysis Unit (PD) who have received a RT between May 1995 and March 2015 gathering medical history data relating to the peritoneal catheter removal and complications.

Results: 108 patients transplanted from PD, 32 women/76 men with a mean age at the time of TR 50 +/- 13 years (range 16-80) were analyzed. Two patients received RT of living donor and 106 of cadaver. The catheter used in all was a straight Tenckhoff with two cuffs. If renal therapy substitution was needed posttransplantation all patients were treated with hemodialysis. The catheter was removed during surgery in nine patients (8%) due to exit or tunnel infection by Staphylococcus aureus or Pseudomonas aeruginosa. The withdrawal was delayed in 91 patients (84%) and 8 has not yet been removed. The average withdrawal time was 4.1 +/- 2.7 months. The indication of withdrawn was: stable renal function in 85 (93%), stable pancreatic and renal function in 4 and exit site infection in 2 (3%). Mean creatinine at the time of removal was 2.1 mg/dl +/- 1.8 mg / dl. All catheters were removed surgically under local anesthesia. The mean duration of hospitalization was 2.1 +/- 1.8 days (0-12). Four patients (3.7%) had complications during withdrawal (one hematoma, two hemorrhagic shock and one surgical wound infection). 15 (18%) patients suffered complications before withdrawal: 13 exit site infection, one peritonitis associated with urinary fistula and one spontaneous peritonitis.

Conclusions: In our experience the removal of the peritoneal catheter may be delayed until renal graft function were stabilize since the rate of complication is low compared with another studies.

PUB595

Clinical Outcomes by Differences in Therapy Among Peritoneal Dialysis Patients Hironori Nakamura, Anayama Mariko, Yasushi Makino, Masaki Nagasawa. *Dept of Nephrology, Shinonoi General Hospital, Nagano, Japan.*

Background: Studies evaluating the outcomes of peritoneal dialysis (PD) technique and patient survival, including those among patients who switch from PD to hemodialysis (HD), are scarce.

Methods: This retrospective study screened 120 patients in whom PD was initiated between January 1998 and December 2012 at our hospital. Of these, patients those who were transferred to another hospital, those who received transplantation, or those who did not have follow-up data were excluded. Fifty-two patients (age, mean ± SD: 69.2 ± 12.6 years) were included to investigate the time of survival based on PD technique and overall survival, including those patients who switched to HD, and to evaluate the correlation between survival time and pharmacotherapy at the initiation of PD.

Results: Time (in months) on PD, HD, and overall survival were 34.3 ± 30.0, 18.5 ± 43.4, and 52.6 ± 52.3, respectively. Comparison between the APD (n = 20) and non-APD patients (n = 28) showed that time on PD was 45.3 ± 34.4 vs. 31.3 ± 26.0 months, time on HD was 39.0 ± 40.6 (n = 8) vs. 81.8 ± 72.5 (n = 8) months, and overall survival time was 60.9 ± 49.9 vs. 54.7 ± 55.4 months, respectively. Comparison between groups with (n = 41) and without use of icodextrin (n = 7) showed time on PD was 10.8 ± 6.0 vs. 41.4 ± 30.1 months, time on HD was 49.6 ± 45.0 (n = 3) vs. 62.9 ± 65.3 (n = 13) months, and the survival time was 32.1 ± 41.7 vs. 61.6 ± 53.6 months. When analyzed by age groups of <60, 61–70, 71–80, and >81 years: time on PD (months) was 47.2 ± 38.4 (n = 14), 45.2 ± 23.4 (n = 15), 19.8 ± 27.0 (n = 10), and 21.2 ± 19.2 (n = 13), respectively. Time on HD was 22.8 ± 44.2 (n = 6), 14.6 ± 36.3 (n = 5), 8.7 ± 28.2 (n = 1), 26.3 ± 60.1 (n = 4), respectively; and survival time was 70.1 ± 52.8, 59.2 ± 41.9, 28.5 ± 39.7, and 46.7 ± 67.2 months.

Conclusions: The time on dialysis and survival time may be underestimated because of the exclusion of patients who are currently on dialysis. Compared with non-APD patients, APD patients had longer time on PD and overall survival time. Patients who needed icodextrin when commencing PD had shorter time on PD and overall survival time.

PUB596

Combined Markers of Protein-Energy Wasting and Inflammation Predict Clinical Outcomes in Incident Peritoneal Dialysis Patients Chan Ho Kim,¹ Jung Tak Park,² Seung Hyeok Han,² Tae-Hyun Yoo,² Shin-Wook Kang.² ¹Internal Medicine, Catholic Kwandong Univ College of Medicine, Incheon, Korea; ²Internal Medicine, College of Medicine, Yonsei Univ, Seoul, Korea.

Background: Protein-energy wasting (PEW) and chronic inflammation are not only common but are known as predictors of adverse clinical outcomes in end stage renal disease (ESRD) patients. Whether the combined values of serum albumin, high sensitivity C-reactive protein (hs-CRP), and body mass index (BMI) have an additive impact on clinical outcomes compared to each variable by itself in incident peritoneal dialysis (PD) patients was evaluated.

Methods: A prospective cohort of 565 incident PD patients from the Clinical Research Center for ESRD in Korea was selected. Patients were divided into two groups based on the baseline levels of albumin (≥ and <3.8 g/dL), hs-CRP (≥ and <0.45 mg/dL), and BMI (≥ and <23 kg/m²). Primary outcome was the composite of all-cause mortality and unplanned hospitalization.

Results: The mean age was 51.4 years and 60.0% were male. During a median follow-up duration of 27 months, 50 patients (8.8%) died and unplanned hospitalization events occurred in 123 patients (21.8%). Univariate analysis revealed an increase in primary outcome risk with lower albumin and elevated hs-CRP compared to higher albumin and lower hs-CRP, respectively. A similar tendency was observed with lower BMI and primary outcome, although without statistical significance. Regarding the combination of these variables, Cox proportional hazards analysis revealed that patients with any two risk factors and all three risk factors exhibited significantly higher hazard ratios for primary outcome compared to patients without any single risk factor. The combination of these factors retained a significantly higher HR for predicting primary outcome, even after adjusting for other confounders.

Conclusions: The combination of serum albumin, hs-CRP, and BMI at the time of PD commencement was a significant independent risk factor for the composite outcome of all-cause death and unplanned hospitalization in incident PD patients.

PUB597

Single Center Experience with a Peritoneal Dialysis Cycler with Advanced Patient Interactive Screen: Impact on Patient Training Lili Chan,¹ Ma shelda Cabus-Fojas,¹ Marcia A. Duffoo,¹ Catherine Firanek,² James A. Sloand,² Jaime Uribarri.¹ ¹Mount Sinai; ²Baxter.

Background: Learning proper device use and clinical concepts of care must be internalized by patients to successfully perform PD at home. With increasingly diverse patients going on PD and increasing adoption of urgent start PD, there is a need for simpler devices. Enhancing the learning environment with methods including visual, graphical and voice will improve the educational experience leaving the patient with better understanding of the procedure.
Methods: Automated PD training was undertaken at a university based home dialysis program using a novel APD device (AMIA). 5 patients were trained on the device in a 1:1 nurse to patient ratio. The cycler provided on screen instructions using a touch screen interface with voice guidance, text instructions and animation. Each patient was trained according to standardized outlines and sequential training progression from CAPD to APD techniques. Training included RN demonstration followed by patient direct interaction with the device. Instructions were displayed on a touch screen, along with verbal and graphical cues. Patient training completion required consistency of error free setup.
Results:

Patient	Age (years)	Gender	Etiology of renal disease	Incident (I)/ Prevalent (P)	Urgent (U)/ Routine (R)	Training Days
1	30	F	Hypertension/ NSAID	I	U	2
2	47	F	FSGS	I	U	3
3	49	F	Calcineurin Inhib Toxicity	P-HD	R	5
4	68	M	FSGS	P-HD	R	4
5	41	F	Lupus Nephritis	P-APD	R	4

5 patients aged 30-68 yrs (mean 47), 80% female with a minimum of HS education completed training. Device training ranged from 2-3 days for urgent start patients and 4-5 days in routine start patients.
Conclusions: From our experience, training times were similar or reduced using the AMIA cycler and allowed the ability to efficiently train urgent start patients. Observed advantages of the new cycler included: 1) less need for memorization 2) distinction of a beginner vs advanced mode 3) online alarm troubleshooting 4) presence of an air detector in patients' line 5) multiple prescription capability. The step by step instructions and online problem solving of the new device may impact positively the efficiency and understanding of these patients.

PUB598

Peritoneal Dialysis-Related Peritonitis in a Single Center: 10 Years Experience Patricia O. Costa, Carla M V Melo, Jordanio P. Oliveira, Flavia A. Nobrega, Jandson P. Oliveira, Kleyton Andrade Bastos. *Dept of Medicine, Federal Univ of Sergipe, Aracaju, Sergipe, Brazil.*

Background: Peritonitis remains as the main Peritoneal Dialysis (PD)- related complication. It is estimated that it contributes directly to 20% of dropout and is related to 16% of all deaths. This study proposes to evaluate episodes of PD-related peritonitis and describe its incidence, causative organisms and possible predictors in patients belonging to a DP program from a reference center at Aracaju-Sergipe-Brazil.
Methods: Retrospective cohort study that evaluated 565 patients who stayed for at least 30 days in the technique, between 01/01/2003 and 12/31/2012, with a mean age of 54 ± 19 years, 55% male, 62% less than 8 years of regular study and 88% with monthly income less than 5 national minimum wages. They remained in DP by an average of 713.5 ± 714.2 days. Since 2011, was initiated daily use of gentamicin at the exit site of the peritoneal catheter.
Results: Most patients (59%) showed no peritonitis. The global index was 1 episode every 27.03 months. It was recorded the lowest rate in 2012 (1 episode every 45.6 months), while the highest were in 2003 and 2005 (1 episode every 23.2 and 22.2 months, respectively). *S. aureus* was the most prevalent germ (23%), followed by *E. coli* (9%) and *Alcaligenes* sp (6%). The culture was negative in 31% of cases. There was healing of peritonitis in 71% of cases, with better outcome in gram-positive bacteria (83%). Gram-negative healed in 61% of cases. It identified a higher risk of peritonitis in patients with history of exit site infection (relative risk = 1.24; 95% confidence interval = 1.02 - 1.50; p <0.05). There was no significant difference between the groups, with or without peritonitis, in terms of sociodemographic factors.
Conclusions: Despite the bad social indicators of the study population, the incidence of peritonitis follows the recommendations of the International Society for Peritoneal Dialysis (ISPD), with a reduction of rates along the years, especially after the introduction of gentamicin. Similar as described by other authors, exit site infection was recognized as a peritonitis' predictor, so it is extremely important to perform preventive strategies.

PUB599

Placement of Peritoneal Dialysis Catheters: Not Limited to Operating Rooms Sijie Zheng,³ Todd Drasin,² Jeanne A. Darbinian,⁴ Paul Dybbro,² Neelam M. Bhalla.¹ ¹Nephrology, Kaiser Permanente Northern California, Hayward, CA; ²Interventional Radiology, Kaiser Permanente Northern California, Hayward, CA; ³Nephrology, Kaiser Permanente Northern California, Oakland, CA; ⁴Div of Research, Kaiser Permanente, Oakland, CA.

Background: As of December 2012, only 7% of ESRD patients in the USA utilize Peritoneal Dialysis (PD) for renal replacement therapy, despite many advantages of PD over hemodialysis (HD). One factor leading to low PD utilization is the lack of experienced surgeons available to place PD catheters in a timely manner. Interventional Radiologists (IR) can help with catheter placement. As of December 2014, Kaiser Permanente achieved a 23% PD rate among its ESRD population. One factor that contributed to the high percentage of PD utilization is a skilled IR service in the Greater Southern Alameda Area (GSAA) that facilitates the placement of PD catheters in a timely manner. We report a large number of PD catheters placed by GSAA IR physicians from January, 2011 to December, 2013 and compare to PD catheters placed by laparoscopic surgeons in the nearby East Bay Area (EBA) and Diablo Service Area (DSA) during the same time period.
Methods: We retrospectively analyzed KPNC electronic data base from 1/1/2011 – 12/31/2013. We extracted data from GSAA where IR placed PD catheters using an Advanced Image guided Percutaneous (AIP) technique. We also extracted data from the EBA and DSA where surgeons placed PD catheters using the Advanced Laparoscopic Surgical (ALS) technique.
Results: We identified 203 PD catheters placed by GSAA IR with the AIP technique and 316 PD catheters placed by EBA/DSA surgeons using the ALS technique. Overall, GSAA IR placed 39% of all PD catheters across the 3 areas during the study time period.
Conclusions: IR placed a significant percentage of overall PD catheters in 3 areas of our integrated health care system. In doing so, they overcame one of the barriers to high PD penetration in ESRD patients. In areas where there is a shortage of skilled surgeons, one can consider utilizing IR to solve this problem. Currently we are studying the outcomes of these two approaches.

Body Composition and Cardiovascular Outcomes Using Continuous Automated Peritoneal Dialysis – A Prospective Cohort Study Carlos Alberto Garza, Gabriela Leal, Bernardo Moguel. *Dept of Nephrology, National Inst of Cardiology, Mexico City, Federal District, Mexico.*

Background: Fluid overload (FO) due to compliance in Continuous Ambulatory Peritoneal Dialysis (CAPD) is common. Efforts to achieve dry weight and avoid cardiovascular outcomes (CO) are lessen from inaccurate body composition(BC) estimations despite best clinical assessment.
Methods: We'll follow BC, multiple frequency bioelectrical impedance(InBody S10, InBody Co),standard laboratories and CO, in all new patients to continuous Automated Peritoneal Dialysis(APD) previously in a CAPD. Measurements at baseline (CAPD), 1 month and every visit to the dialysis clinic thereafter (APD) for a 5 year period.
Results: These are the first data of BODY cohort study. Initial 10 subjects are described, 4 men and 6 women, median age 27 years(17-46), height 159.5cm(146-166), baseline and first follow up variables are in Table 1. Wilcoxon rank test for related samples was performed. We found that PD modality switch to APD, at 1 month, reflected a body composition transition with statistical significance (P <0.05), within the EBW/TBW ratio at expense of trunk compartment. Most likely from improved dialysis adherence

"-"not statistically significant

Conclusions: We consider that APD, on the ground of increased, uninterrupted and rigorously performed therapy, is an appropriate method to optimize FO and aim for dry weight in PD. Further recruitment of patients and follow up of the BODY Cohort study is expected to confirm this hypothesis.

The Changes in Bicarbonate Level and Ionized Ca/ Corrected Ca Ratio of Patients Receiving Peritoneal Dialysis Using Bicarbonate/Lactate-Buffered Solution Emi Kimoto, Nanae Matsuo, Masamitsu Morishita, Mami Nakamura, Yukio Maruyama, Yasuyuki Nakada, Masatsugu Nakao, Yudo Tanno, Ichiro Ohkido, Hiroyasu Yamamoto, Keitaro Yokoyama, Takashi Yokoo. *Div of Nephrology and Hypertension, Dept of Internal Medicine, Jikei Univ School of Medicine, Tokyo, Japan.*

Background: Recently, PD solution which contains 25mEq/L bicarbonate and 10mEq/L lactate (Bicarbonate/Lactate-buffered peritoneal dialysis solution; B/L solution) is developed in Japan. Because of high concentration of lactate (40mEq/L) of conventional peritoneal dialysis (PD) solution, patients have generally higher serum bicarbonate level than those of patients receiving hemodialysis (HD). The new B/L solution is expected not only its biocompatibility but also improving excess correction of acidosis. Under the metabolic alkalosis environment, we reported that PD patients have lower levels of ionized Ca (iCa) at the same corrected Ca (cCa) levels. Thus, we hypothesized that iCa / cCa ratio increased after switching PD solution from Lactate-buffered to B/L solution.

Methods: We recruited 28 patients (55 ± 13 years, male 82%, PD duration 42 ± 21 months) who switched from Lactate-buffered to B/L solution, and investigated changes in serum bicarbonate, iCa, and cCa levels.

Results: After switching solution, serum bicarbonate decreased (26.7 ± 3.2 vs 24.8 ± 2.5, P<0.01), and cCa did not change (9.3 ± 0.5 vs 9.3 ± 0.5, P=0.63). Neither iCa nor iCa/cCa ratio increased significantly (1.12 ± 0.09 vs 1.11 ± 0.09, P=0.48; 0.120 ± 0.007 vs 0.119 ± 0.006, P=0.54, respectively).

Change of parameters before and after switching bicarbonate solution

Conclusions: Conversion to B/L solution from lactate solution was associated with lower serum bicarbonate. Unfortunately, iCa did not change. Further investigations are needed to confirm the utility of the monitoring of iCa for the management of chronic kidney disease - mineral and bone disorder (CKD-MBD) in PD patients.

PUB602

Road to Success: One Academic Medical Center's Experience Building a Peritoneal Dialysis Clinic Yazan M. Alia, William A. Schlueter, Erwin E. Morales, Maria A. Gavino, Shubhada N. Ahya, Robin E. Watson. *Nephrology, Northwestern Memorial Hospital, Chicago, IL.*

Background: Peritoneal Dialysis (PD) is an option for renal replacement therapy. The US Renal Data System 2012 Annual Report states that the annual per-patient HD cost is approximately \$87,500 whereas for PD it is \$66,750. In addition, studies have demonstrated that some aspects of quality of life are improved in PD patients compared with HD patients. Despite this, PD is underutilized in the US. Northwestern Medicine's PD Program was initiated in 01/2014 with 4 nephrologists and 10 patients who transferred from a neighboring PD Unit. From 02/2014 to 04/2015, Northwestern's Peritoneal Dialysis Clinic grew to 50 peritoneal dialysis patients.

Methods: We included all patients who started on PD (or transferred to PD) in PD Clinic between the periods of 2/14 and 4/15. Patients excluded from this analysis stopped PD within this period for the following reasons: switched to HD, expired, recovered kidney function, or underwent transplantation.

PD growth overtime

Results: From January 2014 to April 2015, PD Clinic grew to 50 patients. The age range is 22-86 years and mean age is 54.4 years. Thirty-one (62%) are men. Twenty-one (42%) are African American, 13 (26%) are Caucasian, 11 (22%) are Hispanic, and 5 are of Asian descent.

Conclusions: We describe a single, academic medical center experience on growth of PD Clinic from 0 to 50 patients within 14 months. Obstacles to PD Clinic growth included lack of availability of dialysate in mid 2014 and lack of experience with Urgent Start PD. However, with time, both nephrologist and surgeons and medical staff grew comfortable with this method of dialysis initiation. Features that facilitated successful and timely growth are: 1-realtime options training, 2-surgeon cooperation, 3-physical proximity to CKD Clinic and to inpatient floors, 4-continuity of care for patient-physician from outpatient CKD Clinic to inpatient setting to outpatient Home Dialysis Clinic.

PUB603

Peritoneal Membrane Transport Evaluation in Peritoneal Dialysis Using Traditional PET, Modified PET and Mini-PET Miguel C. Riella,⁴ Jacek Waniewski,² Bengt Lindholm,³ Marcelo Nascimento,¹ ¹Univ Federal do Parana, Curitiba, Parana, Brazil; ²Inst Biocybernetics and Biomedical Engineering, Warsaw, Poland; ³Baxter Novum and Renal Medicine, Karolinska Inst, Stockholm, Sweden; ⁴Pro-Renal Foundation, Curitiba, Parana, Brazil.

Background: Peritoneal equilibration test (PET) is widely used for evaluating peritoneal transport; however, additional methods have been described to facilitate and improve this evaluation. Here we compared traditional PET (PET) with two newer methods, mini-PET and modified PET (mod-PET), which are increasingly used to investigate ultrafiltration capacity and peritoneal membrane characteristics in patients undergoing peritoneal dialysis.

Methods: Twenty-one non-diabetic adult patients on peritoneal dialysis (PD) for >3 months underwent: PET (2.27%; 4 h), mini-PET (3.86%; 1 h) and mod-PET (3.86%; 4 h). Results of dialysate to plasma concentration ratios for creatinine (D/P Cr) and sodium (D/P Na), and dialysate to initial glucose concentration (D/D0 glucose) at the end of each test were compared by analysis of variance (ANOVA), Pearson correlation and Bland-Altman test.

Results: Whereas D/P Cr was not significantly different between PET and mod-PET (p=0.746) there were significant differences between mini-PET and both PET (p<0.001) and mod-PET (p<0.001). D/P Cr for PET correlated with D/P Cr for mod-PET (r=0.387; p=0.009) but not with D/P Cr for mini-PET (r=0.088; p=0.241). Bland Altman test showed no significant bias of D/P Cr for PET vs mod-PET (-0.029; p=0.201) but a systematic difference (0.206; p<0.001) of D/P Cr for PET vs mini-PET. Whereas measurements of D/D0 glucose and D/P Na were in general not comparable nor significantly correlated, ultrafiltration during PET and mini-PET were weakly correlated (r=0.260; p=0.009).

Conclusions: These results confirm that characterization of transport status based on D/P Cr may not necessarily differ between conventional PET and mod-PET.

PUB604

Low Level of Albumin Is a Risk Factor for Short-Term Mortality of PD Patients Kenji Harada. *Kokura Memorial Hospital; Kokura Memorial Hospital.*

Background: Mortality of HD(hemodialysis) patients are reported, but few reports about PD(peritoneal dialysis) patients. This study aims to investigate clinical features of PD patients, their prognostic risk factors, and to establish a prognostic model for predicting their short-term mortality(1-2 years).

Methods: We investigated the mortality about PD patients(n=269, age:65 year old±13.7, male/female 173/96, PD vintage within 2 years, DM:121), and the influence of several parameters from 2009 to 2012. The dead and the transferred HD were excluded within 90 days. Finally 241 patients are remained. The survival rates for one year and two years were 91 % and 72 %. Infection was the most causes of death(53%). We investigated between death and several parameters(age, sex, blood pressure, albumin, hemoglobin, Ca, P, whole PTH, TC) by univariate analysis with JMP12, SAS. Those physical and laboratory data are measured at one month after PD started. Age and level of albumin were correlated with death. We hypothesized that low albuminuria and malnutrition influenced the rate of death. We divided three categories, from group A(albumin≥3.3, n=82) and group B(2.8≤albumin<3.3, n=89), group C(albumin<2.7, n=73).Cox proportional hazards regression model was used to analyse prognostic risk factors and establish prognostic model.

Results: There were significant differences between group B and A (Hazard Ratio: 2.611, $p=0.0116$, 95%CI: 1.232-6.009), group B and C (Hazard Ratio: 6.031, $p<0.001$, 95%CI: 2.975-13.53), group C and A (Hazard Ratio: 2.309, $p=0.0029$, 95%CI: 1.33-4.09). In addition these groups were analysed by adjustment factor such as age, sex, blood pressure, hemoglobin, Ca, P, whole PTH, TC with multivariable analysis. The results proved that there were tended to be correlation between group B and A (Hazard Ratio: 1.963, $p=0.09$, 95%CI: 0.901-4.61). There were significant differences between group B and C (Hazard Ratio: 4.00, $p=0.003$, 95%CI: 1.866-9.35), group C and A (Hazard Ratio: 2.037, $p=0.0029$, 95%CI: 1.165-3.63).

Conclusions: Low level of albumin increases the mortality of PD patients gradually. Therefore we may decrease the mortality of PD patients by improving nutritional condition and infection control when PD patients are introduced.

PUB605

The Effect of Neutral pH versus Conventional Peritoneal Dialysis Solutions on Peritoneal Permeability Atsushi Ueda, Kei Nagai, Toshiaki Usui, Joichi Usui, Kunihiro Yamagata, Chie Saito. Univ of Tsukuba, Tsukuba, Japan.

Background: Biocompatible peritoneal dialysis (PD) solutions have been anticipated to reduce oxidative stress more than conventional PD solutions, however, previous reports suggested peritoneal permeability have not been changed. This study was undertaken to investigate the peritoneal transport status from PD initiation, using biocompatible or conventional PD solutions.

Methods: We employed retrospectively 101 patients who started PD and divided into three groups. Acid group was consisted of 76 patients who used only conventional low pH solutions, and neutral pH group was consisted of 19 patients who used only biocompatible neutral pH solutions during the subsequent two years. The rest of six patients used low pH solutions at the initial phase of PD, then switched to neutral pH solutions. The ratios of dialysate to plasma creatinine concentration at 4 hour (D/P_{cre}) in peritoneal equilibration test were measured at every year. We evaluated D/P_{cre} levels at the initiation and two years after between acid and neutral pH groups, and also the D/P_{cre} movements before and after switching PD solutions of the six patients.

Results: There was no significant difference on the D/P_{cre} values between at the start and two years after in the acid and neutral pH groups respectively. D/P_{cre} change between at the start and two years after in the acid group was not significant different compared to that of the neutral pH group. However, D/P_{cre} declined significantly one year after switching PD solutions from acid to neutral pH.

Fig. 1-A

Fig. 1-B

Conclusions: It was not observed obvious beneficial effects of neutral pH solutions on peritoneal permeability within two years PD duration. However, the transient effect in decreasing peritoneal permeability was found, and suggested that biocompatible solutions may preserve peritoneal functions compared to conventional solutions in a long time period.

PUB606

Predictive Power of Serum Cystatin C Assessing Residual Renal Function in Patients on Peritoneal Dialysis Jong Man Park,¹ Sang Heon Song,¹ Eun Young Seong,¹ Harin Rhee,¹ Ihm Soo Kwak,¹ Il Young Kim,² Dong Won Lee,² Soo Bong Lee,² Woo Jin Jung,¹ Su Min Park,¹ Min Jung Kim,² Joo Hui Kim.² ¹Internal Medicine, Pusan National Univ Hospital, Busan, Republic of Korea; ²Internal Medicine, Pusan National Univ Yangsan Hospital, Yangsan, Republic of Korea.

Background: Residual renal function (RRF) is of considerable importance for patient survival on peritoneal dialysis. In clinical practice, the RRF is usually measured by assessing the urine concentrations of urea and creatinine and total urine output and the process is cumbersome and time consuming. Cystatin C has proposed to be used in place of RRF measurement. This study aims to investigate the predictive power of cystatin C in peritoneal dialysis patients.

Methods: This study included 54 patients on peritoneal dialysis who had evaluated RRF, serum cystatin C and serum creatinine. RRF was measured using the 24-hour urea-creatinine clearance method and cystatin C based glomerular filtration rate (eGFR_{cysC}) was estimated using the Hoek's formula. RRF and cystatin C were followed up for 6 months at least. The rate of RRF decline and slope of serum cystatin C were assessed by regression.

Results: Patients were on peritoneal dialysis for a median of 30 months and average serum concentrations of cystatin C was 5.41 ± 1.06 mg/L. Among the 54 patients, sixteen was anuric and seven became anuric during follow up. The patients with RRF had significantly lower cystatin C levels ($p=0.001$). RRF was correlated with cystatin C ($\gamma = -0.687$, $p<0.01$). In simple linear regression, RRF was associated with cystatin C ($\gamma = 0.687$, $p<0.001$), eGFR_{cysC} ($\gamma = 0.741$, $p<0.001$) and creatinine ($\gamma = 0.662$, $p<0.001$). The slope of serum

cystatin C was correlated with the rate of RRF decline ($\gamma = 0.616$, $p<0.001$) during follow up. The overall loss of RRF group had a higher level of serum cystatin C at the point of dialysis initiation ($p = 0.017$).

Conclusions: Serum cystatin C level might be convenient parameter for estimating the RRF and serum cystatin C at the point of dialysis initiation might be a predictive marker of preservation of RRF. Further studies about the cystatin C based equations are required to replace creatinine/urea clearance measured RRF.

PUB607

Peritoneal Dialysis: A Decade Experience at a Reference Centre in Brazil

Patricia O. Costa, Carla M.V. Melo, Flavia A. Nobrega, Jordano P. Oliveira, Jandson P. Oliveira, Kleyton Andrade Bastos. Dept of Medicine, Federal Univ of Sergipe, Aracaju, Sergipe, Brazil.

Background: Peritoneal Dialysis (PD) is underutilized in most countries. The Brazilian prevalence is around 9%. This study aims to describe the ten years experience on PD in a dialysis center in Northeast of Brazil (Aracaju-Sergipe). Unlike other national programs, negative selection for DP is not an attribute of this dialysis unit.

Methods: Retrospective cohort study that evaluated the sociodemographic and clinical profiles, comorbidities, peritonitis, hospitalizations and death causes of 565 patients who remained in PD for at least 30 days from 01/01/2003 to 12/31/2012.

Results: Patients were mostly men (55%), living outside Sergipe's capital (56%), had a mean age of 54 ± 19 years old when started on dialysis, were illiterate or had less than 4 school years (62%) and had a family income less than 5 national minimum wages per month (88%). The etiology of nephropathy was identified in 54% of cases, diabetic nephropathy (46%) and hypertensive nephrosclerosis (22%) were the most prevalent. Hypertension was the main comorbidity (76%). DP was the initial dialysis modality for 53% of patients, mainly as an emergency (58%), and only 9% of patients had undergone predialysis care for at least six months. Patients remained in PD by an average of $710.5 (\pm 714.2)$ days, and 61% of them also underwent hemodialysis (HD) at some point during their dialysis treatment. 676 peritoneal catheters were implanted (1.19/patient), 75% by trocar, by nephrologist, mostly Tenckhoff (58%). The main cause of dropout were infectious complications related to therapy (17%). The peritonitis index was 1 episode every 27.03 months, and *S. aureus* was the most prevalent etiological agent (22%). There were 1045 hospitalizations during follow up, most frequently due to infections (48%). The cause of death was identified in 64% of cases, mostly from cardiovascular diseases (50%).

Conclusions: In this study, patients had predominantly low socioeconomic status and did not have access to predialysis treatment, however, peritonitis rates and catheter complications are similar to those reported in other international series. HD and PD are shown as complementary techniques.

Implementation of Clinical Practice Guidelines on Antimicrobial Prophylaxis in Peritoneal Dialysis Patients Denise Campbell,¹ Fiona Brown,²

John F. Collins,³ Jonathan C. Craig,¹ Martin P. Gallagher,⁴ David W. Johnson,⁵ Geoffrey S. Kirkland,⁶ Subramanian K. Kumar,⁷ Wai Hon Lim,⁸ Dwarakanathan Ranganathan,⁹ Walaa W. Saweirs,¹⁰ Germaine Wong,¹ David Mudge.⁵ ¹School of Public Health, Univ of Sydney, Sydney, New South Wales, Australia; ²Nephrology, Monash Univ, Clayton, Victoria, Australia; ³Renal Medicine, Auckland City Hospital, Auckland, New Zealand; ⁴Renal and Metabolic Div, George Inst for Global Health, Sydney, New South Wales, Australia; ⁵Nephrology, Princess Alexandra Hospital, Woolloongabba, Queensland, Australia; ⁶Nephrology, Royal Hobart Hospital, Hobart, Tasmania, Australia; ⁷Renal Unit, Gosford Hospital, Gosford, New South Wales, Australia; ⁸Renal Medicine, Sir Charles Gairdner Hospital, Perth, Western Australia, Australia; ⁹Nephrology, Royal Brisbane & Women's Hospital, Herston, Queensland, Australia; ¹⁰Renal Unit, Whangarei Hospital, Whangarei, New Zealand.

Background: Despite the existence of international guidelines, peritoneal dialysis (PD)-related infections vary widely across Australian and New Zealand units, with multiple units reporting suboptimal rates and variable practice.

Methods: The current practice and barriers to guideline uptake were evaluated in eight PD units located in Australia and New Zealand in 2011. A multifaceted intervention was developed which included case report forms, a patient diary, a 'Preventing Peritonitis Checklist', an Emergency Department flyer, a letter to the patient's general practitioner, a medical card, and a poster summarizing ISPD and KHA-CARI guidelines.

Results: At baseline (1 Jan-31 Dec 2011), exit-site infection (ESI) rates ranged from 0.06-0.53 episodes/patient-year; peritonitis from 0.31-0.86 episodes/patient-year; and fungal peritonitis from 0.00-0.08 episodes/patient-year. After implementation (9 Dec 2013-8 Dec 2014), the ESI rates were 0.00-0.22 episodes/patient-year; peritonitis was 0.29-0.49 episodes/patient-year; and fungal peritonitis was 0.00-0.14 episodes/patient-year.

Conclusions: Implementing the various tools resulted in improvement in the ESI and peritonitis rates but the difference was not statistically significant ($P=0.15$ and $P=0.08$). There was no statistically significant difference in the fungal peritonitis rate ($P=0.64$).

Funding: Government Support - Non-U.S.

Survival Analysis of 326 Continuous Ambulatory Peritoneal Dialysis (CAPD) Patients Hao Zhang, Liu Li, Bin Yi, Wei Li. *The Third Xiangya Hospital, Central South Univ, Changsha, Hunan, China.*

Background: This study aimed to identify clinical outcomes and risk factors that may affect potential prognosis of ESRD (end-stage renal disease) patients who receiving continuous ambulatory peritoneal dialysis(CAPD) in Southern China.

Methods: ESRD patients who initiated CAPD between period Aug 1st 2002 to Mar 31st 2010 in The Third Xiangya Hospital, affiliated with Central South University were reviewed retrospectively. Demographic data including age at initiation, gender, body mass index(BMI), blood pressure, primary causes of ESRD and dialysis vintage, biochemical data including hemoglobin (HB), serum albumin(Alb), HDL(high-density lipoprotein), LDL(low-density lipoprotein), TL(total cholesterol), TG(triglyceride), immunoreactive parathyroid hormone (iPTH), serum phosphorus, serum calcium and residual renal function(eGFR) were collected from medical records. Outcome of death or technique failure from any causes were selected. All-cause mortality and survival rate were analyzed using variance analysis and COX regression.

Results: A total of 326 CAPD patients(199 male and 127 female)were identified in this study. The mean age was 50.73±14.99 years, median dialysis vintage was 46(2-144) months. Primary glomerulonephritis was the most common cause of ESRD (50.6%). The overall 1-, 3- and 5- patient survival rate were 95.4%, 79.3% and 46.2%, and 1-, 3- and 5- technique survival rate were 90.8%, 67.2% and 43.6%, respectively. Significant differences in age, BMI, hemoglobin, albumin, eGFR between groups were found. No statistical significances were found in gender and primary causes of ESRD. In multivariate cox regression analysis, patient technique survival were associated with BMI (HR=1.230(1.154-1.310), p=0.000), Alb (HR=0.913(0.882-0.945), p=0.000), HB (HR=0.981(0.971-0.992), p=0.000), eGFR (HR=0.818(0.750-0.884), p=0.000).

Conclusions: The results suggested that obesity, anemia, hypoalbuminemia, lower eGFR at the commencement were independent risk factors for technique survival in CAPD patients.

PUB610

Factors Influence the Baseline Peritoneal Transport Status Hao Zhang, Bin Yi, Cuiling Hou. *The Third Xiangya Hospital, Central South Univ, Changsha, Hunan, China.*

Background: Baseline peritoneal solute transport rate(PSTR) is an independent risk factor for total and cardiovascular(CV) mortality in the PD(peritoneal dialysis) population. The determinants of PSTR in incident PD patients are still under debate. Our objective was to explore the influence factors of baseline PSTR.

Methods: (1) 205 incident PD patients who had a standard peritoneal equilibration test(PET) within 1-3 months after commencing PD and without peritonitis history were enrolled. Pre-dialysis clinical parameters and biochemical indexes were assessed. 205 individuals were divided into two groups according to the baseline PET. High transport group: PET>0.65, Low transport group: PET < 0.65. (2) Pre-dialysis serum advanced oxidation protein products (AOPP) and dialysate AOPP, GPx, hsCRP, IL-1beta, TGF-beta1 of 59 patients among the enrolled 205 individuals were detected.

Results: (1) High baseline PET are more likely to be male(male: 77.3% vs 52.5%, p = 0.001), had lower serum albumin(34.0±4.40g/L vs 35.9±4.55g/L, p=0.005) and TG levels(1.11±0.62 mmol/L vs 1.28±0.57mmol/L, p=0.047) compared to the low baseline PET. Gender (r = 0.299, p = 0.299), serum albumin(r = 0.199, p = 0.199) and TG level(r = 0.140, p = 0.140) are correlated with the baseline PET respectively. Multiple stepwise linear regression analysis shows that gender (B = 0.085, p = 0.085), serum albumin (B = 0.005, p = 0.005) are associated with baseline PET independently. Multivariate Logistic analysis showed that men (OR = 3.314, p = 0.001), hypoalbuminemia (OR = 2.552, p = 2.552) are independent risk factors for high baseline PET.ROC curve display that when serum albumin < 35.8 g/L, it is likely to have a high baseline PET. (2) High baseline PET had a relatively high level of dialysate TGF-beta1(1.58±0.33ng/ml vs 1.75±0.30 ng/ml, p=0.049) than the low transport status. No statistical differences were found in serum AOPP and dialysate AOPP, GPx, hsCRP, IL-1beta between groups. Dialysate TGF-beta1 (r = 0.336, p = 0.009) relative to the baseline PET independently.

Conclusions: (1) Male, hypoalbuminemia, high dialysate TGF-beta1 level are independent predictors of fast baseline PSTR. (2) When serum albumin < 35.8 g/L, it is likely to have a high baseline PSTR.

PUB611

Influence of Peritoneal Transport Rate in Diabetic Patients on Peritoneal Dialysis: A Single Center Experience in Saudi Arabia Naveed Aslam. *Nephrology, Prince Sultan Military Medical City, Riyadh, Saudi Arabia.*

Background: Measurement of the peritoneal membrane transport features is crucial for both the characterization of its functional state and for the prescription of the adequate dialysis dose. It has been reported that increased peritoneal transport rate (PTR) is associated with lower patient survival, but the influence of diabetes mellitus (DM) on the PTR is still controversial. The objective of this study is to describe the PTR and its correlation, in terms of technique and patient survival, in diabetic patients on peritoneal dialysis (PD).

Methods: In a retrospective, single-center study, we evaluated a total of 84 diabetic patients, newly started on PD between January 2004 and December 2010. Peritoneal equilibration test (PET) status was recorded and patients were classified as one of the

following four peritoneal transport types: high (H), high average (HA), low average (LA) and low (L) transporters. Inflammatory and nutritional markers along with routine renal parameters were assessed. Withdrawal from PD and death were recorded.

Results: The average age of patients starting PD was 76.3 ± 7.2 with a prevalence of male gender (70%). 80% of the patients showed high peritoneal transport rate (High: 28%, High-Average: 52%, Low-Average: 20%, Low: 2%). The 1, 3 and 5 year patient survival rates were 78%, 62% and 42% respectively. Technique survival rates were 64%, 52% and 24% respectively. Only 10% of the patients could perform their PD therapy without the assistance of any family member or nurses. Only 70% of the patients were on APD among high transporters. Albumin level and CRP were negatively associated with patient survival.

Conclusions: Our data suggest that diabetic PD patients tend to be significantly high peritoneal transporters with worse prognosis in terms of patient and technique survival. This result is similar to what several large studies had reported in the literature. For diabetic PD patients, PET should be carefully evaluated and accordingly the prescription of short dwells, which have found their natural application in APD, should be kept in mind as a treatment option. The high transport rate is a contributory factor in low serum albumin levels.

PUB612

Practical Experience with Acute Peritoneal Dialysis (PD) as Initial Dialysis Modality Jiri Vlasak. *FMC, Sokolov, Czech Republic.*

Background: Hemodialysis (HD) is the predominant renal replacement therapy (RRT) in new end-stage renal disease (ESDR) patients in the Czech Republic. One of many reasons for this situation is that roughly 40% patients with ESDR are "late referral". Due to the lack of predialysis education, these patients have limited knowledge about dialysis options. Usually, hemodialysis is performed after the central catheter placement.

Methods: Between November 2012 and April 2015, 15 patients with urgent need of dialysis were successfully initiated in our center on PD as the first option treatment.

Results: In two patients, we started PD immediately after the catheter insertion and on the second or third day in 13 patients. Exchanges were conducted in the out-patient dialysis center under the constant supervision of an experienced PD nurse in the modified mode-supine position, small volume solutions with 1.5% of glucose, 6-8 exchanges daily, using automated peritoneal dialysis (APD). Only one patient was treated in the local hospital because of severe uremia related symptoms. Exchanges were well tolerated. We did not observe any early complications (leak, malfunction of the catheter, infection, bleeding etc). All patients were educated 2-3 weeks after the start of acute PD regimen and we observed a strong adherence to PD method in all 15 patients.

Conclusions: Based on our experience, acute peritoneal dialysis can be successfully administered under the conditions of outpatient care in the majority of ESDR patients with the urgent need of dialysis if three preconditions are met. First, the team of well-educated staff in PD, especially in APD. Second, a close cooperation with surgeon experienced in laparoscopically assisted puncture technique of PD catheter. Third, the ability to introduce the PD catheter as urgent surgery.

PUB613

Cause of Failure in Chronic Peritoneal Dialysis Catheters Elizabeth Huerta calixto. *Nephrology, Hospital Angeles Puebla, Puebla, Mexico.*

Background: One of most common treatment of end stage kidney failure is peritoneal dialysis. Encapsulating peritoneal sclerosis is a complication in which the osmotic capacity of peritoneal barrier is lost, mainly due to infections. This pathology has different clinical presentations that oblige to use different diagnostic and therapeutic methods.

Methods: I was a survey conducted retrospective, descriptive and cross that included June 1, 2008 to May 30, 2014 in nephrology department of Angeles Hospital.

Results: Clinical and imagine presentation in three different patients, we analyze each separately as well as their solutions. These include delimitation of the affected zone, sterilization of the cavity and it's collapse, even the renal transplantation.

Conclusions: Different clinical presentations of the encapsulating peritoneal sclerosis oblige to design evaluation and treatment for each patient in particular, using all the imagine and laparoscopic methods.

PUB614

Take on Characteristics of Incident PD Patients in a Multicentre Multinational Integrated Care Setting Belen Marron,¹ Marietta Torok,² Delia Timofte,³ Janusz Ostrowski,⁴ Jose C. Divino-Filho,¹ *Diaverum Home Therapies. Medical Office, Diaverum, Munich, Germany; ²Szeged Diaverum Clinic, Diaverum, Szeged, Hungary; ³Sema Diaverum Clinic, Diaverum, Bucharest, Romania; ⁴Wlclawek Diaverum Clinic, Diaverum, Wlclawek, Poland.*

Background: Our institution as a Renal Service provider is committed to integrated care, offering all types of RRT and focusing in patient's choice. Objectives: To analyze HD and PD take on and its relationship with the type of previous referral and provided care.

Methods: Retrospective analysis of 547 incident patients starting dialysis in 23 HD/PD clinics in 2012. Early referral (ER) considered if patient known ≥ 3months in Nephrology, and scheduled initiation of dialysis with a permanent access was considered planned (P).

Results: Population: 30% diabetes, mean age 64 years, 84% with previous medical care of renal disease, 49 % late referral, 80% modality informed, 58 % unplanned start, 11% PD (3% early switch from urgent HD). PD therapy in non-planned start applied in 5/59 PD patients. No differences in HD/PD take on were observed for gender, diabetes, initial renal and predialysis follow up, at structured units or in elapsed time between early

follow up and dialysis start. PD patients (p=0.02) received more modality information than HD (92% vs. 78%) and were mainly under 50 years (p <0.001). PD incidence varied according with different studied groups

Studied groups: n (% vs.col.)	All patients n=547	HD n=488	PD n=59	p value
ER + P	168 (31)	133 (27)	35 (59)	< 0.001
Late referral + P	63 (12)	58 (12)	5 (9)	
ER + Unplanned start	113 (20)	104 (21)	9 (15)	
Late referral + Unplanned start	203 (37)	193 (40)	10 (17)	
Optimal care: ER + modality informed + P	121 (22)	96 (20)	25 (42)	

Conclusions: Despite commitment to offer PD/HD as complementary treatments, PD incidence is still low. Optimal care provision is important to improve outcomes but also to involve patients in their therapy choice.

PUB615

The Adsorption Kinetics Profile of Aminoglycoside Antibiotics During Lixelle S-35 Cartridge Hemoperfusion Marco Sartori,^{1,2} Angela Casas,¹ Silvia De Rosa,¹ Mirella Zancato,² Leopolda Zampieri,¹ Davide Giavarina,¹ Claudio Ronco.¹ ¹International Renal Research Inst of Vicenza, St. Bortolo Hospital, Vicenza, Italy; ²Dept of Pharmaceutical and Pharmacological Sciences, Univ of Padua, Padua, Italy.

Background: The bactericidal activity against Gram(-)mo of Tobramycin(TOB)and Gentamicin(GEN)is concentration-dependent.It is therefore fundamental achieving the maximum drug plasma levels.Lixelle S-35 cartridge is a sorbent used in dialysis-related-amyloidosis which can modified the drug plasma levels.The aim of *in vitro* study was to evaluate the TOB and GEN adsorption removal by Lixelle S-35.

Methods: We performed mock direct hemoperfusion (DHP;Q₀=100ml/min;Bellco prototype dialysis machine)for 120 min using Lixelle S-35 cartridge.Human blood was diluted with fresh frozen plasma in order to achieve appropriate rheological characteristics(Hct 30%;650mL each bag;n=6).Blood was separately spiked with TOB(11.00±0.42 mg/L;n=3)and GEN(12.80±1.06mg/L;n=3)then it was circulated into the system.Samples were taken from arterial(Cpin)and venous(Cpout)lines at 5,10,60 and 120 min.Sample levels were measured by TOBR and GENT Flex methods(Siemens Healthcare,Newark,NJ,USA)for TOB and GEN,rspectively.The adsorption kinetics profiles were calculated.

Results: At the of DHP TOB and GEN levels were 7.13±0.18 and 7.20±0.90mg/L. Ratio Cpout/Cpin rose rapidly during the first 5 min then reach plateau for both antibiotics as shown Fig.On mass balance analysis,the total mass of antibiotics introduced into the system decreased from 5.12±0.25 to 3.22±0.50 and from 6.16±0.51 to 3.32±0.41mg for TOB and GEN,rspectively.The TOB mass adsorption was 37.20% whereas GEN was 46.20%.

Conclusions: Our *in vitro* study indicates an high adsorption rate for both aminoglycosides.This should be considered when TOB or GEN are used in pts treated with Lixelle S-35 cartridge.A supplemental dose may be needed to maximixed efficacy.

PUB616

Analysis of Some Aminoglycoside Antimicrobials in Human Plasma by HILIC-MS/MS Shinya Omiya,^{1,2} Xiao-Pen Lee,² Takeshi Kumazawa,² Keizo Sato,² Kiyoko Inui,¹ Tomoaki Miyazaki,¹ Yoshihiko Inoue,¹ Ashio Yoshimura.¹ ¹Dept of Medicine, Div of Nephrology, Showa Univ Fujigaoka Hospital, Kanagawa, Japan; ²Dept of Legal Medicine, Showa Univ School of Medicine, Tokyo, Japan.

Background: Aminoglycoside(AG) antimicrobials(AMBs) have been used for a treatment of bacterial infections,especially by acid-fast bacteria.However,their acute overdose or chronic abuse can cause serious side effects,such as difficulty in hearing, interstitial nephritis resulting in renal failure and even sudden death from anaphylactic shock.In such cases,there is a great need to identify and quantify AG AMBs in the blood from patients or cadavers.We earlier reported an analytical procedure for nine AG AMBs

in human serum by capillary HPLC/mass spectrometry(MS).Although this method works well for identification of the drug,it is semi-quantitative unless a suitable isotopic internal standard is used.

Methods: A simple,rapid,sensitive and quantitative method is presented for the analysis of six AG AMBs (streptomycin, ribostamycin, kanamycin, amikacin, dibekacin, arbekacin) in human plasma samples by hydrophilic interaction liquid chromatography(HILIC)-tandem MS(MS/MS).A small volume(150ul) of plasma spiked with six drugs was diluted with 350ml of acetonitrile containing 0.1% formic acid.After centrifugation,100ul of the clear supernatant extract was directly injected into the HILIC-MS/MS,without any solvent evaporation and reconstitution steps.The chromatographic separation of the AG AMBs was achieved on Unison UK-Amino HILIC column(50mm x 3mm i.d.,particle size 3um)with a linear gradient elution system composed of 0.1% formic acid and acetonitrile.

Results: All drugs showed base peaks due to [M+H]⁺ ions by HILIC-MS with positive ion electrospray ionization,and the product ions were produced from each [M+H]⁺ ion by HILIC-MS/MS.Quantification was made by selected reaction monitoring.The data obtained from actual determination of the AG antimicrobials in human plasma after their oral or intramuscular administration are also presensted for validation of the methods.

Conclusions: This method would seem to be useful in clinical and forensic medicine because of its ability in both identification and quantification of the drugs.

