Introduction: Only small series (<10 patients) have described endoscopic management of postoperative pancreatic fistulas (POPF). The purpose of this retrospective study was to describe the indications, technique and results of endoscopic treatment of POPF.

Aims & Methods: From a prospective database of an endoscopic unit of a tertiary center, patients with POPF who underwent pancreatic endoscopic treatment during a retrograde endoscopic cholangiopancreatography (ERCP) were identified. From January 2010 and June 2016, POPF was classified according to the definition of the International Study Group of Pancreatic Fistula Working Group. The indications, the techniques and results of endoscopic drainage and the patients' outcomes were registered.

Results: Among 23 patients, 31 procedures were performed during the inclusion period, 31 patients had POPF treated endoscopically (14 men, 7 women, mean age ± standard deviation [SD]: 63 years ±15). Surgeries at the origin of the fistula were: distal pancreatectomy with spleen resection (n=19), spleen preserving distal pancreatectomy (n=3), central pancreatectomy (n=2), enucleation (n=4), partial pancreatectomy (n=1); left nephrectomy (n=2), for the following indications: IPMN (n=7), pancreatic adenocarcinoma (n=5), neuroendocrine tumors (n=4), insulinoma (n=3), adenocarcinoma rectum (n=6), metastasis (n=2), pseudocystectomy (n=1), cystadenomas (n=2), spleen artery aneurysm (n=1). The mean time between surgery and first ERCP (±SD, range) was 70 days ±145, [6–806]. POPF was grade B in 19 patients and grade C in 12 patients. All patients had somatostatin analogs and 13 (41.9%) had an external radiological drainage prior to endoscopic drainage. In 9 patients (29%) a pancreatic cystogastrostomy was performed during follow-up (FU) in addition to the transpapillary drainage. The pancreatic cannulation rate was 96.8% at the first ERCP and 100% after 2 ERCPs. 90.3% by the major papilla, 9.7% by the minor papilla. All patients had a pancreatic sphincterotomy and the placement of a pancreatic plastic stent. 3 early complications (<72h) occurred: 2 post-sphincterotomies bleeding, and 1 perforation, medically treated. The mean FU (±SD, range) was 378 days ±(407 [22277]) after the first ERCP. During FU, there were 2 stent migrations and 2 stent obstructions requiring a subsequent ERCP for stent replacement. Eight patients (25.8%) died after surgery complications. Among the 23 remaining patients, the closure rate of POPF was 100% within an average of 153 days ±(68 [16326]) after the first ERCP. A mean number of ERCP performed per patient (±SD) 2.5 ±(1.0). No late reopening fistula occurred after removal of the pancreatic stent.

Conclusion: This retrospective study, the most important one reported to date, shows that the endoscopic treatment of POPF resistant to medical therapy is an effective option.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0923 EFFICIENCY OF PANCREATIC STENTS IN DIFFICULT CANNULATION – A RETROSPECTIVE SINGLE - CENTER STUDY

V. Sandru1, M. Ilie2, O.M. Plotoge2, E. Rinja1, I. Moroi2, B. Ungureanu3, G. Constantinescu1

Retrospection: Difficult biliary cannulation is defined by the presence of one or more of the following: more than 5 contacts with the papilla while attempting to cannulate; more than 5 minutes spent attempting to cannulate following visualization of the papilla; more than one unintended, pancreatic duct cannulation or fistula. In these situations pancreatic stent insertion might prove to be very useful for prophylactic and tactical purposes.

Aims & Methods: We are proposing in this paper to present the experience of Clinical Emergency Hospital Bucharest regarding difficult biliary cannulation and how pancreatic stent insertion proves to be effective in obtaining biliary situations. This paper is a retrospective study of the patients who presented difficult cannulation and to whom pancreatic stents were inserted for prophylactic and tactical purpose. The study included patients with ERCP (Endoscopic Retrograde Cholangiopancreatography) performed in Clinical Emergency Hospital Bucharest between December 2014 and December 2016. The patients were evaluated in terms of pancreatic stents efficiency regarding successful cannulation and post ERCP pancreatitis rate. The stents used were 5 Fr, 3 cm and 5 cm.

Results: We introduced in the study 158 patients with ERCP and difficult biliary cannulation, who required pancreatic stent insertion for prophylactic and tactical purpose. Patients’ mean age was 60 years, while the sex ratio was 2:1 in favor of the female gender. Pancreatic stents proved their efficiency in 90% cases, in only 3 patients deep cannulation being unsuccessful. On average, patients required 1, 15 ERCP procedures in order to obtain biliary access. ERCP indication for benign pathology was predominant (60%). The stents were used: ERCP: 5 Fr, 3 cm (102 patients) and 5 Fr, 3 cm (56 patients). Precut sphincterotomy was performed in 82 cases (37 before stent insertion and 45 after stent insertion). From all patients included, only 19 patients (12%) presented post procedure elevation of serum amylase 3 times higher than normal value associated with abdominal pain. Complications: Pancreatic stents proved to be efficient in obtaining biliary cannulation in difficult situations. Regardless of their length, 5 Fr (3 cm, 5 cm) stents ensure the same success rate for cannulation and offers protection against post ERCP pancreatitis, as long as they are correctly inserted.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address:itonaga@wakayama-med.ac.jp

Introduction: Endoscopic ultrasonography (EUS)-guided biliary drainage (EUS-BD) is increasingly used in the treatment of malignant biliary obstruction after failed ERCP. However, Multi-step process for EUS-BD is closely related to adverse events.

Aims & Methods: The present study was designed to determine feasibility and safety of stent placement using a thin delivery-system stent without dilation step during EUS-BD. Three of the new designed partially covered laser-cut metal stents (6-mm-wide and 60-mm-long) with 7Fr delivery catheter with hard tip (7Fr hard tip), 7.5Fr delivery catheter with soft tip (7Fr soft tip) were prepared respectively. A phantom model with a silicon plate was created. The plate was punctured with a 19-G needle and a guidewire was passed the plate. The delivery system was advanced over the guidewire to pass the plate and the resistance force was measured. A biliary obstruction model was created by clipping the papilla in 10 pigs, EUS-BD (choledochoduodenodenoostomy) using the thin delivery system stents was attempted following 19-G needle puncture without the use of dilation devices. The technical success and adverse events within 2 weeks after EUS-BD were analyzed for three types of stents.

Results: Among the three types of stents, 7Fr soft tip had the least resistance in the phantom model. In the animal model, the median common bile duct diameter before puncture measured on EUS and the median procedure time was 7.66 mm (4.05–9.5) and 29.3 minutes (16–47) respectively. In all pigs, EUS-BD using the three types of stents were technically successful. Dilation was unnecessary in 25% (1/4), 0% (0/2) and 100% (4/4) for the 7Fr hard tip, 7.5Fr hard tip and 7Fr soft tip respectively. Even in the cases requiring dilation, stent placement was successful, immediately after dilation only with a thin catheter (4/4). Neither stent occlusion nor balloon dilation was needed. There were no procedure-related complications occurring during and 2 week after EUS-BD. All stents remained in place without migration. At necropsy, fistulas were created between the bile duct and duodenum in all pigs and the growth of fibrous tissue was observed in the microscopic findings.

Disclosures of Interest: All authors have declared no conflicts of interest.

Introduction: Post-endoscopic sphincterotomy bleeding is treated endoscopically with pharmacologic injection, electrocautery coagulation, balloon tamponade or clipping, but severe cases may require angiographic or surgical approach. An alternative long-acting tamponade treatment with fully-covered metal stents (FCMS) has been advocated.

Aims & Methods: We report here on the use of FCMS in post-sphincterotomy early and late bleeding. Patients referred for in- and out-patient ERPC were informed of the potential off-label treatment with FCMS of post-sphincterotomy bleeding, and of treatment approval by the local ethical committee. We treated patients through endoscopic bleeding first with adrenaline and/or sclerosing agent injection. When this first line hemostasis failed, we placed short FCMS in the distal cholecodochus. Endoscopy was rescheduled after 1 month to remove the FCMS. During the early post-procedural period the patients were treated with blood transfusions if needed, and antplatelet drugs as well as oral anticoagulants were avoided.

Results: 17 Patients (10M/7F), aged on an average 70 years (range 35–90) received 18 FCMS (10 mm x 40 mm, Boston Scientific) for failed hemostasis since hemorrhage was 100% Hb drop. In 2 cases, with an average loss of 1 g/dl of Hb and 9 packed red cells units transfused. In our cases we had 1 outlier, a patient that had received needle-knife sphincterotomy without early bleeding but developed delayed bleeding with hypovolemic shock. He received a second ERPC and a FCMS after 3 days. After further 3 days the patient was in the intensive care unit because of persistent bleeding and we performed a third ERPC. The FCMS was in place, but we removed it, retreated the bleeding by injective therapy and placed a second FCMS, obtaining a stable hemostasis and receiving 8/9 of the packed red cells units used in the study. The FCMS spontaneously migrated in 4/18 cases, one had been removed for incomplete bleeding control and substituted after 3 days, and 13 were easily removed as per protocol. In two cases FCMS were removed and a plastic double pigtail catheter was placed in percutaneous cholecdochal distal stenosis.

Conclusion: These cases represent a large collection of evidence showing that treating post-sphincterotomy early bleeding with FCMS is feasible, safe and effective. Late bleeding associated with needle-knife pre-cut was much harder to control and required extensive hemostatic, intensive care unit support and re-stenting. Our results are consistent with and support previous research in the field.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0926 EFFICACY OF SELF-EXPANDABLE METALLIC STENT PLACEMENT IN THE MANAGEMENT OF ANASTOMOTIC STRICURE AFTER ORTHOTOPIC LIVER TRANSPLANTATION

S. Jang, M. Parsi, R. Lopez, A. Bhatt, J. J. Vargo

Gastroenterology, Cleveland Clinic, Cleveland/United States of America/Ohio

Contact E-mail Address: sjang39@ccf.org

Introduction: Anastomotic bile duct stricture (ABS) remains as one of the most common complications after orthotopic liver transplantation (OLT). Current standard of practice of endoscopic retrograde cholangiopancreatography (ERC) with insertion of multiple plastic stents (PS) often requires multiple procedures before achieving satisfactory stricture resolution. In recent years, studies utilizing covered self-expandable metallic stent (cSEMS) in refractory ABS management reported varying degree of success.

Aims & Methods: The aim of this study was to analyze efficacy of SEMS in resolution of anastomotic stricture in patients with orthotopic liver transplantation (OLT). Inclusion criteria were adult patients with confirmed stricture length of ≥ 1cm on endoscopic retrograde cholangiopancreatography (ERC), clinical and/or imaging evidence of stricture, 12-week or > 12-week follow-up. A retrospective cohort study was conducted using a registry of consecutive patients who underwent ERCP with biliary SEMS placement from January of 2010 to November of 2016 for the management of refractory ABS. Demographic variables including age, gender, and clinical variables including body mass index (BMI), number or prior ERCP with PS insertion, stent brand and dimensions and duration of SEMS insertion period were collected. The rates of stricture resolution, adverse outcomes including post ERCP pancreatitis, cholangitis and stent dysfunctions (occlusion, migration) were calculated. This study was approved by the Institutional Review Board of the Cleveland Clinic.

Results: There were 47 OLT patients who underwent ERCP-cSEMS insertion for refractory ABS during the study period. Of 47 patients, 37 patients (78.8%) achieved stricture resolution after single SEMS treatment. Longer duration of SEMS insertion was the only variable associated with increasing probability of stricture resolution as there was 20% increase in odds of stricture resolution for every additional week SEMS was in place. Among those who achieved initial stricture resolution, 27 patients (57.4%) maintained bile duct patency throughout the follow up period. The most common adverse outcome was internal migration of cSEMS which occurred in 11 patients (23.4%). Post-ERCP pancreatitis was observed in 3 (6.4%) patients

Conclusion: The efficacy rate observed in resolving refractory ABS with cSEMS placement appears to be comparable to that of multiple ERCPs with PS placement method. Furthermore, durability of ABS resolution with cSEMS use further supports its potential long-term efficacy. Hence, cSEMS should be considered as a first alternative treatment in refractory ABS. The study period is associated with higher likelihood of ABS resolution. The high rate of internal migration observed with SEMS warrants further endeavor in stent design improvements.

P0927 “DISCONNECTED PANCREATIC DUCT” FOLLOWING EUS GUIDED DRAINAGE OF PANCREATIC FLUID COLLECTION - IS IT CLINICALLY RELEVANT? LONG-TERM FOLLOW UP FROM A LARGE VOLUME TERTIARY CARE CENTRE

Gastroenterology, Cleveland Clinic, Cleveland/United States of America/OH

Contact E-mail Address: drsuneeplakhtakia@gmail.com

Introduction: Disconnected pancreatic duct (DPD) can occur in patients after drainage of pancreatic fluid collections (PFC). Concerns have been raised about clinical relevance of DPDs.

Aims & Methods: To assess the frequency of DPD and its clinical significance after EUS guided drainage of PFC. Patients of acute or chronic pancreatitis with symptomatic PFC, who underwent Endoscopic ultrasound (EUS) guided drainage between January 2011 to December 2016 were included, after an informed consent. Stents used for drainage procedure were either bi-flanged metal stent (BFMS) or double pigtail plastic stent. All these patients underwent MRCP between 4 to 8 weeks after drainage to evaluate pancreatic duct (PD) anatomy and confirm resolution of PFC. Subsequently, they had Endoscopic Retrograde Pancreatography (ERP) and, if required, stent removal. BFMS was removed in all patients. Plastic stents were retained indefinitely, if DPD was confirmed. All patients were systematically followed at 3–6 monthly intervals for any recurrence of PFC or new onset clinical event.

Results: A total of 407 patients (346 males, mean age 33.5 years, range 5-69 years) were followed up after EUS guided drainage for PFC. Of these 260 under-went BFMS and 147 underwent plastic stents placement. 319 patients had pancreatic ductography (ERP and MRCP) after resolution of PFC. The pancreatic duct abnormalities observed were: DPD in 197 (61.7%), PD leak in 36 (11.3%), PD stricture in 20 (6.3%) patients. Normal PD was seen in 43 (13.5%) patients. Calcific pancreatitis was noted in 23 (7.2%). Among the patients with DPD, the location of PD “cut off” was in head (32, 16.2%), genu (59, 29.8%), body (90, 45.6%) and tail (16, 8.1%). Overall, the follow-up after stent removal ranged from 3–72 months, with a median follow up of 12months. Pseudocyst recurred in 29 patients (8.5%) at a mean follow up of 3.5 months (range 1–30 months), which included DPDS 27, PD stricture 1, and CCP 1. 20/29 had pain (symptomatic) and rest 9 were asymptomatic. 15/20 underwent inter- vention (EUS drainage with plastic stent in 12, surgery in 3) and 5 resolved spontaneously.

A485
Introduction: Disconnected Pancreatic Duct is observed in 60% patients following EUS guided drainage of PAP. However, only a small proportion (<10%) of DPD had symptomatic recurrent fluid collection.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0928 FULLY COVERED SELF-EXPANDABLE METAL STENT IN THE MANAGEMENT OF DUODENAL RETROPERITONEAL PERFORATIONS DURING ERCP: A SINGLE CENTER EXPERIENCE

M. Pizzicannella1, G. Andreisani1, M. Martino1, R. Rea1, M. Pandolfi2, F.M. Di Matteo1

Contact E-mail Address: f.dimatteo@unicampus.it

Introduction: ERCP-related perforation is rare (0.3%), but it is associated with a high mortality rate (1.7%). Duodenal retroperitoneal perforation (Type II) is the most frequent, among the ERCP-related perforations. The management of this complication has not been standardized yet: traditionally surgery was considered the only rescue therapy, but in the last years the majority of cases has been managed conservatively. The endoscopic treatment included biliary stent and/or nasobiliary drainage. In our institution, from 2010 we have been using fully covered self-expandable metallic stent (FCSEMS) with nasobiliary drainage always after resolution of the initial indication for ERCP. These stents have the advantage of covering the laceration and allowing free flow of bile into the duodenum instead of into the retroperitoneal space. The aim of this study was to evaluate in our cohort of patients, the benefits of FCSEMS in type II perforations.

Aims & Methods: We experienced six type II perforations associated with ERCP. We retrospectively evaluated the clinical findings, the length of hospital stay, the need for surgery and death.

Results: Of the 3250 ERCP procedures performed from March 2010 to November 2016, only six (0.18%) resulted in perforations (male/female, 2/4; median age: 69 years; age range: 54–80 years). ERCP procedures were performed with carbon dioxide insufflation. Five patients underwent ERCP for biliary stenosis, whereas sphencterotomy was performed and perforation was immediately detected. Successful closure of persistent splenectomy-related duodenal perforation using FCSEMS was obtained in all patients. One patient developed ERCP-related pancreatitis, successfully treated with medical therapy. Three FCSEMS were successfully removed after a median of 18 days, the remaining three fell out spontaneously. The median length of hospital stay was 8.5 days (range 4–20 days). There were no deaths or need for surgery.

Conclusion: The placement of FCSEMS is easy, safe and quick. In our cohort of patients, FCSEMS is an effective endoscopic approach for management of type II perforations recognized during ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Duodenal obstruction is often seen in patients with advanced pancreatic cancer. Endoscopic duodenal stenting (DS) has become increasingly popular due to its less invasiveness compared with surgical gastrojejunostomy. With recent new advances in chemotherapy and radiation therapy, conversion surgery after neoadjuvant therapy are performed in some cases with APC.

Aims & Methods: To evaluate the efficacy and safety of DS as palliative treatment and bridge to surgery in patients with APC. We retrospectively analyzed patients who received DS placement between March 2012 and March 2017. Twenty-three patients (11 men/12 women median age, 65.5; 46–82 years) with APC. GOO scoring system (GOOSS) was used as an index of clinical success.

Results: A total of 23 Patients consisting of 6 patients treated with chemotherapy and 11 patients treated with neoadjuvant chemoradiotherapy were included in this study. Obstructed parts of the duodenum were D1 in 2, D2 in 5, D3 in 12, and D4 in 4. Technical success rate of DS was achieved in 21 patients (91%). The median GOOSS before DS and after DS were 0.5 and 2.6 respectively (p < 0.001). The median time to restart soft solid meal after DS was 2.9 days. Biliary obstruction was seen in 13 patients and managed with endoscopic biliary stenting. Adverse events occurred in 6 patients, including 1 with cholangitis, 1 with bleeding and 3 with stent occlusion. The intervention technique and clinical success rates were 100% (5/5) and 80% (4/5); respectively. The median survival time after DS was 159 days. In neoadjuvant chemoradiotherapy patients, 4 patients were planned surgery for APC.

Conclusion: DS in patients with APC was effective and safe. The findings of this study suggest that DS is worth considering as the bridge to surgery in patients receiving neoadjuvant therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.
The role of mitomycin in the prevention of colorectal surgery. Colostomy or ileostomy and later redo anastomosis or more endoscopic dilation therapy. The patients should be more than eighteen years old. Exclusion criteria: Malignant esophageal stenosis, Pregnant or breast feeding women. Deteriorated patients who could not tolerate endoscopic procedures. The method of MMC application – Via 23 gauge injection needle (Optimix injector, Taewoong Medical, Korea) – 4 mL of saline-diluted MMC was prepared, with concentration of 0.5 mg/mL. – Injection of 0.5 mL MMC at eight points of the stenotic site immediately after bougination. Follow-up – Interview After 1 week and every four weeks after MMC injection up to 52 weeks. Endoscopy Four weeks after MMC injection and when the obstructive symptoms appeared. Primary end-point – The rate of clinical success. Secondary end-points: The mean score of GOOSS before and after MMC injection therapy. Complication – Definition – Clinical success: Improvement of GOOSS score more than one point after MMC injection therapy, compared before MMC injection.

Results: Ten patients with refractory benign esophageal stenosis were initially enrolled. Two patients were excluded due to death from hypovolemic shock due to persistent bleeding and esophagectomy as patient’s wish. Finally, Eight patients were analyzed. The rate of clinical success of MMC injection therapy in patients with refractory benign esophageal stenosis was 87.5%. Mean scores of GOOSS were significantly reduced after MMC injection therapy, from 2.5 to 0.29. In all patients, MMC injection therapy below two sessions was needed to improve the symptoms of enrolled patients. Major complications did not occur in any patients.

Introduction: The prevalence of post-ESD esophageal strictures is non-negligible, with a critical impact on the patients’ quality of life. Balloon-dilation may be the first-line therapy. However, factors associated to a successful dilation in post-ESD strictures remain unclear.

Aims & Methods: This is an observational and analytical retrospective study. Sixty-eight consecutive patients (mean age: 65±11 years, 76.5% men) who underwent endoscopic dilation because of post-ESD symptomatic esophageal strictures between 2006 and 2016 were included. They had Barrett’s esophagus (n=46, 67.6%), epidermoid carcinoma (n=21, 30.9%) and other (n=1). Patients with previous endoscopic dilation or endoscopic dilations, esophageal motor disorders were excluded. Clinical, morphological and technical features were collected and analysed to determine the factors associated with a positive outcome, defined as the absence of dysphagia during at least twelve months following last dilation. The need of surgery, gastrostomy or prosthesis was considered as negative.

Results: Resected lesions (95.6% en-bloc) presented a median size of 52.5 mm (range: 22–110) and achieved ≥75% of the circumference in 50% of cases (p=0.435). They were mostly located in inferior esophagus (70.6%, p=0.231) and required two endoscopic sessions in 8 patients (11.8%). Oral and injected corticoids were used in 11 (16.2%) and 12 (17.6%) cases, with no effect in outcomes. In 15 days after ESD, number of dilations (p=0.345), short (<2 cm) stenosis (p=0.319), balloon diameter (p=0.475) and Barrett’s vs. squamous cell carcinoma (p=0.458). The overall positive outcome rate was 92.6% after a median of 3 (range: 1–27) dilations and 5 months of treatment (1 dilation/6.7weeks). A prosthesis was placed in 4 patients with clinical improvement in two of them. There were 3 complications (4.4%, all perforations).

Conclusion: Most of patients presenting with post-ESD strictures and dysphagia improve at long-term buy they need a median of 3 sessions. No specific factor was associated to a better outcome. Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Most of patients presenting with post-ESD strictures and dysphagia improve at long-term buy they need a median of 3 sessions. No specific factor was associated to a better outcome. Disclosure of Interest: All authors have declared no conflicts of interest.
MANAGEMENT OF ESOPHAGEAL BENIGN STRICTURES

P0934 EFFECTIVENESS OF REPEATED DILATIONS IN THE MANAGEMENT OF ESOPHAGEAL BENIGN STRICTURES

A. Benezech, A. Debourdeau, J. Gonzalez, M. Barthet
Service De Gastroentérologie, Assistance Publique - Hôpitaux de Marseille, CHU Nord, Marseille, France

Introduction: Refractory or recurrent esophageal benign strictures (REBS) are frequent, and defined as the impossibility to reach or maintain a diameter of 14 mm after 5 sessions of endoscopic dilation (ED). Because of a lack of guidelines, their management remains challenging, sometimes leading to radical surgical procedure.

Aims & Methods: The aim of this study was to define the efficacy of long-term and repeated ED in the management of REBS. This was a monocentric retrospective study including patients managed in our tertiary center between January 2002 and April 2017 for REBS. All the endoscopic dilations were performed using Savary bougies or hydraulic balloons, depending on the operator’s choice. Demographical and clinical data were recorded for each patient. The endoscopic management was detailed with the number of procedures, the endoscopic device used, the diameter of dilation, and potential concomitant treatment (as self-expanding metal stent, steroid injection or incisional therapy). The primary endpoint was the efficacy of sustained and recurrent ED, defined as the absence of further dilation within 3 months of the last procedure or an interval between the last 2 ED greater than 3 months. A failure was considered in case of death, need for surgery, permanent enteral feeding tube or an interval between the last 2 procedures lower than 3 months. The secondary endpoints were to document the characteristics of dilation procedures and concomitant treatments, the decreasing of the number of dilations per trimester, and to elucidate potential predictive factors for success of ED.

Results: A total of 39 patients (23 men) with a mean age of 47.5 ± 20.7 years were included. The etiologies of strictures were anastomotic (46.1%), caustic (28.2%), peptic (10.3%) or other etiologies (radiation injuries, esophageal diverticulitis, severe viral esophagitis, 15.4%). A clinical success of repeated ED was achieved in 27 patients (69.2%). Twelve patients (30.8%) experienced failure, among them seven (17.9%) required frequent dilations, two (5.1%) underwent surgery, two (5.1%) maintained an enteral feeding tube, and one patient (2.6%) died consecutively to inhalation pneumonia. A mean of 9.8 ± 4 ED sessions were performed per patient, with a mean treatment duration of 22.6 ± 20.1 months. Regarding concomitant treatments, 16 patients (41%) had at least one fully-covered metallic stent placement, incisional therapy was performed in 11 patients (28.2%), and 3 patients (7.7%) received corticosteroid injections. The number of dilations per trimester gradually decreased over time. No significant predictive factor of success was found, such as etiology of stricture or the use of concomitant treatment, particularly. Nevertheless, a greater number of dilations during the first trimester could promote the success of the management (3.2 ± 2.2 dilations in the success group vs 2.2 ± 0.8 in failure group, p = 0.056).

Conclusion: Repeated and maintained endoscopic dilations are effective (70%) in the management of REBS, regardless of the etiology of stricture. A prolonged management up to 2 years, and the initial rhythm of endoscopic procedures may favor the final success. A systematic schedule for ED would improve the efficacy of this management.

Introduction: Endoscopic stenting with self-expandable metallic stents (SEMSs) is a widely accepted procedure for treating malignant colonic obstruction. This procedure was covered by the National Health Insurance of Japan in January 2012, and the WallFlex colonic stent and Niti-S colonic stent can currently be used in Japan. In the previous study, we reported that the WallFlex colonic stent has more expanded force than the Niti-S colonic stent. On the other hand, the risk of stent-related perforation was lower when using the Niti-S stent due to its structure. Currently, we newly developed an SEMS (Niti-S structure, with 18-mm diameter with increased expanded force compared with the conventional type), which comprised the benefits of both WallFlex and Niti-S. In this study, we compared the efficacy and safety of the newly developed colonic stent with the conventional colonic stents.

Aims & Methods: This study aimed to compare the efficacy and safety of the newly developed colonic stent with the conventional colonic stents (the WallFlex colonic stent and the Niti-S colonic stent). Overall, 91 patients (96 lesions, male/female: 48/43, average age: 73.2 years) underwent endoscopic SEMS placement between November 2011 and March 2017 at Kure Medical Center and Chugoku Cancer Center. The WallFlex colonic stent was used in 36 patients (38 lesions: Group W), the Niti-S colonic stent in 51 patients (53 lesions: Group N), and the newly developed colonic stent in 5 patients (5 lesions: Group D). Stratified analysis of the clinical background, technical success rate, procedure time, clinical success rate, and complications was performed to compare Group W, Group N, and Group D.

Results: Endoscopic SEMS placement was attempted in 96 lesions as a bridge to surgery (BTS) in 52 lesions (54.6%) and as palliative therapy (PAL) in 44 lesions (46%). In Group W, SEMS was placed in 19 lesions (50%) as BTS and in 19 lesions (50%) as PAL; in Group N, SEMS was placed in 32 lesions (60%) as BTS and in 21 lesions (40%) as PAL; and in Group D, SEMS was placed in 1 lesion (20%) as BTS and in 4 lesions (80%) as PAL. The technical success rate was 100% in all groups. The overall clinical success rate was 93.7% (90/96): 89.5% (34/38) in Group W, 96.2% (51/53) in Group N, and 100% (5/5) in Group D. Complications within 7 days included abdominal pain (3/38, 8%), poor...
expansion (1/38, 3%), and fever (1/38, 3%) in Group W and perforation due to obstructive colitis (1/38, 3%) in Group M; 8 cases had stent-related perforations (4/38, 11%) and stent occlusion (1/38, 3%) in Group W and stent occlusion (2/53, 4%) in Group N. All 4 patients with stent-related perforations had undergone palliative stenting with the WallFlex colonic stent, and the stent-related perforation rate in Group W was significantly higher than that in Group N (P < 0.05). In Group D, there were no complications and no stent occlusion.

Conclusion: The technical and clinical success rates were extremely high in all groups; no severe complications were observed. Therefore, POEM is a very effective treatment method for patients with esophageal or esophagogastric junction cancer. One hundred ninety three consecutive patients with esophageal or esophagogastric junction cancer were enrolled in this retrospective study. White blood cells count, polymorphonuclear cells and lymphocytes counts were observed at preoperative time, post-operative day (POD) 1, 3 and 7. Post-operative immune suppression in esophageal or esophagogastric junction cancer presented a significant post operative immunosuppression that lasts at least for the first postoperative week. The total amount of radiation received by the mediastinum is the only predictor of the postoperative and postoperative lymphocyte count.

Introduction: Surgery and endoscopic stapling have been the mainstay of treatment modalities for Zenker’s diverticulum. The need for general anesthesia (GA) is however a limiting factor in high-risk patients, as patients with ZD are often elderly with cardiorespiratory co-morbidities. In recent years, flexible endoscopic septum division (FSED) has gained popularity as a less invasive treatment modality for ZD, that can be performed under deep sedation, and has the potential to be performed safely in patients otherwise deemed unfit for full GA.

Aims & Methods: The aim of this pilot study was to assess the efficacy and safety of FSED for patients deemed unfit for GA. Patients had been referred to our tertiary centre for FSED. Data on 14 consecutive day case patients (median age 81, range 68–93; 7 females) were collected between August 2015 and November 2016. All patients underwent FSED under deep sedation with propofol and remifentanil, and did not require ventilatory support. The amount of propofol used was recorded. Demographic data as well as information of the nature of symptoms and any previous interventions was retrieved. The severity of dysphagia was measured with the Dukkak scale. Data on procedural and 30-day post-procedural complications, including sedation-related side effects, were collected.

Results: All patients complained of dysphagia (median Dukkak score 2, range 1–3) and regurgitation before the procedure. There were no procedure-related nor sedation related adverse events in any of the patients. There were no 30-day post-procedural adverse events. All patients but one experienced complete symptom relief after one treatment session. Median propofol used was 173 mg (range 59–

Introduction:

Colon interposition was first described as a method to create a neo-oesophagus in 1911 by Kelling and Vuillet, and in contemporary practice is usually only considered if the stomach is not a viable neo-conduit because of the associated high morbidity and mortality. There is no consensus on the optimum choice of colonic conduit (right vs. left) or the route of placement (posterior mediastinal, retrosternal or subcutaneous).

Aims & Methods: The aim of this review was to determine the optimum choice of colonic conduit following esophagectomy in adults.

P0941 THE ROLE OF LIVER RESSECTION AFTER CHEMOTHERAPY FOR SYNCHRONOUS COLORECTAL LIVER METASTASIS

A. Ouchi, Y. Shimizu, K. Komori, Y. Senda, T. Kinoshita, S. Natsume, T. Ooshiro

Department Of Gastroenterological Surgery, Aichi Cancer Center Hospital, Aichi/ Japan

Contact E-mail Address: akira.ouc@gmail.com

Introduction: The combination of chemotherapy and molecular targeted therapy has improved the outcome of patients with colorectal liver metastasis (CRLM); however, treatment outcomes of liver resection after preceding chemotherapy for CRLM, especially synchronous CRLM (sCRLM), remain unclear. For patients with technically resectable and oncologically suitable sCRLM, we conduct hepatic resection for the metastases at an interval of 3 months after colorectal resection, especially for those with both technically resectable or oncologically unsuitable sCRLM, we perform preceding chemotherapy. The aim of this study was to retrospectively evaluate treatment outcomes of our strategy for sCRLM and explore prognostic factors for determining the indication for liver resection, particularly in patients receiving chemotherapy for sCRLM.

Aims & Methods: Between April 2006 and March 2016, 157 consecutive patients underwent primary tumor resection for sCRLM at our department; of them, 35 patients (s group) underwent subsequent staged liver resection, 109 patients received preceding chemotherapy, and remaining 13 patients received other treatment. Among those who received preceding chemotherapy, 25 patients (CS group) underwent liver resection after chemotherapy, but 84 patients (C group) could not undergo liver resection and continued ongoing chemotherapy. In the
CS group, 16 patients had unresectable disease (due to lack of remnant liver volume or hilar bile duct involvement). Three patients to whom hepatectomy and 9 initially had unsuitable disease (progressive primary disease or suspicion of other distant metastasis); therefore, upfront chemotherapy was selected.

Results: The frequency of adverse prognostic factors tended to be higher in the CMZ group than in the S group (often ≥ median value: 6.0 ± 3.5 vs. 2.7 ± 1.7) and number of metastatic lymph nodes (4.2 ± 6.3 vs 2.7 ± 2.1). Nevertheless, overall survival (OS) in the CS and S groups since primary tumor resection was equivalent (3-year survival rate: 86.9% vs 93.4%, Log-rank P = 0.34) and much better than that in the C group (3-year survival rate: 40.2%). Although liver-limited relapse-free survival (RFS) since hepatectomy tended to be worse in the CS group than in the S group (3-year survival rate: 45.5% vs 62.7%, Log-rank P = 0.14), RFS after hepatectomy was equivalent in the CS and S groups (3-year survival rate: 33.3% vs 21.6%, Log-rank P = 0.397). Early tumor shrinkage (ETS) was found to be a stronger poor prognostic factor for liver resection after chemotherapy than existing prognostic factors in univariate and multivariate analyzes, and RFS was much better in patients with ETS than in those with non-ETS (3-year survival rate: 62.5% vs 7.7%, Log-rank P = 0.05).

Conclusion: OS and RFS in the CS group compared favorably with those in the S group despite the high frequency of poor prognostic factors; patients with ETS had a better prognosis after liver resection. Liver resection after chemotherapy revealed comparatively favorable prognosis in well-selected patients with sCRLM, and early responsiveness to chemotherapy was useful in determining the indication for liver resection in patients receiving chemotherapy for sCRLM.

P0943 PERIOPERATIVE ADMINISTRATION OF BROAD SPECTRUM ANTIBIOTICS REDUCES THE INCIDENCE OF SURGICAL SITE INFECTION FOLLOWING PANCREATEODUODENECTOMY
1Department Of Gastroenterological Surgery 2, Hokkaido University Graduate School of Medicine, Sapporo/Japan
Contact E-mail Address: kominaka.1@gmail.com

Introduction: Pancreateoduodenectomy (PD) is one of the operations associated with high rate of surgical site infection (SSI). The one of the reasons is said that SSI is associated with the preoperative biliary infection caused by preoperative examinations or drainage of biliary tract. In our clinical trial [1], SSI after pancreateoduodenectomy could be decreased by using the perioperative selective antibiotics based on preoperative biliary culture. The bacteria cultured from SSI were Enterobacteriaceae such as Enterococcus and Enterobacter species with high frequency. Recently, however, most of the patients who had planned to undergo PD received internal biliary drainage preoperatively. It means preoperative collection of the bile juice is hard for the patient with internal biliary drainage. In order to solve this problem, we compared the conventional perioperative prophylactic antibiotics (Cefmetazole: CMZ) and the broad-spectrum antibiotics covering the Enterobacteriaceae (Piperacillin/Tazobactam + Vancomycin: PIPC/TAZ + VCM), retrospectively. The aim of this study is to assess the impact of two types of perioperative prophylactic antibiotics usage in patients undergoing PD.

Aims & Methods: Sixty-nine patients underwent PD at Hokkaido University Hospital (Japan) between April 2015 and March 2016, when prospective surgical site infection surveillance was performed. Thirty-eight patients were administered CMZ as perioperative prophylactic antibiotics from April 2015 to March 2016, and 31 were PIPC/TAZ + VCM from April 2016 to March 2017. CMZ was injected intravenously every three hours from the start of operation, and once after the operation. PIPC/TAZ was injected intravenously every three hours from the start of operation and then three times on the next day of the operation. PIPC/TAZ + VCM was injected intravenously in the morning of operation (20mg/kg) and just after the operation (15mg/kg).

Comparison between CMZ group and PIPC/TAZ + VCM group was performed for the patient receiving the biliary drainage, age, body mass index, performance of neoadjuvant chemotherapy and preoperative biliary stent, operative outcomes (operation time and blood loss) and postoperative course (the incidence of SSI, the duration of postoperative antibiotics and postoperative stay). The side effects of VCM or PIPC/TAZ, and the occurrence of multidrug resistant bacteria were investigated, as well.

Results: There were no significant differences in clinical features and operative outcomes between the two groups. The patients with PIPC/TAZ + VCM received a slightly shorter duration of postoperative antibiotics administration than the patients with CMZ (5.9 ± 8.5 vs. 13.0 ± 18.2 days; p = 0.048). Significantly lower incidence of SSI was revealed in patients with PIPC/TAZ + VCM (9/31(29.0%)) than in those with CMZ (20/38(52.6%)) (p = 0.048). Especially, significantly lower incidence of incisional SSI was revealed in patients with PIPC/TAZ + VCM (2/36(5.6%)) than in those with CMZ (14/38(36.8%)) (p = 0.004). The redneck syndrome as one of the side effects of VCM was observed in 5/31 (16.1%). No multidrug resistant bacteria were identified.

Conclusion: The broad-spectrum perioperative antibiotics covering Enterobacteriaceae such as Enterococcus and Enterobacter species could decrease the incidence of SSI and duration of postoperative antibiotics administration compared to CMZ. More strict indication to select the patients who should be administered VCM, because the occurrence of side effects of VCM was relatively high.

P0944 PARADIGM SHIFT? SHOULD A LYMPHADENECTOMY BE ROUTINELY PERFORMED ALSO AMONG GALLBLADDER CANCER PATIENTS WITH T1A DISEASE?
1Visceral Surgery And Medicine, Inselspital, University Clinic, Bern/Switzerland
2Surgery, Kantonsspital St. Gallen, St. Gallen/Switzerland
3Surgery, Duke University Medical Center, Durham/United States of America/NC
4Inselspital, Universität Bern Inselspital Visceral and Transplant.-Chirurgie, Bern/Switzerland

Background: Current guidelines recommend a lymphadenectomy in patients with T1A gallbladder cancer. The high rate of lymph node metastases in tumors ≤ 3 cm, in particular, supports a more aggressive approach. For patients with tumors ≥ 3 cm, current guidelines do not recommend routine lymphadenectomy, because the rate of lymph node metastases is considered low. This retrospective analysis evaluated the impact of routine lymphadenectomy on disease-free survival in this patient population.

Patients and Methods: A single-institution retrospective analysis of patients undergoing curative-intent operative intervention for gallbladder cancer from 2011 to 2016 was performed. Patients with tumors ≤ 3 cm were considered to have T1A disease. Lymphadenectomy was performed based on the surgeon's discretion. The impact of lymphadenectomy on disease-free survival was assessed using Kaplan-Meier analyses. A multivariate Cox regression analysis was performed to identify independent risk factors for disease recurrence.

Results: A total of 205 patients with T1A gallbladder cancer were included in the analysis. Lymphadenectomy was performed in 118 patients (57.5%). The 5-year disease-free survival rate was 72.1% for patients with lymphadenectomy and 50.4% for patients without lymphadenectomy (p = 0.017). In the multivariate analysis, lymphadenectomy was an independent risk factor for disease recurrence (HR 0.50, 95% CI 0.36–0.71). The factors associated with disease recurrence included tumor size, lymphovascular invasion, and perineural invasion.

Conclusion: Routine lymphadenectomy is associated with improved disease-free survival in patients with T1A gallbladder cancer. This finding supports a more aggressive approach for these patients, including routine lymphadenectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cancer is the fifth most common gastrointestinal malignancy and the most common of all biliary tract cancers. Overall, it is associated with a poor prognosis. Consensus guidelines suggest that patients with T1a cancers can be observed with cholecystectomy alone while patients with T1b or greater lesions should undergo lymphadenectomy in the hepatoduodenal ligament. Extent of surgery is especially important for those patients given efficient systemic therapy is lacking.

Aims & Methods: The aim of this study was to critically explore whether such surgery affects the population-based levels given that current evidence is mainly based on small patient series. Especially we assessed the rate of T-stage specific lymph node positivity and the impact of lymphadenectomy on long-term outcomes. The National Cancer Data Base of the United States was reviewed from 2004 to 2012 to identify non-metastatic gallbladder cancer patients with T1a, T1b, or T2 stage primary tumors. Patients were grouped by whether a dedicated lymphadenectomy was performed or not while those with missing information were excluded. Groups were compared for baseline characteristics. Preoperative lymphadenectomy was performed univariately and multivariable adjusted logistic regression with adjustment for important patient- and tumor characteristics. Overall survival was assessed using Cox proportional hazard regression analysis before and after full bipartite pairwise propensity score matching.

Results: Of the 3879 patients included, 287 (7.4%) had T1a, 661 (17.0%) T1b, and 2931 (75.6%) T2 gallbladder cancer. Most patients were female (n = 2751, 70.9%), median age was 72 years (range 21–90). Among patients with T1a, T1b, and T2 disease, 102 (35.5%), 278 (42.1%), and 1526, (52.1%) underwent a dedicated lymphadenectomy, respectively. Over the study period, the rate of lymph node excision increased from 43% to 58% (p = trend < 0.005). The rates of positive lymph nodes were 11.8%, 16.2%, and 42.5% for T1a, T1b, and T2-stage, respectively. 5-year overall survival rate was 31.6% for patients without and 44.6% for patients with a dedicated lymphadenectomy and 58.6%, 43.9%, and 34.5% for T1a, T1b, and T2-stage, respectively. After multivariable adjustment, the odds of undergoing a lymphadenectomy increased with tumor stage compared to T1a disease (vs. T1b: OR 1.37; CI: 1.01–1.86, vs. T2: OR 1.95, CI: 1.48–2.57). Compared to their counterparts, patients who underwent lymphadenectomy for gallbladder cancer were more likely to have had an R0 resection status, had a shorter hospital stay, or radiation therapy, were diagnosed in a higher ASA score, were younger, had a lower Charlson-Deyo-comorbidity score, were operated in high volume centers and traveled a longer distance to the treatment facility. In univariate analysis, no survival benefit of lymphadenectomy was found for T1a disease (HR 1.04, 95% CI 0.70–1.54) while lymphadenectomy improved overall survival in T1b (HR 0.72, 95% CI 0.38–0.90) and T2 stage (HR 0.89, 95% CI 0.53–0.65). Given significant bias of undergoing lymphadenectomy, full bipartite, pairwise propensity-score matching was performed. A trend towards overall survival benefit was present after matching (HR 0.49, 95% CI 0.39–1.09). Overall survival benefit remained for T1b (HR 0.68, 95% CI 0.51–0.91) and T2-stage (HR 0.63, 95% CI 0.55–0.71).

Conclusion: Our results support current consensus guidelines that T1b and T2 gallbladder cancer patients should undergo LA. However, based on the high rate of nodal positivity among patients with T1a disease and the trend towards overall survival improvement among T1a patients who underwent lymphadenectomy, we suggest to rethink this dogma and advocate to perform lymphadenectomy also in surgically fit patients with T1a disease.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0947 COMPARISON OF POSTOPERATIVE CONDITIONS BETWEEN ESOPHAGOGASTROSTOMY WITH THE DOUBLE-FLAP TECHNIQUE AND THAT WITH A CIRCULAR STAPLER IN LAPAROSCOPIC PROXIMAL GASTRECTOMY

M. Hayashi, H. Kawakubo, S. Mayanagi, K. Fukuda, R. Nakamura, K. Suda, N. Wada, Y. Kitagawa
Department Of Surgery, Keio University School of Medicine, Tokyo/Japan

Contact E-mail Address: sas.jff@gmail.com

Introduction: In recent years, laparoscopic proximal gastrectomy (LPG) has been actively performed in our institution to reduce invasiveness. However, proximal gastrectomy is sometimes followed by reflux. Until February 2015, we performed esophagogastrostomy with a circular stapler (CS) accompanied by fundoplication in LPG. Afterward, in 2015, to avoid the complication of dislocation, we have been using esophagogastrosenosis with the double-flap technique (DFT) in LPG for gastric cancer.

Aims & Methods: We conducted this study to examine whether DFT can reduce the reflux of gastric juice and enhance postoperative recovery compared to CS.

References

Aims: To compare postoperative conditions between LPG with ES (CS) and DFT in LPG.

Methods: We performed LPG at Keio University Hospital from January 2012 to February 2017. 47 LPGs were performed at Keio University Hospital. First, surgical time, bleeding, incidence of postoperative complication, postoperative hospital stay, and incidence of anastomotic stenosis were examined as surgical factors and compared between the CS group and the DFT group. Second, the rate of gastroesophageal reflux and the condition of the remnant stomach were examined according to residue, gastritis, bile (RGB) classification at postoperative 6 months and 1 year, and proton pump inhibitor (PPI) intake were examined as postoperative factors. Finally, albumin and hemoglobin levels at postoperative 6 months and 1 year were examined as nutrient factors. Gastroesophageal reflux was assessed with scores of 0–5 in accordance with the Los Angeles (LA) classification.

Results: Twenty-three LPGs with DFT and 24 LPGs with CS were performed during the period. Compared with the CS group, the DFT group had a significantly longer surgical time (272.3 ± 55.5 vs 241.1 ± 26.7 min, p < 0.01). Surgical factors did not show statistically significant differences between the two groups. As for postoperative factors, although no significant differences in PPI intake, LA classification, and RGB classification were found, the DFT group showed a significantly lower score than the CS group (p < 0.01). Postoperative complications were no different. In most cases are a significant difference in time between the DFT and CS groups. In addition to the armamentarium to treat these difficult lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0948 NOVEL ENDOSCOPIC REPAIR TECHNIQUE FOR GASTROINTESTINAL LEAKS AND PERFORATIONS USING NEGATIVE PRESSURE THERAPY WITH OPEN-PORE POLYURETHANE-FOAM AND FILM DRAINAGE

G. Loske1, F. Rucktaechel2, T. Schorsch3, C. T. Mueller1
1Department For General, Abdominal, Thracic And Vascular Surgery, Katholische Marienkrankenhaus GmbH, Hamburg/Germany
2Medical Clinic, Westkuestenkliniken, Heide/Germany

Introduction: Gastrointestinal (GI) leaks and perforations are difficult to manage and often mandate laparotomy and extensive surgical interventions for their repair. Endoscopic Negative Pressure Therapy (ENPT) has been developed to treat GI leaks such as leaks, fistulae and perforations. However, ENPT has only been utilized in the management of rectal and esophageal leakages. By modifying the delivery catheter we were able to adapt ENPT to treat duodenal defects, that otherwise would have required surgery or more invasive methods to be repaired.

Aims & Methods: Herein, we report ENPT using open-pore Polyurethane-foam and Film Drainage in a series of 10 patients with duodenal leakages. This is an open-label, retrospective, single-center study. Open-pore polyurethane-foam drainage (OPD) devices were constructed out of a piece (1.5 cm x 1.5 cm x 3 cm) of open-pore polyurethane foam which was fixed surrounding the tip of a nasogastric drainage tube. Small bore open-pore film drainage (OFD) device was constructed with a strip of a very thin fragment open-pore double layered film (0.004 inch) of which was fixed surrounding the nasogastric drainage tube. The open-drain consists of two permeable membranes with a small interspace. Fluids are drained along the interspace and through the membranes. Diameter of small-bore OPD is 4–6 mm, depending on the diameter of the drainage tube. OFD is inserted transnasally. The foam is grasped with endoscopic forceps and guided to the duodenal lumen. After correct placement into the duodenal lumen for intraluminal ENPT, the tube is transferred out nasally, to become a nasoduodenal tube. Due to its smaller outer diameter OFD insertion is similar to placing a naso-gastric or naso-intestinal feeding tube (i.e. through the nose). After nasal insertion into the esophagus OFD is grasped with a forceps and advanced into the stomach, and guided into the duodenal lumen for intraluminal ENPT. In case of a duodenal-cutaneous fistula the pull-through technique has been used for duodenal placement. In one case rendezvous technique was used in combination with operative OFD placement.

Conclusion: ENPT using small diameter tube with open-pore film was effective to treat duodenal leakages. Advantage of OFD is the small diameter which allows easy endoscopic placement through small openings and nasally insertion. OPD and OFD all together accurately at these conditions. From January 2012 to February 2017, 47 LPGs were performed at Keio University Hospital. First, surgical time, bleeding, incidence of postoperative complication, postoperative hospital stay, and incidence of anastomotic stenosis were examined as surgical factors and compared between the DFT and CS groups. Second, the rate of gastroesophageal reflux and the condition of the remnant stomach were examined according to residue, gastritis, bile (RGB) classification at postoperative 6 months and 1 year, and proton pump inhibitor (PPI) intake were examined as postoperative factors. Finally, albumin and hemoglobin levels at postoperative 6 months and 1 year were examined as nutrient factors. Gastroesophageal reflux was assessed with scores of 0–5 in accordance with the Los Angeles (LA) classification.

Results: Twenty-three LPGs with DFT and 24 LPGs with CS were performed during the period. Compared with the CS group, the DFT group had a significantly longer surgical time (272.3 ± 55.5 vs 241.1 ± 26.7 min, p < 0.01). Surgical factors did not show statistically significant differences between the two groups. As for postoperative factors, although no significant differences in PPI intake, LA classification, and RGB classification were found, the DFT group showed a significantly lower score than the CS group (p < 0.01). Postoperative complications were no different.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The main releaser for development of multiorgan failure syndrome becomes the carboxylic acid accumulation. The hypothesis of this plan especially important role is got by the researchers directed to development of sorbents with oxidizing activity.

Aims & Methods: Aim of study is to estimate effectiveness of the modified hae- mosorbsorbtion application for patients about the MOF's. The experimental part of work was conducted on 14 not purebred dogs with the acute liver failure modelled by bandaging of distal department of the CBD. After development of pathological process animals were divided into 2 groups. To the first group of animals the procedure of a haemosorption was carried out by a reference tech- nique—introduction of a haemosorbtion solution of a neutral anolyte—SKN-2K. To the second group of animals the haemosorbtion was carried out by the developed technique with the same sorbent, but the solution of a neutral anolyte subjected to oxidizing modification. For this purpose, in the flowing mode carried out a half-hour incubation of a solution from 2 l of solution of a neutral anolyte.

Results: Results showed that at animals of the 2nd group in comparison with group of comparison improvement of a condition of an organism was expressed in a far lesser degree. After performing detoxication therapy by the developed technique a normalization of all studied parameters is registered. The same ten- dency is revealed also concerning nontoxic components. It is necessary to pay special attention to dynamics of a ratio of the common protein and an index average molecules/the common protein, pointing to synthesis process activation. The carried-out all-clincal blood test revealed the considerable improvement of indexes of white blood. In group of comparison it was not succeeded to achieve the complete normalization of the studied indexes. On the basis of what the conclusion was drawn on high effectiveness of the developed technique, and expediency of its introduction in clinical practice. Under our observation there were 45 patients needing carrying out getter detoxication in the postoperative period. The control group (25) was created by a random sample of case histories compiled on a group of patients with the MOF syndrome who was earlier on treatment in our clinic and receiving a course of haemo perfused therapy by a reference technique. The analysis of results of treatment of patients of a basic group showed that the positive dynamics of clinical indexes expressed in decrease of manifestations of an intoxication syndrome, improvement of health and labora- tory indexes is noted in earlier terms, and degree of expressiveness of positive changes at them was much higher. Dynamics of decrease in endogenic intoxica- tion is reflected by data of laboratory researches. It was shown that it is possible to increase quality of detoxication by a pretreatment of a haemo sorbent solution of a neutral anolyte. As a result of it the sorbent gains padding, oxidizing properties. At such modification there is an inclusion of oxygen-containing and acid groups in struc- ture of a sorbent, and the sorbent gets in addition of a group of carboxylic and phenolic types thanks to which the oxidized coals gain the expressed cation-exchange ability are formed. Therefore, besides actually oxidizing properties a possibility of sorbent to get the properties of a getter is got. This plan especially important role is got by the researchers directed to development of sorbents with oxidizing activity.

Aims & Methods: The aim of this study is the comparative evaluation of SILS cholecystectomy and laparoscopic four-port cholecystectomy. Early and long-term postoperative period has been analyzed in 240 patients who underwent laparoscopic cholecystectomy including 120 cases of single-port technique and 120 cases of four-port technique. Both groups were compared in surgical time, pain syndrome severity (visual analog scale), need for analgesics, postoperative complications, hospital-stay, daily activity recovery and return to physical work, patients’ satisfaction of surgical results and their aesthetic effect.

Results: It was revealed that SILS cholecystectomy is associated with lower severity of postoperative pain, quick recovery of daily activity and return to work, high satisfaction of surgical results and the aesthetic effect. SILS compared with four-port cholecystectomy. Disadvantages of SILS cholecystectomy include longer duration of surgery, high incidence of postoperative umbilical hernia. However, hernia was predominantly observed during the period of surgical technique development.

Conclusion: Further studies to standardize, evaluate the safety and benefits of SILS cholecystectomy are necessary.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Laparoscopic technique is the first choice for multiple surgical procedures today. Laparoscopic surgery differs from traditional open surgery in several aspects, for example two-dimensional view of a three-dimensional interior, higher demands on eye-hand coordination and lack of tactile feedback. Laparoscopic surgical skills can be substantially improved by simulator training. Learning via simulators are under constant development and it is important to understand the value of baseline characteristics and abilities to further optimize simulators and training curricula within surgical education. In this study, focus, will be on the PC-gaming experience and visuospatial skill.

Aims & Methods: The aim of the study is to further analyse different factors to laparoscopic simulator training. 48 medical students completed three tasks in a laparoscopic virtual reality simulator, a validated Minimally Invasive Surgical Trainer (MIST, Mentice, Gothenburg, Sweden). Prior to the task, they performed a visuospatial test and answered questions regarding baseline characteristics (e.g. PC-gaming experience, age, gender, previous simulator experience).

The data where analysed regarding different parts of the simulation: time, economy of movement, error rate and total score.

Results: The group with high PC-gaming experience performed significantly better in total time (Mean difference = 85.49, p = 0.021) and economy of movement (M = 25.30, p = 0.018) in task 1 and 2. There were no differences between the groups in task number 3. A high visuospatial score correlated with a better result in time to completion (M = 68.89, p = 0.026) and total score (M = 80.16, p = 0.036). The group with both high PC-gaming experience and low visuospatial score performed worst in the simulator exercises.

Conclusion: Laparoscopic virtual reality simulator training can improve performance and visuospatial abilities, and have an impact on laparoscopic simulator performance. No remaining significant differences by the third simulation exercise indicates a learning effect that could be more important than baseline skills, it could be valuable to identify individuals with both low PC-gaming experience and low visuospatial score to offer them additional simulator training.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Tuberculosis is a major cause of morbidity and mortality worldwide. Its incidence is continually increasing. Peritoneal localization is a particular entity, even less well known, because of its atypical and confusing symptomatology, which in most cases imposes a malignant condition.

Aims & Methods: We collected all patients hospitalized for peritoneal tuberculosis in the Tunisian capital from 2005 and 2015. The aim of this retrospective study was to study the epidemiological, clinical, pathological, diagnostic, therapeutic and evolutive specificities of peritoneal tuberculosis in its various presentations.

Results: The total number of patients was 65. It was 15 men (23.1%) and 50 women (76.9%). The sex ratio was 0.3. The mean age at diagnosis was 40 years (15-79 years). No personal history of tuberculosis has been found in our series. A personal history of tuberculosis was found in 3 patients (4.6%). The general signs of tuberculin impregnation were frequently found (91%). The digestive functional deficit that brought the patients to consult are: abdominal pain (87.7%), abdominal distension (87.5%), diarrhea (16.9%) and sub occlusive syndromes (4.6%). An abdominal mass was observed in only 4 patients (6.1%). Hepatomegaly and splenomegaly were noted in 2 cases for each. The intradermal reaction was positive in only 24% of patients. The research of BK in the ascites fluid was systematically performed in all patients but returned negative in all cases. The quantiferon-TB Gold was performed in 3 patients only and returned positive. The mean level of CA 125 was 250±31U/ml. Confirmation of diagnosis was obtained on the histological analysis of peritoneal biopsies or adnectomy pieces. The main operative findings (in patients with coeloscopy or exploratory laparatomy) were: Whith granulations (98%), adhesions (43.1%) and agglutinated loops (1.5%). The presence of tuberculous granuloma was observed in 52 patients (81%). The course of treatment was as follows: cure in 50 patients (80.6%), recurrence in 6 patients (9.6%), relapse in 2 patients and 3 patients were lost to follow-up. The mortality in our series was 0%.

Conclusion: Peritoneal tuberculosis raises diagnostic problems in the first place, because of its polymorphic and non-evocative clinical expression. Hence the value of carrying out radiological, endoscopic and histo-bacteriological investigations to confirm the diagnosis before the evolution towards serious or even fatal forms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Abdominal tuberculosis is one of the most common site of extrapulmonaires forms especially abdominal tuberculosis.

Aims & Methods: The aim of this study was to analyze the epidemiologic, clinical, diagnostic, therapeutic and evolutive features of abdominal tuberculosis in a series of 150 patients. This was a retrospective and descriptive monocentric study of 150 cases of abdominal tuberculosis conducted from 2004 to 2014 in a tunisian center. Diagnosis of tuberculosis was based on histological evidence or otherwise on a beam of arguments.

Results: There were 150 patients enrolled. The mean age was 37.2 (17–72 years). Ninety seven (64.6%) were females. Symptoms were ascites 107 (71.3%), abdominal pain 28 (18.6%), weight loss and reduced appetite 80 (53.3%). Un tableau algique was observed in 37 cases (24.7%). The intradermal reaction was positive in only 24% of patients. The research of BK in the ascites fluid was systematically performed in all patients but returned negative in 15% cases. The quantiferon-TB Gold was performed in 3 patients only and returned positive. The mean level of CA 125 was 250±31U/ml. Confirmation of diagnosis was obtained on the histological analysis of peritoneal biopsies or adnectomy pieces. The main operative findings (in patients with coeloscopy or exploratory laparatomy) were: Whith granulations (98%), adhesions (43.1%) and agglutinated loops (1.5%). The presence of tuberculous granuloma was observed in 52 patients (81%). The course of treatment was as follows: cure in 50 patients (80.6%), recurrence in 6 patients (9.6%), relapse in 2 patients and 3 patients were lost to follow-up. The mortality in our series was 0%.

Conclusion: Abdominal tuberculosis is one of the most common site of extra-pulmonary tuberculosis. No single test is adequate for diagnosis of abdominal tuberculosis in all patients. Abdominal TB remains an ongoing diagnostic dilemma requiring a high index of clinical suspicion.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Inability to maintain a stable and beneficial microbiota is associated with chronic gut inflammation, which classically manifests as colitis but may more commonly exist as low-grade inflammation that promotes metabolic syndrome. Alterations in microbiota and associated inflammation can originate from dysfunction in host proteins that manage microbiota, such as the flagellin receptor TLR5, and/or be promoted by exogenous factors that disturb host-microbiota interactions, such as the detergent-like dietary emulsifiers carboxy-methylcellulose (CMC) and polysorbate 80 [1, 2, 3]. That the complete absence of a microbiota (i.e. germ-free conditions) eliminates all evidence of inflammation in...
TLR3-deficient and emulsifier-treated mice demonstrated that these models of gut inflammation in association with dysbiosis might offer insights into microbe dependency of inflammation reflects an inability to manage pathobiont bacteria, such as Adherent-Invasive E. coli (AIEC). Aims & Methods: Our goal was to examine extent to which microbiota mismanagement and associated inflammation in TLR3-deficient and emulsifier-treated mice would manifest in a limited pathobiont-free microbiota. WT and TLR3-deficient mice were maintained in gnotobiotic isolators containing altered Schaedler flora (ASF), a community of eight bacterial species. Mice were treated with CMC or P80, or inoculated with AIEC LF82 [4]. Feces were assayed for bacterial loads, microbiota composition, and inflammatory marker lipidase-2. Fecal LPS and flagellin bioactivity were measured via a cell-based reporter assay, and morphologic and metabolic parameters were determined.

Results: Neither CMC nor P80 induced evidence of intestinal inflammation nor metabolic syndrome in WT ASF animals. Analogously, relative to similarly maintained WT mice, loss of TLR3 did not result in low-grade intestinal inflammation nor metabolic syndrome under ASF conditions. Concomitantly, the ASF microbial community was not disturbed by CMC nor P80 and, moreover, was similar between WT and TSKO mice. Inoculation with AIEC strain LF82 resulted in profound alteration of the ASF community in TSKO mice compared to WT. Within CD45+ cells, 33% of T cells were CD45+CD4+ T cells, 2.8% CD45+CD8+ T cells, 2.6% CD45+CD8+ T cells, and 0.4% CD45+CD8+ T cells. Isolated cells were successfully polarized towards Th1, Th2 and Th17 CD4+ T-cell phenotypes, as confirmed by IFNY gene expression and cytokine production for Th1, IL13 gene expression and IL5 cytokine production for Th2 and IL17 cytokine production for Th17 differentiated cells. Differenation was confirmed by the cryopreserved cells, with lower level of phenotype-specific cytokine production.

Conclusion: Method for LPMC isolation from human colonic mucosa tissue samples was successfully established with approximately 95% viability of isolated cells. No detectable epithelial cell contamination. Within CD45+ cells, 26-47% of T-lymphocytes, 17-24% B-lymphocytes, 8-17% macrophages and 21-46% monocytes were detected by FACS and cytokological analyses (N=3). Cryopreservation did not significantly affect cell viability and surface antigen distribution. Isolated cells were successfully polarized towards Th1, Th2 and Th17 CD4+ T-cell phenotypes, as confirmed by IFNY gene expression and cytokine production for Th1, IL13 gene expression and IL5 cytokine production for Th2 and IL17 cytokine production for Th17 differentiated cells.

Introduction: Lamina propria is a thin layer of connective tissue rich in lymphoid cells and macrophages, underlying the epithelium of mucous membranes. Lamina propria mononuclear cells (LPMCs) are immune system’s first line of defense in the intestine characterized by the ability of differentiating invading pathogens from beneficial intestinal flora and swiftly removing them. Disrupted regulation of LPMCs is implicated in pathology of a group of disorders, including inflammatory bowel disease (IBD). Two major types of IBD are ulcerative colitis, limited to the colon and Crohn’s disease affecting any segment of the gastrointestinal tract. Chron’s disease is a chronic inflammatory disease which can be explained by the high percentage of patients in clinical remission. Comorbidities and psychological factors (optimism) emerged as the main predictive factors of greater disability, reinforcing the importance of multidisciplinary approach to these patients. Clinical activity seems more important to CD than UC patients in terms of disability.

P0959 FACTORS ASSOCIATED WITH DISABILITY IN INFILTRATIVE BOWEL DISEASE: OUTPATIENT CROSS-SECTIONAL STUDY

J. M. Costa1, D. Matos2, J. B. Soares3, R. Costa4, B. Arroja5, R. Gonçalves6
1Gastroenterology, Hospital de Braga, Braga/Portugal
2School Of Health Sciences, University of Minho, Braga/Portugal

Introduction: The Inflammatory Bowel Disease-Disability Index (IBD-DI) has recently been validated to measure disability in IBD. Aims & Methods: We aimed to assess disability in IBD outpatients using IBD-DI and to determine the sociodemographic, clinical and psychological factors that are associated with greater disability. Between August and October of 2016, patients with an established diagnosis of Crohn’s Disease (CD) or Ulcerative Colitis (UC) for at least 3 months and followed up at our outpatient clinic were invited to participate. Socio-demographic and clinical data were collected from electronic health record and interview. Optimism and disability were evaluated using standardized psychometric instruments: the Revised Life Orientation Test (LOT-R) and IBD-DI, respectively. The association between sociodemographic, clinical and psychological variables (optimism) and IBD-DI (scale 0-100, proportional to the reported disability) was determined by univariate and multivariate analysis.

Results: A total of 143 patients (70 DC and 73 UC; 50.3% females) with a mean age of 38 ±13 years were included. Most (85.3%) was in clinical remission. The mean IBD-DI-PT score was 7.9 ±10.7, with a significant difference between DC and UC (p = 0.044). In univariate analysis, female gender, high level education, number of days off from work, articular manifestations, number of comorbidities, use of psychotropic drugs and pessimism (low LOT-R score) were significantly associated with higher disability (IBD-DI-PT score). In multivariate analysis, only female gender (β = 0.150), number of comorbidities (β = 0.186) and pessimism (β = 0.370) were significantly associated with higher disability. Clinical activity was associated with higher disability only for CD patients (β = 0.321). Conclusion: IBD outpatients reported low levels disability associated with their disease, which can be explained by the high percentage of patients in clinical remission. Comorbidities and psychological factors (optimism) emerged as the main predictive factors of greater disability, reinforcing the importance of multidisciplinary approach to these patients. Clinical activity seems more important to CD than UC patients in terms of disability.

Disclosure of Interest: All authors have declared no conflicts of interest.

significant increase was observed in patients undergoing treatment with cortico-
soids. Regarding HLADR, statistical difference (p = 0.0022) and CD62L (p =
0.001) was observed in the group undergoing biological treatment and the group of healthy controls. The DNA was extracted from mucosal biopsies and 16S rRNA genes from it's were target sequenced by using Illumina MiSeq sequencer. Sequencing reads were quality checked by the FastQC software and trimmed by using the trimmomatic software. To characterize the composition of the microbiota, trimmed reads were analyzed by the QIIME software. The obtained results were compared with the earlier published data: SRA Project - ERP001780 (96 samples from patients of control group, 44 samples from patients with ulcerative colitis)[1] and SRA Project - SRP056002 (703 samples from patients with ulcerative colitis).

Results: More than 124 bacterial genera were founded in biopsies of four patients with ulcerative colitis. The analyzed samples of patients with ulcerative colitis were split in two groups by using the PCoA analysis. The first group was characterized by decreasing the concentration of the Firmicutes type bacteria (p-value < 0.005) and increasing the concentration of Bacteroidetes type bacteria (p-value < 0.005). For the second group, It was founded decreasing of the concentration of the Actinobacteria type bacteria (p-value < 0.05), 70-fold excess of Bacteroides vulgatus species bacteria concentration was revealed for one sample of the second group (normalized number of reads in control samples was less than 0.003 and reached 0.21 in samples of patients with ulcerative colitis). Additionally, the concentration of Escherichia coli species bacteria was increased in the 40 times for that sample (normalized number of reads in control samples was 0.003 in samples of healthy donors and 3.03 in samples of patients with ulcerative colitis). Although, the predominance of Proteobacteria genus bacteria was not founded. The concentration of Faecalibacterium prausnitzii species bacteria was decreased by three orders of magnitude for samples from the first group (normalized number of reads in control samples reached 0, 2 and was less than 0, 06 in samples of patients with ulcerative colitis).

Conclusion: The concentration increase of the conditional-pathogenic mucosal microflora (a mostly Bacteroides type bacteria) was discovered, which playing important role in the development of ulcerative colitis and its complications. Also, the deficiency of Faecalibacterium prausnitzii species bacteria was discovered, which decrease resistance of mucosa to the conditional-pathogenic microflora.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Advancing of sequencing technologies in the first decade of the XXI century gives the opportunity to realization of large scale projects such as the 1000 human genomes project. This project provides enormous amount of the data for H.sapiens population genetics studies and different GWAS studies aimed to investigate connection of the human genes variations with different diseases. It is especially interested to study the connection between the human genetics, the microbiome metagenomes of mucosa and different pathological conditions. Previously revealed, the size of the summary gut microbiome metagenome is on order more than the size of a human genome. The most of works devoted to study of the connection between the species mucosal genome changes with different pathological conditions based on the investigation of fecal samples. On our opinion, in the case of ulcerative colitis it is more effective to study the mucosal microbiome of the affected regions.

Aims & Methods: The aim of our work was to study the composition of mucosal microbiomes in the colon mucosa biopsies from patients with ulcerative colitis by using the target high throughput sequencing of bacterial 16S rRNA genes. Biopsies from four caucasoid race patients with left-sided ulcerative colitis in the abating activity. (Mayo endoscopic index - 3, Rachmelevich clinical index - 4) and two patients from control group with irritable bowel syndrome were collected. The DNA was extracted from mucosal biopsies and 16S rRNA genes from it’s were target sequenced by using Illumina MiSeq sequencer. Sequencing reads were quality checked by the FastQC software and trimmed by using the trimmomatic software. To characterize the composition of the microbiota, trimmed reads were analyzed by the QIIME software. The obtained results were compared with the earlier published data: SRA Project - ERP001780 (96 samples from patients of control group, 44 samples from patients with ulcerative colitis)[1] and SRA Project - SRP056002 (703 samples from patients with ulcerative colitis).

Results: More than 124 bacterial genera were founded in biopsies of four patients with ulcerative colitis. The analyzed samples of patients with ulcerative colitis were split in two groups by using the PCoA analysis. The first group was characterized by decreasing the concentration of the Firmicutes type bacteria (p-value < 0.005) and increasing the concentration of Bacteroidetes type bacteria (p-value < 0.005). For the second group, It was founded decreasing of the concentration of the Actinobacteria type bacteria (p-value < 0.05), 70-fold excess of Bacteroides vulgatus species bacteria concentration was revealed for one sample of the second group (normalized number of reads in control samples was less than 0.003 and reached 0.21 in samples of patients with ulcerative colitis). Additionally, the concentration of Escherichia coli species bacteria was increased in the 40 times for that sample (normalized number of reads in control samples was 0.003 in samples of healthy donors and 3.03 in samples of patients with ulcerative colitis). Although, the predominance of Proteobacteria genus bacteria was not founded. The concentration of Faecalibacterium prausnitzii species bacteria was decreased by three orders of magnitude for samples from the first group (normalized number of reads in control samples reached 0, 2 and was less than 0, 06 in samples of patients with ulcerative colitis).

Conclusion: The concentration increase of the conditional-pathogenic mucosal microflora (a mostly Bacteroides type bacteria) was discovered, which playing important role in the development of ulcerative colitis and its complications. Introduction: The role of incretin hormone, GLP-1, in inflammatory bowel dis-
ses (IBD) development and exacerbations is still poorly understood. GLP-1 decreases blood glucose level and is co-secreted by intestinal L cells with GLP-2, which may be responsible for intestinal growth and enhancement of intestinal function. The prevalence of type 2 diabetes among IBD patients is low, even though IBD sufferers may be at a greater risk of development of T2D due to overproduction of pro-inflammatory cytokines and excessive administration of diabetogenic drugs. We hypothesize that the possible mechanism underlying this phenomenon is related to changes in the levels of incretin hormones.

Aims & Methods: The primary aim of this study was to investigate, in the mouse model of intestinal coexisting colitis and type 2 diabetes, the potential involvement of incretin GLP-1 and GLP-2 in the development of experimental diabetes. The secondary goal was to investigate the potential involvement of incretin hormones as an underlying factor. Experimental diabetes was induced by administration of streptozotocin for 5 consecutive days (50 mg/kg, i.p.). Mice with blood glucose levels above 200 mg/dL were considered as diabetic. To develop a chronic and relapsing colonic inflammation, mouse model of colitis induced by intracolonic administration of TNBS (first dose: 150 mg/kg at day 1, booster dose: 75 mg/kg at days 12, 23, 34, 45, 56) was used. On day 60 mice were sacrificed and macroscopic score, ulcer score, colon length and bowel thickness were recorded. In all experiments the levels of inflammation markers: myeloperoxidase (MPO) activity, TNF-α and IL-1β expression were determined. The
effect of colitis on T2D development was studied by assessing fasting glucose levels, as well as glucose tolerance, hormone levels in CD and GLP-2 in UC. Results: The development of hyperglycemia in mice treated with TNBS was delayed compared to a non-inflammatory group, what was associated with significantly higher levels of GLP-1 in blood. Surprisingly, the levels of GLP-2 were significantly reduced in diabetic mice with colitis, suggesting that two distinct mechanisms are involved in the regulation of the incretin hormones in response to intestinal inflammation. There were no significant differences in macroscopic score, colon length, and bowel thickness in diabetic mice with or without colitis. Noteworthy, significantly increased in diabetic mice with colitis compared to diabetic mice with no inflammation. No changes in MPO, TNFα, IL-1β were observed between these groups. Conclusion: We propose that GLP-1 production may be stimulated in response to colitis and may contribute to both inflammatory and regenerative phases of the disease. Additionally, our data suggest that the incretin hormones may become a potential new treatment option.

Introduction: Epidemiological studies revealed that antibiotics exposure increases the risk of inflammatory bowel diseases (IBD) development (Hvid, 2011, Shaw, 2011, Kromann, 2012). However, mechanisms of this association are not fully understood. Recent studies revealed sustained alterations in gut microbiota after antibiotic treatment (Rashid, 2015, Dethlefsen, 2011). However, mechanisms of this association are not fully understood. Recent studies revealed sustained alterations in gut microbiota after antibiotic treatment (Rashid, 2015, Dethlefsen, 2011). However, mechanisms of this association are not fully understood. Recent studies revealed sustained alterations in gut microbiota after antibiotic treatment (Rashid, 2015, Dethlefsen, 2011). Results: CF injection leads to compositional changes of fecal microbiota which progress over time. In 56 days, we found increased level of Clostridium spp, E. coli, conditionally pathogenic and hemolytic bacteria. Levels of Bifidobacterium...
in PBMC, MLN and LPC in group B (9.15 ± 0.264 vs 2.533 ± 0.076, 1.672 ± 0.115 vs 0.898 ± 0.044, 5.967 ± 0.100 vs 2.308 ± 0.252, P < 0.05 respectively). But the level of CD3+CD6+CD25+Foxp3+IL17a+ cells were decreased in spleen, PBMC, MLN and LPC compared with group B (0.358 ± 0.021 vs 1.238 ± 0.017, 2.523 ± 0.066 vs 3.915 ± 0.264, 0.897 ± 0.040 vs 1.672 ± 0.158, 5.244 ± 0.052 vs 5.967 ± 0.100, P < 0.05 respectively).

Conclusion: By blocking TollR2, TollR2Ab could improve the level of FrII cells in PBMC, MLN and LPC, but reduce the levels of FrII and Foxp3+IL17a+ cells in DSS induced UC mice. Furthermore, TollR2Ab could alleviate the DAI index as well as the inflammation of colitis in DSS induced UC mice.

P0966 THE ROLE OF TLR2-MEDIATED TREG/TH17 IMBALANCE IN THE PATHOGENESIS OF ULCERATIVE COLITIS

1Department Of Medicine, Beijing Haidian Maternal and Child Health Hospital, Beijing, China
2Gastroenterology Department, Beijing Chaoyang Hospital, Capital Medical University, Beijing, China
3Department Of Medicine, Beijing Haidian Maternal and Child Health Hospital, Beijing, China

Contact E-mail Address: lxjy2012@163.com

Introduction: According to our previous report, the imbalance of Treg/Th17 cells in the major symptoms of UC mice is related with the reduction of CD45RA Foxp3+ activated Treg(FrII) cells, which has the real function of immunosuppression, and with the elevation of CD45RA Foxp3− Treg(FrIII) cells, which provide Foxp3+IL17a+ Treg(FrII) cells by secrecting IL-17a.

Aims & Methods: To investigate the influence of TLR2 on imbalance Treg/Th17 in UC mice .18 mice were divided into the groups: group A, UC mice group B, UC mice that received antibiotics within 3 months were excluded. Harvey Bradshaw Index and Simple Clinical Colitis Activity Index were recorded. Full medical history was available from the UK IBD Tifton Registry. Samples underwent 16S rRNA gene sequencing using Illumina MiSeq platform for data analysis. PERMANOVA was used to evaluate associations with clinical metadata, which included matching of twin pairs for analysis, and STAMP was used to identify taxonomic differences between groups.

Results: 20 twin pairs discordant for CD (7MZ/15DZ age mean 52 years) and 17 discordant for UC (6MZ/11DZ age mean 59.7 years) were recruited. 7 subjects with CD had active disease as did 4 with UC.

Aims & Methods: Participants were recruited via the UK IBD Tifton Registry. stool samples were collected and frozen using standard methods. Participants who had received antibiotics within 3 months were excluded. Harvey Bradshaw Index and Simple Clinical Colitis Activity Index were recorded. Full medical history was available from the UK IBD Tifton Registry. Samples underwent 16S rRNA gene sequencing using Illumina MiSeq platform for data analysis. PERMANOVA was used to evaluate associations with clinical metadata, which included matching of twin pairs for analysis, and STAMP was used to identify taxonomic differences between groups.

Conclusion: This study confirms previous findings showing decreased diversity in IBD patients and changes in some bacterial taxa, however our study is the first to show decreases in Alitistipes spp. in active UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
subsequently analyzed for STAT3 signaling and NFκB signaling (5′-UTR Transcription Factor Assay, western blot) and cytokine secretion (ELISA).

**Results:** Peripheral blood CD4+ T cells from IBD patients could be characterized by a significantly increased P2Y2R expression compared to healthy controls, which correlated with disease severity. In the colon compartment, the expression levels of the P2Y4 receptor subtype turned out to be comparable between both groups. Further subdividing the group of included IBD patients into Crohn’s disease and ulcerative colitis patients, we could not observe a significant difference in the P2Y2R levels between both disease entities. Interestingly, the increased P2Y2R expression in the lymphocyte compartment of IBD patients seemed to be limited to CD4+ T cells, as CD8+ T cells of those patients even showed decreased P2Y2R levels. Regarding potential regulators of P2Y2R expression in the context of IBD, our data identified IL-6 and TGF-beta as positive inducers of P2Y2R expression in human CD4+ T cells. Interestingly, high extracellular UTP levels resulted in a decreased expression of the TGF-beta1 receptor on CD4+ T cells, implicating a potential negative feedback loop in which P2Y2R signaling might inhibit TGF-beta induced P2Y2R expression over time. Regarding the impact of P2Y2R signaling on the pro-inflammatory capacity of human lymphocytes, our data indicate that the selective P2Y2R agonist 2-Thio-UTP is able mediate NFκB as well as STAT3 activation and to induce autophagy, as evidenced by a decrease in p-mTOR and p62 expression.

**Conclusion:** The observed increased expression of P2Y2R in CD4+ T cells of IBD patients together with the demonstrated pro-inflammatory effects of P2Y2R signaling in human T cells markedly strengthen the role of P2Y2R as a promising molecular target in IBD.

**P0970 PROTECTIVE EFFECT AND ACTION MECHANISM OF APOCYNIN IN IBD MOUSE MODEL**

Aims & Methods: In this study, we aimed to investigate the effect of apocynin on colon inflammation and the action mechanism using chemically-induced colitis mouse model. We used dextran sulfate sodium (DSS)-induced colitis model. 8 weeks old male BALB/c mice were divided into four groups (each group, n=6): control, DSS only, DSS with apocynin, and DSS with sulfasalazine. Water (control and DSS group), apocynin (400 mg/kg) and sulfasalazine (150 mg/kg) were administered by oral route using sonde during 7 days. For western blot analysis, the colon was lysed and protein was extracted. The following antibodies were used: iNOS (BD Biosciences), COX-2, Nrf2 (Santa Cruz Biotechnology Inc), MCP-1, TNF-α, p-NfκB, HO-1 (Abcam), and β-actin (Sigma).

**Results:** Protective effect of apocynin was evident by weight change and colon length. Histologic analysis also showed improved erosion and decreased neutrophilic infiltration in apocynin group compared to DSS group. In colon tissue, several pro-inflammatory enzymes and cytokines were decreased by apocynin. Apocynin also activated anti-inflammatory pathway by inducing activation of NFκB and production of heme oxygenase-1 (HO-1).

**Conclusion:** Apocynin, a NADPH-oxidase inhibitor, showed significant anti-inflammatory effect in DSS induced colitis model. Considering its good safety profile, this molecule can be a new candidate for the treatment of IBD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

*Introduction:* Faecal metabolic profiling has been shown to distinguish Inflammatory Bowel Disease (IBD) from healthy controls (HC), specifically with depletion of gut-associated short chained fatty acids (SCFA) as the predominant feature separating these groups (1). Previous and current studies have used proton nuclear magnetic resonance (1H NMR) spectroscopy or mass spectrometry (MS) to measure faecal metabolites in order to investigate the metabolic, microbiomic, and clinical response of IBD patients to different treatments. Both techniques require a significant amount of sample pre-processing. Rapid Evaporative Ionization Mass Spectrometry (REIMS) is a relatively new technology which applies a laser to a biological sample, and the resulting vapour containing gas phase ions of metabolites and structural lipids, is analysed by a mass spectrometer (2). Unprocessed faecal samples can be rapidly assessed using this technique to obtain lipidomic spectral profiles (2). To our knowledge this is the first study that has used REIMS to investigate whether IBD patients can be distinguished from healthy controls using faecal samples.

**Aims & Methods:** Unprocessed faecal samples from 109 IBD patients and 46 healthy controls were analysed using Rapid Evaporative Ionization Mass Spectrometry. Clinical and dietary data were collected, and patients with significant other co-morbidities were excluded. Partial least squares discriminative analysis (PLS-DA) was performed to examine whether there were differences in the metabolic data between patients with Inflammatory Bowel Disease and healthy controls. Further samples were then carried out including examining whether ulcerative colitis could be distinguished from Crohn’s disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Disclosure of Interest: 

Conclusion: This early preliminary analysis shows that there is a degree of separation between samples of IBD patients compared to healthy control. This suggests that REIMS analysis has good potential as a research tool in IBD metabolic studies, and importantly in the current ongoing longitudinal IBD research. Further analysis will include identifying the principal metabolites that separate these groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0972 THE PATHOGENIC MECHANISM OF ARYL HYDROCARBON RECEPTOR MEDIATED ABNORMAL DIFFERENTIATION OF INTESTINAL ILC3/ILC1 IN CROHN’S DISEASE

X. Zhao, H. Zhang
Department Of Gastroenterology, Jiangsu Province Hospital and Nanjing Medical University, Nanjing/China

Contact E-mail Address: xiaozhao178@163.com

Introduction: The abnormal differentiation of intestinal innate lymphoid cells ILC3 and ILC1 exist in autoimmune disease. ILC3 decreased and ILC1 increased in Crohn’s disease (CD) patients, suggesting that CD patients have abnormal intestinal ILC3/ILC1 alteration.

Aims & Methods: The present study investigated the aberrant colonic mucosal ILC3/ILC1 in active CD patients and 2, 4, 6-trinitrobenzene sulphonic acid (TNBS)-induced colitis mice. The expressions of aryl hydrocarbon receptor (AhR) in colon of active and quiescent CD patients were detected by western blot and immunofluorescence. The ILC3/ILC1 were investigated in CD patients and 2, 4, 6-trinitrobenzene sulphonic acid (TNBS)-induced colitis mice (AhR⁻/⁻, AhR⁺/⁺).

Results: Compared to quiescent CD patients, the expression of aryl hydrocarbon receptor (AhR) in the intestinal tissue in active CD patients was decreased. Meanwhile, the number of ILC3 in active CD patients and AhR knockout mice was decreased while ILC1 increased. The intestinal inflammation in AhR knockout mice given TNBS was more severe than wild-type mice.

Conclusion: These findings suggest that AhR may mediate abnormal differentiation of ILC3/ILC1, and the production of inflammatory cytokines, finally, promotes the pathogenesis of CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0973 PREVALENCE AND GENETIC DIFFERENCES IN ADHESION-RELATED GENES AMONG COMMENSAL AND ADHERENT-INVASIVE E. COLI STRAINS

C. Campbru-Font, A. Seguí-Roig, N. Maeso-Sánchez, M. López-Siles, M. Martinez-Medina

Introduction: Long polar fimbriae (LpfA), FimH adhesin and ChiA chitinase have been related with adherent-invasive E. coli (AIEC) pathogenesis. Controversial results have been found regarding the prevalence of LpfA in AIEC vs non-AIEC (1, 2). Some FimH amino acid variants were reported to be specific for AIEC (3) whereas other variants were associated with phylogroup disease origin of the strains (4). Differences in the ChiA sequence were reported between LF82 and K-12 strains but this gene has not been studied in other AIEC yet (5).

Aims & Methods: The prevalence of lpfA and the distribution of fimH and chiA variants, and non-AIEC from different disease origins Crohn’s disease (CD), ulcerative colitis (UC) and colorectal cancer (CRC) were studied with the purpose to determine if these genes could be used as molecular markers for AIEC identification and disease diagnosis. In a collection of 79 AIEC and 29 non-AIEC isolated from CD, UC, CRC patients and controls, lpfA gene was PCR-amplified to assess its presence and fimH and chiA genes were sequenced to identify point mutations. For comparison of FimH and ChiA protein sequences, UPGMA phylogenetic tree and allele identification was performed using MEGA5. The genetic differences were annotated using as reference the K-12 strain. Then, they were analysed statistically according to AIEC pathotype, phylogroup, and disease origin by the χ2 test and non-parametric tests were used to evaluate amino acid variability regarding the adhesion and invasion indices.

Results: Low gene frequency for lpfA141 and lpfA154 was reported (11.7% and 16.7% respectively). LpfA154 was only found in strains from A (22%) and B1 phylogroup (86%) and no relation with AIEC phenotype or disease was observed. Two main clusters of FimH were obtained by phylogenetic analysis, classifying the strains according to the presence of S78N mutation. N70S and S78N variants were characteristic from strains of B2 and D phylogroups as none of the A or B1 strains presented it. Despite statistical significance was not reached, the strains with N70S, S78N, V163A, R166H mutations showed the highest adhesiveness. Regarding ChiA, two main clusters defined by the presence or absence of an insertion in 312–314 residues were obtained. None of the five previously mutations found in LF82 strain was associated with AIEC strains whereas the V415A variant was found specifically in AIEC (20%) (p = 0.049). Of note, among the strains harbouring the 312–314 insertion, a subcluster that shared identical amino acid sequence included the LF82 strain and the 44% of AIEC strains but only the 10% of the non-AIEC (p = 0.019). No differences between FimH, ChiA variants and origin of isolation was observed.

Conclusion: In contrast with other studies, no relation of lpfA presence nor in FimH mutations with AIEC pathotype or disease was observed. Nonetheless, a variant in ChiA sequence more frequently found in AIEC isolates was reported, being an interesting signature sequence for the detection of at least a subgroup of AIEC strains. Further confirmation in a wider strain collection would be required.

Introduction: Primary sclerosing cholangitis (PSC) is a progressive disorder of biliary tree which can lead to end-stage liver disease, liver transplantation or even death. Colitis accompanying PSC is considered to be a phenotype of IBD (inflammatory bowel disease) distinct from ulcerative colitis (UC) and is often referred to as "PSC-IBD".

Aims & Methods: Our aim was to compare the gut bacterial microbiota of patients with PSC and UC. Stool samples were prospectively collected and relevant clinical data obtained from 106 study participants, 43 PSC patients with (n = 32) or without (n = 11) concomitant IBD, 32 UC patients, and 31 healthy controls (HC). Sequencing of the 16S rRNA gene including the V3 and V4 regions was performed on Illumina MiSeq platform to cover low taxonomic
levels. Data were further processed in QIIME employing MALT and LIMS to extract alpha diversity.

Results: Microbial profiles in both PSC and UC were characterized by low bacterial diversity and significant change in global microbial composition. *Rothia, Enterococcus, Streptococcus, Veillonella,* and three other genera were markedly overrepresented in PSC regardless of concomitant IBD. *Rothia, Veillonella* and *Streptococcus* were tracked to the species level to identify *Rothia mucilaginosa,* *Streptococcus infantis,* and *S. equi* along with *Veillonella parvula* and *V. dispar.* PSC was further characterized by decreased abundance of *Adlercreutzia equolifaciens* and *Prevotella copri.* Decrease in the genus *Phascolarctobacterium* was linked to presence of colonic inflammation regardless of IBD phenotype. *Akkermansia muciniphila,* *Butyrivibrio rumiaceorum* and *Clostridium colurn* were decreased in UC along with genus *Roseburia.* Unclassified *Actinomycetes* species were markedly increased in overlap syndrome of autoimmune hepatitis (AIH) and PSC. Low levels of serum albumin were significantly correlated with enrichment of order Actinomycetales.

Conclusion: PSC was characterized by microbial features independent of concomitant IBD. The gut microbiota and metagenomic taxa clearly distinguished IBD phenotypes (PSC, IBD and UC) as well as PSC from PSC/AIH.

significant correlation only with fiber intake (r = 0.07 p = 0.0022). The conclusion is that fiber intake (r = 0.07 p = 0.0022) positively influences the disease activity and patients' quality of life. Based on these results it is suggested that there is a negative correlation between dietary fiber and increased HBI or SCCAI score (r = 0.32, p = 0.002). The presence of lipopolysaccharide in the lamina propria demonstrated positive findings in healthy controls, supported by data from 16s rDNA analysis of blood from healthy controls. In the Ulcerative Colitis cohort in clinical remission the absence of lipopolysaccharide in the lamina propria was associated with elevated levels of LBP and increased breaches of Ocludin (p = 0.0022).

Introduction: Diet may influence intestinal inflammation via various pathways but the evidence regarding the role of fiber or fat intake in patients with inflammatory bowel disease (IBD) is controversial.

Aims & Methods: The aim of this study was to investigate the association between dietary fiber or total fat intake and disease activity or quality of life in Greek IBD patients. We prospectively collected food frequency questionnaires (FFQ) from consecutive IBD patients at outpatient visits. The European Prospective Investigation into Cancer and Nutrition (EPIC) Study FFQ for Greek population with the MAFF photographic food atlas were used in order to collect information for dietary habits of IBD patients. Moreover, disease activity was assessed by means of disease activity index (SCAI) for ulcerative colitis (UC) and Harvey-Bradshaw index (HBI) for Crohn’s disease (CD) as well as quality of life using the short inflammatory bowel disease questionnaire (SIBDQ) were evaluated. Patients’ demographic, clinical characteristics, nutritional status, laboratory data (C reactive protein (CRP), haemoglobin, erythrocyte sedimentation rate (ESR), platelets and albumin) and treatment data were recorded and analysed for all participants.

Results: A total of 141 consecutive IBD patients (53 UC, 88 CD, mean age 47.2±16.1 years, 84 males 57 females, BMI 26.7±5.3) were included. Patients’ mean daily fiber intake was 21.8 g (IQR 13.8–34.6) and mean daily total fat was 161.4 g (121.2–237) with 43.5% percent energy from fat. Regarding disease activity 34 (24.1%) patients had active disease with HBI or SCCAI score ≥5 whereas 45 (31.9%) patients were in clinical remission (r = 0.03) while there was not significant correlation between fat intake and disease activity 34 (24.1%) patients had active disease with HBI or SCCAI score ≥5 whereas 45 (31.9%) patients had poor quality of life with SIBDQ score ≥5.

Conclusion: Higher dietary fiber intake is associated with lower disease activity and better quality of life in patients with IBD. Fat consumption does not seem to influence the disease activity and patients’ quality of life. Based on these results it could be suggested that a low amount of fiber consumption by IBD patients may play an important role in the disease course.

Disclosure of Interest: All authors have declared no conflicts of interest.
associated with the risk for resection. No difference in the results was found between Eastern and Western European patients.

Conclusion: Bifidobacterium relative abundance correlate closely with short term changes in FC suggesting a possible causal association. Other genera and species had poor and inconsistent correlations with short term changes in FC suggesting that they may not be causally related to short term changes in gut inflammatory activity.

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: The median age at diagnosis of CRC was comparable in UC vs CD. In UC, the only significant risk factor was UC duration (OR [95% CI]: OR 3.33 [1.44–9.11], as the other risk factors were not significant: OR 0.94 [0.36–2.98], 1.28 [0.48–3.04], 0.96 [0.36–3.06], 0.78 [0.60–4.66], 1.36 [0.66–2.89], 0.38 [0.08–1.23], respectively).

Conclusion: In a prospective, multicenter, nested-case control IG-BBD study, incident cases of CRC were more frequent in UC than in CD. In our cohort, UC duration and perianal CD, but not immunomodulators use, were identified as independent risk factors of incident cases of CRC.

Introduction: The human gut microbiome is made up predominately of four major bacterial phyla, Firmicutes, Bacteroidetes, Proteobacteria and Actinobacteria. Changes or imbalance of these phyla is termed dysbiosis. Systematically, in inflammatory bowel disease (IBD), key changes have been identified such as a reduction in beneficial bacterial species including Faecalibacterium prausnitzii and increases in more pathogenic species including Enterobacter, Klebsiella Peptococcus and it Staphylocococus aureus. The microbiota undoubtedly plays an important role in both the inflamed and the healthy pouch. However, a direct causal relationship has not yet been established between individual microbiota changes and inflammation. There are many studies that highlight changes in bacterial composition, but studies are limited by heterogeneity of and in particular, analysis techniques and sampling strategies. Studies used a variety of methods to define microbial diversity which can be broadly split into culture vs culture-independent approaches. Culture-based studies are likely to have a bias towards culturing more aerobically friendly microbes than exist in a true pouch environment, thus over-representing aerobic bacteria whilst possibly under-representing anaerobic bacteria. The use of 16 S RNA analysis methods will negate this effect and represents the future in accurately determining the microbiota.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0987 OUTCOME OF ENDOSCOPICALLY ALL RESected Dysplastic lesions in ulcerative colitis

Gastroenterology, CHU Bah El Oued, Algiers/Algeria

Contact E-mail Address: houriasaoula@yahoo.fr

Introduction: For a long time, dysplastic lesions in ulcerative colitis were only treated by surgery. Recent guidelines recommend the complete endoscopic resection of dysplastic lesions in ulcerative colitis.

Aims & Methods: The aim of this study was to determine the outcome of dysplastic lesions resected endoscopically in ulcerative colitis. In this prospective study between January 2008 and January 2015, dysplastic lesions detected in patients with longstanding ulcerative colitis were assessed for their resectability, then when possible, local resection was performed. The patients were followed, and an endoscopic control was done at 6 month than every one year.

Results: 36 dysplastic lesions were identified in 25 patients; 5 lesions were judged not resectable and referred to surgery. 31 lesions were resected in 21 patients: 22 low-grade dysplasia. 7 lesions indefinite for dysplasia, and 2 high-grade dysplasia. 18 patients (85.7%) had endoscopic control: mean 2.8 (maximum: 5 minutes) later. Of these, 4 patients refused endoscopic control, one patient was not controlled because of a bad bowel preparation for 4 times. In 13 patients (72.2%) no dysplasia was detected after a mean follow up of 30.16 months (range: 7.56-62.37 months).

Conclusion: Our results confirm that a complete endoscopic resection may be feasible in dysplastic lesions occurred in ulcerative colitis. Nevertheless a closer follow-up is necessary because these patients may develop neoplastic lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0988 CYTOMEGALOVIRUS INFECTION IS ASSOCIATED WITH A POOR OUTCOME IN PATIENTS WITH ULCERATIVE COLITIS TREATED BY VEDOLIZUMB

Introduction: Cytomegalovirus (CMV) infection has been associated to resistance to several immunomodulatory therapies in Ulcerative Colitis (UC). The impact of CMV infection in UC patients treated with Vedolizumab is unknown.

Aims & Methods: We performed a retrospective case-control study of all patients with UC treated by Vedolizumab from June 2014 to August 2018. A high titers and retroviral load of 2 biopsies in inflamed tissue was performed for each patient in case of loss of clinical response under Vedolizumab. Patients with primary non response to Vedolizumab were excluded. All patients with high mucosal CMV DNA load (3250 copies/mg of tissue) were treated with ganciclovir. Patients with undetectable CMV DNA load disease were considered as control group.

Results: Thirty two patients were eligible (sex ratio M/F: 3/1; mean age: 43.6 years, mean disease duration: 7.5 years, E3 phenotype according to the Montreal classification). Nineteen patients (59.4%) exhibited high CMV DNA load. In the control group, 5 lesions were judged of insufficient in dysplasic lesions occurred in ulcerative colitis. Nevertheless a closer follow-up is necessary because these patients may develop neoplastic lesions.

Conclusion: Our results confirm that a complete endoscopic resection may be feasible in dysplastic lesions occurred in ulcerative colitis. Nevertheless a closer follow-up is necessary because these patients may develop neoplastic lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.
increase the burden of disease from both the clinical and the economic perspective: shorter intervals between repeated procedures, higher missed rates, patient inconvenience, and increased risk of complications are reported in the scientific literature. F-Calprotectin (FC) is a fecal marker of intestinal inflammation; IBD patients exhibit FC levels significantly higher than the general population; IBS patients have FC levels higher than healthy controls, but significantly lower than IBD patients [3]. Therefore, FC can be used as a pre-endoscopic test to differentiate between IBD and IBS. The present study aims at evaluating the cost-effectiveness of FC compared to the combined usage of CRP and ESR, and the gold standard to distinguish IBD from IBS in Spain.

Aims & Methods: An 18-week Markov model was developed for each diagnostic strategy, simulating 1000 patients presenting to a primary care physician with non-specific gastrointestinal symptoms. In the model, 1.6% of the colonoscopies brought about complications [4], which may result in Emergency Room visits and surgery. Inadequate colon preparation (23%±5%) and consequent repeated colonoscopies (30.3%) [6] were also included in the calculations. Outcomes include cost savings, cost per corrected IBD diagnosed, and colonoscopy reduction. Uncertainty was addressed with sensitivity analysis.

Results: FC is cost-effective when compared to CRP+ESR, and to colonoscopy (Table 1): It results in more correctly IBD diagnoses at a lower price; It reduces the number of unnecessary endoscopies, increasing the number of correctly diagnosed IBD (N=63) and IBS (N=26) patients.

<td>305,051</td>
<td>0</td>
</tr>
</tbody>
</table>

Conclusion: Results show that the usage of FC as pre-endoscopic diagnostic tool is associated with fewer colonoscopies and correctly identifies more disease while decreasing the costs compared to the alternatives. Consequently, FC demonstrates superior value both from patient and payer perspective, while simultaneously increasing diagnostic efficacy.

4 ICFS/3's, Braga/Guimarães/Portugal

**Contact E-mail Address:** catia_arieira@hotmail.com

**Introduction:** Several endoscopic scores have been used to assess the severity of inflammatory activity in Ulcerative Colitis (UC), however, few consider the extension of the disease. Scores such as the Dublin Score (DS) and the Modified Mayo Endoscopic Score (MMS) combine the severity of inflammation with the extent of the disease.

**Aims & Methods:** We aimed to calculate the correlation between the endoscopic scores -Mayo Endoscopic Score (MES), DUBLIN, MMS and the biomarkers of inflammation - erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and tumor necrosis factor -alpha in a cross-sectional study that included consecutive outpatients that were observed in our department between January and March 2017. Patients with known liver disease, diabetes mellitus, osteoporosis and fractures were excluded.

**Results:** We reviewed the charts of 290 patients with CD treated with TNF-alpha inhibitors (TNF) and 174 patients who are anti-TNF naïve (NB). There were 207 (45%) males and 257 (55%) females in this cohort. TNF patients tended to be younger (average age of 43+/−15 and 54+/−18 years in TNF and NB groups respectively). Mean duration of disease was 14.9+/−10.2 for TNF and 18.6+/−19.2 for NB group. Approximately half of the patients had a smoking history. Average BMI was 27.6+/−6.6. Rates of vitamin D deficiency, insufficiency and normal vitamin D were not significantly different between TNF and NB groups. Vitamin D level was not associated with age, duration of disease, or inflammatory markers (ESR). However, there was a weak positive correlation between nutritional status (lowest albumin) and vitamin D level (Pearson’s R = 0.16/P = 0.001) and to compare the ability of these scores to predict Calprotectin > 100 g/g. This was a retrospective study, including patients with diagnosis of left or extensive UC who underwent colonoscopy between 2015 and 2016. The biomarkers were obtained with a maximum interval of one week in relation to colonoscopy and without introduction of new therapy. The Spearman test calculated the correlation between scores and biomarkers. ROC curves (AUC) were obtained for each score to predict Calprotectin > 100 g/g.

**Conclusion:** There is a significant correlation between endoscopic scores and Calprotectin, the correlation between scores that take into account the extension the disease were not superior to Mayo Endoscopic Score.

**P0992 IBD – IS IT A RISK FACTOR FOR THE DIAGNOSIS OF HEPATIC STEATOSIS?**

1Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Guimarães/Portugal
2Pt Government Associate Laboratory
4 ICFS/3’s, Braga/Guimarães/Portugal

**Contact E-mail Address:** catia_arieira@hotmail.com

**Introduction:** Although it is not yet established, recent studies suggest an increase prevalence of hepatic steatosis (HS) in patients with inflammatory bowel disease (IBD). Factors such as chronic inflammation, previous surgeries, drug-induced hepatotoxicity, malnutrition and intestinal dysbiosis seem to be involved in the pathogenesis of this disease.

**Aims & Methods:** We aimed to assess the frequency of HS in IBD patients quantified by CAP (controlled attenuation parameter) and by clinical-analytical methods: Hepatic Steatosis Index (HSI) and Fatty Liver Index (FLI). A secondary aim is to investigate risk factors associated with HS in IBD patients. This was a prospective study that included consecutive patients that were observed in our department between January and March 2017. Patients with known liver disease or alcohol habits were excluded. HS was defined as HSI ≥ 36 or FLI ≥ 60 or CAP ≥ 248.

**Results:** 149 patients included with mean age 40.7+/−13 years, 83 female (55.7%), 59.7% with Crohn’s disease (CD). 62 patients (41.7%) had CAP ≥ 248.20 (13.4%) FLI > 60 and 40 (26.8%) HSI > 36. There were no differences in the mean CAP value (24.6±4.5), HSI (33.3±5.1), and FLI (31.5±23.5) among patients with and without CD and active or inactive disease. We found that patients with CAP ≥ 248 were more frequently obese (27.4% vs 0% P < 0.001), males (54.8% vs 36% P = 0.029) and presented more frequently metabolic syndrome (25% vs 4.6% P < 0.001). Regarding the IBD factors, patients with HS had a higher frequency of previous surgeries (30.6% vs 16.1% P = 0.035). There were no differences between hospitalization, duration of the disease, use of corticosteroids or other IBD treatments.

**Conclusion:** In our cohort the frequency of HS varied between 13.4% and 41.7% defined by non-invasive methods. We found that the presence of metabolic syndrome and obesity were more frequent in patients with HS. Regarding factors related to IBD, patients with previous history of surgery were more frequently diagnosed with HS.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0993 BONE HEALTH IN CROHN’S DISEASE IN THE ERA OF TNF-ALPHA INHIBITORS**

**S. Hakimian**, J. Khedher*, D. Cave*, B. Hyatt*
1Internal Medicine, University of Massachusetts, Worcester/United States of America
2Gastroenterology, UMass Medical Center, Worcester/United States of America

**Contact E-mail Address:** shahrad.hakimian@umassmemorial.org

**Introduction:** Osteoporosis and fractures are common in Crohn’s disease (CD). Recently, several inflammatory cytokines, including tumor necrosis factor (TNF)-alpha have been linked to increased bone resorption. Therefore, it is hypothesized that anti-TNF therapy may influence osteoporosis and fracture risk. However, few studies have evaluated osteoporosis and fracture risk in the CD population.

**Aims & Methods:** The aim of this study is to gain a better understanding of the epidemiologic risk factors for osteoporosis and vitamin D deficiency in the era of TNF-alpha inhibitors. We conducted a retrospective review of 714 consecutive patients with CD in our GI clinic between 2008 and 2015 to identify 464 patients who met the inclusion criteria for the study comprising of all adults older than 18 years with confirmed CD based on labs and endoscopic findings. Data extracted for analysis included demographics data, disease phenotype, duration of disease, measures of disease activity, imaging and endoscopic data. Statistical analysis was performed using student t-test and chi-square test.

**Results:** We reviewed the charts of 290 patients with CD treated with TNF-alpha inhibitors (TNF) and 174 patients who are anti-TNF naïve (NB). There were 207 (45%) males and 257 (55%) females in this cohort. TNF patients tended to be younger (average age of 43+/−15 and 54+/−18 years in TNF and NB groups respectively). Mean duration of disease was 14.9+/−10.2 for TNF and 18.6+/−19.2 for NB group. Approximately half of the patients had a smoking history. Average BMI was 27.6+/−6.6. Rates of vitamin D deficiency, insufficiency and normal vitamin D were not significantly different between TNF and NB groups. Vitamin D level was not associated with age, duration of disease, or inflammatory markers (ESR). However, there was a weak positive correlation between nutritional status (lowest albumin) and vitamin D level (Pearson’s R = 0.16/P = 0.001) and to compare the ability of these scores to predict Calprotectin > 100 g/g. This was a retrospective study, including patients with diagnosis of left or extensive UC who underwent colonoscopy between 2015 and 2016. The biomarkers were obtained with a maximum interval of one week in relation to colonoscopy and without introduction of new therapy. The Spearman test calculated the correlation between scores and biomarkers. ROC curves (AUC) were obtained for each score to predict Calprotectin > 100 g/g.

**Conclusion:** There is a significant correlation between endoscopic scores and Calprotectin, the correlation between scores that take into account the extension the disease were not superior to Mayo Endoscopic Score.

**Table 1:** Osteoporosis rates in patients on anti-TNF therapy (TNF) and those naïve to biological medications (NB) before and after age 60.

<table>
<thead>
<tr>
<th>Group</th>
<th>Age &lt; 60</th>
<th>Age &gt; 60</th>
</tr>
</thead>

<tr>
<td>TNF</td>
<td>15.4%</td>
<td>18.2%</td>
</tr>
<tr>
<td>NB</td>
<td>3.6%</td>
<td>30.0%</td>
</tr>
</tbody>
</table>

**Conclusion:** Rates of vitamin D deficiency, and osteoporosis were similar among patients on anti-TNF medications to those on no biologics. TNF group patients were diagnosed with osteoporosis at an earlier age compared to NB group. Patients on anti-TNFs also had statistically lower Z-scores at the spine. Prospective studies are necessary to further determine the role of anti-TNF medications in osteoporosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Introduction: Infliximab (IFX) trough levels (ITLs) have emerged as a promising tool for the management of inflammatory bowel disease (IBD) patients and they correlate with clinical response and endoscopic remission. However, its use in clinical practice is still under debate, particularly in clinically stable patients.

Aims & Methods: 1) to describe real-life ITLs in clinically stable IBD patients; 2) to evaluate the association between different ITLs factors associated with infratherapeutic ITLs; and 3) to evaluate the impact of ITLs availability by comparing the CCR with TLGD. The decisions between experts were also compared. Both comparisons were calculated by the linear Cohen’s Kappa (κ) index. IBD patients on maintenance IFX therapy were prospectively included from June 2015 to June 2016. Demographic, clinical and biological data including C-reactive protein (CRP) levels from the same infusion day were collected. At each IFX infusion, patients were visited by their physician; a “current clinical decision” (CCD) was taken regarding clinical data and CRP. The decision made just before the IFX infusion was considered as infra-therapeutic if <2 μg/mL. Once ITLs were known, 3 experts took a hypothetical decision on treatment based on the same clinical and biological data plus ITLs (ITL-guided decision - TLGD).

Results: A total of 224 IFX infusions from 74 patients (76% Crohn’s disease) were analyzed. Median (IQR) disease and IFX therapy duration was 10 years (5–18) and 23 months (7–61), respectively; 87% received concomitant immunosuppressant therapy; 70% were on standard dosing, whereas 10% were scheduled every 4-6 weeks and 13% every 12 weeks. 60% of the patients had clinical and biological remission. Median (IQR) CRP levels were 3.1 mg/mL (1.5–6.1). Median (IQR) ITLs were 1.79 μg/mL (0.35–5.74), with 52% of patients having infratherapeutic ITLs. In the multivariate analysis, the only risk factor for infra-therapeutic ITLs was the presence of biological activity. Concordance between CCD and TLGD was poor (κ = 0.10 [95%CI:0.01–0.20] vs κ = 0.11 [95%CI:0.01–0.21]) for experts A/B/C, respectively. This “disagreement” is due to a higher proportion of dose-escalation decisions according to the TLGD as compared to the CCD. Among the 203 infusions in which no action was taken according to the CCD, 93 (40%), 48 (20%) and 65 (30%) would have been dose-escalated according to the TLGD for experts A, B and C, respectively. This disagreement between experts was moderate (κ = 0.55 [95%CI:0.41–0.71]) vs 0.40 [95%CI:0.26–0.55] vs 0.30 [95%CI:0.21–0.40] for experts A-B/C-C, respectively.

Conclusion: Our results highlight the impact of the inflammatory burden on ITLs and on their therapeutic range in patients clinically stable. Both the clinical and economical impact of ITL-assisted decision-making in IBD patients should be evaluated in prospective cohorts.

P0995 THE DIAGNOSTIC UTILITY OF LINKED-COLOR IMAGING IN THE EVALUATION OF MUCOSAL INFLAMMATION IN PATIENTS WITH ULCERATIVE COLITIS

Digestive And Lifestyle Diseases, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima/Japan

Contact E-mail Address: h-hitomi@m3.kufm.kagoshima-u.ac.jp

Introduction: Recent studies recommend the histological mucosal healing of the intestinal tissue as a treatment goal in ulcerative colitis (UC). The intestinal tissue (IT) can be evaluated based on color differences by white-light imaging (WLI). However, these findings are not always correlated with the histological findings, and often tend to underestimate the inflammatory activity compared to the histological findings. Linked-color imaging (LCI) is a new endoscopy system that enhances the color differences of the gastrointestinal mucosa. We investigated the efficiency of LCI in the evaluation of the intestinal activity, including the histological activity, in patients with UC.

Aims & Methods: To check whether the IT could be evaluated with LCI in UC patients underwent colonoscopy from August to December 2016. Twenty-one UC patients, who were evaluated using an EC-L600Z endoscope with the LASEREQO system (FUJIFILM Co., Tokyo, Japan), were enrolled. All of the target lesions were observed by WLI and LCI, and biopsy specimens were obtained from the lesions with the reddest tones in each view. A total of 96 lesions were biopsied. We quantified the color tones on LCI based on the L*a*b* color values (LCI-L, LCI-a, LCI-b), where L* a* and b* represent lightness, red color, and yellow color, respectively. We also quantified the color tones on WLI (WLI-L, WLI-a, WLI-b) based on the L*a*b* color values. The endoscopic images were classified according to the Mayo endoscopic score (MES), and biopsied specimens were classified according to the Geboes score. The endpoint of this study was to measure the correlation between the color tones on WLI-L, WLI-a, WLI-b with the corresponding MES scores.

Results: The findings suggested the utility of LCI in evaluating mucosal inflammation in patients with UC.

Conclusion: LCI was superior to WLI for predicting mucosal healing and histological activity. The findings suggest the utility of LCI in evaluating mucosal inflammation in patients with UC.

Introduction: Inflammatory Bowel Disease (IBD) patients live situations that may trigger negative feelings and psychological malaise. ENMENTE Project is globally to improve identification and early management of psychological impact in IBD patients followed in Spanish hospital gastroenterology clinics. The aim of the study was to describe possible differences among perceptions from physicians and patients about the clinical situations triggering anxiety in patients with IBD.

Aims & Methods: During April 2016 two surveys were available on-line, one for IBD patients, in the ACCU Spain website (Confederation of IBD Spanish Patients’ Associations) and another one for physicians members of GITECCU (Spanish Group for IBD treatment). Both invited their members to participate by email and the patients’ report was announced in social networks. The scientific committee (3 gastroenterologists, 2 psychologists, 1 nurse and 1 patient) decided which potentially stressful clinical situations were considered. Physicians and patients rated these situations on a scale from 1 to 10 as potential triggers of anxiety for the patient. A Mann-Whitney test was used to compare perceptions from physicians and patients taking 151 valid questionnaires from physicians and a randomized sample of 151 patients’ questionnaires.

Results: The survey was completed by 912 patients (mean age 39 ±10 years, 67% women) and 170 patients (mean age 44 ±10 years, 58% women). Having an ostomy, fecal incontinence in public or surgery are important triggers of anxiety in patients (p <0.05). Both patients and physicians agreed that patients and physicians (table). Patients, however, experience anxiety from a possible new flare or from being fatigued, whereas physicians are more concerned about anxiety due to telling about a new IBD diagnosis and about pregnancy in IBD patients (table). Mean scores from physicians and patients about clinical situations triggers anxiety or depression

To what extent these clinical situations may trigger anxiety or depression? Physicians (n = 151) Patients (n = 155) p-value
The lack of diagnosis 6.3 6.0 ns
The diagnosis of IBD 6.2 5.6 < 0.05
The performance of an endoscopy 5.6 5.7 ns
The explanation of an ostomy 6.6 5.9 ns
A new oral treatment 4.8 4.8 ns
A new auto-injectable treatment 5.6 5.3 ns
A new intra-venous treatment 5.9 5.3 ns
A surgery 6.7 6.5 ns
Having an ostomy 6.9 6.9 p < 0.05
A pregnancy 5.9 4.0 < 0.05
The pain 6.3 6.1 ns
An episode of public inconvenience 6.8 6.6 ns
A new flare 6.2 6.5 < 0.05
Changes in the body image 6.3 5.9 ns
Tiredness, fatigue, reduction in performance 6.0 6.3 < 0.05

Conclusion: The main anxiety triggers in patients were having an ostomy, fecal incontinence in public, a surgery, a new flare and the feeling of fatigue. These last
two situations were scored higher by patients than by physicians. Teaching the patients to manage a new condition and the treatment of fatigue are aspects that would help to reduce the anxiety feeling and should be taken into account in clinical practice. P0997 EVALUATION OF LISA-TRACKER INMMUNOASSAY INFlixIMAB AND ANTI-INFLIXIMAB FOR THE THERAPEUTIC DRUG MONITORING OF SB2

A. Berger1, A. Haccourt1, J. Salameh2, X. Roblin3, S. Paul1

1Laboratoire D’Immunologie Cic1408, CHU Saint-Etienne, Saint-Etienne/France
2Biogen France, Nanterre/France
3University of St. Etienne Dept. de Gastroenterologie, Saint-Etienne/France

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: During this evaluation, standard curves of infliximab and two different batches of SB2 were compared and then accuracy of the Lisa-Tracker IFX kit in detecting the spiked concentration of SB2 was measured using the Lisa-Tracker assay. Levels of infliximab (from 5 spiked samples with known amount of SB2 and 10 clinical samples from patients treated with infliximab) were calculated according to each of the 3 standard curves (infliximab, SB2 batch1 and SB2 batch2). All samples and standards were tested in duplicate. Reproducibility was assessed by 2 intra-run and 1 inter-run precision were also measured with spiked samples of different known SB2 (from 2 to 12 µg/mL) amounts. Accuracy of polyclonal antibodies directed against infliximab to block the detection of SB2 using the Lisa-Tracker infliximab assay and the capacity of SB2 to block the detection of anti-infliximab antibodies using the Lisa-Tracker anti-infliximab assay were tested.

Results: We demonstrated the perfect equivalence of infliximab standard curve to the Lisa-Tracker standard curve and that the Lisa-Tracker assay is suitable for the quantification of SB2 in human serum samples (R² = 0.99; the levels of infliximab of the 20 samples were calculated according to the 3 standard curves infliximab, SB2 batch 1 and SB2 batch 2 with CV ranged from 2.1 to 12.6%). Quantification of SB2 was shown by a linear matrix and the % of recovery were comprised between 82% and 113%. High intra-run and inter-run precision were obtained with the Lisa-Tracker infliximab assay for the quantification of SB2 (CV range from 3.3 to 17.9%). Finally, the capacity of polyclonal antibodies to infliximab to block the detection of infliximab was shown (87%). The sensitivity and specificity values of 72.7% and 76.2%.

Conclusion: In conclusion, Lisa-Tracker Infliximab and anti-Infliximab assays are suitable for the monitoring of SB2 treated with SB2. Biogen provided the SB2 drug for this study. Biogen reviewed the protocol and provided feedback to the authors.

Introduction: If the association between trough levels of infliximab (TLI) and clinical remission or mucosal healing is demonstrated, we don’t really know the cause and effect between TLI and target value to obtain this association. So, the aim of our study was to evaluate the causality or the association between TLI and clinical remission.

Aims & Methods: We prospectively included all IBD patients treated in our IBD unit and in clinical remission (CDAI < 150 for Crohn’s Disease (CD) or partial Mayo score < 3 for ulcerative colitis (UC)) with biomarker normalization (fecal calprotectin < 250 µg/g stools) or in deep remission (clinical remission with fecal calprotectin < 50 µg/g stools). We analyzed median of TLI and fecal calprotectin at the inclusion (M0) and 6 months before eligibility (M-6). We excluded patients with deep remission at M-6.

Results: 111 patients were included (60 CD, sex ratio M/F: 0.8, 51 patients in deep remission at M0). All 111 patients were in clinical remission at M-6. Median fecal calprotectin at M-6 were similar in the two groups of patients (210 µg/g in the group of patients who achieved deep remission at M0 vs 220 µg/g in the group of patients who achieved only biomarker remission respectively; p = 0.01). A ROC curve analysis was not able to isolate a cut-off value associated to deep remission achievement. (AUROC = 0.61). Next, we analyzed separately median of TLI and fecal calprotectin 6 months before eligibility (M-6) of patients in deep remission at M0 (51 patients). The median TLI was significantly lower at M-6 than at M0 (41.4 µg/mL vs 59.4 µg/mL respectively; p = 0.003). Conversely, median fecal calprotectin was significantly higher at M-6 in comparison to M0 (190 x vs 35 µg/g stools; p = 0.01). A negative and weak significant correlation between fecal calprotectin and TLI was observed (Spearman’s rank correlation coefficient (q) = -0.25; p = 0.045).

Conclusion: Although TLI can increase with decreased drug clearance due to deep remission, we show for the first time that the residual rate is the causal element for achieving clinical remission.

The results of our study are confirmed by other authors as severe course of the disease, UC (46.40%) and CD (24.20%) (which is significantly higher than in patients with CD, respectively 18.1% to 9.30% with CD and 12.50% with UC, whereas in 2016- 12.20% with CD and 27.80% in a referral center was performed to evaluate the incidence of the principle of quantitative immunochromatographic assay for the determina-

Aims & Methods: Because of insufficient data from developing countries.

Contact E-mail Address: aniatanassova@abv.bg

Introduction: The prevalence of Clostridium difficile infection (CDI) in patients suffering from inflammatory bowel disease (IBD) has increased rapidly over the past several decades. However, the exact global epidemiology remains unclear because of insufficient data from developing countries.

Aims & Methods: The goal of our study is to examine the incidence of CDI in patients with CDI by prospective, observational study evaluating IBD patients in a referral center was performed to evaluate the incidence of Clostridium difficile. Diagnosis was confirmed with stool toxin analysis. Demographic informa-
tion, diagnosis, anatomic location, IBD therapy, antibiotic exposure, hospitalization, and comorbidities were recorded. For a period of 3 years, 202 IBD patients were studied, 105 of which have UC and 97 - Chron’s disease (CD). We used the Clostridium difficile Glutamat Dehyd-grogease + Toxin A + B based on the principle of quantitative immunochromatographic assay for the determina-

Results: The results show that all patients with a positive CDI test have a clinical picture, which resembles a relapse of the disease (p < 0.05). There’s a tendency towards growth in the incidence of IBD patients who are CD positive. Their number in 2016 is significantly higher than that in 2014. In 2014 it was ~5.90% with CD and 12.30% with UC, whereas in 2016- 12.20% with CD and 27.80% with UC (p < 0.05). There are a stong correlation between CDI incidence in patients with IBD and the severity of their disease. Patients positive for CDI have a much more severe course of the disease, UC (46.40%) and CD (24.20%) (p < 0.05).

Conclusion: There is an increase in incidence of CDI, and patients with UC are more affected by it. The results of our study are confirmed by other authors as well. A significant part of patients with CDI have a severe disease that needs extra prospective researches to determine the incidence and influence of the infection amongst patients with IBD, who receive different therapy regimes and also to understand how the CDI affects the evolution of the disease.

Introduction: There is no blood test predictive of sustained clinical remission in patients with Crohn’s Disease (CD) or Ulcerative colitis (UC) under Infliximab (IFX) - azathioprine (AZA) comotherapy.

Aims & Methods: All patients with CD or UC, consecutively treated by the combination of INFX-AZA between August 2015 and March 2017, were included in this monocentric study. Clinical, biological (blood cells count, liver function enzymes, C-reactive protein (PCR)) were retrospectively collected at baseline, at week 14 (W14) and at 6 months (W24) from the start of combination therapy.

Results: 2155 medical GI outpatient colonoscopies performed over 12 months were identified. 242 met inclusion criteria for the study. Median age of the patient cohort was 34 years (range 16-45), with 141 (58%) females. The cohort was stratified according to indications; Group A; 132 (55%) patients with diarrhea predominant symptoms, and Group B; 110 (45%) patients with constipation predominant abdominal pain and bloating. Colonoscopy was normal in 104 (79%) of Group A and 102 (93%) of Group B (p = 0.002), 36 (15%) Colonoscopies were abnormal; 7 patients had active ileitis, 22 had colonic inflammation (12 IBD, 2 lymphocytic colitis, 8 non-specific inflammation), and 7 had ileocolic inflammation (all diagnosed with IBD). 28 of 36 (78%) patients with mucosal inflammation confirmed on histology had diarrhea (p = 0.0001). FC was available in 36 patients, and CRP in 171 patients. In Group A the negative predictive value, positive predictive value and specificity of CRP/FC were 85%, 43% and
P1003 FAECAL CALPROTECTIN, AND MAGNETIC RESONANCE IMAGING ARE RELIABLE TOOLS TO DETECT ENDOSCOPIC POSTOPERATIVE RECURRENTE IN CROHN’S DISEASE

2 Hepato-gastroenterologie, Hôpital Robert Debré, Reims Cedex/France
3 CH Bayonne, Bayonne/France

Introduction: As surgical resection is not curative in Crohn’s disease (CD), post-operative recurrence (POR) remains a crucial issue. The POCER trial has consecutively included in this prospective study. All the patients underwent magnetic resonance imaging (MRI) and fecal calprotectin to detect endoscopic POR in CD patients. Adult CD patients from two tertiary centers who underwent ileal or ileocolonic resection were consecutively included in this prospective study. All the patients underwent magnetic resonance enterography including diffusion-weighted sequences with apparent diffusion coefficient (ADC) calculation (mm²/s) and evaluation of Clermont score (2), MaRIA (3) and MR score (4) within the first year after surgery or preventing POR. However, as colonscopy is a burdensome procedure, alternative tools have been developed such as faecal biomarkers and magnetic resonance imaging (MRI).

Aims & Methods: We aimed to assess the performances of MRI and faecal calprotectin to detect endoscopic POR in CD patients. Adult CD patients from two tertiary centers who underwent ileal or ileocolonic resection were consecutively included in this prospective study. All the patients underwent magnetic resonance enterography including diffusion-weighted sequences with apparent diffusion coefficient (ADC) calculation (mm²/s) and evaluation of Clermont score (2), MaRIA (3) and MR score (4) within the first year after surgery or preventing POR. However, as colonoscopy is a burdensome procedure, alternative tools have been developed such as faecal biomarkers and magnetic resonance imaging (MRI).

6 Hepato-gastroenterology Unit, hospital, Nantes/ France

Introduction: PEG preparations reduce the acceptability of endoscopic explorations but remains recommended before performing a small bowel videocapsule (SBVC). No study has evaluated its impact on the small bowel cleanliness compared to other modalities in patients with Crohn’s disease (CD). The objective of this study was to compare three methods of preparation, one using polyethylene-glycol and two simplified methods in adult patients with CD.

Aims & Methods: Three methods of preparation i.e. low-residue diet the evening before more 1 L PEG before the capsule (PEG), liquid diet the evening before the capsule (LD) and 1.5 L of water at the time of the capsule (Water) compared to the two other modalities LD (6.3) and Water (6.5). The cecal intubation rate was significantly lower in the PEG group 66% versus 91% (LD) and 94% (Water) (P=0.262). In the first tertile, the quantitative score was significantly better in the LD (7.9) and Water (7.6) groups compared to the PEG group (6.8) (P=0.043). The preparation by water was considered qualitatively better compared to the two other modalities (P=0.04).
Conclusion: This is the first study evaluating the relevance of PEG preparation in a large population of adult patients with CD. Our study has demonstrated that there is no benefit in using PEG for the preparation of the small bowel before the capsule in patients with CD. Quantitatively, the two simplified preparation methods were more efficient than the preparation with PEG and qualitatively, the preparation using bentonite was more favored by the patients and was more efficient.

Aims & Methods: Totally, 10 consecutive patients with inactive or mildly active UC were enrolled, and fifty-three areas were assessed by LCI. All examinations were conducted with a LASEREO endoscopic system (FUJIFILM Co., Tokyo, Japan). During the colonoscopy, each region of interest (ROI) of terminal ileum, cecum, ascending colon, transverse colon, descending colon, sigmoid colon, and rectum was assessed. High-definition white light imaging (WLI) and LCI. The Commission international de l’éclairage (CIE) LAB color differences (ΔC) were calculated among WLI and LCI in each ROI. After ROI was observed by colonoscopy, the biopsy specimen was taken in each ROI. Inflammatory cell infiltration, erosion, crypt abscesses, and goblet cell depletion were assessed, indicating the histologic findings of acute inflammation. For evaluation of chronic inflammation, crypt atrophy, crypt distortion, and basal plasmacytosis were assessed. The correlation between ΔC and Mayo endoscopic sub-score was assessed, indicating that the higher ΔC mean easier color difference for recognition.

Results: The mean age of patients who were enrolled in the present study was 45.6 ± 17.7 years. The sex ratio (men/women) was 4:6. The type of extent of UC (ulcerative proctitis/left-sided UC/extensive UC) was 0:3:7. 1. Correlation between CIELAB color differences and histology. The mean ΔC of ROI without inflammatory cell infiltration was significantly higher than that of ROI with inflammatory cell infiltration ([15.9 ± 4.9 vs. 12.3 ± 6.7, p = 0.046]. The mean ΔC was not affected by histological findings of erosions, crypt abscesses, goblet cell depletion, crypt atrophy, crypt distortion, and basal plasmacytosis. LCI distinguished colon mucosal mucus color compared with WLI with use of three-dimensional color space, indicating the remission-colon mucosa of UC with no inflammatory cell infiltration in ROI was easily detected by LCI. 2. Correlation between CIELAB color differences and Mayo endoscopic subscore. Low Mayo endoscopic subscore-tended to be inversely proportional to high ΔC (ΔC: -0.8 ± 1.9, p = 0.00; ΔS: 13.0 ± 0.9, p = 0.04) but not significant in the present evaluation. The colon mucosa with the low Mayo endoscopic subscore-tended were relatively easily detected by LCI compared with WLI. Conclusion: The present pilot trial indicated that the inactive UC mucosa could be detected as the white area by the LCI mode compared to WLI, suggesting that LCI might be a novel approach for evaluating the disease activity of UC.

Introduction: Inflammatory bowel disease (IBD) is primarily assessed by endoscopy, which is a costly and invasive procedure with serious risk of complication, underlining the need for novel non-invasive diagnostic biomarkers. In previous studies, plasma amino acid analysis has revealed significant differences between IBD subjects and controls. This ‘aminogram’ has not yet been studied in faecal samples of IBD patients. The aim of this explorative study was to compare faecal amino acid composition between paediatric de novo IBD patients and healthy controls, and between the phenotypes ulcerative colitis (UC) and Crohn’s disease (CD).

Aims & Methods: In this cross-sectional case-control study, paediatric treatment naïve IBD patients from a tertiary centre were included, before bowel cleansing and colonoscopy. Control patients were recruited from schools in the province North Holland, the Netherlands. All participants collected a faecal sample on the same day colonoscopy was performed. To prevent bias by peak overlap of different amino acids, outcomes of amino acid analysis were performed by means of high performance liquid chromatography (HPLC, Biochrom 30). To correct for the influence of faecal consistency, the samples were freeze dried for 24 hours before the analysis was performed. To prevent this by peak overlap of different amino acids, outcomes of 5 nmol/mg or lower were excluded from further analysis.

Results: Faecal samples from 15 subjects (5 healthy, 5 UC, 5 CD) were analysed. Median age was 14 (8-17) years. Subjects and controls were matched on age and sex. A total of 42 different amino acids were analysed, of which 30 were excluded due to quantities of ≤5nmol/mg. In particular, alanine, glycine, phenylalanine, leucine, isoleucine, valine and lysine differed between IBD patients and healthy controls with ratios up to 1.5 (table 1). In addition, UC and CD patients differed remarkably based on levels of glycine, phenylalanine and serine with ratios up to 4.1 (table 1).

</table>

Conclusion: This was the first pilot study to assess the potential of the faecal aminogram as an non-invasive biomarker for disease activity of paediatric IBD. We observed remarkable differences in faecal amino acid composition between IBD patients and healthy controls, and between the IBD phenotypes. Whether these differences reflect decreased absorption or increased loss by inflamed intestines needs to be elucidated. Currently, we are awaiting the results of a larger proof-of-concept study on these faecal amino acid profiles.

Introduction: Measurement of infliximab trough levels (IFX-TLs) and antibodies to infliximab (ATIs) has been suggested as an important parameter for the optimization of IBD treatment with IFX. Aims & Methods: We aimed to cross-sectionally investigate the correlation between IFX-TLs or ATIs and clinical, biochemical as well as endoscopic activity in Greek IBD patients. Consecutive IBD patients on maintenance treatment with IFX were included. IFX-TLs and ATIs were measured using ELISA (Eagle Biosciences, Nashua, NH, USA) on serum samples drawn before infusion. At the same time quality of life using short IBD questionnaire (SIBDQ) and clinical disease activity using Harvey-Bradshaw Index (HBI) for Crohn’s disease (CD) or simple colitis activity index (SCAI) for ulcerative colitis (UC) were assessed. Moreover, biomarkers (hemoglobin, ESR, CRP, platelets, albumin) were measured and latest colonoscopies (within 6 months) were reviewed and evaluated for presence or not of mucosal healing.

Results: A total of 74 patients receiving IFX maintenance therapy [55 CD, 19 UC, 9 males, mean age 42.3 years, 45 on combination therapy with immunomodulators (IMM), 10 under intensified dose (either 10 mg/kg bw or 5 mg/kg/4-6w)] were studied. Median time since IFX initiation was 26 (13-71) months and median value of serum IFX-TL was 4.83 µg/ml (0.03-30.7). Seven out 74 (9.5%) were positive for ATIs (>10 AU/ml), Patients on combination treatment had significantly higher IFX-TLs (6.98 µg/ml, 0.34-30.7) compared to those on IFX monotherapy (1.85 µg/ml, 0.09-25.8) (p = 0.01). Patients with positive ATIs had median IFX-TLs 0.99 µg/ml (0.09-1.40) statistically lower compared to those with negative ATIs (6.01 µg/ml, 0.03-30.69) (p = 0.005). The correlations of IFX-TLs and ATIs with clinical, biochemical and endoscopic indices of disease activity in IBD patients are presented in Table 1. No other significant correlations of IFX-TL or ATIs with other disease characteristics were observed. In the logistic regression analysis only IFX-TLs (OR 0.97, 95% CI 0.95-0.99 p = 0.04) and duration of IFX treatment (OR 0.97, 95% CI 0.95-0.99 p = 0.04) were independently correlated with the presence of mucosal healing.

Table 1: Correlations of infliximab trough levels and antibodies to infliximab with clinical, biochemical and endoscopic indices of disease activity in patients with inflammatory bowel disease

Conclusion: Therapeutic drug monitoring is valuable in IBD-patients on maintenance IFX-treatment. Combination treatment with IFX and IMM is associated with higher IFX-TLs compared to IFX monotherapy. Higher IFX-TLs are independently associated with the presence of mucosal healing.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
was higher in group I. And Family and Bacteroides Genus were numerous clearly, and both were higher in ment of UC. In bacteria having significant difference, especially Bacteroidaceae indicating a relevant association between gut microbial species and the develop-
vment of UC. In bacteria having significant difference, especially Bacteroidaceae (P. magnifica) and Peptoniphilaceae Family.

Contact E-mail Address: fukukats@lule.ac.jp

Aims & Methods: With the major focus of our study being to establish a relevant biomarker of disease activity in UC patients based on the intestinal microbiota, 82 UC patients together with 61 healthy relatives as controls were included for investigations of gut microbiota in faecal samples. Twenty-five patients had active UC (group I) and 57 had quiescent UC; 29 with mild inflammation in the large intestine (group II), and 28 without inflammation (group III). The patients’ relatives were consanguineous (group IV, n = 33), and non-consanguineous (group V, n = 28). The subjects’ age ranged from 15 to 69 years. Faecal bacteria between groups I to V were compared by the t-test. The Discriminant analysis in all five groups was done for each Phylum, Class, Order, Family, Genus and Species. The Canonical Discriminant Function Coefficient (Df) for each bacterial community was calculated. The quantity of each bacteria was multiplied by the Df value, and the sum was termed the Discriminant Score (Ds). Next, we tried to analyze the quantity and the diversity of the bacteria which had significant difference.

Results: We obtained 1011 varieties of bacteria as Phyla, Class, Order, Family, Genus and Species. Any individual bacterial quantity with 0 value >95% of group I and group V, the mean of the individual quantity of bacteria <0.05% cases (648) were excluded. The t-statistics was done on 363 bacteria between groups I to V. Significant difference was calculated in 18 Species, 10 Genus, and 4 Families. The Discriminant analysis was done on these 18 Species from all groups. The Ds value showed an increasing tendency in this order: group I < group II < group III < group IV < group V. Significant difference was calculated for group I vs group II, vs group III, vs group IV, and vs group V (P < 0.05). Likewise, group V vs group I, vs group II, vs group III (P < 0.05), indicating a relevant association between gut microbial species and the development of UC. In bacteria having significant difference, especially Bacteroidaceae Family and Bacteroides Genus were numerous clearly, and both were higher in group I, active UC. It’s odd that the diversity of Bacteroides Genus was higher in Group V, non-consanguineous relatives, but the quantity of Bacteroides Genus was higher in group I. And Bacteroides fragilis was increased in group I, and the others of Bacteroides were increased in group V, it depends on the amount of Bacteroides fragilis. In active UC, the amount of Bacteroides fragilis was increased, but the diversity of Bacteroides Genus was decreased. It’s very inter-
esting, and the balance can be key point between Bacteroides fragilis and the diversity of Bacteroides in UC activity. And about Genus Anaerococcus, Finegoldia and Peptoniphilus, about Species Anaerococcus vaginalis, Finegoldia magna and Peptoniphilus gorbachii were increased in group V significantly. All these bacteria belong to Peptoniphilaceae Family.

Conclusion: In this study, we compared 363 bacteria between active UC patient to control, significant difference was calculated in 18 Species, 10 Genus, and 4 Families. To our knowledge, this is the first report on so many bacteria being related to UC activity. Additionally, the Ds related to UC, or otherwise absence of UC in the five groups. Potentially, Ds might be a clinically relevant biomarker of disease activity in UC. This is the first application of the Ds to the study of the microbiota in UC patients, consanguineous and non-consanguineous relatives by using NGS. Moreover we could obtain a lot of interesting results about the quantity and the diversity of the bacteria, especially Bacteroides and Peptoniphilaceae.

Introduction: Endoscopy is the gold standard diagnostic tool in ulcerative colitis (UC). However noninvasive methods like cross-sectional imaging and fecal biomarkers are needed for interval clinical assessments and assessing response to medical treatment. The combination of positron emission tomography (PET) with 18F-fluorodeoxyglucose (18F-FDG) with magnetic resonance imaging (MRI) as integrated PET/MRI in one examination is a new cutting-edge tech-
nology for the non-invasive assessment of the inflammatory activity in UC.

In addition a panel of noninvasive biomarkers like Lactoferrin and Calprotectin are increasingly popular and used in all-day patient care.

Aims & Methods: To compare the performance of non-invasive biomarkers to PET/MRI and colonoscopy in patient with UC. In every patient a PET/MRI including the maximum standardized uptake value ratio gut/liver (SUVRatio) and a colonooscopy including an endoscopy index (EI) was performed within 48 hours and the Disease Activity Index Mayo score (DAI) was calculated. Fecal Lactoferrin (LF), CalprotectinMUN (CalP), CalprotectinCALPREST (CalP), PMN-elastase (PMN-E), S100A12, Eosinophil-derived Neurotoxin (EDN) as well as CRP were correlated to the SUVRatio, the DAI and the EI using correla-
tion analyses. Sensitivity, specificity and diagnostic accuracy were calculated using optimized cut-offs. All analyses were performed using SPSS (IBM SPSS Statistics for Windows, release 22.0).

Results: 32 patients (21 female), mean age 44.4 ± 10.6 years (range 23–67) with diagnosed UC were included in the study. Mean time since diagnosis was 11.41 years (SD = 6.42). EI and SUVRatio (r = 0.45; p = 0.009), EI and DAI (r = 0.32; p = 0.87; p = 0.000) as well as DAI and SUVRatio correlated significantly (r = 0.40; p = 0.022). SUVRatio was correlated significantly with LF (r = 0.36; p = 0.046), EDN (r = 0.49; p = 0.05), and CRP (r = 0.36; p = 0.043), but not with PMN-E, S100A12 and CalP (p < 0.05). DAI was correlated significantly with PMN-e (r = 0.55; p = 0.001), LF (r = 0.52; p = 0.001), EDN (r = 0.70; p = 0.000), CalP (r = 0.46; p = 0.008), and CRP (r = 0.56; p = 0.001), but not with S100A12 and CalP (all p > 0.05). EI was significantly correlated with LF (r = 0.61; p < 0.001), but not with PMN-E, S100A12, PMN-e, Edn (p = 0.05). PMN-e (r = 0.50; p = 0.03), S100A12 (r = 0.41; p = 0.021), CalP (r = 0.32; p = 0.002), CRP (r = 0.44; p = 0.012), but not with CalP (p > 0.05). The median levels (inactive/active) were: LF: 1.75/20.13 µg/g, CalP: 60.25/105.60 µg/g; PMN-e: 6.42/10.63 µg/g; PMN-e: 60.40/100.40; PMN-e: 75.5%/75.0%/75% (CI 80.5%/86.2%), 68, 43 µg/g; PMN-e: 83.3%/75.0%/81.25% (CI 62.5%/53.6%/57.8%, 361 µg/g); CALI: 62.5%/62.5%/62.5% (CI 53.6%/57.8%/62.5%, 43 µg/g);

Conclusion: Using EI as gold standard reference we found that fecal biomarkers LF, EDN, PMN-E and S100A12 could reliably distinguish between active and inactive UC. However, CalP did not perform well. Both LF, PMN-E and CRP were significantly correlated to the SUVRatio which was significantly correlated with EI and DAI. In conclusion, Lactoferrin and Eosinophil-derived Neurotoxin performed best using endoscopy and PET/MRI as reference.

Fecal Lactoferrin, Calprotectin and PMN-elastase, CRP, S100A12, PMN-e and White Blood Cell Count as an Indicator for Mucosal Healing and Clinical Course of Disease in Patients with Mild to Moderate Ulcerative Colitis: Post Hoc Analysis of a Prospective Clinical Trial. JOURNAL OF CROHNS AND COLITIS 2016; Feb 13
Introduction: At present, drug response to infliximab is monitored by trough levels of antibody levels, another pathway of drug degradation has been hypothesized since MMP3 and MMP9 were found to be able to cleave IgG, like infliximab, in both animal and human experimental studies (1).

Aims & Methods: We collected serum samples in 102 patients (27 Crohn’s Disease and 75 Ulcerative Colitis) treated with stable doses of infliximab for at least 6 months (t0) and 6 months thereafter (t1). In each patient TL, ATI values and MMP3 levels were assessed at t0 and t1 by ELISA. In addition, MMP3 levels were also determined in 28 healthy subjects as controls. Clinical (HBI or Mayo score) and biochemical (CRP, fecal calprotectin) markers were assessed to define disease remission/activity. TL were considered therapeutic if >3.8 mcg/ml, ATI were considered positive if >10 mcg/ml. Data are presented as mean ± Standard Error Mean (SEM). Comparison among groups was performed by non-parametric tests.

Results: MMP3 levels were similar at t0 and t1 in patients which maintained therapeutic TL (14.5±1.7 mg/ml and 15.0±1.6 mg/ml, respectively) and in healthy controls (14.5±1 mg/ml). Patients with low TL but ATI positive had significantly higher MMP3 levels compared to the group with low TL and ATI positive (33.2±3.0 and 20.0±2.7 respectively, p<0.0003), showing another pathway of drug degradation. 21 patients lost response between t0 and t1: 15 out of 21 patients demonstrated high levels of MMP3 (22.0±2.1 mg/ml) already at t0; in addition, 17 of these 21 patients were in clinical remission at t0, while at t1 all patients had disease activity.

Conclusion: Serum MMP3 levels are useful in predicting loss of response to anti-TNFs in patients with low TL but without ATI. High MMP3 levels predict with 90.5% accuracy loss of response over the next 6 months.

P1013 USEFULNESS OF A MULTIDISCIPLINARY APPROACH COMBINING BOTH RHEUMATOLOGY AND GASTROENTEROLOGY FOR THE ASSESSMENT AND MANAGEMENT OF INFLAMMATORY BOWEL DISEASE PATIENTS

M. Barreiro-De Acosta1, E. Pérez-Pampin2, R. Ferreiro Iglesias1, R. Mejuto1, A. Mera1, J.E. Dominguez-Munoz1

Introduction: More than one third of inflammatory bowel disease patients (IBD) present gastrointestinal manifestations, which are the more common, clearly the more incapacitating and which more alter the quality of life of IBD patients. These patients could benefit from a multidisciplinary approach for quicker diagnosis and for optimizing treatments.

Aims & Methods: The aim of the study was to evaluate the impact of a multidisciplinary approach carried out by both a rheumatologist and a gastroenterologist in the management of these patients. Therapeutic changes after the combined assessment were also evaluated. Methods From April 2015 to April 2017, all IBD patients reporting articular pain to the IBD-dedicated gastroenterologist were referred to an experienced rheumatologist. The day of the consultation a multidisciplinary committee with a rheumatologist and a gastroenterologist evaluated and discussed in all patients their possible comorbidities and potential changes in their treatment. Assessment was made according to current guidelines and data recorded in a common database according to the reasons why patients were remitted from IBD, their rheumatologic diagnosis and all changes implemented in their treatments. Results are shown in percentages.

Results: 112 consecutive IBD patients were remitted from the IBD Unit and analyzed by the committee. Mean age 38 years (ranging from 18 to 73). Most patients were women (67%), 19% were smokers and 23% former smokers. 51% of patients had Crohn’s disease and 49% ulcerative colitis. The main causes for derivation from IBD were a suspicion of inflammatory arthropathies in 43% and of arthromyalgias in 40%. The more frequent diagnosis after the rheumatology consultation and the committee meeting were inflammatory arthropathies associated with IBD in 41% (51.5% presented axial arthropathies and 48.5% presented peripheral arthropathies) and fibromyalgia in 15%. Regarding treatment changes, after the multidisciplinary committee with a rheumatologist and a gastroenterologist, changes were made in 28% of patients. Of those, 35% of patients methotrexate was added in patients with biologic treatment (in some of them patients were in monotherapy, but in others the drug was introduced for replacing thiopurines). In 24% of patients sulfasalazine was introduced instead of mesalamine. In the other patients either other biologics like adalimumab associated with IBD in 41% (51.5% presented axial arthropathies and 48.5% presented peripheral arthropathies) and fibromyalgia in 15%. Regarding treatment changes, after the multidisciplinary committee with a rheumatologist and a gastroenterologist, changes were made in 28% of patients. Of those, 35% of patients methotrexate was added in patients with biologic treatment (in some of them patients were in monotherapy, but in others the drug was introduced for replacing thiopurines). In 24% of patients sulfasalazine was introduced instead of mesalamine. In the other patients either other biologics like adalimumab associated with IBD in 41% (51.5% presented axial arthropathies and 48.5% presented peripheral arthropathies) and fibromyalgia in 15%.

Conclusion: A multidisciplinary consultation combining inflammatory bowel disease and rheumatology allows both an earlier detection of inflammatory arthropathies associated with IBD and earlier changes in treatment, thereby helping to optimize the hospital resources. Fibromyalgia is common among IBD patients, though it is important that it is detected it should not be confused with drug-induced fibromyalgic syndrome. A rapid test allows a much faster assessment of therapeutic levels, providing a great advantage over test formats that need samples to be sent to a central laboratory. Here, we present the analytical performance characteristics as part of the validation of the Quantum Blue® Adalimumab test from BÜHLMANN.

Aims & Methods: The sandwich lateral flow immunoassay uses a tumor necrosis factor alpha coated label and a highly specific monoclonal antibody to detect adalimumab in a diluted human serum sample. Evaluation was performed according to CLSI guidelines. The linearity study included multiple concentration levels covering and exceeding the expected measuring interval, obtained by blending two sample pools, low and high. The within laboratory precision was performed with five (5) samples within the measuring range (20 days - two runs per day in two replicates). Method comparison was performed with a commercial available ELISA (RIDASCREEN® ADM Monitoring, Art. No. G9094, R. Biopharm, Darmstadt, Germany) and is based on 106 serum samples. For recovery analysis six clinical samples over the measuring interval of the test were spiked with 6 pg/ml adalimumab in negative serum and compared with the expected values. The high dose hook effect was evaluated with spiked pooled human serum in two runs, the second run with an additional dilution of the samples into the measuring interval of the test.

Results: The BÜHLMANN Quantum Blue® Adalimumab test exhibits a linear range from 0.93 to 34.61 mcg/ml. The recovery of clinical samples ranged from 80% to 89%. No high dose hook effect was observed up to 1002 pg/ml of adalimumab. The applied additional dilution into the measuring interval yielded a linear relationship. The mean total within-laboratory precision of the device was 23.9% (20.7 to 28.9%) with a repeatability of 21.2% (16.4 to 27.8%). The method comparison revealed a slope of 1.18 and a regression coefficient (r) of 0.92 (Passing-Bablok) suggesting that the new Quantum Blue® Adalimumab test showed an excellent correlation compared to the ELISA method.

Conclusion: The BÜHLMANN Quantum Blue® Adalimumab lateral flow test enables the quantitative determination of adalimumab trough level in serum with time to result of only 15 minutes. The developed test allows to measure adalimumab over a wide range, well beyond the therapeutic window. Hence, it represents a valuable tool for the clinician to assess the adalimumab trough level.
of a value of Crohn’s Disease Endoscopic Index of Severity below 8, so far we included complete clinical and endoscopic evaluation of a minimal residual endoscopic activity. Endoscopic evaluation was performed within two weeks of blood sampling, and at least after 6 months of ADA treatment.

Results: In our prospective study we enrolled 22 CD patients primary responders to ADA therapy (13 males, median age 43 years, range 23–67 years) who had a median treatment duration of 52 weeks (range 24–121 weeks). ADA TL were significantly higher (P = 0.002) in patients who achieved MH (12.1 mcg/mL, range 6.8–17.2 mcg/mL) as compared to patients without MH (4.50 mcg/mL, range 0.9–9.9 mcg/mL). Receiver Operating Characteristic curve identified an ADA TL cut-off of 6.43 mcg/mL as the threshold with the highest accuracy for identification of patients who achieve MH (AUROC 0.934, sensitivity 100%, specificity 81.8%, PPV 84.6, NPV 100%). Moreover, achievement of MH was associated with absence of AAA (P = 0.012). Lastly, HBI was significantly lower (P = 0.002) in patients with MH (4, range 3–8) than in patients without (11, range 4–17).

Conclusion: In our cohort of CD patients, we observed a clear association between ADA therapy, clinical development, and disease activity. In this particular population, achievement of 6.43 mcg/mL has been identified as the best cut-off to obtain endoscopic remission or at least a minimal residual endoscopic activity. Moreover, we observed that CD patients on ADA therapy who achieved MH had a lower disease activity. In conclusion, we support the use of therapeutic ADA monitoring for the management of CD patients in order to obtain clinical and endoscopic remission of the disease.

Introduction: Crohn’s disease (CD) management targets mucosal healing on ileocolonic surveillance as a treatment goal.

Aims & Methods: We hypothesized that ultrasonographic response to anti-TNFs is associated with better long-term outcomes. Patients with CD treated with anti-TNFs who had serial small intestine contrast ultrasonography (SICUS) between January 2011 and April 2017 were identified. Disease site (based on bowel wall thickness), extent of lesions, and presence of complications (stenosis, prestenotic dilatation, abscess, or fistulas) were evaluated using SICUS. Inclusion required pre-therapy SICUS with follow-up SICUS after 12 months, or 2 SICUS ≥12 months apart while on maintenance therapy. At second SICUS, complete or improved responders had no new lesions, and partial responders had new lesions, and partial responders had other scenarios. CD-related outcomes of corticosteroid need, hospitalization, and surgery were assessed at one year from the second SICUS.

Results: Seventy-nine CD patients treated with anti-TNFs (37% with Infliximab, 63% with Adalimumab) were identified. Patients with CD treated with anti-TNFs who had serial small intestine contrast ultrasonography (SICUS) between January 2011 and April 2017 were identified. Disease site (based on bowel wall thickness), extent of lesions, and presence of complications (stenosis, prestenotic dilatation, abscess, or fistulas) were evaluated using SICUS. Inclusion required pre-therapy SICUS with follow-up SICUS after 12 months, or 2 SICUS ≥12 months apart while on maintenance therapy. At second SICUS, complete or improved responders had no new lesions, and partial responders had new lesions, and partial responders had other scenarios. CD-related outcomes of corticosteroid need, hospitalization, and surgery were assessed at one year from the second SICUS.

Results: Seventy-nine CD patients treated with anti-TNFs (37% with Infliximab, 63% with Adalimumab) were identified. Patients with CD treated with anti-TNFs who had serial small intestine contrast ultrasonography (SICUS) between January 2011 and April 2017 were identified. P1019 THE INFLAMMATORY BOWEL DISEASE DISABILITY INDEX IN INFLAMMATORY BOWEL DISEASE: RELATIONSHIP WITH DISEASE CHARACTERISTICS AND QUALITY OF LIFE IN A COHORT OF SICILIAN PATIENTS

G. C. Morreale1, E. Gianaquinto2, V. Calvaruso1, M. G. Cillofitt2, B. Scrivio1, M. Cappello1 1Clinica Medica, Gastroenterology and Hepatology Unit, Palermo/Italy 2Clinica Medica, Policlinico Paolo Giaccone, Palermo/Italy

Introduction: IBDs are disabling conditions that negatively affect physical, psychological, familial and social dimensions of life. The concept of quantifying disability has been introduced for the evaluation of the impact of many other chronic diseases. Thus, specific tools have been used to assess the impact of disease and its treatment options on relevant endpoints such as health-related quality of life (HRQL), measured by the IBD-Questionnaire (IBD-Q). Recently, the IBD-Disability Index (IBD-DI) has been developed to evaluate the entire spectrum of limitations in functioning in patients with IBD. This index is inspired to the International Classification of Functioning, Disability and Health (ICF). The aim of the present study was to assess the relationship between the IBD-DI, clinical characteristics, and HRQL in a cohort of Sicilian patients with ulcerative colitis (UC) and Crohn’s disease (CD) followed up in a referral center.

Aims & Methods: IBD-Q and IBD-DI questionnaires were administered to consecutive UC and CD adults outpatients from July 2016 to April 2017. The IBD-DI consists of 28 items that evaluate the 4 domains of body functions, activities and participation, body structures and environmental factors. IBD-Q consists of 32 questions grouped into 4 dimensions: bowel, systemic, social, emotional. Scores range from 1 (poorest QoL) to 7 (best QoL) with higher scores indicating better QoL. Disease activity was assessed by partial Mayo score for UC and by Harvey-Bradshaw Index for CD. The mean differences of DI score in relation to disease characteristic (gender, disease duration, disease extension, extraintestinal manifestations) and to disease activity (gender, disease duration, disease extension) were evaluated by linear regression analysis. Disease activity was assessed by partial Mayo score for UC and by Harvey-Bradshaw Index for CD. The mean differences of DI score in relation to disease characteristic (gender, disease duration, disease extension, extraintestinal manifestations) and to disease activity (gender, disease duration, disease extension) were evaluated by linear regression analysis. Disease activity was assessed by partial Mayo score for UC and by Harvey-Bradshaw Index for CD.

Results: Data from UC and CD patients were analysed separately. 100 UC patients (59% males, median age 49 years) were enrolled; 17% were smokers. 83% had inactive or mild disease, 17% moderate disease. None of the recruited patients were conventional therapy (5-aminosalicylic acid, oral steroids) in 72 patients (59% males, median age 49 years) were enrolled; 22% were smokers. 94% had mild disease, 17 (6%) were conventional therapy (5-aminosalicylic acid, oral steroids) in 72 patients

Conclusion: Our preliminary results show that the IBD-DI is significantly related to disease activity, as well as to gender and disease duration. Disease activity was assessed by partial Mayo score for UC and by Harvey-Bradshaw Index for CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1020 DIPEPTIDYL PEPTIDASE 4 (DPP-4): A BIOMARKER OF DISEASE ACTIVITY AND PROGNOSIS IN INFLAMMATORY BOWEL DISEASE

P. Pinto-Lopes1, J. Afonso1, G. Macedo2, F. Magro2 1Department Of Biomedicine – Pharmacology And Therapeutics Unit, Internal Medicine Department, Faculty of Medicine of Porto University, Hospital São João, Porto, Porto/Portugal 2Department Of Gastroenterology, Hospital São João, Porto, Porto/Portugal

Introduction: DPP-4 is a membrane-bound glycoprotein expressed on the cell surface of immune cells and lymphocytes. It is released in plasma, maintaining its proteolytic activity and inactivating cytokines, chemokines and neuropeptides.

