

HOW INTERNAL KNEE COMPRESSIVE FORCES ARE MOST EFFECTIVELY REDUCED BY APPLIED HIP, KNEE AND ANKLE JOINT MOMENTS

Jonas S. Stoltze, John Rasmussen and Michael S. Andersen

The XXVI Congress of the International Society of Biomechanics, Brisbane, Australia, July 24

Department of Material and Production Engineering, Aalborg University

E-mail: jss@m-tech.aau.dk

- >9.5 million EU KOA patients (Peat G. et. al, 2001)
- Multi-factorial disease
 - Genetic
 - Previous ligament ruptures
 - Overloading

Non-invasive treatments of KOA

Modified picture from
(Pollo et al. 2002)

- Skin surface displacement
- MCL may be too stiff
- Shifts load but not reducing

Investigate how internal knee joint loads depend on external moments

Hypothesis: Joint loads depend as much on muscle contraction as on KAM

10 healthy subjects, 3 gait trials each (self-selected speed)

- Recorded with marker-based motion capture
- Measured ground reaction force

Skals et. al, 2016

Apply external joint moments to simulate a brace *in-silico*

- **40%** compensation of muscle work → Reducing joint load

Apply external joint moments to simulate a brace *in-silico*

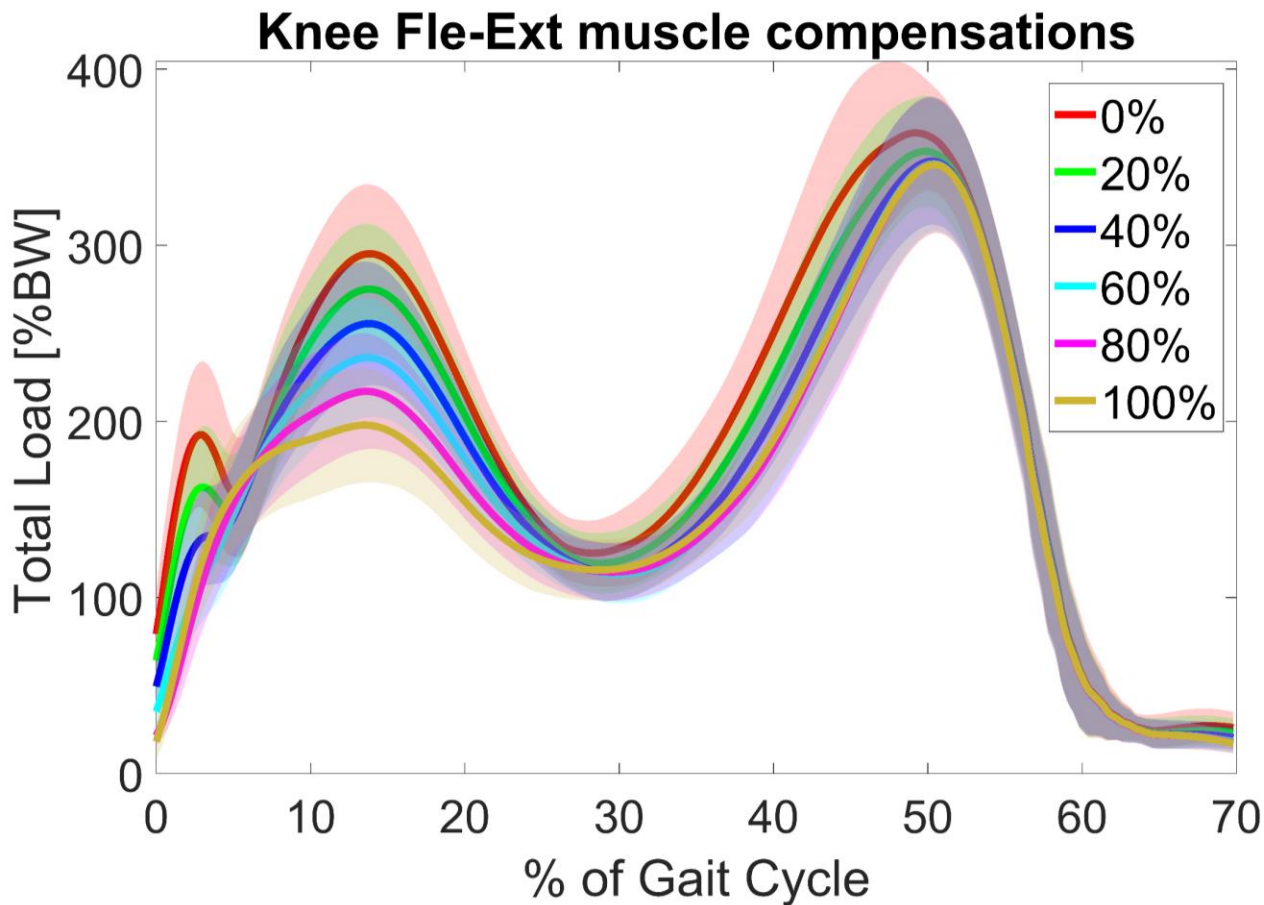

- **40%** compensating muscle work → Reducing joint load

Example of knee flex-ext

Results – Parameter study