PUB617

Prevalence of Chronic Musculoskeletal Pain Among Hemodialysis Patients Magdy M. Elsharkawy, Cherry Reda, Haitham Ezzat, Amr Mohab. *Nephrology Dept, Ain Shams Univ, Egypt.*

Background: Chronic musculoskeletal (MS) pain is common in patients with end stage renal disease (ESRD) undergoing hemodialysis; however information regarding its frequency and prevalence is relatively scarce.

Methods: A cross-sectional study was conducted on 100 ESRD patients on maintenance hemodialysis 3 times per week for at least 3 months. Chronic musculoskeletal pain was evaluated using the VON KROFF questionnaire for grading the severity of musculoskeletal pain. Correlation was done between chronic MS pain and physical findings of motor and sensory systems examination. In addition, correlation was also done between chronic MS pain and serum intact Parathormone (i-PTH), serum corrected calcium, serum phosphorus, serum alkaline phosphatase, serum albumin & hemoglobin level.

Results: Mean age was 57.46 years. Mean dialysis duration was 3.80 years. 42% were females and 58% males. In our study, 37% of the patients had low disability low intensity of pain i.e. little affection on the daily, social & work activity(grade 1),37% of the patients had low disability high intensity of pain (grade 2) while 26% of them had high disability high intensity of pain i.e. moderate limitation of the daily, social, recreational & work activities (grade 3). Chronic musculoskeletal pain showed positive correlation with muscle state, tenderness and power (p<0.001, p<0.001, p=0.001 respectively). Grade 3 disability patients had the highest level of serum Ca and i-PTH which were significantly different from grade 1 and 2 patients (p<0.001, p=0.013 respectively). While serum albumin level was lowest in grade 3 patients (p=0.025).

Conclusions: Chronic MS pain is common in ESRD patients.Disturbed mineral metabolism is strongly associated with chronic MS pain in long-term HD patients. Musculoskeletal system involvement remains a common problem that limits the physical function of patients with ESRD.

PUB618

Practice Patterns of United States Nephrologists in Blood Pressure Medication Use when Transitioning Patients to Dialysis Mary C. Mallappallil,¹ Steven Fishbane,² Rimda Wanchoo,² Andrea Roche-Recinos,¹ Subodh J. Saggi,¹ Moro O. Salifu.¹ ¹Internal Medicine- Div of Nephrology, SUNY Downstate School of Medicine, Brooklyn, NY; ²Internal Medicine -Div of Nephrology, Hofstra North Shore LIJ School of Medicine, Great Neck, NY.

Background: As there is no standard approach to transition a patient in chronic kidney disease (CKD)-5 to CKD5-Dialysis in regards to adjustment of diuretics, BP medication, optimal frequency of medication reconciliation (MR) and determination of dry weight (DW) we conducted a survey to determine how US nephrologists transition a patient from CKD5 to CKD5D in these aspects.

Methods: We designed an anonymous electronic survey with 39 questions and sent it to practicing nephrologists in the US after IRB approval.

Results: 120 US Nephrologists replied to the survey; 60% were in Nephrology for more than 10 years. Most (79%) used furosemide in CKD 5, (66%) used a combination of furosemide and metolazone. The first choice of diuretics in CKD5 was furosemide (79%), bumetidine (12%) and torsemide (9%) (p<0.005). In CKD5D, 45% used diuretics daily, 29% on non-dialysis days and 26% discontinued them(p=0.02). In CKD 5, 63% would continueACEI or ARB. In CKD5D, 84% of responders had at least 30% of patients on ACEI/ARB and most (64%) would not stop these medications despite hyperkalemia. The majority (79%) did not change ACEI to those that were not dialyzed out. The perceived most effective BP medication in CKD5D in decreasing order: Nifedipine/amlodipine (36%), ACEI/ARB(29%), beta blockers(17%), diuretics(13%) and others(4%); (p<0.0005). Most responders (70%) prescribed BP medication on non-dialysis days only and 88% thought that high BP in the first month could be controlled with ultrafiltration. The first MR in new CKD5D was monthly (78%), weekly (12%) and as needed only (8%). DW was determined in the first week(31%) and the first month(52%). Of those surveyed, 59% felt HTN in CKD5D hadt multiple causes.

Conclusions: Transitioning patients from CKD5 to CKD5D continues to remain challenging in terms of adjustment of BP medication. Variations in practice regarding the frequency of medication use may benefit from guidelines.

PUB619

First Dialysis Prescription and Access Use: A Survey of United States Nephrologists Mary C. Mallappallil,¹ Steven Fishbane,² Rimda Wanchoo,² Andrea Roche-Recinos,¹ Subodh J. Saggi,¹ Moro O. Salifu.¹ ¹*Internal Medicine-Renal Div, SUNY Downstate School of Medicine, Brooklyn, NY;* ²*Div of Nephrology, Hofstra North Shore LIJ School of Medicine, Great Neck, NY.*

Background: As there is no standard approach to initiate renal replacement therapy in CKD5patients in regard to location of first treatment, access and dialysis prescription we conducted a survey of US nephrologists to better identify current practice patterns.

Methods: We created an anonymous electronic survey with 39 questions that was validated then approved by the IRB. Aggregate data was analyzed using descriptive statistics, avoiding duplicate responses.

Results: 120 US nephrologists replied to the survey, 60% were in nephrology practice for more than 10 years. The first hemodialysis (HD) treatment was as inpatient (22%), outpatient (29%) or either (49.5%). At the first HD, most nephrologists (92%) used a blood flow (BF)<300 mL/minute; 65% would use lower than usual dialysate flow rates (DFR) and 47% would use a smaller dialyzer. Ninety six percent prescribed less time than usual, even with blood urea nitrogen less than 100 mg/dL. About 45% replied that only 10 -50% of patients meeting criteria for peritoneal dialysis were actually started on this modality (p<0.005). Of the participants 47% noted that only 10 – 50% of patients who were eligible for transplant were listed, and the majority of responders (83%) noted that less than 10% of their patients got a preemptive transplant (p<0.0005). A patient educator was available to 64% of the participants. First dialysis with a permanent access was noted among 30-60% of patients by 43% of responders and in more than 60% of patients by 22% of responders. Of the participants 73% replied that the majority (>60%) of their patients got vein mapping before access creation. The time between vein mapping and access creation was one week to one month (61%) and more than one month (26%), (p<0.005) . The number of angioplasties that were acceptable prior to primary access failure was noted as 2, (25%) 3 (25%) or more than 4(24%).

Conclusions: There is variation in practice in several areas in regard to the initial dialysis session in CKD5D which may benefit from guidelines.

PUB620

How to Dialyze a Patient with Left Ventricular Assist Device in a Chronic Dialysis Unit? A Practical Protocol Sadiq Ahmed,¹ Debbie Baker.² ¹*Univ of Kentucky;* ²*Davita.*

Background: To provide chronic HD treatments to ESRD patients with LVAD in a chronic unit in the community is a challenge and a relatively new experience for nephrologists. As LVADs have revolutionized the treatment of advance heart failure there are rising numbers of these patients developing ESRD with need for HD in the community. Development of a practical , simple and safe protocol is needed to dialyze these patients in the chronic units.

Methods: This protocol and safety check list is developed to provide routine HD treatment for patients with LVAD and successfully implemented in a chronic dialysis unit in the community setting. The special policy and procedure relevant to this protocol , safety check list and standing orders for the dialysis nurses were approved by the governing body before dialysis staffs were trained. The VAD coordinator is present during first training.

Results: This protocol is a step by step guidance for the dialysis staff. The whole process has 3 components. 1.A supplemental informed consent signed by the patient to cover for additional higher risk of HD with LVAD. 2.Guidance and check list for the dialysis staffs for assessments of LVAD patients with additional documentation before starting HD treatment. 3.Standing order to be followed by staff during dialysis of LVAD patient on top of regular dialysis orders. # 2 and 3 covers patient assessment, verification of LVAD equipment ,power supplies and special hemodynamic monitoring of these patients during HD.

LVAD check list
Presence of support person who waits in lobby after power base is connected
Fully charged extra batteries for LVAD & backup system controller
Power base unit connected to electrical outlet & Patient connected to unit
Charge nurse to review LVAD log and trends
Document Pump Flow, Pump Speed & Pulsativity index for treatment and previous day
Obtain doppler, lubricant & sphygmomanometer for every 30 minute BP check
Initiate HD
Document LVAD assesment, doppler pressure, communications with MD and VAD coordinator
Review Post weight with carge Nurse if > 1 KG above TW notify MD

Conclusions: This protocol to provide incenter HD to patients with LVAD in a chronic unit is simple & safe. It can be implemented in a chronic HD unit.

PUB621

Association Among Calcium, Phosphorus, and Parathyroid Hormone with Aortic Ring Calcification in a Cohort of Hemodialysis Patients Arturo Reyes Marin. *Nephrology, Hospital Juarez de Mexico, DF, Mexico.*

Background: The prevalence of vascular calcification in dialytic therapy is 40-92%, values increased in serum levels of calcium (Ca), phosphorus (P) and parathyroid hormone (PTH) have been associated with high calcification progression and cardiovascular mortality. It has been described association among serum levels of Ca, P, Ca-P product and PTH with aortic ring calcification in patients with chronic renal disease (CRD). We did an observational and descriptive study, in the nephrology department of Hospital Juarez de Mexico, with a cohort of 95 hemodialysis patients, the aim of study was to evaluate the association among aortic ring calcification by torax radiography with the serum levels of Ca, P and PTH.

Methods: Adult patients in hemodialysis were included, patients with severe malnutrition, cancer and mental abnormalities were excluded. We used 2 scales (torax radiography), in order to assessment the aortic ring calcification and we did correlation coefficient among Ca, P, PTH and 2 scales. We used Pearson correlation coefficient for analysis and Bland-Altman test for analysis of concordance among Ca, P, PTH and 2 scales.

Results: They were 95 adult patients: 50 (52%) men and 45 (48%) women, average age was 40.7 years old. We found weak negative correlation between Ca and PTH (r = - 0.28, p > 0.05)), weak positive association was found between P and PTH (r = 0.30, p > 0.05), correlation between PTH and CaxP (r = 0.36), p > 0.05), PTH and 2 scales (r = 0.5, p>0.05). In the scales that we used to evaluate vascular calcification (torax radiography) showed high scores, however the intraclass correlation coefficient between scales and PTH, Ca and P (0.33) showed not statistical significance.

Conclusions: Despite that vascular calcification was high by torax radiography, the association among scales (torax radiography) and serum levels of Ca, P and PTH was not statistical significant. There are other important factors that can explain the progression of vascular calcification and the traditional markers for calcification: Ca, P and PTH are not enough for explain it.

PUB622

β2-Microglobulin Removal: Comparison Between Lixelle S-35 Cartridge Coupled with High-Flux Dialysis versus Online-Hemodiafiltration Marco Sartori,^{1,2} Sara Samoni,¹ Federico Nalesso,¹ Alessandra Brendolan,¹ Mauro Neri,¹ Francesco Garzotto,¹ Silvia De Rosa,¹ Mirella Zancato,² Claudio Ronco.² ¹*International Renal Research Inst of Vicenza, St. Bortolo Hospital, Vicenza, Italy;* ²*Dept of Pharmaceutical and Pharmacological Sciences, Univ of Padua, Padua, Italy.*

Background: Lixelle is a sorbent used to treat dialysis-related amyloidosis due to β2-microglobulin(β2-MG)deposit. The aim of this study was to assess the impact of Lixelle S-35 coupled with High-Flux Dialysis(HFD)vs online Hemodiafiltration(OL-HDF)in 2 pts.

Methods: We enrolled 2 pts with β2-MG levels over15mg/L,treated with OL-HDF. *Case 1.* Male,57yrs old with BMI35.5Kg/m². We collected samples previous and after pre/post-reinfusion OL-HDF(n=3). Then the pt was shifted to HFD+Lixelle S-35(n=3; Q_B=380mL/min; Q_D=500mL/min; ΔBW=2.87±0.42Kg). *Case 2.* Male,72yrs old, BMI26.8Kg/m². We collected samples previous and after post-reinfusion OL-HDF(n=3). Then the pt was shifted to HFD+Lixelle S-35(n=3; Q_B=300mL/min; Q_D=500mL/min; ΔBW=3.1±0.53Kg). We compared the data obtained in each treatment.

Results: *Case 1.* Before and after pre/post-reinfusion OL-HDF and HFD+Lixelle S-35, β2-MG levels were 18.26±3.91 and 5.00±0.18, 27.34±1.45 and 7.96±0.77mg/L, respectively. There was no difference between pre/post-reinfusion OL-HDF(71.44%)and HFD+Lixelle S-35(70.90%)β2-MG removal rate[RR]. *Case 2.* Before and after post-reinfusion OL-HDF and HFD+Lixelle S-35 β2-MG levels were 13.68±4.10 and 4.66±0.24, 17.23±1.55 and 5.13±0.60mg/L, respectively. There was difference between post-reinfusion OL-HDF(63.44%)and HFD+Lixelle S-35(70.09%)β2-MG removal rate. We did not observe any adverse reactions and/or side effects potentially related to Lixelle S-35.

Conclusions: Our preliminary results indicate that HFD+Lixelle S-35 seems to be more efficient in β2-MG removal than post-reinfusion OL-HDF, whereas no differences have been found with pre/post-reinfusion OL-HDF. More studies are needed.

Does Dialysis Influence Treg Cells? A Meta-Analysis Carlotta Caprara,¹ Gilbert R. Kinsey,² Wenjun Xin,³ Jennie Z. Ma,³ Valentina Corradi,¹ Elisa Scalzotto,¹ Francesca K. Martino,¹ Mark D. Okusa,² Mitchell H. Rosner,² Fiorenza Ferrari,¹ Claudio Ronco.¹ ¹*International Renal Research Inst Vicenza (IRRV), Dept of Nephrology, Dialysis & Transplantation, St. Bortolo Hospital, Vicenza, Italy;* ²*Medicine, Univ of Virginia, Charlottesville;* ³*Public Health Sciences, Univ of Virginia, Charlottesville.*

Background: The immunological state of patients with ESRD is dysregulated. Regulatory T (Treg) cells comprise a small proportion of the total lymphocyte population yet regulate key immune responses across a variety of disease settings. Contrasting results have been reported about the influence of dialysis on Treg cells. Our aim is to determine whether the available literature support a positive or negative influence of dialysis on Treg cells.

Methods: After screening 84 published studieies (PubMed and Web of Science) we included 10 that evaluated Treg cells in ESRD patients. Of these, 5 studies that included comparable healthy controls (HCs) and hemodialysis (HD) patients and used similar criteria for determining the percentage of Treg cells in total CD4 T cells were subjected to a meta-analysis.

Results: A total of 99 HD patients and 88 age-matched HCs were included in these 5 studies. Using the fixed effect model a significant difference in the percentage of Treg cells in total CD4 T between HD and HCs was observed ($P<0.001$). The mean difference in Treg percentage was -2.34% in HD patients vs. HCs. Several discrepancies were noted between studies that may be due to the lack of consistent criteria for Treg cell identification and use of different type of dialysis membranes which was not specified in all articles.

Conclusions: The available literature comparing Tregs in HD patients and HCs suggest HD is associated with a reduction in Tregs. A limitation is that only a few articles consider uremic patients (ESRD not on dialysis) as a control group for HD. Furthermore, no studies have investigated Treg cells in the same patient before and then after initiating dialysis. This type of study will be critical to understanding the influence of dialysis on Treg cells. Furthermore, the clinical significance of these changes in Treg cell numbers will need to be elucidated.

PUB624

Combination of Insulin Degludec (IDeg) and Liraglutide (Lira) (IDeg+Lira) Is Potentially Superior to Basal-Bolus Insulin Therapy (BB) in Hemodialysis (HD) Patients with Type 2 Diabetes (T2DM) – An Assessment by Continuous Glucose Monitoring (CGM) Satoshi Funakoshi,¹ Jyunichiro Hashiguchi,¹ Kenji Sawase,¹ Osamu Sasaki,¹ Hiroshi Ichinose,¹ Miwa Shirahama,¹ Miki Yano,¹ Yutaka Mori,³ Takuhisa Uchino,¹ Kazunori Utsunomiya,³ Yoko Obata,² Tomoya Nishino,² Takashi Harada.¹ ¹*Nagasaki Kidney Center, Japan;* ²*Dept of Internal Medicine, Nagasaki Univ Graduate School of Medicine, Japan;* ³*Dept of Diabetology, Jikei Univ, Japan.*

Background: During HD, plasma glucose (PG) level drops due to various factors including clearance gap between glucose and insulin, and then rebounds to hyperglycemic state after HD. Therefore, it may be difficult for conventional BB to control these complicated PG changes in HD patients with T2DM. Recently a free combination of any insulin and Lira has been approved in Japan.

Methods: Eight adults with T2DM, glycoalbumin (GA) of $>20\%$, fasting C-peptide of >8 ng/ml and treated with BB including IDeg (5-74 units) + insulin lispro (5-30 units) were converted to daily injections of the free combination of same dose of IDeg and 0.9mg of Lira (IDeg+Lira), then IDeg was titrated to achieve an appropriate fasting plasma glucose level. Glycemic control was assessed by CGM and the mean amplitude of glycemic excursions (MAGE) was calculated before and after the conversion.

Results: As shown in figure 1, after 4-8 weeks of change from BB, mean both MAGE and PG were significantly decreased as shown in figure. Six out of 8 patients reported gastrointestinal adverse events, but these events were transient.

Conclusions: IDeg+Lira can potentially be superior compared with BB in controlling glycemic fluctuations in HD with T2DM.

PUB625

More Nephrologist Visits Are Associated with Lower Cost of Care for Dialysis Patients Hao Han, Jane Brzozowski, Sheetal Chaudhuri, John W. Larkin, Mahathi Mothali, Len A. Usvyat, Terry Ketchersid, Franklin W. Maddux. *Fresenius Medical Care North America, Waltham, MA.*

Background: Medicare patients with end stage renal disease (ESRD) are treated by nephrologists, primary care providers (PCPs), cardiologists and other specialties on a regular basis. We investigated the relationship of visits to these providers and total costs of care.

Methods: Medicare 100% ESRD data for patients with evidence of dialysis at any time during January 1, 2010 through December 31, 2011 were analyzed. Nephrologist, PCP and cardiologist visits were determined by specialty codes of Part B claims (including both in- and out-patient visits). All data was aggregated at the Metropolitan Statistical Area level (MSA). We computed a ratio of nephrologist visits to PCP visits per MSA as well as nephrologist visits to cardiologist visits per MSA during the above period (visits were calculated on a per patient per month basis). Total costs of care (per member per month [PMPM]) were determined by aggregating Medicare Part A and B costs. Comparisons of ratios were performed using t-tests for quartiles of PMPM for two specialty visit ratios.

Results: Claims for 368,711 patients were analyzed. Patients in the lower quartiles of total cost had significantly more nephrologist visits relative to PCPs and cardiologists.

Ratios by Quartiles of Total Cost

Conclusions: These results indicate that higher ratios of nephrologist visits to cardiologist/PCP visits are significantly associated with decreased cost on a MSA level. Taken that nephrologist visits tend to be constant (due to the monthly capitated payment), these results may be revealing a “sicker” and therefore more expensive population of patients on a MSA level that require more medical attention from a cardiologist or PCP, likely due to hospitalizations. Adjustments for underlying disease should be considered.

PUB626

Prediction of Non-Adherence to Hemodialysis Treatment Regimens Yue Jiao,¹ Daniel E. Geary,¹ Theresa J. Hetzel,¹ Sheetal Chaudhuri,¹ Mahathi Mothali,¹ Terry Ketchersid,¹ Dugan Maddux,¹ John W. Larkin,¹ Peter Kotanko,^{2,3} Brian Scott Ash,¹ Len A. Usvyat,¹ Franklin W. Maddux.¹ ¹*Fresenius Medical Care North America, Waltham, MA;* ²*Renal Research Inst, New York, NY;* ³*Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Non-adherence with hemodialysis (HD) treatment regimens is known to be associated with increased morbidity and mortality. The aim of this project was to develop a predictive model (PM) to identify HD patients who will likely have unexcused no shows to routine dialysis treatments within the next week.

Methods: Using data between 1/1/2014 and 12/31/2014 from the Fresenius Medical Care Knowledge Center and 2014 weather data from the National Oceanic and Atmospheric Administration’s National Centers for Environmental Information, PMs were designed and developed for prediction of unexcused no shows in patients not residing in a nursing home. Various PMs were investigated and included the generalized linear model, partitioning and regression trees, artificial neural networks, and generalized additive model (GAM). In all, 1,554,833 records stratified in weekly intervals on 60 variables from 172,854 patients were utilized. Variables included data on the patient’s history of unexcused no shows, demographics, comorbidities, laboratories, holidays, sporting events, and weather. A multi-tier prediction process was performed with respect to the availability of data. The area under the curve (AUC), sensitivities and specificities were investigated to determine the model with the highest performance.

Results: Best performing model had AUC of 0.87 for the multi-tier PMs utilizing a 30% test dataset. A small pilot test on 860 patients for three weeks utilizing optimal Youden index as the cutoff value to predict the high probability of the unexcused no show events achieved an average sensitivity of 0.57 and specificity of 0.95.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

Conclusions: This pilot test of the developed modeling demonstrates that PM can assist in identifying patients with a high probability for unexcused missed HD treatments. Additional studies are needed to further analyze the potential of predictions for and interventions associated with reducing unexcused no show events.

PUB627

Factors Influencing Residual Renal Function Decrease in Hemodialysis Treated Patients Fernando Caravaca-Fontan, Milagros Fernandez-Lucas, Jose L. Teruel, Saul Enrique Pampa, Estefania Yerovi, Maria Delgado yagüe, Fernando Liano. *Nephrology, Hospital Univ Ramon y Cajal, Madrid, Spain.*

Background: We have shown in previous studies that maintenance of residual renal function in hemodialysis treated patients is conditioned by the number of weekly sessions, and is better in patients who start treatment with a twice weekly schedule. The aim of this study is to analyse the influence of other variables in the preservation of residual renal function.

Methods: Of the 174 consecutive patients who started hemodialysis treatment in the hospital, 98 began with 2-weekly sessions (2HD group), and 76 with 3-weekly sessions (3HD group). Residual renal function was measured every two months (mean urea and creatinine clearance).

Results: Decrease in residual renal function was lower in the 2HD group (median 0.19 vs 0.46 ml/min/month, p=0.005). In both groups the residual renal function decrease was higher in the patients from the transplant program than in those from predialysis: 2HD group: median 0.93 vs 0.17 ml/min/month, p=0.003; 3HD group: median 0.76 vs 0.32 ml/min/month, p=0.005. Neither the initial schedule, sex or etiology of the renal disease influenced the decrease in residual renal function in either of the two groups of patients. Moreover we found no correlation between the decrease in residual renal function with age, the renal function at the start of dialysis or with the Charlson comorbidity index. Of the 98 patients who began with the 2HD schedule, 45 went on to dialysis three times a week when the residual renal function was less than 3 ml/min: these patients had a mean of 10±8 months on the 2HD schedule. The length of time on this model was not influenced either by age, sex, etiology of the nephropathy, comorbidity index, scheduled start or basal renal function.

Conclusions: The decrease in residual renal function in the patient treated with hemodialysis depends basically on the number of weekly sessions with which the dialysis treatment was started. Of all the variables analysed only the return to dialysis due to graft loss conditioned a higher decrease in residual renal function in both groups of patients.

PUB628

Circadian Blood Pressure Behaviour in Hemodialysis Patients Dimitrios Petras,¹ Kyriakos Dimitriadis,² Panagiota E. Giannou,¹ Eirini Andrikou,² Konstantinos Tsioufis.² *¹Nephrology Dept, Hippokration Hospital, Athens, Greece; ²First Cardiology Clinic, Hippokration Hospital Univ of Athens, Athens, Greece.*

Background: Blood pressure (BP) evaluation and management in haemodialysis (HD) patients is often a matter of debate. During HD hypotension as well as a paradoxical rise in BP may be documented. Intradialytic BP is also variable depending mostly from the weight gain between the HD sessions. We investigated circadian BP behavior in the setting of HD.

Methods: We studied 38 patients with ESRD (68% men, mean age 62±19 years, 52% hypertensive) that underwent HD three times a week in the HD unit of our hospital and were at their ideal dry weight. Ambulatory BP monitoring was applied one hour before an HD session and was set to measure BP every 30 minutes and until arrival for the next HD session, for a total of two subsequent 24-hour periods. Blood pressure dipping was defined as [(daytime systolic BP – nighttime systolic BP)/ daytime systolic BP]. Patients were defined as dippers if BP dipping was >10% and risers if BP dipping <0%.

Results: Body weight before and after the HD session was 78±28Kg and 75±27mmHg respectively. Ambulatory systolic/diastolic BP increased not significantly from 127±23/70±13mmHg to 130±19/71±11mmHg (p>0.05) from the first to the second 24-hour period. Mean dipping was 1.5±7.8% in the first day and further decreased to -0.94±6.8% in the second day. Accordingly, in the first 24-hour period, only 6 patients (16%) were dippers and reduced to 2 patient in the following day (5%). Sixteen patients (42%) and 18 patients (47%) were risers at the first and second 24-hour period respectively.

Conclusions: Daytime systolic BP does not substantially change during the 48-hour period extending from HD to HD session. Yet, prevalence of the non-dipper as well as the riser pattern is high and further increases during the interdialytic period. Patients with this BP pattern are at high risk for coronary artery disease, especially if other comorbidities coexist. Ambulatory BP monitoring in ESRD patients is a promising non invasive technique for the recognition of future heart disease.

PUB629

In Vitro Dialysability of SNF472, a Novel Inhibitor of Vascular Calcification, Using Conventional Hemodialysis and Hemodiafiltration Joan Perelló,¹ Miquel Gomez Umbert,² Nestor Yesid Rodriguez,² Carolina Salcedo,¹ Miquel D. Ferrer,¹ Juan Manuel Buades,³ Maria del mar Perez,³ Eva Martín Becerra,⁴ Francisco Maduell.² *¹Sanifit, Palma, Spain; ²Nephrol. and Renal Transpl., Hosp. Clinic, Barcelona, Spain; ³Nephrol., Hosp. Son Llàtzer, Palma, Spain; ⁴Kinrel, Madrid, Spain.*

Background: SNF472 is being developed for the treatment of calciphylaxis and cardiovascular calcification in end stage renal disease patients on hemodialysis. The intended use of SNF472 is intravenous infusion during dialysis; therefore our aim was to assess its possible dialyzation and its effects on calcium (Ca) chelation.

Methods: Dialysability of SNF472 was assessed using online hemodiafiltration (OL-HDF) and conventional hemodialysis (HD) systems. The interaction of SNF472 with the system was assessed under bypass conditions (dialysis in off-mode). One liter of heparinized fresh blood spiked with 8 mg/dl creatinine was introduced in a container maintained at 37 °C and a one hour dialysis session was simulated. 66.6, 30 and 10 mg/L SNF472 were infused during the first 20 minutes of dialysis. Samples were obtained at different time points and creatinine, total and ionized Ca and SNF472 levels were quantified.

Results: No dialyzation of SNF472 was detected at 30 and 66.6 mg/L neither in OL-HDF nor in HD systems. Dialyzation was measured at 10 mg/L SNF472 both in OL-HDF and in HD, with an estimated clearance (Cl) of 39 and 18 mL/min, respectively. Creatinine showed a Cl of 231 and 220 mL/min, respectively. In bypass conditions, blood Ca was chelated during the 20 minutes of SNF472 infusion when added at 66.6 mg/mL. However, when the system was switched to the dialysis mode, the Ca in the dialysis bath compensated the chelating effect of SNF472 and Ca levels remained unaltered.

Conclusions: SNF472 dialyses with a low Cl. SNF472 levels increase in blood during infusion and dialysis does not prevent from attaining potentially therapeutic levels. As SNF472 will be infused during the whole dialysis session, this low Cl is not expected to affect system exposure. The chelating effects of SNF472 on Ca are compensated by the Ca in the dialysis bath, so no hypocalcemia is expected. Supported by REDINREN RD012/0021 and RETOS COLABORACIÓN RTC-2014-2460-1 grants.

PUB630

A Simple and Cost Effective Approach to Ultra-Pure Dialysate Anthony M. Valeri,¹ Bobby C. Lee,² John Duffy,³ Robin Ferrer,⁴ Ronald Villota,⁴ Greg C. Riccardi,³ Edmond P. Wong.³ *¹Dept of Medicine, Columbia Univ, New York, NY; ²Dept of Pharmacy, New York-Presbyterian Hospital (Columbia), New York, NY; ³Dept of Biomedical Engineering, New York-Presbyterian Hospital (Columbia), New York, NY; ⁴Dept of Nursing, New York-Presbyterian Hospital (Columbia), New York, NY.*

Background: Ultrapure dialysate has been shown to reduce inflammation and improve nutritional and anemia parameters in patients on chronic maintenance hemodialysis. The Nephros^(®) DSU (Dual Stage Ultrafilter, Nephros^(®) Inc, River Edge, NJ) has been shown to reduce bacterial counts and endotoxin levels by at least a 5-log order of magnitude.

Methods: We performed an observational trial of this filter in a hospital-based acute dialysis facility in the USA.

Results: There were 23 chronic stable hemodialysis outpatients treated during the 6 months before and after the installation of the Nephros^(®) filters. The mean age was 51 (range 12-91), 61% male, predominantly Hispanic (70% Hispanic, 17% African-American, 9% Caucasian, 4% Asian) and 30% diabetic. Comparing data from the 6 month period after the installation of the filters to the preceding 6 months, there was an increase in the mean hemoglobin level of 0.5 gms/dL (p=0.010) with a reduction in the mean weekly darbopoietin dose of 14.6 mcg or 40% (P<0.001) translating to a reduction in the ESA resistance index (weekly ESA dose/hemoglobin level) of 1.52 (p<0.001). During this time period, indirect inflammatory markers showed a reduction in the mean WBC count from 7,000 to 6,600 x 10⁹ /L (p=0.008) and an increase in serum albumin from 3.6 to 3.7 (p=0.024). The mean spKt/V was unchanged during the 2 time periods (from 1.609 to 1.607, p=0.30).

	Hemoglobin (gms/dL)		Darbopoietin dose (mcg/week)		ESA resistance index (ESA/Hgb)	
	Pre	Post	Pre	Post	Pre	Post
Mean	10.3	10.8	36.3	21.7	3.54	2.03
Interquartile Range	10.1-10.8	10.5-11.1	21.5-40.0	15.9-25.6	2.06-4.42	1.46-2.25
p-value (post vs. pre)		0.010		<0.001		<0.001

Conclusions: In conclusion, the use of the Nephros^(®) DSU filter to further reduce endotoxin exposure in chronic hemodialysis patients can result in improved ESA responsiveness and a lower ESA dose.

PUB631

Care Delivery Models for End Stage Renal Disease: A Systematic Review Maria Lourdes Gonzalez Suarez,¹ Priya Ramar,² Sagar Chawla,³ LaTonya J. Hickson,^{1,2} Nilay D. Shah,² Bjoerg Thorsteinsdottir.^{1,2} ¹*Dept of Medicine, Mayo Clinic; ²Mayo Clinic Kern Center for the Science of Health Care Delivery, Mayo Clinic; ³Mayo Medical School, Mayo Clinic, Rochester, MN.*

Background: Reimbursement for dialysis care has led the way for the broader transition to a value-based payment model. As payment policy for dialysis evolves, a better understanding of the evidence around care delivery models that optimize outcomes and increase the value of care for dialysis patients is essential. Limited evidence exists about which care delivery models are most effective.

Methods: Multiple databases were searched for comparative studies of care delivery models for ESRD published between 2000 and 2014. The intervention had to include >5 dialysis patients over age 18 years and receiving treatment, >6 months follow up, and reported patient important outcomes i.e. mortality, important clinical outcomes, hospitalizations and quality of life. Data was abstracted by reviewer pairs; study quality was evaluated using Cochrane and Newcastle-Ottawa tools.

Results: 1841 abstracts were screened, 59 full-text articles were reviewed, and 23 studies with 87,281 patients were included for final analysis. The interventions included nutritional (n=4), multidisciplinary care (n=6), satellite programs (n=3), home dialysis (n=3), access monitoring (n=2), physician contact (n=4), and nocturnal dialysis (n=1). Most were observational studies of decent quality with representativeness and incomplete follow up being the main potential sources of bias. Two randomized studies on home dialysis and pharmacist care, had attrition as the main risk of bias. Most interventions showed positive effect raising concern of publication bias. Overall, hospitalizations were significantly lower in the intervention group despite large heterogeneity IRR: 0.824, 95% CI 0.781, 0.868, p<0.001, I²=95.6%.

Conclusions: Multiple interventions have the potential to improve the outcomes of dialysis patients but have not been compared in terms of safety and effectiveness. Limited evidence is available to inform dialysis practice redesign to adapt to new payment structures. Further studies are needed to define best delivery models for dialysis care.

PUB632

Symmetrical Dimethylarginine (SDMA) Is Poorly Cleared by Standard Hemodialysis Mirela A. Dobre,¹ Peter B. De Ore,² Timothy W. Meyer,³ Thomas H. Hostetter.¹ ¹*Case Western Reserve Univ; ²Centers for Dialysis Care, Cleveland; ³Stanford Univ School of Medicine.*

Background: High SDMA levels have been associated with an increased risk for cardiovascular disease in patients with normal or reduced renal function. The effect of hemodialysis on SDMA has not been thoroughly studied.

Methods: We measured SDMA levels and its handling by hemodialysis and by the normal kidney in subjects with ESRD on chronic hemodialysis (n= 7) and in normal controls (n=6).

Results: The mean (SD) SDMA levels in ESRD were six times higher than in normal controls, 3.35(0.65) vs 0.53(0.25) μ M, p<0.001. For comparison pre-dialysis BUN levels was 44.1(23.1)mg/dl in ESRD, and 14.9(3.2) mg/dl in controls. The fractional reduction of SDMA was significantly lower than that of urea, 47.4(11.5)%, vs 76.7(4.7)%, p<0.001; and the volume of distribution was much higher 58.5(14.5)L vs 35.5(10.4)L for urea. Also the urinary clearance of SDMA [78.2 (33.5) ml/min] in normal individuals was higher than that of urea 55.2(13.7) ml/min. SDMA production rates were similar 46.7(9.4) vs 52.3 (13.9) mmoles/day, ESRD vs normals, p>0.05.

Conclusions: In summary, SDMA circulates at high levels in hemodialysis patients due at least in part to its relatively high clearance by the normal kidney, relative to urea, and its larger volume of distribution. The latter suggests that SDMA is likely to be localized in the intracellular compartment, and therefore less available for clearance by standard hemodialysis.

PUB633

On-Line Hemodiafiltration Is Efficient for Inflammation and Phosphorus Control Nadia Guimaraes- Souza, Thais Nemoto Matsui, Adriano Luiz Ammirati, Maria C.C. Andreoli, Ana C M S Ramos, Fabiana Dias Carneiro, Bento C. Santos. *Dialysis Center, Hospital Israelita Albert Einstein, Brazil.*

Background: High efficiency on-line hemodiafiltration is efficient to remove uremic toxins and phosphorus. Many studies had demonstrated the impact of this modality in mortality. The main objective of this study was to analyze the high efficiency on-line hemodiafiltration ability to remove phosphorus and reactive C protein.

Methods: This is a prospective study with end stage chronic kidney disease patients undergoing dialysis with high levels of phosphorus. High efficiency on-line hemodiafiltration, as described as a reposition volume higher than 22Lts, was used for a period of at least one year of follow-up. Beta-2- microglobulin, pre dialysis urea, post dialysis urea, reactive C protein, hemoglobin and phosphorus were collect from patients before starting on-line hemodiafiltration treatment and every month.

Results: Patients included in this study were 54.45 \pm 16.75 years old; they were on hemodialysis for at least for one year. 58% had hypertension or coronaryopathy. Hemodialysis dose as single pool Kt/V were significantly higher (1.21 \pm 0.20 vs 1.36 \pm 0.16; p<0.001) and this difference was kept for all follow-up. In six months of high efficiency hemodiafiltration we also found a decrease on phosphorus levels (7.9 \pm 2.4 vs 7.3 \pm 2.01 p<0.001) in one year follow up, phosphorus levels were still significantly lower than in the conventional

hemodialysis (7.3 \pm 2.01 vs 5.6 \pm 2.03 p=0.001). We also observed a decline in the need for erythropoietin doses in six months (p=0.04) associated with a higher hemoglobin levels (p<0.001). Reactive C protein showed significantly lower levels after six months of on-line hemodiafiltration (p=0.004).

Conclusions: High efficiency on-line hemodiafiltration is an efficient method of reduction of reactive C protein and may reduce costs due to reduced doses of erythropoietin analogus.

PUB634

On-Line Hemodiafiltration Filters a Comparative Study Nadia Guimaraes- Souza, Adriano Luiz Ammirati, Thais Nemoto Matsui, Maria C.C. Andreoli, Fabiana Dias Carneiro, Ana C M S Ramos, Bento C. Santos. *Dialysis Center, Hospital Israelita Albert Einstein, Brazil.*

Background: High efficiency on-line hemodiafiltration is the best method for middle molecules and phosphorus remotion. Many studies had demonstrated the efficiency of this method in mortality reduction. The main objective of this study was to compare the three filters available for on-line HDF comparing the ability to remove urea, phosphorus and beta-2-microglobulin.

Methods: Prospective cross-over study including four patients and three available filters for hemodiafiltration. All section of on-line hemodiafiltration was made with high efficiency (23-25lt). Filters HDF 100, FX100 e HDF80COR were compared. Urea, phosphorus and beta-2 microglobulin were collected before and after first use of each filter A reduction ratio was calculated to compare the treatments.

Results: 76% of patients were man, the middle age (61.3 \pm 5), 76% of patients were diabetics and had peripheral neuropathy and 34% had coronaryopathy. FX100 filter showed significantly higher dialysis dose compared to FX80COR (p=0.03); the same was observed for urea reduction ratio (p=0.04). Beta-2-microglobulin and phosphorus reduction ratio were similar between all filters.

Conclusions: FX100 and HDF100 filter were similar for urea remotion ratio. There were no differences for other molecules.

PUB635

Satisfaction of Patients on Dialysis Unit Jorge Nicolas Abdala. *Nephrology, Militar Hospital, Cordoba, Capital, Argentina.*

Background: The assesment of the nsatisfaction of patients in Dialysis, is a useful tool to meet patient needs; axis on which the care serevice is based. In turn it allows to identify the deficient areas.

Methods: Objective 1) To know the views of patients about the service that is offered in each of the areas of focus. 2) To analyze the profile of satisfaction of patients they expressed their overall dissatisfaction. Prospective, descriptive study conducted at the Dialysis Unit of the Military Hospital Córdoba, conducted between 15/11/2014 to 15/12/2014. Inclusion criteria: All patients attending the service, wich received some form of dialysis (hemodialysis-DP) in the period. Exclusion criteria: a) diagnosos of cognitive dementia, b) Carrying less than three month of treatment c) not be psychological and physical conditions to answer the survey. A qualitative survey, structured ajar, applied voluntary and anonymous.

Results: 95 surveys of the total population comprised 111 patients were taken; of wich 85 are for patients undergoing hemodialysis and 10 patients on CAPD. By studying the "General Satisfaction" in all aspect of the service that is offered to the patients responses they were largely positive, 80 % of the sample expressed feeling satisfied, while 20 % responded negatively. The results denote that carriers are those who receive the worst assessment by patients. The ambient temperatura for both dialysis room to the waiting room appears as an aspect also of disagreement. The most valued aspect is the power receduring treatment, both the quality and quantity as well as the attention of the professionals: technical, medical and social worked, in that order.

Conclusions: 1. As a managment tool, it should be rated as positive aspects stimulate and work on correcting the negative aspects. 2. The level of dissatisfaction is directly related to dialysis treatment time of the patient, the longer, higher degree of dissatisfaction. 3. It is advisable conduct regular surveys on the degree of patient satisfaction Dialysis, and that will help improve their quality of life.

PUB636

Correlation Between Calcium Phosphorus Product and Hypertension in ESRD Patients on Maintenance Hemodialysis Shoaib Islam,¹ Hafiz I. Ahmad,¹ Syed Rizwan Bokhari,¹ Arif Asif.² ¹*Dept of Nephrology, Allama Iqbal Medical College/ Jinnah Hospital, Lahore, Pakistan; ²Div of Nephrology and Hypertension, Albany Medical College, Albany, NY.*

Background: Increased levels of serum calcium, phosphorous and product of serum calcium and phosphorus (Ca x P) in end stage renal disease (ESRD) patients has been shown to be associated with increased mean arterial blood pressure (MAP). The available data is limited and no study has been done in Pakistan. We conducted a cross sectional study to determine the correlation between mean arterial blood pressure (MAP) and serum calcium-phosphorous product in our ESRD patients on hemodialysis.

Methods: Blood Pressure of all the prevalent ESRD patients in a single dialysis center was recorded and mean arterial blood pressure (MAP) was calculated pre and post dialysis. All patients were clinically euvolemic. Serum calcium and phosphorous levels were measured and Calcium-phosphorus product (CaxP) was calculated. The product above 50 and the MAP above 93 were taken as high.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

Results: Of the 60 ESRD patients, 35(58.3%) were males with mean age was 39.5±5 years. High CaxP product was seen in 18 (30%) patients with high pre-dialysis MAP in 8 (44%) and high post-dialysis MAP in 4 (22%) patients respectively. Of 42 (70%) patients with CaxP product below 50 high pre-dialysis MAP was seen in 31(73%) and high post dialysis MAP was seen in 29 (69%) patients.

Conclusions: This study showed that high CaxP product (>50) is not correlated with high pre and post-dialysis MAP. The results are not consistent with earlier studies done in developed countries. Larger studies are needed to re-evaluate these findings.

PUB637

Behaviour of Ankle-Brachial Index During Hemodialysis: Effect of Calcium Dialysate Concentration Zaida Noemy Cabrera Jimenez,¹ Rosa M.A. Moyses,^{1,2} Bruno C. Silva,¹ Luciene dos Reis,¹ Wagner Dominguez,¹ Fabiana Gracioli,¹ Rosilene M. Elias.¹ ¹Nephrology, Univ of Sao Paulo, Sao Paulo, SP, Brazil; ²Univ Nove de Julho- UNINOVE, Sao Paulo, SP, Brazil.

Background: Ankle-brachial index (ABI) is a simple way to access cardiovascular risk. Both low (<0.9) and high (>1.3) ABI are associated with increased mortality risk in patients on hemodialysis (HD). However, little is known regarding the acute variation of ABI (from pre to post hemodialysis), and also whether the calcium dialysate content [Ca] may interfere with this variability. We aimed to investigate the impact of [Ca] 3.5 vs. 2.5 on the variability of ABI during HD.

Methods: Incident patients on HD for up to 90days were included. ABI was evaluated pre- and post-HD in the midweek session of two consecutive weeks with [Ca] 3.5 and 2.5, respectively. Biochemical variables, electrical bioimpedance and non-invasive hemodynamic (Finapres®) were assessed.

Results: 17 patients (10 men) aged 42 ± 17 years were included. ABI pre- and post-HD with [Ca] 3.5 and 2.5 were 1.2 ± 0.1, 1.1 ± 0.1, 1.1 ± 0.2, and 1.2 ± 0.1, respectively. Although the mean ABI values were within normal range, there was a great variability in the ABI, such that in 9 patients it increased using [Ca] 3.5, with 5 patients (29%) changing classification while in 6 patients it increased using [Ca] 2.5 with 3 patients (18%) changing classification. A [Ca] 3.5 was associated with an increase in serum calcium and a decrease in parathyroid hormone, while during a [Ca] 2.5 occurred a more pronounced blood pressure drop and consequent raise of peripheral arterial resistance. As the ultrafiltration rate was similar with [Ca] 3.5 and 2.5, there was no difference in total, extra- and intracellular water removal. ABI correlated with pre HD serum aldosterone (r= -0.515, p=0.002). Multiple regression analysis revealed that pre HD aldosterone and also a [Ca] were independently associated with the delta of ABI during dialysis, even adjusting for cardiac debit and ultrafiltration rate.

Conclusions: ABI presents great variability during a conventional HD. However, whether an acute decrease in ABI by using a [Ca] 2.5 may impact the long-term mortality deserves further investigation.

PUB638

Variation in the Intracranial Pressure During Hemodialysis in a Patient with Subdural Hematoma on Propofol Rhea Bhargava,¹ Omkar U. Vaidya.^{1,2} ¹Dept of Internal Medicine, Univ of Missouri- Kansas City, Kansas City, MO; ²Dept of Nephrology and Hypertension, Univ of Missouri- Kansas City, Kansas City, MO; ³Dept of Critical Care, Saint Lukes Hospital, Kansas City, MO.

Background: Dialysis disequilibrium syndrome (DDS) is a rare but potentially serious complication of hemodialysis. Pathophysiology of this disorder is explained by the 'reverse urea effect'. This can be difficult to detect in patients in the neuro-intensive care unit given their compromised CNS status. However it is imperative to diagnose DDS especially in this population as intracranial pressure (ICP) instability during hemodialysis can lead to micro circulatory defects.

Methods: 60 y/o male with ESRD admitted for left frontal subdural hematoma, underwent evacuation with ventricular drain placement. He was intubated and sedated. BP 142/69 mmHg, Pulse 122 bpm, Temp of 37.3 °C, RR of 34 and SpO2 100%. The remaining physical examination was unremarkable. Hemodialysis (HD) was performed on 3 contiguous days. ICP and the changes in cerebral perfusion pressure (CPP) were monitored every 15 minutes during hemodialysis. Sedation with propofol which was started on Day1, was weaned off completely by the session on day three. The patient seized after the 3rd hemodialysis session. CT scan of the head was unremarkable. He was eventually discharged on day 14 and made full recovery.

Results: ICP and CPP during hemodialysis decreased in the first 30 minutes and maximum variation was between 45-120 minutes. Peak ICP pressure during HD: Day 1: 5 mmHg; Day 2: 15 mmHg and Day 3: 25 mm Hg. Maximum change in CPP from baseline during HD: Day1: 20 mm Hg; Day 2: 22mm Hg and Day 3: 47 mmHg.

Conclusions: ICP monitoring during hemodialysis is a useful modality to identify neurological complications in patients who have undergone neurosurgical interventions. Propofol along with being a sedative can lower ICP and hence prevent or mask the effects of hemodialysis on ICP. In the present case, net change in CPP could have led to seizure activity on the 3rd day of hemodialysis.

PUB639

Characterization of T Regulatory Type 1 (Tr1) Cells in Naïve and Transplanted Non-Human Primates Ruichao Yu, Makoto Tonsho, Philip Spencer, Sibylle Bernard-stoecklin, Gilles Benichou, Joren Madsen. *Center for Transplantation Sciences, Harvard Medical School, Massachusetts General Hospital, Boston, MA.*

Background: T regulatory Type 1 (Tr1) cells are peripheral CD4⁺FoxP3⁺ regulatory T cells expressing CD49b and LAG-3 in mice and humans. Mouse Tr1 cells inhibit antigen-presenting cell (APC) activation via secretion of IL-10 and TGF-β and via cell-contact dependent mechanisms mediated through their expression of programmed cell death (PD)-1. However, the phenotype and functions of Tr1 cells non-human primates are still unknown.

Methods: Mononuclear cells were isolated from the peripheral blood of cynomolgus monkeys (PBMCs). First, co-expression of CD49b and LAG-3 was compared among bona fide CD4⁺CD25^{high}FoxP3⁺ Tregs and CD4⁺CD25^{low}Foxp3⁺ using flow cytometry. Second, cytokines (IL-10, TGF-β, IFN-γ, IL-4, IL-17 etc.) were processed after polyclonal activation via anti-CD3/CD28 Ab-coated beads. Next, we compared PD-L1 and CD45RO expression by Tr1 cells collected from the PBMCs of naïve monkeys, monkeys undergoing rejection of kidney allografts and monkeys which have been rendered tolerant of kidney allografts via donor mixed hematopoietic chimerism induction and leukocyte costimulation blockade.

Results: In cynomolgus monkeys, CD49b and LAG-3 were co-expressed on CD4⁺CD25^{low}Foxp3⁺ Tr1 lymphocytes but not on CD4⁺FoxP3⁺ Tregs. After polyclonal activation via anti-CD3/CD28 Ab-coated beads, virtually all Tr1 cells secreted high levels of IL-10 anti-inflammatory cytokine but no pro-inflammatory IFN-γ or IL-17 cytokines. We observed a significant expansion of Tr1 cells expressing a memory phenotype (CD45RO) and the immunomodulatory receptor PD-L1 in tolerant but not other animals.

Conclusions: Our data show that the surface markers CD49b and LAG-3 can be used to distinguish Tr1 from "classical" FoxP3⁺ Tregs in cynomolgus monkeys. Tr1 cells are likely to inhibit T cell responses mediated by PD-1/PD-L1 interactions. The contribution of these activated Tr1 cells to induction and maintenance of organ allograft tolerance in non-human primates is under investigation.