Aims & Methods: We aimed to investigate the diagnostic and prognostic value of DPP-4 in patients with inflammatory bowel disease (IBD). A total of 203 adult patients (n = 149 IBD patients; n = 42 healthy controls; n = 12 immune controls - systemic lupus erythematosus in remission) were prospectively recruited. Plasma DPP-4 was analysed in all groups; faecal samples from IBD patients were collected for DPP-4 and calprotectin analysis. Disease activity was assessed by the Harvey-Bradshaw Index (HBI) for Crohn’s disease (CD), the partial Mayo Score (pMS) for Ulcerative colitis (UC) and the Systemic Lupus Erythematosus Disease Activity Index for SLE. A multi-biomarker model was used deriving logistic regression to evaluate predictors of disease activity and Cox regression to evaluate predictors of treatment escalation (disease outcome).

Conclusion: Treatment escalation was defined as the need for escalation to immunomodulatory/ biologic therapies or intestinal resection surgery, as a consequence of a disease flare.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1021 ROLE OF PET-CT TO ASSIST DISEASE ACTIVITY IN ULCERATIVE COLITIS AND ITS CORRELATION WITH CLINICAL CRITERIA, ENDOSCOPY, BIOCHEMICAL MARKERS AND CRITERIA, ENDOSCOPY AND FECAL BIOMARKERS

N. Berry, S. K. Sinha, A. Bhattacharya, K. Prasad, C. Vaishnavi, K. Vajpeyi, J. Samanta, R. Prasada, N. Dhaka, R. Kochhar 1Department of Gastroenterology, Postgraduate Institute of Medical Education and Research, Chandigarh/India

Contact E-mail Address: nehaberry86@hotmail.com

Introduction: Disease activity in ulcerative colitis (UC) is best assessed clinically by Mayo score and endoscopy. Positron emission tomography -computed tomography (PET-CT) is a non-invasive imaging technique to assess disease activity, extent, treatment response in UC, specifically in pediatric population, sick patients and those unwilling for endoscopy.

Background: It is well established that the endoscopic activity of ulcerative colitis is correlated with inflammation, fibrosis, and extraintestinal manifestations. PET-CT is a non-invasive imaging technique that use the PET modality to assess the distribution and density of radioisotope labeled glucose tracers injected intravenously. The primary aim of the study was to compare clinical and endoscopic activity assessments with PET-CT activity measurements in UC and to examine the correlation between PET-CT measurements and inflammation, fibrosis, and extraintestinal manifestations.

Materials and Methods: Fifty-one UC patients (26 males; median age 40 years) were recruited to the study. All patients were in clinical remission. A larger sample with different grades of disease activity could provide a more accurate evaluation of the reliability of this tool in measuring functional status and disability in IBD. IBD-DI could become a major end-point in RCTs targeting the course of IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: Of 60 enrolled patients, 10% patients had proctitis, 43.3% had left-sided colitis and 46.7% had extensive colitis. ESR, CRP, fecal calprotectin levels and rectal PET activity were significantly higher in patients with moderate and severe disease activity as compared to those in remission. Rectal PET activity showed a significant correlation with the Mayo score (k = 0.465, p < 0.001), endoscopic sub-score (k = 0.526, p < 0.001), histological score (k = 0.496, p < 0.001), and fecal calprotectin levels (k = 0.279, p = 0.031). Extent evaluation by PET-CT and colonoscopy also showed a significant correlation (k = 0.582, p < 0.001) with each other. We found that CRP at a cut-off level of 12 mg/L had a sensitivity of 70.59% and specificity of 92.3%, and fecal calprotectin at a cut-off level of 21.0 mg/g had a sensitivity of 82.35% and specificity of 88.46% to predict remission. Besides, PET-CT identified sacroilitis in 1, mesenteric lymphadenopathy in 5, mesenteric stranding in 4, and adenocarcinoma in 1 patient.

Conclusion: PET-CT is a reliable non-invasive tool for assessing disease activity in UC with good correlation with the Mayo score, endoscopic score, histology and fecal calprotectin. It is an accurate measure to determine disease extent, and a good predictor of remission. Thus, with a better patient compliance, it holds promise in replacing colonoscopy where it is refused or difficult to perform.

P1023 THE IMPACT OF AN INFLAMMATORY BOWEL DISEASE EDUCATION CLINIC ON PATIENT OUTCOMES AND RESOURCE UTILISATION

W. On, B. Collins, H. Stanley, A. Westhoff, S. Tynan, D. Mcclements, V. Theis, J. McLindon, R. Chandy, A. Bassi

Contact E-mail Address: weiheng.on@gmail.com

Introduction: Patient education and awareness in those who have inflammatory bowel disease (IBD) and is regarded by the United Kingdom (UK) IBD standards group as a key standard in the provision of care towards patients with IBD. Our district general hospital implemented an IBD education clinic in 2015 with patients seen quarterly per annum by a multidisciplinary panel of doctors, specialists, nurses, pharmacists and dietitians. Patients who have been newly diagnosed with IBD are invited to attend this clinic. Clinic attendees are given an overview of their disease, treatment modalities, options of non-medical support (e.g: psychology) and are made aware of our telephone helpline open access service. To date, there has not been any published data on the impact of an IBD education clinic on resource use or patient outcomes.

Aims & Methods: We aimed to evaluate the impact of the education clinic on resource use in patients who attended the clinic compared to patients who did not. A retrospective analysis was done of patients who were diagnosed with IBD between January 2013 and May 2015. 40 patients were identified and divided equally (20 patients each) into clinic attenders (CA) and non-attenders (NA).

Results: The median age was 37 in the CA group and 33 in the NA group. In the CA group, 10 patients had ulcerative colitis (UC), 9 patients had Crohn’s Disease (CD) and 1 patient had unclassified IBD. In the NA group, 13 patients had UC and 7 patients had CD. The median of resource use and patient outcomes over a 12 month period (from diagnosis in the NA group and from clinic attendance in the CA group) is detailed in the table below.

</table>

Conclusion: In our cohort of patients, patients who attended the IBD education clinic were more likely to utilise our open access IBD telephone helpline service. There was a trend towards increased frequency of outpatient clinic appointments and blood tests in patients who did not attend the IBD education clinic although this was not statistically significant. There were no differences in the rates of hospital admissions or steroid courses in either group. The limitations of our data include the small sample size and short follow-up period.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1024 EMERGING ROLE OF IL-33/ST2 LEVELS IN PREDICTING CLINICAL RESPONSE TO ANTI-TNF THERAPY IN ULCERATIVE COLITIS

L.R. Lopetuso1, V. Petito1, C. Graziani2, T. T. Pizazzro2, F. Scaldaferri1, A. Gasbarri1

Introduction: Tumor necrosis factor (TNF) inhibitors (anti-TNF) are considered to be the mainstay of medical management in moderate-severe Ulcerative Colitis (UC). The role of IL-33 and its receptor, ST2, in intestinal inflammation is incompletely understood, with both pro-inflammatory and regulatory properties described. Recent evidence has shown that anti-TNF is able to modulate the role of IL-33 in inflammatory conditions.

Aims & Methods: The aim of our study was to explore the potential role of the IL-33/ST2 axis in the mucosal healing process mediated by anti-TNF therapy in UC. Endoscopic Mayo score was calculated before the first anti-TNF infusion (T0) and after 6 weeks (T2). 24 UC patients (Mayo score at T0>2) were enrolled. Anti-TNF antibodies were measured by capture ELISA before each infusion and anti-Infliximab antibodies (ATI) by a bridging ELISA. Serum samples were collected and ELISA performed to assess IL-33/ST2 protein levels. Intestinal biopsies were also taken from the rectum and IHC was done to evaluate mucosal IL-33/ST2 expression and localization.

Results: IL-33 protein levels were significantly increased in responders vs. non-responders, both at T0 and T2. Among responders, IL-33 protein was slightly reduced at T2 vs. T0, while unchanged in non-responders. Interestingly, significantly higher levels of ST2 were found in responders vs. non-responders at T0, with no differences between groups were found at T2. Among responders, ST2 levels were dramatically reduced at T2 vs. T0. No significant differences were found in non-responders at both time points. Healthy controls showed significantly lower levels of both IL-33 and ST2 compared to the UC patients. IHC confirmed these observations. In particular, IL-33 and ST2 staining was more intense within the inflamed and ulcerated mucosa of responders compared to non-responders at T0. After 6 weeks, ST2 staining was even more evident in responders, notably localized to the healed mucosa and in close proximity to areas of re-epithelialization. Little to no staining for both IL-33 and ST2 was found in healthy controls at both time points. ELISA measurements. The investigator defined remission based on clinical (Harvey-Bradshaw score), biological and endoscopic or imaging technics; partial or no remission was defined when any one of these three criteria was not fulfilled.

Conclusion: Our results suggest a possible role for IL-33/ST2 in predicting gut mucosal wound healing in patients with moderate-to-severe UC treated with anti-TNF therapy. Further studies are underway to determine mechanisms of action that support these findings.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Higher infliximab (IFX) serum concentrations have been associated with higher rates of clinical remission in inflammatory bowel disease patients1,2. However, the correlation between IFX trough levels (TL) during the induction phase in a medium or long-term remission in Crohn’s disease (CD) patients is less clear3. Aims & Methods: We aimed to analyse whether the IFX-TL were able to predict medium (22 weeks) and long-term (54 weeks) remission in CD patients. Consecutive CD patients receiving IFX (5 mg/kg at weeks 0, 2, 6 and every eight weeks at least until 22 weeks) were included retrospectively. IFX-TL were measured by capture ELISA and anti-Infliximab antibodies (ATI) by a bridging ELISA before each infusion. Clinical response and biological parameters were also measured. The investigator defined remission based on clinical (Harvey-Bradshaw score), biological and endoscopic or imaging technics; partial or no response, as well as intensification decided by investigators were considered as non-remission patients. U-Mann Whitney test was used to assess association between IFX-TL and remission. ROC curves were included to obtain cut-points for clinical use.

Results: 32 CD patients were screened, but finally 29 analysed, because 3 patients had IFX discontinued at week 14. Baseline characteristics included: 16 female: 55.2%, 55.2% (n=16) smokers, 30.6% (n=9) ex-smoker, 70% (n=21) ileal or ileo-ileal involvement, 44.8% inflammatory behavior, with 6.9% previous abdominal surgery and 86.2% on concomitant immunosuppressant, 34.5% non-naive to biological ther- apy. Over week 22, 44.3% patients were in remission; on week 54, 40% were in remission.

Week 6 1) Median (IQR) IFX-TL(g/mL) 22 24.6 (18.4–41.3) 12.7 (5.2–22.2)
Week 11 2) Median (IQR) Ifx-TL(g/mL) 22 24.6 (18.4–41.3) 12.7 (5.2–22.2)
Week 14 3) Median (IQR) Ifx-TL(g/mL) 22 24.6 (18.4–41.3) 12.7 (5.2–22.2)
Week 22 4) Median (IQR) Ifx-TL(g/mL) 22 24.6 (18.4–41.3) 12.7 (5.2–22.2)
Week 30 5) Median (IQR) Ifx-TL(g/mL) 22 24.6 (18.4–41.3) 12.7 (5.2–22.2)
Week 54 6) Median (IQR) Ifx-TL(g/mL) 22 24.6 (18.4–41.3) 12.7 (5.2–22.2)

On week 6, IFX-TL > 24 g/mL was associated with remission at week 22 (ROC 0.83; S: 61.5%, Sp: 81.3%) and at week 54 (ROC 0.79; S: 60%, E: 80%). On week 14, IFX-TL > 11 g/mL was associated with remission at week 22 (ROC 0.80; S: 41.7%, Sp: 93.8%) and at week 54 (ROC 0.70; S: 44.4%, Sp: 86.7%). Conclusion: IFX-TL during the induction period are associated with remission at least 12 months. Optimal TL ranges associated to remission can be calculated to guide clinical decisions. can be calculated to guide clinical decisions.

Disclosure of Interest: All authors have declared no conflicts of interest.

References:
active in 5 (12%) in remission in 35 (88%) pts. Endoscopic activity: CD: Complete tissue was incomplete in 2/40 pts. In the 24 pts with no previous surgery, SES-CD was: 0 (n = 4), 1 (n = 4), 3 (n = 5), 4 (n = 6), 6 (n = 2); 8 (n = 9); 3 (n = 2); 10 (n = 1); 11 (n = 1); 12 (n = 1); 13 (n = 1); 20 (n = 1); 19 (n = 1) pts (median 4 [0–
19]; activity: 20/24 [80%], remission: 4/24 [20%]). In the 16 pts with previous surgery the Rutgeerts’ score was: 0 (n = 3); 1 (n = 1), 2 (n = 6); 3 (n = 2) 4 (n = 4); recurrence: 2/16 [75%]). Histologic activity: CD: The GhAS was 0 (n = 3); 1 (n = 1); 2 (n = 3); 4 (n = 6); 2 (n = 2); 7 (n = 1); 9 (n = 1) in pts without previous surgery, and 0 (n = 3); (n = 9); 3 (n = 1); 10 (n = 1) in pts with previous surgery. In CD, the histological score showed a slightly significant correlation with SES-CD (r = 0.41; p = 0.046) and no correlation with the Rutgeerts’ score (r = 0.31; p = 0.247).

Conclusion: In a prospective study, a significant correlation was observed between clinic, endoscopic and histological activity in UC. Histological activity may be observed in UC patients in endoscopic remission, thus suggesting that this finding may represent a predictive marker of clinical relapse.

Introduction: Assays to measure TNF inhibitors and anti-drug antibodies (ADAb) in patient serum are being utilized to manage failure to respond and monitor clinical response to TNF inhibitors. Adalimumab (ADA) and Infliximab (IFX) are commonly used_IbD regimens. To calculate the corresponding anti-drug antibody levels, analysis of patient samples is required. The relationship between serum IFX and ADA concentrations and corresponding antibody levels were determined from 57,961 infliximab and adalimumab patient samples from 2012–2016. 43% exhibited anti-drug antibodies. We found that low-titer antibodies do not appear to impact drug levels. Our findings are consistent with American Gastroenterological Association Critical Care Pathways for Crohn’s Disease and Ulcerative Colitis and high Ab levels were managed very differently (increase drug/converter immunomodulator vs. switch drug within class). High resolution antibody assays may be helpful in dosing TNF inhibitors and in other treatment and management decisions.

Disclosure of Interest: All authors have declared no conflicts of interest.

### P1029 MOLECULAR SURROGATES OF HISTOLOGIC ACTIVITY IN CROHN’S DISEASE

C. Monast1, K. Li2, E. Mysklin3, C. Brodmerkel3, J. Friedman1, F. Baribaud1
1Janssen Research & Development, LLC, Spring House/United States of America/PA
2Clarivate Analytics, Boston/United States of America/MA

**Contact E-mail Address:** emonast1@ITS.JNJ.com

**Introduction:** Biomarkers of inflammatory bowel disease activity have been researched for decades but objections of markers of disease severity that support clinical decision-making are still needed. Well-established markers include serum C-reactive protein and fecal calprotectin, but their use as a standalone surrogate for disease activity has been controversial. We hypothesize that novel objective markers of tissue inflammation are best identified at the site of disease with a tissue-level assessment of disease activity.

**Aims & Methods:** Biopsy samples were obtained from participants in the UNITI trials of ustekinumab in moderate-to-severe Crohn’s disease. The UNITI induction trials included two cohorts, patients who failed ≥1 TNF antagonists (UNITI-1) or patients who failed conventional therapies (UNITI-2). Pairs of adjacent biopsies were taken from the rectum, splenic flexure, and ileum. One biopsy from each pair was assessed by Global Histology Disease Activity Score (GHAS) while the other was submitted to microarray analysis. Partial least squares regression and random forest were used to identify biomarkers associated with histological severity in the UNITI-1 cohort. Robustness of the resulting models was assessed using cross-validation within the training set and multiple external validation sets (defined within the UNITI-1 and UNITI-2 cohorts).

**Results:** In UNITI-1, a single multivariate model comprising 16 genes was identified that predicted histological activities in rectum or splenic flexure biopsies. This model was characterized by R²=0.78 for the training set, and R²=0.59, 0.54, and 0.32 on external validation sets also from UNITI-1. A separate 14-gene model capturing histological activity in ileal biopsies was characterized by R²=0.5 for the training set and R²=0.45 in the external validation set. In general, both models contained genes related to tissue degradation, barrier function, and immune regulation, including CXCL11 (I-TAC). Both models retained performance in external validation datasets from UNITI-2 but exhibited lower performance. De novo models generated from UNITI-2 also exhibited lower performance. Indeed, weighted gene co-expression network analysis indicated weaker associations between gene expression and histology scores for UNITI-2 compared to UNITI-1 subjects.

**Conclusion:** Our analysis supports the ability of biopsy transcriptionomics combined with machine learning approaches to capture disease-relevant variability in Crohn’s disease and, more importantly, supports the use of similar approaches to identify additional surrogate markers. Interestingly, this approach was more successful in the TNF antagonist failure cohort compared to the conventional therapy failure cohort. We hypothesize that this is related to increased strength of the transcriptional signal in the TNF antagonist failure cohort. We identified specific genes that could be used together as surrogates for histologic measurement, which may not be susceptible to the subjectivity inherent in GHAS scoring.

### P1030 INDIRECT TREATMENT COMPARISON OF USTEKINUMAB VERSUS OTHER BIOLOGICS IN MODERATE-TO-SEVERE CROHN’S DISEASE PATIENTS HAVING FAILED ANTI-TNF THERAPY – A 1-YEAR TREATMENT SEQUENCE ANALYSIS INCLUDING DELAYED RESPONDERS

**Introduction:** Indirect evidence is needed to inform the clinical efficacy of ustekinumab in Crohn’s disease (CD). Indirect treatment comparisons in CD are challenged by withdrawal trial designs limiting placebo arm tractivity. This treatment sequence analysis builds on previous work proposing a solution to challenges inherent to CD data to compare one year efficacy of biologics in CD patients having failed anti-TNF therapy. Analyses accounted for delayed responders (induction non-responders attaining response after additional doses) to generate more comprehensive estimates of biologics’ relative efficacies.

**Aims & Methods:** A systematic literature review identified randomized controlled trials in CD patients having failed anti-TNF therapy for induction and maintenance of ustekinumab (UST), adalimumab (ADA), or vedolizumab (VDZ). Clinical response (CDAI-100 point reduction) and remission (CDAI ≤150) were assessed. The probability of achieving response after induction was multiplied by the conditional probability of maintaining response/achieving remission at one year. Separate calculations were conducted for early and delayed responders. Their respective treatment sequence rates were summed to obtain overall response and remission rates. Placebo rates were imputed using data from patients induced and maintained on placebo from the IM-UNITI study, adjusted for responder and remitter induction rates. Bayesian analyses generated relative

### P1028 MOLECULAR SURROGATES OF HISTOLOGIC ACTIVITY IN CROHN’S DISEASE

**Contact:** Laura.Mesana@amaris.com

**Reference**

odds ratios (OR), credible intervals (CrI), and posterior distribution probabilities for superiority of UST.

Results: Accounting for delayed responders, the absolute proportions of patients having maintained response and being in remission at one year were 30% of patients receiving UST every 8 weeks, 19% of those receiving VDZ every 4 weeks, and 33% of patients receiving ADA every other week or weekly. Based on a one-year treatment sequence analysis, probabilities for UST to be better than VDZ for achieving and maintaining response and remission were 99%(OR[CrI]:1.941[0.73,4.89]) and 98%(OR[CrI]:1.32[0.100,2.36]), respectively. UST had higher likelihoods of remission than ADA given weekly (95%, OR[CrI]:1.36[0.72,2.58]) or every other week (85%, OR[CrI]:1.40[0.74,2.68]).

Conclusion: This approach deals with methodological issues inherent to CD trial data. In CD patients having failed anti-TNF therapy, ustekinumab had higher likelihoods of response or remission than adalimumab and vedolizumab over a one-year treatment sequence. Additional induction doses and continued maintenance therapy with ustekinumab have demonstrated benefits in delayed responders compared to other biologics. Previous research is limited to indirect treatment comparisons in early responders only. Including delayed responders provides a more accurate picture of CD patients’ response to biologics and better informs clinical practice.

P1032 EFFICACY AND TOLERABILITY OF INITIATING, OR SWITCHING TO, INFLIXIMAB BIOSIMILAR CT-P13 IN INFLAMMATORY BOWEL DISEASE (IBD): A LARGE SINGLE-CENTRE EXPERIENCE

Gastroenterology, Leeds Teaching Hospital, Leeds/United Kingdom

Contact E-mail Address: raguprakash.ratnakumaran@nhs.net

Introduction: Anti-TNF therapies have revolutionised the management of IBD. Recently, the infliximab (IFX) biosimilar (CT-P13) received market authorisation for IBD allowing cost benefits with switches to CT-P13 with annual savings of £1million in savings.

Methods: A single-centre retrospective cohort study involving 854 patients (70kg patient receiving 5mg/kg w/e weekly). We present experience of switching patients from the original IFX to CT-P13 for new and existing patients.

Aims & Methods: Recorded baseline characteristics included indication, age, sex, disease duration, treatment duration, concomitant immunomodulators, baseline CRP and Hb/Mayo scores. Response to IFX induction was assessed retrospectively using symptoms and CRP. Treatment response and remission rates, primary and secondary loss of response rates, and adverse events in patients who initiated IFX in the 12 months pre-Feb 2016 were compared with those who initiated CT-P13 in the 12 months post-Feb 2016. Sustained response was compared for existing IFX patients who switched to CT-P13 in Feb 2016 against those who continued with the original IFX. Drug and antibody levels were measured before switch and at 3, 6, and 12 months post.

Results: 53 patients commenced IFX in the 12 months pre-Feb 2016 (26 Crohn’s Disease (CD), 13 fistulating CD, 13 Ulcerative Colitis (UC), 1 IBD-Undclassified (IBD-U)) compared with 69 patients who commenced CT-P13 in the subsequent 12 months (2CD, 9 fistulating CD, 35UC, 38BD-U). Baseline characteristics did not differ, with a greater proportion of UC patients in the CT-P13 cohort (51% v 24.5% (p = 0.003)). This group had a higher mean CRP (20.2 v 10.6 (p = 0.008)) although a lower median Mayo score (5 v 11 (p = 0.007)). There was no difference in response (12(23%) v 15 (21.74%) (p = 0.905)), remission (14(26%) v 29(42%) (p = 0.074)), primary non-response (8(15%) v 4.5% (p = 0.087)), secondary loss of response (12(23%) v 15(21.74%) (p = 0.905)), or adverse events (6(11%) v 6(7%) (p = 0.629)) in those who initiated original IFX compared with CT-P13 post-Feb 2016. Six patients from the original IFX group had a higher mean CRP (20.2 v 10.6 (p = 0.008)). Loss of response or discontinuation of therapy at 12 months post-switch was significantly lower in those with therapeutic drug levels and no significant antibodies compared with patients with loss of therapeutic drug levels and no signifcant antibodies (18/20% v 7(100%) (p < 0.0001) and 67/6% v 86% (p = 0.0001) respectively).

Conclusion: There was no significant difference in response and remission rates, primary and secondary loss of response, or adverse events between originator IFX and CT-P13 during the first 12 months after switching. The presence of low undetectable drug levels and significant antibodies pre-switch was associated with loss of response and discontinuation of treatment. Switching to CT-P13 in 191 patients in our unit lead to >£1million in savings.

Contact E-mail Address: s.shinzaki@med.osaka-u.ac.jp

Introduction: Helicobacter pylori (H. pylori) infection is associated with a variety of gastrointestinal conditions including Inflammatory Bowel Disease (IBD).

Methods: This is a single-centre, prospective, randomized, double-blind, placebo-controlled trial comparing the efficacy and safety of a standard regimen of omeprazole, amoxicillin and clarithromycin plus metronidazole vs. omeprazole and amoxicillin in adult patients with IBD undergoing medical treatment of their IBD. The primary endpoint was the proportion of patients with successful eradication at 8 weeks. The secondary endpoints were changes in symptom scores and quality of life measures. The primary analysis was based on all patients who had a complete 8 week follow-up and were evaluable for response. The study included patients with Crohn's disease (CD), Ulcerative colitis (UC), and IBD-unclassified.

Results: A total of 30 patients were enrolled in the study, of whom 28 completed the study protocol and 26 were evaluable for efficacy analysis. The overall success rate for the eradication group (23/28) was significantly higher compared to the placebo group (4/26) (p = 0.002). There were no significant differences in symptom scores and quality of life measures between the two groups.

Conclusion: This study demonstrates the efficacy and safety of a triple-drug regimen for H. pylori eradication in patients with IBD undergoing medical treatment of their IBD. The study also suggests that this regimen may have potential for use in other gastrointestinal conditions associated with H. pylori infection.
Contact E-mail Address: shinziaki@gh.med.osaka-u.ac.jp

Introduction: Low prevalence of Helicobacter pylori (HP) infection has been reported in Crohn's disease (CD). HP infection was estimated at 5% in inflammatory bowel disease (IBD), however, it is unclear whether the eradication therapy for HP can exacerbate disease activity of IBD. We then aimed to clarify the safety and efficacy of HP eradication in patients with IBD.

Aims & Methods: This was a multicenter, retrospective cohort study in 26 institutions. Patients who eradicated HP by proton pump inhibitor and amoxicillin-based triple therapy after the diagnosis of IBD (ulcerative colitis (UC) or Crohn's disease (CD)) from March 2005 to July 2015 were enrolled. Two IBD patients with the same gender, age at diagnosis, sex, disease activity, severity, and observation period were matched with each HP-eradicated patient were enrolled in the same institution. Disease activity of IBD at baseline, 2 and 6 months after observation (eradication) was investigated. Eradication of IBD was defined as increase/addition of IBD drug, IBD-associated hospitalization or surgery; and physicians' assessment was also analyzed. Factors associated with exacerbation of IBD were assessed by univariate and multivariate logistic regression analysis.

Results: A total of 429 IBD (378 UC and 51 CD) patients, including 144 patients who eradicated HP (eradication group) and 285 control patients (non-eradication group), were enrolled. IBD exacerbation rates in 2 and 6 months of observation were 16.2% (17/106) and 11.8% (17/144) in eradication group, which showed no significant differences compared with those of 4.9% (14/285) and 7.7% (22/285) in non-eradication group. Physicians' assessment showed similar results in terms of disease exacerbation, but in 2 months of observation no patient was improved in eradication group whereas 3.2% (9/285) of patients was improved in non-eradication group (P = 0.019). Multivariate analysis revealed that the independent factor of IBD exacerbation after HP eradication was active disease at baseline (OR 5.395% CI: 1.5–16.9), P = 0.011). HP was eradicated in 82.9% (102/123) of patients using clarithromycin as first-line treatment and 90.4% (19/21) using metronidazole as second-line, both of which were comparable with previous reports in non-IBD patients.

Conclusion: HP eradication therapy does not exacerbate disease activity of IBD without affecting eradication but may improve disease activity, suggesting that careful observation is necessary after eradication, especially for patients with active disease.

Introduction: According to infliximab (IFX) license in inflammatory bowel diseases (IBD), infusion doses are based on patient weight. In daily practice, treatment is prepared by pharmacist after clinical patient assessment, leading to an increased duration of hospital stay and consequently costs. A pharmacokinetic study (1) has shown that a weight-based dose (WBD) strategy does not reduce interindividual variability of IFX trough levels when compared to fixed doses. According to these findings, our hospital implemented dose banding (DB) of IFX infusions, defined by doses rounded up or down according to one of eight pre-determined standard doses with a maximum theoretical deviation of +/-5%, that allowed to prepare infusions at the pharmacy before patient admission.

Aims & Methods: The aim of the study was to compare hospitalisation length of stay (LOS) in the IFX DB group as compared to those treated by WBD. From February to March 2017, we conducted a prospective, case-control study in our unit, including all IBD patients admitted for an IFX infusion. Patients who should receive an IFX dose between 250 and 800 mg were included in the DB group (treatment pre-prepared at the pharmacy, sent to the hospital unit before patient admission and administered just after the clinical validation). Patients who should receive an IFX dose below 250 mg or above 800 mg were included in the WBD group (treatment prepared after clinical validation including weight, and then sent to the hospital unit). Patients were analysed only when precise length of stay could be obtained and measured in minutes. Primary objective was to compare the length of stay at hospital in both groups. Secondary objective was to compare the proportion of IFX doses cancelled, reattributed and/or wasted infusions and the saved or wasted price associated (reimbursement price of one 100 mg IFX vial: 382.28 €).

Results: Among the 373 IBD patients treated by IFX during the study period, 116 (31%) patients (51M/65F; median age: 41 years) were included in the study (75 in the DB group and 41 in the WBD group) corresponding to 128 infusions (84 in DB and 44 in WBD groups). Mean length of hospitalisation stay were 238 ± 21 min in the DB group and 308 ± 32 min in the DB group, respectively (p < 0.001). DB was associated with a mean reduction of length of stay by 23%, corresponding to 70 minutes per patient. DB reduced significantly the mean duration of stay by decreasing the waiting time between clinical assessment and start of the infusion: 16 min vs. 84 min with WBD (p = 0.0001). During the study, none of the 44 (0%) infusion in the WBD group was cancelled while 3/84 (3.5%) were cancelled in the DB group (p=0.55). Two out of these three infusions could be reattributed to other patients, saving 2801€.

Conclusion: When used routinely in IBD, IFX DB is associated with a shortened length of stay as compared to WBD, with a mean reduction of 70 minutes per patient. As IFX DB seems having similar efficacy to weight-based doses, it may improve functioning of daily hospitalisation units.

Introduction: Rapidity of response to treatment in CD is now considered a field of major interest, due to the importance of achieving the highest benefit in the shortest possible time. There are no studies specifically designed to evaluate the rapidity of response to ADA neither other anti-TNF therapies. The aim of this trial was to evaluate the rapidity of onset of clinical response to ADA therapy.

Aims & Methods: Adult anti-TNF naïve patients with active luminal (Harvey-Bradshaw Index (HBI) ≥3) moderate-to-severe CD (excluding penetrating and structuring disease), with no response to a full and adequate course of therapy with corticosteroids and/or immunosuppressants, were enrolled in this international, prospective, open label, single arm and multicenter clinical trial. Patients received standardized ADA treatment (160 mg – 80 mg – 40 mg eow).

The HBI was evaluated to determine the response at day 4 and week 1; and clinical remission at weeks 2, 4, 12. Response was defined as a decrease of, at least, 3 points in the HBI global score and remission was defined as HBI global score < 5. CRP (C Reactive Protein) and fecal calprotectin (FC) were analyzed at baseline, day 4, week 2, 4, 12. The modified intention to treat (mITT) population was the primary population for efficacy analysis and consisted of all patients enrolled in the study who had received at least one dose of ADA. Treatment-emergent serious adverse events (AEs) were recorded to assess safety throughout the study until 70 days after last treatment dose. All patients who received at least one dose of ADA were included in the safety population.

Statistical analyses were performed by the t-test or the Wilcoxon signed rank test, as applicable. Time to clinical response was analyzed using a Kaplan-Meier survival analysis model.

Results: 86 anti-TNF naïve patients were analyzed. A response at day 4 and week 1, was experienced by 60.5% and 74.4% of patients, respectively. Remission was achieved by 53.5% of patients at week 2, 61.6% at week 4 and 54.7% at week 12. The median time to obtain response was 4.0 days (95% confidence interval (CI): 1.0, 4.0) and the median time to remission was 7.0 days (95%CI: 4.0, 14.0).

During the study, 42.5% of the patients suffered from any adverse event (AE). Only 3 patients (3.5%) showed a serious AE.

Conclusion: ADA produces rapid clinical remission and response since day 4 in patients with moderate-to-severe CD unresponsive to therapy with corticosteroids and/or immunosuppressants.

**Results:**

No ADRs of hypophosphatemia were reported. In patients dosed with 1000 mg iron isomaltoside, Hb increase was statistically significantly higher in patients dosed with >1000 mg iron isomaltoside, respectively (p = 0.5). Similar frequencies were observed in the IBD subgroup (14.3% vs. 12.1%, p = 0.8). 0.5% of the patients experienced a serious ADR (2 events in 2 patients; grand mal convolution and syncope). ADRs with a patient frequency >1% are shown in the table below:

No ADRs of hypophosphatemia were reported. In patients dosed with <1000 mg iron isomaltoside, Hb increase was with a mean of 1.72 (95% confidence interval (CI) 0.12) g/dL from baseline to week 3, 2.00 (0.12) g/dL to week 4, and 2.32 (0.13) g/dL to week 8. In patients dosed with >1000 mg iron isomaltoside, Hb increased with a mean of 2.04 (0.10) g/dL from baseline to week 3, 2.51 (0.09) g/dL to week 4, and 3.01 (0.12) g/dL to week 8. The observed increase in Hb was statistically significantly higher in patients dosed with >1000 mg iron isomaltoside (p = 0.04). In the IBD subgroup, a similar dose-dependent statistically increase in Hb was observed at week 3 and onwards (p < 0.02).

**Conclusion:**

No dose-response for ADRs was observed with administration of high doses of iron isomaltoside in patients with gastrointestinal diseases.

P1040 OUTCOMES OF PATIENTS IN REMISSION WITH INFLAMMATORY BOWEL DISEASE WITH UNDETECTABLE INFlixIMAB TROUGH LEVELS AND POSITIVE ANTIBODIES TO INFlixIMAB

G.S.Z. Tun1, R. W. Downey1, K. Robinson1, A. Wright1, L. Marshall1, M. F. Hale1, A. J. Lobo1
1Gastroenterology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom

Introduction: The formation of antibodies to infliximab (ATI) is associated with increased drug clearance. Patients with undetectable infliximab (IFX) levels and positive ATI may indicate a group who may no longer be benefitting from the drug. However, the optimal treatment decision when the patient is clinically well remains unclear.

Aims & Methods: The aim was to assess the course of disease of patients in remission, with undetectable IFX levels and positive antibodies. IFX trough levels and ATI were measured in all patients attending for IFX infusions from May 2016 to April 2017 at a large single referral centre. Results were retrospectively reviewed in March 2017 to identify patients with undetectable (<0.8 mg/L) IFX trough levels and positive ATI (>10 mg/L). A local guideline suggested that in well patients of this cohort, patients should be switched to an alternative biologic if duration of IFX treatment was <12 months, or if the duration of therapy was ≥12 months to consider withdrawal of IFX or to assess disease activity - with withdrawal of IFX in inactive disease or a switch to an alternative biologic for active disease. Trough levels for IFX and ATI were measured using direct solid phase immunoassay (Biohit, UK). Relapse was defined as worsening of symptoms attributable to the inflammatory bowel disease, requiring an alteration in treatment. Kaplan-Meier with Tarone-Ware test was used to analyse survival curves for our model used to analyse the impact of the different treatment decision on the rate of relapse.

Results: 47/223 patients had undetectable IFX drug levels with positive ATI. Follow-up data was available in 45 patients. 17 patients were assessed as having active disease (2 primary, 15 secondary loss of response). Of the 28 in remission (at time of most recent TDM, median Harvey Bradshaw Index (HBI) 3.5; median Simple Clinical Colitis Activity Index (SCCAI) 2.5), 79% had a HBI/SCCAI ≤5 but all were deemed to be in remission at time of review. 6/28 patients had received prior anti-tumour necrosis factor-α antagonists and 14/28 were receiving concomitant immunosuppression (thiopurines; 12 methotrexate 2). Of these patients in remission, 7 continued on IFX (1 dose escalated), 13 had IFX withdrawn and 8 were switched to an alternative biologic (adalimumab 4; vedolizumab 3; ustekinumab 1). In those who were switched to a different biological therapy 3/8 flared (38%), compared to 1/7 in those who continued on IFX (14%) and 4/13 in those who were withdrawn from IFX (31%); median follow up duration of 7.5 months (range 2–10 months). There was no significant difference in the survival curves regarding rate of relapse based on the different management decisions taken (p = 0.81, Figure 1). Patients withdrawn from IFX were not at an increased risk of relapse compared to those who continued on treatment (hazard ratio 1.62, p = 0.59) nor those who were switched to an alternative biologic (hazard ratio 1.42, p = 0.65). Figure 1. Kaplan Meier of the rate of relapse during follow-up of patients in clinical response with undetectable IFX levels with positive ATI who were continued on IFX (n = 7), switched to an alternative biologic (n = 8) and withdrawn from IFX (n = 13) (p = 0.81).

Conclusion: Our data suggests that withdrawal of IFX in selected patients with undetectable IFX levels and positive ATI is not associated with an increased risk of flare. Although not statistically significant, the rate of relapses in those who continued on infliximab was lower compared to those who were switched or withdrawn from therapy, however further follow-up analysis only those TDMs ≥2 recommended in this group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1041 PHARMACOKINETIC SIMILARITY OF ABP 710 TO INFlixIMAB: RESULTS FROM A SINGLE-BLIND, SINGLE-DOSE, PARALLEL-GROUP STUDY IN HEALTHY SUBJECTS

Contact E-mail Address: vchow@amgen.com

Introduction: ABP 710 is being developed as a biosimilar to infliximab, an anti-tumour necrosis factor monoclonal antibody. Analytical and functional comparison between ABP 710 and infliximab have been completed. This report describes the results of a Phase 1 pharmacokinetic (PK) equivalence study comparing ABP 710 with infliximab.

Aims & Methods: This was a single-blind, single-dose, 3-arm, parallel-group study in healthy adults. Subjects were randomised to receive a 5 mg/kg intravenous (IV) infusion of ABP 710 or infliximab sourced from the EU and the US. Blood was drawn prior to start of infusion. The primary outcome was demonstration of PK similarity of ABP 710 with infliximab EU and with infliximab US. ABP 710 and infliximab US were based on area under the serum concentration-time curve from time 0 to infinity (AUC0–inf) as the primary endpoint. The criteria to achieve PK equivalence were for geometric mean (GM) ratio and its 90% confidence interval to be within the range of 0.80 to 1.25. Secondary endpoints included maximum observed serum concentration (Cmax) and safety, and immunogenicity.

Results: A total of 148 subjects received study treatment (ABP 710: n = 49; infliximab EU: n = 49; infliximab US: n = 50). After a single dose, the adjusted least square (LS) GM of AUC0–inf and Cmax were as follows: ABP 710, 33559 ± 12370 μg/mL and 123 ± 12 μg/mL; infliximab EU, 33706 ± 12189 μg/mL and 121 ± 12 μg/mL; infliximab US, 37523 ± 21345 μg/mL and 127 ± 12 μg/mL. The ratios of adjusted LS GM (90% CI) for AUC0–inf and Cmax between ABP 710 and infliximab EU were 0.996 (0.9042, 1.0963) and 1.021 (0.9624, 1.0827) and that between ABP 710 and infliximab US were 0.894 (0.8122, 0.9848) and 0.972 (0.9167, 1.0301). The ratios of adjusted LS GM (90% CIs) of AUC0–inf and Cmax between infliximab US and infliximab EU were 1.113 (1.0115, 1.2252) and 1.05 (0.9906, 1.1388). The 90% CIs of these ratios were fully contained within the 0.80 to 1.25 interval, confirming PK similarity between ABP 710 and infliximab, as well as between infliximab EU and infliximab US. There were no serious adverse events, serious adverse events, or treatment-emergent adverse events (TEAEs) leading to discontinuation from the study. 1 subject in the infliximab EU group developed polyarthritis that resolved with treatment and the subject completed the study. The incidence of TEAEs was similar in the 3 groups (ABP 710: 83.7%; infliximab EU: 83.7%; infliximab US: 86.0%); the majority was mild or moderate. The most frequently reported TEAEs were somnolence, headache, nasopharyngitis, upper respiratory tract infection, nausea, and lethargy. All subjects tested negative for antidrug antibodies (ADAs) prior to dosing. At the end of the study, 20/29 subjects in ABP 710, 27% of 29 subjects in infliximab EU, and 32% on infliximab US were positive for binding ADAs; 13% on ABP 710, 19% in infliximab EU and 10% on infliximab US were positive for neutralising ADAs.

Conclusion: Results of this study demonstrate PK similarity between ABP 710 and infliximab sourced from the EU and the US, as well as between infliximab EU and infliximab US following a single 5 mg/kg IV infusion in healthy subjects. The safety and immunogenicity profiles were comparable among treatment groups.

Contact E-mail Address: hari.patel@takeda.com

Introduction: Complex perianal fistulas (CPF) are common among Crohn’s disease (CD) patients and are associated with substantial morbidity. The burden and management of CPF are poorly studied.

Aims & Methods: To systematically review the literature on epidemiology, global disease burden, and treatment outcomes for CPF in CD patients. PubMed, Embase, and Cochrane were searched for relevant articles published from 2000
forward; congress abstracts were searched from 2011 forward. CPFs were defined as fistulas with intersphincteric, transphincteric, suprasphincteric, extraspincteric, or horseshoe tracts. Results: 353 records were reviewed by 2 independent researchers, and 63 relevant articles and abstracts were selected for inclusion (including 3 epidemiology and 3 burden; the rest were treatment guidelines/patterns or treatment outcome studies). The estimated cumulative incidence of CPF in CD, based mostly on studies conducted in referral centers, ranges from 12%–14% (2 studies). CPF can result in significant morbidity and greatly diminished quality of life; up to 59% of patients (1 study) are at risk of fecal incontinence. Treatment options include a combination of medical and surgical interventions. However, across all options identified, a high proportion of patients experience treatment failure (lack of or inadequate response) and relapse (Table). Only 4 identified studies were conducted specifically in patients refractory to anti-tumor necrosis factor (TNF) agents—a population with high unmet needs (one study of fistuliprost injections of infliximab, and three studies of surgical interventions). Available data suggest that anti-TNF-α dose escalation or switching between different anti-TNF-α agents is of limited value (2 studies). Table – Rates of treatment failure and relapse or reoccurrence among patients with complex perianal fistula Crohn’s Disease. Conclusion: CPFs in CD pose substantial clinical burden. There is a high unmet need for effective treatment options for CPF in CD patients, especially those refractory to anti-TNF-α agents, as evidenced by high treatment failure and relapse rates.

P1043 VITAMIN D IS RELATED TO THE EFFECTS OF ANTI-TNF TREATMENT IN CROHN’S DISEASE PATIENTS

1Gastroenterology, Federal University of Goiás, Goiânia/Brazil
2Surgery, Organização Panamericana de Gastroenterologia (OPGE), Goiânia/Brazil

Contact E-mail Address: maurobafutto@yahoo.com.br

Introduction: Vitamin D deficiency is common in patients with Crohn’s disease (CD). It is believed that this deficiency is related to the CD activity. Vitamin D supplementation has many effects, including immunomodulation. However, the role of Vitamin D (VD) in severe CD patients using Anti-TNF is still unclear. Aims & Methods: To evaluate the results of the VD replacement at different doses; check possible immunomodulatory action of vitamin D in CD patients with Anti-TNF. We conducted a double-blind, randomized, prospective study. 42 patients were selected with history of moderate to severe CD in use of anti-TNF, of both sexes, between 18 to 60 years, with dosage of 25-hydroxyvitamin D < 75 nmol/L (30 ng/ml) who signed the informed consent. We excluded patients with less than 18 or over 70 years, pregnant women, chronic kidney or liver disease, sarcoidosis, tuberculosis, hyper- or hypoparathyroidism, neoplasias, use of anticonvulsants; and patients who received calcium supplements or VD in the last 6 months. 30 patients were randomized. Patients were submitted to a questionnaire of sun exposure, quality of life (IBDQ), clinical examination, VD dosage, C-reactive protein (CRP), fcalc alcaperton (FC) and were divided into three groups: 1 Group (G1): 10 patients receiving 2,000 U/V D, VO/week for 8 weeks. 2 Group (G2): 10 patients receiving 10,000 U/V D, VO/week for 8 weeks. 3 Group (G3): 10 patients receiving 100,000 U/V D, VO/week for 8 weeks. At the end of 8 weeks the patients answered IBDOQ and were submitted to VD, FC and CRP dosage. All patients were followed for 52 weeks and checked for disease activity recurrence (CDAI ≥ 150, FC > 300, CT scan), CRP and VD levels.

Results: IBDOQ improvement was observed in all groups with statistically significant results in G2 (p = 0.04) and G3 (p = 0.01). Increased VD were observed in all groups (G1: SD × mean = SD): G1: -19.5 ± 5.1 × 24.6 ± 6.7 p = 0.07; G2 - (19.1 ± 4.1 x 26.5 ± 5.8) p = 0.04; G3 -19.5 ± 6.4 × 46 ± 4.6 ± 12.7) p < 0.0001. CRP dosage were reduced, although not statistically significant, at G2 and G3 (5.8 ± 4 × 3 ± 9.2 ± 8.3) p = 0.18 (5.2 ± 7.3 × 2.4 ± 3.6) p = 0.2; and increased in G1 (8.1 ± 10, x 3 ± 14, 3 ± 19,9) p = 0.3. There was a significant decrease in FC in G3 (1014 ± 850 × 483 ± 564) p = 0.04, no significant decrease in G2 (767 ± 751 ± 823 ± 535) p = 0.2, and increase in G1 (1101 ± 744 ± 1357 ± 819) p = 0.4. 52 follow up showed that recurrent disease activity were predominat in patients with VD < 30 (p = 0.004) and statistically significant were observed in disease activity recurrence rate (p = 0.006). FC (p = 0.02) and CRP (p = 0.01) when compared patients with VD > 30 and VD < 30. Conclusion: 50,000 U/week was the best dosage for VD replacement and is related to immunomodulation. Most of patients with CD in Anti-TNF therapy have recurrent disease when VD < 30 and a high remission rate with VD > 30. VD levels are related to the effects of Anti-TNF therapy in CD patients.

Introduction: Golimumab is approved for the treatment of moderate to severe ulcerative colitis, but not Crohn’s disease (CD). Therefore, its potential efficacy in CD remains largely unknown. Off-label use of drugs is not prohibited in Sweden, and golimumab may have been used for CD treatment.

Results: The study cohort consisted of 95 patients with a median age of 37 (IQR 27-48) years, of whom 40% were men. The majority of the patients (90.5%) had previously experienced treatment failure for at least one anti-TNF agent. At the start of golimumab, 41% were on a concomitant immunomodulator and 16% on corticosteroids. After a median follow-up time of 21 (IQR 10-36) months, 60 (63%) patients had stopped treatment with golimumab. Reasons for discontinuation were inadequate response; n = 45 (75%), intolerance; n = 11 (18%) and other reasons; n = 4 (7%). Estimated drug continuation rates were 75% at 12 weeks and 42% at 52 weeks. Concomitant treatment with corticosteroids at baseline seemed to be associated with a higher risk of discontinuation of golimumab (unadjusted HR: 1.97; 95% CI: 1.04-3.73; p = 0.04), although the association did not remain significant after adjusting for potential confounding factors (adjusted HR: 1.76; 95% CI: 0.84-3.67; p = 0.13).

Aims & Methods: We aimed to describe the CD population that is treated with golimumab in Sweden and to assess the long-term effectiveness, defined as drug continuation rate, as well as identify predictors of drug discontinuation. Patients with CD who received at least one injection of golimumab were identified through the Swedish national quality registry for inflammatory bowel disease (SWIBREG). Duration of golimumab-treatment was illustrated by Kaplan-Meier curves. Univariate and multivariate Cox proportional hazard regression models were used to identify predictors of golimumab discontinuation. The variables sex, age, duration of disease, location, perianal disease, smoking status, previous surgery, concomitant treatment with corticosteroids or immunomodulators at baseline, prior anti-TNF therapy and CRP at baseline were included in the models.

*44 studies reported treatment outcomes for CPF in CD patients. Most studies identified were small and/or non-comparative, and study methodologies, populations, endpoint definitions, and duration of follow-up varied. For studies with mixed populations, only results for patients with CD and CPF were considered. *Defined as lack of or inadequate response to therapy (i.e. lack of complete response). *Defined as standard of care used at each centre excluding anti-TNFs and surgery in 2 studies and as standard medical care at each centre including anti-TNF and surgery in 2 studies.
**P1046 EARLY IMPROVEMENT IN QUALITY OF LIFE IN PATIENTS WITH LUMINAL CROHN’S DISEASE TREATED WITH ADALIMUMAB: DATA FROM RAPIDA TRIAL**

Hospital Universitario del Henares, Madrid/Spain

**Introduction:** Two pharmacological treatments were available for moderate-to-severe Crohn’s disease (CD) and Ulcerative Colitis (UC). However, despite their clinical effectiveness, few data regarding the role on quality of life (QoL) are available.

**Aims & Methods:** To prospectively evaluate disease activity and QoL in a single-centre cohort of CD and UC patients, after introduction of adalimumab. All consecutive adult CD and UC patients who started infliximab (IFX) or adalimumab (ADA) were included. Disease severity was evaluated through laboratory tests (Haemoglobin, C-reactive protein (CRP) and Fecal calprotectin) and commonly used scores (Harvey Bradshaw Index (HBI) for CD and Modified Vagi-Nordic Score for UC (MTWSI) for UC) during the study period.

**Results:** A total of 115 patients were consecutively evaluated, 33 patients were excluded due to non-compliance (13.7%) or drop-out for adverse events or primary non response (17.3%) within 12 months. Eighty-two (71.5%) were included and had a follow-up period of 12 months thereafter; QoL was assessed through the Short-Inflammatory Bowel Disease Questionnaire (S-IBDQ). Twenty-two patients treated with IFX and ADA, respectively, QoL was significantly higher in CD than UC at baseline (median S-IBDQ 49 vs 59; p < 0.004). In CD patients, anti-TNFα determined significant reduction of HBI (median 3 vs 1; p < 0.01), CRP (median 5 vs 2.9 mg/L; p = 0.004), fecal calprotectin (median 429 vs 119 µg/g; p < 0.001) but not haemoglobin (median 13.6 vs 13.2 g/dL, p = 0.25). QoL significantly improved (median S-IBDQ 49 vs 59; p < 0.001), both in IFX and ADA groups (IFX: p = 0.001, ADA: p = 0.02). In UC patients, anti-TNFα therapy improved disease activity (median MTWSI 7 vs 4, p = 0.03), haemoglobin levels (median 11.6 vs 13.2 g/dL, p = 0.006), fecal calprotectin (median 1600 vs 108 µg/g; p = 0.004), but not CRP (median 5 vs 2.9 mg/L, p = 0.08). QoL improved at 12 months (median S-IBDQ 32 vs 56, p = 0.001) both in patients treated with IFX (p = 0.003) and ADA (p = 0.005). No adverse events were reported during the study period.

**Conclusion:** Anti-TNFα therapy is safe and improves disease activity and quality of life of UC and CD patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1048 ENDOSCOPIC AND HISTOLOGIC FINDINGS CORRELATE WITH FREE INFILXIMAB FOUND IN UNINFLAMED TISSUE IN IBD PATIENTS**

H. Bar-Yoseph1, A. Blait2, S. Pressman3, S. Gerass1, B. Ungar4, S. Ben-Horin5, Y. Chowers6

**Contact E-mail Address:** hagababy@gmail.com

**Introduction:** Anti-TNFα agents are widely used in the treatment of inflammatory bowel diseases (IBD). Despite the fact that the intestine is the main therapeutic site of action for these drugs, bioavailability may differ from one patient to another and delays in treatment may result in ineffective drug delivery. In this study the endoscopic and histological findings at the time of endoscopy were correlated with the amount of free infliximab found in the uninflamed tissue at post-surgery.

**Methods:** 26 IBD patients undergoing colectomy for IBD were included in the study. All patients had previously been treated with infliximab prior to surgery. The amount of free infliximab was measured by a newly established enzyme-linked immunosorbent assay. The endoscopic and histological findings were correlated with the amount of free infliximab.

**Results:** The endoscopic and histological findings were correlated with the amount of free infliximab. A significant correlation was found between the amount of free infliximab and the endoscopic and histological findings. The results showed that the endoscopic and histological findings were more severe in patients with a lower amount of free infliximab. The correlation was also found to be significant in the subgroup of patients with Crohn’s disease.

**Conclusion:** The results of this study suggest that the endoscopic and histological findings at the time of endoscopy can be used to predict the amount of free infliximab found in the uninflamed tissue at post-surgery. This may have implications for the treatment of IBD patients using anti-TNFα agents.
target, little or no information is available regarding the ratios of free and TNF-bound infliximab in intestinal tissue. 

**Aims & Methods:** We aimed to assess the presence of free versus TNF-bound infliximab in the intestinal tissue of IBD patients and its possible association with clinical outcomes. Protein was extracted from frozen intestinal tissues of inflamed and non-inflamed tissue, and TNF-bound infliximab were detected using ELISA and normalized to tissue protein concentration. Concurrent serum drug levels (SDL), anti-drug antibodies (ADA), serum TNF-bound infliximab levels, patient’s pharmacotherapy, clinical response based on physician global assessment (PGA), endoscopic appearance (severity determined according to mayo scoring in ulcerative colitis and endoscopist’s assessment of ulceration severity, extent of disease and affected area in Crohn’s disease) and pathological results (severity determined by observing pathologist graded as normal, mild, moderate and severe disease) at the time of colonoscopy were determined. Correlation were performed using Spearman’s rank correlation test.

**Results:** Twenty-four biopsies from 13 patients (11 Crohn’s disease and 2 ulcerative colitis patients) were tested. Non-inflamed tissue infliximab levels, but not inflamed tissue, correlated with SDL (R = 0.8499, p ≤ 0.0037, FDR = 0.0185) and were negatively correlated with the endoscopic appearance (R = -0.7214, p = 0.0185) and pathological severity (R = -0.7095, p = 0.0059). TNF-bound infliximab was measured in both inflamed and non-inflamed specimens and did not correlate with drug levels in the serum or tissue. ADA was only detected in a single patient, precluding statistical analysis. Notably, no TNF-bound infliximab was measured in the serum.

**Conclusion:** These findings show that pharmacokinetic-pharmacodynamics interaction, as measured by SDL, better reflects drug levels in healthy mucosa rather than the inflamed one, and suggest a more complex drug/target interaction in inflamed tissue, which cannot be explained by target binding only. Future studies assessing changes during the course of mucosal healing may allow their use as surrogate markers for this effect.

**3** Christchurch Hospital, Bournemouth/United Kingdom

**4** St. Marks Hospital, Harrow/United Kingdom

**5** IBD Unit, St. Mark’s Hospital, Harrow/United Kingdom

**Contact Email Address:** stephanie.poole@imperial.ac.uk

**Introduction:** Restorative proctocolectomy (RPC) is considered the treatment of choice in patients with ulcerative colitis (UC) who have failed medical therapy and in some patients with familial adenomatous polyposis (FAP). After RPC, about 38–45% of UC patients develop acute pouchitis at 45% of years, for which the mainstream treatment is empirical antibiotics. 10–15% of these patients subsequently develop chronic antibiotic-dependent pouchitis (CAPD), and maintain chronic antibiotic-dependent pouchitis (CDP).

**Background:** The aim of this study was to analyze the presence of free versus TNF-bound infliximab in the intestinal tissue. Crotosodium difficile and tendon rupture are recognized significant complications associated with long-term ciprofloxacin. We aim to evaluate the effectiveness and safety of long-term antibiotic use in patients with chronic pouchitis.

**Aim:** The aim of this study was to analyze the presence of free versus TNF-bound infliximab in the intestinal tissue.

**Methods:** Twenty-four biopsies from 13 patients were included. Patients with baseline disease activity [defined by a patient-reported outcome (PRO2) of at least 8 points] were included for further analysis. Clinical remission was defined as an average daily stool frequency of ≤ 2.8 and an average abdominal pain score ≤ 1.

**Results:** During follow-up, we observed 32 patients develop ATI (19 patients developed antibodies within 6 months of starting IFX treatment, 5 between 6–12 months treatment and 8 after 12 months). At any given time, patients with positive ATI are 3.4 times as likely (p = 0.002) to develop undetectable levels than ATI-negative patients. Transient ATI formation was seen in only 5/162 patients. Figure 1. Graph showing effect of concomitant immunosuppression on time to become antibody to infliximab positive.

**Conclusion:** Although IS therapy protects against ATI formation, the risk of antibody development continues throughout treatment. If concomitant IS is aimed at reducing ATI formation, then this also needs to be continued for the duration of IFX therapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1052 A DRUG-RESISTANT ASSAY CAN BETTER DIRECT THE NEED FOR ADA LUMB DOSE-ESCALATION AFTER INDUCTION THERAPY IN ANTI-TNF NAIVE PATIENTS WITH CROHN’S DISEASE**

**1** Department Of Gastroenterology And Hepatology, University Hospitals Leuven, Leuven/Belgium

**2** Laboratory For Therapeutic And Diagnostic Antibodies, Department Of Pharmaceutical And Pharmacological Sciences, KU Leuven, Leuven/Belgium

**Contact Email Address:** giote.moors@uzleuven.be

**Introduction:** Antidrug antibodies (ADA) may develop in up to 35% of patients with Crohn’s disease (CD) receiving adalimumab (ADM). Although ADA titers to ADM are predominantly neutralizing, standard drug-sensitive assays do not allow ADA measurement in patients with detectable trough levels (TL) and drug-tolerant assays are suboptimal in case of high TL.

**Aims & Methods:** We aimed to identify ADA using a drug-resistant assay, instead of a drug-tolerant assay, and to correlate their presence with clinical outcomes. Therefore, we identified 152 patients with CD who had received ADM as first biological therapy. After retrospective chart assessment, 116 patients with baseline disease activity [defined by a patient-reported outcome (PRO2) of at least 8 points] were included for further analysis. Clinical remission was defined as an average daily stool frequency ≤ 2.8 and an average abdominal pain score ≤ 1. Serum samples were available in 70/116 at week 12 after ADM initiation. ADA presence was determined via both a monoclonal drug-sensitive assay in case of undetectable TL and an in-house developed drug-resistant assay regardless of TL [1].

**Results:** The drug-resistant assay identified presence of ADA in 14 of the 70 (20.0%) patients at week 12, whereas a drug-sensitive assay could detect ADA
in just one of these 14 patients (1.4%) (p < 0.001). Median (IQR) TL were significantly higher in the ADA negative group compared to the ADA positive group [9.21 (7.00–12.99) vs. 3.45 (1.72–5.44) µg/mL, p < 0.001]. A significant correlation between TL and ADA levels could be found (Spearman’s ρ = 0.562, p < 0.001). Although the presence of these ADA was not significantly associated with clinical remission at week 12, a clear tendency towards a positive correlation was observed (ρ = 0.136). During median (IQR) follow-up of 1.46 (0.32–3.48) years, 43 out of 116 patients (37.1%) needed ADM dose-escalation. Importantly, escalation-free-survival significantly differed between ADA positive and ADA negative patients. Univariate analysis could not identify any more factors (weight, BMI, gender, disease behaviour, disease location, CRP, serum albumin, PRO2, concomitant therapy, smoking) associated with ADA presence.

Conclusion: A drug-resistant assay can identify ADA to ADM before all drug has become undetectable. As these ADA at week 12 were significantly associated with need for dose-escalation and can appear before TL drops below the threshold of 4 µg/mL, they may be better to identify those patients who could benefit from dose-escalation. Moreover, the differences in TL between patients at week 12 can finally be explained by the presence of ADA measured with a drug-resistant assay.

Introduction: golimumb (GOL) is a fully human monoclonal antibody to TNFα approved for the treatment of patients with moderate to severe ulcerative colitis (UC) with inadequate response or intolerance to steroids or immunosuppressive therapies. The aim of this study is to evaluate the efficacy and safety of GOL in both biologic naïve (BN) and biologic experienced (BE) patients.

Aims & Methods: Data were prospectively collected from a cohort of UC patients treated with GOL from March 2015 to March 2017 at two centers. Data were analyzed from two patient cohorts, namely BN patients and patients who have already undergone treatment with infliximab or adalimumab (BE). Patients received GOL 200 mg sc. at week 0, GOL 100 mg sc. at week 2, then 50 mg or 100 mg sc. every 4 weeks depending on body weight. The primary outcomes were clinical response rate and incidence of adverse events (AEs).

P1053 ADHESION TO MAINTENANCE THERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE BEFORE AND AFTER THE INTRODUCTION OF THE SHARED MEDICATION RECORD

K. Roehegaard

Department Of Internal Medicine, Randers Regional Hospital, Randers/Denmark

Contact E-mail Address: klaroe@rm.dk

Introduction: Compliance is a significant problem in the medication of patients with chronic diseases, especially during periods where patients are completely unaware of their disease and just take their drugs to prevent disease recurrence. (1) During the last years Shared Medication Record (SMR) was introduced in Denmark. SMR is a national database containing information on current medication of all Danish residents. SMR include information on where, when, and how much medicine the patients by at the pharmacies. Therefore with SMR it becomes possible for doctors to see if patients retrieve the prescribed medicine at the pharmacy. Patients with chronic inflammatory bowel diseases (IBD), ulcerative colitis (UC) or Crohns Disease (CD), have periods of flares of the disease but in many cases also long periods when the disease is in remission. The majority of patients need medication to reduce the risk of recurrence of disease. It means that they need to take medicine even if they have no symptoms of disease. Previous American studies have shown that a number of patients in this situation do not take their medication and thus are at increased risk for relapse of the disease (1). There are no corresponding data for Danish patients. We wanted to find out the proportion of Danish IBD patients in remission who buy the prophylactic treatment as prescribed, and whether this proportion will change when the patients are informed that the doctor can see if they pick up the medicine at the pharmacy.

Aims & Methods: The purpose of this study was to investigate whether Danish patients with IBD in remission buy the prophylactic treatment as prescribed, if these patients buy a larger part of their medicine when they know that the doctor can see which medicines they buy at the pharmacy. 100 consecutive patients with UC or CD in remission for at least six months and treated with a fixed dose of mesalazine, azathioprine, or Mercaptopurine during the preceding six months were enrolled from Randers Regional Hospital Adult Gastroenterological Outpatient Clinic. Patients were randomized 1:1 either to receive information that the doctor could follow their pharmacy refills, or not to get information on this. The patients were not informed that they participated in a study. All patients had a second visit six to 12 months later. Patients who had flares in disease activity during the study period was excluded. Adherence to the treatment was defined as pharmacy refills according to the prescribed dose for at least 80% of the period of the preceding six months. Fisher’s exact test was used as test of independence between groups.

Results: 67% of the patients in the study were adherent to their medical treatment during the first study period decreasing to 48% during the second study period (P < 0.001). There was no difference in the decrease in adherence in between patients informed about SMR and those who were not informed. Younger patients were less prone to adherence compared to older patients at the first study visit (Age groups: 19–39: 40–59/60+; Years, adherence 48/71.6% (P < 0.05). We found no differences related to disease (UC/CD), sex, 5-ASA/antipurins, or administration route (oral/rectal).

Conclusion: Adherence to treatment fell from the first visit when the disease had been in remission for at least 6 months, to the second study visit when the disease had been in remission for at least 12 months. This was independent of whether the patients were aware that the physician could follow their medication refills or not. This might indicate that adherence to medical treatment of IBD decreases over time when the disease is in remission.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: Overall, from data patients were analyzed. Of these, 27 (46%) were BN and 32 (54%) BE. Baseline patient’s characteristics and main study results are shown in Table 1. BN and BE patients were comparable in terms of comorbidity profile, age at diagnosis, disease duration, pattern of previous and concomitant conventional therapies, as well as of disease extension and severity. Overall, surgical intervention after GOL therapy was performed in 13 (22%) cases: 3 (11%) belonging to the BN and 10 (31%) and BE group, respectively (p = 0.2). In 10 (17%) patients AEs were recorded, most of which were gastrointestinal or herpes simplex infections. Of note, two cases of basal cell carcinoma were registered. The rate of AEs did significantly differ among the BN and BE groups (p = 0.5). In 5 (9%) patients AE was responsible for the discontinuation after a median (IQR) period of 4 (1–4) months. Of the 54 (92%) patients who continued therapy, median (IQR) duration of GOL treatment was 7 (4–14) months. At 3 months follow-up, 26 (48%) patients showed clinical response to GOL therapy, while 18 (32%) and 10 (17%) in the BN and BE cohorts (p = 0.8). 28 (52%) patients were non-responders, without a statistically significant difference between the two groups (p = 0.8). At March 2017, 17 (31%) patients maintained clinical response, whereas 37 (69%) failed the treatment. No statistically significant differences were noticed between the BN and BE cohorts concerning the clinical response or the treatment failure (p = 0.5).

Conclusion: In our cohort, clinical response at 3 months follow-up was obtained in almost half of patients while at the last follow-up in one third. BN and BE patients had similar results in terms of clinical response, even though were worse to be a better early response in BN patients. Even if not statistically significant, surgery was required most frequently in the BE group. Rate of AEs was acceptable and similar in both BN and BE patients. Although our findings need to be confirmed in larger series, GOL therapy appears to be safe and to achieve an acceptable disease control in both the biologic naïve and experienced setting.

ETROLIZUMAB TREATMENT IMPROVES HISTOLOGICAL ACTIVITY ASSESSED BY THE ROHTS HISTOPATHOLOGY AND NANCY HISTOLOGICAL INDICES

P1056

Introduction: Etrolizumab, an anti-β7 monoclonal antibody targeting α4β7 and αEβ7 integrins, showed efficacy and safety versus placebo (PBO) during 12 weeks (wk) of induction in patients with moderate-to-severe ulcerative colitis in the Phase 2 EUCALYPTUS trial (Vermeire S. Lancet. 2014;384:309–18). Since a reduction in histologic inflammation has been linked with improved long-term clinical outcome (Bryant RV. Gut. 2016;65:408–14), etrolizumab may appear to be safe and to achieve an acceptable disease control in both the biologic naïve and experienced setting.

Methods: Aims of this study were to confirm the efficacy and safety of etrolizumab and to determine the correlation between endoscopic and histological improvement.

Results: Analysis included 56 patients with BI and data and BL NHI > 1. At wk 10, BI and BL NHI scores decreased by a greater extent with etrolizumab compared with PBO, regardless of anti-tumor necrosis factor α (aTNF) experience (RHI −8.4 vs −1.6; P = 0.032 and NHI −1.2 vs −0.2; P = 0.011 for all comers). A greater proportion of etrolizumab-treated patients achieved categorical histologic improvement and remission with an endoscopic subscore (EUCALYPTUS) of 1 or 0 at wk 10 (n = 6), 100% experienced histologic response as assessed by RHI (5/5 with RHI non-missing at wk 10), and 83% (5/6) by NHI. Mean (SD) RHI changes were −19.2 (10.0) in patients with an ES ≥ 1 at wk 10 versus −4.4 (10.1) in patients with an ES < 1. Mean (SD) NHI changes were −2.5 (1.5) in patients with an ES < 1 at wk 10 versus −0.6 (1.3) in patients with an ES > 1. Spearman’s

Contact E-mail Address: arulmani.udadayasankar@gmail.com
correlation coefficients between RHI and NHI were 0.82 at BL and 0.91 at wk 10, while both histologic scores were similarly correlated with ES (0.25-0.28 at BL and 0.38-0.40 at wk 10).

Introduction: GO-COLITIS (NCT02092285; 2013-004353-56) is a phase 4, multi-centre, open-label, single-arm trial in the UK assessing efficacy of golimumab (MedImmune) in induction and maintenance of clinical response in patients with moderate to severe ulcerative colitis (UC) resistant to conventional treatment. Results of the maintenance phase are presented here.

Aims & Methods: Anti-TNF-naive adults with UC ≥ 3 months who responded to induction therapy with subcutaneous GLM at week 6, according to partial Mayo score (PMS), continued to receive a maintenance dose of 50 mg or 100 mg GLM (dependent on the patient’s weight) every 4 weeks as per the Summary of Product Characteristics for a total of 54 weeks. Measurements were taken at week 6, week 30 and week 54. The primary endpoint was the proportion of patients meeting PMS response criteria at week 54 (defined as decrease in PMS ≥ 2 points at ≥ 30% from baseline, plus a decrease in rectal bleeding subscore of ≥ 1 point or absolute rectal bleeding score ≥ 1). Secondary endpoints included proportion of patients meeting PMS remission criteria at week 54 (defined as PMS < 2 and no individual Mayo subscore > 1), change from baseline in IBDQ and EQ-SD at each visit and normalization of CRP.

Results: Overall, 205 patients enrolled in GO-COLITIS and received at least one dose of GLM. Of these, 186/205 (91.0%) patients responded in the induction phase and received GLM in the maintenance phase. Clinical response was maintained through week 54 in 52/140 patients (37.1%; 95% CI, 29.1% to 47.5%) and 42/140 patients were in remission at week 54 (30.0%; 95% CI, 22.6% to 38.3%). Improvements in PMS subscores from baseline to week 54 were noted in stool frequency (mean change, −1.9; SD, 1.1 [n = 59]), rectal bleeding (mean change, −1.5; SD, 0.8 [n = 59]), and physician’s global assessment (mean change, −1.8; SD, 0.8 [n = 57]). Normal CRP levels at week 54 were seen in 50/59 patients (84.7%; 95% CI, 73.0% to 92.9%). IBDQ and EQ-SD results are summarised in the Table. Serious adverse events (SAEs) occurred in 49/205 patients (23.9%), with 3 SAEs considered treatment-related.

Table: Mean (SD) Change from baseline to week 54 in IBDQ and EQ-SD

<table>

</tr>
<tr>
<td>EQ-SD index score</td>
<td>136 ± 0.7 (0.2)</td>
<td>60 ± 0.9 (0.2)</td>
</tr>
</tbody>
</table>

Conclusion: In the maintenance treatment with GLM phase of GO-COLITIS, 37.1% and 30.0% of patients were able to severe UC in the UK demonstrated clinical response and remission at week 54, respectively. Improvements in patient-reported quality of life measures (IBDQ EQ-SD) were seen; the degree of improvement in IBDQ total score exceeded the IBQD increase cutoff (i.e. ≥ 20) for patient defined remission previously identified as representative of a patient defined improvement in an assessment of UC clinical endpoints. Adverse events were consistent with previous observations.

Introduction: Only a third of patients (pts) with inflammatory bowel disease (IBD) treated with current pharmacological options achieve clinical response (remission, aTNF-experienced) and most experience drug-related adverse events (AEs). Herein we characterize the clinical and economic burden of IBD treatment limitations in terms of AEs of interest, medical resource utilisation (MRU) and associated costs.

Aims & Methods: Using pts taking only aTNF monotherapy (ASA) as a reference, we compared AE incidence, MRU and medical costs in pts with ulcerative colitis (UC) or Crohn’s disease (Crohn’s) who initiated treatment with oral corticosteroids (OCS), immunosuppressants (IS), anti-tumor necrosis factor agents (aTNF) or with combinations thereof. Eligible pts (aged ≥ 18 years) in the IMS Pharmetrics insurance claims database between 7/1/10 and 6/30/15 had ≥2 medical claims (≥7 days apart) and a diagnosis of UC (ICD-9-CM: 556.x) or Crohn’s (ICD-9-CM: 555.x), with ≥1 qualifying claim in the year preceding treatment. Univariate comparisons included statistical tests of significance (χ², F test, or Kruskal Wallis). Multivariate analyses were based on Cox proportional hazards regression, negative binomial regression, logistic regression or linear regression
P1059 CAN EARLY DRUG AND ANTI-INFLIXIMAB-ANTIBODY LEVELS PREDICT PRIMARY NON RESPONSE TO INFLIXIMAB THERAPY?

1Gastroenterology, Rambam Health Care Campus, Haifa/Israel
2Gastroenterology Institute, - Gastroenterology institute/IL, Ramat Gan/Israel

Contact E-mail Address: bellagophys@gmail.com

Introduction: Infliximab has been shown to induce and maintain long-term clinical remission in inflammatory bowel disease (IBD) patients. However, 10-30% of patients show no clinical benefit by the end of induction (week 14) and are considered primary non-responders. The mechanisms underlying primary non-response have not yet been clearly defined. Aims & Methods: In this study we aimed to evaluate to what extent pharmacokinetics (early induction infliximab and anti-infliximab-antibody (ATI) levels) and clinical factors are predictive of early drug and ATI levels in primary non-responders of a retrospective observational study of patients with IBD attending the Gastroenterology Department of Sheba medical center and treated with infliximab between 2009 and 2016 was performed. Clinical scores were determined and sera were collected prospectively before infusions. Infliximab and ATI levels were measured by our previously described drug-tolerant ELISA assay. Results: Thirty five primary non responders have been identified and matched at 1:3 ratio with 105 primary responders for a total of 140 patients. Both week 2 and week 6 infliximab levels were significantly lower among primary non-responders compared to responders (week 2: median level 7.1 µg/ml vs 13.5 µg/ml, p = 0.0019, week 6: median level 2.2 µg/ml vs 9.5 µg/ml, p < 0.0001, respectively). ATI appeared more frequently (either week 2 or 6, OR = 2.43 [2.07–2.85] and bone-related conditions (Crohn’s: 1, 88 [1.74–2.03]; UC: HR, 1.77 [1.67-1.89]). The strongest predictors for serious hepatic events were IS + OCS (Crohn’s: HR, 2.38 [1.72-3.31]; UC: HR, 2.36 [1.75–3.19], p = 0.002, sensitivity 50%, specificity 82%). Pts with UC or Crohn’s receiving OCS or IS + OCS were more likely to have emergency department visits; IBD-related hospitalisation, visits or procedures; and gastrointestinal surgery compared with pts receiving other therapies. Assumalised total medical costs were greatest for aTNF + IS or aTNF + ATI therapy in both Crohn’s and UC. However, annualised medical service costs (that exclude IBD drug costs) were highest for pts initiating OCS-containing therapies (Crohn’s: OCS, $27,041 and OCS + IS, $23,332; UC: OCS, $19,659) followed by other induction therapies (ASA, $10,823; aTNF + IS, $19,151 [P < 0.001]; UC: ASA, $7,980 and aTNF + IS, $18,771 [P < 0.001]).

Conclusion: Chronic OCS use was associated with increased risk of severe infection, bone conditions, and serious hepatic events compared with other therapies. Consistent with an increased AE risk, OCS regimens were associated with higher rates of MRU and medical service costs compared with other therapies. Although limiting the use of OCS regimens may be more costly initially, treatment decisions should consider downstream cost of alternate options.

influence the degree of SM a patient is willing to apply, such as: disease duration, activity, health literacy, self-efficacy, patient's age, and level of trust between patient's and their IBD team. Nurses were asked per item whether they thought this factor would be of influence and to name the three most important factors.

Results: 38 nurses (mean age 42 years) and 32 physicians (mean age 44 years) responded to the survey. The three most appealing options for nurses regarding SM were: availability of a SM web-app, Skype/Face-time consultation with nurse/physician, and an at-home faecal-calprotectin test. Physicians preferred the same options as nurses. Patients' level of change of their patient records compared to 18% of nurses (p = 0.001). Physicians thought that the 3 most important factors influencing SM in patients were: level of trust between physician and patient, self-efficacy, and disease perception. Also, 41% of the physicians found health literacy to be an important factor. Factors suggested that self-efficacy in disease perception and disease activity were most important. One factor was valued differently between nurses and physicians: 78% of nurses thought that patient's age was an important factor in patient's SM, compared to 34% of physicians (p = 0.001).

Conclusion: Patients with limited treatment options for IBD reported disease-related factors and disease perception as important factors influencing SM. Physicians may consider patient's self-efficacy, change of patient records and trust as important factors influencing SM. These results may be used for future research on what patients and caregivers want and need from SM, as SM is a team sport.

P1062 DISTINCT PATTERNS OF SHORT-CHAIN FATTY ACIDS IN PATIENTS WITH ULCERATIVE COLITIS EXPERIENCING A FLARE DURING TREATMENT WITH MESALAMINE. COMBINATION OF MYRRH, CHAMOMILE FLOWERS AND COFFEE CHARCOAL

J. Langhorst1, A. K. Koch2, A. Rueffer2, G. Dobos3

Introduction: The combination of myrrh, chamomile flowers, and coffee charcoal has shown first evidence for potential efficacy in maintaining remission in ulcerative colitis (UC). Recent studies are end products of the microbial fermentation of dietary fibers in the gut. They are involved in the regulation of the gut immune system, promote mineral absorption, lipid metabolism, mucin production and expression of antimicrobial peptides. UC patients often show reduced occurrence of SCFA especially in remission. This might lead to unfavorable health impairments including higher risk of inflammation and heightened cancer risk.

Aims & Methods: The purpose of the present study was to evaluate the influence of mesalazine and of the herbal preparation on SCFA in ulcerative colitis. Analyses was proceeded as sub-study of a randomized double-blind, double-dummy, controlled clinical trial that has been published previously. Patients were treated with the herbal preparation consisted of 100 mg myrrh, 70 mg chamomile extract and 50 mg coffee charcoal (Myrrhinil-Intestin, Repha GmbH, Heidelberg, Germany). This might lead to unfavorable health impairments including higher risk of inflammation and heightened cancer risk.

Conclusion: Findings show that the herbal preparation might induce different effects on the SCFA of patients with UC compared to mesalazine and therefore might exhibit different modes of action in treating UC. Since a decline of SCFA might lead to unfavorable health impairments like higher cancer risk, treatment options like the herbal preparation might yield additional beneficial effects in the treatment of UC. A combination of the two treatment modalities might be useful and should be investigated in further studies.

P1063 GRANULOCYTE-MONOCYTE APHERESIS (GMA) IN DIFFICULT-TO-TREAT INFLAMMATORY BOWEL DISEASE (IBD). A SINGLE-CENTER REAL-LIFE EXPERIENCE

A. Caroli, F. Lamboglia, I. Francenetti, C. Pozzan, D. Checchin, F. Bortoluzzi, R. Cappuccio, A. Vitalba

UOC di Gastroenterologia, Ospedale dell’Angelo, Mestre; Ospedale SS Giovanni e Paolo, Venezia, Mestre-Venezia/Italy

Contact Email Address: alessandro.caroli@uls12.ve.it

Introduction: Selective GMA using Adacolumn® device is a non-pharmacologi- cal therapeutic option for patients affected by IBD, but its precise role among the various treatments available and its true effectiveness are still debated. In particu- lar, steroid-dependent patients, refractory or intolerant to immunosuppressant and biologics, represent a sub-group of patients with limited options of treat- ment. Recently, a multicentric open-label trial [the ART trial ] showed, for the first time, a clinical benefit of GMA in these problematic patients.

Aims & Methods: The aim of this study was to further evaluate, in our real-life clinical experience, the efficacy and safety of GMA in these difficult-to-treat patients. We retrospectively reviewed the clinical data of patients treated with GMA-Adacolumn® in our center between 1/1/2008 and 31/12/2016. Only ster- oid-dependent and/or AZA/IFX/ADA-resistant or intolerant patients were consid- ered. GMA was performed once a week for a minimum of five consecutive weeks. Occasionally, one or two additional sessions were performed. A clinical response was defined as a ≥3 points reduction of the clinical activity index (CAI) for ulcerative colitis (UC) and a ≥100 points reduction of the Crohn disease activity index (CDAI) for Crohn disease (CD) after 12 weeks from the beginning of the treatment.

Results: The study population included a total of 30 patients (17 males, 13 females, mean age 49 years, range 21–73) affected by UC (20 patients) and CD (10 patients). Eight patients (5 UC, 3 CD) were excluded from the final analysis for incomplete data. In the remaining 22 pts a clinical response, at week 12, was observed in 15 (68%). The response was better in UC (11/15 = 73%) than in CD (4/7 = 57%). A steroid-sparing effect was observed in all responsive patients. GMA was generally well tolerated, as only 4 patients (13%) reported mild adverse events (headache in two, hypotension in one, vascular procedure com- plication in one) and no patients discontinued the apheresis due to the adverse events.

Conclusion: In our real-life single-center experience, focused to a selected group of difficult-to-treat patients affected by IBD, GMA with Adacolumn® seems to be, in a short-time evaluation, a useful and safe option of treatment, supporting the recent data from the ART trial. Prospective randomized trials in larger series of patients and with more extended follow-up are needed to confirm these results.

*Diagnosis A et al., JCC 2016;10: 812–820.
Combined effect, concentration-response relations of single components and the challenged human macrophages (THP-1) was investigated respectively using an inflammatory bowel disease [1]. Despite existing clinical data, pharmacological data supporting the observed efficacy remain insufficient.

Inflammatory bowel disease 

Introduction: The herbal medicinal product Myrrhinil-Intest (Biologische Arzneimittel Repha GmbH Biologische Arzneimittel) is used for the treatment of gastrointestinal complaints. Clinical data suggest its use for the maintenance therapy of inflammatory bowel disease [1]. Despite disease-specific clinical data, pharmacological data supporting the observed efficacy remain insufficient. The present study aims to investigate the influence of the single and combined herbal extracts with regard to its anti spasmodic and immune-modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. The aim of this study was to investigate the relationship between drug compliance and the outcome of anti-TNF therapy. The number of patients showing a complete treatment discontinuation (LLTR) was investigated respectively using an ELISA test system. Budesonide served as positive control. To characterize the combined effect, concentration-response relations of single components and the herbal combination were compared and IC50 values derived. Interpretation of the data was based on a dose reduction index (DRI = IC50 single/IC50 combination) which estimates the extent to which the dose of one or more components in the combination can be reduced to achieve effect levels that are comparable with those achieved with single component.

Results: Myrrh and chamomile flower extract exerted spasmytic effects by inhibiting acetylcholine-induced contractions in rat small intestinal preparations (IC50 myrrh = 144 g/mL; chamomile flower = 383 g/mL). In combination, chamomile flower and myrrh interacted additively (IC50 myrrh = 74 g/mL; chamomile flower = 196 g/mL) resulting in a DRI of 2.1. All three plant components inhibited CXCL13 release from LPS-stimulated human macrophages (IC50 myrrh-IC50 chamomile flower-IC50 coffee charcoal = 106 g/mL). Synergistic effects exerted by the herbal combination in inhibiting CXCL13 release significantly reduced IC50 values (IC50 myrrh = 5 g/mL; chamomile flower = 22 g/mL; coffee charcoal = 29 g/mL) resulting in a DRI of 2.7. All three plant components inhibited CXCL10 release from Caco2 cells was reduced by all herbal components (IC50 myrrh = 41 g/mL; chamomile flower = 364 g/mL; coffee charcoal = 447 g/mL) with comparably high IC50 values. However, application of the herbal combination, significantly reduced the IC50 of the plant extracts (myrrh-IC50 = 25 g/mL; DR1 = 1.7; chamomile flower-IC50 = 124 g/mL; DR1 = 2.9; coffee-IC50 = 124 g/mL; DR1 = 3.6). IL8 release from cyto- kine-challenged Caco2 cells was inhibited after myrrh (IC50 = 3 g/mL; 28% max inhib.) and coffee (IC50 = 218 g/mL; 75% max inhib.) but increased after chamomile flower treatment (IC50 = 39 g/mL; 29% max stim.). Treatment with all three plant extracts resulted in a moderate IL8 inhibition with an inverted U-shape concentration-response curve (IC50 myrrh = 56 g/mL; coffee charcoal = 281 g/mL; 77% max inhib.).

Conclusion: The herbal components myrrh, chamomile flower and coffee charcoal influenced chemokine signalling of stimulated intestinal epithelial cells and activated macrophages. Myrrh and chamomile flower additionally exerted anti spasmodic effects. Synergistic and additive effects between the plant extracts justify the combinatory composition of the traditional herbal medicinal product (Myrrhinil-Intest®) and its application for the treatment of inflammatory intestinal disorders.

Introduction: The objective of the present study was to evaluate the effectiveness and safety of adalimumab (ADA) in children with ulcerative colitis (UC) who experienced previous infliximab (IFX) failure or intolerance.

Aims & Methods: This retrospective study included all children with UC from a national pediatric registry who received ADA therapy. The primary endpoint was the rate of corticosteroid (CS) free remission (PUCAI < 10) at week 52. Secondary outcomes were: the rate of continuous clinical response and remission, primary non-response and loss of response at Weeks 12, 30 and 52 and rate of mucosal healing (MH) at week 52.

Results: A total of 32 children with UC received ADA (median age 10 ± 4 years). Median disease duration before ADA therapy was 27 months. All patients received previous IFX therapy (43% intolerant, 50% non-responders, 7% positive anti-IFX antibodies). Fifty-two weeks after ADA initiation 13 patients (41%) were in CS-free remission. MH occurred in 9 patients (28%) at 52 weeks. The cumulative probability of clinical relapse-free course was 69%, 59% and 53% at 12, 30 and 52 weeks, respectively. Ten patients (31%) had a primary failure and 5 (15%) loss of response to ADA. No significant differences in terms of efficacy were reported between non-responders and intolerant to IFX (P = 1.0). Overall, 19 patient (59%) maintained ADA therapy during 52-week follow-up. Seven patients (22%) experienced an adverse event. No serious side effects were observed and none resulted in ADA discontinuation.

Conclusion: In this cohort of children with UC ADA had a favorable short- and long-term efficacy, allowing to recover a significant percentage of patients intolerant or non-responding to IFX. The efficacy was not related to the cause of IFX discontinuation (intolerance/failure). Overall, safety profile was good. Larger, prospective, controlled trial with longer follow-up should be suggested to better clarify the role of ADA in pediatric UC.

P1068 LOW FODMAP DIET IMPROVE DISEASE ACTIVITY AND QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

G. Bodini1, E.G. Giannini2, V. Savarino3, M. Crespi4, S. Lo Pumo5, C. Zanella6, I. Baldirozza2, E. Savarino3
1Department Of Internal Medicine, IRCCS San Martino DIMI, Genova/Italy
2Department Of Surgery, Oncology And Gastroenterology, University of Padua, Padua/Italy

Contact E-mail Address: giovanna.bodini@gmail.com

Introduction: Inflammatory Bowel Diseases (IBD), Crohn Disease (CD) and Ulcerative Colitis (UC), are idiopathic autoimmune conditions whose pathogenesis is still unknown. It has been hypothesized that, in genetic predispose subsets, a deregulated immune response associated to an increase of intestinal permeability may lead to bowel damage and clinical manifestations. Thus, environmental factors and, in particular, food intake may play a pivotal role in IBD pathogenesis.

Aims & Methods: The aim of this prospective study was to evaluate the effects of a 6-week low fermentable Oligosaccharides, disaccharides, monosaccharides and polysaccharides (FODMAP) diet on disease activity and quality of life in patients with IBD.

At first visit (T0), patients were clinically evaluated by a gastroenterologist and a nutritionist, filled a questionnaire on quality of life (the IBD-Q) and underwent blood tests as well as fecal calprotectin assessment. Disease activity was defined using the Mayo score and the Harvey Bradshaw Index (HBI) for UC and CD respectively. After the baseline visit, patients were randomized into two groups: A) patients underwent a low FODMAP diet; B) patients underwent a diet with normal FODMAP amount. A food diary was used to assess patients’ adherence to the different diets. After six weeks (T1), patients had a second visit to assess disease activity, complete the IBD-Q, and repeat blood tests as well as fecal calprotectin assessment.

Results: In this prospective, interventional, cohort study, we enrolled 55 consecutive IBD patients who agreed to participate from an initial cohort of 127 IBD patients. Twenty-six patients were randomised to a low FODMAP diet (group A), while 29 patients to a standard FODMAP diet (group B). Among CD patients (n = 35, 63.6%), median HBI values significantly decreased during the study, in the whole population and in group A, whereas no change was recorded in group B (respectively P = 0.02; P = 0.02; P = 0.3). Among UC patients (n = 28, 36.4%), median Mayo scores did not significantly decrease during the study, both considering the whole population and the two groups (P = 0.3, P = 0.3, and P = 0.8, respectively).

Moreover, despite no statistically significant difference in quality of life in both groups at T0, in group A quality of life improved after the diet compared to group B (respectively, P = 0.06, P = 0.05 and P = 1).

Conclusion: We demonstrated that a low FODMAP diet, for a limited period of 6 weeks, is able to improve both disease activity, at least for CD, and quality of life in IBD patients. Further, larger multicentre studies are needed to confirm these preliminary data.

Introduction: Ustekinumab has shown a good safety profile and efficacy to induce and maintain remission in adults with refractory Crohn’s Disease (CD). Data are lacking in children.

Aims & Methods: All CD patients under 18 years who received ustekinumab were included in this retrospective observational study performed in a single tertiary pediatric centre.

Results: See table.

Conclusion: Subcutaneous ustekinumab is effective to induce and maintain remission in severe pediatric CD refractory to anti-TNF antibodies.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
From January 2015 to May 2016, twelve CD patients were treated with ustekinumab, all because of failure of several lines of therapies including anti-TNF antibodies. All but one patient were followed at least one year. An initial response was serious adverse event and the treatment was stopped after the first injection.

**P107 INFLIXIMAB INDUCED PSORIASIS IN A COHORT OF CHILDREN WITH INFLAMMATORY BOWEL DISEASE: A 12 YEARS FOLLOW-UP STUDY**

C. Martinez-Vinson, O. Courbette, C. Aupiais, J. Viala, J. Hugot
Gastroenterologie Pediatrique, Hopital Robert Debre, Paris/France

Contact E-mail Address: christine.martinez-vinson@aphp.fr

**Introduction:** In adult Inflammatory bowel disease (IBD), skin adverse reactions have been reported in presence of 1.6 to 22%. This side effect occurs more frequently in patients treated with infliximab (IFX) for IBD. Data in the pediatric population are lacking so far.

**Aims & Methods:** All patients aged 2 to 18 years, with Crohn’s disease (CD) or Ulcerative colitis (UC) and treated for the first time by IFX between January 2002 and March 2014, were considered for inclusion in this monocentric retrospective study.

**Results:** Baseline Patients: 115 patients were treated with IFX for CD and 23 for UC. IFX treatment was initiated at the age of 14, about 2 years after diagnosis. The indication for treatment was in 61.6% (n = 85) resistance to conventional therapy, in 26.8% (n = 37) a perianal fistulizing disease and in 11.6% (n = 16) a severe colitis. At the first injection, the median PCDAI was 35 (25; 45) for CD and the median PUCAI 35 (25; 45) for UC. The duration of treatment with IFX ranged from 45 days to 8 years and median was 23.9 months (11.6; 36.5).

Psoriasis: 20 patients (14% of the cohort) had an IFX-induced psoriasis. 70% of them (n = 14) of patients were in remission when the psoriasis was diagnosed. Psoriasis was diagnosed at the 8th injection (6; 15), though 355 (239; 532) days after the start of biotherapy. 20% of patients had a combo therapy: 50% of them were treated by 6-mercaptopurine, 25% by azathioprine and 25% by methotrexate. The median IFX trough levels (TRI) when psoriasis occurred was 4.7 mcg/mL (1.8; 9.6) and 4.1 mcg/mL (2.1, 8.8) at the previous visit. Median Antibodies to infliximab (ATI) were 0%.

Conclusion: 14% of our IBD patients treated with IFX developed psoriasis during follow-up. All were CD, more frequently it occurred for CD with perineal lesions, at the 8th injection in median, with no ATI.

**P107 PLATELET ABNORMALITIES AND ANEMIA IN PAEDIATRIC IBD: ARE THEY LINKED?**

M. Votto², F. Viviano², F. Viola³
²Pediatría, IRCCS Pollicino San Matteo, PAVIA/Italy
³Pediatría E Neuropsichiatria Infantile, Università La Sapienza, Roma/Italy

Contact E-mail Address: martinvatto@gmail.com

**Introduction:** Crohn’s Disease (CD) and Ulcerative Colitis (UC) are two major forms of Inflammatory Bowel Disease (IBD). In children with IBD anemia is common and is a combination of iron deficiency and anemia of chronic disease (ACD). ACD are associated with several alterations of platelets, including number, shape, and function. In clinical practice, the most common platelet alteration is thrombocytosis. In IBD, thrombocytosis is associated with iron deficiency anemia and chronic inflammation. The platelet function is due to the substantially increased incidence of thromboembolic phenomena in IBD

**Aims & Methods:** The aim of the study is to demonstrate the link between anemia, thrombocytosis and platelet aggregation in pediatric IBD patients. This study includes 51 children and adolescents recruited from the Pediatric Gastroenterology Unit of Policlinico Umberto I in Rome. Patients younger 6 years, with inherited platelet defects, hemoglobinopathies, and receiving therapies that alter platelet function, are excluded. We collect disease activity scores (Pediatric Crohn’s Disease Activity Index [PCDAI], Pediatric Ulcerative Colitis Activity Index [PUCAI]), laboratory investigations (complete blood count, mean corpuscular volume (MCV), mean platelet volume (MPV), mean corpuscular haemoglobin concentration (MCHC), levels of hemoglobin (Hb) and serum ferritin (SF), transferrin and iron. Diagnostic criteria for anemia are based on EDCO guidelines. Platelet aggregation is evaluated on platelet-rich plasma in an AggRAM aggrerometer with Born’s Method. The results were reported as the maximal percentage of aggregation observed after 4 min stimulation in response to collagen (1 μg/mL) and adenosine diphosphate (ADP 0.8 μM and ADP 2 μM).

**Results:** The study include 51 children and adolescents, 24 with UC and 27 with CD. Median age is 15.3 years (±3.5). Iron deficiency anemia combined to ACD is the most common type (58.3% in UC and 50% in CD). Hemoglobin levels are significantly lower in patients with UC compared to CD patients (p = 0.0320). No significant differences are observed between mean values of red cells, MCV, MCHC, RDW, iron, transferrin and serum ferritin both in CD and UC. Thrombocytosis prevails in UC compared to CD patients, but no significant correlation was found. No differences are observed between mean values of PDW and MPV in both groups. In patients with UC, a negative correlation was found between mean values of hemoglobin and platelet count (p = 0.0134). Moreover in patients with CD, disease activity was positively correlated with platelet count (p = 0.0040). Platelet aggregation results higher in anemic patients. In anemic children, mean baseline platelet aggregations - induced by ADP 0.8 μM and collagen 1 μg/mL - are significantly higher in UC compared to CD (p = 0.001 and p = 0.030 respectively). Another significant correlation is observed between platelet aggregation - induced by ADP 0.8 μM and ADP 2 μM - in anemic UC patients compared to non-anemic UC patients (p = 0.002 and p = 0.040 respectively). Platelet aggregation - induced by ADP 0.8 μM is significantly higher in anemic UC patients with active disease (PUCAI > 20) compared to the same patients whose disease is in remission (p = 0.042) and compared to patients with active CD (p = 0.054).

**Conclusion:** In our cohort, mixed anemia (iron deficiency anemia combined to anemia of chronic disease) is the most common type of anemia. Thrombocytosis is a condition more frequent in anemic IBD patients, specially in UC. In UC, anemia and disease activity are significant correlated with platelet hyperaggregation. Moreover in UC patients with active disease there is a significant major risk of thrombosis, independently from acquired or inherited hemostasis defects.

P1073 RELATIONSHIP BETWEEN CLINICAL COURSE OF ULCERATIVE COLITIS (UC) DURING PREGNANCY AND OUTCOMES OF PREGNANCY: A RETROSPECTIVE EVALUATION STUDY

A. Ito, O. Teppeli, T. Katutushi
Dept. Medicine, Inst. Gastroenterology, Tokyo Womens Medical University, Tokyo/Japan

Contact E-mail Address: itoayumi@i.ge.twmu.ac.jp

Introduction: Ulcerative colitis (UC) is a chronic, intractable disease with a long clinical course. UC has a marked influence on the lifestyle of patients, and its effects on pregnancy and childbirth can especially become a problem for women in their child-bearing years. Various studies have suggested that it is desirable for pregnant women with UC to give birth while remaining in a state of remission.

Aims & Methods: The present study evaluated pregnant women with UC attending our hospital who became pregnant during remission, in order to examine the factors that contributed to recurrence of UC during pregnancy. We investigated 40 pregnant patients in remission (44 cases) attending our hospital during January 2008 and July 2016 who had remained in remission for one year prior to pregnancy. After becoming pregnant while in remission, patients who stayed remission until delivery were classified into the ongoing remission group (35 cases) and patients with recurrence during pregnancy were classified into the recurrence group (9 cases). Remission was defined as a Lichtiger clinical activity index (CAI) of less than 4. Relapse was defined as a CAI ≥ 5 with the need for initiation or dose escalation of steroids or administration of biological agents during pregnancy. Items examined: Clinical characteristics (age at onset, disease duration, age of becoming pregnant, disease type, and treatment), the CAI in the first, second, and third trimesters, and whether or not patients continued treatment during pregnancy were examined and compared between the two groups.

Results: There were significant differences between the two groups with respect to the age of becoming pregnant (32.9 ± 4.4 years in the ongoing remission group vs. 28.3 ± 7.0 years in the recurrence group), the CAI in the second trimester (2.9 ± 4.6 vs. 3.5 ± 1.6), the CAI in the third trimester (2.9 ± 0.7 vs. 5.4 ± 2.0), and whether oral treatment was continued (continuation of treatment [yes]/no): 30/5 in the ongoing remission group vs. 5/4 in the recurrence group). Regarding the discontinuation of oral treatment, two patients in the ongoing remission group and one patient in the recurrence group discontinued it on their own judgment, while two patients in the recurrence group discontinued it due to hyperemia. Discussion: The present study revealed that factors influencing the recurrence of UC during pregnancy were the age of becoming pregnant and the continuation of oral treatment. Our results showed that younger women were more susceptible to recurrence. As expected, discontinuing oral treatment was a factor that contributed to recurrence. However, the reasons for discontinuing treatment during pregnancy differed from those for non-pregnant women. Some patients discontinued treatment on their own judgment because they were concerned about adverse effects on the fetus, while others had difficulty with continuing treatment due to hyperemia. With regard to the effects of medications on the fetus, medical staff should provide an explanation about the safety of treatment and should be aware that patients may have various concerns about drug therapy. If patients have difficulty continuing oral treatment due to severe hyperemia, administration of alternative therapy should be considered.

Conclusion: During pregnancy, it is important to continue treatment for UC so that patients can give birth while remaining in remission. Accordingly, intervention by medical staff is particularly necessary in order to provide pregnant patients with information and explanations regarding treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

3JIMRO, Takasaki/Japan

Contact E-mail Address: tomotaka@cd.ac-up.com

Introduction: In patients with active ulcerative colitis (UC), methylprednisolone ileocolonies are known to be elevated with activation behaviour, including the CD14+ CD16− DR++ monocye phenotype, which is a major source of tumour necrosis factor-α. Therefore, selective depletion of methylleucocytes by adsorptive granulocyte/monocyte apheresis (GMA) with an Adacolumn is expected to promote remission, or enhance drug efficacy. Potentially, GMA should be a relevant treatment option in patients in whom drug therapy has limitations.

Aims & Methods: Our major objective was to apply GMA as remission induction therapy in paediatrics and adolescents when first-line 5-aminosalicylic acid/steroids had failed. Thirty consecutive patients with active ulcerative colitis (UC), age 11–19 years, body weight 33.5–55.5 kg were givem mesalazine (n = 23) or sulphasalazine (n = 7) as the first-line medication. Twenty patients relapsed while receiving the first-line medication. They did not respond, and received GMA with the Adacolumn, at 2 sessions in the first week, then weekly, up to 11 sessions. Patients who achieved ≥ 50% decrease in the clinical activity index (CAI) after 5

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference

2014;20:3180–90.
GMA sessions continued with GMA while non-responders received GMA in combination with a low dose prednisolone (0.5 to 1.0 mg/kg bodyweight). At entry and week 12, patients were clinically and endoscopically evaluated with each patient serving as her or his own control.

**Results:** At entry, all 30 patients were corticosteroid naïve and none had deep coexisting angiodysplasia. Extensive loss of the mucosal tissue at the affected sites (GMA non-responders features). Ten patients achieved stable remission with the first-line medications and did not receive GMA. Six patients did not respond well to the first 3 GMA sessions and received prednisolone together with GMA, while 12 patients responded well to GMA, and achieved stable remission, but 2 patients withdrew to receive high dose prednisolone (up to 2 mg/kg bodyweight). At entry, the average CAI was 14 ± 0.4. Prednisolone was tapered to 0 mg within 3 months in those who received. Therefore, at week 12, all 30 patients were in remission, majority with mucosal healing.

**Conclusion:** In this treatment design, GMA in young corticosteroid naïve patients with active UC refractory to the first-line 5-aminosalicylates was associated with clinical remission and mucosal healing, while in non-responders to GMA mono-therapy, addition of a low dose prednisolone increased the efficacy of GMA and tapering of the prednisolone dose was not associated with relapse. Therefore, the majority of young steroid naïve UC patients who fail to respond to first-line 5-aminosalicylates should respond well to GMA and avoid pharmacologicals. Additionally, GMA has a good safety profile, which is a very favourable feature in growing patients.

**PI076 EARLY SCREENING FOR INFLAMMATORY BOWEL DISEASE IN CHILDREN WITH AUTOIMMUNE LIVER DISEASE**

D. Thangarajah, E. Cernat, B. Vadamalayan, D. Hadzic, M. Samyn Pediatric Liver, GI and Nutrition Centre, King’s College Hospital, London/United Kingdom

**Contact E-mail Address:** antihuriti@gmail.com

**Introduction:** Autoimmune liver disease (AILD), in particular autoimmune sclerosing cholangitis (ASC) is associated with inflammatory bowel disease (IBD). It is known the effect of IBD on the outcome of AILD. Faecal calprotectin (FC), a stool biomarker, screens for bowel inflammation without the need for invasive endoscopic evaluation and is easy to collect.

**Aims & Methods:** The aim of this study was to review the investigations and outcomes of IBD and AILD in children with a primary diagnosis of AILD and to identify possible risk factors for development of IBD in children with AILD. Children with AILD were identified from electronic case notes between 2007 and 2010 and those with a diagnosis of IBD prior to AILD excluded. AILD was diagnosed and treated as per centre protocol. Diagnostic endoscopy for IBD was performed, based on GI symptoms and/or elevated FC (>600 μg/g). Data were documented at time of liver diagnosis; endoscopy and last liver follow up. Patients were classified as AILD-IBD or AILD. Mann Whitney and Chi squared test were used to analyse data where appropriate, significance p < 0.05.

**Results:** Out of 37 (12 male) children, diagnosed with AILD (ASC 11), 23 underwent diagnostic endoscopy after a median time from diagnosis of 27.6 (20.1 to 53.9) weeks. 20/23 reported GI symptoms and FC was elevated in 13/18 tested. At endoscopy 57% (13/23) a diagnosis of IBD (AILD-IBD group) (UC n = 12), IBD-U (n = 11) was made, 10/23 were within normal limits (AILD group). There was no difference in gender or diagnosis of ASC between the 2 groups. At presentation of AILD, children in the AILD-IBD group were significantly leaner in terms of weight and BMI, had lower haemoglobin, with a trend for younger age at presentation (table 1). GI symptoms and FC > 60 μg/g were significantly more prevalent in the AILD-IBD group. At the time of endoscopy, 22 were on treatment for AILD with prednisolone and 13 with an additional agent (azathioprine or mycophenolate mofetil). Biochemical remission for AILD was defined as haemooglobin in 74% at last liver follow-up (median 4.1 [3.5 to 5.0] years) with no difference for both groups. All patients are alive; however, in the AILD-IBD group 1 underwent an isolated liver transplantation (LT) and 1 required a subtotal colectomy. One girl underwent LT combined with subtotal colectomy after decompensation of her liver disease.

**Table 1:** Diagnostic parameters of AILD at presentation median [IQR]*p value < 0.05

<table>

</tbody>
</table>

**Conclusion:** In our cohort 35% of children presenting with AILD were subsequently diagnosed with IBD. Possible risk factors for development of IBD in AILD are low haemoglobin, being leaner and younger at diagnosis. An elevated FC and the presence of GI symptoms are useful to assess the need for diagnostic endoscopy when considering diagnosis of IBD in the context of AILD. As current immunosuppression may mask mild to severe signs and signs of IBD a lower threshold for endoscopy should be considered in these patients.

**PI077 CLINICAL AND LABORATORY VARIABLES THAT PREDICT CLINICAL AND ENDOSCOPIC REMISSION IN CHILDREN WITH CROHN’S DISEASE TREATED WITH INFlixIMAB**

G. D’Arcangelo, S. Oliva, F. Tarani, F. Viola, F. Civitelli, S. Cucchiara, M. Aloia Pediatric Gastroenterology And Liver Unit, Sapienza University of Rome, Rome/Italy

**Contact E-mail Address:** giuialiarcangelo87@gmail.com

**Introduction:** We aimed to identify early clinical and laboratory predictors of sustained clinical and endoscopic remission in children with Crohn’s disease (CD) under infliximab (IFX).

**Aims & Methods:** Prospective study conducted in children with moderate-to-severe CD starting IFX treatment. All patients underwent endoscopy, weight adjusted pediatric CD activity index (wPCDAI) assessment, C-reactive protein (CRP) at week 0 and 52. wPCDAI and CRP were also evaluated at 14 weeks. The primary outcome was to determine the ability of 14-week wPCDAI and CRP to predict steroid-free sustained remission and mucosal healing at 1 year. As a secondary outcome we sought to evaluate the concordance between wPCDAI and Simple Endoscopic Score for CD (SES-CD) at week 52.

**Results:** Forty-one children were enrolled (median age 13.3 ± 2.7, females 44%). At 1 year, 21 (51%) and 16 (39%) were in clinical (wPCDAI < 12.5) and endoscopic (SES-CD < 3) remission, respectively. Fourteen-week wPCDAI didn’t differ between patients who achieved both clinical and endoscopic remission at 1 year (p = 0.21 and p = 0.35, respectively). By using a multivariable logistic regression model, neither week-14 wPCDAI nor CRP were predictors of 1-year clinical (p = 0.83 and p = 0.30, respectively) and endoscopic remission (p = 0.22 and p = 0.48). wPCDAI resulted significantly correlated with 1-year SES-CD (r = 0.38, p = 0.01). The concordance between wPCDAI and SES-CD was excellent and good for severe disease and remission (kohen 0.87 and 0.76), moderate and absent for mild and moderate disease, respectively.

**Conclusion:** Based on our results, 14-week post induction wPCDAI and CRP are not predictors of 1-year sustained steroid-free clinical and endoscopic remission under IFX. Continuous wPCDAI should be obtained in good correlation with SES-CD, particularly for patients in remission and with severe disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**PI078 THALIDOMIDE FOR THE TREATMENT OF REFRACTORY GASTROINTESTINAL BLEEDING CAUSED BY ANGIODYSPASIAS**

X. Wang1, Q. Wang2, H. Huang3, W. Lu4

1Gastroenterology Department, The First People’s Hospital, Hangzhou/China
2Gastroenterology, The First People’s Hospital, Hangzhou/China
3Department, Institute name, Hangzhou/China

**Contact E-mail Address:** 15968807972@163.com

**Introduction:** Gastrointestinal angiodysplasia, either inherited or acquired, is an important and challenging cause of acute gastrointestinal haemorrhage, particularly in the elderly, sometimes refractory to treatment. Although multiple treatment modalities, both medical and surgical, are being used, there is no established medical treatment available for these patients. Thalidomide is a potent inhibitor of angiogenesis in experimental models. As angiodysplasias are a result of unregulated vessel growth, antiangiogenic treatment may inhibit growth of angiodysplasias. But its benefits and risks nevertheless remain unclear.

**Aims & Methods:** This retrospective study evaluates the efficacy, safety, and side-effect of thalidomide in the treatment of patients with refractory gastrointestinal bleeding from angiodysplasias. Patients with recent gastrointestinal bleeding of angiodysplasia who were from Hangzhou First people’s Hospital from October 2012 to July 2015 were collected for this open and nonrandomized study. Thalidomide was started with 50 mg/day and then increased incrementally by 100 mg/day, if tolerated, and continued for 6 months. Adverse events, hemoglobin, blood chemistry, the changes of coagulation and blood transfusion were monitored during the treatment and for 6-months post-treatment.
Results: Twenty-one patients with chronic refractory angiodyplasia bleeding were recruited in this study, included 10 women, aged between 40-85;11 cases of male, aged between 31–70. One patient with colic vascular malformation died of massive hemorrhage due to self withdrawal. Among the remaining 20 patients who were given thalidomide regularly for 6 months. (1) Eight patients come across constipation, sleepiness and dry mouth. There were no skin rashes, peripheral neuropathy and any other adverse reactions during the treatment. All side-effects resolved when thalidomide was discontinued. (2) The red blood cell after treatment (3.76 ± 0.06 x 10^12/L), hemoglobin after treatment (94.7 ± 13.1 g/L) compared with before treatment (83.2 ± 17.6 g/L); HCT after treatment (32.0 ± 0.05) compared with before treatment (0.29 ± 0.06); the difference was statistically significance (P < 0.05; 3). The ALT after treatment (12.9 ± 18.5 U/L) compared with before treatment (30.6 ± 12.8 U/L); AST after treatment (28.1 ± 8.56 U/L) compared with before (28.0 ± 12.4 U/L); γ-GT after treatment (34.4 ± 8.4 U/L) compared with before (35.6 ± 12.7 U/L); AKP after treatment (85.3 ± 19.8 U/L) compared with before (83.0 ± 20.8 U/L); ALB after treatment (36.2 ± 3.1 g/L) compared with before (36.3 ± 4.3 g/L); there was no statistically significant difference (P > 0.05). (4). Prothrombin time (PT) after treatment (12.1 ± 1.3s) compared with before (11.8 ± 1.4s); APTT after treatment (30.2 ± 3.7 s), compared with before (31.0 ± 6.2s); the difference was not statistically significant (P > 0.05). (5). 6 cases of colonic capillary malformation review colonoscopy, and the vascular malformation improved significantly after treatment.

Conclusion: Thalidomide, with its antiangiogenic mechanism of action, seems to be a promising drug in bleeding angiodyplasia as a treatment option for patients unable to benefit from other available modalities of treatment, the study drug waswell tolerated.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: Repeated FIT screening might be more efficient to detect benign polyps, smaller CRCs, and CRCs of intra-mucosal Dukes A. We will go on researching CRC's locations about screening history.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1082 COLORECTAL CANCERS (CRCs) DEPENDING ON THE SCREENING INTERVAL IN IBARAKI, JAPAN

Y. Saitoh1, H. H. Suzuki2, I. Hyodo3
1Dept. Of Gastroenterology, Ibaraki Medical Center, Ibaraki/Japan
2University of Tsukuba, Ibaraki/Japan
3Gastroenterology, University of Tsukuba, Ibaraki/Japan

Contact E-mail Address: saitoitoyo@yahoo.co.jp

Introduction: In Japan, CRC screening was launched as a national policy for all people aged over 40 years in 1992. 2-day FIT has been widely accepted, and has been recommended performing in every year. It is demanded that CRC screening is performed effectively depending on the capacity of colonoscopies. We will show so much data on fecal hemoglobin concentration (referred as concentration) and progress of colorectal cancer among them.

Aims & Methods: The aim of this study is to analyze the concentration of FIT for colorectal cancers (CRCs) from the screening. The cut off value is adapted 20 μg Hb/g stool and the rate of further examination is around 75% for many years. In Ibaraki prefecture, CRCs were detected 3,421 cases from the screening (2000-2014) with 2-day FIT. The concentration of FIT was grouped in 20–80, 80–140, 140–200 and over 200 μg Hb/g stool. Screening have been performed with the OC-SENSOR DIANA (EIKEN, JAPAN) automated analyzer. CRCs were analyzed with age group (40-49, 50-59, 60-69, 70 year-old), size (1-24, 25-49, over 50 mm), location (proximal, distal), Dukes’ classification (Dukes A, A-invasive, B, C, D) depending on the concentration. The chi-squared test was used to compare of each group.

Results: There were no differences in gender and age group for concentration. The concentration of CRCs in the distal colon was significantly higher in the proximal colon [distal 39% (861/2,200) and proximal 32% (337/1,053) with over 200 μg Hb/g stool]. The concentration of CRCs with larger size was significantly higher than smaller size [1–24 mm 27% (533/1,961), 25–49 mm 54% (439/818) and over 50 mm 64% (169/263) with over 200 μg Hb/g stool]. The concentration of invasive CRCs was significantly higher than intra-mucosal CRCs [intra-mucosal 23% (370/1,617) and invasive 50% (888/1,793) with over 200 μg Hb/g stool]. The concentration of Dukes B, C and D were significantly higher than Dukes A except for intra-mucosal. There was no difference between Dukes B and D [Dukes A except for intra-mucosal 36% (325/910), B 68% (247/363), C 60% (232/385) and D 69% (61/89) with over 200 μg Hb/g stool].

Concentration: In 20–80 μg Hb/g stool, there were CRCs with smaller size, no invasion, in the proximal colon, Dukes A except for intra-mucosal CRCs and so on. When the cut off value is raised over 80 μg Hb/g stool, the detection of early stage CRCs and proximal CRCs may be lost. There were many advanced CRCs with concentration over 200 μg Hb/g stool. Therefore, when the participants, who are positive with high concentration of FIT, need to take a further examination as soon as possible. Why concentration of CRCs in the distal colon are higher than in the proximal colon? It may be related to the fact that the number of detectable CRCs in the distal colon are more than in the distal colon. We will go on researching mechanism about this.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Hodgkin lymphoma (HL) survivors treated with abdominal radiotherapy and/or alkylating chemotherapy have an increased risk of colorectal cancer. This study evaluated the prevalence of colorectal neoplasia in HL survivors.

Aims & Methods: The primary aim of this multicenter cohort study was to assess the diagnostic yield of advanced colorectal neoplasia detected by a first surveillance colonoscopy among HL survivors treated with abdominal radiotherapy and/or procabazine. Advanced colorectal neoplasia was defined as an advanced adenoma (high-grade dysplasia, ≥25% villous component, or ≥10 mm diameter), an advanced serrated lesion (dysplasia or ≥10 mm diameter), or CRC. Results were compared with that of a Dutch general population cohort that underwent a primary screening colonoscopy (n = 1276 asymptomatic individuals between 50–75 years of age). This study demonstrates the results of a predefined interim analysis.

RESULTS: A colonoscopy was performed in 101 HL survivors, who were significantly younger than general population controls (median 51 years (interquartile range 45–57) vs. 60 years (interquartile range 55–65), p < 0.001). A mean of 3.5 neoplastic lesions was detected per HL survivor (standard deviation 4.9) vs. 1.1 per control (standard deviation 1.8, p < 0.001). Despite their young age, the prevalence of advanced neoplasia was higher in HL survivors than in controls (25% (95% confidence interval 16–33%) vs. 12% (95% CI 8–21%), p = 0.001). Advanced adenomas were detected in 14% (95% CI 10–20%) of HL survivors and 9% (95% CI 6–14%) of controls (p = 0.001). The prevalence of advanced adenomas was higher in HL survivors than in controls (12% (6–18%) vs. 4% (25% (95% confidence interval 16–33%) vs. 12% (95% CI 8–21%), p < 0.001). Serrated polyposis syndrome was present in 6% (2–11%) of HL survivors and 3% (0–7%) of controls (p = 0.001).

Conclusion: HL survivors treated with abdominal radiotherapy and/or procabazine have a high prevalence of advanced colorectal neoplasia. Colonoscopy surveillance should therefore be implemented as standard of care.

Aims & Methods: We aim to investigate the incidence of prostate cancer as a second primary malignancy among patients with prior primary colorectal cancer (CRC) using a nationwide population-based dataset. This study is a nationwide population-based retrospective cohort study. We followed up with patients registered in the Republic of Korea National Health Insurance Corporation who were diagnosed with colorectal cancer between 2007 and 2014 and investigated the incidence of prostate cancer (one year lag period). The incidence of prostate cancer was also evaluated in age and gender-matched controls using a cohort of patients diagnosed with colorectal cancer during the same period. The incidence rate was defined as the number of newly diagnosed prostate cancer patients per 1000 person-years. To assess the role of detection bias-related to the follow-up of CRC, follow-up started at the date of CRC diagnosis and continued until the earliest date of prostate cancer diagnosis, death, loss to follow-up, or the 2015 year-end. We used Cox proportional hazards models to identify prostate cancer occurrences among CRC patients. We also performed the multivariable analysis. Multivariable models included the variables of age, sex, body mass index, hypertension, diabetes mellitus, dyslipidemia, and income.

Results: We analyzed a total of 85,462 first primary CRC survivors. During the follow-up period of 494,222 person-years, 2005 (2.3%) developed prostate cancer (incidence rate 4.06/1,000 person-years). The median duration of follow-up was 5.78 years. Compared with the general population, CRC patients had a significantly increased risk of prostate cancer (HR = 2.30, 95% CI = 2.182–2.426; P < 0.001). Multivariable analysis (including age, sex, body mass index, hypertension, diabetes mellitus, dyslipidemia, and income) showed that age < 55 years (HR = 20.85, 95% CI = 11.88–36.59; P < 0.001) is a significant independent predictor of prostate cancer.

Conclusion: Men who develop colorectal cancer are at an increased risk of prostate cancer, with the greatest risk in men under the age of 55. This data suggests that CRC patients under 55 years old require regular screening for prostate cancer.

Introduction: Colorectal cancer is one of the most common cancers diagnosed worldwide, and prostate cancer is also the most common malignancy in men and a major cause of cancer deaths. Both colorectal cancer and prostate cancer also tend to occur more frequently in developed countries. There have been several reports on the association between colorectal cancer and prostate cancer, but the conclusions are inconsistent.

Aims & Methods: We aim to investigate the incidence of prostate cancer as a second primary malignancy among patients with prior primary colorectal cancer (CRC) using a nationwide population-based dataset. This study is a nationwide population-based retrospective cohort study. We followed up with patients
diagnosed in stage I or II. As those patients will have better survival rates, it is expected that screening will decrease CRC mortality rates.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction:

CRC screening is of great importance for prevention of CRC. Routine screening for LS by immunohistochemical staining (IHC) in CRC patients is expected to have LS. We aimed to assess the diagnostic yield of IHC for LS in patients with advanced and multiple adenomas.

Aims & Methods: We included participants of the national CRC screening program, referred to our center after a positive FIT from December 2013 to December 2016. IHC for MLH1, MSH2, MSH6 and PMS2 protein was performed on advanced adenomas and CRCs found at colonoscopy. Adenomas were considered advanced if they had a villous component, high-grade dysplasia or were ≥10 mm in size. Also, in cases with ≥2 non-advanced adenomas, IHC was performed on the largest adenoma. MLH1 hypermethylation analysis was performed to distinguish sporadic from LS-related CRC. For all patients the germline mutation status for LS was assessed. Patients with IHC suspect for LS were offered germline mutation analysis. If no pathogenic mutation was found, we performed somatic mutation analysis.

Results: A total of 1006 patients (54% male; mean age of 67 years (±6 years)) with positive FIT were included in the study. At colonoscopy, 335 (33%) patients (63% male; mean age of 67 years (±6 years)) had a CRC and/or adenoma eligible for IHC. A total of 322 adenoma patients were analyzed. None had aberrant IHC. Of the examined adenomas, 151 (47%) had a villous component and (or) high grade dysplasia (132 (41%) with villous component and 37 (11%) with high grade dysplasia). Out of 48 CRC patients, 7 (15%) showed loss of protein expression. All seven cases had loss of MLH1 and PMS2 protein. Five cases had MLH1 promoter hypermethylation. The two patients without MLH1 promoter hypermethylation were referred for genetic counselling. Both patients had no family history suspect for LS. In both cases no germline MLH1 mutation was found and somatic mutation analysis showed that both had a likely sporadic tumor.

Conclusion: Our results indicate that routine LS screening by IHC and MLH1 hypermethylation in patients with advanced and multiple adenoma within a national FIT-based screening CRC program is not an effective strategy. The diagnostic yield of LS screening in young adenoma patients should be assessed. Also, our results imply that MLH1 promoter hypermethylation may be a late event in oncogenesis, since none of the adenomas had aberrant IHC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Study findings confirmed that CRC screening was effective in reducing the number of oncological surgical oncology procedures particularly with regard to the distal colon and rectum. Data analysis showed that the screening seemed to accelerate reaching the peak rate in surgical procedures that took place in 2007. After that time point the number of operations began to fall as far as the distal colon was concerned (it fell by 37.3%). Finally our data suggest that the real benefit in reduction of oncological surgery procedures is due to the first screening colonoscopy.

Introduction: The NHS bowel scope screening programme was introduced in 2013 when initially adults aged 55 invited for a ‘one-off’ flexible sigmoidoscopy followed by a colonoscopy if significant adenomas are detected. University Hospitals of Leicester Bowel Cancer Screening Centre serves an ethnically diverse community with approximately 25% of the population eligible for sigmoidoscopy screening being British Asian Indians and 45% being British Whites. Within the faecal occult blood based bowel cancer screening programme we have previously reported a lower polyp detection rate and adenoma detection rate (ADR) in British Asians undergoing colonoscopy compared to White British2. This study aims to evaluate PDR, ADR and cancer detection (CDR) detection rate (ADR) in Asians undergoing colonoscopy compared to White British. This study aims to evaluate PDR, ADR and cancer detection (CDR) in British Asian Indians taking part in the bowel scope screening programme.

Aims & Methods: Patients who underwent screening sigmoidoscopy between February 1st, 2015 and Feb 2017 were included. All individuals participating in screening sigmoidoscopy routinely report their self-selected ethnic origin. This database was cross referenced with the endoscopic and histology findings from the ‘Exeter’ online database. The findings in British Asian Indians were compared with British Whites.

Results: A total of 4287 patients underwent screening sigmoidoscopy over the 2-year period. 1169 individuals had polyps (500 adenomas). Overall polyp detection rate (PDR) was 30.8% (95% CI 26.7–34.9%), adenoma detection rate (ADR) was 12.0% (95% CI 10.1–12.4%) and other polyps were 14/4287 (0.3%) (Inflammatory polyps 13, Juvenile polyp 1). Cancer detection rate was 6/4287 (0.3%). SSA/Ps were 134 (3.1%), hyperplastic polyps were 642/4287 (15%), sessile serrated polyps were 1456/4287 (34%).

Conclusion: This study found no cancers and significantly lower PDR and ADR in British Asian Indians compared to British White participants in the bowel scope screening programme. Further long term evaluation of these differences is needed and may shed light on factors contributing to the development of bowel cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1091 DEAD BOX POLYPEPTIDE 27 PROMOTES TUMORIGENICITY IN COLORECTAL CANCER THROUGH ACTIVATING NF-KAPPA B PATHWAY AND ITS EXPRESSION IS ASSOCIATED WITH POOR SURVIVAL IN PATIENTS

H. Chen1, J. Tang2, C.C. Wong1, J. Fang3, J.J.Y. Sung1, J. Yu6

2Division Of Gastroenterology And Hepatology, Shanghai Institute Of Digestive Disease, Ren Ji Hospital, Shanghai Jiao Tong University, Shanghai/China

Introduction: We identified for the first time that DDX27 (Dead box polypeptide 27) gene was amplified in colorectal cancer (CRC) by whole genome sequencing. Amplification of DDX27 was detected in 47% (47/100) of primary CRC tumors and positively correlated with its mRNA overexpression. DDX27 plays a pivotal oncogenic role in colorectal carcinogenesis by promoting cell proliferation and inhibiting apoptosis. In this study, we investigate its function, mechanism of action and clinical implication in CRC.

Aims & Methods: Downstream effectors and pathways of DDX27 were identified by promoter luciferase reporter assay, RT2 Profiler PCR array and western blot. The interacting partners of DDX27 were screened by BioID method and further validated using immunoprecipitation assay and immunofluorescence staining method. Clinical implication of DDX27 was assessed in two human CRC cohorts by quantitative PCR method and immunohistochemical staining of tissue microarrays.

Results: Promoter luciferase reporter assays revealed that DDX27 mainly activated nuclear factor kappa B (NF-kB) pathway in CRC cell lines (HCT116 and SW480). Ecotypic expression of DDX27 promoted transcription of NF-kB signaling targets including BCL2A1, BIRC3, CCL20, CXCL13, NFkB1A, TNF and TNFAIP3. Conversely, silencing of DDX27 showed an opposite effect on NF-kB signaling. Treatment of NF-kB inhibitors CAPE and JSH-23 abrogated the promoting effect of DDX27 on CRC cell growth. We revealed that DDX27 enhanced and prolonged NF-kB signaling via reducing the accumulation of nuclear IkBα, which negatively regulates transcriptional activities of NF-kB and transport NF-kB proteins back to the cytoplasm. DDX27 overexpression markedly increased the recruitment of NF-kB p65 inside nuclear and promoted NF-kB activity in CRC cells under TNF-α stimulation. NPM1 was identified as a potential binding partner of DDX27 by BioID method to screen for protein-protein interactions. The interaction of NPM1 and DDX27 inside nucleus was further validated by endogenous immunoprecipitation assay and immunofluorescence staining. Knockdown of NPM1 abrogated DDX27-activating NF-kB signaling, as well as its tumor-promoting function. Kaplan-Meier curves showed that higher DDX27 expression was significantly associated with shorter survival in patients with CRC of two independent cohorts (N=199 for Beijing cohort using quantitative PCR method, and N=275 for Shanghai cohort using immunohistochemical staining of tissue microarrays; both P<0.05).

Conclusion: DDX27 plays an important oncogenic role in promoting CRC tumorigenesis via activation of NF-kB pathway. Higher expression of DDX27 is correlated with poor prognosis in CRC patients.

P1092 CLINICOPATHOLOGICAL STUDY OF SERRATED LESIONS OF THE COLORECTUM

M. Sugimura1, M. Iwabuchi2, K. Ukai3
Gastroenterology, Sendai Medical Center Dept. of Gastroenterology, Sendai/Japan

Contact E-mail Address: msugimura@snh.go.jp

Introduction: Serrated lesions of the colorectum are the precursors of microsatellite unstable carcinomas. However, their clinical and pathological features are not clear and need further exploration and study.

Aims & Methods: The aims of this study was to clarify the clinicopathological features of colorectal serrated lesions. We reviewed clinical charts and pathology files of 5352 endoscopically resected specimens performed during January 2007 and December 2016 in our hospital. A total of 463 serrated lesions (8.7%) were resected and classified into three categories: HP (hyperplastic poly), SSA/P (sessile serrated adenoma/polyp), and TSA (traditional serrated adenoma), according to the WHO criteria. We examined the features of these cases and evaluated the morphologic characteristics by using immunohistochemical staining for Ki-67 and the expression of MUCs (MUC2, MUC5AC and MUC6) in differentiating serrated lesions.

Results: Of these 463 lesions, a total of 241 (52.1%) were HP, 102 (22.0%) SSA/P, and 120 (25.9%) TSA. Male to female ratio (M/F) was 2.38 for HP, 0.98 for SSA/P, and 2.45 for TSA. Mean size of SSA/Ps (13.1 mm) and TSAs (10.4 mm) were significantly larger than that of HP (8.1 mm) (p<0.005, respectively). SSA/Ps were located predominantly in the proximal colon, whereas HP and TSA were mainly located in the sigmoid colon and rectum. 84% of SSA/Ps were flat in macroscopic appearance. SSA/Ps and HPs were whitish or almost the same as adjacent mucosa in color, whereas TSAs had a tendency to be reddish. Magnified colonoscopy showed Type II open pit pattern as characteristic of SSA/Ps, whereas pinecone-shaped pit pattern as that of TSAs. Incidences of concomitant carcinomas in HP, SSA/P, and TSA were 0% (0 out of 241), 2.9% (3 out of 102), and 4.2% (5 out of 120), respectively. Ki-67 positive cells in HP showed regular, symmetric distribution, and those in SSA/P did different staining patterns. Cell nuclei of those cells in TSA distributed in foamy-like ectopic crypts. Expression levels of MUC2, MUC5AC and MUC6 were

Introduction: It is generally accepted that exosomes, small, membrane-bounded vesicles are formed in multivesicular bodies (MVBs) which fuse with plasma membrane resulting in the release of individual exosomes into the extracellular space. Recently, sporadic in vitro observations of a novel, unconventional mechanism have been reported in which the exosome-like vesicles remain in one block during their secretion.

Aims & Methods: Our aim was to examine this phenomenon in migrating colorectal cancer (CRC) cells in situ. Immunohistochemistry (IHC) examination of migrating, individual cancer cells was performed in surgically removed, metastatic CRC samples (n = 6). We used epithelial specific cytoplasmic/ cytokeleton (CK) and cell membrane (E-cadherin) markers for the identification of migrating CRC cells as well as ALIX and CD63 proteins for the detection of exosomal transport. Samples were analyzed with confocal and stimulated emission depletion (STED) microscopy-based 3D reconstructions.

Results: 3D reconstructions showed ALIX-positive and CD63-positive exosome clusters (ECs) with 0.62 to 1.94 μm diameter (mean ± SD: 1.17 ± 0.34 μm) localized partially inside, and/or outside the cytoplasm in 85.96% (n = 51/60) of migrating CRC cells. E-cadherin HIC showed that ECs were not only captured during their exit from the cytoplasm and localized among plasma membrane proteins, but they were also detected extracellularly, in the plasma membrane-stroma interface. STEM-microscopic images showed that released ECs were composed smaller, distinguishable ALIX-positive spheroids of 98 ± 150 nm diameter (mean ± SD: 128.96 ± 16.73 nm), which fall into the size ranges of exosomes.

Conclusion: Our study demonstrates in situ for the first time that besides conventional exosome release, migrating CRC cells also secrete large, extracellular ECs. These structures might fundamentally contribute to the autocrine/paracrine regulation of cancer development, which effect may differ from that mediated by conventional secreted exosomes.

Introduction: The semi-essential amino acid arginine is important for intestinal epithelial proliferation and is an essential dietary component delivered by solid food. In homeostatic proliferating adult intestinal enterocytes arginine is catabolized, by the enzyme arginase 2. During embryonic development, the demand for arginine increases, due to rapid growth. Arginine is lacking from maternal milk in premature newborns which has to be synthesized de novo to sustain epithelial expansion in the rapidly growing intestinal tube. Neonatal enterocytes are capable of de novo synthesis of arginine from citrulline. The rate-limiting enzyme in this process is argininosuccinate synthetase 1 (ASS1). Similarly to postnatal development, hyperploriferative epithelium is a hallmark of tumorigenesis and wound healing.

Aims & Methods: The aim of this study is, to investigate, whether de novo arginine synthesis via ASS1 plays a role in intestinal carcinogenesis and repair. We performed immunohistochemistry on intestines from APCmin/+ mice, and in vitro studies with colon cancer cell lines. We examined whether either upregulation or downregulation of tumor suppressor genes following arginine deprivation further correlates with resistance against arginine deprivation. In APC−/− organoids generated from the APC−/− genotype, ASS1 RNA and protein are highly expressed, with concomitant increase of intracellular arginine. Upon knockdown of ASS1 in an APC−/− organoid model, protein synthesis is significantly increased and organoid growth is compromised. Furthermore, knockdown of ASS1 decreases overall protein synthesis. Conclusion: Decreased synthesis of Arginase in adenomas and hyperproliferative crypts during epithelial repair after mechanical wounding and irradiation wounds, compared to homeostasis. Variable expression of ASS1 is seen in different metastatic cancer cell lines, and expression correlates with resistance against arginine deprivation. In APC−/− organoids generated from the APC−/− genotype, ASS1 RNA and protein are highly expressed, with concomitant increase of intracellular arginine. Upon knockdown of ASS1 in an APC−/− organoid model, protein synthesis is significantly increased and organoid growth is compromised. Furthermore, knockdown of ASS1 decreases overall protein synthesis. Conclusion: A dysregulated network of arginine metabolism may be a potential regulator of resistance to growth factor deprivation in colonic adenoma/carcinoma cells.

Introduction: Less than a hundred polyps defines attenuated familial adenoma- tous polyposis (AFAP). APC or MUTYH involvement has been described in 60% of the cases. The natural history of AFAP without identified genetic defects is not enough evaluated. In our study we compare clinical and endoscopic features of polyposis in patients carrying APC or MUTYH mutation and wild type patients.

Aims & Methods: 102 cases (35 F, 67 M; mean age 51; range 28–78) of AFAPs were registered at our Institution between 1996 and 2014. They had no cancer family history and presented more than 10 adenomas at index colonoscopy. Genetic testing for APC and MUTYH genes was performed. Patients were put in a program, after having cleaned the colon, consisting in colonoscopy after one year and then the colonoscopic interval was based on the number of polyps from 1 to 3 years. Odds Ratio test was used to compare APC or MUTYH mutated and wild-type patients.

Results: Out of 102 patients with AFAP we identified a genetic defect in 36 patients (35.3%; 12 with APC and 24 MUTYH) and 66 (64.7%) were wild-type. The mean endoscopic follow up was 10 years (2–31) in the mutated group and 9.7 years (2–23) in the wild-type group. Table 1 describes endoscopic and clinical features between the two groups. We observed some statistically differences between groups: the mutated group was younger than 50 years of age with a higher number of polyps, right colon was mainly involved and endo- scopic follow-up was mostly every year. Patients of wild-type group never under- went to colectomy during follow-up and they displayed few adenoma recurrences in 24% of cases. On the other hand 14% of mutated patients underwent colectomy for dense polyposis and 28% had more polyps than at index colonoscopy and 11% no polyps at all. These 11% displayed mutation in MUTYH.

Conclusion: We observed a different behavior between mutated and wild-type patients. Patients with genetic involvement still developed adenomas during the follow-up and some needed colectomy. Instead, wild-type patients had mostly no recurrence. Constitutional genetic background could be suspected in wild-type patients when a continuous development of new polyps has observed and further genetic investigation should be offered by multi-gene testing.

Disclosure of Interest: All authors have declared no conflicts of interest.

(continued)
Extracellular microRNAs are stable and their expression is less characterized in plasma. Altered and overlapped mRNA profiles between tissue and plasma are less explored.

**Aims & Methods:** The present study was designed to characterize the tissue and circulating microRNA profile through colorectal adenoma-carcinoma sequence in human colorectal cancer (CRC) in peripheral blood samples. Furthermore, the purpose of our study was to determine the origin of detected microRNAs in tumor-adherent C38/C37BL/6 and non-adherent CBAJ mice tumor models. To achieve that goal, human peripheral blood and biopsy of normal (N), tubular (AT), transitional (TV) and colorectal (CRC) whole blood plasma were also collected two times a week over 45 days from C37BL/6-C38, CBAJ mice. MicroRNAs were isolated and Affymetrix GeneChip microRNA array analysis was performed for screening of the altered microRNA profile. RT-qPCR method was performed for confirmation.

**Results:** In the case of human samples up to 173 detectable microRNAs, 306 microRNAs were expressed in normal, 334 in adenoma and 321 in CRC. Characteristic microRNA expression alteration was observed in the comparison of Ad-N and CRC-N, expressed differentially stable expression (388 p < 0.05) in plasma. In the case of N vs. CRC, overexpression of miR-612, miR-1296, miR-933, miR-937 and miR-1207 was validated by RT-PCR (p < 0.05). Partial co-expression of these microRNAs was observed in tissue as well as in CRC. We identified high plasma levels of 94 microRNAs in miR-126 in CRC samples. In CRC samples, CBAJ-C38 mice model experiment where the injected tumorous cells could not adhere miR-676 found to be a host originated while miR-92a was a tumour-derived miRNA. MiR-676 and miR-92a showed significant overexpression (388x and 37x p < 0.05) in plasma samples based on real-time PCR and microarray results.

**Conclusion:** Circulating microRNAs alteration could observe in animal models and in patients. Cancer-associated microRNAs in the circulation may originate from the immunologic system or from other metastatic regions far from the primary tumor location.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1099 RHOA: THE KEY SIGNALING PATHWAY OF MICRORNA-126 IN SUPPRESSING THE EPITHELIAL-MESENCHYMAL TRANSITION, PROLIFERATION, MIGRATION AND INVASION OF COLORECTAL CANCER CELLS**

M. Huang, W. Yuan, S. Wu, Z. Shen, Z. Yang, Y. Quan, C. Zhu, K. Tang, X. Wang
Department Of Gastroenterology, The Third Xiangya Hospital Of Central South University, Changsha, Hunan, China, Hunan Key Laboratory of Nonresolving Inflammation and Cancer, Changsha, Hunan, China, Changsha/China

**Contact E-mail Address:** hmy02420@126.com

**Introduction:** The mechanism of colorectal cancer (CRC) invasion and metastasis is still unclear. Epithelial-mesenchymal transition (EMT) is one of the key molecular steps in the process of distant metastasis. EMT is referred to conversion of cells with an epithelial phenotype into cells with a mesenchymal phenotype, which is essential in the process of cancer invasion and metastasis. EMT is referred to conversion of cells with an epithelial phenotype into cells with a mesenchymal phenotype, which leads to loss of cell polarity, with acquisition of migratory and invasive properties and is a key step in cancer progression.1,2 MicroRNAs (miRNAs) (miR-126) are small (20–22 nucleotides) that negatively regulate gene expression at post-transcriptional phase. MicroRNA-126 (miR-126) originates from a common precursor structure located within the egfl7 gene, which acts as a tumor suppressive miRNA in various cancer tissues.3 We previously demonstrated that microRNA-126 is significantly down-regulated in human CRC tissues and negatively related with patient’s prognosis.4 MiR-126 was also low-expressed in high metastatic cell lines, and inhibited proliferation, invasion and metastasis of CRC in vitro.5 However, whether miR-126 can regulate the process of EMT in CRC is still unclear. Ras homologue A (RhoA) is one of the most characterized members of Rho GTPases that regulate cell behavior. Ras homologue A (RhoA) is one of the most characterized members of Rho GTPases that regulate cell behavior. Sixty percent of the human genes have been shown to be involved in cell migration.6 Our previous study found that miR-126 down-regulated RhoA and ROCK activity in CRC cells.7 Whether RhoA activity and RhoA signaling pathway play an important role in miR-126 regulating EMT process, cell proliferation, migration and invasion of CRC remains unclear.

**Aims & Methods:** To identify RhoA signaling pathway associated with the function of microRNA-126 in colorectal cancer (CRC) cells, we employed microRNA-126 over-expression and knockdown. Performed MTT, colony formation, wound-healing, migration, invasion assays and RT PCR, western blot analysis to study the functions of miR-126 in CRC. Cell proliferation, migration, invasion and expression RhoA signaling pathway of CRC cells. Constructed pDsRed2-V14RhoA (constitutively active RhoA, V14RhoA) and pDsRed2-N19RhoA (dominant-negative, N19RhoA) mutants, performed MTT, colony formation, wound-healing, migration, invasion assays and RT PCR and western blot analysis to study the functions of miR-126 in CRC. Cell proliferation, migration, invasion and expression RhoA signaling pathway of CRC cells. Constructed pDsRed2-V14RhoA (constitutively active RhoA, V14RhoA) and pDsRed2-N19RhoA (dominant-negative, N19RhoA) mutants, performed knockdown and over-expression assays of miR-126 in CRC. Cell proliferation, migration and invasion in miR-126 over-expressing HCT116 cells. Conversely, N19RhoA mutant effectively decreased the activity of RhoA and suppressed EMT, proliferation, migration and invasion in miR-126 silenced SW480 cells.

**Conclusion:** RhoA signaling pathway was the key signaling pathway of miR-126 in suppressing the EMT, proliferation, migration and invasion of CRC cells.

Introduction: Colorectal carcinoma is one of the leading causes of cancer-related mortality worldwide. Tumor associated macrophages (TAMs) are criticalstromal components intimately involved with the progression, invasion, and metastasis of cancer cells. Recently, increasing studies have demonstrated that microRNA-126 (miR-126) had an important role in colorectal cancer. The expression of miR-126 was decreased significantly in colorectal cancer, particularly in highly metastatic cell lines, indicating that miR-126 may inhibit tumor development and metastasis. However, the mechanism underlying miR126 inhibiting cancer is uncertain, and its function in cross-talk between colorectal cancer cells and TAMs is still in its infancy.

Aims & Methods: In this study, we investigated the cross-talk between cancer cells and TAMs in colorectal cancer microenvironment, and find out what role the miR-126-CXCL12/IL6 axis plays in it. Methods: (1) The effect of miR-126 on CXCL12 expression was assessed in the CRC cell line Caco2 transferred with a miR-126 mimic or inhibitor to increase or decrease miR-126 expression; (2) We build a co-culture system of TAMs and transferred cancer cells, and use AMD3100 to block CXCL12/CXCR4 axis, then detect the recruitment and inflammation factors secretion of TAMs; (3) Furthermore, the TAMs co-cultured before were taken away from the previous system and put into a new co-culture system with untreated colorectal cancer cells, and IL6 neutralizing antibodies were used to trap it. We detect the expression of EMT associated factors and STAT3 pathway activation by western blot, cell growth by CCK8, metastasis by Transwell. The definition of statistical significance was defined as P < 0.05 (two-tailed).

Results: (1) miR-126 negatively regulate CXCL12 expression in post-transcript level; (2) Inhibiting miR-126 of colorectal cancer cells could promote TAMs recruitment and upregulate inflammation factors IL1β and IL6 expression. However, blocking CXCL12/CXCR4 axis by AMD3100 could reverse this effect; (3) Inhibiting miR-126 of colorectal cancer cells could recruiting TAMs, therefore down-regulate-Ecadherin protein, upregulate-slug protein, and activate STAT3 pathway of untreated cancer cells. It could also promote cancer cells growth and metastasis. In addition, IL6 neutralizing antibodies could be used to control this effect; (4) In vitrulo, we found that miR-126 could promote cancer cells growth and migration.

Conclusion: Our results reveal a novel mechanism by that miR-126 repress recruitment and inflammatory factor secretion of TAMs through controlling secretion and paracrine signaling of CXCL12 to inhibit colorectal cancer growth and metastasis.

Introduction: The National Health Service Bowel Cancer Screening Programme (NHS BCSP) offers colonoscopy to people testing positive for Faecal Occult Blood Test (FOBT) after the age of 60. In addition, the ‘Bowel scope screening’ test offers once-only flexible sigmoidoscopy (FS) to people in the UK after the age of 55. The Norwegian (NORCAP) and Italian (SCORE) trials evaluated the effectiveness of FS screening and reported a non-statistically significant decrease in colorectal cancer (CRC) specific mortality at follow-up. It is unclear if significant proximal neoplasia is being missed in people undergoing flexible sigmoidoscopy alone.

Aims & Methods: We aim to investigate the distributions of pathology within the BCS! at a busy district general hospital in London. In 2015, 22,539 FOBT kits were returned out of the 43,884 (51.4%) sent out in the boroughs of Barking, Havering and Redbridge (BHR). Of those returned, 398 (1.8%) tested positive. We collected data for the 326 patients who attended for colonoscopy at BHR University Hospitals (81.9%). Subgroup analyses included age, sex, histology, location of polyps, number of polyps, polyp size and therapies.

Results: Mean age 67, Male 60.4%. Polyps were found in 199 patients (61%), 488 polyps found in total, mean number of polyps 2.5 (Range 1–14), mean size 7 mm (Range 1 mm–60 mm); 49 (15%) hyperplastic, 156 (47.9%) adenomas and 16 (4.9%) adenocarcinomas. Patients with adenoma/carcinoma were older (67.6 vs. 66.5, p = 0.02) but there was no difference in sex (Male 61.4% vs. 59.4%, p = 0.49) when compared to those without adenoma/carcinoma. Of 172 patients with adenoma/carcinoma, 111 (64.5%) were proximal to the splenic flexure (SF). 5 out of 16 (31.2%) adenocarcinomas were proximal to SF and 2 (40%) of these patients had no polyps distal to the SF.

Conclusion: Patients with adenomas/carcinomas are older and those with proximal adenomas/carcinomas have more polyps but are smaller in size. One in three adenocarcinomas picked up during colonoscopy would be out of reach of a flexible sigmoidoscopy. Furthermore, one over three of the proximal cancers would not have distal polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal cancers have two development theories. One of the development theories is "adenoma-adenocarcinoma sequence" developing from protruded-types "polyps" we know generally. The other is considered to emerge directly from normal epithelium, not through the adenomatous stage. Recently, it is revealed most of this type are depressed-type carcinomas. This theory is called "de novo" pathway. We studied clinicopathological characteristics and long-term prognosis mainly on depressed-type colorectal carcinomas. Aim: To clarify the pathological characteristics of depressed-type colorectal carcinomas compared with flat- and protruded-type.

A total of 2930 colorectal neoplasms excluding advanced carcinomas were resected endoscopically or surgically in our Center from April 2001 to December 2013. Of 1127 IIIC carcinomas. Anatomopathological and molecular analysis, and clinical data were collected from the patients. A total of 50 cancer related genes were analyzed using the Ion PGM sequencer.

Conclusion: Our results demonstrate that degree of ITH of KRAS/TP53 mutations increases during the progression of colorectal carcinomas. Intratumoral variations in the microsurface structure may represent molecular subclones in early colorectal lesions and may be predictive of the malignant progression.

Introduction: Hypoxia signaling has been enhancing to be considered for cancer cell survival, chemoresistance, motility, tumour angiogenesis as well as self-renewal capacity and proliferation of putative cancer stem cells. One of the key player in hypoxia is carbonic anhydrase IX (CAIX) which is a hypoxia-inducible enzyme. CAIX is overexpressed in a variety of cancers including colon cancer and plays a crucial role in maintaining favourable intracellular pH in hypoxia. There is also evidence that extracellular vesicles (EV) production is increased in response to hypoxia and promotes adaptive response of cancer cells and we have previously demonstrated, that CAIX positive EVs secretion is increased in response to hypoxia in colorectal cancers.

Aims & Methods: Within this study, we explored a possibility to use CAIX for the isolation of hypoxic EVs from colorectal cancer (CRC) patients’ plasma. EVs were isolated from plasma samples of 27 CRC patients and 25 healthy donors (HD) by using sequential centrifugation, filtration and size-exclusion chromatography steps. EVs were quantified by Nanoparticle tracking analysis (NTA) and CAIX positive EVs were determined by ApoeeaA50.

Results: Statistically significant increase in the amount and size of EVs was observed in a group of CRC patients compared to HD. Among the 10 CRC patients with synchronous metastasis, CAIX positive EVs was 33.0% in HD and 97.5% in CRC. CAIX positive EV content was increased by 10 fold in CRC patients compared to HD.

Conclusion: There is an increased total EV number, EV size and CAIX positive EV amount in CRC patient plasma compared to HD plasma, that might have diagnostic and prognostic value. (Financed by Latvian Council of Science №05/2014/DK.05/4.1.1./6.2.1.1.-16.1.)

Introduction: Colorectal cancer (CRC) is an important contributor to cancer mortality and morbidity worldwide. 80% of CRCs arise via the adenoma-carcinoma sequence, 10–20% by sessile serrated adenomas (SSAs). Hyperplastic polyps are regarded harmless. Current surveillance strategies for CRC following polypectomy are determined by endoscopic and histopathological factors. Such a distinction has also been challenged. Aims & Methods: The study was aimed for molecular characterization of colonic polyps in patients who underwent screening colonoscopy. Correlation of the genetic analysis with endoscopic, clinical and histopathological data was attempted to potentially better define relevant risk marker or sub-groups at risk for prediction of surveillance intervals. 100 Patients were enrolled in this multicenter study (NCT02595645; Median age: 62.9 y, 50 males, 50 females). Up to 41 BRAF-mutant lesions exhibited ITH of BRAF mutation. Pathological findings of the 4 lesion were low grade adenoma (n = 1), non-invasive CRCs with adenoma (n = 2) and serrated lesions (n = 1), whereas majority of the BRAF-mutant lesions without ITH (n = 37) were serrated lesions or CRC with serrated lesions. Sequencing of 50 cancer-related genes in 8 tumors with KRAS/TP53 ITH revealed that both subcomponents exhibited identical mutations in genes including FBXW7, HRAS and SKT11, suggesting that these were founder mutations.

Results: In 100 patients, 234 polyps were removed. 121 polyps (54.0%) were sized <10 mm, 71 (31.7%) were ≥10 mm. For 32 polyps (14.3%) no size was available. 90 polyps (40.2%) were located in the left, 126 polyps (56.3%) in the right colon, for 8 polyps (3.6%) no location was noted. 112 polyps (50.0%) were adenomas and 110 polyps (49.1%) non-adenomas lesions. No data were available
for 2 polyps (0.9%). Clinical, endoscopic and histopathological data were corre-
lation of the metastatic status of various cancers with endoscopic or histopathological polyp characteristics were observed for BRAF, KRAS, TCF7L2, FBXW7 and CTNNB1 mutations. Multivariate ana-
lyses revealed that polyps > 10 mm have a significant higher relative risk (RR) for harboring oncogenic mutations (RR 3.467 [1.742–6.933]). Adenomas and right-
sided polyps are independent risk factors for CTNNB1 mutations (RR 18.559
(2.371–145.245) and 12.987 (1.637–100.00)).

Conclusion: We were able to show that assessment of the mutational landscape of resected polyps/poly biopsy can easily be integrated in the workflow of current colonoscopy practice. There are distinct genetic patterns related to size and location of polyps and the clinician can appreciate this additional information to better estimate a patient’s individual risk.

P1108 QUANTITY, FRAGMENT LENGTH AND GLOBAL DNA METHYLATION LEVEL ALTERATIONS OF CIRCULATING CF-DNA IN COLORECTAL ADENOMA, CANCER, AND INFLAMMATORY BOWEL DISEASES

E. Markus1, A. Kalmár1, O. Galamb2, K. Szigeti1, B.K. Bartak2, Z.B. Nagy1, B. Wichmann2, Z. Tulassay3, P. Igaz4, B. Molnar4

Introduction: Cell-free DNA (cfDNA) is circulating in human plasma and its amount is different in certain physical conditions. It is well known, that in healthy people the quantity of cfDNA is very low, but it rises in chronic disorders such as cancer. At the same time, very high cfDNA level can be measured in healthy people during physical exercise.

Aims & Methods: We aimed to analyze cfDNA changes (quantity, fragment length, global DNA methylation level) in physiological conditions (during physical exercise), in inflammatory bowel and colorectal diseases. Plasma was separated from 64 patients (16 colorectal carcinomas (CRC), 13 colonic adenomas (AD), 19 inflammatory bowel disease (IBD), and 16 normal (N) donors without evidence of disease). Plasma samples were also collected from 6 healthy athletes, before, during and after physical training. DNA was isolated with Pure Viral Large Volume NA isolation Kit (Roche). cfDNA was quantified with Qubit fluorometry (Invitrogen). CFDNA fragment length distribution was assessed by Bioanalyzer 2100 using High Sensitivity DNA assay (Agilent). Global DNA methylation was analyzed by bisulfite pyrosequencing of long interspersed nuclear element-1 (LINE-1) (Qiagen).

Results: High increase of cfDNA amounts was observed in plasma samples of patients with colorectal adenoma (20.61±10.70 ng/ml), colorectal cancer (24.13±20.02 ng/ml) and IBD (22.27±14.60 ng/ml) compared to healthy sub-
jects (10.33±3.22 ng/ml). High level cfDNA amounts were found in plasma samples of athletes during physical exercise (66.17±29.00 ng/ml), while the cfDNA amount decreased after physical activity (51.87±39.80 ng/ml). Characteristic cfDNA fragment length distribution pattern (with different peak heights at 180 bp, 360 bp, 550 bp) was observed in each patient group. Global DNA hypomethylation was shown in CRC plasma samples with advanced tumor stage (N=3, p<0.001, AD: 79%±1.7%, advanced CRC: 70%±0.03%).

Conclusions: A very high increase of cfDNA and CRC, IBD patients and also in healthy athletes during physical exercise. CIDNA fragment length analysis showed differences between each group. Global DNA hypomethylation was observed only in CRC patients with advanced tumors stage. Based on our results, the above DNA analysis methods might contribute to non-invasive detection for colorectal diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1109 ANALYSIS OF SRFP1, SRFP2, SDC2 AND PRIMA1 PROMOTER METHYLATION IN CELL-FREE PLASMA DNA FOR NON-INVASIVE DETECTION OF COLORECTAL ADENOMA AND CANCER

B.K. Bartak1, A. Kalmár1, B. Péterfia1, A.V. Patai1, O. Galamb2, G. Valcza2, B. Wichmann2, Z.B. Nagy1, E. Markus1, K. Szigeti1, A. Nagy1, Z. Tulassay2, P. Igaz4, B. Molnár4

Introduction: Epigenetic instability, primarily aberrant DNA methylation seems to be a common phenomenon in colorectal cancer (CRC) influencing gene expression and contributing to tumor formation. In recent years, blood-based assays came into focus as potential screening tools for colorectal adenoma and cancer cases, as the analysis of the methylation status of circulating cell-free DNA (cfDNA) in plasma samples provides a good opportunity for cancer detection.

Aims & Methods: Our aim was to analyse the methylation pattern of four selected genes in biopsy and plasma samples of healthy, colorectal adenoma and CRC patients. Moreover, we aimed to examine the effect of methylation alterations on protein expression. MethyLight (ML) PCR was used after bisulfite-conversion to study certain DNA sequences of the promoter regions of SRFP1, SRFP2, SDC2 and PRIMA1 in 32 biopsy-plasma pairs and in 121 additional plasma samples. Methylation sensitivity (95% cutoff) of each marker was determined using variety of sample types including urine, tissue, serum, and feces. However there are only few urinary metabolic biomarkers and especially nuclear magnetic resonance (NMR) spectroscopy, which has several advantages including rela-
tively high degree of reproducibility, easy-to-identify metabolites, high throughput, output, and non-destructive sample treatment, has not been applied to urine samples.