Results – Total compression load

Method – Combined load cases

Hip+Knee

Hip+Ankle

Knee+Ankle

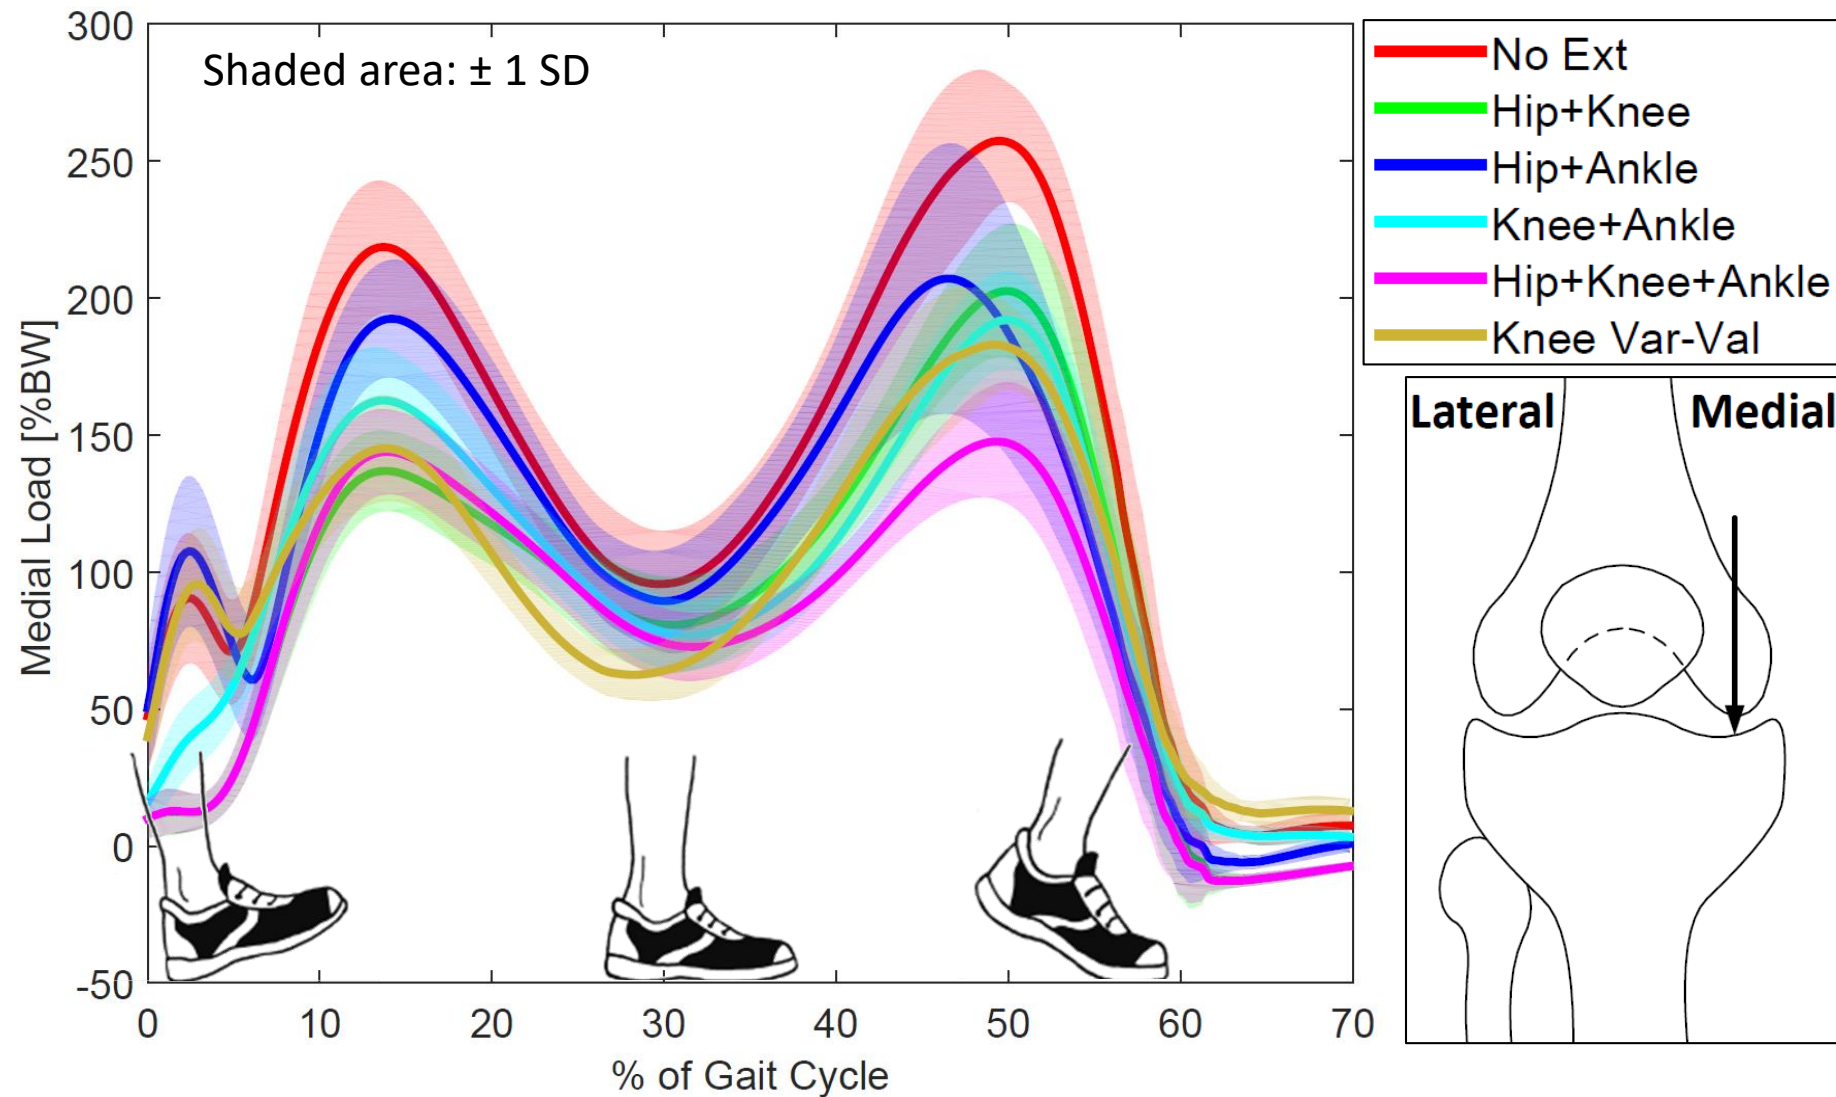

Hip+Knee+Ankle

Results – Total compression load

Results – Medial condyle load

Results – Lateral condyle load

- Useful information for brace development
- Muscle contraction → Joint compressive force
 - First peak: Knee and hip compensation
 - Second peak: Ankle compensation
- The external moment activation is a big challenge
 - Two moments active individually
- Take home message:
Muscle compensation might be a more efficient approach for joint load reduction than external KAM compensation