Urinary MicroRNA-25 as a Potential Biomarker for Detection of Renal Damage in Rats and Renal Transplant Patients Kumiko Nishihara,¹ Masayuki Kanki,¹ Moto Kajiwara,^{2,3} Kei Kurihara,⁴ Takahisa Yano,² Hidehisa Kitada,⁴ Satoshiro Masuda,² Akira Unami.¹ ¹Drug Safety Research Laboratories, Astellas Pharma Inc., Osaka, Japan; ²Dept of Pharmacy, Kyushu Univ Hospital, Fukuoka, Japan; ³Dept of Research and Development of Next Generation Medicine, Faculty of Medical Sciences, Kyushu Univ, Fukuoka, Japan; ⁴Dept of Surgery and Oncology, Graduate School of Medical Sciences, Kyushu Univ, Fukuoka, Japan.

Background: Circulating microRNAs (miRNAs) were proposed as potential biomarkers of various biological functions and diseases in the kidneys. We have found that some urinary miRNAs were useful for detection of cisplatin-induced proximal tubular injury in rats (Kanki M et al., Toxicology. 324, 158, 2014). In this study, we examined the feasibility of miRNAs for renal damage in Japanese patients receiving kidney transplantation as well as rats.

Methods: Gentamicin (100 mg/kg) (model of tubular injury) was daily given for 7 days and puromycin (50 mg/kg) (model of glomerular injury) was given as a single injection to male SD rats. Seven days after the treatment, the urinary levels of 15 miRNAs were determined by real-time PCR. The receiver-operator characteristics (ROC) curve analysis for proximal tubular necrosis was performed including previous cisplatin study. Human urine samples were collected from 30 healthy volunteers and 11 renal transplant patients at 7 days and 2, 10, and 11 weeks after surgery. The levels of 4 miRNAs were determined.

Results: In gentamicin treated rats, the levels of miR-328, let-7a-1, miR-1839, miR-25, miR-140, and miR-378 were increased more than 2-fold with high values of the area under the ROC curve, which were the same or more than those of BUN and serum creatinine, while they were not changed in rats treated with puromycin. Among these miRNAs, miR-25, miR-140-3p, miR-328 and miR-378 were measured in the human urine samples. In human samples, miR-25 at postoperative day 7 in some patients exhibited higher levels than the highest value of those in the volunteers.

Conclusions: Urinary miR-25 but not other miRNAs might be available for detecting renal damage in the postoperative course of renal transplant patients as well as that in the rats with proximal tubular injury.

PUB641

Early Activation of Complement in Renal Ischemia/Reperfusion (I/R) Injury Is Mediated by Pentraxin 3 (PTX3) Synthesized by Peripheral Blood Mononuclear Cells (PBMCs) Giuseppe Castellano,¹ Chiara Divella,¹ Alessandra Stasi,¹ Paola Pontrelli,¹ Matteo Accetturo,¹ Marco Fiorentino,¹ M. Rossini,¹ Vincenzo Montinaro,¹ G. Lucarelli,¹ M. Battaglia,¹ Loreto Gesualdo,¹ Giuseppe Grandaliano.² ¹Dept of Emergency and Organ Transplantation, Univ of Bari, Bari, Italy; ²Dept of Medical and Surgical Sciences, Univ of Foggia, Foggia, Italy.

Background: PTX3 has been recently implicated in the promotion of vascular inflammation via the activation of Complement. Aim of this work was to investigate the possible involvement of PTX3 in renal I/R injury.

Key: TH - Thursday; FR - Friday; SA - Saturday; OR - Oral; PO - Poster; PUB - Publication Only

Underline represents presenting author.

Methods: PBMCs were isolated from blood of patients with Delay graft function (DGF,n=10) and Early graft function (EGF, n=10) at T0 and T24h from transplant. Gene expression profiles of PBMCs from both groups were assessed by Affymetrix technologies. Results were evaluated by statistical analysis and functional pathway analysis and validated by confocal analysis on a swine model of I/R injury. Renal I was induced in 5 pigs by arterial clamping for 30 min and tissues were analyzed at different time points after R (T15', 30', 60').

Results: Microarray analysis (FDR<5% and a FC>1.5) revealed that the expression of PTX3 and C3 were downregulated in EGF compared to DGF patients. On the contrary, the gene CR1 was upregulated in DGF. Furthermore, in the pig model, confocal laser microscopy demonstrated PTX3 deposits already at 15' of R, localized at peritubular (7.7±1.1;p=0.005) and glomerular (8.2±2.5;p=0.03) capillary levels. We found a significant increase in infiltrating interstitial leucocytes such as CD163⁺/PTX3⁺ monocyte-macrophages (6.2±2.1;p=0.05) and SWC3a⁺/PTX3⁺ dendritic cells (3.7±0.5;p=0.05) compared to T0. Finally, we identified tubulo-interstitial FSP1⁺/PTX3⁺ myofibroblast(4.1±1.3;p=0.04). Co-localization between C5b-9/PTX3, PTX3/C1q and PTX3/MBL clearly demonstrated the activation of Classical and Lectin Complement pathways in presence of PTX3 deposits.

Conclusions: Our data would suggest a key role of PTX3 synthesized by peripheral blood mononuclear cells (PBMCs) during DGF leading to an early activation of complement in transplant kidney.

PUB642

The Effect of Combined Treatment of Dipeptidyl Peptidase IV Inhibitor and Metformin in Sirolimus-Induced Diabetes Mellitus Long Jin, Jian Jin, Sun Woo Lim, Byung Ha Chung, Chul Woo Yang. *Transplant Research Center & Div of Nephrology, Dept of Internal Medicine, Seoul, St Mary's Hospital, The Catholic Univ of Korea, Seoul, Korea.*

Background: Optimal treatment of post-transplant diabetes mellitus is still controversial. This study was performed to evaluate whether the combined treatment of DPP IV inhibitor with metformin (MET) is effective in sirolimus (SRL)-induced diabetes mellitus.

Methods: SRL-induced diabetes mellitus was made by treating SRL (0.3 mg/kg) for 3 weeks in rats, and then started to treat DPP IV inhibitor (LC15-0444[LC], 5mg/kg), and/or MET (200 mg/kg) for further 3 weeks. The effect of combined treatment of LC and MET on SRL-induced diabetes mellitus was evaluated by IPGTT and islet size. The oxidative stress was evaluated by measuring 8-OHdG, 4-HHE, MnSOD, and catalase in samples. Insulin secretion capacity was evaluated by glucose-stimulated insulin secretion (GSIS) test using normal isolated rat islets treated with SRL, extendin-4 and/or MET.

Results: SRL treatment for 6 weeks decreased body weight and increased water intake and urine volume compared with vehicle group. SRL treatment significantly increased AUCg from the values obtained during the IPGTT, but LC or MET treatment recovered these value compared with the SRL treatment alone. Combined treatment with LC and MET has more significantly decreased blood glucose level than LC or MET treatment alone. Islet size which was significantly decreased in the SRL group was recovered with combined treatment of LC and MET. SRL treatment significantly increased intense nuclear expression and larger positive area for 8-OHdG and 4-HHE, but combined treatment LC and has significantly decreased expression of 8-OHdG and 4-HHE. The decreased expression of MnSOD and catalase in the SRL group was recovered with combined treatment with LC and MET. The result of GSIS also showed that combined treatment of LC and MET showed higher insulin level than extendin-4 or MET treatment alone.

Conclusions: Combined treatment with LC and MET exerts better glucose control by decreasing oxidative stress caused by SRL. This finding provides the rationale for the combined use of DPP IV inhibitor and MET in SRL-induced diabetes mellitus.

Incidence and Outcomes of Hyponatremia Early Post Lung Transplantation Ekamol Tantisattamo,¹ Aneesh A. Shetty,¹ Bing Ho,¹ John J. Friedewald,¹ Opas Traitanon,¹ Sangeeta Bhorade,² Alexander Haynes,² Amber Nieland,² Lorenzo G. Gallon.¹ ¹*Div of Nephrology and Hypertension;* ²*Pulmonary and Critical Care, Dept of Medicine, Northwestern Univ Feinberg School of Medicine.*

Background: Outcomes of in-hospital hyponatremia in lung transplant recipients are unclear. The aim of this study is to describe the frequency of hyponatremia and outcomes associated with hyponatremia during the early postoperative period.

Methods: We performed a retrospective chart review of all lung transplant recipients at Northwestern Memorial Hospital since the first case performed in July 2014 until May 2015. The severity of hyponatremia was defined as mild, moderate, and severe with serum Na of <135, <130, and <125 mEq/L, respectively.

Results: A total of 13 lung transplant recipients were included. Age at the time of transplantation was 61.5+/-2.2 (SEM) years and 69% was female. The most common indication for transplantation was severe COPD (54%). Serum creatinine at the time of transplantation and at hospital discharge was 0.8+/-0.1 and 1+/-0.2 mg/dL, respectively. Seven patients with postoperative acute kidney injury (AKI) had >2 times longer length of hospitalization (26.2+/-4.8 vs. 10.0+/-1.1 days; p 0.0046) and were more likely to develop postoperative hyponatremia (100% vs. 71%; p=0.151). Among 11 patients with postoperative hyponatremia, 7 were readmitted (5 with hyponatremia and 4 with AKI). At the time of transplant, 8% of the patients had hyponatremia but the incidence was up to 46% at the time of discharge (Table1). Almost half of the patients had persistent hyponatremia during 1 month follow-up.

Conclusions: Lung transplant recipients commonly develop hyponatremia during the immediate post operative period and are more likely to be readmitted with hyponatremia. The incidence of hyponatremia remains high up to 1 month post transplantation. AKI is also a risk for readmission and predicts longer length of hospital stay.

Degree of serum sodium	At trans-plant	3 days	7 days	At discharge	30 days	90 days	180 days
Normal	12(92%)	6(46%)	9(7%)	7(54%)	7(54%)	7	4
Mild	0	4(31%)	0	5(38%)	6(46%)	NA	1
Moderate	1(8%)	0	2(8%)	1(8%)	NA	NA	NA
Severe	0	1(8%)	2(8%)	0	NA	NA	NA
Hypernatremia	0	2(15%)	0	0	NA	NA	NA

Motivations, Challenges, and Attitudes to Self-Management in Kidney Transplant Recipients: A Systematic Review of Qualitative Studies Nathan Jamieson,^{1,2} Camilla Sara Hanson,^{1,2} Michelle A. Josephson,³ Elisa J. Gordon,⁴ Jonathan C. Craig,^{1,2} Fabian Halleck,⁵ Klemens Budde,⁵ Allison Tong.^{1,2} ¹*Centre for Kidney Research, The Children's Hospital at Westmead, Sydney, New South Wales, Australia;* ²*School of Public Health, Univ of Sydney, Sydney, New South Wales, Australia;* ³*Dept of Medicine, The Univ of Chicago, Chicago, IL;* ⁴*Center for Healthcare Studies and Comprehensive Transplant Centre, Northwestern Univ Feinberg School of Medicine, Chicago, IL;* ⁵*Dept of Nephrology, Charité, Universitätsmedizin Berlin, Berlin, Germany.*

Background: Kidney transplantation offers superior life expectancy and quality of life outcomes compared to other renal replacement therapy modalities. However, the complex and ongoing medication and self-management regimens impose a treatment burden on patients, and non-adherence remains a leading cause of graft loss.

Methods: MEDLINE, Embase, PsycINFO, and CINAHL were searched from database inception to October 2014. We used thematic synthesis to analyse the findings.

Results: Fifty studies involving 1238 participants aged from 18 to 82 years across 19 countries were included. We identified five themes: *empowerment through autonomy* (achieving mastery, tracking against tangible targets, developing bodily intuition, routinising and problem-solving, adaptive coping), *prevailing fear of consequences* (inescapable rejection anxiety, aversion to dialysis, minimising future morbidity, trivialisation and denial, defining acceptable risks), *burdensome treatment and responsibilities* (frustrating ambiguities, inadvertent forgetfulness, intrusive side-effects, reversing ingrained behaviours, financial hardship), *over-medicalising life* (dominating focus, evading patienthood, succumbing to burnout), and *social accountability and motivation* (demonstrating gratitude towards medical team, indebtedness to donor, peer learning).

Conclusions: Self-efficacy and social accountability are motivators for self-management, but ongoing adherence can be mentally and physically taxing. Multi-component interventions that incorporate education, psychosocial support, decision aids, and self-monitoring tools may foster self-management capacity and improve transplant outcomes.

PUB646

Characteristics of Patients with Vitamin D Deficiency After Kidney Transplantation in Qatar Mohamed Amin Elesnawi, Abdullah Hamad, Fadwa S. Al-Ali. *Nephrology, Fahd Bin Jasim Kidney Center, Hamad General Hospital, Doha, Qatar.*

Background: Vitamin D deficiency is common among normal people and in patients with chronic kidney disease including dialysis patients. Vitamin D deficiency continues to be prevalent after kidney transplantation (studies showed prevalence of 50-80%) especially with immunosuppression use and sun protection needed for elevated risk of skin cancer . We studied characteristics of kidney transplant patients with vitamin D deficiency in Qatar.

Methods: We reviewed all available records of kidney transplant patients presented to our clinic at Hamad General Hospital in Doha, Qatar between 1/9/2013 and 1/3/2014 and have vitamin D level less than 30 ng/mL. Background data and laboratory tests of patients were obtained. All patients were receiving vitamin D supplements and prednisone within their immunosuppression per institution protocol.

Results: We studied 83 patients. Mean age was 55.5 +/- 16 years. There were 55 males (66%) and 28 females (34 %). Vitamin D deficiency was severe (level than 10 ng/mL) in 15 patients, moderate in 38 (10-19 ng/mL) and mild in 30 patients (20-29 ng/mL). Duration of transplant was 7.9 +/- 2.5 years. Glomerular Filtration Rate was 65.5 +/- 20.6 ml/min. We found no correlation between vitamin D and PTH levels or between vitamin D and GFR levels. Table 1 summarize bone mineral panel in our patients.

	Plasma Level +/- SD
Vitamin D	16.4+/-6.7 ng/ml
Calcium	2.28+/-0.14 mmol/L
Phosphorus	1.2+/-0.26 mmol/L
Alkaline Phosphatase	86.9+/-37.8 u/L
Intact Paathyroid Hormone	146+/-2.1pg/mL

Conclusions: In a study of kidney transplant patients with vitamin D deficiency in Qatar we found that they were predominantly males, have normal calcium, phosphorus and alkaline phosphatase levels, while they have variable degree of elevated PTH with no correlation to vitamin D level. Most patients have mild to moderate vitamin D deficiency (82%) despite receiving vitamin D supplement although the supplement could have decreased the number of patients with severe vitamin D deficiency (18%). Further study could help to evaluate the role of vitamin D supplement in improving vitamin D level in kidney transplant recipients.

PUB647

Comparison of Vitamin D Deficiency Between Young and Elderly Kidney Transplant Recipients Mohamed Amin Elesnawi, Abdullah Hamad, Fadwa S. Al-Ali. *Nephrology, Fahd Bin Jasim Kidney Center, Hamad General Hospital, Doha, Qatar.*

Background: Vitamin D deficiency is common in normal population and in patients with chronic kidney disease including kidney transplant recipients. Elderly patients are vulnerable to vitamin D deficiency with less sun exposure and having multiple medical problems. We compared young versus elderly kidney transplant recipients with vitamin D deficiency in Qatar.

Methods: We reviewed all available records of kidney transplant recipients presented to our clinic at Hamad General Hospital in Qatar between 1/9/2013 and 1/3/2014. Background data and laboratory tests of patients were collected. All patients were receiving vitamin D supplements and prednisone per institution protocol.

Results: 83 patients were included. 41 patients in the young group (< 60 years old) and 42 in the elderly group (> 60 years old). There were 21 females versus 20 males in the young group and 35 males versus 7 females in the elderly group (pValue<0.05). Time on transplant was 9.1 +/- 4.93 years in the young group versus 8.6+/-2.7 in the elderly. Table 1 summarizes laboratory values for kidney transplant patients with vitamin D deficiency.

	Age over 60 years (n=42)	Age less than 60 years (n=41)
Vitamin D	17.7+/-6.4 ng/mL	15.1+/-6.7 ng/mL
Calcium	2.28+/-0.13 mmol/L	2.29+/-0.15 mmol/L
Phosphorus	1.22+/-0.18 mmol/L	1.16+/-0.3 mmol/L
Parathyroid Hormone	148.7+/-238.3 pg/mL	143.9+/-154.8 pg/mL
Alkaline Phosphatase	75.8+/-29 u/L	91.9+/-39.9 u/L
Glomerular Filtration Rate (GFR)	69.9+/-21.4 ml/min	61.2+/-19.2 ml/min

Conclusions: We compared vitamin D deficiency in young versus elderly kidney transplant recipients in Qatar. Although elderly patients have higher vitamin D levels, it was not statistically significant. This could be due to better compliance with vitamin D supplement in the elderly. Although duration on transplant, calcium, phosphorus and intact parathyroid hormone were similar, Glomerular Filtration Rate (GFR) was higher in the elderly. We explain it that almost all kidney transplants in Qatar are from live donors which lead to a higher GFR in the elderly as they are receiving kidneys from younger donors. There was statistically significant smaller number of females than males in the elderly group.

The Current Status of Plasmapheresis Before Living Donor Kidney Transplantation in Japan Norio Hanafusa,¹ Tomoko Usui,¹ Akihiko Matsumoto,¹ Satoko Sakurai,¹ Eisei Noiri,¹ Hideo Yasunaga,² Masaomi Nangaku.¹ ¹*Dept of Hemodialysis and Apheresis, The Univ of Tokyo Hospital, Bunkyo-ku, Tokyo, Japan;* ²*Dept of Clinical Epidemiology and Health Economics, School of Public Health, The Univ of Tokyo, Bunkyo-ku, Tokyo, Japan.*

Background: Plasmapheresis (PP) is utilized to remove alloantibodies before the living donor kidney transplantation (LDKT). The detailed practice patterns of PP before LDKT remains unknown. There also are concerns about the depletion of coagulation factors [Transfus Apher Sci 49: 254, 2013] by PP. We investigated the current status of PP before LDKT with use of the nationwide database.

Methods: The Japanese Diagnosis Procedure Combination Database includes all the patients discharged from hospitals participating in this program between July 2010

and March 2013. Those who received LDKT and PP before LDKT were included into this study. The modalities of PP, fresh frozen plasma (FFP) use, and albumin use were examined. We also investigated the relationship between modalities selected and outcomes such as the length and total costs of the hospital stay, or the amount of blood transfusion as the proxy of bleeding.

Results: In total 775 patients received PP before LDKT during the period. Among them 209 patients were treated only by simple plasma exchange (PE). Remaining 566 patients received double filtration plasmapheresis (DFPP), or cascade filtration. Interestingly, 274 patients treated by DFPP received also PE before transplantation. FFP was used during PP on 109, 180, and 42 patients treated by PE only, DFPP followed by PE, and DFPP only, respectively. Moreover, FFP was infused before the operation on 161 patients who were not used FFP during PP. As a whole 63.5% of total patients received FFP from the start of PP to the day of operation. DFPP followed by PE groups received less amount of blood transfusion (p=0.047), though the length of stay was longer and total costs were higher, compared to DFPP only group.

Conclusions: Many of the patients received FFP, which suggests concerns about the depletion of coagulation factors during PP. The practice patterns were quite heterogeneous and the standardization of the practice patterns is needed to maximize the benefits of PP.

PUB650

Age as a Risk Factor for Acute Rejection in the Renal Transplant Patient Sarah Lamarche, Jean-Philippe Lafrance, Michel Vallee, Duy Tran. *Nephrology, Univ de Montréal, Montréal, QC, Canada.*

Background: It has previously been shown that younger age is associated with a higher risk of acute rejection post renal transplantation. However, those studies were undertaken in times with differing use of immunosuppressive therapies. We thus sought to examine if this trend was still relevant in a contemporary cohort of patients with a new prescription profile.

Methods: We retrospectively reviewed the charts of 217 patients who underwent renal transplantation between the years 2006-2012 at our institution. Baseline characteristics of donors and recipients were examined. Recipients were stratified according to age <30, 30-40, 40-55, 55-65 and >65 years old. Our primary endpoint was the incidence of acute rejection at one year post renal transplantation. Multivariate Cox regression models predicting acute rejection were also fitted to adjust for several confounders.

Results: Regarding baseline recipient characteristics, there was a significant difference in the leading cause of end-stage kidney disease among the groups (glomerulopathy in young recipients and diabetic nephropathy in old recipients). Also, hypertension, diabetes and coronary heart disease were more prevalent in older recipients. Overall, the incidence rate of acute rejection at 1 year in all groups was 19 per patient-year. Statistically significant differences in Kaplan-Meier estimates of rejection at one year were recorded (log rank p=0.03) and those differences were confirmed in multivariable Cox regression analyses. Indeed, individuals aged 30-40 years had a higher risk of developing acute rejection (HR 6.5, 95% CI: 1.9, 22.5) compared to the reference group (40-55). Other significant predictors of acute rejection at 1 year included PRA > 20% (HR 6.8), unrelated living donor (HR 10.2), donor after cardiac death (HR 3.7) and length of initial hospitalisation stay (HR 1.03).

Conclusions: In a contemporary cohort, we recorded a significant difference in patterns of acute rejection following renal transplantation according to age. Indeed, individuals aged 30-40 years were more prone to transplant rejection, even after adjusting for several covariates. This research should fuel additional investigations regarding the biology of this disease.

PUB651

Delta Neutrophil Index as a Marker for Differential Diagnosis Between Acute Graft Pyelonephritis and Acute Graft Rejection Soyon Rhee, Eunjung Kim, Hee Jung Jeon, Ja-Ryong Koo. *Internal Medicine, Nephrology, Hallym Univ of College of Medicine, Seoul, Republic of Korea.*

Background: Acute graft pyelonephritis (AGPN) versus acute graft rejection is a frequently encountered diagnostic and therapeutic dilemma in renal transplant recipients, but little is known about the clinical usefulness of the delta neutrophil index (DNI) value in the differentiation of the two conditions.

Methods: We reviewed the medical records of 86 renal transplant recipients, 45 patients with 51 acute graft rejection episodes and 41 patients with 54 AGPN episodes, at the Kangdong Sacred Heart Hospital from January 2008 to February 2014. Of these episodes, 15 were excluded due to neutropenia (n=4), other infections (n=5), and no available data of procalcitonin levels (n=6). As a result, 72 renal transplant recipients with 90 episodes were enrolled in this study.

Results: AGPN group had significantly higher DNI values than acute graft rejection group (2.9% vs. 1.9%, P<0.001). The area under the ROC curve for DNI value was 0.85 (95% confidence interval [CI]; 0.76-0.92, P< 0.001).

Figure 1

A DNI value of 2.7% was selected as cut-off value for AGPN, and renal transplant recipients with a DNI $\geq 2.7\%$ were found to be at a higher risk of infection than those with a DNI $< 2.7\%$ (odd ratio [OR] 40.50; 95% CI 8.68-189.08; $P < 0.001$). In a multivariate logistic regression analysis, DNI was a significant independent factor for predicting AGPN after adjusting age, sex, log WBC count, log neutrophil count, log lymphocyte count, DNI value, CRP concentration and procalcitonin concentration (OR 4.32; 95% CI 1.81-10.34, $P < 0.001$).

Conclusions: The present study demonstrated that a DNI value above 2.7% was an independent predictive marker for AGPN and an effective marker to differentiate between AGPN and acute graft rejection. Thus, these finding suggest that DNI may be a useful marker in the management of these patients.

PUB652

Effect of Pre-Transplant Dialysis Modality on Outcomes of Living-Donor Kidney Transplantation Recipients Chiaki Kawabata. *General Internal Medicine, Japanese Red Cross Kumamoto Hospital, Kumamoto, Japan.*

Background: There are few studies on living-donor kidney transplantation that compare the outcomes after pre-transplant dialysis modality. We examined the short-term outcomes of living-donor kidney transplantation recipients after peritoneal dialysis (PD) and hemodialysis (HD), respectively.

Methods: 112 patients have undergone living-donor kidney transplantation procedures in our hospital between January 2001 and May 2014. We studied 40 patients, under 40 years of age, with dialysis durations of less than 5 years. We compared 13 PD patients with 27 HD patients and investigated the short-term outcomes.

Results: These two groups showed no significant differences as regards baseline characteristics including dialysis duration, body mass index, type of calcineurin inhibitor or ABO blood type incompatibility. The PD group was younger than the HD group as regards recipient age and donor age (22.5 ± 8.0 years vs 29.1 ± 6.0 years [$p = 0.005$]; and, 50.7 ± 8.2 years vs 56.9 ± 7.1 years [$p = 0.02$], respectively). There were no differences in early post-transplant complications, such as wound infection, bleeding, thrombosis, delayed graft function, or acute rejection. The PD group was better than the HD group in the estimated glomerular filtration rate (eGFR) at discharge (74.3 ± 27.3 ml/min/1.73 m² vs 48.3 ± 12.3 ml/min/1.73 m² [$p = 0.001$]) and eGFR 1 year post-transplantation (68.4 ± 21.8 ml/min/1.73 m² vs 45.6 ± 13.2 ml/min/1.73 m² [$p = 0.003$]).

Conclusions: In the case of younger and less than 5 years of dialysis duration, PD and HD demonstrated no differences in early post-operative complications. PD is significantly better than HD as regards eGFR up to 1 year post-transplantation.

PUB653

Bright Field Microscopy of the Unstained Urine Sediment: A Basic Tool to Identify Decoy Cells due to Polyomavirus BK on Kidney Allograft Recipients During Routine Urinalysis José A. Poloni,^{1,2,3} Gabriel Godinho Pinto,² Maria Giordani,¹ Elizete Keitel,^{1,2} Alessandro C. Pasqualotto,^{1,2} Liane Rotta,² ¹*Irmandade da Santa Casa de Misericórdia de Porto Alegre, Porto Alegre, RS, Brazil;* ²*Univ Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, RS, Brazil;* ³*Control Lab, Rio de Janeiro, RJ, Brazil.*

Background: Polyomavirus BK (BKV) is an important pathogen that can be reactivated in kidney allograft recipients, potentially leading to BKV nephropathy (BKVN), an important cause of graft loss. Decoy cells (DC), urothelial cells or renal tubular epithelial cells modified by the proliferation of BKV, are one of the hallmarks of BKV reactivation and it can be identified in the fresh urine sediment.

Methods: A cohort of 102 kidney transplant patients was followed during months 3 and 6 after the transplant procedure. Urine samples were obtained to detect the presence of DC in the fresh and unstained urine sediment under bright field microscopy (BFM) by two experienced analysts, as well as BKV viruria by qPCR.

Results: DC were found in 15 patients.

Figure 1 – Three decoy cells presented under bright field microscopy (left panel) and under phase contrast microscopy (right panel). Original magnification 400x.

Urine sediment analysis revealed a strong agreement ($P < 0.001$) between the microscopists to both qualitative and quantitative identification of DC. Also, the qualitative comparison of both microscopists to BKV viruria revealed agreement ($P < 0.001$). The positive predictive value, negative predictive value, specificity and accuracy of BFM were 80%, 75%, 97% and 75%, respectively. The sensitivity was 16%.

Conclusions: Despite its limited sensitivity, fresh and unstained urine sediment analysis under BFM is a method that can be used to identify DC due to BKV reactivation. The analysis procedure is fast, cheap and painless. The information obtained during routine urinalysis can lead to the early diagnosis of BKV reactivation helping on the clinical management of the patients. The ability of less trained observers to perform such diagnosis requires further validation.

PUB654

Intravenous Immunoglobulin in the Management of Pneumocystis Pneumonia: A Case Series Musab Elgaali, Muhammad Imran, Matthew Edey. *Hull Royal Infirmary, Hull, United Kingdom.*

Background: Pneumocystis pneumonia (PCP) is a well-recognized complication of renal transplantation. We present 2 cases of severe PCP treated successfully with intravenous immunoglobulin (IVIg), trimethoprim-sulfamethoxazole (TMP-SMX) and withdrawal of immunosuppression. Graft function was maintained despite a high baseline immunological risk.

Methods: Case A: A 32 year-old woman presented 2 years post-transplant with acute cellular rejection treated with steroids. 2 months later she was admitted with respiratory failure due to PCP. She required intubation and ultimately oscillatory ventilation. CMV DNA was detected at low levels in bronchoalveolar lavage (BAL) fluid. IVIg 30g on alternate days (10 doses) was added, in addition to withdrawal of immunosuppression and hydrocortisone replacement. She made a full recovery, with preservation of transplant function throughout. Case B: A 47 year-old woman received a second kidney transplant. Early post-transplant she developed acute antibody mediated rejection managed with plasma exchange then maintenance prednisolone, tacrolimus and mycophenolate. 9 months later she was admitted with respiratory failure and Pneumocystis jirovecii in BAL. She required invasive ventilation and inotropic support. She was treated with intravenous TMP-SMX, but her clinical condition deteriorated with acute kidney injury (AKI) requiring hemofiltration and escalating ventilator requirements. She received IVIg 25g/day for 5 days, replacement hydrocortisone and immunosuppression was withdrawn. Her AKI resolved and later she became ventilator-independent. Graft function was at baseline on discharge. Maintenance immunosuppression was recommenced.

Conclusions: It is understood that immunity against Pneumocystis jirovecii is both B- and T-cell mediated. Thus pooled immunoglobulin might be expected to have some anti-Pneumocystis activity. It is also recognized that IVIg has immunomodulatory properties. In both cases the administration of IVIg allowed withdrawal of immunosuppression apart from replacement steroid without graft rejection despite high immunological risk. Both patients survived life-threatening PCP. We suggest adjunctive therapy with IVIg be considered in severe PCP.

PUB655

Ethical Issues Related to Kidney Donation/Transplantation: Perspective of Indian Doctors Richard S. Fernandes Almeida,¹ Nirmala Almeida,² Karen Almeida,³ Alan F. Almeida.⁴ ¹Lifesupporters Inst of Health Sciences; ²Human Development, Nirmala Niketan College of Home Science; ³Psychology, Mumbai Univ; ⁴Nephrology, PD Hinduja Hospital, Mumbai, India.

Background: Dearth of kidneys for transplantation has provoked the need to evaluate new policies and practices. This spurred the current study which addressed the perspective of doctors regarding emerging ethical issues pertaining to kidney donation/transplantation. **Methods:** The sample consisted of 140 doctors from Mumbai (Age Range=21-80 years, M=38.1, SD=17.95, Males=44.3%, Females=55.7%). A questionnaire, presenting ethical issues related to kidney donation/transplantation, in an agree/disagree format with supporting reasons was employed. The research design was exploratory; data was analyzed quantitatively and qualitatively. **Results:**

Question	Agree%	Reasons (%)*	Dis-agree%	Reasons (%)*
Unrelated transplants should be promoted by the government	75.7	Saves lives (16.4) Remedies organ donor shortage(16.4)	24.3	Misuse of organs (7.1) Higher chances of mismatch/organ rejection(7.1)
Kidney selling should be made legal	22.9	Greater donor availability(7.9) Avoidance of malpractice(6.4)	77.1	May lead to illegal/unethical practices(41.4)
Handicapped should not be kidney donors	24.3	Should not burden them as already challenged health-wise(10.7)	75.7	If informed consent given(20) If kidneys effectively functioning(14.3)
Substance abusers should not be transplant recipients	50.7	Chose to bring deterioration in life(10) Might abuse the transplant(15.7)	49.3	All are entitled to be kidney recipients(22.1)
Younger individuals should be given transplantation preference	60	Longer life expectancy (20) Greater transplantation success(12.9) Higher productivity(12.9)	40	Need-based rather than age-based preference(11.4)
Families of cadaver donors should be given incentives	45.7	Motivates donation(22.9)	54.3	Would lead to commercialization and criminal activities(20.7)
Kidney donation should be made compulsory after death	44.3	Saves lives(26.4)	55.7	Donation is individual's choice, coercion is unethical(44.3)

*Representative

Conclusions: This study is relevant in view of the dearth of Indian research. Educating doctors about medico-ethical issues is the need of the hour.

PUB656

Cardiovascular Risk Management of Renal Transplant Patients Joseph C. Newton, Thalakunte M. Muniraju. *Dumfries and Galloway Royal Infirmary, Dumfries, United Kingdom.*

Background: There is a high burden of cardiovascular disease amongst renal transplant recipients, and it is the most common cause of death with a functioning graft. We have assessed the medical management of all transplant patients in our region by comparing regular monitoring of glycaemia, blood pressure and serum lipids, with appropriate prescription of medicines based on their cardiovascular risk.

Methods: Using the electronic health record information was collected on cardiovascular comorbidities, all current medications, frequency of clinic monitoring, BP and most recent biochemical results for glycaemia, proteinuria and lipid results for the local transplant cohort of 69 patients. Prescription of statins, antihypertensives and aspirin were audited against guidelines from the UK Renal Association (RA) and KDIGO. Cardiovascular risk was calculated using the Joint British Societies Guidelines (JBS2).

Results: Amongst hypertensive patients, 2/28 (7.1%) were not on antihypertensive therapy. Significant proteinuria (uPCR >50) was not common (6/68 = 8.8%), but of these only 2/6 (33.3%) were receiving an ACE inhibitor or ARB. Glycaemic control of diabetic patients was generally good, with 9/12 (75%) achieving target HbA1c of <48 mmol/mol. For non-diabetic patients, 11/56 (19.6%) were found to have a random glucose ≥7. Of these 4/11 (36.4%) had HbA1c checks, one of which confirmed new diabetes. The remaining 7 patients (63.6%) have not had a follow up HbA1c. 20/69 (29.0%) of patients were calculated as >20% cardiovascular risk on the basis of comorbidities or using JBS2. Of these only 12/20 (60%) were on statin therapy. Almost all (6/7 = 85.7%) of patients with vascular disease were taking regular aspirin.

Conclusions: We have identified room for improvement in the management of hypertension and proteinuria. Rates of statin prescription suggest that we often underestimate cardiovascular risk clinically, however, further analysis will be required to determine whether valid reasons exist to support decisions to omit statins or renin-angiotensin

blockade. These audit results will be discussed with local clinicians, and will be added to the electronic record to highlight areas where individual management differs from national guidelines.

PUB657

Preemptive Transplantation Is Associated with Improved Graft Survival: Results from the French Transplant Database Mathilde Reydit,^{1,2} Christian Combe,² Jerome Harambat,² Christian Jacquelinet,³ Pierre Merville,² Lionel Couzi,² Karen Leffondré.¹ ¹INSERM U897, Bordeaux School of Public Health, Bordeaux, France; ²Nephrology and Transplantation, Bordeaux Univ Hospital, Bordeaux, France; ³Agence de la Biomédecine, Paris, France.

Background: Kidney transplantation (KT) is the treatment of choice for end-stage renal disease. In France, preemptive kidney transplantation (PKT) should be considered when glomerular filtration rate is under 20 ml/min/1.73m² but European reports on the results of PKT are scarce. Our objective was to evaluate the impact of PKT on graft and patient survival.

Methods: We analyzed all first kidney-only transplants performed in adults in France between 2002 and 2012. A Cox multivariable model was used to study the impact of PKT on the hazard of graft failure defined as death, return to dialysis, or retransplant, whichever came first.

Results: Between 2002 and 2012, 22 288 patients received a first KT, including 3112 (14%) who had a PKT. Mean recipient age at KT was 50.5 ± 13.4 years, 61.9% were men. Median time of follow-up was 4.7 years. In multivariable analysis, after adjustment for age and sex of recipients, primary kidney disease, donor type (living or deceased donor, expanded criteria donor or standard), HLA mismatches, cold ischemia time, center and year of transplantation, PKT was associated with a 43% reduction in the hazard of graft failure when compared with patients who were treated by dialysis before KT (Hazard ratio (HR) 0.57;IC95% 0.51-0.64). This reduction in the hazard of graft failure was greater after the first year of transplant (HR during the first year 0.69,IC95% 0.57-0.83;HR after the first year 0.51,IC95% 0.45-0.59) and the impact of PKT was also greater in living than in deceased donor recipients (HR in living donor 0.34,IC95% 0.19-0.55;HR in deceased donor 0.59,IC95% 0.52-0.66). Among the subgroup of patients registered on the waiting list before the initiation of dialysis, PKT was associated with a 29% reduction in the hazard of graft failure (HR 0.71;IC 95% 0.58-0.87).

Conclusions: In France, PKT is associated with better graft survival than KT performed after the initiation of dialysis. Nephrologists should prepare patients to PKT rather than to dialysis.

Novel Potential Theranostic Targets in Individuals with Kidney Allograft Dysfunction Roberto Bassi,^{1,2} Monika A. Niewczas,³ Stefania Bussolino,⁵ Valentina De Zan,² Giuseppe Paolo Segoloni,⁶ Antonio Secchi,² Anil K. Chandraker,⁴ Luigi Biancone,⁶ Paolo Fiorina.^{1,2} ¹Nephrology, Boston Children's Hospital, Boston, MA; ²Medicine, San Raffaele Scientific Inst, Milan, Italy; ³Section of Genetics and Epidemiology, Joslin Diabetes Center, Boston, MA; ⁴Transplantation Research Center, Brigham and Women's Hospital, Boston, MA; ⁵Internal Medicine, San Giovanni Battista Hospital, Turin, Italy; ⁶Univ of Torino.

Background: The lack of early diagnostic and therapeutic targets for chronic allograft dysfunction (CAD) is among the major determinants of poor long-term graft survival. Metabolic abnormalities in serum and kidney graft parenchyma may worsen allograft function, while alterations of urinary metabolites may be used as diagnostic biomarkers.

Methods: To explore this hypothesis, we recruited individuals with stable allograft function (n=20), chronic allograft dysfunction (n=20) and healthy controls (n=10), and analyzed their metabolomic profile by *ex vivo* liquid/gas chromatography-mass spectrometry (LC/GS-MS) of serum and urine and *in vivo* two dimensional correlated spectroscopy (2D-COSY) of the kidney graft.

Results: LC/GS-MS revealed serum and urinary abnormalities of amino acids, biogenic amines and acylcarnitines in individuals with worse allograft function (T3) compared to conserved graft function (T1). Particularly, CAD was associated with reduction of serum tryptophan and glutamine (T3 vs. T1, p<0.01) and of urinary histidine (T3 vs. T1, p<0.05). Derivatives of dimethylarginine (DMA; symmetric (S)DMA: T3 vs. T1, p<0.001; p<0.01) and short-chain acylcarnitines (C4; C12: T3 vs. T1, p<0.01; p<0.05) increased in serum, while dopa and dopamine (T3 vs. T1, p<0.01; p<0.001) together with DMA, SDMA and ADMA (T3 vs. T1, p<0.001, p<0.001, p<0.01) decreased in urine. *In vivo* 2D-COSY performed on the same patients revealed reduction (p<0.05) of the parenchymal content of choline, creatine, taurine and threonine in individuals with CAD. Notably, taurine was selectively reduced within the graft parenchyma and increased in serum and urine of individuals with CAD.

Conclusions: Novel potential theranostics targets have been identified with an unbiased *ex vivo* and *in vivo* metabolomic profiling of individuals with CAD.

Good Patient and Graft Survival in Recipients of Kidney Transplantation due to Diabetic Nephropathy Amgad E. El Agroudy. *Internal Medicine Dept, College of Medicine and Medical Sciences, Arabian Gulf Univ, Manama, Bahrain.*

Background: Compared with non-diabetic subjects, patients with type 2 diabetes and end-stage renal disease (ESRD) have seldom been selected for renal transplantation. The aim of this study is to compare patient and graft outcome in kidney transplant patients with diabetes mellitus.

Methods: We retrospectively studied 358 patients who underwent kidney transplantation between 1979 and 2014, including 88 with diabetic ESRD (DM group) (type 1, $n = 8$; type 2, $n = 80$) and 270 with non-diabetic ESRD (NDM group). Mean follow-up was 92 ± 9 (0.1–389) months.

Results: Mean age was higher in the DM group (52.8 vs 44.6 years; $P < .0001$), and there was no significant difference in recipient gender, donor age or donor source. At the end of follow-up, there was no differences between the groups in terms of blood pressure control (DM $139.3 \pm 16.7/81.7 \pm 7.6$ mmHg vs NDM $138.3 \pm 19.7/82.1 \pm 8.1$ mmHg, $P = 0.83/0.80$) and renal function (creatinine, 115.4 ± 47.1 vs 133.4 ± 80.2 $\mu\text{mol/l}$, $P = 0.18$; calculated creatinine clearance, 66 ± 24 vs 68.4 ± 24 ml/min/1.73 m², respectively, $P = 0.9$). In total, 26 patients had acute transplant rejections [8 patients with diabetes vs 18 patients without diabetes, $P = 0.11$]. There was no significant difference in post transplant surgical complications as wound dehiscence or infections. There was a significant high incidence of the urinary tract infection rate in DM group (17 vs 32 patients; $P = .012$). Four out of 22 patients died (18.2%) in the DM group and 10 out of 47 patients died (21.3%) in the NDM group died from cardiovascular disease ($P = 0.17$). The 1-, and 10-year patient survival rates in the DM and NDM groups were 97.5% vs 99% (ns), and 56.8% vs 58.8% (ns), respectively. The 1-, and 10-year graft survival rates were 97.5% vs 70.7% (ns) and 58.9% vs 66.1% (ns), respectively.

Conclusions: Renal transplantation in diabetic ESRD patients yields good results in terms of patient survival and complications, suggesting that renal transplantation can be performed in these patients and should become a more established treatment option.

PUB660

Impact of Pre-Transplant Peritoneal Dialysis Compared with Hemodialysis on the Incidence of Delayed Graft Function in Kidney Transplant Recipients with Lupus Gabriel Contreras, Javier Pagan, Antonio A. Armstrong, Jorge M. Diego, Ian Thomas, Patricia Marie Byers, Alberto J. Sabucedo, Jair Munoz Mendoza, David Roth. *Univ of Miami Miller School of Medicine.*

Background: Delayed graft function (DGF) increases the risk of allograft failure in recipients of kidney transplants.

Methods: In this study, we assessed the impact of pre-transplant peritoneal dialysis (PD) compared with hemodialysis (HD) on the risk of DGF in patients with lupus using logistic regression models.

Results: Three hundred-fifty three of 2513 (14 %) recipients transplanted between 3/22/1994 and 9/27/2006 with complete records in the United Network for Organ Sharing files had DGF. The incidence of DGF was lower in recipients who used PD (68/613 = 11.1%) compared with HD (285/1900 = 15%) prior to transplantation ($P = 0.013$). After adjusting for donor and recipient age, gender and race-ethnicity, type of donor, recipient education and insurance, time of dialysis prior to transplantation, panel reactive antibodies (PRA), human leukocyte antigen (HLA) mismatch, and ABO blood type compatibility, the lower risk for DGF associated with the use of PD compared with HD remained significant (Odds-ratio 0.70 [95% confidence interval 0.53-0.94]; $P = 0.015$). Donor age (1.01 [1.00-1.02] per 1 year), deceased donor transplantation (3.64 [2.59-5.12] living donor as reference), HLA mismatch (1.08 [1.01-1.15] per 1 antigen mismatch), and PRA (1.01 [1.00-1.01] per 1%) were also independently associated with DGF.

Conclusions: In lupus recipients of kidney transplants, the use of PD compared with HD is associated with lower risk of DGF after adjusting for important predictors.

Association Between Dipstick Proteinuria and Allograft Outcomes in Living Donor Kidney Transplant Recipients Joon-sung Park, Jong Wook Choi, Chang Hwa Lee, Gheun-Ho Kim. *Dept of Internal Medicine, Hanyang Univ College of Medicine, Seoul, Republic of Korea.*

Background: Proteinuria is one of the important factors suggestive of kidney function impairment. Previous epidemiologic studies had demonstrated that greater than trace amounts of protein on a casual urine dipstick may be an important predictor of long-term clinical outcomes in general population. In kidney transplant (KT) recipients, there were few data concerning it.

Methods: Thus, we retrospectively analyzed 238 living donor KT recipients to investigate impact of dipstick proteinuria on allograft outcomes. All KT recipients were divided into 2 groups according to dipstick proteinuria: control group ($n=190$), negative; case group ($n=48$), \geq trace. Cox's proportional hazard model with time-dependent covariates was used to encompass compounding effect of covariates that change over time, including vintage and allograft survival time.

Results: As compared with controls, the change of estimated glomerular filtration rate was prominent in recipients with dipstick proteinuria after 3-year post-KT (-1.5 ± 7.1 vs. -4.4 ± 7.4 mL·min⁻¹·1.73 m⁻²·year⁻¹, $P<0.0174$). In Kaplan-Meier analysis, KT recipients in control group had a better dialysis-free survival as compared with cases (201 ± 6 vs. 164 ± 10 months; log-rank $P=0.0118$). In Cox proportional hazard models, trace or more dipstick proteinuria was closely associated with long-term allograft loss (HR=1.964, 95% CI=1.152-3.348), and further adjustment for age and gender did not attenuate this association (HR=1.764, 95% CI=1.050-3.065).

Conclusions: Our results may suggest that presence of small amount protein in urine may be the first sign of deteriorating allograft renal function.

PUB662

Cytomegalovirus Exposure Is Associated with Immunological Sensitization in End-Stage Renal Disease Robert Lam,¹ Rita Suri,² Amitabh Singh,¹ Lakshman Gunaratnam.^{1,3} ¹*Schulich Medicine & Dentistry, Western Univ, London, ON, Canada;* ²*Univ of Montreal, Montreal, QC, Canada;* ³*Matthew Mailing Center, London Health Sciences, London, ON, Canada.*

Background: The presence of antibodies to Human Leukocyte Antigen (HLA) is associated with long transplant wait-times, acute rejection, and poor graft outcomes. While prior transplant, pregnancy, and blood transfusion can trigger HLA antibodies, many sensitized patients have none of these known risk factors. Previous infections have been proposed as a potential cause of "spontaneous" sensitization, but this has not been well studied. Because cytomegalovirus (CMV) is known to modulate the host's immune defenses to avoid identification and clearance, we hypothesized that prior CMV exposure would be associated with HLA sensitization.

Methods: We conducted a cross-sectional study of 150 patients aged ≥ 18 years attending a University Hospital renal pre-transplant assessment clinic over 16 months. Patients with prior transplant were excluded. Demographics, comorbidities, viral serology, peak combined Panel Reactive Antibody (cPRA), blood transfusions, and pregnancies were obtained by chart review; sensitizing events were confirmed by patient questionnaire. Logistic regression was used to identify potential risk factors associated with sensitization, defined as cPRA $>20\%$.

Results: Mean age was 54.2 ± 12.5 yrs, 61% were male, and mean years on dialysis was 2.7 ± 4.2 . Fifty percent were CMV IgG positive and 32% had cPRA $>20\%$. A cPRA $>20\%$ was significantly associated with CMV positive IgG (adjusted odds ratio 2.8, 95%CI 1.3-6.6; $p=0.012$), prior pregnancy (adj OR 4.0, 95%CI 1.7-9.4; $p=0.002$), and blood transfusion (adj OR 3.9, 95%CI 1.7-8.7; $p=0.001$), whereas age, sex, hypertension, diabetes, and years on dialysis were not. In the subgroup of 83 patients with no previous pregnancy or blood transfusion, the prevalence of cPRA $>20\%$ was 24% in CMV positive patients, versus 12% in CMV negative patients (unadj OR 2.3, 95%CI 0.7-7.5; $p=0.152$).

Conclusions: We identified previous CMV exposure as a novel independent risk factor strongly associated with the presence of HLA antibodies. Whether CMV infection triggers HLA sensitization requires further study in prospective longitudinal studies.

The Role of Plasmapheresis in the Treatment of Recurrent Focal Segmental Glomerulosclerosis Juliana Busato Mansur,^{1,3} Gustavo Ferreira da Mata,¹ Tainá Veras de sandes Freitas,³ Gianna Mastroianni-kirsztajn,^{1,3} Helio Tedesco Silva,^{1,3} J. Medina-Pestana.^{1,3} ¹*Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil;* ²*Nephrology, Federal Univ of Sao Paulo, Sao Paulo, Brazil;* ³*Nephrology, Hospital do Rim, Sao Paulo, Brazil.*

Background: Focal segmental glomerulosclerosis (FSGS) has a high recurrence rate after kidney transplantation (Tx). There is no established treatment, although plasmapheresis (PP), alone or with rituximab (RTX), is the most frequent therapeutic intervention. The purpose of this study was to evaluate the clinical-laboratorial profile and outcomes of patients diagnosed with rFSGS or with highly probable rFSGS submitted to PP.

Methods: Retrospective cross-sectional study involving patients with rFSGS submitted to PP between 2003-2014 at Hospital do Rim/UNIFESP.