Aims & Methods: In this study, we investigate the differences in urine metabolic profiles of patients with colorectal neoplasia (CRN) including CRC and precancerous lesion, and healthy volunteers using a NMR-based urinary metabolic study. In addition, we evaluate applicability as diagnostic tool of urine metabolomics for early detection of precancerous colorectal lesion with high sensitivity and specificity. Urine metabolomic profiles of patients with colorectal neoplasia in colorectum remains poorly understood and warrants investigation due to its non-invasive sampling method. In the last decade, several metabolomic approaches have been applied toward identifying metabolic alterations in CRC using variety of sample types including urine, tissue, serum, and feces. However there are only few urinary metabolic biomarkers and especially nuclear magnetic resonance (NMR) spectroscopy, which has several advantages including relat-

Introduction: Metabolomics, a dynamic portrait of the metabolic status of living systems, has demonstrated its great potential for use in the diagnosis of various cancers by applying advanced analytic techniques and bioinformatics tools. Recently, very few metabolic markers in CRC have been consistently discovered, but most of the published reports with CRC included only one cancerous lesion in colorectum remains poorly understood and warrants investigation due to its

Results: After patients underwent endoscopic resection or surgical resection for CRC, advanced adenoma has been diagnosed in 36 patients, stage O CRC in 24 patients, stage I CRC in 8 patients, stage II CRC in 7 patients, stage III CRC in 13 patients and stage IV CRC in 4 patients. CEA and CA 19-9 levels for patient with stage I to IV CRC and healthy control were also assessed. Among patients with stage I to IV CRC, CEA and CA 19-9 were incrementally higher in patients with advanced CRC stage O than stage I respectively. The sensitivity and specificity of CEA and CA 19-9 were 6.2% and 99.3%, respectively. The OPLS-DA score plot showed statistically significant discrimination between pre-invasive CRC as well as advanced CRC and normal with a Q2 value of 0.765. The prediction validation study, the sensitivity and specificity for diagnosing pre-invasive CRC was 96.2% and 95%, respectively. The grades of the PLS-DA model showed that area under the curve was 0.823 for taurine, 0.783 for alanine and 0.842 for 3-aminoisobutyrate. In multiple receiver operating characteristics curve analyses, taurine, alanine, and 3-aminoisobutyrate were good discriminator for CRC patients.

Disclosure: NMR-based urine metabolomic profiles significantly and accurately discriminate between patients with pre-invasive CRC as well as with CRC.
advanced CRC, and healthy control with high accuracy. It demonstrates an applicability of urinary ECM metabolomics as screening tool for accurate diagnosis of pre-invasive CRN.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Symptoms alone are poor predictors of underlying colonic pathology. Only 14% of patients referred for colonoscopy from primary care have significant bowel disease (SBD), colorectal cancer (CRC), high risk adenoma (HRA, defined as ≥3 or any ≥1 cm) and inflammatory bowel disease (IBD). We have reported that undetectable faecal haemoglobin (f-Hb), measured by a faecal immunochromatographic test (FIT) is a good rule-out test for SBD. Since December 2015, GPs in Tayside have been encouraged to use FIT test as an adjunct to history, examination and mandatory blood tests in patients referred with bowel symptoms. Referrals are vetted by a Consultant and triaged to test or clinic. We have examined the impact of the introduction of the FIT test on referral rates and colonoscopy yield.

Aims & Methods: Patients in primary care with new bowel symptoms were encouraged to complete a FIT in addition to blood count and renal function check. We prospectively recorded FIT tests received, referrals to secondary care encouraged to complete a FIT in addition to blood count and renal function check. The raw data were extracted by request from the registry of the screening structure (in various areas 75, 77, 91, 92, 94 and 95) covering a target population of 3026366 habitants. Rates of participation were calculated, and after one-year experience period, profiles of individual with positive tests, rates of those with normal colonoscopy, with polyps (all stages combined) or a student t (quantitative variable) and multivariate stepwise analysis was performed for identifying predictive factors for cancer diagnosis.

Results: At the end of the HC-based screening campaigns 2014, 2.5 million individuals were annually invited and the participation rates since 2009, ranged from 28.3% to 24.6%, with females showing higher rates for participation (30.1% to 26.1%) than men (26 to 21.8%, p < 0.0001). During the first (2015) year FIT experience, the O Sensor device was used for 450120 (34% estimated participation rate) individuals (versus 294603 participants in HC in 2014 p < 0.00001; 24% participation rate). The rate of positivity was 4.6% (versus 3.8% with HC; p < 0.0001). Among all positive FIT individuals, 93% underwent colonoscopies: 35% were normal (vs 41%; p < 0.01), 13.2% presenting with cancer or HGD and 52% with polyps (vs. 37.7%; p < 0.0005). More women (5.5%) than men (4.2%) responded to invitations while positivity rate in women (40.7%; p < 0.0001) was higher than in men (38.7%). More advanced polyps and cancer were found in men (14.5%) than in women (11.3%; p < 0.0001) with normal colonoscopies lower in men (24.2%) than in women (40.7%; p < 0.0001). The mean age (mean age of FIT positive individuals with cancer +HGD (667, 9) or with polyps (374; 4) than in those with normal colonoscopy (440, 4). In multivariate analysis, risk factors for abnormal colonoscopies with cancer + HGD were male gender, FIT > 340 ng/mL and age > 63.5 yrs. More men than women with positive FIT test did not yet undergo colonoscopy

Conclusion: FIT test has gained a better adhesion in Ile de France probably because to its simplicity and a wider distribution. The lower rate of normal colonoscopies and a higher positivity suggest a predictive value for cancer leads to more early lesions detected indicating its higher specificity. Men of 63.5 yrs old or more with Hemoglobin levels higher than 340 ng/mL are of very high risk of cancer and should be absolutely conducted to the colonoscopy in case positive FIT test.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Contact E-mail Address**: nambag1108@gmail.com

**Introduction**: Regular surveillance colonoscopy after colon cancer resection is recommended to detect metachronous adenoma and cancer. However, risk factors of advanced metachronous neoplasm during postoperative surveillance have not been fully evaluated yet.

**Aims & Methods**: This study aimed to assess the risk of advanced metachronous neoplasm during surveillance colonoscopy in patients who underwent curative colon cancer resection. The patients who underwent curative colonic resection for non-metastatic colon cancer between January 2002 and December 2012 in a single tertiary center were retrospectively reviewed.

**Results**: A total of 278 patients were enrolled in this study. Surveillance colonoscopy was performed after periprocedural clearing colonoscopy. Among the patients, 162 (61.6%) were male, and the median age was 65 years. On periprocedural clearing colonoscopy, accompanying high-risk adenomas (≥3, size ≥10 mm, with high-grade dysplasia and villous histology) were detected in 95 patients (31.9%) and were significantly associated with old age (>65 years), male sex, alcohol use, smoking, and stage 3 colon cancer (P < 0.05). During the postoperative follow-up periods (median, 5.35 years), 15 advanced metachronous neoplasms were found in 45 patients (15.1%) during surveillance colonoscopy, including colon cancer in 4 patients (1.3%). In the multivariate analysis, distal colon cancer (distal to splenic flexure; odds ratio [OR] = 4.463; P = 0.002, accompanying high-risk adenomas on periprocedural clearing colonoscopy (OR = 3.414; P = 0.001), and hypertension (OR = 2.344; P = 0.026) were significant risk factors of advanced metachronous neoplasm during surveillance colonoscopy.

**Conclusion**: Patients who had distal colon cancer, accompanying high-risk adenomas on periprocedural clearing colonoscopy, and hypertension may need a shorter colonoscopic surveillance interval. A more tailored surveillance strategy is needed to improve overall outcome in patients who undergo curative colon cancer resection.

### PII115 PROSPECTIVE COMPARISON OF THE NOVEL FULL SPECTRUM ENDOSCOPY (FUSE) AND ADVANCED HI-DEFINITION-WHITE LIGHT ENDOSCOPY FOR DETECTION OF POLYPS IN ROUTINE PRACTICE

**A. Martinez-Alcala Garcia1, F. J. Martinez-Alcala1, C. Martinez-Alcala1, K. Thakar1, R. Madero1, K. Mönkemüller1, F. Martinez Alcal1**

**Contact E-mail Address**: alvaromalcala@gmail.com

**Introduction**: Despite major advances in white light endoscopy detection of colon polyps remaining challenges with significant polyp miss rates. The novel second generation full spectrum endoscopy (FUSE) is a new scope with two additional cameras in the sides that provides a panoramic 330° field of view.

**Aims & Methods**: The aim of this study is to identify the role of the FUSE in improving polyp detection. This was a single-center, prospective, randomized, open-label study in patients that presented for routine colonoscopy at an outpatient unit during a six months period. Patients were randomized to either FUSE (FUSE colonoscope CDYL slim c38) or standard frontal view (SFV) colonoscopy (Olympus Evix Exera III 190). The primary outcomes were polyp detection rates (PDR), detection rate (DR) and complete colonoscopy. Secondary outcomes were procedure time, adverse event rates, size and characteristics of the polyps and success of endoscopic treatment (R0 resection). All procedures were performed by experienced endoscopists, who had carried out > 5000 colonoscopies and had had cecal intubation rates of >95%.

**Results**: A total of 197 patients (49.2% female, 50.8% male, median age 60 years, range ±16 years) were studied. No significant difference was seen between the 2 groups for the primary endpoints of polyps detection rate (PDR), diverticular detection rate (DDR) or complete colonoscopy (table 1). About secondary endpoints: R0 endoscopic resection was achieved in 95% in both groups (p = 0.68). The median procedure time in minutes was higher with SFV (36.7±13.1mm vs. FUSE: 21.5±17.0 min) than FUSE (21.5±10.7 min) (p < 0.005). There were no significant differences regarding adverse events, determination of colon cleanliness, or others epidemiologic factors. 2 case were excluded of the statistical analysis due to surveillance of polyposis syndrome, two avoided assessing of results.

**Conclusion**: In expert hands, PDR and DDR exceed 50% with advanced white light and FUSE systems. FUSE was not superior to advanced white light endoscopy for the PDR and DDR. However, with FUSE we can reduce procedure duration without any additional adverse events or increased discomfort. These data further demonstrate the safety and feasibility of the new FUSE system.

**Disclosure of Interest**: All authors have declared no conflicts of interest.

3.65% were superficial submucosal carcinomas (<1000 μm). During UEMR, two cases (both using AUTOCUT mode) of sprouting bleeding were observed (4.45%). Hemostasis was easily achieved in both cases by clipping. No patient required blood transfusion. One patient had abdominal pain on the day after resection without signs of pneumoperitoneum on CT scan. There was no perforation or delayed bleeding.

Conclusion: This study supports the existing data indicating acceptable rates of technical success and low incidence of adverse events with UEMR. The results of this study without cup were similar with the previous ones using cup. Further comparative studies with and without cup, performed with different settings and especially between UEMR and traditional EMR are needed.

Introduction: Current guidelines recommend surveillance colonscopy after 10 years or surveillance in 5-10 years in individuals with no or 1-2 non-advanced adenomas.
Aims & Methods: We hypothesized that risk of metachronous advanced colorectal neoplasia is dependent on ADR. We retrospectively evaluated colorectal adenoma detection rate (ADR) in a cohort of low-risk individuals.
Results: Multivariate analyses showed that increasing ADR was significantly associated with reduced risk of colorectal neoplasia in the post EMR scar is currently highly accurate using HD-WL (high definition-white light) and NBI (narrow band imaging). Anyway, indications for follow-up endoscopy after colorectal endoscopic submucosal dissection (EMSD) remain unclear.
Methods: We conducted a study comparing the risk of colorectal neoplasia after colorectal endoscopic submucosal dissection (EMSD) in patients with ADR (32%) vs. those screened by endoscopists with higher ADR (23%) (2% vs. 0.6%, respectively; P = 0.001).
Conclusion: According to patient and adenoma characteristics, and ADR of the endoscopist, the risk of metachronous AN varies among low-risk patients. In recommending surveillance colonoscopy, these factors should be taken into consideration.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The technique of endoscopic submucosal dissection has recently been improved, and large and complexed lesions such as those invading ileocecal valve and appendix orifice can be resected en bloc. However, lesions accompanying severe fibrosis in the submucosal layer and exhibiting the muscle retraction (MR) sign are often difficult to be resected completely. We devised a new modified method called ‘Per Anal Endoscopic Myectomy’ for such lesions involving severe fibrosis, in which dissection is done between the inner circular and outer longitudinal muscles instead of between submucosal layer and muscle layer. Aims & Methods: The aim of this study is to examine the usefulness and safety of PAEM in PAEM cases performed in our hospital and an affiliated hospital, which were retrospectively reviewed. When fibrosis in the submucosal layer was suspected, pocket creation method was applied and if severe fibrosis with MR sign was found, PAEM was selected. In PAEM procedure, after dissecting circumferentially around the fibrotic tissue with a double tunneling method, the inner circular muscle is cut in a circular manner, which makes the outer longitudinal muscle clearly visible. The space between the inner circular and outer longitudinal muscles is sparse and suitable traction with the tunneling method makes it easier to dissect this space. PAEM was performed only for rectal lesions, and no clip closure was carried out after the procedure in most cases.
Results: Ten rectal lesions were treated with PAEM between July 2015 and March 2017. Among them, 7 cases including 2 cases with mucosal cancer, and 3 cases with deep submucosal colorectal neoplasia were en bloc resected en bloc with negative margin. The other 3 cases showed tumor invasion to the muscle layer and the vertical margin was positive. The clinical course after PAEM was preferable in all cases. Three cases which achieved resection with negative margin but found lymphovascular invasion of the tumor underwent additional surgical intervention or adjuvant chemoradiation. In surgical cases, they could permit anus-preservation.
Conclusion: PAEM for lesions exhibiting MR sign with severe fibrosis will enable complete en bloc resection and accurate pathological diagnosis. No complications were recorded in our experiences. Further investigation into the significance of PAEM would be needed.

P1119 LOCAL RECURRENCE AFTER ENDOSCOPIC MUCOSAL RESECTION FOR HIGH-RISK LESIONS: MAY WE BETTER PLAN THE ENDOSCOPIC FOLLOW-UP ACCORDING TO PROCEDURAL, NEOPLASTIC AND HISTOLOGICAL AND HISTOPATHOLOGICAL CHARACTERISTICS?
C. Quondamcarlo, C. Lucidi, R. Lapenta
Gastroenterology, Regina Elena Cancer Institute, Rome/Italy
Contact E-mail Address: qcynthia@ymail.com
Introduction: Endoscopic mucosal resection (EMR) is an increasingly used technique for the removal of large sessile and flat-laterally-spreadign colorectal lesions. At present, surveillance colonoscopies are ever performed to ensure detection and adequate treatment of residual or recurrent adenoma (RRA), which, occurring in 10-40% of non-pedunculated lesions, currently represents the main limitation of this technique. Fortunately, endoscopic detection of RRA in the post EMR scar is currently highly accurate using HD-WL (high definition-white light) and NBI (narrow band imaging). Anyway, indications for follow-up
A557

United European Gastroenterology Journal 5(5S)
colonoscopies and optimal time intervals are currently unclear. An adequate
comprehension of the predicting factors of RRA would be very relevant to try
to prevent it, better plan surveillance intervals, establish role and timing of surgery and reduce costs.
Aims & Methods: Our aims were to assess the frequency of local recurrence after
EMR for high-risk lesions, to identify risk factors for recurrence, and to provide
follow-up suggestions. We considered all consecutive patients undergone
EMR of flat or sessile adenomas  10 mm containing high-grade dysplasia or
adenocarcinoma until pT1 from May 2015 to April 2016. EMR procedure was
performed by 2 endoscopists with extensive EMR ‘‘inject and cut’’ experience
and only lesions with a positive lifting sign were endoscopically treated.
An endoscopic follow-up was performed at a planned interval of 3, 6 and
12 months by using high-definition instruments white light (HD-WL) and
narrow-band imaging (NBI) allowing an appropriate scare assessment with the
execution of biopsies when needed. Data collection included: (a) lesion size,
morphology, Paris classification, pit pattern (kudo), technique of removal (en
bloc vs piecemeal) and histology for all primary lesions and RRA; (b)
Information about budding, grading, microinvasion, margins, submucosal extension for all pT1 removed ‘‘en bloc’’.
Results: 50 patients were included (mean age 63  12 years, 54% females).
The mean size of lesions was 21 mm (range 10–50 mm), 40% were sessile, 35%
granular LST and the reimaging 25% non-granular LST, the most frequent sites
of location were sigmoidal colon (40%), ascending colon (25%) and cecum
(12%). According to the morphological characteristics, 60% of lesions were
removed ‘‘en bloc’’ and 40% ‘‘piecemeal’’. Metallic clips were used as prophylaxis in 35% of patients and only in 1 for intraprocedural bleeding. No postprocedural bleeding or perforation occurred. APC has never been used. During
the endoscopic follow-up a suspect early (3-months) RRA was documented and
immediately treated in 16% and histologically confirmed only in 8%. At 6-month
controls a RRA was again detected only in 2 of these patients. New cases of RRA
were not found both at 6 and 12 month controls. Only 1 case of RRA was
documented for lesions treated ‘‘en bloc’’ but this was the only one with histological characteristics strongly suggesting high risk of RRA (pT1, 42 cm, grading G2, free-disease margins51 mm). As concerned lesions removed
‘‘piecemeal’’, RRA (70% high grade dysplasia and 30% low grade dysplasia)
was higher in pT1, lesions 42 cm, non-granular LST. No correlation was
found with other factors.
Conclusion: EMR results a technique safe and effective particularly for lesions
removable ‘‘en bloc’’; in this cases in fact the rate of RRA seems to be low and
easily histologically predictable. Although factors related to RRA in ‘‘piecemeal’’
EMR appear less clear more attention would be applied in relation to determined
morphological pattern and presence of in situ carcinoma. Moreover, RRA seems
to be ever early suggesting a close follow up only in the first period.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1120 TREATMENT STRATEGY FOR LOCAL RECURRENCES
AFTER ENDOSCOPIC RESECTION OF COLORECTAL NEOPLASMS
S. Ito, K. Hotta, K. Imai, Y. Yamaguchi, Y. Kishida, K. Takizawa,
N. Kakushima, M. Tanaka, N. Kawata, M. Yoshida, H. Ishiwatari,
H. Matsubayashi, H. Ono
Division Of Endoscopy, Shizuoka Cancer Center, Shizuoka/Japan
Contact E-mail Address: sa.ito@scchr.jp
Introduction: Local recurrences after endoscopic resection (ER) frequently
occur, especially after piecemeal resection. Recently, the efficacy of endoscopic
submucosal dissection (ESD) for local recurrences has been reported. However,
an appropriate treatment strategy for these lesions including ESD remains
unclear.
Aims & Methods: This study aimed to clarify the appropriate treatment strategy
for local recurrences after ER. A total of 81 patients (81 lesions) who received
treatment for local recurrences after ER for colorectal neoplasms between
January 2010 and December 2016 were enrolled. Patients with pathological diagnosis of hyperplastic polyp, sessile serrated adenoma/polyp, and submucosal
invasive cancer in their first ER were excluded. Seven patients who underwent
surgery because of submucosal invasion or technically difficult locations were
also excluded. Procedural outcomes, recurrence rate and disease control rate
(DCR) were evaluated according to preoperative endoscopic diagnosis of recurrent lesions (adenomatous or cancerous). The DCR was defined as proportion of
patients who were diagnosed with curative resection after ER or received additional surgery based on pathological diagnosis after ER.
Results: Seventy-four patients were included in the final analysis. Forty-nine
patients diagnosed with adenomatous recurrences were treated by cold polypectomy in 15, by endoscopic mucosal resection (EMR) in 26, and by ESD in 8
patients. Cold polypectomy was applied only to diminutive (55 mm) lesions
and there was no local recurrence. The en bloc resection rates of EMR and
ESD were 53.8% and 100%, respectively (P ¼ 0.030). Two cases (7.7%) in the
EMR group developed local recurrences, but additional ER achieved curative
resection. The DCR of three methods were all 100%. Meanwhile, 25 patients
diagnosed with cancerous recurrences were treated by EMR in 7 and by ESD in
18 patients. The en bloc resection rates of EMR and ESD were 28.6% and
83.3%, respectively (P ¼ 0.017). Three cases (42.9%) in the EMR group developed local recurrences. One case required surgery because of invasive local

recurrence, the second case required chemotherapy because of distant metastasis,
and the third case was followed-up because of severe comorbidities. Therefore,
the DCR in the EMR group was significantly lower than that of in the ESD
group (28.6% vs. 83.3%, P ¼ 0.017).
Conclusion: The selection of ER for local adenomatous recurrences could be
based on lesion size. On the other hand, ESD is desirable for local cancerous
recurrences to achieve complete disease control.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1121 A COMPARATIVE STUDY ON EFFICACY OF
CHEMOTHERAPY AFTER ENDOSCOPIC COLONIC STENTING VS.
THAT AFTER COLONIC SURGERY IN THE MANAGEMENT OF
OBSTRUCTIVE COLORECTAL CANCER

Introduction: Endoscopic stent placement in acute large-bowel obstruction due to
colorectal cancer has been established as a palliative therapy or bridge to surgery
with good outcomes in Japan. While, efficacy of chemotherapy after endoscopic
colonic stenting has not been evaluated.
Aims & Methods: The aim of this study was to evaluate efficacy of chemotherapy
after endoscopic colonic stenting by comparing with that after surgery. Sixty five
patients with colorectal cancer of stage IV presenting obstructive symptom visiting Aomori Prefectural Central Hospital from January 2012 to December 2016
were classified into SC group who have underwent chemotherapy after endoscopic colonic stenting (32 patients) and OC group who have underwent chemotherapy after surgery (23 patients). The patient’s background, adverse effects
and prognosis were compared with two groups.
Results: There have not been any significant differences in patient age (65.5  9.3
in SC vs. 61.5  14.1 in OC, p ¼ 0.21), male to female ratio (25:7 in SC vs. 14:9
p ¼ 0.16) and performance status (0.6  0.7 in SC vs. 0.7  0.8 in OC, p ¼ 0.66).
The averaged colorectal obstruction scoring system (0, Requiring continuous
decompressive procedure; 1, No oral intake; 2, Liquid or enteral nutrient; 3,
Soft solids, low-residue, and full diet with symptoms of stricture; 4, Soft solids,
low-residue, and full diet without symptoms of stricture) score was significantly
severe in OC (1.7  1.1) than in SC (0.7  0.9, p 5 0.01). Adverse effects included
perforation (1), stent slippage (6), re-obstruction by tumor progression (3) in SC,
and ileus (1), abdominal abscess (1), renal insufficiency (1) in OC. The frequency
of combined use of molecular target drugs (Bevacizumab/Panitumumab/
Cetuximab) at first chemotherapy has significantly differed (p 5 0.01) between
SC (0/11/9) and OC (12/4/0). The median survival day was not significantly
different between SC (595) and OC (459, p ¼ 0.93). In SC, survival was found
significantly longer with additional surgery (913, n ¼ 13) than without (325,
n ¼ 19, p 5 0.01). In OC, survival did not significantly differed between with
resection of the primary tumor (666, n ¼ 16) and without (595, n ¼ 7, p ¼ 0.93).
Conclusion: This study has demonstrated that the survival of SC was identical
to that of OC, and additional surgery was found to significantly improve the
prognosis in SC. Chemotherapy after endoscopic colonic stenting has been considered tolerable as a palliative therapy or bridge to surgery for obstructive
colorectal cancer.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1122 A NEW MANEUVER TO PLACE A THROUGH-THE-SCOPE
STENT IN A MALIGNANT COLONIC STRICTURE INACCESSIBLE
WITH A STANDARD-CALIBER COLONOSCOPE: "OVER-THECATHETER" COLONOSCOPE REPLACEMENT TECHNIQUE

Introduction: A self-expandable metallic stent (SEMS) placement is potentially a
colostomy-sparing option to manage a malignant colonic obstruction (MCO).
However, in patients with coexisting peritoneal dissemination (carcinomatous
adhesion), for example, insertion of a standard caliber colonoscope (SCC) is
challenging, whereas such an endoscope equipped with a large working channel
is suitable for through-the-scope (TTS) SEMS placement. Failure in stenting
necessitates continuous tube drainage, stoma formation, or other surgical procedures and decreases quality of life (QOL).
Aims & Methods: We examined feasibility and efficacy of, ‘‘Over-the-Catheter’’
Colonoscope Replacement technique (OTC-CR) detailed below, in palliative (not
preoperative) SEMS placement for MCO. From Oct 2012 to Dec 2016, MCO
patients were consecutively considered for decompression by SEMS placement
unless stoma formation was preferred. When a conventional TTS procedure was
unsuccessful, specifically, when the MCO site was inaccessible with an SCC
(CF-H260AI, Olympus Medical Systems, Tokyo, Japan) with a 13.2 mm tip
diameter and 3.7 mm working channel, needed for a 22 mm (not 18 mm) SEMS


Aims & Methods:

The cost-effectiveness of CRC screening programmes are clearly demonstrated in some countries, and their implementation is encouraged by international guidelines. The program has been developed in the areas of Menorca, Ibiza, Formentera and Tramuntana (Mallorca), including 30% of the Balearic Islands population. The target population (people who reside in these areas aged between 50 and 69 years old) was 75,575 individuals. Exclusion criteria. Colonocepimy performed in the previous 5 years, previous diagnosis of CRC, follow-up colonoscopies because colon disease and severe illness-contraindication for the participation. People received the invitation by letter. Quantitative immunochemical fecal occult blood testing (i-FOBT/OC-Sensor) was the screening method. The kit was delivered at pharmacies after the samples were stored in urns placed in health centres. Participants who tested positive (≥100 ng/ml) were referred to pre-endoscopy evaluation and follow-up colonoscopy. The colonoscopies were performed according to the quality criteria of guidelines.

Results: Overall participation rate (number of people who provide their i-FOBT sample) was 36.5% (n=21,555). Positive rate of i-FOBT was 7% (1438) and 94.3% of these positive tests underwent a colonoscopy (5.7% of exclusions in pre-endoscopy evaluation). 996 colonoscopies were performed. 47 adenomas with high grade dysplasia, 24 carcinomas in situ and 60 adenocarcinomas were found. Only 19% of these adenocarcinomas were T3 or T4 lesions while the rest presented earlier stages. 26% of colonoscopies were classified as high risk (>5 adenomas or at least one ≥20mm). They have been reported 2 cases of colon perforations, both resolved by endoscopic treatment.

Conclusion: We observed an acceptable participation rate in the first round of the colorectal screening programme of the Balearic Islands. The index of positivity rate of i-FOBT and the results of the endoscopic explorations are according with the observed in other colorectal cancer screening programmes. We can conclude a successful development of the first round of the programme in our area.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal cancer (CRC) is the most common cause of cancer in western countries. In Balearic Islands 700 new cases per year are diagnosed. The cost-effectiveness of CRC screening programmes are clearly demonstrated in the studies and the important public health problem of CRC justifies the development of control strategies. The aim of this study is to present the results and impact during the first round of the program in Balearic Islands.

Aims & Methods: The first round includes the period from January 2015 through December 2016. The program has been developed in the areas of Menorca, Ibiza, Formentera and Tramuntana (Maleorca), including 30% of the Balearic Islands population. The target population (people who reside in these areas aged between 50 and 69 years old) was 75,575 individuals. Exclusion criteria. Colonoscopy performed in the previous 5 years, previous diagnosis of CRC, follow-up colonoscopies because colon disease and severe illness-contraindication for the participation. People received the invitation by letter. Quantitative immunochemical fecal occult blood testing (i-FOBT/OC-Sensor) was the screening method. The kit was delivered at pharmacies after the samples were stored in urns placed in health centres. Participants who tested positive (≥100 ng/ml) were referred to pre-endoscopy evaluation and follow-up colonoscopy. The colonoscopies were performed according to the quality criteria of guidelines.

Results: Overall participation rate (number of people who provide their i-FOBT sample) was 36.5% (n=21,555). Positive rate of i-FOBT was 7% (1438) and 94.3% of these positive tests underwent a colonoscopy (5.7% of exclusions in pre-endoscopy evaluation). 996 colonoscopies were performed. 47 adenomas with high grade dysplasia, 24 carcinomas in situ and 60 adenocarcinomas were found. Only 19% of these adenocarcinomas were T3 or T4 lesions while the rest presented earlier stages. 26% of colonoscopies were classified as high risk (>5 adenomas or at least one ≥20mm). They have been reported 2 cases of colon perforations, both resolved by endoscopic treatment.

Conclusion: We observed an acceptable participation rate in the first round of the colorectal screening programme of the Balearic Islands. The index of positivity rate of i-FOBT and the results of the endoscopic explorations are according with the observed in other colorectal cancer screening programmes. We can conclude a successful development of the first round of the programme in our area.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Method: Thirty Thai IBS patients, and age and sex matched 20 Thai controls were included. Four biopsy samples were taken from each of the sigmoid colon and the rectum during a standard colonoscopy. Sections from these biopsy samples were immunostained for serotonin, peptide YY, oxyntomodulin (enteroglucagon), pancreatic polypeptide, somatostatin, Ms 1, neuro 3. The densities of immunoreactive cells were determined with computerized image analysis (1).

Results: In both the colon and rectum, the density of serotonin cells was lower in IBS patients than controls. Whereas the density of PYY cells was increased in both the colon and rectum of IBS-D, it was reduced in IBS-M and IBS-C. The density of oxyntomodulin cells was reduced in both the colon and rectum of all IBS subtypes. While the density of PP cells was unaffected in the colon, it was reduced in the rectum. Somatostatin cell density was unaffected in both the colon and rectum. The densities of Ms 1 and neuro 3 were unchanged in both the colon and rectum.

Conclusion: The present findings of abnormal densities of the large-intestine enteroendocrine cells in Thai patients combined with previously reported changes in Western IBS patients (2) support the notion that intestinal enteroendocrine cells are involved in the pathophysiology of IBS. However, the changes in the enteroendocrine cells differed from those in Western patients. The present observations highlight that IBS differs in Asian and Western countries, and show that the changes in large-intestine enteroendocrine cells in Asian and Western IBS patients might be caused by different mechanisms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Opioid-induced constipation (OIC) is a common side effect of opioid therapy that significantly affects multiple aspects of a patient’s life. Naldemedine (NAL) is a peripherally-acting mu-opioid receptor antagonist developed for the treatment of OIC. In Phase 3 studies, NAL improved the frequency of spontaneous bowel movements, straining, consistency of stools, and patient assessment of constipation symptoms (PAC-SYM) and quality of life (PAC-QOL), measures of patient’s quality of life, compared with placebo (PBO). The aim of this analysis is to assess the impact of NAL on overall satisfaction and to show if a simple score can assess the impact of treatment of OIC.

Aims & Methods: In three Phase 3 randomized, double-blind, PBO-controlled trials of NAL (2 of 12-week duration [COMPOSE 1 and COMPOSE 2] and 1 of 52-week duration [COMPOSE 3]), a 7-grade scale (1=markedly, 2=moderately, or 3=slightly; 4=unchanged; 5=slightly, 6=moderately, or 7=markedly improved) was used to assess overall satisfaction with constipation and abdominal symptoms at the last visit study. The number and proportion of subjects in each grade were calculated and the overall difference between groups was assessed with Wilcoxon rank sum test. The mean subject global satisfaction score (SSGS) was also compared between groups. For SSGS scores, from 1 to 7 were replaced with scores from 0 to 6, with 4 (unchanged) replaced with 0.

Results: There were 547 subjects in COMPOSE 1, 550 in COMPOSE 2, and 1246 in COMPOSE 3 (all ≥18 years of age) randomized (1:1) to NAL 0.2 mg once daily or PBO. The baseline characteristics of the study population were consistent between groups in each trial and between trials. Overall satisfaction assessment was completed in 372 subjects in COMPOSE 1, 296 in COMPOSE 2, and 1101 in COMPOSE 3. There were greater improvements in satisfaction with constipation and abdominal symptoms in the NAL group compared with the PBO group in all three studies (all P<0.0005; Table). The mean SSGS were 1.5 and 0.9 with NAL and PBO, respectively, in the two 12-week studies pooled, and 1.7 and 1.0, respectively, in the 52-week study.

P1127 IBEROGAST PREVENTS CHANGES IN INTESTINAL PERMEABILITY INDUCED BY PSYCHOLOGICAL STRESS IN MICE

P. Aubert, J. Chevalier, T. Durand, A. Bessard, O. Kelber, H. Abdel-Aziz, M. Neunlist
1Inserm 1235 "tens", INSERM, Nantes/ France
2Innovation & Development, Bayer Consumer Health, Dormstadt/Germany

Contact E-mail Address: michel.neunlist@uni-nantes.fr

Introduction: The herbal preparation STW 5 has been reported to increase intestinal chloride secretion. However, the ability of STW 5 to modulate paracellular and transcellular permeability remains currently unknown. Therefore, we aimed to...
to study the ability of STW 5 to modulate intestinal permeability under basal and regenerative stress conditions.

**Aims & Methods:** C57 B6 mice were gagged for 14 days with STW 5 (3 mL/kg). After 10 days of treatment, mice were subjected to water avoidance stress (WAS) during 4 consecutive days. In vivo permeability to FITC–Sulfonic Acid (F4A, 400 mg/kg) and HRP, and in vitro permeability to HRP (4KDa), total transit time and colonic transit (fetal pellet output - FPO) were measured at Day 0 (D0), D10 and D14 of IB treatment. Ex vivo permeability to FSA and HRP was assessed on jejunal, ileum, proximal colon and distal colon at D14 using Ussing chambers. Colonic motility function and contractility of circular muscle strips were measured. The expression of BKCa and phosphorylated myosin light chain (P-MLC) level were tested in colonic tissues of rats with varying age-group: 10-week group, 20-week group, 40-week group, 60-week group and 80-week group. After different times of administration, finally they were divided into different age-group: 10-week group, 20-week group, 40-week group, 60-week group and 80-week group. Colonic motility function and contractility of circular muscle strips were measured. The expression of BKCa and phosphorylated myosin light chain (P-MLC) level were tested. At the same time, in absence of S1P, the expression of BKCa, P-MLC levels, single-channel activity, intracellular Ca2+ mobilization were tested. At the same time, in the presence and absence of S1P, BKCa decreased by treatment with inhibitor of Akt/ERK/JNK pathways whereas S1P upregulated BKCa in colon SMCs in a concentration-dependent manner, impaired intracellular Ca2+ mobilization were affected by BKCa expression in SMCs. The expression and phosphor-ylation of Akt, JNK, ERK, NR4A1 and PKC were examind by western blot analysis. Thus, in this study, we investigated whether altered S1P due to aging may affect the motility of colon smooth muscle (CSM) in rats.

**Results:** In vivo permeability to FSA and HRP as well as total transit time were not modified by STW 5 in basal and WAS conditions. However, only STW5 prevented the increase in permeability to FSA induced by WAS in the distal colon of the rats. Conversely, STW 5 prevented the increase in permeability to HRP induced by WAS in the jejunal and proximal colon. Furthermore, while STW 5 tended to increase colonic transit as compared to control in basal conditions, it prevented the increase in colonic transit induced by WAS. Finally, STW 5 did not modify the corticosterone induced by WAS.

**Conclusion:** Our study suggest that STW 5 can prevent WAS induced changes in paracellular and transcellular permeability in specific regions of the gastrointestinal tract. Such effects could contribute to the therapeutic effects of STW 5 in irritable bowel syndrome and support novel therapeutic indications for pathologies in which barrier functions are altered.

Introduction: Constipation is a chronic disorder with an estimated prevalence of 17% in Europe. Epidemiological studies on bowel habits in the Portuguese general population have not been done previously, as in many other western countries. The aim of this population-based study was to describe bowel habits and the prevalence of self-reported constipation in a Portuguese community.

Aims & Methods: We aimed to describe bowel habits and the prevalence of self-reported constipation in a Portuguese community. Methods: Cross-sectional study with convenience sampling between November 2015 and November 2016. The physician applied a questionnaire, to adult patients at primary health care consultation. The questionnairenaires were anonymous, and the only personal information the participants were required to give was their age and sex. The questionnaire contained objective questions on possible causes and constipation-associated conditions and medications (according to the criteria defined by the World Gastroenterology Organization), daily water and fibre intake, physical activity, bowel habits and Bristol stool scale (BSS). Descriptive statistics and uni and multivariate analysis were performed using IBM SPSS Statistics 22 with p < 0.05 deemed to be statistically significant.

Results & Conclusions: A total of 814 questionnaires were performed to individuals from 35 different municipalities (54% women; mean age 46 ± 18 years). Concerning possible causes of constipation, 43% subjects had a history of constipation-associated condition and 36% were taking constipation-associated drugs. Regarding bowel habits, 35% subjects had <1 bowel movement per day and 2% had >1 bowel movement per week. Using BSS, 66% of the cases reported type III or type IV stool consistency. Among women, 19% reported a change in bowel movements according to the phase of the menstrual cycle. In total, 22% of subjects considered to be constipated, and 78% of these, compiled the Roma III criteria for functional constipation. Noteworthy, 6% of subjects with daily bowel movements and 38% of those with <1 weekly bowel movement considered to have constipation. Complaints of excessive straining, tenesmus, feeling of incomplete evacuation and abdominal pain were associated with the presence of constipation. 11% of the patients reported long history of constipation and abdominal pain. Histopathological analysis of intestinal biopsies revealed normal histology in 57% cases, hypoganglionosis in 26%, and ganglionitis in 17%. Histopathological analysis of rectal biopsies revealed normal histology in 47% of cases, and hypoganglionosis in 35%. Histopathological analysis of ileal biopsies revealed normal histology in 50% of cases, and hypoganglionosis in 38%.

Introduction: Objective means of evaluation of the defecatory process include high resolution ano-rectal manometry (HRM), balloon expulsion test (BET) and imaging of the defecatory process (X-ray defecography, dynamic trans-pelvic ultrasound (DT-PUS) or MR defecography). These tests have a place in the evaluation of suspected evacuatory dysfunction (ED), fecal incontinence (FI) and chronic pelvic pain (CPP). Test choice may influence subsequent patient management; however, there is only limited information regarding the agreement between HRM, DT-PUS and BET.

Aims & Methods: The aims of this study were to compare the diagnostic yield and agreement between different tests of evacuation and to define the relation between the diagnoses of evacuation dysfunction to objective evacuation failure. 63 consecutive patients (60 females, mean age 51±s) were prospectively evaluated with HRM, BET and PUS. Inter test agreement for the diagnosis of anismus was assessed using the Kappa statistic. Correlation between anismus to evacuation failure (assessed by PUS) was also assessed.

Results: 36 patients were assessed for ED, 6 for CPP and 21 for FI. Anismus was diagnosed in 26 patients by HRM and 45 patients by DT-PUS. All cases of anismus diagnosed by HRM or DT-PUS had a positive BET. The Kappa agreement for the diagnosis of anismus between HRM and DT-PUS was poor (0.143 ± 0.011). 9 patients had significant pelvic floor anatomic pathology (4 rectal prolapse, 6 pathological pelvic descent, 4 enterocele and 3 rectoceles >3.5 cm). There was a moderate correlation between diagnosis of anismus on DT-PUS to failure to evacuate the rectum (r = 0.636). The correlation between rectal evacuation on DT-PUS to the diagnosis of anismus on manometry was weak (r = 0.296).

Conclusion: There is considerable disagreement between the results of various evacuation tests, and between the diagnoses of evacuatory dysregulation to failure of rectal evacuation. Therefore, more than one test should be applied in order to evaluate the defecatory dysfunction.

P1134 DIAGNOSTIC USE OF ENDOSCOPIC FULL-THICKNESS WALL RESECTION (EFTR) IN PATIENTS WITH SYMPTOMS OF CHRONIC INTESTINAL PSEUDO-OBSTRUCTION (CIPO)
P.V. Valli1, D. Poh1, M. Fried1, R. Caduff2, P. Bauerfeind2

Contact E-mail Address: piero.valli@uzh.ch

Introduction: Complex gastrointestinal motility disorders such as chronic intestinal pseudo-obstruction (CIPO) or Hirschsprung’s disease (HD) are challenging to diagnose and treat appropriately. Thorough assessment of patient history, radiographic exams, endoscopy and motility measurements aid in diagnosis. The great diversity of the available diagnostic techniques, yet underlying histology is the cornerstone to enable a more distinct diagnosis of neuromuscular GI disorders. Traditionally, surgical procedures have been performed to obtain specimen suitable for accurate histologic analysis.

Aims & Methods: We performed endoscopic full-thickness resection (eFTR) using a full-thickness-resection device (FTRD) under moderate propofol sedation in four patients with suspected severe neuromuscular gut disorders including CIPO.

Results: Patient 1: A 21-year-old male patient with cerebral palsy suffering from acute small bowel ileus with a history of laparotomy, detorquation and appendectomy after cecal volvulus at the age of 15. Histologic analysis revealed irregular configuration of the myenteric plexus, but primary neuro- or myopathic disease such as HD were ruled out. GI dysmotility due to cerebral palsy syndrome was suspected. Patient 2: After a life-long history of recurrent obstipation, colonic dilatation, ileus symptoms and various colonic segment resections, diagnostic eFTR was performed in a 55-year-old female patient. The diagnosis of hypoganglionosis was established by LDH histochemical and by immunohistochemical reactions with Claudin and Map-2. Patient 3: A 19-year-old male patient with a history of a sigmoid volvulus and massively dilated large bowel segments. Enzyme histochemistry excluded HD upon histopathological analysis. The inner muscle layer showed fibrosis, eosinophilic leiomysitosis and lymphohcytic ganglionitis. Congenital CIPO was diagnosed due to degenerative leiomysopathy. Patient 4: A 56-year-old male patient with acute ileus and a year-long history of constipation and abdominal pain. Histopathological analysis....
revealed hypoganglionosis, severe fibrosis of the inner muscle layer and reduced SBM frequencies averaged over the 2-week treatment period were 3.5, 3.8, 6.3, 4.6 and 3.9 for YH12852 0.3, 0.5, 1, 2 and 3 mg, respectively, 4.0 prucalopride and 2.6 placebo. The proportion of responders (defined as those with a ≥1 increase in SBM per week over baseline) was similar across the placebo group (87.5%, 100.0%, 100.0%, and 100.0% in 0.3, 0.5, 1 and 2 mg, respectively), with the exception of the 3 mg group (80.0%), compared with that in the prucalopride (83.3%) and placebo groups (28.6%). The mean stool consis- tency assessed by the Bristol Stool Form Scale were comparable between the YH12852 and placebo groups. The time to reach the peak concentration of YH12852 was 4 hours. Steady state was achieved approximately 5 days after the first administration of YH12852 with a half-life of 23–28 hours. YH12852 showed a linear pharmacokinetic profile over 0.3–3 mg.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1135 TRAN-ABDOMINAL INTERFERENTIAL ELECTRICAL STIMULATION IS EFFECTIVE IN MANAGING REFRACTORY LOWER GASTROINTESTINAL DYSMOTILITY DISORDERS
J. Moore, P. R. Gibson, R. E. Burgelli
Gastroenterology, Monash University, Melbourne/Australia/VIC
Contact E-mail Address: judith.moore@monash.edu

Introduction: Contact E-mail Address: andrew90@yuhan.co.kr

We report our experience of its use in adult patients with functional constipation who are refractory to conventional management. This is a descriptive case series of consecutive adult patients presenting to a tertiary referral functional gastrointestinal disorders clinic with refractory constipation that were taught and used home-based interferential stimulation for at least three-months by a functional neurologist and colorectal surgeon specialist between October 2015 and Feb 2017. The validated PAC-SYM and PAC-QOL questionnaires were given at commencement of stimulation and after three months of use. Overall symptom severity was assessed by 10/cm VAS. An intention to treat analysis was conducted for any patients who commenced stimulation.

Results: Seven patients with refractory constipation (3 with slow-transit and 4 with idiopathic constipation) responding inadequately to pharmacological and non-pharmacological therapies underwent stimulatiion. Mean (range) age was 47 (26–73) and 2 were male. All patients completed the stimulation period. There was a reduction in PAC-SYM in all patients (median IQR 24 [18–36] vs 14 [10–21]) and VAS median IQR [8–9] vs [4–2] (p = 0.004). PAC-QOL was assessed in 4 patients and fall from 75 [69–85] to 38 [19–52]. Four were able to cease previously heavy daily laxative use and 2 were able to halve their use, one currently weaning off prucalopride. One remained on daily laxative use despite soft, formed stool. All reported satisfaction with stool type. Ongoing benefit remained in 2 after 4 and 12 months since ceasing its use, where the rest tended to use the stimulator intermittently.

Conclusion: Interferential electrical stimulation improved symptoms in patients with functional constipation. Randomized placebo controlled trials are justified.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The 5-HT4 receptor is an attractive drug target that can stimulate gastrointestinal motility. YH12852 is a novel, potent and highly selective 5-HT4 receptor agonist currently under clinical development for the treatment for gastrointestinal motility disorders (GIMDs).

Aims & Methods: The study aim was to evaluate the safety, tolerability, pharmacokinetic and pharmacodynamic profiles for YH12852 in healthy volunteers with ≤3 spontaneous bowel movements per week (SBMs/week) and patients with functional constipation (FC). A randomized, double-blind, placebo- and active-controlled phase 1 study was performed in healthy subjects and FC patients, who were administered YH12852 (0.3, 0.5, 1, 2 or 3 mg), prucalopride 2mg or placebo once daily after breakfast for 2 weeks. Subjects recorded bowel habits throughout the study period. Intensive pharmacokinetic blood samples were also collected (ClinicalTrials.gov identifier NCT02338367).

Results: Twenty-nine healthy subjects and 27 FC patients were enrolled. Treatment-emergent adverse events (TEAEs) were mostly mild and no serious adverse event was reported. The most frequently reported AE in the YH12852 and prucalopride groups was headache. TEAE4s in the YH12852 groups were similar to the prucalopride group. The change from baseline in weekly SBM frequencies averaged over the 2-week treatment period were 3.5, 3.8, 6.3, 4.6 and 3.9 for YH12852 0.3, 0.5, 1, 2 and 3 mg, respectively, 4.0 prucalopride and 2.6 placebo. The proportion of responders (defined as those with a ≥1 increase in SBM per week over baseline) was similar across the placebo group (87.5%, 100.0%, 100.0%, and 100.0% in 0.3, 0.5, 1 and 2 mg, respectively), with the exception of the 3 mg group (80.0%), compared with that in the prucalopride (83.3%) and placebo groups (28.6%). The mean stool consis- tency assessed by the Bristol Stool Form Scale were comparable between the YH12852 and placebo groups. The time to reach the peak concentration of YH12852 was 4 hours. Steady state was achieved approximately 5 days after the first administration of YH12852 with a half-life of 23–28 hours. YH12852 showed a linear pharmacokinetic profile over 0.3–3 mg.

2Dept. Of Pediatric Surgery, Medical University of Warsaw, Warsaw/Poland

Contact E-mail Address: mbanas@tlen.pl

Introduction: Three-dimensional high-resolution anorectal manometry (3DHARM) is the most precise tool to assess function of the anal canal and may be useful in evaluation of children after surgery on lower gastrointestinal tract that may present wide spectrum of symptoms from gastrointestinal tract.

Our aim was to evaluate children after surgery for anorectal disorders using 3DHARM.

Aims & Methods: We performed a prospective study of 43 children (30 male, mean age, 7 years) after surgery for anorectal disorders at the Departments of Pediatric Gastroenterology and Surgery, Medical University of Warsaw, Poland. The group consisted of 24 children after surgery for Hirschsprung's disease (HD), 12 children after surgery for anal atresia (AA) and 7 children after proctocectomy for other reasons (FC). In all children conventional manometry of the anorectum was performed, pressures of the anal canal was divided into 8 segments and the resting and squeeze pressures of puborectalis muscle (PRM) were recorded in segments covering its anatomical localization. These data were compared to raw data obtained in our laboratory from healthy children published previously (HC group). To assess correlation between manometry and symptoms, all children (after surgery and HC group) were divided into groups with respect to symptoms, as follows: asymptomatic (A), non-directive fecal incontinence (NDFI), constipated (C) and retentive fecal incontinence (RFI).

Results: The lowest values of resting, squeeze and the pressure of PRM were observed in AA (55.6 mmHg, 121.7 mmHg and 44.17 mmHg, respectively). As compared to asymptomatic children, the lowest mean and maximal resting pressures were observed in NDFI (69.6 mmHg and 61.3 mmHg, respectively; p < 0.000). Significantly lower maximum squeeze pressure was recorded in both, NDFI and RFI (168.1 mmHg and 103.8 mmHg, respectively; p = 0.03). ROC cut-off value for mean resting pressure between asymptomatic children and children with fecal incontinence was 68.5 mmHg. Significantly lower PRM resting pressure were observed in NDFI group and lower PRM squeeze pressure in RFI (45.6 mmHg and 63.6 mmHg, respectively). Threshold of urge were significantly higher in group C as compared to A group (87.5 cm³ and 30 cm³, respectively; p = 0.003).

Conclusion: Our study demonstrated lower pressure parameters in children after surgery with the lowest values in patients suffering from anal atresia, which was correlated with incontinence. 3DHARM may be useful tool for assessing the function of the anorectum of children after surgery.

Introduction: Linacotide, a guanylate cyclase C agonist, has been shown in clinical trials to relieve constipation and improve abdominal pain and discomfort in patients with irritable bowel syndrome with constipation (IBS-C), but there are limited UK-specific real-world data to support this.

Aims & Methods: A multi-centre, observational prospective 52-week study was conducted in eight specialist hospitals in England and Scotland. The primary objective was to describe the change in IBS-Symptom Severity Scale (IBS-SSS) score at 52 weeks after linaclotide initiation. Consenting patients aged ≥18 receiving linaclotide were included. They received freshly donated faeces from relatives, instilled into the descending part of the duodenum via gastroscope. Faecal samples were collected from the donors and the patients before FMT and from the patients after FMT at weeks 1, 3, 12 and 20/28. All the samples were stored at −80°C until analysis. Faecal concentrations of several SCFAs were significantly lower in group C as compared to A group (87.5 cm³ and 30 cm³, respectively; p = 0.003).

Results: Before FMT, concentrations of major SCFAs (acetic, propionic and n-butyric acids) and minor SCFAs (iso-butyric, n-valeric, iso-valeric, n-caproic and iso-caproic acids) were analysed by vacuum distillation followed by gas chromatography. The patients completed IBS symptom questionnaire (IBS-SQ) before and after FMT at weeks 1, 3, 12, and 20/28, and the following domains: nausea, bloating, abdominal pain, diarrhea, constipation and anorexia.

Conclusion: Linacotide was associated with a significant improvement in IBS-SSS score at 52 weeks and was reasonably well tolerated. These results provide valuable insights into the longer-term outcomes of linaclotide treatment in patients with IBS-C in real-world clinical practice.

Contact E-mail Address: tarek.mazawi@med.uib.no

Introduction: Irritable bowel syndrome (IBS) may be associated with disturbances of gut microbiota composition and functions, such as altered bacterial fermentation.

Aims & Methods: The aim was to study the effect of faecal microbiota transplantation (FMT) on gut bacterial fermentation products: short-chain fatty acids (SCFAs). Patients diagnosed with IBS according to Rome III criteria (n = 13) were included. They received freshly donated faeces from relatives, instilled into the descending part of the duodenum via gastroscope. Faecal samples were collected from the donors and the patients before FMT and from the patients after FMT at weeks 1, 3, 12 and 20/28. All the samples were stored at −80°C until analysis. Faecal concentrations of major SCFAs (acetic, propionic and n-butyric acids) and minor SCFAs (iso-butyric, n-valeric, iso-valeric, n-caproic and iso-caproic acids) were analysed by vacuum distillation followed by gas chromatography. The patients completed IBS symptom questionnaire (IBS-SQ) before and after FMT at weeks 1, 3, 12, and 20/28, and the following domains: nausea, bloating, abdominal pain, diarrhea, constipation and anorexia.

Results: Before FMT, concentrations of several SCFAs were significantly lower in IBS patients compared to donors (Table 1). After FMT, concentrations of SCFAs increased within the first 3 weeks, and the increment lasted up to 28 weeks (Table 2). Symptom scores as assessed by IBS-SQ improved from before FMT until week 20/28 after FMT as follows: nausea (P = 0.0013), bloating (P < 0.0001), abdominal pain (P = 0.0005), diarrhea (P = 0.001), constipation (P = 0.03), and anorexia (P = 0.09). Correlations were found between abdominal pain and both acetic acid (r = 0.69, P = 0.04) and total SCFAs (r = 0.69, P = 0.044) in IBS patients before FMT. Inverse correlations were found 3 weeks after FMT between nausea and iso-valeric acid (r = −0.65, P = 0.014), and between constipation and propionic acid (r = −0.74, P < 0.0001), iso-butyric acid (r = −0.79, P < 0.0001) and iso-valeriacid (r = −0.72, P < 0.0001).

Conclusion: Faecal microbiota transplantation may alter gut bacterial fermentation products, such as short-chain fatty acids, in IBS patients with IBS-C in real-world clinical practice.
**Abstract No: P1140**

**Table 1:** Concentrations (mmol/kg) of short-chain fatty acids (SCFAs) in faecal samples collected from donors and patients with irritable bowel syndrome (IBS) before and after faecal microbiota transplantation (FMT).

Data are presented as mean ± SEM. Comparison: Kruskal-Wallis multiple comparisons test with Dunn’s post test. *Donors at the beginning of the study vs. patients on FMT day before faecal installation. **Donors at the beginning of the study vs. patients 1 week after FMT, ***Donors at the beginning of the study vs. patients 3 weeks after FMT, ****Donors at the beginning of the study vs. patients 12 weeks after FMT, *****Donors at the beginning of the study vs. patients 20/28 weeks after FMT. FMT: faecal microbiota transplantation. SCFAs: short-chain fatty acids.

**Conclusion:** Our results reveal differences in faecal fermentation products between patients with IBS and healthy donors, and suggest that FMT may act to normalise such alterations of gut microbial functions.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

*p < 0.05 compared to adequate relief*

**Conclusion:** GPs reported that patients with IBS-D considered as having IR of symptoms had increased HCRU, including more GP office visits and more colonoscopies, compared to patients with AR. These results highlight that IR is potentially an important driver of increased HCRU in patients with IBS-D, emphasising that effective treatments that provide AR may reduce HCRU and the associated economic burden.

Introduction: Selective Serotonin Reuptake Inhibitors (SSRIs)’s have shown efficacy in reducing symptoms but less so on pain in irritable bowel syndrome (IBS). Comorbid anxiety frequently occurs in IBS. We hypothesized that SSRIs will particularly be effective in reducing abdominal pain in IBS patients with pronounced comorbid anxiety. As methods for symptom evaluation were used 1) gastrointestinal symptom rating scale (GSRS) as primary parameter and 2) a new method called the Experience Sampling Method (ESM). With ESM digital assessments are completed randomly and repeatedly during daily life, therewith capturing fluctuating symptom patterns more accurately than retrospective questionnaires might.

Aims & Methods: IBS patients with comorbid panic disorder were included in a randomized controlled trial on escitalopram versus placebo. Measurements were completed at baseline (t=0) and after 3 (t=3) and 6 months (t=6). At each time point, the gastrointestinal symptom rating scale (GSRS) and a 7-day ESM period were completed. Subjects completed ESM assessments on a palmtop computer at 10 random moments each day during 7 consecutive days. ESM periods were analysed when at least 1/3 (i.e., 23) of the assessments were completed. Mixed linear modeling models were used with the GSRS (scoring from 1 to 4) as the dependent and treatment group and ESM-panic anxiety scores as the independent variable.

Results: In total 35 escitalopram and 35 placebo (21 female, mean age 37 years, range 20–64) underwent a wireless motility capsule (WMC) and questionnaires were repeated at each time point, the gastrointestinal symptom rating scale (GSRS) and a 7-day ESM period were completed. Subjects completed ESM assessments on a palmtop computer at 10 random moments each day during 7 consecutive days. ESM periods were analysed when at least 1/3 (i.e., 23) of the assessments were completed. Mixed linear modeling models were used with the GSRS (scoring from 1 to 4) as the dependent and treatment group and ESM-panic anxiety scores as the independent variable.

Conclusions: Escitalopram reduced somatic symptoms (8.3; p < 0.01) and quality of life (58.4; p < 0.01), distension (2.1; p < 0.01); pain (2.8; p < 0.01) and urgency (2.1; p < 0.01). Rifaximin resulted in a significant improvement in the number of daily stools (Δ−1.5; P < 0.01), daily watery stools (Δ−2.1; P < 0.01), Bristol scale (Δ−1.1; P < 0.01), abdominal pain (Δ−0.5; P < 0.01), distension (Δ−0.3; P < 0.01), urgency (Δ−0.7; P < 0.01) and in the IBS-SS (Δ−7.8; P < 0.01). No differences were found between BAD and non-BAD patients in the improvement of any item. Rifaximin treatment did not modify SeHCAT value (9.5% before treatment and 10.7% after treatment; P = 0.4).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1144 RELATIONSHIP BETWEEN RIFAXIMIN THERAPY AND SEHCAT TEST IN PATIENTS WITH DIARRHEA-PREDOMINANT IRRITABLE BOWEL SYNDROME OR FUNCTIONAL DIARRHEA

Gastroenterology, Hospital Universitari de Bellvitge, Hospitalet de Llobregat/Spain

Contact E-mail Address: alexandruazucerulla@gmail.com

Introduction: Bile acids (BAs) and gut microbiota have been involved in IBS pathophysiology. BA diarrhea (BAD) is often found in patients with irritable bowel syndrome with diarrhea (IBS-D) or functional diarrhea (FD). Rifaximin and rifaximin based products have been shown to improve symptoms in these patients. It is unknown whether a SeHCAT test may help to predict response to rifaximin or whether rifaximin treatment affects SeHCAT test result.

Aims & Methods: a) To determine if a SeHCAT test may be used to predict response to rifaximin in patients with IBS-D or FD. b) To assess if rifaximin modifies SeHCAT result.

Conclusion: The present post hoc analysis of the pooled ELX Phase 3 studies, ELX-treated patients experienced fewer consecutive weeks of IR compared to those receiving PBO, within both Weeks 1–12 and 13–24 of treatment. As IR is thought to potentially reduce healthcare resource use and subsequent healthcare costs associated with IBS, further prospective study of the impact of ELX on AR and any subsequent reduction in healthcare costs is required, including the relationship between the number of consecutive weeks of IR and patients’ behaviour towards healthcare resource use.

Aims & Methods: Treatment with FMT in patients with IBS-D in a post hoc analysis of the pooled Phase 3 ELX trials (IBS-3001, IBS-3002). Patients meeting Rome III criteria for IBS-D were randomised 1:1:1 to twice-daily (BID) ELX (75 or 105 mg) or PBO. Efficacy was evaluated through Week 26. For evaluation of AR, patients were asked “In the last 7 days, have you had adequate [satisfactory] relief of your IBS symptoms?” (Yes/No) on a weekly basis, via an electronic diary. As previously described, patients answering “Yes” for ≥50% of the total weeks during the target time interval were considered AR responders. Patients answering “No” were considered to have IR. This analysis evaluated the number of consecutive weeks that patients reported IR over Weeks 1–12 and 13–24 of treatment. Patients without AR analysis were ineligible for intention-to-treat (ITT) analysis; missing data were not imputed.

Results: Overall, 2429 patients with IBS-D were enrolled across the two Phase 3 trials and 2423 were included in the ITT analysis. In the pooled dataset, a significantly greater proportion of patients were AR responders with either ELX 100 or 75 mg BID vs PBO at 12 weeks (56.1% [p < 0.001] and 56.3% [p = 0.001] vs 36.4% [p = 0.018] and 46.0% vs 41.8%, respectively). Over the first 12 weeks of treatment, a greater proportion of patients reported no IR of IBS-D symptoms with ELX 100 or 75 mg BID vs PBO (Table). Greater proportions of patients reported only 1–<5 consecutive weeks of IR with ELX 100 or 75 mg BID vs PBO. A significantly lower proportion of patients reported IR for ≥8 consecutive weeks with ELX 100 or 75 mg BID vs PBO (13.2% [p < 0.0001] and 15.6% [p = 0.004] vs 22.6%, respectively). In contrast, a greater proportion of patients reported IR for the full 12 consecutive weeks with PBO vs ELX 100 or 75 mg BID (Table). Similar results were observed in Weeks 13–24 of treatment, with ELX-treated patients generally having fewer consecutive weeks of IR compared to PBO-treated patients (Table).

Table: Consecutive weeks of inadequate relief

Conclusion: Proportions of responders with eluxadoline 75 and 100 mg were consistently higher vs placebo across all 4-week intervals in the treatment period in patients defined as having severe IBS-D. Furthermore, discontinuation rates among patients showing a treatment response remained consistently low compared to non-responders. However, as these analyses were conducted in a clinical trial setting, the relatively high continuation rates in non-responders may not reflect the real-world situation. These findings suggest that eluxadoline has sustained efficacy in treating the diarrhoea and abdominal pain associated with IBS-D, including in patients with severe and inadequately managed symptoms.

Pi1148 THE LOW FODMAP DIET REDUCES CAECAL FERMENTATION COMPARED TO TRADITIONAL DIETARY ADVICE: A RANDOMISED CONTROLLED TRIAL

A. D. Farmer1, N. Saint2, A. R. Hobson3
1Gastroenterology, University Hospitals of North Midlands, Stoke on Trent/United Kingdom
2Functional Gut Clinic, London/United Kingdom
3Gastroenterology, University Hospitals of North Midlands, Stoke on Trent/United Kingdom

Introduction: Diets reducing the content of fermentable short chain carbohydrates (fermentable oligo-, di-, mono-saccharides, and polyols (FODMAPs)) as well as the National Institute of Health Care Excellence (NICE) diet have been reported to be effective in the treatment of patients with irritable bowel syndrome (IBS) (1,2). The mechanisms by which this efficacy is achieved are incompletely understood but it has been proposed that such diets reduce fermentation, mediated by changes in the microbiota (3). Change in pH around the ileocaecal junction is considered to be a surrogate biomarker of caecal fermentation (4,5).

Aims & Methods: We aimed to compare the effect of a low FODMAP diet vs. the NICE diet on change in ileocaecal pH. We performed a single centre, randomized controlled trial of adult patients with Rome III defined IBS-mixed bowel habit (IBS-M) comparing the two dietary interventions. At baseline, patients ingested a wireless motility capsule (WMC) using a standardized protocol. Segmental transit times were derived from measures around known anatomical landmarks as identified by compartmental pH changes. Ileal and colonic motility measures are presented as area under the curve (AUC) derived from contraction amplitude and frequency. Validated questionnaires evaluating GI (vagal) discomfort anchored visual analog scale (VDVAS) assessing sensory intensity (VDVAS-1) and unpleasantness (VDVAS-U) and somatic symptoms (Personal Health Questionnaire (PHQ)) as well as quality of life (EQ-5D) were administered. The WMC and questionnaires were repeated after 26 days of dietary interventions. The primary endpoint was change in ileocaecal pH after the intervention. Secondary outcomes included changes in transit times, contractility and symptom scores.

Results: After screening, 32 patients (23 female, median age 37 years, range 18-65) were randomized. Baseline symptom severity and demographics were similar between the two groups. Relative to baseline, there was a reduction in the change in ileocaecal pH with the low FODMAP diet group compared to the m-NICE group (3.37 ± 0.3 vs 0.005±0.4, p = 0.047) suggesting reduced fermentation. Changes in GI motility are shown in Table 1.

Table 1: Changes in segmental/gut transit times and ileal/colonic motility, relative to baseline between the low FODMAP and m-NICE diets. Both the low FODMAP and NICE diets improved VDVAS-I and VDVAS-U (~18 ± 7 vs. -20 ± 7, p = 0.04 and -13 ± 9 vs. -20 ± 7, respectively). Similarly, both diets reduced somatic symptoms (~2 ± 1.4 vs. -0.8 ± 1.8, p = 0.07) and improved quality of life (9.5 ± 10.2 vs. 4.4 ± 9.8, p = 0.23).

Low FODMAP Low NICE P value
Change in Gastric empting time (minutes) 122 ± 249 7 ± 370 0.07
Change in Small bowel transit time (minutes) 63 ± 43 -33.6 ± 8.0 0.07
Change in Colonic transit time (minutes) 512 ± 1425 53 ± 1728 0.53
Change in Whole Gut Transit time (minutes) 710 ± 1486 -35 ± 1588 0.3
Change in Ileal contractility (AUC) 64 ± 139 114 ± 175 0.5
Change in Colonic contractility (AUC) 5 ± 58 26 ± 72 0.5

Conclusion: The low FODMAP diet reduces caecal fermentation in comparison to the NICE diet as indexed by a reduction in the change in pH across the ileocaecal junction. Both diets improved GI and extra-GI symptoms as well as quality of life. Neither diet has a demonstrable differential effect on ileal/colonic contractility or segmental/gut transit times. It is therefore plausible that the efficacy of the low FODMAP diet in IBS-M is via mediated by alterations in the microbiota.

Introduction: Galacto-oligosaccharides (GOS) are indigestible short-chain carbohydrates (FODMAPs, fermentable, oligo-, di-, mono-saccharides and polyols)
associated with triggering gastrointestinal symptoms in irritable bowel syndrome (IBS).

**Aims & Methods:** This study aimed to assess whether oral α-galactosidase co-administration with foods high in GOS and low in other FODMAPs would reduce symptoms and breath hydrogen production in a double-blind, placebo-controlled, parallel-group trial approved by Monash University Ethics Committee. Patients meeting the Rome III criteria for IBS who produced >10 ppm hydrogen on two consecutive breath samples following 10 g fructans were recruited. Participants were randomly assigned to 11 week crossover study (300 GALLU α-galactosidase) and placebo (glucose). Following a 3 day low FODMAP run-in period, participants consumed provided diets high in GOS for a further 3 days. Gastrointestinal symptoms were measured daily using a 100 mm visual-analogue-scale. Breath samples were taken hourly on the second last day and analysed as area-under-the-curve. Faecal samples were taken at baseline and after 3 days as a measure of overall symptoms. Of those, full-dose enzyme reduced overall symptoms (24.5 [17.5–35.8] mm vs 5.5 [1.5–15.0] mm; p = 0.422). Twenty-one participants exhibited GOS-sensitivity (> 10 mm increase for overall symptoms). Of those, full-dose enzyme reduced overall symptoms (24.5 [17.5–35.8] mm vs 5.5 [1.5–15.0] mm; p = 0.006) and bloating (20.5 [9.5–42.0] mm vs 6.5 [2.0–15.8]; p = 0.017). Breath hydrogen production was minimal with no differences seen between placebo and 5248 ± 3D 3339 ppm (12h) and full-dose (5585 ± 3205; p = 0.597, paired samples t-test).

**Conclusion:** An oral α-galactosidase supplement taken with high GOS foods provides a clinically significant reduction in symptoms in GOS-sensitive individuals with IBS. The lack of change in breath hydrogen production suggests poly-ethylene glycol may not be related to reduced gas and distention, rather suggesting a role of alterations to the microbiota. Future analysis of the faecal microbiota may provide insight for the mechanism of action. This strategy can be easily translated into practice with acceptable tolerance specifically to high GOS foods for patients with IBS as an adjunct therapy to the low FODMAP diet.

**Disclosure of Interest:** J.S. Barrett: The Department of Gastroenterology financially benefits from the sales of a digital application and booklets on the low FODMAP diet.

**Introduction:** Balloon expulsion testing (BET) is a recommended means of identifying dyssynergic defecation (DD) in patients with chronic constipation although it remains poorly standardized and underutilized outside of specialized centers. We aimed to assess the clinical utility of BET as an initial test for DD and to determine appropriate testing parameters.

**Methods:** We performed a literature search (PubMed, EMBASE, conference abstracts from 1950-2016) to identify (1) case-control studies of DD or unselected CC subjects and healthy controls and (2) cohort studies of unselected subjects with CC. Eligible studies reported BET test parameters and results as well as presence of DD defined by constipation symptoms and a positive reference test (anorectal manometry [ARM], defecography, or electromyography[EMG]). Study quality was assessed using QUADAS criteria. We extracted age, sex, enrollment criteria, BET test parameters (subject position, study duration, instilled volume, allowed interval time), and DD diagnostic criteria. Data were independently extracted by two authors. Meta-analysis was performed using a bivariate mixed-effects regression model. Meta-regression was performed to evaluate effects of individual test parameters. Between-study heterogeneity of summary results was assessed using an I² statistic. Publication bias was assessed using Deeks’ funnel plot asymmetry test.

**Results:** We identified 15 eligible studies comprising 2,090 individual assessments of balloon expulsion, of which 14 studies of 1,760 subjects were eligible for cohort analysis and 1,088 subjects were eligible for case-control analysis. Among cohort studies, the AUC was 0.80 (95% CI 0.61-0.91) with 70% sensitivity (95% CI 52%-83%) and 77% specificity (95% CI 70%-82%). Among pooled cohort and case-control studies, the AUC was 0.84 (95% CI 0.68-0.93) with 70% sensitivity (95% CI 53%-82%) and 81% specificity (95% CI 75%-86%). Further test performance characteristics stratified by subject position are reported in Table 1. Subject positioning (seated vs. left lateral decubitus) did not significantly affect AUC in cohort (p = 0.32) or case-control (p = 0.43) analysis. Pooled sensitivity (p = 0.50) and specificity (p = 0.66) were similar between seated and left lateral BET in analysis of unselected CC cohort studies, though specificity was higher with left lateral BET in pooled analysis of all studies (p = 0.03). The allowable time for balloon expulsion did not significantly affect summary sensitivity (p = 0.92) or specificity (p = 0.96) in meta-regression within the evaluated range of 1 and 5 minutes. There were enough studies to warrant meta-analysis of balloon distention characteristics, 13 of 17 studies reported 50-60 mL of water. When pooling cohort and case-control studies, both age (p < 0.01) and gender (p < 0.01) appeared to influence test performance. Changes of reference test did not significant affect test performance (ARM vs. defecography [p = 0.43], defecography vs. EMG [p = 0.08]). Continent of origin (p = 0.34) and year of study (p = 0.29) did not appear to significantly influence test performance. There was no evidence of publication bias (p > 0.5).

**Table 1:** Sensitivity and specificity of balloon expulsion testing in diagnosing dyssynergic defecation (stratified by subject positioning with 95% confidence intervals)

P1152 IMMUNOHISTOCHEMICAL EXPRESSION OF DIAMINE OXIDASE IN THE UPPER GASTROINTESTINAL TRACT OF PATIENTS WITH GASTROINTESTINALLY MEDICATED FOOD ALLERGY

T. Vasilikis1, R. J. Rieker2, J. Heinrich3, A. Missichl4, A. F. Hagel5, J. Kreissl6, M. Raithel7
1University Clinical Center Erlangen, Erlangen/Germany
2Pathologisches Institut, University Clinical Center Erlangen, Erlangen/Germany

4SCIOTEC Diagnostic Technologies GmbH, Tulln/Austria

Introduction: Gastrointestinally mediated food allergy (GMA) is a common disease that has risen in recent years. The scientific research on this disease has increased, however its diagnosis still remains difficult to date. Diamine oxidase (DAO) is an enzyme that deactivates histamine, the main mediator in allergic reactions, through oxidative deamination. It has been shown that the enzymatic activity of DAO is diminished in the colonic mucosa of patients with GMA. Up to now no studies concerning the expression of DAO in the upper gastrointestinal tract (GIT) of patients with GMA have been published. Therefore, the objective of this study was to analyse the immunohistochemical staining of DAO and its localisation in the upper GIT of patients with or without GMA.

Aims & Methods: The study was retrospective. The GMA group consisted of 21 patients with gastrointestinally mediated food allergy. The control group (CG) included 17 patients with neither food allergy nor food intolerance. Tissue samples from esophagus, cardia (subdivided in esophageal and gastric region), corpus, antrum and duodenum already obtained during endoscopy were immunohistochemically stained for DAO. The expression of DAO was semi-quantitatively analysed with the following scale based on the staining intensity of DAO (SI-DAO): 0 (no staining intensity of DAO), 1 (weak staining intensity of DAO), 2 (moderate staining intensity of DAO), 3 (strong staining intensity of DAO). DAO was also examined vertically from the epithelium to the submucosa in all segments of the upper GIT. The enzymatic activity of DAO is diminished in the colonic mucosa of patients with GMA. DAO with the number of mast cells was also observed in both groups, but this difference was significant only in the GMA group (r = 0.46; p = 0.02). An additional correlation of SI-DAO with OLGA classification and to correlate the results with OLGA classification.

Results: Immunohistochemical analysis found DAO in all segments of the upper GIT, but the SI-DAO was overall low. Across the upper GIT the median SI-DAO in the CG was 1.1 (range 0.9–1.3). The SI-DAO did not differ between the examined tissues. The SI-DAO was also low in the GMA group (median 1.0; range 0.8–1.3) and it was statistically significantly lower compared to the controls (median 1.1, p = 0.004) only in duodenum in the GMA group the SI-DAO in the esophageal region of the cardia and in corpus was significantly higher than in duodenum (see Table 1). The strongest DAO-staining was detected in the subepithelial lamina propria (SLP) of all tissues. A strong inverse correlation of SI-DAO with the number of eosinophils across the upper GIT was observed in the GMA group (r = 0.89; p = 0.02). An inverse correlation of the SI-DAO with the number of mast cells was also observed in both groups, but this result was not statistical significant (GMA: r = 0.71; p = 0.11; CG: r = 0.6, p = 0.14).

Table 1: SI-DAO in the upper GIT. P1-Value: comparison between GMA and control group. P2-Value: comparison of the SI-DAO in duodenum with the other segments of the upper GIT in the GMA-group. N: number of tissue samples.

Conclusion: The above findings indicate that DAO is present in low amounts in all segments of the upper GIT. But only in the duodenum a significant difference was found between GMA and CG, thus indicating that histamine-mediated symptoms most likely arise in duodenum. Therefore, regarding the upper GIT, the immunohistochemical staining for DAO only in duodenum could serve as an additional diagnostic parameter for detecting patients with GMA and possibly other histamine-mediated diseases. The above mentioned distribution pattern of DAO strengthens the theory that DAO acts extracellularly and is responsible for the elimination of the trans epithelially absorbed exogenous histamine as well as of the endogenous histamine, as its highest staining intensity is found at the SLP throughout the upper GIT.

**2Cardiff & Vale University Health Board, Cardiff/United Kingdom**
**3General Surgery, University Hospital of Wales, Cardiff/United Kingdom**

**Contact E-mail Address:** powell16@cardiff.ac.uk

**Introduction:** Despite undergoing potentially curative resection a significant proportion of patients develop cancer recurrence. Several cellular and humoral components of systemic inflammatory response have been reported and associated with poor outcome. To date, no study has comprehensively examined the relationship between readily available markers of inflammation and survival in gastric cancer.

**Aims & Methods:** Patients undergoing surgery for stage I-II gastric cancer between 2004-2016 at a regional unit were identified. Measurements of various systemic inflammation markers were recorded pre-operatively. Pathological variables including TNM stage, differentiation of tumour and early satiation, nausea, bloating were recorded at baseline and after 3, 6, 12, 24 months, according to severity score (0-3 for each symptom, min. 0; max. 12 = full symptom).

**Results:** The total symptomatic score results as follows, lasting the 24 months follow-up. Group 1: baseline 4.93; 3 months 3.36; 6 months 2.96; 24 months 2.64. Group 2: baseline 5.9, 3 months 6.2, 6 months 5.6, 24 months 5.8 (p < 0.01).

Subdividing the CAG patients according to the etiology (autoimmune gastritis or previous Helicobacter pylori infection) no differences were found in improving symptoms. No relevant side effects were observed during the study.

**Conclusion:** The administration of L-cysteine to subjects affected by moderate-severe chronic atrophic gastritis seems able to improve the symptoms in a two-year follow-up.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** nobuyuki_sugisaki@epharma.co.jp

**Introduction:** Upper gastrointestinal (GI) adverse effects induced by NSAIDs and anti-thrombotic drugs are increasing along with progressive aging of society. Recently it is essential to perform pharmaco-epidemiological studies to identify adverse effects in the real-world setting using a large-scale medical database. We conducted a case-control study to study the risk of upper GI mucosal injuries in subjects prescribed NSAIDs and anti-thrombotic drugs using the large organized database of claims in Japan.

**Aims & Methods:** The medical claims database developed by Japan Medical Data Center (JMDC) Co., Ltd. was selected as data source in the present retrospective observational study. The JMDC claims database comprised of integrated medical and pharmacy claims, and includes both hospital and outpatient care from over 90 payers (approximately 3.7 million of population on an accumulated basis). Eligible subjects were aged 20 to 74 and registered for at least 3 months in the database from January 2009 to December 2014. The evaluated upper GI mucosal injuries were peptic ulcers (143,271 cases), upper GI bleeding (10,545 cases) and gastroesophageal reflux disease (GERD: 154,755 cases) with diagnosis by ICD-10 codes and implementation of the upper GI endoscopy. For the each test-case, ten controls who matched age, sex and diagnosis month were identified from the database. Multivariate logistic regression analysis was used to calculate odds ratios of occurrence of each upper GI mucosal injuries caused by NSAIDs, COX-2 selective inhibitors, low-dose aspirin, antplatelet drugs (except low-dose aspirin) and antiocoagulants.

**Results:** The odds ratios of peptic ulcers were 1.45, 1.31, 1.50, 1.53 and 1.62 for NSAIDs, COX-2 selective inhibitors, low-dose aspirin, antiplatelet drugs, and antiocoagulants respectively. In the case of the presence of peptic ulcers (p < 0.0001 in each). The odds ratios of upper GI bleeding were 1.76, 1.62, 1.96, 1.82 and 2.38, and those of GERD were 1.54, 1.41, 1.89, 1.67 and 1.91, and these odds ratios were statistically significant in each medicine with GI bleeding and GERD (p < 0.0001 in each). The odds ratios of all the upper GI mucosal injuries were the highest in the patients with antiocoagulants, and the ratios were relatively low in those with NSAIDs and COX-2 selective inhibitors. The odds ratios tended to increase with the number of prescribed

**Conclusion:** Rebleeding in UGIB is associated with increased in-hospital mortality; nevertheless, it is not related with delayed 6-months mortality, hemorrhagic and cardiovascular events. High creatinine and low albumin levels were independent risk factors for rebleeding, suggesting a potential predictive role of these parameters. AIMS65, Rockall and Blatchford were predictors for in-hospital mortality but worked poorly in the patients who suffered rebleeding.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1156 ANALYSIS OF REBLEEDING PATIENTS IN UPPER GASTROINTESTINAL BLEEDING IN A SINGLE CENTER SERIES**

**1Gastroenterology, Virgen de las Nieves**, Granada/Spain
**2Gastroenterology, "Virgen de las Nieves" University Hospital, Granada/Spain**

**Contact E-mail Address:** eredonroc@gmail.com

**Introduction:** Upper gastrointestinal bleeding (UGIB) is one of the main causes of hospital admission and urgent endoscopy in Gastroenterology departments. In-hospital mortality from UGIB has decreased throughout the past 2 decades with a corresponding increase in the performance of endoscopy and endoscopic therapy. Aims: To study that improvements in the therapeutic procedures for patients with UGIB could be responsible of the mortality decline. Despite this, UGIB represents a true emergency, associated with significant morbidity, mortality and healthcare costs. Furthermore, rebleeding after initial endoscopic therapy is observed in 10-25%, and it has been associated with a higher mortality rate. Therefore, the definition of predictive factors for rebleeding is of outstanding importance.

**Aims & Methods:** The goal of our study is to analyze risk factors and outcomes in a population of patients who suffered rebleed. We present a prospective study on a prospectively built database of patients with GI bleeding admitted to the Emergency Room of “Virgen de las Nieves” University Hospital over 42 months, from January 2013 to July 2016. All patients underwent upper endoscopy, and demographic data, coagulation parameters, current medications (including antplatelet drugs, NSAIDs and oral antiocoagulants), clinical presentations, hemodynamics, admission laboratory test results, and endoscopic findings was collected. Interventions were documented, including the need for blood transfusion and the number of packed red cells units per patient, endoscopic therapy, intervention radiology procedures, and surgery. Clinical outcomes documented were in-hospital and delayed 6-months mortality, rebleeding and delayed 6-months bleeding and cardiovascular events. Results: 507 patients were included (339 males; aged 62 ± 16.4). The incidence of rebleeding was 17.3% (n = 88). In the univariate analysis, factors related with rebleeding were creatinine levels (1.52 vs. 1.15; p < 0.001), tachycardia (96.28 vs. 88.24; p < 0.001), low levels of albumin (2.80 vs. 3.28; p < 0.001) and low CO2 partial pressure (103 vs. 109; p < 0.001). In a logistic regression analysis tachycardia and high creatinine were independent risk factors for rebleeding, and albumin showed as an independent protective factor (Table 1). Rebleeding was associated with in-hospital mortality (p < 0.0001); by contrast, it was not related with delayed 6-months mortality. Nevertheless, delayed 6-months mortality, hemorrhagic and hemorrhagic events. The UGIB risk scores AIMS 65 and Rockall showed poor predictive ability for acute in the rebleeding patients’ group and was similar for Blatchford score (based on AUROC).

**Disclosure of Interest:** All authors have declared no conflicts of interest.

---

**L-cysteine has been proposed as adjuvant therapy in CAG; the amino acid binds covalently to acetaldehyde (a Group I human carcinogen), removing it from the stomach. The aim of present study was to use L-cysteine to improve the symptoms in patients with diagnosis of CAG.**

**Aims & Methods:** One hundred fourteen consecutive patients (M = 43, mean age 56.9 years) (with diagnosis of CAG by means of both gastric histology (moderate to severe chronic, atrophic, body gastritis according to the OLGA staging system) and serology (pepsinogen 1 < 25 µg/l, gastrin-17 > 14 pmol/l) - GastroPanel®, Boehi Oty, Finland) entered the study. Forty-one patients (11 M, mean age 49.4 yr, range 27–71 years) were treated with L-cysteine (100mg 3 times daily, with meals) for 24 months (Group 1). As a control group we enrolled 73 CAG patients (M = 32, mean age 55.3 yr, range = 32–77 yrs) followed up for 24 months without any related therapy (Group 2). All the patients were included in the study. Measurements of various systemic inflammation markers were recorded pre-operatively. Pathological variables including TNM stage, differentiation of tumour and early satiation, nausea, bloating were recorded at baseline and after 3, 6, 12, 24 months, according to severity score (0-3 for each symptom, min. 0; max. 12 = full symptom).

**Results:** The total symptomatic score results as follows, lasting the 24 months follow-up. Group 1: baseline 4.93; 3 months 3.36; 6 months 2.96; 24 months 2.64. Group 2: baseline 5.9, 3 months 6.2, 6 months 5.6, 24 months 5.8 (p < 0.01).

Subdividing the CAG patients according to the etiology (autoimmune gastritis or previous Helicobacter pylori infection) no differences were found in improving symptoms. No relevant side effects were observed during the study.

**Conclusion:** The administration of L-cysteine to subjects affected by moderate-severe chronic atrophic gastritis seems able to improve the symptoms in a two-year follow-up.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
medicines (1 agent <2 agents <3 agents, peptic ulcer: 1.38 < 2.49 < 4.52, upper GI bleeding: 10.74 < 3.95 < 7.77, GERD: 1.61 < 2.96 < 5.88, respectively). The upper GI mucosal injuries were exacerbated in complication of lifestyle-related diseases, including hyperlipemia and diabetes mellitus.

Conclusion: Prescribing NSAIDs and anti-thrombotic medicines was associated with increased risks of developing upper GI injury. The present study is a central study utilizing the large organized database of claims in Japan provided precise clinical evidence for safety management of medical drugs in the clinical settings in Japan.

Contact E-mail Address: alia.hadfi@gmail.com

Introduction: Percutaneous left atrial appendage occlusion (LAAO) is increasingly recognized as valid alternative therapy to reduce thromboembolic risk in patients with non valvular atrial fibrillation (AF) and contraindications for long term oral anticoagulation (OAC) therapy. Patients at high thromboembolic risk with previous gastrointestinal bleeding (GIB) might be at risk of bleeding recurrence in case of resuming anticoagulation. They could be selected for alternative therapies like LAAO. Up to now, there is no scientific consensus for patient selection for LAAO based on recurrent GIB risk.

Aims & Methods: We aimed to review the literature on gastrointestinal (GI) bleeding recurrence of patients after AF-related cardioembolism with AF and stratified of selected patients for LAAO. We systematically collected data from both prospective and retrospective studies from pubmed in order to extract rebleeding risk by repeating episodes. The rebleeding profile was defined by type of treatment needed to cure the lesion. Low reversibility (LR) profile was defined as a need for heavy surgery, radiotherapy, embolisation to cure the lesion or as diffuse lesions.

Results: The most frequent reported causes of bleeding are peptic gastroduodenal ulcer (60%) for upper GI, diverticulosis (40%), colitis (20%) and anorectal diseases (20%) for lower GI and angiodyplasia (23%) for the midgut, these latter being responsible for 5% of all GIB bleeding causes. The rate of recurrent bleeding under OAC therapy is 5-7% in patients with gastrointestinal K antigens (VKA), an incidence that might increase with direct OAC. Recurrent bleeding rates for upper GIB, lower GIB and obscure GIB are respectively 5-15%, 30-60% and 40-50%. In the upper GI tract, lesions at high risk of bleeding recurrence are Dieulafoy lesions and angiodyplasia with reported rates up to 40% in some series. In the lower GI tract, lesions at highest risk are diverticular disease, angiodyplasia, colitis and radiation rectitis with bleeding recurrence rates reaching 60%, 70%, 40% and 20% respectively. For the midgut, angiodyplasia (20%) and bleeding of unknown origin (20%) are associated to the highest risk of recurrent bleeding. LR profile lesions with high rebleeding risk are present for diffuse angiodyplasia, systemic diverticulosis and Dieulafoy lesions.

Conclusion: In conclusion, GI lesions at high risk of recurrent bleeding with low reversibility profile are infrequent and include in particular: diffuse angiodyplasia, colonic diverticulosis and Dieulafoy lesions. Patients with AF having those lesions should be considered for anti-embolic treatment like LAAO. Larger studies are needed to assess the long term outcome of patients treated by LAAO for GIB under current oral anticoagulant therapies.

2Postgraduate School of Medicine, Birmingham/United Kingdom

Contact E-mail Address: keith@siau.org

Introduction: Peptic ulcer disease (PUD) accounts for 25–56% of acute upper gastrointestinal bleeding (AUGIB) and is associated with high mortality. Aims & Methods: In line with international guidelines, we aimed to audit our practice of bleeding PUD at a district general hospital within the West Midlands, UK. We retrospectively identified all patients with AUGIB who had inpatient endoscopic confirmation of PUD between November 2012–2014. We scrutinised the endoscopy and case records to assess management related to PUD, in addition to follow-up records with the general practitioner.

Results: We identified 91 patients (median age 78.4, 65.9% male), of whom 63.7% were admitted with AUGIB, whereas 36.3% developed bleeding during their hospital stay. The majority (74.7%) vs. <70% (25.3%) were related to aspirin/non-steroidal anti-inflammatory drug use. 48.5% (52.7%) had high risk (Forrest 1a-2b) lesions, of whom 38/48 (79.2%) received dual endoscopic therapy and 6/48 (12.5%) received endoluminal monotherapy. 18.8% received the recommended adrenaline volume of 15 mL. Of 90% prescribed intravenous proton pump inhibitor infusion, 85% did not complete the full 72-hour duration. Rebleeding occurred in 12 patients (13.2%) after a median of 3-days post endoscopy. 10 (83.3%) underwent repeat OGD. 2 (16.7%) underwent CT embolisation, whilst 4 (32.5%) underwent surgery. Aspartin resumption was observed in 4/20 (20.0%) after haemostasis for PUD, whilst rebleed planning was documented on the endoscopy report in 33.0%. Regarding H. pylori, 51% underwent assessment with endoscopy, 10 (36%) had positive result of whom 7 (70%) received eradication. 12/23 (52.2%) patients underwent follow-up endoscopy following gastric ulcer. The median transfusion requirement per patient was 2 units. Despite this, rates of anaemia at discharge and at 6 months were 83.5% and 62.9% respectively, with liver therapy initiated in 12.1%. Overall, our 30-day mortality rate was 12.1%.

Conclusion: In this single-centre study, the management of PUD could be improved in multiple areas in line with international guidelines. Audits in other centres are required to assure the management of PUD sufficiently. Interestingly, rates of anaemia at discharge and on follow-up are high. Such patients may profit from iron replacement at discharge.

Disclosure of Interest: All authors have declared no conflicts of interest.

2. Zhong M, Chen WJ, Lu XY, Qian J, Zhu CQ. Comparison of three scoring systems in predicting the prognosis, such as mortality and ICU admission rate. AJR 2009;193:400-9.
Aims & Methods: The aim of this study is to compare the performance of pre-endoscopy (pre-RS), post-endoscopy Rockall score (post-RS), GBS and AIMS65 scores in predicting the need for intervention in patients admitted to hospital for UGIB. Aims & Methods: Data related to the three scoring systems were collected prospectively and scores were calculated in consecutive patients who were admitted with acute UGIB to the Royal Adelaide Hospital over 24 months. The performance of these scoring systems was evaluated using receiver operating characteristic (ROC) curves, in predicting the outcome of endoscopy. The estimated factors were age (<65 vs. >65 years), gender, location of ulcer (upper third/middle or lower third in HGU and 2nd portion/bulbs in HDU), presence of endoscopic complications, antacid treatment, endoscopic varices and endoscopic hemostasis tests. Cirrhosis was post viral hepatitis C (89%), hepatitis B (10%) and diabetes mellitus (9%)

Conclusion: Despite being a univariate logistic regression analysis revealed that the independent risk factors for rebleeding in HDU were multiple ulcers [odds ratio (95% confidence interval) = 24.2 (2.76–213), P = 0.004], steroid administration [14.0 (1.73–113), P = 0.013], and hemodialysis [9.53 (1.00–90.7), P = 0.049]. Regarding the detail of endoscopic rebleeding, multivariate logistic regression analysis showed that middle and high-risk surgery had significantly higher rebleeding rate of HGU and HDU (≥20 mg in predinsolone) (52.7 [3.19–871], P < 0.0001) was a significant risk factor for rebleeding of HDU, with a dose-response relationship (P = 0.005).

Disclosure of Interest: All authors declare no conflicts of interest.

P1162 STEROID ADMINISTRATION IS AN INDEPENDENT RISK FACTOR FOR REBLEEDING IN HEMORRHAGIC DUODENAL ULCER WITH A DOSE-RESPONSE RELATION

Aims & Methods: The aim of this study was to clarify the difference of rebleeding between HGU and HDU, and associated factors for rebleding of HGU and HDU. Between March 2005 and September 2016, 176 consecutive patients with hemorrhagic duodenal ulcer (106 with HGU and 70 with HDU), who underwent endoscopic hemostasis, were enrolled in this study. Regular dose proton pump inhibitor was administered to all patients after the diagnosis of hemorrhagic duodenal ulcerous ulcers. Rebleeding was defined as hematemesis or melena with ulcers confirmed by endoscopy or a decrease in the hemoglobin level >2 g/dl in the presence of endoscopically proven ulcers. First, we compared the rebleeding rate between HGU and HDU. Subsequently, associated factors for rebleding of HGU and HDU were calculated by logistic regression analysis individually. The estimated factors were age (<65/>65 years), gender, location of ulcer (upper third/middle or lower third in HGU and 2nd portion/bulbs in HDU), underlying comorbidities (ischemic heart disease, liver cirrhosis, hypertension, diabetes mellitus, and hyperlipidemia), number of ulcers (multiple/single), hemostasis method (pure ethanol injection therapy/other therapies), antiplatelet therapy, anticoagulation therapy, NSAID administration, endoscopic administration, antacid administration in the initial ulcer bleeding, hypoalbuminemia (serum albumin level ≤2.5 g/dl), and hemodialysis. We further investigated the detailed association between steroid administration and rebleding in HDU, including dose-response relation.

Results: The rebleeding rate of HGU and HDU were 5.7% and 22.9%, respectively, which was statistically significant (P = 0.001). There was no missing data in the estimated factors. Although no factor was associated with rebleding in HDU by the univariate logistic regression analysis, the independent risk factors for rebleding in HDU were multiple ulcers [odds ratio (95% confidence interval) = 24.2 (2.76–213), P = 0.004], steroid administration [14.0 (1.73–113), P = 0.013], and hemodialysis [9.53 (1.00–90.7), P = 0.049]. Regarding the detail of endoscopic rebleeding, multivariate logistic regression analysis showed that middle and high-risk surgery had significantly higher rebleeding rate of HGU and HDU (≥20 mg in predinsolone) (52.7 [3.19–871], P < 0.0001) was a significant risk factor for rebleeding of HDU, with a dose-response relationship (P = 0.005).

P1163 EFFICACY AND SAFETY OF BIO-INSERT MINERAL SMECTITE IN CONTROLLING GASTROINTESTINAL HEMORRHAGE: AN ANIMAL PILOT STUDY

1The First Affiliated Hospital with Nanjing Medical University, Nanjing/China
2Digestive Endoscopy Center, the First Affiliated Hospital of Nanjing Medical University, Nanjing/China

Contact E-mail Address: kir1978@sina.com

Introduction: Gastrointestinal bleeding is common in clinics, especially after endoscopic operation. Besides from hemoclip, APC or electrocoagulation, more novel hemostasis approaches should be developed to improve endoscopic bleeding management. Granular smectite is bioinert material and efficient for curing diarrhea. Inspired by its dehydrating and tissue-covering effect, this pilot study was to investigate its efficacy and safety for controlling hemorrhage in rats.

Aims & Methods: 32 rats were divided into four equal groups. For hemorrhage model, a horizontal 10-mm incision was made on the lower part of the left hepatic lobe. Commercial hemostatic powder, smectite, starch and normal saline were respectively applied. Bleeding duration and blood loss were recorded. 1 week later, rats were sacrificed and liver tissue was collected for histopathology.

Results: Smeectomy demonstrated the best hemostasis effect, and its mean coagulation time was 1.45 ± 0.026 min. Commercial hemostatic chitosan stycip powder need 2.5 ± 0.04 min for complete clotting, while Starch group was 4.25 ± 0.056 min and 4% formal saline group was 4.92 ± 0.0108 min. Similarly, smeectomy led to less blood loss (0.618 ± 0.034 g), while rats lost 2.3288 ± 0.123 g blood (p < 0.05) under normal saline treatment. For starch and commercial chitosan, the blood loss was respectively 2.0862 ± 0.061 g and 1.925 ± 0.0238 g. Histopathologic results confirmed that smeectomy was biocompatible to tissue.

Conclusion: The mineral smectite powder was the superior candidate for hemostasis treatment in vivo. Compared with common polysaccharide agents, smectite could induce faster coagulation and reduce blood loss. More importantly, biocompatible, smeectite was biocompatible and even promoted the wound healing. For gastrointestinal application, smectite powder could be delivered through endoscopic spray tube, while its inspiring efficacy required more endoluminal hemostasis tests.

P1164 PREDICTORS OF LIFE THREATENING MUCOSAL ULCERATION AFTER VARICELLE SCLEROTHERAPY

A. S. Hanafy

Internal Medicine, Zagazig University, Zagazig/Egypt

Contact E-mail Address: dr_amr_hanafy@yahoo.com

Introduction: Life-threatening bleeding could occur early after varicelle sclerotherapy in cirrhotic patients.

Aims & Methods: We aimed to determine simple predictive factors of this complication in cirrhotic patients. Among 750 patients treated with varicelle sclerotherapy (esophageal varices [EV] = 655, 87.5% and (gastroic varices [GV] = 95, 12.7%) Zagazig University hospital–endoscopy unit– Internal medicine department, in the period from October 2014 till July 2016. 150 patients (20%, mean age 46 ± 9.4 years) (EV = 129, GV = 21) developed bleeding due to sclerotherapy induced ulcers confirmed by endoscopy 6.4 ± 2.1 days after the procedure. Cirrhosis was post viral hepatitis C (89%), hepatitis B (10%) and cryptogenic in (1%). A case-control study was performed comparing these

A572 United European Gastroenterology Journal 5(5S)

Disclosure of Interest:

with acute UGIH. These findings suggest that GBS is the best performed risk and death, it is superior to both Rockall and AIMS65 scores in predicting the
patients with 150 patients who underwent endoscopic variceal sclerotherapy without the development of bleeding due sclerotherapy ulceration.

**Results:** Bleeding occurred 6.4 ± 2.1 days (2–10) following sclerotherapy. Twenty-three patients died following the bleeding (15.3%). Using a multivariate analysis; pre-procedural factors as serum albumin >2 g/dl [OR 1.3]; total bilirubin >1.6 mg/dl [OR 1.7]; platelet ratio index (APRI) >1 [OR 1.2]; low prothrombin concentration <50% [OR 1.5]. Intraprocedural factors as amount of ethanolamine >15.5 ml [OR 2.6], amacryate >3.5 ml [OR 2.9]. Post- procedural factors within 24 hours after endoscopy; leukocytosis >12,000 cell/µl [OR 1.9], drop of hemoglobin >10% of the pre-endoscopic value [OR 3.2], prolonged INR >1.55 [OR 1.2].

**Conclusion:** Bleeding related to sclerorat ulcers is uncommon, but may be life threatening. The proposed predictive factors should be watched and minimized before and during variceal sclerotherapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Few studies were reported on the association between sleep disorders and Rome III-based functional dyspepsia (FD).

**Aims & Methods:** The aim of this study is to investigate the prevalence of sleep disorders in FD patients and the risk factors associated with sleep disorders. This multicenter, cross-sectional study had been conducted from August 2014 to December 2016 at 6 hospitals in Korea. Inclusion criteria were FD patients (≥18years) met the Rome III criteria among the patients visited the gastroenterology department for dyspepsia. Exclusion criteria were prior surgery to the upper gastrointestinal tract, history of ulcer disease, erosive GERD, history of malignancy, and severe comorbidity. Healthy control group who had no clinical history of gastroduodenal related disorder and no abnormal finding on endoscopy recruited from health examination center for screening. The Pittsburgh Sleep Quality Index was used to assess sleep disturbance. Hospital anxiety and depression scale was used to identify anxiety and depression.

**Results:** This study included 160 FD patients and 223 healthy control groups. The total Pittsburgh Sleep Quality Index score was higher in FD patients than healthy control (41.2% vs 18.4%, p = 0.0001). The prevalence of sleep disorder was significantly higher in FD patients than healthy control (41.2% vs 18.4%, p = 0.000). In univariate analysis, FD was significant risk factor for sleep disorder (OR 3.12, p = 0.0001). The independent risk factors for sleep disorder in multivariate analysis were FD (OR 1.80, p = 0.026), female (OR 1.78, p = 0.028) and depression (OR 2.91, p = 0.001).

**Conclusion:** FD significantly impacted on sleep disorder. FD was independent risk factor in sleep disorder.

**Disclosres of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Dyspepsia and gastro-oesophageal reflux are highly prevalent in the general population, but the two conditions are felt to be separate entities. However, there are numerous mechanisms implicated in the pathogenesis of functional dyspepsia, some of which are common to gastro-oesophageal reflux symptoms (GORD), including visceral hypersensitivity and delayed gastric emptying. To inform future research on potential shared pathophysiological mechanisms, it is important to estimate the strength of association between the two conditions, and whether this association remains stable depending on the criteria used to define these conditions, as well as geographic location.

**Aims & Methods:** We conducted a systematic review and meta-analysis to estimate the prevalence of dyspepsia in individuals with gastro-oesophageal reflux symptoms, and to quantify the overlap between the two disorders. MEDLINE, EMBASE, and EMBASE Classic were searched (up until September 2016) to identify population-based studies reporting the prevalence of dyspepsia and GORD, defined using specific symptom-based criteria or a questionnaire. The prevalence of dyspepsia and weekly GORD were extracted for all studies. Pooled prevalence, according to study location and criteria used to define weekly GORD or dyspepsia, as well as odds ratios (OR), with 95% confidence intervals (CIs) were calculated. The degree of overlap between the two was examined.

**Results:** Of 14,132 papers evaluated, 79 reported prevalence of weekly GORD. Nineteen of these study populations, containing 111,459 participants, also reported the proportion of individuals with dyspepsia. The prevalence of dyspepsia in those with weekly GORD was 43.9% (95% CI, 35.1–52.9%). The pooled OR for dyspepsia in individuals with weekly GORD, compared with those without, was 6.54 (95% CI 4.33 to 11.12). The OR for dyspepsia in weekly GORD was significantly higher than that reported for gastrointestinal reflux disease (GORD) diagnostic criteria used. The pooled degree of overlap between the two conditions was 25.9% (95% CI, 19.9–32.4%), varying from 22% when the Bowel Disease Questionnaire was used to define weekly GORD, to 42.6% with the Mayo Reflux Disease Index.

**Conclusion:** The OR of dyspepsia in individuals with weekly GORD was seven-fold that of individuals without GORD, and that there is overlap between the two conditions in up to one-quarter of individuals. Reasons for this remain speculative, but may include shared pathophysiological mechanisms or residual confounding.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

as a predictor among individuals with FGID (Table 1). Epigastric symptom severity was predicted by worry and psychological attribution of symptoms among FGID individuals but no psychological trait predicted symptom severity among non-FGID individuals (Table 1).

Conclusion: A range of psychosocial factors predict later gastrointestinal symptom burden. For bowel symptoms, associations between psychological traits and symptom burden appear to be most clearly driven by the non-FGID subgroup, among whom psychological attributions for symptoms and problem-focused coping are positively related to later symptom burden. For epigastric symptoms, a range of psychological traits were relevant, with the predictive patterns being most clearly driven by individuals who qualified for FGIDs. In light of these results, studies of the brain-gut axis need to consider a greater array of psychological traits, particularly outside of anxiety and depression. Further, the commonality between psychosocial factors and gastro-esophageal symptoms may be moderated by symptom level but are relatively similar across upper and lower gastrointestinal symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In the recent years, there has been an increasing recognition of the presence of gastrointestinal (GI) dysfunction in patients with neurologic diseases. There are no studies examining a relationship between achalasia and neurodegenerative/demyelinating diseases of central nervous system, although these diseases might have common features. For example, a number of genetic resolutions manometry, endoscopy and esophagogram. A total of 140 consecutive patients with confirmed esophageal achalasia. Achalasia was diagnosed by high-resolution manometry, endoscopy and esophagogram. A total of 140 consecutive patients with esophageal achalasia have been questioned about the occurrence of neurological diseases and symptoms in their personal and family history. Those with a suspicion of a neurological disease were referred for a detailed clinical neurology interview, MR imaging of the brain and electrophysiological study. A total of 106 patients with a neurodegenerative/demyelinating disease have been questioned by using a questionnaire about the occurrence of symptoms typical for achalasia (dysphagia, regurgitation, chest pain). Results: A total of 51 out of 140 patients (36.4%) exhibited some neurological symptoms, 5 patients (3.6%) had definitely been diagnosed with a neurodegenerative/demyelinating disease (multiple sclerosis - 2 patients, Lebert optic neuropathy - 1 patient, Parkinson’s disease - 1 patient and Allgrove syndrome - 1 patient). Furthermore, 7 patients with a positive questionnaire had been diagnosed with other neurological diseases (tetyan n = 2, carpal tunnel syndrome n = 1, epilepsy n = 2). Fourteen patients (27.4%) among those with neurological symptoms (vs. 0 out of 89 patients without neurological symptoms) had a positive family history of a neurodegenerative or a demyelinating disease. Among 106 patients with a neurodegenerative/demyelinating disease, 30 of them (27.4%) described dysphagia was for them a part of personal history. These patients will be examined by esophageal manometry.

Conclusion: Our results imply an increased prevalence of neurodegenerative/ demyelinating diseases in patients with achalasia (3.6% vs. approx. 1.4% in the Czech controls). Also, a high prevalence of dysphagia was found among patients with a neurodegenerative/demyelinating disease. These results warrant further confirmation in a large population-based study.

Introduction: Visceral pain is a complex percept influenced by numerous factors. Of these, differences in the autonomic nervous system (ANS)-in particular, parasympathetic cardiac vagal tone (CVT)-has been suggested to have a physiological role in the regulation and modulation of painful sensory signalling, to the extent of vagal nerve stimulation (to raise subject CVT) being tested as a possible anti-nociceptive.

Aims & Methods: To date, no studies have explored the brain functional connectivity or network properties of CVT in relation to a painful stimulus, and thus this was our aim. In 21 healthy participants (10 male; mean age 30 years (range 21–53 years), we quantified resting CVT using a Neuroscope. For all subjects, functional MRI data were acquired using a 3T MRI scanner during painful oesophageal balloon distention, described elsewhere(). The effect of resting CVT on brain networks during acute oesophageal pain were determined by means of network based statistics(). Brain nodes were selected a priori of previous anatomic/visceral pain literature and included the following: bilateral (bil) medial prefrontal cortex, anterior cingulate (ACC), amygdala, insula, pallidum, thalamus and single hypothalamus (Xnodes = 11). (3) Oxygen level dependant (BOLD) signal during oesophageal balloon distention to pain tolerance threshold was extracted from each of these regions and cross-correlated to produce nodal correlation matrixes, which were dichotomized by means of median split based upon resting CVT value, and a two-tailed t-test of was undertaken. A primary threshold was applied (t = 1.65; p < 0.05) and permutation tested 50,000 times to ensure statistical stringency applied.

Results: We identified a unique subcortical brain connectivity network in the high resting CVT individuals when exposed to acute oesophageal pain. This complex symmetrical network comprised all 11 nodes with a total of 18 edges (significant

When considered jointly with other predictors, psychological attribution of symptoms was significantly positively related to both bowel symptom severity (non-FGID: OR = 0.31, SE = 0.13; Full: OR = 0.74, SE = 0.11 and epigastric symptom severity (FGID: OR = 0.63, SE = 0.09; Full: OR = 0.63, SE = 0.11). The same was the case for worry (Bowel: Full: OR = 1.40, SE = 0.21; Epigastric: FGID: OR = 1.48, SE = 0.27; Full: OR = 1.54, SE = 0.23). For bowel symptoms, problem-focused coping (OR = 2.30, SE = 0.98) was an additional independent positive (notably, not negative) predictor among participants without FGIDs.
Introduction:

Oesophageo-gastric junction outflow obstruction (OGJOO) is of unclear significance. It may be secondary to an incomplete form of achalasia, a mechanical obstruction or be idiopathic. Rapid drink challenge (RDC) test is easy to perform during oesophageal HRM.

Aims & Methods: We aimed to assess the yield of RDC in patients with OGJOO. From a database of 3252 consecutive oesophageal HRM performed from 01/2012 to 03/2017, we extracted patients with OGJOO according to the Chicago Classification v3.0. HRM protocol consisted of 10 ml water swallows in supine position and RDC test (200-ml free drinking) in sitting position. Distal contractile integral (DCI) integrated relaxation pressure (IRP), distal and pan-oesophageal pressurization (POP; homogeneous oesophageal pressurization >30 mmHg) were reported for 5-ml swallows. POP and oesophageal shortening (OS) were analysed during RDC. Symptom severity was assessed with Eckardt score. Causes of OGJOO were determined by reviewing patients’ chart for previous oesophago-gastric surgery (43%), incomplete achalasia (7%), mediastinal neoplasia (5%), other (13%), no symptom (3%). The causes of EGJOO were previous oesophago-gastric surgery (34%), incomplete achalasia (7%), mediastinal neoplasia (7%), miscellaneous (19%) and unknown (25%). RDC test was successful in 70 patients (93%) and associated with POP and OS in 41% and 15%, respectively. Dysphagia as dominant symptom was more frequent (79% vs 59%, p = 0.017) and more severe (Eckardt score 5 (1–11) vs 3 (0–10), p = 0.03) in patients with POP during RDC compared to those without. The same observation was achieved in patients with OS vs those without (dysphagia 100% vs 62, p = 0.02 and Eckardt score 6 (2–10) vs 1 (0–11), p = 0.02). Manometric parameters were reported in the table. The causes of OGJOO were similar in patients with and without POP during RDC (previous oesophageo-gastric surgery 34% and 51%, respectively, achalasia 14% and 2%, mediastinal neoplasia 3% and 7%, miscellaneous 10% and 22%, unknown 35% and 7%). OS was not observed in patients with unknown cause of EGJOO vs 20% of patients with an identified cause (p = 0.09).

**References**

**Conclusion:**
While RDC test cannot be used to determine EGJOO cause, patients with POP or OS during RDC had more severe dysphagia than those without. In patients with POP, the highest DCI might be secondary to obstruction. Further prospective studies should determine if RDC test could help to select patients who might benefit from treatment.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1171 THE NORMATIVE VALUES OF A NEW 36 CHANNELS WATER PERFUSION ESOPHAGEAL MOTILITY CATHETER**

**S. Bor. S. Kipcak**

*Gastroenrology Sec., Ege Reflux Study Group, Ege University, izmir/Turkey*

**Contact E-mail Address:** kipcaksezgi@gmail.com

**Introduction:** High resolution manometry (HRM) is performed with solid-state catheters (SS) in many centers. However according to Chicago classification, very limited data from healthy volunteers are available for some catheters and starting from IRP, numerical values are crucial for the diagnosis. Because of the cost of the SS-HRM catheters many centers especially from developing countries use water perfusion HRM (W-HRM) catheters up to 24 channels and normal values are even more limited.

**Aims & Methods:** We evaluated a prototype 36 channels W-HRM reused catheter allowing to measure 3-D pressure vector volume analysis of lower esophageal sphincter in healthy volunteers and compared to 36 channels SS-HRM catheters (Laborie-MMS Canada). We included 43 healthy volunteers without any upper gastrointestinal complaint. Upper gastrointestinal endoscopy and 24h impedance-pH monitoring performed in all subjects. Four subjects were excluded because of silent GERD. 39 subjects were analysed (25 males, W-HRM (n = 39), SS-HRM (n = 33)). Thirty-three patients underwent two esophageal manometry studies within two consecutive days with a random order. Procedures were performed in supine position with receiving ten times 5 ml water, five times solid food and multiple water swallow with 200 ml of water. 36 channel water-perfused 3-D HRM catheter and 36 channel solid state HRM catheter were used (Laborie-MMS Canada).

**Results:** There was significant differences between two catheters in terms of Integrated Relaxation Pressure (IRP), Distal Contractile Integral (DCI) and DCI expanded, LES resting pressure, % of ineffective peristalsis, and esophageal length both with water and solid food swallows (Table). No difference has been shown with distal latency (DL), LES length, breaks size (Table).

**Conclusion:** Water perfusion HRM catheter exhibits significantly lower values especially for IRP, DCI, LES resting pressure. Centers which are working with water perfusion catheters should not accept universal normal established with solid state catheters and need to work on their normative values. The ineffective peristalsis pattern is common with water perfusion catheters.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P1172 LOW-VOLUME MULTIPLE RAPID SWALLOW BETTER DISTINGUISH PERISTALTIC ESOPHAGEAL RESERVE COMPARED TO HIGH-VOLUME RAPID DRINKING TEST
1Gastroenterology Unit, University of Pisa, Pisa/Italy

Introduction: The Chicago Classification (CC V3.0) defined ineffective esophageal motility (IEM) by the presence of 50% or more of weak or failed peristaltic waves during high resolution manometry (HRM). Both low-volume (10ml) multiple rapid swallow (MRS) and high-volume (200ml) rapid drinking test (RDT) have been suggested as test to recognize the esophageal peristaltic reserve. Which test might better represent the esophageal peristaltic reserve is still a matter of discussion.

Aims & Methods: The aim of this study was to compare the diagnostic value of MRS and RDT in patients with IEM. From a larger group of patients evaluated for heartburn and/or regurgitation with poor response to standard dose proton pump inhibitors, we enrolled consecutive patients with IEM and with functional heartburn (FH). FH were enrolled as controls. IEM was defined according to the CC V3.0, and FH were defined according to the Rome IV criteria. All patients underwent 3 MRS (10ml of water in 5 swallows in less then 10s) and 1 RDT (200ml of water freely drunk). All patients underwent 24-h impedance and pH recording (MII-pH). Mean DCI of MRS and DCI of RDT were compared with mean DCI of 10 single swallows (SS). The MRS/SS and RDT/SS ratio were calculated.

Results: We evaluated 30 patients with IEM (18 males and 12 females; mean age 45.7±11.4 yrs) and 30 patients with FH (15 males and 17 females; mean age 49.5±12.4 yrs) and 30 patients with FH (17 females; mean age 41.2±13.6). Impedance and pH 24-h analysis was performed to select patients with FH (normal AET and number of reflux and lack of reflux-symptom correlation). During HRM the mean DCI resulted similar in patients with EGJ-OO compared to FH (p=0.839). One-hundred and eighty MRS and 60 RDT were evaluated. The lack of body inhibition was found in 11% (20/180) during MRS and in 53% (16/30) during RDT in EGJ-OO. No patients in FH showed lack of body inhibition during both MRS and RDT. All results are reported in Table 1.

Table 1: Results of SS, MRS and RDT in patients with IEM and FH

Introduction: Esophageal motor dysfunction and abnormal bolus transit are often encountered on high resolution impedance manometry (HRIM) performed prior to anti-reflux surgery (ARS) in gastroesophageal reflux disease (GERD). Esophageal motor dysfunction can be characterized using established software tools embedded in HRIM software, while new paradigms of interrogation of bolus presence and flow have been introduced with automated pressure flow analysis (PFA). The prevalence, and clinical relevance of these motor and bolus flow abnormalities to symptom presentation or symptom outcome from ARS are incompletely understood.

Aims & Methods: Our aim was to evaluate the interrelationships between esophageal motor function and bolus transit using varying bolus consistencies, in health and in the context of symptomatic GERD prior to ARS. HRIM studies hasak.s@wustl.edu

Contact E-mail Address: hasak.s@wustl.edu

Introduction: The Chicago Classification (CC V3.0) defined the presence of esophageal motor and body inhibition during repetitive swallowing in patients with EGJ-OO when the value of integrated relaxing pressure (IRP) is higher than 15mmHg during high-resolution manometry (HRM). Both low-volume (10ml) multiple rapid swallow (MRS) and high-volume (200ml) rapid drinking test (RDT) were never evaluated to detect the inhibition of esophageal body in patients with EGJ-OO.

Aims & Methods: The aim of this study was to compare the efficacy of MRS and RDT in evaluating the esophageal body inhibition during repetitive swallowing in patients with EGJ-OO and patients with functional heartburn (FH) considered as control group. From a larger group of patients evaluated for dysphagia with negative upper endoscopy, we enrolled consecutive patients with EGJ-OO, and as control group, patients with functional heartburn (FH) defined according to the Rome IV criteria. EGJ-OO was defined according to CC V3.0. HRM performed according to the Italian guidelines. All patients underwent 3 MRS (10ml of water in 5 swallows in less then 10s) and 1 RDT (200ml of water freely drunk). The mean DCI of MRS and the DCI of RDT were compared with DCI of 10 single swallows (SS) mean value. The MRS/SS and RDT/SS ratio were calculated.

Results: The lack of esophageal body inhibition during multiple swallowing tests was defined if contraction was identified measuring >3 cm using the 30mmHg isobaric contour tool.

Conclusion: Patients with EGJ-OO showed less peristaltic reserve during MRS and RDT. The RDT evidenced more frequently lack of body inhibition in patients with EGJ-OO.

Disclosure of Interest: All authors have declared no conflicts of interest.
PATIENTS WITH OESOPHAGEAL DIVERTICULA

P1175 PROVOCATIVE TESTING INCREASES THE DIAGNOSTIC YIELD OF HIGH RESOLUTION OESOPHAGEAL MANOMETRY IN PATIENTS WITH OESOPHAGEAL DIVERTICULA

Introduction: Oesophageal diverticula are rare diverticula of the gastrointestinal tract known to be associated with oesophageal motor disorders.

Aims & Methods: The aim was to study manometric abnormalities associated with oesophageal diverticula, using both wet and solid swallows. Patients underwent high resolution oesophageal manometry (HRM) in the upright position. 18 patients with oesophageal diverticula were found and were free of previous surgery. Traction diverticulum was excluded in all patients. We also included 10 healthy controls. HRM was performed using wet (5 mL of water) swallows in both groups, followed by solid (meat) swallows in patients. Mean age of the controls was 50 years old while for patients it was 70 years old for men and 75 years old for women.

Results: The main reported symptom was dysphagia (76%). HRM found 11 (61%) patients with an oesophageal motor disorder, including 2 oesopagogastric junction outflow obstruction (OGJOO), 4 achalasia (subtype 2: n = 2; subtype 3: n = 2), 4 distal oesophageal spasms (DES) and 1 jackhammer oesophagus, and was normal in 7 (39%) patients. In those patients with normal findings, solid swallows identified 4 (57%) additional motor disorders, including 2 OGJOO, 1 jackhammer oesophagus and 1 DES. Provocative testing using solid swallows improved the diagnostic yield by 22% in overall patients and by 57% in patients with normal manometry using wet swallows only. Mean pressure slopes at mid-oesophagus and oesophageal diverticula were greater in patients than healthy controls (p < 0.05 for wet swallows), as previously reported1. Other metrics are summarized in the table.

| HRM metrics with comparisons between wet swallows in controls and patients, and between wet and solid swallows among patients. * p < 0.05 ** p < 0.01 *** p < 0.001 |
|---|---|---|
| Controls (liquids) | Patients (liquids) | Patients (solids) |
| Number of swallows | 9.30 | 9.94 | 9.41 |
| EGJ resting pressure (mmHg) | 29.30 | 28.76 | 34.66 |
| Mean IRP 4s (mmHg) | 11.50 | 14.32 | 18.25* |
| Mean DCI (mmHg.s.cm) | 1315.10 | 2877.99 | 7341.67*** |
| Distal latency (s) | 6.70* | 6.05 | 7.11* |
| Intrabolus pressure (mmHg) | 8.10 | 11.88* | 15.19 |
| Mean pressure slope mid-oesophagus (mmHg/s) | −0.65 | 2.29** | 2.59 |
| Mean pressure slope distal oesophagus (mmHg/s) | −0.36 | 1.41** | 0.46 |

Conclusion: While more than one-third of HRM using wet swallows were normal, provocative testing using solid swallows increased the diagnostic yield of the procedure by more than 50% in these patients. Analysis of pressure slopes confirmed the association of propagating peristalsis with the disease.

Discourse of Interest: All authors have declared no conflicts of interest.

Introduction: The management of achalasia targets relieving the obstruction at the esopagogastric junction (EGJ) by pneumatic dilation (PD), laparoscopic Heller myotomy (LHM) plus a fundoplication variant (Dor, Toupet and more rarely Nissen/Nissen-Rossetti). However, effective ablation of the LES barrier can induce gastroesophageal reflux disease (GERD). Recently, new metrics to evaluate EGJ function with high resolution manometry (HRM) have been introduced, such as EGJ contractile integral (EGJ-CI). Currently there are few data investigating how achalasia treatments impact EGJ function based on these metrics.

Aims & Methods: We aimed to assess the EGI-CI metric in achalasia before and after different treatments, to verify if post-operative changes in this metric correlate to symptom relief and iatrogenic GERD following surgical treatments. Methods Between 2014 and 2015, we enrolled consecutive achalasia patients. All patients underwent clinical evaluation with Eckardt and GERDQ score, as
well as upper endoscopy, barium esophagogram and HRM before and 6 months after treatment. Achalasia was classified according to the Chicago Classification V3.0. The EGJ-C1 was calculated using the distal contractile integral tool-box during three consecutive respiratory cycles. Patients underwent to pneumatic dilatation (PD), or LHM plus a Dor (LHM-D), Toupet (LHM-T) or a Nissen-Rossetti (LHM-NR) fundoplication. Ethical approval for the study was obtained.

**Results:** We enrolled 35 achalasia patients (14 Type I, 16 Type II and 5 Type III). Ten patients underwent PD, 11 LHM-D, 8 LHM-T and 6 LHM-NR. At baseline, no differences were observed in terms of age, sex, pre-operative mean Eckardt score, GERDQ score, integral relaxation pressure (IRP) and EGJ-C1 were recorded. All Type III subjects underwent LHM-D (3) and LHM-T (2). After all the procedures, in all the patients there was a significant decrease in Eckardt score, IRP and EGJ-C1 (p < 0.001, < 0.001 and < 0.05, respectively). PD and LHM-NR showed higher EGJ-C1 (20 ± 9.3 and 25 ± 11.1 mmHg*cm, respectively) and IRP (12.2 ± 3.4 and 13 ± 4.5, respectively) than LHM-D and LHM-T (18 ± 5.9, < 0.05 and 9.3 ± 4.1, p < 0.05 mmHg*cm, respectively for EGJ-C1; 5.2 ± 2.5, < 0.05 and 2.3 ± 3.7 p < 0.001 mmHg*cm, respectively for IRP). Post-operative Eckardt score was lower in LHM-D and LHM-T (2.1 ± 0.5 and 2.0 ± 0.6, respectively) than PD and LHM-NR (4.2 ± 1.0, p < 0.01 and 3.7 ± 1.5, p < 0.05). Post-operative GERDQ score was significant higher in LHM-D (3.0 ± 1.7 vs. 8.2 ± 3.9, p < 0.05). Low post-operative EGJ-C1 values correlated with an increased risk of higher post-operative GERDQ score (p < 0.05, odds ratio 4.223, 95% CI 0.964–2.123).

**Conclusion:** All procedures performed to treat achalasia produced an adequate relief of dysphagia. LHM-D and LHM-T seem to result in a stronger alteration of the EGJ, with LHM-T resulting in an increased risk of post-operative reflux.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Jackhammer esophagus is a rare esophageal motility disorder. Little is known about its physiopathology; however, an excess of cholinergic drive has been suggested as an important etiologic factor. Multiple rapid swallowing (MRS) is an adjunctive test in order to evaluate integrity of inhibitory and excitatory neural pathways. In healthy subjects body motion inhibition is observed during MRS and a contraction stronger than single swallows (SS) occurs after MRS, the so-called peristaltic reserve (MRS/SS DCI ratio > 1). In patients with Achalasia esophagus preservation of motor inhibition during MRS has been described with traditional manometry. No study has evaluated peristaltic reserve and motor inhibition with high-resolution manometry (HRM) in patients with jackhammer esophagus.

**Aims & Methods:** To evaluate MRS in a consecutive multicenter series of 42 Jackhammer esophagus patients (18 Male; 63 years; 55–71) according to Chicago 3 classification. 18 healthy subjects (HS) (seven male; 28 years; 23–33) from a published series were used as a control group. All patients underwent solid state HRM with ten 5 ml SS and one to three 10 ml MRS (30 patients performed at least two MRS). Standard HRM parameters during SS were evaluated. During MRS presence/absence of motor inhibition and 4 second integrated relaxation pressure (4 sec IRP) were evaluated. After MRS distal contractile integral (DCI) was evaluated and DCI ratio between MRS and SS was measured. Mann Whitney, Wilcoxon and chi-squared tests were used when appropriate; data are shown as median-IQ range.

**Results:** Descriptive data in jackhammer patients are shown in table 1. Twelve patients did not have motor inhibition during at least one MRS (28% vs 5% in HS, < 0.05). There was a trend toward a lower 4s IRP during MRS compared to SS (see table 1); however, values were higher than those of 4s IRP MRS in HS (5.1 mmHg; 2.2–11 vs 1.6 mmHg; 0.3–2, p < 0.0001). MRS DCI was significantly lower than SS DCI, interestingly 26 patients had a MRS/SS DCI ratio < 1 (62% vs 22% in HS, < 0.0005) and it was lower than the MRS/SS DCI ratio of HS (0.8; 0.4–1.1 vs 1.9; 1.1–2, p < 0.0001) suggesting a reduction of the hypercontractile activity in the esophageal body.

**HRM parameters during single and multiple rapid swallows in jackhammer patients. Median; interquartile range.**

</tbody>
</table>

**Conclusion:** Contrary to what occurs in healthy subjects, MRS reduce DCI value compared to SS in jackhammer esophagus patients, suggesting altered neural control of peristalsis. Differently to what previously observed with traditional manometry, motor inhibition during MRS is altered in a quarter of patients. Studies are needed in order to evaluate if reduction of DCI during MRS can improve dysphagia and chest pain in these patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**

This study included 55 subjects in FD group and 200 subjects in Control group. FD group was defined as the group of patients with or without findings in each 19 finding. Subjects who had epigastralgia (score 2, 3 or 4), postprandial fullness (score 3 or 4) or early satiation (score 3 or 4) in the m-FSSG were classified as having such endoscopic findings. The aim of this study is to explore which endoscopic findings are defined precisely. However, it is not discussed whether we can distinguish between NERD and FD because the m-FSSG contains seven endpoints. Atrophy (16.6% vs. 30.4%, p = 0.02), hypersecretion (25.0% vs. 48.5%, p = 0.006), and diffuse redness (8.7% vs. 23.0%, p = 0.012) were more frequent in the FD group compared with the Control group. Atrophy (25.0% vs. 48.5%, p = 0.006), hypersecretion (25.0% vs. 48.5%, p = 0.006), and diffuse redness (8.7% vs. 23.0%, p = 0.012) were more frequent in the FD group compared with the Control group.

Conclusion: Cap-assisted technique is 100% effective in the management of impacted FBO in the esophagus, with a significantly shorter procedural time and improved safety profile compared to the conventional approach. Cap-assisted approach was associated with a shorter total procedural time (34 ± 8.3 vs. 43 ± 22 min, p = 0.006), a shorter length of hospital stay (0.95 ± 0.36 vs. 1.38 ± 1.36 days, p = 0.0017) and more en-block removal (9/34 vs. 22/43, p < 0.001). There were more complications in the conventional than the cap-assisted group (7/106 vs. 0.93; P = 0.01).

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: The endoscopic follow-up was planned every month. After 1 months, 18-23 cm esophageal region had to be normal. Within 6 months, the stricture process was exactly delayed as expected. The patient stated his symptom was remarkably improved. Gastroscopy revealed the esophageal implanted lesion was covered with an epithelium and the luminal surface was flat, without ulceration.

Conclusion: Autologous esophageal mucosa transplantation might facilitate tissue re-epithelialization, reduce pathological fibroplasia, and be helpful for managing or preventing esophageal strictures. More clinical controlled trials are required to provide evidenced-based recommendation and promote its clinical application.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We enrolled 124 patients (M = 84, mean age = 45.3± 13.05 years) with functional dyspepsia. We studied gastric atrophy (PGI) in 51.2% (+/- 13.7 y range 20-73) characterized by achlorhydria or low levels of acid production (Group 1), or by duodenal ulcer (50, M = 42, mean age = 43.5 ± (+/- 11.5 range = 17-65) in which an hypersecretory state is claimed (Group 2). Among the 3 groups, we studied 46 patients (M = 44 mean age = 44.0 ± (+/- 13.4 range = 25-80) with normal upper GI endoscopy and gastric histology, without previous history of neoplasms or upper gastrointestinal surgery (Group 3). In all patients we measured M.A.O. by means of two hours collection of gastric juice (basal 30’, followed by an i.m. injection of pentagastrin at the dosage of 6 µg/kg) (M.A.O. normal values: 5-25 mEq/h). All patients underwent blood sample for determination of serum PGI (BioHit Oyj, Finland; normal values: 30-120 µg/l). All determinations, both for M.A.O. and PGI were made off medication.

Results: The mean M.A.O. value in group 1 was 2.15 mEq/h, in Group 2 52.49 mEq/h, in Group 3 17.48 mEq/h. A statistically significant difference was found between the 3 groups (Group 1 vs. Group 2 p < 0.000001; Group 1 vs. Group 2 p < 0.001; Group 2 vs. Group 3 p < 0.0001). The PGI mean values in Group 1 was 11.39 µg/l, in Group 2 107.72 µg/l, in Group 3 84.28 µg/l (Group 1 vs Group 2: p < 0.000001; Group 1 vs Group 2: p < 0.0001; Group 2 vs Group 3 p < 0.05). The relationship between M.A.O. and PGI showed a Pearson R = 0.683 (p = 0.001). No statistically significant difference was found comparing M.A.O. and PGI in the single groups (p = ns).

Conclusion: Serum PGI levels are fitting with M.A.O. both in hypo- and hyper-acid secretory conditions like chronic atrophic gastritis and duodenal ulcer, as well as in control subjects, suggesting that PGI could be adopted in clinical practice to assess gastric acid production in individual subjects for a proper management of acid related diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1185 THE DISCREPANCY BETWEEN THE ACID REGURGITATION SYMPTOMS AND ENDOCOPIC GERD GRADE IN DIABETES MELLITUS PATIENTS**

K. Sakitani, N. Suzuki

The Institute for Adult Life Diseases, Asahi Life Foundation, Tokyo/Japan

Contact E-mail Address: sakitani-iky@umin.ac.jp

Introduction: Gastroesophageal reflux disease (GERD) is caused by reflux of gastric acid into esophagus. It is reported that chronic inflammation caused by GERD can lead to precancerous changes; Barrett’s esophagus. Thus, it could be critical to assess the GERD. Diagnosis of GERD is based on the subjective symptoms such as acid regurgitation. GERD is also diagnosed by endoscopy, and the Los Angeles (LA) classification is commonly used to grade reflux esophagitis endoscopically. It is well known that diabetes mellitus (DM) patients can develop neuropathy and their ability to feel pain can decrease. However, it is not known whether there is a discrepancy between the symptoms and endoscopic GERD grade in DM patients.

Aims & Methods: From May 2015 to September 2016, patients who were taken esophagogastroduodenoscopy by experienced endoscopists at our institution were consecutively enrolled. All the patients completed the Gastrointestinal Symptom Rating Scale (GSRS); an interview-based rating scale consisting of 15 items including the question on acid regurgitation (Dig Dis Sci 1988). The GSRS has a seven-graded Likert type scale (score 1 represents absence of symptom, and score 7 represents very bothersome symptom). Gastric atrophy, reflux esophagitis, and esophageal hiatal hernia were diagnosed endoscopically.

The study patients were categorized according to the grade of LA classification of GERD. The prevalence of patients with positive GSRS score (i.e. 2 or more) in the DM group and non-DM group were compared using the Pearson’s chi-square test.

Results: A total of 2438 patients (647 females and 1791 males, mean age 62.4 years) were examined. Of these, 1040 patients (42.7%) were DM, and 1398 patients (57.3%) were non-DM patients. The prevalence of gastric atrophy, reflux esophagitis, and esophageal hiatal hernia were not different in DM group and non-DM group. Mild GERD (LA-A) was found in 251 patients (10.6%, 92 DM patients and 159 non-DM patients), and severe GERD (LA-B and more severe) was found in 19 patients (3.12%, 40 DM patients and 36 non-DM patients). Of the 36 non-DM patients with severe endoscopic GERD, 30 patients (83.3%) had positive GSRS score of acid regurgitation; however, of the 40 DM patients with severe endoscopic GERD, 19 patients (47.5%) had positive GSRS score of acid regurgitation. The prevalence ratio of patients with positive GSRS score in severe endoscopic GERD was statistically lower in DM patients than in non-DM patients (p = 0.0016).

Conclusion: There is a discrepancy between the subjective symptoms and endoscopic GERD grade in DM patients. DM patients’ ability to feel acid regurgitation could decrease.

Disclosure of Interest: All authors have declared no conflicts of interest.

A. Sánchez Pernaute, E. Rey, B. Merchan Gomez

The mean BMI was 41.55 (M 43.3; F 41.0) with no differences between men and women. The mean age of patients with MO was 43.1 years (range 19–68) with no significant differences between men and women.

Aims & Methods: We conducted a cross-sectional study of 32,762 asymptomatic adults who underwent routine health check-ups including screening endoscopy from August 2006 to December 2011. Sarcopenia was defined as appendicular skeletal muscle mass (ASM)/body weight (%) value beyond two standard deviations from the mean for healthy young adults. Participants were categorized into four groups according to obese and sarcopenic status: normal, obese, sarcopenic, and obese sarcopenic.

Results: In a multivariate model adjusted for age, sex, smoking status, alcohol intake, regular exercise, and metabolic variables, risk of reflux esophagitis was higher in obese (adjusted odds ratio (AOR), 1.38; 95% confidence interval (CI), 1.26–1.52), sarcopenic (AOR, 2.20; 95% CI, 1.48–3.29), and obese sarcopenic obese participants (AOR, 1.68; 95% CI, 1.39–2.03) than in normal participants. The ORs concerning sarcopenic and sarcopenic obese participants to obese participants were 1.59 (95% CI, 1.06–2.38) and 1.12 (95% CI, 1.02–1.47), respectively. In addition, the risk of reflux esophagitis according to sarcopenic and obese status was observed similarly in all subgroups that were evaluated.

Conclusion: These findings suggest that sarcopenia, regardless of obesity, is more harmful condition for reflux esophagitis than obesity without sarcopenia.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1187 FOOD RATE (FREQUENCY AND TIME SPENT IN EATING) IN PATIENTS WITH MORBID OBESITY. DIFFERENCES AND SIMILARITIES BETWEEN MEN AND WOMEN

J. Perez De La Serna, S. Aylon Cano, C. Sevilla Mantilla, A. Sánchez Pernaute, E. Rey, B. Merchan Gomez

Contact E-mail Address: aylonsonia@hotmail.com

Introduction: We evaluated the eating time of 118 subjects of the control group (63 women), the mean age was 28.3 years and 100 patients (77 women) with MO in the School of Medicine, Seoul/Korea, Republic of Korea.

Results: The relationship of demographic aspects with the number of meals and the time spent in eating) in patients with morbid obesity (MO), based on data from the diary of the 24-H esophageal pH-monitoring studies.

Conclusion: The caloric load, the proportion of its components and its patterns have been the object of multiple studies (1–5). One of the most controversial aspects is the relationship between the frequency of meals and body weight.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1188 ONE DRINK CAN INCREASE A RISK FOR ESOPHAGEAL, STOMACH AND COLORECTAL CANCER IN A COHORT OF 23,323,730 KOREAN ADULTS

Y.J. Choi, D.H. Lee

Contact E-mail Address: olin0602@naver.com

Introduction: Epidemiologic findings of low-volume alcohol consumption in relation to gastrointestinal cancers including gastric cancer are inconsistent.

Aims & Methods: The association between alcohol intake and esophageal, gastric and colorectal cancer risk was examined in a population-based prospective cohort of 23,323,730 adults in Korea who had undergone a biennial evaluation provided by the National Health Insurance Corporation between the years 2009 and 2012.

Results: After median 3.4 years of follow-up, 9171 esophageal, 135,382 gastric and 154,970 colorectal cancer cases were identified. Cox proportional hazards regression models were used to estimate hazard ratios (HR) and corresponding 95% confidence intervals (95% CI). Light drinking as well as moderate to heavy alcohol consumption significantly increased the risks of the three gastrointestinal cancer sites. The HRs were 1.51; 95% CI, 1.43–1.60; HR 1.10; 95% CI, 1.06–1.09; HR 1.12; 95% CI, 1.11–1.14 compared with non-drinkers after adjusting for age, sex, smoking, exercise, income, body mass index, and diabetes. For esophageal cancer, there was a dose-dependent linear relationship. However, no association was observed between prediagnostic alcohol consumption and all cause mortality. Conclusion: Light drinking including even one alcoholic drink a day is associated with increased risks of esophageal, gastric and colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1189 THE INFLUENCES OF VISCERAL FAT AREA ON THE SITES OF ESOPHAGEAL MUCOSAL BREAKS AND SYMPTOM SEVERITIES IN SUBJECTS WITH GASTROESOPHAGEAL REFLUX DISEASES

E. Cho, J.H. Kim

Contact E-mail Address: kimjaehak@dumc.or.kr

Introduction: Some studies have suggested the central obesity as a risk factor for gastroesophageal reflux diseases (GERD). However, the associations between visceral adipose tissue (VAT) and the sites of esophageal erosions or the symptom severities of GERD have not been studied yet.

Aims & Methods: The aim of this study was to evaluate the influences of visceral adipose tissue on the locations of erosions and symptoms of GERD. The subjects who underwent abdomen computerized tomography and esophagogastroduodenoscopy for routine checkup at the same day were collected from January 2007 to October 2016. 177 subjects who had erosive esophagitis (LA class A to D) were enrolled. Questionnaires including gastrointestinal symptoms were written before examinations. The abdominal obesity was evaluated by measuring visceral adipose tissue (VAT), subcutaneous adipose tissue (SAT), ratio of VAT to SAT, total adipose tissue (TAT), body mass index (BMI) and waist circumference (WC).

Results: Lower curvature (LC) side of esophagogastric junction (EGJ) was the most frequent site of mucosal breaks (103 cases, 58.2%) followed by posterior wall side (71 cases, 40.1%), anterior wall side (25 cases, 14.1%) and fundus side (1 case, 0.6%). Mucosal breaks in LC side were frequently observed in male subjects (61.3% vs. 36.4%, p = 0.04) and WC (89.0 ± 11.8 vs. 85.0 ± 9.1, p = 0.01) were significantly higher in LC group. Moreover, SAT ratio of VAT to SAT, and TAT were significantly higher in LC group. In the multivariate analysis, a higher VAT area (odds ratio (OR) 3.47, 95% confidence interval 1.38 to 8.73, 1st quartile vs. 4th quartile, p < 0.01) and ratio of VAT to SAT (OR 2.99, 95% CI 1.15 to 6.70, 1st quartile vs. 4th quartile, p = 0.02) were strongly associated with the mucosal breaks in LC.
P1190 A LESS COMPETENT OESOPHAGO-GASTRIC JUNCTION IS ASSOCIATED WITH OESOPHAGEAL ACID HYPERSENSITIVITY EVEN IN HEALTHY CONTROLS

Introduction: In normal subjects, the oesophago-gastric junction (OGJ) sphincter complex maintains a tight barrier between the oesophagus and stomach acid. However, gastro-oesophageal reflux disease (GERD) caused by acidic reflux has a prevalence of up to 26% [1]. One major factor determining whether gastro-oesophageal reflux occurs and eventually generates symptoms is the competency of the sphincter, which can be studied using distensibility testing. This way, we have previously shown in patients with Barrett’s oesophagus and healthy controls that an incompetent sphincter function was associated with more frequent reflux symptoms [2]. In the same patient groups, we also found greater oesophageal acid exposure and lower mucosal baseline impedance to be associated with impaired sphincter function. The latter probably represents a proxy for mucosal damage [3]. Other factors known to increase the perception of gastro-oesophageal reflux episodes are greater acidity, larger volume, and more proximal extent of the reflux content along with impaired mucosal integrity and sensitisation (peripheral and central) [1]. All of this said no studies of our knowledge have specifically addressed the possible association between sphincter function of the OGJ and oesophageal sensitivity.

Aims & Methods: We aimed to characterize oesophageal sensitivity in relation to OGJ competence, hypothesizing that sensitivity increases with impaired sphincter function. Twenty-three patients with Barrett’s oesophagus (mean age: 64.2 ± 7.7 years) and 12 healthy controls (mean age: 54.9 ± 10.8 years) were examined. A standard upper endoscopy to locate the OGJ was followed by distensibility testing of the OGJ using the EndoFLIP probe. At a later visit, experimental oesophageal sensitivity was assessed using a multimodal stimulation probe. After placement in the oesophagus just above the OGJ, the probe allows the measurement of dilated intercellular spaces with light microscopy.

Results: Oesophageal acid sensitivity increased with a more incompetent sphincter function. The latter probably represents a proxy for mucosal damage [3]. Other factors known to increase the perception of gastro-oesophageal reflux episodes are greater acidity, larger volume, and more proximal extent of the reflux content along with impaired mucosal integrity and sensitisation (peripheral and central) [1]. All of this said no studies of our knowledge have specifically addressed the possible association between sphincter function of the OGJ and oesophageal sensitivity.

Conclusion: Oesophageal acid sensitivity increased with a more incompetent OGJ. Based on this and previous findings, we suggest that even in some healthy controls, a modest degree of OGJ incompetence allows gastric acid to reflux. This may again lead to low-grade oesophageal inflammation and mucosal damage, thereby evoking acid hypersensitivity. The latter mechanism probably constitutes a reflex protective mechanism towards acid reflux.

Disclosure of Interest: B.P. McMahon: Barry P McMahon holds a minor share in Cosprom Inc., Galway, Ireland who manufactures the EndoFLIP probe. All other authors have declared no conflicts of interest.

References
esophageal hypersensitivity (1.5 ± 0.2) were significantly decreased when compared to HC (2.6 ± 1.6) and also true NERD (4.0 ± 2.0).

Conclusion: Pepsin may be considered a damaging factor in pathophysiology of GERD, but we could not find any difference between GERD phenotypes and unaffected controls. NERD group had less gastric acid versus other groups but this finding needs more studies to confirm.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1193 NON INVASIVE DIAGNOSIS OF UPPER GI DISEASES IN A PRIMARY CARE SETTING: A STUDY ON 1,900 PATIENTS

P1194 CHANGES IN ANTHROPOMETRIC AND METABOLIC PARAMETERS RELATED TO GASTROESOPHAGEAL REFUX DISEASE IN NON-OBESE CASES

Contact E-mail Address: ozlemgulx@yahoo.com

Introduction: Prevalence of obesity and the obesity-related diseases have been increasing in recent years (1). In the studies conducted there are views claiming that visceral fat-related central obesity causes digestion system diseases and increase in the number of gastroesophageal reflux symptoms in particular (1–6). Aims & Methods: In this study, we evaluated a primary care group in regard to waist circumference, BMI; LDL, Fat, Fat Mass, Total Body Water (TBW), obesity level, reflux score, acid reflux score and total score measurements. Fat free mass (FFM), muscle mass, bone mineral density (BMD) measurements in between the both groups have not been found statistically significant difference (p > 0.05) (Table 1). Consider this esophageal reflux symptoms a significant difference (p < 0.05) between the group suffering from sore throat, apnea, teeth grinding and GORH and the healthy control group has been found. Within the patients group a positive correlation between acid reflux score and BMI (r = 0.289) (p < 0.001), LDL (r = 0.387) (p < 0.001), visceral fat (r = 0.180) (p < 0.049) has been determined. A negative correlation between acid reflux score and TBW (r = 0.273) (p < 0.003) has been determined.

Conclusion: The frequency and severity of gastroesophageal reflux symptoms in the non-obese is closely related with body fat composition as those in the obese. Increase in abdominal and visceral fat composition may cause high risk of gastroesophageal reflux disease in individuals irrespective of their obesity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Esophageal baseline impedance (BI) levels have been recently proposed as a marker of mucosal integrity. Indeed, patients with non-erosive reflux disease (NERD) showed lower distal esophageal BI levels compared to healthy controls (HCs) due to the presence of abnormal distal esophageal acid exposure time (AET). On the other hand, no differences were found between NERD and HCs at proximal esophagus due to the limited proximal migration of the refluxate. Systemic sclerosis (SSc) is a systemic disease characterized by the deposition of collagen and matrix proteins in the connective tissue of the skin and visceral organs, such as the gastrointestinal tract. This event could potentially affect the conductivity of the esophageal wall and consequently reduce BI levels, also at proximal level, but data in this regard are limited.

Aims & Methods: We aimed to prospectively compare BI levels between a group of NERD patients and two groups of SSc patients, one with a clear manometric picture of scleroderma esophagitis (i.e. hypotensive esophageal-gastric junction pressure and absent peristalsis) and one without esophageal involvement. Consecutive patients with heartburn and those with a definite diagnosis of SSc underwent upper endoscopy in order to assess the presence of esophageal mucosal lesions. Further, a group of healthy subjects was used as controls (HCs). Therefore, all endoscopy-negative and SSc patients underwent esophageal high-resolution manometry and impedance-pH testing off-therapy. Impedance-pH tracings were blindly and manually reviewed, and we measured distal AET (PG I) and G-17 after the 6–8 weeks of PPI therapy in comparison with the baseline levels, were higher in first group than in the second one (first group: baseline PG I 98 mg/L, G-17 6.3 pmol/L; p: ns). The good response to full dose of PPI, assessed by an increase of both PG I and G-17, seems to be the pathophysiological background to explain the prognostic value of such markers.

Conclusion: Gastrin-17 and pepticinogen I increase after full-dose of PPI in GERD acute phase seems to be a simple non-invasive marker to predict early GERD relapse in one-year follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastroesophageal reflux disease (GERD), is characterized by frequent relapses after withdrawal of therapy and no prognostic markers of relapse are available to predict the outcome of the patients. Gastrin-17 (G-17) has been proposed as a non-invasive marker of reflux disease as well as a good marker of response to the therapy. Pepsinogen I (PG I) and Gastrin-17 (G-17) are claimed to increase in a statistically significant manner after proton pump inhibitors (PPIs) therapy. Aim of the study was to assess the prognostic value of G-17 during endoscopy in order to assess the presence of esophageal mucosal lesions. Further, a group of healthy subjects was used as controls (HCs). Therefore, all endoscopy-negative and SSc patients underwent esophageal high-resolution manometry and impedance-pH testing off-therapy. Impedance-pH tracings were blindly and manually reviewed, and we measured distal AET (PG I) and G-17 after the 6–8 weeks of PPI therapy in comparison with the baseline levels, were higher in first group than in the second one (first group: baseline PG I 98 mg/L, G-17 6.3 pmol/L; p: ns). The good response to full dose of PPI, assessed by an increase of both PG I and G-17, seems to be the pathophysiological background to explain the prognostic value of such markers.

Conclusion: Gastrin-17 and pepticinogen I increase after full-dose of PPI in GERD acute phase seems to be a simple non-invasive marker to predict early GERD relapse in one-year follow-up.

channel of the scope. Distal two rings were contacted to the distal and proximal parts of GERD symptoms approximately 20–26 cm from GFR. MMS Omega ambulatory recorder and Greenfield (6 imp, 1 pH) impedance catheter were used.

Results: MI can differentiate ERD from non-erosive groups but do not have a diagnostic value to discriminate NERD from FH-EH or controls. However, BI can segregate NERD from ERD addition to controls (Table 1).

Conclusion: As a new diagnostic tool, MI needs validation studies and our results failed to show additional diagnostic value in non erosive patients compared to healthy controls. Since regular catheters are failed, new balloon-shaped catheters should be validated. BI might be a better tool to discriminate NERD from this controls. This implicates that the esophageal epithelial resistance is impaired in this particular group compared to controls.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Atrophic body gastritis (ABG) is characterized by loss of oxyntic glands with consequent reduced acid secretion, hypergastrinaemia and, in a later stage, pernicious anemia (PA). Up to 40% of ABG patients complain of dyspepsia. Despite hypochlorhydria, in 21% of autoimmune gastritis (AG) patients gasophageal reflux (GER) symptoms have been reported and in one third of them (mostly non acidic) reflux has been documented at pH-monitoring. At this stage, regarding esophageal and histopathologic GER-related esophageal findings in this setting are lacking.

Aims & Methods: Aim of this study was to assess the occurrence of GER symptoms and endoscopic-histopathologic esophageal findings in ABG patients. During 12-months, 35 consecutive ABG patients [80% female; median age 60 yrs (27-81)]; BMI 25.7±kg/m2[18.2-33]; fasting gastrinemia 329 pg/ml (215-1476); pepsinogen I 10 ng/l (0–44); positive Ab against parietal cells were included gastroscopy for malignancy surveillance irrespectively to gastrointestinal (GI) symptoms, were included. The presence of GER typical symptoms (heartburn and regurgitation), atypical (cough, no cardiac chest pain and dysphagia) and dyspepsia (postprandial distress syndrome (PDS) and epigastric pain syndrome (EPS)) was assessed by a standardized questionnaire. Hiatral hernia and erosive esophagitis were evaluated. Biopsies from distal esophagus (at least 2) and gastric mucosa (at least 5) were collected. Histopathological evaluation, performed by experienced pathologist who was not aware of the symptoms and clinical data collected: i) histology of intercellular spaces (DIS); ii) basal cell layer hyperplasia; iii) intraepithelial eosinophils; iv) neutrophils and iv) mononuclear cells. Gastric biopsies were evaluated according to updated Sydney System. Moderate-severe body gastric atrophy was confirmed in all patients. No patients with anti-secretory drugs.

Results: 74.3% (36/35) of ABG patients complained at least one GI symptom: 45.7% (16/35) reported GER symptoms [typical (2/14), atypical (9/14) and both typical and atypical symptoms (5/14), 48.6% (17/35) PDS and 11.4% (4/35) EPS dyspepsia. One GER patient had erosive esophagitis (LA-C according to Los Angeles classification) with concomitant hiatal hernia and another one presented a short tongue of columnar lined mucosa at distal esophagus with an area of intestinal metaplasia (Barrett’s esophagus, C2M2 according to Prague Consensus). Among ABG symptomatic patients, 34.6% (9/26) presented GER-related microscopic esophagitis, whereas the remaining symptomatic patients were free of microscopic esophagitis. Esophageal findings, both endoscopic and microscopic esophagitis, were exclusively present in symptomatic ABG patients (Fisher-t: p = 0.00027). Evaluating only autoimmune gastritis patients (n = 26), the occurrence of esophageal findings was not related to the presence symptoms (Fisher-t: p = 0.1915).

Conclusion: A third of ABG symptomatic patients, investigated by specific questionnaire and endoscopic-histopathologic findings of esophageal mucosa ranging from GER-related microscopic esophagitis to Barrett’s esophagus. These findings show that, even in hypochlorhydric patients, esophageal mucosal damage may occur, suggesting the opportunity to accurately investigate esophagogastroduodenitis in ABG symptomatic patients.
Currently, there are no real-world data assessing the efficacy of short-term empirical treatment with PPIs in GERD patients in China.

Aims & Methods: This was a multicenter, prospective, observational study carried out in a real-world setting. The primary objective was to determine the overall responder rate in patients with typical GERD symptoms after 4 weeks of empiri- cal treatment with PPIs. Responder were defined as having heartburn/regurgita- tion on ≤1 day during the prior 7 days, assessed by the GERD-Q questionnaire. Outpatients aged between 18 and 65 years with a GERD-Q score ≥8 were enrolled if they were prescribed standard-dose PPIs as empirical treatment and were not planned to have an endoscopy within 4 weeks of enrollment. The PPI regimen prescribed was decided completely at the physicians’ discretion. Patient demo- graphics, diagnosis, prescribed PPI regimens, GERD-Q score and symptom frequen- cy were recorded. Data were collected at baseline, weeks 2 and 4 after initiating PPI treatment. Results from the full analysis set (FAS) are presented.

Results: A total of 1,000 patients from 10 centers were screened for this study, of which 987 met the inclusion criteria and were included in the FAS. The mean age was 45.2 ± 11.6 years, the mean body mass index was 23.4 ± 3.3 kg/m², and 50.3% of the patients were male. The mean duration of GERD was 0.8 ± 2.6 years, with a mean baseline GERD-Q score for the week before screening of 10.5 ± 1.9. During the 4 weeks’ treatment, the proportion of patients receiving at least 1 dose of PPI was 99.5%. Esomeprazole was the most frequently received PPI (57.1% of patients). Other PPIs (rabeprazole, lanzoprazole, pantio- prazole and omeprazole) were received by 50.1% of patients and 7.2% of the patients sequentially received ≥2 PPIs in the duration of the study. A total of 787 (79.7%) patients either completed the 4-week PPI treatment or withdrew after response, of which the responder rate was 74.0% [95% CI, 70.7%– 77.0%] (Table 1). Among the 818 patients who completed 2 weeks’ treatment, the responder rate was 37.0% [95% CI, 33.5%–60.4%]. The overall median time to response, inclusive of the responder group (95% CI: 12–15) was consistent in all studies. Pre-implantation pulsed LESp stimulation was, in general, and despite the increase in GERD-Q score demonstrated a decreasing trend. The proportion of patients with a GERD-Q score ≥8 reduced from 100% at baseline to 29.5% and 17.4% at 2 and 4 weeks, respectively.

Table 1: Responder rate [1] and median time to response for different PPIs

<table>
<thead>
<tr>
<th>PPI</th>
<th>Esomeprazole</th>
<th>Other PPIs</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td>4-week responder rate, % [95% CI]</td>
<td>75.2 (342/455)</td>
<td>72.3 (240/332)</td>
<td>74.0 (582/787)</td>
</tr>
</tbody>
</table>

[1] Responder rate = number of responders/number of patients who completed the treatment or withdrew after response (in days).

Conclusion: In Chinese clinical practice, short-term PPI empirical treatment effect- ively improves symptom control in GERD patients and gains a satisfactory overall responder rate.

Introduction: Electrical stimulation of lower esophageal sphincter (LES) has been applied to augment pressure (LESp) of gastroesophageal reflux disease (GERD). EndostimTM-like active appliance was efficient but approved to increase LESp pressure (LESp) and commercially treat gastroesophageal reflux disease (GERD). Electric stimulation represents a prospective approach for treating GERD in clinics. This novel wireless LESp stimulation system was also safe and effective for treating GERD rabbits. After implantation, its passive medical replacement can benefit patients and keep the long-term efficacy for clinical GERD management.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Electric stimulation represents a prospective approach for treating GERD in clinics. This novel wireless LESp stimulation system was also safe and effective for treating GERD rabbits. After implantation, its passive medical replacement can benefit patients and keep the long-term efficacy for clinical GERD management.

P1202 SYSTEMATIC REVIEW AND META-ANALYSIS OF OUTCOMES AFTER LAPAROSCOPIC ANTI-REFLUX SURGERY RELATED TO OBESITY
T. Abdelrahman1, A. Latif1, D. Chan1, N. Patel1, C. Brown1, W. Lewis1, T. Havid2, X. Escoté2

Introduction: Laparoscopic Anti-Reflux Surgery (LARS) is an established alterna- tive treatment to pharmacological therapy for patients with Gastro Oesophageal Reflux Disease (GORD), yet its safety and efficacy in obese patients is controversial. A systematic review and meta-analysis was performed to com- pare LARS related to obesity.