Results: 70 patients (median age: 29 years, 5-62 years) were included. In 51%, FSGS was identified as the cause of ESRD. Proteinuria >0.5 g/g and >3 g/g was present, respectively, 15 and 64 days after kidney Tx; 70% of patients received a kidney from a deceased (DC) donor; cold ischemia time was 23 H (mean). Tacrolimus, prednisone, azathioprine/micophenolate were the most frequently used immunosuppressive drugs. Incidence of DGF was of 70% and of 19% in cases of DC and living donor's, respectively. The 1st biopsy was on the 24th day (mean) post-Tx and the most prominent diagnosis were acute cellular rejection (21.9%) and acute tubular necrosis (29.7%), with only 17% of rFSGS. Histological diagnosis was confirmed on the 124th day and the beginning of the PP was on the 77th day; 48% presented partial remission after 83 sessions; complete remission occurred in 22% of cases (means). Infectious episodes were the main complication during PP (69%). Part of the patients underwent methylprednisolone (80%) and RTX treatment (34%). The allograft survival in the 1st year was 70.8%, followed by 41.4% and 32.7% at 3 and 5 years respectively.

Conclusions: Laboratorial manifestations of rFSGS occurred early after renal Tx and preceded histological diagnosis. Treatment with PP was related to infectious episodes, low complete remission and important graft loss rates, which reinforces the need for further studies to determine a more efficient treatment.

Successful Treatment of BK Nephropathy with Tacrolimus and mTOR Inhibitors Natalia I. Polanco fernandez, Enrique Morales, Manuel Praga, Esther Gonzalez monte, Eduardo Gutierrez-martinez, Amado Andres. *Nephrology, Hospital Univ 12 de Octubre, Madrid, Spain.*

Background: BK nephropathy (BKN) is a relevant cause of graft dysfunction in kidney transplantation. mTOR inhibitors (mTORi) have been suggested as the best immunosuppression in BKN. However Tacrolimus-free therapy could increases risk of rejection. Since 2009 in patients with BKN we conducted a protocol discontinuing Mycophenolate and decreasing Tacrolimus (TAC) dose in association with mTORi, both with target levels of 5 ng/mL.

Methods: From 2007 to 2013 we diagnosed 22 BKN. Patients diagnosed since 2009 (n= 14, group 1) were treated beginning mTORi and decreasing TAC dose. The others 8 patients suffered significant reduction of immunosuppression (group 2). We analyze renal function, plasma quantitative BK PCR, antiHLA antibodies, rejections and dialysis or dead at final follow-up.

Results: 22 patients were identified. The BKN was diagnosed at 7th month after transplantation (range 2-55). The medium duration of follow-up was 53 months (6-85). Baseline characteristics and evolution are listed in table 1.

	Group 1 (n= 14)	Group 2 (n= 8)
Serum Creatinine at baseline (mg/dl)	1.3 ± 0.36	1.68 ± 0.57
AntiHLA antibodies positives at BKN diagnosis	43% (6)	12.5% (1)
Serum Creatinine at BKN diagnosis (mg/dl)	1.93 ± 0.37	2.4 ± 0.63
Serum Creatinine at final follow-up (mg/dl)	1.6 ± 0.7	3.2 ± 2.2
Dialysis at final follow-up	7.1% (1)	12.5% (1)
Plasma BK viral load at diagnosis (copies/ml)	84369 (10035-8234680)	20674 (10715-1543440)
Patients with negative plasma BK viral load at final follow-up	78.6% (11)	75% (6)
Acute rejection after BKN	0%	12.5% (1)

Although group 1 had a greater immunologic risk and a higher plasma BK viral load at diagnosis, the renal function during follow-up was more favorable than patients from group 2. No rejection episodes were diagnosis in group 1. Only one patient in each group started chronic dialysis at the end of the follow-up (52 and 85 months after BKN diagnosis).

Conclusions: An immunosuppression regimen based in TAC and mTORi is an effective and safety treatment in patients with BKN. This treatment reduces viral load and increases graft survival without increases the rejection risk.

PUB665

A Rare Case of Guillain-Barré Syndrome Associated with Cytomegalovirus Disease in a Renal Transplant Patient Jessica Bian, George P. Bayliss. *Medicine, Rhode Island Hospital, Providence, RI.*

Background: While cytomegalovirus (CMV) infection is associated with Guillain-Barré syndrome (GBS) in the general population, there are few reports of GBS associated with CMV disease in the renal transplant patients. We describe the case of one renal transplant patient who developed GBS after treatment for documented CMV disease.

Methods: The patient is a 62 year-old woman with ESRD from polycystic kidney disease status post deceased donor renal transplant (CMV donor positive/recipient seronegative) on tacrolimus and prednisone. She completed 6 months of CMV prophylaxis with valgancyclovir. Fourteen days after stopping valgancyclovir, she presented with fevers, myalgias, and headache. Tacrolimus level was 6.6 ng/mL on admission. She was diagnosed with CMV disease (serum CMV PCR 2200 copies; CSF CMV PCR undetectable) and started on treatment-dose valgancyclovir. Ten days later, she returned with numbness of her hands and feet. CSF studies were notable for albuminocytologic dissociation. MRI brain and spine was normal. Electromyography showed diffuse sensory motor polyneuropathy consistent with GBS. She developed ascending motor weakness, sensory loss, and areflexia without progression to respiratory compromise, improving with IVIG therapy. She was discharged to rehabilitation.

Results: She returned 7 days later with compartment syndrome of her right arm due to deep venous thromboses of her right subclavian, axillary, and brachial veins with associated hematomas requiring emergent fasciotomy and hematoma evacuation. This was attributed to recent IVIG therapy, as thromboses may occur even in the absence of other risk factors (US boxed warning). She was bridged to warfarin prior to discharge. Of note, she maintained excellent allograft function throughout this complicated course.

Conclusions: This vignette details a case of CMV-associated GBS after renal transplantation. The case is notable for the development of CMV disease shortly after cessation of valgancyclovir prophylaxis in a CMV donor positive/recipient negative renal transplant despite only being on a two-drug immunosuppressive regimen. This may support a longer course of CMV prophylaxis in donor positive/recipient negative transplant.

A Prolonged Warm Ischemia Time Is Associated with Graft Failure and Mortality After Kidney Transplantation Karthik K. Tennankore,¹ Joseph Kim,² Ian P. Alwayn,³ Bryce A. Kiberd.¹ ¹*Medicine, Div of Nephrology, Dalhousie Univ, Halifax, NS, Canada;* ²*Medicine, Div of Nephrology, Univ of Toronto, Toronto, ON, Canada;* ³*Dept of Surgery, Multi-Organ Transplant Program, Dalhousie Univ, Halifax, NS, Canada.*

Background: Warm ischemia time is a potentially modifiable insult to transplanted kidneys, but little is known about its effect on long term patient and graft survival. The purpose of this study was to determine if a prolonged warm ischemia time was associated with death and graft failure after kidney transplantation.

Methods: We conducted a cohort study of adult kidney transplant recipients in the Scientific Registry of Transplant Recipients between 1/1/2000 and 12/31/2013. Warm ischemia time was defined as the time of organ removal from cold storage to reperfusion with warm blood, including surgical anastomosis time. Times were categorized as 0-10, 10-20, 20-30, 30-40, 40-50, 50-60 and ≥60 minutes. Acknowledging that times of <10 minutes were potentially attributed to coding error, 10-20 minutes was chosen as the reference group. The primary outcome was all-cause mortality and graft failure adjusted for recipient, donor, immunological and surgical factors.

Results: Overall, 131,677 patients were included and there were 35,901 events. Relative to patients with warm ischemia times of 10-20 minutes, a longer warm ischemia time was associated with an increased relative hazard for death or graft failure (table 1). The association between warm ischemia time and the composite outcome persisted after stratification by donor type (living versus deceased donor) and delayed graft function status.

Conclusions: Warm ischemia time is associated with long term patient and graft survival after kidney transplantation. Strategies to reduce warm ischemia time should be an important consideration for future study.

Table 1. Adjusted Cox survival analysis for death or graft failure

Warm Time (Minutes)	Death or graft failure Relative Hazard [95% CI]	Death censored graft Failure Relative Hazard [95% CI]
	Events: 35,901	Events: 20,032
0-<10	1.17 [1.09-1.26]	1.15 [1.04-1.27]
10-<20	Ref	Ref
20-<30	1.07 [0.99-1.15]	1.04 [0.94-1.14]
30-<40	1.13 [1.06-1.22]	1.13 [1.03-1.24]
40-<50	1.17 [1.09-1.26]	1.17 [1.06-1.29]
50-<60	1.20 [1.12-1.30]	1.23 [1.11-1.36]
≥60	1.23 [1.15-1.33]	1.25 [1.13-1.37]

Adjusted for donor type (living, standard, expanded criteria), donor race, donor sex, donor diabetes status, donor body mass index categories, number of human leukocyte antigen mismatches, panel reactive antibody categories, induction type, cold ischemia time, and recipient characteristics (age, sex, gender, cause of end-stage renal disease, dialysis vintage, diabetes, coronary artery disease, hypertension, cerebrovascular disease, peripheral vascular disease, chronic lung disease, prior malignancy, previous kidney transplant, body mass index categories)

Clinical Significance of Pre-Transplant 25-Hydroxyvitamin D Levels on Post-Transplant Clinical Outcome Tae Hyun Ban,^{1,2} In-Ae Jang,^{1,2} Bum Soon Choi,^{1,2} Cheol Whee Park,^{1,2} Chul Woo Yang,^{1,2} Yong-Soo Kim,^{1,2} Byung Ha Chung.^{1,2} ¹*Internal Medicine, Seoul St. Mary's Hospital, Seoul, Korea;* ²*Transplant Research Center, Seoul St. Mary's Hospital, Seoul, Korea.*

Background: It is well known that vitamin D shows immune modulating effects in various immunologic disorders and infectious disease. The aim of this study is to investigate the clinical significance of 25(OH)D levels on acute rejection or infection in kidney transplant recipients.

Methods: We included 174 kidney transplant recipients with low immunologic risk between 2011 and 2013. We measured 25(OH)D levels right before transplantation, and investigated whether the level of 25(OH)D predicts the development of acute rejection or infectious complications.

Results: During the first year after the KT, a total 27 cases of biopsy proven acute rejection was detected. 25(OH)D levels showed significant association with the development of acute rejection within the first year from KT. In the high tertile, the rate of acute rejection was 6.9 % (p=0.012). It was significantly lower incidence toward the high tertile. There was significant distinction between each tertile (low and second, p=0.032; second and high, p=0.002). For the prediction of infectious complications, after the 1 year predictive values of 25(OH)D levels were dissipated. During 1 year after KT, a total of 82 (47.1%) cases of infectious complications were detected. Most common causes were 23 (13.2%) cases of CMV and UTI respectively. 25(OH)D levels did not show significant association with either the overall or different types of infectious complications.

Conclusions: Pre-transplant serum 25(OH)D levels are independent predictor of acute rejection in the first year from kidney transplantation. However, they were not associated with infectious episode.

PUB668

Mammalian Target of Rapamycin Inhibitors Withdrawal in Kidney Transplant Recipients: Risk Factors and Related Transplant Outcomes

Lee-Moay Lim,¹ Mei-Chuan Kuo,^{1,2} Hung-Tien Kuo.^{1,2} ¹*Div of Nephrology, Dept of Internal Medicine, Kaohsiung Medical Univ Hospital, Kaohsiung, Taiwan;* ²*Faculty of Renal Care, College of Medicine, Kaohsiung Medical Univ, Kaohsiung, Taiwan.*

Background: With its antiproliferative and antineoplastic properties, Mammalian Target of Rapamycin Inhibitors (MTORi) potentially have important long-term therapeutic consideration in kidney transplantation. Treatment cessation frequently occurs following its unique adverse effects. The objective of this study was to investigate the risk factors for MTORi withdrawal and its impacts on transplant outcomes.

Methods: This retrospective observational study consisted of kidney transplant recipients followed up from January 1999 till May 2015. We examined the risk factor for MTORi withdrawal using multivariate logistic regression analysis. The impacts of MTORi withdrawal on transplant outcomes were analyzed using multivariate Cox regression and logistic regression. $P < 0.05$ was considered as statistically significant.

Results: A total of 111 kidney transplant recipients who received MTORi treatments were included, with 46 patients withdrew (41.0%). The risk factors for mTORi withdrawal included initial proteinuria (adjusted OR= 4.61, $P=0.007$), higher initial serum creatinine (per 1 mg/dl increment, adjusted OR=2.73, $P=0.035$), and glomerulonephritis as primary renal disease (adjusted OR=5.00, $P=0.035$). MTORi withdrawal was associated with an increased risk of graft failure (adjusted HR=3.79, $P=0.027$), but not with patient survival (adjusted HR=0.61, $P=0.595$).

Conclusions: MTORi withdrawal is a strong risk factor for renal graft failure. Proteinuria, poor initial graft function and primary renal disease of glomerulonephritis are predictors for MTORi withdrawal. Earlier identification of risk factors may assist physician to decide the best candidate for MTORi conversion in order to optimize transplantation outcomes.

PUB669

Impact of Donor Age on Longterm Outcomes in Living Donor Kidney Transplants: A Propensity Score Matched Analysis Using Multicenter Cohort

Kyung Don Yoo,¹ Jung Nam An,¹ Jang-Hee Cho,³ Chan-Duck Kim,² Su-Kil Park,³ Dong-Wan Chae,¹ Yun Kyu Oh,¹ Chun Soo Lim,¹ Yon Su Kim,¹ Young hoon Kim,³ Jung Pyo Lee.¹ ¹*Seoul National Univ College of Medicine;* ²*Kyungpook National Univ Hospital;* ³*Asan Medical Center and Univ of Ulsan College of Medicine.*

Background: Recently, kidney transplantation from elderly living donor has been increasing. However, the impact of donor age on outcomes in kidney transplantation recipients has not been well established in Asian.

Methods: This multicenter cohort study included 2,595 adult kidney transplant recipients admitted to 5 major tertiary hospitals in Korea between 1997 and 2012. Patient survival, allograft survival, and biopsy-proven acute rejection (BPAR) were compared between the elderly donors (≥ 50 years) and young donors (18–49 years) by the propensity score matched (PSM) analysis.

Results: The proportion of donor with over 50 years was 21.2% ($N=553$). The mean age in the elderly donor was 54.9 ± 4.3 years old. Despite of difference of donor age, mean recipient age was similar between the groups. Elderly donors were more likely to donate to unrelated recipients. The proportions of recipients with diabetes mellitus (22.8%), serum creatinine and BMI of donor were significantly higher in the elderly donor group than in the young donor-age group. In elderly donor group, recipients' patient survival was worse than younger age group before PSM ($p=0.014$). After PSM, donor age did not affect the recipient's survival ($p=0.305$) and allograft survival ($p=0.077$), however, BPAR was frequently occurred in the allograft from elderly donor ($p=0.019$). In the multivariate Cox regression analysis, elderly donor affected the BPAR-free survival ($p=0.01$, hazard ratio 1.52, 95% confidence interval 1.07-2.17).

Conclusions: Kidney transplantation from elderly donor needs more meticulous management, because donor age could affect acute rejection.

PUB670

Long-Term Outcome of Randomized Trial Comparing Cyclosporine and Tacrolimus Therapy with Steroid Withdrawal in Living-Donor Renal Transplantation: 10-Year Follow-Up

Jin Hae Kim, Jee Eun Park, Do Hee Kim, Hye Ryoung Jang, Jung Eun Lee, Dae Joong Kim, Yoon-Goo Kim, Ha Young Oh, Woosong Huh. *Dept of Medicine, Samsung Medical Center, Sungkyunkwan Univ School of Medicine, Seoul, Republic of Korea.*

Background: The use of steroid withdrawal protocols after kidney transplantation has been increasing because of well-known adverse effects of steroids and the introduction of new effective immunosuppressants. Long-term efficacy and safety of tacrolimus plus mycophenolate mofetil (TAC group) compared with cyclosporine A plus MMF (CsA group) for 10 years were analyzed in renal transplantation patients with low immunologic risk who underwent steroid withdrawal at 6 months after operation.

Methods: Overall 10-year follow-up data of patients who underwent their first living-donor renal transplantation at Samsung Medical Center between September 2000 and August 2003 were retrospectively analyzed. Patients were randomized to CsA or TAC groups and underwent steroid withdrawal at 6 months after renal transplantation. End points were patient and graft survival, and the incidence of acute rejection and post-transplant de-novo comorbidity such as diabetes mellitus.

Results: A total of 117 patients who successfully discontinued steroid treatment were included (55 in CsA group vs. 62 in TAC group). The 10-year patient survival was 96.2% in the CsA group and 98.4% (61/62) in the TAC group ($p=0.495$). The 10-year graft survival rate did not differ between groups (81.3% in CsA vs 91.2% in TAC; $p=0.412$). The cumulative incidence of acute rejection for 10 years after transplantation was 24.5% and 15.6% in the CsA and TAC groups, respectively ($p=0.201$). The incidence of post-transplantation diabetes mellitus was higher in the TAC group compared to the CsA group (10.0% vs 23.3%, respectively; $p=0.046$).

Conclusions: Long-term graft and patient survival, and the incidence of acute rejection were similar between CsA- and TAC-based regimens combined with MMF in low immunologic risk patients who underwent steroid withdrawal 6 months after kidney transplantation.

Dysregulation of Circulating Immunoglobulins in Renal Transplant Recipients

Mukut Minz,¹ Ravi Dhital,¹ Ranjana Walker Minz,² Ashish Sharma,¹ Ritambhara Nada,⁴ Deepesh Kenwar,¹ Sarbpreet Singh.¹ ¹*Transplant Surgery, Post Graduate Inst of Medical Education and Research, Chandigarh, India;* ²*Immunopathology, Post Graduate Inst of Medical Education and Research, Chandigarh, India;* ³*Nephrology, Post Graduate institute of Medical Education and Research, Chandigarh, India;* ⁴*Histopathology, Post Graduate Inst of Medical Education and Research, Chandigarh, India.*

Background: Peripheral levels of serum immunoglobulin reflect humoral immunity. Gross derangements in the immunoglobulin levels might occur in the post-transplant period.

Methods: Peripheral venous blood was periodically collected from patients before (pre-Tx) and after kidney transplantation at 1 Month, 3 Months, 6 Months, 12 Months and at the time of Rejection. Serum was isolated from clotted blood after brief centrifugation at 3000g for 10 minutes. Serum level of IgM, IgA, IgG, IgG1, IgG2, IgG3 and IgG4 were quantified by Nephelometry (MiniNeph™, UK).

Results: This study includes 75 first kidney transplant recipients who were divided into two groups: Rejection group (R, $n=35$) and Non Rejection group (NR, $n=35$). Rejection group was further segregated as cellular ($n=25$) and antibody mediated ($n=9$). Thirty five age and sex matched healthy donors were recruited as control. No differences in the levels of IgG, IgA and IgM were noted in the pre-tx sera and healthy donor sera. Post-transplantation, there is an early decrease in serum IgG and IgA levels in both R and NR groups between 1-3 months and the rate of decrease is higher in patients with rejecting grafts. IgG3 and IgG4 are significantly reduced during rejection ($p < 0.0001$ and 0.0006 respectively). IgG3 levels correlated with cellular rejection, while the rate of decrease of IgG2 and IgG4 was higher in antibody mediated rejection.

Conclusions: Post-transplantation: there is a fall in serum levels of IgA, IgG and its subtypes in both non rejecters and rejecters, more so in the later. Low serum levels of IgG3 and IgG4 could be a pointer to rejection. Significant correlation of IgG3 with cellular rejection embarks that IgG subtypes are dysregulated in cell-mediated rejection.

PUB672

Impact of Kidney Transplantation on Arterial Stiffness in Patients with ESRD

Hyunseon Kim, Chul Woo Yang, Byung ha Chung, Cheol Whee Park, Yong-Soo Kim, Bum soon Choi. *Div of Nephrology, Dept of Internal Medicine, Seoul St. Mary's Hospital, The Catholic Univ of Korea, Seoul, Republic of Korea.*

Background: Arterial stiffness is closely associated with cardiovascular mortality in end-stage renal disease (ESRD) patients. We investigated whether kidney transplantation (KT) can improve arterial stiffness in patients with ESRD.

Methods: We enrolled 171 KT recipients and we measured brachial-ankle pulse wave velocity (baPWV) and ankle-brachial blood pressure index (ABI) before KT, and post KT baPWV and ABI was assessed in a subgroup of 84 patients. First, we investigated cardiovascular (CV) events risk and established influence factors. Second, these patients divided into improvement and non-improvement groups based on change of baPWV after KT which was very strong marker of CV disease prediction. We also compared risk factors which affect arterial stiffness between two groups.

Results: 10 CV events occurred in the overall group, and 7 events in the post KT baPWV subgroup. Risk factors affected CV events of these group were diabetes, high body mass index(BMI) and high baPWV. Overall arterial stiffness measured by baPWV after KT showed significant improvement (1417.5 ± 234.5 cm/s) compared to those of before KT (1503.5 ± 255.2 cm/s) ($p < 0.05$ vs after KT). 55 out of 79 patients (69.6%) showed improvement of baPWV after KT, but 24 patients did not. Between two groups, improvement group showed higher pre-transplant baPWV than no-improvement group (1561.0 ± 263.9 vs. 1371.6 ± 177.1), and multivariate analysis revealed that gender and BMI, degree of decrement of calcium level were an independent risk factor of change of baPWV.

Conclusions: We could expect CV event risk in KT recipients by diabetes, BMI and baPWV, and these were very strong prediction marker of CV event. Arterial stiffness in ESRD patients improves after transplantation, and lower BMI, the amount of calcium decreased, gender affected the improvement of baPWV. PUB673

The Correlation of Donor:Recipient Body-Mass Index (BMI) Ratio and 6-Month Post-Transplant Kidney Function in Known End-Stage Renal Disease (ESRD) Patients Joseph justin Hipolito Regalado. *Internal Medicine, Cardinal Santos Medical Centre (CSMC), San Juan, Metro Manila, Philippines.*

Background: Kidney Transplant (KT) is the preferred treatment for ESRD. The challenge rests in finding appropriate donors. Donor-recipient size mismatch was shown to correspond to donor-recipient nephron supply mismatch, affecting prognosis. Matching nephron supply to recipient needs was proposed to improve outcomes. Patients with a higher BMI relative to their donors were shown to have poorer post-KT graft function. Determining whether measures such as BMI are valid predictors of outcomes is a legitimate area of study. This research sought to determine the association and correlation between Donor-Recipient BMI Ratio and the 6-month post-KT creatinine (crea).

Methods: A review of patients who underwent KT in 2005-2014 at the CSMC was done. Inclusion criteria were Filipinos aged 18 years and above with a graft, coming from a Living Donor, functioning for at least 6 months post-KT (25 Donor-Recipient pairs). Association using Chi-Square and correlation using Multiple Regression Analysis between Donor-Recipient BMI and renal function based on 6 months post-KT crea were determined.

Results: Data showed no statistically significant association ($p = 0.64$) and correlation ($p = 0.77$) between Donor-Recipient BMI ratio and post-KT crea. Statistically significant correlations ($p < 0.10$) were noted between the post-KT crea and the recipient and donor BMI (strong correlation, $r = 0.78$), with a $22.51 \mu\text{mol/L}$ increase in post-KT crea per 1 point increase in the donor BMI, and a $13.51 \mu\text{mol/L}$ decrease in post-KT crea per 1 point increase in recipient BMI.

Conclusions: The data support two schools of thought on donor-recipient selection in improving outcomes. First, recipients are to lose weight to improve BMI before KT due to the increased risk of graft damage from hyperfiltration and lipotoxicity. Second, donors with larger BMI's are better due to a higher nephron reserve. It could be surmised from the study that the donor and recipient BMI's influence the 6-month post-KT crea. The appropriate mathematical instrument defining the relationship between these measures predicting KT outcomes more accurately, however, is yet to be universally established.

PUB674

Incidence of Malignancies in Kidney Transplant Patients – Report from Eastern Province of Saudi Arabia Abdul Razack Amir.¹ *¹Nephrology, Internal Medicine, Johns Hopkins Aramco Healthcare, Dhahran, Eastern, Saudi Arabia;* ²*Internal Medicine, Univ of Dammam, Dammam, Eastern, Saudi Arabia.*

Background: Renal transplant patients have a higher incidence of malignancies due to the use of immunosuppressive medications and concomitant infections.

Methods: Based on the follow up of a single center in Saudi Arabia, the incidence of malignancies patients who underwent kidney transplantation was analyzed.

Results: During the 15 years study period, a total of 221 patients underwent renal transplantation. Eleven patients developed post-transplant malignancies with an average incidence of 4.9%. Two patients had Kaposi sarcoma (0.9%) and two developed Non-Hodgkins lymphoma (0.9%). One case was reported to have transitional cell carcinoma of urinary bladder (0.45%), one had breast cancer (0.45%), one had cervical cancer (0.45%), one developed angiosarcoma (0.45%), and one had hepatocellular carcinoma (0.45%). In addition, two patients developed renal cell carcinoma, one in the native kidney (0.45%), and the other in the transplanted kidney (0.45%). The duration to cancer development ranged from 6-120 months. Mortality rate in renal transplant patients with cancer was higher (55%) than those who did not develop cancer. Risk factors that determined cancer development included patient age, gender, duration of the transplantation and type of immunosuppression. Type of transplant was not found to be a determining factor of cancer development.

Conclusions: The incidence of malignancies in post renal transplant patients in the Kingdom of Saudi Arabia is evidently comparable to that reported in literature. In addition, the data highlights the importance of long term close follow up of renal transplant patients.

PUB675

Left Ventricular Global Longitudinal Strain as Early Detection of Subclinical Myocardial Dysfunction in Renal Transplant Recipients Secundino Cigarran,¹ Jose Lomban,³ Ana Maria Sanjurjo Amado,¹ Diego Coronel,¹ Sheila Casas,³ Juan Latorre,¹ M^a Milagros López hernández,¹ Jesus Calvino,² *¹Nephrology, Hospital Da Costa, Burela, Lugo, Spain;* *²Nephrology, Hospital Lucus Augusti, Lugo, Spain;* *³Cardiology, Hospital Da Costa, Burela, Lugo, Spain.*

Background: Echocardiographic global longitudinal strain (GLS) is recognised as a technique to detect subtle changes in left ventricular function. As in CKD pts, kidney transplant recipients (TXKR) has an increased mortality risk by CV events. Early detection of CV risk is the utmost importance in the TXKR outcomes. The aim of this cross sectional study is to assess the grade of myocardial dysfunction in TXKR without previous CV events & normal left ventricular ejection fraction (LVEF).

Methods: 37 TXKR following >1 yr were included. 44.4% F, 24.5% DM, age 55.4 ± 12.12 yo, GFR-EPI 51.93 ± 23.2 ml/min/m², No previous CV events & LVEF >55%. All of them on stable treatment with ACEI/ARB, CCHB, diuretics added to immunosuppressive drugs (TAC, CSA). Echocardiography 2D Vivid 9 (GE Vigmed Ultrasound ,Horten, Norway), was performed: GLS, LAVI (ml/bsa), E/e', E/A, LVEF following recommendations of American Society of Echocardiography. Body composition analysis were performed by BIVA and serum biomarkers of inflammation, anaemia, mineral bone disease, renal function (GFR-EPI) and CV risk markers. Normal GLS (<-20%) LAVI 24 ml/m² were considered as published for general population Rev Esp Cardiologia 2014;67:651-8.

Results: Mean GLS was $-18.6 \pm 3.78\%$, LVEF $70.8 \pm 8.7\%$, LAVI 30.16 ± 20.4 ml. GFR correlated negatively with GLS ($r = -0.338$, $P < 0.016$) and LAVI ($r = 0.372$, $p = 0.14$). GLS progressed positive as GFR decline (P adjusted 0.025). E/e' 13.06 ± 6.48 ; E/A 0.93 ± 0.28 . Multivariate analysis was significant the relationship between GLS with ACR ($\beta = -0.151$, $p = 0.43$) e P excretion index ($\beta = -0.377$; $p = 0.14$). LAVI correlated with age ($\beta = 0.467$ $p = 0.004$), net acid load ($\beta = -0.345$; $p = 0.23$) and AGEs ($\beta = 0.314$; $p = 0.35$). No other correlations were met.

Conclusions: 66% TXKR show GLS > -20% and 41.6 % LAVI > 24 ml/m². GLS & LAVI echocardiography derived are two valuable measures to assess early subclinical myocardial damage in TXKD. GLS appears more sensitive predictor than LVEF. Studies on TXKD pts are required.

Seronegative Invasive Gastro-Intestinal Cytomegalovirus Disease in Renal Allograft Recipients – A Diagnostic Dilemma! Tissue PCR the Saviour? Anupama Kaul, Dharmendra Bhadauria, Narayan Prasad, Amit Gupta, Raj K. Sharma. *Nephrology, Sanjay Gandhi Post Graduate Inst of Medical Sciences, Lucknow, UP, India.*

Background: CMV as opportunistic infection affecting the gastrointestinal tract is the most common cause for tissue invasive CMV disease occurring in 10-30% of organ transplant recipients. Gastrointestinal CMV disease can be diagnosed in presence of clinical suspicion along with histopathological findings (CMV inclusions) and presence of mucosal lesion(s) on endoscopic examination with corroborative evidences via molecular technique.

Methods: Few cases of CMV infection affecting the gastrointestinal tract show no evidences of dissemination despite use of highly sensitive molecular techniques.

Results: We encountered 6 cases where in despite strong clinical suspicion of Gastrointestinal CMV disease there were seronegative and endoscopic negative evidences for CMV, blind tissue biopsy yielded positive results for CMV disease with excellent improvement with antiviral therapy.

Conclusions: Blind biopsy specimen for tissue PCR could serve as saviour in an immunocompromised individual who has a strong clinical symptomatology for GI-CMV disease in absence of viremia, normal endoscopy and histopathology, so that the early therapeutic interventions could help in excellent patient and graft survival.

PUB677

Allograft Outcome After Desensitization with IVIg: A Single Center Experience Nitender Goyal, Phanicharan Sistla, Anshul Bhalla, Wendy McCallum, Richard Rohrer, Ronald D. Perrone. *Tufts.*

Background: The presence of antibodies to donor human leukocyte antigens (HLA) is a significant barrier to transplantation. High dose intravenous Ig (IVIg) is widely used for desensitization. There is no general consensus on the best approach for desensitization, and long-term data on efficacy of IVIg are unknown.

Methods: We reviewed kidney transplants done from Jan, 2010 to Dec, 2014 at Tufts. Sensitization was defined as PRA >20% and/or presence of donor specific antibody (DSA). Patients who were desensitized with IVIg were identified as cases; those without desensitization served as controls. No attempt was made to desensitize patients awaiting deceased donor kidneys. Baseline characteristics and follow up data were collected at months 3, 6, 12 and 24. A sensitivity analysis was done for patients who received a living donor kidney.

Results: There were 19 patients in the desensitized group and 37 patients in the control group. Mean age at transplant in two groups was 47 ± 12 and 49 ± 12 respectively. In the desensitized group, there were more patients with prior transplant (37% vs 22%), receipt of living donor (95% vs 54%) and positive DSA (89% vs 22%). One patient developed severe side effects from IVIg, requiring discontinuation. Leukopenia and BK viremia were

seen more in non-desensitized patients at 3 months, but significance was not sustained after 3 months (Table). The leukopenia effect was not significant when adjusted for steroid. There was no difference in eGFR in either group, however mean eGFR was higher in those desensitized. Incidence of rejection was very low in both groups (5% vs 8%). When living donor recipients from both groups were compared, the eGFR and leukopenia effect was similar in both groups, and there was no significant difference in BK Viremia.

	No desensitization	Desensitization	p-value
Leukopenia			
3 month	18(49%)	4(21%)	0.04
12 month	5(18%)	5(36%)	0.22
Mean eGFR(sd)			
3 month	61.2(19.5)	68.7(24.8)	0.26
12 month	63.7(20.2)	72.2(25.1)	0.29
BK Viremia			
3 month	7(19%)	0	0.04
12 month	3(12.5%)	1(8%)	0.65

Conclusions: Desensitization with IVIg appears to be safe and effective. The lower incidence of leukopenia in desensitized group can be explained by greater use of steroids.

PUB678

Results of Chinese Renal Transplant Recipients with Post-Transplantation Malignancies Lihui Qu, Hong Jiang, Jianghua Chen. *The Kidney Disease Center, The First Affiliated Hospital, Medical College, Zhejiang Univ, Hangzhou, Zhejiang, China.*

Background: Malignancies are a severe complication of immunosuppressive therapy among renal transplant recipients, representing an important cause of long-term morbidity and mortality.

Methods: A retrospective study of 2700 recipients who underwent renal transplantation between July 1977 and July 2013 was carried out. 51 patients developed the following malignancies at a mean of 55.2 months (range = 1-207) after kidney transplantation. According to the regimen of immunosuppressive agents, all the recipients occurred malignancies were divided into azathioprine group (Aza group, n=21) and mycophenolate mofetil group (MMF group, n=30). The recipient age, gender, interval from renal transplantation to tumor development, long term survival of patient and graft and the ratio of converting to rapamycin of patients were made a comparison in detail between two groups.

Results: 29 patients survived without a recurrence including 28 with graft function (Survival group, n=29), and 22 patients died of malignancies including 21 with graft function (Death group, n=22). In the survival group, only one patient lost the graft after 26 months after immunosuppressant adjustment due to chronic rejection. Renal graft function remained stable in all other patients from diagnosis throughout follow-up. Moreover, 10 patients in the survival group were switched from calcineurin inhibitor-based immunosuppression to rapamycin after the diagnoses of malignancy, otherwise no patient in death group switched to rapamycin. At a mean follow-up of 34.0 months (range = 4-74), all the 10 patients are cancer-free and survived with functional graft. The incidence of death was similar in the Aza group and MMF group.

Conclusions: Our results demonstrate that the incidence of malignancy in renal allograft recipients is much higher than normal population, closely related to the long term use of immunosuppressant. Treating cancer thoroughly and maintaining the function of the transplanted kidney can decrease the risk of death with functional graft. Rapamycin-based immunosuppression blocks the recurrence of nonmetastatic tumors.

PUB679

Basiliximab Induction Therapy, Graft and Patient Survival Sergio Santiago Pedroza-Orozco, Paloma Arleth Zavalza-Camberos, Benjamin Gomez-Navarro. *Nephrology and Transplantation, Inst Mexicano del Seguro Social, CMNO, Guadalajara, Jalisco, Mexico.*

Background: Basiliximab is widely used in clinical practice for induction therapy of renal transplant recipients, expecting to reduce the incidence of acute rejection and improved graft function without increasing adverse events. We evaluate the impact of induction therapy using Basiliximab on relevant clinical outcomes: graft and patient survival, incidence of acute rejection (AR) and incidence of infectious or malignancy complications.

Methods: This retrospective study included all renal allograft recipients who were transplanted between January 2010 and April 2014 and who received Basiliximab as induction therapy. We collected the baseline characteristic of recipients, type of donor, donor's age, HLA matches and immunosuppression at the time of transplantation. The clinical outcomes were evaluated at the first year of transplantation and include: AR incidence, infectious or malignancy complications, serum creatinine and estimated glomerular filtration rate (eGFR) using the 4-variable MDRD formula, as well as graft and recipient survivals.

Results: The demographic characteristics of recipients and donors are in Table 1. Among 662 renal transplant recipients including in this study, only 10.6% (n=70) experienced AR during the first year follow up. The incidence of infectious complications

in the first year after transplantation was 32.3%, mostly urinary tract infection (82%). No episode of malignancy was reported. Graft and patient survival rates were 96.9% and 98.5% respectively.

Recipients mean age (year ± DE): 26 ± 10
HLA matching number: 4 IQR 1
Type of donor: Living related 89% Living unrelated 7% Deceased 4%
Donor's mean age (year ± DE): 38 ± 11
eGFR year 1 (mL/min/1.73m2): 82 ± 26 sCr year 1 (mg/dl): 1.2 ± 0.4

Conclusions: Our findings support previous studies, with similar incidence of AR episodes during the first year posttransplant, accompanied by a similar incidence of infectious and malignant complications, and similar patient and graft survivals at 1 year follow up. We can conclude that basiliximab is associated with excellent graft and patient survival and low rates of AR episodes.

PUB680

Death within the First Year After Kidney Transplantation Paloma Arleth Zavalza-Camberos, Sergio Santiago Pedroza-Orozco, Benjamin Gomez-Navarro. *Nephrology and Transplantation, Inst Mexicano del Seguro Social, CMNO, Guadalajara, Jalisco, Mexico.*

Background: A successful kidney transplant improves the quality of life and reduces the risk of death in most patients when compared with staying on dialysis, however, the survival of transplant patients is lower than general population patients of the same age. This study was performed to evaluate mortality and characteristics of the dead patients.

Methods: It was a retrospective observational study that included all kidney transplant patients between January 1, 2010 to April 30, 2014, at HE-CMNO, IMSS, Guadalajara, Jalisco, Mexico. The follow-up time was one year. Mortality was calculated, the causes of death and characteristics of deceased patients were identified.

Results: During this time 1,047 transplants were performed. 30 deaths (2.86%) were recorded during the first year after transplantation. Regarding the type of donor: 12/102 (11.76%) patients with brain death donor died, and 18/945 (1.9%) patients with living donor died. The causes of death were 20 (66.66%) infections, 6 (20%) cardiovascular events, 2 (6.66%) related to graft rejection event and 2 (6.66%) unknown. The average time of transplantation to death was 2 months 27.4 days with a SD of ± 2 months 29.1 days; 70% of deaths occurred in the first 3 months after transplantation. The average time in dialysis was 5 years, with a SD ± 3 years 4.4 months; 83.3% of patients had more than two years on dialysis. Most patients who died had thymoglobulin induction, but patients were older, had more comorbidities, more time on dialysis, increased immunological risk and they had a brain death donor. Finally, 76.7% of patients who died had functional graft.

Conclusions: In our hospital, 1 year mortality postkidney transplantation is low, but there are many individual patient factors that contribute to the risk of mortality increases significantly in them and there we could intervene.

PUB681

Granzyme B Level and Acute Kidney Allograft Rejection: Impact on One Year Survival in Mexican Population Perla Edith Simancas Ruiz,¹ Caridad Aurea Leal,² Benjamin Gomez-Navarro.¹ *¹Nephrology and Transplant, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico; ²Surgical Research, Inst Mexicano del Seguro Social, Guadalajara, Jalisco, Mexico.*

Background: Exposure to insufficient levels or discontinuation of immunosuppressants often increases the risk of rejection. Creatinine is the most useful test to monitor graft function. However, it is a poor predictor of rejection and often raises only after significant damage has occurred to the graft, so the identification of early biomarkers is mandatory. Granzyme B has been tested as a marker of acute rejection, with high specificity and sensitivity in different types of sample and has also enabled the identification of subclinical

rejection. The elevation of both the mRNA and protein has been associated with a worse prognosis of allograft. **OBJECTIVE:** Explore the association between serum levels of Granzyme B and acute rejection after one year post-transplant.

Methods: Kidney recipients transplanted between January 2008 and March 2009. Donors (n=38) and healthy subjects (n=6) were also included. The relation of granzyme B levels determined by ELISA with graft function and rejection was studied.

Results:

Receptor age (n=94)	26 ± 10 yr
Induction therapy:	
Basiliximab	46%
Daclizumab	39%
Thymoglobulin	2%
CMV	
High	21%
Moderate	72%
Low	7%
One year creatinine	1.66 mg/dL
Rejection:	46% :
Borderline	31%
Banff 1A	56%
Banff ≥1B	14%
Chronic nephropathy	46%

Granzyme level in patients (n = 43) was 12.5 pg/ml while the reference group (n = 6) was 1.5 pg/ml (p <0.001). Comparison between patients with rejection (n = 14) and non-rejection (n = 20) was not statistically significant, nor the development of interstitial fibrosis year. The correlation between creatinine, GFT and granzyme level showed a trend to significance (n = 66, r = 0.30, p = 0.06).

Conclusions: The level of granzyme B was not associated with one year post-transplant rejection. However immune system activation is suggested by the higher level of granzyme in patients vs control group. Continuous analysis of patients.

PUB682

Epidemiological Analysis of Post Transplant Glomerulonephritis Pratik Das, Santosh Kumar, Rohit Rungta. *Nephrology and Transplantation, Rabindranath Tagore International Inst of Cardiac Sciences, Kolkata, West Bengal, India.*

Background: Post-transplant glomerulonephritis is an important cause of graft dysfunction and consequent graft loss. Aim of the study is to identify the incidence and outcome of glomerulonephritis in post-transplant patients.

Methods: We retrospectively evaluated all the patients who underwent renal allograft biopsy between January 2010 to January 2014, for graft dysfunction, proteinuria or active urinary sediments. All protocol biopsies were excluded from the study. Graft biopsies were evaluated by light microscopy and indirect immunofluorescence study. Out of 285 graft biopsies 242 biopsies were taken into study. Biopsies showing evidences of glomerulonephritis were further evaluated for incidence of individual types of glomerulonephritis and their outcome at the end of one year post diagnosis.

Results: Based on biopsy findings among 242 renal allograft biopsies taken in study 42(17.35%) had post-transplant glomerulonephritis. Further the incidence of individual glomerulonephritis were 14(33.3%) for focal segmental glomerulosclerosis, 13(31%) for IgA nephropathy, 8(19%) for membranoproliferative glomerulonephritis, 4(9.6%) for pauci-immune crescentic GN, 2(4.8%) for anti-glomerular basement membrane disease and 1(2.3%) for membranous nephropathy. On follow up for one year 30(71.4%) patients lost their graft and became dialysis dependent irrespective of treatment. When compared to this outcome with other causes of graft dysfunction (rejection or infection) , results are inferior in terms of graft and patient loss.

Conclusions: We conclude that post-transplant glomerulonephritis is strongly associated with poor kidney allograft survival. Therefore, optimal management of recurrent or *de novo* glomerulonephritis should be the critical focus of post-transplant care.

PUB683

Impact of Hemoglobin Concentration on Mortality After Renal Transplantation Vitoria C. Vilela,¹ Marcos A. Meniconi,¹ J. Medina-Pestana,¹ Miguel Cendoroglo Neto,^{1,2} Miguel A Goes.^{1,2} *¹Nephrology Div, Federal Univ of Sao Paulo, Sao Paulo, Brazil; ²Nephrology Div, Hospital Israelita Albert Einstein, Sao Paulo, Brazil.*

Background: Kidney transplant recipients have chronic anemia, irrespective of the time from transplantation. Objective: To assess the impact of hemoglobin concentration on mortality after renal transplantation.

Methods: A total of 233 patients who underwent renal transplantation at one center (Hospital do Rim) were prospectively analyzed. Follow-up time was 6 years, from January 2008 through December 2014. Data on demographics, ESRD etiology, pre-transplantation dialysis, transplant characteristics, and immunosuppression regimen. Two-sample t test were used to compare differences between two groups (mortality versus non-mortality groups) and χ^2 to analyze categorical variables. Binary logistic regression was used to determine the impact of factors on outcome-mortality.

Results: The main causes of ESRD were diabetes (35%) and hypertension (20%). Transplants from living donors occurred in 59%. During the entire follow-up period, there were 24 (10%) deaths within 3+1 yr after renal transplantation. 7 (29%) from cardiovascular

disease and 17 (71%) died from infection. We observed that mortality group were older (p<0.001) and longer time on dialysis (4+2.5, 2.5+2.0 yr; p=0.006). Hemoglobin (Hb) concentration was lower in mortality (10.7+2.3) than non-mortality (12.0+2.42; p=0.01) group. Patients who used mycophenolate had lower mortality (p = 0.04). There is no correlation between Age and Hb (r=-0.02; p=0.8). Age (p = 0.01) and Hb concentration (p =0.02) were independent predictors of mortality.

Conclusions: This study shows that a lower Hb concentration is an independent predictor of mortality in renal transplant patients.

PUB684

Prediction of Recipients Survival in Deceased Donor Kidney Transplant Using Korean Network for Organ Sharing Database Kyung Don Yoo,¹ Junhyug Noh,² Hajeong Lee,¹ Dong Ki Kim,¹ Chun Soo Lim,¹ Young hoon Kim,³ Yon Su Kim,¹ Gunhee Kim,² Jung Pyo Lee.¹ *¹Seoul National Univ College of Medicine; ²Seoul National Univ College of Engineering; ³Univ of Ulsan.*

Background: The Korean Network for Organ Sharing (KONOS) was founded in 2000 for organ allocation in Korea. It has been allows medical doctors and researchers to fully access the national population-based raw data about KT recipients. We propose a novel prediction approach of recipient survival based on machine learning techniques using KONOS data.

Methods: Our dataset is collected from 2000 to 2014 by the KONOS. We design a novel prediction model that uses all of the follow-up recipients' data including censored ones, on which estimated death risks are weighted accordingly. We compare this approach with the baseline model that uses only uncensored data by the CART (Classification And Regression Trees) modeling.

Results: We analyze 5,430 recipients' records with more than 31 attributes, among which we choose 15 independent attributes to learn our models. The proposed weighted algorithm leads a better performance when predicting survival rates of transplant recipients within 6 years, but fails to show any significant difference from the baseline for those more than 7 years after transplantation. Using the decision-tree models, we find that the inotropic agent usage of donor management is the most important predictor, which estimates in 51.3% of 10-year mortality. In the age ≥ 51.5 group, non-diabetes recipients, waiting period < 4years, and donor age < 23.5 years show significant associations with better 10YRS. The results are consistent with our hypothesis that poor donor status, recipients' longer waiting time and advanced age are associated with poor prognosis.

Year after transplantation	1	3	5	7	9
Baseline model AUC	0.644	0.665	0.759	0.832	0.862
Weighted Model AUC	0.653	0.678	0.777	0.822	0.794

Conclusions: In this study, we show that the proposed machine learning based models with weights of estimated-death risks can present more accurate and flexible than baseline models for predicting in long-term survival rates of kidney transplant recipients.

PUB685

Perforin Expression in Renal Allograft Biopsies Michele T. Rooney,¹ Ping L. Zhang,² Dilip Samarapungavan,³ Randolph Alexander Hennigar.⁴ *¹Incyte Diagnostics, Spokane, WA; ²Anatomic Pathology, William Beaumont Hospitals, Royal Oak, MI; ³Nephrology, William Beaumont Hospitals, Royal Oak, MI; ⁴Nephropathology Associates, Little Rock, AR.*

Background: Perforin is a cytotoxic protein in effector lymphocytes that facilitates targeted cell killing and it has an established role in allograft rejection. A diagnostic value has not been delineated. We examined perforin expression in renal transplant biopsies by immunohistochemistry (IHC) and found that positive lymphocytes are confined largely to the microvasculature in cases of active cellular rejection (ACR). The goal of this study is to investigate whether perforin IHC is a useful metric in identifying and classifying acute rejection in renal transplant biopsies.

Methods: Renal transplant biopsies accessioned over a one-year period were selected to include cases showing no acute rejection, acute tubular injury, BK nephritis, ACR types 1 and 2, and C4d+ antibody-mediated rejection (AMR), according to the 2013 revised Banff Classification. IHC using a mouse monoclonal anti-perforin antibody was performed on each case. Perforin positive cells/10 high power (400X) fields (hpf) were counted from slides identified by number only.

Results: Most rejection-negative cases had < 10 perforin-positive cells/10 hpf. Biopsies showing type 1A ACR, excluding one outlier, did not exhibit a significant increase in perforin-positive cells relative to rejection-negative cases. In contrast, cases of type 1B and 2 ACR, and C4d+ AMR displayed significantly increased perforin-positive cells (p = 0.0001) with most showing > 40/ 10 hpf. Cases of AMR contained the highest number of perforin-positive cells (p = .0352). Cases of BK nephritis varied widely from < 10 to > 50/ 10 hpf. 2 of 3 cases with > 50 had a recent history of ACR developing BK infection upon increasing immunosuppression, raising the possibility of coexisting BK and rejection.

Conclusions: Further study is needed, but our data suggests that increased numbers of perforin-positive lymphocytes correlate with more aggressive forms of rejection, and that perforin IHC may be a useful ancillary test for acute allograft rejection of type 1B or higher.

PUB686

Is It Safe to Transplant Sensitized Patients? Analysis of 1,002 Consecutive Kidney Transplants Anna Rita Aguirre, Patricia Soares Souza, Fabiana Agena, Daisa R.S. David, Flavio Jota Paula, Elias David-Neto, Maria Cristina R. Castro. *Renal Transplant Service, Hospital das Clinicas - Univ of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Background: From 2009-13, 24% of kidney recipients in our center had antiHLA antibodies(aHLA abs). Obj: To compare the risks of rejection, patient and graft survival when transplants(Tx) were performed with or without aHLA abs and with or without DSAs. To compare mortality between patients transplanted with aHLA abs to mortality in the waiting list.

Methods: Retrospective study, which included all isolated kidney Tx in patients older than 18yo, performed between jan09 and dec13(N1002). We analysed the incidence of TCMR and ABMR in the 1st year after Tx. Median follow-up time was 32mo. Graft and patient survival were evaluated by Kaplan Meyer estimates.

Results: In 741 Tx(74%), no aHLA abs were detected(ARP=0) and 261(26%) had PRA>0. Among Tx with PRA=0, 658(89%) did not have rejection in the 1st year, 77(10,4%) had TCMR and 6(0,81%) had ABMR. Among Tx with PRA>0 without DSAs(149), 129(86,6%) did not have rejection, 16(11%) had TCMR and 7(4,7%) had ABMR. In Tx with PRA>0% with DSA(91), 58(62,4%) did not have rejection, 7(7,5%) had TCMR and 31(33,4%) had ABMR. ABMR was more frequent when there was a DSA(p<0,0001). Graft survival did not differ according to ARP or DSA in groups with no rejection, TCMR and ABMR. There were more graft losses in the whole sample when a DSA was detected(p<0,0001) or when RAMA occurred, in comparison to no rejection(p<0,0001) and TCMR(p 0,0143) . Regarding patient survival, there was no influence of aHLA abs and DSAs, nor influence of TCMR or ABMR. In recipients with aHLA abs, mortality was 11% in 32mo, or 4,12% per year, smaller than in the waiting list in our state, which was 5,61% in the same period.

Conclusions: There was no difference in patient survival after 32 mo between patients with or without aHLA abs or DSAs, or even between patients with or without ABMR. However, there were more graft losses in recipients with aHLA abs and with ABMR. Mortality after Tx among sensitized patients hasn't been larger than in the waiting list. We conclude that transplanting the sensitized patient does not increase mortality risk.

PUB687

Response of Anti Blood Group Antibodies to Desensitization Procedures and Kidney Transplantation Bharat V. Shah, Zaheer Amin Virani, Prashant J. Rajput. *Inst of Renal Sciences, Global Hospitals, Mumbai, Maharashtra, India.*

Background: ABO-incompatible (ABOi) kidney transplantation (KT) is option for overcoming the shortage of organ donors. Before performing ABOi transplant, it is important to reduce anti-blood group antibody titers (ABGAT) by desensitization. The aim of our study was to determine: 1) Baseline ABGAT in patients undergoing ABOi KT, 2) Response of ABGAT to desensitization and 3) Behavior of ABGAT after KT.

Methods: Nineteen (13 male and 6 female) ABO-I patients (6-O, 8-A and 5-B blood groups) studied. The IgG and IgM ABGAT were determined using column agglutination technique (CAT). Desensitization was attempted if baseline IgG ABGAT > 1:32. For desensitization, besides rituximab, Plamapheresis (PP) and/or Glycosorb was used. Desensitization considered successful if IgG ABGAT dropped to < 1:32. ABGAT monitored daily or alternate days for 1 week after transplant, twice a week in the 2nd week and weekly for next 2 weeks.

Results: The baseline IgG antibody titres ranged from 1:4 to > 1:512 (median 1:64) while IgM antibody titres ranged from 1:2 to > 1:512, (median 1:32). In one case with baseline titre <1:4 no desensitization was done. In 15 cases, PP alone was attempted. In 3 of these cases (with baseline titre > 1:512), the titres could not be reduced to < 1:32 and transplant was not done. Based on this experience, we used Glycosorb with or without PP in next 3 cases with titres > 1:512. All of these 3 cases could be desensitized. Of the 16 patients who were transplanted, the titres remained < 1: 64 (median 1:8) after transplant in 15. None of them required PP or Glycosorb treatment after transplant. In one patient, IgG ABGAT rose to > 1:128 in the first week after KT. Biopsy was suggestive of acute antibody mediated rejection and was treated with PP, Rituximab and Bortezomib.

Conclusions: Majority of our patients have low baseline ABGAT. In cases with low ABGAT, Rituximab (2 doses of 200 mg weekly) and 2 to 3 sessions of PP bring down titres to < 1:32. For baseline titres > 1:512, use of Glycosorb may be required. After KT titres remain < 1:64 in most and this is not associated with any graft dysfunction. One may consider an allograft biopsy if IgG ABGAT is > 1:128 in the first 2 weeks.

PUB688

Temporal Characteristics of End Stage Renal Disease due to Tuberous Sclerosis in United States, 2001- 2010 Donna J. Claes,¹ Sarah J. Kizilbash,¹ Hassan N. Ibrahim,² Robert N. Foley,² Scott Reule.² ¹*Pediatrics, Nephrology, Univ of Minnesota, Minneapolis, MN;* ²*Internal Medicine, Nephrology, Univ of Minnesota, Minneapolis, MN.*

Background: Tuberous sclerosis (TS) is an autosomal dominant, multisystem disorder characterized by hamartomas in various organs with renal involvement occurring in approximately 50 to 80% of patients. Although renal involvement may result in end-stage renal disease (ESRD), studies examining the characteristic of ESRD in patients with TS are limited.

Methods: Census data was combined with data from the USRDS for all patients diagnosed with ESRD from 2001-2010 (n=1,072,161). A total of 367 patients with ESRD

due to TS were identified. Incidence rates and standardized incidence ratios (SIR) were computed using Poisson distribution and standardized using 2001-2002 as reference. Hazards ratios adjusting for age, sex, race and ethnicity (AHR) were calculated for outcomes.

Results: In 2001-2002, the overall incidence rate of ESRD due to TS was 1 per 10 million person years (PMPY) and the SIR remained largely unchanged over the observation period. Those with ESRD due to TS were more likely to be < 40 years (23.2% vs. 9.2%), white ethnicity (81.5% vs. 65.5%), and lack diabetes (81.2% vs. 48.1%). Compared to those with ESRD due to other causes, odds ratios adjusted for age, sex, race and ethnicity (AOR) were highest for females (1.83) and those with eGFR > 15ml/min (1.31). Factors associated lower AOR included age 40-64 years (0.29), age ≥ 65 years (0.25), and black race (0.33). Over the study period, 53.7% of TS patients died, 27.3% were listed and 10.6% were transplanted. The AHR for outcomes demonstrated those < 40 years of age were more likely to be listed for renal transplant, receive renal transplant and survive.

Conclusions: The incidence of ESRD due to TS remained largely unchanged from 2001 through 2010. Our results indicated gender and racial differences in the odds of ESRD due to TS.

PUB689

The Impact of Hepatitis C Virus Infection on the Clinical Course, Short-Term and Long-Term Outcome in Renal Transplant Recipients – A Retrospective Study Pratik Das, Rohit Rungta, Santosh Kumar. *Nephrology and Transplantation, Rabindranath Tagore International Inst of Cardiac Sciences, Kolkata, West Bengal, India.*

Background: Hepatitis C infection is common in patients of end stage renal disease with increased morbidity and mortality post-transplant. The aim of the study was to find out the impact of HCV infection on graft and patient outcome and compare it with the non HCV infected post-transplant cohort.

Methods: We retrospectively analysed patient and graft survival of HCV infected (after virological remission) post renal transplant patients from 2008 to 2014 with a median follow up of 24 months and compared them with our HCV negative statistically matched cohort.

Results: Outcome analysis was done at 6, 12, 18 and 24 months in terms of liver dysfunction, acute rejections, infections, hospitalization and death. Results were further tabulated as shown.

VARIABLES	HCV positive patients	hcv negative patients	P value
1.Patients(n)	51	1381	
2.Induction with ATG	26(50%)	700(50.68%)	NS
3.Tacrolimus	34(66.67%)	1196(86.9%)	<0.05
4.Cyclosporin	17(33.3%)	185(13.1%)	<0.05
5.Infection	05(9.8%)	117(8.5%)	NS
6.Abnormal LFT	08(15.6%)	NA	-
7.1 year patient survival	96.1%	97%	NS
8.2 year patient survival	92%	93.2%	NS
9.Hospitalization	24 episodes	621 episodes	NS

Results were found not to be statistically different from non HCV infected renal allograft recipients.

Conclusions: HCV infected end stage renal disease patients may undergo renal transplantation safely after virological remission and outcome is not different from other renal transplant recipients.

PUB690

Patient and Graft Survival in Pediatric Kidney Transplantation: A Single-Center Experience According to Transplant Era Marta Monteverde,¹ Juan Carlos Lopez,¹ Gerardo Nyman,¹ Liliana Briones.¹ ¹*Nephrology Unit, Hospital JP Garrahan, Buenos Aires, CABA, Argentina;* ²*Urology Unit, Hospital JP Garrahan, Buenos Aires, CABA, Argentina.*

Background: Improvements in the management of kidney transplantation has improved in the last 20 yeras. However the long term results in terms of graft survival and morbidity still require more research.

Methods: We evaluated 744 pediatric renal transplants (RTX), 551 with deceased donor (DD) and 222 with living-related donor (LRD), between 1988- 2015. We divided this time in 2 periods: 1988-2000 and 2001-2015. Patient and graft survival were calculated for each period for LD and DD recipient. We analyzed causes of mortality, causes of graft failure and risk factors for graft loss. Mean age at RTX was 11.6 y (r: 3.7-19.5). Median time of follow-up was 54.5 months (IQR: 22.4-90.1) months.

Results: Patient and graft survival for DD have significantly increased in the recent era (p=0.0002; p=0.0013 resp).Chronic rejection was the first cause of graft loss in both eras (61.9% vs 61.11%); Vascular thrombosis decreased (14.9% vs 5.5%; p= <0.001), and also Death with a Functioning Graft (15.8% vs 8.3%; p=<0.001). Acute rejection during the first 30 days post RTX + relapse of the original disease increased (0% vs 9.7%). First cause of death in both eras was bacterial infection (77% vs 66%). No death due to PTLD were seen in 2001-2015. Independent Risk factors for graft loss for DD recipients were: FSGS

as cause of ESRD (HR: 3.1; CI 95%: 2-4.8), DGF (HR: 2.8; CI 95%: 2-4) and Receiving no induction therapy (HR: 2.1; CI 95% 1.3-3.5). For LRD recipients: DGF (HR: 5.2; CI: 2.9-9.3) and Age at RTX > 12y (HR: 2.2; CI95%: 1.2-3.9).

Conclusions: Patient and graft survival has significantly improved for DD in the recent era. Chronic rejection remains a the major cause of graft failure. No death from malignancy were observed in the recent era.

Graft Survival	1y (% SE)	3y (%SE)	5y (%SE)	7y (%SE)	10y (%SE)
LD(1988-2000)	97 (0.001)	90.5 (0.02)	85 (0.03)	78.2 (0.03)	65.3 (0.04)
LD(2001-2015)	96 (0.02)	90 (0.03)	87 (0.03)	80.6 (0.06)	76.1 (0.07)

DD(2001- 2015)	94.7 (0.01)	86.8 (0.02)	82.7 (0.02)	74.5 (0.03)	58.6 (0.07)

PUB691

Impact of Rituximab Induction on Short Term Outcome of Kidney Transplant Recipients Bharat V. Shah, Prashant J. Rajput, Zaheer Amin Virani. *Inst of Renal Sciences, Global Hospitals, Mumbai, Maharashtra, India.*

Background: Acute graft rejection remains a major problem in kidney transplant (KT) recipients. Induction with Thymoglobulin or Basiliximab is a KDIGO recommendation to minimize the risk of acute rejection. However, these induction agents do not eliminate the risk of antibody mediated rejection. Recent studies of ABO incompatible (ABOi) transplant using Rituximab, in addition to standard induction and maintenance immunosuppression (IS) have shown better outcome than ABO compatible (Kohei N, Tanabe K Am J Transplantation 2012; 12: 469-476) transplants. Therefore our aim was to study efficacy and safety of Rituximab induction in addition to single dose Thymoglobulin induction in living donor (LD) KT patients.

Methods: The study included 53 adult LD KT recipients transplanted between 3/1/14 and 2/28/15 and followed for at least 3 months after KT. Of these, 39 were (ABOc) transplants and 14 were (ABOi) transplants. Rituximab 200 mg was given within a week before transplant. ABOi recipients received an additional 200 mg Rituximab on the day of transplant. Thymoglobulin 1 mg/kg was used only on the day of transplant. Maintenance immunosuppression included Tacrolimus, MMF and tapering doses of prednisolone in all. All patients received valgancyclovir and cotrimoxazole prophylaxis. The short term outcome of these patients (Ritux group) was compared to that of 53 historic controls (control group) who received only thymoglobulin 1 mg/kg on the day of KT.

Results: There was no difference in characteristics (age, sex, etiology of CKD, donor characteristics, HLA mismatch) of patients in the 2 groups. Six patients in the Ritux group developed acute rejection (5, cellular and 1 antibody mediated). Six patients in the control group developed acute rejection (2 cellular and 4 antibody mediated). The patient and graft survival at 3 months was 100% in Ritux group. The patient survival was 100% in control group. One graft was lost from antibody mediated rejection in control group. Infections within 3 months after KT were similar in both groups.

Conclusions: Rituximab induction is safe in KT. It reduces the risk of antibody mediated rejection without increasing infectious complications in the early period after KT.

PUB692

Epo Use in Pregnant Renopancreas Transplant Patients Amelia R. Heguilen, Alicia M. Lapidus, Liliana Susana Voto, Ricardo M. Heguilen. *Medicine, Hospital Juan A. Fernandez, Buenos Aires, Argentina.*

Background: Pancreas-kidney transplantation (Tx) improves life and reproductive function. Anaemia (AN) is common in this population. Prenatal counselling address potential fetal complications; as well as worsening anaemia, hypertension, preeclampsia, gestational diabetes, acute rejection or graft loss. The aim of this study was to evaluate the use of Erythropoietin (rHuEpo) during pregnancy in Tx recipients.

Methods: Four double Tx (cadaveric donor) recipients, underwent successful pregnancies after a complex medical history of diabetes in their childhood with retinopathy & polyneuropathy, two with hypothyroidism, and end stage renal disease. They were all switched into a pregnancy-friendly schedule with azathioprine, tacrolimus and low prednisone dose. Iron supplements (IS) and rHuEpo were prescribed because of anaemia progression. Because of hypo-responsiveness to rHuEpo, doses were increased to 8000 U/week in the 4 pt.in the third trimester.

Results: Serum creatinine (mg/dL) remained initially stable (1.28 ± 0.1); increased near delivery (36.2 wks) to 1.45 ± 0.1 and remained (1.32 ± 0.09) mg /dl postpartum. Blood pressure also increased near term without need of medication, serum uric acid rose to 6.2 ± 0.6 mg/dl and mild proteinuria (550 ± 155 mg/d) developed. They were all normoglycemic, with normal pancreatic and hepatic function throughout pregnancy and postpartum. rHuEpo and IS were stable mothers H^{1a} (24.7%) and HB (8.2 g/dl) with normal ferric parameters. and reticulocytes. Fetal heart rate was normal. One pt developed preterm premature rupture of membranes; all pt delivered vaginally healthy babies, weight: 2100 ± 320 g. (IUGR) with no evidence of congenital anomalies. There was no postpartum hypertension and they continued with stable renal and HCT parameters. Three months later serum creatinine returned to baseline and no proteinuria was detected. rHuepo need to be decreased in all pt. postpartum, newborns outcome was uneventful.

Conclusions: According to our study the administration of human recombinant erythropoietin has a beneficial effect in pregnancy without side effects. Preterm delivery, IUGR and low birth weight are common in this population probably due to other drug adverse effects.

PUB693

Acute Rejection Incidence in Deceased Kidney Transplant Recipients with Delayed Graft Function After Single Dose Thymoglobulin Igor Gouveia Pietrobom, Laila Almeida Viana, Cinthia Montenegro Teixeira, Andre Caires Alvino Lima, Mayara Ivani de paula, Geovana Basso, Tainá Veras de sandes Freitas, J. Medina-Pestana, Helio Tedesco Silva. *Hospital do Rim, Federal Univ of Sao Paulo, São Paulo, Brazil.*

Background: Thymoglobulin (rATG) induction has proven efficacy. However, it remains unclear what is the best dosing regimen.

Methods: From August 8th, 2014 immunosuppression protocol was changed at our institution to induction with single dose thymoglobulin to all deceased donor kidney transplant recipients. This retrospective study evaluated the incidence of acute rejection (AR) in deceased kidney transplant recipients with delayed donor graft function (DGF) before and after the adoption of a new induction protocol.

Results: Pre-protocol Group 1 - 96 patients transplanted between 12/31/2013 and 08/08/2014; Standard criteria deceased donors (SCD) (without induction, tacrolimus 0.1mg/kg/dose, prednisone and azathioprine) or expanded criteria deceased donors (ECD) (induction with thymoglobulin 6mg / kg, tacrolimus 0.05 mg/Kg/dose, prednisone and mycophenolate sodium) versus Group 2 (new protocol) , 87 patients transplanted between 08/08/2014 and 03/31/2015, subdivided in the same way, receiving the same maintenance therapy and thymoglobulin induction 3mg/kg single dose. In both groups, the population was overwhelmingly male (63% vs. 55%), young (47 vs. 46 years) and low immunological risk. The incidence of AR in G1 vs. G2, SCD subgroup was 13%, vs. 4% (p = 0.09). When compared ECD recipients, the incidence of rejection was similar between G1 vs. G2 (15% vs. 14%, p = 1.0), respectively.

Conclusions: In the SCD kidney transplant recipients, the incidence of AR was numerically lower in the group that received induction with single dose rATG 3mg / kg and induction with a reduced dose of rATG was not inferior in the ECD group.

PUB694

Cardiovascular Changes After Kidney Donation Fernando H. Margulis. *Nefrología y Trasplante Renal, Hospital General de Agudos Cosme Argerich, CABA, Buenos Aires, Argentina.*

Background: The aim of our study was to investigate the changes in cardiovascular structure and endothelial function after donation in kidney donors.

Methods: Fourteen living kidney donors (both genders) without history of kidney disease, diabetes, cardiovascular events or hypertension, who participated in the donor screening protocol with subsequent donation, were included. Office blood pressure (OBP), ambulatory blood pressure monitoring (ABPM), left ventricular mass index (LVMI), arterial stiffness (AS) and endothelial function (EF) were measured before and one year after the donation. AS was assessed from the left index finger using a digital photoplethysmograph (Pulse Trace; Micro Medical), that uses a simplified analysis of the digital volume pulse wave, to assess endothelium dependent arterial vasodilation, 400 ug of salbutamol was given by inhalation. Data were expressed as mean ± SD or median and IR. Student t test and Wicoxon test were used for data with normal and nonparametric distribution respectively, p<0.05 were considered to be statistically significant.

Results: The mean age of the cohort was 47 ± 8 (range, 30 – 56) years. At one year after donation the mean BMI (27.1 ± 2.6, P<0.006), median OBP (89 (86, 92), P<0.023) and median serum creatinine (1.14 (0.99, 1.42), P<0.001) were significantly increased as compared to baseline (26.4 ± 3; 85 (76, 92) and 0.78 (0.74, 0.97), respectively). The estimated glomerular filtration rate levels by MDRD 4 formula at 1 year (57.4 ± 12ml/min/1.73 m², P<0.0001) were significantly decreased as compared to baseline (82.2 ± 10 ml/min/1.73 m²). We did not find significantly differences in mean 24hs bAPM (84 ± 8 mmHg, P=0.940), mean LVMI (96.6 ± 17 g/m², P=0.727), mean AS (7.78 ± 2.3 m/s, P=0.210) and median EF (5.1% (0.8, 13.3), P=0.374) compared to baseline (85 ± 7 mmHg; 99.8 ± 31.6 g/m²; 9.03 ± 2.3 m/s and 10% (-1.6, 34.6), respectively).

Conclusions: Our study demonstrated that after an year, reduced nephron mass because of kidney donation was not associated with changes in cardiovascular structure and endothelial function.

Funding: Government Support - Non-U.S.

A Rare Case of Chronic Lymphocytic Inflammation with Pontine Perivascular Enhancement Responsive to Steroids (CLIPPERS) After Kidney Transplantation Maria C. Bermudez, Mayurkumar Gohel, Ali Javed, Michael F. Schultz. *Nephrology, Geisinger Medical Center, Danville, PA.*

Background: Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPERS) is a recently described inflammatory condition of the central nervous system. To date 50 cases have been reported in the literature, however none have been reported following renal transplantation.

Methods: 47 year old Hispanic male, status post diseased donor kidney transplant in 2008, with history of hypertension and diabetes, presented to our clinic with several months of progressive dizziness, unsteady gait and right facial numbness that progressed to diplopia and right facial palsy. An MRI of the brain with gadolinium revealed a 1.3 cm mass with a ring-like target appearance in the right brachium pontis and dorsal pons. MR spectroscopy revealed mild elevation of choline, suggesting demyelinating disease versus lymphoma or other high-grade malignancy. Given his long term immunosuppression, malignancy or an infectious process were considered as the main diagnostic possibilities. An extensive evaluation included serial lumbar punctures for cytology and a variety of

viral, fungal and bacterial cultures. Cytologic and serologic studies were unremarkable. Flow cytometry analysis of the spinal fluid showed no evidence of lymphoma. A brain biopsy was performed revealing non-specific perivascular lymphoplasmocytic infiltrate with no evidence of lymphoma or infection. Additionally, myelin stain was positive ruling out demyelinating disease. Our patient was started on high-dose steroids with remarkable improvement of his symptoms. Diagnosis of CLIPPERS was made.

Conclusions: CLIPPERS is a rare and poorly recognized CNS inflammatory condition. To our knowledge, this is the first case reported after renal transplantation. More studies are needed to determine the pathophysiology of CLIPPERS in immunosuppressed patients and whether it could represent a pre-malignant state. Duration of treatment and follow up is yet to be determined. In this case, treatment with steroids has let to symptomatic improvement over a month and close follow-up continues.

PUB696

The Impact of Post-Transplant Hemoglobin and Creatinine Level on Renal Allograft Survival Luiz Fernando Christiani, Fernanda Paula Feres Rios Da Costa, Ana Flavia Baldoni, Alicia Imada, Kelly Rodrigues, Maria Izabel Neves de Holanda Barbosa, G  ssika Marcelo Gomes, Cl  udia Fagundes. *Nephrology, Hospital Federal de Bonsucesso, Rio de Janeiro, Brazil.*

Background: Anemia is a common finding after kidney transplantation. The roll and the prevalence of Posttransplantation anemia (PTA) in predicting renal allograft outcomes still vary between different studies. In this study, we aim to assess the prevalence of anemia at one and six months post transplant and its correlation with 1 year renal allograft survival.

Methods: Anemia was defined by an absolute level of hemoglobin less than 11 g/dL. Hemoglobin and creatinine level were assessed at one, six and twelve-month after transplantation.

Results: We included 261 consecutive patients who underwent renal transplant from January/2010 to June/2012. Mean recipient age was 42±10 years and 56% were male. Prevalence of anemia was 42% at 1 month, 16% at 6 months and 9% at 12 months. Hemoglobin and creatinine level at first month of transplantation were 11.2±2 and 1.8±1.0 for patients with functional allograft vs. 9.4±2.1 and 4.8±3.4 for those who return to dialysis within 12 months (p<0.001 for both comparisons). Overall patient and graft survival was 8% and 10%, respectively. On multivariate analysis, creatinine and hemoglobin level were independently associated with poor graft survival at 12 months. The best cut-off selected by receiver operating characteristic curve analysis was 10.8 g/dL for Hemoglobin level, (AUROC 0.74 (0.63-0.86), p<0.001), and 2.25 mg/dL, for serum creatinine (AUROC 0.77 (0.62-0.91, p<0.001). Combining the best points of those two variable could identify patients at risk of graft loss. Patients who met both criteria (Hb < 10.8 g/dL and Creatinine > 2.25 mg/dL) had 59% graft survival at 1-year, whereas allograft survival was 98.5% for patients without any criteria (Hb > 10.8 g/dL and Creatinine < 2.25 mg/dL).

Conclusions: Prevalence of anemia was high in the first month after transplant and persisted in a substantial proportion of functioning kidney transplant recipients. Early (1-month) hemoglobin and creatinine level can predict 1 year-graft survival.

PUB697

Examining Adverse Weight Gain After Kidney Transplantation Biruh Workenesh,¹ Linda W. Moore,² William E. Mitch.¹ ¹*Medicine/Nephrology, Baylor College of Medicine, Houston, TX;* ²*Transplant Medicine, Houston Methodist Hospital, Houston, TX.*

Background: Between 15,000-17,000 patients with end-stage renal disease (ESRD) receive a kidney transplant in the United States every year. Among the most consequential complications to these patients are adverse weight gain and the development of diabetes, commonly termed New-Onset Diabetes After Transplantation (NODAT) with consequent CV mortality. However, there is no consensus about the exact nature of the weight gain that routinely occurs after kidney transplantation (i.e., relative changes in fat vs. muscle vs. fluid volume) and how this relates to insulin resistance. We wish to test the hypothesis that weight gain is primarily due to an increase in fat mass.

Methods: We are conducting a longitudinal study in ESRD patients anticipating receiving a live donor kidney transplant. We are studying subjects before kidney transplant, at 12 weeks and 1 year after they have received living donor kidney transplant to measure changes body composition and other indices. Body composition was characterized by DEXA as well as total body potassium (a gold standard measure of muscle mass).

Results: Results from 5 subjects who completed baseline assessment and 3 months post-transplant reveals there is significant gain in adipose weight gain in all cases.

Additionally, we discovered there is significant loss in skeletal muscle mass (p=0.032) measured by total body potassium.

Conclusions: We have not studied enough to conclude whether changes in energy expenditure and diet contribute to adipose weight gain and whether there is acute nitrogen (muscle) loss perioperatively. Ultimately, methods to identify patients at high risk for adverse weight gain and related metabolic disorders before transplant are greatly needed.

PUB698

Effect of Mycophenolate Mofetil Dose on BK Virus Infection in Kidney Transplant Recipients Vedran Pasara,¹ Danica Galesic Ljubanovic,² Mladen Knotek.¹ ¹*Dept of Medicine, Renal Div, Univ of Zagreb Medical School, Merkur Hospital, Zagreb, Croatia;* ²*Dept of Pathology, Univ of Zagreb Medical School, Dubrava Univ Hospital, Zagreb, Croatia.*

Background: Intensity of overall immunosuppression is a risk factor for BK virus infection (BKVI). However, the exact impact of exposure to tacrolimus and mycophenolate mofetil (MMF) to BKVI is unclear. The aim of this study was to determine if BKVI in kidney transplant (KT) recipients (KTR) is associated with drug exposure to MMF.

Methods: This prospective randomised controlled clinical trial (NCT01860183) included 36 KTR who underwent KT from May 2013 to February 2015 at Clinical Hospital Merkur. Immunosuppression consisted of basiliximab induction, with tacrolimus, MMF+steroid maintenance. KTR were randomized in two groups, with respect to MMF dose (2g or 3 g daily). Urine cytology for decoy cells was performed at prespecified time-points posttransplant. KTR were followed up to 12 months post KT. Graft biopsy was performed per protocol at 2, 6 and 12 months, or in case of graft dysfunction. Kaplan-Meier analysis with log-rank test was used to assess graft survival. A Cox regression was used to determine variables associated with graft survival.

Results: 13 (37.1%) KTR had decoy cells in urine, 4 (11.4%) KTR had biopsy-proven BK virus-associated nephropathy (BKVAN). The mean time-to-occurrence was 4.8 months for decoy cells and 4.3 months for BKVAN. Cumulative one-year overall graft survival was 93.5%. Incidence of decoy cells, BKVAN, or acute rejection was similar in the two MMF groups. Rejection was not a risk factor for decoy cell positivity or for BKVAN.

Conclusions: MMF dose may not increase risk for BKVI after kidney transplantation.

Malignancy following Renal Transplantation Lourdes de la Vara Iniesta,¹ Francisco Llamas Fuentes,² Inmaculada Lorenzo Gonzalez,² Carmen Gomez Roldan.² ¹*Virgen de la Luz Hospital, Cuenca;* ²*Univ Hospital of Albacete, Albacete.*

Background: There is retrospective experience in many reports about the association between the intensity of immunosuppression and the higher frequency of malignancy. Objective: Analyse and describe our centre's experience.

Methods: 275 transplant patients were analyzed. A record was made of the frequency, anatomic-pathological diagnostics, location, the mean interval between transplantation and diagnostics (latency time), follow-up time, use of antilymphocyte-antibodies, affectionation by cytomegalovirus, rejection and immunosuppressive therapy.

Results: Of 273 patients, 9.52%(26) were diagnosed of cancer. The majority, 93.43%(24), corresponded to De novo malignancy, 7.7%(2) were recurrences of pre-existing disease. The mean age at diagnosis was 63.19±7.24years. The latency time was 63.65months (11-114), although there is a notable but unexplained reduction over the last five year (33,50vs63,65 months). The average follow-up time was 97.54months. The most frequent malignancies were skin cancers, predominantly Basal-cell and Squamous-cell carcinomas. The incidence of other tumors was similar to the general population. The most common causes of chronic renal failure was the glomerular and interstitial disorders. The risk of neoplasm was 0.36%, 4.36% and 9.52% at one, five and ten years after the kidney transplant. No association was detected with use of antilymphocyte-antibodies, CMV infection, rejection episodes or different immunosuppressive therapy. At the time of analysis, 84.60%(22) of patients had functioning graft, 7.70%(2) had returned to dialysis and 7.70%(2) had died, both due to the cancer.

Conclusions: Our experience is similar to what is reported in the literature. The incidence of cancer is higher than expected in the general population and increases according to the duration of the immunosuppression. Skin cancers were the most frequent malignancies. Unlike other studies, there was a low incidence of lymphoproliferative disorder and Kaposi's sarcoma, and the incidence of other solid malignancies being similar to that of the general population. To reduce the development of malignancies must be one of our objectives.

PUB700

Lipidapheresis in 3 Sisters with Familial Hypercholesterolemia Christina Taylan,¹ Andrea Schlune,² Thomas Meissner,² Lutz Thorsten Weber.¹ ¹*Pediatric Nephrology, Univ Hospital of Cologne, Cologne, Germany;* ²*Dept of Pediatrics, Neonatology and Cardiology, Univ Hospital of Duesseldorf, Duesseldorf, Germany.*

Background: Familial hypercholesterolemia (FH) is the most common monogenic form of hypercholesterolemia. It carries the risk of premature coronary heart disease. As the atherosclerotic burden is dependent on the degree and duration of exposure to raised LDL-cholesterol levels, early diagnosis and effective treatment are imperative. Statins are the mainstay in the management of these patients. Lipoprotein-apheresis becomes recently more established in patients with severe dyslipidemia. Together these treatments improve the prognosis of FH. Most children fail to attain targeted lipid goals owing to persistent shortcomings in diagnosis and treatment.

Methods: Three siblings with a LDLR mutation (p.Trp577Arg) being on statins (20 mg/d Atorvastatin) and Ezetimib (10 mg/d) for 12 months with still LDL-C plasma concentrations of above 300-500 mg/dl started once weekly a double filtration plasmapheresis (DFPP) with a single plasma volume to be treated.

Results: After each LDL-apheresis LDL-C concentration of 100-150 mg/dl could be reached. (66-70% reduction). After 6 months plasma volume to treat was doubled because of a rebound within 7 days with LDL-C concentration up to 300-350 mg/dl. But though after each session LDL-C concentration decreased to 50-100 mg/dl the rebound was still evident after 7 days of therapy pause. With a treatment regime with twice plasma volume every 3-4 days the children finally attained a stable pre-treatment LDL-C concentration of 120-170 mg/dl. Another 2 months later statin therapy was stopped because of underlying mutation with assumed non receptor function. Neither the effectiveness of each apheresis nor the LDL-C concentration after 4 days showed any change.

Conclusions: In pediatric FH patients with high levels of LDL-cholesterol plasma concentration it might be necessary to treat instead of conservative medication with apheresis in high frequency and with high plasma volumes to reach a durable decrease in LDL-cholesterol plasma concentration. The use of cholesterol uptake-inhibitors should be considered.

PUB701

Thrombomodulin Up-Regulation in Preeclamptic Nephropathy Is Associated with Parietal Cell Activation Rosanne Jane Turner,¹ Maria Elisabeth Penning,¹ Malu Zandbergen,¹ Eliyahu V. Khankin,² S. Ananth Karumanchi,² Jan A. Bruijn,¹ Kitty Bloemenkamp,³ Hans J. Baelde.¹ ¹*Pathology, LUMC, Leiden, Netherlands;* ²*Howard Hughes Medical Inst and Dept of Medicine, Obstetrics and Gynecology, Beth Israel Deaconess Medical Center, Boston, MA;* ³*Obstetrics, LUMC, Leiden, Netherlands.*

Background: Preeclampsia is a pregnancy-specific syndrome characterized by angiogenic imbalance and endothelial dysfunction. This endothelial dysfunction leads to kidney damage, i.e. glomerular endotheliosis, increased podocyte turnover and proteinuria. Thrombomodulin (TM) facilitates maintenance of glomerular endothelium by inhibiting coagulation, inflammation and apoptosis. In preeclampsia, levels of soluble thrombomodulin in the circulation are increased. We hypothesize that glomerular thrombomodulin expression is increased in preeclampsia and set out to correlate thrombomodulin expression with endothelium and podocyte damage.

Methods: A nationwide, ethics committee-approved search of the Dutch Pathology Registry (PALGA) was conducted; this revealed renal autopsy material from 11 women with preeclampsia according to the ISSHP definition, from 22 normotensive pregnant controls and from 14 hypertensive non-pregnant controls. Kidneys from 13 sFLT-1 transfected mice and controls were collected. Samples were stained for TM and fibrin and markers of endothelium and podocyte damage were investigated.

Results: TM expression was increased in glomeruli from preeclampsia patients (82%) compared to pregnant, (41%, P=0.03) and hypertensive controls (21%, P=0.004). In sFLT-1 transfected mice TM expression was the same as in controls. TM expression correlated with activation of parietal epithelial cells (P=0.023), but not with endotheliosis or endothelial fibrin deposits (P>0.05).

Conclusions: TM expression in the kidney is increased in preeclampsia. This is associated with parietal cell activation and not with endothelial damage or fibrin deposits. TM apparently exerts cytoprotective and not anticoagulant effects in the kidney in preeclampsia. Glomerular damage induced by sFLT-1 did not increase TM expression in a mouse model; this indicates that the increased TM expression in humans is probably not caused by this anti-angiogenic factor alone.

PUB702

Cadmium Induces Matrix Metalloproteinase-9 Expression via NADPH Oxidase/ROS-Dependent EGFR Signals in Human Endothelial Cells Nam ho Kim. *Internal Medicine, Chonnam Natuinal Univ Hospital, Gwangju, Korea.*

Background: Cadmium, a widespread cumulative pollutant, is a known human carcinogen, associated with inflammation and tumor. Matrix metalloproteinase-9(MMP-9) plays a pivotal role in inflammatory reaction and tumor metastasis, however, the mechanisms underlying MMP-9 expression induced by cadmium remains obscure in human endothelial cells.

Methods: Here, cadmium elevated MMP-9 expression and enzyme activity, as well as MMP-9 promoter-driven luciferase activity, in a dose and time dependent manner in ECV304 human endothelial cells. Moreover, cadmium activated phosphorylation of EGFR, Akt, Erk1/2, JNK1/2, p38MAPK and promoted NF-κB and AP-1 binding.

Results: Specific inhibition and mutagenesis study shows that EGFR, Akt, Erk1/2, JNK1/2 and transcription factor NF-κB and AP-1 were related to cadmium-induced MMP-9 expression in ECV304 cells. Akt and MAPKs (Erk1/2 and JNK1/2) functioned as upstream signaling molecules in the activation of NF-κB and AP-1, respectively. Furthermore, Cadmium increased ROS production and the ROS-producing NADPH oxidase. Cadmium translocates p47phox, a key subunit of NADPH oxidase, to the cell membrane. The exogenous H₂O₂ increased MMP-9 mRNA expression. And that, inhibition of ROS by ROS scavenger (NAC) or NADPH oxidase inhibitor (DPI) attenuated EGFR, Akt, MAPK(Erk1/2, JNK1/2, p38MAPK) activation, and MMP-9 expression. Likewise, inhibition of EGFR phosphorylation prevented the activation of AKT, MAPKs(Erk1/2, p38MAPK). Finally, ECV304 cells treated with cadmium displayed markedly invasiveness, which was partially abrogated by MMP-9 neutralizing antibodies.

Conclusions: These results demonstrated that cadmium induces MMP-9 expression via NADPH oxidase/ROS-dependent EGFR/Akt/NF-κB and EGFR/MAPKs(Erk1/2, JNK1/2)/AP-1 signaling pathways and, in turn, stimulates invasiveness in human endothelial ECV304 cells. These findings provide further insight into the molecular mechanisms in the carcinogenesis effect of cadmium.

PUB703

Exosomes from Activated Kidney Fibroblast Have Ambivalent Potential Effect on Atherosclerosis Fumitoshi Nishio, Noritoshi Kato, Yoshio Funahashi, Takuji Ishimoto, Tomoki Kosugi, Naotake Tsuboi, Shoichi Maruyama, Seichi Matsuo. *Nephrology, Nagoya Univ Graduate School of Medicine, Nagoya, Aichi-Pref, Japan.*

Background: Exosomes are small (50-140nm) membrane vesicles of endosomal origin that contain host cell's proteins, mRNAs, and microRNAs (miRNAs). The body of evidence revealed that these contents were biologically active, and had roles in intracellular communication. Especially tumor-derived exosomes has been intensively exploited and proven to be associated with distant metastasis. On the other hand, it is well known that CKD patients are at risk of cardiovascular diseases, but the mechanism of this distant organ crosstalk is not fully understood. Under the hypothesis that exosomes are involved in cardio-renal syndrome (CRS), the aim of this study is to explore the role of exosomes from kidney fibroblasts, which are activated in diseased kidney, on vascular endothelial cells.

Methods: We isolated Exosomes from culture media of TGF-β stimulated rat kidney fibroblasts cell line (NRK-49f) by ultracentrifugation technique. Cultured vascular endothelial cells (RAOEC; Rat Aortic Endothelial Cells) were stimulated by these exosomes or exosomes from unstimulated fibroblast. Then we evaluated the expression of genes, which associated with atherosclerosis by qPCR.

Results: RAOEC stimulated with exosomes from TGF-β activated kidney fibroblast (RAOEC-T) showed higher expression of PIGF and lower expression of Flt-1, ABCA-1 than control (RAOEC-C). This expression pattern is compatible with atherosclerotic change. On the other hand, RAOEC-T showed reduced expression of adhesion molecules such as ICAM-1/VCAM-1 and E-selectin compare with RAOEC-C.

Conclusions: So far, CRS is supposed to be caused by uremic factor, RAS system, chronic inflammation, and so on. From this study, we showed that exosomes from activated kidney fibroblasts have ambivalent roles in atherosclerosis by modulating the expression of adhesion molecules, metabolic factor, and VEGF system on endothelial cells. Further studies are needed to elucidate the contribution level of exosomes on CRS.

PUB704

Prevalence of Metabolic Syndrome in Patients with End Stage Renal Disease: Relevance of Biomarkers Vinod K. Bansal,¹ Jennifer Saluk,² Debra Hoppensteadt,² Daneyal Syed,² Schuhaarazad Abro,² Jawed Fareed.² ¹*Nephrology, Loyola Univ Medical Center, Maywood, IL;* ²*Pathology, Loyola Univ Medical Center, Maywood, IL.*

Background: Since the metabolic syndrome (MetS) and chronic kidney disease (CKD) share many of the same risk factors and similar inflammatory pathogenesis, many studies have suggested a correlation between CKD and MetS, and shown that patients with MetS are more likely to develop CKD. The purpose is to investigate metabolic biomarker levels in ESRD patients to evaluate their relevance to ESRD and to provide insight into the pathogenic ESRD processes and the development of associated comorbidities.

Methods: Plasma samples were retrospectively collected from 89 ESRD patients prior to maintenance hemodialysis. Normal human plasma samples (female & male, 18-35 years old) were purchased from George King Biomedical Inc. (Overland Park, KS). Samples

were stored at -80°C. Biochips were purchased from RANDOX (Co. Antrim, Northern Ireland) to test C peptide, ferritin, IL-6, resistin, insulin, TNF α , IL-1 α , leptin, PAI-1. These biomarkers were tested on 82 ESRD and 17 normal samples.

Results: All biomarkers, except insulin, were significantly elevated in Patients with ESRD compared to normal (p values are 0.05 - .0001). MetS patients with ESRD, as compared to non-MetS Patients with ESRD, had significantly elevated Leptin (P=0.002), and the correlation between MetS and Leptin levels was significant (P<0.0001, r=0.43). All other biomarkers showed no significant difference between ESRD+MetS and ESRD-MetS patients. Furthermore, when leptin levels for Patients with ESRD were broken down into ESRD+MetS and ESRD-MetS, ESRD+MetS vs. normal was significant (P=0.0003), but ESRD-MetS vs. normal was not (P=0.6).

Conclusions: Elevated biomarkers suggest an ongoing inflammatory process in ESRD patients. Insulin levels were not significantly elevated in ESRD patients, possibly attributed to the high Leptin levels, which can interfere with insulin secretion and signaling. ESRD+MetS and ESRD-MetS populations are not statistically different for all other biomarkers. This suggests that biomarker elevation is due to ESRD pathogenesis, rather than due to MetS as a comorbidity.

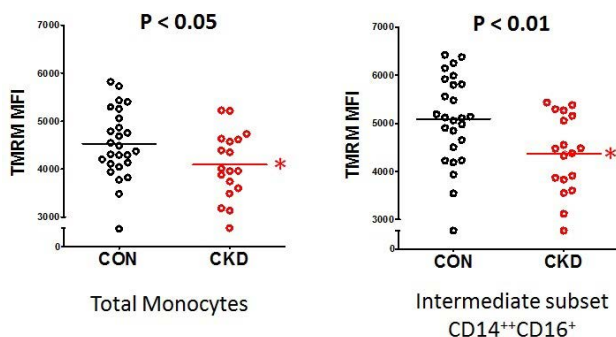

PUB705

Decreased Mitochondrial Membrane Potential in Monocyte Subsets from Patients with Chronic Kidney Disease Ying Wang,¹ Eric Joseph Lai,¹ Annie Febus,¹ Yuan Zhang,² Linda Vernocchi,¹ Anjali Ganda.¹ ¹Div of Nephrology, Dept of Medicine, Columbia Univ Medical Center, New York, NY; ²Dept of Biostatistics, Mailman School of Public Health, Columbia Univ, New York, NY.

Background: Particular monocyte subsets are associated with future cardiovascular events in patients with chronic kidney disease (CKD), and the underlying mechanisms require further investigation. Previous studies have suggested impaired mitochondrial function in patients on dialysis, while little is known about mitochondrial functionality in monocyte subsets from non-dialyzed patients with CKD. Given that mitochondrial dysfunction has been linked to atherosclerosis, we hypothesized that non-dialyzed patients with CKD would have mitochondrial dysfunction in monocyte subsets which could accelerate atherosclerosis in patients with CKD.

Methods: Monocyte subsets from 18 adult CKD patients (eGFR<30 ml/min/1.73 m²) and 26 matched controls (eGFR \geq 60 ml/min/1.73 m²) were freshly analyzed by flow cytometry. Mitochondrial membrane potential (DYm), as a measure of mitochondrial functionality, was determined by the mean fluorescence intensity (MFI) of TMRM (tetramethylrhodamine methyl ester).

Results: DYm was significantly reduced by 10% in patients with CKD vs. controls in total monocytes (P<0.05). Interestingly, the intermediate monocyte subset (CD14⁺⁺CD16⁺), which has the highest DYm among all the monocyte subsets and has been shown to predict future cardiovascular events in CKD patients, had the most pronounced reduction in DYm (14% lower, P<0.01) in patients with CKD vs. controls.

Conclusions: Patients with CKD demonstrate mitochondrial dysfunction in total monocytes and monocyte subsets. Mechanistic and prospective studies are needed to examine the relationship between monocyte mitochondrial dysfunction, atherosclerosis, and future cardiovascular events in CKD patients.

PUB706

Paricalcitol Upregulates Renal Klotho and Restores Uremia-Induced Endothelial Integrity Disruption Marc Vila cuenca,¹ Robert H.j. Beelen,¹ Marc G. Vervloet,² ¹Molecular Cell Biology & Immunology, VU Univ Medical Center, Amsterdam, Netherlands; ²Nephrology, VU Univ Medical Center, Amsterdam, Netherlands.

Background: Klotho deficiency in chronic kidney disease (CKD) is associated with the disruption of the endothelial integrity. Active vitamin D induces klotho expression. Hence, active vitamin D may limit endothelial layer disruption.

Methods: Male wistar rats were assigned into one of four groups: Control; Vitamin D deficiency, induced with Vitamin D deficient diet; Uremic, developed after ¾ nephrectomy; Uremic + Vitamin D deficiency. Animals were treated with Paricalcitol or vehicle control during 7 weeks. Serum samples were analyzed for 25D and 1,25D. Evans Blue was injected

for estimation of the endothelial thoracic aorta and lung permeability and quantified using spectrophotometry. To determine the levels of Klotho, qPCR and WesternBlot was performed in kidney tissue.

Results: Average 25D levels were 9.83 nmol/L while 1,25D levels were below the detection levels (20pmol/L) after the induction Vitamin D deficiency. mRNA and protein levels of Klotho in the Kidney were decreased in Vitamin D deficient and uremic rats and restored after Paricalcitol treatment. Aortic Evans blue leakage increased in all uremic rats regardless of vitamin D level, compared with the control group and restored after Paricalcitol treatment (p=0.03). Uremia did not induce pulmonary leakage, but paricalcitol lowered it compared to control and uremic condition (p=0.04). Figure shows uremic with/without D-deficiency together.

Conclusions: CKD induces aortic endothelial leakage, while the deficit of vitamin D on its own did not. Paricalcitol completely rescued endothelial leakage induced by CKD. In parallel, Klotho expression increased upon this treatment and may mediate the beneficial effect on the endothelium. To explain the difference between aortic and pulmonary tissue, additional studies are required.

PUB707

Altered Intra-Aortic Expression of the Renin-Angiotensin System Is Associated with Arterial Aging in Mice Hye Eun Yoon,^{1,2} Eun Nim Kim,¹ Min Young Kim,¹ Ji Hee Lim,¹ Cheol Whee Park,¹ Bum Soon Choi.¹ ¹Internal Medicine, The Catholic Univ of Korea, Seoul, Korea; ²Internal Medicine, Incheon St. Mary's Hospital, Incheon, Korea.

Background: Aging is the major risk factor of cardiovascular disease and results in progressive decline in physiological function and structural abnormalities of vasculature. The renin-angiotensin system (RAS) is the key player in cardiovascular diseases. This study evaluated whether the change in the RAS is associated with arterial aging.

Methods: Histologic changes and expressions of angiotensin, angiotensin converting enzyme 1 (ACE1), angiotensin II type 1 receptor (AT₁R), angiotensin II type 2 receptor (AT₂R), and antioxidant enzymes, superoxide dismutase 1 (SOD1) and superoxide dismutase 2 (SOD2), were measured in the thoracic aortas from 2-month-old, 12-month-old, and 24-month-old C57/BL6 mice.

Results: Twenty-four-month-old mice showed significantly increased aortic media thickness compared to 2-month-old mice (1.6-fold). The aortic expression of angiotensin was increased in 12-month-old (1.2-fold) and 24-month-old mice (1.3-fold) compared to 2-month old mice. Similarly, the expression of ACE1 was increased in 12-month-old (1.2-fold) and 24-month-old mice (3-fold) compared to 2-month-old mice. The AT₁R/AT₂R ratios were increased in 12-month-old (1.3-fold) and 24-month-old mice (1.5-fold) compared with 2-month-old mice. The expressions of SOD1 and SOD2 were decreased in 12-month-old (0.8-fold and 0.6-fold, respectively) and 24-month-old mice (0.6-fold and 0.5-fold, respectively) compared with 2-month-old mice.

Conclusions: Age-related intra-aortic activation of the RAS was associated with reduced antioxidant enzymes and hypertrophy of the aorta. These results suggest that the altered expression of the RAS contributes to the increased susceptibility to vascular injury in the elderly population.

Funding: Government Support - Non-U.S.

PUB708

Upregulation of Microparticles, Tissue Factor, Adhesion Molecules, Nitric Oxide and Adiponectin in End Stage Renal Disease Vinod K. Bansal,¹ Daneal Syed,² Debra Hoppensteadt,² Jawed Fareed.² ¹Nephrology, Loyola Univ Medical Center, Maywood, IL; ²Pathology, Loyola Univ Medical Center, Maywood, IL.

Background: End stage renal disease (ESRD) represents the final stage of chronic kidney disease characterized by kidney failure (GFR <15 mL/min/1.73 m²). To understand the pathophysiology of ESRD, we measured the circulating levels of microparticles (MP), tissue factor (TF), adhesion molecules, such as p-selectin (P-Sel), soluble ICAM (s-ICAM), nitric oxide (NO) and adiponectin (AD).