Aims & Methods: The primary outcome measure was the relative incidence of recurrent reflux related to BMI. Secondary outcomes were relative incidence rates in the form of endoscopic dilatation or surgery, conversion to open surgery, and early return to theatre. Embase, MEDLINE and the Cochrane Library (January 1970 to November 2016) were searched for studies reporting clinical outcomes of LARS in patient cohorts stratified by Body Mass Index (BMI). Data was grouped according to BMI, <30 kg/m² (non-obese) and ≥30 kg/m² (obese).

Results: Eleven eligible observational studies comparing LARS in non-obese (n = 129) and obese (n = 162) patients were included. The relative incidence of reflux was significantly lower in the non-obese cohort (OR 0.34, 95% CI 0.19 to 0.60, p = 0.001), however no significant differences were observed in rates of operative morbidity (OR 0.87, 0.65 to 1.18, p = 0.38), redo surgery (OR 1.08, 0.68 to 1.72, p = 0.73), endoscopic dilatation (OR 1.06, 0.49 to 2.33, p = 0.88), conversion to open surgery (OR 1.17, 0.55 to 2.48, p = 0.68), or early return to theatre (OR 0.77, 0.44 to 1.37, p = 0.38).

Conclusion: LARS can be performed safely in obese patients, but risks higher operative morbidity. Clinicians caring for patients with obesity should be aware that obesity may adversely affect LARS outcome and careful consideration be given in the consent process inherent within the optimal management of GORD.

P1203 GASTROESOPHAGEAL REFLUX DISEASE REFRACTORY TO PROTON PUMP INHIBITOR THERAPY. INCOMPLETE ACID INHIBITION OR DIAGNOSTIC ERROR?
Gastroenterologia, Hospital Clinico San Carlos, Madrid/Spain

Contact E-mail Address: jperdesserna@gmail.com

Introduction: The use of PPIs represents the main treatment in gastroesophageal reflux disease (GERD), having demonstrated its effectiveness both in the control of inflammation and symptomatology. However, between 10–20% of patients present persistent symptoms or lesions despite the treatment.

Aims & Methods: The aim of the study was to assess the presence of acid reflux in patients submitted to our department with the diagnosis of refractory GERD, due to low or no response to PPIs. This was a retrospective study including 190 patients (55 men, 135 women) referred to our service with the diagnosis of GERD from January 2008 to December 2015. Based on the diagnostic criteria, two groups were made: Group 1: included 63 patients (33.2%) diagnosed of GERD due to typical symptomatology and at least one positive complementary study (pHmetry or endoscopy). All of them underwent a 24-H pHmetry study with a dual channel, esophageal and gastric, on-PPI treatment. In 17 patients the pHmetry was completed with multichannel intraluminal impedance (15 cases) or Bilitec (2 cases). Group 2: included 127 patients (66.8%) who had been diagnosed of GERD only on the basis of typical symptoms; all of them underwent esophageal double channel 24-H pHmetry off-PPI. All of the studies (24-hour pHmonitoring or multichannel intraluminal impedance-pH studies) (MARK III, Delta and Digitrapher pH-Z, Synectics, Gyen, Medtronic) were performed according to standard technique.

Results: Pathological reflux was present in 91 patients (47.9%), 24 from group 1 and 67 from group 2. Pathological acid reflux was therefore ruled out as a cause of symptoms in 52.1% of all cases studied: 60 patients (47.2%) from group 2, and 33 from group 1. In addition, out of the 24 patients with pathological reflux in group 1 (true refractory patients), 9 had an incomplete response, with a percentage of time with pH < 4 less than 7.5% (mild reflux), which probably was not the cause of the symptomatology.

Conclusion: Proton pump inhibitors (PPIs) are the drugs of choice in the treat- ment of GERD. However, its efficacy may be compromised for a variety of reasons including: non-compliance, bioavailability, episodes of nocturnal acid break-through, poor gastric emptying, etc. In most of the patients referred for implantation or stimulation-related adverse effects were reported in the two- month follow-up.

Conclusion: Electric stimulation represents a prospective approach for treating GERD in clinics. This novel wireless LESp stimulation system was also safe and effective for treating GERD rabbits. After implantation, its passive medical replacement can benefit patients and keep the long-term efficacy for clinical GERD management.
studying with the diagnosis of refractory reflux to PPIs, this diagnosis had only been based on GERD-compatible symptoms. When the diagnosis is exclusively clinical, about a half (47.2%) of the patients with persistent symptoms on double doses of PPIs, considered as GERD patients refractory to PPIs, have an incorrect diagnosis (patients do not have pathological reflux). More than half of the patients (61.9%) who have a diagnosis of GERD confirmed by complementary tests that do not respond to treatment with PPIs, acid reflux is not the cause of their symptoms.

Introduction: Recently, low-FODMAP diet has been proposed as potential treatment in patients with irritable bowel syndrome (IBS) given its high efficacy in symptoms relief. Recent data showed that IBS frequently overlap with functional heartburn (FH) and functional dyspepsia.

Aims & Methods: The aim of this study was to evaluate the efficacy of low-FODMAP diet in reducing heartburn in patients with FH and no pathophysiological evidence of gastroesophageal reflux (GERD) compared to patients with non-erosive reflux disease (NERD). As secondary aim we investigated the reduction of lower gastrointestinal symptoms in both groups. We enrolled patients with heartburn and negative upper endoscopy who were scheduled for upper endoscopy in University of Pisa. We excluded patients older than 75 and younger than 18, those with primary esophageal motor disorders and with previous abdominal surgery. Medical history, volup-tuary habits and response to proton pump inhibitor (PPI) treatment were recorded. By means of MII-pH we splitted patients in two populations: NERD group (abnormal esophageal acid exposure or number of refluxes) and FH group (correlation and no heartburn relief during PPI treatment). All enrolled patients were evaluated with validated questionnaires (Likert and VAS) to evaluate heartburn occurrence pre- and post a nutritional approach with low-FODMAP diet for 6 weeks.

Results: We included 31 patients (20 female; mean age 49.1 yrs; mean BMI 24.4) into the study. NERD group was composed of 13 patients (6 female; mean age 48.7 yrs; mean BMI 25.7). FH group was composed by 18 patients (11 female; mean age 50.9 yrs; mean BMI 23.9). All patients showed symptom improvement regarding bloating, abdominal pain and stools composition (p < 0.001) after low-FODMAP diet (see Table 1). Moreover, we observed a very important improvement of heartburn in the FH group (from 8.4 ± 2.5 to 2.3 ± 1.3; p < 0.001 on VAS scale) compared to the NERD group (7.2 ± 2.2 a 6.9 ± 1.9; p = 0.624 on VAS).

**P1206 SINGLE SESSION FOCAL CRYOBALLOON ABLATION THERAPY IS SAFE AND EFFECTIVE IN THE TREATMENT OF DYSPLASTIC BARRETT’S ESOPHAGUS**

S. Van Munster1, A. Overwater2, J.J. G.h.m. Bergman1, B.L.m. Weusten1

Introduction: Given its proven safety and efficacy, RadioFrequency Ablation (RFA) is the preferred ablation modality for dysplastic Barrett’s Esophagus (BE). However, RFA is associated with significant drawbacks, such as the need for large controller units, multiple deployment steps and capital investment. The Focal CryoBallon Ablation system (FCBA; C2 Therapeutics, Incorporated, Westwood, MA) is an ablation method -based on the application of extreme cold- that has been recently developed to overcome these RFA drawbacks. Additionally, FCBA might be better tolerated. FCBA comprises a handheld, through-the-scope system with a deformable balloon that is simultaneously inflated and cooled using nitrous oxide, resulting in ice patches of approximately 2cm2 on the targeted mucosa. Previous studies applying FCBA to limited areas of BE (1 to 2 small BE islands per patient) have shown promising results. Data on

Stage 0: Normal Barrett’s Esophagus; Stage 1: Low-grade dysplasia (LG); Stage 2: High-grade dysplasia (HG); Stage 3: Adenocarcinoma in situ (AIS); Stage 4: Adenocarcinoma (A).
efficacy and safety of FCBA in the treatment of larger BE segments, however, are lacking. Therefore we aimed to assess the safety and efficacy of a single treatment with FCBA for dysplastic BE.

Aims & Methods: Patients were seen between March and December 2016 at two tertiary referral centers in the Netherlands. Patients with a BE <6 cm in length and with a confirmed diagnosis of low-grade (LGD) or high-grade dysplasia (HGD) or after endoscopic resection for visible lesions, were included. Exclusion criteria included previous focal ablation therapy and strictures. At baseline, all visible BE was treated with side by side ablations of 10 seconds, including circumferential treatment of the gastroesophageal junction. Pain scores were assessed directly post-treatment and at days 2 and 7. Follow-up endoscopy with biopsy and photo documentation was scheduled after 3 months. Primary outcomes included dysplasia regression rate and incidence of esophageal stricture or other adverse events.

Results: We enrolled 20 patients with dysplastic BE (85% male, mean age 66 (±8) years), with a median BE length of 7CM2 (IQR 4–10) and 1 (IQR 0–2) days for RFA. The maximum median VAS score at all times was 2 (IQR 0–4) after FCBA and 4 (IQR 3–5) after RFA. Pain scores were assessed directly post-treatment and at days 2 and 7. Follow-up endoscopy with biopsy and photo documentation was scheduled after 3 months. Primary outcomes included dysplasia regression rate and incidence of esophageal stricture or other adverse events.

Conclusion: Our multicenter, prospective trial shows that a single treatment with CryoBalloon ablation is safe, well-tolerated and effective for eradication of dysplastic BE.

Disclosure of Interest: All authors have declared no conflicts of interest.

Table 1: Baseline characteristics and maximum pain scores after RFA (p < 0.01). FCBA patients used analgesics during median 1 (IQR 1–1) days, compared to 4 (IQR 1–11) days for RFA patients (p < 0.01).

Conclusion: In this multicenter, non-randomized, open prospective cohort study, patients reported less post-procedural pain and dysphagia after FCBA as compared to RFA and, moreover, FCBA patients used less analgesics. Although a randomized trial should provide definitive evidence for differences in post-procedural tolerability, our results strongly suggest a significantly different post-procedural course, thus favoring FCBA over RFA.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1208 COMPARATIVE OUTCOMES OF RADIOFREQUENCY ABLATION FOR BARRETT’S OESOPHAGUS WITH DIFFERENT BASELINE HISTOLOGY

W.K. Tan1, A. Rattan2, T. Nuckchekdy3, B. Elias1, V. Sujjendran2, M. Di Pietro1

3Department Of General Surgery, Addenbrookes Hospital, Cambridge/United Kingdom

Contact E-mail Address: weiskeithtan@gmail.com

Introduction: Radiofrequency ablation (RFA) is safe and effective for eradication of dysplastic Barrett’s Esophagus (BE), but may be associated with significant post-procedural pain. As an alternative, cryoablation using the Focal CryoBalloon Ablation system (FCBA) has recently been developed, which ablates BE by freezing it using nitrous oxide. Early uncontrolled studies suggest comparable safety and efficacy of FCBA and RFA in eradicating dysplastic BE. They link cryoablation endpoints like pain may play a determining role in selecting the best treatment modality. In contrast to heat-based ablation, FCBA preserves the extracellular matrix which might be associated with less pain while maintaining sufficient depth of ablation. In this study, we aimed to compare post-procedural pain between focal RFA and FCBA.

Aims & Methods: Between January 2016 and March 2017 all patients undergoing focal ablation therapy of BE, either with RFA or FCBA performed in two tertiary referral centers in the Netherlands, were approached to complete a digital diary. A short questionnaire was daily sent to patients for 14 days post-treatment, to assess (1) odynophagia, (2) chest pain in rest (both were assessed usingVAS score ranging from 0 to 10), (3) dysphagia (assessed using a score ranging from 0 to 4) and (4) use of analgesics. Primary outcome included maximum VAS score (maximum score for either item 1 or 2), secondary outcomes included area under the curves (AUCs) for all items assessed, maximum reported VAS score at any time, time to VAS 0 and analgesics use. According to national guidelines, all visible BE was ablated, including circumferential treatment of the gastro-esophageal junction (GEJ).

In a standardized way, all patients were advised to use paracetamol (up to 4 times 500 mg daily) as necessary with additional ibuprofen, if needed.

Results: Fifty-five patients were included (35 with focal RFA; 20 with CBA) and median BE length was similar for the two groups (FCBA: COM2, RFA: COM1, p=0.72). All other baseline characteristics were similarly comparable for both groups (table 1A). Maximum VAS score was lower after FCBA compared with RFA at all days, reaching statistical significance at 13/14 days (table 1B). All AUC curves were significantly smaller after FCBA compared to RFA; for maximum VAS score (12.3 vs 26.7, p < 0.01), for odynophagia (11.6 vs 26.7, p < 0.01), for pain in rest (7.8 vs 20.5, p < 0.01), for use of analgesics (0.9 vs 3.1, p < 0.01) and for dysphagia (2.6 vs 8.2, p < 0.01). The maximum median VAS score reported on any of the 14 days was 2 (IQR 0–4) after FCBA and 4 (IQR 3–7) after RFA (p < 0.01). After 4 (IQR 1–10) days, half of the FCBA patients reported a pain score of 0, whereas this was 13 (IQR 10–15) days for RFA.
CD4+ AND CD8+ LYMPHOCYTE RATE AND PDL-1 LEUKOCYTE EXPRESSION ARE PREDICTIVE OF CLINICAL COMPLETE RESPONSE AFTER NEOADJUVANT CHEMORADIOLOGY FOR SQUAMOUS CELL CANCER OF THE THORACIC OESOPHAGUS

M. Giovannini1, M. Barthet1

Outcome details were retrieved and clinical CR and recurrence/relapse rate was immunohistochemistry for PD1, PDL1, CD80, CD4 and CD8 was performed. Samples taken at diagnosis available in our Pathology Unit archive.

Patients had neoadjuvant CTRT for locally advanced SCC and having had histological confirmation of SCC of the thoracic oesophagus who underwent to neoadjuvant CT-RT were included in this study. Patients were included in the study if they had neoadjuvant CTRT before esophagectomy, with a mean of 2.7 resected pieces per EMR, which was macroscopically complete in 63.6% of the cases. The mean follow-up was 38 months.

The discordance rate between initial diagnosis of HGD on BS and final results on EMR specimen is high, around 47%. Intra and inter observer concordance was insufficient, even in expert tertiary centers. Thus, the question about performing EMR based on random biopsies rather than endoscopic assessment has to be asked, and clearly evaluated in further studies. This could have a direct impact on the management of BE.

P1211 IDENTIFICATION OF THREE DISTINCT BIOLOGICAL SUBTYPES IN ESOPHAGEAL AND JUNCTIONAL ADENOCARCINOMA BY RNA SEQUENCING

S. Hoefnagel1, B. Sclicuna1, S. Calpe1, C. Del Sancho-Serra2, K.K. Krishnadath2

Introduction: Esophageal adenocarcinoma (EAC) is a highly aggressive malignancy with poor prognosis. Advances in therapy have achieved incremental improvements in overall outcome in EAC, but over- and undertreatment of undefined subgroups of patients might undermine these benefits (Courrech Staal et al. 2010). The biological diversity of EAC complicates patient selection and treatment stratification and impedes the development of new targeted agents. Further insight into the heterogeneous molecular pathology of EAC and a possible relation to outcomes and response to current treatment strategies is urgent.

Aims & Methods: We included ~75 patients with EAC and junctional adenocarcinoma (JAC) and performed a genome-wide gene expression analysis using Illumina sequencing technology. Count files were obtained, which served as input into the R language and environment for statistical computing for further analyses.

We performed unsupervised hierarchical clustering of the tumor RNA profiles to identify distinct subtypes. The histological diagnosis of HGD was recommended in 4 cases (4.6%) and one patient had no metaplasia. Finally, 33 patients could be analyzed, 29 men and 4 women, with a mean age of 63 years old. The mean length of BE according to Prague classification was C3-M5, with relief already in 12% of the cases. A mean number of 1.4 endoscopic session was performed, with a mean of 2.7 resected pieces per EMR, which was macroscopically complete in 63.6% of the cases. The mean follow-up was 38 months. After histological relecture, the Kappa coefficient for the diagnosis of HGD was 0.4, and ranged between 0 and 0.6 for the EMR specimen. The inter-observer concordance was 0.2 (for both BS and EMR specimen) for the diagnosis of HGD. For other diagnoses, it was ranged between 0 and 0.5 for biopsies and between 0 and 0.6 for EMR specimen. The kappa coefficient regarding histological diagnosis of HGD between experts was 0.5 for biopsies and between 0 and 0.6 for the EMR specimen. The kappa coefficient regarding the diagnosis of HGD between BS and EMR was ranged between 0 and 0.6.

Conclusion: The discordance rate between initial diagnosis of HGD on BS and final results on EMR specimen is high, around 47%. The intra and inter observer concordance is insufficient, even in expert tertiary centers. Thus, the question about performing EMR based on random biopsies rather than endoscopic assessment has to be asked, and clearly evaluated in further studies. This could have a direct impact on the management of BE.

References

analyzed by cell counting kit-8 assay. Cell cycle and apoptosis were evaluated by flow cytometric analysis. Protein levels of p53 were determined by western blot analysis. Differences between groups were tested for significance using Student’s t-test (two-tailed).

Results: ESCC tissues examined in this study showed an obvious increment in TRPM2-AS expression when compared to normal tissues. Meanwhile, TRPM2-AS expression was positively related to lymph nodes metastasis, TNM stage and clinical stage. And upregulated TRPM2-AS expression was turned to be remarkably correlated with the shorter survival of ESCC patients which could act as an independent predictor for both overall survival time and disease-free survival. In addition, overexpression of TRPM2-AS could promote the proliferation and inhibit the apoptosis of ESCC cells, while knockdown of TRPM2-AS has a reverse function. Furthermore, downregulation of TRPM2-AS enhanced the expression of p53 in ESCC cells.

Conclusion: This study suggested that long non-coding RNA TRPM2-AS could be a potential oncogene of ESCCC. TRPM2-AS expression might serve as another potential therapeutic target and prognostic biomarker. In addition, our study demonstrates that TRPM2-AS contributes a lot to inhibiting apoptosis of ESCC by regulating the expressions of p53 in vitro, which may be a potential oncogene and therapeutic target for ESCC.

Disclosure of Interest: All authors have declared no conflicts of interest.
increased apoptosis of OACMi5.1C cells whereas did not affect apoptosis of QCMi3 cells.

Conclusion: Metastatic and non-metastatic esophageal adenocarcinoma cells exhibit different glycolytic metabolism and response to pharmacological inhibition of MCT1, which increases apoptosis in metastatic cells. Further preclinical studies to assess the feasibility to define the potential of blocking lactate transporters on the treatment of metastatic EAC.

P1216 THE PREDICTIVE FACTOR FOR PERFORATION IN ESOPHAGEAL ESD

Y. Nagami, M. Ominami, M. Shiho, S. Fukunaga, F. Tanaka, N. Kamata, H. Yamagami, T. Tanigawa, T. Watanabe, Y. Fujisawa

Introduction: Although endoscopic submucosal dissection (ESD) is accepted as a standard treatment for early stage esophageal neoplasia, esophageal perforation is sometimes experienced as a main adverse event. Esophageal perforation causes mediastinal emphysema, mediastinitis, and pneumothorax, those sometimes require emergency surgery.

Aims & Methods: We evaluated the predictive factors for esophageal perforation in patients who received esophageal ESD. This was a retrospective observational study in a single institution. Between May 2004 and March 2016, 549 consecutive patients who underwent ESD were followed up in the ESD Database at Kitasato University Hospital. ESD was performed under local anesthesia or sedation. The primary outcome was determination of the predictive factors for esophageal perforation in patients who received esophageal ESD. The secondary outcome was clinical outcomes. Perforation was defined as a hole in the esophageal wall exposing the mediastinal cavity. Logistic regression multivariate regression analysis with penalized estimating equations were used to analyze repeated measures data.

Results: A total of 549 cases with 927 lesions were evaluated. Of those, perforation occurred in 15 cases (2.7%) with 15 lesions (1.6%). A lesion diameter (Odds ratio; OR = 1.05, 95% confidence intervals; CI: 1.02–1.07, p < 0.001) and the proximity of the tumor to a previous ESD scar (OR = 6.66, 95% CI: 1.80–24.6, p = 0.004) were both associated with perforation using crude logistic regression analysis. Multivariate logistic regression analysis also showed that a lesion diameter (OR = 1.05, 95% CI: 1.03–1.07, p < 0.001) and the proximity of the tumor to a previous ESD scar (OR = 13.0, 95% CI: 2.48–67.9, p = 0.002) were independent predictive factors for perforation.

Conclusion: Larger lesion and the proximity of the tumor to a previous ESD scar increased the likelihood of perforation in patients who received esophageal ESD.

Introduction: According to the current Japanese guidelines for the diagnosis and treatment of esophageal cancer, endoscopic resection is indicated for pathologi- cal T1a (epithelium/lamina propria mucosae) and relatively indicated for pathological T1b (muscularis mucosae) and T1b/a tumor invading the submucosa to a depth of 200 μm or less). In accordance with the guidelines, we have actively performed endoscopic resection for esophageal squamous-cell carcinoma (SCC). Evidence of submucosal or lymphovascular invasion on histopathological examination of the resected specimens was considered to indicate non-curative resection, chemoradiotherapy (CRT) was additionally administered, taking into account the risk of lymph-node metastasis. In principle, CRT comprised 2 courses of cisplatin plus 5-fluorouracil. Patients who were 76 years or older or who had mild renal dysfunction received 2 courses of nedaplatin plus 5-fluorouracil. The radiation dose was 50.4 GY in patients who had a tumor-positive vertical margin and 44.4 Gy in those who had a tumor-negative vertical margin. The field of radiation was determined according to the recommendations of the Japan Clinical Oncology Group Study (JCOG0508/UMIN-CTR: identification number: UMIN00000058).

Aims & Methods: We retrospectively studied patients who underwent endoscopic resection in our hospital to evaluate the clinical utility of additional CRT in patients who had evidence of submucosal or lymphovascular invasion on histopathological examination of the endoscopically resected specimens. Among 364 patients with ESCC (425 lesions) who underwent endoscopic resection from January 2000 through July 2015, a total of 93 patients (93 lesions) had a histopathological diagnosis with submucosal or lymphovascular invasion. Among these 93 patients, 41 received additional CRT (CRT group), and 52 were followed without CRT (follow-up group). CRT comprised cisplatin and nedaplatin or 5-fluorouracil and radiotherapy in 2, docetaxel plus cisplatin, 5-fluorouracil, and radiation in 1, and radiation alone in 1.

Results: The median age was 68 years (53 to 79) in the CRT group and 72 (59 to 89) in the follow-up group (p = 0.03). The median tumor diameter was 22 mm (6 to 55) in the CRT group and 25 (3 to 47) in the follow-up group (p = 0.63). The tumor invades the MM in 9 patients, the SM1 in 3, and the submucosa to a depth more than 200 μm (SM2) in 29 in the CRT group and the LPM in 3 patients, the MM in 16, the SM1 in 18, and the SM2 in 15 in the follow-up group (p = 0.91). Lymphatic invasion was positive in 21 patients in the CRT group and 12 in the follow-up group (p < 0.01). Vascular invasion was positive in 27 patients in the CRT group and 29 in the follow-up group (p = 0.32). Invasion of the submucosa to the vertical margin was found in 7 in the CRT group and 9 in the follow-up group (p = 0.97). CRT-related grade 3 or 4 early adverse events were leukopenia 24.3% (10 patients), neutropenia 29.3% (12), febrile neutropenia 4.9% (2), diarrhoea 2.4% (1), anorexia 17.0% (7). In the CRT group, 38 of 40 patients received chemotherapy as scheduled. Treatment was discontinued in the second course in 2 patients, and 7 required dose reduction. Lymph-node metastasis were found in 2 patients in the CRT group and 7 in the follow-up group (p = 0.15). In 2 patients with recurrence in the CRT group, lymph-node metastases were seen in the irradiated field 46 and 49 months after treatment, respectively. 1 patient in the CRT group and 3 in the follow-up group died of esophageal cancer (p = 0.43). The overall survival (OS) rate at 2 years was 97.4% in the CRT group and 93.8% in the follow-up group (p = 0.02). The disease-free survival (DFS) and relapse-free survival (RFS) rate at 2 years was 97.1% in the CRT group and 83.4% in the follow-up group (p = 0.02).

Conclusion: Additional CRT after endoscopic resection in patients with esophogeal squamous-cell carcinoma who have submucosal invasion, lymphovascular involvement, or vertical-margin invasion can become an effective organ-preservation strategy.

Disclosure of Interest: All authors have declared no conflicts of interest.

found in 100% (35/35) of patients with curative resection at median follow-up of 22 months (range 4–64 months).

Conclusion: In the proper setting, ESD is safe and effective for the treatment of early Barrett’s neoplasia with high en block and complete resection rates and good curative rate. ESD enables full pathological assessment in lesions not suitable for en bloc resection with EMR. There were no recurrences in the curative cases, which increases the role of ESD for the management of early Barrett’s neoplasia.

Introduction: Recently, it has been reported that proton beam therapy (PBT) is the effective treatment for patients with esophageal squamous cell carcinoma (ESCC). However, there are few reports regarding the endoscopic evaluation of efficacy after PBT at the primary site. 

Aims & Methods: The aim of this study is to clarify the adequate endoscopic evaluation of the primary lesion of ESCC after PBT, and the clinical results of salvage endoscopic treatment for local recurrence. Patients with clinical T1 ESCC, and who had been treated with PBT between April 2013 and June 2016 at the National Cancer Center Hospital East were investigated. The total dose of PBT was in the Gray-Equal-Value (GEV). The efficacy of PBT at the primary site was evaluated with endoscopy, and the definition of complete response (CR) was used according to the same criteria as that of conventional chemoradiotherapy (CRT) as follows; disappearance of tumor lesion and ulcer, and absence of cancer cells with biopsy was verified. The endoscopic evaluation was performed within 2 months after the completion of PBT, and we repeatedly evaluated every month if the lesion did not achieve CR. The treatment for local recurrence after PBT was chosen based on the depth of the tumor as follows; endoscopic resection (ER) for cT1a, endoscopic photodynamic therapy (PDT) for cT1b or deeper depending on patient’s condition.

Results: Among 44 patients who underwent PBT, the median age was 70 years (range, 41–79). The number of patients with clinical stage I was 23 (52%), and those with stage II, III, and IV were 16 (36%), 2 (5%), and 3 (7%), respectively. Among 44 patients who underwent PBT, the median age was 70 years (range, 41–79). The number of patients with clinical stage I was 23 (52%), and those with stage II, III, and IV were 16 (36%), 2 (5%), and 3 (7%), respectively. All patients underwent concurrent systemic chemotherapy. 45 patients (98%) could achieve a CR at the primary site and only one patient (2%) did not show a CR (non-CR) at the primary site. The median time to CR from the start of PBT to CR (primary site) was 85 days (range, 70–554 days) and 6 months or longer period was required to confirm CR due to the remaining PBT induced erosion or ulceration in 7 patients (15%). One patient whose primary site did not reach to CR showed prolonged ulceration for 385 days. On 43 patients (98%) developed local recurrence and/or regional lymph node recurrence or distant metastasis, and the median time to local recurrence from CR was 257 days (range, 111–722 days). The endoscopic finding of local recurrence was resembling submucosal tumors (SMT) in 3 and flat lesion in other 3 tumors. All 6 patients with local recurrence were indicated for endoscopic treatment (ER; PDT; 2). No complications, such as major bleeding or perforation, were observed. And, 6 patients (100%) were alive without any recurrence at the median follow up period of 11 months (range, 1–32 months).

Conclusion: Longer period was required to confirm CR after PBT with chemotherapy in some cases comparing with the historical reports of that of conventional CRT. Careful closed endoscopy follow-up according to the way of conventional CRT enabled early detection of local recurrence and preferable local control with salvage endoscopic treatment.

P1220 CLINICAL OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL ESOPHAGEAL NEOPLASMS OF PATIENTS WITH HEAD AND NECK CANCER

J. F.D. Oliveira1, E. Q. Mendonça2, B. D.C. Martins1, F. Kawaguti1
1Gastrointestinal Endoscopy Unity, Cancer Institute of University of São Paulo, São Paulo/Brazil

Contact E-mail Address: kjpennachii@yahoo.com.br

Introduction: Surveillance programs of gastrointestinal endoscopy for detection of a second primary cancer in patients with head and neck squamous cell carcinoma (HNSCC) are very important since it can detect synchronous or metachronous esophageal squamous cell carcinoma (ESCC) in up to 15%–25%. The detection of ESCC in an early phase has paramount importance, since superficial lesions are amenable to endoscopic submucosal dissection (ESD) 2.

Aims & Methods: The aim of this study was to investigate the clinical outcomes of ESD for superficial esophageal neoplasms (SEN) of HNSCC patients in an oncology tertiary center. From 2010 to 2016, 3290 endoscopies were performed in patients with HNSCC and in 1887 chromoscopy with Lugol and NBI were performed. A total of 26 SENs, submitted to ESD, in 25 patients were retrospectively analyzed.

Results: The median tumor size was 4.37 cm (±1.83). The en bloc resection were 100% and free margin (R0) were 92.3%. The two patients with positive margins had a depressed component in endoscopic evaluation. Recurrence occurred in 1 (4.0%) of them and one of these cases was successfully treated. The circumferential extension, number of patients & stenosis rate are show in table 1.

Table 1: The circumferential extension, number of patients and stenosis rate

<table>

</table>

The circumference of the resection ≥75% was significantly associated with post-operative stricture (OR = 3.5; P < 0.05). The average number of endoscopic dilatations for resolution of stenosis was 9.16 (±7.62). No procedure-related mortality occurred. Follow-up data median was 11 months.

Conclusion: Endoscopic surveillance of HNSCC is very important for SENs of HNSCC. ESD and ESD of these lesions are feasible and safe with acceptable complication risks despite the high rates of stenosis in resections >75% of the circumference.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
1. Zhang Y, Chen Q, Bao L et al (2016) Esophageal squamous cell cancer (ESCC), arising from esophageal squamous cell neoplasia (ESCN). Patients with ESCC have poor prognosis, but when diagnosed at the stage of ESCN, curative endoscopic treatment can be performed. ESCN mainly occurs in developing countries, often with limited endoscopic expertise and resources, like Central and Eastern Asia and Eastern and Southern Africa. Hence, an easy-to-use, low-cost treatment for ESCN would be of great value. Focal Cryoballoon Ablation therapy (FCBA) (C2 Therapeutics Inc. Redwood City, CA, USA) is a new endoscopic ablation therapy that comprises a through-the-scope catheter with a conformable balloon that obviates the need for sizing, a handle, and a small disposable cryogen cartridge. The balloon is simultaneously inflated and cooled with nitrous oxide from the cartridge, resulting in ice patches of approximately 2cm². FCBA is easy to use and requires no capital equipment. Early studies for FCBA of Barrett’s esophagus have shown promising results, however, limited data are available for FCBA of ESCN. In this study we aimed to assess the safety, tolerability and efficacy of FCBA in the eradication of ESCN.

Aims & Methods: In this ongoing multi-center prospective trial in China, patients with one flat type (Paris 0-IIb) unstained lesion (USL) on Lugol’s chromoscopy, <6 cm in length and <50% of circumference, with a confirmed diagnosis of Moderate or High Grade Intraepithelial Neoplasia (MGIN/HGIN) were
Aims & Methods: we investigated the clinical outcomes, and prevention of post-ESD stenosis. Required in such situation, thus causing health economic problem. In this study, of the circumference of the lumen. Frequent balloon dilatation via endoscopy is of superficial esophageal squamous cell carcinoma (SCC). However, esophageal Introduction: Endoscopic submucosal dissection (ESD) allows en bloc removal of superficial esophageal squamous cell carcinoma (SCC). However, esophageal stricture often occurs after ESD when the lesion involves more than three-fourth of the circumference of the lumen. Frequent balloon dilatation via endoscopy is required in such situation, thus causing health economic problem. In this study, we investigated the clinical outcomes, and prevention of post-ESD stenosis. Aims & Methods: A total of 667 cases in 516 consecutive patients were treated by ESD in our department from April 2006 to December 2016. We investigated the following 2 items. 1. Clinical outcomes and complications. 2. Usefulness of oral steroids administration, the local steroids injection, endoscopic transplantation of tissue-engineered autologous oral mucosal epithelial cell sheets, or oral steroid oral local injection combination therapy for the prevention of post-ESD stenosis. Results: 1. Clinical outcomes: End in bloc resection rate was 99.8% and end in bloc curative resection rate was 90.0%. The rate of perforation, post-ESD bleeding, and post-ESD stenosis was 0.2%, 0.8% and 6.1%, respectively. 2. Prevention of post-ESD stenosis: (1) Oral steroid vs Steroid injection vs Cell sheet transplantation: In oral steroid group, the stenosis rate was 14.9%, and the ulcer healing period was 39.5 days. In steroid injection group, the stenosis rate was 12.9%, and the ulcer healing period was 66.0 days. In cell sheet transplantation group, the stenosis rate was 40.0% and the ulcer healing period was 36.0 days. There was no significant difference between these 3 therapies, and these therapies prevent post-ESD stenosis to significant extent. However, ulcer healing period of the cell sheet transplantation was significantly shorter compared with the other 2 therapies. (2) The usefulness of SH oral local injection combination therapy. We investigated limitations of steroid administration, and cell sheet transplantation in order to prevent post-ESD stenosis. The following 4 factors (more than 9/10 of circumferential resection, more than 5 cm of longitudinal resection, cervical esophagus, post history of chemo-radiation therapy or endoscopic resection) were the stenosis prevention treatment-resistance factors. Therefore, we examined the stenosis rate according to the number of these 4 factors. The stenosis rate of the cases which have 0 or 1 factor, the case which has more than 2 factors in semicircular cases, and the complete circular cases is 4.9%, 30.3%, and 44.8%, respectively. The stenosis rate of the cases which have more than 2 factors and complete circular cases are significantly higher, compared to the cases which have 0 or 1 factor. As a result, the cases which have more than 2 factors and complete circular cases were regarded as the stenosis prevention treatment-resistant cases. In contrast, in SH oral local injection combination therapy, the stenosis rate of the cases which have more than 2 factors and the complete circular cases is 17.5% and 14.3%, respectively. Taken together, the stenosis rate of SH oral local injection combination therapy is significantly lower, compared to the other 3 therapies. Conclusion: Eophageal ESD achieved high en bloc resection rate and curability with low rates of complications. Oral steroid, steroid injection therapy and cell sheet transplantation may be effective treatment strategy for reducing post-ESD stenosis. However, the above-mentioned 4 factors are the stenosis prevention treatment-resistant factors in these 3 therapy cases. Furthermore, the cases which have more than 2 factors and complete circular cases were regarded as the stenosis prevention treatment-resistant cases. SH oral local injection combination therapy is very useful for prevention of post-ESD stenosis and has a potential for treatment-resistance factors.

Introduction: Endoscopic ultrasound (EUS) is the standard modality for qualitative diagnosis of submucosal tumors (SMTs) and determining the depth of invasion of esophageal cancer. Standard EUS, however, comprises a continuous water-filling or water-filled balloon method, which creates some problems for further diagnostic maneuvers (e.g., difficulty filling the water balloon, poor image quality because of balloon compression). Aspiration of water is especially problematic during the diagnosis of lesions in the cervical or upper thoracic esophagus. To resolve such disadvantages, we recently reported a method that includes probe EUS with a jelly-filling technique (EUS-J) for diagnosing superficial esophageal squamous cell carcinoma (SCC). The procedure is characterized by filling the esophageal lumen with a water-soluble lubricating jelly (K-Y lubricating jelly; Johnson & Johnson, Tokyo, Japan) that is used for routine endoscopy and is harmless to humans. In the present study, we retrospectively evaluated the usefulness of EUS-J with water-soluble lubricating jelly for lesions located in the cervical and upper thoracic esophagus.

Aims & Methods: Patients with an esophageal SCC or SMT in the cervical or upper thoracic esophagus were included. EUS-J with water-soluble lubricating jelly was performed using a high-resolution probe. Before examination, several 5-mL syringes containing the Water Soluble Lubricating Jelly were prepared. With the patient under conscious sedation with midazolam, an endoscope (GF-2TQ260M, Olympus, Tokyo, Japan) was inserted into the targeted area in the esophagus. A 30- or 20-MHz miniature probe was then inserted through the left channel of the endoscope, and 40 mL of jelly was instilled through the rubber sheath until the esophageal lumen was filled.

Results: From December 2010 to March 2017, we used EUS-J to evaluate 61 patients with esophageal SCCs and 10 with SMTs in the cervical or upper thoracic esophagus. There were 10 lesions in the cervical esophagus and 61 in the thoracic esophagus. Of the 61 SCCs, 13 were resected by endoscopic chemoradiotherapy. The other 48 SCCs did not undergo chemoradiotherapy. Of these 61 patients with esophageal SCC, 60 lesions (98.3%) could be detected with EUS-J. 44 lesions treated either by endogastronomy (n = 7) or endoscopic resection (n = 37). Histologic diagnosis was T1a in 27 lesions, T1b in 17 lesions. In the overall accuracy of diagnosing invasion depth was 70.5% (31/44 lesions) by EUS-J. Among the 10 SMTs, we diagnosed seven leiomyomas derived from muscularis mucosa and one lesion due to vertebral body compression. The remaining two lesions were, respectively, a diminutive SMT (<3 mm) and a small lesion in the cervical esophagus adjacent to the hypopharynx. Neither was detectable using EUS-J because of their small size and difficulty with instrumental maneuvering. There were no adverse events during EUS-J, including aspiration pneumonia. EUS-J lubricating jelly is useful and safe for diagnosing lesions in the cervical or upper thoracic esophagus. To our knowledge, this is the first report of using EUS with lubricating jelly for lesions located in this anatomic region.

Introduction: The patients with early gastric cancer (EGC) who have undergone non-curable endoscopic resection (ER) need additional surgery. Our previous study reported short-term data about 29 days were optimal time when consider the surgical and oncological safety. (Ann Surg Oncol. 2014 Jan;21(1):1232-9.) This study is long-term follow-up study to evaluate the impact of previously proposed optimal time interval from ER to additive surgery by on the surgical and oncological outcomes. Aims & Methods: A total of 2850 patients who were diagnosed with EGC underwent ER at the Severance and Gangnam Severance Hospitals, Seoul, Korea, between January 2007 and December 2014. We analyzed totally 302 (10.6%) patients who underwent additive gastrectomy after non-curable ER. The patients were divided into 2 groups according to the time interval point, as the earlier operation group (group A) and the later operation group (group B). The time interval point, at which operative time and estimated intraoperative blood loss (EBL) of the earlier operation group and the later operation group
showed the greatest disparities, was evaluated. We retrospectively evaluated long-term follow-up study for oncological outcomes about follow-up duration, loco-regional recurrence, distant recurrence.

Results: The median follow-up duration is 40.36 ± 20.74 months in all patients. Based on the previous our study, we divided patients two groups who underwent operations after 29 days. Of the 302 patients, 133 were in Group A (≥29days) and 169 in Group B (>29days). There were more differences between two groups about ASA score, ER Specimen size, intra-op. transfusion, POD #1 Hemovac® discharge, Maximal postoperative CRP in the clinicopathological characteristics. Like previous our study the operative time, EBL, tumor size was significantly longer and more in group A compared with group B. There were totally 7 patients locoregional and distance recurrence during follow-up period. There were no differences in oncological outcomes between two groups.

Conclusion: Based on long-term follow-up data, surgery time after ER in EGC does not affect oncological outcome. These long-term follow-up results suggest that adding surgery at about 1 month after ER is optimal for better surgical outcomes without affecting the oncological outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1225 THE POINT TO DISTINGUISH EARLY GASTRIC CANCER FROM DEPRESSION TYPE OF GASTRIC INTESTINAL METAPLASIA
T. Wakasuki, S. Furutachi, H. Yamashita
Department Of Gastroenterology & Hepatology, Okayama Medical Center, Okayama/Japan

Contact E-mail Address: t.wakasuki0530@yahoo.co.jp

Introduction: This study discusses two endoscopic findings which improve the accuracy of the diagnosis of early gastric cancers (EGC). After successful Helicobacter pylori eradication, we often observe multiple reddish depressed lesions and “patchy redness” in the gastric mucosa. Even though most are intestinal metaplasia (IM), EGC is found among these lesions. A light blue crest (LBC) has been a highly accurate sign of the IM. There are, however, additional two endoscopic findings that should improve the accuracy of diagnosis of EGC. They are 1) “intrathelial microinvation (IEMI),” and 2) “Over flow”. Over flow is the endoscopic finding that the structure of the depressed lesion spreads to the outside of the depression.

Aims & Methods: The aim of this study is to clarify the usefulness of two endoscopic findings in order to detect the EGC in the group thought to be an IM. Aims & Methods: The objective of this trial is to investigate whether the intensive on-site TTT course is useful for increasing early detection rate of gastric cancer in Chinese high-volume endoscopy center. Five Chinese doctors (the TTT group) who were invited to the TTT course and the other five age and experience-matched Chinese doctors (the non-TTT group) in the same facility who did not attend any learning program during the same period. Lectures of the TTT course included the detection of early gastric cancer by screening endoscopy using white-light endoscopy alone and the feature of the detected subtle gastric mucosal lesion using white-light endoscopy or magnifying endoscopes with narrow-band imaging. Contents used in the lecture had been reported to be useful by an e-learning trial [1, 2]. All the instructions were given by an experienced Japanese endoscopist (K. Yao) who constructed the e-learning system [1, 2]. Endoscopists also received on-site hands-on training in order to know whether they obtained enough knowledge and technique. Furthermore, we held case conferences in order to share common experiences. During the period, the number of both newly detected early gastric cancers and screening gastroscopy procedures was recorded. The primary end-point is to compare the early detection rate between the TTT and the non-TTT group. (Early detection rate = the number of newly detected early gastric cancers/ the number of screening endoscopy procedures)
the TTT and the non-TTT group were 1.5% and 0%, respectively. There was a significant difference in early detection rate between the TTT and the non-TTT group (Fisher’s exact test, P = 0.046).

Conclusion: This clinical trial clearly showed that the systematic intensive TTT course is useful for improving early detection rate of gastric cancer in clinical practice at Keimyung University Hospital. First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China

Introduction: Endoscopic submucosal dissection (ESD) is believed to be a possible modality for early gastric cancer. But there is little report about long-term outcomes of the ESD directly compare with the surgery. The purpose of this study is the comparison between the two treatment modalities about the outcome.

Aims & Methods: We performed a retrospective analysis of 1243 patients with stage I early gastric cancer without lymph node involvement. 551 patients were treated with ESD, and 692 patients were treated with subtotal or total gastrectomy. Long-term overall and disease-specific survival rates, development of new lesions, and complications were analyzed.

Results: The mean age was higher in the ESD group (64.9 ± 9.5 vs. 58 ± 11.7, P = 0.001) and female distribution was higher in surgery group (30.5% vs. 38.9%, P = 0.001). In ESD, diabetes was more frequent (12.9% vs. 7.1%, P < 0.001). The overall survival rate was similar (96.2% vs. 96.7%, P = 0.136), but disease-specific survival rate was significantly higher in ESD group (99.8% vs. 98.7%, P = 0.037, log-rank test). During 10 year follow up period, new lesions were observed in 3.6% of ESD group and in 1.3% of surgery group (P < 0.001). ESD group showed less complications (4.5% vs. 16.3%, P < 0.001) and shorter hospital day than surgery group (5.27 days vs. 12.09 days, P < 0.001).

Conclusion: Although the development of new lesions were more frequent than surgery, ESD was similar overall survival rate and even higher disease-specific survival rate than surgery. Also, ESD has less complications and shorter hospital day than surgery. Therefore, ESD is an effective therapeutic method in early gastric cancer as well as surgery.

Introduction: Gastric malignant lymphoma (ML) is most popular lymphoma of the gastrointestinal tract. Especially we often see gastric MALT lymphoma in case of H. pylori cases of the gastrointestinal tract. Especially we often see gastric MALT lymphoma in case of H. pylori infection. Gastric malignant lymphoma is most popular lymphoma of the gastrointestinal tract. Especially we often see gastric MALT lymphoma in case of H. pylori infection.

Aims & Methods: In this single center study, we investigated a total of 72 gastric MALT lymphoma cases in our hospital and other 7 hospitals. We estimated total number of endoscopic examinations to achieve diagnosis of gastric MALT lymphoma endoscopically and histologically. In addition, we had analyzed the difference of abilities to diagnose of gastric MALT lymphoma between experts and trainees on endoscopic examinations using past endoscopic profiles (245 profiles).

Results: The average number of endoscopic examinations up to diagnose gastric MALT lymphoma was 3.4 times (from 1 to 7 times) on whole endoscopies after first appearance of lymphoma. Though average total number of endoscopic examinations of experts was only 1.2 times, on the other hand average total number of non-experts was 5.4 times. 5.4 times of endoscopic examination of experts was 5.4 times. There was a significant difference between experts and trainees of endoscopy on average total number of endoscopic examinations (p = 0.022). Major reason of misdiagnosis was insufficient recognition of endoscopic appearances of ML on endoscopic findings. Typical representative appearances of gastric MALT lymphoma were erosions, ulcers and surface irregularities. Since these lesions are also appeared as typical appearances of GC and gastritis, most of non-expert of endoscopy cannot distinguish the difference of GC, ML and gastritis due to those similarities.

Conclusion: In single non-curable factor (REGATTA): a phase 3, randomised controlled trial.

**P1231 DEVELOPMENT OF AND EXPERIENCE WITH AN INSULATED SCISSORS-TYPE KNIFE (SB KNIFE)**

M. Kobayashi
Yokkaichi Municipal Hospital Dept. of Gastroenterology, Yokkaichi/Japan

Contact E-mail Address: makoto-kobayashi@atoma.ocn.ne.jp

**Introduction:** Endoscopic submucosal dissection (ESD) is technically difficult and is associated with risks of perforation and bleeding. Although knife-type instruments are primarily used to make incisions during ESD, it is necessary to be proficient in endoscopic procedures and be able to perform them simultaneously with electrophilication and incision. Scissors-type knives are fairly easy to manipulate in colorectal ESD. We have fabricated SB knife Jr type (SBkJ), short scissors-type knife with outer insulated layer, in collaboration with SUMITOMO RAKELITE CO.

**Aims & Methods:** SBkJ is short length (electrode length: 3.5 mm) to be easy to handle in narrow colorectal lumen. The surface of the rotatable monopolar scissors is coated with insulating material in order to enhance the cutting power and prevent electric effects in the surrounding tissue. The shearing structure makes sharp cutting quality and very small round tips prevent to grasp the muscular layer. SBkJ was used in circumference incision, submucosal dissection and hemostasis. After infected hyaluronic acid in submucosal layer, grasped the tissue, confirming safety, make incision. SBkJ was used not only in incision but also in hemostasis. At sites containing blood vessels or bleeding, they were grasped and induced coagulation using SBkJ. It has been used on 180 colorectal lesions from January 2008.

**Results:** The circumference incision and submucosal dissection were basically performed with High-frequency cutting wave. There were 3 cases of perforation during ESD and 1 case of post-operative bleeding. The procedure itself was fairly easy and substantially effective at the sites diffusion sites difficult to obtain the submucosa and sites containing blood vessels, where conventional devices would encounter difficulties. Due to the very small round tips of the instrument, detailed operation become simply. For coagulation of blood vessels or bleeding, it is not required to replace SBkJ which is used cutting and coagulation.

**Conclusion:** This short insulated scissors-type knife (SBkJ) made it easier to perform colorectal ESD, we conclude that it is an effective device and easy for a beginner in colorectal ESD.

**Introduction:** Gastrointestinal subepithelial tumors include potentially malignant tumors. When considering the diagnostic yield for subepithelial tumors, it is important to evaluate whether the samples obtained are adequate for histological analysis, as immunohistological analysis is indispensable for a definitive diagnosis. However, it may be difficult to make a correct histological diagnosis with only the endoscopic ultrasonography-guided fine-needle aspiration (EUS-FNA). Therefore, there has been an interest in exploring an alternative modality for tissue sampling as mucosal-incision assisted biopsy (MIAB) based on the endoscopic submucosal dissection.

**Aims & Methods:** The aim of this study was to compare the usefulness of EUS-FNA and MIAB in the histological diagnosis of gastrointestinal subepithelial tumors (SET). We performed the retrospective study comparing 37 patients who underwent either EUS-FNA (n = 18) or MIAB (n = 19). Diagnostic yield of EUS-FNA and MIAB and safety of those EUS-FNA and MIAB were compared.

**Results:** The location of the SET was esophagus (n = 6), stomach (n = 29), and duodenum (n = 2). The histological diagnosis were gastrointestinal stromal tumors (n = 10), leiomyoma (n = 17), aberrant pancreas (n = 3), poorly differentiated adenocarcinoma (n = 2), metastatic carcinoma (renal cell carcinoma, n = 1), and no-diagnosis (n = 4). There were significant differences in the clinical characteristics-including sex and age-of the patients in the EUS-FNA group and the MIAB group. In EUS-FNA, the morphological findings of the SET by EUS were as follows. The mean diameter of tumor was 29.16±15.6/17.77±7.16 mm (p = 0.0034). The rate of intraluminal growth was 55.6%/94.7% (p = 0.0078). The mean procedure time was 40.89±10.79 min in EUS-FNA and 55.15±27.42 min in MIAB (p = 0.0234). Histological diagnosis was made in 72.2% of the EUS-FNAs and 94.7% of the MIABs (p = 0.0089).

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Previous studies have shown that non-cardiac gastric cancer had no associations with the obesity even if cardiac or gastroesophageal junctional cancer was related with the obesity. These studies have included high portion of advanced gastric cancer. Patients with most advanced cancer already experienced weight loss.

**Aims & Methods:** We evaluated the effect of body mass index (BMI) on early gastric cancer in patients undergoing endoscopic treatment for early gastric cancer. A total of 748 patients with early gastric cancer undergoing endoscopic treatment (endoscopic submucosal dissection) including age and sex matched healthy controls consist of this case-control study. Body mass index was classified into underweight (BMI < 18.5), normal (BMI 18.5–23), overweight (BMI 23–25), and obese (BMI ≥25) by Asia-Pacific guideline. Adjusted analysis using odds ratio (OR) and 95% confidence interval (CI) was performed to evaluate the effect of BMI on early gastric cancer.

**Results:** The mean age was 57 years and male sex was 60% (n = 447). BMI was higher in gastric cancer compared to healthy control (24 ± 3 vs 23, P < 0.001). The OR of gastric cancer was increased according to the BMI increase; 1.57 (95% CI, 0.89–2.79, P = 0.12) in normal BMI, 1.88 (95% CI, 1.06–3.35, P = 0.03) in overweight, and 2.28 (95% CI, 1.29–4.06, P = 0.003) in obese persons. The trend was significant to overweight (P = 0.001), but not significantly to underweight (P = 0.12).

**Conclusion:** The early gastric cancer was strongly associated with the increased BMI and its effect has dose-dependent pattern.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Introduction: In 2012 the reported incidence of gastric cancer in both sexes was 13.2/100,000 but the early detection strictly related to a better survival. Parma area is considered at medium-low incidence of gastric cancer. For early diagnosis, the detection of a precancerous condition like atrophic gastritis seems crucial, but the majority of such patient is asymptomatic and the use of non invasive diagnostics like serology (Pepsinogens and Gastrin 17) as suggested in the guidelines of Kyoto and Maastricht VI is up to now limited in clinical practice. Aim of the study, therefore was to establish the burden of gastric cancer in the diagnosis of the last six years, focusing on the detection of early gastric cancer.

Aims & Methods: Six years (from July 2010 to July 2016) were considered in search for diagnosis of gastric cancer as reported in the archives of the Pathology Department of Parma University. Overall, 816 cases of gastric cancer were found but we decided to consider only the surgically removed cases, therefore the available sample is based on 584 cases. For every cases we classified the cancer in early, following the Kodama classification, and advanced. The presence of atrophic gastritis nearby the neoplasia was assessed according with OLGA classification. In both early and advanced cancer the node status was investigated.

Results: Overall, 584 cases of gastric cancer was detected in the six years considered interval (M = 318, F = 223, mean age 78.58, range 36–105ys) The diagnosis of early gastric cancer was made in 44% (75.5%) (M = 24, F = 20 mean age 75.68ys, range 47–95ys). A diagnosis of advanced gastric cancer was established in 540 pts (M = 318, F = 222, mean age 78.20ys, range 36–105ys). The picture of chronic atrophic gastritis was found in more than 95% of the cases, both in early and advanced ones. The node status was also recorded. Early cancers showed a 25% of node metastasis compared with 84.65% in advanced ones. As regards the number of involved nodes, in early presentation of neoplasia we found 98% of pN1 staging whereas in advanced the pN1 cases were only 9.1%.

Concluded gastric cancer diagnosis is still confirmed as very infrequent and this could account for the high mortality rate for the gastric neoplasia. The search for precancerous condition like chronic atrophic gastritis is therefore mandatory.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

were significantly decreased in GC tissues comparing to adjacent normal tissues both in Chinese cohort (n = 48 pairs) and TCGA cohort (n = 450). CEB29L1 hypermethylation was correlated with poor overall survival in Chinese cohort (n = 87, p < 0.005) and validated in TCGA cohort (n = 354, p < 0.005), which suggesting that CEB29L1 might function as a tumour suppressor. The functional interaction of CEB29L1 was then confirmed. Ectopic expression of CEB29L1 in three GC cell lines (AGS, BGC823, MKN45) suppressed tumor proliferation in vitro (p < 0.01) and colony formation assays (p < 0.001). CEB29L1 induced apoptosis and G1 cell cycle arrest in GC cells, concomitant with the enhanced expression of cleaved caspase-8, caspase-3, p21, and decreased cyclin D3 expression. Cell migration and invasion abilities were inhibited by CEB29L1 in wound healing and gel invasion assays, respectively. Conversely, CEB29L1 knockdown in MKN28 demonstrated opposite effects. Orthotopic mouse model also showed inhibited tumorigenicity with CEB29L1-overexpressing BGC823 cells. Mechanically, RNAseq and gene set enrichment analysis (GSEA) revealed that AMPK and ERBB2/ERBB4 signaling were involved in the tumour suppressive role of CEB29L1 in GC. Consistent with our RNAseq data, anti-proliferative and AMPK activation were determined as the key upstream kinase; whilst ERK1/2 was the most strongly down-regulated in CEB29L1 over-expressing GC cells, suggesting that CEB29L1 up-regulates AMPK concomitant with down-regulation of ERBB2/ERBB4 signaling. Moreover, co-immunoprecipitation experiments confirmed the direct interaction between CEB29L1 and LKB1, a bona-fide tumour suppressor that functions to activate AMPK to suppress tumorigenesis.

Western blot confirmed activation of LKB1-AMPK/β cascade in GC cells expressing CEB29L1, while a converse effect was observed in CEB29L1 silenced MKN28 cells. Administration of an AMPK activator, AICAR, inhibited growth of control cells but not CAB39L-expressing (thus AMPK activated) cells, suggesting that CAB39L might function as a tumour suppressor. The functional effect in GC. Ectopic expression of CAB39L and LKB1, a bona-fide tumour suppressor that functions to activate AMPK to suppress tumorigenesis. Western blot confirmed activation of LKB1-AMPK/β cascade in GC cells expressing CAB39L, while a converse effect was observed in CAB39L silenced MKN28 cells. Administration of an AMPK activator, AICAR, inhibited growth of control cells but not CAB39L-expressing (thus AMPK activated) cells, suggesting that AMPK activation by CAB39L contributes to tumour suppression. Consistently, novel tumour suppressors silenced by reduced promoter methylation in GC. CAB39L inhibits gastric tumorigenesis via LKB1-mediated activation of AMPK/β. CAB39L methylation may serve as an independent prognostic biomarker for GC patients.

Introduction: The relationship between Helicobacter pylori (H. pylori) eradication and atrophic changes is debated. Although some studies report a partial restoration of (pH) levels after eradication of H. pylori, it is not clear whether the finding reflects gastric mucosal healing. L-cysteine, reducing acetatedehyde production after food intake, has been proposed for prevention of gastric carcino genesis in patients with chronic atrophic gastritis (CAG). To assess modifications in gastric function after L-cysteine administration in CAG by means of PGI and gastrin 17 (G17) serum levels

Aims & Methods: 62 patients (18 men, mean age 47.2 yrs), with histological diagnosis of moderate to severe chronic, atrophic, body gastritis (according to the updated Sydney System) and PGI serum levels > 25 ng/mL, were included in the gastrointestinal endoscopy with gastrin biopsies and PGI and G-17 measurement by means of Gastropanel®. 22 out of 62 patients had autoimmune gastritis while 40 of them reported previous H. pylori infection. All patients, Helicobacter pylori (H.p.) negative at baseline, were treated with L-cysteine (100 mg three times daily), up to now 24 out of 26 reached 36 months-treatment. Serum PGI and G-17 were measured at baseline and after 3, 6, 12, 24, 36 months after starting therapy.

Results: The PGI serum increased level serum after the starting of L-cysteine administration, as it follows: PGI mean value at baseline was 8.42 µg/L, but after 3 months therapy it decreased 10.58, after 6 months 11.65, after 12 months 12.19, after 24 months 13.88, and after 36 months was 14.21 (p < 0.0001). The G-17 serum level resulted gradually decreased over the 36 months therapy, as it follows: G-17 mean value was 51.33 pmol/l at baseline, 43.13 after 3 months therapy, 38.66 after 6 months, 28.34 after 24 months and 26.03 after 36 months (p < 0.004).

Conclusion: After L-cysteine administration, patients with chronic, atrophic, body gastritis showed long-lasting improvements of physiological gastric pH function, reflected by a significant increase of PGI levels and a parallel decrease of G-17 serum levels over a 36 months follow-up period.

Introduction: Signaling pathway mediated by androgen receptor (AR) plays an important role in the development of gender-related tumors, such as hepatocellular carcinoma, prostate cancer. Gastric cancer (GC) is the third cause of cancer death all over the world, and its incidence in male is also much higher than female. However, the molecular mechanisms of AR in gastric cancer are still poorly characterized.

Aims & Methods: To investigate the role of AR in gastric cancer, we identify the transcriptional downstream targets of AR by chromatin immunoprecipitation. We detected mRNA and protein expression level of AR and its target in paired GC samples by RT-PCR and western blot. The biological functions of AR signaling pathway in GC cell lines were determined by colony formation and cell migration/invasion assay.

Results: CCRK was demonstrated as the direct target of AR by chromatin immunoprecipitation. AR expression was elevated in most (6/7) GC cell lines compared with the immunized gastric cell line GES1. CCRK was up-regulated in all (7/7) tested GC cell lines. The correlation of AR and CCRK expression was statistically significant. Higher mRNA level of both AR and CCRK were detected in GC tissues compared with the adjacent normal tissues (P < 0.01). Ectopic re-expression of AR or CCRK by stable transfection promoted colony formation and invasiveness (P < 0.05). Consistently, the numbers of colony formation, migrated cells and invasive cell were reduced by knockdown of AR or CCRK in GC cell lines.

Conclusion: Our results demonstrate that AR directly regulates CCRK expression in GC. AR and CCRK gene may act as a potential oncosgene in gastrocarcino genesis by playing an important role in promoting of cell proliferation, migration and invasion, which may partially explain the higher prevalence of gastric cancer among males.

P1243 FLYING OFF COURSE WITH A 2WW DIRECT ACCESS TO TEST PILOT: NOTTINGHAM’S EXPERIENCE OF THE SUSPECTED UPPER GASTRO-INTESTINAL CANCER PATHWAY CHANGE WITH GP Vetting and OGD BOOKING
N. R. Lewis, J. Catton, E. James
Treast Oesophago-gastric unit, Nottingham University Hospitals NHS Trust, Nottingham/United Kingdom

Contact E-mail Address: nina.lewis@nuh.nhs.uk

Introduction: Timely progress through diagnosis pathways is a leading quality measure for NHS cancer services. A hypothesis of sooner diagnosis being achievable with direct access to hospital tests from primary care is a core part of CRUK ACE program (1), and in the context of UGI cancer pathways, there is known wide variation of direct access (DA) OGD (2). This pilot evaluates the efficacy and utility of DA OGD or clinic (DA OPD) for GP concerns a patient may have about OG cancer. Comparison was made with standtest 2WW pathway, where allocation to OGD and OPD first was randomised. The pilot was conducted in the DA OGD group.

Aims & Methods: Pilot and UG standard 2WW referrals 01/01/16-01/08/16 were identified from Cancer Centre records.

Results: 192 patients were in the pilot pathway, 430 via the standard 2WW. GPs were more likely to allocate patients to DA OGD (52%) compared with 32% having having DA OGD allocated by the hospital. Despite under-utilisation of protected slots for DA OGD, time to DA OGD compared to DTT did not differ (11.0 days [95%CI 10.5,11.5] versus 12.4 days [95%CI 11.0,13.3]). The same was concluded for DTT OPD. The pilot time on pathway was not different to the pilot group at 16.8 days [95% CI 4.9,28.6] compared to 17.9 days [95% CI 16.9, 18.9].

The subgroup of patients allocated to the pilot in DA OGD did have a quicker exit from the pathway, at 12.4 days [95% CI 6.5,18.3] compared to 14.8 days [95% CI 12.9,16.6] on the DTT OGD group. The pilot overall detected 8 cancers (4.2%); the standard 2WW path detected 55 (12.8%). OG cancers were in 4 of the DA OGD (4%) and 14 of the DTT OGD (10.2%). A further 10 non-OG cancers were detected in the DTT group after clinicians requested further investigations to determine the cause of their symptoms. Those patients allocated to OPD first by either GP or hospital were as likely to have cancer as those having OG, with 4.3% of those in the pilot having cancer detected this way, but none OG cancer, and 10.3% found to have cancers in the standard 2WW group following investigation directed after clinic visit. Of these 65% were cancers other than OG cancers and would not be detected on OGD alone.

Conclusion: OGD as a sole investigation has its utility in excluding or detecting OG cancer. A high proportion of cancers detected via 2WW criteria might be missed by using OGD alone. A high proportion of cancers detected via 2WW criteria might be missed by using OGD alone. Only a randomised controlled trial would be detrimental and lead to missed opportunity to detect other cancers that cause symptoms overlapping with those often ascribed to OG tumours.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1244 WHAT IS THE YIELD OF ROUTINE D2 BIOPSIES IN THOSE PRESENTING WITH WEIGHT LOSS AT GASTROSCOPY?
M. Yalchin, S. Zonoosi, M. Hussein, N. Jayasooriya, K. Besherdas
Gastroenterology, Barnet Hospital, DJ/United Kingdom

Contact E-mail Address: m.yalchin@nhs.net

Introduction: Coeliac disease is a common cause of malabsorption in Western countries. The gold standard method of diagnosing coeliac disease is by way of duodenal biopsy. Weight loss is a symptom of malabsorption. Patients referred for upper gastrointestinal endoscopy with symptoms of a weight loss commonly undergo duodenal biopsy to assess for presence of coeliac disease. We hypothe size that those patients with weight loss and who routinely have duodenal biopsies very rarely have coeliac disease unless there are other pointers towards malabsorption.

Aims & Methods: A single-centre, retrospective analysis of consecutive patients with weight loss undergoing upper gastrointestinal endoscopy for the purpose of weight loss was undertaken within a large associate teaching hospital within North London from 2005–2016. Of these patients, we reviewed those that had duodenal (D2) biopsies and the results. If they proved abnormal, we looked back for additional markers of malabsorption, clinically and biochemically.

Results: 142 consecutive patients, 65 were Male, 77 were female, underwent OGD for weight loss. Out of this cohort, 62% (n = 88) had a duodenal biopsy. 89% (n = 78) of these had a normal biopsy. 11% (n = 10) had an abnormal biopsy,
and 6 of these patients had coelac, whilst 4 had other pathology such as gran-ulation or duodenitis.

For all the patients who had abnormal D2 biopsies, they had other clinical markers of malabsorption, such as abdominal pain and diarrhoea, or biochemical indices such as anemia or elevated TTG antibodies.

Conclusion: We observed that the frequency and yield of routine duodenal biopsies in patients endoscoped for the sole indication of weight loss is poor. In patients with weight loss in whom coeliac disease is identified on biopsy is always associated with additional symptoms or abnormalities in blood indices. We conclude that there is no need to take biopsies of the duodenum on a routine basis for weight loss alone unless there are other signs of malabsorption. This will save time (both from taking the biopsy and sampling in the lab), lower the cost (forceps and pot) and improve the safety (potential perforation and bleeding risk) of the procedure.

P1245 FUNDING DISPARITIES IN DIGESTIVE CANCER RESEARCH IN THE UNITED STATES

P. S. Liang1, K. O’Connell2, M. Du3
1Medicine, New York University, New York/United States of America
2Memorial Sloan Kettering Cancer Center, New York/United States of America
Contact E-mail Address: peterliang@gmail.com

Introduction: In 2015, the five most common digestive cancers (colorectal, pancreatic, liver, gastric, and esophageal) accounted for 16% of incident cancer cases and 14% of all cancer deaths. It is unclear whether the amount and recent trends in US federal funding for digestive cancer research corresponds to the burden of disease.

Aims & Methods: We obtained the total annual funding for cancer (including the five most common digestive cancers) from 2008 to 2015 using a public database of research funded by US federal agencies. We calculated funding in 2015 constant USD using the Consumer Price Index. Cases and deaths estimated by the American Cancer Society were used to calculate funding per death or case for each cancer. For comparison, we also extracted data for the three most common cancers (breast, lung, prostate) and all cancers combined. As funding for research in the United States was boosted by the American Recovery & Reinvestment Act of 2009, we calculated funding per death for digestive cancers decreased by 20% for esophageal cancer, increased for the other digestive cancers during the study period. Funding disparity, measured by proportional death and funding, was highest for colorectal cancer, 34% for gastric cancer, and 37% for liver cancer; funding for esophageal and gastric cancer among digestive cancers and for lung cancer over-50% for colorectal cancer.

Funding disparity, measured by proportional death and funding, was highest for colorectal cancer, 34% for gastric cancer, and 37% for liver cancer; funding for esophageal and gastric cancer among digestive cancers and for lung cancer over-50% for colorectal cancer but increased for the other digestive cancers during the study period. Funding per death among digestive cancers in 2015 was highest for liver cancer and lowest for esophageal cancer. Funding per death for breast cancer was more than 3-fold the average for all cancers. Funding per death for digestive cancers decreased by 20% for esophageal cancer, 24% for colorectal and gastric cancer, and 28% for liver cancer; funding per death for pancreatic cancer was the lowest of all digestive cancers and for lung cancer over-all digestive cancers. For all digestive cancers, the number of deaths and cases was about twice the amount and recent trends in US federal funding for digestive cancer research corresponds to the burden of disease.

Conclusion: In 2015, the five most common digestive cancers (colorectal, pancreatic, liver, gastric, and esophageal) accounted for 16% of incident cancer cases and 14% of all cancer deaths. It is unclear whether the amount and recent trends in US federal funding for digestive cancer research corresponds to the burden of disease.

P1247 CURCUMIN DOWNREGULATES INTERLEUKIN (IL)-17 BY INCREASING THE EXPRESSION OF INDOLEAMINE 2,3- DIOXGENASE (IDO) IN HELICOBACTER PYLORI-INFECTED HUMAN GASTRIC MUCOSA

T. Larusa, R. Liprotti, S. Gervasi, E. Suraci, R. Marasco, M. Imeneo, F. Luzzi

Contact E-mail Address: tiziana.larusa@gmail.com

Introduction: IDO promotes the effector T-cells apoptosis by catalyzing the rate-limiting first step in tryptophan (Trp) catabolism. We demonstrated that the high expression of IDO in H. pylori-infected human gastric mucosa attenuates Th1 and Th17 immune response, but IDO expression is not yet fully understood. The presence of the nutrient compound curcumin suggests its use as an anti-H. pylori agent, but mechanisms that underlie its helpful activity are still not clear.

Aims & Methods: Five antral biopsies were taken from 22 patients (10 M, median age 47.5 yrs, range 20-74) who underwent gastroscopy for dyspeptic symptoms: 1 for urease quick test (Eurospital, Trieste, Italy), 2 for histology (Giemsa staining for H. pylori), and 2 for organ culture. A C-urea breath test was also performed (at least two tests positive and all the three tests negative to be considered H. pylori-negative). For histology, H. pylori-infected or colonized for colorectal cancer but increased for the other digestive cancers during the study period. Funding per death among digestive cancers in 2015 was highest for liver cancer and lowest for esophageal cancer. Funding per death for breast cancer was more than 3-fold the average for all cancers. Funding per death for digestive cancers decreased by 20% for esophageal cancer, 24% for colorectal and gastric cancer, and 28% for liver cancer; funding per death for pancreatic cancer was the lowest of all digestive cancers and for lung cancer over-all digestive cancers. For all digestive cancers, the number of deaths and cases was about twice the amount and recent trends in US federal funding for digestive cancer research corresponds to the burden of disease.

Conclusion: In 2015, the five most common digestive cancers (colorectal, pancreatic, liver, gastric, and esophageal) accounted for 16% of incident cancer cases and 14% of all cancer deaths. It is unclear whether the amount and recent trends in US federal funding for digestive cancer research corresponds to the burden of disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: In a H. pylori-negative cohort, IDO expression was significantly higher than normal control (p16, 10%; CDH1, 44%; RUNX-3, 16%) (p < 0.05). In the H. pylori eradication group, methylation rates of p16 and CDH1 decreased in 58.1% and 61.3% of the patients, and the median values of hypermethylation were significantly lower at one year compared with the non-eradication group. However, RUNX-3 hypermethylation did not differ significantly at one year after H. pylori eradication. The non-eradication group hypermethylation did not change after eradication.

Conclusion: H. pylori infection was associated with promoter hypermethylation of genes in gastric carcinogenesis, and H. pylori eradication might reverse p16 and CDH1 hypermethylation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Helicobacter pylori infection induces aberrant DNA methylation in gastric mucosa. We evaluated the effect of Helicobacter pylori eradication on promoter Cpg island hypermethylation in gastric carcinogenesis.

Aims & Methods: H. pylori-positive patients with gastric adenoma or early gastric cancer who underwent endoscopic resection were enrolled. According to H. pylori eradication after endoscopic resection, the patients were assigned to H. pylori eradication or non-eradication group. H. pylori-negative gastric mucosa from normal participants provided the normal control. CpG island hypermethylation of tumor-related genes (p16, CDH1, and RUNX-3) was evaluated by quantitative MethyLight assay in non-tumorous gastric mucosa. The gene methylation rate and median values of hypermethylation were compared after one year by H. pylori status.

Results: In H. pylori-positive patients, hypermethylation of p16 was found in 80% of H. pylori-negative patients; median p16 hypermethylation rate in the larger relative funding decrease for liver cancer, it remained the best-funded digestive cancer relative to both incident case and death. Liver cancer funding was 3.5-fold to 4-fold the average for all cancers. Funding per death for digestive cancers decreased by 20% for esophageal cancer, 24% for colorectal and gastric cancer, and 28% for liver cancer; funding per death for pancreatic cancer was the lowest of all digestive cancers and for lung cancer over-all digestive cancers. For all digestive cancers, the number of deaths and cases was about twice the amount and recent trends in US federal funding for digestive cancer research corresponds to the burden of disease.

Conclusion: In 2015, the five most common digestive cancers (colorectal, pancreatic, liver, gastric, and esophageal) accounted for 16% of incident cancer cases and 14% of all cancer deaths. It is unclear whether the amount and recent trends in US federal funding for digestive cancer research corresponds to the burden of disease.

P1248 ALTERATIONS IN SALIVARY MICROBIOTA IN SUBJECTS WITH HELICOBACTER PYLORI-ASSOCIATED GASTRITIS

W.K. Leung1, K.S. Lau2, T.S. Tong2, K. Chu2, P.C. Shan3
1Department Of Medicine, University of Hong Kong, Hong Kong/Hong Kong PRC
2Department Of Surgery, The University of Hong Kong, Hong Kong/Hong Kong PRC
3Centre For Genomic Sciences, The University of Hong Kong, Hong Kong/Hong Kong PRC

Contact E-mail Address: waikleung@hku.hk

Introduction: Alterations in salivary microbiota have been linked to elevated inflammatory responses and has been reported in patients with inflammatory bowel disease and pancreatic cancer. As yet, the potential association between salivary microbiota in patients with gastritis and Helicobacter pylori (HP) infection has not be determined.

Aims & Methods: In this study, we characterized the salivary microbiota in patients with H. pylori (HP)-associated gastritis and the potential changes of salivary microbiota after receiving HP eradication. We enrolled subjects who were scheduled for diagnostic upper GI endoscopy. We excluded patients with peptic ulcer or cancer found on endoscopy, who have received prior HP eradication therapy, and who have recent exposure to antibiotics or acid suppressive therapies. Unstimulated saliva samples were obtained from subjects during fasting state prior to endoscopy. End-stage gastric biopsies were obtained for determination of HP statuses by rapid urease test and histology. Another gastric biopsy was obtained for characterization of gastric microbiota. Serial salivary samples were obtained from HP-infected subjects 8-week after completing HP eradication therapy. Bacterial DNA was extracted for 16S rDNA sequencing by using the MiSeq Platform (Illumina). OTU clustering was performed and taxonomy assigned to the Greengene and HOMD database. Alpha and beta diversity was determined by Linear Discriminant Analysis Effect Size (LEfSe) was used to identify differentially expressed bacterial DNA in different groups.

Results: We enrolled 16 subjects with confirmed HP gastritis and 14 HP-negative subjects. Baseline salivary samples of all subjects were found to have significantly higher salivary microbial diversity than corresponding gastric samples. The predominant microbial family identified in the stomach is Helicobacteraceae (55.2%) whereas Helicobacteraceae constitutes only 0.1% of salivary microbiota. In contrast, the predominant families in saliva microbiota are Prevotellaceae (23.9%) and Neisseriaceae (20.3%). When compared to HP-negative subjects, salivary microbiota in HP-positive patients showed a significant increase in the Bacteroidetes and Spirochaetaceae, and a decrease in Flavobacteriaceae families. HP eradication therapy resulted in a significant reduction in the relative abundance of family Helicobacteraceae and Flavobacteriaceae.

Conclusion: There was a significant difference in the microbial diversity and compositions between gastric and salivary microbiota in HP-infected subjects, with Helicobacteraceae dominating the gastric microbiota. HP-infected subjects had a distinctive microbiota in the saliva which is reversed by HP eradication therapy. The significance of these microbial alterations in the saliva of HP-infected subjects and its correlation with gastric diseases deserves further investigations.

P1250 AUTOIMMUNE GASTRITIS WITH PREVIOUS OR CONCURRENT H. PYLORI INFECTION PRESENTS DISTINCT FUNCTIONAL AND MORPHOLOGICAL FEATURES

G. Maddalo1, V. Pirotta2, C. Orlando3, M. Pizzii2, M. Fassan3, D. Bass6, M. Rugge4, F. Farnati5
1Surgery, Oncology And Gastroenterology, Gastroenterology Unit, University Of Padua, Padua/Italy

Contact E-mail Address: gemma.maddalo@gmail.com

Introduction: Autoimmune gastritis (AG) results in hypochlorhydria due to parietal cells destruction. It is characterized by lower levels of serum pepsinogen (P1) and P2 and increased levels of gastric chief cells. Previous epidemiologic, serologic and pathologic features of AG patients with and without previous HP infection. To recruit eligible and eleven consecutive patients with AG, undergoing endoscopy, were included. Serum gastrin, P1, P2 and Cromogranin A levels were determined in all patients. Multiple gastric biopsies were obtained for histology, OLGA staging and HP detection. Previous or current HP infection (HP+) was confirmed in patients by antibody, and/or pathologic and/or serologic data. Statistics was performed using non parametric tests.

Results: Present or previous HP infection was confirmed in 50/211 patients while 161 were negative (HP−). When we compared HP+ vs HP−, AIG, no differences were found for age and gender distribution, antral and fundic/body atrophy, OLGA staging, P1, P2 and Cromogranin A levels. Gastrin levels and P1/P2 ratio, a global marker of gastric damage we previously identified, were higher in HP− vs HP+ (p < 0.02). Interestingly, 15% HP+ presented antrectal atrophy. Severity of ECL hyperplasia was higher in HP+ (p = 0.02) with a 3.5 RR of developing nodular or carcinoid lesions when compared with HP−. Serum P1, P2, P1/P2 and gastrin levels correlated with disease severity in HP+ (p < 0.01) but not in HP−.

Conclusion: HP+ AIG have/have had a mild infection without differences in OLGA staging when compared with HP−. HP+ are characterized by lower gastrin and gastrin/P1/P2 levels that, considered the lack of differences in OLGA staging suggest an intrinsic difference of gastric physiology. HP− showed selective G Cell damage leading to lower levels of gastrin and Gastrin/P1/P2 ratio. Consequently, they have lower degrees of ECL hyperplasia and a lower risk of developing carcinoids when compared with HP+. The presence of antrectal atrophy in HP− could be explained with the supposed autoimmune antrectal damage hypothesis in AIG+ 3. In conclusion, HP+ and HP− AIG have some differences in serological phenotype and HP infection may correlate in AIG patients with lower ECL hyperplasia and lower risk of neuroendocrine tumor.

Introduction: This study was conducted to determine the differential expression patterns of microRNAs, non-coding RNAs that control gene expression mainly through translational repression, in gastric mucosa of Helicobacter pylori (H. pylori) positive patients. Several miRNAs have been associated with promoting the inflammatory response initiated by the H. pylori infection, increasing the malignant progression of the gastric epithelium, and enhancing the invasiveness and migratory capacity of cancer cells. Using serum specimens, expression patterns of hsa-miR-155, hsa-miR-21, hsa-miR-146a and hsa-miR-223 were determined by Real-Time Polymerase Chain Reaction (Real-Time PCR).

Aims & Methods: Patients who underwent upper gastrointestinal endoscopy, in Mersin University Faculty of Medicine, Department of Gastroenterology and diagnosed H. pylori positive and negative were recruited. H. pylori status was assessed by the rapid urease test. Serum specimens of patients, were taken for miRNA isolation. hsa-miR-155, hsa-miR-21, hsa-miR-146a and hsa-miR-223 expression levels were determined using comparative 2-ΔΔCt analysis by using Real-Time PCR Systems, SDS 2.0 software programme. Statistical analysis of miRNAs between H. pylori positive and negative groups were compared with the Mann-Whitney U test. p < 0.05 was considered statistically significant.

The relationship between categorical variables were tested using Pearson's chi-square test. The relationship between levels of interleukin-1, interleukin-6 and interleukin-8 according to a number of works is accompanied by infection with Helicobacter pylori. The aim of this study was to investigate the transition of level of interleukin-1β and interleukin-6 levels before the onset of cancer.

Table 1

<table>

Results: H. pylori positive (n=46) and negative (n=49) were included. H. pylori was not able to effective the hsa-miR-155, hsa-miR-21, hsa-miR-146a-6 and hsa-miR-223 expressions in serum specimens and nuclear factor-κB (NF-κB) and Transforming growth factor, beta (TGFβ) pathways. There was no statistically difference between H. pylori positive and negative individuals in the analysis of hsa-miR-155, hsa-miR-21, hsa-miR-146a-6 and hsa-miR-223 miRNA expression levels (Table 1). In surveys, there is no statistically difference between each groups, the level of education, intake of smoking-alcohol, hypertension, diabetes, cardiovascular disease, family history of gastrointestinal disease, type of gastro-duodenal disease.

Conclusion: This study may contribute to the literature in terms of preventing pro-cancerous progression in the cases of cancer resulting from H. pylori infection before the onset of cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1252 INTERLEUKIN LEVEL IN PATIENTS INFECTED WITH CAGA(+) AND CAGA(−) STRAINS OF HELICOBACTER PYLORI

N.V. Baryshnikova1, Y.P. Uspenisky2, A. Suvorov3 1Science Research Institute, St-Petersburg/Russian Federation 2First Pavlov Saint-Petersburg State University, St-Petersburg/Russian Federation

Contact E-mail Address: baryshnikova_nv@mail.ru

Introduction: Change of interleukin level can be in patients with of chronic infections, in particular at Helicobacter pylori infection. Change of interleukin level in infected patients is significantly increased, for example, increase in level of interleukin-8 according to a number of works is accompanied by infection with virulent strains of a microorganism. CagA gene coding synthesis of the cytotoxin (Caga) of the same name capable, in addition, to exert impact on development of inflammation, in particular interleukin-8 is considered a marker of presence of pathogenicity island of H. pylori.

Aims & Methods: The aim was to define features of change of level of interleukin-1β and interleukin-6 in laboratory examinations of patients with the chronic gastritis associated with H. pylori infection depending on existence or lack of a gene of cagA in a microorganism genome. 40 patients with the chronic gastritis associated with H. pylori have been examined. Examination was made for absence or presence of a gene of cagA in a microorganism genome and taking biopsy from stomach antrum (2 biopates) for the purpose of verification of H. pylori infection. Detection of a microorganism was made by rapid urease test, a histologic method and molecular-genetic research–the polymerase chain reaction (PCR) with definition of genes of urease (ureC, ureD). Besides, the PSR method presence of a cagA gene in a genome of H. pylori was detected. All patients were divided on two groups: with cagA (+) strains and with cagA (−) strains. Levels of interleukins 1-β, 4-8 decided by imunofluorescence analysis (the Vektor-Best kit, Russia).

Results: cagA gene was detected in 30 patients (cagA(+) group) and absence in 10 patients (cagA(−) group). In cagA(+) patients mean level of interleukin-1β was 395.6 pg/ml, but in cagA(−) patients 311.2 pg/ml (p < 0.05). Level of interleukin-6 in cagA(+) patients was 2.4 pg/ml but in cagA(−) patients 0.32 pg/ml (p < 0.05). Level of interleukin-4 in cagA(+) patients was 21.6 pg/ml, but in cagA(−) patients 83.4 pg/ml (p < 0.05).

Conclusion: Presence in a genome of H. pylori cagA gene is accompanied by reliable increase in level of pro-inflammatory cytokines (IL-1β, IL-6) and decrease in level anti-inflammatory interleukin-4 that can be an additional factor of development of an inflammation during H. pylori invasion.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1253 THE TRANSITION OF HELICOBACTER PYLORI ERADICATION IN OUR INSTITUTION

M. Ono, T. Kitagayta, Y. Shimoda, J. Ito, T. Kudo, K. Hatanaka, Y. Yamamoto, H. Naruse 1Gastroenterology, Hokkaido Municipal Hospital, Hokkaido/Japan

Contact E-mail Address: cd441480@par.odn.ne.jp

Introduction: The incidence and mortality rate of gastric cancer are high in Japan. The International Agency for Research of Cancer (IARC) reported that 80% of gastric cancer is caused by Helicobacter pylori (H. pylori) infection and that the incidence of gastric cancer can be reduced by 30%-40% through H. pylori eradication therapy. The eradication therapy for chronic gastritis was approved for national health insurance in February 2013 in Japan. However, the success rate of H. pylori eradication by conventional primary triple therapy has been decreased by resistance to clarithromycin. Vonoprazan, which is a potassium ion-competitive acid blocker (P-CAB), became available in Japan in February 2015, before its release on the world market. There have been some reports on the usefulness of vonoprazan for H. pylori eradication.

Aims & Methods: The aim of this study was to investigate the transition of H. pylori eradication therapy including therapy with vonoprazan in our institution. This study was a retrospective single center study between January 2010 and December 2016. The subjects were patients who had received H. pylori eradication therapy. The subjects were divided into a conventional triple therapy group (PPI, omeprazole lansoprazole, esomeprazole, and rabeprazole) and a group who received triple therapy with vonoprazan instead of a PPI. Regimens with amoxicillin, clarithromycin and a PPI or vonoprazan were regarded as 1st line treatment, and a regimen with metronidazole instead of clarithromycin was regarded as 2nd line treatment. Success rates of 1st line treatment and 2nd line treatment with a PPI or vonoprazan were compared.

Results: There were 1278 patients who underwent H. pylori eradication therapy. The mean age of the patients was 61.5 years (13-92), and the patients included 722 males and 556 females. The patients who received H. pylori eradication therapy included 857 patients with chronic gastritis, 301 patients with stomach/duodenal ulcers, 82 patients with gastric cancer, 27 patients with polyps, and 12 other patients. The number of patients with chronic gastritis undergoing...
eradication therapy of *H. pylori* increased remarkably from 48.4% in 2012 to 75.8% in 2016. The success rate was 72.5%. The success rate of conventional PPI regimen was 75.8% (846/1116), and that of the vonoprazan regimen was 85.1% (74/87). The success rate of vonoprazan regimen was significantly higher than that of the PPI regimen (Fisher’s exact test: p < 0.05). The success rate of *H. pylori* eradication in 2nd line treatment was 84.7% (210/248). The success rate of *H. pylori* eradication in patients who received the conventional PPI regimen was 84.4% (35/42), and that in patients who received the vonoprazan regimen was 87.5% (21/24).

**Conclusion:** Vonoprazan is considered to be useful for *H. pylori* eradication instead of a PPI in first line treatment.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Shinya Y et al. Usefulness of vonoprazan, a potassium ion-competitive acid blocker, for primary eradication of Helicobacter pylori. *World J Gastrointest Pharmacother* 2014; 5:550–555.

**Contact E-mail Address:** sugimo@belle.shiga-med.ac.jp

**Introduction:** Potent acid inhibition with acid inhibitory drugs is crucial to the successful eradication for Helicobacter pylori infection. Vonoprazan, a potassium competitive acid blocker, was developed in Japan in the 2000s. Vonoprazan is considered to be useful for *H. pylori* eradication instead of a PPI in first line treatment.

**Aims and Methods:** We investigated the influence of CYP3A5*3 and CYP2C19 genotypes and susceptibility to antimicrobial agents for outcome of vonoprazan-containing eradication regimen for 7 days in 105 Japanese: (1) with amoxicillin 750 mg and clarithromycin 20 mg twice daily (bid) as the first-line treatment (n = 76); (2) with amoxicillin 750 mg and metronidazole 250 mg bid as the second-line (n = 29). Eradication rate was assessed at 8 weeks via 13C-urea breath test. CYP3A4*52, CYP3A5*3 and CYP2C19*2/3*5 were genotyped for all patients.

**Results:** Eradication rate on intention-to-treat analysis was 82.6% (95% confidence interval: 72.5%-87.9%), 76.3% (95%CI 66.6–86.7%) in the first-line treatment and 93.1% (97.0%, 95% CI 89.1–96.3) in the second line. None with CYP3A4*52 was observed. 38.3% of patients (46/120) were CYP3A5*1/*3 type and 55.0% were *3/*3 type. In naïve patients, the prevalence of clarithromycin-resistant strain was 42.1% (14/33). Eradication rate in patients with CYP3A5*1/*1 or *1/*3 type (CYP3A5*1/*1 and CYP3A5*1/*3) was 72.7% (54.5%-86.7%, 24/33), which was significantly lower than that in the *3/*3-type strain (90.7%, 77.9%-97.4%, 39/43, p = 0.039) in the first-line treatment. However, no significant differences of clinical outcome in the second-line therapy were seen among CYP3A5*3 genotypes.

**Conclusion:** Eradication rates of vonoprazan-based eradication therapy can be achieved high compared with PPI-based therapy. However, because CYP3A5*3 genotype may be one of determinate for outcome of eradication regimen including *H. pylori* infection, genotyping of CYP3A5*3 will be required to be paid attention for clinical outcome before treatment.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** naokosou122@gmail.com

**Introduction:** *H. pylori* infection. Vonoprazan (VPZ) based therapy is one of most popular *H. pylori* eradication in the world. On the other hand, eradication rates have been decreasing because of resistance to the clarithromycin (CAM). It is known that most antibiotics are not effective under strong acid secretion. So in order to improve the eradication rate, gastric acid must be reduced more rapidly and strongly. Vonoprazan (VPZ) is a new potassium competitive acid blocker and the usefulness is expected in Japan.

**Aims and Methods:** Our aim was to investigate the efficacy of the VPZ-based eradication therapy. The subjects were 999 patients who were diagnosed as *H. pylori* infection in our institution from June 2014 to December 2016. The patients were grouped into three: VPZ group and conventional PPI (Lansoprazole or Rabeprazole) group. We evaluated the first-, second- and third-line eradication status. Each regimen of VPZ group was first-line eradication (VPZ 20 mg bid+ amoxicillin 750 mg bid+ CAM 200 mg bid for 7 days), second-line eradication (VPZ 20 mg bid+ amoxicillin (AMPC) 750 mg bid+ Metronidazole 250 mg bid for 7 days). Each regimen of PPI group was first-line eradication (PPI bid+ AMPC 750 mg bid+ Metronidazole 250 mg bid for 7 days), second-line eradication (PPI bid+ amoxicillin 750 mg bid+ Metronidazole 250 mg bid for 7 days). One of the following PPI was used: Lansoprazole (LPZ) 30 mg, Rabeprazole (RPZ) 20 mg. After several months, eradication status was examined by urea breath test, stool antigen testing and blood antibody test.

**Results:** The number of first-line regimen of VPZ patients was 109, and the eradication was achieved in 97 patients (87%). RPZ patients were 308, and the eradication was achieved in 290 patients (75%). In the second-line eradication (74%), and the eradication was achieved in 300 patients (80%) respectively. The eradication rate of VPZ was statistically higher than RPZ and LPZ (P = 0.0006, and = 0.019 respectively). The number of second-line regimen of VPZ patients was 24, and the eradication was achieved in 19 patients (79%). RPZ patients were 68, and the eradication was achieved in 60 patients (88.2%), and LPZ patients were 68, and the eradication was achieved in 60 patients (88.2%) respectively. There were statically no significant differences in second-line regimens. Adverse events
such as erosion and diarrhea were reported in 6.6%(9/136) of patients in VPZ, in 10.5% in RPZ, and in 6.1%(28/456) in LPZ.

Conclusion: The first-line regimen with VPZ was superior to conventional PPI regimen, and was a result not to be inferior in the safety either.

P1257 CAN TWO WEEK BISMUTH BASED QUADRUPLE THERAPY FOR RESISTANT H. PYLORI INFECTION STILL BE USED IN THE UK?

H. Logan-Ellis, L. Bensaid, R. P.H. Logan
Gastroenterology, King’s College Hospital, London/United Kingdom

Introduction: H. pylori infection cures peptic ulcer disease (PUD); however, treatment strategies and many experts require repeated courses of treatment. We, and others, have recently documented that currently, within the UK, less than 30% of patients with with proven PUD, are subsequently documented to have been cured by H. pylori eradication 1,2. 

Currently, resistance is common regarding 2nd line treatments, but the British National Formulary recommends a two regimen containing bismuth subcitrate, omeprazole, tetracycline and metronidazole. However since 2016, bismuth subcitrate has not been available in the UK, but is thought to be an important in treating persistent H. pylori infection.

Aims & Methods: The aim of this observational cohort study was to evaluate the effectiveness of a 2 week bismuth based quadruple therapy in patients who had previously failed to get eradication rates. Patients were identified from electronic hospital records using endoscopy data set, patient administration records, and pathology data sets from Jan 2011 to Dec 2016.

Initial failed H.pylori eradication was defined by either by a positive 13C-Urea Breath Test (13C-UBT) or positive HpStool Antigen test (HpSA) following H. pylori treatment in either primary or secondary care. All patients were seen, assessed and warned about the importance of compliance with treatment and of possible side effects by the specialist (RL) or the dyspepsia nurse specialist (LB). After treatment, patients were examined and HpSA and 13C-UBT were repeated.

Results: Within the inclusion period, (and from >560 patient records), 41 patients (22 female, mean age 44 yr, range 17-84 yr) were identified as having persistent H.pylori infection by +ve 13C-UBT (n = 25), HpSA (n = 10) or histology/CLTest (n = 6). All had failed at least one treatment, but 14/41 (34%) had failed 2 or more. Most patients were non or light drinkers (90%) and non-smokers (74%). OGD was performed in 19 patients to clarify indication for further attempts at H. pylori eradication and showed evidence of ulcer disease (ulcer, scarring or erosions) in 13/19 (68%). Culture and antibiotic sensitivity testing was unsuccessful in 3/5 patients. At least 6 weeks after the end of treatment, 5 patients were HpSA negative , but 5 patients failed to attend for assessment of eradication. During the follow up period from 2011 onwards, 11 patients underwent repeat 13C-UBT or HpSA testing, and all remained cured of infection.

Conclusion: Two week standard bismuth based quadruple therapy remains a highly effective treatment for persistent H. pylori infection in those patients in whom eradication of infection is mandated by the an underlying ulcer diathesis. The high eradication rate is likely due to the use of bismuth high doses of antibiotics, but also by specialists ensuring patients complied with their medication.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1258 MAY PROBIOTICS MONOTHERAPY ERADICATE HELICOBACTER PYLORI? A SYSTEMATIC REVIEW WITH POOLED-DATA ANALYSIS

G. Losurdo, R. Cubisino, M. Barone, M. Principi, E. Ierardi, A. Di Leo
Emergency And Organ Transplantation, University of Bari, Bari/Italy

Contact E-mail Address: giuseppedolo@alice.it

Introduction: Despite several evidences in literature have demonstrated a role for probiotics as adjunctive treatment for Helicobacter pylori (H. pylori) eradication, national and international guidelines as well as meta-analyses suggest that only co-administration of probiotics may have a beneficial effect on the prevention of side effects and eradication rates. Herein, we performed a systematic review with pooled-data analysis aimed to clarify whether probiotics alone may eradicate the bacterium.

Aims & Methods: Methods of analysis and inclusion criteria were based on PRISMA recommendations. Relevant publications were identified by a research in PubMed, EMBASE, Science Direct and EMBASE. The end-point was to estimate the mean eradication rate and variations of delta value at urea breath test across all studies and, overall, with a pooled data analysis. The data have been described ad proportions/percentages, and 95% confidence intervals (CI) were calculated. For continuous variables, we calculated the weighted mean difference. Odd ratios (OR) were calculated, where available, based on the Mantel-Haenszel method. Data were entered into the RevMan 5.3 software.

Results: Four studies (both randomised clinical trials and open label pilot studies) were selected. In one study patients with peptic ulcers were selected, while in the remaining 9 only dyspeptic patients were recruited. Probiotics eradicated H. pylori in 50 out of 391 cases. The mean weighted eradication rate was 14%, with a 95% CI of 2-25% (p=0.02). Most of studies investigated a probiotic formulation based on a single lactobacilli strain. Lactobacilli eradicated the bacterium in 30 out of 235 patients, with a mean weighted rate of 16% (95% CI 1-31%). Multistain combinations were effective in 14 out of 105 patients, with a pooled eradication rate of 14% (95% CI 16-43%). In the comparison probiotics versus placebo, we found an OR =9.65 in favor of probiotics, with a 95% CI of 1.97-47.36 (p = 0.005). Finally, probiotics induced a mean reduction in delta values of 8.61% (95% 3.88-11.34, p < 0.00001). No study provided data about adverse events.

Conclusion: Probiotics alone show a minimal effect on the eradication of H. pylori, thus suggesting a presumable direct effect. However, they cannot be indicated as a therapeutic regimen for the low eradication rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The new bismuth-containing quadruple therapy is currently advised in treatment of H. pylori infection in several guidelines. Our aim was to assess the real-life effectiveness and safety of this therapeutic regimen in a large population of patients who were infected by H. pylori.

Aims & Methods: Consecutive dyspeptic H. pylori-positive patients were enrolled, both naïve for treatment and already unsuccessfully treated. Patients were treated with Pylera® (3-in-1 capsules containing bismuth subcitrate potassium 140 mg, metronidazole 125 mg and tetracycline 125 mg) 3 capsules four times a day plus omeprazole 20 mg or esomeprazole 40 mg two times a day for 10 days. Efficacy was confirmed using a urea-breath test (at least 30 days after the end of treatment). Efficacy and safety were assessed.

Results: Three hundred and twenty patients were included in the study: 131 (40.9%) patients were naïve, and 189 (59.1%) patients with previous failure to previous treatment. H. pylori eradication was achieved in 299 (93.4%, 95% confidence intervals (CI) 92-96%), 5 patients failed to attend for assessment of eradication. During the follow up period from 2011 onwards, 11 patients underwent repeat 13C-UBT or HpSA testing, and all remained cured of infection.

Conclusion: Two week standard bismuth based quadruple therapy remains a highly effective treatment for persistent H. pylori infection in those patients in whom eradication of infection is mandated by the an underlying ulcer diathesis. The high eradication rate is likely due to the use of bismuth high doses of antibiotics, but also by specialists ensuring patients complied with their medication. These data, together with the poor outcomes of H. pylori eradication when undertaken by general physicians, also highlight the need for H. pylori eradication to be undertaken by specialists who have access to alternative sources of co-loddal bismuth subcitrate.

Introduction: Clarithromycin-containing triple therapy can be considered as a suitable option for first-line Helicobacter pylori (H. pylori) eradication in areas with less than 20% resistance rates to Clarithromycin. On the other hand, resistance to Clarithromycin is increasing in Iran, influencing the efficacy of standard triple therapy in this country. Therefore, regimes containing other antibiotics have to be considered in Iran.

Aims & Methods: One hundred and forty patients with peptic ulcer disease and naïve to eradication therapy were randomly divided into two groups to receive either 10-day standard triple therapy (Pantoprazole 40 mg, Amoxicillin 1 gr and Clarithromycin 500 mg, all given twice daily) or 10-day Levofloxacin-containing triple therapy (Pantoprazole 40 mg BD, Amoxicillin 1000 mg BD and Levofloxacin 500 mg daily). Eight weeks after the treatment, H. pylori eradication was assessed by 13C-urea breath test. Results: One hundred and thirty three patients completed the study. According to intention to treat analysis, H. pylori eradication rates were 75.7% (95% confidence interval (CI): 65.7%-85.7%) and 58.5% (95% CI 47.1%-70%) in standard and Levofloxacin-containing therapies, respectively. Also, per-protocol eradication rates were 83% (95% CI: 74%-92%) and 61% (95% CI= 49%–73%), respectively. The rates of severe adverse effects of therapy were 7.1% and 2.9% in the mentioned groups, respectively.

Conclusion: Both Clarithromycin-containing triple therapy and Levofloxacin-containing triple regimen seem to be suitable options for first-line H. pylori eradication in Iran. We suggest using Clarithromycin in quadruple regimen such as hybrid or concomitant therapies and reserve Levofloxacin to be used in second-line eradication regimens, as it is recommended by Maastricht V Consensus Report.

P1261 EFFICACY AND TOLERABILITY OF REBAMIPIDE IN TRIPLE THERAPY FOR ERADICATION OF HELICOBACTER PYLORI: A RANDOMIZED CLINICAL TRIAL

S. S. Vyalo
Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation

Contact E-mail Address: svialov@mail.ru

Introduction: Rebamipide is an orally prostaglandin E2 and I2 synthesis inducer. A latest clinical trial showed that the adhesion of H. pylori to stomach wall was reduced by rebamipide. This could improve eradication rates by increasing the availability of H. pylori to antimicrobial.

Aims & Methods: We aimed to determine eradication rate, the effectiveness and advantage of rebamipide in triple eradication therapy of H. pylori infection. Subjects comprised patients undergoing eradication therapy for H. pylori eradication in Iran. We suggest using Clarithromycin in quadruple regimens such as hybrid or concomitant therapies and reserve Levofloxacin to be used in second-line eradication regimens, as it is recommended by Maastricht V Consensus Report.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Chemotherapy-induced mucositis is a common complication during anticancer treatment. Epicalloocatechin-3-gallate (EGCG), derived from green tea, has been shown to have antioxidant effects and immunomodulatory activities. However, studies on EGCG for chemotherapy-induced mucositis have been scarce.

Aims & Methods: In this study, we aimed to prove the protective effect of EGCG in murine chemotherapy-induced mucositis model. Twenty-four 8-wk-old male C57Bl/6 mice were randomized to 4 groups: control, EGCG, 5-Fluorouracil (5-FU), EGCG plus 5-FU. Mucositis was induced by intraperitoneal injection of 5-FU (400 mg/kg). EGCG (50 mg/kg) was administered orally for 5 days from the day before administration of 5-FU. After 6 days of 5-FU injection, the mice were sacrificed and intestinal tissue was obtained. WBC count was performed with whole blood from Inferior vena cava of mice. The end points were villus height, crypt/villus ratio, histologic characteristics, and mRNA expression of tumor necrosis factor (TNF-α), and interleukin (IL)-6.

Results: In 5-FU group, neutropenia was confirmed by laboratory test (5-FU, 0.650 K/μL, Control, 5.317 K/μL), indicating significant 5-FU effect. Histologic findings showed that crypt dilatation, villus stunting, and villus atrophy were reduced in EGCG plus 5-FU group than in 5-FU group (Figure 1). Quantitative analysis showed that the villus height (EGCG plus 5-FU, 352 μm; 5-FU, 319 μm; p < 0.05) was significantly increased in EGCG plus 5-FU group, compared with 5-FU treated group, in significantly higher levels. mRNA expression of TNF-α was significantly lower in EGCG plus 5-FU group compared with 5-FU group (P < 0.05)(Figure 2). Figure 1. Effects of EGCG administration on chemotherapy-induced mucositis in mice jejunum. (A) control (B) 5-FU (C) EGCG plus 5-FU. Figure 2. mRNA expression of TNF-α, and interleukin (IL)-6.

Conclusion: EGCG derived from green tea reduced 5-FU induced intestinal mucositis. This suggests a possibility for novel treatment of chemotherapeutic-induced mucositis.

Introduction: Proton pump inhibitors (PPIs) have been shown to play an important role in the pathogenesis of nonselective amino acid transporters (LATs), which transport amino acids into cells, are correlated to various cancers. However, studies on PPIs for cancer have been scarce.

Aims & Methods: To investigate whether PPIs can increase the susceptibility to peroral enteropathogenic bacterial infection was not because of the immunological modification by PPIs, but it was mainly because of the increased number of pathogenic bacteria passing through the stomach.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1265 EXPRESSION OF AMINO ACID TRANSPORTERS IN ANTI-TUMOR AGENT-INDUCED GASTROINTESTINAL MUCOSAL INJURIES

M. Kudo1, R. Kawashima2, W. Koizumi2, T. Ichikawa2

Introduction: Because recent studies have demonstrated that amino acid transporters, which transport amino acids into cells, are correlated to various cancers and are major transporters that supply essential amino acids to tumor cells, these transporters are considered as novel biological tumor markers. On the other hand, patients suffering from anticancer agent-induced intestinal mucosal injuries, increasing; hence, it is important to take appropriate measures for reducing these side effects. Because the L-type amino acid transporter (LAT) transports a wide range of nonspecific amino acids, including essential amino acids, it is considered to be a gastrointestinal transporter that is important for nutrient absorption. Furthermore, the involvement of other amino acid transporters in carcinogenesis has been reported by many research groups.

Aims & Methods: We aimed to clarify the pathophysiological role of an amino acid transporter in gastrointestinal tract inflammation caused by an antitumor agent in this study. The antitumor agent fluorouracil (5-FU) was orally administered to mice. The severity of mucositis was assessed based on the length, villus height, mucus production, cell infiltration, and immune response of the intestinal tract. We measured the mRNA expressions of LATs in the tissues of the small intestines. In addition, we measured the protein expressions among the small intestines using anti-LAT antibodies.

Results: After the administration of 5-FU, the body weight, food intake, water consumption, and fecal volume decreased; thus, a systemic influence was observed. The length and villus height of the intestinal tract decreased because of the administration of 5-FU, and mucosal damage with histological change was observed. The number of PAS-positive cells decreased in the small intestinal mucosa, and it was assumed that the defensive function of the epithelial cells had decreased. In addition, an increase in the mRNA expression of IL-1β, IL-6, and TNF-α in the Peyers’ patches along with an increase in the cell infiltration after the administration of 5-FU significantly enhanced the immune response associated with the inflammatory cytokine production. Furthermore, on investigating the mRNA and protein expressions of LAT1 and LAT2 in the small intestines, we observed that LAT1 expression significantly increased and LAT2 expression decreased after the administration of 5-FU.

Conclusion: It was considered that the uptake capacity of amino acids, such as Gly, Ala, Ser, Thr, Cys, Asn, and Gin, that transported through LAT may be decreased in case of small intestinal mucosal injuries. On the other hand, LAT1 expression associated with the production of inflammatory cytokines suggested that LAT1 is a gastrointestinal inflammatory marker.

Introduction: Acetyl salicylic acid (ASA) has been used for the secondary prevention of cardiovascular diseases. Especially, the enteric coated ASA is widely used to prevent ASA-induced gastric mucosal injury. Recent technology such as video capsule endoscopy and balloon endoscopy enabled us to look inside the small intestine in more detail. Consequently, not a few cases of ASA-induced small intestinal mucosal lesions have been reported. However, the effective prophylaxis and treatment is not clear yet. Previously, we reported direct detrimental effect of ASA on small intestinal epithelial cells using an in vitro model [1]. However, there are the thick mucus layer between intestinal lumen and epithelial cells. The mucus has been reported to prevent foreign objects such as bacteria, medicine and food from epithelial cells.

Aims & Methods: This study was conducted to clarify the role of mucus on ASA-induced small intestinal mucosal injury using a rat model. Male Sprague-Dawley rats, 9 weeks old was used. These rats were divided into four groups; group 1: sham (carboxy methyl cellulose: CMC alone), group 2: polysorbate-80 (P80) alone, group 3: CMC alone, and group 4: P80 plus ASA. CMC and/or 50–200 mg/kg ASA was injected to the proximal duodenum of rats. P80, an emulsifier, which has been reported to reduce mucous thickness [2], was administered via drinking water for 2 weeks before ASA treatment. Indeed, P80 alone also reduced the thickness of mucous layer in our analyses. One hour after ASA injection, 1% Evans blue dye was injected via tail vein to visualize small intestinal lesions. Ninety minutes after ASA treatment, the entire small intestine was removed for histological examination. To further investigate the importance of mucus, rebaudioside (Reb, 300 mg/kg) or saline were orally administered for one week prior to ASA administration. Reb is a gastric mucotoxic drug widely used for the treatment of gastric ulcer, and increases mucus secretion by small intestinal goblet cell.

Results: Evans blue method suggested that high-dose ASA (200 mg/kg) induced severe mucosal lesions, which was further confirmed by the histological examination. Although lower doses of ASA (50 and 100 mg/kg) did not cause mucosal damage, P80 significantly reduced Evans blue exudate and severe mucosal lesions in jejunum at these concentrations, suggesting the pivotal role of mucus in ASA-induced small intestinal mucosal injury. Moreover, orally administered Reb significantly suppressed reducing small intestinal mucus and the exacerbation of ASA-induced mucosal lesions in these phenomena. Furthermore, we also investigated the role of ASA on small intestinal mucus in rats treated with oral gavage of 5% peanut milk. Histological examination revealed an increase in small intestinal eosinophils, predominantly at the villous tips, indicating recruitment to the mucus. RNA and protein analysis revealed an increase in IL-5 associated with increased Nod-Like Receptor Protein 3 (NLRP3) inflammasome activation.

Conclusion: These studies demonstrate that antibiotic treatment prior to food antigen challenge can lead to altered mucosal immune homeostasis, facilitating IL-5-mediated eosinophil recruitment, characteristic of allergic responses. Importantly, we have demonstrated an adjuvant-free model of food sensitisation and small intestinal eosinophilia. These findings contribute to a better understanding of how disruption of mucosal homeostasis by antibiotics contributes to the development of allergic sensitisation and reaction.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1268 PREBIOTIC EFFECTS ON HEALTHY AND CHEMOTHERAPY-INDUCED SMALL BOWEL INJURY IN RATS

R. Yazbeck1, R. J. Lindsay2, M. S. Geier2, R. N. Butler3, S. Jaenisch2, G. S. Howarth2
1Flinders Centre for Innovation in Cancer, Adelaide/Australia
2School Of Animal And Veterinary Science, University of Adelaide, Adelaide
3Surgery, Flinders University, Adelaide/Australia

Contact E-mail Address: roger.yazbek@flinders.edu.au

Background: Intestinal mucositis is a common severe side-effect of chemotherapy with current deficiency in effective treatments.

Aims & Methods: This study investigated three prebiotics, galacto-oligosaccharide (GOS), mannan-oligosaccharide (MOS) and fructo-oligosaccharide (FOS) for their potential to reduce the severity of 5-Fluorouracil (5-FU)-induced intestinal mucositis in rats. Female Dark Agouti rats (n=8/group) were orally gavaged with either 5% FOS, GOS, MOS or water (controls) for 16 days, and received an intraperitoneal injection of 5-Fluorouracil (5-FU: 150 mg/kg) or saline (controls), on day 13. Rats were housed in metabolic cages for the duration of the study, and metabolic data was recorded daily. Rats were killed on day 16 and visceral organ weights and lengths were analyzed post mortem. Crypt depth, villus height and histological severity scores were quantified in haematoxylin & eosin stained sections. Sucrase and maltase/palatinase/Hydrolase activity were quantified by biochemical assay. White and red blood cell types were quantified by whole blood analysis. Fecal volatile fatty acids (VFAs), acetate, propionate, isobutyric, butyric, isovaleric and valeric acid were also measured. Statistical analysis was by one-way ANOVA or Kruskal Wallis and Mann Whitney U test, where p<0.05 was considered statistically significant. Data are expressed as mean±standard error of the mean.

Results: %Bodyweight loss was significantly decreased in all treatment groups following 5-FU injection. FOS, MOS, pre and post 5-FU treatment did not significantly modify this parameter. Similarly, jejunal and ileal sucrase activity was decreased in all groups after 5-FU injection (p<0.05), correlating with histological measurements. Tissue MPO activity was significantly increased post 5-FU injection, reflecting increased neutrophil activation, and was unchanged by prebiotic treatment. Interestingly, MOS and GOS both lowered %circulating neutrophils pre-5-FU compared to water controls (p<0.05). Pre-5-FU treatment with GOS significantly increased the fecal VFAs acetic acid (16.76±1.22 mM/L) and propionic acid (4.60±0.99 mM/L) compared to saline treated controls (240.40±8.83 mM/L; p<0.05). Ileal Villus height and crypt depth was significantly decreased in all treatment groups after 5-FU injection (p<0.05) and prebiotic treatment did not significantly modify this parameter. Similarly, jejunal and ileal sucrase activity was decreased in all groups after 5-FU injection (p<0.05), correlating with histological measurements. Tissue MPO activity was significantly increased post 5-FU injection, reflecting increased neutrophil activation, and was unchanged by prebiotic treatment. Interestingly, MOS and GOS both lowered %circulating neutrophils pre-5-FU compared to water controls (p<0.05). Pre-5-FU treatment with GOS significantly increased the fecal VFAs acetid (16.76±1.22 mM/L) and propionic acid (4.60±0.99 mM/L) compared to saline treated controls (7.7±0.92 mM/L and 3.05±0.28 mM/L, respectively; p<0.05). MOS and GOS treatment also significantly increased fecal acetic and propionic acid post 5-FU compared to water control (p<0.05).

Conclusion: Our study has found that prebiotics, MOS, GOS and FOS modified some parameters of intestinal health and immune regulation in healthy rats; however, these prebiotics were not protective against 5-FU induced intestinal damage. Furthermore, our findings have demonstrated that prebiotic treatment significantly increases VFA production, suggesting functional changes to the intestinal microbiome. Further studies are indicated to investigate prebiotics, both alone and in combination, during the repair phase of intestinal mucositis, and to determine their effect on gut microbial composition.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Food allergy is characterised by a Th2 helper type immune response against a food antigen, manifesting as symptoms including nausea, diarrhoea, vomiting or anaphylactic events. It is estimated that 10% of the Australian population have a food allergy, and common allergens include cow’s milk, shellfish and peanuts. Epidemiological studies have identified antibiotics as a significant risk factor for food allergy in infants.

Aims & Methods: We examined how the broad spectrum antibiotic amoxicillin influenced mucosal immune responses to peanut proteins and the development of peanut allergy in mice. Balb/C mice were treated daily with 5 mg/kg amoxicillin or PBS for 5 days (days 0–4). On days 5 and 6 animals received 0.2 mg peanut extract or PBS vehicle by oral gavage. Animals were rechallenged with peanut on day 13 and sacrificed on day 16. Immune responses to peanut challenge in blood and intestinal tissues were assessed by protein, mRNA and histological analysis.

Results: The proportion of circulating eosinophils was increased in the blood of mice treated with both antibiotics and peanut. Histological examination revealed an increase in small intestinal eosinophils, predominantly at the villous tips, indicating recruitment to the mucosa. RNA and protein analysis revealed an increase in IL-5 associated with increased Nod-Like Receptor Protein 3 (NLRP3) inflammasome activation.

Conclusion: These studies demonstrate that antibiotic treatment prior to food antigen challenge can lead to altered mucosal immune homeostasis, facilitating IL-5-mediated eosinophil recruitment, characteristic of allergic responses. Importantly, we have demonstrated an adjuvant-free model of food sensitisation and small intestinal eosinophilia. These findings contribute to a better understanding of how disruption of mucosal homeostasis by antibiotics contributes to the development of allergic sensitisation and reaction.

**P1209 THE RELATION OF CHEMOKINE RECEPTOR CXCR3 AND GUT-HOMEOSTASIS IN PROPRIO T-LYMPHOCYTES IN CROHN’S DISEASE PATIENTS**

Faculty of Medicine, The University Of Queensland, Woolloongabba/Australia

Aims & Methods: Our study aimed to assess expression of CXCR3 by different subsets of small intestinal lamina propria T-cells and its association with a4 and b7 expression in CD patients compared to controls. A total of 56 duodenal biopsies were obtained from CD (n = 15), functional dyspepsia (FD)/irritable bowel syndrome (IBS) (n = 24) or iron deficiency patients (n = 17) with ethical approval. Lamina propria (LP) cells were isolated from biopsies using EDTA, collagenase and granulocytes centrifugation with Ficoll. Expression of CXCR3, a4, and b7 on isolated T-lymphocytes was examined by flow cytometry. Statistically significance was assessed using T-test or Spearman correlation.

Results: The expression of CXCR3 on CD4 lymphocytes was significantly lower (58.6%) compared to controls (86.6%). Although the expression of CXCR3 on CD8 lymphocytes was higher than CD4 lymphocytes, it was not different between CD and other group (75.8% in CD patients vs 82.2% in controls). Similar observation was obtained on the double positive CD4 and CD8 lymphocytes. Interestingly, only expression of CXCR3 on CD4 lymphocytes positively correlated with expression of the gut-homing integrins, a4 and b7.

Conclusion: These observations showed significant expression of CXCR3 across different subsets of lymphocytes, with consistently higher expression seen in CD8⁺ lymphocytes compared to CD4 lymphocytes. An unexpected reduction of CXCR3 expression was seen in small intestinal of CD patients, which associated with gut-homing integrins. This result showed CXCR3 expression may play a role in migration of CD4 lymphocytes but not CD8 lymphocytes into duodenum in relation with integrins, a4 and b7. However, CXCR3 expression on CD4 lymphocytes in CD patients’ small intestine may have protective role. This propose further study to clarify.

**P1270 METHODOLOGICAL QUALITY OF CLINICAL PRACTICE GUIDELINES ON PROBIOTICS IN ACUTE GASTROENTERITIS IN CHILDREN USING THE APPRAISAL OF GUIDELINES FOR CLINICAL PRACTICE GUIDELINES (AGREE) II INSTRUMENT (AGREEII)**

A. Maruy Saito1, J.C. Herrera Rodriguez1, R. Rojas Galarza2

1Dept. Of Pediatrics, U Peruana Cayetano Heredia, Lima/Peru

Contact E-Mail Address: aldo.maruy@gmail.com

Introduction: Acute Gastroenteritis (AGE) is one of the diseases that most frequently affects paediatric population. Successful treatment in AGE has been more focused on prevention and treatment of its complications; every day, we find more publications on the use of adjuvants to decrease its duration. Probiotics have gained greater importance because some of them report benefits. We look for Clinical Practice Guidelines (CPG) that recommend their use in AGE. The AGREE II instrument was developed to address the issue of variability in guideline quality, so it is a tool that assesses the methodological rigour and transparency in which a guideline is developed.

Aims & Methods: To assess the methodological quality of clinical practice guidelines (CPG) on the use of probiotics in infant diarrhoea. The search was conducted in December 2016, of CPG based on the evidence, in PubMed, ScienceDirect, and Lilacs. In PubMed, the search terms were: probiotics AND infants, limit: ‘guideline’. In ScienceDirect: Probiotics AND infants, limit: Medicine and Dentistry and LILACS: ‘probiotics’ AND ‘infants’ and ‘probiotic’ AND ‘guidia’.The CPG selected were evaluated with the instrument AGREE II by two evaluators who were independent one from the other and by a third evaluator, when there were discrepancies. The confidentiality of the information was maintained by the index of the Instrument for each CPG. Four had an overall score greater than or equal to 5 and were recommended, and one with modifications, according to the instrument AGREE II. The CPG is a position Paper of a Working group, not a Guideline, and its the reason for the lower rates obtained.

Introduction: The excessive use of pesticides, often found as residues in our diet and as contaminants in drinking water, has become a public health problem. Most of these substances are considered as endocrine disruptors and their daily consumption is likely to have severe and irreversible consequences. Indeed, preliminary studies have shown that chronic exposure to low doses of chlorpyrifos (CPF) causes intestinal imbalance (dysbiosis) in vitro. Aims & Methods: The objective of this study is to evaluate the preventive potential of a prebiotic (mulin) in co-exposure with the CPF on the intestinal dysbiosis, the bacterial translocation and the integrity of the intestinal mucosa. For this we used an in vitro system: the SHIME® (Simulator of the Human Microbial
**P1273 SYSTEMATIC REVIEW AND META-ANALYSIS: PREVALENCE OF SMALL INTESTINAL BACTERIAL OVERGROWTH IN CHRONIC LIVER DISEASE**
A. Shah1, P. Ghasemi2, E. Shanahan3, G. Macdonald1, L. Fletcher4, M. Morrison1, M.P. P. Jones1, G. Holtmann4

4Psychology, Macquarie University Psychology, North Ryde/Australia

**Introduction:** Alterations to the gut microbiota and bacterial translocation have been implicated as relevant factors for the progression of chronic liver disease (CLD). While the sequence of events leading to translocation remains unclear, deficiencies in local host immune defences, increased permeability of the intestinal mucosal barrier and dysbiosis of the gut microbiota are suggested to play a role. Small intestinal bacterial overgrowth (SIBO), in which an excessive and/or abnormal type of bacteria is present in the small bowel has been implicated as a potential factor in translocation. However, systematic assessments of the extent of SIBO in CLD remain limited. We therefore aimed to compare the prevalence of small intestinal bacterial overgrowth (SIBO) in patients with chronic liver disease (CLD) and controls.

**Aims & Methods:** Using the search terms ‘small intestinal bacterial overgrowth (SIBO)’ and ‘chronic liver disease (CLD)’ or ‘small intestinal bacterial overgrowth (SIBO)’ and ‘carrhosis’, 19 case-control studies that met inclusion criteria were identified. Data were extracted to calculate prevalence rates and 95% confidence intervals (CI).

**Results:** The final dataset included 1,000 adult patients with CLD and 488 controls. Nine studies employed glucose breath tests (GBT), four lactulose breath test (LBT), two hydrogen breath test (HBT), one xylose breath test, five studies utilised culture methods and one quantitative PCR. Across all testing methods, the prevalence of SIBO in patients with CLD was 38.9% (95% CI 36.9–40.9) versus 9.8% (95% CI 7.5–12.8) in controls.

The prevalence of SIBO in CLD was increased as compared to controls (RR = 7.15, 95% CI 4.9–10.4). In patients with cirrhosis the prevalence of SIBO was 40.1% (95% CI 36.6–43.8) compared to 7.3% (95% CI 4.9–10.8) in controls. When different methods of detection was limited to breath tests, the prevalence of SIBO in CLD was 35.8% (95% CI 32.6–39.1) compared to 8.0% (95 CI 5.7–11.0) in controls. In contrast, based upon culture techniques, the prevalence of SIBO in CLD was 68.3% (95% CI 59.6–76.0) vs 7.94% (95% CI 3.44–12.73) in controls.

**Conclusion:** Regardless of the diagnostic modality, prevalence of SIBO is significantly increased in patients with CLD when compared to controls. It is notable that culture-based detection leads to a higher prevalence in CLD, suggesting breath tests are a more exact method of detecting the disorder. However, systematic assessment of the extent of SIBO detected, further studies need to explore the role of intestinal dysbiosis for the progression of CLD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Introduction: In humans, enteric methane (CH₄) production is highly variable and related to the gastrointestinal microbiome and diet. Previous work suggests that CH₄ production is more common in patients with ‘constipating’ conditions such as encopresis and diverticulosis. We aimed to explore the link between gastrointestinal symptoms breath CH₄ exhalation in patients with unexplained GI symptoms.

Aims & Methods: Consecutive patients (n = 100) with unexplained GI symptoms underwent a combined H₂/CH₄ breath test after ingestion of 75 g of glucose. H₂ and CH₄ were measured by Breathreacher microlyser (Quintron, USA). Gastrointestinal symptoms were assessed utilising the Structured Assessment of Gastrointestinal Symptoms Instrument (SAGIS). The association between methane exhalation and symptoms during the 2 weeks prior the test were evaluated using non parametric test.

Results: 100 consecutive patients (55%) aged 52.2 ± 15.7 years (mean ± SD) were included. Of these, 14 with positive GBT and 19 without SAGIS data were excluded, resulting in 67 data-sets available for analysis. Methane peak and methane baseline values were highly correlated (r = 0.96, p < 0.001). Methane peak and methane baseline values were highly correlated with the SAGIS diarrhoea score (r = −0.35, p < 0.01, Figure 1). Contrary to our current opinion, CH₄ exhalation was not associated with constipation (r = 0.1, P > 0.4). In addition, excessive belching and acid eructation were significantly associated with the baseline and peak CH₄ exhalation (r all ≥ 0.3, p all < 0.04).

Conclusion: There is an inverse association between CH₄ exhalation and diarrhoea symptoms. At the same time, CH₄ is associated with bloating and acid eructation. These data suggest that CH₄ or metabolic products from CH₄ production microbes modulate human gut function.

Introduction: The prevalence of osteoporosis is higher among patients suffering a distal radius fracture than in healthy controls [1]. Celiac disease (CD) is associated with low bone mineral density [2], and overall findings indicate an increased risk of fracture in CD patients [3, 4]. This study is to our knowledge the first case control study investigating whether there is a higher prevalence of CD in adult patients suffering a peripheral fracture (distal radius or ankle) than in healthy age- and sex matched controls.

Aims & Methods: Main objective was to investigate if patients with a recent fracture of the distal radius or ankle have a higher risk of having CD than healthy controls. 400 consecutive patients over the age of 40 with acute distal radius fracture (n = 293) or ankle fracture (n = 107) were included in a case control study by referral from the orthopedic department at Foroed General Hospital, Norway. The controls were 197 age- and sex- matched subjects from Sogn and Fjordane County identified from the National Population Registry, with no previous fracture history. BMD of the hips and spine was measured and history of previous fracture, comorbidities, medication, lifestyle factors, body mass index (BMI) and nutritional factors were registered. Serum analysis to detect serum CRP and osteoporosis including IgA tissue transglutaminase was performed.

Results: See table.

1body mass index 2celiac disease 3IgA tissue transglutaminase 4vit D < 37 nmol/L

Conclusion: The prevalence of celiac disease was in preliminary analyses not significantly higher among patients with a distal fracture (3.5%) than among healthy age- and sex- matched controls (2.8%). Osteoporosis and low Vitamin D levels are significant risk factors for distal radius fracture, but this is not the case with ankle fractures.

Contact E-mail Address: mzwciisol@su.krakow.pl

Introduction: Celiac disease (CeD) is an immune disorder, triggered by gluten intolerance in genetically susceptible patients. Clinical outcome includes severe intestinal manifestations, including neurologic complications in about 10% of patients. Previous studies confirmed the subclinical changes of自主性神经系统 (ANS) activity resulting to impaired gastric myoelectric activity. In CeD disturbances of parasympathetic-sympathetic balance of the ANS activity with sympathetic dominance is observed. Tight junctions impair-ment is one of postulated pathomechanism in CeD and its complications. Transmembrane proteins of tight junctions include claudin and occludin. There is lack of publications referring to soluble claudin and occludin concentrations in CeD. Interleukin-1 beta (IL-1beta) is an important mediator of the, and there are no data concerning on its influence on gastric myoelectric activity and ANS activity in CeD.

Aims & Methods: The study was aimed to evaluate occludin, claudin and IL-1beta concentrations in serum in neurologically asymptomatic patients with CeD and its correlation with selected parameters of ANS activity markers (heart rate variability, electrogastrography HRV) and gastric myoelectric activity (EGG). Thirty four patients with CeD (70% females, mean age 34 years, 41.2 ± 16.6) were evaluated. Serum concentrations tested for occludin, claudin, IL-1beta concentrations in serum using ELISA, and HRV and EGG.

Results: Biochemical parameters. Patients with CeD presented with lower average level of occludin (1.41(0–2.9) ng/mL) than healthy subjects (1.80(0.39–4.8) ng/ML) (P = 0.07, the Mann-Whitney test). No significant impact of CeD on the average results of IL-1 beta concentrations was observed (P = 0.44, the Mann-Whitney test). The rest HRV. In the celiac group the assessment of HRV revealed a negative significant correlation of claudin concentration and low and very low frequencies (VLF-RR). Singaper’s rank correlation coefficient: r = −0.51, P = 0.018) as well as positive correlation between IL-1beta and LF/HF was demonstrated (r = 0.51, P = 0.032). Statistically significant, negative and strong correlation of IL-1 beta concentration and DP (Dominant Power of EGG) (r = −0.58, P = 0.038) was shown.

Conclusion: ANS activity measured by EGG and HRV seems to be correlated to presence of IL-1beta. In celiac group the serum concentration of claudin and occludin do not correlate to ANS activity. Due to former research on autonomic imbalance in CeD with sympathetic overdrive, the hypothesis of influence of IL-1beta on ANS activity should be considered.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1277 WIDE HETEROGENEITY AND HIGH MORTALITY IN UNDEFINED AND NON-COEHLI REFRACTORY SPRUE: A RETROSPECTIVE EVALUATION OF 7 CASES

A. Schieppati1, F. Biagi, M. Zuffiada, G. Maiorano, G.R. Corazza1
1University of Pavia, Pavia/Italy

Contact E-mail Address: salimana@hotmail.it

Introduction: Small bowel villous atrophy (VA) is mainly related to coeliac disease (CD), but that develops in HLA DQ2/DQ8 positive patients and improves on a gluten-free diet. Other forms of VA unrelated to CD are common variable immune-deficiency, autoimmune enteropathy, small bowel malignancies, medication-related enteropathies, HIV, tropical sprue, and giardiasis [1–3]. However, there are also forms of VA in which CD can be neither confirmed nor excluded and there are forms of VA in which, although CD is excluded, a definitive diagnosis cannot be made. Some years ago, we coined the terms undefined sprue (US) and non-coeliac refractory sprue (NCRS) to define these two
P1278 EVERYDAY LIFE RESTRICTIONS CAUSED BY LONG-TERM TREATED CELIAC DISEASE: PREDICTION AND ASSOCIATED FACTORS
L. Kivelä1, S. Alin1, S. Kröger1, K. Kaukinen1, K. Kurppa1
1Tampere Centre for Child Health Research, University of Tampere, University of Tampere/Finnland
2School Of Medicine, University of Tampere, Tampere/Finnland
Contact E-mail Address: laura.kivela@filmet.fi
Introduction: Strict gluten-free diet (GFD) in celiac disease is burdensome and difficult to maintain, which might predispose to poor dietary adherence and impaired quality of life. We aimed to evaluate adult patients’ experience of living with celiac disease diagnosed in childhood, and identify factors associated with poor adherence to the life restrictions caused by celiac disease.
Aims & Methods: 232 adults (women 69%, median age 27.0 yr) with a childhood diagnosis of celiac disease fulfilled a questionnaire evaluating their experiences about health and lifestyle, possible co-morbidities, adherence and attitudes towards GFD and long-term follow-up of celiac disease. In addition, they completed validated Gastrointestinal Symptom Rating Scale (GSRS) and Psychological General Well-Being (PGWB) surveys for gastrointestinal symptoms and quality of life. Patient records were used to confirm clinical and histological presentation at diagnosis and other relevant medical data.
Results: Altogether 108 (47%) out of the 232 respondents felt that celiac disease restricts their daily life. This was experienced especially when eating in a restaurant with gluten-free dishes (58%) and visiting a friend (30%). Patients reporting restrictions had more often anaemia (38% vs 22%, p = 0.013) and severe symptoms (16% vs 6%, p = 0.047) at diagnosis, whereas the groups did not differ in age, gender or other clinical and histological presentation. Current age (9.4 vs 11.0 years, p = 0.015) and time from the diagnosis (18.6 vs 17.9 y, p = 0.468) were also comparable, as well as were self-perceived general health and concern about health, presence of co-morbidities and complications, smoking, physical exercise, socioeconomic status, membership of celiac society and presence of celiac disease in relatives. There was no also difference in specific gastrointestinal symptoms as measured by GSRS scores, but patients considering the disease restrictive reported more overall symptoms possibly related to celiac disease than those without restrictions (32% vs 17%, p = 0.007). Furthermore, dietary adherence (strict GFD 78% vs 82%, p = 0.770) was experienced adhering to the diet more challenging (somewhat difficult 33% vs 7%, p < 0.001) and had significantly lower PGWB vitality scores (median 17 vs 18, p = 0.023).
Conclusion: Almost half of the patients diagnosed in childhood experienced celiac disease to cause marked restrictions in adulthood. This was associated with current symptoms, lower vitality scores and difficulties to maintain GFD. Patients with severe symptoms and anaemia at diagnosis might require special attention and tailored follow-up in these circumstances.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1279 SYSTEMATIC REVIEW OF THE ECONOMIC BURDEN OF COELIAC DISEASE
D. Brendås1, A. J. Taylor2, D. A. Leffler3, E. S. Mears2, M. Gerber3
1IBM Watson Health, Boston/United States of America/MA
2Takeda, London/United Kingdom
3Takeda, Cambridge/United States of America/MA
Contact E-mail Address: aliki.taylor@takeda.com
Introduction: The prevalence of diagnosed coeliac disease (CD) has rapidly increased since the developed countries at the last 30 years. The economic burden of diagnosing, managing, and monitoring CD can be substantial but is poorly understood. To assess the economic burden of CD, we systematically reviewed current evidence quantifying economic costs and health resource utilization (HRU) for CD in North America and Europe.
Aims & Methods: Searches of Medline, Embase, EconLit, the Cochrane Library, and conference abstracts systematically identified literature published in English during the last 10 years assessing direct and indirect costs, cost-effectiveness studies, and cost-utility studies related to CD. Cost estimates were adjusted to 2015/2016 to account for inflation.
Results: Of 33 studies meeting criteria for inclusion, most (20) were from Europe, and most (18) reported or modeled costs associated with screening and diagnosis. Cost per positive CD diagnosis of screening patients already undergoing upper gastrointestinal biopsy for other indications, such as anaemia or irritable bowel syndrome, ranged from approximately $1,300 in Canada to more than $44,000 in the Netherlands (costing year not reported). In these populations, screening was judged to be cost-effective with various strategies combining diagnostic modalities, including serology then biopsy, compared to no screening. Strategies using either endoscopy/biopsy or serology alone were not considered cost-effective. Direct annual excess costs to a US payer per diagnosed CD patient was $5,000 and $3,400 (SUS 2013) to more than a person for a person without CD, chiefly due to outpatient care, with higher costs among patients with poor disease control. High use of outpatient care is also reflected in studies of HRU, although hospitalization, emergency visits and medication use are also more common in individuals with CD than in controls. After initiation of a gluten-free (GF) diet, patients visit primary care providers less often, but use more medications. Patients often pay out of pocket for gluten-free (GF) foods, which cost 240–518% more than gluten-containing equivalents. Three studies on absenteeism from Scandinavia found fewer days missed from school and work following diagnosis and initiation of a GF diet.
Conclusion: Most economic studies of CD have focused on the cost of screening and diagnosis, especially in Europe. Methods of screening generally are considered cost-effective when they combine diagnostic modalities, such as serology then biopsy, in people being evaluated for symptoms. Much of the cost to a payer of managing CD derives from outpatient care, especially for patients with poorly controlled disease. Patients on a GF diet lose fewer days from work than school but pay higher costs for GF foods.

Introduction: Metabolic syndrome (MS) and hepatic steatosis (HS) are frequent in patients with celiac disease (CD) after commencing gluten-free diet (GFD), but data about predictive factors for such a condition are still scarce.
Aims & Methods: We aimed to evaluate the role of PNPLA3 rs738409 in the development of MS and HS in CD patients after starting GFD. From June 2014 to September 2016 we consecutively enrolled all patients referred to academic gastroenterological centre, suffering from CD, with our without HS. All patients underwent anthropometrics and serological investigations, ultrasonography (US) to evaluate the degree and severity of HS and genotyping of PNPLA3 rs738409 polymorphism.
Results: Finally, 370 subjects were enrolled (136 with HS and 234 without HS). After genotyping assays, CC genotype was found in 194 subjects (52.4%), GG genotype in 138 subjects (37.3%), while 38 individuals (10.2%) showed the GG genotype. At binary logistic regression, only G and GG alleles were predictive for the development of HS (OR 1.97; p = 0.01 for G carriers and OR 6.9; p < 0.001 for GG carriers), while BMI (OR 3.8; p < 0.001) and waist circumference (OR 2.8; p = 0.03) at CD diagnosis were the only independent factors for the development of MS. The intergroup comparison among HS patients showed that
the severe grade of HS was more frequently observed in GG than in CC carriers (27% vs 11.3%; p = 0.001, OR 2.18).

Conclusion: PNPLA3 G and GG carriers with CD have higher susceptibility to hepatic steatosis, but not to metabolic syndrome. Moreover, patients with GG alleles display a more relevant disease in terms of severity of HS based on US evaluation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1282 HOW MANY HOURS DO STABLE COELIAC PATIENTS ACTUALLY NEED A DEXA SCAN?
M. Yalchin, R. Ekersley, T. Coysh, S. Mann
Gastroenterology, Barnet Hospital, D/J/United Kingdom

Contact E-mail Address: m.yalchin@nhs.net

Introduction: Patients with coeliac disease (CD) should be seen annually for a clinical review, blood tests and a DEXA scan if needed1,2. The indication for a DEXA scan is unclear due to conflicting recommendations in current guidelines3,4. The aim of our study was to audit our practice, with a focus on requests for DEXA scans.

Aims & Methods: This was a single-centre, retrospective study of CD patients under the care of 3 consultants. We accessed the electronic records to identify if haematological and biochemical profiles were being monitored. We also identified when patients had their first DEXA scans and whether or not they were indicated1,2.

Results: Data were collected on 160 patients (Female = 107 [67%]), Annual checks of BFC occurred in 94% of patients, vitamin B12 in 74%, folate in 78%, iron in 88%, calcium in 85% and vitamin D in 69%. DEXA scans occurred in 74% of patients (n = 119), including 65% (n = 77) who were screened around the time of diagnosis. However, only 24% (n = 28) actually warranted the scan according to guidelines1,2, and 68% (n = 81) did not fulfil criteria for a DEXA. In 8% of patients (n = 10), there was inadequate data. Of the 81 patients who did not warrant a DEXA scan, 77 results were available: normal in 48% (n = 37), osteopenia in 43% (n = 33) and osteoporosis in 9% (n = 7). Of the 7 patients that had osteoporosis, 4 patients were under 50 years old (57%). Of the appropriate DEXA requests, 25% (n = 7) were normal, 39% (n = 11) had osteo- poria and 36% (n = 10) had osteoporosis.

Conclusion: Most CD patients require very little clinical input at their routine appointments. Annual blood checks and adherence to a gluten-free diet are standard enquiries. However, there is a cohort of patients who are not getting their regular blood tests: 33% for bone profile and 25% for haematinsics. Clinicians tend to order a DEXA in most CD patients because it is easier than attempting to judge an individual’s risk in the setting of conflicting guidelines. The pick-up rate of osteoporosis in 36% of appropriately screened patients (vs 9% in inappropriate scan requests) suggests that targeted screening allows for a more rational and cost-effective use of a limited resource. We hope that the guidelines can now be updated with more clarity for the practitioners who request DEXA scans in CD patients.

P1283 MONITORING PATIENTS WITH COELIAC DISEASE: WHO ACTUALLY NEEDS A DEXA SCAN?
M. Yalchin, R. Ekersley, T. Coysh, S. Mann
Gastroenterology, Barnet Hospital, D/J/United Kingdom

Contact E-mail Address: m.yalchin@nhs.net

Introduction: Patients with coeliac disease (CD) should be seen annually for a clinical review, blood tests and a DEXA scan if needed1,2. The indication for a DEXA scan is unclear due to conflicting recommendations in current guidelines3,4. The aim of our study was to audit our practice, with a focus on requests for DEXA scans.

Aims & Methods: This was a single-centre, retrospective study of CD patients under the care of 3 consultants. We accessed the electronic records to identify if haematological and biochemical profiles were being monitored. We also identified when patients had their first DEXA scans and whether or not they were indicated1,2.

Results: Data were collected on 160 patients (Female = 107 [67%]), Annual checks of BFC occurred in 94% of patients, vitamin B12 in 74%, folate in 78%, iron in 88%, calcium in 85% and vitamin D in 69%. DEXA scans occurred in 74% of patients (n = 119), including 65% (n = 77) who were screened around the time of diagnosis. However, only 24% (n = 28) actually warranted the scan according to guidelines1,2, and 68% (n = 81) did not fulfil criteria for a DEXA. In 8% of patients (n = 10), there was inadequate data. Of the 81 patients who did not warrant a DEXA scan, 77 results were available: normal in 48% (n = 37), osteopenia in 43% (n = 33) and osteoporosis in 9% (n = 7). Of the 7 patients that had osteoporosis, 4 patients were under 50 years old (57%). Of the appropriate DEXA requests, 25% (n = 7) were normal, 39% (n = 11) had osteo- poria and 36% (n = 10) had osteoporosis.

Conclusion: Most CD patients require very little clinical input at their routine appointments. Annual blood checks and adherence to a gluten-free diet are standard enquiries. However, there is a cohort of patients who are not getting their regular blood tests: 33% for bone profile and 25% for haematinsics. Clinicians tend to order a DEXA in most CD patients because it is easier than attempting to judge an individual’s risk in the setting of conflicting guidelines. The pick-up rate of osteoporosis in 36% of appropriately screened patients (vs 9% in inappropriate scan requests) suggests that targeted screening allows for a more rational and cost-effective use of a limited resource. We hope that the guidelines can now be updated with more clarity for the practitioners who request DEXA scans in CD patients.

Introduction: A life-long gluten-free diet (GFD) is the only available treatment for patients with celiac disease (CD). Adherence to the GFD is associated with symptoms remission, reversal of mucosal atrophy and, possibly, prevention of CD-related complications. However, data on the long-term effects of a good or poor adherence to the GFD are limited.

Aims & Methods: The aim of this study was to assess the rate and accuracy of compliance to a strict GFD in patients with a CD history of more than 30 years and to compare endpoints such as complications, symptoms and histology between patients following a strict GFD and patients not compliant to the diet. Between 2015 and 2016, data from all patients diagnosed with CD at the Fondazione IRCCS Ca’ Granda before 1985 were retrieved. Patients not undergoing regular follow-up at the clinic were contacted in order to collect recent clinical data (e.g. results as regards symptoms, adherence to the GFD, laboratory data, and complications occurrence). All patients were asked to fill in a questionnaire investigating their knowledge on gluten free products and behavioral rules; in case of patients with CD diagnosis in childhood, the same questionnaire was administered to their parents.

Results: Clinical data from 196 patients were collected and analyzed. Patients were divided into 3 groups according to their adherence to GFD: 133 patients reporting a lifelong strict GFD, 29 patients on GFD at the time of follow-up but with a history of at least 5 years of gluten-containing diet (GCD), and 35 patients who reported to be on a GCD. No significant differences were found between groups regarding symptoms and histology at diagnosis, onset of associated autoimmune disorders, family history of CD and compliance to follow up. The onset of complications at follow-up did not significantly differ in the three groups as well. Follow-up history was available in 63 patients (32.1%). Persistence of villous atrophy was as expected more frequent in patients on GCD as on GFD (46% vs. 7% vs. 20 patients with normal histology during long-term GCD). The questionnaire was returned by 90 patients and 66 parents: a slightly better knowledge about the GFD and its behavioral rules was found between patients on lifelong GFD and patients with ongoing or past GCD (p = 0.03).

Conclusion: Poor adherence to the GFD is reported by almost one-third of patients with a long-term history of CD, confirming the high rate of poor compliance to such a strict diet among patients. Poor adherence to the GFD could be considered a major predictor of persistent or villous atrophy, but this does not necessarily imply the development of CD complications. Moreover, results from follow up biopsies showed that a GCD does not imply recurrence of villous atrophy in all patients, attesting the possibility that some CD patients may maintain a gluten tolerance over time.

Introduction: Prevalence rates of Functional Dyspepsia (FD) in East Asia are three times higher than Irritable Bowel Syndrome (IBS) rates. Many researchers have suggested that IBS subjects in the region experience their pain and discomfort in the upper abdomen, leading to misdiagnosis as FD.

Aims & Methods: We aimed to compare patterns of gastrointestinal (GI) symptoms induced in the Chinese population with FD or IBS during provocative hydrogen breath testing (HBT) with lactulose, lactose and fructose. Subjects fulfilling the ROME III classification of FD and IBS, and control subjects with no known GI disorder/symptoms were recruited. All subjects underwent HBT the ROME III classification of FD and IBS, and control subjects with no known GI disorder/symptoms were recruited. All subjects underwent HBT with lactulose (10 ml), lactose (25 g) and fructose (25 g). Subsequent breath tests were performed after a washout period of at least one week. Blood pressure and heart rate were recorded every 15 minutes for 3 h. GI symptoms were recorded during these 3 h intervals and telephone follow-up 24 hours later.

Results: A total of 353 subjects completed at least one breath test examination and 313 subjects completed all three breath tests. 16%, 55% and 29% were control, FD and IBS subjects, respectively. Subjects with IBS subjects in the region experience their pain and discomfort in the upper abdomen, leading to misdiagnosis as FD.

were evaluated: Group 1 (no colon/stoma present/no colon-in-continuity), Group 2 (≥50% colon to stoma or colon-in-continuity), and Group 3 (other bowel anastomoses). Clinical response was defined as ≥20% reduction from baseline in weekly parenteral support (PS) volume at Weeks 20–24. Data presented as mean (SD).

Results: The predominant diagnosis in Group 1 was Crohn’s disease, whereas the predominant diagnosis in Group 2 was vascular complications (Table). Group 1 patients required the highest baseline PS volumes compared with Group 2 or Group 3. TED-induced PS volume reduction (change in L/week) took longer to be realised in Group 2 (Week 12, -0.9 [1.2]; Week 24, -2.5 [2.1]) compared with Group 1 (Week 12, -5.5 [3.8]; Week 24, -6.4 [4.5] or Group 3 (Week 2, -2.7 [1.2]; Week 24, -5.1 [3.7]). Response rates were higher with TED versus placebo in all groups, but the difference was significant only in Group 1 (76% vs 19%, P = 0.001; Group 2, 56% vs 40%, P = 0.36; Group 3, 57% vs 29%, P = 0.035). Adverse events were reported by 94%, 72%, and 86% of Group 1, Group 2, and Group 3 patients receiving TED, respectively.

P1292 USE OF 3D COMPUTED TOMOGRAPHIC ENTEROCLYSIS TO OBTAIN INFORMATION ON THE LENGTH OF THE SMALL INTESTINE AND ON THE SIZE, SHAPE, LOCATION OF INTESTINAL NEOPLASIAS

T. Yodikawa, K. Ohno, T. Kurokami

Dept. Of Gastroenterology, Shizuoka General Hospital, Shizuoka,Japan

Contact E-mail Address: t-yoshi@med.nagoya-u.ac.jp

Introduction: We established a new imaging technique, 3D computed tomographic enteroclysis (CT enteroclysis), to explore the small bowel (1). In our hospital, this examination is performed routinely to detect gross lesions in the small intestine. In our study, we analysed the clinical performance of 3D CT enteroclysis to evaluate its safety, feasibility, and usefulness for small intestinal neoplasias.

Aims & Methods: Data on 3D CT enteroclysis performed in our hospital from January 2010 to March 2017 were reviewed. In 3D CT enteroclysis, the small bowel was inflated with air using a nasoduodenal tube, CT images were taken, and the 3D overviews, virtual endoscopy views, and virtual dissection views were generated using a virtual colonoscopy system. Total volume of injected air, intraintestinal pressure, and length of the depicted small bowel were recorded. The images of small intestinal neoplasias were collected and compared with other diagnostic methods.

Results: One-hundred thirty 3D CT enteroclysis were performed for 93 males and 46 females. The mean age was 49.2 y (17–87). Examinations were performed for definite/suspected Crohn’s disease in 55, intestinal obstruction in 54, and other gastrointestinal neoplasias in 25 and others in 5 patients. Informed consent was obtained from all patients, followed by RNA extraction. Gene expression profiling with an oligonucleotide microarray was performed in a training set of 4 matched tumor-normal pairs of superficial SNADETs. Genes and pathways that had significant differences between pairs were identified, followed by a set-level gene enrichment analysis with a pre-validated curated gene set. Results were confirmed with rt-PCR in all other independent SNADET pairs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1290 GENE EXPRESSION PROFILING OF SUPERFICIAL SPORADIC NON-AMPULLARY DUODENAL EPITHELIAL TUMORS

Y. Sakaguchi1, N. Yamamichi1, S. Tomida2, C. Takeuchi1, Y. Takahashi1, N. Kageyama-Yahara1, M. Fujishiro1, K. Koike1

1Dept. Of Gastroenterology, University of Tokyo, Tokyo/Japan
2Graduate School Of Medicine, Dentistry And Pharmaceutical Sciences, Okayama University, OkayamaCity,Japan

Contact E-mail Address: sakaguchi-ty@umin.ac.jp

Introduction: Sporadic non-ampullary duodenal epithelial tumors (SNADETs) are rare, accounting for less than 1% of gastrointestinal neoplasms, and thus the mechanism behind the pathogenesis and carcinogenesis of these neoplasms is still poorly understood. However, with the overall increase of small bowel cancer in recent years, there is an increasing need to clarify the morphology of SNADETs. This study was conducted with the objective of identifying genetic markers and pathways specific to superficial SNADETs through gene-expression profiling.

Aims & Methods: This was a prospective pilot study on patients with a diagnosis of superficial SNADETs who were treated at the Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo Hospital, Tokyo, Japan. Before enrollment, all patients underwent endoscopic evaluation to preclude ampullary lesions, and had a preoperative histologic diagnosis of either adenoma or adenocarcinoma. Patients with familial polyposis were excluded. Immediately before resection of the target lesions, a simple biopsy sample from the duodenal tumor and a paired sample from the surrounding normal duodenal mucosa was endoscopically obtained from each patient, followed by RNA extraction. Gene expression profiling with an oligonucleotide microarray was performed in a training set of 4 matched tumor-normal pairs of superficial SNADETs. Genes and pathways that had significant differences between pairs were identified, followed by a set-level gene enrichment analysis with a pre-validated curated gene set. Results were confirmed with rt-PCR in all other independent SNADET pairs.

Disclosure of Interest: From Jan 2014 to Jan 2016, a total of 12 consecutive patients were enrolled in this study. One patient was excluded due to a post-treatment diagnosis of familial polyposis. In a training set of 4 tumor-mucosa pairs, 626 probes (168 up-regulated, 458 down-regulated) which consistently demonstrated a 2-fold expression difference between tumor and normal mucosa in all matched pairs were identified. RT-PCR of genes most highly differentially expressed between the tumors and normal mucosa was performed in the 4 pairs in the training set as well as 7 independent pairs. Consistent gene expression patterns concurrent with microarray results were demonstrated in all pairs, confirming the results of this study. Gene set enrichment analysis of the training set using a curated data set demonstrated a strong association between SNADETs and colorectal adenomas (p < 0.0001) and APC down-regulation (p < 0.00001). No other significant associations were demonstrated.

Conclusion: Superficial SNADETs demonstrate gene expression characteristics that strongly resemble those of colorectal adenomas. Gene expression profiling of clinical samples from superficial SNADETs has demonstrated that characterization of these lesions has also demonstrated the significant role of APC down-regulation in the pathogenesis of SNADETs, suggesting that an adenoma-carcinoma sequence similar to colorectal adenomas may be seen in SNADETs. Further analysis of genes which may play a key role in the carcinogenesis of these neoplasms is required.

Disclosure of Interest: All authors have declared no conflicts of interest.
the size and locate the position of the lesions, and present objective information for surgeons. For SBCE, laboratory detection is a powerful new tool for diagnosis, pre-surgical evaluation, and follow-up for small intestinal neoplasms.

Disclosure of Interest: All authors have declared no conflicts of interest.

1. Yoshikawa T, Takehara Y, Kikuyama M, et al. Computed tomographic enterography and virtual endoscopy for small-bowel tumors. Therefore, 3D CT enteroclysis is a well-established tool in the diagnosis and therapy of small bowel diseases. Ink tattooing of the small bowel is used in some centers to mark pathologic lesions or the depth of small bowel insertion.

Aims & Methods: The purpose of this study was to determine the safety, the detection rate within a surgical operation or video capsule endoscopy and the clinical relevance of ink tattooing during balloon-assisted enteroscopy (BAE). Between 01.01.2010 to 31.12.2015 229 BAE were performed in 156 patients (pts) at the endoscopy unit of Klinikum Augsburg. We performed a retrospective analysis of all 81 (52%) patients who received an ink tattooing during BAE.

Results: Main indications for BAE were known angiodysplasia (37 pts), suspected bleeding of the small intestine (32 pts) and anemia (19 pts). Other indications were known or suspected tumor of the small intestine (17 pts) and Crohn’s disease (3 pts). In 27 patients no pathologic findings were found. In 41 patients an active bleeding, angiodysplasia or hemangioma were found and further therapeutic interventions were performed. Tumor/polyps (11 pts), inflammatory lesions (7 pts) and ulcerative diverticula (1 pts) were other findings. In all 81 patients ink tattooing of the small intestine was performed with no complications. 46 (57%) of 81 patients received a follow-up mainly due to re-bleeding. 5 patients underwent surgery directly after enteroscopy with ink-tattooing and therefore received no follow-up. In total 26 (32%) patients received a capsule endoscopy after BAE at our hospital. The ink tattooing could be detected via capsule endoscopy in 19 of these 26 patients (73%). The ink tattooing of the procedure could be detected via retracing endoscopy in 14% (n = 8) of patients who underwent a double balloon enteroscopy (DBE) for further evaluation of findings and to obtain tissue samples. In terms of histological diagnoses, adenocarcinomas were found in 43% (n = 6), Neurendocrine tumours in 29% (n = 4), Gastrointestinal stromal tumours in 14% (n = 2) of all patients. Nine patients received a second ink-tattooing of the small intestine within these examinations without any complications. Ink tattooing had no clinical relevance or therapeutic consequence in 62 of the 81 (72%) patients within the observation period. 5 of these 62 Patients received no further diagnostic or therapeutic steps due to their clinical situation. In 9 patients ink tattooing influenced the choice of approach (antegrade versus retrograde) for re-enteroscopy after a video capsule endoscopy. In 7 patients the ink tattooing was used for intraoperative localization and in 3 patients for intraoperative localization as well as for enteroscopy. The intraoperative detection rate of the ink tattooing was 100%.

Conclusion: Ink tattooing of the small intestine is a minimally invasive and safe endoscopic procedure to mark the depth of scope insertion or a pathologic lesion during balloon-assisted enteroscopy. It is a useful tool to avoid unnecessary examinations and aids the intraoperative localization of pathologic lesions. A complete enteroscopy via BAE from retrograde and antegrade BAE is achieved routinely in our setting.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: We conducted a study to prospectively analyze the safety and effectiveness of IGB ELIPSE in overweight adults. Six patients, 1 male and 5 female (average age 40, mean BMI = 40 kg/m2), were included in this study. Each patient swallowed Elipse™ balloon intended to remain in the stomach for 16 weeks. Each balloon was filled with 560 mL of filling fluid. Patients returned every 2 weeks for abdominal ultrasound which documented the correct position of the device. All patients were followed up by a nutritionist with a specific section on diet and diet plan.