Methods: Plasma samples were collected from 119 ESRD patients undergoing maintenance hemodialysis to profile various inflammatory biomarkers. 100 normal plasma samples were collected from healthy individuals. MP levels were measured using an annexin

binding method (Hyphen Biomedical, Paris, France). NO was measured using a kit from R&D systems (Minneapolis, Minnesota) and ELISA methods for TF, P-Selectin and adiponectin were obtained from R&D systems. A chromogenic substrate method was used to measure heparin.

Results: MP levels were elevated in the ESRD group (28.1nm + 6.1nm vs. the control 8.9nm +1.3nm). Tissue factor levels were found to be increased in the ESRD group (20.4±6.1pg/ml) vs the control (11.9±2.8pg/ml). The nitric oxide level was markedly higher in the ESRD group (32±17uM) vs the controls (7±3uM). The p-selectin levels were elevated in the ESRD group (46±20ng/ml) vs the control (31±3ng/ml). The soluble ICAM levels were higher in the ESRD group (250±112ng/ml) vs the control (180±19ng/ml). Interestingly, the adiponectin levels were also increased in the ESRD group (19.2±9.3ug/ml) vs the control (11.2±4.1ug/ml). Detectable levels of heparin (.05 – 0.20 U/ml) were measured in the ESRD group.

Conclusions: These studies suggest that MP, TF, NO, p-selectin and s-ICAM levels are increased in the ESRD patient. It is of interest to note that despite that a significant number of ESRD patients were diabetic; the AD levels were increased. These results also suggest that while ESRD represents a pro-inflammatory/hypercoagulable state, the repeated administration of heparin and other drugs may contribute to the regulation of the hemostatic process and inflammatory balance.

PUB709

Coronary Artery Calcification and All-Cause Mortality in RRT Patients with Diabetes: 5 Year Survival Analysis Ramin Tolouian,¹ Sean M. Connery,² Kyari Sumayin Ngamdu,² ¹Internal Medicine, Eastern Virginia Medical School, Norfolk, VA; ²Internal Medicine, Texas Tech Univ HSC El Paso, El Paso, TX.

Background: Vascular calcification is a significant sequela of ESRD. A Coronary Artery Calcification (CAC) Agatston score ≥ 300 has been associated with adverse cardiovascular events & increased mortality. The purpose was to evaluate all-cause mortality rates in ESRD with diabetes.

Methods: 113 diabetic pts undergoing RRT had CAC scoring by sub-second gated helical CT standard Agatston scoring system, slice thickness 3mm. Patients were categorized into 3 groups according to CAC score: 0, 1-299, ≥ 300 (Low, Medium, High Risk). Survival of 3 groups was calculated using Kaplan-Meier curves for all-cause mortality for 5 year period after CAC. Unadjusted and risk-factor adjusted for age & length of time on dialysis Cox proportional hazard modeling was used to estimate time to all-cause mortality.

Results: 5 year survival was 92%, 60%, 46% for Low, Medium, High Risk CAC groups.

	Low (n=25)	Medium (n=46)	High (n=42)
Age, yrs	47 ±11	57 ±11*	61 ±9**
Months on Dialysis	40 ±35	23 ±20	40 ±35□
Mean ±SD, p<0.05 *Low vs Medium, **Medium vs High, □Medium vs High ANOVA			

There was a statistically significant difference between survival curves, Gehan-Breslow p = 0.031, but no difference between Medium & High Risk curves pairwise multiple comparison procedures Holm-Sidak method (p=0.1). Adjusting for covariates of age & length of time on dialysis at time of scan did not make a significant difference in survival curves, Age HR = 1.034 (0.99-1.07 95% CI), time on dialysis HR = 1.004 (0.99-1.01 95%).

Mortality in Medium & High groups was 40% & 50% while only 8% in low group. **Conclusions:** Any level of CAC, regardless of severity, in HD pts with diabetes has a significant impact on survival. CAC might be useful predicting mortality in this population.

PUB710

Elevated Toll Like Receptor 4 Expression and Macrophage Infiltration Is Found in High Dose Vitamin D-Induced Non-Uremic Vascular Calcification Jianheng Zhou,^{1,2} Yuan Min Wang,¹ Helen Williams,³ Anne M. Durkan,¹ Geoff yu Zhang,¹ Huiling Wu,⁴ Andrew Sawyer,¹ Stephen I. Alexander,¹ David C. Harris,² Vincent W.S. Lee.² ¹Centre for Kidney Research, Children's Hospital at Westmead, Sydney, NSW, Australia; ²Centre for Transplantation and Renal Research, Univ of Sydney at Westmead Millennium Inst, Westmead, Sydney, NSW, Australia; ³Vascular Biology Research Centre, Surgery, Univ of Sydney, Westmead Hospital, Sydney, NSW, Australia; ⁴Transplant Research Group, Royal Prince Alfred Hospital, Sydney, New South Wales, Australia.

Background: Vascular calcification is strongly associated with cardiovascular morbidity and mortality. Several studies have suggested that monocytes/macrophages are involved in arterial vascular calcification, while the involvement of the TLR4 pathway in vascular calcification has also been proposed.

Methods: Male C57BL/6 mice aged 8 weeks were injected with a high dose of vitamin D (50000IU/kg/day) subcutaneously for 3 days at 0, 24 and 48 hours. All mice were sacrificed 3 days after the final administration of vitamin D. Kidneys were assessed histologically. Whole aortas were dissected. Macrophage infiltration and TLR4 expression was assessed by immunohistochemistry and histology and vascular calcification by Von Kossa staining.

Results: High dose vitamin D treatment did not induce kidney fibrosis or injury in C57BL/6 mice within the short time frame, as assessed by GT fibrosis score and PAS tubular damage score. High dose vitamin D treated mice demonstrated significantly higher calcium deposition in the aortic arteries (17.45% of vessel area) compared to controls (1.2% p<0.05). This was accompanied by a greater level of macrophage infiltration and TLR4 expression in these arteries compared to controls.

Conclusions: Accelerated vascular calcification was induced in mice with high dose vitamin D treatment. These data also identify a potential role for macrophages and the TLR4 pathway in vascular calcification.

PUB711

Lack of Correlation of Pyrophosphate Levels with Survival and Coronary Artery Calcification in Hemodialysis Patients Ramin Tolouian,¹ Sean M. Connery,² ¹Internal Medicine, Div of Nephrology, Eastern Virginia Medical School; ²Internal Medicine, Texas Tech Univ HSC El Paso.

Background: Vascular calcification is an important predictor of cardiovascular mortality in ESRD. Decreased levels of inorganic pyrophosphate (PPi) are thought to increase vascular calcification. The purpose of this study was to evaluate the association of PPi & coronary calcification scores in maintenance HD patients and all-cause mortality over 5 years.

Methods: 98 maintenance HD patients were studied (mean ±SD): Age (yr.) 57 ±10.7, HD vintage (month) 36 ±37.6. Platelet free plasma PPi was measured by radiometric, enzymatic method as described by Tolouian. Coronary arterial calcification score (CACS) was measured by sub-second gated helical computed tomography with an Imatron C-150 XL ultra fast CT scanner using a standard protocol for vascular calcification. Patients were categorized into 3 groups according to their CAC score: 0, 1-300, and > 300.

Results:

	CACS 0 (n=17)	CACS 1-299 (n=40)	CACS ≥300 (n=41)
PPi (µM)	1.49 ±0.37	1.60 ±0.56	1.56 ±0.46
Age (yrs)	51 ±11.0	58 ±11.3	60 ±9.0*
Months on HD	32 ±27.2	25 ±21.5	47 ±49.5 ‡
* p<0.5 Low vs High, ‡Medium vs High ANOVA, Dunnett T3			

The covariate PPi had no significant effect on the hazard rate, log rank p=0.61. After adjusting for covariates of PPi, age, length of time on HD at time of measurement the log rank statistic for the survival curves is not great enough to exclude the possibility that the difference is due to random sampling variability; there is not a statistically significant difference (P = 0.614).

Conclusions: The difference in 5 year survival rate in dialysis patients based on the severity of vascular calcification is not influenced by pyrophosphate levels. This supports the multi-factorial nature of vascular calcification.

PUB712

Aortic Artery Calcification and Cardiac Valve Calcification Is Associated with Mortality in Chinese Hemodialysis Patients: A 3.5 Year Follow-Up
 Xiaonong Chen,¹ Zijin Chen,¹ Xiaobo Ma,¹ Bei Ding,² Huawei Ling,² Zhongwei Shi,³ Nan Chen.¹ ¹Nephrology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ, Shanghai, China; ²Radiology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ, Shanghai, China; ³Cardiology, Ruijin Hospital Affiliated to Shanghai Jiaotong Univ, Shanghai, China.

Background: Aim to investigate the relationship among aortic artery calcification(AAC), cardiac valve calcification(CVC) and mortality in maintenance haemodialysis(MHD) patients.

Methods: The study included 110 MHD patients. All MHD patients were treated in Shanghai Ruijin Hospital in July 2011. Follow-up these patients for 42 months.

Results: Totally 110 MHD patients were involved in this study. 64(58.2%) patients were male, and the mean age was 55.2±15.0 years old, the mean dialysis duration was 41.7±38.1 months. 25.5% patients had cardiac valve calcification, while 61.8% had visible calcification. After 42 months follow-up, 26(22.7%) patients died, including 16 cases death from cardiovascular events, 5 cases respiratory failure, 3 cases tumor metastasis, 1 case deep venous thrombosis and 1 case abandon treatment. Kaplan-Meier analysis showed that patients with AAC or CVC had a significant greater number of all-cause and cardiovascular deaths than those without. In multivariate analyses, the presence of AAC was a significant factor associated with all-cause mortality (HR 3.149, P=0.025) in addition to lower albumin level and lower 25(OH)D level. The presence of CVC was a significant factor associated with cardiovascular mortality (HR 3.800, P=0.029) in addition to lower albumin level and lower 25(OH)D level.

Table1. multivariate Cox proportional hazards analysis for all-cause mortality

Cox proportional hazards model			
	Hazard Ratio	95% Confidence Interval	P
Sex (male vs female)	1.673	0.634-4.417	0.299
Age (/1 y)	1.034	0.992-1.078	0.112
ALB (/1g/L)	0.820	0.725-0.927	0.002
25(OH)D (/1nmol/L)	0.981	0.965-0.998	0.024
CVC (presence vs absence)	1.563	0.637-3.836	0.330
AAC (presence vs absence)	3.149	0.889-11.159	0.025

Table2. multivariate Cox proportional hazards analysis for cardiovascular mortality

Cox proportional hazards model			
	Hazard Ratio	95% Confidence Interval	P
Age (/1 y)	1.008	0.975-1.062	0.757
ALB (/1g/L)	0.847	0.728-0.984	0.030
25(OH)D (/1nmol/L)	0.962	0.941-0.984	0.001
CVC (presence vs absence)	3.800	1.150-12.558	0.029
AAC (presence vs absence)	2.391	0.631-9.060	0.200

Figure1. The Kaplan-Meier analysis of all-causemortality (P=0.002 and P=0.001)

Figure2. The Kaplan-Meier analysis of cardiovascular mortality (P=0.049 and P<0.001)

Conclusions: The presence of AAC and CVC were independently associated with mortality in MHD patients. Regular follow-up by X-ray and echocardiography could be useful method to stratify mortality risk in MHD patients.

Beneficial Effect of the Vasopressin AV1a and AV2 Receptor Blocker Conivaptan (C) on the Renal Alterations Resulting from Mild Heat-Induced Dehydration (MHID) and Rehydration with a 10% Fructose (F) Beverage
 L. Gabriela Sanchez-Lozada,¹ Fernando E. Garcia-arroyo,¹ Monica Gabriela Blas-Marron,¹ Jose Pedraza-chaverri,² Cecilia Zazueta,³ Magdalena Cristobal,¹ Edilia Tapia.¹ ¹Renal Physiopathology, INCICH, Mexico City, DF, Mexico; ²Biology, UNAM, Mexico City, DF, Mexico; ³Cardiovasc BioMed, INCICH, Mexico City, DF, Mexico.

Background: The aims of this study were: 1.To define a possible synergistic effect between fructose and vasopressin during MHID, and 2. To evaluate the potential therapeutic benefit of C (3mg/kg BW) on this condition.

Methods: Six groups of male Wistar rats were MHID (37°C/ 1 h/day) and rehydrated with the selected beverage during 30 days: Water (W)+Veh, W+C, F+Veh, F+C, Stevia (S)+Veh and S+C. A group of normal control (NC) rats was studied as reference. After 30 days plasma and urine parameters were evaluated, renal cortex mitochondria were isolated and respiratory control rate (RCR) was evaluated with malate/glutamate (M/G) and succinate/rotenone (S/R) substrates.

Results:

PUB714

Lack of Aquaretic Effects of the Kappa Opioid Agonist Nalbuphine following Multiple Ascending Oral Doses in Healthy Volunteers Amale Hawi,¹ Thomas Sciascia,² Vandana S. Mathur.³ ¹Hawi Consulting, Ridgefield, CT; ²Trevi Therapeutics, New Haven, CT; ³Mathur Consulting, Woodside, CA.

Background: Nalbuphine is a mixed μ-antagonist and κ-agonist opioid drug that may suppress itch in hemodialysis patients with pruritus following oral administration of nalbuphine HCl extended release (ER) tablets. However, as a class, kappa opioid agonists have aquaretic effects in both animals and humans, which can be treatment-limiting. In this Phase 1 study, the potential of nalbuphine to induce aquaretic effects was explored in healthy subjects.

Methods: Healthy male and female subjects (n=9) were administered oral doses of nalbuphine escalated every 2-3 days from 30 mg QD on Day1 to 30 mg BID, 60 mg BID, 120 mg BID, and 180 mg BID over a 2-week period. Urine output and vital signs were measured pre-treatment and at multiple time points on Days -1 through 14.

Results: Repeated measurements of urine volume with progressively higher nalbuphine doses over the 6-fold dose range showed no evidence of increased urine output related to dose or duration of time on nalbuphine. Urine specific gravity remained within the normal range (1.001-1.03) and did not decline in any subject during treatment. None of the subjects developed hypernatremia nor was there a trend of rising serum sodium with all values remaining within the normal range. There were no dose-related reductions in blood pressure and none of the subjects developed hypotension. The mean systolic blood pressure remained consistently in the 108–128 mmHg range. Likewise, heart rate remained normal throughout the study with no HR >73 beats per minutes.

Conclusions: There was no evidence of an aquaretic effect at nalbuphine oral doses up to 180 mg BID in healthy subjects, the most sensitive population in which such effects may be observed.

Dose (mg) AM/PM	Study Day	24-hour Urine Volume (L)	Serum Na (mEq/L)
0	-1	-	139.8 (1.56)

Dosing from 30 mg QD Day1 to BID 30 mg (Day2) to 60 mg (Day4, PM) to 120 mg (Day7, PM) to 180 mg (Day10, PM) to 180 mg QD on Day13

PUB715

Urinary Excretion Pattern of Exosomal Aquaporin-2 in Nephronophthisis Mice Hiroko Sonoda, Nobuyuki Mikoda, Sayaka Oshikawa, Masahiro Ikeda. *Veterinary Pharmacology, Univ of Miyazaki, Miyazaki, Japan.*

Background: Nephronophthisis (NPHP), an inherited disorder, is the most frequent genetic cause of end-stage renal failure in children. So far, twenty responsible genes have been identified, including the *NPHP3*. The pcy mouse with missense mutation in *Nphp3* gene orthologous to human *NPHP3* is an animal model of NPHP. So far, renal aquaporin-2 water channel (AQP2) expression in pcy mice has been shown to be up-regulated, accompanied by both polyuria and urinary concentrating defect. Urinary exosomes, known to be released into urine from epithelial cells in all nephron segments, have been reported to selectively contain renal functional proteins, including AQP2. In this study, we examined whether the level of urinary exosomal AQP2 excretion was altered in pcy mice.

Methods: Urine samples were collected for 20 hrs from either pcy mice or the control DBA/2 mice, at 7, 16, and 21 weeks of age, respectively. Urinary exosomes were isolated by differential centrifugation. The levels of urinary exosomal and renal protein were analyzed by immunoblotting.

Results: Although urinary volume in pcy mice was not altered at 7 weeks of age, those were significantly increased at 16 and 21 weeks of age in comparison with age-matched control mice. Urine osmolality was significantly decreased in pcy mice at all ages examined in this study. Urinary exosomal AQP2 protein levels in pcy mice were dramatically increased at 16 weeks of age, whereas those at 7 and 21 weeks of age were not significantly increased. Similarly, a transient increase in urinary excretion of exosomal tumor susceptibility gene 101 protein (TSG101), frequently used as an exosome marker protein, was observed in pcy mice at 16 weeks of age. The levels of renal AQP2 protein in pcy mice at 16 weeks of age or older were significantly higher than those in the control mice.

Conclusions: Urinary exosomal AQP2 protein excretion was transiently increased in pcy mice and this increase appeared to be related to both the number of exosomes excreted into the urine and its renal abundance.

PUB716

Low Osmolar Diet and Adjusted Water Intake for Vasopressin Suppression in ADPKD Osama W. Amro,^{1,2} Jessica K. Paulus,² Farzad Noubary,² Ronald D. Perrone.^{1,2} ¹Nephrology, Tufts Medical Center; ²Tufts Univ School of Medicine.

Background: Autosomal dominant polycystic kidney disease (ADPKD) affects 12.5 million persons worldwide and accounts for 10% of patients with end-stage renal disease in the United States. Vasopressin is a known detrimental factor in disease progression and cyst enlargement.

Methods: This randomized controlled trial examined the effect of a novel approach of combining low osmolar diet and adjusted water intake on vasopressin, measured by change in urinary osmolality, and total daily urinary solute in 34 patients with early ADPKD. Participants were randomized to receive a low osmolar diet (low sodium (1500 mg/day), low protein (0.8 gram/kg body weight) diet) followed by adjusted water intake to achieve a urine osmolality of 280 mOsm/kg versus no intervention for two weeks duration, with equal (1:1) allocation. Permuted block randomization was performed within strata of age and sex.

Results: Baseline characteristics of the two groups were similar. Compared with baseline, the mean urine osmolality significantly declined from 426 (±193) to 258 (±110) mOsm/kg (P= 0.007) but not in the control group. At 2 weeks, levels significantly differed between groups (P= 0.04).

Total urinary solute decreased only in the low osmolar diet group and significantly differed between groups at 2 weeks (P=0.03). The two week adherence rate to diet and adjusted water intake was 70% with a mean water prescription of 2.6 liters/daily.

Conclusions: We identified a novel step wise dietary intervention that led to significant reduction in vasopressin as measured by reduction in 24 hour urine osmolality in patients with early ADPKD. Furthermore, this dietary intervention led to significant reduction in water required for vasopressin suppression. Long-term studies are needed to evaluate diet and adjusted water intake adherence, and determine if the reduction in vasopressin slows ADPKD progression.

CRISPR-Cas9-Mediated Deletion of Myosin Light Chain Kinase in Cultured Collecting Duct Cells Kiyoshi Isobe, Viswanathan Raghuram, Pablo Sandoval, Chin-Rang Yang, Chung-Lin Chou, Mark A. Knepper. *Systems Biology Center, NHLBI, NIH.*

Background: Regulation of osmotic water transport in the renal cortical collecting duct by vasopressin is in part dependent on membrane trafficking of aquaporin-2 (AQP2) to the apical plasma membrane of the principal cells. It is known that trafficking of AQP2 is in part dependent on changes in AQP2 phosphorylation. We previously proposed that AQP2 trafficking is dependent on the protein kinase Myosin Light Chain Kinase (MLCK; gene symbol: *Mylk*). Here, we test the role of MLCK in AQP2 phosphorylation and trafficking, utilizing CRISPR-Cas9 generated mutations in MLCK in cultured mouse mpkCCD cells.

Methods: We used CRISPR-Cas9 genome-editing to mutate the catalytic region of the *Mylk* gene. Clones were generated with 4 different guide RNAs and were characterized by genomic sequencing and immunoblotting. Effects of the deletions were assessed by immunoblotting and immunofluorescence immunocytochemistry of AQP2.

Results: Multiple clones with mutations in the catalytic domain of MLCK were generated. Western blots showed absence of MLCK protein in MLCK-deleted clones. Controls were clones that express MLCK without mutations in the catalytic domain, but may contain off-target modifications. AQP2 protein abundance varied over a broad range, among all MLCK-deleted (n=4) and control (n=4) lines, but, on average, was not affected by the deletion. Immunocytochemistry showed that vasopressin stimulates redistribution of AQP2 to the apical plasma membrane in both control cells and MLCK-deleted cells. Vasopressin-dependent phosphorylation of AQP2 at Ser256 and Ser269 was not significantly reduced in MLCK-deleted cells.

Conclusions: The results demonstrate the feasibility of CRISPR-Cas9-mediated genome editing in mouse mpkCCD cells. Our experiments in mouse cultured collecting duct cells provide evidence that vasopressin-induced phosphorylation of AQP2 and redistribution of AQP2 to the apical plasma membrane can occur independently of myosin light chain kinase.

PUB718

The PDZ Domain-Containing Protein Harmonin Is a Binding Partner of Sodium-Coupled Monocarboxylate Transporter 2 Nobuyuki Onizawa,^{1,2} Naoyuki Otani,¹ Promsuk Jutabha,¹ Motoshi Ouchi,¹ Hajime Hasegawa,² Naohiko Anzai.¹ ¹*Dept of Pharmacology and Toxicology, Dokkyo Medical Univ School of Medicine, Mibu, Tochigi, Japan;* ²*Dept of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical Univ, Kavagoe, Saitama, Japan.*

Background: Lactate is freely filtered and extensively reabsorbed in the proximal tubule to prevent the loss of this valuable metabolite from the body. Sodium-coupled monocarboxylate transporter SMCT2(SLC5A12) mediates the transport of pyruvate, nicotinate and lactate (Gopal et al., BBA. 2007). In contrast to its well characterized transport properties, less information is available on the regulatory mechanism of SMCT2. The C-terminal domain of SMCT2 is exposed to the cytoplasmic compartment and contains the PDZ motif, one of the famous protein-protein interaction modules, suggesting that it may interact with PDZ proteins.

Methods: We used the yeast two-hybrid screening to investigate the putative SMCT2-associated proteins that modulate its transport function. Using the SMCT2 C-terminal tail (SMCT2-CT) as bait, we performed a yeast two-hybrid screen of a cDNA library constructed from the human adult kidney. Next, to further confirm the interaction between SMCT2 and harmonin, we performed a co-immunoprecipitation study using anti-harmonin antibodies.

Results: In the yeast two-hybrid screening, 34 positive clones were obtained from a total of 1.2×10^7 independent colonies screened. Of these, 8 yielded an identical sequence encoding the gene for the PDZ protein PDZK1 (manuscript in preparation), and 1 yielded an identical sequence encoding the gene for the PDZ protein Harmonin. Deletion of C-terminal PDZ motif abolished the interaction with harmonin in the yeast two-hybrid system. Furthermore, co-immunoprecipitation studies revealed that the SMCT2 interacted directly with harmonin.

Conclusions: Harmonin was identified as the binding partner for SMCT2. The elucidation of these interactions may further our understanding of the function and regulation of monocarboxylate (e.g., lactate) transport in the human kidney.

PUB719

Stimulation of V1a Receptor Increases Renal Uric Acid Clearance via ABCG2 Transporter – Insight into Hypouricemia in SIADH Kei Taniguchi, Yoshifuru Tamura, Shigeru Shibata, Shunya Uchida. *Dept of Internal Medicine, Teikyo Univ School of Medicine, Itabashi, Tokyo, Japan.*

Background: Hypouricemia seen in the subjects with syndrome of inappropriate secretion of antidiuretic hormone (SIADH) is pathognomonic but the mechanism of hypouricemia remains to be clarified. V2 receptor agonist ‘desmopressin’ induced hyponatremia but not hypouricemia in human unlike SIADH (G Decaux, JASN, 1996). Therefore, we hypothesized that V1 receptor but not V2 receptor may play a role in inducing hypouricemia. In the present study, we examined the changes in serum uric acid, urinary uric acid excretion and expression of uric acid transporters in response to V1a receptor agonist ‘terlipressin’.

Methods: Terlipressin was subcutaneously infused by osmotic mini pump to 7-week-old male Wistar rats (n = 9). Control rats were infused with normal saline (n = 9). The rats were sacrificed to obtain renal cortical tissues at 3 days.

Results: Serum uric acid significantly decreased and the excretion of urinary uric acid significantly increased in the terlipressin group. Thus, fractional excretion of uric acid increased from $1.20 \pm 0.28\%$ to $3.10 \pm 0.56\%$ ($P < 0.001$). The expression of ATP-binding cassette transporter, sub-family G, member 2 (ABCG2) significantly increased in the terlipressin group. Other uric acid transporters did not significantly change.

Conclusions: These results suggest that stimulation of V1a receptor increases renal uric acid clearance probably via upregulation of ABCG2, leading to hypouricemia seen in SIADH patients.

PUB720

Fluorescein Angiography and the Kidney: Friend or Foe? Mohamed E. Elraggal,¹ Ahmed Fathy Elkerai,² Ahmed M. Abdelhadi,³ Ashraf Nabil Abdalla.⁴ ¹*Nephrology, Kidney and Urology Center, Alexandria, Egypt;* ²*Nephrology, Alexandria Univ, Alexandria, Egypt;* ³*Ophthalmology, Alexandria Univ, Alexandria, Egypt;* ⁴*Pharmacology, Umm Al-Qura Univ, Saudi Arabia.*

Background: Fluorescein angiography (FA) is an indispensable tool for diagnosis and management of diabetic retinopathy (DR). However, safety of fluorescein sodium on renal functions is not fully understood.

Methods: 100 type 2 diabetic patients presenting to the ophthalmology outpatient clinic at Alexandria main university hospital were included in our study. Serum creatinine and cystatin-C were measured just before and 2 days after FA. Urinary NGAL as a tubular biomarker was measured also before and 4 hours after FA. Renal injury was defined as 25 % increase in serum creatinine or cystatin-C.

Results: The mean of serum creatinine was 0.99 ± 0.36 mg/dl and 1.0 ± 0.36 mg/dl before and after FA respectively with no statistically significant change ($P=0.061$). Only one patient (out of 100) experienced more than 25% rise in serum creatinine from baseline. Serum Cystatin-C and urinary NGAL increased significantly after FA ($P>0.001$). Mean of serum Cystatin-C was 0.89 ± 0.34 mg/l and 0.95 ± 0.36 mg/l before and after FA respectively. 11 patients experienced more than 25% rise in serum cystatin-C from baseline. Mean of urinary NGAL was 21.78 ± 23.90 ng/ml and 27.15 ± 28.17 ng/ml before and after FA respectively.

Conclusions: Using ordinary renal biomarkers as serum creatinine, FA was thought to be kidney friendly. Nevertheless, using more sensitive early biomarkers as serum cystatin-C and urinary NGAL, FA is not as innocent as previously thought. A creatinine negative, biomarker positive change may implicate a form of subclinical AKI.

Transcultural Adaptation and Validation of the Mexican Version of the Kidney Disease Questionnaire KDQOL-SF36 Version 1.3 Edgar Dehesa Lopez,¹ Ricardo Correa-Rotter,² David Olvera,³ Carlos Gonzalez Parra,⁴ Rafael Baizabal.⁵ ¹*Dept of Nephrology, Research and Teaching Center in Health Sciences (CIDOCS), Culiacan, Sinaloa, Mexico;* ²*Dept of Nephrology, National Inst of Medical Sciences and Nutrition Salvador Zubiran, Mexico, D.F, Mexico;* ³*Dept of Nephrology, Hospital ISSSTE, Ciudad Valles, San Luis Potosi, Mexico;* ⁴*Department of Nephrology, Christus Murgueza UPAEP, Puebla, Mexico;* ⁵*Dept of Nephrology, Hospital ISSSTE, Xalapa, Veracruz, Mexico.*

Background: The evaluation of health-related quality of life through the application of efficient, reliable and simple instruments is a relatively new concept in the practice of nephrology. The aim of the study was to translate the Kidney Disease Quality of Life Short Form 36 KDQOL-SF36 v1.3 questionnaire into the Spanish language, to adapt it culturally and to validate it in the Mexican population.

Methods: The translation, transcultural adaptation and validation of the Mexican version of KDQOL-SF36 was performed according to the recommendations of RAND Health. The validity was evaluated using Cronbach's α . The test-retest reliability was evaluated using interobserver and intraobserver intraclass correlation coefficients (ICCs).

Results: The questionnaires were applied to 194 Mexican patients with end stage chronic kidney disease in chronic hemodialysis. The average age was 54 ± 16 years, and 54.6.1% were males. The Mexican version proved reliable with intra- and interobserver ICCs ≥ 0.7 in most of the dimensions evaluated, with a range between 0.5 and 0.9. The validity of the questionnaire was acceptable, with an internal items-dimensions consistency between 0.4 and 0.9, dimensions-total of 0.725 and items-total of 0.921.

Table 1.–Reliability and construct validity of the Mexican version of KDQOL-SF36 v1.3.

Conclusions: The psychometric properties evaluated in the Mexican version of the KDQOL-SF36 v1.3 demonstrated that it is a valid and reliable instrument,with psychometric results similar to the original version.

PUB722

Urinary Neutrophil Gelatinase Associated Lipocalin Beyond AKI, Relation to Renal and Patient Survival Ahmed Fathy Elkeraie,¹ Mohammed Megahed,² Ahmed Elkhodary,² ¹*Nephrology, Alexandria Univ, Alexandria, Egypt;* ²*Critical Care, Alexandria Univ, Alexandria, Egypt.*

Background: Neutrophil gelatinase-associated lipocalin (NGAL) has been postulated as an early, sensitive, non-invasive biomarker for acute kidney injury (AKI). The aim of this study was to evaluate urinary NGAL levels as a predictor of early AKI (first 5 days) in severely traumatized patients associated with hemorrhagic shock.

Methods: This is a prospective observational study on 57 adult trauma patients presented with severe trauma (ISS ≥ 16) and hemorrhagic shock to the units of Critical Care Medicine Department in Alexandria Main University Hospital and Mostafa Kamel Armed Forces Hospital. Urinary NGAL was measured upon admission and 48 hrs after trauma. Presence of AKI was defined by Acute Kidney Injury Network (AKIN) criteria.

Results: Using AKIN criteria, a total of 13 patients were identified with AKI (incidence of 37.14%). Those who subsequently developed AKI had a striking rise in urinary NGAL early after trauma and a sustained increase over next 48 hrs. The urinary NGAL levels of the AKI group (group A) were significantly higher than non AKI (group B) both on admission and 48 hrs later. For cut-off point >29 ng/mL, urinary NGAL 48 hrs after trauma sensitivity, specificity, positive and negative predictive values were 84.62, 95.45, 91.67and 91.30, respectively. In the analysis of urinary NGAL (on admission) performance for predicting clinical outcomes; Using a cutoff value of 30 ng/ mL the area under the receiver-operating characteristic curve for in-hospital mortality and the need for RRT during the first week was 0.768, 0.903 respectively. Odds of in-hospital mortality increased by 12.7% for every 30ng/ml increase in urinary NGAL on admission, confirming the usefulness of NGAL in predicting clinical outcomes.

Conclusions: Urinary NGAL is an early and reliable predictive marker of AKI in severely traumatized patients presented with hemorrhagic shock and also a predictor of adverse clinical outcomes. The important clinical utility of this biomarker in patient care, might facilitate early renal protective interventions with the hope of improvement in the renal and patient outcomes.

PUB723

Epidemiology and Prognosis of Community Acquired Acute Kidney Injury versus Hospital Acquired Acute Kidney Injury Edgar Dehesa Lopez,¹ Melissa Rodriguez,² Rodolfo Radames Salas Zazueta,² Daniel Antonio Hernandez Quintero,² Hector Guillermo Peña Peredia,² Berenice Tamayo Garcia.² ¹*Dept of Nephrology, Research and Teaching Center in Health Sciences (CIDOCS), Culiacan, Sinaloa, Mexico;* ²*Research and Teaching Center in Health Sciences (CIDOCS), Culiacan, Mexico.*

Background: The epidemiological characteristics and prognosis of patients with community acquired acute kidney injury (C-AKI) vs hospital acquired acute kidney injury (H-AKI) have not been thoroughly studied.

Methods: A total of 192 patients admitted to internal medicine service were studied. AKI was diagnosed and classified at time of admission (C-AKI) or posteriorly during hospitalization.AKI was defined according to the Acute Kidney Injury Network (AKIN) and serum sCr. The etiology, severity and evolution of the AKI episodes were compared among patients with C-AKI and H-AKI.

Results: C-AKI incidence was 22.4% (n=43) and H-AKI was 5.7% (n=11),giving an overall incidence of 28.1%.AKIN 1 stage was present in 51.7%,AKIN 2 in 12.9% and AKIN 3 in 35.4%.Renal factors were the most frequent etiology of AKI in 55.6%, prerenal in 38.9% and obstructive in 5.6%.Oliguric AKI was observed in 25.9%.

Hemodialysis was required in 9.3% of cases.The recovered AKI was observed in 75.9% at the time of hospital discharge.The length of hospital stay (9±9 vs 7±6 days;p<0.05) and mortality (18.5 vs 7.2%; p=0.02) were greater in patients with AKI compared with patients without AKI.Patients with H-AKI had a longer hospital stay (15±12 vs. 8±8; p<0.05) and a statistical trend to higher mortality (36.4% vs 14%;p=0.08) in relation to patients with C-AKI.

Table 1.–Clinical and prognostic differences between C-AKI vs H-AKI

	C-AKI		H-AKI		P
	n=42	%	n=11	%	
AKI severity					
Stage 1	17	39.5%	2	18.2%	NS
Stage 2	5	11.6%	5	45.5%	0.03
Stage 3	21	48.8%	4	36.4%	NS
Etiology of AKI					
Prerenal	15	34.9%	3	27.3%	0.54
Renal	25	58.1%	8	72.7%	
Postrenal	3	7.0%	0	0.0%	
Oliguria	8	18.6%	6	54.5%	0.01
Hemodialysis	5	11.6%	0	0.0%	0.23
Discharged with recovered AKI	33	76.7%	8	72.7%	0.78
Etiology of renal AKI:					
Acute tubular necrosis	19	76.0%	6	75.0%	0.95
Glomerulonephritis	6	24.0%	2	25.0%	
Nephrotoxic drugs	0	0.0%	0	0.0%	
AKI days	5±4		5±3		NS

AKI= Acute kidney injury; C-AKI = Community acquired acute kidney injury; H-AKI= Hospital acquired acute kidney injury

Conclusions: AKI was a frequent diagnosis on hospital admission or during hospitalization.C-AKI and H-AKI added a negative effect on the prognosis.H-AKI episodes were more severe and were associated with a longer hospital stay and an statistical trend in mortality in comparison with C-AKI.

PUB724

Drug Utilization Patterns and Factors Associated with Acute Kidney Injury in an Intensive Care Unit at a Brazilian Public Hospital – A Prospective Cohort Study Danielly Botelho Soares,¹ Gabriela Rebouças Botelho,¹ Flávia Fialho Girundi,¹ Fernando Antonio Botoni,² Maria Auxiliadora Parreiras Martins.¹ ¹*School of Pharmacy, Univ Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil;* ²*School of Medicine, Univ Federal de Minas Gerais, Belo Horizonte, Minas Gerais, Brazil.*

Background: Acute kidney injury (AKI) is associated with a significant increase in morbidity, mortality and health care costs. In intensive care units (ICU), the cause of AKI is commonly associated with multiple factors, among which the use of potentially nephrotoxic drugs is often neglected as a preventable cause of AKI.

Methods: This is a prospective cohort study that evaluated the AKI as a primary outcome in ICU patients at a teaching hospital in Belo Horizonte, Brazil. Length of stay greater than 24 hours and hospital stay lower or equal to 7 days were evaluated for potential eligibility. To be enrolled, patients should not present kidney dysfunction at the time of ICU admission.

Results: Data collection was performed from October 2014 to February 2015, including 122 patients, mostly originated from the surgical department (46.7%). An average of 22.0 ± 9.4 drugs was prescribed and 2-24 potentially nephrotoxic drugs were used per patient. Mechanical ventilation was required for 67.2% of patients and at least one vasoactive drug was used in 68.0% of cases. An incidence of AKI was observed in23.8% of patients, among them 34.5% required dialysis, 24.1% reached the third stage of AKI and 31.8% were referred to additional treatment after ICU discharge. Eleven (9%) patients died and 63.6% of them developed AKI. The bivariate analysis showed that age (p = 0.006) and APACHE II score (p = 0.003) had higher median among patients who developed AKI compared to those who did not develop AKI. In the logistic regression, the number of medications (OR: 1.15; 95% CI: 1.05 to 1.26) presented a statistically significant correlation with the development of AKI.

Conclusions: These results demonstrate that the identification of factors associated with AKI in ICU patients is very important for the early identification of renal dysfunction induced by drugs, providing conditions for appropriate prevention and treatment of the extent of kidney damage.

PUB725

Clinical, Dialytic and Laboratorial Factors Associated with Poor Health Related Quality of Life in Mexicans Hemodialysis PatientsEdgar Dehesa Lopez,¹ David Olvera,² Carlos Gonzalez parra,³ Rafael Baizabal.⁴¹*Dept of Nephrology, Research and Teaching Center in Health Sciences (CIDOCS), Culiacan, Sinaloa, Mexico;* ²*Dept of Nephrology, Hospital ISSSTE, Ciudad Valles, San Luis Potosi, Mexico;* ³*Dept of Nephrology, IMSS, Puebla, Mexico;* ⁴*Department of Nephrology, Hospital ISSSTE, Xalapa, Veracruz, Mexico.***Background:** The evaluation of health related quality of life (HRQOL) in hemodialysis patients has recently gained great importance because it has proven to be an independent predictor of clinical outcomes.**Methods:** Cross-sectional study. The validated Mexican version of the KDQOL-SF36 v1.3 questionnaire were applied to 194 adult patients with ESRD on hemodialysis in different regions of Mexico. According to the global score of questionnaire, patients were grouped in: patients with poor HRQOL (global score below the median) and patients with good HRQOL (global score greater than the median). Logistic regression was used to investigate the effects of clinical, dialytic and laboratorial factors on HRQOL.**Results:** The average age was 54±16 with 54.6.1% male. Comorbidities were: hypertension in 86.6%, diabetes mellitus 2 in 57.2% and dyslipidemia in 7.2%. The vascular access was a catheter in 55.2% and fistula in 44.8% of the cases. Diabetes mellitus and the use of catheters as vascular access were more frequent in patients with poor quality of life. On the other hand, phosphorus >5.5 mg/dl and albumin >4g/dl were more frequent in patients with good quality of life. There were no differences in age, KtV, hemoglobin and calcium between groups. Table 1 shown the clinical, dialytic and laboratorial factors studied in the multivariate logistic analysis.**Table 1.** Multivariate logistic regression analysis of clinical, dialytic and laboratorial factors associated with poor HRQOL.

Variables	OR	CI 95%		p
		Lower	Upper	
Age (years)	1.02	0.99	1.05	0.23
Gender (male vs female)	0.87	0.40	1.89	0.73
Diabetes mellitus (yes/no)	1.35	0.56	3.24	0.50
Vascular access (catheter vs fistula)	3.03	1.30	7.09	0.01
Hemoglobin (<9 g/dl vs >9 g/dl)	1.23	0.46	3.26	0.68
Albumin (< 4 g/dl vs > 4 g/dl)	3.30	1.37	7.98	0.01
KtV (<1.4 vs >1.4)	1.02	0.40	2.60	0.97
Calcium (<8.5 mg/dl reference)				
Calcium (8.5-10 mg/dl)	1.56	0.65	3.78	0.32
Calcium (>10 mg/dl)	0.55	0.18	1.65	0.28
Phosphorus (<4.5 mg/dl reference)				
Phosphorus (4.5-5.5 mg/dl)	2.45	0.30	19.77	0.40
Phosphorus (>5.5 mg/dl)	1.15	0.14	9.28	0.90
Hemodialysis stay (months)	1.02	1.00	1.04	0.03

OR=odds ratio; CI=Confidence interval; HRQOL: Health related quality of life

Conclusions: The associated factors with poor HRQOL in Mexicans hemodialysis patients were: the time spent in hemodialysis, serum albumin <4 g/dl and use of catheter for vascular access.

KEYWORD INDEX

The number refers to the location of the body of the abstract in the publication section.

- AASK (African American Study of Kidney Disease and Hypertension)** TH-PO642, TH-PO643, SA-OR092, SA-PO498, SA-PO616, PUB158
- ABC transporter** SA-PO347, SA-PO543, PUB719
- access blood flow** TH-PO850, TH-PO868, TH-PO876, TH-PO881, TH-PO882, FR-PO717, FR-PO718
- access flow rate** TH-PO671, TH-PO860, FR-PO700, FR-PO712, FR-PO714, PUB065, PUB483
- ACE inhibitors** TH-PO323, TH-PO329, TH-PO367, TH-PO618, FR-PO196, FR-PO317, FR-PO342, SA-OR006, SA-OR108, SA-PO617, SA-PO657, PUB036, PUB092, PUB504
- acidosis** ... TH-PO607, TH-PO1039, TH-PO1042, TH-PO1059, FR-OR002, FR-OR005, FR-OR006, FR-OR108, FR-OR110, FR-PO003, FR-PO007, FR-PO036, FR-PO113, FR-PO535, FR-PO1058, SA-OR111, SA-PO023, SA-PO087, SA-PO092, SA-PO198, SA-PO771, SA-PO896, SA-PO897, SA-PO898, SA-PO899, SA-PO900, SA-PO901, SA-PO932, SA-PO933, SA-PO934, SA-PO935, SA-PO938, SA-PO939, SA-PO940, SA-PO945, SA-PO946, PUB006, PUB199, PUB400, PUB449, PUB455, PUB462, PUB463, PUB601
- activated vitamin D** TH-OR110, TH-PO161, TH-PO170, TH-PO271, TH-PO310, TH-PO509, TH-PO512, FR-PO033, FR-PO041, FR-PO340, SA-PO803, SA-PO811, SA-PO812, PUB189, PUB287, PUB541, PUB706
- acute allograft rejection** FR-PO073, FR-PO1004, FR-PO1032, SA-OR058, SA-PO009, SA-PO963, SA-PO966, SA-PO972, SA-PO993, PUB013, PUB398, PUB670
- acute kidney failure** TH-OR101, TH-OR102, TH-OR104, TH-OR107, TH-PO006, TH-PO007, TH-PO009, TH-PO010, TH-PO015, TH-PO016, TH-PO020, TH-PO021, TH-PO026, TH-PO027, TH-PO040, TH-PO042, TH-PO043, TH-PO050, TH-PO051, TH-PO054, TH-PO056, TH-PO059, TH-PO060, TH-PO061, TH-PO064, TH-PO065, TH-PO067, TH-PO069, TH-PO070, TH-PO073, TH-PO077, TH-PO082, TH-PO087, TH-PO090, TH-PO092, TH-PO093, TH-PO095, TH-PO096, TH-PO100, TH-PO101, TH-PO103, TH-PO104, TH-PO109, TH-PO110, TH-PO114, TH-PO117, TH-PO118, TH-PO121, TH-PO584, TH-PO736, TH-PO1029, TH-PO1032, TH-PO1041, TH-PO1051, TH-PO1053, TH-PO1061, TH-PO1067, TH-PO1073, TH-PO1074, TH-PO1075, TH-PO1078, TH-PO1082, TH-PO1090, TH-PO1094, TH-PO1095, TH-PO1101, TH-PO1102, TH-PO1111, **acute kidney failure (continued)** TH-PO1114, TH-PO1119, FR-OR099, FR-OR100, FR-OR106, FR-PO017, FR-PO024, FR-PO042, FR-PO070, FR-PO077, FR-PO095, FR-PO105, FR-PO217, FR-PO218, FR-PO225, FR-PO231, FR-PO232, FR-PO241, FR-PO242, FR-PO244, FR-PO245, FR-PO246, FR-PO249, FR-PO251, FR-PO253, FR-PO258, FR-PO263, FR-PO277, FR-PO364, FR-PO371, FR-PO415, FR-PO458, FR-PO459, FR-PO460, FR-PO465, FR-PO467, FR-PO468, FR-PO469, FR-PO471, FR-PO472, FR-PO473, FR-PO474, FR-PO479, FR-PO480, FR-PO485, FR-PO486, FR-PO489, FR-PO490, FR-PO491, FR-PO493, FR-PO494, FR-PO495, FR-PO496, FR-PO498, FR-PO500, FR-PO501, FR-PO503, FR-PO504, FR-PO506, FR-PO529, FR-PO872, SA-OR100, SA-OR104, SA-OR105, SA-OR107, SA-PO005, SA-PO013, SA-PO023, SA-PO025, SA-PO044, SA-PO045, SA-PO048, SA-PO052, SA-PO062, SA-PO066, SA-PO067, SA-PO071, SA-PO075, SA-PO079, SA-PO080, SA-PO083, SA-PO088, SA-PO089, SA-PO094, SA-PO095, SA-PO114, SA-PO118, SA-PO127, SA-PO143, SA-PO144, SA-PO145, SA-PO146, SA-PO187, SA-PO188, SA-PO191, SA-PO192, SA-PO193, SA-PO195, SA-PO196, SA-PO199, SA-PO200, SA-PO201, SA-PO202, SA-PO203, SA-PO204, SA-PO207, SA-PO208, SA-PO209, SA-PO210, SA-PO212, SA-PO216, SA-PO217, SA-PO218, SA-PO219, SA-PO220, SA-PO224, SA-PO227, SA-PO230, SA-PO231, SA-PO233, SA-PO236, SA-PO237, SA-PO239, SA-PO242, SA-PO244, SA-PO245, SA-PO250, SA-PO251, SA-PO254, SA-PO256, SA-PO267, SA-PO268, SA-PO270, SA-PO271, SA-PO279, SA-PO282, SA-PO283, SA-PO284, SA-PO293, SA-PO333, SA-PO441, SA-PO465, SA-PO514, SA-PO531, SA-PO532, SA-PO770, SA-PO896, SA-PO907, SA-PO1053, SA-PO1054, PUB001, PUB007, PUB011, PUB012, PUB015, PUB016, PUB017, PUB018, PUB019, PUB023, PUB029, PUB032, PUB033, PUB034, PUB035, PUB036, PUB037, PUB038, PUB041, PUB042, PUB043, PUB044, PUB045, PUB050, PUB055, PUB056, PUB057, PUB058, PUB059, PUB061, PUB062, PUB065, PUB071, PUB181, PUB218, PUB240, PUB248, PUB249, PUB312, PUB394, PUB421, PUB425, PUB429, PUB438, PUB444, PUB450, PUB503, PUB643, PUB722, PUB723

HI-OR01

Empagliflozin and Cardiovascular Outcomes in Patients with Type 2 Diabetes and Chronic Kidney Disease Christoph Wanner,¹ John M. Lachin,² David H. Fitchett,³ Silvio E. Inzucchi,⁴ Maximilian von Eynatten,⁵ Michaela Mattheus,⁵ Odd Erik Johansen,⁶ Hans-Juergen Woerle,⁵ Uli Christian Broedl,⁵ Bernard Zinman,^{7,8} ¹Dept of Medicine, Würzburg Univ Clinic, Würzburg, Germany; ²The Biostatistics Center, The George Washington Univ, Rockville, MD; ³St Michael's Hospital, Div of Cardiology, Univ of Toronto, Toronto, Canada; ⁴Section of Endocrinology, Yale Univ School of Medicine, New Haven, CT; ⁵Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; ⁶Boehringer Ingelheim Norway KS, Asker, Norway; ⁷Lunenfeld-Tanenbaum Research Inst, Mount Sinai Hospital, Toronto, Canada; ⁸Div of Endocrinology, Univ of Toronto, Toronto, Canada.

Background: Patients with type 2 diabetes (T2D) and chronic kidney disease (CKD) are at high risk of cardiovascular (CV) events and premature death. Empagliflozin is a sodium glucose co-transporter (SGLT)-2 inhibitor used in the treatment of T2D.

Methods: In EMPA-REG OUTCOME®, we explored long-term CV outcomes with empagliflozin vs placebo when added to standard of care in 7020 T2D patients with established CV disease. Inclusion criteria included eGFR ≥30ml/min/1.73m². Patients (mean age 63 years, male 71%, mean HbA1c 8.1%) were randomized 1:1:1 to empagliflozin 10 mg, 25 mg or placebo.

Results: Most patients had impaired kidney function (52.2% stage 2, 17.8% stage 3a, 7.7% stage 3b CKD) while 28.7% and 11.0%, respectively, had moderately (30-300mg/g) or severely (>300 mg/g) increased urine albumin to creatinine excretion. After a median follow-up of 3.1 years, the primary outcome (first occurrence of non-fatal myocardial infarction, non-fatal stroke, or CV death) occurred in a lower percentage of patients on empagliflozin (10.5%) than placebo (12.1%) (HR 0.86 [0.74-0.99]; p=0.04). This result was driven by a 38% reduction in CV death vs placebo (HR 0.62 [0.49-0.77]; p<0.001), with no difference in the risk of heart attack or stroke. Empagliflozin reduced hospitalization for heart failure by 35% (HR 0.65 [0.50-0.85]; p=0.0017). Pre-defined subgroup analyses on CV outcomes in patients with T2D and CKD will be presented.

Conclusions: Empagliflozin reduces CV morbidity and mortality in patients with T2D and various degrees of CKD.

HI-OR02

High Dose Perioperative Atorvastatin and Acute Kidney Injury Following Cardiac Surgery Frederic Tremaine Billings, Chad E. Wagner, Patty Hendricks, Yaping Shi, Michael R. Petracek, Nancy J. Brown. *Vanderbilt Univ, Nashville, TN.*

Background: Hydroxy-methylglutaryl-coenzyme A reductase inhibitors (statins) affect several mechanisms underlying acute kidney injury (AKI), a common and dangerous complication after cardiac surgery. We hypothesized that short-term high-dose perioperative atorvastatin would reduce AKI following cardiac surgery.

Methods: We randomized elective cardiac surgery patients, stratified by chronic kidney disease (CKD), to atorvastatin or matching-placebo starting the day prior to surgery until hospital discharge in pre-study statin naïve subjects or until the day after surgery in pre-study statin-using subjects. Our primary endpoint was AKI by AKIN criteria.

Results: The study was stopped on recommendations of the DSMB after 653 of 820 subjects completed the study due to futility and an increased incidence of AKI among statin-naïve subjects with CKD randomized to atorvastatin. AKI occurred in 20.8% of subjects randomized to atorvastatin versus 19.5% randomized to placebo (P=0.75). Among statin-naïve subjects (n=199), however, AKI occurred in 21.6% randomized to atorvastatin versus 13.4% randomized to placebo (p=0.14), and 52.9% vs. 15.8%, P=0.03, in patients with CKD (n=36). Serum creatinine concentrations increased a median of 0.11 (-0.11 – 0.56) versus 0.05 (-0.12 – 0.33) mg/dl in statin-naïve patients randomized to atorvastatin versus placebo (P=0.007), and this effect was magnified among those with CKD, whereserum creatinine concentrations increased by 0.26 (-0.22 – 0.94) versus -0.06 mg/dl (-0.16 – 0.41), P=0.04.

Underline represents presenting author/disclosure.

Conclusions: High-dose perioperative atorvastatin treatment does not reduce AKI following cardiac surgery and may increase risk in patients with CKD who are naïve to statin treatment. Perioperative continuation or short-term withdrawal of statin treatment in statin-using patients does not affect AKI.

HI-OR03

Effect of Methylprednisolone on Acute Kidney Injury in Patients Undergoing Cardiac Surgery with Cardiopulmonary Bypass Amit X. Garg,¹ Richard P. Whitlock,² ¹Western Univ, London, Canada; ²McMaster Univ, Hamilton, Canada and the Population Health Research Inst; for the SIRS Investigators.

Background: Acute kidney injury is a common complication of the 20 million cardiac surgeries performed worldwide each year. We conducted a substudy of the Steroids In caRdiac Surgery (SIRS) trial to determine whether methylprednisolone alters the risk of acute kidney injury in patients undergoing cardiac surgery with cardiopulmonary bypass [substudy protocol BMJ Open 2014 Mar 5;4(3): e004842].

Methods: This was a randomized clinical trial of 7,286 high-risk patients undergoing cardiac surgery with cardiopulmonary bypass from 79 centres in 18 countries between June 2007 and December 2013. Patients were assigned to take intravenous methylprednisolone (250 mg at anesthetic induction and 250 mg at initiation of cardiopulmonary bypass) or placebo. Patients, care givers and outcome-assessors were blinded to allocation. Acute kidney injury was defined as ≥50% or ≥ 26.5 mmol/L (≥ 0.3 mg/dL) increase in the postoperative serum creatinine concentration from the preoperative concentration in the 14 days following surgery, or new dialysis in the 30 days following surgery.

Results: Methylprednisolone (n=3,647) versus placebo (n=3,639) did not alter the risk of acute kidney injury (40.9% versus 39.5%, respectively; relative risk 1.03 [95% CI, 0.96 to 1.11]). Results were consistent with multiple alternate continuous and categorical definitions of acute kidney injury, and in the subgroup with baseline chronic kidney disease.

Conclusions: Amongst patients undergoing cardiac surgery with cardiopulmonary bypass, the use of corticosteroids in the perioperative period did not alter the risk of acute kidney injury. Trial Registration: NCT00427388

	Number of Events (%)		Relative Risk (95% CI)

The NEFIGAN Trial: NEFECON, a Novel Targeted Release Formulation of Budesonide, Reduces Proteinuria and Stabilizes eGFR in IgA Nephropathy Patients at Risk of ESRD Bengt C. Fellstrom,¹ Rosanna Coppo,² John Feehally,³ Jürgen Floege,⁴ Johan W. De Fijter,⁵ Alan G. Jardine,⁶ Francesco Locatelli,⁷ Bart D. Maes,⁸ Alex Mercer,⁹ Fernanda Ortiz,¹⁰ Manuel Praga,¹¹ Søren Schwartz Sørensen,¹² Vladimir Tesar.¹³ ¹Uppsala Univ Hospital; ²Univ Turin; ³Univ Leicester; ⁴RWTH Univ Aachen; ⁵Leiden Univ Medical Center; ⁶Univ Glasgow; ⁷Ospedale A Manzoni, Lecco; ⁸AZ Delta Roeselare; ⁹Pharmalink; ¹⁰Helsinki Univ Hospital; ¹¹Hospital 12 de Octubre, Madrid; ¹²Rigshospitalet, Copenhagen; ¹³Charles Univ, Prague.

Background: IgA nephropathy (IgAN) is the most prevalent primary chronic glomerular disease. Despite RAS blockade, >25% of patients progress to ESRD within 20 years. This study evaluated a novel budesonide formulation (NEFECON) targeted for release in the distal ileum, where Peyer's patches reside, in patients at risk of ESRD despite optimized RAS blockade.

Methods: Double-blind, placebo-controlled study in 150 patients (62 sites, 10 EU countries) with primary IgAN, proteinuria (UPCR ≥0.5 g/g OR urine protein ≥0.75 g/d) and eGFR CKD-EPI ≥45 mL/min/1.73m² randomized to 8 or 16 mg/d NEFECON or placebo (1:1:1), after 6 mo run-in phase to optimize RAS blockade. Primary endpoint: reduction in UPCR at 9 mo of treatment; secondary: mean percentage change in eGFR.

Results: Baseline data were similar across groups; BP was 127-128/78-80 mmHg, UPCR 0.76-0.83 g/g, and eGFR 72-85 mL/min/1.73m². Primary endpoint was met at the pre-specified interim analysis. Mean UPCR decreased by 24% (NEFECON 8+16 mg/d) vs 3% increase (placebo) at 9 mo (p=0.007); reduction in the 16 mg/d group was 27% (p=0.009). At final analysis, mean change in eGFR was -4.7 mL/min/1.73m² for placebo compared with 0.32 and 1.95 mL/min/1.73m² for NEFECON 8 and 16 mg/d, respectively; difference in mean percentage change in eGFR achieved statistical significance for 8 mg/d (p=0.006) and 16 mg/d (p=0.003). Adverse event rates were higher in NEFECON groups (88-94%) than placebo (84%). Two serious adverse events were assessed as possibly related to NEFECON; deteriorated renal function (in follow-up) and deep vein thrombosis.

Conclusions: NEFECON reduced UPCR and maintained eGFR in patients with primary IgAN at risk of progression to ESRD despite optimized RAS blockade. Treatment was generally well-tolerated.

HI-OR05

Randomized Trial on Efficacy of Mycophenolate Mofetil versus Tacrolimus in Maintaining Remission in Children with Steroid Resistant Nephrotic Syndrome Aditi Sinha, Arvind Bagga. *All India Inst of Medical Sciences, New Delhi, India.*

Background: Since prolonged therapy with tacrolimus (Tac) causes nephrotoxicity, this RCT examined non-inferiority of mycophenolate mofetil (MMF) to Tac in maintaining remission in patients with steroid resistant nephrotic syndrome (SRNS). CTRI/2012/03/00247

Methods: Following approvals, 84 patients with SRNS (1-18 yr; minimal change 48, FSGS 36) & eGFR >60 ml/min/1.73m² received Tac (0.15 mg/kg/d; trough 4-8 ng/ml) for 6-months. Stratifying for histology & type of response, patients with complete (Up/Uc <0.2 mg/mg) or partial remission (Up/Uc 0.2-2, albumin >2.5 g/dl) were randomized to continue Tac or receive MMF (0.75-1 g/m²/d), prednisone & enalapril. Primary outcome, at 12-mo, was proportion with remission or infrequent relapses. Therapy failure was recurrent SRNS, frequent relapses or >1 SAE. Enrolment was closed after interim intention-to-treat analysis of outcome in 1/3 sample.

Results: Baseline features were similar. Therapy with MMF led to significantly higher treatment failure, prednisone dose & SAE; eGFR change was similar. On multivariate regression, hazards of treatment failure were high with MMF (HR 9.7, adjusted for histology, type of resistance & remission; P<0.0001).

Baseline	Tac, N=31	MMF, N=29
Minimal change/FSGS	17/16	17/12
Initial resistance	15	13
Age months	76±46	77±46
Complete/partial remission	19/12	18/11
Albumin g/dl	4.2±0.5	4.3±0.5
OUTCOMES		
Satisfactory remission^	28; 90%	13; 48%
Complete/partial remission	17	12
Infrequent relapses	11	1
Treatment failure^	3	16
Frequent relapses	3	8
Steroid resistance	0	8
Relapse/yr	0.8±1.0	1.3±1.3
Prednisone mg/kg/d^	0.3±0.2	0.5±0.4
Change eGFR ml/min/1.73m ²	-6±35	-19±31
P<0.0005;^0.028		

Conclusions: Therapy with MMF is inferior to Tac in maintaining Tac induced remission in patients with SRNS

HI-OR06

Prevention of Bone Mineral Density Loss in De Novo Kidney Transplant Recipients with Twice-Yearly Denosumab: A Randomized Controlled Trial (ClinicalTrials.gov number NCT01377467) Rudolf P. Wuthrich,¹ Diana P. Frey,² Jens Gunther Brockmann,³ Thomas Fehr,¹ Thomas F. Mueller,¹ Lanja Saleh,⁴ Arnold Von Eckardstein,⁴ Nicole Graf,⁵ Marco Bonani.¹ ¹*Div of Nephrology*; ²*Div of Rheumatology*; ³*Div of Visceral and Transplantation Surgery*; ⁴*Inst of Clinical Chemistry, Univ Hospital, Zurich, Switzerland*; ⁵*Graf Biostatistics, Winterthur, Switzerland.*

Background: Kidney transplantation is associated with bone loss and an increased risk of fracture. Since current therapeutic options to prevent bone loss are limited we assessed the efficacy and safety of Receptor Activator of Nuclear Factor κB Ligand (RANKL) inhibition with denosumab to improve bone mineralization in the first year after kidney transplantation.

Methods: We enrolled 108 kidney transplant recipients and randomized 90 patients two weeks after surgery in a 1:1 ratio to receive denosumab (subcutaneous injections of 60 mg denosumab at baseline and after 6 months) or no treatment. The primary endpoint was the percentage change in bone mineral density (BMD) measured by DXA at the lumbar spine at 12 months.

Results: After 12 months, the primary outcome of total lumbar spine BMD increased by 4.6% (95% CI 3.3-5.9%) in 46 patients in the denosumab group and decreased by -0.5% (95% CI -1.8-0.9%) in 44 patients in the control group (between-group difference 5.1%, 95% CI 3.1-7.0%, p<0.0001). Denosumab also significantly increased BMD at the total hip by 1.9% (95% CI 0.1 to 3.7%; p=0.035) over that in the control group at 12 months. HR-pQCT in a subgroup of 24 patients showed that denosumab also significantly increased BMD and cortical thickness at the distal tibia and radius (p<0.05). Biomarkers of bone resorption (β-CTX, urine deoxypyridinoline) and bone formation (P1NP, BSAP) markedly decreased with denosumab (p<0.0001). Episodes of cystitis and asymptomatic hypocalcemia occurred more often with denosumab, whereas graft function, rate of rejections and incidence of opportunistic infections were similar.

Conclusions: Antagonizing RANKL with denosumab effectively increased BMD in *de novo* kidney transplant recipients, but was associated with more frequent episodes of urinary tract infection and decreased calcemia.

HI-OR07

Randomized, Double-Blind, Placebo-Controlled, Parallel, 3-Arm Study of Safety and Anti-Pruritic Efficacy of Nalbuphine HCl ER Tablets in Hemodialysis Patients with Uremic Pruritus Vandana S. Mathur,¹ Jayant Kumar,⁵ Paul W. Crawford,³ Howard Hait,⁴ Thomas Sciascia.² ¹*MathurConsulting*; ²*Trevi Therapeutics*; ³*Research by Design*; ⁴*Edenridge Consulting*; ⁵*Renal Medical Associates.*

Background: Uremic pruritus (UP) is associated with decrements in quality of life and sleep and higher mortality. UP pathogenesis may involve endogenous κ/μ opioid ligand ratio imbalance. Nalbuphine ER tablets (NAL) are a κ-opioid agonist/μ-opioid antagonist being developed for chronic pruritic conditions.

Methods: 373 hemodialysis patients (HDP) with mean baseline numerical rating scale score (NRS) ≥ 4.5 for worst itching (0 [no itch] -10 [worst possible itching]) were randomized 1:1:1 to NAL 60 mg (n = 128), NAL 120 mg (n=120), or placebo (n = 125) and treated for 8 weeks.

Results: Demographics, dialysis adequacy and vintage, phosphorus, parathyroid hormone, pruritus duration, and antihistamine use were similar in the 3 arms at baseline. The primary efficacy endpoint was the change from Baseline to the Evaluation Period (Weeks 7 and 8) in the NRS for each dose of NAL, with pre-specified hierarchical ordering – the 120 mg vs. placebo comparison was performed first. The mean (SD) NRS in the NAL 120 mg group declined from 6.94 (1.46) to 3.51 (2.11), with an LS mean decline vs. placebo = -0.73 (0.31), p = 0.017. The mean NRS in the NAL 60 mg group declined from 6.87 (1.40) to 4.95 (2.10), with an LS mean decline vs. placebo = -0.24 (0.31), p = 0.432. A statistically significant mean reduction for NAL 120 compared to placebo was observed as early as one week following titration. The most common adverse events were nausea, vomiting, dizziness and somnolence with incidence rates of these events quickly approaching that of placebo after the first week of titration. Among subjects with NRS ≥7 (post-hoc analysis), NAL 120 reduced NRS by 4.48 (SD) vs. 3.16 (SD) vs. placebo (p=0.007) with sleep quality (Itch MOS sleep scale) improved significantly (p=0.006).

Conclusions: Nalbuphine ER tablets at a dose of 120 mg BID were safe and significantly reduced itching intensity.

HI-OR08

The Omega-3 Fatty Acids (Fish Oils) and Aspirin in Vascular Access Outcomes in Renal Disease (FAVOURED) Study: A Randomised Placebo-Controlled Trial Ashley B. Irish.^{1,2} ¹*Nephrology, Fiona Stanley Hospital, Perth, Western Australia, Australia*; ²*Australasian Kidney Trials Network, Univ of Queensland, Brisbane, Queensland, Australia.*

Background: Increasing the use of arteriovenous fistulae (AVF) to improve haemodialysis access is limited by early thrombosis and maturation failure. Omega-3 polyunsaturated fatty acids (w3FA) may prevent these complications by inhibition of platelet aggregation, vasoconstriction, intimal hyperplasia and inflammation.

Underline represents presenting author/disclosure.

Methods: This international, randomised, double-blind, placebo-controlled trial examined whether 3 months therapy with w3FA (4g/day) reduced primary AVF failure at 12 months after AVF creation. AVF failure was defined as AVF thrombosis and/or abandonment and/or cannulation failure. A subset of patients received aspirin (100mg/day) or matching placebo in addition to w3FA or placebo in a factorial design (n=388).

Results: The 567 randomised participants had a mean age of 55 years, 63% were male and 46% diabetic. AVF failure occurred in 128/270 (47%) participants assigned to w3FA compared with 125/266 (47%) assigned to placebo (relative risk adjusted for aspirin use [RR] 1.03, 95% confidence interval [CI] 0.86-1.23, $p=0.78$). Regarding each component of AVF failure, w3FA did not reduce the risk of thrombosis (22% vs 23%, RR 0.98, 95% CI 0.72-1.34, $p=0.90$), AVF abandonment (19% vs 22%, RR 0.87, CI 0.62-1.22, $p=0.43$) or cannulation failure (40% vs 39%, RR 1.03, 0.83-1.26, $p=0.81$). A subgroup difference was observed for diabetes mellitus (interaction $p=0.038$; RR 1.30 vs 0.78; diabetics vs non-diabetics) but not for age, gender, AVF site, dialysis modality and cardiovascular disease. There was no difference in any serious adverse event (AE), 9.2% vs 13.0%, $p=0.14$; bleeding, 8.1% vs 10.9% $p=0.26$, or gastrointestinal AE, 4.9% vs 5.4%, $p=0.86$. The risk of AVF failure was similar (45% vs 43%, RR 1.05, 95% CI 0.84-1.31) in the subset of participants randomised to aspirin or placebo-aspirin as part of the factorial design.

Conclusions: Three months of w3FA intake was ineffective in reducing primary AVF failure at 12 months. Aspirin may be similarly ineffective. There was no increased risk of bleeding. Neither w3FA nor aspirin increased the proportion of useable de novo AVF.

The Remote Ischemic Preconditioning in Cardiac Surgery Trial (Remote IMPACT) Michael Walsh.^{1,2} ¹McMaster Univ; ²Population Health Research Inst.

Background: Cardiac surgery is frequently complicated by ischemia-reperfusion injury which can lead to kidney and myocardial injury. Preoperative Remote Ischemic Preconditioning (RIPC), cycles of brief ischemia to a limb alternating with reperfusion, may reduce the frequency or severity of organ injury after cardiac surgery.

Methods: We randomly allocated 258 patients at high risk for death after cardiac surgery to receive either RIPC or a sham procedure immediately after induction of anesthesia. RIPC consisted of 3 cycles of thigh tourniquet inflation to 300 mmHg for 5 minutes followed by 5 minutes reperfusion. The sham group tourniquets were inflated to 15 mmHg. Patients and care providers were blinded. The main clinical outcomes were change in creatinine over the first 4 postoperative days and the peak CK-MB within 24 hours of surgery. Other outcomes were assessed to 30 days after randomization. Analyses were performed according to the intention-to-treat principle.

Results: We randomized 128 patients to RIPC and 130 to sham. No patients were lost to follow-up. There was no significant between group differences in postoperative change in creatinine ($p=0.79$) or peak CK-MB ($p=0.18$) (Figure 1). We found no significant differences in the frequency of acute kidney injury (34% vs 31%), myocardial injury (24% vs 19%), stroke (4% vs 3%) or mortality (6% vs 5%) at 30 days.

Figure 1. Mean and 95% confidence intervals of creatinine over time for the RIPC (green diamonds) and sham (blue circles) groups.

Conclusions: In this trial RIPC did not affect markers of kidney and myocardial injury. These results fail to provide proof-of-concept that RIPC may impact clinically important outcomes in the cardiac surgery setting.

SA-PO1092

Nephrotoxicity of Invasive and Noninvasive Coronary Angiography: Randomized Controlled Study of Intracoronary and Intravenous Contrast Agent Administration Eva Schöenberger,¹ Patricia D. Bady,² Peter Martus,³ Elke Zimmermann,² Michael Laule,⁴ Marc Dewey.² ¹Anesthesiology, Charité, Berlin, Germany; ²Radiology, Charité, Berlin, Germany; ³Inst for Clinical Epidemiology and Applied Biostatistics, Eberhard Karls Univ, Tübingen, Germany; ⁴Cardiology, Charité, Berlin, Germany.

Background: Iodinated contrast agents can have nephrotoxic effects. It is unknown whether nephrotoxicity is more likely following intracoronary or intravenous contrast agent administration.

Methods: We randomly assigned patients with suspected coronary disease to either intracoronary contrast agent for invasive coronary angiography (ICA) or intravenous administration for coronary computed tomography angiography (CTA). The same low-osmolar nonionic contrast agent with a concentration of 350 mg iodine per milliliter was used for ICA and CTA. Blood samples were taken before and at two time points after ICA and CTA (18 to 24 hours and 46 to 50 hours) to identify contrast-induced acute kidney injury defined according to the most commonly used definition as an increase in creatinine of at least 0.5 mg per deciliter or 25%.

Results: We enrolled 340 patients of whom 10 and 4 dropped out from the ICA and CTA group, respectively, leaving 161 and 165 patients who underwent ICA and CTA until September 8, 2015. Baseline creatinine levels in the ICA (0.85±0.19) and the CTA group (0.87±0.21 mg per deciliter) were similar ($P=0.34$). Follow-up creatinine was not available in 3 and 5 patients in the ICA and CTA group, respectively. Twenty-one of the 158 patients in the ICA group (13%) had an increase in creatinine of at least 0.5 mg per deciliter or 25%, as compared with 9 of the 160 patients in the CTA group (6%; $P<0.05$). In patients without coronary disease on ICA or CTA, such a creatinine increase was found in 17 of the 134 patients in the ICA group (13%) and 6 of the 139 patients in the CTA group (4%; $P<0.05$). No patient without coronary disease in the CTA group had an increase in creatinine according to the KDIGO definition of at least 0.3 mg per deciliter or 50%, but 6 of the 134 patients in the ICA group (4%; $P<0.05$).

Conclusions: Nephrotoxicity may be more likely after intracoronary than after intravenous contrast agent administration.

Funding: Government Support - Non-U.S.

SA-PO1093

Efficacy and Safety of Bosutinib in Autosomal Dominant Polycystic Kidney Disease: A Phase 2, Randomized, Double-Blind, Placebo-Controlled Study Kazimierz Ciechanowski,¹ Vladimir Tesar,² York P. Pei,³ Irina Barash,⁴ Megan Shannon,⁵ Ruifeng Li,⁶ Jason Williams,⁷ Matteo Leviseti,⁸ Steven Arkin,⁶ Andreas L. Serra.⁹ ¹Pomeranian Medical Univ, Szczecin, Poland; ²Charles Univ, Prague, Czech Republic; ³Univ Health Network, Toronto, Ontario, Canada; ⁴Icahn School of Medicine at Mount Sinai, New York, NY; ⁵Pfizer Inc, San Diego, CA; ⁶Pfizer Inc, Cambridge, MA; ⁷Sanofi US, Bridgewater, NJ; ⁸Roche Pharma Research and Development, Basel, Switzerland; ⁹Inst für Allgemeine Innere Medizin und Nephrologie, Suisse ADPKD Hirslanden, Zurich, Switzerland.

Background: Src overactivation has been linked to the pathogenesis of autosomal dominant polycystic kidney disease (ADPKD). We assessed efficacy and safety of bosutinib (BOS), an oral dual Src/Abl tyrosine kinase inhibitor, in ADPKD patients (pts).

Methods: In this phase 2, multicenter study (NCT01233869), ADPKD pts with estimated glomerular filtration rate ≥ 60 mL/min/1.73 m² and magnetic resonance image (MRI)-confirmed total kidney volume (TKV) ≥ 750 cc were randomized 1:1 to placebo (PBO), 200 mg/d, or 400 mg/d of oral BOS for ≥ 24 mo. The primary endpoint was annualized TKV % change. Pts treated for ≥ 2 wk who had an MRI after a 30-d washout period were in the modified intent-to-treat (mITT) analysis.

Results: 169 of 172 enrolled pts received ≥ 1 dose of treatment. 24 pts who initially received 400 mg/d BOS were later reduced to 200 mg/d BOS per protocol. 88 pts (52%) were in the mITT population (200 mg/d, n=27; 400 mg/d, n=7; 400 to 200 mg/d, n=21; PBO, n=33) after discontinuations (unrelated to study drug, 27%; study drug-related adverse events, 17%; consent withdrawal, 14%). Annual rate of kidney enlargement was significantly reduced for pooled BOS vs PBO (0.84% vs 4.74%, respectively, 95% CI for difference in annualized rates [2.02-5.74]; $p<0.0001$) and was 65.2% lower for BOS 200 mg/d vs PBO (1.63% vs 4.74%, respectively, 95% CI [0.93 to 5.23]; $p=0.005$). Gastrointestinal (GI) effects were dose-dependent for BOS; the overall safety profile, including GI toxicities, was consistent with the known profile of BOS.

Conclusions: BOS reduced the annual rate of kidney enlargement vs PBO in ADPKD pts, and the safety profile was consistent with the BOS label.

Low Osmolar Diet and Adjusted Water Intake for Vasopressin Suppression in ADPKD: A Randomized Controlled Trial Osama W. Amro,^{1,2} Jessica K. Paulus,^{1,2} Farzad Noubary,^{1,2} Ronald D. Perrone.^{1,2} ¹Nephrology, Tufts Medical Center, Boston, MA; ²Tufts Univ School of Medicine.

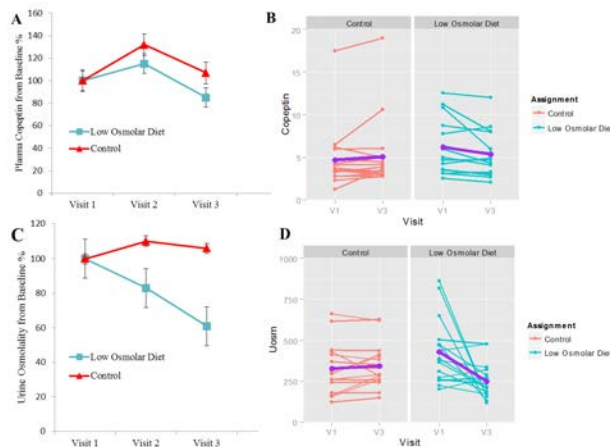

Background: Autosomal dominant polycystic kidney disease (ADPKD) affects 12.5 million persons worldwide. Vasopressin promotes disease progression.

Methods: This randomized trial examined the effect of combining a low osmolar diet and adjusted water intake on vasopressin as measured by change in plasma copeptin, and

Underline represents presenting author/disclosure.

urinary osmolality in 34 ADPKD patients. Participants were randomized to receive a low osmolar diet (low sodium (1500 mg/day), low protein (0.8 gram/kg body weight) diet) followed by adjusted water intake to achieve a urine osmolality of ≤ 280 mOsm/L versus no intervention for two weeks.

Results: Change from baseline to two weeks between intervention and control groups was statistically significant for the primary outcome of copeptin and urine osmolality (-0.86 ± 1.3 pmole/L versus $+0.39 \pm 1.2$ pmole/L ($p=0.009$) and -167 ± 264 mOsm/L versus $+20 \pm 80$ mOsm/L (0.007) respectively). Mean plasma copeptin and urine osmolality declined from 6.2 ± 3.05 to 5.3 ± 2.5 pmole/L ($p=0.3$) and from 426 ± 193 to 258 ± 117 mOsm/L ($p=0.003$) respectively in the intervention group compared to a non-significant increase from 4.7 ± 3.6 to 5.07 ± 4 pmole/L ($p=0.7$) and from 329 ± 159 to 349 ± 139 mOsm/L ($p=0.6$) in the control group.

Total urinary solute decreased only in the intervention group and significantly differed between groups at week one ($p=0.03$) reducing mean water prescription from 3.2 to 2.6 liter/day.

Conclusions: we developed a step wise dietary intervention that led to significant reduction in vasopressin in ADPKD patients. Furthermore, this intervention led to reduction in water required for vasopressin suppression. Long-term studies are needed to determine if vasopressin suppression slows ADPKD progression.

Funding: Other NIH Support - Dr. Amro is supported by NIH 5T32DK007777 institutional training grant. This project was performed and Dr. Perrone were supported in part by the National Center for Advancing Translational Sciences (NCATS), National Institutes of Health (NIH), Grant Number UL1 TR001064.

A Phase 2, Double-Blind, Randomized Study of Fresolimumab or Placebo in Patients with Steroid-Resistant Primary Focal Segmental Glomerulosclerosis James A. Tumlin,¹ Flavio Vincenti,² Fernando C. Fervenza,³ Kirk N. Campbell,⁴ Montserrat M. Diaz Encarnacion,⁵ Manuel Praga,⁶ Denyse Thornley-Brown,⁷ Francisco Verissimo Veronese,⁸ Beverly Accomando,⁹ Sara Engstrand,¹⁰ Steven R. Ledbetter,¹⁰ Julie Lin,¹⁰ John F. Neylan.¹⁰ ¹UT Coll. of Med., Chattanooga, TN; ²UCSF, San Francisco, CA; ³Mayo Clinic, Rochester, MN; ⁴Icahn Sch. of Med. at Mt. Sinai, New York, NY; ⁵Fundacion Puigvert, Barcelona, Spain; ⁶Hosp. Univ 12 de Oct., Madrid, Spain; ⁷Univ of Alabama at Birmingham, AL; ⁸Hosp. de Clinicas de Porto Alegre, Brazil; ⁹Sanofi, Cambridge, MA; ¹⁰Formerly Genzyme, Sanofi.

Background: Steroid-resistant primary FSGS confers substantial risk of morbidity & progressive kidney failure. Fresolimumab (freso), a neutralizing mAb to all 3 isoforms of TGF- β , is a potential new treatment.

Methods: 36 pts with biopsy-proven nephrotic-range FSGS randomized to freso 1mg/kg ($n=14$) v 4mg/kg ($n=12$) v placebo (PL) ($n=10$) for D112, allowed immunosuppressives after D112 & followed up double-blind for D252. 1° outcome: proteinuria remission; 2° outcomes included changes in Up/c & eGFR.

Results: Pts: 53% male; median 41 y; 17% Black, 31% Hisp. Baseline (BL) median Up/c: 6.19mg/mg; eGFR, 63 ml/min/1.73 m². 72% pts received prior CNL. Durable partial remission ($>50\%$ Up/c decrease from BL to <3 mg/mg): 3 pts, 1mg/kg; 2 pts, 4mg/kg; 1 pt, PL; 1 additional pt on 1mg/kg had steep & consistent Up/c decline from 17–4mg/mg. All 7 freso responders were Black/Hisp. Mean Up/c changes at D112: -18.5% (1mg/kg, $P=0.008$), +10.5% (4mg/kg, $P=0.52$), +9.0% (PL, $P=0.91$). eGFR showed nonsignificant trend for stability in freso v decline in PL. Freso was generally well tolerated with no significant difference in AEs in low v high doses.

Number of Patients							
Fresolimumab 1 mg/kg	14	14	14	14	14	14	14
Fresolimumab 4 mg/kg	12	12	12	12	12	11	11
Placebo	10	10	10	10	10	10	9
Fresolimumab Pooled	26	26	26	26	25	25	25

Conclusions: In steroid-resistant FSGS, freso may be associated with proteinuria remission. Black & Hisp pts may have higher response rates. Freso merits continued evaluation in FSGS.

Effects of Sustained-Release Beraprost Sodium in Patients with Primary Glomerular Disease or Nephrosclerosis: The CASSIOPEIR Study Toshiro Fujita,¹ Xueqing Yu,² Suhnggwon Kim,³ Hidetomo Nakamoto,⁴ Hideki Origasa,⁵ Hajimu Kurumatani,⁶ Takashi Kiriya.⁷ ¹The Univ of Tokyo, Tokyo, Japan; ²The First Affiliated Hospital, Sun Yat-sen Univ, Guangzhou, Guangdong, China; ³Seoul National Univ Hospital, Seoul, Korea; ⁴Saitama Medical Univ, Saitama, Japan; ⁵The Univ of Toyama, Toyama, Japan; ⁶Toray Industries, Inc, Tokyo, Japan; ⁷Astellas Pharma Inc., Tokyo, Japan.

Background: No single treatment, except RAS inhibitors, can delay progression of CKD. TRK-100STP, a sustained-release tablet of an orally-active prostacyclin analogue, beraprost sodium, is suggested to suppress worsening of renal filtration function. We aimed to demonstrate superiority of TRK-100STP over placebo in patients with CKD, either as primary glomerular disease or nephrosclerosis; determine the recommended dose of TRK-100STP; and evaluate its safety profile.

Methods: We performed a randomized, double-blind, placebo-controlled, parallel-group comparative study at 160 sites in seven Asian-Pacific countries and regions (CASSIOPEIR: CRF Asian Study with Oral PGI₂ Derivative for Evaluating Improvement of Renal Function). Patients entered a run-in period with oral administration of placebo twice daily for two to eight weeks. Patients meeting the inclusion/exclusion criteria at the end of the run-in period ($n=892$) were randomized to TRK-100STP 120 mg, TRK-100STP 240 mg, or placebo for a treatment period of two to four years. The primary efficacy endpoint was the time to first occurrence of a renal composite endpoint: doubling of SCr or occurrence of end-stage renal disease. ClinicalTrials.gov identifier: NCT01090037.

Results: No significant differences were evident observed in renal composite endpoints between TRK-100STP and placebo (2-sided 5% significance level, $P=0.5674$). The overall incidence of adverse events and adverse drug reactions was comparable between the treatment arms.

Conclusions: TRK-100STP did not demonstrate superiority over placebo, and the recommended therapeutic dose for patients with CKD either primary glomerular disease or nephrosclerosis was not determined. However, no findings raised safety concerns in the comparison between TRK-100STP and placebo.

SA-PO1097

Corticosteroid Monotherapy versus Combined Immunosuppression in IgA Nephropathy: Insights from the STOP-IgA Trial Jürgen Floege,¹ Thomas Rauen,¹ Frank Eitner,³ Christina Fitzner,² Ralf-Dieter Hilgers.² ¹Nephrology, RWTH Aachen Univ, Aachen, Germany; ²Biostatistics, RWTH Aachen Univ, Aachen, Germany; ³Bayer AG, Wuppertal, Germany; ⁴For the STOP-IgA Investigators.

Background: In high-risk IgA nephropathy (IgAN) the value of immunosuppression is controversial.

Methods: We recently reported a randomized, controlled trial in IgAN patients (STOP-IgA trial). Following 6 months of optimized supportive treatment 162 trial participants, who still displayed a proteinuria >0.75 g/d, entered a 3 year study phase and were randomized to continue on supportive therapy (SUP) or to receive additional immunosuppression (IMM). IMM-patients with an eGFR >60 ml/min/1.73m² received a 6-month corticosteroid monotherapy ("Pozzi-protocol"). Patients with an eGFR of 30 to

Underline represents presenting author/disclosure.

59 ml/min/1.73m² received cyclophosphamide for 3 months, followed by azathioprine, plus oral prednisolone ("Ballardie protocol"). Primary endpoints were (i) full clinical remission (proteinuria < 0.2 g/g and eGFR loss of < 5 ml/min) and (ii) eGFR loss >15 ml/min from baseline to trial end.

Results: Here we report a secondary analysis of the two IMM subgroups versus corresponding SUP patients matched for eGFR. The intention-to-treat (ITT) analysis assuming a worst-case scenario at 3 years is shown in the table.

Endpoint	GFR >60 ml/min/1.73m ² IMM vs. SUP (n = 55 vs. 54)	GFR 30-59 ml/min/1.73m ² IMM vs. SUP (n = 27 vs. 26)
Full clinical remission	OR 5.23 (95%-CI 1.29-21.15), p=0.020	OR 2.77 (95%-CI 0.38-32.29), p=0.319
eGFR loss >15 ml/min	OR 0.65 (95%-CI 0.27-1.56), p=0.333	OR 1.62 (95%-CI 0.49-5.61), p=0.428

Patients treated with the Pozzi protocol had a transient decrease in proteinuria after 12 months and significantly less microhematuria at trial end compared to matched SUP patients. In the group with the low eGFR range, there were no significant differences between both arms. Compared to supportive care, more patients receiving immunosuppression developed severe infections, impaired glucose tolerance and weight gain in year one.

Conclusions: Our secondary analyses provide little evidence for a stabilization of renal function with immunosuppression in the group with an eGFR >60 ml/min and no evidence for a benefit in patients with a lower eGFR.

A Randomized Trial of Rituximab in Advanced IgA Nephropathy

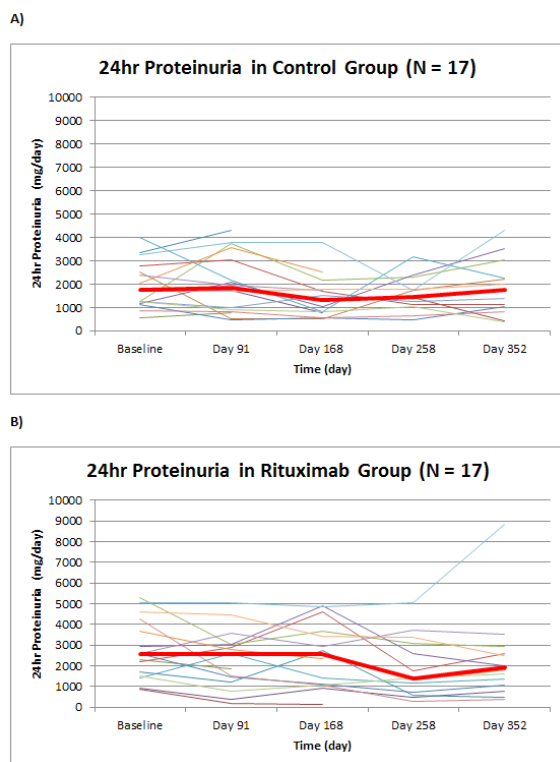

Richard A. Lafayette,¹ Pietro A. Canetta,² Brad H. Rovin,³ Gerald B. Appel,² Marie C. Hogan,⁴ Stephen B. Erickson,⁴ Fernando C. Fervenza.⁴ ¹Stanford Univ, Stanford, CA; ²Columbia Univ, New York, NY; ³Ohio State Univ, Columbus, OH; ⁴Mayo Clinic, Rochester, NY.

Background: IgA nephropathy (IgAN) frequently leads to progressive renal dysfunction. Present immunosuppressive treatment remains uncertain in terms of benefit and risks side effects. B cells are an attractive target in IgAN so we performed a pilot trial of rituximab in subjects at high risk of progression.

Methods: Patients with biopsy proven IgAN, more than 1 g/d of proteinuria despite RAASI (or >0.5 g/d if on dual RAASI), well controlled blood pressure (BP) and eGFR <90ml/min were randomized to 1 year of rituximab therapy (4g total) vs ongoing BP control, fish oil and use of RAASI. They were followed for B cell depletion, effects on proteinuria and changes in eGFR. Safety signals were also followed.

Results: 34 patients were randomized. Baseline serum creatinine was 1.5±0.5 mg/dl and proteinuria was 2.1, 0.6-5.5 g/d. There was no change in BP during the study. Treatment with rituximab resulted in significant B cell depletion and was generally well tolerated. There was no change in renal function during the study in either group. Rituximab treatment had no significant effect on proteinuria compared to baseline or control patients, and 3/17 patients in each group experienced a ≥ 50% reduction in proteinuria during the study.

Figure 1: Proteinuria in (A) Control vs. (B) Rituximab Groups. The heavy weight red line represents median data.

Underline represents presenting author/disclosure.

Conclusions: In this small study, rituximab therapy had no influence on renal function or proteinuria in subjects with advanced disease due to IgA nephropathy. There were numerically greater reductions in proteinuria, but this did not reach significance. Few patients had substantial responses in either group. These results do not support the use of rituximab as treatment for patients with IgA nephropathy.

Establishing Endpoints for Lupus Nephritis Clinical Trials: Progress by the Kidney Health Initiative/Lupus Nephritis Trials Network Collaboration

Brad H. Rovin,¹ Meggan Mackay,² Joanna Stein,² Maria Dall'Era,⁴ Kenneth Kalunian,³ Martin L. Lesser,² Melissa West.⁵ ¹Ohio State Univ; ²Feinstein Inst; ³Univ Calif San Diego; ⁴Univ Calif San Francisco; ⁵American Society of Nephrology.

Background: There are no universally accepted endpoints for lupus nephritis (LN) clinical drug trials. To obtain approval of new therapies a uniform endpoint that can be applied to future LN trials is needed. The optimal endpoint is a short-term measurement that accurately reflects long-term kidney survival. The present work was undertaken to define LN trial endpoints.

Methods: Clinical data at LN flare (baseline) and during serial follow-up (minimum 22 months) from 751 patients were analyzed. Clinical variables at baseline and after 6 and 12 months were tested as predictors of adverse long-term renal outcomes, in this case time to new chronic kidney disease (CKD), defined as a sustained increase in serum creatinine (SCR) ≥30%. Multivariable Cox regression analysis was used to model time to CKD.

Results: After accounting for missing data 507 patients were included in the final analysis. This cohort was 89% female, 56% White, 20% Asian and 14% Black. The average baseline SCR was 1.2±0.7 mg/dl, proteinuria was 4.1±3.4 g/d, and eGFR by CKD^{EP} was 81±35 ml/min. Median follow-up was 42 months (range: 22-147 months). By univariate analysis urine RBCs, race, complement C3, SCR, eGFR and proteinuria were potential significant predictors of time to CKD. By multivariate modeling the significant predictors of future CKD were: SCR at 12 months (p=0.0005, Hazard Ratio (HR) 1.8 (95%CI: 1.3-2.5)); proteinuria at 12 months (p<0.0001; HR 1.6 (1.3-1.8)); and an increase in eGFR >10% from baseline to 12 months compared to no change in eGFR (p<0.0001; HR 0.4 (0.3-0.6)).

Conclusions: We have identified 3 highly significant predictors of time to CKD in LN patients that can be measured during the first 12 months of treatment for flare. These can be developed into a composite endpoint for future LN therapeutic trials. Unexpectedly, small improvements in eGFR appear to predict renal survival. Also, because urine RBCs do not appear to predict time to CKD, it may be possible to exclude urinalysis as an endpoint component in future clinical trials.

Grazoprevir (GZR)/Elbasvir (EBR) Treatment of Hepatitis C Virus (HCV) Infection in Patients with Chronic Kidney Disease Stage 4/5: Final Results of the C-SURFER Phase 3 Study

David Roth,¹ Annette Bruchfeld,² Paul Martin,¹ David R. Nelson,³ Marcelo Silva,⁴ Howard Mounour,⁵ Laurent Alric,⁶ Shuyan Wan,⁷ Beth Jackson,⁷ Bach-Yen Nguyen,⁷ Janice Wahl,⁷ Eliav Barr,⁷ Wayne L. Greaves.⁷ ¹Univ of Miami, Miami, FL; ²Karolinska Inst, Stockholm, Sweden; ³Univ of Florida, Gainesville, FL; ⁴Hospital Univ Austral, Pilar, Buenos Aires, Argentina; ⁵Houston Methodist Hospital, Houston, TX; ⁶Hôpital de Purpan, Toulouse, France; ⁷Merck & Co., Inc., Kenilworth, NJ.

Background: Limited options are available for treating HCV infection in patients with advanced kidney disease. C-SURFER is the first randomized, placebo-controlled phase 3 study to evaluate an all-oral, ribavirin-free regimen in CKD 4/5 patients.

Methods: 224 patients with HCV genotype (G)1 and CKD 4/5 ± hemodialysis (HD) were randomized to GZR/EBR 100/50mg (Immediate Treatment Group, ITG; n=111) or placebo for 12 weeks. Placebo subjects (deferred treatment group, DTG; n=113) received GZR/EBR after placebo therapy. 11 additional subjects received GZR/EBR with intensive pharmacokinetic (PK) sampling. The primary safety comparison was GZR/EBR vs. placebo. The primary efficacy endpoint, sustained virologic response (SVR) 12 weeks post-therapy in the ITG+PK group, was reported previously. Here we report the final results, including data from subjects who received GZR/EBR after placebo.

Results: In the placebo-controlled phase, serious adverse events (AEs) occurred in 16 (14%) GZR/EBR and 17 (15%) placebo subjects; discontinuation due to an AE in GZR/EBR and placebo subjects was 0% and 4%. SVR12 in all subjects who received GZR/EBR was 94.6% (ITG+PK, 94.3% [115/122]; DTG after placebo, 95.0% [96/101]). 12 subjects failed to attain SVR12: virologic relapse, n=3; discontinuation for AE, n=1; admin reason, n=8. Excluding subjects who discontinued for reasons unrelated to study drug, overall SVR12 was 98.6% (211/214). PK data indicate no need for dose adjustment in HD patients (geometric mean ratio [HD/non-HD] ranged from 0.67-0.85 for GZR and 1.43-1.67 for EBR).

Conclusions: Once-daily GZR/EBR for 12 weeks was highly effective with a low rate of adverse events in patients with advanced kidney disease and HCV G1 infection.

Long-Term (52-Week) Efficacy and Safety of ZS-9 in the Treatment of Hyperkalemia: Interim Results From a Phase 3 Open-Label, Multi-Center, Multi-Dose Maintenance Study James A. Tumlin,¹ Mikhail Kosiborod,² Pablo E. Pergola,³ Wajeh Y. Qunibi,⁴ David K. Packham,⁵ Simon D. Roger,⁶ Edgar V. Lerma,⁷ Steven Fishbane,⁸ Henrik S. Rasmussen,⁹ Bruce S. Spinowitz.¹⁰ ¹U of Tennessee College of Medicine, TN; ²Saint Luke's Mid America Heart Inst., MO; ³Renal Associates PA, TX; ⁴U of Texas Health Science Center, TX; ⁵Melbourne Renal Research Group, Australia; ⁶Renal Research, Gosford, Australia; ⁷U of Illinois, IL; ⁸North Shore U. Hospital, NY; ⁹ZS Pharma, Inc., TX; ¹⁰Weill Medical College, NY.

Background: Hyperkalemia (HK) is a common and potentially lethal electrolyte disorder, often induced with the use of renin-angiotensin-aldosterone inhibitors (RAASi). Currently, the use of RAASi is prevented by HK and thus the potential for cardiac and renal protective effects of these agents is limited. In previous studies, ZS-9 (sodium zirconium cyclosilicate), a selective K⁺-ion trap, significantly lowered serum K⁺ and maintained normokalemia (NK) for up to 28 days. We present the results to date of the largest ever phase 3 trial examining the efficacy of ZS-9 in treating HK patients for up to 52wks.

Methods: ZS-005 (target N=750) is a multicenter, ongoing, open-label study evaluating ZS-9 treatment for 52wks in ambulatory pts with HK (K⁺ ≥ 5.1 mEq/L) with or without concurrent RAASi therapy. In the acute phase (AP), pts with HK received 10g ZS-9 TID over a 24-72hr period until NK (K⁺ 3.5-5.0 mEq/L) was achieved. Pts achieving NK were enrolled in a 52wk maintenance phase (MP) starting with 5g ZS-9 QD. There were no restrictions on diet and ZS-9 could be titrated to maintain NK. Primary outcomes were proportion of pts with mean K⁺ ≤ 5.1 mEq/L during MP and safety of ZS-9.

Results: To date, 583 pts with a mean baseline K⁺ of 5.6 mEq/L (15% ≥ 6.0 mEq/L) entered the study. Overall, 575 (99%) normalized K⁺ in AP and transitioned to the MP. To date, K⁺ was maintained at ≤ 5.1 and < 5.5 mEq/L in 87% and 99% of patients, respectively. The incidence and severity of adverse events were similar to that of previous studies.

Conclusions: ZS-9 acutely reduced K⁺ levels in pts with HK and maintained NK for up to 52wks irrespective of RAASi use. ZS-9 may control HK, both emergent and long-term, while allowing continued use of cardio- and reno-protective RAASi.

Interleukin-1 Inhibition and Vascular Function in Patients with Chronic Kidney Disease (CKD): A Randomized Controlled Trial Kristen L. Nowak,¹ Michel Chonchol,¹ Talat Alp Ikizler,² Heather Farmer,¹ Natjalie Salas,² Rafia I. Chaudhry,² Wei Wang,¹ Gerard John Smits,¹ Adriana Hung.^{2,3} ¹Univ of Colorado Denver; ²Vanderbilt Univ; ³VA Tennessee Valley Healthcare System.

Background: Vascular endothelial dysfunction and increased arterial stiffness contribute to increased cardiovascular risk in CKD patients who exhibit chronic systemic inflammation. As chronic inflammation is a key mechanism contributing to vascular dysfunction, blocking inflammation may reduce cardiovascular risk in CKD.