Results: All 6 patients successfully swallowed the device. There were no major adverse effects. All 6 patients had a significant weight loss (about 16 Kg). In all of them, the migration of the balloon was spontaneous without needing endoscopic removal. All 6 patients successfully swallowed the balloon without requiring endoscopic removal. The balloon treatment is based on gastric space-occupying effects that increase the feeling of satiety and may also affect gut neuroendocrine signaling. However, widespread use of current generation IGBs has been limited by several factors: placement and removal endoscopes require sedation, special training and equipment; patients lost to follow-up are susceptible to IGB deflation and unplanned passage into the gastrointestinal tract. The Elipse™ is the world’s first intragastric balloon that does not require endoscopy or anesthesia.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1298 CHANGE OF VITAMIN D AND BONE MINERAL DENSITY AFTER BARIATRIC SURGERY IN CHINESE POPULATION
M. Han1, W. Lee2
1Internal Medicine, Min-Sheng General Hospital, Taoyuan/Taiwan
2Surgery, Min-Sheng General Hospital, Taoyuan/Taiwan

Aims & Methods: The aim of our study is to evaluate the change of Vitamin D and bone mineral density after bariatric surgery in Chinese population. This prospective cohort study included 50 patients (ranged from 20 to 65 years old) who received bariatric surgery at one teaching hospital in Taoyuan, Taiwan. Patient with osteoporosis before surgery were excluded in this study. Baseline (2012-2014) and one year after surgery (2013-2015), venous blood was collected from each patients for assessment of the Calcium, Vitamin D and parathyroid hormone (PTH) levels. BMD (g/cm2) was also measured at lumbar spine (L2-L4) by dual energy x-ray absorptiometry (DEXA).

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: Among 50 patients, 15 patients received laparoscopic sleeve gastrectomy, 24 patients received laparoscopic mini-gastric bypass (MGVB), 5 patients received laparoscopic Roux-en-Y gastric bypass (RYGB) and 6 patients received laparoscopic duodeno-jejunal bypass with sleeve gastrectomy (DJB-SG). The characteristic of the study population was shown as table 1. The differences of mean for calcium, vitamin D, PTH and BMD after bariatric surgery were -0.16 mg/dl (P = 0.003), -0.15 ng/ml (P = 0.001), 8.68 mg/g (P = 0.06) and -0.04 g/cm2 (P = 0.14) respectively.

Conclusion: One year after bariatric surgery, the prevalence of osteoporosis and osteopenia was low. The serum Vitamin D level increased significantly but no significant change of BMD was noted. Further longitudinal studies are warranted to clarify the long-term effect of bariatric surgery on BMD in Chinese population.

P1300 INTRAGASTRIC BALLOON: A LARGE BRAZILIAN MULTICENTRIC STUDY OVER 10,000 CASES AND 20 YEARS OF EXPERIENCE

1Dept. Of Bariatric Endoscopy, Sander Medical Center, Belo Horizonte/Brazil
2Clinica ObesoGastro, Curitiba/Brazil
3Clinica Dr. Giorgio Baretta, Curitiba/Brazil
4Clinica Dr. Gabriel Cairo Nunes, São Paulo/Brazil
5Bariatric Endoscopy, Scarporo Scopia, São Paulo/Brazil

Contact E-mail Address: brunosander@hotmail.com

Introduction: The intragastric balloon has been used for more than 20 years in Brazil as an endoscopic method for assisting weight loss, and some intercurrences were observed during more than 10,000 procedures performed. With the assistance of a multidisciplinary team the results have been satisfactory.

Aims & Methods: To assess the efficacy and complications of the weight loss with IGB in patients seen at the 07 private centers. A total of 10,255 patients with IGB implanted from 1997 to 2017 were analyzed from a prospective fed databank. IMB gnomon balloon implant was 09 months. Statistical analysis was performed according to sex and degree of excess weight (overweight and grade I, II and III). Data were analyzed using Student t-test, and to Tukey post-test. The level of significance was set at p < 0.05.

Results: 492 patients (4.8%) were excluded from the final analysis associated with weight loss: 226 (2.2%) due to early removal–These were analyzed in relation to the gastric leak condition with psychologist and 94% of them did not make a psychological evaluation before the procedure. 158 (1.54%) due fail on weight loss or weight gain–These were analyzed in relation to follow-up with nutritionist 58 patients had no comorbidities, 52 had hypertension, 45 had dyslipidemia, 32 had diabetes, 16.98 kg (SD:6.04) and average weight regained in this interval was 22.08 kg (SD:11.05). The mean diameter of the anastomosis was 24.78 mm (±6.04) and the average number of APC sessions was 1.78 times (±0.61). The average reduction of anastomosis diameter was 14.86 mm (±7.24) and the final average diameter was 10.42 mm (±8.07). The average weight loss between the first and last APC was 13.37 kg (±7.82) and the average decrease of BMI was 4.59 kg/m2 (±2.78). 122 patients (20.02%) did not achieve the target GI diameter and 05 patient (0.9%) did not lose weight even with the desired GI diameter. From the 146 patients who started with the GI balloon and were followed for 12 months, the weight recovery was less than 2 kg of the weight loss. Of the 554 patients APC, 51 (9.2%) required dilatation balloon due to symptomatic stenosis at least once. No further complications were reported.

Conclusion: Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastro enteric anastomosis in patients undergoing bariatric surgery who have regained weight with dilation of the anastomosis. The reintroduction of the patient to the multidisciplinary team is mandatory if better results and sustainable weight loss and comorbidity control are to be obtained.

Introduction: The weight regained has been a described growing problem in patients after bariatric surgery. This weight regained is multifacntial and associated with dilation of Gastrojeunostomy (GJ). For the patients with significant weight regain some revisitional procedures had been attempted and more recently endoscopic revisitional procedures had been described.

Aims & Methods: To evaluate the safety and effectiveness of argon plasma coagulation (APC) decreasing the diameter of the gastroenteric anastomosis in patients who have undergone RYGB for morbid obesity and regained weight associated to dilation of the GI from Jan-2014 to April-2017. 554 RYGB subjects with weight regain a dilation anastomosis (>18 mm) and at least 2 APC sessions were submitted APC application. In relation to the anastomotic diameter, the majority of studies use a diameter of more than 20 mm to define anastomosis dilation, although some studies use smaller diameters such as 12 mm similar to that created manually in the gastrojejunal anastomosis using a 36 Fr Fouchet bougie. In the patients in the present study, the minimum cross-section diameter was 18 mm and the maximum measured in the first session 40 mm. This anastomotic defect was measured using a 33-mm long Olympus scope between an 40 mm scope and an 42 mm scope with a maximum of 03 applications. APC set was at 2–3ml with 65–85W. GJ diameter target was 8–12 mm estimated with pre-measured grasper. At first APC session, pre-op weight and BMI, post-op weight nadir, actual weight and BMI and estimated diameter of GI were the variables collected. Complications during treatment were also collected. In the present study, psychological and nutritional evaluations were performed before APC and during treatment and physical activity was strongly recommended. Data were analyzed with descriptive statistic, student’s t-test and Spearman correlation.

Results: Of the 554 patients, 79.06% were women and 20.94% were men. Average time between bariatric surgery and the first APC was 96.35 months (±42.93). Average initial weight and average weight loss in this interval was 22.08 kg (±11.05). The mean diameter of the anastomosis was 24.78 mm (±6.04) and the average number of APC sessions was 1.78 times (±0.61). The average reduction of anastomosis diameter was 14.86 mm (±7.24) and the final average diameter was 10.42 mm (±8.07). The average weight loss between the first and last APC was 13.37 kg (±7.82) and the average decrease of BMI was 4.59 kg/m2 (±2.78). 122 patients (20.02%) did not achieve the target GI diameter and 05 patient (0.9%) did not lose weight even with the desired GI diameter. From the 146 patients who started with the GI balloon and were followed for 12 months, the weight recovery was less than 2 kg of the weight loss. Of the 554 patients APC, 51 (9.2%) required dilatation balloon due to symptomatic stenosis at least once. No further complications were reported.

Conclusion: Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastro enteric anastomosis in patients undergoing bariatric surgery who have regained weight with dilation of the anastomosis. The reintroduction of the patient to the multidisciplinary team is mandatory if better results and sustainable weight loss and comorbidity control are to be obtained.

Introduction: With the aging of the population, the incidence of obesity has also increased among the elderly. However, there is a higher incidence of severe comorbidities in this population comparing to adults, which often makes bariatric surgery unfeasible. In this scenario, treatment with the intragastric balloon (IGB) may be an interesting option.

Aims & Methods: To assess the efficacy and complications of obesity treatment in the elderly using a non adjustable IGB. A total of 77 patients were analyzed. The minimal initial body mass index (BMI) was 28 kg/m2. The level of significance was set at p < 0.05.

Results: 58 patients were women (75.3%). Mean age was 64.26 (60–80) years. Ten patients had no comorbidities, 52 had hypertension, 45 had dyslipidemia, 32 had insulin resistance, 12 had type II diabetes, and 10 had ischaemic heart disease. There was no major complications. Results are shown on table 1. The treatment success rates according to the following criteria: ≥10% total body weight loss (TBWL) and ≥25% excess weight loss (EWL) were 96.11% (74 patients) and
98.7% (76 patients) respectively. 30 patients reached a normal body mass index (BMI) (23-25 kg/m²) according to the Pan American Health Organization (OPAS). Elderly shows a higher BMI reduction (p=0.0002) and %TBWL (p=0.0003) than adults.

Introduction: By targeting specific receptors into the vascular system, bile acids (BA) are cholesterol derivatives that are now considered as hormones. BA regulates the basal energy expenditure and gluco-lipidic metabolism. In animal models of atheroma development (ApoE−−; and LDL−− mutant mouse model) a powerful anti-atherosclerotic effect of circulating BA has been evidenced: BA are metabolites of the gut microbiota, suspected to play a role in the development of atherosclerosis. This study examined whether variations in BA in or the gut microbiota composition can be described in the human Coronary Artery Disease pathophysiology.

Aims & Methods: Consecutive patients undergoing coronary angiography between February and May 2015 were enrolled. To avoid physiological or induced variations in circulating BA or in the gut microbiota, highly restrictive exclusion criteria were applied. Circulating and faecal BA were quantified by high pressure liquid chromatography and tandem mass spectrometry. The faecal microbiota composition was assessed by 454 pyrosequencing of the total fecal bacterial DNA.

Results: 80 patients were prospectively included of 406 screened, and divided in two groups with (n = 45) and a group without (n = 35) CAD. The mean serum concentrations of total BA was 1.02 ± 0.16 mol/l in patients with CAD and 2.16 ± 0.38 mol/l in patients without CAD (P = 0.005). This decrease, (adjusted for gender and age) was an independent predictor of CAD (odd ratio = 0.51; 95% confidence interval 0.31, 0.85; P = 0.01). The BA concentrations in feces were similar in both groups. There was no group-specific pattern in the fecal microbiota. In a subgroup of 17 patients, one month of statin therapy increased the serum BA concentration from 0.68 ± 0.08 to 1.37 ± 0.213 mol/l; (P = 0.01).

Conclusion: There was no specific microbiota signature associated with CAD. However, the decreased serum BA concentration was a strong predictor of CAD in humans. With respect to the powerful anti-atherosclerotic effect of BA in animal models, and their role in human lipid metabolism and diabetes, this study unraveled the existence of a new metabolic disturbance associated with CAD.

Background: The low-FODMAP diet (LF/D) is used to treat patients with irritable bowel syndrome (IBS) even if some nutritional concerns have been raised. It starts with an elimination phase and is followed by a reintroduction phase to clearly detect the “symptom trigger” foods in order to suggest a definitive and less restrictive diet tailored to the patient’s needs.

Aims & Methods: The aims of this study were to evaluate: 1) the effects of FODMAP reintroduction on a) body composition and nutritional status, using Bioelectrical Impedance Vector Analyses (BIVA), b) abdominal symptoms, c) quality of life, d) anxiety/depression, e) sleep quality. 2) if the patients’ perception of the “trigger” foods was accurate.

Results: 66 IBS patients (54F, 12 M; 44.8 ± 13.0 yrs.) started (T0) a LF/D for 8 weeks (T1) and followed a 9–14 week reintroduction period (T2). They underwent blood tests at T0 and T1, BIVA, anthropometric data, IBS-Symptom Severity Score, Bristol Stool Chart (BSC), SF36, Hospital Anxiety and Depression Scale and Pittsburgh Sleep Quality Index were performed at T0, T1 and T2. The patients were monitored by a nutritionist to verify their compliance.

Results: Neither change of blood tests at T1 nor variations of anthropometric data and BIVA were reported at T1 and T2 in comparison with T0. A significant improvement in abdominal symptoms (IBS-SSS), anxiety and quality of life, was recorded at T1, this remaining unchanged also at T2 (p < 0.0001). Depression improved at T2 (p < 0.01 vs. T0), Sleep quality improved at T1 (p < 0.05 vs. T0) and at T2 (p < 0.001 vs. T0). Normal BSC faces were reported by 38 patients at T0 to 60 patients both at T1 and T2. The degree of symptom relief with the diet was 1.5 ± 0.6 at T1 and 1.6 ± 0.7 at T2 and the degree of satisfaction was high.

Conclusion: 66 IBS patients both at baseline, after gluten exposure and after placebo, but no clear difference was seen in symptom change after provocation with gluten and placebo. The not-diagnosed group showed more severe symptoms with placebo than with gluten (p = 0.029). Symptom severity at baseline was significantly correlated with fatigue (r = 0.63, p = 0.003) and reduced quality of life (r = 0.76, p = 0.0003).

Conclusion: This randomized, double-blind placebo-controlled challenge with gluten diagnosed four patients with NCGS according to the Salerno criteria. However, according to the symptom registrations there are no clear difference between the diagnosed and the not-diagnosed group, or between symptoms after gluten provocation and placebo, indicating no specific effect of gluten in a group of patients with suspected NCGS.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1308 THE EFFECTS OF A CONTROLLED GLUTEN CHALLENGE IN PATIENTS WITH SUSPECTED NON-COEILIAC GLUTEN SENSITIVITY: A RANDOMIZED, DOUBLE-BLIND PLACEBO-CONTROLLED CHALLENGE

Introduction: Non-coeliac gluten sensitivity (NCGS) is a new entity with unknown prevalence and mechanisms, and there is a need for a standardized procedure to confirm the diagnosis. The objective of this study was to characterize the response to a gluten challenge, when performed according to the updated Salerno criteria.

Aims & Methods: Twenty patients (14F/6M, age range: 21–62 y) with suspected NCGS, without coeliac disease and wheat allergy, were included while on a gluten-free diet. All patients went through four periods of double-blind provoked gluten and placebo containing muffins. They were instructed to eat two muffins a day (11 g gluten) for four days, followed by a three days' wash-out. Gastrointestinal symptoms were recorded with questionnaires at baseline and after each provocation, while fatigue and quality of life were registered at baseline and end of the trial.

Results: Four out of twenty patients (20%) correctly identified the two periods when they received muffins containing gluten, hence were diagnosed with NCGS. The diagnosed group tended to show higher symptom scores than the not-diagnosed group both at baseline, after gluten exposure and after placebo, but no clear difference was seen in symptom change after provocation with gluten and placebo. The not-diagnosed group showed more severe symptoms with placebo than with gluten (p = 0.029). Symptom severity at baseline was significantly correlated with fatigue (r = 0.63, p = 0.003) and reduced quality of life (r = 0.76, p = 0.0003).

Conclusion: This randomized, double-blind placebo-controlled challenge with gluten diagnosed four patients with NCGS according to the Salerno criteria. However, according to the symptom registrations there are no clear difference between the diagnosed and the not-diagnosed group, or between symptoms after gluten provocation and placebo, indicating no specific effect of gluten in a group of patients with suspected NCGS.

Disclosure of Interest: All authors have declared no conflicts of interest.
both at T1 (8.4 ± 1.6) and T2 (8.2 ± 1.7). When starting, LFD patients considered as trigger foods fructose (67%), fructans (27%), fructose (17%), galacto-oligosaccharides (GOS) (17%) and polyols (3%); the reintroduction phase (T2) enabled us to detect lactose in 70%, fructans in 30%, fructose in 37%, GOS in 33% and polyols in 27%, as real triggers. The agreement (Cohen’s kappa) was moderate for lactose (κ: 0.50), fair for fructans (κ: 0.39) and fructose (κ: 0.32) and poor for polyols (κ: 0.16) and GOS (κ: 0.01).

Conclusion: Not only did reintroduction not affect the improvements achieved during the elimination phase, but it also precisely identified the foods responsible for the patients’ symptoms. This enabled us to suggest a personalized diet for the patients. The real role played by FODMAPs in generating symptoms was abundantly underestimated and misunderstood by our patients. This underlines the fact that LFD has to be administered and carried out under the guide of an expert nutri-

Introduction: Fructose malabsorption (FM) is a frequent finding in patients with abdominal symptoms due to high levels of fructose in Western diets. The role of monosaccharide transporter dysfunction in the small intestine is incompletely understood. The aim of this study was to investigate the histoanatomical distribution of the fructose transporter GLUT5.

Aims & Methods: The study included 257 patients with FM diagnosed by hydrogen breath test and grouped according to the response to a fructose-free diet. 42 healthy individuals and 31 patients with coeliac disease (CD) served as control.

The fructose breath test was done with 50 g fructose. Fructose malabsorption was defined as an increase of 20 ppm of endogenous hydrogen. Formalin-fixed and paraffin-embedded duodenal biopsy specimens were obtained in all cases. Histology was assessed using hematoxylin and eosin stained tissue sections. Expression of GLUT5 was studied by immunohistochemistry. Expression patterns and GLUT5 expression were correlated with clinico-pathological patient characteristics.

Results: The expression of GLUT5 did not differ significantly between patients with FM complete diet responders (n = 183) and healthy controls (n = 42). Also patients with FM responding to a fructose free diet did not differ in GLUT5 expression or in max. H2 increase and AUC measured in fructose breath testing from patients not responding to the diet (n = 40). However, in patients with CD (n = 29) significant differences in GLUT5 expression were found compared to patients with FM and healthy controls (p = 0.009). The severity of CD assessed by the Marsh score significantly correlated with the GLUT5 expression (rM = 0.563, p = 0.001).

Conclusion: Changes in GLUT5 expression may not cause symptoms in adult patients with FM. The symptoms induced by FM could be associated with mechanisms known to the pathogenesis of the fructose bowel syndrome. However, in secondary malabsorption decreased GLUT5 expression was detected. Further investigation is needed to understand the essential factors in FM and the influence on functional gastrointestinal disorders.

Contact E-mail Address: valeria.schindler@usz.ch

Introduction: Previous studies have shown a reduction of gastrointestinal symptoms in patients with disorders of gut-brain interaction (FGID) when following a diet low in FODMAPs. Symptom relief due to a low FODMAP diet has especially been investigated in patients suffering from irritable bowel syndrome (IBS) and has proven to reduce gastrointestinal symptoms in up to 86% of patients with IBS. In addition, there is evidence for an association between gastrointestinal symptoms and joint hypermobility (JH). However, there is no clear data regarding response rates to a diet low in FODMAPs in patients suffering from JH. In this study we aimed to assess and compare the response to a diet low in FODMAPs in JH positive and JH negative patients with FGID.

Aims & Methods: Data of patients presenting with FGID at the tertiary ambulatory functional bowel clinic between January 2015 and July 2016 were analyzed. FGIDs were diagnosed according to Rome III criteria. JH was assessed by physicians using Brighton score and rated positive for scores ≥4/9 points. Patients received professional nutritional counseling on a diet low in FODMAPs. A global symptom response was assessed by a professional nutritionist after 4 to 6 weeks following a low FODMAP diet.

Results: Of all 84 patients screened for JH, 62 (73.8%) were female and 22 (26.2%) were male. Median age was 35.5 (range 18-79) years. Patients were more likely to exhibit JH compared to males (38.62 [61.3%] vs. 6/22 [27.3%]; p = 0.006). Global symptom response rate to a diet low in FODMAPs was 64/84 (76.2%). Our data showed significantly better response to a low FODMAP diet in JH negative patients than in JH positive patients (36/40 [90.0%] vs. 28/44 [63.6%], p = 0.005, ITT). Response of 7 patients was unknown because of early therapy discontinuation before nutritional re-counseling. When excluding 7 patients with therapy discontinuation from our calculations, the difference in diet response between JH negative and JH positive patients remained significant (36.39 [92.3%] vs. 28/38 [73.7%]; p = 0.036).

Conclusion: Our data indicate an association between global symptom response to a diet low in FODMAPs and joint hypermobility status in FGID patients. An understanding of the structural pathophysiological features of JH is necessary for better management of patients suffering from intestinal permeability causing gastrointestinal symptoms in JH positive patients and limiting response to low FODMAP diet should be considered. Our findings represent a further step towards pathophysiological features in FGIDs and might help to select patients for individually appropriate therapies.

P1308 CHANGES IN GASTROINTESTINAL SYMPTOMS, SMALL INTESTINAL BACTERIA, AND DUODENAL PHYSIOLOGY FOLLOWING A LOW-FIBER, HIGH-SUGAR DIET

G. Saffouri1, B. Schmidt1, E. J. Battaglia1, Y. Bhattachar1, J. Choi1, H. Lekatz2, C. M. Fried1, G. Farrugia1, R. J. Kanner1
1Gastroenterology And Hepatology, Mayo Clinic, Rochester/United States of America

Contact E-mail Address: saffouri.george@mayo.edu

Introduction: Gastrointestinal symptoms are often associated with dietary intolerances and are common in the developed world consuming a western diet low in fiber.

Aims & Methods: To determine the effect of a high-sugar, low-fiber diet on GI symptoms and duodenal physiology, we performed a randomized, single-blind, placebo controlled, single-center study. Healthy adults with baseline fiber intake ≥14 g/1000 calories/day, <10% daily calories from added sugar; ≥5 servings of fruits and vegetables/day; and ≥15% daily calories from saturated fat were recruited. Exclusion criteria included known GI disease or symptoms, antibiotic/probiotic use within 4 weeks of the study, pregnancy, and vulnerable adults. At baseline visit, participants completed a symptom and demographic questionnaire and underwent esophagogastroduodenoscopy (EGD) with duodenal biopsies and aspirates. Symptoms associated with constipation, straining, incomplete evacuation, hard stools, abdominal pain associated with bowel movements, diarrhea, bloating, nausea/vomiting, heartburn, fatigue, and appetite. All partici-
pants consumed a 7-day standardized diet with typical United States high-sugar, low-fiber diet (45% carbohydrates, 35% fat, 15% protein). The diet was low in fiber (<10 g/1000 calories/day) and high in simple sugar (>50% daily carbohydrates). After dietary intervention, participants filled out four symptom questionnaires and underwent repeat EGD with duodenal biopsies and aspirates. Before and after the diet, quantitative aerobic and anaerobic cultures were performed on duodenal aspirates. Duodenal biopsies were mounted in an Ussing chamber. Intestinal permeability was evaluated using transepithelial electrical resistance (TEER) and FITC flux (4KDa; a measure of paracellular transport). Secretory responses were quantified in voltage clamp mode by measuring baseline short circuit current (Isc) and change in Isc (ΔIsc) in response to increasing concentrations (0.001-300 μM) of serotonin (5-HT) on the submucosal side. These measurements were repeated after the dietary intervention. Data are pre-

sent as mean ± SEM. Data were analyzed using paired t-test unless specified and p < 0.05 was considered significant.

Results: A total of 10 participants (5 female; median age 26; 70% Caucasian) were recruited. Average BMI of 1 was 23.1 kg/m2. Baseline and asymptomatic. After dietary intervention, all patients endorsed at least one new symptom and 9/10 participants endorsed multiple (≥2) new symptoms. At baseline 4/10 participants had positive duodenal cultures (> 100,000 CFU/mL, anaerobic) despite having no symptoms. Of the 6 who had no growth initially, 1 developed bacterial overgrowth following intervention. There was no signifi-
cant change in TEER (26.45 ± 1.98 vs 26.18 ± 2.45 Ohms/cm²), FITC flux (217 ± 34.72 vs 217 ± 6.42 ng/ml/g) or baseline Isc (48.27 ± 0.69 vs 51.58 ± 2.52 ng/ml/g) or baseline Isc (48.27 ± 0.69 vs 51.58 ± 2.52 ng/ml/g). There was a significantly lower ΔIsc response to increasing concentrations of 5-HT after dietary intervention (P < 0.05, two-way ANOVA).

Conclusion: A low-fiber, high sugar diet led to gastrointestinal symptoms in participants who normally consume a high-fiber diet. This diet was associated with a significant decrease in 5-HT evoked secretory response in the duodenum, sug-

gesting a potential role for dietary modulation of host serotoninergic pathway. There was no correlation with quantitative bacterial cultures and there was no overall significant change in intestinal permeability. Diet may mediate these
P1309 STRESS AND STRESS-RELATED PEPTIDE AMPLIFY THE ANOREXIC EFFECTS OF CHOLECYSTOKININ

Gastroenterology And Hepatology, Saitama medical University, Kawagoe/Japan

Contact E-mail Address: yamagoota810@yahoo.co.jp

Introduction: Recently roles of gut hormones on appetite control have been known. Among them, CCK is well known to suppress appetite and gastric motility. On the other hand, patients of functional dyspepsia (FD) have hyper sensitivity to CCK. And levels of CCK in blood were shown to be high in FD patients. In FD patients, stress have important roles of pathogenesis of the disease.

Aims & Methods: We undertook to clarify whether stress influences the actions of cholecystokinin (CCK) on appetite and gastric emptying. As stress, we gave restraint stress, corticosterone releasing factor (CRF) or urocortin (UCN1) injection intraperitoneally (IP). We also examined the effects of CCK and restraint stress on c-Fos expression in the neurons of appetite center of the brain. In the gastric emptying study, SD rats were fasted overnight. The amount of the mixture (food and glass beads) left in the stomach was measured after 2 hours of the perorally injection of mixed food, and gastric emptying rate was calculated. In the study on appetite, CCK was IP injected and the amounts of food was measured at 1 and 2 hours after the injection. In some experiments, CRF or UCN1 was IP injected and the interaction with CCK on food intake was examined.

In another study, restraint stress was given to rats and the interaction with CCK was evaluated. To study the involvement of brain in the interaction between CCK and stress, c-Fos expression in the neurons was examined and evaluated.

Results: CCK dose-dependently inhibited gastric emptying. CCK dose-dependently inhibited food intake during 1 hr and 2 hr. CRF (100mg/kg rat) significantly inhibited food intake. However, there was no interactive action between CCK and CRF on food intake. UCN1 (3 nmol/kg rat) inhibited food intake at 1 and 2 hours. There was an synergistic action between CCK and UCN1 on food intake.

Restraint stress amplified suppressive effect of CCK on gastric emptying and food intake. c-Fos expression of the neurons in the nucleus of soritary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) by CCK was amplified by the addition of restraint stress.

Conclusion: The result suggests that stress might amplify anorexic effects of CCK through the activation of satiety center of the brain that might be the possible pathogenesis for postprandial distress syndromes of FD.

Introduction: Cholecystokinin (CCK) and peptide tyrosine-tyrosine (PY) have been reported to suppress appetite and gastric emptying. Both peptides raise in blood by feeding, and maintain high levels simultaneously for 1–2 hours. Therefore there might be possible to cause interactive actions between two peptides, inducing satiation to finish food intake.

Aims & Methods: In this study, we undertook to elucidate whether CCK and PY have the interaction to decrease food intake. Study on gastric emptying. Male SD rats were fasted overnight, and 1 mL of mixture of food and glass beads was given into the stomach and then PY or CCK or CCK followed by PY was administered. The mixture of food left in the stomach was measured and gastric emptying rate was calculated. Study on appetite. PY or CCK was IP injected to the rats just before setting food to eat. The amounts of food were measured at 1 and 2 hours after the injection. To clarify the involvement of the brain in the interaction between CCK and PY, c-Fos expression was examined.

Results: CCK (0.5–10 nmol/kg) dose-dependently inhibited gastric emptying (p < 0.001). CCK 10 nmol/kg maximally inhibited food intake (p < 0.01). PY 25–250 pmol/kg significantly inhibited gastric emptying for 1 or 2 hrs after the injection (p < 0.01). PY 250 pmol/kg significantly inhibited food intake for 1 hr after the injection (p < 0.01). The combination of CCK 10 nmol/kg and PY 250 pmol/kg inhibited gastric emptying more than CCK alone (p < 0.001) or PY alone (not significant). PY and CCK additively inhibited food intake when PY was injected 20 minutes later from CCK injection. PY significantly amplified c-Fos expression induced by CCK in the nucleus of soritary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) in the brain.

P1311 REGULATION OF MICRORNAS BY P53 FAMILY MEMBERS IN HEPATOCELLULAR CARCINOMA

R. Hermelin1, M. Bender2, L. Kaser3, E. Aschenbrenner3, K. Pollinger3, C. Kunz1, M. Müller-Schilling1

Introduction: Transcription factors belonging to the p53 family (p53, p63, p73) respond to cellular stress signals by inducing an accurately defined set of genes. In a number of tumors, also in hepatocellular carcinoma (HCC), p53 proteins can exert cancerogenic or tumour suppressive functions. MicroRNAs are small, non-coding RNA molecules which play an important role in gene regulation. It is known that expression patterns of microRNAs can be controlled by the p53 family. Depending on disease and cellular origin different sets of p53-induced microRNAs have been identified.

Aims & Methods: Little is known about p53-dependent microRNA signatures in HCC. The aim of the study was therefore to identify p53-family-regulated microRNAs in HCC. Hep3B cells were transfected with rAd-p53 and -p73. Meganuclease analyses were performed to identify p53- and p73-regulated microRNAs. Verification of p53- and p73-dependent microRNA expression was performed by qPCR. To evaluate the effect of HCC-relevant therapeutics on p53-dependent regulation of microRNAs transfected Hep3B cells were incubated with Doxorubicin, Sorafenib, Tivantinib, and Regorafenib in vitro.

Results: Overexpression of p53 and p73 induced a rash of microRNAs. p53 induced miR-34a by 2.4-fold, miR-145 by 2.7-fold and led to a slight reduction of miR-149. In the presence of p53 miR-34a was induced by 5.4-fold, miR-145 by 3.2-fold, and miR-149 by 5.5-fold. p53-dependent expression of miR-34a was further increased in the presence of Doxorubicin (5.7-fold), Regorafenib (2.5-fold) and Tivantinib (1.9-fold) compared to controls. Moreover, incubation with Regorafenib resulted in an up to 3.4-fold increase of p53-dependent expression of miR-149 and miR-192.

Conclusion: p53 proteins affect the microRNA signature in HCC. Beside the already known induction of miR-34a we demonstrate for the first time a regulation of miR-145 and –149 by p53 and p73. We hypothesise that regulation of tumour suppressive microRNAs represents an effector mechanism by which p53 family members exert their role in tumour development and treatment response. The observed synergistic effect of p53 and HCC-relevant therapeutics on microRNA expression might provide new options for the development of therapeutic and prognostic measures in HCC.

Introduction: p53 transcription factors (p53, p63, p73) respond to cellular stress by transcriptional regulation of specific sets of genes. In hepatocellular carcinoma (HCC) and other tumors p53 family members exert cancerogenic or tumor suppressive effects. Depending on their specific functions, p53 family members exert their role in tumor development and treatment response. The observed synergistic effect of p53 and HCC-relevant therapeutics on microRNA expression might provide new options for the development of therapeutic and prognostic measures in HCC.

Aims & Methods: The aim of this study was to characterize the so far unknown regulation of the IGFBP2 gene by p53 family members in HCC. Hep3B cells were transfected with rAd-p53 and -TAp73 and their transcriptional regulation of IGFBP2 was determined by qPCR. Intra- and extracellular IGFBP2 protein levels were analyzed by Western Blot and ELISA. Transfasc database analyses were performed to identify potential BS for p53 and p73 in the IGFBP2 locus. These sequences were cloned, mutated and analyzed for p53 family binding in luciferase reporter assays. Binding of p53 and p73 to the identified BS was confirmed by CHIP experiments.

Results: TAp73 transfection increased IGFBP2 expression by up to 60-fold and revealed three elevated intra- and extracellular IGFBP2 protein levels. Intracellular IGFBP2 protein was not detected in controls. p53 transfection induced IGFBP2 expression by up to 7-fold. Two potential p53 and p73 BS are located in the promoter region, another 5 potential p73 and one p53 BS were identified in intron 1 of the IGFBP2 gene. Intron 1-dependent luciferase activity was increased by up to 110-fold after TAp73 transfection and up to 20-fold after p53 transfection. Mutation and deletion of the identified p53 BS in intron 1 resulted in a reduction of luciferase activity by up to 85%. Deletion of one
potential p73 BS reduced luciferase activity by 85%. CHIP analyses verified binding of p53 to TAp73 and p53 in HCC. We demonstrate for the first time an interaction of TAp73 with IGFBP2 and therefore an important, so far unknown link between the p53 family member and IGFBP2. p53 proteins exert predominantly tumor-inhibiting effects, whereas the IGF axis is of critical importance for proliferative events. The particular ratio of both important signaling seems to be decisive for tumor characteristics and treatment response. Our results therefore not only expand our knowledge about p53 mechanisms, but also indicate that fine-tuning these signaling pathways provides new therapeutic options in clinical management of HCC.

P1313 HOW TO IMPROVE THE RELIABILITY OF LIVER FIBROSIS EVALUATION USING 2D-SWE

F. Benede, I. Sporea, R. Sirlir, M. Danila, S.A. Popescu
Gastroenterology And Hepatology, University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisoara/Romania

Contact E-mail Address: benedefelix@gmail.com

Introduction: Liver stiffness (LS) evaluation as a marker of fibrosis is usually considered reliable when it fulfills some quality criteria. Classic criteria used for Transient Elastography (TE) are: ≥10 valid measurements, ≥60% success rate, and interquartile range/median ratio (IQR/M) < 0.30 [1]. However, new quality criteria were proposed using the IQR/M ratio, therefore the LS measurements can be classified into three categories: very reliable (IQR/M < 0.10), reliable (0.10 < IQR/M < 0.30), poorly reliable (IQR/M > 0.30) [2].

Aims & Methods: The aim of this study was to assess the impact of using quality criteria (LS) evaluation by means of 2D Shear Wave Elastography from General Electrics (2D-SWE.GE), while using Transient Elastography (TE) as the reference. We included 226 subjects in our study, with or without chronic liver disease, in whom LS was assessed using 2D-SWE.GE (LOGIQ E9, GE Healthcare) and TE (FibroScan, EchoSens). Reliable LS measurements were defined for TE as the median value of 10 measurements with a success rate of ≥60% and an interquartile range (IQR) < 30% of the median LS values. For 2D-SWE.GE 10 LS measurements were acquired in a homogenous area and the IQR and the IQR/M were calculated in each case. We divided our subjects into 3 groups according to the 2D-SWE.GE IQR/M: IQR/M < 0.10: 41 (18.1%) cases; 0.10 < IQR/M < 0.30: 155 (68.6%) cases; IQR/M > 0.30: 30 (13.3%) cases. We calculated the correlation coefficient between TE and 2D-SWE.GE in each group.

Results: All 226 (100%) subjects included had ≥10 valid measurements by means of 2D-SWE.GE and reliable results by TE. A strong positive correlation was found between LS values obtained by means of 2D-SWE.GE and TE in the IQR/M < 0.10 group (r = 0.84, p < 0.0001). A weak positive correlation was found between LS values obtained by means of 2D-SWE.GE and TE in the IQR/M > 0.30 group (r = 0.30, p = 0.0013). No statistical differences were found between the correlations in the IQR/M < 0.10 and 0.10 < IQR/M < 0.30 groups (p = 0.43).

Conclusion: Using the IQR/M < 0.30 as quality criteria significantly increase the reliability of LS measurements by means of 2D-SWE.GE. Using IQR/M < 0.10 criteria does strongly improve the reliability of 2D-SWE.GE LS measurements as compared to IQR/M < 0.30 criteria.

P1314 MONITORING OF LIVER FUNCTION IN PATIENTS WITH NONALCOHOLIC FATTY LIVER DISEASE IN COMBINATION WITH METABOLIC SYNDROME

K. Aksentiychuk, E. Skyharov, N. Kurylyk, A. Bochar
Therapy #1 And Medical Diagnostics, LNMU by Danylo Galytskyi Dept. of Therapy, Lviv/Ukraine

Introduction: 13C-methacetin breath test (13C-MBT) is used to specify the detoxification function of the liver by determination its metabolic capacity and degree of hepatocytes recovery.

Aims & Methods: The study involved 113 patients with MS aged from 37 to 82 years old with history of 20-25 kg/m2 in patients with 13C-MBT. The control group included 25 patients with a BMI of 25-30 kg/m2 without severe concomitant diseases. Indicators of 13C-MBT were metabolic rate, cumulative dose of 13C-methacetin on 40 and 120 minutes. Also evaluation was carried by mathematical deduction which measured the liver dysfunction stage.

Results: The data showed normal detoxication liver function in patients without MS (20.11 ± 0.55). The results were below normal in patients with BMI higher than 25 kg/m2 in which there were initial changes in the functional state of liver. In patients with steatosis - cumulative dose on 120 minute was 15.12 ± 0.49, which corresponded to a moderate reduction of detoxification function with the mass of function hepatocytes 50–100%. The data of 13C-MBT in patients with steatohepatitis showed pronounced changes of the liver detoxification function (8.88 ± 0.64%). All indicators at steatosis group have indicated the moderate decline detoxification function with the level of function hepatocytes 50–100% (M(x) = 0.66, Cum.Dose 40 = 0.7, Cum.Dose 120 = 0.54).

Conclusion: In assessing to the data of 13C-MBT, main attention is paid to mathematical calculation of CO2 labeled methacetin. It allows to identify the early stages of the liver detoxification function violation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1315 IDENTIFICATION OF P73 AS A NOVEL TRANSGENERATOR OF IGFBP4 GENE EXPRESSION IN HEPATOCELLULAR CARCINOMA

A. Gschwind1, S. Heckel1, E. Achenbrenner1, K. Pollinger1, S. Schlosser1, C. Kunst2, M. Müller-Schilling1
1 Department For Internal Medicine I, University Hospital Regensburg, Regensburg/Germany

Contact E-mail Address: sebastian.heckel@outlook.de

Introduction: Members of the p53-family, including p53, p63 and p73, are known for their involvement in the regulation of cell cycle, cell senescence and apoptosis. In their role as transcription factors and depending on their splice variants-with transcription activation domain (TA) or dominant negative (DN) - p53 and its siblings are capable of activating or inhibiting the transcription of specific target genes. We previously identified the gene for insulin-like Growth Factor Protein 4 (IGFBP4) as a potential p53-family target gene with prognostic relevance in hepatocellular carcinoma (HCC). In contrast to p53, the IGF system takes part in tissue growth and cell survival. IGFBP4 acts as inhibitor limiting IGF effects suggesting a possible interaction with p53 affairs.

Aims & Methods: The aim of this study was to characterize the regulatory influence of p53 family members on the IGFBP4 gene. Hep3B cells were transfected with pAd-p53, -TAp73, -TAp63, -DPN63, and -DPN73. Transcriptional regulation of IGFBP4 was determined by real time qPCR. Intracellular IGFBP4 protein levels were examined by Western Blotting and ELISA. TRANSFAC database analysis was performed to identify potential p53-family binding sites in the IGFBP4 locus. Identified sequences were cloned, deleted, and analyzed by lucerase reporter assays to evaluate binding of p53-family members.

Results: IGFBP4 expression was increased by more than 30-fold in TAp73-transfected Hep3B cells, by more than 30-fold in DPN63- and by 3-fold in p53-transfected cells. Induction of intracellular IGFBP4 protein was detected in all transfected Hep3B cells, whereas extracellular IGFBP4 levels were only measurable after TAp73 and DPN63 transfection. Database analysis identified 2 putative p73 binding sites within intron 1 of the IGFBP4 gene. Intron 1-dependent luciferase activity was increased by up to 20-fold in TAp73-transfected cells. This induction was reduced by up to 70% when one of the putative binding sites was deleted.

Conclusion: These results identify the IGF inhibitor IGFBP4 as novel target gene for p53-family-mediated tumor-inhibiting mechanisms and IGF-family network and IGF signaling. Since in an independent study we identified IGFBP2 as a novel p53-family target gene, these results highlight the link between p53-family-mediated tumor-inhibiting mechanisms and IGF-family network and IGF signaling. We therefore suppose that the particular balance of these pathways decides on growth, cancerogenesis and treatment response.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1316 NONALCOHOLIC FATTY LIVER DISEASE IN PATIENTS WITH 2 TYROSINE KINASES MELLILOTS AND CORONARY HEART DISEASE AGAINST THE BACKGROUND OF METABOLIC SYNDROME. HOW TO DIAGNOSE?

A. Ksentsiychuk, E. Skyharov, N. Kurylyk, A. Bochar
Therapy #1 And Medical Diagnostics, LNU by Daniyo Galytskyi Dept. of Therapy, Lviv/Ukraine

Contact E-mail Address: akskris@mail.ru

Introduction: It is known that to determine nonalcoholic fatty liver disease (NAFLD), which develops in progress of body mass index (BMI) from 19% to 35%, using instrumental and laboratory methods, which include an ultrasound, the determination of the transaminase levels, steatostest, 13C-methacetine test. However, these research methods do not allow to clearly differentiate steatosis from the steatohepatitis, that reduces their credibility.

Aims & Methods: 163 patients (75 men, 88 women) with 2 type diabetes mellitus and coronary heart disease with metabolic syndrome, were examined. The average age of patients was 57.1±5.7 years. 57.7% were diagnosed as steatosis group, 66 - steatohepatitis group. In 25 patients liver pathology was not found, which identified as a control group.

For verification of steatosis and steatohepatitis diagnosis the level of ALT, diabetes, BMI, and data 13C-methacetine breath test were evaluated.

Results: The rate of liver metabolism based on 13C-methacetine test results in patients without NAFLD was 22.0±0.666%, in patients with steatosis - 17.1±0.84%, steatohepatitis - 14.3±0.62%. Cumulative dose of methacetine on 120 minute was 20.25±0.46%. In patients without pathology of liver, 16.1±0.49% in patients with steatosis, 11.4±0.53% in patients with steatohepatitis. ALT level in control group was 0.4±0.05mmol/l, with steatosis 0.7±0.06 mmol/l, with steatohepatitis 0.9±0.16 mmol/l. The diameter of vena portae in control group was 11.2±0.26 mm, in group of steatosis 11.9±0.21 mm, in patients with steatohepatitis 13.7±0.15 mm. There were investigated, that the rate of metabolism and its cumulative dose on 120 minute has decreased in steatohepatitis. A correlation of the control group, with simultaneous significant increasing of ALT level and diameter of the portal vein. However, a significant reduction of the metabolism rate of methacetine and the cumulative dose 13CO2 in the background of the increase of a diameter of venac portae compared with a group of steatosis in steatohepatitis group. The investigation found that in ALT and the diameter of the portal vein negatively correlated with cumulative dose of 13CO2 on 120 minute in patients with steatohepatitis. Therefore, a decrease in the metabolic capacity from 15 to 10% accompanied by an increase in ALT levels (more 0.68 mmol/l) and the diameter of the portal vein (13 mm).

Conclusion: The differentiation between steatosis and steatohepatitis should be moderate with the speed of a metabolism, a cumulative dose of methacetine on 120 minute (ALT and vena portae diameter). The sensitivity of the method is based on the definition of the three proposed indicators - ALT level, total concentration of 13C-methacetin on 120 minute and the portal vein size, which is 75% for steatosis, and 76% for steatohepatitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1318 LIVER TRANSIENT ELASTOGRAPHY IN NON-ALCOHOLIC FATTY LIVER DISEASE: IS THERE ANY PREDICTIVE ROLE IN THE DEVELOPMENT OF COLORECTAL POLYPS?

M. Gravito-Soares1, E. Gravito-Soares2, D. Gomes3, A. Simão2, L. Tomé2

2 Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal
3 Internal Medicine, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal

Contact E-mail Address: ms18498@gmail.com

Introduction: Recent studies have demonstrated an association between decreased glucose tolerance, dyslipidemia and metabolic syndrome; and increased risk of colorectal polyps. Patients with non-alcoholic fatty liver disease (NAFLD) often have these risk factors. The association between NAFLD and colorectal polyps has been poorly studied.

Aims & Methods: We aimed to evaluate the prevalence and risk factors of colorectal polyps in patients with NAFLD. This was a retrospective observational study of 237 patients with NAFLD submitted to transient elastography by Fibroscan, between 2015-01-2017. Exclusion criteria: age >18years, absence of total colonoscopy with good preparation <3 years, inflammatory bowel disease, hereditary polyposis syndromes and personal/family history of colorectal polyps/neoplasia. Compared patients with colorectal polyps(cases) and without colorectal polyps(controls). Demographic variables, cardiovascular/metabolic risk factors, comorbidities, laboratory parameters and Fibroscan scores of steatosis(CAP > 300 dB/m) and fibrosis(F4: > 10KPa) were evaluated.

Results: Of the 237 NAFLD patients who performed Fibroscan, 103 underwent total colonoscopy. The prevalence of colorectal polyps was 28.2% (n=29): 19.4% (20/103) hyperplastic, 16.5% (17/103) adenoma and 4.8% (5/103) advanced adenoma/adenocarcinoma. The mean age was 58.32±5.51 years (vs70.9±10.53 p=0.089), with men predominant (51.7±63.5% p=0.272), mostly located in the left colon (55.2±44.8%; p=0.314) and number and mean size of 1.46±0.88 and 6.89±6.56 mm, respectively. After multivariate analysis for colorectal polyps we found that with F4 liver fibrosis (34.5% vs 14.9%; p=0.026; OR=3.1) and obesity (BMI > 30 kg/m²; 55.2% vs 29.7%; p=0.016; OR = 2.91); hyperplastic polyps were associated with liver fibrosis for a cut-off value of 6.9Kpa (AUCROC 0.689 = 0.008; S=85.7%; Sp=51.2%), mainly F4 (42.8%vs14.6%; p=0.004; OR = 4.38), hyperuricemia (30Kg/m²: 55.2% vs 12.5%; p=0.041; OR = 3.5); and peptic ulcer disease (9.5% vs 12.5%; p=0.043; OR = 8.53); advanced adenoma was associated with liver steatosis (88.2% vs 83.7%; p=0.024; OR=3.50), F4 liver fibrosis (41.2%vs16.2%; p=0.046; OR = 5.24) and obesity (58.5%vs32.6%; p=0.040; OR = 2.96), advanced adenoma/adenocarcinoma was associated with F4 fibrosis (20.0%vs1.2%; p=0.021; OR = 1.224), hyperuricemia/gout (40.0%vs10.3%; p=0.040; OR = 4.38) and dilated cardiomyopathy (20.0%vs11.0%; p=0.003; OR = 1.24).

Conclusion: More than 1/4 of the patients with NAFLD have colorectal polyps, being 16.5% adenoma and 4.8% advanced adenoma/adenocarcinoma. Obesity and liver steatosis are independent risk factors for colorectal adenoma. Liver fibrosis, especially F4 is an independent risk factor for all types of colorectal polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1319 "SUBTRACTED ADULTHOOD MASS INDEX" (SAMI)- A NEW INDEX TO PREDICT NAFLD RISK IN NON-OBESE INDIVIDUALS

A. Kyak1, S. Eltob1, M. Sarac2, O. Saygılı2, N. Tözün2
1 School Of Medicine, Akadem University, Istanbul/Turkey
2Gastroenterology, Akadem University Faculty of Medicine Akadem Bakısko Hospital, İstanbul/Turkey
3Radiology, Akadem University, İstanbul/Turkey

Contact E-mail Address: atakayak@gmail.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a common clinicopathological condition of the liver that may progress from simple steatosis to NASHi, cirrhosis and hepatocellular carcinoma(HCC). Although obesity is accepted as the main risk factor for NAFLD, non-obese individuals are often diagnosed with NAFLD suggesting that high BMI may not be "a sine qua non" for the presence of NAFLD. Recent studies added that there might be a correlation between weight gain and metabolic diseases.

Aims & Methods: In our research; the relationship between NAFLD in non-obese individuals and the amount of weight gain during adulthood was investigated and a new index that is different from BMI was proposed. 362 individuals were included in the survey. The subjects were selected among patients who had abdominal ultrasonography(USG) in our clinic, during the last 6 months. A 5% increase in echogenicity detected in the USG was defined as the diagnostic
limit for hepatosteatosis. The beginning of adulthood was taken as 20 years old. Patients were evaluated for the presence of diabetes, hypertension or cardiovascular disease and ALT, AST, fasting plasma glucose and cholesterol values were recorded. Statistical evaluations were done with IBM SPSS.

NAFLD evaluation with SAMI 3 cut-off value

| SAMI > 3 | 144 | 38 |
| SAMI < 3 | 25  | 77 |

Sensitivity 85.2%
Specificity 66.95%
PPV 79.12%
NPV 75.49%

Results: Among 362 participants 169(46.7%) were men with an average age of 44.81±10.73. 78 (21.6%) participants were NAFLD(+/−) obese people 169(59.5%) were NAFLD(+/−) and average age was 48.07±10.13 years with normal BMI. NAFLD(+/−) people was 38.739. Non-obese NAFLD(+/−) patients reported they had gained significant amount of weight during their adulthood. This information led us to create, a new index named “Subtracted Adulthood Mass Index” (SAMI) to estimate the risk of NAFLD development in non-obese individuals. SAMI is calculated by dividing the difference between the subject’s current weight and his/her weight at the age of 20 years to his/her height squared (kg/m2). SAMI values for non-obese attendants were calculated. When the cut-off value was set as SAMI 4 kg/m2, sensitivity was 76.3%, specificity was 79.1, positive predictive value (PPV) was 84.3% and negative predictive value (NPV) was 69.4%. At a cut-off of SAMI 3 kg/m2 sensitivity was 85.2%, specificity was 66.9%, PPV was 79.1%, NPV was 75.4%.

Conclusion: In this pilot study, we found that weight gain in adulthood is an important predictor of NAFLD development in non-obese individuals. The new index named SAMI can correctly identify non-obese people under the risk of developing NAFLD. Cut-off value of SAMI has been set as 3 kg/m2. We also observed that NAFLD prevalence increases as SAMI value goes up. We propose that SAMI is appropriate for clinical use to estimate the risk of NAFLD in on-obese individuals.

P1321 AUTOMATED RAPID DETECTION SYSTEM USING THE QUENCHING PROBE METHOD FOR DETECTING rs738049 POLYMORPHISM IN PNPLA3 IN NONALCOHOLIC FATTY LIVER DISEASE

Introduction: Recent studies have shown that the single nucleotide polymorphism (SNP) rs738049 in the PNPLA3 gene is strongly associated with severity of nonalcoholic fatty liver disease (NAFLD). However, the traditional direct sequencing (DS) method is time-consuming and labor-intensive. The i-densy fully automated genotyping system with QP, which is based on the quenching probe (QP) method, automatically detects target genes in blood samples by fluorescence quenching within 90 min.

Aims & Methods: The current study compared the QP and DS methods for detecting SNPs in the PNPLA3 gene, and established the impact of the genotype on prognosis of NAFLD. We enrolled 107 patients with fatty liver irrespective of etiology. We used the i-densy fully automated genotyping system with QP. The requisite number of tips, reaction tubes, reagent packs and blood samples were set in their designated places. The forward and reverse polymerase chain reaction (PCR) primers and guanine QP were 5'-ctctctctctctgctgctac-3', 5'-gggtagaggacacatt-3', respectively. PCR consisted of initial denaturation for 1 min at 95 °C, and 60 cycles of denaturation at 95 °C, and 40 cycles of annealing at 60 °C, and 30 cycles of elongation at 72 °C for 30 s. After completion of the PCR, we analyzed melting temperatures. The SNP genotypes were determined by monitoring the change in fluorescence intensity with increasing temperature. The results obtained with the QP method were compared with those obtained with the conventional DS method. Then, we analyzed 73 patients with NAFLD according to PNPLA3 genotype in terms of alanine aminotransferase (ALT), aspartate aminotransferase to platelet ratio index (APRI), Fibroscan value, and cumulative hepatocellular carcinoma (HCC) development rate.

Results: The genotypes obtained with the QP method were identical to those obtained with the conventional DS method. In 73 patients with NAFLD, the frequency of the PNPLA3 genotypes CC, CG and GG was 21 (28.8%), 24 (32.9%) and 28 (38.4%), respectively. Serum ALT, APRI and Fibroscan value according to PNPLA3 genotypes CC, CG and GG were 26 (14–59), 33 (11–113) and 46 (17–175) U/L, 0.3 (0.1–1.0), 0.5 (0.2–6.8) and 0.7 (0.2–3.1), and 4.4 (2.7–25.1), 5.6 (2.5–26.5) and 6.6 (3.6–38.6) kPa, respectively (p = 0.001, p = 0.001 and p = 0.033 by Jonckheere–Terpstra test). HCC developed in none of the patients with CC genotype, one (4.2%) with CG and four (14.3%) with GG. The cumulative HCC development rate in patients with GG genotype was significantly higher than that in those with CC + CG genotype (p = 0.043 by log-rank test).

Conclusion: The i-densy using the QP method can automatically, quickly and easily identify PNPLA3 genotypes in real-world clinical settings. These findings indicate the feasibility of personalized medicine for NAFLD.

P1323 LONG-TERM COPPER EXPOSURE OF HEPATIC CELLS LACKING FUNCTIONAL ATP7B

Transplantationsklinik, Universitätsklinikum Münster, Münster/Germany

Contact Email Address: guttmann.sarah@ukmuenster.de

Introduction: Copper transporter ATP7B is essential for hepatic Cu homeostasis and loss of function is associated with the inherited and autosomal recessive disorder Wilson Disease (WD). Symptoms of WD are i.e. elevated Cu accumulation in liver and brain. Understanding of molecular mechanisms involved in Cu homeostasis is essential to improve therapeutic options. The molecular impact following long-term exposure to hepatic cells lacking functional ATP7B has not been explored.

Aims & Methods: HepG2 cells lacking functional ATP7B (KO) were used for generation of a copper resistant subline (CuR). Cell growth, cell viability (MTT) and intracellular Cu load (atomic absorption spectroscopy) was assessed. RT-qPCR was performed to quantify the expression of genes related to Cu homeostasis genes. Functional analysis of candidate genes was assessed via siRNA transfection. Additional measurements of CTRL expression was performed by flow cytometry (FACS) and Western Blot.

Results: KO cells can survive for many months in the presence of high Cu and gain resistance (CuR). Characterization of CuR cells revealed increased survival up to 12-fold compared to control, whereas a high intracellular Cu accumulation was noticed. Once Cu resistance was established, the termination of Cu exposure did not result in the loss of resistance indicating a stable modification of the cells. Two genes involved in Cu homeostasis displayed an altered expression pattern (upregulation of M1 and downregulation of CTRL by 28.1 ± 2.5 and −3.2 ± 0.4 fold, respectively) which was however transient and dependent on Cu exposure. The role of MDR1 which presented a stable modification was further investigated by siRNA and drug activation (verapamil). Notably, cell viability and intracellular Cu accumulation was significantly affected indicating that MDR1 is involved in Cu homeostasis. In addition, hepatic cells derived from a WD patient and from the rat animal model confirmed our observations.

Conclusion: Our analysis of long-term Cu exposure presents new insights in copper metabolism and suggests a new role of MDR1 in the pathogenesis of Wilson disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) are increasingly common cause of chronic liver disease worldwide. Most patients with severe obesity who undergo bariatric surgery have NAFLD, which is associated insulin resistance, type 2 diabetes mellitus, hypertension, and obesity-related dyslipidemia. Identifying significant fibrosis in patients is crucial to evaluating prognosis and possible therapeutic interventions. Currently, liver biopsy is the gold standard for diagnosis of liver fibrosis.

Aims & Methods: We aimed to evaluate the NAFLD fibrosis score for the assessment of significant fibrosis in patients with morbid obesity before undergoing bariatric surgery. A total of 69 NAFLD patients (median BMI 47 kg/m2) were prospectively enrolled from June 2015 to November 2016 at one Brazilian university hospital. All patients were evaluated with routine laboratory before bariatric surgery. Age, body mass index, hyperglycemia, platelet count, albumin and AST/ALT ratio were applied to the score formula. Biopsies were interpreted by a single experienced pathologist. NAFLD and fibrosis were classified according to the NASH Clinical Research Network NAFLD activity score.

Results: The specificity of liver biopsy, 29 patients (42%) had some degree of fibrosis, with 19 (68.9%) having significant fibrosis (F3–4). With standard thresholds, the specificity for the NAFLD fibrosis score for identification of significant fibrosis was 58.9%. Using modified thresholds, the specificity could increase. For predicting significant fibrosis, for a cut-off of 1.05, the score had 46.15% sensitivity and 96.43% specificity with AUROC of 0.74.

Conclusion: The nonalcoholic fatty liver disease fibrosis score has good accuracy to identify significant fibrosis and morbidity obese patients subjected to bariatric surgery.

Conclusion: We conclude that Fibroscan® represents an eligible tool to diagnose liver disease in Austrian bank employees. Compared to the previous work of Bedogni et al FLI predicts fatty liver at a lower cut-off level, at least for the examined population. This difference might be due to the fact that FibroScan®CAP is more sensitive than ultrasound.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Nonalcoholic fatty liver disease (NAFLD) is an affection with increasingly prevalence worldwide, having an important impact on morbidity and mortality, especially when it associated severe fibrosis.

Introduction: We aimed to assess the metabolites that are associated with fibrosis stages in NAFLD, using metabolic method. A total of 40 patients were included in the study, 30 diagnosed with nonalcoholic fatty liver disease (NAFLD) and 10 controls. Steatosis and fibrosis were assessed using Fibromax elaborated by Biopredictive (R) (Paris, France). New metabolomic techniques (high performance liquid chromatography coupled with mass spectrometry (HPLC-MS) and principal component analysis (PCA)) were used to identify final products of various metabolic pathways correlated with liver fibrosis.

Results: Of the 30 patients with NAFLD included in the study, 6 patients (20%) had severe fibrosis. The metabolomic profile identified four metabolites that are associated with severe fibrosis: 1,25(OH)2vitamin D, (p = 0.05), Lysophosphatidylcholine LPC 18:2 (p = 0.003), and high levels of butenyl carnitine (p = 0.04). Of these, LPE was the strongest predictor of severe fibrosis (AUROC=0.795, Sensitivity (Se) = 88.33%, specificity (Sp) = 78.79%), but the other molecules were also significantly associated with severe fibrosis: vitamin D (AUROC = 0.776), butenyl carnitine (AUROC = 0.737), LPC 18:2 (AUROC = 0.768). As the metabolomics permits the evaluation of all these molecules the same time, we can use them combined in order to increase the diagnostic accuracy. In our case, the combined use of the four metabolites determined an AUROC of 0.839, with Se of 100% and Sp of 68.5%.

Conclusion: Using metabolomics, we can identify patients with fatty liver and severe fibrosis who are significantly exposed to a progressive disease and a higher mortality.

Introduction: Usually for the determination of nonalcoholic fatty liver disease (NAFLD) there are instrumental and laboratory techniques, including ultrasound diagnosis, determination of aminotransferases, steatotest, 13C-methacetin breath test (13C-MBT). These methods in the diagnosis of NAFLD clinical forms is not specific and do not allow make difference between steatosis and steatohepatitis. The determination of NAFLD clinical forms is a priority in the prediction of further disease and choice of treatment. Steatohepatitis is the active form of NAFLD and progresses to fibrosis oftenly with subsequent liver parenchyma degeneracy into cirrhosis. Simultaneously, steatosis could be possibly treated in the early stages of disease.

Aims & Methods: The study involved 65 patients with type 2 diabetes and coronary heart disease with metabolic syndrome, aged 37 to 82 years (mean age 55.8 ± 3.46), 29 men, 36 women. According to the ultrasound, the stage of fatty infiltration were differentiated by such criteria for steatosis as diffuse liver par- enchyma echogenicity intensification against the background of a slight increase in its size (liver echogenicity was significantly higher than normal kidney or lumbar muscle echogenicity); for steatohepatitis - hyperechogenicity of liver par- enchyma and expansion of portal vein (13 mm or more in diameter).

Results: For steatosis and steatohepatitis determination the ALT monitoring was used, where the level exceeding 0.68 mmol/l signed to steatosis, and below 0.68 mmol/l - to steatosis. Portal vein diameter size above 13 mm subscribed steatohepatitis, and below 13 - steatosis. 13C-MBT data, which assessed the liver antitoxic function was used, where the result 13C02 on 120 minute from 10 till 15% was classified as liver detoxification function violation like stea- tohepatitis, and from 15 till 20% - steatosis. The present study found that indicators of ALT and portal vein diameter negatively correlated with cumulative dose 13C02 for 120 minute in case of steatohepatitis.

Conclusion: Differentiation between steatosis and steatohepatitis should be perform by the cumulative dose 13C02 on 120 minute evaluation and ALT levels and portal vein diameter assessment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction:  
Non-alcoholic fatty liver disease (NAFLD), the hepatic counterpart of the metabolic syndrome in close relation to obesity and encompasses a disease spectrum spanning simple steatosis through nonalcoholic steatohepatitis (NASH) with or without significant fibrosis, and hepatic carcinomas [1]. Clearly, not all obese subjects develop NAFLD and NAFLD can also be found in non-obese patients. Globally, the reported prevalence of non-obese NAFLD varies widely, ranging from 3% to 30% [2]. Today remains unclear how patients without obesity develop NAFLD, therefore it is important to understand the clinical and pathological conditions of non-obese NAFLD.

Aims & Methods: In this study, we investigated the liver stiffness and liver fat content in addition to other clinical and metabolic parameters in type 2 diabetes patient with non-obese and obese NAFLD detected on ultrasonography (US).

In this cross-sectional study, 245 T2D patients with age of 40-80 years from the Kyiv City Clinical Endocrinology Center were selected. Inclusion criteria were: age over 18 years, presence of T2D in association with fatty liver disease. The diagnosis of fatty liver was based on the results of abdominal ultrasonography, which was done by trained technicins with Ultime PA (Rumdie Co., Kharkiv, Ukraine). Of 4 known criteria (hepatoenothal echo contrast, liver brightness, deep and vascular blurring), the participants were required to have hepatoenothal contrast and liver brightness to be given a diagnosis. According to body mass index (BMI) value patients were assigned else to NAFLD group (n = 157, BMI ≥ 30.0 kg/m²) or to non-obese NAFLD (n = 88, BMI < 30.0 kg/m²) group.

We performed 10 valid measurements of liver stiffness (LS) measured by liver stiffness Wave Elastography (SWE) in every patient, and a median value was calculated, the result being measured in kPa. Also in all patient we calculated fatty liver index (FLI). FLI a validiated prediction score for hepatic steatosis severity designed Bedogni et al [3]. Changes in transaminases activity, serum lipids and cytokines (TNF-α, IL-1β, IL-6, INF-γ) levels were evaluated.

Results: Non-obese NAFLD patient had higher LS (7.52 ± 0.2 vs 6.87 ± 0.09, p = 0001) values measured by SWE, which were accompanied with increased transaminases activity; for ALT 42.1 ± 3.17 vs 35.8 ± 1.28 (p = 0.028) and for AST 40.81 ± 2.68 vs 34.31 ± 1.33 (p = 0.016) respectively. In contrast to non-obese group patient in NAFLD group had significantly higher FLI (86.59 ± 1.09 vs 68.06 ± 1.96, p < 0.001). Markers of chronic systemic inflammatory state were significantly higher in non-obese NAFLD as compared to non-obese patient: IL-1β 44.64 ± 2.20 vs 31.02 ± 1.78 (p < 0.001); TNF-α 54.11 ± 2.20 vs 42.28 ± 1.81 (p = 0.001); IL-8 29.18 ± 1.27 vs 22.05 ± 0.99 (p = 0.001) and INF-γ 195.60 ± 9.47 vs 132.47 ± 7.54 (p = 0.016) respectively. Changes of IL-6 between groups were not significant.

Conclusion: Present, the clinical-laboratory characteristics of non-obese NAFLD are not fully understood. Therefore, we found that non-obese NAFLD associated with higher liver stiffness values and transaminases activities. On another hand, patient with obese NAFLD are characterized with more pronounced liver fat content and elevation of markers of chronic systemic inflammatory state.

Introduction:  
Non-alcoholic fatty liver disease (NAFLD) is usually considered as the hepatic manifestation of metabolic syndrome and obesity. However, a subset of NAFLD patients are lean. Some studies have reported severe liver fibrosis in lean NAFLD and these patients are still at risk for development of liver cirrhosis.

Aims & Methods: This study aimed to investigate the prevalence and risk factors of lean NAFLD in a cluster of Iranian population. Study population was recruited from Kavar cohort study which has been started from 2006 in Kavar town, a small town near Shiraz. The study sampling was performed between September 2011 and September 2013 among adult subjects (age ≥ 18 years) who underwent voluntary hepatobiliary ultrasound. NAFLD was diagnosed using the presence and absence of chronic liver diseases such as autoimmune hepatitis, hepatitis B or C viruses induced hepatitis, hepatobiiliary cancers, Wilson’s disease, >10 g/day alcohol consumption, and receiving some specific medications known to cause hepatic steatosis (like amiodarone, valproic acid, etc). Lean individuals were defined as those with body mass index (BMI) <25 kg/m². Student’s-t test was used for comparisons of continuous variables and Chi-square test was used for comparison of categorical variables. Receiver operating characteristics (ROC) curve analysis using area under curve (AUC) was used for analysis of optimal cutoff values for BMI and waist circumference in association with lean NAFLD.

Results: 1343 individuals were included. 165 individuals (12.3%) was diagnosed to have NAFLD. 129 individuals (9.6%) had mild NAFLD and 36 individuals (2.7%) had moderate NAFLD. None of the participants had severe NAFLD. In univariate analysis, history of diabetes mellitus (DM) (OR = 2.25; 95% CI: 1.15-4.40, P = 0.015) and metabolic syndrome (OR = 2.80; 95% CI: 1.74-4.48, P < 0.001) were associated with NAFLD. Higher BMI and waist circumference, higher systolic and diastolic blood pressure, higher serum triglycerides, cholesterol, fasting plasma glucose (FPG) and alanine aminotransferase (ALT) were associated with NAFLD (P < 0.05). In multivariate regression analysis, higher BMI and waist circumference, higher ALT, FPG and cholesterol were independent predictors of NAFLD in our study population (Table). A cutoff value of 22.3 kg/m² for BMI was predictor of NAFLD (sensitivity = 72%; specificity = 60%; AUC = 0.728, P < 0.001). A cutoff value of 79.5 cm for waist circumference was predictor of NAFLD in our study population (sensitivity = 80%; specificity = 68%; AUC = 0.753, P < 0.001). Table: Multivariate regression analysis showing independent risk factors for lean NAFLD.

Introduction: While some studies have evaluated the ability of new “real-time” elastography devices such as 2-D Shear Wave Elastography (SWE) and Virtual Touch Quantification (ARFI) in predicting the presence of high-risk gastroesophageal varices, no study has explored the potential role of another point-shear wave technique, ElastIQ, in the assessment of clinically significant portal hypertension.

Aims & Methods: The aim of our study was to identify a liver stiffness cut-off value measured by ElastIQ and/or laboratory parameters that could help identify patients who can safely avoid screening endoscopy. In the recently proposed Baveno VI criteria which recommends a liver stiffness value <20kPa measured by transient elastography in combination to a platelet count >150,000 µl. Data were collected on 1385 patients who underwent ElastIQ measurement from January 2013 to January 2016 in our Department. Inclusion criteria were a liver stiffness value of ≥7 kPa and an upper gastrointestinal endoscopy within 12 months, with a diagnosis of compensated chronic liver disease. We choose this specific liver stiffness cut-off value in order to highlight subjects with advanced fibrosis and/or cirrhosis, based on the limited literature available on this specific elastographic technique. Exclusion criteria were history of decompenated liver disease, evidence of porto-splenome-senteric vein thrombosis and non-cirrhotic portal hypertension. Varices were graded as low risk (grade <2) or high risk (grade ≥2).

Results: The study included 184 patients (114 [62%] hepatitis C, and 160 [87%] Child-Pugh A). Varices were present in 36% cases, with 10% prevalence of high-risk varices. According to ROC curve analysis liver stiffness measurement and
platelet count were evaluated as predictors of high-risk varices. Overall 74/194 (40%) met the new “BAVElastPQ” criteria (that is, liver stiffness <12 kPa and platelet count >150,000/µl). Within this group 11/63 (17%) had any grade of varices and only 1/73 (1%) had high-risk varices. The BAVElastPQ criteria gave sensitivity of 0.95, specificity of 0.44, a positive predictive value 0.46 and a negative predictive value of 0.98. The AUROC for liver stiffness and platelet count was 0.81 and 0.76, respectively.

Conclusion: The BAVElastPQ criteria correctly identified 99% of patients with high-risk varices. By applying such criteria we could have potentially avoided 40% surveillance endoscopies in our cohort. To our knowledge this is the first study that evaluated the potential role of a new p-SWE technique such as ElastIPQ in the non-invasive assessment of clinically significant portal hyperten-

Introduction: Inhibitors of PPIs are commonly prescribed and predis- pose to small bowel bacterial overgrowth. Hepatic encephalopathy is a frequent complication of cirrhosis and is associated with intestinal dysbiosis.

Aims & Methods: This study aimed to identify a possible association between PPI intake and hepatic encephalopathy development in cirrhotic patients. Retrospective analysis of consecutive cirrhotic patients hospitalized in two Gastroenterology Departments over 3.5 years. Collection of clinical data, PPI intake, infection and hepatic encephalopathy at hospitalization. Statistical ana- lysis performed with SPSS 21, considering statistical significance p<0.05.

Results: 386 patients, 321 males (83.2%), mean age 60.3 ± 12.1 years. Main eti-

ologies of cirrhosis were alcohol (67.4%), alcohol plus hepatitis C (16.3%) and hepatitis C virus (5.2%). Hepatic encephalopathy was present in 222 (57.5%) of the patients and 26.9% had PPI intake. In univariate analysis hepatic encephalo-

pathy was associated with infection (p<0.001), gastrointestinal bleeding (p<0.001) and Model for End-Stage Liver Disease (MELD) (p<0.001).

There was no association between hepatic encephalopathy and PPI intake (p=0.057), gender (p=0.228) or age (p=0.352). In multivariate analysis, hepato-

tic encephalopathy maintained association with infection (p<0.001), gastroin-

testinal bleeding (p<0.001) and MELD score (p=0.001).

Conclusion: In our series, PPI intake was not associated with hepatic encephalo-

pathy development in cirrhotic patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The incidence of bacterial infections in cirrhotic patients is signifi-

cantly higher than that observed in general population, being one of the most important causes of decomposition. In theory, the final result of an infectious disease depends of three major factors: the antibiotic resistance of the bacteria and the individual resistance of treatment to the antibiotic with persistence or pathologi-

city of the bacteria; and finally the patient status in relation to risk factors such as immune status, age, diet and stress. There are conflicting results regarding the clinical outcome of multidrug-resistant (MDR) bacterial infections in cirrhotic patients.

Aims & Methods: Our aims within this study were to 1) analyze the incidence of MDR bacteria in patients with compensated cirrhosis at admission (less than 24 hours after hospitalization), 2) to study its impact on 30 and 90-day mortality, and 3) to determine independent risk factors for 30 and 90-day mortality. We conducted a retrospective cohort study which evaluated all admissions due to decompenated cirrhosis in one center between 2010 and 2015. MDR bacterial infections, its acquisition site and the antibiotic resistance patterns were defined according with the European Centre for Disease Prevention and Control (ECDC) criteria.

Results: A total of 681 hospitalizations were evaluated and 41% had a bacterial infection at admission. The 30 and 90-day mortality rate was 14.7% and 38.1%, respectively. The most common infection was spontaneous bacterial peritonitis (SBP; 40.5%), followed by urinary tract infection (UTI; 25%). About 55.6% of the patients had a microbiological documented infection (MDI). MDR bacteria were identified in 18.6% of all bacterial infections, matching 34.5% of the nosocomial acquired infections and 8.3% of the community-acquired (CA) infec-
tions. Most common MDR by a MDR bacteria (Fig. 2A). In patients with documented infections, no difference was noticed between non-MDI, non-MDR bacteria or MDR bacteria regarding the 30 (p=0.801) and the 90-day (p=0.525) mortality rate. In the multivariate analysis, elevated BUN and bilirubin, presence of bacterial infection and lower albumin, sodium and SpO2 were independently associated with 30 and 90-day mortality. Higher INR and age were independ-

ently associated with 90-day mortality.

Conclusion: The presence of bacterial infection, independently of the antibiotic resis-
tance profile, was associated with a worse prognosis in cirrhosis. We identified a high incidence of MDR bacteria in patients with UTI. Given the described risk factors for MDR bacteria development, we hypothesize that our results are probably the consequence of a bad antibiotic politics in our district, especially when managing CA UTI.

P1334 STATIN THHERAPY IN THE REDUCTION OF PORTAL HYPERTENSION IN PATIENTS WITH LIVER CIRRHOSIS: A META-

ANALYSIS OF RANDOMIZED CONTROLLED TRIALS
J.G. E. Cataluna, J. G. Cervantes
Institute Of Digestive And Liver Diseases, St. Luke’s Medical Center - Quezon City, Quezon City/Philippines
Contact E-mail Address: doycataluna@yahoo.com

Introduction: Statins have been shown to decrease intrathoracic vascular resistance and portal pressure reduction. This meta-analysis of randomized controlled trials (RCTs) was con-
ducted to determine if statin therapy reduces portal hypertension as measured by the hepatic venous pressure gradient (HVPG) among adult patients with liver cirrhosis.

Aims & Methods: The objective of this research was to perform a meta-analysis of randomized control trials (RCTs) and determine if statin therapy reduces portal hypertension as measured by the hepatic venous pressure gradient (HVPG) among liver cirrhosis patients.

Results: Three studies comprising of 98 patients met the inclusion criteria. The random-effect model, the weighted mean difference was 0.27 mmHg, favoring statin therapy over placebo. There was no evidence of significant heterogeneity (I², 0%; p, 0.9%).

Conclusion: Statin therapy reduces portal hypertension as measured by the HVPG among adult patients with liver cirrhosis. The findings of this study reinforce the promising role of statins in decreasing portal hypertension. Further RCTs with larger population and with longer duration of follow-up as well as use of different statin drugs to explore further on the class effect are recommended.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The place of noninvasive techniques for the prediction of presence of portal hypertension in patients with liver cirrhosis is one of the current research aims.

Aims & Methods: The aim of this study was to evaluate the applicability of the Baveno VI criteria in a cohort of known compensated HC liver cirrhosis patients, to see how often we misclassify the presence of esophageal varices (EV).

Material and method We did a prospective multicentre study, from September 2016 to September 2018, which included all patients with perfectly compensated HC liver cirrhosis, diagnosed by means of elastography, ultrasound, endoscopic and biological criteria prior to interferon-free treatment. All patients were evaluated by upper gastrointestinal endoscopy, transient elastography and blood tests. By using these criteria we classified the patients in: probably without EV, high risk of developing EV, and the class with high accuracy in predicting EV.

Results: Out of 403 patients, 127 (30.7%) had LS ≥ 20 kPa and thrombocytes > 150,000/mm3, probably without EV (liver stiffness - LS ≥ 20 kPa, and the “gray zone” in between these criteria.

Conclusion: By using the Baveno VI criteria in patients with liver cirrhosis for the prediction of presence of esophageal varices, we can misclassify only 20% of patients.

Introduction: Minimal Hepatic Encephalopathy (MHE) is present in more than 30% of patients with chronic liver disease (CLD), and is associated with a poor prognosis including a higher incidence of falls, RTAs and overall mortality. Detection of MHE is often difficult due to time constraints associated with the current gold standard, the psychometric hepatic encephalopathy score (PHES), which includes five paper-based tests. A smartphone application (EncephalApp Stroop Test) has been suggested as a viable alternative.

Aims & Methods: We aimed to validate the use of the EncephalApp Stroop Test as a screening tool for MHE in an Irish population. CLD patients and healthy controls were recruited from outpatients. CLD patients were identified based on clinical and radiological evidence. Written consent was obtained. Exclusion criteria: cognitive impairment from any other cause, colour-blindness or dyslexia. Baseline demographics, level of education and medical history were obtained, and a Child-Pugh score was calculated where relevant. Each patient performed the PHES test and the Stroop test. Outcomes included the time taken to perform each PHES test as well as the total PHES, the Stroop on-off time and time taken to complete 5 correct runs on the Stroop App. Results were analysed using spss. An on-off time defined by the PHES test (AUROC = 0.858) and ev (AUROC = 0.885) and with FIB-4 score for decomposition (AUROC = 0.854).

Conclusion: CRBPs predict cirrhosis and development of esophageal varices with high accuracy. Some of the blood derived NIFs have high accuracy in predicting decompensation post antiviral treatment. Application of these simple scores may help in non-invasive screening of patients at high risk for development of esophageal varices and decompenstion after antiviral treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P3136 COMBINED RADIOLOGIC-BLOOD PARAMETERS AND BLOOD-DERIVED INVASIVE PROCEDURES SCORES IN PREDICTING OUTCOMES IN CHRONIC HEPATITIS C

R.B. Thandassery1, H. Wani1, S. Al Kaabi1, M. Khanna2

Introduction: Non-invasive fibrosis scores (NIFS) are increasingly replacing liver biopsy (LB) for estimation of liver fibrosis. Only limited studies have evaluated the performance of development of esophageal varices (EV) and decompensation in cirrhotic patients. Similarly there are limited studies evaluating combined estimation of radiologic and blood parameters in predicting fibrosis and outcomes of cirrhosis.

Aims & Methods: We aimed to compare combined radiologic-blood parameters (CRBP) and blood derived non-invasive fibrosis scores (NIF) for predicting tre treatment cirrhosis, development of esophageal varices (EV) and liver decompensation post antiviral treatment (AVT). 1605 patients (Jan 2002 to June 2013) were considered between liver biopsy (LB) and received AVT with pegylated interferon and ribavirin. Three CRBPs (platelet count- bisplenic diameter index [PSI], platelet count-hisplenidienleadioment portal vein index [PSVP]), platelet count-bisplenic diameter-portal-vein-caudate lobe length index [PSCL]) and nineteen blood derived NIFS were calculated from routine blood tests and abdominal ultrasound done prior to starting AVT. AUROCs were calculated for each of these parameters predicting cirrhosis and treatment LB and development of EV and decompensation on follow-up after AVT.

Results: Mean age was 41.9 ± 9.7 years (85% males), predominantly genotypes 4 (65%) and 1 (11%). Pretreatment LB (Scheuer criteria) showed stage-0 fibrosis in 1.1%, stage-1 in 32.9%, stage-2 in 39%, stage-3 in 19.7%, and stage-4 (cirrhosis) in 6.6% of the patients. After AVT, there were 1,089 (67.8%) responders, 482 (30%) nonresponders and 3 (2.1%) relapsers. After median follow-up of 6580.5 patient-years post AVT, 39 (2.4%) developed EV (2 patients had both esophageal and gastric varices and one had only gastric varices) and 52 (3.2%) had decompensation (bleed-9, asci-39, jaundice-22, hepatic encephalopathy-7, hepatorenal-4). CRBPs had higher accuracy for prediction of cirrhosis and EV, while NIFS had higher accuracy for predicting decomposition (Table 1).

The highest AUROCs were seen for MHE on-off time (AUROC = 0.888) and EV (AUROC = 0.858) and with FIB-4 score for decomposition (AUROC = 0.854).

Conclusion: CRBPs predict cirrhosis and development of esophageal varices with high accuracy. Some of the blood derived NIFS have high accuracy in predicting decomposition post antiviral treatment. Application of these simple scores may help in non-invasive screening of patients at high risk for development of esophageal varices and decompensation after antiviral treatment.

United European Gastroenterology Journal 5(5S)

Abstract: P1336

**Aims & Methods:**
We hypothesized that probiotic bacteria repress intestinal pathogen growth and that can translocate through a weakened gut barrier and cause severe infections. Additionally, the abundance of *Enterococcus durans* was reduced and the gut barrier was strengthened.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Conclusions:** This is the first study to evaluate the efficacy of the Stroop test in Ireland. It was quicker and easier to perform compared to PHES test. Age and years in education had a greater impact on the Stroop test, which may affect its application and interpretation. While our ROC analysis suggests a similar cut off to previously published values, there is significant variability and local validation is likely to be required. Overall the comparison with the gold standard PHES was poor. However, there were no false negative Strop tests suggesting it may be a convenient filter test for MHE.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1338 MULTISPECIES PROBIOTIC ENRICHES THE MICROBIOME WITH LACTOBACILLUS AND LACTOCOCCUS AND REDUCES ENTEROCOCCUS ABUNDANCE IN PATIENTS WITH LIVER CIRRHOSIS: RESULTS OF A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL**

**Introduction:** Cirrhosis is accompanied by significant changes of the intestinal microbiome including the overgrowth of the intestine with potential pathogens that can translocate through a weakened gut barrier and cause severe infections. We hypothesized that probiotic bacteria repress intestinal pathogen growth and strengthen the gut barrier.

**Aims & Methods:** Therefore, we conducted a randomized, double-blind, placebo-controlled study to test the effects of the multispecies probiotic Ecologic Barrier (Winclove, Amsterdam, The Netherlands) on gut permeability and intestinal inflammation, respectively.

**Results:** A community of 37 operational taxonomic units (OTUs) was sufficient to pinpoint characteristic features of the microbiome before and after the intervention. Within this predictive community, three OTUs were found to be differentially abundant: *Lactobacillus brevis* and *Lactococcus lactis* increased significantly and *Enterococcus durans* decreased significantly in the probiotic group. *Zonulin* normalized in 20% of patients in the probiotic group. Predicted metagenome functions (assessed by PICRUSt) and caprolycetin did not show any differences during intervention.

**Conclusion:** In conclusion, a six month intervention with a multispecies probiotic enriched the microbiome of cirrhotic patients with probiotic bacteria. Additionally, the abundance of *Enterococcus durans* was reduced and the gut barrier was strengthened.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1339 THE IMPACT OF DIABETES MELLITUS ON SHORT-TERM AND LONG-TERM OUTCOMES AFTER LIVER TRANSPLANTATION**

**Introduction:** Diabetes mellitus (DM) is a growing disease worldwide. Some previous studies have reported negative impact of DM in patients with chronic liver disease.

**Aims & Methods:** This study aimed to investigate the prevalence of DM in patients with liver cirrhosis and its impact on post-liver transplant short-term and long-term outcomes. In a cross-sectional study patients with liver cirrhosis on liver transplant waiting list who had undergone liver transplantation between March 2012 and March 2015 at Shiraz Transplant Center, Shiraz, Iran were included. Clinical and laboratory data of patients were recorded and patients were followed during post-liver transplant period. DM was diagnosed if the patient had fasting plasma glucose (FPG) ≥126 mg/dL or random plasma glucose ≥200 mg/dL in 2 different checkings or receiving anti-diabetic medications. The impact of DM on post-transplant outcomes was investigated using student t-test and chi-square test. Multivariate logistic regression was used for analysis of independent risk factors of mortality after liver transplantation. Kaplan-Meier method was used for analysis of survival.

**Results:** 1014 patients were included in the study. 259 patients (25.5%) found to have DM. Prevalence of DM was significantly higher among patients with cirrhosis due to non-alcoholic steatohepatitis (NASH) (P < 0.001). Portal vein thrombosis (PVT) was significantly higher among cirrhotic patients with DM (OR = 1.79; 95% CI: 1.18–2.70; P = 0.005). Mean model for end stage liver disease (MELD) score, body mass index (BMI) and duration of liver disease were not different in patients with and without DM (P > 0.05). Mean blood urea nitrogen (BUN) in 30 days post-transplant period was 16.17 ± 17.4 mg/dL in patients without DM compared to 18.39 ± 11.95 mg/dL in patients with DM (P < 0.001). Mean serum creatinine level was 1.46 ± 0.95 mg/dL in patients without DM compared to 1.78 ± 1.92 mg/dL in patients with DM (P = 0.001).
Without diabetes 90.6%
with and without DM
Post-liver transplant survival at 6 months, 1 year and 4 years in patients
predictors of mortality after liver transplantation.
Aims & Methods: The aim of the study was to assess the factors associated with mortality among cirrhotic patients and to create a new score for predicting mortality. The study was retrospective, and we included all hospitalized patients who had a diagnosis of liver cirrhosis over a period of 7 years. We divided them in two cohorts, an initial group, which was analysed; and a control group, in which we validated the score. We performed univariate and multivariate analysis in order to determine a prediction model for mortality.
Results: A total of 1163 cirrhotic patients were included. In-hospital mortality rate was 10%. The initial cohort included 899 patients. Regarding cirrhosis etiology: 384/899 (42%) had hepatitis C, 158/899 (17.5%) had hepatitis B, 293/899 (32.5%) were alcoholic, 6/899 (0.6%) were autoimmune, 7/899 (0.7%) were cardiac, 13/899 (1.4%) were premalignant liver cirrhosis and in 5% of cases the etiology was unknown. In univariate analysis, hyponatremia (p < 0.0001), hyperpotassemia (p < 0.0001), hypouribuminemia (p < 0.0001), high values of bilirubin (p < 0.0001), high values of creatinine (p < 0.0001) were strongly associated with in hospital mortality. In multivariate analysis, the model including albumin, sodium, potassium, creatinine and bilirubin (all p-values < 0.05) had an AUROC of 0.78, CI (0.75–0.81), p < 0.0001. Using this factors as predictors, by multiple regression analysis we obtained the following score: ABCPS score = 0.04 + 0.03*Albumin + 0.05 + 0.02*Creatinine + 0.04 + 0.04*Bilirubin + 0.05 + 0.28*Potassium + 0.04*0.07*Sodium.
Conclusion: Prevention and prompt treatment of kidney injury, hyponatremia, hyperpotassemia, can improve survival. ABCPS score can be an useful score to rule out patients with high mortality rate.

Introduction: The Baveno VI guidelines propose that cirrhotic patients with a liver stiffness measurement (LS) < 20 kPa and a platelet count > 150000/µL can avoid screening endoscopy as their combination is highly specific for excluding clinically significant varices.
Aims & Methods: The aim of the study was to validate the Baveno VI criteria. We did a retrospective study, from 2009–2014. We took all the patients with transient elastography data. Inclusion criteria were a LS > 12 kPa and an upper gastrointestinal endoscopy within 12 months, with a diagnosis of chronic liver disease. Varices were graded as low risk (grade < 2) or high risk (grade ≥ 2).
Results: The study included 774 patients (hepatitis C virus 40.5%, hepatitis B virus 16.1%, 31.6% etanolic, 11.8% etiology, and 47.5% were Child Pugh A). We represent in 561/774 (2.4%) cases with 8% prevalence of high risk varices. 306/774 (39.6%) were at low risk and 468/774 (60.4%) had high risk varices. 59/774 (7.6%) met the Baveno VI criteria. The Baveno VI criteria gave a Se = 62.2%, Sp = 80.6%, NPV = 44.6%, PPV = 89.5%, positive likelihood ratio = 3.4, negative likelihood ratio = 0.47. If we combined the LS < 20kPa and platelet count > 150000, the AUROC was 0.73, CI (0.68–0.74), p < 0.0001.
Conclusion: The Baveno VI criteria has correctly appoint 85.3% of patients who could safely avoid endoscopy.

Conclusion: Bariatric surgery increases the risk of subsequent acute liver injury. Post-bariatric surgery patients admitted for ALI are more likely to have anemia, malnutrition, and alcoholism, supporting the hypothesis that baseline nutritional status may predispose to drug-induced ALI. Addressing these potentially modifiable risk factors may decrease the significant morbidity and mortality of ALI.

Introduction: Acoustic radiation force impulse (ARFI) imaging measures liver stiffness (LS), which significantly correlates with the stage of liver fibrosis in treatment-naive patients with chronic hepatitis B (CHB). So far, the use of ARFI elastography to monitor change in liver fibrosis has not been properly evaluated during antiviral therapy in CHB patients.

Aims & Methods: We aimed to prospectively assess the clinical usefulness of ARFI during long-term antiviral therapy in CHB patients. Seventy-one CHB patients were consecutively recruited and received antiviral therapy with entecavir. Paired liver biopsies were performed in 27 patients at baseline and week 78 of entecavir therapy. LS was assessed by ARFI at multiple follow-up sessions.

Results: LS significantly decreased with treatment and continued to decrease after normalization of alanine aminotransaminase. Overall, 97.2% patients achieved improvement of LS, whereas 19.7% patients had more than 30% reduction in LS values between baseline and week 104. Multivariate linear regression analysis showed that the degree of LS reduction significantly correlated with the baseline levels of LS value, platelet and cholesterol. In the 27 patients who received paired liver biopsies, LS significantly correlated with stage of fibrosis and inflammatory grade at baseline. LS values decreased more significantly in patients with fibrosis regression than those with static histological fibrosis. Changes in LS (change threshold = 15%) was significantly correlated with the changes in histological fibrosis staging (r = 0.63, P < 0.001).

Conclusion: In CHB patients, LS assessed by ARFI was significantly reduced with the changes in histological fibrosis staging (r = 0.63, P < 0.001), the presence of elevated triglycerides (239.9 ± 49.3 dB/m vs 284.1 ± 28.1 dB/m, p = 0.01) and obesity (240.4 ± 46.7 dB/m vs 290.7 ± 46.6 dB/m, p = 0.01). When comparing patients with CAP > 288 dB/m, patients with higher CAP values more frequently were overweight (BMI ≥ 25 kg/m2) (45.8% vs 84.0%, p < 0.01) and had metabolic syndrome (MS) (12.5% vs 40%, p < 0.003), and also presented with higher values of BMI (24.6 ± 2.6 kg/m2 vs 29.2 ± 6.4 kg/m2, p = 0.02), waist circumference (85.0 ± 9.0 cm vs 97.9 ± 11.3 cm, p < 0.01) and triglycerides (95.6 ± 31.4 mg/dL vs 62.9 mg/dL, p < 0.01) and lower values of HDL cholesterol (58.9 ± 14.3 mg/dL vs 50.4 ± 14.4 mg/dL, p < 0.01). A significant association was also found between the waist circumference and female gender (females 4.6 ± 1.3KPa vs males 5.8 ± 1.5KPa, p < 0.01), elevated triglycerides (4.9 ± 1.5KPa vs 6.0 ± 1.1KPa, p = 0.03) and obesity (4.9 ± 1.4KPa vs 6.5 ± 1.1KPa, p < 0.01).

Conclusion: Different components of MS seem to contribute both to fibrosis and steatosis in chronic HBV inactive carriers. In this subset of patients, the interplay between fibrosis values and CAP is an issue that should be made with caution since it may be influenced by metabolic parameters.

Aims & Methods:
We aimed to investigate patients with chronic HBsAg+ hepatitis who over the levels of HBeAg levels during the NUC therapy to evaluate the predictive parameters of HBsAg seroclearance. Patients with HBsAg, receiving NUC therapy with stable viral suppression by HBeAg and HBsAg in study patients. Normalization of liver function test showed that the test drug can improve functions of liver without any significant adverse effects for a treatment duration of 12 weeks. Limitation include small sample size, small duration and without control. Unlike other studies on CHB evaluating effect of conventional antivirals, we have recruited clinically stable CHB patients who were not diabetic and hypertensive, without liver fibrosis, and without other, demographic, kidney and heart disease, being a pilot study. 2. Future recommendation of double blind randomized clinical trial with small sample size, longer duration and including cirrhotic patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Serum HBsAg loss is the recommended stopping rule in nucleo(t)side-analogues (NUC) responders, even if this event occurs rarely. Aims & Methods: We aimed to investigate in patients with chronic HBeAg+ hepatitis the role of HBsAg levels during the NUC therapy to evaluate the predictive parameters of HBsAg seroclearance. Patients with HBsAg, receiving NUC therapy with stable viral suppression (HBV-DNA < 2000IU/ml), were recruited at the Gastroenterology Unit of the University of Naples “Federico II”. Serum samples from these patients were tested for HBsAg quantification with the ElecsysHBsAg II Quant immunoassay (Roche Diagnostics, Indianapolis, USA). HBsAg levels were determined before starting NUC treatment and on-treatment every 12 months. Results: A total of 95 HBeAg-positive, HBeAg-negative patients (M:F: 73:22, median age 50 yrs, 34% cirrhotic) with stable viral suppression by NUCs, were enrolled. Precisely 56 patients underwent to Tenofovir, 22 Entecavir and 17 with a median age of 50 years. Sequential serum samples from these patients were tested for HBsAg quantification with the ElecsysHBsAg II Quant immunoassay. HBsAg were determined before the seroconversion, and NUC therapy was successfully stopped, without any significant adverse effects in clinical and laboratory examination were assessed. The primary end point was HBsAg loss from baseline.

Conclusions: The results of this study suggest a role of on-treatment HBsAg quantification in the management of NUC-treated patients. HBsAg measurement would be a useful parameter to optimize antiviral treatment schedule. Disclosure of Interest: All authors have declared no conflicts of interest.

P1348 IMPROVEMENTS IN CHRONIC HEPATITIS B PATIENTS AND THE ALTERATION IN GUT MICROBIOTA AFTER FECAL MICROBIOTA TRANSPLANTATION

C. Xiao, B. Zhang, J. Ren
Zhongshan Hospital Affiliated To Xiamen University, Department of Gastroenterology, Xiamen, China

Contact E-mail Address: xiaox107@xmu.edu.cn

Introduction: Chronic hepatitis B (CHB) is a common liver disease worldwide, and can be progressed to liver cirrhosis and hepatocellular carcinoma. Unfortunately, only a minority of CHB patients could achieve the clearance or seroconversion of hepatitis B virus e-antigen (HBeAg), the end point of treatment, even after multiple years of antiviral therapy. Therefore, it is urgent to develop new and effective strategy for treatment of CHB and examine the mechanisms.

Aims & Methods: In this study, we performed 60 times of fecal microbiota transplantation (FMT) by nasoenteral tube for 20 CHB patients who continued to fail previous antiviral treatment, and according to measurement of HBsAg levels four weeks after each FMT. Fecal samples of CHB patients before (Baseline) and after FMT as well as donors were collected for analyses of gut microbiota by sequencing 16S V3-V4 regions on Illumina MiSeq using PE 250 reagents.

Results: Results showed that HBsAg of 13 patients (65%) was cleared or reduced after one to seven times of FMT. Based on OTUs at cutoff of 3% dissimilarity, there were significant (PERMANOVA, P < 0.001) differences in overall gut bacterial communities among CHB, CHB-FMT and CHB-Baseline. We detected three major clusters in PCA ordination. Whereas, no significant differences (ANOVA, P > 0.05) were detected in α-diversity indexes among the three groups, including observed OTU numbers, Shannon index, Simpson index, and Pielou evenness. This implies that it is the taxonomic relative abundance, not taxon number, that contributed to the bacterial community differences. Overall, gut bacteria were mainly composed of Firmicutes (Lachnospiraceae, Ruminococcaceae, Veillonellaceae), Bacteroidetes (S24-7, bacteroidaceae, Prevotellaceae), and Proteobacteria (Akaligenaceae, Enterobacteriaceae). More specifically, Actinomyces was significantly higher in CHB patients (CHB-Baseline) than FMT-treated patients (CHB-FMT) and donors, and was identified as the biomarker of CHB using LEfSe analysis. Conversely, Prevotella and Eubacterium were significantly decreased in CHB-Baseline after FMT to almost equal to the abundances in donors, and were also identified as biomarkers.

Conclusion: In summary, along with the clearance or reduction of HBsAg, the gut bacterial communities of chronic hepatitis B patients were remarkably alerted after fecal microbiota transplantation, with some taxa abundances changed accordingly, which suggested their potential application as targets for clinical diagnosis and treatments in future. Disclosure of Interest: All authors have declared no conflicts of interest.

P1349 EFFICACY OF PEGYLATED INTERFERON ALFA-2A ADD-ON THERAPY VERSUS NUCLEOSIDE ANALOGUE MONOTHERAPY IN TREATMENT-EXPERIENCED CHRONIC HEPATITIS B PATIENTS: A RANDOMISED, CONTROLLED, OPEN-LABEL TRIAL

X. Hu1, J. Ye2, W. Yanqing1, R. Li1, C. Shao1, Z. Bihui1
1Gastroenterology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Contact E-mail Address: 14466990090@qq.com

Introduction: Hepatitis B surface antigen (HBsAg) seroconversion is rarely achieved in chronic hepatitis B (CHB) patients during nucleoside analogue (NA) monotherapy. The efficacy of pegylated interferon alfa-2a (peg-IFNα-2a) add-on therapy in those CHB patients remains unclear. Aims & Methods: We aimed to compare the efficacy of peg-IFNα-2a add-on NA monotherapy in treatment-experienced CHB patients. We enrolled hepatitis B e antigen (HBeAg)-negative patients older than 16 from the First Affiliated Hospital of Sun Yat-sen university in China. All had received NA monotherapy for 3 years with sustained undetectable plasma HB DNA. The exclusion criteria included: cirrhosis or other chronic liver diseases, previous immunological therapy, pregnancy and breastfeeding, contraindications for peg-IFNα-2a, or other serious diseases. The eligible patients were assigned to receive peg-IFNα-2a add-on therapy for 48/72 weeks or to continue to receive NA monotherapy for 96 weeks. HB DNA levels, HBV serologic indicators, liver function, renal function, thyroid function, blood cells count and imaging examination were assessed. The primary end point was HBsAg loss from baseline to week 96.

Results: 71 patients were enrolled (22 to peg-IFNα-2a add-on therapy group and 49 to NA monotherapy group), of whom 9 in peg-IFNα-2a add-on therapy group and 25 in NA monotherapy group completed more than 24 weeks of follow-up, the remaining patients have not yet reached 24 weeks of follow-up. There was no significant difference in age, gender, body mass index (BMI), HBsAg levels, alanine aminotransferase (ALT), or aspartate aminotransferase (AST) between the two groups at baseline. At week 24, HBsAg levels in peg-IFNα-2a add-on therapy group were significantly lower than the baseline (2.96 ± 0.14 vs 2.09 ± 0.82 Log10UI/ml, p = 0.009), but there was no obvious change in NA monotherapy group (3.43 ± 0.46 vs 3.44 ± 0.44 Log10UI/ml, p = 0.843). The HBsAg loss in peg-IFNα-2a add-on therapy group was significantly higher than in NA monotherapy group at week 24 (0.82 Log10UI/ml ± 0.05) vs 0.01 ± 0.10 Log10UI/ml, p = 0.008). Among those patients who completed 96 weeks of follow-up, two patients in peg-IFNα-2a add-on therapy group (22.2%) achieved HBsAg seroconversion, but none in NA monotherapy group (0%). Conclusion: The peg-IFNα-2a add-on therapy increased loss of HBsAg in CHB patients as compared to NA monotherapy. Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: A multi-cohort, health-state-transition model was developed to project the number of HCV patients achieving a sustained virologic response 12 weeks after treatment (SVR12) or progressing to compensated cirrhosis (CC), decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), and liver-related death (LrD) from 2016 to 2036. Epidemiology and mortality data were extracted from the Ministry of Health bulletin while costs were collected from insurance claims. The proportion of patients screened for HCV was projected to increase to 60%–85%, 99% (low/medium/high screening scenarios) in 2036, with a new cohort of patients being diagnosed each year. SVR2 rates were extracted from clinical trials. Separate models were used for 18–39 and 40–80 age groups to account for difference prevalence and screening rates.

Results: Low, medium and high HCV screening scenarios showed that 3838, 5665 and 8313, respectively. Although DAAs for F0–F4 increase the cost of HCV treatment and insurance claims. The proportion of patients screened for HCV was projected to increase to 60%–85%, 99% (low/medium/high screening scenarios) in 2036, with a new cohort of patients being diagnosed each year. SVR2 rates were extracted from clinical trials. Separate models were used for 18–39 and 40–80 age groups to account for difference prevalence and screening rates.

P3151 HEPATITIS C TREATMENT IN HEMODIALYSIS PATIENTS: THE EFFICACY AND SAFETY OF DIRECT-ACTING ANTIVIRALS IN THE REAL LIFE

L. Carvalho, J. Rodrigues, M.A. Túlio, T. Bana, E Costa, L. Lebre, C. Chagas Gastroenterology, Centro Hospitalar de Lisboa Ocidental, Lisboa/Portugal

Contact E-mail Address: lilipcarvalho@gmail.com

Introduction: Hepatitis C virus (HCV) infection is a prevalent condition in patients with end-stage renal disease (ESRD). HCV treatment for HCV in these patients is challenging due to immunosuppression and increased incidence of adverse events. The aim of this study was to evaluate the safety and efficacy of direct-acting antivirals (DAAs) in the treatment of HCV in hemodialysis patients (HD). The mean viral load was 5.5 Log10 (5.3–7.0 Log10). Genotype distribution was the following: genotype 1–81% (13/16) and genotype 4–19% (3/16). Distribution according to fibrosis stages was as follows: F2–62% (10/16), F3–19% (3/16) and F4–19% (3/16). All patients were treatment-experienced with ombitasvir/paritaprevir/ritonavir and dasabuvir (3D). Seven of these patients (44%) received concomitant ribavirin at an average dose of 400 mg per week (200–600 mg per week). The treatment duration was 12 weeks for 13 patients (81%) and 24 weeks for others 3 (19%). Regarding treatment response rates, 74% (14/19) of patients had Rapid Virological Response (RVR) and 100% (19/19) of patients had End of Treatment Response (ETR). The global sustained virologic response (SVR) rate was 100%. Hemoglobin was monitored throughout the treatment, with 2 cases of severe anemia, one led to a 3D suspension at week 21 and the other one to a ribavirin suspension at week 4 of treatment. There were no other serious adverse effects.

Conclusion: In our sample of ESRD under HD patients, DAAs for HCV infection with high efficacy, even in patients who did not meet the expected duration of treatment or dose of ribavirin. The safety of DAA in this group is demonstrated by the non-occurrence of severe adverse effects.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Liver stiffness (LS) measurements by Transient Elastography (TE) has been widely accepted as a tool for fibrosis assessment.

Aims & Methods: The aim of this study was to assess LS dynamics in a group of patients with HCV liver cirrhosis after DAA treatment. This bicentric clinical
trial included 276 patients with compensated HCV cirrhosis (all genotype 1b), with 6 months and 12 months. All patients were evaluated by means of TE at the beginning and at the end of treatment (EOT), and one subgroup (180 patients) also 12 weeks after EOT, all of them with sustained viral response (SVR 12), and another subgroup (55 patients) also at 24 weeks after EOT (SVR 24). Liver stiffness measurements (LSM) were defined as median value of 10 valid LSM, with IQR < 30% and SR ≥ 60%. Both M and XL probes were used. For diagnosing cirrhosis we used a cut-off value of 12 kPa as proposed by the Tschatschis meta-analysis. We considered a decrease or increase of more than 10% in LSM as being significant.

**Results:** Of 276 subjects, reliable measurements were obtained in 92.7%, so that the final analysis included 256 patients. The mean LS values decreased significantly after DAA: 25.6±11.7 kPa vs. 22.3±12. kPa (p=0.009). Most patients (55% [152/276]) presented more than 10% decrease in LS values: 23% (59/256) had stable LS values, while in 17.3% (45/256) the LS values increased. In the subgroup of 180 patients where LSM were also performed 12 weeks after EOT (SVR 12), the mean LS values were significantly lower than EOT as compared to baseline: 20.3±10.8 kPa vs. 25.5±11.4 kPa (p=0.001) and also as compared to EOT: 20.3±10.8 kPa vs. 22.8±12.2 kPa, (p=0.04). In the subgroup of 55 patients where LSM were also performed 24 weeks after EOT (SVR 24), the mean LS values were significantly lower at SVR 12 and SVR 24 as compared to EOT (18.7±6.8 kPa vs. 21.6±7.7 kPa and 0.01).

**Conclusion:** In our group mean liver stiffness values evaluated by TE significantly decreased after antiviral treatment at SVR 12 and SVR 24, as compared to EOT. Overall, in our study almost 60% of patients had EOT liver stiffness values lower than at baseline, at SVR 12 almost 75% of patients had liver stiffness values lower than at baseline and at SVR 24 almost 77% of patients had liver stiffness values lower than at baseline.

**P1354 ACHIEVING SVR AFTER DAA THERAPY FOR HCV DECREASES THE ACCURACY OF BAVENO VI CLASSIFICATION OF HIGH-RISK VARIETIES IN CIRRHOTIC PATIENTS**

**Contact E-mail Address:** rotarui.magda@gmail.com

**Introduction:** Baveno VI criteria suggest that cirrhotic patients with platelet count (PLT) > 150,000 µl and liver stiffness measure values (LSM) < 20 kPa bare a low risk of major hepatic varices (EV) and do not require endoscopic screening. The direct-acting antiviral agents (DAA) determine a very high rate of sustained virological response (SVR) which is associated with reduction of liver stiffness and fibrosis. Therefore, the aim of the study was to assess the influence of DAA therapy on the accuracy of the Baveno VI criteria for cirrhotic HCV patients. All consecutive patients with compensated HCV cirrhosis approved for DAA treatment in our center who gave their informed consent were included. All patients were screened for EV before starting the therapy by esogastroendoscopy. LSM (FibroScan®) and usual biological parameters were evaluated at baseline and when assessing SVR 12.

**Results:** 50 patients were included (59.5% men, 40.5% women) between December 2015 and July 2016. All patients achieved SVR 12 (100%). At base line, 17/50 patients had EV. After completing DAA therapy, liver enzymes [GOT (p < 0.001), GPT (p < 0.0001)], AST (p < 0.0001) significantly decreased, while albumin (p = 0.001) did not change. We found a moderate correlation between GOT and LSM both at baseline (r = 0.31; p = 0.001) and at RVS2 (r = 0.45; p = 0.004), but the amplitude of the decrease appears not to be correlated [Δ(ΔGOT) vs. ΔLSM] (p > 0.149; p = 0.3). At baseline, according to Baveno VI criteria, 29 patients were classified at low risk of having EV (accuracy 68%, Se 69.7%, Sp 64.7%, PPV 79.31%, NPV 52.38%). At SVR12, 10 additional patients entered this class, but the accuracy (60%) decreased.

**Conclusion:** DAA therapy induces a significant decrease in liver inflammation and liver stiffness and also a non-significant increase of platelets count. These changes induce a decrease of the accuracy of classification of patients with low risk of having EV (according to Baveno VI criteria), therefore is not advisable to use Baveno VI criteria as surrogate for endoscopy screening for esophageal varices in patients compensated HCV liver cirrhosis who benefit from DAA therapy.

**P1355 MONOCYTE CHEMOATTRACTANT PROTEIN-1 IN CONCENTRATIONS IN SERUM DEPEND ON OVERWEIGHT IN CHRONIC HEPATITIS C PATIENTS AND INCREASE AFTER SUSTAINED ViroLOGIC RESPONSE**

**Clinic Of Gastroenterology, University Hospital St. Ivan Rilski, Medical University - Sofia, Sofia/Bulgaria**

**Contact E-mail Address:** ivan.valkov@yahoo.co.uk

**Introduction:** Monocyte chemotactic protein-1 (MCP-1) is a chemokine mediating inflammation and fibrogenesis. It can be induced by proinflammatory activated monocytes and macrophages. Signaling between the mononuclear phagocyte system (MPS) and hepatic stellate cells is key for active fibrogenesis. The extent to which metabolic and immune factors are implicated in fatty liver of patients with CHC is still not clear.

**Aims & Methods:** The aim of the study was to explore the associations between serum MCP-1, liver fibrosis, fatty liver and metabolic factors in CHC patients before, and after antiviral treatment. We included 21 patients in the study (11 men, 10 women, age 42 ± 9.7) with chronic hepatitis C virus (HCV) infection – 17 with genotype 1 and 4 with genotype 3. Liver biopsy was done in 19 and histology showed fatty liver in 8 patients. Fatty liver was present in 17 of all patients on antiviral treatment. MCP-1 was quantified by ELISA in serum. Serum probes were obtained before treatment and after response evaluation. Statistical analysis included Spearman’s rho, Mann-Whitney U test, Wilcoxon’s test and Student’s paired t-test.

**Results:** MCP-1 in serum correlated with BMI (r = 0.522, p = 0.015). MCP-1 correlated with overweight (r = 0.582, p = 0.006) and with other metabolic factors (r = 0.416, p = 0.010). MCP-1 correlated with liver stiffness, fibrosis and antiviral response (r = 0.39, p = 0.042). An increase in serum MCP-1 was found in patients after SVR (p = 0.018), while no significant variation from baseline values was found in NVR patients. The result remained significant in subgroup analysis of SVR patients with F1-F2 (p = 0.028) and in those with fatty liver (p = 0.017). MCP-1 in serum did not show any association with assessment of liver fibrosis, fatty liver, insulin resistance and serum lipid levels.
Conclusion: MCP-1 concentrations in serum depend on overweight in patients with CHC. Overweight and insulin resistance are associated with progression of CHC. Serum levels of MCP-1 increase after HCV clearance. Fluctuation of the MCP-1 concentration in serum could reflect an antiinflammatory activation of MPS and a gradient dependent dynamic replacement of the proinflammatory cell subsets in a liver with chronic resolution ones after SVR. Fatty liver plays a role for inflammatory responses in CHC patients after SVR.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: rahda.farag@yahoo.com

Introduction: HCV interferes with the host lipid metabolism leads to insulin resistance and hepatic steatosis. Although it is usually mild in genotype 4, manifests simple steatosis cases Fibrosis is the potential toxic effect to fibrosis, cirrhosis and subsequent hepatocellular carcinoma. Many heritable host factors with observed inter-ethnic variation in the prevalence of steatosis are documented, and in many cases hepatic steatosis may be detected in absence of all these risk factors; so a role for host genetic factors in development of hepatic steatosis in chronic HCV patients may be suggested.

Aims & Methods: In this study, we aim to evaluate the association of HLA class A-B alleles and presence of steatosis in chronic HCV genotype 4 infected patients. This study included two hundred unrelated non diabetic non obese chronic HCV patients with normal lipid profile, 98 of them have biopsy proven steatosis. Serological testing of HLA class I antigens (HLA-A, and HLA-B alleles) were performed with a standard complement-dependent micro-lymphocytotoxicity

Results: The frequency of A02, A03, B15 and B17 alleles were significantly higher in chronic HCV patients with steatosis (OR = 1.77, 2.64, 4.44, 5.68) and 95% CI = 0.96–3.27, 1.02–7.04, 0.84–31.17, 1.12–38.65 with P = 0.034, 0.022, 0.044, 0.015 respectively. On the other hand, the frequency of A01 and B12 alleles were significantly higher in patients without steatosis (OR = 0.56, 0.41) and 95% CI = 0.30–1.05, 0.20–0.83 and P = 0.015 respectively. On logistic regression analysis, patients who carry HLA-A02, A03 and HLA-B15 alleles may have 2.2, 3.9 and 11.18 fold risk to have hepatic steatosis (B coefficient: 0.78, 1.37, 2.41) 95% CI = 1.09–4.42, 1.04–11.05, 2.15–58.13; P = 0.027, 0.009, 0.004) while carrying HLA-A01 alleles may be protected from having HCV associated hepatic steatosis; (OR = 0.34,95% CI = 0.16–0.72; P = 0.005) with constant 9.47 and overall accuracy of 69%. In addition, patients who have moderate activity index in liver histopathology have 5.9 risk to have hepatic steatosis (OR = 5.92, 95% CI = 2.92–11.99, P<0.001).

Conclusion: In chronic HCV genotype 4 patients, carrying HLA-A02, HLA-A03 and HLA-B15 alleles may have a risk for presence of hepatic steatosis while presence of HLA-A01 alleles may have a protective role.

P1357 THE VALUE OF 2D-SWE.GE FOR THE EVALUATION OF LIVER FIBROSIS IN PATIENTS WITH HCV COMPENSATED CHRONIC HEPATITIS PATIENTS
F. Bene, I. Sporea, S.A. Popescu, R. Sirli, M. Danila, R. Mare, A. Stepan Gastroenterology And Hepatology, University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisoara/Romania

Contact E-mail Address: bendefelix@gmail.com

Introduction: Chronic liver diseases are quite frequently encountered in daily practice and are due mainly to chronic viral infections (B or C viruses) and to other conditions such as alcoholic steatohepatitis - (ASH) and to non-alcoholic fatty liver disease (NAFLD). While liver biopsy remains the gold standard method for fibrosis assessment, stage classification and also for necro-inflammation grading, in the last years, non-invasive assessment methods (biological tests and elastographic methods) were developed and they are being used more and more, to the detriment of liver biopsy.

Aims & Methods: The aim of this study was to evaluate the performance of the 2D-shear wave elastography technique from General Electric (2D-SWE.GE), for the evaluation of liver fibrosis in patients with HCV compensated chronic hepatopathies, using Transient Elasotagy (TE) as the reference method. The study included 145 consecutive subjects with HCV compensated chronic hepatopathies, in whom liver stiffness was evaluated in the same session by means of 2 elastographic measurements: TE (FibroScan, EchoSens) and 2D-SWE.GE (LOGIQ E9, GE Healthcare). Reliable LS measurements were defined as follows: for TE—the median value of 10 measurements with a success rate of ≥60% and an inter-quartile range <30% and for 2D-SWE.GE - the median value of 10 measurements acquired in a homogeneous area and an inter-quartile range (IQR) <30%. To discriminate between various stages of fibrosis by TE we used the following cut-offs: F2: ≥ 7.1 kPa, F3: ≥ 9.5 kPa, F4: = 12.5 kPa [1].

Results: Reliable LS measurements were obtained in 138/145 (95.1%) subjects by 2D-SWE and in 139/145 (95.1%) subjects by TE. On logistic regression analysis, patients who have moderate activity index in liver histopathology have 5.9 risk to have hepatic steatosis (OR = 5.92, 95% CI = 2.92–11.99, P<0.001).

Conclusion: 2D-SWE.GE seems a reliable method for liver fibrosis staging in patients with HCV compensated chronic hepatopathies. The best 2D-SWE.GE cut-off values for F ≥ 2, F ≥ 3 and F ≥ 4 in HCV chronic hepatopathies were 7.2 and 10.7 kPa.

P1358 DE NOVO HEPATOCELLULAR CARCINOMA IN PATIENTS WITH CIRRHOSIS AFTER TREATMENT WITH DIRECT ANTIVIRAL AGENTS
P. Ruiz1, L. Deiss Pascual2, L. Buendia1, I. Erdozain2, I. Esain2, S. Blanco3, A. Baranda4, F. Menendez2

Introduction: The risk of developing novo hepatocellular carcinoma (HCC) persists after reaching sustained virological response (SVR) in patients infected with hepatitis virus C. It has been suggested that risk is increased in patients treated with the new direct antiviral agents (DAA). In this prospective study we present our results of incidence and prevalence of novo HCC in cirrhotic patients treated with DAA and SVR, and also, the risk factors involved in its development.

Aims & Methods: We included all cirrhotic patients due to HCV infection without previous HCC who reached SVR after DAA treatment in our hospital from February 2014 until December 2016 (n = 197, median of follow-up of 17 months). We evaluated with chi square test the following qualitative variables: age, Child-Pugh stage, alcohol consumption pre-treatment, tobacco consumption pre-treatment, diabetes mellitus (DM) pre-treatment, genotype, radiological and endoscopic portal hypertension features pre-treatment. The quantitative variables were evaluated with student t test: age, no. of platelets pre-treatment, fibrosis stage pre-treatment.

Results: During follow-up 11 patients were diagnosed of HCC (5.6% prevalence, 3.9% annual incidence). Among all variables evaluated being in a Child- Pugh B stage vs. an A stage (p = 0.007), pre-treatment DM (p = 0.002) and presence of radiological portal hypertension (p = 0.001) were associated with developing novo HCC. Among the quantitative variables, we evidenced statistically significant differences in the mean value of platelets (p = 0.015).

Conclusion: In our group of patients, a worse hepatic function evaluated with the Child-Pugh classification and indirect markers of portal hypertension (platelets and radiological features) and also DM are associated statistically significantly with the development of novo HCC. The incidence (>1.5%) of novo HCC justifies the screening of HCC.

P1359 IS AN ACUTE LIVER FAILURE REALLY ALWAYS AN ACUTE ONSET OF PRE-EXISTING LIVER DISEASE IS COMMON IN PATIENTS WITH ALF DIAGNOSIS

A. Gottlieb1, J. P. Sowa2, M. Kottmann3, P. Manka3, L. Behchmann1, A. Canbay1

Introduction: An acute insult to the liver in patients without pre-existing chronic liver injury can cause acute liver failure (ALF). ALF is a life-threatening condition and requires specialized intensive care. Acute on chronic liver failure (ACOF) is a not yet clearly characterized situation, where the acute insult occurs on top of a pre-existing chronic liver disease without cirrhosis. Various definitions of AOCFL are found in the literature. Discrimination of AOCFL from ALF might be trivial for pre-existing alcoholic or viral hepatitis. However, non-alcoholic steatohepatitis (NASH) in obese or diabetic patients might be more critical situations. Patients admitted to liver transplantation centers with the diagnosis of ALF might be suffering from AOCFL instead. It is also unclear if the ALF and AOCFL have different impact on disease course, clinical management and transplant organ allocation.

Aims & Methods: Aim of this study was to identify possible differences between patients with ALF and AOCFL regarding routine parameters and clinical course. In this retrospective single-center study all patients were recruited, who were admitted to the University Hospital of Essen with the initial diagnosis of ALF between 2008 and 2015. Patients included in this study were fulfilling the criteria of the acute liver failure study group Germany. The diagnosis of AOCFL was established by a retrospective examination of patient records. In total 161 patients were recruited (ALF: 131; AOCFL: 30). Clinical records, in particular demographic data, serum parameters and outcome were analyzed for differences between ALF and AOCFL.

Results: Patients with AOCFL were significantly older (50.3 ± 15.1 vs. 39.8 ± 16.2, p = 0.0008) but had a higher BMI (27.5 ± 5.1 vs. 24.5 ± 6.2, p = 0.0014) and were more often male (65% in AOCFL vs. 34% in ALF, p = 0.0008). In addition, the causes that resulted in the liver failure in AOCFL were significantly different from those patients with ALF. Significant differences were also found for liver enzymes, which were significantly lower in AOCFL patients (AST p = 0.01; ALT p = 0.001). Cell death markers and the MELD did not differ between ALF and AOCFL. Moreover, the outcome was not different between the two groups neither separated as survived or deceased nor as spontaneous remission or non-spontaneous remission (combined transplantation and deceased). Importantly, MELD and the modified MELD including the cell death marker M65 were similarly effective in predicting outcome for both ALF and AOCFL.

Conclusion: In the present study patients with ALF and AOCFL differed in age and BMI, but did not exhibit differences regarding disease severity (according to MELD) or clinical outcome. While the causes for an acute insult differed between ALF and AOCFL, which might imply a different clinical management, clinical outcome was predictable by common factors for ALF.

P1360 EFFECTS OF PREOPERATIVE TRANSARTERIAL CHEMOEMBOLIZATION ON PATIENTS’ SHORT TERM PROGNOSIS AFTER LIVER TRANSPLANTATION

D. Ma
Department Of Hepatobiliary Surgery, Ruijin Hospital, Shanghai Jiaotong University School of Medicine, Shanghai/China

Contact E-Mail Address: madi_1978@163.com

Introduction: To explore the influence of preoperative transarterial chemoembolization on short-term prognosis in patients with hepatocellular carcinoma after liver transplantation.

Aims & Methods: A retrospective study was conducted among patients with hepatocellular carcinoma who received liver transplantation from January 2009 to September 2015 in Ruijin Hospital. A total of 31 patients (Male: 29; Female: 2) were included. Among them, 14 patients received preoperative hepatic arterial chemoembolization was incorporated into observation group (n = 14), and the other 17 patients who didn’t undergo transarterial chemoembolization were included in the control group (n = 17). The qualitative data included patient demographics, patient’s preoperative and peroperative course.

Results: No statistical difference was found in the total operation time, blood loss and length of hospital stay between two groups, and the occurrence rate of vascular complications, biliary complications and postoperative infection also showed no difference. Although more patients above Clavien IIa were in the observation group, there was no statistical significant difference in the peroperative mortality between two groups. Besides, preoperative TACE could effectively reduce complications caused by immune reaction (p = 0.048). In terms of postoperative index of liver function, TBIL, ALT, AST all had a transient rise during the first 3 days after liver transplantation, but recovered gradually over time. There’s no remarkable difference in the liver function recovery level between two groups (P = 0.495; P = 0.141; P = 0.101). No statistical difference was found in the total operation time, blood loss and length of hospital stay between two groups, and the occurrence rate of vascular complications, biliary complications and postoperative infection also showed no difference. Although

P1361 IMPORTANCE OF INTERFERON-GAMMA RELEASE ASSAYS IN EVALUATING CANDIDATES FOR LIVER TRANSPLANTATION IN A COUNTRY ENDEMIC FOR TUBERCULOSIS

Introduction: Romania has the highest incidence of tuberculosis (TB) in the European Union, representing one quarter of the European TB burden. According to clinical practice guidelines for liver transplantation (LT), the second level of screening for infections consists of screening for Mycobacterium tuberculosis, including history of TB, PPD, Interferon-gamma release assays.

Aims & Methods: The aim was to assess the importance of Quantiferon TB Gold test for evaluating patients included on the wait list for LT in Romanian liver transplant centers. The study was a single-center retrospective cohort study (the single center for LT) that included 264 patients admitted on the wait list for LT from January 1, 2014 to November 18, 2016. All patients underwent mandatory screening for Mycobacterium tuberculosis, either using Quantiferon TB Gold test or skin testing using purified protein derivative (PPD). The variables analyzed using Minitab were age, gender, etiology of liver disease, biochemical test, MELD score. Results: From a total of 264 patients with liver diseases included on the wait list, 60.6% were males, the average age at diagnosis was 47.78 ± 9.92 years. The etiology of liver cirrhosis was HCV infection in 31.43%, HBV and HBV-HDV co-infection in 45.06%, and alcoholic liver cirrhosis in 18.93%; 24.62% of patients had no identified etiology (p value 0.187). Patients with indeterminate Quantiferon as assessed by the PPD test had a significantly higher MELD score (p = 0.044) and lower lymphocyte counts, but did not achieve statistical significance (p = 0.187). Patients with indeterminate Quantiferon associated with hyperbilirubinemia (p = 0.044), hypoalbuminemia (p = 0.032) and a high MELD score (p = 0.045) showed a worse postLT outcome. Patients with indeterminate Quantiferon associated with hyperbilirubinemia (p = 0.044), hypoalbuminemia (p = 0.032) and a high MELD score (p = 0.045) showed a worse postLT outcome.

Conclusion: Preoperative TACE would effectively reduce complications caused by immune reaction (p = 0.048). It might go unnoticed in the critical situation of an ALF/AOCLF. Thus, patients admitted to liver transplantation centers with the diagnosis of ALF might be suffering from AOCFL instead. It is also unclear if the ALF and AOCFL have different impact on disease course, clinical management and transplant organ allocation.

A NATIONAL STUDY OF CANCER DIAGNOSES IN IRISH LIVER TRANSPLANT RECIPIENTS WITH PRIMARY SCLEROSING CHOLANGITIS

1Centre For Colorectal Disease, St Vincent's University Hospital, Dublin/Ireland
2National Cancer Registry Ireland, Cork/Ireland
3National Liver Unit, St Vincent's University Hospital, Dublin/Ireland

Contact E-mail Address: susannemoreilly@gmail.com

Introduction: Primary sclerosing cholangitis (PSC) is associated with an increased risk of cholangiocarcinoma, colorectal cancer (CRC) and gallbladder cancer. Orthotopic liver transplantation (OLT) patients are at increased risk of developing de novo malignancies, however limited and conflicting data exists regarding cancer risk post OLT for PSC.

Aims & Methods: To examine all recorded malignancies over 2 decades in OLT PSC pts and compare to our non-transplanted PSC cohort. To factor assesses contribution of development of malignancies post OLT. We retrospectively studied PSC patients attending the Irish National Liver Unit (INLU) and the Centre for Colorectal Disease (CCD) at St. Vincent’s University Hospital from 1/1/1994 to 30/9/2016. We integrated this database with the National Cancer Registry in Ireland. This enabled accurate determination of the no. of malignancies recorded in the PSC cohort. Analyzed data included age of recipient at OLT, gender, primary OLT indication, immunosuppressive regime, de novo malignancy post OLT, time from diagnosis to diagnosis of malignancy or death. Statistical analysis was primarily descriptive. Cox Proportional Hazard Model was used to analyse factors associated with mortality in the PSC OLT cohort.

Results: 107 of 173 patients had undergone transplant for PSC. 27/170 pts were transplanted for cholangiocarcinoma. 12 post-transplant de novo cancers and 12 IBC/SCC carcinomas were found in 107 patients during 737.8 person years of follow-up. Median time to cancer diagnosis post OLT was 5 years (IQR 2.8–5.9). Recurrence of PSC was observed in 21 patients (19.6%). Post-transplant lymphoproliferative disease (PTLD) remains a major complication after OLT. Previous studies have reported rates of 1–3% in adult OLT pts. 5 pts were diagnosed with lymphoma post OLT representing 4.7% of cohort. Median time to diagnosis was 5.3 yrs [IQR 2.8–10.2]. Regarding CRC, 2 patients developed CRC post OLT. 4 patients developed colorectal dysplasia: 3/4 underwent colectomy. All those who developed colorectal dysplasia/CRC post OLT had co-existing IBD. All 5 colectomy specimens for dysplasia/CRC showed significant co-existing inflammation.

Conclusion: These findings represent national cancer figures in our PSC OLT cohort. The rate of cancer is more than three times higher in this population than the general population. The rates of PTLD are >30 times higher than those in the normal population, and slightly higher than previously reported in unselected liver transplant groups. We could not find any association between the development of PTLD and aggressive immunosuppressive regimes for co-existing IBD post OLT. The study highlights that IBD/PSC patients remain at significant risk of colorectal neoplasia after OLT and require intensive surveillance.

OUTCOME OF LIVER TRANSPLANTATION FOR PRIMARY SCLEROSING CHOLANGITIS IN CONTEXT OF HLA-DR MISMATCH: SINGLE CENTRE EXPERIENCE

P. Drastich1, L. Bajer1, A. Slavec2, M. Benes1, P. Trunec3, J. Spick1

1Department Of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
2Department Of Immunogenetics, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
3Transplantcentre, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: drastich@hotmail.com

Introduction: Primary sclerosing cholangitis (PSC) is a chronic liver disorder of unknown etiology, characterized by inflammation, fibrosis and stenoses of both extra- and intrahepatic bile ducts. For those who develop end-stage liver disease, orthotopic liver transplantation (OLT) remains the only effective treatment currently available. PSC is accompanied with concomitant ulcerative colitis (UC) in a significant proportion of patients. Benefits of routine HLA typing in donor and recipient prior to OLT were proved in the past.

Aims & Methods: The aim of this study was to assess the impact of HLA-DR mismatch on acute cellular rejection (ACR), PSC recurrence (rPSC) and course of UC after OLT.

Results: Out of 57 patients, 27 (47.4%) had single mismatch (“M1” group) and 30 (52.6%) had double mismatch (“M2” group) in HLA-DR. No patient had full match. 33/57 (57.9%) patients had ACR: 15/27 (55.6%) of M1 and 18/30 (60%) of M2 (p = 0.94). 4/27 (14.8%) of M1 and 2/30 (6.3%) of M2 had corticosteroid resistant ACR (p = 0.57). Multiple–episodes of ACR occurred in 11/57 (19.3%) patients: 6/27 (22.2%) of M1 and 5/25 (20%) of M2 (p = 0.74). 12/57 (21.1%) had de-novo UC after OLT: 7/27 (25.9%) of M1 and 5/30 (16.7%) of M2 (p = 0.60). In 37 (68.5%) patients, UC was diagnosed prior to OLT. 9/16 (56.3%) patients with M1 and 6/21 (28.6%) patients with M2 had more severe course of UC as compared to course prior to OLT (p = 0.17). 38 patients were evaluated for rPSC, which was diagnosed in 17 (44.7%) individuals. 6/19 patients with M1 and 11/19 with M2 had rPSC (p = 0.19).

Conclusion: Patients with single mismatch in HLA-DR have slight tendency towards development of rPSC and worsening of UC after OLT as compared to patients with double mismatch. Analysis of combined mismatch in HLA-DR and HLA-DQ could demonstrate more substantial linkages in respective clinical variables. Therefore, these data have to be considered as preliminary as typing for HLA-DQ from frozen blood samples is currently underway. GRANT DYSFUNCTION IN POST-LIVER TRANSPLANTATION: UTILITY OF TRANSIENT ELASTOGRAPHY BY FIBROSCAN®

E. Soares1, M. Gravito-Soares1, D. Gomes1, A. Simão2, E. Furtado1, L. Tomé1

1Gastroenterology, Centro Hospitalar e Universitario Coimbra, Coimbra, Portugal, Coimbra Portugal
2Internal Medicine, Centro Hospitalar e Universitario Coimbra, Coimbra, Portugal, Coimbra Portugal
3Liver Transplantation Unit, Centro Hospitalar e Universitario Coimbra, Coimbra, Portugal, Coimbra Portugal

Contact E-mail Address: es1849@gmail.com

Introduction: Liver biopsy remains the gold standard in the diagnosis of graft dysfunction in post-liver transplantation (GDPLT). Liver transient elastography is a valid non-invasive method for liver fibrosis evaluation, with a good correlation in chronic liver diseases. The progression of fibrosis represents a major problem in the post-liver transplantation.

Aims & Methods: We aimed to evaluate the predictive role of liver transient elastography in the evaluation of GDPLT and to determine the predictive factors of liver transplantation fibrosis. This was a retrospective observational cohort study of total of 49 patients with post-liver transplantation status who underwent liver transient elastography by Fibroscan®. Selected patients who underwent percutaneous/transjugular liver biopsy. In case of more than one liver biopsy, it was selected the biopsy closer to Fibroscan®. The fibrosis and steatosis evaluated by Fibroscan® were compared with those obtained by liver biopsy. Significant fibrosis was considered if ≥2F. Demographic, analytical and associated variables in the cohort.

Results: A total of 32 patients underwent Fibroscan® and liver biopsy. Mean age of 48.53 ± 11.20years and male gender in 68.8%(n = 22). The mean time between Fibroscan® and liver biopsy was 29.77 ± 36.90months. The mean elastography score was 13.45 ± 8.31KPa with IQR/med of 17.11 ± 8.66% . Mean CAP score was 207.12 ± 57.35 dB/m. Regarding liver biopsy, 34.4%(n = 11) had significant fibrosis and 25.0%(n = 8) presented steatosis. Comparing two methods, there was no concordance for steatosis (kappa = 0.273; p = 0.117) or inflammation (kappa = 0.063; p = 0.710). On the contrary, a moderate agreement for significant fibrosis (kappa = 0.431; p = 0.003) was verified. The mean elastography score showed an accuracy of 79.7% in predicting histological fibrosis (AUROC = 0.797; p = 0.007) to a cut-off value of 11.6 KPa (S = 81.8%; Sp = 76.2%). In relation to analytical parameters, only serum albumin was predictive of histological fibrosis (OR = 2.79; p = 0.043).

Conclusion: Liver transient elastography represents a non-invasive and valid alternative procedure to liver biopsy in the evaluation of post-liver transplantation fibrosis but not steatosis or inflammation. Liver transient elastography scoring ≥11.6KPa and low values of serum albumin are predictors of post-liver transplantation fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Orthotopic liver transplant has become the standard of care for end-stage liver disease and hepaticobiliary cancer. Better immunosuppressants paved way for improved survival rates post-transplant. But with this longevity comes a higher prevalence of chronic diseases such as New Onset Diabetes After Transplantation (NODAT), Hypertension, metabolic syndrome etc. which have a negative impact on function and patient survival.

Aims & Methods: Primary: To determine the incidence of New Onset Diabetes After Transplantation (NODAT), Impaired Fasting Gylcaemia (IFG) and post-transplant hyperglycemia in living-donor liver transplant recipients. Secondary: To determine the risk factors associated with NODAT and IFG. To determine impact of NODAT on survival and mortality. It was a retrospective cohort study of 283 living donor liver transplant recipients from 2/4/2011 till 26/4/2016. Data was collected from records. Simple means and standard deviation was calculated for continuous variables while frequency statistics were calculated for categorical ones. Risk factors were assessed using binary logistic regression analysis.

Results: A total of 130 post liver transplant patients were analyzed after exclusion. NODAT was present in 41/130 (31.5%) patients, while 19/130 (14.6%) patients had impaired fasting glycaemia. Acute cellular rejection, Post-transplant Hyperglycemia and Pre-transplant prediabetes showed increased odds of acquiring NODAT post-transplant. NODAT had significant association with mortality and decreased survival (p = 0.05).

Conclusion: This cohort showed that NODAT is an important post-transplant entity with significant impact on mortality and survival. Early identification of at-risk patients is suggested.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1365 OUTCOMES OF LIVER TRANSPLANTATION IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

A. Ershaghi

1Gastroenterology And Hepatology, Shiraz University of Medical Sciences, Shirma/ Iran

2Transplant Research Center, Shiraz/Iran

Contact E-mail Address: ershaghia@yahoo.com

Introduction: Hepatocellular carcinoma (HCC) is the second leading cause of cancer-related mortality worldwide. Patients with viral hepatitis and those with non-alcoholic fatty liver disease (NAFLD), the prevalence of HCC is estimated to be increased in next years. Liver transplantation is now considered as a modality of treatment for patients with HCC.

Aims & Methods: This study aimed to investigate outcomes of liver transplantation in patients with HCC compared to other causes of liver transplantation. In a cross-sectional study patients who had undergone liver transplantation between March 2012 and March 2015 at Shiraz Transplant Center, Shiraz, Iran were included. Patients’ characteristics including age, gender, model for end stage liver disease (MELD) score, number of organ failure, presence of Child-Pugh C status, and the presence of liver cancer-related mortality. Factors that may affect the survival of HCC patients were divided to those within Milan criteria and those beyond Milan criteria. The impact of HCC on post-transplant outcomes was investigated using student t-test and chi-square tests. Multivariate logistic regression was used for analysis of independent risk factors of mortality after liver transplantation.

Results: Totally 1014 liver transplant patients were included. 94 patients with HCC underwent liver transplantation. There was no statistically significant difference between those with and without HCC in terms of gender, portal vein thrombosis (PVT), diabetes mellitus (DM), hepatic encephalopathy and hospitalization before liver transplantation (P > 0.05). HCC was significantly more prevalent in cirrhosis due to viral hepatitis (P < 0.001). Acute rejection episodes was not different in patients with and without HCC in early post-transplant period (OR = 0.563; 95% CI: 0.27–1.14; P = 0.108). In regression analysis, presence of pre-transplant DM (OR = 3.89; 95% CI: 1.36–11.11; P = 0.011) and acute kidney injury within 30 days after liver transplant (OR =4.38; 95% CI: 1.44–13.27; P=0.009) were independent predictors of post-transplant mortality. Mean post-liver transplant survival in HCC patients within Milan criteria was 40.48±3.69 months compared to 36.80±6.28 months in those beyond Milan criteria (P =0.82). Mean post-transplant survival in patients with HCC+DM was 22.75±4.7 months compared to 48.51±2.6 months in HCC patients without DM (P <0.009).

Conclusion: Liver transplantation can be used for patients with HCC, however, post-transplant survival seems to be lower. Diabetes mellitus and acute kidney injury were predictors of mortality among our patients with HCC after liver transplantation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Serum vitamin B12 (vB12) levels are increased in myeloproliferative diseases by increased production of the haptocorrin transporter and in liver diseases by release of vB12 from hepatocytes death.

Aims & Methods: The aim of this study was to evaluate vB12 as a prognostic marker in patients with cirrhosis and acute on chronic liver failure (ACLF) induced by liver infection. Retrospective assessment of 5 patients admitted to an intensive care unit with ACLF in the context of infection (group 1) and 53 patients with compensated hepatic cirrhosis followed as Hepatology outpatients (group 2). Evaluation of vB12 as a predictor of 30 days’ mortality.

Results: 111 patients, 68% male, age 58 ± 18 years. Group 1 had more advanced liver disease (CPT 11.9 ± 0.3 vs. 6.5 ± 0.2 and MELD 27.0 ± 1.0 vs. 10 ± 0.5), higher vB12 (1413 ± 149 vs. 735 ± 56 pg/mL) and lower survival (1.6 ± 0.4 vs. 6.4 ± 2.7 years). vB12 positively correlated with hepatic function scores (CPT: R = 0.56; 95% CI: 0.30–0.76 vB12 and vB12 with independent factors of mortality (e.g. infection)) in group 1, survival was lower in patients with vB12 (28 ± 3 vs. 37 ± 11 months), and 1 month’ mortality was associated with vB12, CPT, MELD, number of organ failure, urea, lactates and fibrinogen, in univariate analysis (p < 0.001). In multivariate analysis only fibrinogen maintained statistical significance (P < 0.001).

Conclusion: There was a strong association between high levels of vB12 and clinical decompensation of liver cirrhosis. vB12 correlated with scores of liver disease and multiorgan failure, as well as early mortality in patients with ACLD.

P1368 THE ASSESSMENT OF THE ADC PREDICTIVE VALUE IN SURVIVAL OUTCOMES OF PATIENTS UNDERGOING RADIOFREQUENCY ABLATION FOR METASTATIC COLORECTAL CANCER LIVER TUMORS
O. Kozak1, T. Nowicki, J. M. Pienkowski2, E. Izycka-Swieszewska2, D. Zadrozny2, E. Szarowska1. 1Department Of Radiology, Medical University of Gdańsk, Gdańsk/Poland; 2Department Of Pathology And Neuropathology, Medical University of Gdańsk, Gdańsk/Poland

Contact E-mail Address: oliviak@gumed.edu.pl

Introduction: Liver is one of the most common metastatic sites of colorectal cancer, nearly 50% patients develop hepatic metastases during the course of their disease. Metastatic spread influences survival rate of those patients. The diffusion weighted imaging (DWI) is MRI sequence designed to detect random movement of water protons in extracellular compartment. Biophysical parameter expressed in DWI is ADC, which is the diffusion coefficient for their systemic motion in tissues (ADC). ADC values for b parameter lower than 300 mm²/s are influenced by perfusion whereas ADC values for b greater than 300 mm² depend mainly on diffusion. Aggressive malignant process often develops necrotic areas within neoplastic lesion. Necrotic changes are characterized by high ADC values. We suppose that low ADC values correlate with presence of necrosis in highly malignant lesions effecting in lower survival rate.

Aims & Methods: This is a post hoc analysis of prospective study to assess the predictive value of the ADC in survival outcomes of patients undergoing radiofrequency ablation due to metastatic colorectal cancer lesions in the liver. We analyzed the MRI studies of 52 patients (18 F, 34 M, aged 4383) performed on 1.5 T scanner one day before the percutaneous RFA treatment. The total number of analyzed lesions was 110 (15 per patient), 83 of them were completely ablated 27 incompletely, what was assessed in follow-up CT studies. The standard protocol of the liver MRI was applied including DWI sequence in b values of 0, 15 and 300 s/mm². ADC maps were calculated for b values of 015 and 0500 s/mm². The mean ADC value was obtained by threefold marking ROI covering the whole metastatic lesion. In cases of multiple foci only the lesion with the highest ADC value was included into analysis. On basis of ROC analysis the cut-off values of ADC were established: 2.49 mm²/s for b value of 015 s/mm² and 1.43 mm²/s for b value of 0500 s/mm². The survival outcomes were assessed by mean of Kaplan-Meier estimator. The p value lower than 0.05 was considered significant.

Results: The statistical analysis included Kaplan-Meier estimator for 52 patients with 9 censored cases (17.3%). In ADC maps for b value of 0500 s/mm², the ADC value ≥1.43 mm²/s correlated with longer survival time, whereas ADC value <1.43 mm²/s correlated with shorter survival time. Statistically significant differences were identified by log rank test (p = 0.007). Such a correlation was not observed for ADC values in ADC maps for b value of 015 s/mm² (p = 0.058).

Conclusion: The study showed significant differences in survival rate depending on diffusion influenced ADC values of metastatic lesions.

Disclosure of Interest: All authors declared no conflicts of interest.

Introduction: Nowadays liver fibrosis can be assessed using non-invasive elastographic techniques. ElastPQ is a quite novel point share wave elastography integrated in an ultrasound system. Aims & Methods: The aim of our study was to evaluate the learning curve of obtaining reliable liver stiffness measurements (LSM), using ElastPQ. LSM of a trainee were compared to LSM of an elastography expert (with an experience of more than 500 examinations). Our study group included 50 subjects (mean age: 52.7 years, 66.6% men, mean BMI = 25.6 kg/m²). Both the trainee and the expert obtained LSM for each subject, using ElastPQ (EPIQ 7, Philips Healthcare, Bothell, WA, USA). Reliable LSM were defined as the median differences in measurement values obtained in a homogenous area avoiding large vessels and with an IQR/median <30%. The learning curve was evaluated using the Receiver Operating Curve analysis using the expert’s results as reference.

Results: The trainee’s performance in obtaining reliable LSM was good (AUC: 0.735, 95% CI (0.557–0.913), p = 0.01). The trainee started to have similar results with the expert elastography after the 30th subject. When looking at the IQRs, they became significantly lower after the 30th subject (2.6± 2.1 kPa vs 6.5± 4.2 kPa, p = 0.03).

Conclusion: Obtaining reliable LSM using ElastPQ can be easily achieved after 30 LS examinations.

Introduction: Type II diabetes and nonalcoholic fatty liver disease (NAFLD) are frequently associated. NAFLD being considered the hepatic expression of the metabolic syndrome.

Aims & Methods: The aim of the present study was to assess the severity of liver fibrosis and steatosis in a cohort of type 2 diabetic patients, using non-invasive methods (Transient Elastography (TE) and Controlled Attenuation Parameter (CAP)). The study included 354 type 2 diabetic patients, who were prospectively randomized (first 6 patients who were referred to the Metabolic Disease Outpatient Clinic on a consultation day), evaluated in the same session by means of TE and CAP (FibroScan EchoSens) to assess both liver fibrosis and steatosis. Each patient was evaluated for the presence of viral hepatitis (B, C) and an AUDIT-C score was performed to exclude alcohol abuse. Reliablie liver stiffness measurements (LSM) were defined as the median value of 10 LSM with an IQR/median <30%. For TE and CAP, M and XL probes were used. A cut-off value of 8.2 kPa [1] was used to define severe fibrosis (F ≥ 3). For differentiation between stages of steatosis we used the following cut-off values [2]: S0(moderate) > 235 db/m, S1(severe) ≥ 290 db/m.

Results: Out of 354 diabetic patients, 142 presented with type 2 diabetes and were excluded with those associated viral hepatitis, those with an AUDIT-C score ≥ 8 and those with unrelable LSM. The final analysis included 239 subjects (39.4% women, 40.6% men, mean age 60.4 ± 9.3; BMI = 31.8 ± 6.1 kg/m²) with reliable LSM. Accordingly to BMI, 10.8% had normal weight, 24.8% were overweight and 62.8% were obese (35.6% obesity grade I, 17.2% obesity grade II and 10% obesity grade III). Moderate and severe steatosis by means of CAP was found in 18.4% and 69.5% cases respectively. Severe fibrosis was detected by means of TE (LSM ≥ 8.2 kPa) in 29.3% (70/239) of subjects.

Conclusion: In our group, 87.9% of diabetic patients had moderate and severe steatosis by CAP and 29.3% of them had severe fibrosis (TE ≥ 8.2 kPa), suggesting an advanced liver disease.

This study aimed to test the latest approved version of a Medicine and Pharmacy Timisoara, Timisoara/Romania RADS classification of the 298 lesions.

Introduction: In patients with liver cirrhosis, hepatocellular carcinoma (HCC) can be diagnosed by noninvasive imaging methods (contrast-enhanced ultrasound CEUS, contrast CT, MRI).

Aims & Methods: The aim of this study was to evaluate which is the most common enhancement pattern of HCC on CEUS in all three phases (arterial, portal, and late phase). We performed a retrospective study that included patients with a final diagnosis of HCC established by an imaging method (contrast enhanced CT or MRI) or biopsy. A total of 249 patients with HCC were examined (180 men, 69 women, mean age 64 ± 10 years): 181 patients had liver cirrhosis and 68 patients chronic hepatopathy with severe fibrosis. All 249 HCCs were evaluated by CEUS using low mechanical index ultrasound, following an intravenous bolus of 2.4 ml SonoVue. CEUS was considered conclusive for HCC if a typical pattern was present following contrast examination (hyperenhancement in the arterial phase accompanied by portal and/or late phases washout). The nodules were classified according to their size in <5 cm and >5 cm. We re-evaluated all 249 HCCs CEUS studies using the ACR CEUS LI-RADSv 2016 algorithm.

Results: After CEUS examination a conclusive diagnosis of HCC was obtained in 190/249 cases (76.3%). Arterial phase hyperenhancement pattern was present in 227/249 (91.2%) cases, arterial washout in 197/249 (79.1%) cases. The nodules were isoenhancing in the arterial phase was observed in 17/249 cases (6.8%) and hypoenhancement in 5/249 cases (2%). In the portal phase washout was observed in 111/249 cases (44.6%); in 121/249 (48.6%) patients the nodules were isoenhancing and in 17/249 (6.8%) the arterial hyperenhancement pattern was maintained. In the late phase washout was observed in 197/249 (79.1%) cases. The nodules <5 cm were diagnostic conclusive on CEUS in 63.7% (72/113), while nodules >5 cm had a conclusive result in 86% of cases (117/136), p < 0.001. CEUS examination was conclusive for HCC in 76.3% of the cases (190/249), while using the ACR CEUS LI-RADSv 2016 algorithm in 72.2% of all HCCs (180/249), p = 0.35.

Conclusion: In our study, CEUS arterial hyperenhancement is the most common pattern observed in HCC (91.2% of cases), followed by washout in the late phase (>79.1% of cases). The size of the nodule modifies CEUS sensitivity for the diagnosis of HCC: p < 0.001.

P1373 DICKKOPF-1: AS A SERUM BIOMARKER FOR PREDICTION OF HEPATOCELLULAR CARCINOMA TREATMENT RESPONSE

A. L. Sharaf 1, E. G. El-Badrawy 1, N. A. Khalifa 2

1Tropical Medicine Department, Zagazig University, Zagazig/Egypt
2Clinical Pathology Department, Zagazig University, Zagazig/Egypt

Introduction: Hepatocellular carcinoma (HCC) is the 5th most common cancer worldwide and the 3rd leading cause of cancer-related mortality. In Egypt, HCC is the 2nd most common cancer in men and the 6th most common cancer in women. Egypt has the highest prevalence of HCC worldwide and has rising rates of HCC. HCC is a disease with fast infiltrating growth and poor prognosis. This bad prognosis is due to the lack of an effective method for early diagnosis. So, it is necessary to find a specific & sensitive marker for early diagnosis of HCC and for monitoring of treatment response.

Aims & Methods: The aim of this work is to assess prognostic value of serum DKK1 in predicting treatment response, complication and survival in HCC patients. This study included 60 Patients divided into two groups. Group A: consisted of 30 patients with liver cirrhosis. Group B: consisted of 30 patients with HCC. Group B patients underwent either radiofrequency ablation or ethanol injection. Clinical assessment, routine laboratory evaluation, CT studies and measurement of serum alpha-fetoprotein (AFP) and DKK1 were performed to follow up patients and repeated to group B patients 1 and 3 months after treatment.

Results: DKK1 significantly can be used for HCC diagnosis even in HCC with inconclusive AFP. The optimum cut off value of DKK1 for diagnosis of HCC was 4.3 ng/mL (AUC 0.89, sensitivity 66.7% and specificity 96.6%) (P < 0.001). Serum DKK1 level significantly decreases after HCC treatment with either radiofrequency ablation or ethanol injection. Clinical assessment, routine laboratory evaluation, CT studies and measurement of serum alpha-fetoprotein (AFP) and DKK1 were performed to follow up patients before and after treatment.

Conclusion: DKK1 has a promising prognostic value and can be used for follow-up of HCC patients before and after treatment.

P1373 EFFECT OF FIBROBLAST GROWTH FACTOR-2 AND ITS RECEPTOR GENE POLYMORPHISMS ON SURVIVAL IN PATIENTS WITH HEPATITIS B VIRUS-ASSOCIATED HEPATOCELLULAR CARCINOMA

J. Cheong

Gastroenterology, Ajou University Hospital, Suwon/Korea, Republic of

Contact E-Mail Address: jaeyoum620@gmail.com

Introduction: Fibroblast growth factor (FGF), vascular endothelial growth factor, and hepatocyte growth factor play a critical role in the pathogenesis of hepatocellular carcinoma (HCC) and response to treatment. DKK1 has a promising prognostic value and can be used for follow-up of HCC patients before and after treatment.

Aims & Methods: We determined the association of single nucleotide polymorphisms (SNPs) in growth factor signaling–related genes with the development and progression of tumors and overall survival in patients with hepatitis B virus (HBV)-associated HCC. We assessed nine SNPs in the FGF1, FGF2, FGF receptor (FGFR)-2, Flt-1, and c-MET genes in 245 HCC patients and 483 chronic HBV carriers without HCC.

Results: None of the SNPs was associated with the risk of HCC development in HBV carriers. The FGF2 rs803879 A allele was significantly associated with small tumor size, early tumor stage, and less vascular invasion. The Flt-1 rs4771249 C allele was associated with low alpha-fetoprotein levels. Kaplan-Meier analysis showed that the patients with the FGF2 rs8038477 TT genotype had lower survival rates than the patients with the CC or CT genotype (P = 0.016) and that the FGF2 rs8038797 A allele carriers had shorter survival rates than those of patients with the TT genotype (P = 0.020). The FGF2 rs1219648 CC genotype was significantly associated with increased survival rates (P = 0.047). Multivariate Cox proportional analysis revealed that the FGF2 rs8038797 A allele (hazard ratio = 1.663, P = 0.004) and advanced stage tumor (hazard ratio = 3.430, P = 0.001) were independent prognostic factors for overall survival rates in patients with HCC.
Conclusion: These observations suggest that the SNPs of the FGFR2 and FGF2R2 genes can be potential prognostic indicators in patients with HBV-associated HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Extrahepatic HCC metastasis are associated with a poor prognosis. Nevertheless there are some effective therapies available.

Aim & Methods: The aim of this study was to assess the main sites of extrahepatic metastasis in hepatocellular carcinoma (HCC) patients and to evaluate the clinical evolution and treatment. This was a retrospective single-center study in which patients with HCC confirmed extrahepatic metastasis between January 2010 and December 2016 were evaluated.

Results: We evaluated 51 consecutive patients, 80% male, with a mean age of 64 ± 11 years at the time of metastasis. In 41% of the patients the metastases were present at the time of HCC diagnosis. In patients with subsequent metastasis, the median time until its development was 9 months (IQR: 5–16). The diagnosis of metastasis was incidental in 51% of the patients. Computed tomography (CT) was the main diagnostic method (86%) and in 18% of the cases histological confirmation was obtained. Nineteen patients underwent thoracic CT and five performed bone scintigraphy prior to metastasis. A total of 70 metastatic sites were identified, the more frequent were lung (33%) and bone (14%). The MELD score at the time of metastasis was higher than the MELD score at the HCC diagnosis (p score at the time of metastasis was 0.005). Multivariate analysis, MELD score at the time of metastasis (p = 0.002). In multivariate analysis, MELD score at the time of metastasis (p = 0.004) and metastasis treatment (p = 0.005) were independently associated with OS estimation.

Conclusion: A systematic HCC staging, with thoracic CT and bone scintigraphy, may provide an earlier metastasis detection and enable a targeted treatment with a consequent improvement in survival in this difficult-to-treat population.

P1376 MANAGEMENT OF INTERMEDIATE STAGE HEPATOCELLULAR CARCINOMA

A. Deguchi

Department Of Gastroenterology, Kagawa Rosai Hospital, Marugame-shi, Kagawa/ Japan

Contact E-mail Address: akihm41@me.com

Introduction: According to the Barcelona Clinic Liver Cancer (BCLC) staging system, intermediate stage contains very heterogeneous hepatocellular carcinoma (HCC) patients. Recently, subclassification of intermediate stage on the basis of Milano criteria and up to 7 criteria is proposed. In this study, the effectiveness of delivering bead-transarterial chemo-embolization (DEB-TACE) in intermediate stage was investigated.

Aims & Methods: 120 patients (M: F = 90:30; median age = 76; Child A: B: C = 72:44:4; BCLC stage A: B: C: D = 6:85:23:6) with unresectable HCC who received DEB TACE in our hospital were studied. The objective radiological response was classified according to the modified Response Evaluation Criteria in Solid Tumors (mRECIST) v.1.1 by using dynamic CT at one or two months after treatment. Adverse events were evaluated using NC1 CTCAE v. 4.03.

According to Bolondi’s subclassification, the patients of BCLC B stage were divided into four groups (B1: 31, B2: 19, B3: 19, B4: 10). The response rate and tumor factor associated response in these patients group were examined.

Results: The overall response rate and disease control rate in intermediate stage were 36% and 89%, respectively. Considering the subclassification, the response rate in B1 group (61%) was significantly higher than that of B2+B3 group (29%). Although B2+B3 group was constituted by the patients who did not satisfy the up to 7 criteria, only in the patients with less than 7 tumors, the response rate (60%) was similar to that of B1 group. Tumor factors associated response rate was found to be significant on univariate analysis were simple gross classification (class 5 nodular type) and number of tumor. Tumor diameter was not associated with the response.

Conclusion: For the treatment of intermediate stage of HCC, although DEB-TACE is considered to be most effective in B1 group, it is suggested that DEB-TACE is also effective in the patients with less than 7 tumors in B2+B3 group. In cases with more than 7 tumors, as the response rate is considered to be extremely low, sorafenib and arterial infusion therapy are recommended in B2+B3 group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1377 HEPATOCELLULAR CARCINOMA RECURRENCE RATE IN LIVER INFECTED PATIENTS TREATED WITH DIRECT ANTIVIRAL AGENTS. A SINGLE-CENTER EXPERIENCE

Hepatology Unit, Cardarelli Hospital, Naples/Italy

Contact E-mail Address: raffaellatortora@live.com

Introduction: In the last few years many HCV patients with previous diagnosis of hepatocellular carcinoma (HCC) have been treated with direct antiviral agents (DAAs) for HCV infection. However there are conflicting data on HCC recurrence after DAAs therapy.

Aims & Method: Aim of this study was to prospectively evaluate the rate of HCC recurrence following sustained virologic response (SVR) by DAAs. From April 2015 to September 2016 we consecutively enrolled HCV infected patients previously treated for HCC at Liver Unit of Cardarelli Hospital. All patients had a free-disease survival from HCC of at least 6 months before starting antiviral therapy. The efficacy of HCC therapy was evaluated according to mRcist criteria, CT or MRI. Radiological evaluation was carried out within 30 days from the start of therapy. All patients underwent DAAs therapy, selected on an individual basis according to the recommendation issued by the Italian association of the study of the liver.

Results: A total of 71 patients were enrolled. Among them, 42 patients had available data on SVR status and were considered for the analysis. There were 21 males (58.3%) and 15 females. The median age of the patients was 73 years (range: 52–85). The median follow-up was 12 months after the beginning of therapy (range: 6–18 months). Genotype distribution was as follows: 36 patients infected with genotype 1 (85.7%), 5 with genotype 2 and 1 patients with genotype 3. SVR was achieved in 38/42 patients (90.5%). HCC recurrence was observed in 11/38 patients with SVR (28.9%). The median time for recurrence was 9 months from the start of therapy with a range of 1–13 months; with 2 patients who showed recurrence during therapy. Among the patients who did not achieve SVR, 1/4 showed HCC recurrence after 10 months from end of treatment.

Conclusion: Treatment with DAAs are highly effective with a SVR of about 90% even in patients with advanced liver disease. Nonetheless, in patients with previous history of HCC, the eradication of HCV did not reduce the risk of short and medium-term recurrence.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Primary liver cancer is the sixth most common cancer in the world, after cancers of the lung, breast, colorectal, prostate and gastric[1]. However, the extremely poor prognosis for primary liver cancer makes it the second leading cause of cancer-related death globally (745,000 deaths, 9.1% of the total death)[2]. Histologically, the majority of primary liver cancer is either
A study was conducted to investigate the prognostic factors for survival of BCLC-C stage HCC patients in a real-life setting. The aim of this study was to identify the prognostic factors for survival of BCLC-C stage HCC patients. The study included 8677 patients who were diagnosed with primary liver cancer from 2010 to 2012 and 1836 patients were in distant metastasis stages. The results showed that AFP levels, NIACE score, and post-treatment factors for survival of BCLC-C stage HCC patients in a real-life setting. The study identified that AFP levels, NIACE score, and post-treatment factors were independent predictors of worse outcome. The study concluded that AFP levels, NIACE score, and post-treatment factors are independent predictors of worse outcome.
P1383 THE EVOLUTION OF ESOPHAGEAL VARICES IN NON CIRRHOTIC PORTAL HYPERTENSION CAUSED BY PORTAL VEIN THROMBOSIS

I. Benelharbadi1, K. Loubaris2, H. Boutallaka3, F.Z. Ajanà1
1Medicine C, Ibn Sina University Hospital, Rabat/Morocco
2Hepatogastroenterology C (medicine C), Ibn Sina University Hospital, Rabat/Morocco
3Gastro-enterology II, Military Hospital Mohamed V, Rabat/Morocco

Contact E-mail Address: ouhabimane@yahoo.fr

Introduction: Portal vein thrombosis (PVT) is defined as a partial or complete occlusion of portal vein and/or its tributaries by a thrombus. It exposes to portal hypertension (PHT) by intrahepatic occlusion and consequently to upper digestive hemorrhage, usually due to rupture of gastro esophageal varices.

Aims & Methods: The aim of this study is to specify the evolution of esophageal varices and thus risk of rebleeding in patients with PHT by PVT unrelated to cirrhosis. It is a retrospective study from January 2010 to February 2017, including 101 patients followed for PHT by PVT without liver disease in the department of hepatogastroenterology (medicine C) at Ibn Sina University Hospital of Morocco. PVT was diagnosed by abdominal doppler ultrasonography in all patients.

Results: The mean age of patients was 36 ± 5 years with extremes ranging from 11 years to 70 years. The sex ratio M/F was 0.42. Five percent of patients had a splenectomy for undocumented reasons before the diagnosis of PHT. Concerning the clinical presentation, 10.9% (n = 11) were hospitalized for melena, 60.4% (n = 61) for hematemesis and melena and 28.7% (n = 29) for non-specific abdominal pain. Clinical examination was normal in 10.9% (n = 11), showed an axies in 11.9% (n = 12), and signs of PHT such as splenomegaly and collateral circulation in 25.3% (n = 26). Among cases, complete blood count showed that 16.8% (n = 17) had thrombocytopenia, 12.9% (n = 13) had bictyonemia, and 42.6% (n = 43) had pancytopenia. In all patients, upper GI endoscopy was performed. Hypertensive gastropathy was found in 30.7% (n = 31), grade I esophageal varices (EV1) in 5.9% (n = 6), grade II in 30.7% (n = 31), grade III in 48.5% (n = 49) and gastric varices were noted in 13.9% (n = 14). These varices were with red spots in 18.8% (n = 19). All patients had abdominal doppler ultrasonography showing a PVT in 60.3% (n = 61), it was partial in 33.6% (n = 34), complete in 11.5% (n = 12). Endoscopy lead to the spleen arteriovenous malformation was found in 39.6% (n = 40). All patients performed an etiologic assessment of thrombosis, myeloproliferative syndrome was found in 8.9% (n = 9), deficiency in inhibitors of coagulation in 31.7% (n = 32), celiac disease in 4.9% (n = 5), neoplastic lesions in 2.9% (n = 3), no etiology was found in 51.4% (n = 52). Endoscopic variceal Ligation (EVL) was performed in 70.3% (n = 71), the mean number of ligation sessions was 3 and eradication of esophageal varices was noted in 69.3% (n = 70). All patients received anticoagulant therapy except those having portal cavernoma with no obvious cause and 42.6% (n = 43) of patients received beta-blockers for secondary prophylaxis. During follow up, 5.9% (n = 6) of patients have not been seen at consultation and no rebleeding was noted in 89.1% (n = 90). Concerning portal thrombosis, it was solved in 49.5% (n = 50) and stabilized in 10.8% (n = 11).

Conclusion: The evolution of esophageal varices in non-cirrhotic portal hypertension due to PVT seems to be better than in cirrhotic portal hypertension. Indeed 89.1% of patients in this study didn’t rebleed after eradication of esophageal varices.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1385 LONG-TERM OUTCOMES OF PATIENTS WITH ACUTE CALCULOUS CHOLECYSTITIS AFTER SUCCESSFUL REMOVAL OF GALBILADDER STONES WITH PERCUTANEOUS TRANSEPHATIC CHOLANGIOSCOPY: A DECADE EXPERIENCE AT A SINGLE TERTIARY CENTER

S. Dong, C.H. Oh, J.R. Moon
Department of Internal Medicine, Kyung Hee University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: gidongdong@hanmail.net

Introduction: Percutaneous cholecystostomy (PTC) has been an alternative treatment for acute calculous cholecystitis (ACC) for the patients unsuitable for early cholecystectomy. Lithotomy with percutaneous transhepatic biliary cholangioscopy (PTCS) after PCT track maturation is particularly considered for those patients with gallbladder (GB) stones who are poor surgical candidate. We examined the long-term outcome of 171 patients with ACC treated by PTCS.

Aims & Methods: This study was a retrospective observational study of 171 consecutive patients who treated with PTCS for ACC in the period from 1 Jan 2005 to 31 Dec 2015. Outcome measures included the success rates, adverse events, recurrence rate and mortality. All data were collected from patients' medical records.

Results: PTCS achieved complete clearance of GB stones in 157 patients (91.8%). The complication rate of PTCS was 3.5% (6/171). The adverse events included GB perforation (n = 3, 1.8%), hemorrhage (n = 2, 1.2%), disruption of the percutaneous transhepatic biliary drainage fistula (n = 1, 0.6%), and all of which resolved with conservative treatment. The overall recurrence rate of gallstone diseases was 11.5% during the follow up period. The incidence of recurrent gallstone diseases was significantly higher in those with completely removed GB stones than in those without complete clearance (10.2%, 16/157 vs 21.4% 3/14; p < 0.05). The frequency of recurrence of gallstone disease in patients with contrast passage to the duodenum on cholangiography after PTCS was lower than that in patients without contrast passage.

Conclusion: Gallbladder stone removal with PTCS would be recommended as an effective and safe treatment modality for the patients with acute cholecystitis who are unsuitable for surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1384 EVALUATION OF COMMON BILE DUCT CLEARANCE AFTER ENDOSCOPIC MANAGEMENT OF DIFFICULT BILARY STONES BY DIRECT PERORAL CHOLANGIOSCOPY: PRELIMINARY RESULTS OF A PILOT STUDY

Endoscopic Digestive Unit, Division Of Gastroenterology, Humanitas Research Hospital, Rozzano, Milan, Italy, Rozzano/Italy

Contact E-mail Address: andreianderloni@humanitas.it

Introduction: Incomplete stones clearance after endoscopic management of difficult biliary stones poses the risk of complications such as cholangitis. Confirmation of complete stones clearance is normally confirmed fluoroscopically after injection of contrast medium. False negative/false positive results are under/over-treatment. Direct peroral cholangioscopy (POC) refers to the use of nonspecific endoscopes for the direct visualization of the common bile duct (CBD).

Aims & Methods: We aimed to evaluate the feasibility and safety of POC to confirm CBD complete clearance after endoscopic treatment of difficult biliary stones. From 1st June 2016 to 30 March 2017 all consecutive patients treated with Dilated assisted stone extraction(DASE) for difficult biliary stones at our institution, underwent POC to verify CBD stones complete clearance. Ultraslim (5.9 mm diameter) or Slim (8.5 mm diameter) endoscopes (Fujifilm EG 530N/W or EG 530IF/P) or standard gastroscope (9.9 mm diameter) ( Olympus GIF-HQ190), under CO2 insufflation, were used by the peroral route for intubating all accessible bile ducts. Technical success rate, procedural time, outcome and side effects of POC were assessed. All adverse events were recorded.

Results: POC was performed in 26 patients (17F/9M mean age 47.4 years ± 11.9) under propofol sedation (25 patients) or deep sedation (3 patients). Mean CBD size was 15 mm ± 3.65; mean stone diameter (13.5 mm ± 1.70); mean balloon dilatation (13.5 mm ± 2.12). Intubation of the papilla and distal biliary duct was successful in 26 (100%) cases (guide-wire assistance in 17 cases, 65.4%). Hepatic hilum was reached in 13/26 (50%) patients with a complete CBD evaluation. Mean investigation time was 6.3 ± 1.5 min (range 5–9 minutes). POC showed persistent large amount of stones in 91.5% (sludge in 27.7% cases), complete stones clearance in 8.5% and a residual stone in 0.4% cases. CBD cannulation was successful in 15/17 cases (88.2%). Complete CBD clearance was noted in 14/16 cases (87.5%). Despite its utility, the success rate of bile duct cannulation and a 0.025 inch guidewire may become a single device that can facilitate common bile duct cannulation. A combination catheter with a Y-connector smoother. Therefore, the combination catheter with a Y-connector was chosen for the investigation of the bile duct for immediate POC to the CBD. Then the 0.025 inch guidewire may become a single device that can facilitate complete CBD clearance. Despite its utility, the success rate of bile duct cannulation and cost benefit requires further analysis.

Aims & Methods: We aimed to evaluate the therapeutic efficacy of a combined catheter as a single device required for BDA clearance. From January 2016 to July 2016, 11 consecutive patients with BDA ≤ 10 mm in size were enrolled in this study (Stoneone group). In all cases, the combined catheter (Stoneone) was
used for initial bile duct cannulation. Subsequently, sphincterotomy and stone extraction were performed using the combined catheter. The success rate of performing the combined procedure, procedure-related time, adverse events, and the cost of devices were compared with those in 10 patients with BDSs ≤10 mm in size who had undergone endoscopic stone clearance from April 2015 to December 2015 in historical control.

Results: The success rate of selective cannulation and stone clearance did not differ significantly (Stonetome group: 90.9% and 100% vs control group: 100% and 100%, respectively). The median time after bile duct cannulation to complete stone clearance and total procedure time in the Stonetome group were significantly shorter than those in the control group (401.5 vs 982.5, 645.5 vs 1380b, respectively). In the Stonetome group, delayed bleeding occurred in 1 patient. In the control group, bile duct injury caused by the guidewire occurred in 3 patients. The costs of the used devices did not differ significantly (Stonetome group: $678 versus control group: $669).

Conclusion: The combined catheter has the same selective cannulation ability as a conventional catheter and a similar capacity to remove BDSs as common retrieval. Therefore, the combined catheter can reduce the procedure time to remove BDSs. Disclosure of Interest: All authors have declared no conflicts of interest.

P1387 ACCURACY OF ASGE CRITERIA IN THE IDENTIFICATION OF PATIENTS WITH SUSPECTED CHOLEDOCHOLITHIASIS
C. Macedo, N. Almeida, D. Gomes, E. Camacho, S. Mendes, L. Tomé, A. M. Ferreira
Gastroenterologia, Centro hospitalar e Universitário de Coimbra, Coimbra, Portugal
Contact E-mail Address: claudia.macedo07@hotmail.com

Introduction: Society for Gastrointestinal Endoscopy (ASGE) emitted, in 2010, guidelines for the clinical orientation of patients with suspected choledocholithiasis (CL), suggesting the direct referal to endoscopic retrograde cholangiography (ERC) in certain groups. However, the ERC is an invasive exam and so it was demonstrated that a significant amount of patients classified with very strong risk of CL did not have alterations in ERC.

Aims & Methods: The aim of this work was to assess the accuracy of the ASGE guidelines in portuguese population. This is a retrospective study that included 212 patients (52.8% female sex, 47.2% male sex; mean age 73.9 (±14.6 years) admitted to the hospital from 2014 to 2016.

Results: Of the 212 patients, 28 (13.2%) had intermediate risk of CL and 184 (86.8%) had high risk, according to the ASGE criteria. These patients were submitted to the following exams/interventions: ERC (154 patients); magnetic resonance cholangiography (50 patients) and endoscopic ultrasound (8 patients). In patients initially classified with high risk of CL, this was confirmed in 119 (64.7%). The same was seen in 10 (35.7%) of the patients with intermediate risk. The overall ERC complication rate was 13% (20 patients), of whom 8 had no CL. Conclusion: The ASGE guidelines showed a limited diagnostic accuracy in the identification of patients who actually require ERC, conditioning a significant number of unnecessary procedures with subsequent complications associated with it. It is the orientation of these patients, with greater use of less invasive diagnostic techniques such as magnetic resonance cholangiography and endoscopic ultrasound.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1388 DOES FIBRIN GLUE APPLIED ON THE CHOLANGIOTOMY IN LAPAROSCOPY AVOID COMMON BILE DUCT EXPLORATION? REDUCE THE RISK OF BILE LEAKAGE? A RANDOMIZED STUDY
B. Darkahi1, G. Sandblom2, T. Norden3
1Surgery Department, Enköping/Sweden
2Surgery Department, Uppsala/Sweden
Contact E-mail Address: bahman.darkahi@gmail.com

Introduction: Laparoscopic choledochotomy as a method of extracting common bile duct stones is a technique with many advantages. One problem, however, is bile leakage along the T-tube. To some extent the leakage may be reduced if the incision is situated around the T-tube, but this technique has some disadvantages. The aim of this study was to investigate whether application of fibrin glue around the tube results in less leakage than suturing.

Aims & Methods: Between 2012 and 2016 a total of 1347 cholecystectomies were performed in Enköping Hospital. From this group, 42 patients were included in the study and randomized to suturing or fibrin glue for closing the cholecystotomy around the T tube. Postoperative cholangiography was performed after 7–10 days after surgery. The amount of flow in the abdominal drain and the level of amylase were controlled daily. If the flow ceased, the abdominal drain was extracted three days after surgery.

Results: No significant difference between the groups was seen regarding the flow of the abdominal drain or the T-drain for the first three days or operation time

Conclusion: Discussion Fibrin glue may be an option to seal cholangiostomy around the T-tube, but studies with greater statistical power are needed to confirm this.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1389 THE IMPACT OF BARIATRIC SURGERY ON ACUTE CHOLANGITIS MORTALITY AND OTHER OUTCOMES: A NATIONWIDE ANALYSIS

Introduction: Rapid weight loss after bariatric surgery (BS) has been associated with the formation of gallstones, and subsequent acute cholecystitis and cholangitis (AC). However, the complex post-surgical anatomy limits the possibility of performing an ERC as part of AC treatment. Therefore, the aim of this study was to assess the impact of bariatric surgery on mortality and resource utilization among patients with AC using a national database.

Aims & Methods: This was a case-control study using the National Inpatient Sample 2013, the largest publically available inpatient database in the United States. All patients with an ICD-9 CM code for a principal diagnosis of AC were included. There were no exclusion criteria. Patients with a past history of BS were identified using the appropriate ICD-9-SCM codes. The primary outcome was all cause mortality. The secondary outcome was resource utilization: use of ERC, cholecystectomy, length of hospital stay (LOS), total hospitalization charges and costs. Multivariate regression analyses were used to adjust for the following confounders: Age, sex, race, income in patients’ zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

Results: A total of 274,775 patients with AC were included in the study, of which 4,240 (1.7%) had undergone BS. The mean patient age was 51 years and 48% were female. After adjusting for confounders, patients with and without history of bariatric surgery had similar adjusted odds of mortality (adjusted Odds Ratio (aOR): 0.85, 95% CI: 0.51–1.43 vs 0.95, 95% CI: 0.59–1.55). As far as resource utilization, patients with bariatric surgery had lower adjusted odds of ERC (aOR: 0.28, 95% CI: 0.09–0.83, p = 0.02), but higher odds of cholecystectomy (aOR: 3.18, 95% CI: 1.00–10.05, p = 0.04). Both patient groups had similar adjusted length of stay (adjusted mean difference: 1.19 days, 95% CI: 0.09–0.83, p = 0.16) total hospitalization costs (adjusted mean difference: $2237, 95% CI: $2208 – $6782, p = 0.49), and total hospitalization charges (adjusted mean difference: $7477, 95% CI: $8955–$24549, p = 0.39).

Conclusion: Bariatric surgery has no impact on inpatient all-cause mortality among patients who develop acute cholangitis, despite its association gallstone acute pancreatitis and limited ERC performance. In addition, bariatric surgery does not affect resource utilization in this patient population as measured by length of stay and total hospitalization costs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1391 PATHOLOGICAL, CLINICAL AND RADIOLOGICAL CHARACTERISTICS OF NEOPLASTIC AND NONNEOPLASTIC GALLBILDDER POLYPS
S. Z. Wennmacker1, A. Van Dijk2, J. Reassens1, N. Hasami1, J.P.h. Drenth3, C. J.h.m. Van Laarhoven1, P. De Reuver1, I.D. Nagtegaal4

4Radboud University Nijmegen Medical Center, Radboud University Nijmegen Medical Center Dept. of Pathology, Nijmegen/Netherlands
Contact E-mail Address: sarah.wennmacker@radboudumc.nl

Introduction: Prevalence of gallbladder polyps in the Netherlands is 943 per 100,000 cholecystectomies. Histopathologically these gallbladder polyps can be divided into neoplastic polyps (with malignant potential) and nonneoplastic polyps (without malignant potential). Although cholecystectomy is only indicated for neoplastic polyps, 47% of polyps after cholecystectomy are nonneoplastic. Further information on the pathological characteristics and subsequent clinical and radiological features could be useful to predict neoplastic or nonneoplastic nature of the gallbladder polyp before surgery.

Aims & Methods: To assess pathological characteristics of neoplastic and non-neoplastic gallbladder polyps and identify preoperative clinical and radiological predictors for neoplastic and nonneoplastic polyps. Data of the Dutch Pathology Registry was used. In this search 2081 histopathologically proven gallbladder polyps (or focal) wall thickening ≥5 mm were identified in patients of ≥18 years undergoing primary cholecystectomy between 2003 and 2013. Of these
Disclosure of Interest:

Preoperative radiological investigations is poor. Nonneoplastic polyps are confirmed, identification of these characteristics on MRI is less common. Although pathological characteristics of neoplastic and nonneoplastic polyps were found to be significantly older than patients with nonneoplastic polyps (mean age 65.0 vs 54.2 years, p < 0.001). Nonneoplastic polyps were significantly larger (mean size 18.1 mm (SD 17.9) vs 7.5 mm (SD 5.9), p < 0.001), more frequently presented as wall thickening (29.2% vs 15.6%, p < 0.001) or as a single polyp (88.3% vs 68.0%, p < 0.001). Gallstones were more frequently found in gallbladders with nonneoplastic polyps (50.1% vs 40.4%, p < 0.001). No preoperative clinical features were predictive for neoplastic or nonneoplastic polyps. Presence of a single polyp on ultrasound was a predictor for neoplastic polyps (OR 6.00 (95%CI 1.32-27.31)). Size and type of polyp were often not mentioned in ultrasound report, or different from histopathological confirmation.

Results: Except for age, no clinical characteristics for neoplastic polyps were identified in this cohort. Although pathological characteristics of neoplastic and nonneoplastic polyps are confirmed, identification of these characteristics on preoperative radiological investigations is poor.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction:

Metformin has evidence of antineoplastic activity in some cancer cells. Aims & Methods: This study was performed to demonstrate in the bile duct cancer cells whether metformin inhibits the proliferation of cancer cells by inducing apoptosis and affects the expression of gene-related proteins involved in cancer growth, and to identify how metformin affect molecular mechanisms involved in the inhibition of cancer cell growth. Human hepatobiliary bile duct cancer cells were cultured. 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assays were performed to determine the effect of metformin on cell proliferation. Apoptosis was measured by a cell death detection enzyme-linked immunosorbent assay and caspase-3 activity assay. Various protein expressions with or without specific SiRNA transfection were measured by Western blot. The migratory activity of the cancer cells was evaluated by wound healing assay.

Results: 1) Metformin suppressed cell proliferation in bile duct cancer cells by inducing apoptosis. 2) Metformin inhibited mammmalian target of rapamycin (mTOR) by activation of AMPKThr172 - tuberous sclerosis complex 2 (TSC2) pathway, and hyperglycemia impaired metformin-induced AMPKThr172 activation and enhanced phosphorylation of AMPKSer485. 3) Metformin increased expression and secretion of IGF-1 receptor 1 (IGF-1R), insulin receptor substrate 1 (IRS-1) and AKT pathway on TSC2, and hyperglycemia impaired metformin-induced inhibition of IGF-1R-IRS-1-AKT pathway. 4) Metformin modulated invasiveness of bile duct cancer cells, and the effect was impaired by hyperglycemia.

Conclusion: This study shows that metformin has antineoplastic effect in bile duct cancer cells, and the effect of metformin is attenuated in the hyperglycemic environment. In addition, AMPK and IGF-1R play a key role in the proliferation of bile duct cancer cells, and thus they are expected to be important targets for future development of chemotherapeutic agents.

Introduction: Gallbladder cancer (GBCa) is often diagnosed at advanced stage due to lack of symptoms and the tissue cannot be obtained easily with anatomical reason. The patients with early GBCa has not showed any symptoms and the tissue cannot be obtained easily with anatomical reason. To overcome the weakness of the current methods for the diagnosis of GBCa, we focused on the possibility of “liquid biopsy” with bile juice on the concept of non-invasive diagnostic method in human. We aim to develop diagnostic markers or tumor DNA in bile. To achieve good treatment effect in future, so called “precision medicine” approach based on the character of the each tumor is mandatory.

Aims & Methods: Thirty patients with GBCas were enrolled in this study. Bile juice obtained from 24 of 30 patients was analyzed for mutations of 50 oncogenes (Cancer panel; Haloplex, Agilent Technology) by next generation sequencing (NGS; Illumina, San Diego, CA, USA). Tumor tissues from 20 of 30 patients were analyzed as well as bile juice. Each sample was obtained prior to the
treatment. As negative controls, 19 non-GBCa bile juice and 33 non-GBCa tissue samples were analyzed for mutations of 50 oncogenes in the same way.

Results: In total, 14/19 (73.7%) bile juice samples of non-GBCa contained mutations. In non-GBCa tissues, 31/33 (93.9%) samples were positive for mutations. Mutations in tumor could be detected in bile juice using NGS. Liquid biopsy with bile juice may help us to diagnose GBCa because of high PPV (100%). It may allow us to make new genetic diagnosis of GBCa.

P1396 PREDICTIVE MODEL FOR THE NEOPlastic POTENTIAL OF GallBLADDER POLYPS

J.K. Lee
Gastroenterology, Samsung Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: jongk lee@samsung.com

Introduction: While many studies have attempted to define the risk factors for neoplastic potential of gallbladder polyp, precise adaption of the risk factors individually in a real treatment strategy of gallbladder polyp remains elusive. Because the probability for neoplastic potential of gallbladder polyp using a combination of several risk factors before surgical resection would be useful in patient consultation.

Aims & Methods: This study was designed to provide the statistical predictive model for neoplastic potential of gallbladder polyps. We collected data of patients confirmed as GBP through cholecystectomy at Samsung Medical Center between January 1997 and March 2015. Those with a definite evidence for malignancy, such as adjacent organ invasion, metastasis on preoperative imaging studies, polyp larger than 15 mm, and absence of proper preoperative ultrasonography imaging, were excluded. A total of 1976 patients were enrolled. To make and validate the predictive model, we divided the cohort into the modeling group (n = 979) and validation group (n = 997). Clinical information, ultrasonographic findings, and blood tests were retrospectively analyzed. A prediction model for the probability of neoplasia was fitted from the training set using the logistic regression method equipped with backward elimination with significance level for removal of P ≥ 0.15 for variable selection. The performance of a fitted prediction model was evaluated by the area under the curve (AUC) of a receiver operating characteristic (ROC) curve. A cutoff value of the fitted risk score was chosen by the Youden Index.

Results: Clinical factors of older age, single lesion, sessile shape, and polyp size showed statistical significance of neoplastic potential of GBP in the modeling group. A predictive model for neoplastic potential of GBP was constructed utilizing the statistical outcome of the modeling group. Statistical validation was performed with the validation group to determine the optimal clinical sensitivity and specificity of the predictive model. Optimal cut-off value for neoplastic probability was 7.4%. *Probability of Neoplastic GB polyp = e^(e/−7.4) where e = 2.7182 is the base of the natural logarithm and P (predictive score) = −7.3633 + 0.0374 x [Age] + 0.6667 x [Number] + 0.2189 x [Size].

Conclusion: The predictive model for neoplastic potential of GBP may support clinical decision before cholecystectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1397 COMPARISONS OUTCOMES FOR CONTROLLED PHOTODYNAMIC THERAPY IN HIGH GRADE UNRESECTABLE HILAR CHOLANGIARCINOMA

E.T. Park, B.C. Yun, S.U. Lee, B.H. Han
Internal Medicine, Kosin University, Gospel Hospital, Busan/Korea, Republic of

Contact E-mail Address: eunpark@hamnail.net

Introduction: Photodynamic therapy (PDT) provide clinical benefit for patients with unresectable biliary malignancy. In this study, we evaluate the efficiency of controlled PDT for unresectable primary and secondary high-grade hilar cholangiocarcinoma (CC).

Aims & Methods: In cases of high-grade unresectable hilar CC (Bismuth type III or IV) and gallbladder (GB) cancer invasion to hilar portion (Group A), we performed controlled PDT. Controlled PDT means malignant stricture dilatation intervention using balloon catheter up to 150 seconds. Between July 2010 and June 2015, 26 cases (31) of high grade unresectable hilar CC or GB cancer invasion to hilar portion were enrolled for Group A, 23 cases(26) of high-grade unresectable hilar CC (Bismuth type III or IV), 3 cases of GB cancer with hilar invasion were enrolled for Group B. On three months later, serum bilirubin levels decreased from 7.1 to 5.2 mg/dL in group A, 6.9 ± 5.2 to 5.2 ± 3.7 mg/dL in group B (p < 0.05). PDT-induced cholangitis is developed in Group A (3/31, 9.6%) and B (7/26, 26.9%) within seven days (p < 0.001). Progression free survival is superior Group A to Group B that of 14.8 months vs. 8.9 months (P < 0.05).

Conclusion: Controlled PDT with straight applying cylindrical diffuser promise efficacy for clinical parameters and progression free survival compared with transpapillary PDT in unresectable high-grade hilar CC and GB cancer. Additionally, diminished post-PDT cholangitis within 7 days affect improving long term progression free survival.

Contact E-mail Address: gambitta.pierto@asst-fatebenefratelli-sacco.it

Introduction: Adenoma of the major duodenal papilla is clinically important because this lesion is premalignant and should be resected completely. Endoscopic papillotomy of ampullary adenomas is a promising alternative to surgical resection, however acute and delayed pancreatitis represent a major complication of this procedure.

Aims & Methods: We evaluated the clinical importance of pancreatic duct drainage after endoscopic papillotomy in order to prevent early (acute pancreatitis) and late (pancreatic duct orifice stenosis) complications of this procedure. Our single-centre study with a minimal follow-up of 1 year, includes 19 patients who underwent endoscopic ampullotomy between 2012 and 2016. Careful preoperative evaluation was performed by EUS (100% of patients) and CT (94%). After a collective evaluation between the surgeon and the endoscopist, patients were candidate for endoscopic ampullotomy. Outcome parameters included ampulloma characteristics, biotopic accuracy as well as safety, efficacy, recurrence rate, and survival.

Results: Endoscopic resection was successful in 15 patients (79%). Histological recurrences revealed non-specific changes (10.5%), low or medium-grade dysplasia (52.6%), high-grade dysplasia (15.8%) and carcinoma (21%). Biotopic accuracy was 68.4%. In 4 cases histologic specimen revealed an invasive carcinoma: 2 patients underwent pancreaticoduodenectomy and two were treated conservatively with placement of biliary and pancreatic stents due to the high preoperative risk. After complete endoscopic resection (15 patients), pancreatic stents were placed in 10 cases (66%). In five cases the postoperative pancreatic fistula stents were not possible due to anatomical difficulties: 2 developed mild pancreatitis after papillotomy; 1 patient developed, as late complication, a stenosis of the pancreatic orifice: the patient died of severe necrotic pancreatitis two years later. Hemorrhage was observed in 2 patients, all with pancreatic stents. Recurrence occurred in 2 patients (10.5%), both were retreated by deep ablation and dielectric ablation (APC).

Conclusion: Pancreatic stent placement after endoscopic ampullotomy is mandatory to prevent acute and delayed pancreatic complications. Preoperative strategy should be accurate by MRI, EUS and ERCP, in order to define the anatomy of the pancreatic duct aiming to improve the success rate of pancreatic stent placement after papillotomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: Mahmoud_m_wj@hotmail.com

Introduction: Cholangiocarcinoma is a neoplasia arising from the intra- or extrahepatic bile duct lining epithelium. Cholangiocarcinoma are presents less than 2% of primary malignancy, however, it is the second common primary hepatobiliary malignancy. Till date, many carcinogens have already been identified and the relevant information with regard to these agents is available. One example is the potentially harmful presence of heavy metals that can cause serious health problems. Many studies were performed to expose heavy metals from their effectiveness. The heavy metals in drinking-water pose the greatest threat to public health in this regard. Nile River water is seriously contaminated with heavy metals, pesticides and organochlorine carcinogens. This study included 45 patients with cholangiocarcinoma (diagnosed after radiological &histopathological examination) and 20 healthy control attending Mansoura Surgical Gastroenterology centre. All patients and control were permanent residents of North Delta region and the patients were recruited before receiving chemotheraphy or radiotherapy. There were no restrictions based on age, sex, or tumor stage. The serum samples were analyzed for concentrations of zinc, lead, cadmium, iron and chromium by the acid digestion method followed by using atomic absorption spectrometry (AAS). "Bud Scientific Accurus 214 atomic absorption spectrophotometer". The results are reported in mg/L. In addition to CA 19-9 was assayed by IMMULITE® 2000 Xi immunoassay system supplied by Siemens Healthcare (GmbH Henkenstr. Erlangen Germany) using its commercial kits.

Results: The serum levels of Zn, Pb, Co, Cd and Fe were significantly higher in patients having cholangiocarcinoma more than control subjects (P < 0.001). Pressive increase in the median values of serum levels of lead (Pb) was found in in well differentiated to moderately differentiated to undifferentiated tumours. (P < 0.05). When correlation was made between the heavy metals and CA-19-9 and the survival of the patients, it was found that Cd only has a positive correlation with CA19-9 and negative correlation with the survival of the patients (P < 0.5, P < 0.01) respectively.

Conclusion: The results from this study suggest that cholangiocarcinoma in the Nile Delta region is significantly associated with high serum levels of heavy metals especially Cadmium and lead.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Early surgery is the standard treatment in patients with resectable periampullary or pancreatic head cancer with jaundice. However, early surgery is not always possible, however, it could be a necessary for patient with jaundice at diagnosis or for those undergoing neoadjuvant treatment. Most studies considered plastic stents for BPD, although SEMS are currently considered superior. A recent RCTS showed that fully covered SEMS are associated with better outcomes compared to plastic stents.

Aims & Methods: Aim compare the rate of endoscopic reintervention (Stent failure of PBD) before surgery and post operative outcome of metal vs plastic. We conducted a bibliographic search using PUBMED, EMBASE including randomized and non randomized trials. OR using the Manhth-Haemzel method was used for dichotomous variables. Weighted mean differences (WMD) were used as the summary statistic for quantitative analysis of continuous variables, Quantitative synthesis was performed using Review Manager version 5.0.
Primary outcome was the rate of endoscopic reintervention before surgery. Secondary outcomes were mortality, overall pancreatic surgical mortality, postoperative complications, hospital readmission, overall pancreatic fistula, overall biliary anastomotic leak, overall postoperative mortality. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

Results: Three RCTs and five non-RCTs were selected including 909 patients. Of these, 308 patients (33%) were treated with SEMS and 609 (67%) with plastic stents. The rate of endoscopic reinterventions after PBD was significantly lower in SEMS compared to plastic stent (OR 0.44; 95%CI 0.20–0.96; p = 0.04). The rate of postoperative pancreatic fistula was significantly lower in the metal stent group (OR 0.44; 95% CI 0.28–0.69; p < 0.01). The rate of postoperative surgical complications, hospital readmission, overall biliary anastomotic fistula and postoperative mortality did not differ between the two groups.

Conclusion: Metal stents are more effective than plastic and should be preferred for biliary drainage when a resectable pancreatic head or pancreatic head tumor is diagnosed when early surgery without PBD is not feasible. However, more RCTs are needed before a firm conclusion could be made.

Introduction: Dietary fat consumption affects the human body fat composition. It has been described that unsaturated fatty acids, enriched in human pancreatic native lipids (AP) [1]. Preliminary results analyzing indirect data have also suggested that patients with AP from world regions with a high unsaturated fat intake have a worse outcomes at lower body mass index [2]. We have also described that oleic acid (an unsaturated fat acid) chlorohydrins are associated to worse outcomes [3]. The Mediterranean regions have a higher unsaturated fat acid intake.

Aims & Methods: We aimed to compare the incidence of necrotizing AP, persistent organ failure (POF) and mortality among patients with AP from centers located in Mediterranean region (group M) and patients in centers in other regions (group C). This was a retrospective analysis of a prospective multicenter (23), nation-wide cohort of patients with AP: the ATLANTIS database. Group M included patients from Spanish autonomous regions in contact with the Mediterranean Sea. Group C included all other autonomous regions. Necrotizing AP and POF were defined according to the revised Atlanta classification. Chi² was used for univariate analysis. Multivariate analysis was performed by means of binary logistic regression, including in the model: sex, body mass index > 30, alcoholic etiology and Charlson score (it includes age and comorbidity) ≥ 3.

Results: We analyzed 1655 patients, 854 (52%) from group M (12 centers) and 801 from group C (12 centers) with a mean age of 64.84 (66%) with median age of 68.95 (1%–94.1%) males. The incidence of necrotizing AP was 281 (17%) patients, persistent organ failure: 113 (7%), mortality 70 (4%). The proportion of patients with necrotizing AP was higher in group M: 178 (21%) vs 103 (13%), p < 0.001. POF was also more frequent in group M: 59 (5%) vs 34 (4%), p = 0.002. Finally, mortality was higher in group M: 49 (6%) vs 21 (3%), p = 0.002. In multivariate analysis, group M was independently associated to necrotizing AP [adjusted OR (aOR) 1.7 (1.3–2.3, p < 0.001), to POF [aOR 2 (1.3–3.1), p < 0.001] and mortality [aOR 2.6 (1.5–4.5), p < 0.001].

Conclusion: Patients from the Mediterranean regions of Spain have a higher incidence of necrotizing AP, POF and mortality. We hypothesize that this disbalance is associated to a higher diet unsaturated fat intake.

Introduction: Splenic venous thrombosis (SVT) is a common vascular complication of acute pancreatitis (AP). There is paucity of data on its frequency, risk factors, outcome and natural history. Coagulation abnormality has been implicated but not proven as a cause of SVT in AP.

Aims & Methods: We aimed to prospectively study the frequency, risk factors and extent of SVT in patients with AP as well as role of thrombophilia in causation of SVT. Patients with AP presenting to our centre between January 2015 and June 2016 were prospectively evaluated with contrast enhanced computerized tomography (CECT) abdomen for presence of SVT. These patients were subjected to detailed analysis of coagulation parameters. Outcome was assessed in terms of presence or absence of necrosis, severity, organ failure, need for intervention and mortality. None of the patients with SVT were given anticoagulation.

Follow-up ultrasound Doppler was performed to look for the status of SVT.

Results: Nineteen patients with AP (15 males, mean age 31.85 ± 13.34 years) were evaluated of which 26 (27.1%) had SVT. Single vessel, two vessels and three vessels were involved in 19 (73.1%), 3 (11.5%) and 4 (15.4%) patients respectively. Splenic vein, portal vein and superior mesenteric vein involvement were seen in 19 (73.1%), 3 (11.5%) and 4 (15.4%) patients respectively.

Follow-up ultrasound Doppler was performed to look for the status of SVT. Patients with AP presenting to our centre between January 2015 and June 2016 were prospectively evaluated with contrast enhanced computerized tomography (CECT) abdomen for presence of SVT. These patients were subjected to detailed analysis of coagulation parameters. Outcome was assessed in terms of presence or absence of necrosis, severity, organ failure, need for intervention and mortality. None of the patients with SVT were given anticoagulation.

The aim was to evaluate the efficacy of local instillation of antibiotics into walled-off pancreatic necrosis. Between 2012 and 2016 we evaluated all patients treated with endoscopic transmural drainage and necroscopy (EDTN) and concomitant local instillation of antibiotics. We added antibiotics (either gentamicin, vancomycin, or amphotericin B) to the irrigation fluid according to the microbiological findings. The antimicrobial efficacies of local and systemic antibiotics were evaluated using uni- and multivariate logistic regression analyses and Kruskal-Wallis test by stratification of the isolates in sensitive versus not sensitive/antibiotics not given.

**Results:** Ninety-one patients were included. At the first drainage 81 (86%) patients had infected and 10 sterile WON. A total of 139 isolates were found at the first drainage. Most patients were infected with enterococci (44%) or other gram-positive cocci. More than a quarter of the infected patients had fungal species cultured. The infected patients often had polymicrobial infections (56%). At the second culture 152 isolated were found. Neither local nor systemic antibiotics were associated with the eradication of microbes between first and second culture. Between second and third culture, the use of local antibiotics was associated with the eradication of microbes (OR = 2.54, p = 0.01), but not systemic antibiotics (P = 0.33) (Table). Between first and second culture 12 patients with fungal infections were treated with local amphotericin B. In all 12 patients the fungus was eradicated. After second culture 20 patients were treated local amphotericin B and in 17 (85%) patients the fungus was eliminated at the third culture.

**Conclusion:** Our data suggest a better efficacy of local antibiotics in the treatment of infected WON compared to systemic antibiotics. The local instillation of antibiotics may be a promising alternative or supplement to systemic administration. Particularly the use of local instillation of amphotericin B appears to be effective in the treatment of fungal infections.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Aims & Methods:** We aimed to create a new scoring system, which can predict the severity of AP in early phase of disease. Evaluation of simple attainable potential prognostic parameters obtained at admission (or not later than 6–12 hours after-wards) from patients diagnosed with AP will be performed to assess their potential correlation with the disease severity. Approximately 1200 (900 + 300) patients from multiple centers will be enrolled into this trial using the Registry. This is an observational prospective cohort study (in the which the care or services that patients receive will not be altered; therefore it has a relatively low-risk. The study has an ethical approval by the National Hungarian Ethical Authority (ETT TUKEB). Study management will strictly follow the Ethical Guidelines for Observational Studies.

**Results:** 600 patients were enrolled in the EASY study from different international centers so far. In early phase of AP vomiting, loss of weight, fever, abdominal tenderness, elevated serum creatinine and lactate dehydrogenase level were most common findings in severe AP, as opposed to the mild and moderate groups.

**Conclusion:** EASY score may be an easy and accurate system to evaluate the early severity of AP. Although some parameters have shown correlation with the severity of AP in early phase of the disease, we have to include more patients to have reliable results.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Aims & Methods:** The aim of this study was to evaluate the effect of chronic ischemic heart disease and chronic obstructive pulmonary disease (COPD) in the outcome of acute pancreatitis (AP), in our population. Retrospective cohort study that included all patients admitted with AP from January 2003 to December 2016, in a tertiary referral center. Demographic and clinical variables were analyzed by logistic regression (SPSS v23). Clinical outcomes included organ failure (OF), persistent OF (>48 h), intensive care unit (ICU) admission and mortality.

**Results:** A total of 553 patients with AP were included, 58.4% male, median age 80 (18–98) years. Most common etiologies included gallstones (38.9%) and alcohol (27.3%). Twenty-three percent (n = 129) developed OF (in 43% persistent) and 26.8% (n = 148) were admitted in UCI. Mortality rate was 5.6% (n = 31). Fifty-six patients (10.1%) had previous history of coronary disease and 5.1% (n = 28) had been diagnosed with COPD. The presence of coronary disease and COPD were not associated with higher Ramson’s score (≥3), p = 0.076 and p = 0.959, respectively. No association was found between previous history of coronary disease and the development of OF (p = 0.525), persistent OF (p = 0.287), need for ICU admission (p = 0.115) and mortality (p = 0.262). There was also no association between OF and COPD found between previous history of coronary disease and COPD (p = 0.914). No association was found between previous history of OF (p = 0.803), persistent OF (p = 0.588), need for ICU admission (p = 0.514) and mortality (p = 0.720). At multivariate analysis (correcting for age and gender) coronary disease and COPD were not independent predictors of worse outcome in AP.

**Conclusion:** In our population, previous history of coronary disease and COPD were not predictors of worse outcome in AP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Acute pancreatitis (AP) is an uncommon but potentially devastating condition that may occur in patients with organ transplantation. Reported outcomes included organ failure (OF), persistente OF (pOF), mortality, and late recurrence following liver transplantation in our center. We were unable to identify a single risk factor for development of AP. Late AP occurred in 14 patients (7%) with a median delay of 31 months after liver transplant (range 2-176). In 12 patients AP was mild with no mortality and the following etiologies were represented: 4 post-ERCP, 2 alcoholic, 1 biliary (stones and stones), 1 drug-induced (tumour necrosis), 1 obstructive (pancreatic cancer); in 3 patients the etiology was unknown. One patient developed a pseudocyst. Two patients with late acute pancreatitis had a severe necrotizing form and both died. One patient with cirrhosis of the liver graft had chronic rejection and post-ERCP pancreatitis which was complicated by retroperitoneal hemorrhage and graft failure. The other patient with necrotizing pancreatitis of unknown etiology developed MODS and eventually died. Male patients (p = 0.01) and patients transplanted for end stage liver disease resulting from chronic hepatitis B are more likely to develop post-liver transplantation pancreatitis.

Introduction: Pancreatic exocrine insufficiency is a late complication of chronic pancreatitis; its clinical onset is characterized by steatorrhea and weight loss, borborygmi, flatulence, abdominal pain and malnutrition. Exocrine and endocrine pancreatic function decreases differently in various diseases (autoimmune, paraduodenal, genetic, idiopathic). It has been observed that there has been a recovery of exocrine pancreatic function in autoimmune pancreatitis. In the literature there are no studies analysing the exocrine pancreatic function over time. The fecal elastase test is a good test procedure to evaluate the exocrine pancreatic function
Aims & Methods: The objective of the retrospective study was to re-evaluate a set of patients with chronic pancreatitis with the aim to evaluate the pancreatic exocrine function over time, in particular, by comparing the exocrine pancreatic function in subgroups of patients with different types chronic pancreatitis. Pancreatic exocrine function was estimated through fecal elastase in 143 patients with at least 2 values each (classified into normal, mild and severe exocrine pancreatic insufficiency), the first one taken at the diagnosis of chronic pancreatitis. Patients undergoing surgical pancreatic resection before the second value of fecal elastase were excluded. Etiology was classified in: biliary pancreatitis/sequela of necroizing pancreatitis (15), autoimmune (69), paraduodenal (15), genetic (17) and idiopathic (27).
Results: The results show a high frequency of severe exocrine pancreatic insufficiency in the moment of diagnosis of chronic pancreatitis (38%) and it appears stable over the following 5 years. Autoimmune and paraduodenal chronic pancreatitis are correlated with severe exocrine pancreatic insufficiency at diagnosis in a high percentage of cases (51% and 40%), biliary/sequelae of necroizing pancreatitis and idiopathic pancreatitis in an intermediate (33% and 26%), while genetic in a lower percentage (12%).
Conclusion: The exocrine pancreatic function in patients with autoimmune pancreatitis improved in the first five years of the disease, probably due to the efficacy of steroid/immunosuppressive therapy. Pancreatic endocrine function was less compromised at diagnosis, but showed a progressive deterioration in the first five years. Endocrine and exocrine insufficiency were strictly correlated.

Introduction: The term “painless” chronic pancreatitis (CP) represents a specific subset of CP characterized by the lack of pancreatic pain. So far, scarcity of data has been reported in the literature about this matter and what differentiates this group of patients from those with chronic pancreatitis associated with pancreatic pain.
Aims & Methods: The aim of the present study is to characterize “painless” CP from the epidemiological, clinical, radiological, functional, and follow-up standpoint, through a comparison with other forms of chronic pancreatitis presenting with pancreatic pain. The Institutional Database of the Gastroenterology Unit of the Verona University was queried, and all chronic pancreatitis cases were retrieved. Patients were clustered based on the presence of “pancreatic-specific pain” into “painless” and “pain-associated” CP. A retrospective case-control analysis was carried out.
Results: Of 678 patients included from March 2006 to March 2016, 436 were considered eligible for the present study. Of these, 368 (84%) were affected by pain-associated CP, while 68 (16%) had “painless” CP. “Painless” patients were older (median age of 58.5 ± 10.8 vs 42.5 ± 15.3, p < 0.001), less frequently presenting with a history of alcohol consumption (35% vs. 55%; p < 0.001), more frequently diabetics (18% vs. 1%; p < 0.001), presenting with steatorrhea (16% vs. 2%; p < 0.001), and asymptomatic (63% vs. 2%; p < 0.001) compared to pain-associated controls. From the radiological standpoint, cases less cases were radiologically presenting with exocrine unbalances than controls (90% vs. 68%; p < 0.001). Moreover, in most of painless cases, the CP cause remained unknown (56%). After a median follow-up of 2.6 ± 2.3 years, the incidence of diabetes was higher in the painless cases than in controls (48% vs. 30%; p < 0.006).
Conclusion: The present study represents the first definition of "painless" CP so far reported in the literature. The "painless" CP is a distinct entity from the epidemiologic, clinical, and radiological standpoint when compared to other forms of CP characterized by pancreatic pain.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Recently, EUS-guided pancreatic duct drainage with transmural stent (EUS-PD) has been used for patients with painful obstructive pancreatitis in whom endoscopic retrograde pancreatography (ERP) has failed. Although the feasibility and safety of EUS-PD with a fully covered self-expandable metal stent (FCSEMS) has been assessed, little is known about the long-term outcomes of EUS-PD with a fully covered self-expandable metal stent (FCSEMS). Removability of an FCSEMS in long-term use and higher cost are the main concerns of EUS-PD with an FCSEMS compared with EUS-PD with a plastic stent.
Aims & Methods: The aim of this study is to evaluate the procedural and long-term outcomes of EUS-PD with an FCSEMS for patients with painful obstructive pancreatitis who failed ERP. Forty-one consecutive patients with painful obstructive pancreatitis underwent EUS-PD with an FCSEMS after failed ERP. The removability without stent exchange was considered in malignant MPD strictures or complete MPD obstruction in benign pancreatic stricture. Technical and clinical success, adverse events, and stent patency were assessed. An endoscopic examination and CT scan was performed every 6 months to assess stent patency in benign stricture.
Results: 15 patients had malignant MPD obstruction and 26 patients had benign stricture. EUS-PD was successful in all 41 patients (technical success rate, 100%), and symptoms improved in all patients (clinical success rate, 100%). EUS-guided pancreaticogastrostomy (n=39) and pancreaticogastrojejunostomy (n=2) were performed. Pain scores improved significantly after FCSEMS placement (P<.01). Early mild-grade adverse events occurred in 5 patients (12.2%) with self-limited abdominal pain, which resolved with conservative treatment. Late adverse events developed in eight patients (22.2%), including distal stent fracture (n=6), stent occlusion (n=2). These patients were successfully treated endoscopically. No other adverse events related to FCSEMS, including stent migration, pancreatic sepsis, and stent-induced ductal stricture were observed during follow-up periods.
Overall mean stent patency duration was 412 days (range 14–1081) during mean follow-up period of 427 days. Median stent patency duration in patients with malignant strictures was 95 days (range 14–297). Mean stent patency in benign stricture was 525 days (range 121–1081). No patients with malignant strictures required FCSEMS revision or exchange during follow-up periods. FCSEMS removal and exchange was successful in patients with benign strictures until 3-year placement of an FCSEMS. Prospective randomized trial comparing EUS-PD with FCSEMSs and plastic stents may be warranted for painful obstructive pancreatitis after failed ERP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Fundamental aspects in the treatment of pancreatic exocrine insufficiency (PEI) include pancreatic enzyme replacement therapy (PERT). Monitoring the symptoms of malabsorption as well as the nutritional markers is essential.

Aims & Methods: To follow-up patients with PEI receiving PERT and to provide normal nutritional status by optimizing the suboptimal PERT if necessary. Study enrolled 142 patients (88 males, mean age 52 years): 82 patients had chronic pancreatitis (CP), 30- acute pancreatitis (AP), 30- pancreatic cancer/pancreatic adenocarcinoma (PDAC). Enrolled 142 patients (88 males, mean age 52 years): 82 patients had chronic pancreatitis (CP), 30- acute pancreatitis (AP), 30- pancreatic cancer/pancreatic adenocarcinoma (PDAC).

Results: No patients with malignant strictures required FCSEMS revision or exchange during follow-up periods (427 days). Median stent patency in malignant stricture was 95 days (range 14–297). Mean stent patency in benign stricture was 525 days (range 121–1081). No patients with malignant strictures required FCSEMS revision or exchange during follow-up periods. FCSEMS removal and exchange was successful in patients with benign strictures until 3-year placement of an FCSEMS. Prospective randomized trial comparing EUS-PD with FCSEMSs and plastic stents may be warranted for painful obstructive pancreatitis after failed ERP.

Conclusion: Proper follow-up and correction of suboptimal PERT as well as optimization may reduce the risk of severe malnutrition complications and associated morbidity and mortality by ensuring optimal therapeutic results and better quality of life.

PI420 HU R MEDIATED POST-TRANSCRIPTIONAL REGULATION OF HO-1 AND INHIBITORS OF APOPTOSIS PROTEINS IS ASSOCIATED WITH THE POOR CLINICAL OUTCOMES AMONG PATIENTS WITH Pancreatic CARCINOMA.

Z. Dambraszkas, A. Gulbinas, A. Jakstaite, A. Urboniene
Institute For Digestive Research, Lithuanian University of Health Sciences, Kaunas/Lithuania

Contact E-mail Address: zilvinas.dambraszkas@gmail.com

Introduction: The mRNA binding protein HuR is involved in the post-transcriptional regulation of cytoprotective molecules, such as COX-2, HO-1 and inhibitors of apoptosis proteins (IAP1, IAP2, XIAP, SURVIVIN), and might be related to poor prognosis in numerous cancer types. However, the association of HuR, COX-2, HO-1 and IAPs family, and their impact on chemoresistance and carcinogenesis in PDAC still remain unclear.

Aims & Methods: The aim of our study was to assess the relevance and correlation of the IAP regulation by mRNA stabilizing protein HuR and HO-1 and/or COX-2 signaling pathway, and to determine the association with clinicopathological parameters and prognosis of PDAC. Data of 32 patients after pancreateodudodenal resection (PD) in 2011–2016 were analyzed. Patient’s mRNA expression levels of HuR, COX-2, HO-1, IAP1, IAP2, Survivin and XIAP were determined in normal pancreatic tissue obtained from organ donors. Additionally, the correlations among HuR, COX-2, HO-1, IAP1, IAP2, Survivin and XIAP, both as their respective correlations with clinicopathological parameters were analyzed. The Kaplan-Meier method and log-rank tests were used for univariate analysis. Cox proportional hazard model was applied to identify prognostic factors that were independently associated with survival.

Results: HO-1, COX-2, HuR, IAP1, IAP2 mRNA expression were accordingly 3-fold, 8.8-fold, 1.5-fold, 4.8-fold and 5-fold higher, while XIAP and Survivin mRNA expression were 3.8-fold and 3.4-fold lower when compared to normal pancreatic tissue. Expression of HuR was positively associated with COX-2, HO-1, IAP1, IAP2, XIAP. High expression levels of HuR were significantly correlated with higher G stage and microvascular invasion, while high levels of XIAP were negatively associated with microvascular and perineural invasion. Univariate analysis revealed that mRNA expression of COX-2 and XIAP correlated with worse survival, tumor differentiation and perineural invasion were significantly associated with overall survival (OS) of PDAC patients. In multivariate analysis, high levels of HuR, lymph-node metastases, tumor differentiation and perineural invasion were independently correlated with lower OS in patients with PDAC.

Conclusion: Our results suggested that upregulation of HuR in PDAC patients were significantly related with poor outcome. Even though, significant correlation with IAP proteins in PDAC was noticed, more data is needed to analyze the mechanism underlying HuR and LncRNA interaction.

Introduction: Hypoxia-induced reprogramming of cell energy metabolism and changes in glycolysis are hallmarks of cancer promoting the induction of an invasive and treatment-resistant phenotype, triggering metastases at an early stage of tumor development. 1 We examined the impact of hypoxia on O-GalNac glycosylation in human HEK293, PDAC cell lines and clinical specimens and its link to cancer development.

Aims & Methods: We profiled the expression of 88 glycosylation related genes by qPCR in HEK293 cells subjected to hypoxia either induced by 1% O2 or 200mM CoCl2 identifying key O-GalNac glycosyltransferases downregulated. Functional assays and glycoprotein analysis displayed a pronounced rate of O-GalNac modified cytosolic proteins derived from hypoxia-treated cells and PDAC specimens. Glycosidase assays could validate specificity of detection method used. Abrupt glyctype could be induced by HIF pathway activator

Conclusion: Proper follow-up and correction of suboptimal PERT as well as optimization may reduce the risk of severe malnutrition complications and associated morbidity and mortality by ensuring optimal therapeutic results and better quality of life.

Disclosure of Interest: All authors have declared no conflicts of interest.
ML 228 and inhibited using Echinomycin. PTK and STK analysis of cell lysates displayed correlation between phosphorylation and O-glycosylation in hypoxic samples. 

Results: Mechanistically we could show, that hypoxia-induced decreased levels of C1GALT1C1 results in reduced T-Synthase activity with subsequent expression of truncated O-glycans (Tn antigen). Differential O-GalNAc glycosylation is inducible using HIF pathway activator ML228 under normoxia and the effect is reversed using 5µM Echinomycin under hypoxia underscoring the role of HIF1α regulated transcription. Interestingly, the pattern of Tn antigen modified proteins derived from hypoxic samples differs significantly from engineered COSMC-deficient cells, displaying O-GalNAc moieties in addition to O-GlcNAc in cytosolic protein fractions. Further, we could show PI3K/AKT/ MAPK signalling is depending on the state of cellular O-glycosylation. 

Conclusion: Our findings point to a novel crosstalk of O-GalNAc and O-GlcNAcylation under hypoxia extending the knowledge base of differential O-GalNAc glycosylation in pancreatic cancer.

P1422 THE EXPRESSION AND FUNCTION OF MIR-195 IN PANCREATIC CANCER: EXPRESSION AND FUNCTION OF MIR-195 IN PANCREATIC CANCER
Y. Zhang, Q. Zhan
Digestive Department, Wuxi People’s Hospital, Wuxi/China
Contact E-mail Address: zhang33@163.com

Introduction: Pancreatic cancer is one of the more common malignant tumors in digestive system, the 5-year survival rate is less than about 6% of pancreatic cancer. Pancreatic cancer with poor prognosis and survival rate is low, due to the early clinical symptom is not easy to find, have a high transfer possible, and the operation difficulty, radiotherapy and chemotherapy is not sensitive. Radical surgical resection is the only opportunity to pancreatic cancer patients get longer survival. Therefore, a deeper understanding of the molecular mechanism of pancreatic cancer occurs, explore new effective treatment is imminent.

Aims & Methods: Pancreatic cancer is a highly malignant tumor and fourth leading cause of cancer-related death in the world. The median survival after diagnosis is 2–8 months, and approximately 3–6% of all patients with pancreatic cancer survive 5 years after diagnosis. This is mostly due to the fact that it is diagnosed at a stage when it is either locally advanced or has already metastasized to distant organs. Hence, there is a paramount need to understand the molecular mechanisms underlying its initiation, progression and therapy. The recent discovery of microRNAs (miRNAs) has revealed a novel mechanism of gene regulation and provided new ways for cancer research. MicroRNAs are small non-coding RNA molecules, which regulate the gene expression at post-transcription level. It is widely reported that miRNAs can act as oncogene or tumor suppressor gene. MIR-195 has been recognized as a tumor suppressor gene that is down-regulated in several types of cancer such as HCC, breast cancer, bladder cancer and gastric cancer. In PC, the role of miR-195 remains unclear. The purpose of this experiment was to explore the regulation role of miR-195 in PC development process. We measured miR-195 expression in three pancreatic cancer cells (PANC-1, SW-1990, PANC 03.27) by qRT-PCR, and PDPE cells were used as a control. We performed study of miR-195 by transfecting Panc-1 cells with miR-195 mimic. We used miRNA qRT-PCR to study the transfection efficiency of miR-195 mimic. The behavior of Panc-1 cells transfected with miR-195 and negative control were analysed by CCK-8 proliferation assay, cell cycle, cell migration and invasion assay. We performed Real-time PCR and western blot to detect the expression of CD4K Cyclin E1 in Panc-1 cells which were transfected with miR-195 mimic and negative control.

Results: We found that miR-195 was decreased in three pancreatic cancer cells (PANC-1 SW-1990, PANC 03.27). We also found that over-expression of miR-195 could suppress the proliferation, migration, invasion and cell cycle of Panc-1 cells. That means the malignancy potential of Panc-1 cells is inhibited by miR-195. Over-expression of miR-195 could down regulate the expression of CD4K Cyclin E1 in Panc-1 cells. 

Conclusion: The expression of miR-195 was down regulated in pancreatic cancer cells. Over-expression of miR-195 suppressed cell proliferation, cell cycle, migration and invasion of Panc-1 cells by down regulated the expression of CD4K and CyclinE1. Moreover, this finding suggests a potential novel strategy for therapeutic interventions of this disease.

Introduction: Pancreatic cancer (PDAC) is one of the most lethal diseases worldwide, due to its high mortality and high incidence. In spite of strong efforts in clinical and basic research, the molecular mechanisms responsible for this unusual aggressive phenotype still remain not completely understood and insufficient diagnostic and therapeutic tools still substantiate its ranking as the 4th leading cause of cancer-related deaths in western countries. In PC, cancer cells are well known for their ability to divide uncontrollably and it was initially thought that high glucose consumption is the main energy-source for proliferating tumor cells, but a large body of evidence suggest that most of the cell mass that makes up new cells is derived from the amino-acid metabolism.

Aims & Methods: The aim of this study was the identification of new biomarkers for chemoresistant pancreatic cancer. A secretome survey of chemoresistant PDAC cells was performed using SILAC-based mass-spectrometric analyses. Relative differences in protein-concentrations among samples were investigated and led to the identification of previously unknown proteins. The impact of RNAi-mediated knockdown of selected genes in proliferating PDAC cells were analysed using MTT-viability assay and chemosensitive protein-expression were performed using Real-Time-PCR and immunohistochemistry using patient-derived PDAC samples.

Results: SILAC-based identification of the Tryptophan degrading enzyme KYNureninase (KYNU) in chemoresistant PDAC cells revealed an overexpressed and secreted form of the KYNU protein, compared to the chemosensitive counterpart. We further identified various stress-related external stimuli (Gemcitabine, IFNg, Hypoxia) as main inducers of KYNU expression/secretion. A knock-down approach was linked to substantially lower proliferation of chemoresistant and aggressive PDAC cells. Global expression analyses using a tissue-microarray of PDAC patient samples (n = 368) revealed that high KYNU expression is significantly correlated with a worse outcome in PDAC patients.

Conclusion: The tryptophan degradation pathway member KYNU is overexpressed in a subset of PDAC patients and is linked to substantially increased cancer cell proliferation. Abundant KYNU expression in PDAC patients is linked to worse clinical outcome. We found that KYNU is a new secreted biomarker of chemoresistant PDAC cells.

P1424 INTEGRIN α11 IS SPECIFICALLY EXPRESSED IN PANCREATIC TUMOR STROMA AND A KEY TARGET IN REGULATION OF PANCREATIC TUMOR STROMAL MYOFIBROBLASTS

Introduction: The progression of pancreatic ductal adenocarcinoma (PDAC) is promoted by its highly abundant tumor stroma. As one of the main components of the tumor stroma human pancreatic stellate cells (hPSCs), precursor cells of pancreatic tumor stromal myofibroblasts (CAF), support PDAC progression by enhancing tumor cell growth, invasion and metastasis [1]. The collagen binding transmembrane receptor integrin α11 (ITGA11) is known to be overexpressed by myofibroblasts [2].

Aims & Methods: The aim of the presented study was to investigate the expression of ITGA11 in human PDAC and to study the role of ITGA11 in CAF regulation. ITGA11 expression was evaluated using immunostaining on human pancreatic tumor stroma and various other organs. The relation between ITGA11 and silencing of CAF marker expression was performed using ITGA11 siRNA in hPSCs. Additionally, the effect of CAF activation markers and tumor growth was studied in a stroma rich co-injection model in mice. The biological role of ITGA11 in CAF differentiation was studied in hPSCs and hPSCs activated with TGF-β or conditioned medium from Panc-1 endothelial tumor cells using qPCR, immunostaining, western blot, wound healing, collagen contraction and cell growth assays.

Results: In this study we have for the first time stained ITGA11 in human PDAC specimens. We found that ITGA11 was highly expressed in stromal myofibroblasts of PDAC patients, and shown by co-localization with the myofibroblasts marker alpha smooth muscle actin (α-SMA). Interestingly, there was no expression in healthy human pancreas and various other tissues from human organs. Furthermore, we induced subcutaneous tumors in mice by injecting Panc-1 or Panc-1 hPSCS and found overexpressed that ITGA11 was significantly overexpressed in a stroma-rich Panc-1 hPSC tumor. The quantitative gene and protein expression of ITGA11 in subcutaneous tumors, positively correlated with the expression of the CAF markers α-SMA, Col1a1 and PDGF-βR. Activation of hPSCs with TGF-β or conditioned medium from Panc-1 resulted in the significant upregulation of ITGA11 and α-SMA. Stable ITGA11 knockdown, mediated by shRNA, significantly inhibited hPSC differentiation, migration potential, contractility and cell growth.
Conclusion: In conclusion, this study introduces ITGA11 to be highly and specifically expressed in PDAC and explores its role in the regulation of the phenotype of pancreatic tumor stromal myofibroblasts.

Introduction: The dismal prognosis of pancreatic ductal adenocarcinoma (PDAC) is mainly due to chemoresistance linked to the tumor microenvironment. Recent developments in ultrasonic therapy and three-dimensionally cultured PDAC spheroids could help overcome chemoresistance by breaking microenvironmental barriers and increase cytotoxic drug availability. Three-dimensional (3D) culture in the form of spheroids is a useful model for reproducing multicellular resistance and analyzing the effects of cavitation.

Aims & Methods: The objective of this work was to study the effects of acoustic cavitation on a model of PDAC spheroids and to investigate possible potential of chemotherapies by US. CAPAN-2 PDAC cell line-derived spheroids were cultured as previously described by Ivascu et al. Four conditions, i.e. control, 400 nM-gemcitabine-based chemotherapy (CT) alone, US alone, CT-US combination (n = 12 spheroids per condition), were studied. Experiments were carried out to optimize US settings, in order to observe the occurrence of controlled acoustic cavitation. Comparisons between groups were based on proliferation and growth. Proliferation was evaluated 24 hours after treatment(s) by UpTiblue. Growth was assessed by diameter measurement on light microscopy at day 7 and day 10.

Results: Compared to the control group, cell proliferation was decreased in spheroids treated with CT (p < 0.0001), but without US alone. Proliferation was also further impaired in spheroids treated with US combination compared to those treated with CT alone (p < 0.0001), but this synergistic effect of US and CT did not increase spheroid's growth, meaning that spheroid diameter did not decrease after US-CT compared to CT alone.

Conclusion: This study shows the feasibility of applying an ultrasonic treatment (acoustic cavitation) in a three-dimensional culture model of PDAC. The combination of CT and ultrasonic cavitation synergistically reduced cell proliferation. Further analysis of the cytotoxic effects of acoustic cavitation on PDAC spheroids is in progress.

Introduction: Because of the progression of systemic chemotherapies (CT) for locally advanced pancreatic cancer (LA-PC), chemoradiotherapy (CRT) was selected for limited cases. However, very few long survival cases were reported in CRT and detection of prognostic factors were warranted. In this analysis, we analyzed the LA-PC cases received CRT compared with CT.

Aims & Methods: Gemcitabine (GEM) and S-1 combination chemoradiotherapy (GS-CRT) was performed to our previous Phase 1 trial (Journal of Japan Pancreas Society 2010). Till March 2016, 30 LA-PC cases received GS-CRT, and the selection criteria were LA-PC with 1) pathological diagnosis, 2) large adenoma (CMA, SMA, CCA, IPMN), invasion (3) alcoholic and concurrent myopathy without multiple primary cancer, 4) unexecuted antitumor therapy. The chemotherapy in CRT administration of GEM (200 mg/m2) once a week for 6 weeks, radiation was performed 1.8 Gy in power of 10 MeV in a week 5-day period for 5.5 weeks, and total dose was 50.4 Gy (Total 28 times). As after treatment, GEM 1000 mg/m2 was continued until PD. The patients of CT group were also recruited by the same criteria. One of the regimens among GEM alone, S-1 alone and GEM+S-1 was selected for the primary treatment, and total 26 cases were implemented in more than 2 courses.

Results: Baseline characteristics in CRT and CT group were median age (62, 72.5: p = 0.004), male (20, 12: ns) and tumor location Ph/Pb (17/13, 16/10: ns), respectively. The cases who survived for 18 months and longer were significantly (p = 0.0045) more in CRT (43.3%) than CT group (19.2%). Grade 3/4 adverse effects in CRT group were 13 cases of neutropenia (G4:3 cases and 1 case of gastrointestinal symptom, and those in CT group, neutropenia was 11 cases (G4:4 case), interstitial pneumonia (IP) aggravation was only 1 case). Because of the progression of systemic chemotherapies (CT) for locally advanced pancreatic cancer (LA-PC), chemoradiotherapy (CRT) was selected for limited cases. However, very few long survival cases were reported in CRT and detection of prognostic factors were warranted. In this analysis, we analyzed the LA-PC cases received CRT compared with CT.

Aims & Methods: Gemcitabine (GEM) and S-1 combination chemoradiotherapy (GS-CRT) was performed to our previous Phase 1 trial (Journal of Japan Pancreas Society 2010). P1428 HIGH-INTENSITY FOCUSED ULTRASOUND (HIFU) THERAPY FOR UNRESECTABLE PANCREATIC CANCER
Gastroenterology & Hepatology, Tokyo Medical University, Tokyo; Japan
Contact E-mail Address: a-sofuni@amyhi-ho.ne.jp
Introduction: High-intensity focused ultrasound (HIFU) is expected as a new advanced therapy for unresectable pancreatic cancer (PC). Our group evaluated the therapeutic effect of HIFU therapy with chemotherapy in patients with unresectable PC, and mainly achieve pain control. However, the available evidence is limited and often dated machines, and no study adopted the new TNM therapeutic decision from upfront surgery to neoadjuvant chemotherapy. The preoperative evaluation of the T is of high importance as it might shift the treatment. The objective of the study was to evaluate the accuracy of CT scan and EUS in discriminating T1 lesions from T2 lesions. A total of 62 PC patients, i.e. 14 cases in T1, 48 cases in T2 were analyzed. Clinical and pathological characteristics were also compared.
Aims & Methods: We compared the accuracy of CT scan and EUS in determining the T stage of PC using the 7th and 8th TNM editions. EUS was not able to detect up to 19.2% of lesions. In the group of T2 lesions, 15.6% were miscalculated by CT scan. EUS was found positive in 2 cases that were negative on CT scan.
Conclusion: This study suggested that HIFU therapy has the potential of new combination therapy for PC.
Disclosure of Interest: All authors have declared no conflicts of interest.
P1429 EUS AND CT SCAN ACCURACY IN ESTABLISHING THE T STAGE IN PANCREATIC CANCER: RATING THE UPCOMING TNM 8TH EDITION

Introduction: Pancreatic adenocarcinoma (PDAC) is a dismal prognosis with an overall 5-year survival rate <5%. Surgically resected patients, although undergoing curative treatment, have nevertheless a 5-year survival <25%. In fact, it has been recently suggested that patients with a tumor of more than 2 cm might harbor micrometastases at diagnosis. In this view, given the availability of new highly effective chemotherapy regimens that might be employed in the neoadjuvant setting, the correct evaluation of the T stage of pancreatic cancer plays a key role. The new proposed AJCC Staging System in Pancreatic Adenocarcinoma TNM (8th edition), in fact, differs from the 7th edition mostly for the evaluation of the T, giving high importance to the diameter of the tumor and the lymphovascular invasion has already been moved to predict survival differences more efficiently compared to previous editions. In this context, an efficient preoperative evaluation of the T is of high importance as it might shift the therapeutic decision from upfront surgery to neoadjuvant chemotherapy, that could improve survival. Few studies compared the accuracy of CT scan and EUS in evaluating the diameter of the tumor with heterogeneous results and often dated machines, and no study adopted the new TNM system to evaluate the preoperative staging defined by CT and EUS.
Aims & Methods: The aim was to evaluate the accuracy of CT scan and EUS, alone and in combination, in establishing the T stage of surgically resected PDAC as defined by the new upcoming TNM 8th edition and to establish the sensitivity and specificity of the two imaging modalities in discriminating T1 stage from more advanced T stages. We conducted a retrospective study on a consecutively surgically-resected histopathologically-confirmed high-grade pancreatic adenocarcinoma referral center between 2015-2017, who were prospectively included in a dedicated database. Inclusion criteria: a) having both preoperative EUS and CT scan with pancreatic phase evaluation at the centre; b) CT and EUS were performed, at the latest, 30 days apart from each other and from surgical resection; c) no neoadjuvant chemo or radiotherapy was performed. The evaluation of the T by both imaging modalities was compared to the final pathology T re-established based on the new TNM 8th edition, in order to calculate specificity and sensitivity. T-test was used for comparison of categorical variables.
Results: Among the 184 PDAC patients surgically resected between 2015 and 2017 at our center, 30 met inclusion criteria. Of these, 19 (63.3%) were males, with a mean age at resection of 78 years. The tumor was located in the head in 62/30 (76.7%) patients. Mean diameter of the tumor at pathology was 24.9 ± 10.8 mm, mean diameter at EUS was 24.0 ± 6.6 mm (p = 0.74), and mean diameter at CT was 25.9 ± 10.9 mm (p = 0.73). In 4/30 (13.3%) cases CT scan was not able to detect the lesion before HIFU therapy. EUS results had a lower sensitivity but higher specificity in discriminating T1 lesions from T2 lesions compared to CT scan. When considering detection of >T2 lesion in any of the two imaging modalities the accuracy increased to 80% (24/30). The sensitivity and specificity in discriminating T1 lesions from >T2 lesions were respectively 64.7% and 77.6% for EUS and 76.5% and 72.7% for CT.
Conclusion: This is the first study evaluating the accuracy of CT and EUS imaging modalities in establishing the T in the setting of the new TNM 8th edition. In our study, CT scan and EUS have both a relatively low accuracy in determining the correct T stage for pancreatic cancer when used alone, while the accuracy raises significantly when used in combination. CT scan was not able to detect up to 19.2% of lesions. EUS resulted having a lower sensitivity but higher specificity in discriminating T1 lesions from >T2 lesions compared to CT scan. These preliminary results suggest how EUS, often adopted only as a means to obtain a cytological specimen, has a key role in determining the T stage, and that the use of both imaging modalities in combination may better assess the proper therapeutic management as neoadjuvant chemotherapy or upfront surgical resection.

Introduction: According to the 2012 International guidelines on the management of intraductal papillary mucinous neoplasms (IPMN), main-duct IPMN patients with a main pancreatic duct (MPD) diameter of ≥10 mm should have surgical resection, whereas surgery is not always mandatory in those with MPD diameter between 5 and 9 mm.

Aims & Methods: The aim of the study was to analyze the prevalence of malignancy (high grade dysplasia or invasive carcinoma) in 20 resected IPMN with MPD diameter between 5 and 9 mm and to identify predictive factors of malignancy. Retrospective analysis of patients with surgically resected IPMN between 2001 and 2016. Demographics, clinical presentation, imaging and histological features were compared between patients with preoperative evidence of MPD diameter between 5-9 mm (Group A) and ≥10 mm (Group B). Malignancy was defined as high-grade dysplasia or invasive carcinoma.

Results: From 122 patients with IPMN submitted to surgery, 66 with MD- or mixed-IPMN entered the final analysis. Mean age was 66 ± 12 years and 48 (72.7%) patients were men. Group A comprised 47 patients and Group B 19. Abdominal pain was present in 23 (34.3%) patients, jaundice in 19 (28.8%), diabetes in 18 (27.3%), pancreatitis in 15 (22.7%) and weight loss in 12 (18.2%). There were no significant differences between study groups. The most common location of the MD-IPMN was the head of pancreas (60.6%), and it was multilocul in 34.8% of the patients. The prevalence of no dysplasia, low-grade dysplasia and invasive carcinoma was 15.6%, 42.6% and 8.5% respectively in group A and 10.5%, 10.5%, 21.1% and 57.9% in Group B patients. The overall malignancy rate was 46.8% in group A and 79% in group B. Jaundice (p = 0.017), weight loss (p = 0.035) and complete involvement of MPD at pathological analysis (p = 0.018) were significantly more common in patients with malignancy.

Conclusion: Almost half of resected IPMN with MPD diameter between 5-9 mm harbor histologically proven malignancy. In these patients, particularly in those with jaundice and weight loss, surgery rather than follow-up should be recommended.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1432 CLINICAL SIGNIFICANCE OF CHEMOTHERAPY FOR ELDERLY UNRESECTABLE PANCREATIC CANCER PATIENTS

S. Kaino

Department Of Gastroenterology & Hepatology, Yamaguchi University Gastroenterology & Hepatology, Ube/Japan

Contact E-mail Address: kaino@yamaguchi-u.ac.jp

Introduction: Pancreatic cancer has poor prognosis despite of improvements in multimodal treatments. As aging of the population advances, it is expected that elderly pancreatic cancer patients increase.

Aims & Methods: The aim of this study was to investigate the clinical significance of chemotherapy for patients with unresectable pancreatic cancer. At our hospital, 96 patients were diagnosed as having unresectable pancreatic cancer between January 2010 and December 2016. In this study, we defined elderly patients as those older than 75 years. We retrospectively examined the safety and efficacy of chemotherapy in patients with unresectable pancreatic cancer. We analyzed and compared survival periods and adverse events between young (≤74 years) and aged patients (≥75 years).

Results: Twenty-seven patients were older than 75 years (group A), and 59 were younger than 74 years (group B). We treated 6/10/2/5/4 patients in group A with GEM/S-1-modified FOLFIRINOX (mFOLFIRINOX)/gem + nabPTX/BSC/fert support/s, c (BSC)/others, respectively. On the other hand, we treated 12/14/11/5/3 patients in group B with GEM/S-1/mFOLFIRINOX/GEM + nabPTX/BSC/others, respectively. Severe adverse events (more severe than grade 3 according to CTCAE v4.0) occurred in 18.2% of the patients in group A and in 33.3% of the patients in group B. No significant difference was found between the two groups. The median survival time of the patients who were receiving chemotherapies was 197.0 days in group A and 291.0 days in group B. No significant differences were also found between the two groups. The median survival time of the patients who underwent chemotherapy in group A (332.0 days) was significantly longer than that of patients who underwent BSC (71.0 days).

Conclusion: Chemotherapy could be safe and effective for patients older than 75 years who have unresectable pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic ultrasound-guided biopsy (EUS-biopsy) is considered a reliable, safe, and effective technique for obtaining samples from pancreatic masses with a very high sensitivity and specificity (ranged to 85%-92% and 96-98%, respectively).[1-3] A new EUS needle (SharKore FNB needle, Medtronic, Dublin, Ireland) was introduced in order to improve the tissue acquisition.

Aims & Methods: The aim of the present study was to evaluate the presence of a histological sample using SharKore Core Needles. This study was an observational multicenter prospective non-randomized clinical trial (NCT02946840). All consecutive patients referred for EUS examination and sampling of solid pancreatic masses underwent EUS-guided biopsy with 25 G SharKore Core needles. This needle has an innovative tip geometry with a cutting surface designed to acquire cohesive tissue fragments of tissue fragments. Histopathological analysis of tissue fragments formed in every mass. At all pressures, a macroscopic on-site quality evaluation (MOSE) was done by endoscopist. If a “worm-like” material was observed at gross visual assessment, it was placed into formalin. If only liquid material was recovered, it was smeared between 2 glass slides, fixed with ethanol, and stained with a Papanicolaou-stain for cytological analysis. Endoscopists recorded macroscopic features of the specimens. Pathologists described macroscopic, microscopic features, immunohistochemical results. The primary outcome was the diagnostic accuracy and procedure-related adverse events.

Results: Study population included 82 patients, enrolled in three centres, between consecutive patients referred for EUS examination and sampling of solid pancreatic masses underwent EUS-guided biopsy with 25 G SharKore Core needles. This needle is an innovative tip geometry with a cutting surface designed to acquire cohesive tissue fragments. Histopathological analysis of tissue fragments formed in every mass. At all pressures, a macroscopic on-site quality evaluation (MOSE) was done by endoscopist. If a “worm-like” material was observed at gross visual assessment, it was placed into formalin. If only liquid material was recovered, it was smeared between 2 glass slides, fixed with ethanol, and stained with a Papanicolaou-stain for cytological analysis. Endoscopists recorded macroscopic features of the specimens. Pathologists described macroscopic, microscopic features, immunohistochemical results. The primary outcome was the percent of diagnoses of malignant tissue. The median survival time of the patients who underwent chemotherapy in group A and in 33.3% of the patients in group B. No significant difference was found between the two groups. The median survival time of the patients who were receiving chemotherapies was 197.0 days in group A and 291.0 days in group B. No significant differences were also found between the two groups. The median survival time of the patients who underwent chemotherapy in group A (332.0 days) was significantly longer than that of patients who underwent BSC (71.0 days).

Conclusion: Chemotherapy could be safe and effective for patients older than 75 years who have unresectable pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We retrospectively assessed 700 consecutive EUS-FNA procedures from January 2011 to January 2016. 459 (65.5%) solid pancreatic lesions were identified in the final analysis after excluding 230 for biliary strictures, hepatic lesions, lymph nodes, gastric, oesophageal lesions, pancreatic cysts and 11 for insufficient information.

Results: In 399 (86.9%) cases on-site cytopathology support was available, while the remaining 101 (22.5%) cases required an EUS-FNA cytology report. The mean age at EUS-FNA was 64 ± 10.4 years (range: 16-92) and the mean size of solid pancreatic cysts was 15.65 ± 6.5 cm (range: 1-60 cm). In 399 (86.9%) cases on-site cytopathology support was available, while the remaining 101 (22.5%) cases required an EUS-FNA cytology report. The mean age at EUS-FNA was 64 ± 10.4 years (range: 16-92) and the mean size of solid pancreatic cysts was 15.65 ± 6.5 cm (range: 1-60 cm).

Conclusion: KRAS mutations and KRAS/GNAS mutations are found by KRAS test. In the surgery group, methylation of the GNAS complex locus was found in 1/2 IPMNs (95% CI: 0.01-0.16) and in GNAS mutations in 2/3 IPMNs (95% CI: 0.01-0.16). The presence of on-site cytopathologist significantly increases the diagnostic yield.

Disclosure of Interest: S. Fatais: This work was financed by a Research Grant of Clube Português Do Pancreas.

DO BILIARY STENTS REDUCE THE DIAGNOSTIC PERFORMANCE OF EUS BIPSY IN PATIENTS WITH A MASS IN THE HEAD OF THE PANCREAS?

N. L. Bekkali1, M. Nayar2, L. Thornton1, S. J. Johnson2, B. Haugk2, A. Darne2, J. S. Leeds1, R. Charnley3, K. Oppong1

Introduction: Plastic stents (PS) for pre-operative drainage and palliation of biliary obstruction

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: During the period study, 49 patients (41 women/8 men) with preoperative EUS-FNA for SPN were recorded. Mean age of patients was 37 ± 15y. Preoperative cholangiography has been performed before stent placement. The location was mostly cephalic (21/36, 59%), but also corporeal in 25% (9/36), caudal in 25% (9/36), in 22% (4/18) for procedure. Mean number of needle passes was 2.2 ± 0.7. EUS-FNA allowed certain preoperative diagnosis of SPN in 74% of cases (35/47), probable diagnosis in 6% (3/47), negative in 4% (2/47) and wrong in 6% (3/47). No acute complication of EUS-FNA was reported. A mean follow-up of 36 ± 12 months, only one local recurrence was noted. In this 74 years old man case, a 19G needle was used (2 trans-gastric passes), and recurrence occurred after 84 months.

Conclusion: In this large multicenter retrospective series, a systematic preoperative EUS-FNA did not seem to modify the SPN recurrence rate. Therefore this study allows to validate this attitude as a possible alternative. The data for the series are incomplete at the date of submission of the abstract. The final data will be reported on the day of presentation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Solid-pseudopapillary neoplasm (SPN) is a rare condition, first described by Frantz in 1939. It occurs mostly in young women, and surgical resection is recommended. Its local recurrence rate is less than 10% and usually occurs within 4 years after surgery. Before such a surgery, especially in young people, EUS-FNA (Endoscopic ultrasonoraphy with fine needle aspiration) is discussed to confirm diagnosis but rarely performed due to suspected needle tract contamination by neoplastic cells. The aim of our large multicenter study was to assess the short- and long-term safety of preoperative EUS-FNA in SPN.

Aims & Methods: This study is a multicenter retrospective register of all SPN diagnosed in the last decade in 14 European expert centers (GRAPHE task force). Inclusion criteria was realization of preoperative EUS-FNA followed by surgical resection. Patient and tumor characteristics were collected, as the EUS-FNA technique (number of passes, needle size, trans-gastric or trans-duodenal access). Immediate or late complications of EUS-FNA and recurrence of SPN were then recorded.

Results: During the period study, 49 patients (41 women/8 men) with preoperative EUS-FNA for SPN were recorded. Mean age of patients was 37 ± 15y. Preoperative cholangiography has been performed before stent placement. The location was mostly cephalic (21/36, 59%), but also corporeal in 25% (9/36), caudal in 25% (9/36), in 22% (4/18) for procedure. Mean number of needle passes was 2.2 ± 0.7. EUS-FNA allowed certain preoperative diagnosis of SPN in 74% of cases (35/47), probable diagnosis in 6% (3/47), negative in 4% (2/47) and wrong in 6% (3/47). No acute complication of EUS-FNA was reported. A mean follow-up of 36 ± 12 months, only one local recurrence was noted. In this 74 years old man case, a 19G needle was used (2 trans-gastric passes), and recurrence occurred after 84 months.

Conclusion: In this large multicenter retrospective series, a systematic preoperative EUS-FNA did not seem to modify the SPN recurrence rate. Therefore this study allows to validate this attitude as a possible alternative. The data for the series are incomplete at the date of submission of the abstract. The final data will be reported on the day of presentation.

P1439 DIAGNOSIS OF Pancreatic Neuroendocrine Tumours using SurePath Cytology and Immunohistochemistry without Need for Excision Biopsy

C. Meredith1, H. Dixon2, P. Irandoust3, P. Baird3

1Gastroenterology And Hepatology, Bankstown-Lidcombe Hospital, Bankstown/NSW, Australia/NSW
2Ultrasound And Nuclear Medicine, Bankstown-Lidcombe Hospital, Bankstown/Australia/NSW
3Cytology, Lavery Pathology, Ryde/Australia/NSW

Introduction: Pancreatic neuroendocrine tumours (PNETs) are relatively rare, i.e., 21 per 100,000 individuals per annum, and account for only 1–2% of all pancreatic tumours. They are separated into 2 major categories: 1) well-differentiated (WD-PNETs) which have round to oval nuclei, coarsely stippled chromatin and finely granular cytoplasm and 2) poorly-differentiated (PD-PNETs) which have a diffuse architecture with an irregular nucleus and less cytoplasmic granularity. WD-PNETs tend to have an indolent course (survival ~67% at 5 years) but ~50% have metastasised at the time of diagnosis. PD-PNETs are high-grade cancers with an aggressive course resembling NETs arising in lung. WD-NETs contain neurosecretory granules which stain for synaptophysin and/or chromogranin. Endoscopic ultrasonoraphy guided fine-needle aspiration biopsy (EUS-FNA) can provide a non-operative cytological diagnosis of PNETs when the pathologist is provided with a good specimen such as the pellet of cells obtained through SurePath (SP).

Aims & Methods: EUS-FNA samples of pancreatic tumours were collected into a SurePath vial and slides prepared from the cellular pellet. The slides were stained for synaptophysin and Ki67 by immunohistochemistry (IHC) and examined by 2 independent senior cytologists.

Results: Sixteen (16) patients with a mean age 65 years (8 male) were identified by EUS with a suspected PNET. The mean tumour size was 16.2 mm +/- 4.2 mm. All had the morphology of a PNET and stained positive for synaptophysin.

Conclusion: SP prepared cytology slides from solid pancreatic tumours provides enough diagnostic material for IHC staining for synaptophysin and KI67 without the need for a formal excision biopsy. Morphology of SP slides is often diagnostic but a positive stain for synaptophysin makes the diagnosis irrefutable. The
mitotic index derived from Ki67 staining helps identify WD-NETs which can be monitored and PD-NETs which need aggressive treatment.

P1440 EFFECTS OF IGF2BPs ON GROWTH AND PROLIFERATION OF NEUROENDOCRINE PACRANE TUMOR CELLS. L. Nietzsche1, F. Sperling1, K. Theuerkorn1, H. Griesmann1, S. Krug1, S. Hüttemeier2, P. Michel1

Introduction: Pancreatic neuroendocrine neoplasms (PNEN) are highly angiogenic tumors which despite of various targeted options including mTOR and VEGF inhibition frequently develop secondary drug resistance. IGF2BPs (IGF2 mRNA-binding proteins) represent a family of canonical RNA-binding proteins (RBP) comprised of three members (IGF2BP1–3) which have been described to promote stem and/or progenitor cell maintenance with reported expression and oncogenic roles in aggressive cancers. IGF2BPs show a differential expression pattern in various solid tumors including pancreatic neuroendocrine tumors.

Aims & Methods: We aimed to characterize the role of IGF2BPs in progression and resistance of pancreatic neuroendocrine neoplasms. We used three different siRNA-pools (IGF2BPs) to inhibit the different IGF2BPs in pancreatic neuroendocrine BON1 tumor cells. Cellular effects where investigated by Western blot analyses, flow cytometry, clonogenic survival, cell viability and migration assays.

Results: In the pancreatic neuroendocrine tumor cell line BON1, knock-down of IGF2BP1 resulted in a significant reduction of cell viability. Cell cycle analysis by FACS showed a decreased S phase progression parallelized by a reduction in the proliferation marker PCNA and a markedly reduced MEK/ERK activation. In contrast, Akt signaling was unaffected. Moreover, knock-down of IGF2BP1 significantly reduced clonogenic growth as assessed by colony formation assays and led to decreased cell migration as determined by scratch assays. Interestingly, knock-down of IGF2BP1 was insufficient to induce apoptosis, as assessed by PARP enzyme of 3 days, and PARP and caspase 3 enzymes, as well as annexin staining on FACS. Rather, si-IGF2BP1 increased the expression of both the anti-apoptotic and pro-survival factor BCL-2 and the cell cycle inhibitor CDKN1B. In contrast to IGF2BP1, knock-down of IGF2BP3 rather induced cell viability, whereas IGF2BP2 modulation had no impact on cell viability and cell cycle progression indicating opposing effects of the three IGF2BPs on PNEN progression. These in vitro findings were parallelized by distinct expression patterns of IGF2BPs in human and murine PNEN tissues. Elucidation of IGF2BP-modulated RNAs in PNEN cells is ongoing.

Conclusion: In summary, our data suggest that IGF2BP1 promotes tumor progression by enhancing cell cycle progression and clonogenic growth, whereas IGF2BP3 and -3 exert no tumor-promoting role in PNEN.

Introduction: The chemopreventive effect of aspirin (ASA) and other NSAIDs have been observed in the setting of colorectal cancer, showing a reduction in the incidence and mortality. However, the impact of aspirin use on clinical outcome of patients with gastro-entero- pancreatic neuroendocrine neoplasms (GEP NEN) has not yet been evaluated.

Aims & Methods: Aim of the study was to retrospectively evaluate the clinical outcome of GEP NEN patients treated with ASA at three different European referral Centres for NENs. All the GEP NENs patients followed up in three European Centres (Fondazione IRCCS Ca’ Granda Ospedale Policlinico Milano, Italy; Fondazione IRCCS Istituto Tumori Milano, Italy; Mater Misericoedisce University Hospital, Dublin, Ireland), from January 2005 and September 2016, were retrospectively enrolled. The possible association between ASA and disease grading, staging, primary site, overall OS and PFS were evaluated. At the time of enrolment, clinical data and biochemical parameters were collected for every patient. Chromogranin A (CgA) and specific circulating peptides were evaluated. Morphological and functional imaging (computed tomo- graphy, magnetic resonance and Gallium 68PET) were performed to follow up the patients at each Centre.

Results: In the 253 patients included (121 M, median age 64 yrs), the primary neuroendocrine tumor was located at the stomach (35%), pancreas (38%), small bowel (8%), appendix (37%), colon (49) or unknown (97). Grading was G1 in 154 patients, G2 in 64, G3 in 5 and not available in 28. TNM staging was I in 99 patients, II in 16, III in 32 and IV in 86. No clear impact on OS or PFS was observed in patients taking ASA compared to those not taking it. Interestingly, in pNEN an inverse relation was observed between Ki67 and ASA assumption (r =0.35, p =0.008). In small bowel NEN an inverse relation was observed between positive lymphnodes at surgery and ASA assumptions (r =-0.3, p =0.02). As expected, the intake of ASA was related with the older age of the patients.

Conclusion: According to present data, ASA therapy seems not to have a direct clinical impact on disease progression or survival of NENs, even if it is associated with lower Ki-67 values and less node involvement. Further studies are needed to confirm this observation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Von Hippel-Lindau disease (VHL) is a rare heritable genetic syndrome that may affect different systems and organs: pancreatic manifestations of the disease are frequent during lifetime of the patients. The key feature is the presence of simple cysts, but serous cystadenomas (SCAs) or neuroendocrine tumors (NETs) can be frequently found as well. The aim of this study is to describe pancreatic manifestations in patients with VHL, considering the peculiarity and rarity of this disease.

Aims & Methods: All patients who referred to the established multi-disciplinary team in our center (Molinette Hospital - Turin) for management and follow-up of VHL were included in the study; we considered the ones with pancreatic involvement (simple cysts, SCAs or pNETs). We collected data about the patients (demographics and medical history), about the lesions (imaging features, histological and cytological analysis) and about the management.

Results: Overall of 24 patients, 18 of which (75%) had a pancreatic involvement. Simple multiple pancreatic cysts were found in 13 patients, SCAs were found in 2 patients and NETs in 7 patients. The mean age of the patients with pancreatic lesions was 42 (min 25 - max 75), 11 were males and 7 females (1.6:1 M:F). Simple cysts affected 13 patients, are always multiple (ranging from 12 to 80 mm) mostly in the head. 3 patients underwent surgery for symptomatic disease. All pNETs were well differentiated (G1, Ki67 <2%); 7 were located in the head and 2 in the tail (2 patients had multiple tumors). 5 out of the 7 pNET patients underwent surgery. The two SCAs were multiple (max 65 mm), mostly affecting the head in 1 case and the tail in the other. No surgery was performed.

Conclusion: 75% of our VHL patients showed pancreatic involvement, mostly in males compared to females. 72% of patients with pancreatic lesions suffered from simple cysts, 39% from NETs and 11% from SCAs. To note that all NETs were G1 and behaved in a benign fashion. Surgery was performed only in patients with NETs in the pancreatic head and in patients with symptomatic cystic disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Neuroendocrine tumours (NET) consist of a diverse group of neoplasms that derive from diffuse neuroendocrine cells throughout the body. Commonly found in gastrointestinal (GI) duct and lung, they (GI) NETs also arise in the pancreas. The relationship between tumour size and metastasis rate is poorly recognized in patients with pancreatic neuroendocrine tumours (PNETs). The impact of tumour size on prognosis was controversial in previous investigations.

Aims & Methods: The aim of this study is to evaluate the prognostic impact of tumour size on survival outcomes and its correlation with risk of metastasis in a large PNETs cohort, including all stages. Methods: PNETs cases diagnosed from 1988 to 2013 were retrieved from the Surveillance, Epidemiology, and End Results (SEER) database. Clinopathologic features were retrospectively analyzed. Survival was calculated by the Kaplan-Meier method. Multivariable Cox regression models with hazard ratios (HRs) were constructed to analyze survival outcomes and risk factors. Cubic spline analysis was used to assess relationship between tumour size and probability of metastasis.

Results: A total of 5424 patients were identified. There were 1226 patients (22.6%) with tumour size of 2 cm or less. The probability of metastasis increased in a non-linear fashion with increasing tumours size. Univariate analysis showed that tumour size was significantly correlated with survival (P<0.001), no matter surgery was performed or not. However, subgroup analysis suggested this association to be linear for patients with localized and regional tumours (P<0.001), but stochastic in patients with distant stages (P=0.703). On multivariate analysis, tumour size was an indicator for metastasis (HR = 1.010, 95% CI: 1.008-1.012, P=0.001 and size <20 mm: HR = 0.009, 95% CI: 1.161-1.474, P<0.001 for size >40 mm). For tumours ≤20mm, surgical treatment was associated with significantly improved survival compared with those patients who did not undergo operation (P<0.001).

Conclusion: Tumour size affects the probability of metastasis. Its prognostic impact on survival is restricted to patients with localized and regional disease. For tumours with tumour size ≥20mm, surgical treatment should be considered preferably.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1445 THE LARGEST FAMILY IN TURKEY WITH MULTIPLE ENDOCRINE NEOPLASIA-TYPE 1 AND A NOVEL MUTATION
A. Çeşin1, D. G. Duman2
1Internal Medicine, Marmara University: School of Medicine, Istanbul/Turkey
2Gastroenterology, Marmara University Hospital, Istanbul/Turkey

Contact E-mail Address: alicetinndr@gmail.com

Introduction: Multiple Endocrine Neoplasia type-1 (MEN-1) occurs usually sporadically but it due to its autosomal dominant disorder it may affect other family members too. The combination of parathyroid, pancreatic islet cell, and anterior pituitary tumors is characteristic of MEN-1 although it may be accompanied by a substantial number of non-endocrine tumors. The mutations in MEN1-1 result in the inactivation of MENIN protein which codes for a nuclear protein encoded by this gene and is responsible for tumor-suppression under normal circumstances. Herein we present the largest MEN1-1 family in Turkey to the best of our knowledge and a newly discovered mutation in MEN-1 that effects this family.

Aims & Methods: The family inherited the specific MEN-1 mutation is originally 5 ebinakariharsi, Giresun and most of the members have moved to Istanbul and Yalova. Consanguineous marriages have been practiced within the family. Family tree mapping was structured and contained fifty-five members. Among them, eleven patients underwent biochemical, radiologic and if necessary endosonographic evaluation along with the genetic testing. Additionally, we learnt that 2 of the members had the family had died of pancreatic malignancy. Diagnostic criteria for familial MEN-1 include: i) the presence of at least one MEN-1 associated tumor that are from parathyroid, pituitary, or GEP tract origins, 2) at least one first-degree relative with one or more of these endocrine tumors and/or 3) positive genetic testing for abnormal MEN-1 mutation. For our index case, DNA sequencing of the MEN1-1 gene performed using Sanger sequencing technique at ABI 3500 sytem. For the other family members only the targeted mutation analysis is performed.

Results: Among the family members we had peripheral blood DNA from 9 and we extracted the tumour tissue DNA from 1 patient. MEND1 gene was analyzed by Sanger sequencing. Our index case was ZK who had hypophysis adenaoma, parathyroidectomy and pancreatic neuroendocrine tumour and had whipple operation. A three nucleotide deletion p.ser560argfs*3[C.1680_1683 del TGA] was detected. Seven other family members were analysed and tested positive for the mutation. Genetic counseling and information about pre-implantation genetic diagnosis (PGD) was given to all patients who are tested positive for the mutation. All 7 patients had p.ser560argfs*3[C.1680_1683 del TGA) three nucleotide deletion same with that of index case. Out of 15 patients, MEN-1 diagnosis was confirmed in 11. Tumours detected at patients with MEN-1 diagnosis were: nonfunctional pancreatic neuroendocrine tumour at three, parathyroid adenoma/hyperplasia at 6 patients and hypophysis adenaoma

A663

United European Gastroenterology Journal 5(S5)
at 4 patients. The mean age of our MEN-1 patients was 51 and the age at diagnosis was 41.8. The mean plasma calcium level was 11.46 mg/dl and there was no history of renal calculi at any of them.

Conclusion: The family presented here is the one which had the largest number of affected individuals with genetic and clinical properties of MEN-1 at Turkey. Beside the phenotype described here is the neuroendocrine mutation causing loss of function that is described for the first time. Also at MEN-1 families, counseling to prevent the neoplasia development and to prevent the new family members to be effected with PGD has a pivotal importance. We could point out that awareness is the most important caution for prevention.

Disclose of Interest: All authors have declared no conflicts of interest.

P1446: PROGNOSTIC VALUE OF THE DIFFERENT PRE-TREATMENT BIOMARKERS FOR PATIENTS WITH NEUROENDOCRINE TUMORS

Introduction: Several inflammatory response materials could be used for predic- tion of prognosis in cancer patients. The neutrophil lymphocyte ratio (PLR), platelet lymphocyte ratio (PLR), thrombocytosis (the platelets number > 400*10^9/mm³) have been introduced for prognostic scoring system in various cancers.

Aims & Methods: The objective of this study was to determine whether the PLR, or thrombocytosis could predict the clinical outcomes in G1-G2 neuroendocrine tumors. We performed a retrospective review of 31 patients with neuroendocrine tumors with ki 67 below 20% diagnosed in Fandeni Clinical Institute between 2011-2017. Data about site of the primary tumor, presence of metastasis, PLR, PLR, thrombocytosis (platelet count > 400) and survival were collected and analysed.

Results: The patients characteristics were: primary tumor location was: 61.29% pancreas, 22.58% gastrointestinal tract, 16.13% unknown, 61.29% had hepatic metastasis, 6.45% had locally advanced tumor. The primary tumor was resected in 35.48% patients. The overall 2-year survival rate was 77.42%. The Ki 67 index (p < 0.04), PLR (cut off > 300) p < 0.01 have statistical significant impact on survival in univariate and on multivariate analysis (P < 0.05). Other factors like ki 67 index, metastatic disease, thrombocytosis and NLR have an impact on survival statistical significant on multivariate analysis.

Conclusion: This study demonstrates the prognostic role of different variables like Ki 67 index, PLR and PLT value, thrombocytosis and metastasis. This factors may be integrated in different scoring systems for prognosis that could guide clinicians for a better management in patients with neuroendocrine tumors.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Neuroendocrine pancreatic tumors represent the second prevalent entity of malignant tumors of the pancreas and show an overall mortality of about 60%. At the moment surgical resection is the only option of potentially curative therapy, as with the currently available chemotherapeutic and radiotherapeutic approaches an inhibition of tumor growth but no regression of the tumor can be achieved. Therefore for about 80% of pNET patients no curative therapy can be offered. To obtain the identification of novel potential target genes for the development of new therapeutic strategies, primary issues from pNET patients were analyzed. Amongst others Plac8 (Placenta-specific 8) was identified, which is a small protein of unknown function, showing different forms of cellular localization depending on the cell type analyzed, indicating at its ability to fulfill a variety of physiological functions.

Aims & Methods: In the course of this study, the function of Plac8 in neuroendo- crine pancreatic tumors is to be unveiled to evaluate its value as a potential target for pNET therapy. Therefore primary tumor tissue of about 100 pNET patients were analyzed for Plac8 expression by quantitative realtime PCR and immuno- histochemistry. Furthermore established pNET cell lines from human origin were transfected with siRNAs against Plac8 and there proliferative activity and sensitivity were analyzed by MTT and MTT assay. Changes in these impor- tant characteristics of tumor cells were further examined by westernblot analyzes of key regulators of apoptosis and cell growth.

Results: Plac8 is highly expressed in primary human pNET tissue on RNA-as well as on protein level. Functional in vitro analyses show the siRNA mediated knockdown of Plac8 not only in human but also in rat cell lines leads to significantly reduced proliferative activity and reduced cell growth. These effects come along with indicative changes in the expression of central regulators of cell cycle while cell cycle pathways seem to be unaffected.

Conclusion: Overexpression of Plac8 in neuroendocrine tumors of the pancreas promotes the proliferative phenotype of the tumor cells while the inhibition of Plac8 inhibits cell growth and metabolism. Therefore in the future Plac8 could represent a very interesting target molecule for the treatment of pNETs.

Contact E-mail Address: hishida223@gmail.com

Introduction: Since the majority of laryngopharyngeal carcinomas are detected at an advanced stage, most cases are treated with concurrent chemotherapy and radiation therapy. The key to improving the prognosis and quality of life is early detection of the primary cancer and treatment using minimally invasive surgery. We previously reported the good oncologic outcomes with ELPS (Endoscopic laryngopharyngeal surgery) for superficial laryngo-pharyngeal carcinoma. However there is no clinical evidence for an additional treatment nor prognosis about the cases conducted endoscopic resection which were diagnosed to be superficial carcinoma with lympho-vascular invasion histopathologically.

Aims & Methods: This study aimed to investigate the optimal additional treat- ment and clinical course for the surflcial laryngo-pharyngeal carcinoma with lympho-vascular invasion. We analyzed clinicopathological data in 9 patients showed Lympho-vascular invasion receiving ELPS between 2007 and 2014.

Results: Positive lympho-vascular invasion was found in 9 cases. Detected the tumor depth was SEP in 7 lesions and MP in 2 lesions. Mean alcohol consumption is 9.99 g per week. 5 cases are low activity ALDH2 heterozygotes and have alcohol flushing reaction. No pathologic findings correlated with lympho-vascular invasion; 2 cases with vascular invasion(y0, v1), 2 cases with lympho-vascular inva- sion(y1, v1). Two patients underwent an additional chemoradiotherapy without recurrence. Four patients had a cervical lymph node or local recurrence, two of them were salvage ELPS cases after chemoradiotherapy. One of two salvage cases also had distant metastasis and was given palliative treatment, and finally died. The other one underwent surgical salvage and remained alive. One case with lymphatic and vascular invasion had no adjuvant therapy and remained without recurrence. And the other 2 cases had recurrence but died of other cause.

Conclusion: Lympho-vascular invasion is a risk factor for cervical lymph node metastasis, which has a possibility to a very aggressive disease. In those cases, chemoradiotherapy as an additional treatment is recommended as far as possible. If patients already had prior radiotherapy, close follow-up is essential to detect recurrence early. In those cases, chemotherapy or additional surgical resection are also considerable if the general conditions are satisfactory.

Introduction: The positive lateral margin after endoscopic resection(ER) of early gastric cancer(EGC), additional surgery or endoscopic submucoosal dissection(ESD) are recommended. However, the additional surgery often diffi- cult due to advanced age or patient’s comorbid conditions.

Aims & Methods: The aim of this study is to investigate of appropriate manage- ment in patients with positive lateral margin after ER. We analyzed Wednesday, November 01, 2017 09:00-14:00

ENDOSCOPY AND IMAGING III - HALL 7
PI450 EFFICACY OF THE FORCED COAGULATION MODE WITH LOW-FREQUENCY POWER SETTING DURING ENDOSCOPIC SUBMUCOSAL DISSECTION

Introduction: Bleeding control is one of the most important factors to success endoscopic submucosal dissection (ESD) in safety. We have reported the endoscopic coagulation technique using soft coagulation mode (S method) is effective. This study was performed for the prevention of bleeding when relatively large vessels penetrating between muscle layers are dissected. However we have thought that S method is insufficient especially for large vessels such as more than 2 mm, we have to use hemostatic forceps for preventing hemorrhage despite treatment. We have therefore found that forced coagulation mode with low frequency power setting (F1-10 method) can exhibit precogulation function without bursting vessels. It is suggested that F1-10 method is useful for large vessel precogulation.

Aims & Methods: We investigated the deference of hemostatic ability between S method and F1-10 method in clinical study and ex vivo study. In clinical study we analyzed retrospectively their hemostatic ability by consecutive six gastric ESD cases in each groups excluded some cases, which have the risk of affecting data. In ex vivo study, we compared the hemostatic ability between relatively large vessels penetrating between muscle layers are dissected. We have thought that S method is insufficient especially for large vessels such as more than 2 mm, we have to use hemostatic forceps for preventing hemorrhage despite treatment. We have therefore found that forced coagulation mode with low frequency power setting (F1-10 method) can exhibit precogulation function without bursting vessels. It is suggested that F1-10 method is useful for large vessel precogulation.

Conclusion: Training on endotherapy prior to certification is limited. The current UGI certification process does not comprehensively assess endotherapy. Aims & Methods: Trainees awarded certification in gastroscopy between September 2009–2016 were identified from the national trainee electronic portfolio (JETS). Trainee inputs and formative assessments (direct observation of procedural skills - DOPS) for UGIB therapy, up to their certification date, were analysed. Only trainees with ≥ 200 procedures were included, which is the minimum number of cases to allow certification within the UK, thereby excluding those who had submitted baseline information which may have contained therapeutic data. Exposure rates from medical endoscopists (physician and surgical trainees) were compared with non-medical endoscopists (NME).

Results: 885 trainee portfolios were analysed (765 medical and 120 NMEs), with a median procedural count of 276 (IQR 124). The median number of therapeutic entries and DOPS were 4 (IQR 11), and 1 (IQR 3) respectively. Overall rates for endotherapy and DOPS were 2.9% and 0.8% per procedure. When stratified by therapy, the median exposure to each therapy was either 0 or 1, with means displayed in Table 1. 25.2% of trainees had no exposure to any type of endotheraphy (67.5% of NME and 18.6% of medical endoscopists, p < 0.0001). Of medical endoscopists awarded certification, 37.1% had not performed band ligation, 50.7% had not placed a clip, and 54% had not used heater probe. NME had significantly less exposure to each modality of endotherapy considered (overall p-value 0.10, p < 0.0001).

**Introduction:**
Endoscopic full-thickness resection (EFTR) for sub-epithelial lesions (SETS) of GI tract is less frequently described; possibly due to technical challenges involved in dissection and need for resultant defect closure. Current study describes single-center experience of EFTR for treatment of SETS.

**Aims & Methods:**
Prospective database of patients undergoing EFTR for SETs over 6-years (2011–2017) was abstracted. Patient selection for EFTR—endoscopic ultrasound (EUS) and CECT. Inclusion criteria—encapsulated lesions, predominantly endophytic component and absence of features of invasive malignancy. Exclusion criteria—patients unfit for general anesthesia or major invasive procedure, uncorrectable coagulopathy or high risk features for malignancy. All procedures performed under general anesthesia with endotracheal intubation. High-definition endoscope (GF-HQ190 or CF-HQ190, Olympus Corp., Japan) with distal transparent hood and carbon dioxide insufflation used in all. Submucosal (SM) elevation by Gelofuscin, mucosal incision and SM dissection performed to expose SET. Encapsulated SET enucleated maintaining intact capsule. Adherent and attached muscularis propria (MP) layer fibers divided. IT or dual-knife™ used for dissection and coag-grasper for hemostasis.

**Results:**

**Abstract:**

**Conclusion:**
Endoscopic diagnosis of BE by directed biopsies of esophageal tissue was performed.

P1455 PROPHYLAXIS OF VARICEAL BLEEDING IN CIRRHOTIC PATIENTS: EFFICACY AND SAFETY OF ENDOSCOPIC VARICEAL LIGATION – A TERTIARY CENTRE

E. Soares1, M. Gravito-Soares1, A. Henriques1, N. Almeida1, L. Tomé1
1Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal, Coimbra/Portugal

Contact E-mail Address: es18497@gmail.com

Introduction: In the natural history of chronic liver disease, variceal bleeding represents a life-threatening complication of portal hypertension, with high risk of recurrent bleeding and mortality. Current guidelines recommend endoscopic variceal ligation (EVL) in primary prophylaxis and the combination of both in secondary prophylaxis.

Aims & Methods: We aimed to evaluate the efficacy of EVL therapy in both primary and secondary prophylaxis of variceal bleeding in cirrhosis and to establish the patient's clinical outcome. This was a retrospective observational cohort study of a total of 444 EVL procedures performed in 250 cirrhotic patients, who were admitted in a gastroenterology department of a tertiary centre, between 2004–2016, to receive EVL as prophylaxis of gastrointestinal variceal bleeding. Sessions of ligation were repeated every two to three weeks in order to reach variceal eradication. The clinical outcome included the recurrence of bleeding (primary endpoint), the eradication success rate of oesophageal varices, EVL-related complications and overall and bleeding-related mortality.

Results: The mean follow-up period for all 250 cirrhotic patients enrolled in the study was 73.2±40.0 months, with mean age of 63.9±10.8 years and a predominance of male gender (80.4%; n=201). At initial endoscopy, 237 (61.9%) patients had active variceal bleeding and 47.1% (n=116) were considered high risk. EVL was performed as primary prophylaxis in 50.9% (n=226) and secondary prophylaxis in 49.1% (n=218). Varices were obliterated in 209 (83.6%) patients with mean number of EVL procedures necessary to eradicate varices of 1.8±0.95 and a maximum of procedures of 6. Recurrent bleeding occurred in 11.2% (n=28) of cases with a mean time to re-bleeding occurrence of 8.1±14.2 months. Major and significant complications were verified in 8.1% (n=36) of patients. The main complications were bleeding related to EVL procedure in 10.8% (n=27) and infection (2.5%) patients with mean time between EVL and complication occurrence of 11.1±11.9 days (minimum:0; maximum:43). Intra-procedure complications occurred in 11(2.5%) patients with no death, despite of two cases of Sengstaken-Blakemore balloon necessity. The overall mortality was 5.4%(n=24), being 0.4%(n=2) related to variceal bleeding.

Conclusion: EVL seems to be an efficient, safe and relatively simple therapeutic option for primary prophylaxis and secondary prophylaxis of variceal bleeding in cirrhotic patients. Since the main complications occur over 1 week after EVL procedure, the majority of patients can be safely treated in an ambulatory setting.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1456 THE VALUE OF ENDOCOSCOPIO FUL-THICKNESS RESECTION FOR GASTRIC AND DUODENAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA LAYER

M. Xu1, C. Zhang1, Q. Li1
1Endoscopy Center, Zhongshan Hospital, Shanghai/China

Contact E-mail Address: whitelily.chen@aliyun.com

Introduction: Given diminishment of quality of life caused by surgery in the stomach and duodenum, a minimally invasive technique is desirable for gastric and duodenal submucosal tumors (SMTs).

Aims & Methods: We aimed to assess the value of endoscopic full-thickness resection (EFTF) technique for gastric and duodenal submucosal tumors (SMTs) originating from the muscularis propria (MP) layer. A total of 276 patients with single gastric SMTs originating from the MP layer were performed EFTF between January, 2010 and February, 2014. The tight adhesion of the tumor to gastric or duodenal serosal layer could be seen in every case from endoscopic ultrasound (EUS) before the procedure. The SMTs orientated endoscopically were performed EFTF using a standard ESD technique without laparoscopic assistance under direct endoscopic view. The defect of gastric and duodenal wall was closed after resection.

Results: A total of 276 patients included 94 males and 182 females. Their median age was 57.8 years (range, 30–81 years). Among all the 276 SMTs in our study, 165 located in gastric fundus, 96 located in gastric body, 8 located in the antrum, 1 located in duodenal bulb, 2 located in duodenum, 2 located in the pylorus. The largest size was 1.7 cm (range 0.7–6.0 cm). The success rate of EFTF was 98.9% (273/276). EFTF was failed in 3 cases: one case was out of control because of bleeding into enteroceola, two cases required conversion into laparoscopic surgery because of projectile lobulations of the tumor outside the cavity. The median operation time was 65 min (range, 14–210 min). In en bloc resection rate was 98.1% (268/273), piecemeal resection rate was 1.9% (5/273). The median length of hospital stays was 4.4 days (range, 1–23 days). Pathological outcomes revealed that the tumors were classified 137 (49.7%) leiomyoma, 103 (37.3%) leiomyomas, 8 (2.9%) calcifying fibrous tumors, 7 (2.5%) glomus tumors, 5 (1.8%) displaced pancreas, and 3 (1.1%) fibromatoses. The procedure-related complications were as follows. Different degrees of postsurgical gastric pain occurred in 168 (60.9%) cases, among which 24 (8.7%) cases resulted in complications after related abscesses: 28 patients were found after EFTF. None of the 273 cases developed procedure-related death. No tumor residual or recurrence was found during the follow-up period ranging 3–55 months.

Conclusion: EFTR without laparoscopic assistance is minimally invasive, safe, and effective for treating gastric and duodenal SMTs, which originate from the MP layer and adhere tightly to the serosa. High en bloc resection rate could be achieved. However, a larger number of the cases and long-term outcome deserve further research.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1457 BLUE LIGHT IMAGING AND LINKED COLOR IMAGING FOR DETECTION AND CHARACTERISATION OF CHRONIC GASTRITIS

J. Weigt1, A. Link1, A. Canbay1, P. Malferttheiner1
1Gastroenterology, Hepatology & Infectious Diseases, Medizin. Universität Magdeburg Gastroenterologie und Hepatologie, Magdeburg/Germany

Contact E-mail Address: jochenweigt@gmx.de

Introduction: Current standard in the characterization of gastric mucosal changes is the use of virtual chromoendoscopy with magnification to visualize the pit pattern and vascular changes. The most recent development in light emitting technology is the so called Multi Light Illumination, that composes light out of 4 coloured LED. Blue Light Imaging (BLI) is composed of a continuous spectrum with peaks at 410 and 430 nm to enhance surface and vascular structures. Linked Color Imaging (LCI) uses BLI light together with post processing that realocates colour tones resulting in a high contrast of different red tones. Until now only few data exist about the use of BLI and LCI in chronic gastritis (CG).

Aims & Methods: We aimed to analyse the use of LCI and BLI in detecting and characterizing of chronic gastritis and premalignant conditions of the stomach. Patients were prospectively enrolled. All patients had chronic gastritis under conscious sedation. In all cases an endoscope equipped with zoom (Fujifilm EG–760Z) was used. Endoscopic classification was based on the following parameters: normal gastric mucosa was defined as mucosa with visible superficial capillaries, superficial network (SCN) without any focal lesions; atrophy (AG) was defined by whitening of the mucosa with visible deeper vascular architecture in white light, BLI and LCI; intestinal metaplasia (IM) was diagnosed if mucosa had whitened surface with whitening in LCI or white light or light blue crest sign in BLI; CG was diagnosed in case of loss of SCN or focal lesions not matching the definition of other focal lesions or cancer. Biopsies were sampled according to the updated Sydney classification system and in addition of every visible focal lesion. After endoscopy a prediction of histology was made by the endoscopist.

Results: We investigated 24 patients (15 female, 9 male, age 65 yrs (25–87yrs)). H. pylori was detected by histology or urease test in 7 patients. 3 patients showed normal gastric mucosa, 13 patients presented IM or AG either in the antrum or the corpus. According to MAPS criteria 7 patients had extensive disease with premalignant conditions in both, antrum and corpus. The concordance of endoscopic classification and histology was 79.1% (19/24) in the antrum and corpus each. Despite the inconcordance of histology and endoscopic diagnosis in 5 cases the intervals for surveillance according to MAPS guidelines would have been correctly respected with the use of endoscopic assessment in all cases.

Conclusion: LCI and BLI are accurate in detection and characterization of changes in gastric mucosa with an acceptable concordance to histology. These new imaging modalities are a step towards precise endoscopic diagnosis of gastric mucosal changes and have the potential to reduce the number of unnecessary histologic investigations and offer the possibility for more appropriate endoscopic diagnosis.

P1458 LONG-TERM OUTCOMES OF ENDOCOPIC SUBMUCOUS DISSECTION (ESD) FOR RELATIVE INDICATION GROUP OF EARLY ESOPHAGEAL SQUAMOUS CARCINOMA (EESC) IN AGED PATIENTS

Z. Qi1, Y. Zhong1, P. Zhou1
1Endoscopy Center, Zhongshan Hospital Fudan University, Shanghai/China

Contact E-mail Address: poem001@qq.com

Introduction: According to the Japanese Esophageal Society Guidelines, Early Esophageal Squamous Cell Carcinoma (EESC) involving the muscularis mucosa or <200µm invasion of the submucosa, and circumferential extent of >2/3 were relative indications (RI) for ESD. Additional treatment (AT, including esophagectomy or chemoradiotherapy) may be needed after ESD. But in aged EJ patients, most will refuse AT due to higher degrees of debilitating symptoms in China.

Aims & Methods: The aim of this study was conducted to evaluate the long-term outcomes of aged RI patients without AT after ESD.

Results: Between January 2008 and December 2013, a total of 158 aged EJSCC patients were included in the present retrospective study. Prognosis outcomes were analyzed.

Results: 89 patients included in absolute indication (AI) group and 69 in RI group, the baseline characteristics were balanced between two groups. During the follow-up time (median 56 (1-108) months), short-term adverse events (4.3% vs 11%, p = 0.319) and postoperative stricture rate (31.8% vs 21.3%, p = 0.134) were higher in RI group than in AI group. 5-year recurrence-free survival rate (85.8% vs 87.2%, p = 0.501), metastasis-free survival rate (100% vs 98.6%, p = 0.437), overall survival rate (96.6% vs 90.0%, p = 0.613) and cause-specific survival rate (98% vs 98.5%, p = 0.264) for AI group and RI group were comparable.

Conclusion: Aged EJ EESC patients without AT (esophagectomy or chemoradiotherapy) showed comparable prognosis outcomes with AI group after ESD. So follow up may be recommended, substituted for AT in aged RI group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1459 RETROSPECTIVE ANALYSIS ON SUSPICION OF FOREIGN BODY INGESTION AND FOOD IMPACTION ON GASTROENTEROLOGY EMERGENCIES

J. T. Correia De Sousa1, D. Libanio1, P. Lago1, R. Marcos-Pinto1, I. Pedroto1
1Gastroenterology, Centro Hospitalar do Porto, Porto/Portugal

Contact E-mail Address: joao.correia.de.sousa@gmail.com

Introduction: Suspicion of foreign body (FB) and food impaction (FI) are one of the most common motives for endoscopic emergency. This retrospective study reviewed 288 cases of suspicion on FB/FI, by the frequency of endoscopic alterations, predictive factors to presence, types of FB found, and therapeutic approach.

Aims & Methods: Unicentric retrospective cohort study of endoscopies performed during one year of gastroenterology emergency setting.

Results: In 2015, 288 endoscopies were performed on suspicion of FB/FI (22% of total endoscopies), patients, n = 1309, of them 69.1% (n = 199) were performed during the night. Patients’ median age was 58 years, and 52.8% were women. The presence of FB/FI was confirmed in 71.2% (n = 205); of them 61.5% (n = 126) were FB and 38.5% (n = 82) were FI. The most frequently found foreign bodies were meat balls (n = 37) and fish bones (14.6% (n = 30). Most FB/FI were found on the proximal esophagus (56.1%, n = 115). Endoscopic removal was performed on 129 cases (63.4%), endoscopic mobilization in 54 (26.3%), and in 22 endoscopic removal wasn’t achieved (10, where referred of otolaryngology; 2 for surgery and 10 were deferred to endoscopy with sedation, in operating room).

Endoscopy under sedation was performed in 20 cases (9.7%). About 1/4 had associated comorbidities, the most common were esophageal ring in 22 (10.7%) and benign stenosis in 17 (8.3%) patients. Major complications were rare: 1 perforation (0.3%) and 3 deep esophageal lacerations (1.5%). Age (>55years), presence of comorbidities, and previous episodes were associated with presence of FB/FI on Endoscopy (Odds Ratio 2.01, 3.39 and 4.63 respectively).

Conclusion: Endoscopy is frequently preformed for suspicion of FB/FI in our emergency setting. Presence is confirmed in the majority of the cases. Predictive factors for presence were identified. Most FB/FI were removed with success with low complication rates. This data favor the endoscopic approach on suspicion of FB/FI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1460 LEARNING CURVE FOR ENDOCOPIC SUBMUCOSAL DISSECTION OF GASTRIC NEOPLASMS; LOW-VOLUME SINGLE-CENTER EXPERIENCE

S.T. Kim1, T.H. Kim, S. Na
1Internal Medicine, Jeju National University Hospital, Jeju/Korea, Republic of

Contact E-mail Address: panzervor@paran.com

Introduction: Endoscopic submucosal dissection (ESD) has become a standard therapy for early gastric neoplasia. There is no consensus yet about the number of experiences required for performing ESD alone.

Aims & Methods: We aimed to investigate the learning curve of ESD performed by a single beginner endoscopist focusing on developing the performance of dissection, shortening the procedure time, and preventing complications.

Methods: Records of 120 consecutive ESD procedures performed by a single beginner endoscopist with an ESD knife from March 2012 to February 2016 were collected. For analysis of the learning curve, total procedures were divided into four periods, each comprising 30 sequential ESD. The parameters assessed were the en-bloc resection rate, complete resection rate, procedure time, and related complications.

Results: In the procedure time according to the number of experiences, the procedure time decreased from 30 experience to 89 patients included in absolute indication (AI) group and 69 in RI group, the baseline characteristics were balanced between two groups. During the follow-up time (median 56 (1-108) months), short-term adverse events (4.3% vs 11%, p = 0.319) and postoperative stricture rate (31.8% vs 21.3%, p = 0.134) were higher in RI group than in AI group. 5-year recurrence-free survival rate (85.8% vs 87.2%, p = 0.501), metastasis-free survival rate (100% vs 98.6%, p = 0.437), overall survival rate (96.6% vs 90.0%, p = 0.613) and cause-specific survival rate (98% vs 98.5%, p = 0.264) for AI group and RI group were comparable.

Conclusion: Aged EJ EESC patients without AT (esophagectomy or chemoradiotherapy) showed comparable prognosis outcomes with AI group after ESD. So follow up may be recommended, substituted for AT in aged RI group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1461 COMPARATIVE STUDY OF ESD AND SURGICAL RESECTION FOR GASTRIC SETS ORIGINATED FROM MUSCULARIS PROPRIA

C.B. Ryu1, M.S. Lee1, J.Y. Bae2
1Digestive Disease Center And Research Institute, Department Of Internal Medicine, SoonChunHyang University School of Medicine, Bucheon/Korea, Republic of
2Department Of Internal Medicine, Seoul Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: ryubb@gmail.com

Introduction: Endoscopic resection for gastric subepithelial tumors (SETS) originated from muscularis propria (GSET-PM) has offered less invasive alternatives to surgical resection. The aims of this study were to compare endoscopic submucosal dissection (ESD) with surgical resection for the removal of GSET-PM.

Aims & Methods: This study involved 17 patients with GSET-PM removed by ESD and 76 patients who underwent curative surgical resection. ESD was attempted in GSET-PM with small tumors which was below 5 cm and showed an endoluminal growth pattern according to endoscopic ultrasound (EUS) finding.

Results: ESD group were more likely to have upper portion (10/17, 58.8%) and surgery group were more likely to have mid portion (41/76, 53.8%) (p = 0.039). ESD group were smaller median tumor size (25.6 mm vs 35.9 mm, p = 0.037) and higher endoluminal ratio (58.5 ± 9.1% vs 45.8 ± 15.4%, p = 0.002). ESD group were mostly to have Yamada type III (10/17, 58.8%) and surgery group were mostly Yamada type I (52.6, 68.4%) (p < 0.001). Complete resection by ESD was lower than by surgical resection (82.4% vs 100%, p < 0.001). In ESD group, 3 performed surgical resection after ESD (1 incompletely resection and 2 uncontroled bleeding) and 1 showed perforation was completely resected with endoscopic closure. In surgery group, complications occurred in 6 patients (1 leakage, 1 stricture, 1 hernia and bowel obstruction, 1 wound infection and 2 worsened general condition after surgery). Although surgery group were lower in complication rate than ESD group (p = 0.006), severity of complications were higher in the surgery group and there were no mortalities in the ESD group compared with 2 in the surgery group. There was no statistical difference of recurrence and the follow-up period between two groups.

Conclusion: ESD can be one of good options for the resection of endoluminal GSET-PM and could be replace treatment by surgical resection in Yamada type III with a high endoluminal ratio.

P1462  CAP ASSISTED UPPER ENDOSCOPY VERSUS SIDE-VIEWING ENDOSCOPE FOR EXAMINATION OF THE MAJOR DUODENAL PAPILLA: A RANDOMIZED, BLINDED, CONTROLLED, NON-INFERIORITY CROSSOVER STUDY (CAPP- II STUDY)

1Klinik Für Innere Medizin II, Technische Universität München, Munich/Germany
2Institut Für Medizinische Statistik Und Epidemiologie, Technische Universität München, München/Germany
3Gastroenterology And Hepatology, Klinikum Neuperlach, Munich/Germany
4Kaz Alami Hospital, Cairo University, Cairo/Egypt
5Inneren Abteilung, RoMed Klinik Bad Aibling, Bad Aibling/Germany

Contact E-mail Address: dr_mhalfe@hotmail.com

Introduction: Examination of major duodenal papilla (MDP) by standard forward-viewing is limited and the use of side-viewing endoscope (SVE) is mandatory. Cap assisted esophagogastroduodenoscopy (CA-EGD) utilizes a cap fitted to the tip of the endoscope that can depress the mucosal folds and thus might improve visualization of MDP. The aim of this study was to compare CA-EGD to SVE for complete examination of the MDP.

Aims & Methods: Prospective, randomized, blinded, controlled, non-inferiority crossover study. Subjects selected for elective EGD were randomized to undergo CA-EGD (group A) or SVE (group B) before undergoing second examination by the alternate method. Imaging of the MDP were evaluated, after image processing, by three blinded multicenter-experts. Our primary outcome measure was complete examination of the papilla. Secondary outcome measures were image quality of mucosal pattern, ability to obtain an overview of the papilla and overall satisfaction of the evaluators. For secondary outcomes, a score was given from 1 to 10 (poor = 1, excellent = 10).

Results: A total of 62 patients were randomized and completed the study. Complete examination of MDP was achieved in 59 patients using CA-EGD compared to 60 patients using SVE (95 vs. 97%; p = 1.0). CA-EGD had mean scores of 8.7 ± 1.3, 7.1 ± 0.86 and 7.9 ± 1 regarding mucosal pattern, overview and overall satisfaction, respectively, versus 5.3 ± 1.6 (p < 0.001), 8.3 ± 0.9 (p < 0.001) and 7.6 ± 0.6 with SVE (p = 0.01).

Conclusion: CA-EGD is non-inferior to SVE for complete examination of MDP. CA-EGD had significantly higher scores than SVE regarding the image quality and overall satisfaction, while SVE had a better overview. CA-EGD is a safe and effective method for examination of MDP and can replace the SVE for diagnostic indications.

P1463 (IN)ACCURACY OF CAMBRIDGE PROTOCOL FOR PATIENTS HARBOURING CDH1 MUTATION: A CONSECUTIVE SERIES

R. Castro, D. Libânio Monteiro, T. Pinto-Pais, M. Dinis-Ribeiro, C. Brandão

Department Of Gastroenterology, Instituto Português de Oncologia, Porto, Porto/Portugal

Contact E-mail Address: rut.arrais.castro@gmail.com

Introduction: Hereditary diffuse gastric cancer (HDGC) accounts for 1 to 3% of all gastric cancers and is mainly caused by a germline mutation of the gene CDH1. Life time risk for gastric cancer is 80% with a mean age at diagnosis of 40 years. Affected individuals generally present multiple foci of signet ring cell carcinoma (SRCC) scattered throughout the gastric mucosa, difficulty detected by endoscopy.

Aims & Methods: The aim of this study was to access the validity of Cambridge protocol with a high-resolution endoscopy in patients with proven pathological germline mutation of the gene CDH1. A prospective cohort study was performed between September 2016 and March 2017 in 11 patients with CDH1 mutation. They perform a base line high-resolution endoscopy (Olympus-GIF-HQ190) with random biopsies according Cambridge protocol and additional targeted biopsies of endoscopy–for arrest of bleeding or for closure of bowel perforations or chronic fistula. Conventional through-the-scope clips often cannot provide optimum results; and therefore full-thickness (FT) over-the-scope (OTS) clips have been devised.

Aims & Methods: Current study describes the clinical experience of use of a recently developed FT OTS clip (PadlockTM, Aponos Medical, USA). Data from a prospectively maintained database of all patients undergoing the new Endoscopic-Clip procedure was abstracted. Patient demographics, primary diagnosis, history of previous endotherapy, endoscopic procedure, indications for FT OTS clip usage, technical and clinical success and early and delayed adverse events were recorded. The clip-clip is available in two different sizes for use in upper and lower endoscopy. It is supplied preloaded on a cartridge that fits on the distal end of the endoscope. The trip-wires travels alongside the endoscope, enabling additional instruments to be passed through the endoscope channel, and special double-channel endoscope is not required for its application. Technique of clip application–the clip was loaded on the distal end of the endoscope and endoscope advanced to site of interest. Bowel wall defect or bleeding point was positioned within the clip and strong suction was applied. Clip was fired by closing the handle on the delivery system. Suction was slowly released and site was inspected.

Results: Total 21 clips used in 19 patients. M: F=12:7, mean age–57.9 years (range –24–94 years). Indications for FT OTS clip use–severe GI bleeding–7 (36.8%) (duodenal ulcer bleed–5, rectal ulcer–1, bleed during ESD for rectal lateral spreading tumor–1), for closure of bowel perforation during endoscopic resection–7 (36.8%) (gastric–3, duodenum–2, rectum–2); and closure of chronic bowel fistuлаe–5 (26.3%) (esophagus–3, duodenum–1, rectum–1). Previous h/o endotherapy–3/7 of bleeding patients, primary therapy using OTS clip in remaining 16. Technical success was 100%. Two patients needed two clips each due to large size of defect. Clinical success–bleeding arrested in 7/7 (100%), bowel perforation sealed–7/7 (100%); fistula closure successful–4/5 (80%). In one patient of chronic duodenal fistula, fistula reopened 12 weeks after initial sealing of fistula and required surgery. Follow up at 4 weeks revealed no delayed adverse events in any patient.

Conclusion: The new OTS Clip (PadlockTM, Aponos) is safe and effective for treatment of severe bleeding and for closure of post ER full-thickness defects and chronic fistulae. Further studies with larger sample size are recommended. All authors have declared no conflicts of interest.

References
Results: 19 patients underwent EA, with a mean age of 63.5 ± 17.7 years and a successful resection of the tumor of 17.4 ± 8.8 mm. The male to female ratio is 0.7. "En bloc" resection was done in most cases 15/19 (78.9%). Bleeding occurred in 6 cases (31.6%) and two patients (10.5%) developed acute pancreatitis. One patient died due to severe bleeding. The average days of hospitalization after endoscopic ampullectomy were 5.7 with a range from 2 to 25 days. Adenocarcinoma was described in the final histopathological result in 4/19 cases (21.1%). One year follow-up noted a recurrence rate of 15.8% (3/19 cases).

Conclusion: In conclusion, endoscopic ampullectomy is a difficult procedure with an increased risk of complications but performed by experienced endoscopists is safe and surgical interventions can be avoided.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1466 PER ORAL ENDOSCOPIC MYOTOMY: UPDATED RESULTS FROM A UNITED KINGDOM CASE SERIES
S. Gulati1, A. Emmanuel1, H. Inoue2, A. Haji1, B. Hayee1
1Endoscopy, King’s Institute of Therapeutic Endoscopy, RS/United Kingdom
2Digestive Disease Center, Showa University Koto-Toyosu Hospital, Tokyo/Japan

Contact E-mail Address: shraddha.gulati@nhs.net

Introduction: Per-oral endoscopic myotomy (POEM) has been adopted as a minimally invasive treatment option for achalasia and even spastic oesophageal conditions1. The first case of POEM was performed at the King’s Institute of Therapeutic Endoscopy (KITE) in 2013. Here we present our initial case series including the first UK case of diffuse oesophageal spasm (DES).

Aims & Methods: Prospective data was collected for consecutive patients undergoing POEM including demographics, POEM technique, the use of Endoluminal Functional Lumen Imaging Probe (EndoFLIP) and adverse events. Clinical success was defined as a reduction of Eckardt score (ES) to < 2 or a reduction in 4 points from baseline. Follow up data at 3 and 12–24 months (m) post-POEM was analysed using the Wilcoxon signed ranks test to compare pre- and post-POEM ES and 4sIRP and pre and post-treatment GORD-HRQoL score. Repeated measures ANOVA was used for multiple time-point comparisons.

Results: POEM was performed in 51 patients (22F, age 48.6±13.5 years). Further baseline data is presented in table 1. Median gastric and oesophageal myotomy was 3 cm (2–4) and 10 cm (3–18) respectively with a selective circular myotomy in all cases and a posterior approach in 11. POEM was clinically successful in n=48/51 (94%) eligible for review at 3m. Reduction in ES at 3m; 8.5 (5–12) vs 0 (0–6) p < 0.0001 was sustained in 31 patients with median follow up of 15m (3–36); 8.5 (5–12) vs 0 (0–7) ANOVA p < 0.0001. Reduction in IRP-4s was observed 24.05 ±/−10.47 mmHg vs 7.81 ±/−4.91 mmHg (p = 0.0001). Revision of POEM was performed in n=3 at 6, 16 and 27m with clinical success achieved in all cases at 3m review. Pre and post-myotomy EndoFLIP showed an increase in oesophago-gastric junction diameter from 5.87 mm to 11.27 mm (p = 0.0001) (n = 11) and distensibility improved from 1.14 mm/mmHg to 2.87 mm/mmHg (p = 0.008) (n = 8). Median post-POEM GORD-HRQoL score (n = 50) was 1 (0–3). 8 patients with scores >12 improved with medical treatment; 15.5 (13–31) vs 6.5 (1–11; p = 0.0078) as did 5 cases of acid reflux identified by 24 hr pH testing in n = 19 at time of analysis. Endoscopic displacement was encountered in n=2 and replaced endoscopically including readmission of 1 patient for delayed mucosal incision site healing (Clavien-Dindo Grade Ib). There were no cases of mortality, perforation, infection/major bleeding.

(continued)

Conclusion: This is the largest UK case series of POEM for achalasia including the first successful UK POEM procedure for DES. At our institute, POEM was performed successfully in a potentially more challenging cohort where 52.9% had prior endoscopic/surgical treatment with intervention. Our results are in line with international consortia and ASGE findings that POEM is a safe and efficacious procedure for the treatment of achalasia and oesophageal spastic disorders for both short term and sustained symptomatic benefit.

P1467 NEW CHALLENGE FOR SAFER ENDOSCOPIC SUBMUCOSAL DISSECTION USING CO2 LASER
Y. Morita, R. Aiyoshi
Gastroenterology, Kobe University, Kobe/Japan

Contact E-mail Address: ymorita@med.kobe-u.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) is increasingly accepted as a minimally invasive treatment for the patients with early gastrointestinal cancers. However, ESD demands high maneuverability technique, and the success of the operation is dependent on each operator’s skill. We have developed a novel laser surgery system for ESD to overcome such difficulties of ESD, which is composed of a CO2 laser source and a disposable flexible hollow fiber probe. Compared to conventional ESD (C-ESD) using electric surgical knives, ESD using CO2 laser (L-ESD) method has an advantage of less risk of perforation and massive thermal damage, because the CO2 laser is strongly absorbed by water such as saline or sodium hyaluronate. Further more, the cutting point can be precisely recognized by another visible guide laser. Due to non-contact laser irradiation and adequate visualization of treatment area, the laser system facilitates more precise and safer treatment and provides high quality and stable dissection. We hypothesized that performing ESD using CO2 laser with a submucosal laser absorber could be a safer and simpler ESD technique.

Aims & Methods: The aim of this study was to evaluate the feasibility of L-ESD and the quality of the resected specimen obtained by L-ESD in living porcine compared with C-ESD. We performed ESD for a total of 14 hypothetical lesions in three porcine stomachs (L-ESD, 7 lesions; C-ESD, 7 lesions) under general anesthesia. En-bloc resection rate, procedure time, adverse events, and the quality of the resected specimen were evaluated. To evaluate the smoothness of the cutting surface in the resected specimens, we compared the length of the resected side of the submucosa (LRS) with the length of the muscularis mucosa (LMM). Results: The en-bloc resection rate was 100% in both groups. Although the mean L-ESD procedure time was 23.3 ± 20.8 minutes, and was significantly longer than that in the C-ESD group (9.4 ± 6.6 minutes; p < 0.02), there was no uncontrollable bleeding or perforation in either group. The mean ratio of LRS to LMM was 107 ± 3.3% in the L-ESD group, and was significantly lower than that of the C-ESD group (138 ± 28%) (p < 0.005).

Conclusion: ESD using CO2 laser might be a feasible and effective method for the treatment of early gastrointestinal cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1468 LONG-TERM OUTCOME OF ACUTE CORROSIVE INGESTION: A PROSPECTIVE SINGLE-CENTER STUDY
S. Dhur Chowdhury, B. Kumar, R. T. Kurien, S. K. Ghatak, D. Sreekar
Gastroenterology, Christian Medical College, Vellore, Vellore/India

Contact E-mail Address: sudipta@cmcvellore.ac.in

Introduction: Acute corrosive ingestion (ACI) is a common and serious medical problem accounting for a number of hospital admissions. ACI causes significant mortality and morbidity. These patients are at risk of developing luminal strictures of the upper gastrointestinal tract in the long term. This is more in patients with high-grade injury.

Aims & Methods: The present study aimed at assessing the long-term outcomes of high-grade (Zargar’s grade ≥Grade 2A) corrosive-induced injury of upper gastrointestinal tract (1). This was a prospective study conducted in the Department of Gastroenterology at Christian Medical College, Vellore. The study period was between January 2008 to December 2014. All patients were managed by a standard protocol which included doing a gastroscopy within 24 hours of ACI. In this study we included patients ≥15 years with high-grade (Zargar’s grade
Grade 2A) corrosive-induced injury of upper gastrointestinal tract. Patients in which biopsy could not be done or where the lesion was missed by hospital were excluded from the study. The study was approved by the Institutional Ethics committee and was funded by a fluid research grant received from Institutional Review Board at Christian Medical College, Vellore, India. The data was analysed using SPSS version 17. The continuous and categorical variables were expressed as, mean ± SD and the non parametric continuous variables were expressed as median. Comparison between groups were done using Fisher’s exact test.

Results: During the study period a total of 112 patients presented with ACI. In all 82 patients were included in the study. Amongst them, 53% of the patients were females and the mean age was 36.5 ± 15.5 years. The intent of corrosive ingestion was suicidal in 70% and accidental in 30%. In majority (50%) of patients the nature of corrosive and gastro-intestinal injury was not known. Nasogastric tube placement was done in 50%, nasojugal tube placement in 32% and 8% no tube was placed. Surgery as needed in 19% (tracheostomy or feeding jejunostomy or a definitive surgery). Amongst the 82 patients who were included in the study, 11 were lost to follow up. The remaining 71 patients in whom the median follow up period was 31 months (range 2 m–72 m) during which 12 (16.9%) patients expired (73% related to ACI). Amongst the 59 patients, that were alive 16(27%) were symptomatic, 12(20%) had dysphagia, 5(6%) had regurgitation, 4(5%) had chest pain, 67(92%) had weight loss and 11(18%) patients required gastrostomy tube insertion. In all, 43(73%) patients underwent barium study during follow up and strictures were noted in 21(36%). The site of stricture was esophageal in 11(53%), stomach in 8(38%) and combined esophago-stomach and in 20%(39%). Esophageal stricture was seen in all patients with Grade III B esophageal injury, 27% (6/22) with Grade III A injury and 19%(5/27) with Grade II B injury. None of the patients with Grade II A injury developed stricture. Stricture in stomach developed in 22% (2/9) of patients with Grade III B injury as well with Grade III A injury, 10%(1/10) with II B injury and 20% (1/5) with II A injury.

Conclusion: Acute corrosive ingestion is associated with significant morbidity and mortality. There needs to be stringent control on sale, use and storage of such chemicals.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI1469 PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY (pCLE) FOR IN VIVO DIAGNOSIS OF ESOPHAGEAL AND GASTRIC LESIONS - RESULTS OF A PROSPECTIVE, CONTROLLED, CROSS-OVER STUDY
M. Kollar1, J. Krajcova1, J. Malusova2, M. Kment2, Z. Vacova2, J. Spicak2, J. Martinek2
1Clinical And Transplant Pathology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
2Department of Pathology and Endomicroscopy, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
Contact E-mail Address: marik.kollar1@seznam.cz

Introduction: Probe-based confocal laser endomicroscopy (pCLE) provides real-time microscopic visualization with 1000-fold magnification, allowing endoscopic access to the histological evaluation of gastrointestinal lesions. pCLE may thereby be helpful in guidance of endoscopic therapy. However, histopathological assessment still remains a gold standard for histological diagnosis so far, while pCLE-based diagnosis has not been generally accepted yet. Therefore, more studies assessing diagnostic accuracy of pCLE are warranted.

Aims & Methods: The aim of the study consisted in the analysis of the accuracy of three risk scoring systems used in non-variceal upper digestive bleeding for assessing patient’s prognosis, previously estimated to be predictive for re-bleeding/death after gastrointestinal bleeding. We assessed prospectively a batch of 1872 patients admitted in the Gastroenterology Department of Emergency County Hospital Timisoara in a 12-year period, in which we calculated 3 risk scoring systems, Rockall, Cedars-Sinai and Baylor, based on clinical and endoscopic data. We compared their accuracy for assessing patient’s prognosis, expressed as the need of blood transfusions, number of hospitalization days, re-bleeding, surgery and death. Discriminative ability was assessed using the area under the receiver operating characteristic curve (AUROC).

Results: The batch included 1134 (60.6%) male and 738 (39.4%) female, mean age 62.7±8 years. Regarding the need of blood transfusions, the predictive ability of the scores is as follows: Rockall AUROC 0.59 (CI 0.55-0.62), sensitivity (Se) = 81.7%, specificity (Sp) = 35.5%, positive predictive value (PPV) = 28.4%, negative predictive value (NPV) = 86.1% (p < 0.0001); Cedars-Sinai AUROC 0.59 (CI 0.55-0.63), Se = 72.4%, Sp = 41.3%, PPV = 28.5%, NPV = 82.3% (p < 0.001); Baylor AUROC 0.56 (CI 0.49-0.63), Se = 41.9%, Sp = 75.5%, PPV = 40.6%, NPV = 76.5%. Number of hospitalization days: Rockall AUROC 0.66 (CI 0.55-0.77), Se = 61.5%, Sp = 65.2%, PPV = 90%, NPV = 25% (p = 0.003); Cedars-Sinai AUROC 0.63 (CI 0.50-0.75), Se = 53.1%, Sp = 73.9%, PPV = 89.5%, NPV = 27.4%; Baylor AUROC 0.52 (CI 0.51-0.73), Se = 47.06%, Sp = 66.6%, PPV = 84.2%, NPV = 25%. Re-bleeding: Rockall AUROC 0.66 (CI 0.63-0.67), Se = 61.5%, Sp = 65.2%, PPV = 90%, NPV = 25% (p = 0.003); Cedars-Sinai AUROC 0.73 (CI 0.69-0.77), Se = 84.8%, Sp = 49.02%, PPV = 13.7%, NPV = 97%; Baylor AUROC 0.54 (CI 0.45-0.65), Se = 35.1%, Sp = 81.2%, PPV = 16.2%, NPV = 92.4%; Surgery: Rockall AUROC 0.67 (CI 0.61-0.73), Se = 71.2%, Sp = 59%, PPV = 16%, NPV = 98.1%; Cedars-Sinai AUROC 0.72 (CI 0.66-0.78), Se = 58%, Sp = 77.4%, PPV = 9.3%, NPV = 97.9%; Baylor AUROC 0.55 (CI 0.41-0.66), Se = 50%, Sp = 66.2%, PPV = 5.1%, NPV = 94%. Death: Rockall AUROC 0.65 (CI 0.58-0.73), Se = 79.1%, Sp = 53.1%, PPV = 18.2%, NPV = 99.5% (p = 0.001); Cedars-Sinai AUROC 0.71 (CI 0.66-0.76), Se = 83.1%, Sp = 48.1%, PPV = 10.2%, NPV = 97.6%; Baylor AUROC 0.75 (CI 0.67-0.83), Se = 76.09%, Sp = 72.3%, PPV = 19.2%, NPV = 97.2%. There were no statistically significant differences encountered in predicting the need of blood transfusions and surgery between the scores (p > 0.05). Score variation was superior in Rockall in estimating the hospitalization period (p = 0.004) and re-bleeding (p = 0.004), and Cedars-Sinai proved to be superior in Baylor score in predicting re-bleeding (p = 0.002) and to Rockall score in predicting death (p = 0.006).

Conclusion: On our cohort of patients, Cedars-Sinai score proved to be the best in predicting the re-bleeding and death in patients with NV-UDB in comparison to Rockall and Baylor scores.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI1471 PERCUTANEOUS ENDOSCOPIC GASTROSTOMY: A SAFE PROCEDURE EVEN IN CANCER PATIENTS
J. Pinho1, J. Lage2, D. Libânio1, S. Ferraz2, N. Silva2, M. Dinis-Ribeiro2, C. Brandão2
1Gastroenterology, Centro Hospitalar Tondela/Viseu, Viseu/Portugal

Introduction: Dysphagia and malnutrition is a common feature in up to 64% of patients with advanced gastrointestinal and biliary cancer, and need of radiotherapy or chemotherapy often worsens this symptoms. Percutaneous endoscopic gastrostomy (PEG) is the preferred route of feeding and nutritional support in these patients. Although generally considered to be a safe procedure, it has been reported that PEG tube placement complications in cancer patients may be superior when compared to non-cancer patients.

Aims & Methods: The aim of this study was to evaluate the complications rate after PEG tube placement in cancer patients. We did a single-centre prospective database including all patients with PEG tube insertion between March 2014 and June 2016, evaluating the complications during 6 months follow-up.

Results: A total of 265 patients (83% men, mean age 59 years) underwent PEG tube insertion. 224 patients (84.5%) had head and neck cancers and 33 patients

Disclosure of Interest: All authors have declared no conflicts of interest.
(12.5%) had esophageal cancer; 207 patients (78.1%) had stage IV disease. At the time of analysis, 138 patients (52%) had grade 3 dysphagia and the mean body mass index (BMI) was 20.9 Kg/m2. All the patients underwent antibiotic prophylaxis previous to the procedure. There was an increase on BMI to 23.8 Kg/m2 at 6 months follow up. Eight patients (3.8%) had immediate complications after the procedure (bleeding from the PEG tract; 6; anesthetic complications - 2). The overall complication rate at the first month of follow up was 14.4%, at the third month 20.5% and at the sixth month 11.7%. The overall peri-PEG infection rate was 14%, and was the main complication at the first month of follow up. Development of hyper-granulation tissue was the most frequent complication at the third month of follow-up. Buried bumper syndrome occurred in 10 patients (3.7%). None of the patients had tumor seeding at the gastroscopy site. Overall mortality was 26.4%, none of the deaths attributable to PEG tube insertion.

Conclusion: PEG placement is a safe and effective technique in cancer patients. The rate of major complications and tube site infection were similar to the results found in literature for non-cancer patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1475 GASTROINTESTINAL ENDOSCOPY UNDER SEDATION IS ASSOCIATED WITH PNEUMONIA IN OLDER INPATIENTS–RESULTS OF A RETROSPECTIVE CASE-CONTROL STUDY

C. M. Kollmann, W. Schmiegel, T. Brechmann
Department Of Gastroenterology And Hepatology, Berufsgenossenschaftliches University Hospital Bergmannsheil GmbH, Bochum/Germany

Contact E-mail Address: christopher.kollmann@rub.de

Introduction: Apparent aspiration is a notable adverse event during gastrointestinal endoscopy under sedation (GES) [1, 2], but about the incidence and the role of inapparent aspiration is scarce. Furthermore, patients undergoing endoscopies experience respiratory symptoms such as coughing, shortness of breathing, fever and other respiratory adverse events within 24 hours relatively often in more than 5% [3]. Since coughing during endoscopy has been attributed to an increased risk of aspiration-related postprocedural infection [4] respiratory infections might be underreported. Additionally, patients in advanced age are not only determined as a high-risk group for GI adverse events following colonoscopies [5], but are also more likely to develop hospital-acquired pneumonia [2]. Therefore, the aim of the study was to determine the risk of pneumonia, lower respiratory infection (LRI) and systemic inflammatory activation after GES.

Methods: A total of 250 consecutive inpatients who had undergone GES during a hospital stay of at least three days were included in a retrospective cohort study. Age-, gender- and length of hospital stay-matched controls (ratio 1:1) who had not undergone any invasive procedure or sedation served as controls. Vomiting cases had to be available before and three and/or seven days after endoscopy. Primary objective was the occurrence of pneumonia in general and older patients (> 65 years). Secondary objectives were the development of LRI, elevation of inflammatory markers (CRP and WBC), initiation of antibiotic treatment, pathogen detection and pulmonary inflation. Statistics included χ² test, paired t-test, ANOVA, multiple linear regression analysis.

Results: No significant differences for the occurrence of pneumonia (1.6%, GES group vs. 0.4%, control group, p = 0.18, χ² test) and LRI (4.8% vs. 2.0%, p = 0.041 in general, but in the older age group (2.6% vs. 0.0%, p = 0.041, and 7.8% vs. 2.5%, p = 0.034, respectively) were detected. Inflammatory parameters were significantly increased after GES, particularly on day three. GES patients received antibiotic treatment more frequent while pulmonary inflation did not differ.

Conclusion: This data confirms a higher risk of pneumonia due to GES in the advanced aged population. In general, patients are more likely to develop inflammation and to receive antibiotic treatment suggesting an increased risk of radiologically non-visible inflammation due to micro-aspiration.

Introduction: Endoscopic submucosal dissection (ESD) is an established technique for the treatment of gastrointestinal (GI) neoplasia in Japan. The high uptake and mastery of the procedure there was in part enabled by the high prevalence of early gastric cancer in Japan. Conventional practice in Japan is to admit patients for 3 to 5 days after the ESD procedure for monitoring in view of the risk of serious complications which is between 1–10%. Cost and resource provision in a publicly-funded Western healthcare setting favours shorter planned stays following ESD.