Methods: In a two-site, double-blind trial, n=42 patients with stage 3-4 CKD were randomized to receive either the interleukin-1 (IL-1) trap rilonacept (subcutaneous injection; loading dose of 320 mg followed by 160 mg/wk) or placebo for 12 weeks. All patients were receiving optimal treatment of hypertension, diabetes, and/or hypercholesterolemia, with 64% and 62% receiving a statin and an ACE inhibitor or ARB, respectively. The co-primary endpoints were change in brachial artery flow-mediated dilation [FMD_{BA}] and aortic pulse-wave velocity [aPWV] after 4, 8 and 12 weeks using mixed effects models. Secondary endpoints were change in high-sensitivity C-reactive protein (hsCRP), ΔFMD_{BA} following an acute infusion of ascorbic acid known to inhibit superoxide production (n=23), and vascular endothelial cell protein expression of NADPH oxidase (n=13).

Results: Participants were 63±11 (mean±s.d.) years of age, 24% female and 24% Black, with eGFR 38±13 ml/min/1.73m². Rilonacept improved FMD_{BA} (baseline: 3.8±3.1%, 12 wks: 4.9±3.2%) compared to placebo (baseline: 3.4±2.1%, 12 wks: 2.5±2.3%; p<0.01), without changing aPWV (p=0.52). Rilonacept also reduced hsCRP levels (baseline: 4.6 (1.9, 8.22) [median (interquartile range)], 12 wks: 2.16 (0.96, 7.38) mg/L; p<0.01), and endothelial cell NADPH oxidase expression (p<0.05). Acute infusion of ascorbic acid tended to improve FMD_{BA} in the placebo (p=0.07) but not the rilonacept group (p=0.56), indicating reduced vascular oxidative stress. Overall, rilonacept was well tolerated.

Conclusions: 12 weeks of treatment with an IL-1 trap improved FMD_{BA} without changing aPWV in patients with stage 3-4 CKD. This was associated with a reduction in systemic inflammation and vascular oxidative stress.

Abstract Withdrawn

SA-PO1104

Impact of Vitamin D Supplementation on Endothelial and Vascular Function in Patients with Chronic Kidney Disease: A Randomized, Double Blind, Placebo-Controlled Trial Vivek Kumar,¹ Ashok Kumar Yadav,¹ Vinod Sharma,¹ Manphool Singhal,² Anupam Lal,² Debasish Banerjee,³ Vivekanand Jha.¹ ¹Nephrology, Postgraduate Inst of Medical Education and Research, Chandigarh, Chandigarh, India; ²Radiodiagnosis, Postgraduate Inst of Medical Education and Research, Chandigarh, Chandigarh, India; ³Nephrology, St. George's Univ Hospitals NHS Foundation Trust, London, London, United Kingdom.

Background: Vitamin D deficiency is associated with mortality in CKD patients. We investigated the effect of Vitamin D supplementation on endothelial and vascular function in patients with non-diabetic CKD stage 3-4.

Methods: In a prospective, randomized, double blind, placebo-controlled trial, 120 patients with non-diabetic CKD stage 3-4 and vitamin D deficiency [serum 25(OH)D <20ng/ml] aged 18-70 years were randomized (1:1) to receive either two directly observed oral doses of 300,000 IU of cholecalciferol at 0 and 8 weeks or matching placebo. The pre-specified primary outcome was 40% change in endothelium dependent brachial artery flow mediated dilatation (FMD) at 16 weeks. Secondary outcome measures included changes in pulse wave velocity (PWV), augmentation index (AI), and serum biomarkers.

Results: Baseline FMD was identical in both arms (7.65±2.24% vs 7.85±2.34%). Intervention arm showed a significant increase in serum 25(OH)D (+24.9 ng/ml, 95% CI: 21.8 to 28.06, p<0.0001), and the number of subjects meeting the primary end point (70% vs 5%, p<0.0001). FMD change was 5.42% (95% CI: 4.44 to 6.40%) in the intervention arm and -0.07% (95% CI: -0.70 to 0.58%) in placebo arm. Intervention led to favorable changes in PWV (-0.94 m/s, 95% CI: -1.30 to -0.58, p<0.0001), E-selectin (-3.68 ng/ml, 95% CI: -8.1 to 0.7 p=0.028), IL-6 (-2.0 pg/ml, 95% CI: -2.96 to -0.8 p=0.001), FGF-23 (-14.7 pg/ml, 95% CI: -28.5 to -1.0 p=0.036) and 1,25(OH)₂D (+15.5 pg/ml, 95% CI: 5.4 to 25.5, p=0.003). These did not change significantly in the control group. No changes were observed in AI, vWF and hs-CRP in either group.

Conclusions: In non-diabetic patients with stage 3-4 CKD and vitamin D deficiency, vitamin D supplementation leads to improvement in endothelial function, markers of inflammation and arterial stiffness.

Funding: Government Support - Non-U.S.

Effect of Cholecalciferol versus Calcitriol on Vascular Endothelial Function in CKD: A Randomized Active-Controlled Trial Jessica B. Kendrick,^{1,2} Gerard John Smits,¹ Emily Decker,¹ Heather Farmer,¹ Michel Chonchol.¹ ¹Univ of Colorado School of Medicine, Aurora, CO; ²Denver Health Medical Center, Denver, CO.

Background: Epidemiological studies have shown that vitamin D is associated with decreased cardiovascular morbidity and mortality, but the effects of vitamin D administration on patient outcomes in chronic kidney disease (CKD) are lacking. We conducted a prospective, double-blinded, randomized trial to determine the effects of oral cholecalciferol vs. calcitriol on vascular endothelial function over 24 weeks in patients with CKD stage 3-4.

Methods: 128 patients with CKD stage 3-4 (estimated GFR 15-44 ml/min/1.73m²) with vitamin D deficiency, defined as serum 25-hydroxyvitamin D level (25(OH)D) < 30 ng/mL, were randomly assigned to receive either cholecalciferol (4000 IU daily x 4 weeks then 2000 IU daily x 20 weeks) or calcitriol (0.25 mcg daily x 4 weeks then 0.5 mcg daily x 20 weeks). The primary endpoint was change in brachial artery flow mediated dilation (FMD_{BA}) over 24 weeks. Secondary endpoints included changes in parameters of mineral bone disease and plasma concentrations of inflammatory cytokines (C-reactive protein and interleukin-6).

Results: 115 patients completed the study. The mean (SD) age and eGFR was 58.1 ± 12.4 years and 33.1 ± 10.2 ml/min/1.73m², respectively. In the cholecalciferol group, mean 25(OH)D levels increased from 22.7 ± 7.5 ng/mL to 33.5 ± 7.9 ng/mL. There was no change in 25(OH)D levels in the calcitriol group. Parathyroid hormone levels decreased significantly in the calcitriol group compared to the cholecalciferol group (p=0.001). At 24 weeks, the change in FMD_{BA} did not differ significantly between treatment groups (cholecalciferol group -0.72%, 95% CI -1.97 to 0.54 vs. calcitriol group 0.29%, 95% CI -0.72 to 1.29, p=0.44). There was no significant change in C-reactive protein or interleukin-6 concentrations between the two groups. Episodes of hypercalcemia were more frequent in the calcitriol group (n=4) compared with the cholecalciferol group (n=1).

Conclusions: Twenty-four week therapy with cholecalciferol or calcitriol did not improve vascular endothelial function or reduce inflammation in patients with CKD.

SA-PO1106

Vitamin D Receptor Activation and Dietary Sodium Restriction to Reduce Residual Albuminuria in Chronic Kidney Disease Martin H. De Borst,¹ Charlotte A. Keyzer,¹ Fenna van Breda,² Marc G. Vervloet,² Gozewijn Dirk Laverman,³ Marc H. Hemmelder,⁴ Wilbert M. Janssen,⁵ Hiddo Jan Lambers Heerspink,¹ Stephan J.L. Bakker,¹ Gerjan Navis.¹ ¹UMC Groningen; ²VUmc Amsterdam; ³ZGT Almelo; ⁴MC Leeuwarden; ⁵Martini Hospital Groningen, Netherlands.

Background: Reduction of residual albuminuria during single-agent RAAS-blockade is associated with improved cardiorenal outcomes in CKD. Both vitamin D receptor activators (VDRA) and dietary sodium restriction reduce residual albuminuria. Previous data suggested that sodium restriction is not required for optimal albuminuria reduction by VDRA. We studied the individual and combined effects of paricalcitol and sodium restriction on residual albuminuria during optimally dosed ACEi in CKD.

Methods: In a multi-center, randomized, placebo-controlled cross-over trial, 45 patients with non-diabetic CKD stage 1-3 and residual albuminuria >300 mg/24h despite ramipril 10 mg/d and BP <140/90 mmHg were treated during four 8-week periods with paricalcitol (PARI, 2 µg/day) or placebo (PLAC), each combined with a low (LS, 2.5 gr Na⁺/d) or regular sodium (RS, 4 gr Na⁺/d) diet, in random order. Linear mixed-effect models for repeated measurements were used to determine treatment effect.

Results: In the *intention-to-treat* analysis, albuminuria was 1,060 [778 to 1,443] (geometric mean [95% CI]) mg/24h during RS+PLAC. During RS+PARI, albuminuria was 990 [755 to 1,299] mg/24h (-12.5% [-26.0% to 26.3%] vs. RS+PLAC, *P*=0.2). LS+PLAC reduced albuminuria to 717 [512 to 1,005] mg/24h (-25.4% [-52.6% to -2.3%] vs. RS+PLAC, *P*<0.001). LS+PARI provided the strongest albuminuria reduction to 683 [502 to 929] mg/24h (-31.7% [-55.0% to -0.9%], *P*<0.001 vs. RS+PLAC), although the additional reduction by PARI beyond the effect of LS was non-significant (*P*=0.6). However, in a *per protocol* analysis (≥95% compliance, N=34) PARI did reduce residual albuminuria beyond the effect of LS (*P*=0.04).

Conclusions: The combination of paricalcitol and moderate dietary sodium restriction provided the strongest reduction of residual albuminuria during optimal ACEi; the effect was mainly driven by sodium restriction. Our findings underline the relevance of sodium restriction, possibly combined with paricalcitol, to optimize albuminuria reduction.

SA-PO1107

Vascular Function and Uric Acid Lowering via Allopurinol in Stage III CKD: Results of a Double-Blinded Randomized Placebo-Controlled Study Diana I. Jalal,¹ Emily Decker,¹ Loni J. Perrenoud,¹ Nina Bispham,² Tapan Mehta,¹ Gerard John Smits,¹ Richard J. Johnson.¹ ¹Medicine/ Renal Div, UC AMC, Aurora, CO; ²Integrative Physiology, UC Boulder, Boulder, CO.

Background: Observational studies suggest that asymptomatic hyperuricemia associates with vascular disease in chronic kidney disease (CKD). A recent study suggested that lowering serum urate with allopurinol improves endothelial function in elderly adults with stage III CKD. It remains unknown if lowering serum urate improves endothelial function in adult subjects with stage III CKD.

Methods: 80 adult subjects (18-70) years of age with stage III CKD and asymptomatic hyperuricemia (≥7 mg/dL in men and ≥6 mg/dL in women) were randomized to receive placebo or allopurinol (100 mg tablets) for 12 weeks. The study was double-blinded and subjects were instructed to take 1 tablet for 1 week, 2 tablets for another week, and 3 tablets thereafter. Changes (from baseline) between both groups were compared by Wilcoxon rank-sum test.

Results: No significant differences existed between both groups at baseline. After 12 weeks, allopurinol lowered serum urate significantly. FMD increased in the allopurinol group compared to placebo; but this was not statistically significant. NMD increased with allopurinol but decreased with placebo; *p* value = 0.14. These data are shown in Table 1. There were no significant differences between allopurinol and placebo for systolic or diastolic blood pressure, markers of inflammation, or markers of oxidative stress. 10 subjects withdrew from the study. A few adverse events were noted in both groups including 1 gout attack in each group. 1 subject died during the study due to a cardiac event.

Variable	Placebo	Allopurinol	P value
Serum Urate(mg/dL)	0.05(1.54)	-3.24(1.35)	<0.0001
FMD(%change)	0.16(4.05)	0.91(3.9)	0.47
NMD(%change)	-1.29(5.33)	0.93(6.05)	0.14

Conclusions: Allopurinol effectively and safely lowered serum urate in adults with stage III CKD and asymptomatic hyperuricemia but this did not improve endothelial function significantly. There was tendency towards improved NMD suggesting that hyperuricemia may negatively impact vascular smooth muscle function in stage III CKD.

Podocyturia Is an Earlier and Superior Predictor of Cardiovascular Outcomes Than Is Albuminuria Assaad Antoine Eid,¹ Robert Habib,² Kamal F Badr.² ¹Anatomy, Cell Biology and Physiological Sciences, American Univ of Beirut - Faculty of Medicine, Beirut, Beirut, Lebanon; ²Internal Medicine, American Univ of Beirut - Faculty of Medicine, Beirut, Beirut, Lebanon.

Background: Increased urinary albumin excretion rate (AER), a predictor of cardiovascular events, results from abnormally increased albumin filtration accompanying injury to glomerular endothelial and epithelial cells (“podocytes”). Since AER is modified by renal proximal tubule albumin retrieval, we hypothesized that urinary podocyte shedding, podocyturia, would be a more relevant and earlier biomarker of endothelial injury (and CVD) than moderate albuminuria.

Methods: 106 Type II diabetic subjects (mean age: 46/60 men/women) with normal AER [<2.26 mg/mmol (20 µg/mg) creatinine] and free of overt cardiovascular disease (CVD) were enrolled. AER and podocyte-specific proteins (podocin and nephrin) mRNA were measured at baseline (visit 1), 3-4 years later (visit 2) and at 7 years (visit 3). Development of cardio vascular diseases VD - defined as coronary disease, cerebrovascular disease and/or peripheral vascular disease (can be removed to fit words counting)- was collected as outcome. 7-year Kaplan-Meier time-to-event (log rank) data were compared in baseline biomarker tercile groups (low, intermediate, high).

Results: All three biomarkers increased significantly between visits (*P*<0.001). AER terciles exhibited similar time to CVD (*p*=0.127), which was in contrast with the step-wise and substantial increase in CVD events with increasing podocin and nephrin levels (*P*<0.001). Considering all three biomarkers as continuous factors, the covariate-adjusted hazard ratios (95% confidence intervals) [HR] were highest for podocin mRNA [HR=15.9 (6.1-41.8); *p*<0.001], intermediate for nephrin mRNA [HR=7.61 (3.75-15.5); *p*<0.001] and lowest for AER [HR=1.17 (1.01-1.36); *p*=0.041].

Conclusions: Compared to traditional AER, podocyturia predicts more accurately and at an earlier time point the presence of silent systemic vascular injury, that manifests as overt cardiovascular events.

Empagliflozin Reduces Microalbuminuria and Macroalbuminuria in Patients with Type 2 Diabetes David Cherney,¹ Søren Søgaard Lund,² Bruce A. Perkins,³ Per-Henrik Groop,^{4,5} Mark E. Cooper,⁵ Stefan Kaspers,² Susanne Crowe,² Hans-Juergen Woerle,² Maximilian von Eynatten.² ¹Toronto General Hospital, Univ of Toronto, Canada; ²Boehringer Ingelheim Pharma GmbH & Co. KG, Ingelheim, Germany; ³Mount Sinai Hospital, Univ of Toronto, Canada; ⁴Univ of Helsinki and Helsinki Univ Hospital, Folkhälsan Research Center, Helsinki, Finland; ⁵Baker IDI Heart and Diabetes Inst, Melbourne, Australia.

Background: Reductions in HbA1c, systolic blood pressure (SBP), and weight with the highly selective SGLT2 inhibitor empagliflozin in patients with type 2 diabetes (T2D) may favorably impact albuminuria.

Methods: Using data pooled from 5 Phase III, randomized clinical trials, we assessed the effect of empagliflozin 10 or 25 mg for 24 weeks on urine albumin to creatinine ratio (UACR) in patients with T2D and prevalent microalbuminuria (UACR 30–300 mg/g; *n*=636) or macroalbuminuria (UACR >300 mg/g; *n*=215) at baseline.

Results: Empagliflozin reduced UACR vs placebo in patients with T2D and microalbuminuria (-32%; *p*<0.001) or macroalbuminuria (-41%; *p*=0.001) after controlling for baseline log (UACR), HbA1c, SBP, estimated glomerular filtration rate (MDRD), region, study and treatment (Figure). Adjusted mean (SE) changes in HbA1c, weight, SBP and diastolic BP with empagliflozin vs placebo were -0.50 (0.07) %, -1.6 (0.2) kg, -4.4 (1.1) mmHg and -2.3 (0.6) mmHg, respectively, in patients with microalbuminuria (all *p*<0.001), and -0.53 (0.13) %, -1.8 (0.4) kg, -6.3 (2.0) mmHg and -2.2 (1.1) mmHg, respectively, in patients with macroalbuminuria (all *p*<0.05). Linear regression analyses showed that changes in HbA1c, weight and SBP accounted for a maximum of half the UACR-lowering effect.

Underline represents presenting author/disclosure.

Conclusions: SGLT2 inhibition with empagliflozin reduced UACR by >30% in patients with T2D and prevalent microalbuminuria or macroalbuminuria, independent of its known metabolic and hemodynamic effects.

Vadadustat, a Novel Oral Treatment for Anemia of Chronic Kidney Disease, Maintains Stable Hemoglobin Levels in Dialysis Patients Converting from Erythropoiesis-Stimulating Agents Volker H. Haase,¹ Charlotte S. Hartman,² Bradley J. Maroni,² Ramin Farzaneh-Far,² Peter A. McCullough,³ ¹Div of Nephrology and Hypertension, Vanderbilt Univ Medical Center, Nashville, TN; ²Akebia Therapeutics, Inc., Cambridge, MA; ³Baylor Univ Medical Center, Dallas, TX.

Background: Vadadustat is a novel, oral agent that stimulates erythropoiesis by stabilizing hypoxia-inducible factor (HIF). Prior studies in patients with Non-Dialysis Dependent Chronic Kidney Disease (NDD-CKD) have shown that vadadustat results in controlled, dose-dependent increases in hemoglobin (Hb) and enhances iron mobilization and utilization. Here we present data from a Phase 2 trial of vadadustat in hemodialysis patients.

Methods: A multi-center, open-label, 16-week trial was designed to assess Hb response, safety, and tolerability of vadadustat. The trial enrolled 94 hemodialysis patients (Hb 9 - 12 g/dL), who were maintained on erythropoiesis-stimulating agents (ESAs) prior to study entry. Patients were converted from ESA to vadadustat, and assigned to 1 of 3 dose cohorts: 300 mg once daily (QD); 450 mg QD; or 450 mg three times weekly (TIW). The primary efficacy analysis was to evaluate mean Hb changes from baseline at weeks 7/8, and weeks 15/16. From week 8, dose could be adjusted as needed to maintain Hb. All patients were iron replete at baseline and throughout the study; IV iron use was allowed.

Results: Vadadustat maintained stable Hb levels in all 3 dose cohorts during the 16 week treatment period following conversion from ESA.

Mean Hb levels (g/dL) in Modified Intent-To-Treat (MITT) population			
Dose Cohort	Baseline	Week 7/8	Week 15/16
300mg QD	10.4	10.4	10.3
450mg QD	10.6	10.3	10.5
450mg TIW	10.5	10.2	10.4

One subject in the 300mg QD cohort had a single Hb excursion to 13.1 g/dL. Adverse events were balanced across the 3 cohorts. Serious adverse events (SAEs) were reported in 13 subjects (13.8%), which was within the expected range (13 - 17 subjects). No drug-related SAEs, nor deaths, were reported.

Conclusions: Vadadustat safely and effectively maintained Hb levels in dialysis patients who were converted from injectable ESAs.

Autologous Erythropoietin Production by the TARGT Gene Therapy Platform Maintains Stable Hb for 6-12 Month in ESRD Patients without the Need for ESA Administration Shany Blum,¹ Nir Shapir,¹ Reem Miari,¹ Shai Efrati,³ Pablo E. Pergola,⁴ Garry A. Neil,² ¹Medgenics Medical Israel Ltd., Misgav, Israel; ²Medgenics Inc, Wayne, PA; ³Research & Development and Nephrology Units, Assaf-Harofeh Medical Center, Zerifin, Israel; ⁴Renal Associates PA, San Antonio, TX.

Background: Recombinant human erythropoietin (rHuEPO) administration to iron replete patients corrects anemia in most patients with ESRD, but doses result in supra-physiological peak serum concentration (C_{max}) of EPO that may cause thromboembolic complications. The Transduced Autologous Restorative Gene Therapy system (TARGTTM) is an ex-vivo gene therapy, providing autologous, continuous protein therapies at physiological ranges that was used encoding for the human erythropoietin gene (TARGT_{EPO}) for these studies. Patient dermal tissue biopsies (MOs) are transduced with a Helper-Dependent Adenoviral Vector containing the EPO gene and then re-implanted subcutaneously to deliver the required EPO dose.

Methods: We present initial results from 3 ongoing open label ascending dose studies of TARGT_{EPO} in patients with anemia due to CKD undergoing either Hemo or Peritoneal Dialysis.

Results: Thus far 14 patients were enrolled in all protocols. Follow up is ongoing with the first implanted patient being followed with stable EPO secretion and stable Hb for over 14 months from a single implantation without the need for rHuEPO or blood transfusion. Results obtained suggest that treatment with TARGT_{EPO} stabilize serum EPO levels at the physiological range of £20 mIU/ml resulting in Hb levels between 9-12 g/dL. Comparative analysis of serum EPO levels revealed significantly lower C_{max} with TARGT_{EPO} compared to rHuEPO and an order of magnitude less overall EPO exposure as calculated by Area Under the Curve which may confer significant clinical benefit. No treatment related serious adverse events have been reported.

Conclusions: TARGT_{EPO} is a promising novel therapy for the treatment of anemia of CKD and potentially for other protein deficient diseases.

Monitoring in Dialysis (MiD) Study: Exploring the Timeline and Etiology of Increased Arrhythmias in Hemodialysis (HD) Patients Prabir Roy-Chaudhury,¹ Don E. Williamson,² James A. Tumlin,³ Vijay K. Kher,⁴ Vikranth Reddy,⁵ Kowdle Chandrasekhar Prakash,⁶ David M. Charytan,⁷ Suresh Chandra Tiwari,⁸ Saurabh Pokhariyal,⁹ Amber S. Podoll,¹⁰ ¹Univ of Arizona, Tucson; ²Nephrology Associates, Augusta; ³Univ of Tennessee, Chattanooga; ⁴Medanta Medicity; ⁵CARE Hospital, Hyderabad; ⁶Apollo Hospitals-Chennai; ⁷Brigham and Women's Hospital; ⁸Fortis-Vasant Kunj, Delhi; ⁹Fortis, Gurgaon; ¹⁰Univ of Texas, Houston.

Background: Sudden cardiac death (SCD), likely due to cardiac arrhythmias (CA) is the most important cause of mortality in the HD population. We herein present data on the timeline and potential etiology of CA in HD patients (pts).

Methods: The MiD study (n=66) characterized the type and frequency of CA in 3x/wk HD pts over 6 mths, using an implanted loop recorder (Medtronic Reveal). Reviewer confirmed arrhythmias (RCA;all documented CA) and clinically significant arrhythmias (CSA;brady/asystole/VT/ symptomatic), were linked to the dialysis cycle, pt wt and pre/post-session electrolytes, using negative binomial mixed effects regression analyses.

Results: Mean age was 56.3±12.2; 64% diabetic; 70% male; HD vintage 4.3±5.1 yrs. 97% and 67% of pts had a RCA/CSA. Most CSA occurred during the intradialytic period of the first weekly HD and then decreased in subsequent sessions. Univariate analyses identified increased pre and post wt, high pre HD potassium (K) and drop in K as risk factors for RCA. Multivariate analyses (adjusted for DM, yrs on HD, pre-wt), identified higher pre HD K levels as a predictor for increased RCA. The highest risk of arrhythmia occurred in pts with high K drops AND substantial volume removal (p=0.03).

Underline represents presenting author/disclosure.

Conclusions: These data establish linkages between intra-dialytic CSA and the long interdialytic period, and also identify a unique interaction between fluid removal and K in the generation of RCA. This suggests for the first time, that future data driven targeting of these parameters might reduce CA and potentially SCD in HD pts.

SA-PO1113

The Occurrence of Cardiac Arrhythmias in Hemodialysis Patients is Linked to the Hemodialysis Procedure and to Electrolyte Abnormalities as Recorded by Implantable Loop Recorders Christian Combe,^{1,2} Antoine Benard,^{1,2} Hélène Savel,^{1,2} F. Sacher.^{1,2} ¹CHU & Univ. Bordeaux, Bordeaux, France; ²Rythmodial Study Group.

Background: Sudden cardiac death (SCD) is the most common mode of death among hemodialysis (HD) patients (pts). Little is known about the terminal arrhythmic events in these pts. Our objective was to identify the mechanisms which may lead to SCD in HD pts using an implantable loop recorder (ILR, Reveal XT®, Medtronic).

Methods: Pts from 9 HD centers have been included in the study. Continuous monitoring of the cardiac rhythm has been performed using the remote monitoring capability of the ILR device (Carelink®). Clinical, biological, and technical HD parameters and medications have been recorded for at least 1 year. General joint frailty model for recurrent event data were used to analyze associations between these parameters and the occurrence of cardiac rhythm events.

Results: 72 pts (65.1±8.6 yrs, 52M) have been included. Causes of ESRD were diabetes (n=32) and hypertension (n=19). 22 pts had an ischemic cardiomyopathy. In multivariate analyses, the occurrence of conduction abnormalities (n=64) was associated to high potassium (K⁺) concentrations (K⁺>5mM, RR=5.22, p<10⁻⁴) and to body weight (bw) variation during HD (RR per %bw/h 3.22, p<10⁻³). There was no association with serum calcium, hemoglobin, HD bath ions, blood pressure. Ventricular arrhythmias >150/min (n=11) were associated only to high K⁺ levels (K⁺>5mM, RR=13.35, p<0.05), to low K⁺ levels (K⁺<4 mM, RR=24.48, p<0.01), and to high phosphate levels (Pi>45mg/L, RR=5.64, p<0.04). Atrial fibrillation was the most frequent event (n=255), with less clear associations with patient-dependent and HD-dependent variables. In 6 SCD patients, ILR tracings demonstrated progressive bradycardia followed by asystole.

Conclusions: Our data show that the various types of arrhythmias and conduction abnormalities occurring in HD pts are linked to different pathophysiological mechanisms, with a central role of serum K⁺ levels, levels lower than 4 mM or higher than 5 mM being deleterious. Rapid body weight variations were linked to ventricular arrhythmias. Therapeutic strategies aimed at controlling these factors can be drawn from our study.

SA-PO1115

Comparison of the Efficacy and Safety of Intravenous (IV) Etelcalcetide (AMG 416) and Oral Cinacalcet (CIN) in Patients on Hemodialysis (HD) with Secondary Hyperparathyroidism (sHPT) Kevin J. Martin,¹ Geoffrey A. Block,² Sunfa Cheng,³ Bastian Dehmel,³ Reshma Kewalramani,³ David M. Spiegel,⁴ Hao Wang,³ Glenn Matthew Chertow.⁵ ¹St Louis Univ SOM, St. Louis, MO; ²Denver Neph, Denver, CO; ³Amgen; ⁴Relypsa; ⁵Stanford Univ SOM, Palo Alto, CA.

Background: This is a randomized, active controlled, double-blind, double dummy study comparing the efficacy and safety of a novel IV calcimimetic, AMG 416, with CIN.

Methods: Patients receiving HD with PTH >500 pg/ml, albumin-corrected calcium (cCa) ≥8.3 mg/dL, and no CIN use for 3 months were randomized 1:1 to AMG 416 IV/oral placebo or oral CIN/IV placebo for 26 weeks (wks). Doses were titrated at wks 5, 9, 13, 17 based on the prior wk's PTH and cCa. AMG 416 was started at 5mg and titrated by 2.5 or 5mg up to 15mg 3 times weekly with HD. CIN was started at 30mg and titrated up to 180mg daily per label. Target PTH was ≤100 and ≤300 pg/ml. Primary endpoint was noninferiority on >30% reduction in PTH during wks 20-26. Secondary endpoints were >30% reduction in PTH (superiority analysis), >50% reduction in PTH, mean days of nausea or vomiting (n/v) (patient reported outcome) per wk in the first 8 wks.

Results: 683 subjects were randomized (340 AMG 416, 343 CIN), 553 completed the trial (84% AMG 416, 86% CIN). AMG 416 was noninferior to CIN on the primary endpoint. AMG 416 was superior on >30% reduction in PTH (68% AMG 416, 58% CIN, p=0.004) and >50% reduction in PTH (52% AMG 416, 40% CIN, p=0.001). Mean days of n/v in the first 8 wks did not differ (0.4 AMG 416, 0.3 CIN, NS). The most common adverse event (AE) in either group was blood calcium decreased (69% AMG 416, 60% CIN), mostly mild to moderate severity. Heart failure related AEs were reported in 10 (3.0%) AMG 416 subjects and 2 (0.6%) CIN subjects, of which 5 and 1, respectively, were serious. 9 (3%) subjects receiving AMG 416 and 6 (2%) receiving CIN had fatal treatment-emergent AEs – all unrelated to study drug.

Conclusions: AMG 416 achieved a >50% and a >30% reduction in PTH in more subjects compared to CIN. Hypocalcemia was seen more often with AMG 416. Nausea and vomiting did not differ. IV AMG 416 is more efficacious than oral CIN for the treatment of sHPT in patients on HD.

A Trial Assessing Use of a Wearable Artificial Kidney (WAK) in Patients Undergoing Maintenance Hemodialysis Victor Gura,¹ Matthew B. Rivara,² Raj P. Munshi,² Scott D. Bieber,² Masoud Beizai,³ Carlos J. Ezon,³ Larry Kessler,² Jonathan Himmelfarb.² ¹Cedars Sinai- UCLA, Los Angeles, CA; ²Univ of Washington, Seattle, WA; ³Blood Purification Technologies Inc, Beverly Hills, CA.

Background: Current stationary dialysis machines hinder mobility and limit activities of daily life during dialysis treatments. There is a critical need for new technologies to increase patient autonomy, enhance quality of life, and allow for increased patient rehabilitation.

Methods: This is the first FDA-approved human trial of the WAK, a miniaturized, wearable hemodialysis machine based on dialysate-regenerating sorbent technology (NCT02280005). We aimed to determine the safety and efficacy of the WAK in maintaining euolemia and achieving solute clearance and electrolyte homeostasis over 24 hours.

Results: All patients remained hemodynamically stable, and there were no serious adverse events. Serum electrolytes and hemoglobin remained stable over the treatment period for all subjects. Six out of seven patients ambulated while receiving WAK treatment. Fluid removal was consistent with prescribed ultrafiltration rates. Mean blood flow was 42 ± 24 and dialysate flow was 43±20 ml/min with no laboratory evidence of hemolysis. Mean BUN, creatinine, and phosphorus clearances were 21 ± 13, 20 ± 11, and 22 ± 12 ml/min respectively during the first hour of treatment. In one subject, treatment was discontinued due to clotting after 4 hours. In a second subject, treatment was discontinued due to discoloration of dialysate observed after 10 hours. The trial was stopped after the 7th subject due to device-related malfunctions. These included excessive CO2 bubbles in the dialysate, variable blood and dialysate flows, and tubing leaks during the priming phase. Redesign and re-manufacturing of the WAK prototype will be required prior to additional human studies.

Conclusions: Treatment with the WAK was well tolerated, resulted in effective uremic solute clearance and maintenance of electrolyte and fluid homeostasis. These results serve as proof-of-concept of the WAK as a viable novel dialysis technology.

CR845, a Novel Kappa Opioid Receptor Agonist Reduces Moderate-to-Severe Pruritus and Improves Quality of Life in Chronic Kidney Disease Patients Undergoing Hemodialysis Robert Spencer,¹ Vandana S. Mathur,² James A. Tumlin,³ Joseph W. Stauffer,¹ Frederique Menzaghi.¹ ¹Cara Therapeutics, Inc., Shelton, CT; ²Mathur Consulting, San Francisco, CA; ³Univ of Tennessee, Chattanooga, TN.

Background: Approximately 40% of US hemodialysis (HD) patients experience moderate-to-severe itching, which negatively affect their mental and physical health (e.g., sleep loss, depression, higher antibiotic and erythropoietin use and increased mortality). The etiology of this condition is likely multi-factorial, including immune system dysfunction and imbalance of mu/kappa endogenous opioids. CR845 is a novel and well-tolerated kappa opioid receptor (KOR) agonist with limited central nervous system entry, thereby preferentially activating KOR on peripheral neurons and immune cells.

Methods: In this Phase 2 double-blind, randomized (1:1), placebo-controlled clinical study, 65 prevalent US HD patients with persistent (~ 5 years) moderate-to-severe pruritus (baseline VAS ~68 mm, 0=no itch; 100 mm =worst itch) were treated with 1 mcg/kg intravenous CR845 or placebo following each HD session for 2 weeks. Antihistamines were discontinued 1 week prior to the study.

Results: The primary endpoint was met (VAS change in worst itch intensity from baseline to Days 12-15), with a significant difference in itch intensity between placebo and CR845-treated patients (p=0.016). CR845-treated patients had a 50% mean reduction in itch intensity from baseline. The 1st secondary endpoint was also met with a significant improvement in Skindex-10, a validated patient-reported outcome measure of pruritus-related quality of life (p =0.031). Furthermore, a trend for a sleep improvement was observed (SLP9).

Conclusions: Short-term treatment with CR845 significantly reduced itch intensity and improved quality of life in HD patients with moderate-to-severe pruritus. Thus, CR845 appears to have substantial potential to alleviate the symptoms and consequences of this frequently incapacitating condition for which existing treatments have often provided little or no relief. These data also support the opioid/immune etiology of this condition.

The ASSertID Study: Feasibility Randomised Controlled Trial of Drug Treatment for Depression in Patients on Haemodialysis Ayman Guirguis,^{1,2,3} Michael K. Almond,⁴ Joseph Chilcot,⁵ Andrew Davenport,⁶ Clara Day,⁷ Naomi Fineberg,^{2,3} Karin Friedli,² Benjamin Spencer,⁵ David Wellsted,² Ken Farrington,^{1,2} ¹East & North Hertfordshire NHS Trust, United Kingdom; ²Univ of Hertfordshire, United Kingdom; ³Hertfordshire Partnership Univ NHS Trust, United Kingdom; ⁴Southend Univ Hospitals NHS Trust, United Kingdom; ⁵King's College London, United Kingdom; ⁶Royal free London NHS Trust, United Kingdom; ⁷Univ Hospitals Birmingham NHS Trust, United Kingdom.

Background: Major Depressive Disorder (MDD) is common in patients on Haemodialysis (HD) but there is little evidence of benefit from antidepressants. Hence we undertook a multicentre feasibility Randomised Controlled Trial (RCT) of sertraline versus placebo.

Methods: A screening phase identified patients with Beck Depression Inventory (BDI-II) score ¹16. Those meeting eligibility criteria, underwent psychiatric assessment (Mini International Neuropsychiatric Interview). Consenting patients with mild to moderate MDD and Montgomery-Åsberg Depression Rating Scale (MADRS) score ¹18 were randomised to sertraline or placebo. Follow-up by study psychiatrist: week 2, month 2, 4 and 6 monthly by study nurses. Initial dose was 50 mg with titration to 100 mg if required.

Results: Of 1355 patients approached, 715 consented for screening. BDI-II ¹16 was present in 231 (32.3%), 58 (25.1%) were ineligible due to current treatment for MDD. Sixty-three underwent psychiatric assessment. MDD was diagnosed in 37; 30 consented to the RCT (mean age 61 ±15; 71% male; 60% white). Twenty-one (70%) completed the trial, 8 (of 15) on sertraline and 13 (of 15) on placebo. Over 6 months, BDI-II and MADRS scores decreased ($t(17)=-6.3$, $p<0.001$ and $t(20)=11.3$, $p<0.001$ respectively). There was no reliable difference between the sertraline and placebo groups. Fewer on sertraline completed (6 withdrawals and one death versus 2 withdrawals on placebo [$C2=3.97$, $p=0.046$]). There was a trend towards a greater fall in MADRS scores by month 2 on sertraline (effect size 0.37; lower bound >0).

Conclusions: This feasibility study is the largest RCT investigating the use of antidepressants in HD patients with MDD. Similar significant improvement in MDD occurred over 6 months in both groups. Recovery may have been quicker on sertraline.

SA-PO1119

Randomised Controlled Trial to Determine the Appropriate Time to Initiate Peritoneal Dialysis after Insertion of Catheter to Minimise Complications Helen G. Healy,¹ George T. John,¹ Edward Yeoh,¹ Nicola Williams,¹ Thin M. Han,² Lakshmanan Jeyaseelan,³ Kavitha Ramanathan,³ Dwarakanathan Ranganathan,¹ ¹Renal Dept, Royal Brisbane & Women's Hospital, Brisbane, Queensland, Australia; ²Renal Dept, Rockhampton Hospital, Rockhampton, Queensland, Australia; ³Dept of Statistics, Christian Medical College, Vellore, India.

Background: The optimal time for the commencement of peritoneal dialysis (PD) after PD catheter insertion is not well known. If dialysis is started too soon after insertion, dialysate leaks and infection may occur. However by starting PD earlier, morbidity and costs can be reduced through less need for haemodialysis. This is the first randomised controlled trial to determine the safest and shortest interval to commence PD after catheter insertion.

Methods: All consecutive patients undergoing PD catheter insertion at the Royal Brisbane and Women's Hospital and Rockhampton Hospital from 1st March 2008 to 31st May 2013, and who met the inclusion and exclusion criteria were invited to participate in the study. Participants were randomised to one of three groups. Group 1 (G₁) commenced PD at one week, group 2 (G₂) at two weeks and group 3 (G₃) at four weeks after Tenckhoff catheter insertion. The groups were stratified by hospital and the presence of diabetes. Primary outcomes were the incidence of peritoneal fluid leaks or PD related infection during the 4 weeks after commencement of PD.

Results: 122 participants were recruited, with 39, 42 and 41 randomised to groups G₁, G₂ and G₃ respectively. The primary outcome of either catheter leaks or infection was significantly different in both intention to treat (ITT) and per protocol (PP) analyses ($p=0.016$ and 0.006 respectively). Multiple pairwise comparison showed a significant difference between G1 and G3 in PP analysis (p -value=0.010) but not in the ITT analysis.

Conclusions: Overall complications were higher in patients commencing PD one week after catheter insertion compared with the other two groups.

The Effects of Normal Saline and an Acetate-Buffered Crystalloid Solution on Hyperkalemia in Deceased Donor Renal Transplantation: A Randomized Blinded Trial Laura Elisabeth Harris, Peter F. Mount, Francesco L. Ierino, David A. Story, Glenn M. Eastwood, Larry McNicol, Rinaldo Bellomo, Laurence Weinberg. Austin Health, Melbourne, Victoria, Australia.

Background: Perioperative administration of 0.9% normal saline (NS) in deceased donor renal transplantation is associated with hyperchloremic metabolic acidosis, but the effect of NS on the risk of hyperkalemia or delayed graft function is unknown. We compared the effect of NS to an acetate buffered crystalloid solution (Plasmalyte-148) (PL), on the incidence of hyperkalemia, acid base status, and delayed graft function in deceased donor renal transplant patients.

Methods: Blinded randomized single-centre trial conducted in a renal transplant unit of a tertiary hospital. Patients were randomized to NS or PL for perioperative fluid management. The primary outcome was hyperkalemia (≥ 5.5 mM) within the first 48 h postoperatively. Secondary outcomes were acid base disturbances; delayed graft function and hospital length of stay.

Results: Forty-nine patients were randomized: 25 to NS and 24 to PL. Baseline characteristics were similar in both groups. The median [IQR] total volume of fluid administered was 6446mL [4807,8075] for NS and 7776mL [5140,9080] for PL ($p=0.3$). The incidence of hyperkalemia in the first 48 hours postoperatively was higher in the NS group: 20 patients (80%) vs. 12 patients (50%) in the PL group ($p=0.04$). Sixteen patients (64%) in the NS group required treatment for hyperkalemia compared to 5 patients (21%) in the PL group ($p=0.003$). The peak serum potassium in the 48 h postoperative period was higher in the NS group (6.1 ± 0.8 vs. 5.4 ± 0.9 mM, $p=0.009$). Patients receiving NS were more acidemic ($pH: 7.32 \pm 0.06$, vs. 7.39 ± 0.05 , $p=0.001$) and had higher serum chloride (107 mM vs. 101 mM, $p<0.001$) at the end of surgery. There were no significant differences in delayed graft function or hospital length of stay.

Conclusions: Deceased donor renal transplant patients that received NS developed hyperchloremic metabolic acidosis with an increased incidence of hyperkalemia when compared to PL. This study supports the use of acetate buffered crystalloid solutions for perioperative fluid management in patients undergoing deceased donor renal transplantation.

Eculizumab in Prevention of Acute Antibody-Mediated Rejection in Sensitized Deceased-Donor Kidney Transplant Recipients: Updated 12-Month Outcomes D. Glotz,¹ G. Russ,³ Lionel Rostaing,³ Christophe M. Legendre,³ Steven J. Chadban,³ J. Grinyo,³ Nizam Mamode,³ Gunnar Tufveson,³ Lionel Couzi,³ P. Riggotti,³ Y. Lebranchu,³ S. Sandrini,³ W. Marks,² ¹Hôpital Saint-Louis, Paris, France, Metropolitan; ²Alexion Pharmaceuticals, Inc., Cheshire, CT; ³The International Eculizumab Transplant Study Group.

Background: Complement activation by preformed DSA is the major mechanism of acute antibody-mediated rejection (aAMR) in sensitized, kidney transplant recipients (SKTR). In a previous interim study report, the C5 inhibitor eculizumab (Ec) appeared effective in preventing aAMR in deceased donor (DD) SKTR compared to historical controls. We now report 12-month efficacy and safety data from a Sept 2015 update of this ongoing, open-label, single-arm trial.

Methods: SKTR defined as current DSA >3000MFI detected by SAB; or B- or T-cell flow cytometric crossmatch ³300 and ≤ 500 mean channel shift; or historical positive complement-dependent cytotoxicity crossmatch to donor HLA. All recipients received Ec 1200mg postoperative day (POD) 0 prior to reperfusion, 900mg on POD 1, 7, 14, and 28, and 1200mg at wks 5, 7, and 9. Recipients received Rabbit ATG for induction and corticosteroids, tacrolimus, and mycophenolate for maintenance immunosuppression. Plasmapheresis was not allowed through Post-transplant week 9. The primary composite endpoint was clinically significant, biopsy (bx)-proven aAMR grade II/III (Banff 2007, based on centrally read bx), graft loss, death, or loss to follow-up at 9wks. Graft and patient (pt) survival were estimated by K-M.

Results: 80 pts were transplanted (48 F, 32 M); median age 52y (range, 24–70). 7 of 80 SKTR had aAMR (8.8%) compared to 30% expected for historical controls. 11/80 SKTR met the 9wk composite primary endpoint based on local bx (13.8% [95% CI 7.1–23.3]). Graft survival at 6 and 12mo was 93.7% and 88.7%, respectively; pt survival at 6 and 12mo was 97.4%. SCr levels (mg/dL) at baseline, 1 and 12mo were 7.43 (± 2.51), $n=79$; 1.86 (± 1.07), $n=74$; and 1.63 (± 0.76), $n=69$. No new safety concerns were identified.

Conclusions: Ec appeared to be effective in reducing aAMR in SKTR. Pt and graft survival and kidney function at 12mo were similar to those expected for non-sensitized KTR. Ec was well tolerated.

SA-PO1123

Impact of De Novo Donor Specific Antibodies on Graft Outcomes in Kidney Transplant Recipients following Early Switch from Calcineurin Inhibitor to Everolimus: Analysis of the ELEVATE Trial Johan W. De Fijter, Hallvard Holdaas, Patricia M. Lopez, Peter Bernhardt, Zailong Wang, Frans Claas, Wolfgang Arns, Josep M. Cruzado, Markus van der Giet. For the ELEVATE Study Group.

Background: Development of *de novo* donor specific HLA-antibodies (dnDSA) after kidney transplantation (KTx) is associated with an increased risk of antibody-mediated rejection (AMR) and graft failure. The ELEVATE study evaluated the impact of early conversion from CNIs to everolimus (EVR) after KTx and prospectively explored the status and development of DSAs.

Methods: In this 24 month (M), multicentre study KTx recipients were randomized at 10–14 weeks post-Tx to convert from CNI to EVR ($n=360$: C0 6–10 ng/mL) or continue CNI ($n=357$: C0, tacrolimus 5–10 ng/mL, cyclosporine 100–250 ng/mL); all received enteric-coated mycophenolate sodium (MPS) + corticosteroids. Blood samples were collected at

baseline, randomization (RND), M12 and M24 or at time of rejection episodes and analysed by Lumindex/SAB assay in one central lab. dnDSA was defined by a MFI value ≥ 500 any time post-RND in patients with MFI <500 at RND.

Results: Baseline characteristics were comparable between groups. Incidence of preformed DSA (MFI ≥ 500 at baseline) against HLA class-I or -II was low (table A). Overall, incidence of dnDSA HLA class-I was higher with EVR/MPS treatment vs CN1/MPS at M12 and M24. The incidence of dnHLA Class-II antibodies was dominated by anti-DQ in the CsA/MPS [Irm]group (table B). No association between *de novo* (either HLA class-I or -II) antibodies and a diagnosis of AMR or tBPAR was evident in this population up to M24 (table C, D).

Conclusions: Early conversion to EVR at 3M post-Tx did not increase the risk of dnDSA formation vs CN1 continuation. Moreover, no association was observed between development of dnDSA and AMR or tBPAR, even with the lowest detection thresholds.

TABLE 3: DSA outcomes

A) incidence of pre-formed DSA

HLA Class I	EVR	Baseline			HLA Class II	EVR	Baseline		
		CN1					MPS		
		Total	TAC	CsA			Total	TAC	CsA
MFI ≥ 500	HLA A	3.4	3.9	4.4	2.6	HLA DR	0.8	4.1	4.5
	HLA B	4.5	4.9	5.7	3.5	HLA DQ	0.7	7.1	8.3
MFI ≥ 2000	HLA A	2.5	1.7	2.0	1.3	HLA DR	2.5	1.0	1.5
	HLA B	3.3	1.5	1.5	2.4	HLA DQ	4.2	1.2	0.0

B) incidence of de novo DSA (%)

HLA Class I	EVR	M12			HLA Class II	EVR	M12			HLA Class I	EVR	M24			HLA Class II	EVR	M24

Donor-Derived Cell-Free DNA in Plasma Increases with Rejection and Decreases after Treatment in Kidney Transplant Recipients
Marica Grskovic,¹ Brian Christie,¹ David Hiller,¹ Robert Woodward,¹ Jim Yee,¹ Flavio Vincenti.² ¹CareDx, Inc., Brisbane, CA; ²UCSF, San Francisco, CA.

Background: Donor-derived cell-free DNA (dd-cfDNA) is an emerging biomarker of acute cellular rejection in organ transplant recipients. The utility of determining plasma levels of dd-cfDNA aimed at diagnosing rejection and evaluating treatment response was assessed in kidney transplant recipients in a longitudinal observational trial.

Methods: Clinical status, biopsy grade (performed in response to elevated serum creatinine) and plasma were collected at 326 routine surveillance visits from 101 patients. Samples from nine patients assigned a biopsy grade I, II or III (NIH criteria) were classified as rejection (R). Samples from seventeen patients assigned a biopsy grade 0 were classified as quiescent (Q). cfDNA extracted from plasma was amplified at targeted SNPs and analyzed using a sensitive and accurate Next Generation Sequencing assay to quantify dd-cfDNA levels without the need to separately genotype the donor. Standard statistical measures of significance were used.

Results: dd-cfDNA levels were significantly higher (p=0.029) in patients with biopsy-confirmed rejection (R, mean 4.23%) compared to quiescent patients (Q, mean 0.96%). Creatinine levels were not significantly different between R and Q patients (p=0.69; mean 4 and 3.1 mg/dL, respectively). Longitudinal sample analysis from 15 patients showed increased dd-cfDNA levels following transplant (mean 2.8%) with reduction to levels below 1% by two weeks post transplantation. In 3 cases with clinically treated biopsy-confirmed rejection and 2 serial samples following the rejection, levels of dd-cfDNA decreased following rejection treatment.

Conclusions: dd-cfDNA shows promise as a biomarker of rejection that may be used for non-invasive surveillance of kidney allograft status and treatment response. The ongoing measurement of cfDNA may allow clinicians to better personalize care and improve patient outcomes.