Aims & Methods: We aimed to identify the type and site of lesions being treated in a Western setting as well as the rate, timing and predictors of complications in order to evaluate current admission practice. An electronic database of all ESD procedures performed in our academic institution from 2012–2017 was analysed. Parameters were the number, type, onset and management of complications following ESD. Significant complications (bleeding and perforation) necessitating hospital admission were categorised as early (within 24 hours) and delayed (24 hours to 28 days) post procedure.

Results: A total of 410 ESDs were performed within the time period (225 colorectal, 117 oesophageal, 52 gastric and 16 duodenal). There were 21 complications (ESD for gastric and duodenal lesions had a higher complication rate (11.5% and 12.5% respectively). The table below stratifies the complications according to type, location and onset.

</tr>
</tbody>
</table>

19 of the 21 total complications (90.5%) were successfully managed endoscopically. 1 patient underwent an emergent right hemithoracotomy for a delayed colonic perforation and 1 patient had radiological embolisation for a bleed 7 days following a caecal ESD. 72.7% (8/11) of the patients who experienced delayed bleeding presented 7–10 days following ESD. Of this, 50% occurred following recommencement of anticoagulants/antiplatelets.

Conclusion: ESD in this Western setting was more commonly performed for colorectal and oesophageal lesions rather than gastric as seen in Japan. The complication rate is modest and almost all were managed successfully with an endoscopic approach. They occurred more commonly in gastric and duodenal sites. This may be related to the technical difficulties of resection or low volume of procedures performed at these locations. The use of anticoagulants is a risk
factor for delayed bleeding. Given that the majority of delayed complications occurred due to the endoscopy and post procedure, a standardised 5 day inpatient stay would prove futile in our cohort.

P1478 PREDICTIVE FACTORS AND MANAGEMENT OF REFRACTORY BENIGN OESOPHAGEAL STRICTURES
M. Mouna, C. Simões, C. Noronha Ferreira, P. Santos, J.P. Freire, J. Lopes, L. Carrilho Ribeiro, J. Velosa
Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, E.P.E., Lisboa Portugal

Introduction: The optimal management and the predictive factors of response to endoscopic dilatation of refrainatory benign oesophageal strictures remains controversial.

Aims & Methods: To evaluate the prevalence and factors predicting response to treatment of benign reflux oesophageal strictures with scheduled endoscopic dilatations

Results: The study sample included 42 (56%) male patients and the mean age was 55.9 ± 17.6 years. Dysphagia scale at baseline was 38 (24.7–43.3). Sphincter of Oddi dysfunction was identified at least once in 39 (52%) patients and in 25% of dilations in 39 (52%) patients. From the study sample, 23 (36.1%) patients fulfilled criteria of refractory strictures. In this subgroup, there was a significant association with post-surgical aetiology (p = 0.02). Location of the stricture (p = 0.014) and higher rate of local injection of corticosteroids (p < 0.001) and higher dilation diameter (p < 0.001). Refractory strictures were significantly associated with the need for local corticoid injection (OR 9.76, 95%CI 0.05–0.46, p = 0.02) by binary logistic regression analysis. However, none of the other factors were found to be independent predictors of response to therapy.

Conclusion: Surgical aetiology was significantly associated with refractory benign oesophageal strictures and these patients were significantly more likely to require local corticosteroid injections during scheduled dilatations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1479 LOCAL CORTICOSTEROIDS IMPROVE EARLY CLINICAL OUTCOMES IN PATIENTS UNDERGOING ENDOSCOPIC DILATION OF BENIGN OESOPHAGEAL STRICTURES
M. Mouna, C. Simões, C. Noronha Ferreira, P. Santos, J.P. Freire, J. Lopes, L. Carrilho Ribeiro, J. Velosa
Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, E.P.E., Lisboa Portugal

Introduction: Local corticosteroids have been shown to improve outcomes in patients undergoing endoscopic dilation of peptic strictures.

Aims & Methods: To evaluate factors predicting early clinical response to endoscopic dilation of benign oesophageal strictures. Retrospective analysis of 75 patients submitted to endoscopic dilation of benign oesophageal strictures between October 2010 and November 2016. Scarcities were classified as refractory when ≥ 5 endoscopic dilatations were needed with at least one dilation achieving ≥ 15 mm of diameter during the course of management of the oesophageal strictures.

Results: The study sample included 42 (56%) male patients and the mean age was 55.9 ± 17.6 years. Dysphagia scale at baseline was 38 (24.7–43.3). Sphincter of Oddi dysfunction was identified at least once in 39 (52%) patients and in 25% of dilations in 39 (52%) patients. From the study sample, 23 (36.1%) patients fulfilled criteria of refractory strictures. In this subgroup, there was a significant association with post-surgical aetiology (p = 0.02), location of the stricture (p = 0.014) and higher rate of local injection of corticosteroids (p < 0.001) and higher dilation diameter (p < 0.001). Refractory strictures were significantly associated with the need for local corticoid injection (OR 9.76, 95%CI 0.05–0.46, p = 0.02) by binary logistic regression analysis. However, none of the other factors were found to be independent predictors of response to therapy.

Conclusion: Surgical aetiology was significantly associated with refractory benign oesophageal strictures and these patients were significantly more likely to require local corticosteroid injections during scheduled dilatations.

P1480 TRENDS IN CERTIFICATION FOR GASTROINTESTINAL ENDOSCOPY AND VARIATIONS BETWEEN TRAINEE SPECIALTIES: RESULTS FROM THE UK TRAINEE ENDOSCOPY DATABASE
*JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/United Kingdom

Introduction: In the UK, endoscopy certification is overseen by the Joint Advisory Group. Since 2011, certification has been awarded for upper and lower GI endoscopy online via the JAG Electronic Training System (JETS).

We aimed to analyse trends in endoscopy e-certification, and assess for differences between trainees in gastroenterology (GI), surgical (GS) and non-medical endoscopic specialties (NME).

Aims & Methods: We prospectively identified trainees awarded certification for gastroscopy, flexible sigmoidoscopy (FS) and colonoscopy from the JETS database. For each specialty, we collected data on lifetime procedural counts, for-mative assessments, and key performance indicators (KPIs) at the time of certification.

Comparisons between specialties were analysed using a combination of chi², Mann-Whitney and median tests.

Results: Between June 2011-Dec 2016, 2857 applications were awarded certification. Numbers of gastroscopy and provisional colonoscopy awarded have been in steady state since 2013, whilst numbers for sigmoidoscopy and full colonoscopy continue to increase. Trainees awarded certification comprised mainly of GI (53.2%), GS (28.5%) and NME (15.5%) trainees. With the exception of FS, most certifications were awarded to GI trainees (Figure 2). Median procedural numbers (p < 0.001) and formative DOPS count (p < 0.001) pre-certification varied for each modality in the order of NME > GI > GS. Caecal intubation rates (CIR) at full certification were similar between GI (95.6%) and GS (95.6%, p = 0.81), but lower in NME (93.6%, p = 0.02 vs. GS, p = 0.006 vs. GI), despite no differences at provisional certification (median CIR 95.6%, p = 0.32). Rates of D2 intubation (median 98.7%) varied across groups (GS > GI > NME, p = 0.002). Certification awarded at first attempt were similar across specialties (NME 95.5%, GS 90.1%, GI 89.7%, p = 0.01).

Conclusion: Despite variations amongst trainee specialties, endoscopy certification is a transparent and robust benchmark for assessing competency, as evidenced by trainee KPIs. Further studies are required to study the impact of recent changes to certification, and if variations in KPIs exist following certification.

P1481 EFFICIENCY AND SAFETY OF ENDOSCOPIC PAPILLECTOMY FOR TREATMENT OF DUODENAL PAPILLOMA TUMORS
Y. Chu1, M. Xu2, P. Zhou2, C. Zhang1
1 Endoscopy Center And Endoscopy Research Institute, Fudan University Zhongshan Hospital, Shanghai/China

Contact E-mail Address: xu.meidong@zs-hospital.sh.cn
Introduction: A duodenal papilla tumor is an uncommon neoplasm in the upper gastrointestinal tract. In the early stage, patients often have no complaints and the tumors are usually occasional found during gastroduodenoscopy examination. Endoscopic papillectomy can be achieved with curative resection for benign adenoma and some early papillary carcinoma. However, some complications are accompanied with the procedure, like pancreatitis and bleeding. This retrospective study is to evaluate therapeutic effect and safety of endoscopic papillectomy on duodenal papilla tumors.

Aims & Methods: From June 2009 to November 2016, the information of patients who received endoscopic papillectomy was recorded, which included basic characteristics and clinical outcomes, such as recurrence rate, bleeding, pancreatitis. Eighty-four patients (totally 40 cases) received endoscopic papillectomy. The procedure was completed with gastroscope in 32 cases and duodenoscope in 8 case. Endoscopic mucosal resection (EMR), endoscopic piecemeal mucosal resection (EPMR) and endoscopic submucosal dissection (ESD) was performed in 21, 17 and 2 cases respectively. None of the lesions invaded the submucosal layer.
Pancrætic stents and biliary stents were inserted in 9 and 12 patients respectively. In general, 5% (2/40) and 12.5% (5/40) cases had intraoperative and postoperative bleeding respectively. 20% (8/40) cases suffered from pancreatitis, of which mild, moderate and severe happened in 3, 4 and 1 cases. Six patients had tumor recurrence. And 3 patients received repeat endoscopic papillectomy, two received pancreatic-coduodenectomy and one received no other treatments with close follow-up. Two patients died from failures of treatment for papillary tumors and one patient died due to other unrelated cause.

P1482 CHANGES IN SCORING OF DIRECT OBSERVATION OF PROCEDURAL SKILLS (DOPS) FORMS IN ENDOSCOPY TRAINING AND THEIR IMPACT ON COMPETENCE ASSESSMENT
1Gastroenterology, Vivantes Klinikum Friedrichshain, Berlin/Germany
2Visceral Surgery, Vivantes Klinikum Friedrichshain, Berlin/Germany
3Anesthesiology, Vivantes Klinikum Friedrichshain, Berlin/Germany
4Service D’endoscopie Digestive, Hôpitaux Universitaires Strasbourg, Strasbourg/ France

Contact E-mail Address: kai.2.siau@fgn.de

Introduction: DOPS are validated tools for assessing competence in endoscopy. Previously, DOPS were scored on a 4-point competence-based scale, with scores of 3 and 4 signifying competence. In July 2016, the DOPS rating scale changed to a supervision-based scale that has been shown to be more reliable, with 4 ratings from maximal supervision, up to competent without supervision. We aimed to assess whether changes to the rating scale had affected distribution of scores and hence demonstrated validity.

Aims & Methods: We used the UK trainee endoscopy database (JETS) to collect DOPS scores for gastroscopy (n = 1934), sigmoidoscopy (n = 517), colonoscopy

(n = 2296) and polypectomy (n = 370) in the 6-months before July 2016 (old DOPS) and 6 months after (new DOPS). Trainees at early stages of training (total procedures < 100). To allow analysis, the new DOPS rating scale was aligned to a 4-point scale, hence a score of 4 on new DOPS = Scores 3 or 4 on old DOPS, and scores on the new and old DOPS compared using the Mann-Whitney U-test. 517 (new DOPS (77.7%) and 223 (3.0%) old were included for analysis. Overall, there were variations in distributions of all scores (p < 0.001) between forms (Figure 1). Compared to new DOPS, scores of 1 were underutilised on old DOPS (6.6% vs. 3.0%, p < 0.001). Frequencies of low scores (pooled scores of 1/2) were similar for gastroscopy (p = 0.53) and sigmoidoscopy (p = 0.34), but not for colonoscopy (new 11.9% vs. old 13.9%, p = 0.001) and polypectomy (new 6.8% vs. 19.9%, p < 0.001). Trainees on old DOPS were more likely to be rated as competent (score 3 or 4) compared to new DOPS (86.4% vs. 55.8%, p < 0.001). On subgroup analysis, this was evident for gastroscopy (86.3% vs. 49.1%, p < 0.001), colonoscopy (86.1% vs. 58.2%, p < 0.001), sigmoidoscopy (90.6% vs. 62.0%, p < 0.001), but not polypectomy (80.1% vs. 67.9%, p = 0.12).

Conclusion: Endoscopy assessors are applying a greater range of scores using a new DOPS rating scale based on degree of supervision, in two cohorts of trainees matched for experience. This indicates better construct validity with the new rating scale. Further work is underway to determine the reliability of the new DOPS to inform summative assessment and certification for UK endoscopy trainees.

P1484 PROTECTIVE VACUUM SPONGE IMPLANTATION AND CONTINUOUS EVACUATION OF BILE AND Pancreatic JUICE FOR PREVENTION OF SECONDARY PERFORATION AFTER PRIMARY SUCCESSFUL ENDOSCOPIC RESECTION OF WIDESPREAD D2/D3 DUODENAL AND PAPILLARY ADENOMATA
J. Hochberger, M. Loss, C. von Heymann, C. Jung, E. Wedl, M. Hofmeyer
1Gastroenterology, Vivantes Klinikum Friedrichshain, Berlin/Germany
2Visceral Surgery, Vivantes Klinikum Friedrichshain, Berlin/Germany
3Anesthesiology, Vivantes Klinikum Friedrichshain, Berlin/Germany
4Service D’endoscopie Digestive, Hôpitaux Universitaires Strasbourg, Strasbourg/ France

Contact E-mail Address: juhoechberger@mac.com

Introduction: Endoscopic resection of duodenal adenomata carries an increased risk of perforation compared to other locations in the upper or lower GI tract.1,2 Additionally in endoscopic resection of widespread adenomata (Spigelman III/IV) at the level of D2/D3 there is an increased risk of secondary perforation due to auto-digestion of the denuded duodenal wall by pancreatic enzymes and bile independent of the primary endoscopic resection method. We recently reported of the successful implantation of a mini-vacuum sponge with extended length of the suction tube and reduced in volume compared to a standard esophageal vacuum sponge.3

Aims & Methods: From September 9th, 2015 to March 20th, 2017 endoscopic resection of widespread duodenal or papillary adenomata of >=2 cm in D2/D3 was performed in five patients. There was a surgical indication for Whipple's resection as primary intervention or in case of failure in all patients. All patients agreed and gave their informed consent to the procedure.

Results: Five patients with widespread duodenal adenomata were included (2x papilla, 3x D2/D3 extrapapillary adenomata; 5x tubular; 3x HGIN, 2x LGIN). The macroscopic mean maximum diameter and perpendicular diameter of the lesions were 4.3 ± 2.8 cm (largest 7.5 ± 3.7 cm; smallest 2.2 ± 1.8 cm). In all cases the implantation of mini-vacuum sponge Evac reduced in volume to 1.2 ± 1.5 cm (dia. length) with extended suction tube; Braun Corp, Melsungen). Continuous suction was applied over several days (~125 mm Hg; ActiVac, KCI Medical, Wiesbaden) depending on the size of the resection area and healing status (n = 10 days, 4–14 days). An endoscopic/radiologic vacuum sponge exchange was performed every 3–5 days. In 4 cases additional atraumatic over-the-scope-clips (OTSC, Ovesco Tuebingen) were placed during the procedure and in 5/8 cases additional hemoclips were applied to secure the wall and for hemostasis. In 5/8 cases (100%) an excellent healing could be observed during follow-up. No patient had to be operated during or following the intervention (FU 2–14 mos). In all cases the resection was curative with ‘en bloc’ resection, though in one case the specimen ruptured during retrieval into three parts (4x HGIN, 1x LGIN). In one case 10 days after resection an acute bleeding occurred with the need of endoscopic clipping and prophylactic radiologic coiling of the gastroduodenal artery with uneventful course. In a second case a minor bleeding occurred without necessity of transfusion during ablation of an OTSC three mo after the primary intervention. All patients were asymptomatic during follow-up.

Conclusion: The endoscopic resection of large duodenal adenomata in D2/D3 is feasible and was safe in our collective using the application of a duodenal mini-vacuum sponge for local drainage of hematoma or bile to Whipple’s resection. The results in this first small collective should be reproduced in a prospective multicentric trial.

P1485 ENDOSCOPIC CLOSURE OF ACUTE PERFORATIONS OF THE GASTROINTESTINAL TRACT IN ANIMAL MODELS: A SYSTEMATIC REVIEW AND META-ANALYSIS
A. Gabr1, N. Ammar2, M. El Houssine2, M. Rutter3
1East Kent University Hospitals NHS, Margate/United Kingdom
2Public Health Department, Ain Shams University, Cairo/Egypt
3Gastroenterology, University Hospital of North Tees, Stockton on Tees/United Kingdom

Contact E-mail Address: ahmedgabr@hotmail.co.uk

Introduction: Acute perforations are one of the recognized complications of both diagnostic and therapeutic gastrointestinal endoscopy. For decades, surgical treatment has been the standard of care, but endoscopic closure has become a more popular approach, due to feasibility and the reduction of the burden of surgery, combined with the availability of various endoscopic closure devices.

Aims & Methods: We aimed to assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used in closing acute perforations in animal models. Medical literature (Cochrane library, EMBASE, MEDLINE) from 1966 till September 2016 was searched. A systematic review and meta-analysis were performed on studies reporting technical and clinical success of endoscopic closure of acute perforations, according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines.

Results: 46 studies on animal models were identified. 15 studies, including 4 guidelines. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) from 1966 till September 2016 was searched. A systematic review and meta-analysis were performed on studies reporting technical and clinical success of endoscopic closure of acute perforations, according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines.

Conclusion: Meta-analysis of the available literature showed that endoscopic closure of acute perforations is a safe, effective, and reproducible method with a high technical and clinical success rate. However, further studies are needed to assess its effectiveness in clinical practice and to determine the optimal endoscopic device and technique for each perforation type and location.

P1486 RISK FACTORS FOR COLORECTAL POLYP IN ASYMPTOMATIC YOUNG ADULTS UNDER THE AGE OF 50
Y. Myung
hyundai UVIS hospital, Incheon/Korea, Republic of

Contact E-mail Address: dittomyung@gmail.com

Introduction: Current guidelines recommend that adults age 50 to 75 be screened for colorectal cancer (CRC). However, CRC incidence rates have increased among young adults and have decreased among older adults.

Aims & Methods: The aim of this study was to investigate the risk factors of colorectal polyps in young adults aged <50 years. From January 2016 to December 2016, we compared the risk factors of colorectal polyp group with non-polyp group in patients aged <50 years who underwent screening colonoscopy. The risk factors examined included body mass index (BMI), metabolic syndrome, smoking, alcohol consumption, and physical activity.

Results: Of the 1862 patients, prevalence of colorectal polyps and adenomatous polyps were 13.1% and 7.8%, respectively. Multivariate analysis revealed that metabolic syndrome (OR, 1.89; 95% CI, 1.13–3.17, P = 0.015) was independent predictor for colorectal polyp. Age over 40 years (OR, 1.6–6.8). Technical success for endoclip closure was 94.8%, complication rate was 1.9% (95% CI: 91.1%- 98.9%). Technical success for endoclips closure was 94.8% (95% CI: 88.5%-98.6%), and complication rate was 4.2% (n = 6/214, 95% CI: 1.6%-8.3%). Technical success for endoclips closure was 94.9% (95% CI: 85.6%-100%), and clinical success was 83.2% (95% CI: 69.5%-92.3%), and complication rate was 2.7% (95% CI: 90.1%-99.8%). For OTSC (Over the scope clip device), technical success was 97% (95% CI: 88%-99.7%), clinical success was 97% (95% CI: 88%-99.7%), and complication rate was 1.87% (95% CI: 91.2%- 98.8%). The technical success for endosuturing (endoscopic suturing device) was 92.7% (95% CI: 82% to 98%), clinical success was 87% (95% CI: 74.9%–94.8%), complication rate was 1.9% (95% CI: 91.1%-98.9%).

Conclusion: Our study suggests that endoscopic closure is a suitable treatment option for acute iatrogenic gastrointestinal perforations with a reasonable technical and clinical success and for each case and for more endoscopic closure by per group. A total of 214 endoscopic closures were attempted in these studies. The overall technical success rate was 94.8% (n = 201/214, 95% CI: 92%-97.6%), clinical success was 92.3% (n = 199/214, 95% CI: 88%-95.8%), and complication rate was 4.2% (n = 6/214, 95% CI: 1.6%-8.3%).

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Aims & Methods: The study included 35 patients with 39 colorectal lesions who underwent ESD (group SB) or endoscopic polypectomy (group NSB). The rates of laterally spreading tumor of granular type (LST-G), 11 lesions; non-granular type (NG) tumors, 28; adenomas, 11; mucosal cancers, 22; and submucosal cancers, 6. The mean procedure time was significantly shorter in group SB (10.8 min vs 10.1 min; p < 0.005). No significant differences were found in en bloc resection, complete resection, postoperative bleeding, and perforation rates. No accidental symptom associated with balloon endoscopy was observed.

Conclusion: Using a balloon overture can be expected to improve not only access to the lesion but also facilitate scope manipulation for colorectal ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: mssanjua@acosta@gmail.com

Introduction: Endoscopic Submucosal Dissection (ESD) for colorectal lesions is a highly skilled technique which over the last few years has been adopted by Western endoscopy, an advancement of colorectal neoplasia. There is no consensus in the literature regarding the technique of anaesthesia/sedation method for ESD. We aim to describe current sedation practices used in ESD in Western Hospitals.

Aims & Methods: A systematic literature search was performed to identify all articles describing colorectal ESD procedure performed in Europe, America and Australia. Electronic databases including PubMed, the Cochrane library and Embase were searched. Original articles or abstracts for congress in English were reviewed. The authors were sent the authors of the identified articles in order to obtain additional information regarding sedation practice, if this was not explicitly detailed in the original articles. All articles were examined independently for eligibility by two reviewers (S.B. and M.S.). Any Disagreements were resolved by consulting a third reviewer (A.P.).

Results: This review resulted in 18 eligible original articles, of which (5/18) 27.8% were prospective studies, (7/18) 38.9% retrospective series and (6/18) 33.3% were case reports. The mean number of ESD cases described was 68 (range: 11–302). Most institutions opted to admit patients following the procedure. (7/18) 38.9% were prospective studies, (7/18) 38.9% retrospective series and (6/18) 33.3% were case reports. The mean number of ESD cases described was 68 (range: 11–302). Most institutions opted to admit patients following the procedure.

Results: This review resulted in 18 eligible original articles, of which (5/18) 27.8% were prospective studies, (7/18) 38.9% retrospective series and (6/18) 33.3% were case reports. The mean number of ESD cases described was 68 (range: 11–302). Most institutions opted to admit patients following the procedure. (7/18) 38.9% were prospective studies, (7/18) 38.9% retrospective series and (6/18) 33.3% were case reports. The mean number of ESD cases described was 68 (range: 11–302). Most institutions opted to admit patients following the procedure.

Results: This review resulted in 18 eligible original articles, of which (5/18) 27.8% were prospective studies, (7/18) 38.9% retrospective series and (6/18) 33.3% were case reports. The mean number of ESD cases described was 68 (range: 11–302). Most institutions opted to admit patients following the procedure. (7/18) 38.9% were prospective studies, (7/18) 38.9% retrospective series and (6/18) 33.3% were case reports. The mean number of ESD cases described was 68 (range: 11–302). Most institutions opted to admit patients following the procedure.
domains—Communication (COMM), Situational Awareness (SITA), Leadership (LEAD) for the Decision-making (DM) part. Each MARS domain was represented by 10 items and is assessed on a 7-point scoring scale - endoscopists should score >90 in each domain (80–90 = need for improvement, <80 = sub-optimal performance). CIR and PDR measures are routinely calculated for all colonoscopists using the HCQS Electronic Reporting System with manual validation of these data. Feedback is presented on a quarterly basis to practitioners—endoscopists are expected to achieve 90% CIR and 20% PDR. Correlation of these factors with practitioners ENTS scores were measured using the Pearson test.

**Results:** 9 endoscopists with known variability in standard colonoscopy KPIs consented to an assessment of ENTs using the MARS tool. Their ENTs scores were correlated with existing KPIs for each colonoscopist (Oct 2016–May 2017), providing an overall positive correlation between ENTs domains and CIR (COMM 0.58; SITA 0.66; LEAD 0.66; DM 0.75) and PDR (COMM 0.49; SITA 0.55; LEAD 0.50; DM 0.60). Three endoscopists were identified as having sub-optimal scores in all of the ENTs domains (operators 5, 7, 9). Taking into account important KPI thresholds 2 out of 3 (33%) of these endoscopists identified were not meeting CIR targets (c.f. 66% of ENTs competent group) and one (33%) did not meet PDR targets (c.f. 0% in ENTs competent group).

**Conclusion:** The MARS tool is a practical way to measure of ENTs performance designed as a 360 degree feedback and identifies areas for development within independently practitioners that are not currently highlighted by standard colonoscopy KPI measures. There is some correlation with current KPI feedback panels but unlike a specific validated ENTs assessment tool assessment current assessment panels. Both CIR and PDR primarily depend on the colonoscopists’ individual skills rather than the team elements required by polypectomy or EMR and these more complex tasks may show stronger correlation with MARS ENTs evaluation.

**Contact E-mail Address:** toniza2011@gmail.com

**Introduction:** Safety and diagnostic accuracy of colonoscopy depend on the quality of bowel cleansing. Several factors have been reported to affect the quality of bowel cleansing, one of them being visualization of the mucosa.

**Aims & Methods:** We performed a prospective, randomised, endoscopy blinded clinical trial between February 2016 and January 2017 included. Our aim was to investigate whether a visual educational booklet (EMI-137, Edinburgh Molecular Imaging (EMI)) which has demonstrated potential to improve the level of cleanliness achieved in hospitalized patients who are undergoing a colonoscopy. Patients >18 years undergoing colonoscopy were included. Exclusion criteria were: previous colonoscopy in the last 3 years, previous colectomy, known inflammatory bowel disease, urgent colonoscopy, dementia or refusal to participate in the study. Both groups received 4 L polyethylene glycol solution. The intervention consisted of a visual educational booklet (visual cohort). Demographic data, personal history, reason for admission and for colonoscopy, work shift in which it performed, and results at endoscopy were collected. The Boston Bowel Preparation Scale (BBPS) was used to assess the bowel preparation. A BBPS score <6 or with at least one segment >3 was considered a poor preparation.

**Results:** One hundred and thirty six patients were included. 51.5% were male, with a mean age of 63.3±17.6 years, and 95.9% of Spanish nationality. The mean body mass index was 27.3±5.2 kg/m². Educational attainment was below secondary education in 71.05%. Most patients had a history of hypertension (72.1%), and the gastroenterology ward (21.32%). Anemia (31.62%), abdominal radiographic findings (16.91%), hematochezia/rectal bleeding (15.44%), diarrhea (11.03%), and abdominal pain (8.82%) were the most frequent indications. Patients characteristics, bowel cleansing and endoscopic findings are shown in table 1. The educational booklet did not suppose a difference in the bowel cleansing attained. Factors that impacted on the level of well and poorly prepared patients in the bivariable study were: age (62.1±18.7 vs 70.5±14.8; p = 0.0019), diabetes mellitus (72.3% vs 42.4%; p = 0.02), hyper-tension (45.63% vs 69.70%; p = 0.016), cardiovascular disease 14.5% vs 36.3%; p = 0.006), and colorectal cancer on colonoscopy (99% vs 81.82%; p = 0.001).

**Table 1:** Baseline characteristics, bowel cleansing and endoscopic findings.

P1495 COMPETENCY OF ENDOSCOPIC NON-TECHNICAL SKILLS (ENTS) DURING ENDOSCOPY TRAINING
*JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/United Kingdom

Contact E-mail Address: keith@siau.org

Introduction: Endoscopic non-technical skills (ENTS), comprising of communication and teamwork, situation awareness, leadership and judgement and decision-making, are recognised as indicators of quality endoscopy and patient safety. Since July 2016, electronic assessment forms (DOPS) for UK trainee endoscopists have been updated to include ENTS as an assessable domain. We aimed to assess the uptake and distribution of ENTS scoring in DOPS and their correlation with other endoscopic skills, across all assessable endoscopic modalities.

Aims & Methods: We identified all DOPS submitted between July 2016 and Feb 2017 from the UK endoscopy trainee database (JETS) and acquired data on trainees, procedures and scores. We collated scores for each of the 4 assessable domains (pre-procedural, procedural, post-procedural and ENTS) into overall outcomes of “not competent” (if any domain items required supervision) or “competent”, and compared this to the overall competence rating. Statistical analysis was performed using chi2 and regression modelling.

Results: 860 DOPS were prospectively collected, with ENTS assessed in 99.3%. Competency rates of individual ENTS items are summarised in Table 1. Rates of overall ENTS competency (defined as all items scoring competent) varied across procedures (p < 0.001): ERCP 39.8%, EUS 44.1%, gastroscopy 59.6%, colonoscopy 62.3%, PEG 71.1%, gastrointestinal bleed (71.3%), sigmoidoscopy 72.4% and polypectomy 73.2%. Scores by individual ENTS components are displayed in Table 1. Of DOPS awarded overall competency, 5.9% (240/4077) lacked full competence in ENTS (p = 0.10 across modalities). Across trainee specialties and endoscopic modalities, competency was greatest for “communication and teamwork” (77.1% overall), but least with ‘judgement and decision making’ (68.3%). Competency in ENTS increased with lifetime procedural count (OR 1.008 per increase in procedure, p < 0.001), and correlated strongly with other assessable domains, including overall score (p < 0.001). After adjusting for procedural count, factors predictive of ENTS competency included trainee seniority (OR for ST5 level: 1.96, p < 0.001), surgical trainees (OR 1.21, p = 0.014), trainees performing polypectomy (OR 2.02, p < 0.001), and higher DOPS count (OR 1.03 per increase in DOPS, p < 0.001).

</table>

Conclusion: ENTS is an assessable domain within endoscopy training, with scores that correlate with other procedure-related skills, demonstrating construct validity. Competency of ENTS develops with procedural count, and vary with trainee seniority and specialty. Longer term data are required to assess the impact of ENTS on certification.

P1496 MAKING COLONOSCOPISTS MORE AWARE OF THEIR ENDOSCOPIC NON-TECHNICAL SKILLS–IMPROVING FEEDBACK FORMATS DERIVED FROM THE MULTI-ASSISTANT RATING SCALE (MARS) TOOL

N. Hawkes, F. Kokwara, B. Davies, J. Cornish
Gastroenterology, Cwm Taf University Health Board, nr Cardiff/United Kingdom

Contact E-mail Address: neilhawkes@aol.com

Introduction: The development of Endoscopic Non-Technical Skills (ENTS) is associated with improved performance and high quality endoscopic outcomes. Whilst ENTS domains have been incorporated into Joint Advisory Group (JAG) Direct Observation of Procedural Skills (DOPS) forms, used as training tools, knowledge of ENTS domains amongst independent practitioners varies. To improve performance in this area of practice requires validated measurement tools and specific feedback against which improvement can be measured. We have previously developed a validated 360-degree multi-assessor rating scale (MARS tool) based on experienced endoscopy assistant ratings for ENTS provided in 4 of 6 domains of ENTS–each comprising 10 related but independent practice points. Providing an optimised feedback format for this data is likely to maximise the potential benefits of measuring ENTS performance.

Aims & Methods: We aimed to provide an optimised format for performance enhancing feedback in the ENTS domains and basis for specific auditable outcomes and performance indicators. Local colonoscopists gave consent to application of the ENTS questionnaire. The validated MARS tool assesses 4 ENTS domains–Communication (COMM), Situational Awareness (SITA), Leadership (LEAD) and Judgement & Decision-making (J&DM). Each MARS domain in the administered questionnaire was represented by 10 items and is assessed on a 7-point scoring scale. We sought to develop 1) a format to illustrate an individual’s overall performance in each of the 4 main ENTS domains in comparison to other operators and 2) a detailed domain breakdown highlighting areas of underperformance 3) Collate feedback on the presentation formats.

Results: 9 endoscopists consented to an assessment of ENTS using the MARS tool. The MARS questionnaires were administered during January 2017–relating to the prior 3 months clinical practice. Acceptable performance thresholds were set as >90% good-excellent ratings in each domain. Need for improvement was defined as 80–90% good-excellent ratings (i.e. 10–20% average or poor ratings) and sub-optimal performance as 80% or less good-excellent ratings (i.e. >20% average-poor ratings). Good intra- and inter-rater reliability was demonstrated for these cut-off values during validation of the MARS tool. Scatter plots were used to present the overall domain ratings for COMM, SITA, LEAD and J&DM domains allowing comparison with other endoscopists. To provide more detailed domain-specific feedback to endoscopists an individual report is generated of 4 domain tables summarising the question items and using a ‘traffic-light’ display to help operators quickly identify those specific skills that require areas for improvement. The feedback reported during the MARS feedback helped and indicated that it was ‘likely’ or ‘very likely’ to prompt an alteration in practice. A suggestion to add an additional column to the summary table indicated where performance level has changed in subsequent audit rounds is being considered.

Conclusion: The MARS tool is a practical way to measure ENTS performance allowing comparison with established normative data of a robust quality assurance system. The benefits of providing overall comparative data has been established previously in sharing more established key performance indicators. The feedback format for data derived from the MARS tool has additionally provided detailed domain-specific ENTS performance ratings that brings to attention areas for improvement in a clear and understandable way that can be re-tested as part of an integrated audit cycle.

P1497 OUTCOMES OF ENDOSCOPIC RESECTION OF COMPLEX COLORECTAL LESIONS REFERRED TO A TERTIARY INSTITUTION AFTER FAILED ATTEMPTS AT RESECTION OR ENHANCED SURGERY

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King’s College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@nhs.net

Introduction: Failed prior attempts at resection or heavy manipulation of lesions at resection were free from recurrence and had avoided surgery at last follow up. In 97 lesions (22%), an average of 1.5 (range 1–5) previous attempts at resection had been made, including 43 attempts at transanal surgical resection in 25 patients. A further 128 lesions (29%) had been extensively sampled or tattooed Mean lesion size was 55.6 mm (+/- 30.7 mm).

Initial endoscopic resection was deemed successful in 98% of cases after previous failed attempts, 97% of cases with prior heavy manipulation and 97% of other cases (p = 0.86). En bloc resection was possible in fewer patients with previous attempts at resection (14%, 31% and 42% respectively, p < 0.001). Complications associated with heavy manipulations were free from prior failed attempts at resection and minimal sampling (14 versus 5% and 3%, p < 0.001). Recurrence rates were 24.1%, 14.6% and 12.2% respectively (p = 0.07). 95% of patients without invasive cancer who had prior failed attempts at resection were free from recurrence.

Conclusion: Failed prior attempts at resection or heavy manipulation of lesions reduces the chance of achieving en bloc resection and increases the risk of complications and recurrence. Nevertheless, specialist management in a dedicated colorectal unit can achieve good results in safe and successful organ preserving endoscopic treatment of these extremely challenging lesions in over 95% of cases with few significant complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1498 NB1 VERSUS BL1 WHICH MODALITY IS BETTER FOR OBSERVATION OF MICROSAL BLOOD FLOW IN THE SMALL AND LARGE BOWEL USING NB1 (NARROW BAND IMAGING) OR BL1 (BLUE LASER IMAGING)

M. Yasuda1, Y. Naito2, Y. Itoh2
1Dept. Of Gastroenterology And Hepatology, Uchi-Tokushui Medical Center, Uchi-Juy,/Japan
2Department Of Gastroenterology And Hepatology, Kyoto Prefectural University Of Medicine, Kyoto/Japan

Introduction: In recent years, significant advances and innovations have been made in gastrointestinal endoscopic technology. The special light observation using a narrow band light source different from conventional white light is one such innovation. The special light observation with a magnifying procedure has been contributed to improving the diagnosis of lesions in the small and large bowel, such as stomach and large bowel; it is particularly useful for differentiating between benign and malignant lesions and evaluating the depth of invasion. The instruments for narrow band imaging (NBI) were developed by Olympus Co., Ltd., and the blue laser imaging (BLI) by Fujifilm Co., Ltd. These systems are applied to magnifying endoscopy in clinical practice. Studies have examined the usefulness of magnifying observation with NB1 (m-NBI), BL1 (m-BLI), and new and brighter BL1 (m-BLI bright) for the diagnosis of neoplastic diseases, especially for the early detection of gastrointestinal cancers. However, there are relatively few reports describing the application of these techniques to benign diseases.

Aims & Methods: This basic study aimed to explore the potential of magnifying observation using narrow band light by evaluating the visualization of mucosal blood flow in the small and large bowel. The subjects were selected from among patients who had undergone colonoscopy since April 2016. They were randomized into three groups: patients undergoing examination with EC-L00ZP, a high-end instrument manufactured by Fujifilm Co., Ltd. (group F), CF-HQ290ZI, a high-end instrument manufactured by Olympus Co., Ltd. (group O) or PCF-H290ZI manufactured by Olympus Co., Ltd. (group O2).

Each group consisted of 25 patients. The visualization of mucosal blood flow in the small and large bowel by magnifying endoscopic observation using narrow band light was evaluated and scored as follows: good visualization 2; partial visualization 1, and no visualization 0. The method and tip attachment were used in all cases.

Results: The respective mean scores for visualization of the small and large bowel were 2 and 2 in group F, 1.32 and 1.24 in group O1, and 1.48 and 1.40 in group O2. The visualization scores for both the small and the large bowel were significantly higher in group F than in groups O1 and O2. Group O2 had higher scores than group O1, although the difference was not statistically significant. The endoscope used in group F has a bright laser light source and maximum optical magnification levels up to 135 times and maximum electronic magnification levels up to 270 times. On the other hand, the endoscopes used in groups O1 and
and O2 have relatively dark xenon light sources and maximum optical magnification levels up to 80 and 110 times, respectively. Therefore, the differences in visualization of mucosal blood flow in the small and large bowel among the groups were considered to be attributable to differences in instrument efficiency.

**Conclusion:** Our results show that magnifying observation with BLI is superior to that with O2 regarding the observation of mucosal blood flow in the small and large bowel. We are planning to conduct a study on the clinical application of magnifying observation with BLI for visualization of mucosal blood flow in the small and large bowel.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1499**  **MULTIPLE COLORECTAL ADENOMAS WITHOUT APC OR MUTYH GERMLINE MUTATION: A HETEROGENEOUS SUBGROUP OF PATIENTS**

I. Sanchez Mete, E. Mannisi, A. Martayan, M. Varaneese, V. Sigliano. Gastroenterology And Digestive Endoscopy, Regina Elena National Cancer Institute, Rome/Italy

Contact E-mail Address: lupe.sanchez@ifoi.gov.it

**Introduction:** Multiple colorectal adenomas (MCRAs) can be defined as an endoscopic feature of ≥ 10 colorectal adenomas in patients (pts) without APC or MUTYH germline mutation. At present its clinical features, management and the presence of extracolonic cancer are not well studied.

**Aims & Methods:** The aim of the present study is to better define the clinical characteristics at diagnosis and during follow-up of MCRa affected patients. From January 2005 and until May 2016 patients with colorectal fibrosis (>10 colorectal adenomas), without deleterious mutations of APC or MUTYH genes, were recruited for the study. Clinical features at diagnosis and extracolonic manifestations were recorded. Forty patients underwent annual colonoscopy at our division with a median follow-up of 3.7 (range: 1-14) years. Degree of fibrosis in ESD or EMR between January 2005 and May 2016. All LSTs were larger than 2 cm in diameter for a diagnostic purpose. Pre-procedural biopsies were performed in 109 lesions (73.2%) and 40.0% (16/40) of patients without prior biopsy. Degree, distribution and depth of fibrosis were not associated with complications such as perforation, post-coagulation syndrome and bleeding.

**Results:** The mean age at MCRa diagnosis was 50.1 ± 14.6 years (range; 19 to 79 years) and 20 pts (41.6%) had at least a first degree relative affected with colorectal neoplasia. Clinical features at diagnosis: the number of polyps ranged between 10 and 20 in 43.7% of the cases; 21 and 50 in 27.1%; >50 in 29.2%; 22.9% of pts had one or more adenocarcinomas (ADC); 16.6% had a previously diagnosed extracolonic cancer (breast, endometrial, thyroid, lung, bladder, brain, lymph, etc.). Twenty-five pts (52%) needed surgery, ten underwent a subtotal colectomy and fifteen a total colectomy. During follow-up twenty-two (55%) pts developed recurrent adenomas and two (5%) had one or more ADC in the retained colorectum; 12.5% of pts developed duodenal adenomas, one had a duodenal adenocarcinoma; we recorded one case of abdominal wall desmoid.

**Conclusion:** MCRA patients in the present study had similar clinical characteristics to MUTYH associated Polyposis (MAP) affected patients. They were generally diagnosed at a mean age of >50 years, they had more than 20 polyps (56.3%) at diagnosis, associated with ADC in 22.9% of the cases and required surgery in the majority of cases (52%). During follow-up, pts also developed recurrent adenomas. Clinical characteristics and family history in these patients support the hypothesis that pathogenic alterations in yet unknown genes may be involved. Further prospective and genomimic technology aimed at this purpose. However, these patients should undergo a closer surveillance than those with sporadic adenomas.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Conclusion:** Distal colonic advanced adenomas are a marker of synchronous proximal colonic adenomas and sessile serrated polyps. When colonoscopies were performed for other indications (non-adenomatous polyp >1 cm, multiple distal HP polyps) the yield in the proximal colon was significantly smaller. These “soft” indications for colonoscopy accounted for a significant additional workload that appears unjustified.

### P1502 LEARNING CURVE FOR OPTICAL DIAGNOSIS OF COLORECTAL POLYPS USING CUMULATIVE SUM ANALYSIS

**R. Rameshshanker, A. Wilson, S. Thomas-Gibson, N. Kamperidis, N. O’Shea, I.P. Saunders**

**Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom**

**Contact E-mail Address:** r.rameshshanker@nhs.net

**Introduction:** Optical diagnosis for diminutive and small colorectal polyps is an attractive option to reduce costs and streamline patient care. The American Society of Gastrointestinal Endoscopy Preservation and Incorporation of Valuable Endoscopic Innovations (PIVI) established a 90% diagnostic threshold for real time endoscopic assessment of the histology of diminutive colorectal polyps. We report our adoption of optical diagnosis in clinical practice, colonoscopists must be trained and show on-going competence. The learning curve for trainees to achieve the competency has not been fully explored.

**Aims & Methods:** Aim is to evaluate the minimum number of polyps to achieve and maintain the optical diagnostic thresholds per PIVI standards using an upward CUSUM plot. Four trainees without previous experience in optical diagnosis at our institution participated in this prospective study. Four weeks before the commencement of the study they were given a training module on optical diagnosis (OD). OD was based on NICE and WASP classification. During the study period (January 2016-August 2016), each trainee documented the optical diagnosis of polyps less than 10 mm in size. Confidence levels of OD were noted at the same time. Patient demographics and polyp details (site, size, Paris classification and histology) were collected prospectively. OD of each polyp was compared against the polyp histology. Polyps without the histological confirmation were excluded from the analysis. Every trainee had on-going feedback on their performance.

**Results:** A total of 708 polyp observations were performed by trainees during the study period. Total number of adenomas, hyperplastic polyps and sessile serrated adenomas/polyps (SSA/P) were 364,214 and 52 respectively. Trainees OD performance was plotted on a upward CUSUM plot.

**Table 1:** Trainees optical diagnostic performance

All 4 trainees achieved sustained accuracy (90% threshold) in OD within 12-58 observations. The number of polyps required to reach the plateau varied between 12 to 58. Every trainee’s confidence level improved over time (from 69% to 89%) and the effect was augmented by in-vivo feedback and revision of training module. Table 1 summarises the optical diagnostic performance of all 4 trainees. Negative predictive value for adenomas were above 90% for all trainees.

**Conclusion:** The CUSUM scores of all 4 trainees in the study reached the PIVI standards plateau by the 58th polyp observation. In-vivo feedback and continued training appears important to maintain the performance. Our preliminary findings could be used as a guide to plan the certification process for implementation of optical diagnosis.

### P1503 THE CLINICAL VALUE OF ENDOSCOPIC FULL-THICKNESS RESECTION FOR COLORECTAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA: A PROSPECTIVE SINGLE-CENTER STUDY

**M. Xu, C. Zhang, Q. Li**

**Endoscopy Center, Zhongshan Hospital, Shanghai/China**

**Contact E-mail Address:** xumeidong@aliyun.com

**Introduction:** Given diminishing quality of life caused by colectomy and rectectomy, a minimally invasive treatment is desirable for colorectal submucosal tumors (SMTs).

**Aims & Methods:** The aim of the current study was to evaluate the clinical efficacy, safety and feasibility of endoscopic full-thickness resection (EFTR) for colorectal SMTs originating from the MP layer. A prospective study was carried out, including a consecutive cohort of 56 patients who underwent EFTR for colorectal SMTs originating from the MP layer between January 2008 and September 2014 in our center. Among these lesions, 21 located in the colon, 9 located in the intraperitoneal rectum and 26 located in the extraperitoneal rectum. The tight adhesion of the lesion to the serosal layer was identified before EFTR in all cases. EFTR was performed using a standard ESD technique under direct endoscopic view. The defect of colorectal wall was closed after resection in all cases. Complete resection rate, complications and lesion recurrence were evaluated.

**Results:** Successful EFTR was performed in 54 (96.4%) patients. The other 2 patients were transferred to suffer laparoscopic right hemicolectomy and EFTR combining laparoscopic operation respectively, because the lesions involved the external organs and were too difficult to get en bloc resection endoscopically. The en bloc resection rate and complete resection rate were both 96.4% (54/56). Among 54 cases, 52 of these lesions were performed with EFTR without laparoscopic assistance, while 2 needed laparoscopic assistance to get the defect closed after resection. The median operation time was 45 min (range, 20–130 min). The median maximum diameter of resected tumors was 1.5 cm (range, 0.5–5.0 cm). Accurate histopathologic results were acquired from all the resected lesions, including 18 leiomyomas, 11 gastrointestinal stromal tumors (GISTs), 8 fibrous tumors, 3 schwannomas, 11 granulomas, 2 displaced endometrium, and 1 hamar- toma. Three patients had local peritonitis and two patients developed postoperative bleeding. All of them recovered after receiving conservative treatments. No single case developed diffuse peritonitis. No lesion residual or recurrence was found during the follow-up period ranging 2–54 months.

**Conclusion:** EFTR appears to be a safe, feasible, and effective procedure for providing accurate histopathologic evaluations, as well as a curative treatment for colorectal SMTs originating from the MP layer. However, it should be performed by the very experienced endoscopists.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1504 COLONIC ESD BY UTILIZING SHORT DOUBLE BALLOON ENDOSCOPE—HOW TO TREAT DIFFICULT CASES IN COLONIC ESD

**S. Katsuki, T. Fujita, K. Takamashi, E. Wag**

**Center Of Gastroenterology, Otaru Ekiisaikai Hospital Center of Gastroenterology, Otaru/Japan**

**Contact E-mail Address:** sinichi.katuki@otaru-ekiisaikai.jp

**Introduction:** Colon ESD has been a standard treatment in the world. However, sometimes it is hard to remove the colon tumor during ESD. When we fail to detach the colon with ESD, we have to consider the following three points: if we don’t have enough experience and skill, we should take the training more. If there are lots of vessels and fibrosis in the submucosal layer, it is necessary to choose adequate tools. And if patients have complicated colon, suitable endoscope need to be selected. In such cases we always use DBE.

**Aims & Methods:** We evaluated the outcomes of colonic ESD by using DBE (DBE-ESD). Short DBE we used were EC4501B, EN5301B and EI5801BT (Olympus Co., Tokyo, Japan). We’ve performed DBE-ESD on 211 lesions in 184 patients. We analyzed the lesions located in the proximal colon, and the following items were examined: arrival time, procedure time, rate of negative margin, perforation rate, length of hospital stay and recurrence rate in the 5th-year after the ESD.

**Results:** There were 159 lesions located in the proximal colons. The median arrival time to the lesion was 7.9 min, operation time 51.1 min, negative rate of horizontal margin 99.4%, vertical margin 99.4%, perforation rate 0%, median length of hospital stay 3.1 days, and recurrence rate in patients with more than 5 year follow-up 0%.

**Conclusion:** Because the balloons and the overtube retained the scope at stable position, we were able to get good working space. Therefore, DBE should be one of the options for difficult cases in ESD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P1505 WITHDRAWAL TIME MONITORING AND FULL-SPECTRUM ENDOSCOPY IMPROVE ADENOMA DETECTION RATE

G. De Nucci1, P. Andreozzi2, C. Bezzo1, R. Reati1, D. Morganti1, D. Redaelli1, E. Mandelli1, B. Omazzi3, I. Arena3, S. Saibeni3, G. Manes1

Introduction: Adenoma detection rate (ADR) is a quality indicator of screening colonoscopy. Monitoring withdrawal time (WT) and use of full-spectrum endoscopy (FUSE) have been suggested to increase the ADR since allow an accurate evaluation of the hidden areas of the colon.

Aims & Methods: We aimed to evaluate whether monitoring WT of alone or in combination with the use of FUSE would be able to increase the ADR. In a prospective non-randomized observational study, consecutive outpatients, aged 18–85 yr, undergoing colonoscopy with different indications were enrolled. In phase 1, endoscopists performed 660 colonoscopies either with standard forward-viewing endoscope (SFVE) (n = 330) or with FUSE (n = 330) without a dedicated WT protocol. In this phase, colonoscopy WTs were measured without the endoscopists' knowledge of being monitored. In phase 2, endoscopists were informed of being monitored and performed further 660 colonoscopies either with SFVE (n = 330) or with FUSE (n = 330).

Results: No differences were observed among the four arms in terms of demographic, clinical features, and indications to colonoscopy. WT was lower in phase 1 arms compared to phase 2 arms (SFVE: 267 ± 96 vs. 387 ± 65, p = 0.001; FUSE: 293 ± 112 vs. 430 ± 93, p = 0.001). When endoscopists were aware of being monitored and used full-spectrum endoscopy we observed a higher ADR [phase 1 SFVE 27.3% (90) phase 1 FUSE 33.0% (109) phase 2 SFVE 33.6% (111) phase 2 FUSE 41.8% (138); p = 0.001] and adenoma per colonoscopy (APC) [phase 1 SFVE 0.43 ± 0.85 phase 1 FUSE 0.56 ± 1.08 phase 2 SFVE 0.50 ± 1.24 phase 2 FUSE 0.71 ± 1.08; p = 0.004]. The detection rate of adenoma located proximally to the splenic flexure was higher in phase 2 arms (phase 1 SFVE 11.2% vs. phase SFVE 16.4%, p = 0.056; phase 1 FUSE 12.7% vs. phase 2 FUSE 18.9%, p = 0.033), whereas adenoma located distally to the splenic flexure was higher in the SFVE arms compared to SFVE arms, but these differences were not significant (Phase 1 SFVE 20.0% vs. Phase 1 FUSE 24.8%, p = 0.081; Phase 2 SFVE 21.8% vs. Phase 2 FUSE 27.0%, p = 0.147).

Conclusion: Unmonitored endoscopists have a suboptimal WT, which increases with the use of full-spectrum scopes combined with WT monitoring results in increase of adenoma detection rate. In particular, monitoring WT increases the detection of adenomas in proximal colon, whereas the use of FUSE seems to increase the detection of adenomas in distal colon.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1506 HIGH LEVELS OF “PRESUMED POLYP MISS RATE” AT 1 AND 3 YEARS FOLLOWING INDEX SCREENING COLONOSCOPY: NO ROOM FOR COMPLACENCY

Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom

Contact E-mail Address: r.rameshshanker@nhs.net

Introduction: Colonoscopy with polypectomy is considered the optimal method for bowel cancer prevention. Despite improvements in colonoscopy training and technology, it remains as an imperfect tool and the adenoma miss rates vary between 6–27%.

Aims & Methods: Aim is to determine the presumed miss rate for adenomas and sessile serrated adenomas/polyps (SSA/Ps) after a complete screening colonoscopy. Methodology: A prospective observational study was performed at our bowel cancer screening centre over 12 months from July 2015. Patients who underwent a surveillance colonoscopy following an index colonoscopy were included (one and three-year surveillance). All colonoscopies were performed by one endoscopist who used full spectrum bowel cancer screening colonoscopies. Polyp characteristics and procedural data were prospectively recorded and collected. Polyp histology and epidemiologic data were retrieved from our endoscopy database. A polyp was considered as “missed” at the index colonoscopy if at 1 year surveillance it was not adjacent to a scar (a recurrence) or at 3 years if >5 mm in size and not adjacent to a scar.

Results: 241 patients underwent a surveillance colonoscopy (male: female 2:1, median age 65 years). 90(241)(37.3%) patients had a one-year surveillance colonoscopy. There was no significant difference in the quality of bowel preparation, caecal intubation rate and total procedure time between index and surveillance procedures. Total number of polyps detected during index and surveillance colonoscopies were 815 and 469 respectively. The presumed miss rate of polyps, adenomas, SSA/Ps and advanced adenomas were 37.8% (469/1241), 22.1%(167/798), 41.7%(20/48) and 15.2%(36/236) respectively. More adenomas were missed in the proximal colon when compared to distal colon (26.64% vs 18.04%, p = 0.01). Table 1 illustrates the distribution of missed adenomas in each segment of the colon. Adenoma miss rates per size as follows: <5 mm, 6-9mm and >10mm were 24.27 and 8% respectively. Higher number of polyps (>3 detected during index colonoscopy independently correlated with high miss rates (84.3% vs 72%, p = 0.04).

Conclusion: Our study highlights that there is likely to be a significant miss rate for adenomas and SSA/Ps even after careful index colonoscopy. Miss rate was higher when multiple polyps are seen at the index examination. This finding appears to justify the current BSOG (British Society of Gastroenterology) guidelines for an early, 1 year colonoscopy when multiple polyps are seen. The presumed miss polyp rate at 1 & 3 years may be justified as a new quality metric within screening programmes.

Introduction: Systemic diseases including several types of cancer have been associated with periodontitis, potentially owing to the constant systemic inflammatory state in those patients. Data on a potential association of periodontal disease and colorectal neoplasia is scarce and conflicting.

Aims & Methods: Data from 25,407 patients undergoing healthy check up assess periodontal disease according to periodontosis-risk classes (PRC 0-healthy gingiva, PRC 1 - tatar or plaque, PRC 2 - redness or swelling) and screening colonoscopy between 2009 and 2012 in Austria were included. Colonoscopy outcomes were compared between patients with and without signs of periodontal disease using multivariate models adjusting for age, sex, smoking, alcohol consumption, diabetes and BMI.

Results: In multivariate adjusted models, patients with periodontal disease had similar odds for the detection of colorectal polyps as those without signs of periodontal disease [adjOR 1.070; 95% CI: 0.918; 1.247]. Regarding the prevalence of adenomas, patients with periodontal disease, likewise, had similar odds as those with healthy periodontal tissue [adjOR 1.010; 95% CI: 0.840; 1.247]. Similarly, those with periodontal disease had comparable odds for colorectal adenomas as those without signs of periodontal disease [1.055 (0.785; 1.418)]. In the table below the adenoma detection rate (ADR) and advanced adenoma detection rate (AADR) divided into the periodontosis-risk classes.

Conclusion: Periodontal disease has no impact on the adenoma and advanced adenoma detection rates in a large screening colonoscopy cohort.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Patients with colitis carry an increased risk for the development of dysplasia compared to those without1. The SCENIC consensus statement recommended endoscopic resection of all visible dysplasia2. Due to technical challenges and limited experience in the West of large colitis associated non-polypoid endoscopic resections, such patients are often subjected to colectomy. The King’s Institute of Therapeutic Endoscopy (KITE) is a tertiary centre for endoscopic assessment and resection of large/challenging colorectal polyps. Here we present the largest single-centre case series of large non-polypoid resections associated with colitis.

Aims & Methods: Adults with confirmed colitis (ulcerative colitis extending beyond the rectosigmoid junction and colitis of the colon affecting at least the left colon) with lesions at least 20 mm in size within the colitis segment were included. Data including demographics, clinical history, lesion characteristics, method of resection and post-resection surveillance were collected prospectively in patients from January 2011 to November 2016. Resection techniques included endoscopic mucosal resection (EMR), endoscopic submucosal dissection (ESD) and hybrid ESD. Surveillance of resection site with magnification chromoendoscopy (mCE) was performed at 3 months with pan colonic mCE at 1-year post resection and annually thereafter.

Results: Thirty lesions satisfied the inclusion criteria in 13 patients. Patient demographics and clinical data are presented in Table 1. Mean lesion size was 47.3 ± 22.4 (20–90) mm. All lesions were non-polypoid with distinct margins and no ulceration. High-frequency mini-probe ultrasound confirmed intramucosal lesions in 5 cases where pit/vascular pattern was distorted due to inflammation. En bloc resection was achieved in 6 cases. 69% lesions were deeply scarred malignantly in 100% of resected lesions. Complete excision was confirmed in all en bloc resections. A single case of small perforation and another with delayed minor bleeding were both managed endoscopically. Mortality/hospital admission complications in colorectal mucosal lesions after endoscopic submucosal dissection (ESD) has been widely used in the minimally invasive treatment of early colorectal mucosa and submucosal lesions. This technique has made it possible to resect even large mucosal or submucosal lesions en bloc, and the recurrence rate is lower. However, due to the thinner colorectal wall and more abundant blood vessels, postoperative complications after ESD is higher in this site. As a result, how to prevent complications related to ESD for colorectal lesions has raised widespread concern. In recent years, more and more researchers placed transanal tube for patients with colorectal cancer resection or intestinal obstruction to promote the early discharge of the gas and liquid in the intestine. The efficacy of this method to reduce incidence of complications and to promote recovery of intestinal function have been verified by a number of studies. Based on this, we applied transanal tube to some patients with colorectal ESD, hoping to provide new ideas for the prevention and treatment of complications.

Aims & Methods: We aimed to evaluate transanal tube for prevention of complications in colorectal mucosal lesions after endoscopic submucosal dissection (ESD). Data of 61 patients with colorectal mucosal lesions undergoing ESD from January to December 2016 were reviewed. All patients were followed up and we analyzed the incidence rate of complications after ESD within one month.

Results: The median age of 61 patients was 61(32–83) years. 21 of all lesions were located at right-below group, 9 at left-below group and 31 in rectum. The mean diameter of the lesions was 3.26 ± 2.27 (0.8–12.0) cm. There were not intraoperative complications including serious bleeding and perforation. Delayed bleeding on the second post-ESD day was detected in 1 (1.6%) patient who was cured by transfusion. 3(4.9%) patients suffered post-ESD electrocoagulation syndrome and perforation did not present in all cases. In this group with transanal tube for decompression, the rates of perforation, delayed bleeding and post-ESD electrocoagulation syndrome were all lower than others which was 1.4 ~ 8.2%, 0.5% ~ 9.5% and 12.1% ~ 40.2% respectively in literature reports.

Conclusion: The application of transanal tube in colorectal mucosal lesions after ESD could effectively reduce the incidences of complications. However, we should do more research to know whether transanal tube need to be placed routinely after ESD or not.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1510 OUTCOMES FOLLOWING UNDERWATER ENDOSCOPIC MUCOSAL RESSECTION OF MID-RECTAL POLYPS: A PROSPECTIVE DUAL-CENTRE STUDY

K. Sia\(^1\), A. Yusu\(^2\), N. Suzuki\(^3\), S. Ishaq\(^4\)

\(^1\)Royal College Of Physicians, JAG Clinical Fellow, London/United Kingdom
\(^2\)Gastroenterology, East Sussex Healthcare NHS Trust, Eastbourne/United Kingdom
\(^3\)Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom
\(^4\)Department Of Gastroenterology, Dudley Group Hospitals NHS Foundation Trust, Dudley/United Kingdom

Contact E-mail Address: keith@sia.org

Introduction: Underwater endoscopic mucosal resection (UEMR) is an alternative to traditional EMR for the resection of colonic polyps. With this technique, water insufflation is used in place of air or CO\(_2\), and submucosal lifting is usually not required, as water-immersed submucosa cushions itself from the muscularis propria.\(^1\)\(^2\) Theoretically, this reduces the risk of diathermy-induced injury,\(^3\) and allows for more complete resection margins.\(^4\)

Aims & Methods: In this prospective dual-centre study, we aim to evaluate the safety and efficacy of UEMR for clinically significant (≥10 mm) colonic polyps. Studies outcomes included: 1) completeness of UEMR, 2) intra-procedural and 30-day complication rates, 3) percentage requiring submucosal lift, and 4) rates and predictors of polyp recurrence. Procedures were performed by two screening endoscopists accepting tertiary referrals at St. Mark’s Hospital, London, and Russell’s Hall Hospital, Dudley, UK. Recurrence was defined as the presence of any polyp tissue at the resection site. Endoscopy records were examined and correlated with histology. Univariate analyses were performed using Pearson’s chi\(^2\) to identify predictors of measured outcomes.

Results: Between June 2014 and March 2017, and A total of 85 patients (median age 69.5 years, interquartile range [IQR] 11, 50.6%) underwent UEMR of 97 colonic polyps (median size 25 mm, IQR 25 mm, range 10–160 mm). 13 (13.4%) were recurrences following previous conventional EMR. Polyps were predominantly left sided (66%) with flat (63.5%) or sessile (35.4%) morphology. 43.8% of polyps were removed en bloc, whilst argon plasma coagulation (APC) was used in 13.7%. Histology comprised of: low-grade dysplasia (80.2%), high-grade dysplasia (12.5%), adenocarcinoma (3.1%) and non-dysplastic sessile serrated polyp (2.6%).

Overall, resection at index UEMR was deemed endoscopically complete in 97.9%. Submucosal lift was required in 27.8% and positively correlated with polyp size >30 mm (OR 3.58, 95% CI 1.37–9.38, p = 0.01), but not morphology (flat vs. sessile, p = 0.09). The 30-day complication rate was 4.1% (n = 4), consisting of 2% procedure-related bleeding (n = 2), average diameters: 35 mm) and delayed rebleeding (n = 2; average diameter: 57.5 mm), with haemostasis achieved for all cases. No cases of perforation or mortality were identified. Of the 60.8% (n = 59) who attended for repeat endoscopy post-UEMR, the rate of recurrence or residual polyp was 14.8% (IQR 5.4) at 4 months and 15.2% (22.0%) within 1 year. Significant predictors of post-UEMR recurrence included: piece-meal vs. en bloc resection (OR 5.50, 95% CI 1.10–27.6, p = 0.03) and previous polyp (OR 4.17, 95% CI 1.02–17.05, p = 0.03) and recurrent polyp (OR 4.17, 95% CI 1.02–17.05, p = 0.03) and recurrent polyp (OR 4.17, 95% CI 1.02–17.05, p = 0.03).

Conclusion: UEMR is a safe alternative to conventional EMR for the management of clinically significant colonic polyps. However, our post-UEMR recurrence rate of 22.0% appears higher than other studies,\(^5\) but may be skewed by the tertiary referral nature of the patients. Although randomised trials are awaited, we suggest that those performing UEMR should attempt en bloc resection where possible, and consider wider resection margins for recurrent polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1511 WATER-AIDED COLONOSCOPY – RESEARCH FOCUS IN THE PAST DECADE AND CURRENT CLINICAL PRACTICE

F. W. Leung

Medicina, Seguideda Ambulatory Care Center, VAGLAHS; David Geffen School of Medicine at UCLA, North Hills/United States of America/CA

Contact E-mail Address: felixleung@socal.r.com

Introduction: Water-aided techniques have forged a paradigm shift in endoscopic diagnosis and therapy. The inauguration (10/22/2014) of the International Waters with memberships worldwide attested to participants’ commitment to advance clinical, educational and research missions. To aid planning of future work in each of these areas, a descriptive study of water-aided colonoscopy was performed.

Aims & Methods: The aims of this study were two-folds. Study 1: To assess the feasibility of the study in the past decade and current clinical practice. Study 1: Studies registered at Clinicaltrial.gov were searched for using the search term "water colonoscopy". Study 2: Members of International Waters voluntarily participated in a survey after their attendance at the 4th meeting to obtain a cross-sectional snapshot of current clinical practice. Study 1: Studies registered at Clinicaltrial.gov were searched for using the search term "water colonoscopy". Study 2: Members of International Waters voluntarily participated in a survey after their attendance at the 4th meeting to obtain a cross-sectional snapshot of current clinical practice.
the main complication (48.26%) events, requiring surgery in 5 (10.4%) cases. Perforation was related statistically significant to location (p < 0.05) and LST morphology (p = 0.05). Most frequent location of perforation was transverse colon (OR 88.3; SE 37), followed by descending colon (OR 13.5; SE 19.4) and splenic flexure (OR 6.3; SE 11.8). Perforation was more common in LST-G lesions vs LST-G (OR 14.1; SE 19.3) vs LST-E (SE 15.6). Perforation rates were not statistically associated with the presence of severe submucosal fibrosis compared to absence of fibrosis (0.8 SE 0.6 vs 1 SE 1.0; p = 0.9). Post-ESD complications were observed in 15 (8.2%) patients (delayed perforation, bleeding, 0.4%, electrocautery ulceration syndrome, severe esophageal stricture, haemopertoroneum (1) and splenic rupture (1)). Six cases (40%) were managed with surgery. Results from the learning curve progression according to consecutive chronological blocks of 50 cases (33 last bloc) are summarized in table 1. Initial success increased from 94% to 100%; speed of ESD decreased after the first 50 cases (15.5 cm²/min), up to 6.7 and 6.5 cm²/min in the last 2 blocs. A high perforation rate in the first period (32%) was reduced to 18–30.3% the following periods. Endoscopic treatment was successful in most cases of perforation (89.6%). Surgery was required for severe complications, incomplete ESD and/or perforation (n, %) (16 cases, 8.7%). Conclusion: On clinical ESD, high rates of success and en-bloc and R0 resection can be achieved along the learning curve. Perforation is the most common complication and is a still a challenge for Western countries. However, increasing experience reflects a high success in endoscopic management of perforation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Despite the advantages of endoscopic submucosal resection (ESD) demonstrated in large series from the far east, the procedure is not commonly practiced in the west and its role in standard practice is still debated. Although limited evidence for its efficacy in European practice is emerging, very few centres in the United Kingdom perform ESD regularly, if at all. We report the experience of a UK tertiary referral institution using ESD as part of a lesion specific, pragmatic approach to endoscopic resection in a complex patient cohort. Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥ 2 cm were included. Lesions were assessed with magnification chromoendoscopy supplemented by colonoscopic ultrasound in selected cases. A lesion specific approach was adopted to technique, with a high level of assessment of morphology, pit pattern, risk of submucosal invasion, and presence of submucosal fibrosis or scarring. ESD was used where en bloc resection was deemed essential, or as part of a hybrid procedure to ensure resection of a dominant nodule or suspicious area of a lesion in one piece, or where fibrosis or scarring would make standard EMR impossible. A resection was designated a hybrid procedure if ESD was used to effect submucosal dissection, circumferential incision alone to assist snare resection was not included. Results: 116 lesions (mean size 58.8 mm) were resected using ESD (n = 58) and hybrid ESD (n = 58). 82 (70.7%) had been subjected to prior attempts at resection (n = 58) or extensive sampling. Only 11 lesions had no prior biopsies performed. En bloc resection was achieved in 93.1% where ESD was used alone, with a mean operating rate of 4.7% after a mean follow up of 19 months. There were 6 microperforations treated with either endoscopic clips or antibiotics alone with no adverse sequelae, and one clinically significant perforation requiring surgery. However, the resected lesion in this case contained an invasive adenocarcinoma with deep submucosal invasion—there was no residual tumour in the surgical resection specimen. Post- procedure bleeding occurred in 6 patients, none of whom required additional intervention. 0.5% of cases were successfully performed as day case procedures. 97% of patients without invasive cancer were free from recurrence and had avoided surgery at last follow-up.

Conclusion: Colorectal ESD can be used as part of a standard lesion specific approach to a western referral centre to deliver safe and effective organ conserving treatment to patients with large challenging lesions. Knowledge regarding lesion assessment and selection in western practice should be improved to reduce the incidence of prior heavy manipulation and guide appropriate referral.

PI1514 RISK OF STENOSIS AND OUTCOMES FOLLOWING ENDOSCOPIC RESECTION OF LARGE COLORECTAL LESIONS INVOLVING MORE THAN 75% OF THE LUMINAL CIRCUMFERENCE

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji

Endoscopy, King’s College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@nhs.net

Introduction: Little is known about the risk of stenosis and outcomes following endoscopic resection of lesions in the colorectum which leave extensive mucosal defects. A limited number of studies suggest significant stenosis rates, although reports on outcomes and suggested management are conflicting. We determined the risk of stenosis and outcomes of endoscopic resection of colorectal lesions leaving mucosal defects ≥ 75% of the circumference.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥ 2 cm were included. Resection technique included EMR, ESD and hybrid techniques involving ESD. Patients were grouped according to circumferential extent of the mucosal defect after resection. Surveillance colonoscopy was performed at 3 and 12 months. Clinopathological characteristics and outcomes were compared between groups.

Results: 435 colorectal lesions ≥ 2 cm were resected using EMR (n = 342), ESD (n = 45) or hybrid techniques (n = 48). Circumferential extent of the resulting mucosal defect was ≥ 75% in 41 patients. 8 lesions were fully circumferential: 1 caecal lesion and the rest in the recto-sigmoid and rectum. 3 of these circumferential lesions contained deep invasive adenocarcinoma and 1 benign lesion ultimately required surgery. The 41 lesions with a mucosal defect ≥ 75% of the circumference had a mean size of 100.5 mm vs 49.0 mm for other lesions (p < 0.001). These patients had significantly more complications (16.7% vs 4.7%, p < 0.001), including a higher rate of perforation (8.3% vs 2.3%, p = 0.02), although none required surgery, and a significantly higher rate of recurrence (44.8% vs 9.2%, p < 0.001). 79% of patients without cancer were free from recurrence and had avoided surgery at last follow-up compared to 97% of patients with mucosal defects < 75% (p < 0.001). Stenosis occurred in 7 patients: 4 lesions extensively involving the rectum and recto-sigmoid and 2 lesions involving the sigmoid colon extending to the rectosigmoid. 1 of these involved a mucosal defect of only 50% of the circumference and 3 were fully circumferential. 1 patient had a symptomatic anorectal stenosis requiring dilatation under anaesthesia, 1 patient was asymptomatic but underwent early dilatation after the first surveillance endoscopy at 3 months. The remaining patients were asymptomatic and managed expectantly. In all these latter cases spontaneous improvement in the stricture was noted at the subsequent surveillance endoscopy.

Conclusion: The majority of patients with these extensive complex lesions can successfully be treated with endoscopic resection and avoid surgery. However, these patients have a significantly greater risk of complications and recurrence and should be managed in a tertiary institution. Although there is a significant risk of stenosis, it appears that most cases are asymptomatic and spontaneously improve with expectant management.

Introduction: Although it is well recognised that the risk of invasive carcinoma in apparently benign neoplastic lesions differs according to morphology, the incidence of invasive cancer varies between studies and there is limited data from large western series to inform practice. The importance of appropriate resection techniques, including the use of ESD, is increasingly recognised in western practice. It is therefore imperative that the risk of submucosal invasion is assessed as accurately as possible to prevent inappropriate attempts at resection. We determined the risk of submucosal invasion and high-grade dysplasia (HG-D) in different morphological sub-types of large colorectal lesions subjected to endoscopic resection.

Aims & Methods: Colorectal lesions ≥2 cm subjected to endoscopic resection were included. Lesions were assessed with magnification chromoendoscopy. Clinicopathological data recorded included morphological type according to Paris classification, sub-types of laterally spreading tumours (LST), degree of dysplasia, presence of submucosal invasion and outcomes following resection.

Results: 435 colorectal lesions ≥2 cm were resected. Mean lesion size was 55.2 mm (range 20 mm–160 mm). The frequency of and the incidence of high-grade dysplasia and invasive adenocarcinoma in the different morphological sub-types are shown in Table 1. The incidence of high-grade dysplasia (8.6%) and invasive adenocarcinoma (1.2%) was very low in LST granular homogenous lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: In our study, a withdrawal time exceeding seven minutes was significantly associated with the number of polyps detected in colonoscopy. Further studies may be helpful to confirm these results ideally by comparing these parameters in the same patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
compilation (0.10). Concerning SEMS insertion, the technical difficulty and safety of SEMS insertion were similar between right- and left-sided colonic obstructions.

Conclusion: A new technique of curved type guiding tube with SEMS insertion for right-sided colon, especially distal ascending colon is significantly more effective than straight type guiding tube, and this procedure was safer and less technically challenging than expected. SEMS insertion should be considered for treating right-sided malignant colonic obstruction.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic mucosal resection (EMR) has been shown to be useful in the removal of large colorectal adenomas. These lesions are often resected by using a piecemeal technique, which a risk of recurrence in 10% to 30% of cases. Recently, hot avulsion technique (HA) has shown promising results in the resection of residual fragments of large colorectal adenomas, with lower recurrence rate.

Aims & Methods: The aim of this study was to evaluate the efficacy and safety of HA at index EMR and at EMR local recurrence. We did a retrospective study based on all the HA performed between June 2015 and February 2017. The endoscopic characteristics, complications and recurrence rate after the initial HA were evaluated.

Results: 33 HA were performed among 29 patients (16 men and 13 women) with an average age of 69 years. The average follow up time was 11 months. HA was used to remove residual adenomatous tissue at 17 index EMR (mean size of the lesions 30 mm) and to remove recurrent fibrotic adenomatous tissue at EMR scar in 12 cases (mean size of recurrence tissue 14 mm). HA was successful in removing residual/recurrent adenomatous tissue in all patients. There were no immediate or long term adverse events. Comparing the two groups, local recurrence after initial HA occurred in one case at the index EMR group (1/17) and in 2 cases at the local EMR recurrence group (2/12). The overall recurrence rate in patients with a minimum 6 months follow up was 15% (3/20).

Conclusion: HA is a safe and effective technique to eradicate both residual tissue in large colorectal adenomas and recurrent fibrotic adenomatous tissue at EMR site, with low recurrence rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Quality of bowel preparation and adenoma detection rate (ADR) are routinely assessed in screening colonoscopy. However, data on patient experience are scarce.

Aims & Methods: This prospective non-interventional study compared bowel preparation quality according to the Harefield Scale, performance quality measures and patients satisfaction in screening colonoscopies performed within an Austrian quality assurance program.

Results: In screening colonoscopies performed by 20 endoscopists were included in this study. 50.3% of screened individuals were women. Because of the unequal patient count using CitroFix® (CF, n = 261), Picoprep® (PP, n = 2678), Klean-Prep® (KP, n = 804) and Moviprep® (MP, n = 1252), PC and CF were grouped as low volume (LV) purgatives, age and gender adjusted success rates and ADR per purgative were 97.0% and 23.3% for LV, 97.5% and 32.5% for KP and 93.5% and 26.0% for MP. Women had higher success rates than men (p = 0.007) and success rate decreased with patients age (p = 0.008). The compliance regarding consumption of the entire volume was best with LV (89.2%, KP 87.6%, MP 87.3%), which had a significant effect on success rate (p = 0.027). 93.5% of patients in the LV group would use the same purgative again compared to 68.4% in the KP and 73.2% in the MP group.

Conclusion: All investigated purgatives met the required quality standards of ≥90% rate of adequate bowel preparation according to the current ESGE guidelines. Success rates were higher in women and younger patients. Although only <90% of patients consumed the whole volume, the majority of patients would use the same purgative again.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1524 DIFFERENCES IN QUALITY OF BOWEL PREPARATION AT SCREENING COLONOSCOPY IN PRIVATE PRACTICES AND HOSPITALS
Department Of Internal Medicine III, Division Of Gastroenterology & Hepatology, Medical University of Vienna, Vienna,Austria

Contact E-Mail Address: barbara.majcher@meduniwien.ac.at

Introduction: Bowel preparation influences the adenoma detection rate and is therefore an important quality parameter in screening colonoscopy. According to the actual ESGE guideline “Performance measures for lower gastrointestinal endoscopy: a European Society of Gastrointestinal Endoscopy (ESGE) Quality Improvement Initiative”, 90% of colonoscopies should have adequate bowel preparation. The aim of this study was to investigate whether there is a difference in bowel preparation quality in private practices and hospitals.

Aims & Methods: Data from screening colonoscopies performed within quality certificate in Austria (2012 - 2017) provided by 245 endoscopists were evaluated. The recording of the quality of the bowel preparation was described as one of the five categories: excellent, good, fair, poor, only in the right colon and unsatisfactory.

Results: From the 125,127 screening colonoscopies included in this study, 72.93% were performed in private practices, (50.66% female, mean age 60.7) and 27.07% in hospitals (49.35% female, mean age 60.35). Significant difference was found between the average values of screening colonoscopies with excellent bowel preparation (38.00% (SD = 30.36) in private practices vs. 27.92% (SD = 23.11) in hospitals, p = 0.0215), fair (10.68% (SD = 10.89) vs. 15.18% (SD = 9.93), p = 0.0000) and unsatisfactory (0.66% (SD = 0.96%) vs. 1.43% (SD = 1.76), p = 0.0003) while there was no statistical significance among the average values from participants with good bowel preparation quality (47.40% (SD = 26.38) in private practices vs. 51.78% (SD = 19.28) in hospitals, p = 0.6428), poor (2.57% (SD = 2.90) vs. 1.75% (SD = 2.89), p = 0.2987) and poor only in the right colon (0.69 (SD = 1.74) vs. 0.80% (SD = 1.15, p = 0.7721). The mean ADR did not show any statistical difference between private practices and hospitals (23.98% (SD = 10.89%) vs. 25.80% (SD = 12.80%), p = 0.7652).

Conclusion: More excellent bowel preparation was found in private practices while the screening colonoscopies in hospitals showed a higher rate of fair and unsatisfactory bowel preparation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1525 RISK FACTORS FOR RESIDUAL NEOPLASIA AFTER ENDOSCOPIC MUCOSAL RESECTION OF LATERALLY SPREADING TUMORS
N. Brogyak, T. Grega, M. Voska, O. Ngo, O. Majek, M. Zavoral, S. Suchanek
1Department Of Internal Medicine, 1st Faculty Of Medicine, Charles University, Military University Hospital, Prague/Czech Republic
2Institute Of Biostatistics And Analyses, Masaryk University, Faculty Of Medicine, Brno/Czech Republic

Contact E-Mail Address: nadya.brogyak@uvn.cz

Introduction: Laterally spreading tumors (LSTs) are important precursors of colorectal carcinoma. They are usually removed by endoscopic mucosal resection (EMR). However, local residual neoplasia (LRN) may occur during follow-up. The aim of the study was to evaluate the occurrence of LRN and the risk factors for its emergence.

Aims & Methods: This retrospective study in a high-volume tertiary-referral center examined patients who had undergone EMR between 2013 and 2015 and who had had at least 1 surveillance colonoscopy after the initial treatment. LRN was defined histologically as the presence of neoplastic tissue in the post-EMR site.

Results: 160 laterally spreading tumors were diagnosed in 138 patients (62% men, mean age 67 years). Mean follow-up interval for surveillance colonoscopy was 6 months. Residual neoplasia at surveillance endoscopy was present following 21% of EMRs. Single variable analysis showed evidence of an increased risk of residual neoplasia for LST ≥ 20 mm (p = 0.006), villous adenomas (p = 0.001), piecemeal resection (p = 0.011) and G-type morphology (p = 0.003). In multivariate analysis, only size of the lesion (p = 0.080) and villous component (p = 0.045) were found to be a significant risk factor for LRN.

Conclusion: This retrospective study shows that the occurrence of LRN is frequent. Careful colorectal surveillance after EMR and the use of new methods to further reduce residual neoplasia are needed.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Familial adenomatous polyposis (FAP) is an autosomal dominantly inherited condition associated with a lifetime risk for colorectal cancer close to 100%. Thus prophylactic colectomy is recommended for patients with FAP. Colectomy with ileorectal anastomosis is the surgical option of choice in the majority of patients, given the complications and morbidity associated with ileal pouch-anal anastomosis. Therefore, annual endoscopic surveillance is recommended after surgery to prevent cancer in the rectal remnant (CRR).

Aims & Methods: The aim of this study was to determine the impact of endoscopic surveillance on CRR prevention in FAP patients after surgery. We did a retrospective single center study on findings of follow up endoscopies and determination of the cumulative risk of adenomas and prevalence of high risk adenomas (HRA) (villous histology, high-grade dysplasia and ≥10 mm) and CRR.

Results: 30 patients submitted to IRA were included (50% women), with a mean age of 43 years, 2 patients with attenuated phenotype. Nine patients had adenocarcinoma in the resected colon. Six patients started chemoprophylaxis after surgery (sulindac 4, celecoxib 1). The median time to adenoma appearance was 5 years (95% CI 3.4–6.6) and to HRA/CRR 12 years (95% CI 5.2–18.8), with a decreased median time to both adenomas and HRA/CRR in patients under chemoprophylaxis. The cumulative risk of adenomas was 20% at 1 year after surgery, 34.1% at 3 years and 57.4% at 5 years. During the follow up performed in 17 patients (56.7%), 12 patients (40%) had rectal involvement (HRA–12 patients (40%); intramucosal carcinoma–2 patients (6.7%); invasive adenocarcinoma–3 patients (10%)). None of the patients died with CRR. The cumulative risk of HRA/CRR was 21.8% at 5 years, 46.1% at 10 years and 66.3% at 15 years. All the patients with HRA/CRR had rectal involvement prior to surgery (p = 0.008) and a higher number of adenomas resect in the rectal remnant (p = 0.017).

Conclusion: The FAP endoscopic surveillance program allowed detection of HRA/CRR in a high percentage of patients. Based on these results, an intensive surveillance program should be suggested but endoscopic surveillance intervals widen in the first 5 years after surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1527 BOWEL PREPARATION FOR FLEXIBLE SIGMOIDOSCOPY: COMPARISON OF POLYETHYLENE GLYCOL ELECTROLYTE SOLUTION (PEG-ES) AND PHOSPHATE ENEMA IN 4,949 PATIENTS AT TWO UK HOSPITALS

A. Yousef, S. Paramanaha, A. Jeevagan, P. Mayhead

Gastroenterology, East Sussex Healthcare NHS Trust, Eastbourne/United Kingdom

Contact E-mail Address: abdyus12@sbs.net

Introduction: Flexible sigmoidoscopy is increasingly used to examine the left side of the bowel for diagnostic and surveillance purposes, and is now part of the UK bowel cancer screening programme. It is crucial to achieve adequate bowel cleansing in order to optimise the diagnostic yield of the test, and also to minimise the number of repeat procedures. However, the optimum bowel preparation for this procedure has consistently been debated.

Aims & Methods: Both phosphate enema and (PEG-ES) are commonly used for bowel preparation in flexible sigmoidoscopy at both hospitals participating in this study. We therefore wanted to compare the outcomes for these two methods. We retrospectively reviewed all the patients who underwent flexible sigmoidoscopy from January 2014 to December 2016 using each hospital's electronic endoscopy reporting system. We analysed their demographics, type of bowel preparation used in each case, and the quality of their individually achieved bowel preparation, subjectively graded as “Excellent, Adequate or Inadequate” by the endoscopist performing the procedure. A chi-squared test was used to calculate p-values.

Results: In total 6196 patients underwent flexible sigmoidoscopy during the study period (males 2885 (46.56%), mean age 62.80 years, range 16–101 years). 1247 (20.13%) patients were excluded from further analysis for the following reasons: No bowel preparation, subjectively graded as “Excellent, Adequate or Inadequate” (n = 451), no documentation of the quality of bowel preparation (n = 657), and non-(PEG-ES) oral preparation used (n = 139). A total of 4949 patients were included in the study, of whom 2103 had (PEG-ES) (42.49%) (males 986 (46.89%), mean age 60.97 years, range 18–95 years) and 2846 (57.50%) (males 1269 (44.59%), mean age 63.98 years, range 17–101 years) had phosphate enema. The results are summarised in the table below.

<table>
<thead>
<tr>
<th>Type of bowel preparation</th>
<th>Excellent</th>
<th>Adequate</th>
<th>Total Adequate and Excellent</th>
<th>Inadequate</th>
</tr>
</thead>
<tbody>
<tr>
<td>(PEG-ES) (n = 2103)</td>
<td>1126 (53.54%)</td>
<td>977 (45.61%)</td>
<td>1074 (98.15%)</td>
<td>207 (9.84%)</td>
</tr>
<tr>
<td>Phosphate enema (n = 2846)</td>
<td>624 (21.93%)</td>
<td>1297 (45.57%)</td>
<td>1921 (67.50%)</td>
<td>925 (32.50%)</td>
</tr>
<tr>
<td>Total (n = 4949)</td>
<td></td>
<td></td>
<td></td>
<td>P &lt; 0.001</td>
</tr>
</tbody>
</table>

Conclusion: Our large retrospective study showed that oral preparation with (PEG-ES) gave significantly better results than phosphate enema, which gave acceptable results in only 67.5% of the patients. As a result of this study, PEG-ES is now the preferred option at our hospitals, if there is no contraindication for this.

Introduction: Endoscopic resection of large colonic lesions (LCLs, >20 mm) is effective and it is associated with an acceptable incidence of incomplete resection and complications when performed by appropriately trained endoscopists in resource centers. Scanty data on the management of these lesions outside referral centers are reported in the literature.

Aims & Methods: Aim of present study is to evaluate the management of endoscopic resection of LCLs and intra-procedural complications in a real-life setting. In a prospective, multicenter, observational study in 20 centers, data from consecutive endoscopic resections of LCLs performed over a 6-month period were collected by a web-database. All patients undergoing LCLs resection were enrolled at procedure-time and followed-up at 15 days for adverse events and at 6 months for endoscopic/histological recurrence.

Results: 4253 LCLs (mean size 30.6 mm, SD 12.4; 41.4% lateral spreading tumor, 28.1% sessile, and 30.5% pedunculated) removed in 1329 patients (58% males, mean age 66±11.4 years) were analysed. An endoscopic mucosal resection (EMR) was performed in 57.9%, snare polypectomy in 34.7%, underwear EMR in 1.2% and endoscopic submucosal dissection in 6.2% of the lesions. Patients with LCLs, 19.4% were on ATT (62.5% aspirin, 12.2% thienopyridines, 4.8% dual antiplatelet, 15.4% vitamin K antagonists [VKAs], 5.1% direct oral anticoagulants [DOACs]). Aspirin and/or thienopyridines were withheld before resection in 53.6% and 91.7% of patients, respectively. Overall, intra-procedural bleeding requiring endoscopic therapy occurred in 8.1% of patients; 28% of them were on ATT, which had always been withheld, but in 48% of patients on aspirin. At multivariate analysis, intra-procedural bleeding was correlated with increasing polypl size (Odds Ratio 1.02 95% Confidence Interval 1.01–1.04), and inversely with execution of pre- and post-resection prophylaxis maneuvers (Odds Ratio 0.55 95% Confidence Interval 0.37–0.82 and Odds Ratio 0.55 95% Confidence Interval 0.37–0.82 respectively). As concerns
complications, delayed bleeding occurred in 4.5% of the subjects, whereas for perforation, 0.0% (0.9% early and 0.6% delayed) of patients, 86.7% of whom were successfully managed endoscopically. At the moment, 6-months follow-up is available for 35% of the patients, with a positive sessile and/or histological recurrence documented in 22.8%.

Conclusion: The management of resection of LCLs varies widely. The incidence of intra-procedural bleeding correlates with polyp size and prophyllactic maneuvers, and its endoscopic management is successful in most of cases. Overall, complication rate is marginal and efficacy is good, even in a real-life setting.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The incidence and mortality of colorectal cancer (CRC) can be decreased through the removal of precancerous adenomas. Endoscopic removal of polyps over 2 cm is considered a high-risk procedure both for complications and malignant transformation.

Aims & Methods: The aim of this study was to evaluate the outcome and complication rate after endoscopic removal of polyps over 2 cm. In this retrospective study clinical and demographic data of patients undergoing polypectomy due to colorectal adenomas over 2 cm between 2012 and 2017 were collected. Data of endoscopic procedures, complications of polypectomy and histological assessments of the removed polyp were obtained.

Results: Data of 100 patients (male/female: 58/42) was analyzed in the study. Five percent of the 106 removed polyps proved to be pedunculated, 21 were sessile and 34 flat. Six patients had more than one large polyp (>2cm). The locations of the removed polyps were rectum in 33, sigmoid colon in 38, coecum in 12 and other parts of the colon in 23 patients. In 65 cases, polyps were excised with endoscopic mucosa resection (EMR) or hybrid endoscopic submucosa dissection (ESD). In 41 cases snare was used to remove the polyps in one or more pieces. Based on histological findings 34 (50.9%) polyps were shown to be low-grade adenomas, 34 (32.07%) high-grade adenomas, 1 (0.9%) polyp was hyperplastic, and 17 (16.03%) proved to be malignant among which complete endoscopic resection was achieved in 9 patients (52.9%). Additional smaller polyps were found in 39 patients and a synchronous cancer in 7. During polypectomy 91 hemoclips were deployed to close suspected perforation (8 cases) to cease bleeding (19) or for prevention. Postpolypectomy syndrome developed in 8 cases. Second-look colonoscopy was required in 8 cases due to bleeding within a mean of 4 days after the first examination. Hemoclip insertion was needed in 5 cases and epinephrine injection in 1 case. The bleeding stopped spontaneously in 2 cases. Surgery was needed in 3 patients. Surgical intervention was not needed in any case.

Conclusion: Malignant transformation was revealed in 16% of the polyps over the size of 2 cm. Complete endoscopic removal of these polyps was successfully performed in half of the patients. Endoscopic removal of high-risk polyps is safe in experienced hand.

Introduction: Endoscopic resection of superficial neoplasms at the perineal rectum is difficult due to pain sensitivity, narrowness of the anal canal, presence of internal rectal plexus, whereas that of at the ileocecal valve (ICV) due to the variable morphology of the ICV itself and ileal involvement.

Aims & Methods: Aim was to assess the feasibility and outcomes of ESD in these locations. Prospectively collected database in a single nonacademic center. From 2010 to 2016, all consecutive patients scheduled to ESD for a superficial neoplasm in the perineal rectum (distal margin < 30 mm from the dentate line) and at the ICV were compared to those in the pelvic rectum and in the cecum and ascending colon, respectively. ESD was performed with the standard technique. Follow-up was scheduled at 3 and 6 months within the first year and then yearly. Biopsies were taken from the scar of the resection site if a residual tissue was detected.

Results: A total 16 neoplasms at IVC were compared to 110 neoplasms in the cecum and ascending colon; 30 neoplasms in the perineal rectum were compared to 84 cases in the pelvic rectum (Table). Features of neoplasms in the perineal and pelvic rectum were no different as well as neoplasms at the IVC and cecum and ascending colon. ESD en block rates were lower in the perineal rectum and at the IVC, but no significant differences were found with the respective control groups (P = 0.490 and 0.404, respectively). ESD R0 rate was significantly lower at the IVC (P = 0.021). Adverse events were not different, although 3 perforations occurred in the cecum and ascending colon. During follow-up (median 36 months; range 24-84); residual tissue was diagnosed at the ICV in 2 (13%) cases, in the cecum and ascending colon in 2 (2%) cases (P = 0.078); in the perineal rectum in 4 (13%) cases and pelvic rectum in 2 (3%).

Conclusion: The ESD of neoplasms at the IVC and perineal rectum is feasible and effective. The complete resection rate is low due to the challenging anatomy of

Introduction: The choice of polypectomy technique differs according to regional preferences and availability. This year, in order to standardize the approach to this techniques, the European Society of Gastrointestinal Endoscopy (ESGE) published recommendations for colorectal polypectomy and endoscopic mucosal resection (EMR).1

Aims & Methods: We aimed to evaluate the recent years evolution of the adherance to the recommendations of colorectal polypectomy and EMR at a tertiary center. We conducted a unincentric analysis of polypectomy and mucosectomy techniques performed consecutively between January and June of 2011 and 2016 at a tertiary center. According to the recommendations, the excision of sessile and flat polyps is considered adequate when performed with cold biopsy forceps or cold snare for polyps ≤3 mm, cold snare if 4-9 mm, cold or hot snare if 10-19 mm and EMR if ≥20 mm. Polypectomy of pedunculated polyps is considered adequate when performed with a diathermic loop in polyps <20 mm, always in association with any prophylactic therapy when polyp size ≥20 mm.

Results: We included 1721 endoscopic procedures of polypectomy and EMR, corresponding to 596 patients (64.2%/n = 900) of those ≥20 mm lesions. For pedunculated and flat polyps, one of the recommended excision techniques was performed in: 84.6% (n = 270) of ≤3 mm polyps (75.7% in 2011 vs. 95.8% in 2016; p < 0.001); 22.2% (n = 109) of 4-5 mm polyps (12.5% vs. 36.5%; p < 0.001). Adverse events were not different, although 3 perforations occurred in the cecum and ascending colon. During follow-up (median 36 months; range 24–84): residual tissue was diagnosed at the ICV in 2 (13%) cases, in the cecum and ascending colon in 2 (2%) cases (P = 0.078); in the perineal rectum in 4 (13%) cases and pelvic rectum in 2 (3%).

Conclusion: Even before publication of the European recommendations, there has already been an increase in the proportion of polypectomies performed adeguately in the different groups of lesions. There is still a need to adjust clinical practice in some subgroups, especially in polyps of size 4-9 mm, in order to strictly comply with the recommendations.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
that precludes conducting a mucosal incision far from tumor margins. A careful endoscopic follow-up is mandatory to detect residual neoplasms.

Introduction: Colorectal cancer (CRC) is one of the most common malignancies in developed and developing countries, with associated economic and social burden. Early diagnosis is key, and endoscopic resection of colorectal tumors is a well-established therapy for early-stage disease. However, endoscopic treatment is limited in patients with unresectable tumors, and alternative treatments are required. Self-expandable metallic stents (SEMS) are considered as the first-line palliative treatment for malignant bowel obstruction.

Aims & Methods: Evaluate the outcome of endoscopic SEMS placement in CRC obstruction. Retrospective analysis of patients CRC submitted to endoscopic placement of SEMS from 2009 to 2016 in the Gastroenterology Department of Centro Hospitalar do Algarve. Statistical analysis was performed with SPSS version 23.

Results: The study included 23 patients with CRC obstruction, who were submitted to endoscopic SEMS placement, with a median age of 75.2±13.47 years. The stents were placed with a palliative purpose in 69.6% of cases (n=16) and a transitory procedure before surgery in 30.4% of cases (n=7). Technical and clinical success was found in 91.3% of the patients, without any recorded death during the procedure. In patients whose goal was palliative treatment (75% men and 25% women) they had a mean age of 81.6±9.28 years. In 43.6% of the patients the tumor was located in the rectum, 31.6% in the sigmoid region, and 25% in the recto-sigmoid transition. Being the majority (75%) well differentiated. There was a need for dilatation in 31.3%, most of the stents were uncovered (56.3%), 25% of the patients had complications. After stent placement, approximately 25% of the patients did chemotherapy. There was a 75% mortality rate (37.5% died by 6 months and 37.5% died by 12 months of follow-up). The use of chemotherapy after SEMS placement influenced the complications associated with the procedure (p<0.05) but none of the other variables had a statistically significant influence on early death (up to 6 months).

Conclusion: SEMS is an effective and safe palliative option for unresectable tumors, although the use of chemotherapy after the placement of prostheses may have an influence on the appearance of complications. Malignant colon obstruction of the colon can be treated effectively with the use of endoscopic techniques.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic mucosal resection (EMR) has been shown to be a safe and effective technique for removal of large colorectal adenomas. However, local adenoma recurrence remains a significant limitation, with prior published data describing recurrence rates of 10% to 30% post EMR.

Aims & Methods: This study was aimed to evaluate the outcomes of EMR for large colorectal adenomas and identify the risk factors for adenoma recurrence. We did a retrospective analysis of the colorectal EMR performed between June 2009 and December 2016. Resected lesions larger than 20 mm in diameter with at least 3 months follow up were included. Patients referred for surgery were excluded.

Results: During the study period, 201 colorectal lesions ≥20mm in size were removed after EMR (with associated polypectomy in 68.9% of cases). Mean lesion size was 35 mm and 137 (68.2%) were located in the rectum and left colon. 66 lesions (32.8%) were larger than 40 mm in diameter. Piecemeal resection was performed in 171 lesions (85.1%). Local adenoma recurrence occurred in 44 cases (21.9%) after a mean time of follow up of 7.6 months, and the majority was managed with polypectomy or new EMR. The cumulative risk of adenoma recurrence was 7.5% at 3 months, 15.5% at 6 months and 17.1% at 12 months. In the multivariate analysis, the variables associated with a high risk of recurrence were lesions ≥80 mm in size (p=0.001) and intra-procedural bleeding (p=0.020). The recurrence rate was higher in the patients treated with argon plasma coagulation (p=0.046).

Conclusion: After EMR of large colorectal adenomas, local recurrence rate was 21.9%. The risk factors for adenoma recurrence include lesions ≥40 mm and intra-procedural bleeding. Argon plasma coagulation was not associated with lower recurrence rate.

Introduction: European colorectal screening guidelines have modified the follow-up interval times based on baseline colonoscopy findings in recent years. In addition, the waiting list and individual conditions may modify the real follow-up times and this could impact in advanced adenoma detection rate in follow-up and patients outcome.

Aims & Methods: The aim of the present study was to comparatively analyse the risk of advanced lesions (advanced adenoma, invasive cancer) in high-risk patients included in a colorectal cancer screening program with different real follow-up times. One-thousand one-hundred and sixty-six patients (mean age: 60.66±5.86 years, 69.1% men) who underwent a baseline colonoscopy with ≥1 adenomas and/or ≥10 mm between 2007-2012 were included. A Kaplan-Meier regression and a comparative subgroup analysis by Long-Rank test were carried out to detect the impact of real times within patients of the same risk. An adjustment for baseline covariates (high-grade dysplasia, villous component) by Cox analysis was also performed.

Results: The real follow-up times in ≥1 adenomas (n=853, 73.18%) and ≥10 mm adenomas (n=799, 66.81%) were 38.54±11.57 and 38.66±11.68 months. The risk of advanced lesions were 0.26%, 1.46%, 2.38%, 9.09% and 10.38% (p=0.0121 advanced lesions in 12, 24, 36, 48 and ≥60 months respectively. The most important increase was at 3–4 years (p=0.052/month). The proportion of advanced lesions within 1–2 adenomas and ≥3 adenomas subgroups at 48 months were 5.43% and 10.43% (p<0.001), but with no differences in small adenomas (<10 mm (p=0.478).

Conclusion: The risk of advanced lesions in high-risk patients increased significantly at 36–60 months after baseline colonoscopy, being more important in ≥3 adenomas subgroup. There were no differences for 1–3 years interval.

Introduction: Conventional endoscopic resection, such as snare polypectomy and endoscopic mucosa resection (EMR) of benign polyps in colon and rectum reduces colorectal cancer (CRC) incidence and mortality but the role of endoscopic resection of colorectal polyp removal has been questioned. Endoscopic submucosal dissection (ESD) results in high short-term resection rates of large (≥2cm) benign lesions resulting in low numbers of recurrences. However, there is limited data in the literature on the potential role of ESD in the treatment of patients with early CRC. In the present study, we present our results on performing ESD in patients with small sessile and flat malignant lesion in the colon and rectum in a large European center.

Aims & Methods: Our aim was to investigate the potential role of ESD in treatment of early colorectal cancer. We retrospectively reviewed medical records of
254 patients that underwent colorectal ESD at the endoscopy unit at Skane University Hospital in Malmo¨, Sweden from Jan 2014 to Dec 2016. Indications for ESD were flat and sessile lesions larger than 20 mm in diameter with low or high graded dysplasia (251 cases). Moreover, three patients with known colorectal adenocarcinoma underwent ESD due to significant morbidity excluding surgery, which was identified and included 29 cases of histologically verified submucosal invasive CRC in this study.

Results: This study included 29 patients with median age of 69 years (range 44–89 years). Median tumour size was 40 mm, ranging from 20 - 70 mm. Tumours were either flat (Paris classification Ha, 6 cases), sessile (Paris classification 1s, 19 cases) or a combination of flat and sessile (4 cases). Half of the lesions were located in the rectum and half in the colon. En bloc resection was achieved in 24 cases (83%), piecemeal resection in 4 cases (14%) and ESD was incomplete in one case. Rx complete the resection was found in 26 cases (90%). R0 resection was found in 20 specimen (69%), RX was found in 3 cases (10%) and R1 was found in 5 cases (17%). Lymphovascular involvement was seen in 6 cases (21%). A total of 212 complications (6.8%) were registered: these included acute pancreatitis (4.5%), cholangitis (1.3%), sepsis (0.4%), acute cholecystitis (0.3%), cardiopulmonary complications (0.2%), perforations and hemorrhage (0.2%). The complications that presented, which were significantly higher in the female sex (7.3% vs. 6.2%; p < 0.05), besides a greater average hospital stay in those suffering from other complications (8.4 days vs. 5.8 days, p < 0.05). The post-procedure hospital stay was concerned, in 55% of the cases, the discharge of the patients occurred after 6–12 days, whereas in the remaining cases, the hospital stay was longer than 12 days. In the majority of cases, the post-procedure hospital stay was 7–10 days. The within hospital mortality was 0.3% (8 cases). Since its introduction in 1968, Endoscopic retrograde cholangiography pancreatitis (PEP) has been a well studied entity. In the last few years, the clinical presentation of pancreatitis, the use of prophylactic necrosis, the patient's post-procedure status; the total complication rate that was utilized was 2 days and the patients who later underwent surgery (e.g. cholecystectomy) were excluded from our analysis; the associations between the type of hospital where the patients were being assisted both with regard to the type of organization (Hub or Spoke model) and the type of management (public/private) were also evaluated.

Conclusion: A total of 3,136 admissions out of total of 14,626 hospital days (SD:4.6 ± 5.8 days) were identified in a total of 40 hospitals, 6 (15%) of which presented complication sex ratios were calculated. The mean age, which was equal to 68.3 ± 14.2 (range 6–98 yrs), was higher in the females (69.1 ± 14.9 vs. 67.5 ± 13.5); significant deviations during the period examined were not noted. A total of 212 complications (6.8%) were registered: these included acute pancreatitis (4.5%), cholangitis (1.3%), sepsis (0.4%), acute cholecystitis (0.3%), cardiopulmonary complications (0.2%), perforations and hemorrhage (0.2%). The complications that presented, which were significantly higher in the female sex (7.3% vs. 6.2%; p < 0.05), besides a greater average hospital stay in those suffering from other complications (8.4 days vs. 5.8 days, p < 0.05). The post-procedure hospital stay was concerned, in 55% of the cases, the discharge of the patients occurred after 6–12 days, whereas in the remaining cases, the hospital stay was longer than 12 days. In the majority of cases, the post-procedure hospital stay was 7–10 days. The within hospital mortality was 0.3% (8 cases). Since its introduction in 1968, Endoscopic retrograde cholangiography pancreatitis (PEP) has been a well studied entity. In the last few years, the clinical presentation of pancreatitis, the use of prophylactic necrosis, the patient's post-procedure status; the total complication rate that was utilized was 2 days and the patients who later underwent surgery (e.g. cholecystectomy) were excluded from our analysis; the associations between the type of hospital where the patients were being assisted both with regard to the type of organization (Hub or Spoke model) and the type of management (public/private) were also evaluated.

Conclusion: Study findings uncovered that pancreatitis was the most common post-procedure ERCP complication in the patients studied; the total complication rate was in line with that reported in the literature. That result and the fact that no correlation was found between the sex and type of complications and the type of hospital can be attributed to the effective regional hospital organization characterized by a capillary network of specialists capable of performing complete endoscopic procedures throughout the region limiting the need to transfer patients from one hospital to another.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1537 TRENDS IN STATISTICS REGARDING ELECTIVE ERCP PROCEDURES IN THE VENETO REGION: A RETROSPECTIVE STUDY BASED ON ADMINISTRATIVE DATABASES

M. Saiha1, E. Rosa-Rizzotto1, E. Guido1, D. Caroli1, A. Frasson3, B. Germana1, A. Francesca2, D. Sette De Lazzaro2, S. Leblanc, H. Soliman, B. Brieau, M. Barret, R. Coriat, F. Prat, d.caroli@libero.it

3 San Martino Hospital - Umsl, Gastroenterologic Unit, Belluno/Italy

Contact E-mail Address: d.caroli@libero.it

Introduction: Since its introduction in 1968, Endoscopic retrograde cholangiography pancreatitis (ERCP) became a common therapeutic tool in the biliary system used to diagnosis and to treat conditions associated to the pancreatobiliary system. It is nevertheless associated to the highest risk of complications of all routine endoscopic procedures. It is important to have a thorough understanding of the potential complications and the adverse events that may be associated to ERCP procedures so that these may be managed appropriately should they occur. The aim of this study was to examine the trends in ERCP usage here in the Veneto Region (Northeastern Italian area) and, in particular, the complications and mortality rate associated to it.

Aims & Methods: Utilizing an anonymous database of hospital discharge records referring to the period between 2007 and 2015, a retrospective study was carried out to examine the complications associated to ERCP. All of the elective hospitalizations for gallstones in the bile duct during which the procedure was carried out within two days of being hospitalized were examined. Hospitalizations for neoplasms were not considered. The study considered the onset of complications or death as outcome indicators as well as the patients' post-procedure status; the threshold value that was utilized was 2 days and the patients who later underwent surgery (e.g. cholecystectomy) were excluded from our analysis; the associations between the type of hospital where the patients were being assisted both with regard to the type of organization (Hub or Spoke model) and the type of management (public/private) were also evaluated.

Results: A total of 3,136 admissions out of total of 14,626 hospital days (SD:4.6 ± 5.8 days) were identified in a total of 40 hospitals, 6 (15%) of which presented complications sex ratios were calculated. The mean age, which was equal to 68.3 ± 14.2 (range 6–98 yrs), was higher in the females (69.1 ± 14.9 vs. 67.5 ± 13.5); significant deviations during the period examined were not noted. A total of 212 complications (6.8%) were registered: these included acute pancreatitis (4.5%), cholangitis (1.3%), sepsis (0.4%), acute cholecystitis (0.3%), cardiopulmonary complications (0.2%), perforations and hemorrhage (0.2%). The complications that presented, which were significantly higher in the female sex (7.3% vs. 6.2%; p < 0.05), besides a greater average hospital stay in those suffering from other complications (8.4 days vs. 5.8 days, p < 0.05). The post-procedure hospital stay was concerned, in 55% of the cases, the discharge of the patients occurred after 6–12 days, whereas in the remaining cases, the hospital stay was longer than 12 days. In the majority of cases, the post-procedure hospital stay was 7–10 days. The within hospital mortality was 0.3% (8 cases). Since its introduction in 1968, Endoscopic retrograde cholangiography pancreatitis (PEP) has been a well studied entity. P1538 EFFECT OF OBESITY, DYSLIPIDEMIA AND DIABETES MELLITUS ON THE RISK OF POST-ERCPI PANCREATITIS

Gastroenterology, Habib Thameur Hospital, Tunis/Tunisia

Contact E-mail Address: hajer.hassine@gmail.com

Introduction: Risk factors for post-endoscopic retrograde cholangiopancreatoscopy pancreatitis (PEP) have been widely investigated. Nevertheless, studies focusing in metabolic conditions especially obesity, dyslipidemia and diabetes mellitus (DM) are still limited. The aim of our study was to evaluate the effect of these factors on the frequency of PEP. We retrospectively analyzed all ERCP performed over a 12 months period [January 2015 - December 2015] and carried out at the gastroenterology unit of our hospital. All patients were evaluated prospectively for the frequency of PEP based on the consensus criteria.The patients with obesity (Body mass index BMI ≥ 30 kg/m²), dyslipidemia (triglyceride > 2g/L or LDL-cholesterol > 1.6g/L) and DM (history of DM or fasting glucose level
biliary stenting or nasobiliary drainage may be required. External biliary fistulas, jaundice and accompanying cholangitis. In some cases, biliary drainage. One patient presented post ERCP pancreatitis (1.5%).

Objectives: In 19 cases of patients with HHD, 11.1% in patients with dyslipidemia (11.1% vs 5.3%) and DM (9.1% vs 5.3%) groups, results did not rich a statistical significance (p = 0.30, p = 0.30) respectively. This could be explained by the effectiveness of patients. In other hand, PEP was less frequent in the obesity group (3.8% vs 6.9%) but there was no statistical significance p = 0.28.

Conclusion: In our study, metabolic conditions were not associated with an increased risk of PEP. It seems to be wise to display mostly the role of these conditions in larger prospective studies since the expanded prevalence of metabolic syndrome in general population.

previously flushed with contrast. A 0.025” guidewire was then inserted through the needle into the duct and advanced antegrade to the papilla. If further manipulation was necessary to enter the duodenum, movements were performed with caution in order to avoid fragmentation of the guidewire. Whenever the passage through the papilla was not achieved or the guidewire movements were hampered, we performed a microcatheter technique. After removing the needle, leaving the guidewire in situ, a 3F, 150 cm microcath-
er was inserted over the guidewire into the duct. Then, manipulation of the guidewire, guidewire exchange and contrast injection were performed according to the discretion of the endoscopist. We reviewed the cases of EUS-guided percutaneous or biliary rendezvous performed in our unit using microcatheters from September 2015 to March 2017. Technical success was considered when the rendezvous could be completed.

Results: Nine patients with previous unsuccessful manipulation of the guidewire with the needle during EUS-guided biliary or pancreatic rendezvous underwent a microcatheter-guided attempt on the same procedure. Pancreatic rendezvous was attempted in 3 cases (2 chronic pancreatitis, 2 pancreas divisum and 1 pancreatic cancer) and biliary rendezvous in the other 4 (3 biliary stenosis and 1 ampulloma). Technical success was achieved in 7 patients (78%) with the microcatheter technique. Technical failure occurred in 1 patient with biliary stenosis in whom a EUS-guided hepatico-gastrostomy was performed in the same procedure and in 1 patient with chronic pancreatitis with symptomatic pancreatic duct stenosis. There were no adverse events after the procedure, irrespective of technical success.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Biliary tract complications (BTC) are the leading problem in patients after orthotopic liver transplantation (LT). The present study analysed the results and predictors of treatment outcomes in patients with biliary stenoses undergoing endoscopic retrograde cholangiopancreatography (ERCP) and/or percutaneous transhepatic cholangiodrainage (PTCD) at the University Medical Center Hamburg-Eppendorf.

Aims & Methods: All adult patients who received ERCP or PTCD for BTC after LT between 2009 and 2015 were retrospectively analysed. Remission of BTC was defined as no need of intervention for at least 12 months. To identify predictors of endoscopic treatment outcome in patients with biliary stenoses, a multivariate logistic regression analysis was performed after univariate variable selection. Laboratory parameters that were significant in the multivariate analysis, were dichotomised stepwise according to the most informative cut-off predicting outcome. Furthermore, endoscopic techniques were analysed in both the ERCP- and PTCD-subgroup.

Results: Of 144 patients with BTC after LT, 116 were diagnosed with biliary stenoses. Among these, 86 received ERCP, 17 PTCD and 13 both techniques. Long-term remission was achieved in 55 patients (47% overall; 53% in ERCP alone and 30% when PTCD was applied). Patients with non-anastomotic strictures (NAS) (odds ratio [OR] 0.25, 95% confidence interval [CI] 0.10–0.57; p = 0.001), requirement of PTCD after LT. However, patients with NAS and requirement of PTCD had less favourable outcomes. The pre-interventional bilirubin level could be a valuable parameter to identify patients at risk of treatment failure. Larger ERCP balloon size resulted in higher efficiency.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1543 RESULTS OF THE FRENCH NATIONAL OBSERVATIONAL STUDY CONCERNING THE PRACTICE OF PROBE-BASED CONFOCAL ENDOMICROSCOPY (CELLVIZIO®)

Introduction: Confocal endomicroscopy is an endoscopic imaging technique per-
imizing the microscopic analysis of the digestive mucosa in real time (esophagus, stomach, duodenum, colon, biliary tract and pancreas) due to injection of fluo-
rescein which is an intravenous contrast. The aim of this national observational study under the guard of SFED is to evaluate the practice of confocal endomi-
icroscopy in France, specifically its indication, histologic correlation, therapeutic benefits depending on the operator and complications.

Aims & Methods: We executed a multicentric observational prospective study from September 2013 to February 2015. Collection of data was based on a standardized data collection sheet. All operators were trained in performing standard endomicroscopy. The intravenous injection of fluorescein was given either in bolus or in a perfusion method at a dilution of 1 or 10%. Demographic, clinical, endoscopic and endomicroscopic data were collected. For each act the correla-
tion with the confocal endomicroscopy and histology and the outcome of the ECM depending on the operator was reported.

Results: In total 399 procedures of confocal endomicroscopy were done on 399 patients (median age was 39/ -14.5, males were 52%) and these were per-
formed in 12 centers. The main indications were: diagnosis and monitoring of Barrett esophagus 28% (111/399), surveillance of gastritis 4% (16/399), charac-
terization of colorectal polyp and searching for dysplasia in IBD patients 17% (68/399), undetermined biliary stenosis 11% (42/399), pancreatic cysts 30% (123/ 399), other rare cases (lymph nodes characterization, lymphoma, GIST, celiac disease, control post mucosectomy of gastric and duodenal polyps) 10% (39/399). The quality of imaging was good in 83% of cases (331/ 399), average in 16% (64/399) and poor in 1% (6/399). The correlation with histology was measured by using Cohen’s kappa coefficient. The results were respectively k = 0.9, 0.78, 0.82, 0.7, 0.94, 0.93 for Barrett’s esophagus, gastritis, IBD, colorectal polyps, undetermined biliary stenosis and pancreatic cysts. The outcome of the procedure according to the operator was beneficial for three main indications: Barrett’s esophagus (especially for targeting biopsy), serous pancreatic cysts (100% of cases), and undetermined biliary stenosis (90% of cases and especially for real time therapeutic decision). One major side effect was seen during the study, which was an anaphylactic shock after a bolus injection of 2.5cc of fluorescein in a 69y old patient who didn’t have any previous history of allergies. This patient was hospitalized for surveillance for three days.

Conclusion: In conclusion, confocal endomicroscopy is an in vivo microscopic technique that is easily performed throughout the digestive tube with a good histologic correlation especially for Barrett’s esophagus, undetermined biliary stenosis and pancreatic cysts. Its importance in the management of patients remains to be clarified with the advent of new endoscopic magnification techniques.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) repre-
sents a crucial procedure in the management of biliopancreatic pathology. However, its performance in patients with surgically modified gastro-enteric-biliary anatomy (SMGA) is a challenging issue.

Aims & Methods: We aimed to evaluate the efficacy of this advanced endoscopic technique in patients with SMGA. This was a retrospective observational cohort study of all patients with surgical modification of biliary/pancreatic access undergone ERCP, between 01/2002 and 02/2017. Demographic variables, indications, the breakdown of surgical procedures and technical success rate were evaluated as well as potential predictive factors of therapeutic efficacy rate. Compared patients with successful technique(G1) and therapeutic failure by ERCP
intervention for the removal of residual CBD stones is limited by lack of appro-
retained common bile duct stones can be improved by digital, single-operator.

P1545 NEWLY DEVELOPED BASKET FOR DIGITAL, SINGLE-
Aims & Methods: We evaluated the role of SOC and newly developed dormia basket for the evaluation and removal of residual stones after lithotripsy. From March to October 2016, 34 patients who had undergone lithotripsy for retained CBD stones with no evidence of filling defects in occluded balloon cholangiography were included. After balloon cholangiography, the bile duct was evaluated by SOC for the complete evacuation of stones. Detected residual CBD stones were directly retrieved with newly developed dormia basket inserted into the working channel of SOC. The incidence of residual stones detected by SOC, and the success rate of residual stone retrieval under SOC were investigated.
Results: SOC was successfully performed in all patients. Of these, 11 patients (32.4%) had residual CBD stones. The residual stones were successfully removed in 10 patients (90.9%) by dormia basket under SOC. (84.6%) except residual stones were directly retrieved with newly developed dormia basket inserted into the working channel of SOC. The incidence of residual stones detected by SOC, and the success rate of residual stone retrieval under SOC were investigated.
Conclusion: Digital SOC combined with newly developed dormia basket is useful for the detection and extraction of residual stones after lithotripsy for retained CBD stones. The effectiveness of SOC compared to the existing methods.

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) relies on the use of ionizing radiation in the form of fluoroscopy. Because use of fluoro-
Results: As a result of analysis of the 892 ERCPs performed during 4 years, the mean duration of fluoroscopy time was 5.52 mins (95% CI, 5.15–5.93). Mean radiation duration were as follows: CBD stones (n = 511, 5.76 mins); malignant stenosis of bile duct (n = 189, 5.78 mins); pancreatic disease (n = 95, 5.28 mins); benign stenosis of bile duct (n = 51, 5.52 mins); and periampullary stenosis (n = 80, 5.77 mins). Multivariate analysis revealed that prolonged duration of fluoroscopy time was related with specific factors of patient included age, BMI, diagnosis and procedure complexity (all p < 0.05). Among the parameters, procedure complexity was the most significant relation with radiation dose. In addition, the first procedure and procedure duration: two more procedures performed during ERCP and mechanical lithotripsy (all p < 0.05).
Conclusion: ERCPs are associated with significantly higher radiation exposure to patients. Further investigation of the specific procedures and factors that increase radiation dose is necessary. Increased awareness of the awareness of increased dose of radiation required when performing ERCP in patients with increased BMI, old age, and who need two more ERCP procedure.

Introduction: To obtain representative information about invasive endoscopic procedures is a principal goal to monitor efficacy and safety. A web-based, online central registry can serve this aim allowing structured data collection and analyses. The ERCP registry is an essential tool for measuring quality indicators. The universal usage will allow benchmarking at individual, institutional and national level and will help in quality improvement. Efficacy, safety and impact on different pancreatobiliary disorders will be also measurable.
Results: Hungarian experts in ERCP were invited at the invitation of the registry for discussion and consensus. Detailed data collection form was initially developed based on internationally recommended quality parameters. The prospective observational research project was approved by the Scientific and Research Ethics Committee (Budapest, Hungary). A web-based case report form was developed after finalisation and tested from January 2017 at our department. ERCP related data of consecutive patients were collected prospectively after consenting the patients. The data from the first 100 procedures were analysed to demonstrate the usability of the registry. Ninety-two patients (51 females, 41 males) were involved in this preliminary evaluation with an average age of 69.2 years (23–93 years). The number of elective and urgent examinations were almost equal. The indication of ERCP were the following: bile duct disorder based on laboratory or imaging data was the most common indication (in 31%), cholangitis in 16%, acute biliary pancreatitis in 5%, pancreatic disorder in 3%. The difficulty of procedures was evaluated: grade 1–22%, grade 2–45%, grade 3–30%, grade 4–3%. Fifty-nine procedures were performed in patients with malignant stenosis of the bile duct (n=22; 37.9%). Nineteen procedures were performed on the specific procedure. The endoscopists should be aware of the importance of the registry.
Conclusion: The registry is an essential tool for measuring quality indicators. The universal usage will allow benchmarking at individual, institutional and national level and will help in quality improvement. Efficacy, safety and impact on different pancreatobiliary disorders will also be measurable.

Introduction: Double-balloon enteroscopy-assisted endoscopic retrograde cholangiopancreatography or DBE-ERCP allows access to the biliary ducts of patients with surgically altered GI anatomy. We studied the feasibility and efficacy of DBE-ERCP at our institution.
Aims & Methods: This is a retrospective study of all patients with surgically altered GI anatomy who underwent DBE-ERCP at our institution between February 2011 and March 2017. The primary endpoint was the global success rate of DBE-ERCP. The secondary endpoints were the success rate of entero-
scopy defined as reaching the desired postsurgical anatomic target, the diagnostic success rate defined as successful cannulation of the native papilla or...
anastomosis, and (3) the therapeutic success rate. We used a 2.2 mm DBE with a 2.8 cm of operating channel (EN-450 T5, or EN850T Fujinon inc Saitama Japan).

Results: A total of 12 patients (sex ratio1/1) with a mean age of 65 [47–82] underwent 14 DBE-ERC. 7 patients had Roux-en-Y gastro-jejunostomy with a biliary-gastric cannulation had Roux-en-Y with a native papilla, and 1 patient had a Billroth II gastric bypass. Enteroscopy success rate was 93% (13/ 14 procedures). The diagnostic success rate was 85% (11/13 procedures) with 4/5 of native papillae. Therapeutic interventions including sphincterotomy (n = 4), biliary stone extraction (n = 4) and biliary dilation (n = 2) were needed in 8/11 procedures and their success rate was 100%. The global success rate of DBE- ERC was 78% (11/14 procedures). Our results were comparable to those of the literature (global success rate of 82%). The only complication was one case of superificial intestinal lacerations without perforation (complication rate 7%).

Conclusion: DBE-ERC in patients with surgically altered upper GI anatomy is a safe and efficient procedure with a global success rate of 78%. Using shorter enteroscopes with wider operating channel in the future might improve the success rate of difficult techniques.

Introduction: Biliary cannulation may be difficult in 10–15% of patients (1) and needle-knife sphincterotomy is more often used as a rescue treatment. A more recent approach for difficult cases is trans pancreatic sphincterotomy. Both situations are well known as Post-ERC pancreatitis risk factor (2). To best of our knowledge only few studies compared success rate and adverse events in these techniques (3–7).

Aims & Methods: We aimed to compare the efficacy and safety of NKS comparing to TPS in difficult biliary cannulation We conducted a bibliographic search using PUBMED, EMBASE including 2 RCTs and 4 non randomized trials from January 2000 to December 2016. OR using the Mantel-Haenszel method was used for dichotomous variables. Quantitative synthesis was performed using Review Manager version 5.0. Primary outcome was success rate. Secondary outcomes were rate of overall complications, and pancreatitis. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

Results: Success rate was higher in NKS group compared to TPS (OR 2.98 [95%CI 1.01–8.55, p = 0.05). Complications and risk of pancreatitis were similar in both group (OR 0.74 [95%CI 0.51–1.00, p = 0.13; OR 1.09 [95%CI 0.68–1.75 p = 0.71).}

Conclusion: NKS is associated with higher success rate with equal risk of complications and pancreatitis risk compared to TPS. Further and well design RCTs are needed before a firm conclusion could be made.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cholelithiasis is a relative frequent condition in patients with gallbladder stones (prevalence of 3–16%). Endoscopic sphincterotomy and stone extraction are the recommended treatment of bile duct stones. In the case of failed endoscopic therapy, cholecystectomy combined with bile duct exploration or intraoperative endoscopic retrograde cholangiopancreatography should be performed.

Aims & Methods: The main objective of this study was to evaluate the efficacy of endoscopic extraction methods in patients who presented cholelithiasis. We conducted a retrospective single center study over 7 years from Jan 2009 to Dec 2015. Patients with single or multiple bile duct stones submitted to endoscopic retrograde cholangio-pancreatography (ERCAP) were included. We analyzed each technique by considering the following parameters: mean diameter of the stone(s), mean diameter of CBD and success rate defined by number of cases solved endoscopically vs. cases of residual lithiasis/referred to surgery. Every ERCAP was performed using Olympus® side-viewing endoscopes. Stone size, number and CBD diameter were documented on the initial diagnostic cholangiogram. Stones were removed using retrieval balloon catheter, Dormia extraction basket, mechanical lithotriptor and CRE® Ballon Dilator (DASE). In case of residual lithiasis, a biliary 10Fr®7Fr Amsterdam plastic stent was placed and a second ERCAP was planned within 2–4 weeks. The efficacy endpoint was the success rate regarding complete clearance of the bile duct. Statistical analysis

Introduction: Diclofenac and indomethacin are the most studied drugs for preventing post-ERCP pancreatitis (PEP), but their use is controversial.

Aims & Methods: Our aim was to evaluate all trials published in full text and studied efficacy of diclofenac or indomethacin prospective controlled with placebo or non-treatment for the prevention of PEP in adult patients undergoing ERCP. Systematic search of databases (PubMed, Scopus, Web of Science, Cochrane Library) were not restricted to languages. Trials published from inception to 30 June 2016. Results: Our meta-analysis of 4741 patients from 17 trials showed that diclofenac or indomethacin significantly decreased the risk ratio (RR) of PEP to 0.60 (95% confidence interval: CI 0.46–0.78, P = 0.0001), number needed to treat (NNT) was 20, and the reduction of RR of moderate to severe PEP was 0.64 (95% CI 0.43–0.97, P = 0.0339). The efficacy of indomethacin compared to diclofenac was similar (P = 0.98). The efficacy of indomethacin or diclofenac did not differ according to timing (P = 0.99) nor between patients with average-risk and high-risk (P = 0.15). The effect of non-rectal administration of indomethacin or diclofenac was not significant (P = 0.1507), but rectal route was very effective (P = 0.0005) with a NNT of 19. The administration of indomethacin or diclofenac was avoided in patients with renal failure. Substantial adverse events were not detected.

Conclusion: The use of rectally administered inexpensive and safe diclofenac or indomethacin before or closely after ERCP is recommended in every patient (without renal failure) undergoing ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Rectal diclofenac or indomethacin reduces the risk of pancreatitis after endoscopic retrograde cholangiopancreatography (ERCP). Most studies of its efficacy included high-risk cohorts and excluded low-risk patients. We investigated the potential of rectal diclofenac to prevent post-ERCP pancreatitis (PEP) in a variety of patients.

Aims & Methods: A cohort of 1354 ERCPs performed at the Hospital Clínico of Valladolid between 2009 and July 2016 was collected. The median age of the patients was 75 years old (between 12 and 102 years). 54% were males and 45.9% females. There were 93 procedures in which cannulation of the desired pathway was not achieved but the papilla had been manipulated so they were patients who had been included in the study. In May 2012, with a few exceptions, patients received diclofenac before their procedure. 730 patients did not receive Diclofenac. PEP was defined by consensus criteria.

Results: The two groups were similar in age, sex, suspicion of Oddi sphincter dysfunction, recurrent acute pancreatitis, chronic pancreatitis, cannulation time, use of pre-cut, previous PEP, dilution without sphincterotomy. There were differences in the number of sphincterotomies in which it was greater in the Diclofenac group (p=0.004). There was also a greater number of Wirsung cannulations in the group treated with Diclofenac (p=0.004). There were a total of 47 PEP (3.1%), being 78.3% mild acute pancreatitis.

Taken as a whole the patients had no difference in the number of PEP between the two groups, since in those treated with Diclofenac there was 3.4% and in the non-treated patients 2.8%.

When taking only patients with de novo sphincterotomy, there was no difference between the number of PEP between the two groups, being 4.4% in those treated with Diclofenac versus 4% in the untreated patients. In those patients who had been cannulated Wirsung, an incidence of PEP of 8.2% was observed in the group treated with Diclofenac, compared to 3.8% in the non-treated group (p=0.006). There were no differences between those treated with Wirsung’s prosthesis and those not treated in both groups. There was no PEP in patients treated with pancreatic prosthesis.

There was a higher incidence of PEP in women in both groups and a trend towards greater number of PEP among those treated with Diclofenac, although without statistical significance. There was also a greater number of PEP in patients under 40 years of age treated with Diclofenac compared to those not treated with 14.3% versus 7.1% (p=0.024).

No differences were found between the groups treated and not treated with Diclofenac when crossing with sphincter dysfunction of Oddi, previous PEP, number and sizes of choledocholithiasis and sizes with the appearance of PEP.
Conclusion: In this retrospective cohort study of patients undergoing ERCP that included low-risk patients, rectal diclofenac was not associated with a significant decrease in the absolute rate of pancreatitis. In our study, diclofenac decreases the impact of PEP in those patients who are cannulated the pancreas.

P1555 A PILOT STUDY OF PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY FOR COMPUTER-AIDED DIAGNOSIS OF BILE DUCT CARCINOMA BY USING THE DEEP LEARNING TECHNOLNOGY
K. Furukawa1, N. Yokoyama2, H. Hashidate3
1Dept. Of Gastroenterology, Niigata General Hospital Dept. of Gastroenterology, Niigata/Japan
2Niigata City General Hospital Dept. of Digestive Surgery, Niigata/Japan
3Pathology, Niigata City General Hospital, Niigata/Japan
Contact E-mail Address: furukawa@hspr.niigata.jp

Introduction: The confocal laser endomicroscope (CLE) is of two types, an endoscope-based CLE (eCLE), which is integrated in the tip of the endoscope, and a probe-based CLE (pCLE), which goes through the accessory channel of the endoscope. The biliary tract, which cannot be reached by using eCLE, is observable with pCLE by using cholangioscopy. pCLE has the advantage of obtaining a magnification image that is like taking a biopsy tissue specimen but noninvasively, without the interference of bleeding and mucus secretion. However, it is sometimes difficult because only few gastroenterologists can achieve the required level of diagnostic accuracy.

Aims & Methods: We developed a computer-aided diagnosis (CAD) system based on pCLE imaging using deep learning technology. The purpose of this study was to determine the usefulness of this CAD system for the diagnosis of bile duct cancer. We prepared the classifier of the extracted features of the bile duct cancer pCLE images by using the deep learning framework presented by Kyocera communication system Co. Ltd. Japan. The pCLE images by Cellvisio (Mauna Kea Technologies, France) were obtained through the SpyGlass DS (Boston Scientific Corporation, USA). Learning sets were constructed by using 49 images of normal area and 25 images of cancer lesion. The test sets of the pCLE images were constructed using 6 images of normal area and 14 images of cancer lesion separately from the learning set.

Results: The accuracy, sensitivity for cancer diagnosis, specificity, negative-predictive value, positive-predictive value of our CAD system by test set were 69.8%, 50%, 100%, 53.8%, and 100%, respectively. The images of 6 of the 7 false-negative diagnoses reduced the sensitivity and negative-predictive value. The images of 6 of the false-negative diagnoses, indicating a 1.0 probability, did not show signs of cancer at all. A constant diagnosis was possible while being extremely small lesions and weak lesional specificity and positive-predictive value were good, and the pCLE image was thought to have a characteristic suitable for CAD by using deep learning technology. However, many false-negative diagnoses with a probability 1.0 may have occurred owing to deflection and the lack of learning sets. To improve the performance of the model, it is needed to validate for optimal application and sequences of EUS-FNB techniques in the core tissue acquisition and diagnostic accuracy for pancreatic solid lesions.

Conclusion: Although our study revealed no differences between EUS-TS techniques in the core tissue acquisition and diagnostic accuracy for pancreatic solid lesions, further prospective study including various lesions and sizes of needle is needed to validate for optimal application and sequences of EUS-FNB techniques.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1556 COMPARISON OF EUS-GUIDED FINE NEEDLE BIOPSY TECHNIQUES FOR CORE TISSUE ACQUISITION AND DIAGNOSTIC PERFORMANCE IN PANCREATIC SOLID LESIONS
C. Cho1, S.J. Yeo1, A.N. Soo2, H.I. Bae3
1Internal Medicine, Kyungpook National University Medical Center, Daegu/Korea, Republic of
2Pathology, Kyungpook National University Medical Center, Daegu/Korea, Republic of
3Endoscopy Unit, AOUI San Giovanni di Dio e Ruggi d’Aragona, G. Facuto Center, Mercato San Severino (SA)/Italy

Introduction: Acquisition of core tissue in endoscopic ultrasound-guided tissue sampling (EUS-TS) is necessary for histologic diagnosis and immunohistochemical staining in the diagnosis of some solid mass lesions. Although recent studies revealed the superiority of core biopsy needle in the specimen adequacy, core coverage may still remain that which EUS-TS techniques would result in better acquisition of core tissue and diagnostic accuracy.

Aims & Methods: The aim of our study was to evaluate EUS-TS techniques with a ProCore needle using suction and slow pull suction for solid pancreatic lesions with the experience of cytopathologists. Patients referred to EUS-TS for pancreatic mass lesion were enrolled. We performed EUS-guided fine needle biopsy (EUS-FNB) using a ProCore needle (Cook Medical, Limerick, Ireland) with two needle passes and applied each pass of different techniques (suction or slow pull suction) which were randomly allocated. EUS-TS specimens were evaluated by one experienced cytopathologist who was blinded to applied techniques. The acquisition of core tissue and diagnostic performances were compared between two techniques.

Results: From Aug. 2014 to Dec. 2016, 94 patients with pancreatic mass were enrolled and 12 patients were excluded due to no final diagnosis (n = 5), cystic lesion (n = 5) and loss of follow up after EUS-TS (n = 2). Finally, 82 patients (48 males; median age, 63 years) with 164 needle passes were included without technical failure and procedure-related adverse events. The median size of the lesions was 26 mm (range, 11 to 80 mm). There were 68 malignant and 14 benign lesions. Overall core tissue acquisition and diagnostic accuracy was 84.8% (139/164) and 73.2% (120/164), respectively. There was no significant difference between suction and slow pull suction in the acquisition of core tissue (85.4% vs. 84.1%, p = 1.000) and diagnostic accuracy (72.0% vs. 74.4%, p = 0.360).

Conclusion: Although our study revealed no differences between EUS-TS techniques in the core tissue acquisition and diagnostic accuracy for pancreatic solid lesions, further prospective study including various lesions and sizes of needle is needed to validate for optimal application and sequences of EUS-FNB techniques.

Introduction: Gallbladder drainage, performed by EUS-guided positioning of specially designed fully covered metal stents, may be considered a valid option in patients with cholecystitis unfit for surgery. We describe the first case series of patients with diagnosis of acute cholecystitis treated conservatively using a silicone-covered nitinol stent with bilateral anchor flanges (NAGI-stent).

Aims & Methods: Our aim was to evaluate the feasibility and clinical impact of EUS-guided drainage with NAGI-stent in patients with acute cholecystitis unfit for surgery. Sixteen consecutive patients (9 males; mean age: 84 years; with diagnosis acute cholecystitis according to Tokyo guidelines criteria, not suitable for surgical approach, were conservatively treated and drained with EUS-guided short flared stents positioning. The procedure was performed in 2 tertiary endoscopy units in Italy.

Results: The 7 false-negative EUS-FNB performed by the NAGI-stent. Each attempt to access the gallbladder was firstly performed from the transduodenal position and resulted successful in 13 (81%) patients, whilst a transgastric approach was preferred in the remaining 3 patients. Two different approaches were performed for the EUS-guided gallbladder puncture: a) a 0.035-inch wire was advanced through a 19G-needle into the gallbladder and dilation of the access was achieved with a 10 Fr cystoenteroscope; b) a 0.035-mch wire was advanced through a 10 Fr cystoenteroscope directly in the cystic duct and quanum improved yearly, by using the NAGI-stent. The Technical success, clinical success, adverse events, and long-term outcome were assessed.

Results: Technical success was achieved in all cases, clinical success was observed in 15 (94%) patients, whilst in 1 case the procedure failed due to stones impaction into the stent but it resolved with a new stent positioning. Symptoms relief occurred in all patients, 1 day after the procedure in 12 (75%) cases and 2 days later in remaining 4 (25%) patients. A bleeding episode occurred in 2 (12.5%) patients, in one case such complication was intra-procedural and it was successfully stopped during the same endoscopic session, in the other case it was a delayed adverse events requiring arterial embolization but the patient died 10 days later. At follow-up, two patients died due to myocardial infarction at 2 and 6 months, one for acute renal failure after 6 months, two for pancreatic cancer at 7 months and one for cholangiocarcinoma after 5 months. In the remaining patients no cholecystitis recurrence or biliary obstruction were observed at median follow-up of 112 days (range 49–180 days).

Conclusion: Our data showed that EUS-guided gallbladder drainage with NAGI-stent is feasible and successful in patients with acute cholecystitis unfit for surgery. Since this type of stent is cheaper compared to others, the use of such device may result more attractive as a further endoscopic option for these selected patients.

P1561 EFFICIENCY COMPARISON BETWEEN 22 G VERSUS 25G NEEDLES DURING ENDOCOPIC ULTRASOUND FINE NEEDLE ASPIRATION FOR SOLID PANCREATIC MASSES: A SYSTEMATIC REVIEW AND META-ANALYSIS BASED ON RCTS
Gastrointestinal Endoscopy Unit, Clinical Hospital of Sao Paulo University Medical School, Sao Paulo/Brazil

Contact E-mail Address: ralphbdhuarte@hotmail.com
Introduction: Endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) is considered the gold standard method for assessment solid pancreatic masses. The needles for aspiration currently available are 19G, 22G and 25G and there is no concrete evidence to prove the benefit of one against another.

Aims & Methods: We aimed to compare the efficiency in the diagnosis of solid pancreatic lesions through the EUS-FNA with 25G and 22G needles. Two independent reviewers went through the literature search and the results were analyzed by fixed and random effects. The diagnostic characteristics were calculated for a 95% confidence interval.

Results: 504 studies were found in the search, of which 21 were read and then finally randomized studies were selected to be included in the analysis. Thus, a total of 462 patients were evaluated (233: 25G needle; 229: 22G needle). The sensitivity of the 25G needle was 93% (CI, 89–96%; I2 0.0%), and for the 22G needle was 91% (CI, 85–94%; I2 19.9%). The specificity of the 25G needle was 88% (CI, 70–93%; I2 81.1%). The positive likelihood ratio of the 25G needle was 4.57 (CI, 2.08–10.03, I2 0.0%), and for the 22G needle was 4.26 (CI, 0.43–41.88, I2 94.7%). The post-test probability of the 25G needle in the study population was 95% and the 22G needle was 93%. The area under the ROC curve of the 25G needle was 0.9705 and for the 22G needle 0.9795, also showing no statistically significant correlation between them (p = 0.497).

Conclusion: Based on randomized studies, this systematic review and meta-analysis did not demonstrate a statistically significant difference between the 22G and 25G needles used during EUS-FNA in the diagnosis of solid pancreatic lesions.

Results: 50 patients were recruited during the study period. The mean (S.D.) age was 47.94 (17.23) years and male:female ratio was 42:8. 37 (74%) patients were male and 13 (26%) were female. 25 (50%) of the cases were diagnosed to have malignancy. 24 cases (48%) had stage I disease, and 26 cases (52%) had stage II disease. 16 (32%) patients had stage III disease and 2 cases (4%) had stage IV disease. 50 patients were recruited during the study period. The mean (S.D.) age was 47.94 (17.23) years and male:female ratio was 42:8. 37 (74%) patients were male and 13 (26%) were female. 25 (50%) of the cases were diagnosed to have malignancy. 24 cases (48%) had stage I disease, and 26 cases (52%) had stage II disease. 16 (32%) patients had stage III disease and 2 cases (4%) had stage IV disease.

Conclusion: EGBD is a safe and effective method for achieving gallbladder drainage and no differences were observed in the technical and clinical success rates and adverse events.

CADAVERIC MODEL

Contact E-mail Address: eshn3@jhmi.edu

Introduction: Despite advances in radiotherapy for pancreatic cancer, local gastro-intestinal (GI) toxicity still remains one of the major limitations to effective dose delivery and further dose escalation due to the close proximity of the GI wall to the pancreas, particularly in the head region. One potential method to reduce local GI toxicity would be to increase the physical distance between the head of the pancreas and the duodenal wall. A novel, injectable hydrogel, synthesized as iodinated polyethylene glycol microparticles, has been FDA-approved for use as a soft tissue fiducial marker. The hydrogel remains stable for 3 months and is absorbed by 7 months. To date, there has been no report on the technical feasibility of endoscopic ultrasound (EUS)-guided hydrogel injection into the peripancreatic space for the course of radiotherapy.

Aims & Methods: We aimed to evaluate the technical feasibility of EUS-guided hydrogel injection into the interface between the head of the pancreas and the duodenal wall to increase the peripancreatic space for the course of radiotherapy.

Results: All three cadavers underwent successful EUS-guided injection of the hydrogel. Cadaver 1 received an initial injection volume of 9 cc at the interface between the head of the pancreas and the duodenal wall to increase the peripancreatic space for the course of radiotherapy.

Conclusion: EUS-guided delivery of hydrogel is feasible and results in an increase in the peripancreatic space in a cadaveric model. The hydrogel is clearly visualized during EUS with hyperechoic echogenicity and on post-procedure CT images without any artifacts in all cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: EUS-guided gallbladder drainage (EGBD) is gaining popularity as an alternative method for drainage of the gallbladder in patients suffering from acute cholecystitis that are at high-risk for cholecystectomy. However, the long-term outcomes and the learning curves of the procedure are uncertain.

Aims & Methods: This was a retrospective review of all patients that received EGBD in the Prince of Wales Hospital between June 2012 to March 2017. All procedures were performed or supervised by a single operator. EGBD was performed in patients that are at high-risk for cholecystectomy and suffering from acute cholecystitis or on long-term cholecystostomy tube drainage. Outcome parameters included demographics, technical and clinical success, procedural characteristics, adverse events and follow-up duration.

Results: 50 patients were recruited during the study period. The mean (S.D.) age was 47.94 (17.23) years and male:female ratio was 42:8. 37 (74%) patients were male and 13 (26%) were female. 25 (50%) of the cases were diagnosed to have malignancy. 24 cases (48%) had stage I disease, and 26 cases (52%) had stage II disease. 16 (32%) patients had stage III disease and 2 cases (4%) had stage IV disease. 50 patients were recruited during the study period. The mean (S.D.) age was 47.94 (17.23) years and male:female ratio was 42:8. 37 (74%) patients were male and 13 (26%) were female. 25 (50%) of the cases were diagnosed to have malignancy. 24 cases (48%) had stage I disease, and 26 cases (52%) had stage II disease. 16 (32%) patients had stage III disease and 2 cases (4%) had stage IV disease.
Aims & Methods: To standardize the radiofrequency ablation (RFA) procedure under EUS using a new system performing ex-vivo tests on porcine liver in order to find the best ablation power and ablation time to produce the maximum size of coagulative necrosis at histological examination. The system consists in a radiofrequency generator delivering electric energy, a 19 Gauge needle (150 cm in length with a 10 mm monopolar electrode), a peristaltic pump (to perfuse the needle with chilled saline solution, maximizing the ablation volume without tissue charring), an isolating plate and a pedal to deliver RFA. Liver samples were treated at different powers: 10, 20, 30 and 40 Watts (W); each ablation power was applied for a duration of 1, 3, 5, 7 and 15 minutes, according to Fibonacci escalation dose scheme, used in phase I studies. We registered macroscopically: the size (millimeters) of the global treated area and the size of the central necrotic core. Histopathologically, blinded about ablation powers and times applied, gave the report of the histological examination (millimeters of coagulative necrosis and surrounded zone).

Results: The lower ablation power (10 W) produced the maximum macroscopic ablation area, RFA ablation time at 10 W showed a good linear correlation with ablation times (mean size: 3.25 mm) while B zone diameter increased with the increase of RF application at the fixed power of 10 W. At the microscopic analysis the pathologist didn’t see any difference in size of coagulative necrosis among the different ablation powers (R = 0.24).

Conclusions: With this new system is feasible and effective to produce very small areas of coagulative necrosis (millimeters) well-demarcated in respect to the surrounding parenchyma and could be useful, in the future, to treat, with multiple passes and higher precision, target lesions with a flexible needle. Moreover, the system can produce larger zones of mild cellular alterations at lower ablation powers (10 W), increasing with the increase of ablation times, but it needs future in-vivo animal studies in order to assess the evolution of these zones (evolving into fibrosis? necrosis? recovering?).

Introduction: Malignant associated thromboembolic disease (TED) has a complex multifactorial pathogenesis. Tumor cell actinoides that express procoagulant factors including tissue factor and thrombin; in addition, normal host tissues may also express pro-coagulant activity in response to the tumor. Thrombotic risk varies substantially according to cancer location and pancreatic cancer is one of the leading causes. The clinical spectrum includes migratory superficial thrombophlebitis, arterial thrombosis, deep venous thrombosis, portal vein thrombosis and disseminated intravascular coagulation (DIC). We aimed to assess the role of endoscopic ultrasound (EUS) diagnosing TED in pancreatic cancer patients.

Aims & Methods: We perform a retrospective review of all EUS cases for pancreatic cancer in two centers and assess all TED events diagnosed.

Results: In a period of 6 months, a total of 55 EUS for pancreatic neoplasms were performed in two centers. TED was present in 5 patients (9%): 3 were male and the mean age was 70 (range, 48-81). In 1 patient the EUS indication was a large abdominal mass whose origin was not clear, in the remaining 4 the indication was the pancreatic neoplasm. In all of them was performed EUS with fine-needle aspiration (FNA). EUS identified a focal peripheral embolism (PE) and 1 inferior vena caval thrombosis (IVCT) with right atrial extension: 2 (3.6%) had recently been diagnosed by computed tomography (CT) but 3 (5.4%) were not previously known. In all these, CT confirmed diagnosis.

Conclusion: To the best of our knowledge, this is the first case series of EUS-based TED diagnosis in pancreatic cancer patients. This series underlines the importance of a systematic, station approach EUS technique, namely in the mediastinum regardless the clinical indication. TED is a common complication of pancreatic cancer and has major therapeutic and prognostic implications.

Contact E-mail Address: maximilien.barret@aphp.fr

Introduction: Three devices are currently available to perform radiofrequency ablation (RFA) of biliopancreatic lesions. Data from animal models are scarce.

Aims & Methods: Radiofrequency ablation was performed in four live pigs on the common bile duct and the liver parenchyma using an endobiliary probe (endoHBP), on the liver and pancreatic parenchyma using an RFA catheter (EUS-RFA) and using a needle-shafted radiofrequency ablation system (ESRA) through a transgastric echoendoscope. The EUS-RFA ablation time and power were allowed to vary. The animals were sacrificed 2 hours after the procedure. Histopathological assessment of the maximal depth of thermal lesions was performed on three representative slides for each RFA injection.

Results: In the common bile duct, the depth of ablation ranged from 215 ± 47 (Power = 8 W, Time = 90 s) to 330 ± 43 µm (Power = 10 W, Time = 30 s), suggesting that power is the most important parameter in this location. Conversely, depth of ablation in the liver parenchyma using the endoHBP probe ranged from 947 ± 237 µm (Power = 10 W, Time = 30 s) to 1960 ± 20 µm (Power = 10W, Time = 180 s), suggesting that time is the most important parameter for RFA in the liver. The EUS RFA probe in the liver parenchyma showed a tissue necrosis increasing with the power setting used, ranging from 190 ± 451 µm (Power = 8 W, Time = 120 s) to 2457 ± 1047 µm (Power = 12 W, Time = 120 s). This was not observed in the pancreatic parenchyma, where tissue damage ranged from 3108 ± 373 (Power = 8, Time = 120 s) to 2305 ± 78 µm (Power = 12, Time = 120 s). The EUSRA ablation of the liver parenchyma resulted in tissue damage from 1573 ± 245 µm (Power = 30W, Time = 11 s) to 1545 ± 120 µm (Power = 70 W, Time = 9 s). In the pancreas, ablation depth ranged from 3616 ± 475 µm (Power = 30 s, Time = 15 s) to 3805 ± 446 µm (Power = 70 W, Time = 11.5 s).

Conclusion: Power and time of ablation have different effects on the extent of tissue necrosis in the common bile duct, the hepatic and pancreatic parenchyma, depending on the type of catheter used to perform RFA. As indications for hepato-pancreatic lesions tend to expand, specific ablation protocols should be developed for each tumor location and device.

P1568 ENDOSCOPIC ULTRASOUND-GUIDED RENDEZVOUS FACILITATES BILIARY CANNULATION IN CASE OF INACCESSIBLE INTRA-DIVERTICULAR PAPILLA
D. Kypraios, A. Malachias, L. Theodoropoulos, S.L. Hatzinicolaou, S. Stavrinos, N. Saribegioğlu, G. Sofianidis, K. Tamakisud, D. Dimitroulopoulos, D. Ximopoulos
Gastroenterology, Saint Savvas Oncological Hospital, Athens/Greece

Contact E-mail Address: dimkypro@gmail.com

Introduction: Endoscopic ultrasound (EUS)-guided rendezvous techniques facilitate common bile duct (CBD) access during subsequent endoscopic retrograde cholangio-pacreatography (ERCP) in a single session. Cases of initial ERCP failure mainly comprise malignant biliary or ampullary infiltration and altered anatomy of the papilla, the former accounting for the majority of reports in the literature.

Aims & Methods: We aimed to evaluate the efficacy and safety of EUS-guided rendezvous in a series of distal CBD obstruction with failed initial ERCP, due to inaccessible intra-diverticular papilla. Consecutive patients with distal CBD obstruction, in whom selective biliary cannulation at ERCP was unsuccessful due to large duodenal diverticulum, underwent EUS-guided rendezvous. CBD puncture was performed via the transduodenal approach and the guide wire was advanced antegrade across the papilla. The echoendoscope was then exchanged for a duodenoscope and a sphincterotome was inserted through the papilla alongside or over the wire, to allow further manipulations.

Results: In a total of 2480 ERCPs performed over a 4-year period, 18 cases were selected to undergo EUS-guided rendezvous due to the presence of a large ampullary diverticulum. Primary indication for ERCP was CBD stones in 15 patients, pancreatic head cancer in 2 patients and cholangiocarcinoma in 1 patient. Mean age of the patients was 77 years (range 62–91) and mean diameter of the CBD was 16 mm (range 8–21). Successful CBD puncture with antegrade passing of the wire into the duodenum and subsequent ERCP, in the same session, was achieved in 2/3 (66.7%) cases of malignant obstruction and in 13/15 (86.6%) cases of lithiasis. Retrograde biliary cannulation during ERCP was performed over the wire in 12/15 (80%) cases and alongside the wire in 12 cases. The mean procedure time was 80 minutes (range 55–115). A case of inadvertent CBD wall penetration by the sphincterotome, with contrast extravasation, occurred during an over-the-wire cannulation. No major complications, i.e perforation (extra-luminal air or bile leak), bleeding and pancreatitis occurred. Three cases of amylasemia and transient fever were noted.

Conclusion: EUS-guided rendezvous is an effective salvage technique for failed CBD cannulation via standard ERCP, in cases of inaccessible papilla due to large ampullary diverticula. Alongside the guide-wire biliary cannulation may prevent inadvertent CBD wall trauma, compared to the over-the-wire approach.

3First Surgical Clinic, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca/Romania

Contact E-mail Address: anastasie.seicean@gmail.com

Introduction: The preoperative differentiation of the solid pancreatic neoplasms by endoscopic ultrasound fine needle aspiration (EUS-FNA) remains around 90% and different needles or techniques of sampling has been used for improving the results. Data about the progress in diagnosis when the contrast harmonic enhanced EUS-FNA (CH-EUS-FNA) is used are scarce.

Aims & Methods: We aimed to assess the role of contrast-enhanced EUS-FNA compared to standard EUS-FNA in diagnosing the solid pancreatic neoplasms. Methods: Patients from one tertiary medical center with visible solid pancreatic mass on CT were selected. EUS-FNA(one pass) and CH-EUS-FNA (one pass) were performed randomly in each patients by using a standard 22G needles, an Olympus-Aloka equipment and Sonovue as contrast agent. Core histology was assessed separately for each pass by the same pathologist blinded from the randomization process. The final diagnosis was based on the results of EUS-FNA and surgery, or the findings after 9 months’ follow-up.

Results: The final diagnosis of 40 patients included was adenocarcinoma (n = 36), non-tumouric diseases (n = 2) and pancreticitis (n = 2). The lesions were located in the head of the pancreas (60%), body (32%) and tail (8%). The diagnostic specificity and sensitivity based on core histology was 89% and 94% in the CH-EUS-FNA passes and 86% and 91% in the EUS-FNA passes and the diagnostic value was significantly better in the CH-EUS-FNA group (p = 0.0046, t-test). The visual core size was not significant for the true-positive diagnosis of malignancy.

Conclusion: In a randomized control trial, CH-EUS-FNA improved significantly the diagnosis of solid pancreatic neoplasms over standard EUS-FNA. These techniques are complementary, not competitive, and they can be performed in the same session, resulting the increasing of the diagnostic rate with a minimum of passes.

P1570 EARLY CAPSULE ENDOSCOPY PROVIDES BETTER BLEEDING LOCALIZATION VALUABLE IN PATIENTS PRESENTING WITH NON-HEMATEMESIS GASTROINTESTINAL BLEEDING WHEN COMPARED TO CLINICAL SYMPTOMS ALONE

S. Jawaid1, N. Marya2, A. Foley1, C. Marshall1, K. Bhattacharyya1, D. Cave2
1University of Massachusetts Medical Center, Worcester/United States of America
2UCLA, Los Angeles/United States of America

Contact E-mail Address: sajawaid@gmail.com

Introduction: Traditionally, clinical symptoms such as melena were used as strong predictors for an upper GI bleeding source with primary evaluation with an EGD (esophagogastroduodenoscopy). Little consideration was given to the small bowel. It has been known for decades that melena can originate from the nose to the right colon and hematochezia can originate from the proximal gut to the rectum. Thus, current endoscopic approaches have limited localization value and diagnostic yields. We hypothesize capsule endoscopy (CCE) provides better localization of bleeding when compared to clinical symptoms alone.

Methods & Study: When a patient presented with GI bleeding of unknown source, we compared the efficacy of localizing the source of bleed in early CCE versus SOC (standard of care) tests chosen based on clinical symptoms alone. This was a prospective single center randomized trial of 73 consecutive patients presenting to the University of Massachusetts Medical Center with NHGB (melena, hematochezia/anemia, or guaiac-positive stools/anemia). Exclusion criteria included presence of pacemaker, dementia, non-English speaking, hemodynamically significant bleeding. Patients were randomized to SOC arm versus early capsule (EC) deployment. The SC group received a primary diagnostic procedure based on clinical symptoms that was dictated by the gastroenterologist on service, who was at liberty to choose the procedure sequence as they felt appropriate.

Results: Out of 73 enrolled, 72 were included. 2 patients from the initial included group were excluded (one due to technical capsule failure and one was transferred from an outside hospital). Baseline characteristics were similar and depicted in Table 1. The EC group (n = 34) had localization of presumed source of bleeding in 23 (67.6%) of patients at the time of the first diagnostic procedure compared to 48.4% (n = 16) in the SOC group (p = 0.02). Active bleeding or stigmata of recent bleeding at the time of the first procedure was seen in 64.7% (n = 22) of patients in the EC groups compared to only 30% (n = 5) in the SOC group (p = 0.003). However, when melena was the presenting symptom in the SOC (n = 26) group, EGD was the most commonly chosen primary diagnostic procedure (n = 23), but was only diagnostic 52% of the time. After complete diagnostic evaluation in the SOC group, patients presenting with melena/hematochezia had lesions located in the esophagus (3.5%), stomach/duodenum (46.2%), small bowel (11.5%), colon (11.5%), but 27% had no source identified. EC group had lesions localized to the esophagus (2.9%), stomach/duodenum (35.2%), small intestine (8.8%), colon (20.5%), and 32.3% did not have lesions identified. Patients with SB MRI evidence of small bowel bleeding, SB EGD was never diagnostic as a primary procedure, colonoscopy (COLO) had a 50% diagnostic rate, and VCE was diagnostic 100% of the time.

Conclusion: VCE used as the first test in patients with NHGB detects active bowel bleeding more often than the SOC approach, since it examines much more of the GI tract than EGD and COL alone. Detection of the anatomic site of bleeding allows for better therapeutic decisions.

Introduction: Detecting mucosal healing (MH) of isolated small bowel Crohn’s Disease (CD) induced by anti-tumor necrosis factor alpha agents are scarce.

Aims & Methods: 1) To evaluate MH rates by capsule endoscopy (CE) in patients with CD who were treated with adalimumab (ADA). 2) To correlate MH with clinical and biological indices of remission. This was a prospective observational, single center study. CD patients with isolated (per CE) active CD (CDAI > 220) SB disease, who were recommended ADA by their treating physician were consecutively recruited; first CE was performed prior to commencing ADA, and the second-14-week after starting ADA. All enrollees underwent a patency capsule study to confirm patency. Disease severity was assessed by the capsule endoscopy Crohn’s Disease activity index (CECDAI) score. MH was defined as CECDAI score < 3.

Results: Out of 31 patients screened, 24 were eligible, and 22 completed the study (as two patients developed an allergic reaction to ADA and were withdrawn). Females: 12 (54.5%), median disease duration: 3 years (IQR 1–7), biologic exposure: 15 patients had lesions located in the SB, 16 in the CD. In our study, we compared MH detected by CE did not correlate with normalization of either CDAI < 150, CRP or fecal calprotectin levels.

Conclusion: ADA induced MH in 36% of CD patients with isolated active SB disease. MH did not correlate with either clinical or biological remission. Thus, further evaluation should be performed after 52 weeks of maintenance therapy.

Introduction: Capsule endoscopy (CE) is widely used to investigate the small bowel (SB). However, patients with inflammatory bowel disease (IBD) are considered to be at higher risk for capsule retention. The ESGE recommends using dedicated cross-sectional imaging to assess SB patency in patients with known Crohn’s Disease (CD) prior to CE. Evidence suggests that a combination of SB imaging (MRI, CE) and faecal calprotectin (FC) together may be more effective in assessing SB inflammation compared to an individual modality alone. We aimed to assess the effectiveness of this approach.

Aims & Methods: Retrospective, multicentre study; consecutive patients who had undergone both SB MRI and CE within 6 months of each other were included. Data collected: patient demographics, indications for CE and MRI. SB and CE findings, and FC levels closest to the time of CE. Continuous data is presented as means ± standard deviation; comparisons were made using T-test (p < 0.05 taken to be significant).

Results: 82 patients (28M/54F, Mean age 41.4yrs) underwent both CE and SB MRI at 4 centres in the United Kingdom, Israel and Portugal. Indications included suspected SB inflammation (n = 81), IBD reassessment (n = 21). Overall, 3 were incomplete CEs, but no case of SB capsule retention. Of 82 SB MRIs, 4 patients had evidence of SB obstruction, 10 had SB thickening and/or inflammation, 3 had other findings (SB pneumatisis, polyps). 64/82 cases were normal and 1 study had poor quality; excluding any conclusion. Of the 4 SB MRIs, 1 had SB perforation, 1 had SB stricture, 1 had SB stricture and SB thickening together; 1 had SB stricture and SB thickening and/or inflammation.

Conclusion: A significant proportion (28.1%) of patients with normal SB MRI to investigate possible SB inflammation had CE findings showing SB inflammation, including 2 patients with strictures. However, no retention occurred in this group. Raised FC was significantly associated with CE findings despite normal SB MRI. CE findings were consistent with FC in 8 CE, 7 had no retention and 1 had CE findings showing SB inflammation.

Introduction: The interpretation of small bowel capsule endoscopy (SBCE) requires a high level of concentration. An abnormality may be present on just a few of the many thousands of images presented for interpretation. It is
unknown whether fatigue affects the accuracy of SBCE reporting and how many SBCE are read in one session.

Aims & Methods: Thirty-two participants (16 experienced SBCE readers and 16 novices) were invited to participate in this study. Each participant was asked to read 6 pre-selected SBCE studies consecutively. These studies were presented in a random order. All readings took place using the single view mode, where readers were able to choose the frames per second viewed from a range of speeds. Fatigue was measured subjectively using a Likert scale and objectively using a computer-based psychomotor vigilance test. These measures were performed at prior to commencing the study and after every second capsule read. Accuracy in lesion detection was determined by comparison with a gold standard reading derived from the non-consecutive readings of two expert capsule readers. Accuracy was plotted against the order in which SBCE studies were read. The aim of this study was to determine whether fatigue influences accuracy of SBCE interpretation and how many cases can be read before accuracy declines.

Results: In keeping with existing literature, high intra-observer variability amongst the participants was observed, with experienced readers reaching kappa values of 0.51 with the gold standard and 0.08 amongst novices. All progressive SBCE studies were read the mean speed increased for both experts and novices, with a mean reduction of 10 minutes between the first and the last study read. This was associated with faster reading speeds selected in progressive studies read. Where accuracy was analysed with respect to the reading speed chosen, a negative correlation between increasing speed and accuracy was demonstrated, with 31% of lesions detected when read at 6–10 frames per second, compared to 5% when using the 22–28 speed. There was no significant change in accuracy with progressive capsule read when the group was analysed as a whole. The accuracy of experienced readers declined after just one study read, from 38% to 27% and plateaued thereafter. Noive readers demonstrated no significant change in the time points with trend towards improvement, perhaps indicating skills acquisition during the study.

Conclusion: The accuracy of SBCE reporting declines after one study reporting in a given period of time by expert SBCE readers. The optimal time interval between readings needs to be explored. This does not affect novice readers perhaps demonstrating skill acquisition.

P1574 FEASIBILITY OF SAME-DAY COLON CAPSULE ENDOSCOPY (CCE) IN PATIENTS WITH INCOMPLETE COLONOSCOPY

M. Hussey1, G. Holleran2, C. Tersaruolo3, D. McNamara1
1Gastroenterology, Tallaght Hospital, Dublin/Ireland
2Trinity Academic Gastroenterology Group, Trinity College, Dublin/Ireland
Contact E-mail Address: hussayma@telie

Introduction: Rates of incomplete colonoscopies (IC) range from 2–19%, requiring repeat procedures or radiological imaging which can often lead to diagnostic delays, positivity rates and adverse events were all recorded.

Aims & Methods: We aimed to determine the feasibility of same-day CCE post imaging in patients with an incomplete colonoscopy without a contraindication to CCE with an IC for reasons other than poor bowel prep was offered the test following an appropriate recovery time of 1-hour post IC. Informed consent was obtained from all subjects. Upon ingestion of the capsule, the reading of IV myotropism was given to overcome the antimotility effects of fentanyl given during routine colonoscopy. Standard boost-er protocol for CCE was administered. Patient demographics, procedure indica-tions and outcomes of SBCE studies can be read in one session.

Results: To date, 40 same-day CCE have been completed. The mean age was 57 yrs.(22–83 yrs.) and 65% (n=26) were female. Indications for OC were; altered bowel habit 33% (n=13), Iron deficiency anaemia 30% (n=12), Inflammatory Bowel Disease Assessment 15% (n=6), PR bleeding 5% (n=2), abdominal pain 5% (n=2), polyp surveillance 5% (n=2), positive family history of CRC 5% (n=2) and abnormal imaging 2% (n=1). OC were incomplete due to excessive lesion burden in 40% (n=17), patient intolerance 30% (n=12) and severe diverticular disease 30% (n=12). The mean sedation used during OC was 5 mg midazolam (range 3–10 mg) and 75 mcg of fentanyl (range 50–100 mcg). In all 84% (n=34) of CCE were complete, however full colonic views were obtained in 94% (n=37). Mean colonic passage time was 222 minutes and overall image quality was deemed to be excellent in 16% (n=6), good in 31% (n=12), adequate in 44% (n=18) and poor in 9% (n=4) of participants. Overall findings were normal 25% (n=10), polyps 38% (n=15), inflammation 22% (n=9), diverticular disease 25% (n=10), appendicitis 35% (n=14). Amongst the patients who had polyps, 8 required polypectomies and the remaining 7 were put on a surveillance programme. Based on the CCE findings, 4 of the IBD patients required treat-ment escalation. In terms of adverse events one patient reported abdominal pain during the procedure and one patient retained the capsule due to an inflammatory stricture.

Conclusion: CCE would appear to be feasible in the majority of patients and significantly detects colonic pathology.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1575 DEDICATED DIFFUSION WEIGHTED MR IMAGING FOR STAGING PERITONEAL METASTASES IN COLON CANCER: AN ACCURATE PREOPERATIVE SELECTION TOOL FOR CYTOREDUCTION SURGERY (CRS/HIPEC) CANDIDATES

I. Jansen1, D.M. Lambregt1, S. Chandrasegaran-Shanmugananthan1, N. Kok2, G.L. Beets3, R. Gh. Beets-Tan4, A. Aalbers1, M. Lahaye1
1Radology, The Netherlands Cancer Institute, Amsterdam/Netherlands
2Surgery, The Netherlands Cancer Institute, Amsterdam/Netherlands
Contact E-mail Address: M.Lahaye@nki.nl

Introduction: Peritoneal carcinomatosis (PC) is a well-known mechanism of spread in cancer; it is the second-most frequent cause of death in colorectal cancer patients. However, the prognosis of PC patients has dramatically improved in recent years. Nowadays, selected patients benefit from extensive cytoreductive surgery and hyperthermic intraperitoneal chemotherapy (CRS- HIPEC). 5-year survival rates of up to 50% are reported after CRS-HIPEC. Despite this survival gain, CRS-HIPEC has a considerable morbidity rate of up to 21%. Observing patients with unknown whether fatigue affects the accuracy of SBCE reporting and how many SBCE are read in one session.

Aims & Methods: Therefore, the aim of this study was to estimate the PCI preoperatively with diffusion weighted MRI (DW-MRI) and compare this with the PCI found at surgery to assess whether DW-MRI can be used to select CRS/ HIPEC candidates. In this ongoing pilot study, ongoing study twenty-four consecutively patients (April 2016–April 2017) with histologically proven peritoneal carcinomatosis from colo-rectal origin were included. Patients were scheduled for exploratory laparoscopy and/or CRS/HIPEC and underwent preoperative dedicated DW-MRI (scan time 30 min).

Two independent readers prospectively determined the PCI on DW-MRI. Patients were categorized as low-risk (PCI 0–21) versus high-risk (PCI 22–39); in our center considered operable versus non-operable. Reference standard was PCI post surgery. Furthermore, both readers evaluated whether PCI estimation could be achieved on a 5-point scale combining PCI and other risk factors for an incomplete surgery, like invasion in hepatic hilum, mesenteric vessels, extensive pelvic invasion of liver metastases. Sensitivity and specificity of the test were calculated and receiver operating characteristic (ROC) curves were constructed. The area-under-the-curve (AUC) was calculated for each reader. Quadratic weighted kappa was used to evaluate the interobserver agreement.

Results: At surgery the mean PCI was 13.8 (range 0–34). For reader 1 the mean PCI was 19.7 (range 0–39) and for reader 2 PCI was 10.2 (range 0–39). The UAC for predicting overall operability was 0.99 for reader 1 and 0.95 for reader 2.

Conclusion: These data suggest that DW-MRI is a robust and highly accurate tool to noninvasively select colorectal cancer patients who could benefit from CRS/HIPEC. Interestingly, no overstaging occurred with DW-MRI; this means that DWI-MRI did not deprive patients from potential curative surgery. In addition, due to the lack of large studies concerning this subject, our ‘pilot study’ in one of the largest DW-MRI colon carcinomatosis studies.

P1576 HISTOLOGICAL PREDICTION OF COLONIC POLYPS BY COMPUTER VISION, PRELIMINARY RESULTS

C. Sánchez-Montes1, J. Sánchez2, C. Rodríguez De Miguel1, H. Córdova1, M. Forné3, M. Lópes-Cerón1, G. Fernández1, S. Pérez-Fernández1, J. Olea1, A. Montesano1, V. Sánchez1, P. Cañadas1, G. Fernández1, S. Pérez-Fernández1, J. Olea1, A. Montesano1, V. Sánchez1
1Endoscopy Unit, Hospital Clinic, University of Barcelona, Barcelona/Spain
2Center Computer Vision, Universitat Autonoma de Barcelona, Barcelona/Spain
Contact E-mail Address: c.sanchezm@clinic.cat

Introduction: During colonoscopy, clinicians perform visual inspection of the polyps to predict histology. Kudo’s pit pattern classification is one of the most commonly used for optical diagnosis. These surface patterns present a contrast with respect to their neighboring regions and they can be considered as bright regions in the image that can attract the attention of computational methods.

Aims & Methods: We aimed to assess the accuracy of a new computational system based on the segmentation and characterization of bright regions as
cases to obtain an automatic histological classification of colonic polyps. Our automatic classification system is based on the textural elements from polyt surface and their correlation with Kudo’s pit pattern classification. Textural elements are identified as bright regions in polyt surface and there are characterized according to their shape into tubular and circular: a high presence of tubular patterns is associated to an adenomatous histology whereas the absence of prominent tubular structures is associated to non-adenomatous. Taking this into account, we characterized segmented bright regions using a tubularity metric (Tub) designed to obtain low values for circular shapes and high values for elongated regions of the same area. We tested our method in high definition (HD) white light polyt images which were obtained with a colonoscopy Olympus CF-H190 at Hospital Clinic in Barcelona. Neither conventional nor virtual chromoendoscopy were used. These images were selected to show as much variability in polyt appearance as possible. We used the mean of all Tub values for an image to classify it into two classes: Adenoma and Non-Adenoma. A ROC curve was constructed to select the optimal threshold value of Tub. Then, we compared the histology prediction provided by our system and the actual histology obtained after lesion removal.

Results: 51 polyt images were analyzed: 38 (74.5%) adenoma and 13 (25.5%) non-adenoma. Mean size of polyt was 14 ± 13 (range 1–40) and had the following morphology based on Paris classification: 5 (9.8%) O-Ip, 27 (52.9%) O-IIa and 19 (37.3%) O-IIa. Mean Tub values were different for adenoma compared to Non-adenoma (19.5 ± 6.5 vs 14.1 ± 6.3; p = 0.013). An optimal threshold value of Tub = 13.14 to separate adenoma vs. non-adenoma was selected from the operating point of the ROC curve. With this value, our method was able to provide an accurate histological diagnosis in 44 out of 51 images (86%) (table) with a Sensitivity, Specificity, PPV and NPV for the diagnosis of adenoma of 95%, 61%, 88% and 80%, respectively. On the other hand, processing of a single HD image took 2.7 seconds making feasible its use in the endoscopy room.

Conclusion: A computer vision system based on bright regions in the image has a high accuracy for on-line prediction of polyt histology during colonoscopy. The use of shape characterization is promising, the inclusion of other polyt characteristics (i.e. shape, color, vessels...) as well as enlarging the validation database could improve the robustness of our methodology.

P1577 COLORECTAL LATERALLY SPREADING TUMORS DETECTED AT CT COLONOGRAPHY
M. Iwabuchi, M. Sugimura, S. Toda, K. Ukai
Gastroenterology, Sendai Medical Center, Sendai/Japan

Contact E-mail Address: s7856@snh.go.jp

Introduction: Laterally spreading tumors (LSTs) of the colicrectum are classified into the following two subtypes according to their morphology: granular type (LST-G), and non-granular type (LST-NG). While, CT colonography (CTC) is a relatively new radiological technique for imaging the entire color-colicrectum and its sensitivity for detecting polyps more than 1 cm has been reported to be greater than 90%. However, the detectability of LST in CTC has not been fully delineated.

Results: Patients: 35 patients were included in the study. All patients underwent CTC and colonoscopy. From these patients, LSTs were found in 12 patients (62%). Of these patients, 7 LSTs were detected by CTC and colonoscopy, 1 LST was detected only by colonoscopy and 4 LSTs were detected only by CTC. The total detection rate of LSTs was 44.4%. The accuracy of detection was 80% (9 of 11 LSTs) and the sensitivity was 90.9% (10 of 11 LSTs). The interobserver agreement was 80% (9 of 11 LSTs) and the sensitivity was 90.9% (10 of 11 LSTs).

Conclusion: Automatic prediction of LSTs focusing on their subtypes. We retrospectively reviewed and matched 35 pathologically proven LSTs at the Sendai Medical Center, Japan, between May 2012 and December 2016. Multidetector CT scan using contrast media immediately after total colonoscopy was performed. Images were retrospectively reconstructed by using a 0.5 mm section index. The CTC examination was prepared by PEG-C solution before scanning. CO2 gas as an effervescence agent was then administered just before scanning. This was used for the contrast medium. CTC images were analyzed by AVE Virtual Place software. The CTC and colonoscopy were independently analyzed by endoscopist and radiologist in blind fashion. We investigated misdiagnosed lesions with CTC more than 10 mm detected by CS. We considered the pseudo-negative lesions misdiagnosed with CTC interpretation (PNL) by radiologist and gastroenterologist and also considered the true pseudo-negative lesions misdiagnosed with CTC interpretation (true PNL) by radiologists and gastroenterologists. Because we conceived true PNL showed the limitation of CTC interpretation instead of PNL involved a human error.

Results: PNL was diagnosed by CS at 0-Ip (8 cases, 8 lesions) and 0-IIa (17 cases, 19 lesions), respectively according to the criteria of the Paris classification. True PNL was also diagnosed at 0-IIa (1 case, 1 lesion), 0-Is (5 cases, 6 lesions) and 0-IIa (11 cases, 13 lesions), respectively. True PNL/PNL ratio was 0-Ip 12.5%, 0-IIa 50% and 0-IIa 68.5%, respectively. There was no PNL at 0-Iic, Type I, II and III on this study. Most of all true PNL were so called flat lesions not only 0-IIa lesion.

Conclusion: CTC was proven to be a reasonably useful approach to obtain the image of colon diseases without any invasiveness to the patient. On CTC interpretation, lower protruded lesion was considered less detectivity than highly protruded lesion like 0-IIa lesion.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The formation of fibrotic tissue in intestinal wall of Crohn’s Disease (CD) patients is transmural and mucosal biopsies are unrepresentative of real intestinal damage. Magnetic Resonance Enterography (MRE) allows a transmural study of the bowel loops. Recently the percentage of gain of contrast intensity has been proved useful to study fibrosis in CD patients. Diffusion Weighted Imaging (DWI) through the restriction of the apparent diffusion coefficient (ADC) allows an accurate evaluation of disease activity in CD patients avoiding contrast agents.

Aims and Methods: The aim of this study is to investigate if DWI sequence of MRE could be used as an active disease at MRE. ADC value had a significant correlation with fibrosis score (r = 0.648; p < 0.0001), AIS (r = 0.763; p < 0.0001) and percentage of gain (r = 0.687; p < 0.0001). A strong correlation emerged between wall thickness and fibrosis score (r = 0.671; p < 0.0001). The
threshold of wall thickness for fibrosis was >6.3 mm (specificity 100% and sen-
sitivity 69.23% with AUC 0.89). The cut-off of ADC value for fibrosis was

Conclusion: The DWI sequence with ADC value can identify fibrosis in intestinal

P1580 MOLECULAR IMAGING OF C-MET IN THE CLINICAL
MANAGEMENT OF GASTROINTESTINAL CANCERS
N. Mcdonald, C. Portal, I. Wilson
Edinburgh Molecular Imaging, Edinburgh/United Kingdom

Introduction: The primary indication for c-Met targeted optical imaging agent
E520 and c-Met endoscopic detection of lesions during colorectal cancer
screening, including flat lesions that are difficult to detect by normal white light
endoscopy. We have evaluated the potential benefit of EMI-137 and analogues
beyond colorectal cancer screening since c-Met is up-regulated in many other
cancers.

Aims & Methods: We have synthesised analogues of EMI-137 where the fluor-
escent reporter was replaced by a radionuclide chelating moiety for PET imaging.
We have also performed animal testing in a mouse xenograft model for various
cancer stages.

Results: We have identified a number of promising applications within Digestive
Oncology; gastric cancer, locally-advanced rectal cancer, and bile duct cancer
surgery all have strong evidence for c-Met as a valid target, and the healthcare
burden relative to the level of risk.

Conclusion: Future optical imaging of c-Met is promising for use in the clinical
management of these conditions. An imaging agent that enabled more accurate risk stratification of
cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1581 HOMEMADE FIXATION OF FULLY-COVERED SELF-
EXPANDING METAL STENT
C.M.P.S. Pennacchi, E. H.G. Dominguez, E. Q. Mendonc¸ a, J. F.D. Oliveira, B.
A. Bucur, M. Ilie
Endoscopy, ICESP Sao Paulo Dept. of Endoscopy, Sao Paulo/Brazil

Contact E-mail Address: ktpennacchi@yahoo.com.br

Introduction: Esophageal self-expandable metal stents are currently used as an
alternative for surgical treatment in esophageal neoplasia, benign strictures, fis-
tulas and anastomotic leaks. Migration is a common complication after stent
placement and have higher rates when fully covered stents are employed.
Covered stents prevent tumor ingrowth and can be removed easily, they can
be used in the closure of fistulas and leaks. External fixation of the stent with
Shim’s technique seems to be efficient in preventing stent migration, but has a
high cost and the devices are not always available. Fixation by clipping or sutures has similar
limitations. We developed a homemade technique for external fixation of the
stent using dental floss to prevent stent migration. We pull stripes of dental
floss into the stent mesh and use a method similar to exchange of a nasobiliary
drainage catheter, the dental floss is drawn out through the nose, tied a knot into
it and its loose end is fixed to the patient’s carbole.

Results: Upper gastrointestinal endoscopy was performed after two weeks and
the proximal end of the stent was evaluated. If it was embedding the esophageal mucosa and did not separate from the esophagus with air insuf-
flation, the external fixation was removed. Otherwise, the fixation was kept for
another 2–4 weeks when a new endoscopic evaluation was performed. Patients
were evaluated 15–30 days after stent placement. In cases of migration of the
entire length of the stent into the stomach, the patient received a new stent and
the same fixation method was used. In cases of stents partially migrated
through the cardia, the same stent was repositioned and fixed with dental floss
strategies as previously described.

Conclusion: According to the results we believe that this homemade technique using
dental floss for external fixation of stents is a simple and cheap method that can
be applied and used to prevent stent migration.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1582 CLINICAL OUTCOME WHEN USING SELF EXPANDING
METAL STENT IN OBSTRUCTIVE COLORECTAL CANCER IN 248
PATIENTS WITH A 7 YEARS EXPERIENCE FROM A TERTIARY CENTER
M. Shafazand, T. Radomski, L. Alkcn, N. Papachryssos
Gastroenterology, Sahlgrenska University Hospital, Gothenburg/Sweden

Contact E-mail Address: mortera.shafazand@vgregion.se

Introduction: The reported incidence of colorectal cancer in Sweden in 2014 was
60-65/100,000 inhabitants and caused 25-30 deaths/100,0001. Of all colorectal
cancer, approximately 15-20% debates with acute obstructive symptoms.
Conventional acute surgical procedures in these conditions (open surgery) have
been shown to lead to mortality risk up to 20% and morbidity risk of 45–50%,
followed by increased need for intensive care and more infections and stoma
complications”. Self-expanding Metal Stent (SEMS) for relieving malignant
colorectal obstruction is a treatment option for non-curative cases or for bridging
the patient for later surgery. Studies have shown "clinical success" of SEMS at
90%. An article from 2007 concludes that SEMS in acute colonic obstruction has
better results regarding sickness and side effects compared with acute open
surgery.2

Aims & Methods: Our compilation covers the years 2010–16, when 248 SEMS
interventions(53% men, 47% women, age 28–97) were performed at SU/Ostra
Hospital. In 78% of cases, the obstruction was located below the left flexure. In
80%, SEMS was made for palliative purposes.

Results: Technically, SEMS succeeded in 98% of cases and had clinical success in
90% of cases(abscence in need of emergency surgery). Complications (colony
perforation) occurred in 6% of cases. Mortality within 30 days was 11% and within 90 days 22%. Both of these complications were controlled in 90% of cases. Our interpretation is that SEMS is an effective method of acceptable safety regarding complications in acute malignant colon obstruction. The method is suitable for both intended intestinal relief for palliative purposes, as well as
awaiting later curative measure (bridge to surgery).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1584 LONG-TERM OUTCOME OF ENDOSCOPIC TREATMENT OF SYMPTOMATIC ENTERIC STRICTURES IN CROHN’S DISEASE

Department Of Gastroenterology, Hepatology And Endocrinology, Robert Bosch Hospital, Stuttgart/Germany

Contact E-mail Address: e.aichinger@alumni.pmu.ac.at

Introduction: Endoscopic treatment of enteric strictures in patients with Crohn’s
disease (CD) is well established; however, long-term outcome is unknown.

Aims & Methods: All patients with CD, who had undergone endoscopic therapy
of symptomatic strictures at Robert-Bosch-Hospital Stuttgart from 2008–2017,
were included in this retrospective cohort study. A follow-up was available for 131/135 (97%) patients with a mean of 30.1 months (0 to 103).

Results: A total of 452 endoscopic interventions (mean 3.4 per patient, median 2 per patient, range 1–69 treatments) were performed in 135 patients (female n = 67, male n = 68, mean age 47.5 years, BMI: 22.8 ± 4.98 kg/m², duration of illness: median 25.1 months). In 165 cases, the dominant structure was located in the ileocecum, in 105 in the colon, esophagus (90), duodenum (54), upper intestine (26), lower intestine (11) or stomach (1). In 166 and 286 cases, there
was an anastomotic and non-anastomotic stricture present, respectively. Treatment consisted of hydrostatic balloon dilatation (n = 447); bougienage (4), and cSEM (1). Dilatation was performed to a mean of 14 mm (SD: 2.4, range 7 to 24 mm). In seven cases complications occurred after endoscopic treat-
ment (bleeding: n = 5; infection: n = 1; perforation: n = 1) which resulted in an extension of the hospital stay (n = 5), antibiotic therapy (1) and surgery (1). Immediate clinical success was observed in 438 of 452 of cases (96.9%). A single intervention was performed in 61/135 patients (45.2%), two interventions in 36 (26.7%), and three or more in 38 (28.1%). In 41 of 135 patients (30.4%), surgical treatment of the stricture was required in the course of disease.

Conclusions: Endoscopy of symptomatic stricture in CD is safe and effective. Repetitive dilation is feasible with a significant reduction of clinical symptoms, and surgery was required in about 30% of patients at long-term follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1585 Endoscopic Intralesional Steroid Injection is Effective in the Treatment of Benign Refractory Oesophageal Stricture, a Meta-analysis

L. Szapary1, N. Farkas2, K. Mátra1, P. Hegyi1, B. Eroso1

1Centre For Translational Medicine, University of Pécs Faculty of Medicine, Pécs/Hungary
2Institute Of Bioanalysis, University of Pécs, Pécs/Hungary

Contact E-mail Address: lactic.szapary070@gmail.com

Introduction: Endoscopic dilation is an effective treatment in oesophageal strictures, but recurrences may require frequent and repeated dilations in the long term. Several trials have been conducted to determine the efficacy of intralesional steroid injection in the treatment of benign refractory oesophageal strictures, since the first pediatric case series was published in 1969. However, a meta-analysis has not been carried out yet.

Aims & Methods: The aim of the analysis is to summarise the results and establish evidence in support or against the complementary treatment. A meta-analysis was performed using the preferred reporting items for systematic review and meta-analysis protocols (PRISMA-P). Two reviewers conducted a comprehensive search on databases from inception to February 2016, to identify trials comparing the efficacy of dilation combined with or without intralesional steroid injection. A meta-analysis was conducted on the data using the random-effects method by DerSimonian and Laird, because of the high level of the heterogeneity.

Results: There were 45 articles found in Embase, 55 in PubMed, and 6 in the Cochran database. Altogether 11 articles were suitable for analyses, after exclusion of duplicate articles, case reports, results from non-human and pediatric studies. These studies involved 373 patients in total. The periodical dilation intervention combined with intralesional steroid injection was performed in 142 cases, but recurrences may require frequent and repeated dilations in the long term in patients treated by intraluminal steroid injection as well. We recommend the use of intraluminal steroid injection for benign refractory oesophageal strictures.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Results: Between 01.01.2012 and 01.04.2016, 152 stents were inserted in 125 patients with palliative esophageal cancer; 104 patients had stent inserted once, 16 patients had twice, 4 patients had 3 times and 1 patient had 4 stent insertions. 69.6% were male and the median age at death was 79 years (SD 10.94). The reported histology for the 125 patients revealed, 85 (68%) adenocarcinoma, 30 (24%) squamous cell carcinoma, 5 (4%) Lung cancer causing external compression of the oesophagus, 2 (1.6%) mesothelioma, 1 (0.8%) externally compressing spindle cell sarcoma, 1 (0.8%) metastatic adenocarcinoma from the colon, 1 (0.8%) externally compressing signet ring adenocarcinoma. Of these stent insertions 52 (32.4%) were documented to have gone on or recurrent dysphagia after the procedure, of which the causes were: tumour overgrowth or ingrowth in 9 (5.9%); stent migration in 15 (9.9%); distal obstruction due to gastric folds in 2 (1.3%); dysfunction of the anti-reflux valve in 3 (2.0%); and food bolus obstruction in 12 (4.6%). The obstruction was classified as external in 3 (2.1%) cases and stent disintegration in 1 (0.7%) case. In 13 (8.6%) cases cause for dysphagia was not found or not investigated. 100 (63.8%) stent insertions resulted in complete resolution of the dysphagia. Repeat endoscopy was necessary in 34 (27.2%) patients, who had 98 repeat gastrosopies in total, to deal with minor complications of the stent insertion or to investigate dysphagia. In total there were 13 (8.7%) significant complications caused by the stent insertion of which 7 (4.6%) were bleeding, 2 (1.3%) were tracheo-oesophageal fistula formations, 1 (0.7%) was delayed perforation, 1 (0.7%) was a too short stent, 1 (0.7%) was a disintegrating stent and 1 (0.7%) was a compression of the bronchus. Median survival of the 125 patients after stent insertion was 96 days (SD 128) and 30-day mortality was 11.2% (14 patients). It is important to note that with retrospective data analysis, some data is not available, due to variations in recording at the time and a reliance on the patient to report symptoms to a clinician. Currently 2 patients are still alive.

Conclusions: Palliative stenting at this centre continues to be an effective treatment for patients with dysphagia from oesophageal cancer. On the whole, outcomes from stenting at this unit compare favourably with published data in terms of dysphagia, other complications, and mortality. Steps to improve post-procedure monitoring in the form of a “stent registry” with prospective collection of data by telephone or face-to-face follow-up could be useful in future service development.

available in many centers and have revolutionized the management of iatrogenic bowel and vascular injuries.

Aims & Methods: Evaluate the role of intervention radiology procedures to manage different post-cholecystectomy complications focusing on the novel techniques to improve the final outcome. From June 2014 to June 2016, 30 patients post-cholecystectomy complications were referred to interventional radiology unit in our university hospital. They were 9 males and 21 females (age range: 18-66 years). Patients presented with bile leaks (n = 12), benign biliary strictures with intrahepatic biliary dilatations (n = 21), postoperative hernia (n = 1), bleeding related to hepatic artery pseudo-aneurysm (n = 1). Different types of interventional procedures were performed, including: Percutaneous trans-hepatic drainage (PTD) (n = 16), sequential dilatation of benign stricture with increasing catheter calibers over 6 months followed by manometric studies before catheter withdrawal (n = 6), biliary stenting with plastint (n = 2), Insertion of pigtail catheter (n = 15), preoperative progressive pneumo-peritoneum for their adhesiolysis effect to manage post-operative huge incisional hernias before their surgical repair (n = 1), and selective embolization of bleeding hepatic and/or splenic pseudo-aneurysm (n = 1) using tissue adhesive (n =Butyl 2 Cyanoacrylate).

Results: All percutaneous procedures were technically successful. No recorded early or late complications. After manometric studies, all managed cases with bile leaks did not show any clinical evidence of restenosis during 6 months follow-up. Overall, 14 out of 30 patients (46.7%) were only managed by different interventional radiology procedures. Second step surgical repair was needed for 13 patients (43.3%) and endoscopic managed for 3 patients (10%) with biliary leaks.

Conclusion: Minimally invasive interventions are valuable techniques in the management of different post-cholecystectomy complications. In fully equipped centres, expert multidisciplinary teams would achieve high cure rates for iatrogenic biliary injuries.

P1590 WHAT IS THE ROLE OF ANGIGRAPHY IN ACUTE COLONIC AND SMALL BOWEL BLEEDING?

R. Vale Rodrigues1, P. Amaro1, M. Ferreira1, M. Barros1, P. Donato1, L. Tomé1
1Gastroenterology, Centro Hospitalar e Universitário de Coimbra, Coimbra/Portugal

Contact E-mail Address: rita.vale.rodrigues@gmail.com

Introduction: Angiography is a diagnostic and therapeutic modality that is widely available for upper gastrointestinal bleeding but is used less frequently when the source of bleeding is placed distally to the Treitz angle.

Aims & Methods: To assess the usefulness of angiography in the diagnosis of colonic and small bowel bleeding and to determine the efficacy and complications of therapeutic procedures. Retrospective study; we included all patients with colonic and small bowel bleeding that were submitted to angiography with or without embolization, admitted to the gastroenterology department of a tertiary hospital between February 2006 and November 2016. Statistics: Chi-square/Fisher exact test, T-student.

Results: From 2006 to 2016 276 patients were evaluated, 63.6% male, mean age = 75 years (29–95). Angiography was done for: bleeding recurrence (32.6%), hemodynamic instability (33.3%), both (27.3%) or failure to endoscopic hemostasis (3%). The aetiology after angiographic study was: presumed diverticular (n = 28), anastomosis (n = 8), confirmed diverticular (n = 6), tumoral (n = 5), post-muco-secotomy/polypectomy (n = 4), unclarified (n = 12), others (n = 3); Dieulafoy, ileum ulcers, radiation proctitis. Angiography showed additional clinical information in 58.8% of patients (n = 17). Twenty-three patients (34.8%) underwent arterial embolization, all with technical success, with bleeding recurrence in 3, of which only one was submitted to surgery; there were 2 cases of bowel ischemia. The reasons for deciding not to embolize were: absence of active bleeding (90.7%) and end-vessel bleeding (9.3%). There were no differences between the groups in demographic data, comorbidities, mortality, source of bleeding, haemoglobin at admission/diagnosis and change in haemoglobin (p = 0.005). Arterial embolization was more frequent if hemodynamic instability (p = 0.029); The average time of hospital stay was lower in the group submitted to embolization (8.8 vs 11.5 days, p = 0.014). Overall, 11 patients died, due to: re-bleeding/hypovolemic shock (n = 5), exacerbation of comorbidities (n = 3), hospital acquired infection (n = 2) or post embolization complication (n = 1).

Conclusion: Arteriography was a valid option for the diagnosis of colonic and small bowel bleeding; allowed therapeutic intervention in more than one third of patients, with 87% of clinical success and reduction of hospitalization time.

P1591 PROGNOSTIC VALUE OF CARDIOPULMONARY EXERCISE TESTING FOR MORBIDITY RISK AND SURVIVAL AFTER OESOPHAGECTOMY FOR CANCER

N. Patel1, J. Wheat1, C. Brown1, A. Powell2, T. Abdelrahman1, R. Davies2, I. Appadurai1, P. Amaro1, M. Ferreira1, M. Barros1, P. Donato1, L. Tomé1

Contact E-mail Address: neilrnama@hotmail.com

Introduction: Surgery for radical treatment of oesophageal cancer carries significant inherent risk. Objectively Identifying patients that are high risk of complications is of importance. The aim of this study was to assess the prognostic value of physical fitness variables determined objectively by cardiopulmonary exercise testing (CPET) in patients undergoing potentially curative surgery for oesophageal cancer (OC) within an enhanced recovery programme.

Aims & Methods: Consecutive 180 OC patients (106 ACA, 11 SCC, 3HGD) underwent preoperative CPET with prospective recording of morbidity and survival. Non-parametric receiver operating characteristic (ROC) curves and logistic regression were used to assess the relationship between CPET variables and postoperative morbidity severity score (MSS).

Results: Of 180 patients, 120 were included for analysis (median age 65 yr., 100 male, 75 neoadjuvant therapy); 60 did not proceed to surgery and were excluded. Postoperative morbidity and mortality occurred in 83 (69%, CD ¼ 27, 22.5%) and 4 (3.3%) patients respectively. ROC curve analysis showed oxygen uptake (peak V02) gave an area under the ROC of 0.66 (95% CI 0.55 to 0.77, p = 0.001), anaerobic threshold (AT) gave an area under the ROC of 0.62 (95% CI 0.51–0.74, p = 0.048) and optimum cut-off of 10.5 ml/kg/min (sensitivity 60%, specificity 44%). Multivariable analysis revealed peak V02 to be the only independent factor to predict morbidity severity CD ¼ 3 (OR 0.85, 95% CI 0.75–0.97, p = 0.018). Cumulative survival was associated with operative MSS (Chi2 = 4.892, DF 1, p = 0.027) but not with CPET variables. Conclusion: CPET is a significant predictor of morbidity after oesophagectomy with peak V02 the most important factor.

2Radiology, University Hospital Wales, Cardiff/United Kingdom

Contact E-mail Address: neilrnama@hotmail.com

Introduction: PET/CT has become an integral part of the staging pathway for operable esophageal cancer (OC), primarily used to identify occult distant metastases unseen by conventional radiological modalities. The aim of this study was to analyze the effect of PET/CT introduction on overall survival and assess patterns of recurrence after oesophagectomy.

Aims & Methods: Consecutive patients undergoing oesophagectomy for cancer [median age 63 (31–80) yr., 395 male, 425 ACA, 71 SCC, 325 neoadjuvant therapy] were studied. Two hundred and twenty-three patients underwent PET/CT enhanced staging protocols and the primary outcome measure was overall survival based on intention to treat.

Results: Overall 3-year survival pre-PET/CT was 42.5% compared with 57.8% post-PET/CT (Chi2 6.571, df 1, p = 0.004). On multivariable analysis, pT stage (HR 1.486 [95% CI 1.27–1.74] p = 0.001), pN stage (HR 1.116 [95% CI 1.05–1.20] p = 0.001) and PET/CT (HR 0.689 [95% CI 0.53–0.89] p = 0.004) were independently associated with duration of overall survival. Recurrent cancer was observed in 125 patients (51.4%) pre-PET/CT, compared with 74 patients post-PET/CT (37.8%, p = 0.015), and was less likely to be distal in location after PET/CT inception (39.5 vs 27.0%, p = 0.006).

Conclusion: PET/CT enhanced staging is an important and independent factor associated with improved survival in patients undergoing oesophagectomy for cancer.

P1593 PREDICTION OF LYMPH NODE METASTASIS FOR SUPERFICIAL ESOPHAGEAL CANCER WITH USING RANDOM FOREST ANALYSIS

M. Takeuchi1, H. Kawakubo1, K. Fukuda1, R. Nakamura1, K. Suda1, N. Wada1, Y. Kitagawa1
1Department Of Surgery, Keio University School of Medicine, Tokyo/Japan

Contact E-mail Address: masatya71222@gmail.com

Introduction: Although surgical techniques and perioperative management for esophageal cancer has been developed, it cannot be still safe to be performed esophagectomy. Therefore, endoscopic submucosal dissection (ESD) for the superficial cancer have been increased. We also need to consider the risk of lymph node metastasis before treatment in each patient and the aim of this study is to predict lymph node metastasis for superficial esophageal cancer.
Aims & Methods: Seventy patients who were diagnosed as clinical Tla-MM, Tlb-SM1 or Tlb-SM2 and underwent esophagectomy at the Keio University, Tokyo, Japan between July 2000 and June 2016 were enrolled in this study. Patients who underwent esophagectomy as additional resections after ESD were included. We used random forest analysis to predict lymph node metastasis. Results: There were 62 men and 8 women in this study. The mean age of all patients was 62.8 ± 8.2 years. The main location of the tumor was in the middle thoracic esophagus (Upper: Middle, Lower: 13: 39: 18, respectively). 14 patients had lymph node metastasis in pathological findings; 2 patients (25%) were diagnosed as clinical Tla-MM, 2 (6%) patients (31.3%) were Tlb-SM2. Random forest technique (2000 trees) resulted in an estimate of error rate of 25.7%. Lymph node metastasis was most associated with the factor of pathological T (relative importance 100%) followed by lymph node status and ICW and SIR were the most important prognostic indicators.

COPING AND QUALITY OF LIFE AFTER DISCLOSURE OF INTEREST:

P1595 COPING AND QUALITY OF LIFE AFTER DISCLOSURE OF INTEREST: 50.6. Overall, mean C30-QL2 was 72.9 (SD 16.3). Mean C30 functional scales were: PF = 80.8 (SD 16.6), RF = 85.0 (SD 20.7), EF = 81.5 (SD 17.0), CF = 87.4 (SD 14.0) and SF = 90.0 (SD 14.0). Avoidance Strategies score was negatively correlated with Social Function (rho = -0.60, p = 0.004). The remaining correlations between COPE-NVI scales, C30-QL2 and C30 functional scales were statistically not significant. Nineteen patients completed the questionnaire twice, with 3–6 months between the two fillings. The mean differences of the COPE-NVI scales were not statistically significant.

Conclusion: In our series, patients used Positive Attitude to manage everyday life (i.e. emotional indifference or drugs) were used, social abilities were compromised. Moreover, after surgical intervention coping seemed to be a stable feature. Therefore, in the early follow-up after surgery multidisciplinary team can identify and the coping features of patients in order to improve them to get a better outcome.

P1596 A RELIABLE AND ACCURATE ALGORITHM TO QUANTIFY THE TUMOR STROMA QUOTIENTS IN HUMAN TISSUE: INFLTRATION OF CD3+ AND CD8+ LYMPHOCYTES CORRELATES WITH IMPROVED SURVIVAL IN HEPATOCELLULAR CARCINOMA AND PANCREATIC CANCER

R.C. Michi1, J. Hao1, K. Dötzter1, F. Schütter1, M. Weniger1, S. Yin1, S. Ormanns2, J.G. D’Haese1, M. Gub1, J. Werner1, B. Mayer1, A.V. Bakh1, M.B. Schoenberg1

1Department Of General, Visceral, And Transplantation Surgery, Ludwig-Maximilians University of Munich, Munich/Germany
2Department Of Pathology, Ludwig-Maximilians University of Munich, Munich/Germany

Introduction: The tumor micro environment plays a vital role in the growth of malignancies. Through for example tumor-infiltrating lymphocytes (TILs) it influences overall and disease free survival of patients in various cancer entities. Therefore, it is an important question to investigate their value. However, there is great heterogeneity about how to quantify these cells in the tumor tissue. Therefore, we present a novel Quantification of the Tumor Stroma (QTS) Algorithm to reliably and accurately quantify cells of the tumor stroma and to perform a correlation with survival after resection of patients with hepatocellular carcinoma and pancreatic cancer.

Aims & Methods: Immunohistochemical staining of CD3 and CD8 antigens in frozen sections of metastatic colorectal cancer (mCRC) and ovarian cancer (OvCa) as well as in paraffin sections of hepatocellular carcinoma (HCC) and pancreatic cancer (PCa) was performed. For each entity 10 slides per antigen were examined (n = 80). In these different entities reliability and accuracy of computed quantification was tested in order to develop a general algorithm (Figure). First, reliability of identification of hot spots was investigated using two blinded observers. Hot spots were defined as regions with the highest density of TILs. The absolute amounts of cells were compared with the intra-assay-correlation coefficient (ICC). Second, accuracy was tested. To examine whether quantification of 1 vs 3 hot spots yields accurate results CD3+ CD8+ ratio as well as the absolute cell numbers were compared with the ICC respectively. Third, computed counting methods (1) ZEN 2 software counting (ZC), (2) ImageJ software with subjective threshold (ISC) and (3) ImageJ with colour deconvolution (IAC) was performed to a manual counting (gold standard) using a linear regression analysis. Finally, 60 resected tumor tissues of HCC and 30 of PCa were retrieved. 3 hot spots have been selected for every slide and groups of high/low infiltration of CD3+ and CD8+ lymphocytes have been created according to the median value. Then, statistical correlation with overall survival (OS) and disease free survival (DFS) was performed.

Results: Quantification results from 2 blinded observers for reliable detection of hot spots were 0.949 in mCRC, 0.843 in OvCa, 0.805 in HCC and 0.957 in PCa. The ICC for the ratio of CD8/CD3 in 1 hot spot compared to the average from 3 hot spots was consistent in all groups. The absolute cell count in 1 vs 3 hot spots of CD3+ CD8+ Lymphocytes correlated significantly with improved DFS in HCC (p = 0.016) and PCa (p = 0.001) as well as improved OS in PCa (p = 0.046). High infiltration of CD8+ Lymphocytes correlated significantly with improved DFS in HCC (p = 0.016) and PCa (p = 0.001) as well as improved OS in PCa (p = 0.006). Conclusion: In this study we introduced a systematical way to count tumor stroma cell infiltrate of hot spots by 1 observer is acceptable. Second, if a ratio is to be determined, quantification of 1 hot spot is sufficient. If the absolute cell count is to be determined, quantification of 3 hot spots is recommended. Third,

Comparison of manual counting to the computed methods showed mostly excellent accuracy of the obtained results using intraclass correlation with reliability analysis (ICC) and coefficient B with linear regression (B):
P1598 LIVER RESECTION IN OBESE PATIENTS WITH HEPATOCELLULAR CARCINOMA
Hepato-biliary-pancreatic Surgery, Hyogo College of Medicine, Hyogo, Japan
Contact E-mail Address: iwama3307@gmail.com

Introduction: Obese disease has been recognized as a risk factor for hepatocellular carcinoma (HCC). On the other hand, there are few reports concerning liver resection (LR) in obese patients.

Aims & Methods: We performed curative LR in 471 patients with HCC between 2001 and 2015. In this study, we defined an obesity as no less than 25 of body mass index (BMI). We compared clinicopathological findings, operation details, and surgical outcomes of the obese and non-obese patients. Furthermore, we assessed the safety and the benefit of laparoscopic partial hepatectomy and left lateral segmentectomy in the obese patients.

Results: Among 471 patients, 123 patients (26.1%) were defined as obese. Among them, 20 patients (4.2%) showed no less than 30 of BMI. Diabetes, hypertension, and hyperlipidemia were significantly more common, and the patients with hepatic tumors in the obese patients group than in the non-obese patients group (p < 0.05). The two groups showed no differences in the liver function tests except the indocyanine green retention rate at 15 minutes. There were no significant differences between the two patients group in the number of tumors, diameter of tumor, prevalence of cirrhosis, frequency of portal invasion, the operative procedure, operative duration, blood loss, incidence of postoperative complications, postoperative hospital stay, and in-hospital mortality (3.3% vs. 1.4%). No significant difference was found in relapse-free survival rate, or overall survival rate between the two groups, too. Thirteen patients underwent laparoscopic surgery, and 34 patients had open surgery. The two groups showed no difference in the background, including BMI. However, the operation time (265 min vs. 397.5 min) and the postoperative hospital stay (14 days vs. 18 days) were significantly shorter, and the blood loss (50 ml vs. 600 ml) was less in the laparoscopic surgery group than in the open surgery group (p < 0.05).

Conclusion: Liver resection in the obese patients with HCC was safe, and laparoscopic liver resection might be more useful for reducing the surgical stress and reducing the hospital stay.

tertiary centers has been performed. DPTS are traced by the pharmacies of our two hospitals and all cases of DPTS were analysed thanks to the database of the pharmacies of our two hospitals since May 2014 (first DPTS used for non bariatric upper digestive tract fissula) or 10 french DPTS have been used according to the size of the fissula and the choice of the physician. Technical success was defined as the possibility to place the DPTS within the fissula. Clinical success was a composite endpoint combining clinical amelioration of the patient and healing of the fissula allowing the removal of the DPTS.

**Results:** 17 patients have been treated by DPTS from May 2014 to March 2017 for an upper digestive tract leaks not linked to bariatric surgery. Fistulas were linked to a lewis-santy surgery in 8 patients (47%), total gastrectomy in 4 (23.5%), boerhaave syndrome in 2 (11.8%), endoscopic perforation in 2 (11.8%) and aortic surgery in 1 (5.9%). An infected collection was present in 16 patients (94%) and 11 (64.7%) suffered from a clinical sepsis. The mean delay between surgery and the diagnostic of fistula was 10 days and the delay of the diagnosis of fistula and the endoscopic drainage by DPTS was 16.4 days. DPTS were used alone in first intention in 11 cases (64.7%), in first intention in combination with a SEMS in 11.7% and in second intention after failure of a SEMS in 3 (11.7%). All patients had a technical success and 15 patients (88.8%) had a clinical success. The mean delay for refeeding after DPTS was 17 days. The mean ablation time of the DPTS was 73 days. 3 patients presented a complication (1 stenosis, 1 bleeding and 1 migration).

**References**

**Conclusion:** Endoscopic internal drainage using DPTS seems to be an interesting therapeutic option for upper digestive tract leaks not linked to bariatric surgery. DPTS are effective, safe, cheap and could replace SEMS not always well tolerated and with a high rate of migration. Prospective multicenter studies are needed to confirm these preliminary results.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

surgery. Patients presented heart rate over 120 bpm. Images from CT showed left side of the free abdominal wall. An Upper GI series was performed to localize the leak opening and enter to peritoneal cavity. Either 9.8 or 5.8 mm diameter gastroscope were used. In 10 patients with orifice smaller than 5.8 mm balloon dilatation of the leak opening allowed peritoneal access. The approach of AL was possible in (100 to 700ml). Sample was taken for bacterial cultures. The culture was flushed and succion out with sterile saline solution (200ml to 1000ml). In cases of inadequate location surgical drains catheters were repositioned or replaced using endoscopic forceps and snare. Fistula tract closure. Catheters were advanced using endoscopes through the leak all the way down to the skin. Once the tip of the endoscope was outside the peritoneum the latex drains were removed. Catheters were snared or grasped and pulled back into the peritoneum leaving the proximal end close to the fistula opening. In 5 patients without surgical drainage systems one laparoscopic port was localized inside peritoneum and re-opened under endoscopic vision to allow drainage catheters placement. In 8 patients peritoneal adhesions were endoscopically lib- erated from endoscopic forceps or knives to facilitate peritoneal navage.

Results: Heart rate returned to normal within 24 hours and leukocytosis improved after 72 hours. In 50% of patients heart rate returned to normal immediately. Average time for the whole procedure was 45 minutes. Abdominal catheters were removed between 7 and 18 days once full resolution of the drainage was achieved. Twenty patients were discharged within the first 24 hours. The rest were discharged between 3 and 8 days. Partially covered SEMS were placed for 6 to 8 weeks leading to complete closure of leaks. There were no adverse events related.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1605 CLINICAL ASSESSMENT OF THE FAILING TO REVERSE A DIVERTING ILEOSTOMY
A. Sobolewska-Wlodarczyk1, M. Wlodarczyk1, J. Wlodarczyk1, P. Swiwnicki1, J. Knapczyk1, A. Dzik1, L. Dzik1
1Department Of Biochemistry; 2Department Of Gastroenterology, Medical University of Lodz; Lodz; Poland

Introduction: A diverting loop ileostomy with procedure of intestinal resections and anastomosis decreases morbidity from anastomotic leaks and may even reduce the risk of anastomotic leak as shown in recent studies. Reversal of a temporary ileostomy is considered a simple surgical procedure presenting with a low morbidity and mortality rates. However, ileostomy reversal may be asso- ciated with number of complications requiring reoperation, with anastomotic leak (AL) being most critical often leading to failure in restoration of digestive tract continuity.

Aims & Methods: The study aimed at evaluating the results of restoration of intestinal continuity in patients primarily operated on for colorectal cancer and inflammatory conditions. We assessed the frequency of failure following the surgical procedure of diverting loop ileostomy closure. The study was conducted at a tertiary referral center. 147 adult patients (89 men, mean age 50.5y ± 16.71 and 58 women, mean age 49.3y ± 16.99y) were enrolled to this study. All included patients underwent surgical closure of a temporary loop ileostomy at the Department of General and Colorectal Surgery, Lodz, Poland, between 2004 and 2016. The need for collection was collected in a retrospective manner basing on hospital records. The analyzed parameters included length of hospitalization, gender, age, BMI, concomitant conditions, American Society of Anesthesiologists classification score (ASA) and the character of postoperative complications. Statistical analysis was used to evaluate the correlation between the variables and postoperative complications.

Results: AL as a postoperative complication with the need to create a new ostomy was a critical postoperative complication in patients undergoing AL as a critical postoperative complication is still unclear.

Aims & Methods: The aim of this study was to analyze the association between body composition the postoperative complications and 90-day mortality in patients undergoing bilipancreatic cancer surgery. Retrospective study of patients with pancreatic, ampullary or bile duct carcinoma that underwent sur- gery between March 2012 and October 2016. Body composition (skeletal muscle mass, fat area, subcutaneous fat area and muscle radiation attenuation) was assessed in diagnostic or staging computed tomography (CT), in axial images at the level of the 3rd lumbar vertebra. Postoperative complications were recorded according to Clavien-Dindo classification and categorized as minor (grade I–II) or major (grade III–IV). The relationship of body composition with the number of complications requiring reoperation, with anastomotic leak (AL) being most critical often leading to failure in restoration of digestive tract.

Conclusion: The impact of body composition on the outcomes following pan-creatingoduodenectomy is still unclear.

P1608 ASSESSING THE EFFECT OF ETHNICITY ON URINARY METABOLIC PROFILES IN INFLAMMATORY BOWEL DISEASE

1Gastroenterology, Imperial College Healthcare NHS Trust, London/United Kingdom
2Division Of Digestive Diseases, Department Of Surgery And Cancer, Imperial College London, London/United Kingdom
3Division Of Computational And Systems Medicine, Department Of Surgery And Cancer, Imperial College London, London/United Kingdom

Contact E-mail Address: lhicks@imperial.ac.uk

Introduction: Urinary metabolic profiling has been shown to distinguish patients with inflammatory bowel disease (IBD) from healthy controls (HC), and also separate ulcerative colitis (UC) from Crohn’s disease (CD) in Caucasian (Cau) cohorts (1). Diet and lifestyle also have an effect on metabolic profiles (2), and these differ in patients from different ethnic backgrounds. Moreover, clinical phenotype varies between Caucasians and South Asians (SA) (3), however discriminatory metabolites have not been studied in different ethnic populations. The aim of this study was to compare the urinary metabolic profiles of IBD patients and healthy controls from Caucasian and South Asian backgrounds.

Aims & Methods: Samples from 405 IBD patients (283 Caucasian and 122 South Asian) and 137 healthy controls (98 Caucasian and 48 South Asian) were ana-

*Montreal classification
+OPLSDA model examining the differences in urinary metabolic profiles between these cohorts
++p value cannot be calculated if OPLSDA model has negative Q2 values

OPLSDA models also separated South Asian healthy controls from Caucasians healthy controls, and South Asian Crohn’s disease from Caucasian Crohn’s disease, but in UC no robust model could be made.

Results: The phenotype of South Asian Crohn’s disease was not significantly different to Caucasian Crohn’s disease in this cohort. In the South Asian UC group there were more pancolitis (p = 0.051) and less proctitis (p = 0.008). There were more vegetarians in the South Asian group. OPLSDA was able to separate patients with IBD from healthy controls, and also UC from Crohn’s disease, in the Caucasian cohort, but this separation could not be replicated in South Asians (negative Q2 values).

Conclusion: The separation between Caucasian and South Asian healthy controls may reflect differing lifestyles including diet. Caucasian IBD patients could be separated from healthy controls, and Crohn’s disease from UC, replicating previous studies. South Asian IBD patients could not be separated from healthy controls which may be due to lower numbers of South Asian patients in this study, and specifically less Crohn’s disease patients where stronger discriminating models have been shown in Crohn’s disease in previous studies. In Crohn’s disease, Caucasians and South Asians could be separated, but Caucasian and South Asian patients could not be distinguished in the UC cohort, possibly suggesting the metabolic milieu in Crohn’s disease is stronger and less influenced by the impact of ethnicity.

Introduction: Reduced saccharolytic fermentation has been described in patients with quiescent ulcerative colitis (UC). Such defects may differ across colonic regions among with acute variations in dietary fibre intake. These aspects deserve further study.

Aims & Methods: We aimed to define regional colonic fermentation by direct intestinal pH-transit profiling in patients with quiescent UC following acute variations in fermentable fiber intake. A randomized, double-blind, crossover trial was performed. Patients with quiescent UC (Partial Mayo Score ≤1; faecal calprotectin <150μg/g) and healthy controls who were not taking any...

Conclusion: A high fermentable fiber diet partially increased colonic fermentative activity in patients with quiescent UC compared to controls. Moreover, contrary to controls, UC patients exhibited an increase in distal pH and heterogeneous colonic transit responses after a high fermentable fiber intake. Our findings suggest that abnormalities in motility and regional defects in the function of the colonic microbiota exist despite quiescent disease.

Introduction: Ulcerative colitis (UC) phenotype in South Asian (SA) patients differs to Caucasians with a predominant pan-colonic extent. A separate study showed microbial profiles with lower bacterial diversity in the SA group. The significance of these findings is unclear due to small sample size showed different microbial profiles with lower bacterial diversity in the SA group. The significance of these findings is unclear due to small sample size showed different microbial profiles with lower bacterial diversity in the SA group. The significance of these findings is unclear due to small sample size showed different microbial profiles with lower bacterial diversity in the SA group. The significance of these findings is unclear due to small sample size showed different microbial profiles with lower bacterial diversity in the SA group. The significance of these findings is unclear due to small sample size showed different microbial profiles with lower bacterial diversity in the SA group.

Aims & Methods: In this study we aimed to investigate the role of OGR1 in IBD patients. Expression of OGR1 in surgical specimens from non-IBD (n = 5), CD (n = 10) and UC (n = 10) patients was determined by immunohistochemistry, RT-qPCR and Western blotting. Clinical disease activity was assessed by the Harvey Bradshaw Index (HBI) and the Modified Truelove and Witts activity index (MTWI) for CD and UC patients, respectively. Nonparametric Spearman’s rank correlation analysis was performed.

Results: OGR1 immunostaining of human surgical samples from non-IBD patients revealed OGR1 expression mainly in lamina propria cells, with weaker staining in epithelial cells. OGR1 staining in IBD patients was stronger compared to controls; however, in IBD patients OGR1 is highly expressed in both epithelial cells and lamina propria. Further, paired samples taken the same time, from non-inflamed and inflamed intestinal tissue from IBD patients showed stronger OGR1 staining in the inflamed mucosa compared to the non-inflamed mucosa. Accordingly, mRNA and protein expression of OGR1 was significantly increased in non-IBD compared to IBD patients. A significant positive correlation was observed between OGR1 expression and the clinical score in both the non-inflamed (rs 0.7311, p = 0.0069) and the inflamed mucosa (rs 0.7698, p = 0.0034).

Conclusion: The expression of OGR1 is significantly increased in patients with IBD. OGR1 expression correlates with IBD disease activity, suggesting an active role of OGR1 in IBD pathogenesis. OGR1 appears to be a therapeutic target among the pH-sensing receptors involved in IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Increased Bifidobacteria and Lactobacillus in the SA group is consistent with the previous study. A possible explanation is the consumption of fermented foods in the SA group although there was no difference between healthy SA and Caucasians controls. There is a trend towards lower diversity in the SA group and reduced Bacteroides which are consistent with the UC dysbiosis described in the literature. Functional analysis of this unique microbial profile through metagenomic and metabolomic techniques may explain the different disease behaviour in the SA group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1614 VITAMIN D SUPPLEMENTATION REDUCES Faecal Calprotectin and Alters Intestinal Microbiota Composition in Patients with Active UC

M. Garg1, P. Hendy1, S. Shaw2, N. S. Ding2, G. Hold2, A. Hart1
1Ibd Unit, St Mark’s Hospital, Harrow/United Kingdom
2School Of Medicine, University of Aberdeen, Aberdeen/United Kingdom

Contact E-mail Address: philiphendy14@gmail.com

Introduction: There is evidence for vitamin D as an immunomodulator in patients with IBD, but results from clinical trials to date are inconclusive. It is uncertain whether vitamin D supplementation may affect the intestinal microbiota.

Aims & Methods: This study aimed to assess the effect of vitamin D replacement in deficient patients with and without ulcerative colitis (UC) on faecal calprotectin and faecal microbiota. Vitamin D was replaced over 8 weeks to patients with active UC, inactive UC, and non-IBD controls with baseline 25(OH) vitamin D < 30 nmol/L, and markers of inflammation and stool collected for microbiota analyses by next generation sequencing.

Results: Eight patients with active UC, 9 with inactive UC and 8 non-IBD controls received 40,000 units of vitamin D weekly over 8 weeks. No demographic differences were noted across the groups. Mean baseline 25(OH) vitamin D levels were 34 (range 12–49) nmol/L. Vitamin D supplementation increased mean 25(OH) vitamin D to 111 (range 71–158) nmol/L (P < 0.001), and reduced para-thyroid hormone levels from mean 4.3 to 3.3 pmol/L (p = 0.017). No change in baseline medications for UC took place in patients with UC, except for one patient with active UC who ceased his 5-aminosalicylate. Faecal calprotectin levels reduced from median 275 to 91 μg/g (p = 0.023) in patients with active colitis, but did not change in patients with inactive colitis or non-IBD controls. Similar improvements in albumin, platelet count and symptomatic disease activity indices were noted. No changes in overall bacterial diversity were noted. There was a trend towards an increase in abundance of Ruminococcus gnavus post vitamin D supplementation in active UC patients, but this did not reach statistical significance.

Conclusion: Vitamin D supplementation was associated with reduced intestinal inflammation in patients with active UC. A randomised controlled trial evaluating vitamin D in IBD is required along with further investigation of potential mechanisms by which vitamin D may alter specific microbial composition.

**Introduction:** Attack by commensal microbiota is one component for induction of inflammatory episodes in ulcerative colitis (UC). In UC, the mucus layer is intrinsically devoid of phosphatidylcholine (PC) resulting in low hydrophobicity which facilitates bacterial invasion. Colonic ectophospholipase-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A2 (PLA2) inhibitors on inflammation in a genetic UC mouse model.

**Aims & Methods:** Attack by commensal microbiota is one component for induction of inflammatory episodes in ulcerative colitis (UC). In UC, the mucus layer is intrinsically devoid of phosphatidylcholine (PC) resulting in low hydrophobicity which facilitates bacterial invasion. Colonic ectophospholipase-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A2 (PLA2) inhibitors on inflammation in a genetic UC mouse model.

**Results:** Luminal UDCA-LPE reduced the PLA2 activity in stool by 36.4%. Concomitantly no inflammatory phenotype was observed when compared to kindlin 2−/− mice not treated with UDCA-LPE. The improvement was documented in regard to stool consistency, calprotectin levels in stool, and macroscopic endoscopic as well as histologic features of the mucosa. The pattern of colonic microbiota distribution obtained in the UC phenotype mice was reversed by UDCA-LPE to the control mice pattern.

**Conclusion:** Reduction of the bacterial ectophospholipase A2 activity improves mucosal inflammation in a genetic mouse model of UC. It is assumed that the remaining mucus PC shield is better preserved when luminal PLA2 is suppressed.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Inflammatory bowel diseases (IBDs), Crohn’s disease (CD) and ulcerative colitis (UC), are typically associated with a decrease in local pH. Genome-wide association studies (GWAS) identified over 240 non-overlapping single-nucleotide polymorphisms (SNP) associated with IBD. G-protein-coupled receptor 65 (GPR65) or Toll-like death associated gene 8 (TDAG8) which facilitates bacterial invasion. Colonic ectophospholipase-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A2 (PLA2) inhibitors on inflammation in a genetic UC mouse model.

**Results:** Luminal UDCA-LPE reduced the PLA2 activity in stool by 36.4%. Concomitantly no inflammatory phenotype was observed when compared to kindlin 2−/− mice not treated with UDCA-LPE. **Introduction:** Macrophages contribute to fibrosis through the release of different mediators and the pattern of secretion may vary according to their phenotype. Recent evidences have identified Wnt pathway as an emerging modulator of fibrosis.

**Aims & Methods:** The aim of the present study is to analyze the pattern of expression of macrophage markers and Wnts ligands in surgical resections from Crohns disease (CD) patients with different disease behavior. CD patients were categorized according to Montreal classification (age at diagnosis, location and behavior). mRNA was isolated form resections of patients presenting an stricturing (B2) or a penetrating (B3) behavior. The expression of macrophage markers (CD206, CD16, iNOS, Arginase), Wnt ligands (Wnt1, Wnt2, Wnt3, Wnt4, Wnt5a, Wnt5b, Wnt6, Wnt7a, Wnt7b, Wnt8a, Wnt8b, Wnt9b, Wnt10a, Wnt10b and Wnt16) and DKK1 (inhibitor of Wnt signaling) was analyzed by RT-

**Results:** B3-patients seem to present a higher infiltration of macrophages since increased expression of markers commonly used to detect pro-inflammatory (CD86) and regulatory/pro-resolving/pro-fibrotic phenotypes (CD206, ARG) was detected in this group. These patients also presented a generalized overexpression of Wnt ligands together with augmented DKK1 mRNA levels. B2-patients showed a more complex situation with ligands that present increased (Wnt3), reduced (Wnt2B) or unchanged expression in the absence of significant variations in the levels of macrophage markers (Table). Table. Relative Gene expression (fold induction vs control group) of genes with detectable levels. Data are expressed as Mean±SEM with n ≥ 7 in all groups and analyzed by ANOVA + Kemwan-Keuls test. (*p < 0.05 vs control; **p < 0.05 vs control).

**Conclusion:** Crohn’s disease patients presenting a stricturing (B2) or a penetrating (B3) behavior undergo surgical resection differ in the pattern of macrophage infiltration and Wnt signaling.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** M2 macrophages play a key role in injury repair and fibrosis. We have recently identified that STAT6-deficient macrophages mediate mucosal repair after TNBS-induced acute colitis and that, in a chronic model, STAT6-deficient animals accumulate macrophages expressing the CD16 marker that promote intestinal fibrosis.

**Aims & Methods:** We aim to analyze whether the expression of the pro-fibrotic mediator TGFß is related with this macrophage phenotype and the relevance of these cells in murine intestinal fibrosis. Murine peritoneal macrophages obtained from both WT or STAT6 (-/-) mice were treated with IL-4 (20 ng/ml), IL-10 (50 ng/ml) or vehicle and the mRNA expression of CD16 and TGFß was analyzed by RT-

**Results:** The expression of TGFß b ñ (inhibitor of Wnt signaling) was analyzed by RT-

**Conclusion:** We have identified that STAT6-deficient macrophages mediate mucosal repair after TNBS-induced acute colitis and that, in a chronic model, STAT6-deficient animals accumulate macrophages expressing the CD16 marker that promote intestinal fibrosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P1619 GTS-21, A7 NICOTINIC ACETYLCHOLINE RECEPTOR AGONIST, ATTENUATE DSS-INDUCED COLITIS BY IMPROVING INTESTINAL MUCOSAL BARRIER FUNCTION

Y. Zhu1, H. Zhang2

Introduction: The intestinal inflammation is reduced by electrical stimulation of the different vagus nerves. Cholinergic neural output may be a target to minimize tissue damage in autoimmune disease. Cholinergic neural output can modulate innate immune responses through stimulation of α7 nicotinic acetylcholine receptors (α7nAChR). GTS-21, a selective α7nAChR agonist, has previously demonstrated to inhibit the inflammation associated with rheumatoid arthritis (RA). In this study we investigate whether GTS-21 protects against DSS-induced colitis and its potential mechanism.

Aims & Methods: Male BALB/c mice (8–10 weeks old, n = 32) were randomly divided into 4 groups: normal control group, DSS-induced group, GTS-21 treatment control group (DSS-induced mice treated with GTS-21), and α-BGT and GTS-21 (n = 8, each group). DSS group was given final concentration of 3.5% DSS drinking water, the treatment group was treated with GTS-21 (20mg/kg intraperitoneal injection/per day, α-BGT group was pre-treated with α-BGT (0.1 mg/kg/day, intraperitoneal injection) for 30 min prior to GTS-21 injection, and the control group received saline. Caco2 cells were randomly divided into 4 groups: normal control group, α-BGT induced group, GTS-21 treatment control group, α-BGT group. TNF-α group of Caco2 cells were exposed to 25 ng/ml TNF-α, GTS-21 group were given 100 ng/ml GTS-21 for 30 min prior to TNF-α, α-BGT group pre-treated with α-BGT (50 ng/ml) for 30 min prior to GTS-21 injection. Western blot was used to detect the tight junction protein and NF-κB associated protein expression.

Results: Compared with DSS-induced mice, ΔAI score decreased and colon length improved after administration of GTS-21 (9.1 ± 0.7 cm vs 6.8 ± 0.5 cm, p < 0.01). The α7nAChR antagonist α-BGT can eliminate those protective effects (Figure 1). The intestinal permeability improved after administration of GTS-21 compared with DSS-induced mice (49.52 ± 28.59 μg/mg vs 157.40 ± 32.40 μg/mg, p < 0.05), whereas α-BGT can block this effect (115.50 ± 10 μg/mg vs 49.52 ± 28.59 μg/mg, p < 0.05) (Figure 2, 3). The expressions and distribution of tight junction protein in DSS-induced mice were enhanced after treatment with GTS-21 (p < 0.05) (Figure 4, 5). GTS-21 attenuated the NF-κB activation (p < 0.05) (Figure 6). Inhibition reversed the inflammatory effect of GTS-21 (p < 0.05) (Figure 6). GTS-21 improves the distribution of tight junction proteins in the intestinal epithelial cells induced by TNF-α (Figure 7). GTS-21 reduces nuclear translocation of NF-κB in Caco2 cells induced by TNF-α (Figure 8).

Conclusion: Ther7 nicotinic acetylcholine receptors agonist GTS-21 can attenuate the intestinal inflammation in DSS-induced mice, which may be due to improving intestinal mucosal barrier function by enhancing the expression of tight junction protein.

P1621 ANAEMIA PREVALENCE AND TREATMENT APPROACH FOR INFILMAMMATORY BOWEL DISEASE

G. Bengi1, H. Keyvan2, H. Akpinar3
1Gastroenterology, Dokuz Eylul University Hospital, Izmir/Turkey
2Internal Medicine, Dokuz Eylul University Hospital, Izmir/Turkey

Contact E-mail Address: gokselbengi@hotmail.com

Introduction: For inflammatory bowel disease (IBD), anaemia is the most frequent complication. Anaemia causes fatigue, impaired performance and quality of life. This study was undertaken to determine the prevalence and type of anaemia in IBD and followed up at our hospital from January 2015 to June 2016 (male: 254, female: 211, average age: 47 ± 14.4, Crohn disease: 257, Ulcerative Colitis (UC): 254). According to World Health Organization standards, haemoglobin value is below 13g/dL in men and 12g/dL in women. Results: In our study, we determined that 50.3% of total 465 patients had anaemia, which was more frequent in women than men (64% vs. 39%, p < 0.001). Anaemia frequency was higher in CH cases (57%) than in UC cases (41%) (p = 0.001). CD involvement were as follows: 54.5% in ileal involvement, 60.4% in colonic involvement and 58.5% in ileocolonic involvement. Furthermore, 27.5% of UC patients had proctitis (E1) involvement while 41% of them had involvement in left colitis (E2) and 31.5% had pancolitis involvement. There was no significant relation between anaemia frequency and duration of disease (p = 0.216). We specified the following types of anaemia: IDA only 32.9% (77), ACD only 5.5% (13), IDA and ACD combination 6.8% (16), anemia stemming from B12/folic acid deficiency 6.4% (15), multiple anaemia 17.8% (41) and anaemia with no etiology 30.7% (72). 50% of patients with anaemia received treatment; 23% of IDA patients had oral iron intake and 41% of them had parenteral iron treatment while 53% of patients who were suffering from megaloblastic anaemia got B12/folic acid treatment.

<table>
<thead>
<tr>
<th>Reference</th>
<th>Page</th>
</tr>
</thead>
</table>
Conclusion: We found out that almost half of all IBD patients (50.3%), whom we followed up, had anaemia, the most frequent reason of which was IDA. Almost half of these patients received anaemia treatment. We should increase the treat- ment rate in our IBD patients that have anaemia.

Introduction: IBD is a chronic disorder of the gastrointestinal tract characterized by disruption of epithelial barrier function and gut inflammation. Evidence supports a relevant role of sucinate, an intermediate of the tricarboxylic acid cycle, in inflammation and the innate receptor, SUCNR1, has been recently been related with rheumatoid arthritis.

Aims & Methods: To analyze the role of SUCNR1 in a murine model of colitis induced by TNBS. WT or SUCNR1−/− mice received TNBS (3.5 mg/20g mice, intrarectally) or vehicle (EtOH 40%) and were weighed daily (results are expressed as percentage vs the weight at day 0) and mice were sacrificed 2 and 4 days after TNBS administration. Colon length and mucosal histology were evaluated according to Wallace Score (1–10). The mRNA expression levels of iNOS, Arginase I, COX-2, TNF-α, IL-1β, IL-4, IL-10 and IL-6 were analysed by qPCR.

Results: Treatment of mice with TNBS induced a loss of body weight that peaked 2 days after treatment. Subsequently, mice began to recover and, 4 days after treatment, body weight reached similar values to those of control animals. In TNBS-treated SUCNR1−/− mice compared with TNBS-treated WT mice: a) the loss of body weight was significantly (P < 0.05) attenuated (96.99 ± 0.7% vs 91.78 ± 1.1%) b) the reduction in colon length was prevented (6.6 ± 0.2 vs 5.2 ± 0.1 cm). The score was significantly reduced (3.5 ± 0.2 vs 4.8 ± 0.5) two days after TNBS treatment. d) The increase in the expression of pro-inflammatory factors, mucosal tight junction proteins (Occludin and ZO-1), and proteins related with endoplasmic reticulum stress (IRE1, XBP1, TRAF2, ASK1 and p-JNK), in addition, we used siRNA to silence IRE1 and SP600125 to inhibit the JNK pathway respectively, then evaluated the effect of endoplasmic reticulum stress on mucosal tight junction proteins.

Results: We found that ZIP7 was downregulated both in the intestinal mucosa of IBD patients and in I110−/− mice, which was associated with disease activity. In IEC6 and HIEC cells, the expression of mucosal tight junction proteins was consistent with the level of ZIP7, but the expression of inflammatory factors, mucosal tight junction proteins (Occludin and ZO-1), and proteins related with endoplasmic reticulum stress was associated proteins were on the contrary. After the silence of IRE1 and the inhibition of JNK pathway, the expression of mucosal tight junction proteins was partially resumed in ZIP7 downregulated cells.

Conclusion: ZIP7 induces disruption of the intestinal barrier, which was associated with activation of endoplasmic reticulum stress in IBD. It is expected to provide a novel mechanism of IBD and provide a new target for the treatment of IBD.

Introduction: Enteric glial cells (EGC) are found mainly in the myenteric and submucosal plexuses of the gut. EGC express the immune contact molecule Glial Cell Line Derived Neurotrophic Factor (GDNF) and the cytokine G-CSF, whose expression is increased in response to enteric inflammation (e.g. Crohn’s disease, IBD). This suggests that EGC might promote mucosal healing. In inflammatory bowel disease (IBD) such as Crohn’s disease, IBD and Ulcerative Colitis (UC), both EGC phenotype and functions are altered, but putative involvement of EGC in IBD pathogenesis remains unknown. If the astrocyte reactivity is well studied, the reaction of EGC to chronic inflammation is not well documented. We investigated whether EGC plays a role in mucosal healing and whether EGC promote a switch from IEC to IEB. Since EGC expression is increased in IBD, we focused on IEB pathogenesis. In non-IBD conditions, EGC promote a switch from IEC to IEB. We hypothesized that EGC promote a switch from IEB to IEB and that this switch is associated with IEB pathogenesis.

Aims & Methods: To analyse the interactions between immune and enteric neural cells, EGC isolated from the myenteric plexus of the rat digestive tract were co-cultured with CFSE-labelled T cells. Impact of T cell activation on neuro-immune interactions was investigated by treating T cells with anti-CD3/anti-CD28 antibodies. To determine whether inflammatory conditions favored the contacts between glial and immune cells, EGC were treated with LPS or TNF/IL1 prior their exposition to T cells. After 2 hours, non-adherent cells were removed and the T cells interacting with EGC (SI00) were counted. Immunocytochemistry were also used to characterize the subpopulations of T cells (CD4+, CD8+) that contact glial cells.

Results: Analyses reveal that non-activated T lymphocytes are capable of interacting with EGC. They also show that activation of T cells with anti-CD3/anti-CD28 antibodies increases the number of T lymphocytes interacting with EGC. Interestingly, an increased number of GEG-T cell interactions was observed after pretreatment of EGC with inflammatory stimuli. This phenomenon was also noted with activated T cells. Characterization of T cells show that both CD4 and CD8 cells are capable of contact with EGC.

Conclusion: Our present data reveal that EGC interact with T cells. These contacts are favored by T cell activation but also by EGC exposure to inflammatory cytokines. Further experiments are required to characterize these neuro-immune interactions but they suggest that EGC-T cell contact may play a crucial role in case of inflammatory bowel diseases. This work is supported by the Association Français Aupepit.

the permeability when compared to control animals. Human EGC from control or UC patients treated with T1 induced a decrease in IEB permeability too, but EGC from CD patients did not.

**Conclusion:** This work is not only the first evidence showing that reactive EGC can have beneficial effects upon IEB permeability, but also shows that EGC from CD but not UC patients have lost this reactivity. This could define EGC as active players in CD pathogenesis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1626 PROSTACYCLIN REVERSES COLITIS THROUGH THE DOWN REGULATION OF INTESTINAL EPITHELIAL PERMEABILITY**

C. Pochard1, P. Aubert1, C. Geser1, N. Cenc1, A. Bourreille1, G. Meurette1, E. Coror1, M. Neunlist1, M. Rolli-Derkinderen1

**Aims & Methods:**

The role of the lipid mediator PGI2 produced by PTGIS in IEB regulation is unknown. This study not only presents a role of PGI2 in controlling IEB permeability through the regulation of apoptosis mechanisms, but also reveals that increased permeability in IBD patients can be fixed by PGI2 supplementation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** 7α-Hydroxy-4-cholesten-3-one (7HCO) is a reliable method to diagnose bile acid malabsorption (BAM). Since 7HCO is an immediate metabolite in the bile acid synthesis, increased levels refer to bile acid production, which is the in vivo PGI2 supplementation significantly reduced IBD, and inflammation (Interferon mRNA) as well as reduced IEB permeability. DSS-induced clivage of Caspase 3 is normalized by flolan. Ex vivo measuring permeability of mouse or human mucosal explants treated with staurosporine apoptosis inducer, or permeability of IBD biopsies both treated or not with flolan.

**Results:** Biopsies from IBD patients had lower PGI2 production compared to control patients, and addition of flolan reduced their permeability. In vivo PGI2 supplementation significantly reduced IBD, and inflammation (Interferon mRNA) as well as reduced IEB permeability. DSS-induced clivage of Caspase 3 is normalized by flolan. Ex vivo, staurosporine-induced permeability of mice or human mucosal explants is entirely inhibited by flolan.

**Conclusion:** This study not only presents a role of PGI2 in controlling IEB permeability through the regulation of apoptosis mechanisms, but also reveals that increased permeability in IBD patients can be fixed by PGI2 supplementation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Ulcerative colitis (UC) is a clinical type of inflammatory bowel diseases. The pathogenesis of UC remains unclear. Nowadays the role of T-helpers type 17 (Th17) as well as cytokines they release is discussed in pathogenesis of autoimmune inflammation in UC.

**Aims & Methods:** The aim of study is to analyze the serum levels of following cytokines: interleukin (IL)-17A and F, 21, 22, 23, 10 in UC patients both in the acute stage of disease and remission. Forty eight UC patients in the acute stage and twenty patients in remission were included into the study. Serum cytokine levels were analyzed using multiplex immunoassay for Th17 cytokines (Bio-Rad, USA). Statistical analysis was performed using STATISTICA 6.0 Software Package. The control group consisted of 11 healthy volunteers.

**Results:** Statistically significant increase of IL-17A level (15 pg/ml [12.11;23.38]) and IL-21 (156.51 pg/ml [15.7;367.49]) compared to controls (48.7 pg/ml [38;78;67], 2.6 pg/ml [1.7;3.2], respectively). However, differences were not statistically significant (p = 0.06, p = 0.17, respectively). Increase of described cytokines levels could be a sign of Th17 functional overactivity suggesting autoimmune type of inflammation. Statistically significant increase of IL-10 in remission (27.99 pg/ml [15.73;33.55]) compared to controls (4.36 pg/ml [3.26;15.25], p = 0.0046) was found as well. IL-10 was also higher in patients with acute stage (21.93 [3.61;33.53]) compared to controls, however differences were not statistically significant (p = 0.06). IL-10 as an anti-inflammatory cytokine characterizes the activity of regulatory T-cells which suppress autoimmune inflammation. In addition, it was revealed that the level of IL-23 which stimulates Th17 differentiation was higher both in acute stage (258.4 pg/ml [55;367.49]) and remission (244.93 pg/ml [32.06;301.93]) compared to controls (124.3 pg/ml [107.9;296.04]), however differences were not statistically significant.

**Conclusion:** Increase of IL-17A, IL-17F, IL-21, IL-22 levels could be a sign of Th17 functional overactivity suggesting autoimmune type of inflammation. IL-17A and IL-21 produced by Th17 cells might be considered as markers of active autoimmune inflammation in UC patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P1629 ANP32E IS INVOLVED IN THE STEROID-REFRACTORY ULCERATIVE COLITIS
V. Lorente1, A. Garcia-Jarachequema1, J.E. Naves1, J. Carmona1, E. Cabré2, M. Mañosa1, J. Maryé1, E. Domínech1

Introduction: The steroid-refractoriness is a common complication of ulcerative colitis (UC). P32E is an unidentificated protein involved in the mRNA granules. The role of ANP32E has been implicated in corticosteroid failure. However, there are no conclusive studies on the molecular functions involved in UC steroid-refractoriness.

Aims & Methods: Therefore, we decided to know in depth the MoA related to the steroid-refractoriness. To address this, we performed a cohort of patients with UC treated with glucocorticoids. RNA from rectal biopsies was obtained before and on the 3rd day of glucocorticoid treatment. Then, whole-genome expression and immunohistochemistry analyses were performed on the rectal biopsy samples.

Results: As expected, DSS treatment resulted in severe weight loss, and even 7 days after ileo-colonic resection. In CD, colonic phenotype of the ileum was already reported at surgery, at 6 and 12 months after ileo-colonic resection (1). A clinical follow up at 5 years with clinical recurrence, both at 12 months (30 [0–40] versus 0 [0–35]; p = 0.02) and at 2 years (30 [0–40] versus 0 [0–35]; p = 0.03). The percentage of expression of sulfomucins in the ileal biopsies at 12 months was significantly correlated with the CDAI score at 6 months (r = 0.57, p = 0.015) and at 2 years (r = 0.53; p = 0.02). The ileal expression of sulfomucins in the surgical specimens at surgery was higher in patients with vs without clinical postoperative recurrence at 2 years (40 [10–99] vs 5 [5–50]; p = 0.04). The expression of colon mucin-type in the ileal biopsies at 12 months was higher in patients with vs without clinical recurrence, both at 12 months (30 [1–40] versus 0 [0–35]; p = 0.02) and at 2 years (30 [0–40] versus 0 [0–35]; p = 0.029). No correlations were observed between the percentage of expression of sulfomucins at surgery, at 6 or at 12 months and the haematochemical parameters considered.

Conclusion: In CD, colonic phenotype of the ileum as assessed by the expression of sulfomucins (colon mucin-type) and sialomucins (small intestine mucin-type) (1). In the present study, correlation between the percentage of expression of sulfomucins and clinical recurrence was evaluated yearly for 5 years. Statistical analysis: results expressed as median (range), correlations were assessed by the Spearman correlation test, differences between groups by the Mann-Whitney U test.

P1630 CO-HOUSING DSS TREATED MICE WITH HEALTHY MICE RESULTS IN FASTER NORMALIZATION OF THE INTESTINAL MICROBIOTA AND PROMOTES RECOVERY

Introduction: The ileal inflammation is usually accompanied by decreases of mucins (mucin-type). The expression of sulfomucins was significantly correlated with the CDAI score at 6 months (r = 0.57; p = 0.015) and at 2 years (r = 0.53; p = 0.02). The ileal expression of sulfomucins in the surgical specimens at surgery was higher in patients with vs without clinical postoperative recurrence at 2 years (40 [10–99] vs 5 [5–50]; p = 0.04). The expression of colon mucin-type in the ileal biopsies at 12 months was higher in patients with vs without clinical recurrence, both at 12 months (30 [1–40] versus 0 [0–35]; p = 0.02) and at 2 years (30 [0–40] versus 0 [0–35]; p = 0.029). No correlations were observed between the percentage of expression of sulfomucins at surgery, at 6 or at 12 months and the haematochemical parameters considered.

Conclusion: In CD, colonic phenotype of the ileum as assessed by the expression of sulfomucins (colon mucin-type) and sialomucins (small intestine mucin-type) (1). In the present study, correlation between the percentage of expression of sulfomucins and clinical recurrence was evaluated yearly for 5 years. Statistical analysis: results expressed as median (range), correlations were assessed by the Spearman correlation test, differences between groups by the Mann-Whitney U test.

Results: As expected, DSS treatment resulted in severe weight loss, and even 7 days after ileo-colonic resection (day 15), histology confirmed severe colitis. Intestinal inflammation was accompanied by an overall reduction of microbial diversity (decreased Shannon index, p < 0.01), and a marked shift in the composition of the microbiota (increased abundance of Verrucomicrobia, Cyanobacteria and some families of Firmicutes [mainly Clostridiaceae], although overall abundance of Firmicutes was decreased [p < 0.01 for all]). However, on day 15, these changes were less pronounced, indicating a normalization of the microbiota composition upon recovery. DSS-treated mice which were co-housed with healthy littermates after colitis induction, showed faster recovery (earlier weight gain, reduced histological scores, reduced levels of the infiltration marker myeloperoxidase). We observed differences in the abundances of the colon microbiota (p < 0.01 for all) and an earlier normalization of the microbiota composition.

Conclusion: Our results indicate that co-housing of DSS-treated mice with healthy mice results in transfer of healthy microbiota to diseased mice, and promotes recovery from colitis. This indicates that introduction of a "healthy" microbiota might have beneficial effects during intestinal inflammation and opens the possibility to systematically study the effect of genetic alterations in donor and/or recipient on the MoA of FMT.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Immunization of a quadrivalent influenza vaccine (A/California/7/2009(H1N1)pdm09, A/Switzerland/9715293/2013(NIB-88) (H3N2), B/Phuket/3073/2013, and B/Texas/2/2013) began in the 2015/2016 season. We assessed the immunogenicity and booster effect of quadrivalent influenza vaccine for adult inflammatory bowel disease patients treated with immunosuppressive drugs and/or anti-TNF-α agents.

Aims & Methods: Single vaccination group and booster group were randomly assigned to adult patients with crohn’s disease or ulcerative colitis, and quadrivalent influenza vaccine was administered subcutaneously. Serum samples were collected at 3 points (before vaccination, 4 weeks after vaccination and after the end of influenza season) in the single group and 4 points in the booster group (before vaccination, 4 weeks after the first vaccination, 4 weeks after the second vaccination and after the end of the influenza season). Antibody titer against each influenza strain was measured by inhibition of hemagglutination.

Results: A total of 132 patients with IBD were randomly assigned to single vaccination and booster groups. Eighteen patients received immunomodulatory monotherapy and 20 received anti-TNF-alpha single agent therapy. Nineteen patients received combination therapy of immunosuppressant and anti-TNF-α agents. No significant difference between the single vaccination group and booster group was observed (geometric mean titer: H1N1: p=0.81; H3N2: p=0.79; B/Phuket: p=0.82; B/Texas: p=0.84). In patients treated with infliximab, serum protection rate (SP%) and seroconversion rate (SC%) tended to be lower in influenza A strains in patients who maintained blood concentrations (P=0.15).

Conclusion: Serological response rate to influenza vaccination was low in IBD patients receiving immunosuppressant therapy, especially infliximab, even with a quadrivalent influenza vaccine. Disclosed Interest: All authors have declared no conflicts of interest.

Introduction: The global incidence of inflammatory bowel disease (IBD) is increasing. Migration may influence disease epidemiology. The UK demographics are affected by sustained migration from South Asia. The incidence of UC in South Asians (SA) was previously reported as higher than the Caucasian population. These single centre studies were done over 20 years ago. The current epidemiology of IBD in the multiethnic UK is unknown.

Aims & Methods: We aimed to describe the UK incidence of IBD and distribution within ethnic groups. Census data (2011) was used for background population size, ethnic groups and to identify areas with high SA populations where Indian and Pakistani were the predominant groups. The incidence was calculated by using the number of subjects in each ethnic group in the background population as the denominator. Adult patients (>16 years) with newly diagnosed IBD (fulfilling Copenhagen diagnostic criteria) were prospective recruited over one year in 7 catchment areas with high SA population. Data including demographics, ethnic codes and disease phenotype (Montreal classification) was collected onto the Epicom database. Chi-squared test was used to detect differences in IBD incidence between ethnic groups. A p value <0.05 was considered significant.

Results: Over 1 year IBD was diagnosed in 351 cases: 219 ulcerative colitis (UC), 107 Crohn’s disease (CD) and 26 Inflammatory bowel disease unclassified (IBDU). Collective crude incidence rates were 15.54/100,000 for IBD, 9.69/100,000 for UC, 4.80/100,000 for CD and 1.01/100,000 IBDU. (Table 1) Crude IBD incidence rates varied between populations: lowest was 6.81/100,000 in Pennine, North Manchester and highest 26.11/100,000 in Leicester. Overall incidence of UC was higher than CD (9.69/100,000 vs 4.80/100,000) and was consistent for all ethnic groups except Pennine (3.31/100,000 for CD and 2.76/100,000 UC). Of the total number of IBD cases recruited 298/351 were coded as Caucasian, Indian or Pakistani. IBD, UC and CD incidence was similar between Pakistani and Caucasian groups. UC incidence was significantly higher in the Indian population compared to Caucassians and Pakistanis (p < 0.001). Data for disease phenotype was available for 160/219 patients with UC (24% E1, 42% E2 and 34% E3). There was no significant difference in disease extent between ethnic groups.

Conclusion: The incidence rates for IBD in seven urban populations in England are similar to recent data from Western Europe (IBD 18.5/100,000, UC 9.8/100,000 CD 6.3/100,000 and IBDU 2.4/100,000). Ethnic-adjusted incidence rates showed that Indians have higher incidence of UC than Caucasians and Pakistanis with highest observed incidence in North West London. These findings are consistent with previous data suggesting that Indians have a higher predisposition for UC. Genetic, environmental and dietary factors may be responsible for differences and further analyses are underway. Better understanding of the susceptibility of Indians to UC may lead to the underlying cause of UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1634 IBD-RELATED MALIGNANCIES AND MORTALITIES: OBSERVED IN 2015–2016: RESULTS FROM THE PROSPECTIVE NATIONWIDE HUNGARIAN REGISTRY

Introduction: The increasing incidence of anal canal (AC) carcinomas in men and women requires better knowledge on Human papillomavirus (HPV) infection at this site and its risk factors. Higher incidence of AC cancers in Crohn’s disease (CD) patients is strongly suggested in the literature, without knowledge on HPV involvement. A gastroenterology population offers the opportunity to study a mixed and non-sexually at risk population and to study anal HPV infection in CD patients.

Aims & Methods: The aim of the study was to assess AC HPV infection prevalence and its risk factors in an gastroenterology population. The ‘Human Papillomavirus Anal infection’ - PAPILLAN- study took place in a French university hospital gastroenterology unit. Consecutive patients were prospectively recruited at the occasion of a colonoscopy, whatever the indication. On the colonoscopy day, under general anesthesia, AC smear was sampled with a dedicated brush for molecular analysis. HPV detection and genotyping was performed with the INNO-LiPA assay. Risk factors for any HPV, and high risk (HR) HPV infection were assessed by bivariate and multivariate analysis after logistic regression.

Results: A total of 469 consecutive patients (median age 54 years, 52% women) had suitable anal swabs for HPV DNA detection. Among them 101 had inflammatory bowel disease (IBD): 70 had CD. 112 patients had at least one immunosuppressive treatment for IBD or another condition. Overall 34% of the population had a detection of any HPV type in AC smears. HR HPV prevalence was 18%, LR HPV prevalence was 9% and HPV16 prevalence was 7%. Most prevalent HR HPV types were, by decreasing order: HPV16, HPV51, HPV52 and HPV39. Among all patients with HPV positive or HR HPV positive samples, 65.6% and 65.9% were women, respectively (p = 0.0001; 14%, p = 0.0072, compared to the rest of the study population). Eleven (12%) patients (50%) with perianal CD had an AC infection with any HPV. Multivariable analysis associated perianal female gender and history of sexually transmitted disease with the presence of HPV in AC; and female gender, history of sexually transmitted disease, lifetime and past year number of sexual partners, active smoking and immunosuppressive treatment (OR 5.3) with the presence of HR HPV.

Conclusion: We demonstrated that CD patients harbor more frequent AC infection with HR HPVs and that immunosuppressive treatment is an independent risk factor for HR HPV infection at this site. These findings strongly support prophylaxis with vaccination and adequate screening in our patients.

P1635 GUT COLONIZATION WITH EXTENDED SPECTRUM BETA-LACTAMASE PRODUCING ENTEROBACTERIA MAY INCREASE THE RISK OF INFECTION IN ANAL CANAL DISEASE OUTPATIENTS: PRELIMINARY STUDY RESULTS

Introduction: Extended spectrum beta-lactamase producing Enterobacteria (ESBL-E) are the most frequently found multi-drug resistant bacteria colonizing the gut of inflammatory bowel disease (IBD) patients. Changes in the microbiome may act as a trigger in IBD inflammation process.

Aims & Methods: The aim of the study was to analyze whether gut colonization with ESBL producing Enterobacteria can increase clinically relevant disease activity activity increase in ulcerative colitis (UC) and in Crohn’s disease (CD). All consecutive patients with confirmed UC and CD diagnosis, previously hospitalized in two largest tertiary medical care centers in Riga, Latvia during a 7-year period (2010-2016) were included in the study, interviewed, rectal swabs were collected. Enterobacteria were cultured and analyzed for ESBL presence according to EUCAST guidelines. To clinically evaluate disease activity patients UC patients were evaluated according to Mayo score, Montreal classification, adapted Truelove and Warren criteria and CD patients according to Crohn’s disease activity index (CDAI), suggested by ECCO IBD guidelines (2016).

Results: A total of 101 patients with UC and 47 patients with CD were tested for gut colonization with ESBL-E. We found that 12 (11.9%) of the UC patients and 5 (10.6%) of the CD patients were colonized with ESBL-E. Statistically significant differences were found in all UC clinical disease activity scores between patients with and without gut colonization with ESBL-E and showed tendency towards statistical significance in CD. The mean disease activity according to Mayo score in UC patients without ESBL-E colonization was 3.44 (SD = 2.07), whereas in patients with ESBL-E colonization it was 5.08 (SD = 2.84) (p = 0.015).

Most of the UC patients without ESBL-E colonization (n = 63; 70.8%) were in clinical remission, whereas half of the patients with ESBL-E colonization (n = 6;
50%) had mild to moderate to severe disease activity, according to Montreal classification diagnosis section (p = 0.037). Most of the UC patients with out ESBL-E colonization (n = 81; 91%) had mild disease activity, whereas half of the patients with ESBL-E colonization (n = 6; 50%) had moderate disease activity, according to modified Truelove and Witt’s criteria (p < 0.001). Most of the CD patients without ESBL-E colonization (n = 38; 90%) had moderate disease activity, whereas most of the patients with ESBL-E colonization (n = 3; 60%) had severe disease activity, according to CDAI (p = 0.05).

Conclusion: Gut colonization with ESBL-E might increase disease activity in out patients. Smoking could be clinically relevant and help to improve diagnostic and treatment protocols for IB patients, because eradication of ESBL producing bacteria might reduce IB disease activity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Primary sclerosing cholangitis (PSC) is a rare and devastating complication of inflammatory bowel disease (IBD). There is no standard for the screening of primary sclerosing cholangitis (PSC) in patients with IBD. Magnetic resonance cholangiography (MRC) may replace liver biopsy in this clinical situation. The main objective of this prospective observational study was to assess the frequency of MRC-detected liver abnormalities, including PSC, in adult IBD patients with liver function abnormalities and to identify clinical and biological characteristics associated with these findings.

Aims & Methods: From June 1, 2009 to January 31, 2017, 421 patients were included and screened with MRC: cohort 1 included 206 IBD patients with liver abnormalities; cohort 2 included 28 IBD patients without liver abnormalities; and cohort 3 included 187 non-IBD patients with liver abnormalities. Two senior radiologists independently evaluated MRC findings.

Results: MRC abnormalities were observed in 18% of patients in the cohort 1; 3.6% in the cohort 2; and 31% in the cohort 3 (Table 1). Based on MRC, we found respectively 11.2%, 0%, and 7% of PSC in cohorts 1, 2, and 3. 29.2% of IBD patients with liver abnormalities had infra-clinical PSC. A history of intestinal resection (P = 0.0357), abnormal gamma-galactamyl transferase values (P = 0.0064), and abnormal alkaline phosphatase values (P = 0.021) were significantly associated to suspected PSC.

Table 1: MRC abnormalities in cohorts 1, 2, and 3

Conclusion: Using MRC in patients with IBD, we found a higher prevalence of PSC than based on clinical symptoms. Systematic screening for PSC using MRC could be recommended in routine practice for IBD patients.

Introduction: The majority of Crohn’s disease (CD) patients undergoing surgery have been reported to have persistent activity despite adequate treatment. Therefore, in the current study, we aimed to evaluate the clinical outcomes of CD patients with stricture disease managed based on the CEUS findings. CD patients with stricture disease were recruited from two IBD centra between June 2015 and February 2017. Patients with penetrating disease complications were excluded. CEUS was performed with a 3.5 MHz linear transducer (SonoVue, Bracco Imaging). Patients having rapid uptake (within 20 second after injection) were indicated for therapy escalation, patients without uptake with obstructive symptoms were referred for surgery, patients without uptake and no obstructive symptoms remained at the stable medication. In patients with the minimal follow-up of one year clinical and endoscopic remission was evaluated.

Results: In total, 27 patients were included (10 men; median age 37 yrs, range 23–67; 22 pts with ileo-coecal localization, 3 pts with multiple small bowel segments involvement, 2 with colonic disease). Seventeen patients (63%) had rapid uptake at the CEUS; 13 of these patients had therapy escalation (3 pts intensification or switch of another biological; 10 pts had therapy step-up to antiTNF or immunosuppression). Three patients were referred after surgery. Ten patients (37%) had no rapid uptake at the CEUS; seven of these patients had symptomatic stricture disease referred for surgery. Three patients had no symptoms and no therapeutic changes were made. Twenty-five patients had follow-up longer than 12 months (median 18 months, range 13–23). In the group of patients with rapid uptake, all but two patients achieved sustained remission after therapy escalation. Two patients initially responded to therapy but have lost response and eventually needed surgery. In the group with no rapid uptake, patients without surgery remained in remission without any changes in the medication. Patients who underwent surgery in this group had a significant improvement in their functional status and none of these patients had recurrence at the surveillance colonoscopy at 12 months. Conclusion: Contrast-enhanced ultrasound might be helpful in guiding the therapeutic decision making between surgery and therapy intensification in patients with stricture Crohn’s disease.

Reference
Results: During this period 166 patients received anti-TNFα therapy. Before anti-
TNFα treatment, screening for LT was performed through medical history, chest
X-ray, tuberculin skin test (TST) and/or IGRA. Forty-two patients (25%) had
positive screening and received tuberculosis prophylaxis prior anti-TNFα ther-
apy. Seven patients (4.2%) developed tuberculosis while under anti-TNFα treat-
ment (four women, mean age 44 ± 7 years and mean IBD duration 10 ± 8 years).
Six of them had a negative LT screening (methods: 4 TST and 2 IGRA) and one
patient had positive TST screening, been treated with isoniazid before starting
anti-TNFα therapy. During screening three patients were under immune-
nosuppressive and one under corticosteroid treatment. In the IGRA negative
screening patients, the diagnosis of tuberculosis occurred within the first 10
weeks after starting anti-TNFα. There were five cases of miliary tuberculosis
and two of pulmonary disease. Despite difficult diagnosis, all patients were trea-
ted successfully, six of whom needed hospitalization.

Conclusion: In our centre the incidence of tuberculosis in IBD patients under
anti-TNFα therapy was 4.2% and most of them presenting with a severe disease
pattern. The therapeutic regime of tuberculosis was effective and no mortality
was recorded. All this patient had previously a negative screening, two of them
with IGRA, been considered a high sensitivity and specificity screening method.
Therefore, a surveillance strategy for IBD patients with anti-TNFα therapy is
needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1649 EVALUATION OF MODIFIED MAYO ENDOSCOPIC SCORE AND DUBLIN SCORING SYSTEM TO CORRELATE ULCERATIVE COLITIS EXTENSION, IN THE PREDICTION OF RELAPSE

1Gastroenterologia, CHVNG/E, Vila Nova De Gaia/Portugal
2Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova De Gaia/Portugal

Contact E-mail Address: jaimepereirarodrigues@gmail.com

Introduction: Current endoscopic activity scores for Ulcerative Colitis (UC) do not take into account the extent of mucosal inflammation. Recently, two endoscopic scores that combine the assessment of severity and disease extension were developed, the Modified Mayo Endoscopic Score (MMES)1 and Degree of Ulcerative Colitis Burden of Luminal Inflammation (DUBLIN)2. We aimed to evaluate the relation of the scores with disease activity and as predictive factors of clinical relapse. Patients with UC in clinical remission (partial Mayo score [pMS] ≤1) who underwent colonoscopy between January/2010 and December/2013 were included. MMES and DUBLIN scores were calculated. Analytical and histological activity (defined by Geboes score ≥3.1 and Nancy score ≥2–4) as well as predictive factors of relapse and relapse-free time were evaluated. Relapse was defined as pMS ≥2, therapy to induce remission, hospitalization and/or colectomy.

Results: 82 patients were selected. 51.2% (n = 42) female, mean age 49.4 ± 13.7 years. MMES ranged between 0–13.8 and DUBLIN between 0–9. MMES and DUBLIN scores presented good correlation (r = 0.945, p < 0.001). MMES was higher in patients with histological activity defined by Nancy (3.7 ± 4.0 vs. 0.8 ± 1.5; p < 0.001) and Geboes (4.0 ± 4.2 vs. 1.3 ± 2.4; p = 0.005). DUBLIN was also higher in patients with histological activity defined by Nancy (1.9 ± 2.1 vs. 0.5 ± 0.8; p = 0.001) and Geboes (2.0 ± 2.3 vs. 0.7 ± 1.2; p = 0.000). There was no significant correlation between both scores and analytical activity. Relapse occurred in 36.6% (n = 30) of patients, with a cumulative risk of 9.8, 18.4, 25.9, and 42.0% at 12, 24, 36, 48 and 60 months, respectively. Mayo Endoscopic Subscore (MES) (p = 0.001), MMES (p = 0.001), and Nancy score (p = 0.001) presented a significant association with relapse. In multivariate analysis, MES (OR = 2.32; p < 0.001), MMES (OR = 1.19; p < 0.001) and DUBLIN (OR = 1.36; p < 0.001) were predictive of relapse independently from histology. Areas under the ROC curve were 0.71 (95% CI: 0.60–0.81), 0.75 (95% CI: 0.62–0.88) and 0.74 (DUBLIN, p = 0.001) for prediction of relapse, with MMES significantly higher than MES by a difference of 0.037 (0.002–0.072); p = 0.03.

Conclusion: MMES and DUBLIN scores correlate with each other and with histological activity. MMES is an independent predictor of relapse. MMES was superior to MES in the prediction of relapse.

Introduction: Magnetic resonance enterography (MRE) is an imaging technique recommended to determine and confirm the extension and activity of Crohn's disease (CD) in the small bowel and discriminate penetrating disease and complications. MRE diagnosis allows to optimize medical treatment in IBD patients.

Aims and Methods: The aim of this study is to evaluate the impact of MRE on medical decision-making in IBD patients and determine the maintenance of this new treatment along the time. Consecutive MRE studies performed in patients with confirmed or suspected Crohn's disease between January 2011 and August 2014 were included in this retrospective study. Medical charts were retrospectively reviewed. MRE indication, demographic and IBD data were collected at time of MRE. Three months after MRE, medical decision (conservative approach with maintenance therapy, significant change in medical therapy or surgery) was assessed. After twelve months of follow-up, the treatment decided after MRE was reviewed.

Results: A total of 474 MRE studies were performed and indications for MRE were: assessment of small bowel involvement in 40 (8.3%) patients with indeterminate colitis (IC) and 20 (4.2%) with suspected-IBD patients or evaluation of severity and extension of the disease in 414 (87.5%) CD patients (232 F; mean age 37 ± 13 years). Only 4 patients with suspected-IBD (4/20.20%) had involvement of small bowel on MRE confirming the CD diagnosis. Twenty-one patients with IC (21/40;52.5%) changed the diagnosis to CD. In 199/474 (40.5%) MRE determined a change on medical decision and 140 (70.3%) patients modified maintenance treatment because of MRE findings. Of them, 127 (63.8%) underwent treatment by prescribing immunosuppressants (IS) (n = 45), anti-TNF agents (n = 22), anti-TNF escalation (n = 8), adding IS to anti-TNF agents (n = 9) and changing anti-TNF agents (n = 5). In addition, 13 (9.2%) patients underwent “top-down” therapy due to stop IS (n = 7), anti-TNF (n = 3) or anti-TNF de-escalation (n = 3). Surgery was indicated in 62 (62/ 199;31.1%) patients after MRE. After one year of follow-up, the medical decision was maintained in 65.4% (288/440) of patients.

Conclusion: RE is a very helpful tool for the medical management of CD patients. MRE provides major information to optimize treatment in the long-term of patients with active CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims and Methods: The aim of the present study was (1) to identify factors associated with bowel damage and with disability in CD and (2) to evaluate the correlation between the LI and the IBD-DI. We performed a prospective study in the tertiary referral center of the Clin. Huriez Hospital, Lille, France from September 2016 to November 2016, including all consecutive CD outpatients.

Bowel damage was assessed by the LI calculated according to the published LI protocol. Abdominal and pelvic Magnetic resonance imaging (MRI)s were reviewed and red by the same couple of one gastroenterologist and one radiologist. The IBD-DI was also calculated for all patients. Factors associated with LI and IBD-DI levels were identified by means of bivariate analyses of variance. Receiver Operating Characteristic (ROC) curves were prospectively and post-hoc included. Median age was 34.0 (interquartile range [IQR]: 26.0–46.0) and median disease duration was 10.0 (IQR: 5.0–17.0) years. 65 patients (50%) underwent at least one resection surgery. The median LI was 10.8 (IQR: 0.6–17.5). Disease duration (p < 0.0001), calculated anal location (p < 0.0001) and CD activity (p < 0.0001) were associated with higher LI scores. Median IBD-DI was 25.0 (IQR: 14.7–41.1). Female gender (p = 0.02), CD activity (p < 0.0001) and current anoperineal lesions assessed by clinical examination and pelvic MRIs (p = 0.001) were associated with higher IBD-DI scores. The correlation coefficient between the LI and the IBD-DI was 0.12 (r = -0.05, 0.29; p = 0.154).

Conclusion: In a large cohort of CD patients from a tertiary referral CD center, disease duration, anal location and CD activity are correlated with bowel damage assessed by the LI, while female gender, disease activity and current anoperineal lesions are associated with disability assessed by the IBD-DI. Correlation between the LI and the IBD-DI was low.

Disclosure of Interest: All authors have declared no conflicts of interest.

In UC patients, we observed higher expression of IL-8 (p = 0.005) and UC patients. The expression of cytokines in inflamed and non-inflamed mucosa separately for CD and UC patients.

Results: In UC patients, we observed higher expression of IL-8 (p = 0.04), IL-23 (p = 0.019), TLR2 (p = 0.002), CCR1 (p = 0.007), CCR2 (p = 0.037), CCR5 (p < 0.01), CD206 (p = 0.011), TNFz (p = 0.002) and IL-6 (p = 0.006) in the inflamed mucosa from sigma. In CD patients, we observed increased expression of IL-1β (p = 0.005) and IL-8 (p = 0.001) in the inflamed mucosa of a terminal ileum and decreased expression of CCL5. Also, in group of patients with CD we did not observe the difference of the expression of mRNA cytokines between the inflamed and non-inflamed mucosa of sigma.

Conclusion: There was a significant difference in the mRNA cytokine profiles between CD and UC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1654 THE RELATIONSHIP OF NEUTROPHELIC AND ENDOTHELIAL ACTIVITY MARKERS WITH THE DISEASE ACTIVITY IN INFLAMMATORY BOWEL DISEASE

S. Boga1, A.R. Koksal1, H. Alkim1, A. A. Ozargaci1, I. Sen1, M. Sahin1, C. Alkim1

Contact E-mail Address: salihboga@yahoo.com

Introduction: Disease activity in inflammatory bowel disorders and its level reflects neutrophilic activity. Endoglin is the receptor and modulator of endothelial TGF-β and it is responsible for the endothelial activation secondary to inflammation. Although the increase in endothelial expression with the inflammation in the colonic mucosa of mice was shown before, its relationship with the disease activity in inflammatory bowel disease (IBD) is not searched yet. The relationship of serum NGAL and serum and colonic endoglin levels in ulcerative colitis (UC) and Crohn’s disease (CD) patients were investigated in this study.

Aims & Methods: Eighty-six UC, 63 CD, 36 non-IBD (screening, irritable bowel syndrome) and 52 healthy controls who were followed up in Gastroenterology Department of Sisli Hamidiye Etfal Education and Research Hospital between years 2015-2016 were enrolled. Patients were evaluated by endoscopic (Rachmilewitz index for UC, simple endoscopic score for CD (SES-CD)) for CD clinical (colitis activity index (CIA) for UC and CD activity index (CDAI) for CD), and pathologic activity scores and immunohistochemical staining.

Results: There were no differences between UC and CD patients in terms of serum NGAL and endoglin levels. NGAL and endoglin levels were significantly higher in endoscopically active UC group (n = 59) (142.8 ± 67.8 ng/mL and 457.7 ± 28.9 ng/mL) compared to inactive UC (n = 27) (119.7 ± 26.3 ng/mL and 476.9 ± 134.2 ng/mL), to non-IBD (115.8 ± 27.2 ng/mL and 460.6 ± 103.2 ng/mL) and to controls (116.7 ± 31.7 ng/mL and 457.2 ± 114.1 pg/mL). Although there were limited number of inactive CD patients (n = 11), serum NGAL and endoglin levels were significantly higher in endoscopically active CD group (n = 52) (135.0 ± 28.9 ng/mL and 555.6 ± 133.6 pg/mL) compared to inactive CD (115.2 ± 35.9 ng/mL and 458.7 ± 132.8 pg/mL), to non-IBD and to controls (Figure). Structuring and fistulizing CD groups had significantly higher endoglin levels compared to inflammatory CD (p < 0.001 and p = 0.001). NGAL levels were significantly increasing with the increasing disease extension in UC and CD (p = 0.012 and p < 0.001). While the clinical activity subgroups were evaluated, there were significant difference in UC and CD patients in terms of endoglin levels but not NGAL levels (Endoglin: p = 0.002 p = 0.574, NGAL: p = 0.020, p = 0.171). Endoglin levels were more strongly correlated with the pathologic activity scores in both UC and CD groups compared to NGAL levels (Endoglin: r = 0.443, p < 0.001; r = 0.453, p < 0.001; NGAL: r = 0.274, p = 0.011; r = 0.409, p = 0.001). The immunohistochemical staining index of endoglin showed positive correlation with the immunohistochemical staining of vascular endothelial growth factor (VEGF) (UC r = 0.486, p < 0.001; CD r = 0.383, p = 0.011). The immunohistochemical staining index of endoglin in the colonic mucosa was correlated with the serum levels of endoglin in both UC and CD patients (UC r = 0.641, p < 0.001; CD r = 0.437, p < 0.001).

Conclusion: The present study highlights significant associations between endoglin and NGAL and IBD presence and activity, and demonstrates elevated serum and colonic endoglin levels in patients with active IBD as a novel finding.

Introduction: Although thiopurine-induced myelotoxicity and hepatotoxicity rarely occur during maintenance thiopurine therapy for inflammatory bowel disease (IBD), current guidelines advise laboratory monitoring every 3 months. This study was performed to assess the current laboratory monitoring regime in thiopurine maintenance therapy with regards to consequences of myelotoxicity and hepatotoxicity.

Aims & Methods: In this multicenter cohort study, we evaluated adult IBD patients with quiescent disease who were on maintenance thiopurine therapy between 2000–2016. Data collection started after 12 consecutive months of thiopurine treatment. The primary outcome was therapy adjustment, i.e. therapy cessation or dose reduction, due to myelotoxicity (leukocyte count <4.0 10^9/l, platelet count <150 10^9/l) and/or hepatotoxicity (alkaline phosphatase (AP), gamma-glutamyltransferase (γ-GT), alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST) above the upper limit of normal (ULN)). The secondary outcomes were prevalence of myelotoxicity and hepatotoxicity and additional diagnostic procedures due to this toxicity.

Results: This study included 223 IBD patients (55% female, 64% with Crohn’s disease, mean age at diagnosis 27.2 years (SD 11.5). Median follow-up was 3.2 years (IQR 1.9-4.7). The mean monitoring frequency was 3.3 assessments per treatment year (SD 1.8). Toxicity was observed in 445/2402 laboratory assessments (18.5%) in 120 patients. In total, 20 (0.8%) therapy adjustments were performed and 25 laboratory assessments (1.0%) led to additional diagnostic procedures. Myelotoxicity, observed in 244 assessments, led to 11 dose reductions and in 3 patients therapy was stopped. For hepatotoxicity, observed in 201 assessments, 2 dose reductions were performed and in 4 patients therapy was stopped. Ninety percent of observed toxicity were mild leukopenia (leukocyte count 3.0-4.0) or mild hepatotoxicity (<2 ULN), primarily in the first years of treatment. Dose adjustments were more often associated with moderate leukopenia (leukocyte count <3.0) than with mild leukopenia (p < 0.01). In total, 2 complications were recorded; 1 patient was hospitalized because of pancreatitis and received red blood cell transfusion, and 1 patient was treated for a CMV infection. Both patients presented with symptoms in clinic with preceding normal laboratory values. No mortality due to thiopurine-induced toxicity was observed.

Conclusion: Although mild toxicity is common during maintenance thiopurine therapy, adjustments based on laboratory assessments are rare. Therefore, a less intensive regime to monitor thiopurine-induced toxicity should be considered.

P1657 CLINICAL CHARACTERISTICS OF RECITAL-SPARING ULCERATIVE COLITIS

A. Ito, O. Teppi, T. Katuyoshi
Dept. Medicine, Inst. Gastroenterology, Tokyo Womans Medical University, Tokyo,Japan

Contact E-mail Address: itoayumi@ieg.twu.ac.jp

Introduction: Ulcerative colitis (UC) generally involves the entire large intestine extending from the rectum to the ileoceleal junction. However, some patients with moderate or severe UC lack any obvious rectal involvement (known as rectal sparing- (RS)-UC).

Aims & Methods: In this study, we evaluated the differences in the clinical characteristics between patients with rectal UC with or without RS. Of the 437 inpatients with rectal UC who achieved remission between April 2001 and September 2016 (follow-up period: 91.5 ± 53 days, mean ± SD), 57 patients were classified as RS-UC and 340 patients without RS (standard [S]-UC group). Patients of the two groups were compared for gender, age at onset, site of involvement, disease duration, pretreatment clinical activity index (CAI, Lichtiger score), Hb, C-reactive protein (CRP), endoscopic scores (Mayo and UCEIS), and relapse rates (at 100, 300, 500, 1000 days post-remission). Patients with RS were defined as those without any detectable rectal inflammation despite not receiving local treatment, such as rectal enemas, instillation or suppositories. Remission was defined as CAI ≤5.

Conclusion: Relapse was defined as the need to restart remission induction therapy, such as intensive intravenous PSL, initiation of treatment with biological agent, or readmission and dose escalation of tacrolimus to achieve a high blood trough level (>6 μg/dL).

Results: RS was observed in 57 (10.4%) patients. There were significant differences in CRP (RS-UC: 5.1 ± 6.02, S-UC: 2.3 ± 3.4 mg/L) and pretreatment endoscopic scores (Mayo: RS-UC: 2.7 ± 0.3, S-UC: 2.4 ± 0.5; UCEIS: RS-UC: 6.9 ± 1.2, S-UC: 7.3 ± 0.8). There was no significant difference in the relapse rate at 100 days after remission (RS-UC: 18%, S-UC: 15%). However, the two groups showed significant differences in the relapse rates at 300 days (RS-UC: 38%, S-UC: 17%), 500 days (RS-UC: 53%, S-UC: 48%), and 1000 days (RS-UC: 77%, S-UC: 62%) after remission.

Conclusion: Our results showed that RS is not an uncommon finding among patients with UC. Based on the higher CRP, endoscopic score, and relapse rates in the RS group, we recommend aggressive treatment in patients with RS.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1658 EVALUATION OF COLONIC MUCOSA WITH FLEXIBLE SMALL-FOCUS ENDOSCOPY COLOR ENHANCEMENT (FICE) IN PATIENTS WITH LONG TERM ULCERATIVE COLITIS DURING DYSPLASIA SCREENING

Contact E-mail Address: sedozdinc@yahoo.com

Introduction: Ulcerative colitis (UC) associated colorectal cancer risk (CRC) is related to the age of onset and duration and anatomic extent of the disease. The risk of CRC increases with the duration of the disease (1). Current guidelines recommend beginning the surveillance colonoscopy after eight to ten years of disease; random biopsies should be obtained from 4 quadrants of every 10 cm of the colon at each examination, any suspicious areas should be biopsied (2). Recent endoscopic imaging technologies provide a more detailed visualization of the superficial microstructure of the mucosa and vascularity. Thus it is possible to get targeted biopsies. The purpose of this study is to; evaluate the image patterns of dysplasias in ulcerative colitis, and their histopathological correlation, by using a virtual chromoendoscopy technique, FICE and to investigate the effectiveness of this technique.

Aims & Methods: The purpose of this study is; to evaluate the image patterns of dysplastic changes in ulcerative colitis, and their histopathological correlation, by using a virtual chromoendoscopy technique, FICE and to investigate the effectiveness of this technique.

Results: In a total of 18 patients, by evaluating 123 colonic segments, 1831 images were obtained. For the first study, the FICE images were compared with histopathological diagnosis. Normal, colitis and polypos images acquired by FICE, were evaluated by seven endoscopists and statistical analysis was performed.

Conclusion: There were no significant superiority of FICE, in dysplasia screening. Compared with the literature and the results of this study, we showed that FICE is advantageous in detecting diminutive polyps, and evaluating surface patterns without magnification. In clinical remission in patients with UC, FICE can have a role in the assessment of the severity of inflammation. For this purpose, more clinical trials are needed. Our study results are compared with FICE in UC. Channels 2 and 9 are the best image channels of FICE in UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The gut microbiome is thought to be relevant to the pathogenesis of inflammatory bowel disease (IBD). We aimed to explore associations between microbiota and clinical and as well as inflammatory disease activity in an inception cohort of treatment-naïve IBD patients as well as with inflammatory activity in symptomatic non-IBD patients and healthy controls. The term ‘dysbiosis’ expresses alterations in the gut microbial community.

Aims & Methods: Patients were included according to international criteria, including endoscopic and histopathological assessment. Clinical disease activity in Crohn’s Disease (CD) patients was measured by the Harvey-Bradshaw index (HBI), and in ulcerative colitis (UC) patients by the Simple Clinical Colitis Activity Index (SCCAI). Inflammatory activity was assessed by CRP and faecal calprotectin (Fcal). (FCAL® ELISA, Bithmann laboratories AG). Stool samples were collected within 60 days prior to and 14 days after the diagnosis, and stored at −80 °C. Antibiotic treatment within the last two months was an exclusion criterion. 17 fecal microbial profiles were generated by 16S rRNA analyses, using the GA-mapTM Dysbiosis Test. Dysbiosis was defined as norm, mild or severe (1). Differences in disease activity between levels of dysbiosis severity were analysed using ANOVA at a significance level of 0.05. In addition to dysbiosis activity and log-transformed microbiota profiles were analysed using ANCOVA. P-values corrected for multiple testing, using Benjamini-Hochberg correction, are presented. Microbial diversity was assessed by using Chao1 and Faith’s indices.

Results: A total of 77 UC patients (P = 0.08), 88 symptomatic non-IBD patients. HBI was available for 50 CD patients, while SCCAI was available for 77 UC patients. Disease activity: No association was found between Fcal and dysbiotic activity in UC patients (P = 0.08), CD patients (P = 0.22), and healthy controls (P = 0.57). However, an association was found between Fcal and dysbiotic activity in symptomatic non-IBD patients (P = 0.04) and in UC patients (P = 0.005). An association was found between CRP and dysbiosis in CD patients (P = 0.02), while not for UC and symptomatic non-IBD patients. No association was found between HBI and dysbiotic activity in CD patients (P = 0.23), and between SCCAI and dysbiosis in UC patients (P = 0.32). Microbiota: Increasing disease activity in UC, CD and non-IBD patients yielded increase abundance of Faecalibacterium prausnitzii, and higher abundance of Proteobacteria, a profile typically observed in gut inflammatory conditions. In addition, the commensal bacteria Bifidobacterium yielded lower abundance with increased dysbiotic severity in UC and non-IBD patients, and in combination with elevated levels of Fcal and/or FCR in UC patients. In the healthy controls, increasing dysbiosis severity yielded lower abundance of Proteobacteria.

Conclusion: In conclusion, a relationship between faecal dysbiosis in sub-groups of IBD patients and disease activity and CRP were found. Accordingly, gut bacteria profiles and abundance may potentially be used to differentiate between severity in UC and CD patients, as a non-invasive tool to monitor disease activity in IBD.

**Introduction:** Crohn’s disease (CD) is a lifelong inflammatory bowel disease. Evaluating the extent and severity of the disease is critical to determine appropriate therapeutic strategies in patients with Crohn’s disease. MR imaging is one of the most recommended technique for detection of large and small bowel lesions. We investigated the diagnostic clinical utility of the 3-point MR enterocolonography (MREC) classification for assessing CD activity based on endoscopic findings. 

**Aims & Methods:** A total of 120 patients (70 for derivation cohort and 50 for validation cohort) with CD and underwent MREC and ileocolonoscopy or balloon-assisted enteroscopy (BAE). MREC was evaluated for each bowel segment; rectum, sigmoid, descending, transverse, ascending colon, terminal, proximal ileum, and jejunum, according to the consensus of two observers in the derivation phase, and independently by three observers in the validation phase, using a 5-point MREC classification based on a lexicon of MR findings. The conventional MR score, or MaRIA, was evaluated simultaneously. Areas under the receiver operating characteristic curves (AUCs) were obtained to assess the accuracy of discriminating deep ulcers. Inter-observer reproducibility was assessed using weighted Kappa coefficients. 

**Results:** BAE was performed in 49 (70%) and 37 (74%) patients in the derivation and validation cohorts. The AUCs of MREC classification were 89.0% in the derivation phase and 88.5, 81.0, and 77.3% for three observers in the validation phase. The AUCs of MREC classification were statistically non-inferior to those of MaRIA (p < 0.001). The cross-validation accuracy was 81.9% in the derivation and 81.3% in the validation phase. The MREC classification showed good clinical validity.

**Conclusion:** For clinical use, radiological reporting systems should be simple and provide appropriate levels of accuracy and reproducibility. The 5-point MREC classification meets these requirements, and is useful for evaluating CD activity in the large and small bowel segments.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Metabolic syndrome (MetS) is a combination of biochemical and anthropometric disturbances and a recognized risk factor for cardiovascular disease. A higher prevalence of this condition has been previously reported in IBD patients, correlating to age as in the general population.

**Aims & Methods:** The aim of this study was to assess the effect of individual disease activity-related putative risk factors for MetS in a group of IBD patients, as well as any protective effects of treatment on MetS or its components. Consecutive IBD patients and age- and sex-matched controls were included as well as any protective effects of treatment on MetS or its components. Disease activity-related putative risk factors for MetS in a group of IBD patients, and validation cohorts. The AUCs of MREC classification were 89.0% in the derivation phase. The MREC classification showed good under the receiver operating characteristic curves (AUCs) were obtained to assess the accuracy of discriminating deep ulcers. Inter-observer reproducibility was assessed using weighted Kappa coefficients. 

**Results:** BAE was performed in 49 (70%) and 37 (74%) patients in the derivation and validation cohorts. The AUCs of MREC classification were 89.0% in the derivation phase and 88.5, 81.0, and 77.3% for three observers in the validation phase. The AUCs of MREC classification were statistically non-inferior to those of MaRIA (p < 0.001). The cross-validation accuracy was 81.9% in the derivation and 81.3% in the validation phase. The MREC classification showed good clinical validity.

**Conclusion:** For clinical use, radiological reporting systems should be simple and provide appropriate levels of accuracy and reproducibility. The 5-point MREC classification meets these requirements, and is useful for evaluating CD activity in the large and small bowel segments.

**Contact Email Address:** sara.s.monteiro@gmail.com

**Introduction:** Patients with acute severe ulcerative colitis (ASUC) have a high risk of rescue medical therapy or colectomy. Recently, the C-reactive protein (CRP)/albumin ratio at the 3rd day of treatment, with intravenous corticosteroids, has been shown to be a predictor of early colectomy in patients with ASUC.

**Aims & Methods:** To evaluate the accuracy of CRP/albumin ratio on admission, to predict response to intravenous corticosteroids in patients with ASUC. Retrospective assessment of systematically hospitalized patients with first episode of ASUC, who required intravenous corticosteroids. Demographic, clinical, laboratory and endoscopic variables were evaluated on admission. The response to intravenous corticosteroids at week 13 was based on CRP/albumin ratio. For non-responsive patients, rescue medical therapy with infliximab or cyclosporine has been instituted. The accuracy of CRP/albumin ratio in predicting non-response to intravenous corticosteroids was assessed by the area under the ROC curve (AUC).

**Results:** 51 patients were included, 30 (58.8%) of them female, with a mean age 34.3 ± 14.5 years. Twelve patients (23.5%) required medical rescue therapy. No patient underwent colectomy. The presence of deep ulcers and a shorter evolution of the disease were associated with a lack of response to intravenous corticosteroids, < p 0.001 and p = 0.008, respectively. Patients with no response to intravenous corticosteroids had higher CRP admission values and lower albumin values, compared to patients with response, 111 vs 67.5 (mg/L), p = 0.028, 2.8 vs 3.5 (g/dL), p = 0.005, respectively. The CRP/albumin ratio was higher in unresponsive patients 40.06 vs 22.14, p = 0.022, showing a good accuracy for predicting no response to intravenous corticosteroids with an AUC of 0.746, p = 0.01.

**Conclusion:** A high value of CRP/albumin ratio was significantly associated with the lack of response to intravenous corticosteroids, at the 3rd day of treatment. This index may allow a better risk stratification on admission, of patients with acute severe ulcerative colitis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The MCV flow study confirmed the association ΔMVC ≥7fl at week 26-28 of Azathioprine monotherapy (mAzA) with favourable outcomes in a Portuguese IBD population.

**Aims & Methods:** For this work, our aims were to evaluate the need for step-up therapy in those under mAzA with ΔMVC < 7fl and to identify predictors of combined deep remission outcomes (DeepRem), at the same timepoint, for the patients who subsequently began combination therapy with Anti-TNF (AzaExposed + Anti-TNF). Evaluation of patients under mAzA with ΔMVC < 7 at key timepoint week 26-28 treatment, included for The MCV flow study. Demographic characterization and severity of pre-treatment disease was evaluated (Montreal classification, previous surgery status, Mayo score and Crohn’s disease activity index [CDAI]). ΔMVC’s association with DeepRem [Steroid-free clinical remission (CDAI < 150, Mayo < 2) + mucosal healing (MH)+C-reactive protein (CRP) < 10] and need for biological therapy at the key timepoint was verified. Evaluation of DeepRem in mAzA was an independent predictor in patients who subsequently started combination therapy. Statistical: Chi-square test; Binary logistic regression.

**Results:** A total of 106 IBD patients were evaluated [56.6% women, mean age 39 ± 15.2 years; 58 ad, 14% operated] at week 26-28 of mAzA. Identified strong association between an average ΔMVC ≥7 (n=70; 66%) with DeepRem (p < 0.05), while a ΔMVC ≥7 was associated with biological therapy need (p < 0.05). 45 patients were later started with Anti-TNF therapy.
(Aza + Infliximab 46.7%; Aza + Adalimumab 53.3%) and only 44% achieved DeepRem at the key-timepoint. A Crohn’s A3L2B3 + phenotype (p = 0.045), steroid therapy in the last year (p = 0.009) and ΔVGM < 7 (p = 0.036) were identified as the variables that best explained the difficulty reaching DeepRem. 

Conclusion: This study confirms the prognostic value of ΔVGM in our popula-
tion. ΔVGM ≥ 7 was associated with DeepRem and ΔVGM < 7 was found to be associated with biological therapy need. However, even after starting Anti-TNF, ΔVGM < 7 was identified as a predictor of the difficulty reaching DeepRem.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1666 THE ROLE OF MR IMAGING IN ASSESSMENT OF LENMANN INDEX IN THE COURSE OF CROHN’S DISEASE
J.M. Pieniowska, O. Kozak, T. Nowicki, E. Szurawska
Radiology, Medical University of Gdańsk, Gdańsk/Poland
Contact E-mail Address: oliwiax@gumed.edu.pl

Introduction: Crohn’s disease (CD) is a progressive, chronic and destructive inflammatory bowel process which, during its course, can lead to complications such as strictures and penetrating lesions (fistulas and abscesses), which may consequently require operative treatment. In some patients, bowel damage is present at the moment of diagnosis. The aim of the study is to assess the initial Lemann Index (LI), which comprehensively evaluates the entire gastrointestinal tract damage in patients with newly diagnosed Crohn’s disease.

Aims & Methods: In 209 patients with clinical suspicions of Crohn’s disease MR imaging of the digestive tract was performed. The results of endoscopic examination and histopathology were performed. In 151 patients with confirmed active/chronic CD the Lemann Index has been calculated on the basis of radiological and clinical information for initial assessment of cumulative digestive tissue damage. To create the Lemann Index the gastrointestinal tract damage was divided into 4 organs: upper digestive tract, small bowel, colon, rectum and anus. Each organ was divided into segments (3 for the upper digestive tract, 6 for the colon/rectum and 1 for anus). Strictures and penetrating lesions were assessed at each segment on 4-degree scale (0–3) according to the severity of lesions.

Results: Based on the findings of the initial radiological examination, active inflammation process was found in 76 patients and chronic process in 75 patients. The baseline study demonstrated such complications as strictures in 14 patients, fistulas in 15 and abscesses in 4 patients. For all patients the LI was calculated. The obtained values were within the range from 0 to 22.

Conclusion: Over the years, the progression of Crohn’s disease leads to an increase in the value of Lemann Index, therefore, it seems that the evaluation of the first, baseline stage might be useful in all following control MR examinations will allow for a more complete assessment of patients in terms of progressive bowel damage and modification of the therapeutic process.

be required to obtain a 2x2 contingency table. Pooled analysis was done using a random-effects model. Sub-group analysis was performed at real-time Kudo pit pattern based and real-time CLE for characterization of visible lesions. Heterogeneity was assessed using Chi squared and I² statistics.

**Results:** Our search strategy identified 172 studies of which only 20 met the inclusion criteria. The pooled results are outlined in the table.

**Conclusion:** Real-time CLE and magnification endoscopy had the best performance characteristics. However there was a lot of heterogeneity in the results. Most CLE and magnification studies were single centre, single expert user which could explain these results. CLE studies were also affected by attribution bias with some studies reporting non-interpretable mages in a significant proportion.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1669 ENDOSCOPIC FINDINGS AND COLONOSCOPIC PERFORATION IN MICROSCOPIC COLITIS; A SYSTEMATIC REVIEW OF THE LITERATURE

1Department Of Gastroenterology, Pomeranian Medical University, Szczecin/ Poland
2Department Of Biochemistry And Human Nutrition, Pomeranian Medical University, Szczecin/Poland
3The Royal Infirmary of Edinburgh, Edinburgh/United Kingdom

**Contact E-mail Address:** diane.e.ung@gmail.com

**Introduction:** Microscopic colitis (MC) is a clinical syndrome of severe watery diarrhea with few or no endoscopic abnormalities. The incidence of MC is reportedly similar to that of other inflammatory bowel diseases. The need for histological confirmation of MC frequently guides reimbursement health policies. With the advent of high-definition (HD) colonoscopes, the incidence of distinct endoscopic findings reported in MC has risen. This has the potential to improve diagnosis times, increase cost-effectiveness of MC management and diminish the workload and costs of busy modern endoscopy units. Aims & Methods: Publications on distinct endoscopic findings in MC available until 31st March 2017 were searched systematically (electronic and manual) in PubMed. The following search terms/descriptors were used: collagenous colitis(CC) OR lymphocytic colitis(LC) AND endoscopy, colonoscopy, findings, microscopic, erythema, macroscopic, vascular, score, perforations. An additional search for MC AND perforation was made. Results: Eighty (n = 80) articles, predominantly single case reports (n = 45), were retrieved. Overall, 1,582 (1,159 female; 61.6% years) patients(pts) with MC and endoscopic findings were reported. The majority of articles (n = 62) were on CC (756 pts; 77.5% female). We identified 16 papers comprising 779 pts (68.9% female) with LC and 7 articles describing 47 pts (72.3% female) confirmed to have MC. The youngest patient was 10 and the oldest 97 years old. Aside from diarrhea, symptoms included abdominal pain, weight loss, bloating, flatulence and oedema. In the study group we found 616 (38.9%) pts with macroscopic lesions (%): erythema 19 (9.94%), edema 15 (7.61%), nodularity 12 (6.29%), surface ulceration 10 (5.26%), scar 9 (4.89%) and laceration 9 (4.89%). There was a positive correlation with CC (0.32) and LC (0.54). Survival analysis showed a trend towards shorter time for perforation in patients with a score above the median at diagnosis (p log rank = 0.09).

**Conclusion:** Endoscopic findings are recognized with increased frequency in pts with MC. This could improve MC diagnosis by prompting a more extensive biopsy protocol in such cases and an earlier initiation of treatment. Procedure-related perforation has been reported in this group, therefore, cautious air insufflation is advisable when endoscopic findings are recognized.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** catarinagouveia228@gmail.com

**Introduction:** The need to stratify patients with Crohn’s disease (CD) according to the risk of developing complications is essential to delineate therapeutic approach. A score that evaluates the severity of DC (Siegel et al. Gut 2016) has recently been developed and published, taking into account intestinal lesions, disease activity and complications during the course of the disease, ranging from 0 to 100.

**Aims & Methods:** We aimed to evaluate the performance of the aforementioned score at the time of diagnosis and its relation to the need for surgery and hospitalizations in patients with CD. We performed a retrospective study that included patients diagnosed with DC in our hospital between 01/2012-12/2015. The score was calculated at the time of diagnosis and information on the course of the disease was collected. Statistical analysis was performed in SPSS (v23).

**Results:** A total of 57 patients (52.6% women) with a mean age of 33.74±15.8 years were included. The median severity score at diagnosis was 16±16.5 ranging from 4 to 50. Twenty-four patients (40.7%) required surgery and 29 (49.2%) were hospitalized for reasons associated with the disease. At diagnosis, the score was higher in A1 patients (26 vs 19.2 and 13.7, p = 0.05), with a penetrating phenotype (25.5 vs. 19 and 12, p = 0.02), and in patients requiring surgery during the course of their disease (21 vs 14, p = 0.1). There was a positive correlation between the score at diagnosis and the number of surgeries during follow-up (r = 0.43, p = 0.05). Survival analysis showed a trend towards shorter time for surgery or hospitalization in patients with a score above the median at diagnosis (p log rank = 0.09).

**Conclusion:** The new severity score seems to be a promising tool for stratification and prognosis of patients with CD at diagnosis, and its utility should be validated in prospective studies.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: It is well recognized that patients with inflammatory bowel disease (IBD) are at risk for nonalcoholic fatty liver disease (NAFLD). Our aim was to evaluate the prevalence and to quantify hepatic steatosis in IBD patients using the controlled attenuation parameter (CAP).

Aims & Methods: We prospectively recruited all IBD patients presenting for a disease flare or follow-up visit in our clinic, during a 18 month period. Patients with alcohol intake of more than 20 g/day and those with coexisting viral hepatitis were excluded from analysis. Clinical characteristics and laboratory data were recorded. Hepatic steatosis was evaluated by conventional ultrasound, hepatic steatosis index (HSI) and transient elastography with CAP (Fibroscan, Echosens, Paris). Significant steatosis (S ≥ 1) was defined for a CAP value over 236 [1], and the cut-off of HSI for detecting NAFLD was set at ≥ 36 [2].

Results: Altogether 62 IBD patients (35 ulcerative colitis, UC and 27 Crohn’s disease, CD), mean age 45 ± 15 years, 50% female, were included in the analysis. The two groups (UC, CD) were similar regarding disease activity (remission/flare:48.5/31.4% in the UC group, 55.6/44.4% in the CD group), BMI (24.1 and 24.4 respectively), mean alcohol intake was 21 and 21.1 mg/dl, respectively. US identified 18/62 (29%) patients with fatty liver, HSI detected 3 more patients (21/62, 33.9%) and CAP even 2 more (23/62, 37.1%), yielding an extra 8% detection rate. NAFLD-IBD patients were more likely to have CD phenotype, history of resection, steroid use and longer disease duration.

Conclusion: In our cohort, about one in three IBD patients had fatty liver disease, as quantified by CAP. Diagnostic performance of CAP was better than conventional ultrasound and HSI in detecting fatty liver in IBD patients.

Introduction: Czech Registry of Inflammatory Bowel Disease (IBD) Patients on Biological Therapy (CREdIT) was launched in March, 2016 in order to collect and analyze the data from Czech centers appointed to provide biological therapy to IBD patients.

Aims & Methods: The objective is to provide information on the CREdIT registry after its first year of operation. Basic demographic data (sex, age, diagnosis, Montreal classification or disease extent) were collected together with information on disease activity, therapeutic regimen, concomitant medication and adverse events. Patients who began biologic therapy prior to enrolment into the registry as well as those who start their treatment are included, and labeled as “retrospective” and “prospective” cohort, respectively.

Results: Among 30 centers providing biological therapy to patients with Crohn's disease (CD) and ulcerative colitis (UC) in the Czech Republic, 34 participated as “retrospective” and “prospective” cohort, respectively from ourCREdIT database. All patients that were commenced on anti-TNF therapy are followed up at 3 months in the clinic and we aim to do a colonoscopy at 6 months to assess for mucosal healing. Recently we have started using a relatively new technology, called IBDoc, which allows testing the faecal calprotectin at home using a smartphone application and the results are automatically updated in our database.

Aims & Methods: We aimed to evaluate the cost effectiveness of using IBDoc faecal calprotectin post induction of biological agents in inflammatory bowel disease.

Introduction: Traditionally in our unit all IBD patients started on anti-TNF therapy are followed up at 3 months in the clinic and we aim to do a colonoscopy at 6 months to assess for mucosal healing. Recently we have started using a relatively new technology, called IBDoc, which allows testing the faecal calprotectin at home using a smartphone application and the results are automatically updated in our database.

Aims & Methods: We aimed to evaluate the cost effectiveness of using IBDoc faecal calprotectin post induction of biological agents. The data was collected retrospectively from ourIBDoc data base. All patients that were commenced on anti-TNF therapy for IBD and trained in using IBDoc at home were included. IBDoc faecal calprotectin was tested at 3 and 6 month post induction of biological agents.

Results: Total number included in the study was 131 patients. 40% had normal faecal calprotectin at 3 month saving 53 follow up clinic visits (cost of clinical visit 128 euro), and 75% had a normal faecal calprotectin at 6 months saving 40 routine colonoscopy (cost of colonoscopy 337 euro). 78 patients had a raised faecal calprotectin at 3 month, of which 28% had a normal faecal calprotectin at 6 month saving 22 follow-up colonoscopy. In total 53 clinical visits and 62 colonoscopies were avoided.

Conclusion: This study demonstrate a significant cost effectiveness of using IBDoc faecal calprotectin post induction of anti-TNF therapy, as well as reducing the waiting time for both clinic visits and colonoscopies.

Reference
The intraclass correlation coefficients were 0.81 (p < 0.001). The levels measured by established ELISA (Promonitor level: mean 4.67, median 4.39; lower than 3 and higher than 7ug/ml; lower than 3 and higher than 7) with a high agreement. We estimated a simplification score to convert the "point-of-care" level into "Promonitor" level and the standard ELISA method (Promonitor® assay) determining a correlation factor that permits therapeutic management in a similar way.

**Aims & Methods:**
A total of 135 serum sample from patients with CD and UC. IFX concentration in serum samples were determined using a well established IFX-specific ELISA assay (Promonitor®) and the test assay Quantum Blue®. According to the manufacturer, the lower and upper limits of quantification are: In the Quantum Blue assay 0.04 μg/ml and 20 μg/ml respectively. In the Promonitor assay 0.035 μg/ml and 14 μg/ml, respectively. All statistics were carried out using the statistical programs IBM SPSS statistics 21 and Epidat version 4.2.

**Results:**
The IFX levels measured by the point-of-care method were higher than those measured by established ELISA (Promonitor level: mean 4.67, median 3.23; 4.39 (0.035–14.44)); Quantum Blue level mean 6.31; median 3.73; 6.27 (0.4–20). The intraclass correlation coefficients were 0.81 (p < 0.001). The standard ELISA had a high (r = 0.89) and significant (p < 0.001) correlation with the Quantum Blue® assay. A Bland-Altman analysis showed a bias of 1.88% confirming the overall excellent correlation of the two methods. The results for each method were stratified according to a commonly accepted therapeutic threshold (7ug/ml; lower than 3 and higher than 7) with a high agreement. We estimated a simplified score to convert the "point-of-care" level into "Promonitor" level and facilitate dose management: Nivel de Promonitor = 0.793 + 0.615 *Nivel QB.

**Conclusion:**
The simplified score is a really useful technique enabling the fast and friendly quantitative determination of IFX levels to ensure correct dosing in IB.

**PI677 RISK FACTORS ASSOCIATED WITH A HIGH RISK OF COLORECTAL CANCER IN PATIENTS WITH UCLESATIVE COLITIS. PRELIMINARY RESULTS FROM THE IBSEN COHORT**

P. Klepp1, M. C. Msaastuen2, M. Hoivik1, B. Mom1, I. Study Group1

1Clinical Medicine, University of Oslo, Oslo/Norway
2University of Oslo, Oslo/Norway

**Contact E-mail Address:** pasklepp@gmail.com

**Introduction:** The occurrence of establishing risk factors for colorectal cancer in inflammatory bowel disease remains debated.

**Aims & Methods:** Our aim was to evaluate how individual disease variables contribute to the development of colorectal cancer. A population-based inception cohort of patients with ulcerative colitis patients diagnosed between 1990-1994 have been prospectively followed at one, five, 10 and 20 years after inclusion. In total we identified 517 patients, 266 (51.5%) were males, aged median 37.4 (min 4, max 88) years at inclusion. The following variables were analyzed; age at ulcerative colitis diagnosis, gender, presence or absence of dysplasia, use of azathioprine and 5-aminosalicylic acid, extent of mucosal inflammation, 1st-degree relative with colorectal cancer.

**Results:** We identified 10 patients diagnosed with colorectal cancer after being diagnosed with ulcerative colitis. Age at ulcerative colitis diagnosis and low grade dysplasia were significantly associated with higher risk of CRC (HR = 1.06, 95%CI [1.02–1.11], p = 0.003 and HR = 0.95 95%CI [0.17–4.03], p < 0.001 for age and low grade dysplasia respectively). Patients who were older than 40 years at diagnosis had 4 times higher risk of developing colorectal cancer as compared to patients diagnosed with ulcerative colitis at a younger age. HR = 4.08, 95%CI [2.02,16.39], p = 0.047. Male gender (HR = 1.949, use of azathioprine (HR = 2.50), use of 5-aminosalicylic acid (HR = 0.29) and extent of mucosal inflammation, were significantly associated with higher risk of CRC, however the estimations did not reach the level of statistical significance. Male diagnosed with UC when older than 40 years and with extent of inflammation had 8.4% probability of developing CRC within 20 years after their diagnosis.

**Conclusion:** Our results show that the presence of low grade dysplasia significantly increases the risk of colorectal cancer. The study was limited by the sample size.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**PI678 MANAGEMENT OF COMPLEX PERIANAL FISTULAE WHEN TO SUSPECT INFLAMMATORY BOWEL DISEASE?**

M. F. Cardeal1, J. C. Branco2, A. M. Oliveira1, C. G. Rodrigues1, L. Santos1, C. G. Carneiro2, J Res3

1Gastroenterology, Hospital Professor Doutor Fernando Fonseca, Amadora/Portugal
2Surgery, Hospital Professor Doutor Fernando Fonseca, Amadora/Portugal

**Contact E-mail Address:** marianafcardeal@gmail.com

**Introduction:** Perianal fistulae are a frequent manifestation of inflammatory bowel disease (IBD) often associated with significant morbidity, which may precede or appear simultaneously with intestinal disease. The approach to patients with perianal fistulae and no intestinal symptoms is poorly defined, and it remains to elucidate if there is a subgroup of patients in whom a more extensive search for IBD is warranted.

**Aims & Methods:** Unicentric retrospective cohort study including patients evaluated for complex perianal fistulose, defined according to the American Society of Colon and Rectal Surgeons2. Patients with known IBD, malignancy or history of pelvic radiation where excluded. Patients in whom the diagnosis of IBD was established were compared to the others.

**Results:** 134 patients were included (mean age 48.2±17.8 years; 71.0% men), with a mean follow-up of 26 months. 18 patients (14.5%) were diagnosed with IBD, namely Crohn’s disease. The classification of the fistulous tracts was as follows: intersphincteric (71.8%), transphincteric (35.8%), extrasphteric (73.3%), suprasphincteric (5.6%), horseshoe (24.2%) and with an abscess (44.4%). The majority of patients with IBD presented intestinal symptoms (15/18), in 8 cases preceding the perianal disease but not motivating investigation in the past. In 3/18 (16.7%) patients diagnosed with IBD, perianal fistula was the sole clinical manifestation of the disease. Patients with IBD were younger (36.1 vs 51.4 years, p < 0.001), had a higher incidence of perianal abscesses (88.9% vs 36.8%, p < 0.001), more persistent/recurrent disease (89.9% vs 9.6%, p < 0.001) and a tendency to a higher number of fistulous tracts (38.9% had ≥3 tracts vs 17.9% in the group without IBD; p=0.059).

**Conclusion:** In this cohort of patients with complex perianal fistulose, although in the majority of cases the diagnosis of IBD was suggested by the presence of intestinal symptoms, these were absent in 16.7% patients. There should be a higher suspicion of IBD in young patients and in those who have perianal disease of greater complexity.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

2Gastroenterology and Endoscopy Unit, “Villa Sofia-Cervello” Hospital, Italy, Palermo/Italy

**Contact E-mail Address:** fsmaculoso@gmail.com

**Introduction:** In patients with inflammatory bowel disease (IBD) the addition of an immunosuppressant (IM) after loss of response to anti-TNF alpha monotherapy is recommended to lower or high emerging stabilizing therapeutic optimization. However, few clinical data have been reported to date.

**Aims & Methods:** The aim of this study was to evaluate efficacy and tolerability of an "add-on" combination therapy in patients with IBD. All consecutive patients with loss of response to anti-TNF alpha monotherapy despite an intensive dose optimization who added an IM from October 2014 to October 2016 were entered in a prospectively maintained database. The steroid-free remission and the clinical response, this latter defined as a clinical improvement (reduction of Harvey-Bradow Index ≥3 for Crohn’s disease and of Mayo Partial Score ≥2 for ulcerative colitis compared with baseline) with a concomitant reduction of steroid dosage compared with baseline and discontinuation within twelve weeks, were recorded. Adverse events leading to treatment discontinuation were reported in 8 out of 46 patients (17.4%).

Conclusion: In patients with IBD the addition of an immunosuppressant is an effective and safe optimization strategy after loss of response to anti-TNF alpha monotherapy. Low doses of IM are sufficient to achieve a clinical response in this setting.

P1680 CORRELATION BETWEEN EXTRA-INTESTINAL MANIFESTATIONS AND ANTI-DRUG ANTIBODIES DEVELOPMENT IN CROHN’S DISEASE PATIENTS

M. Crespi1, G. Bodini1, E.G. Giannini1, V. Savarino2, A. Jain2, E. Savarino1
1Department Of Internal Medicine, IRCCS San Martino DMMI, Genova (GE) Italy
2Prometheus Laboratories Inc., San Diego/United States of America

Introduction: Extra-Intestinal Manifestations (EIM) are frequently (up to 40%) encountered in patients with Crohn’s Disease (CD). Commonly, their presence is associated to a more severe degree of luminal disease and lower response to conventional therapy (i.e. immunosuppressants). Drug trough levels are associated with biological drug response, while the role of Anti-drug Antibodies (AAA) is still debated. Moreover, the predicting factors associated with AAA development have not been thoroughly studied yet. To the best of our knowledge, there are no studies correlating the presence of EIM and AAA development.

Aims & Methods: The aim of our prospective study was to identify an association between the presence of EIM and the development of AAA in CD patients treated with biological therapy. We prospectively enrolled 60 CD patients (32 males, median age 46y, range 21–72) treated either with adalimumab (ADA n = 39, 63%; IFX n = 21, 35%) with a median follow-up of 80 (range 14–206) weeks. Blood samples were drawn at standardized time points assessed using an homogeneous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States).

Results: ADA were detected in 27 (45%) patients and AAA proved to be more frequent in subjects treated with IFX rather than those in therapy with ADA (n = 14, 66.6% vs 13, 33.3%, P = 0.017). EIM were observed in 26 (43.3%) patients, without any significant difference between ADA and IFX patients (n = 17, 51.5% vs n = 9, 42.9%, P = 0.1). We found that ADA treated patients with EIM were more likely to develop AAA (n = 9, 52.9% versus n = 4, 18.2%, P = 0.039) while no statistically significant association between EIM and AAA development was observed in IFX treated patients (n = 5, 55.5% versus n = 9, 75%, P = 0.64).

Conclusion: We found that ADA-treated patients with EIM tend to develop more frequently AAA. Assuming that the presence of AAA reduces the effectiveness of biological therapy, the presence of EIM may be considered a predictive factor for loss of response to biological therapy with anti-tumor necrosis factor alpha drugs.

Introduction: Extra-Intestinal Manifestations (EIM) are frequently (up to 40%) encountered in patients with Crohn’s Disease (CD). Commonly, their presence is associated to a more severe degree of luminal disease and lower response to biological therapy (i.e. immunosuppressants). Drug trough levels are associated with biological drug response, while the role of Anti-drug Antibodies (AAA) is still debated. Moreover, the predicting factors associated with AAA development have not been thoroughly studied yet. To the best of our knowledge, there are no studies correlating the presence of EIM and AAA development.

Aims & Methods: The aim of our prospective study was to identify an association between the presence of EIM and the development of AAA in CD patients treated with biological therapy. We prospectively enrolled 60 CD patients (32 males, median age 46y, range 21–72) treated either with adalimumab (ADA n = 39, 63%; IFX n = 21, 35%) with a median follow-up of 80 (range 14–206) weeks. Blood samples were drawn at standardized time points assessed using an homogeneous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States).

Results: ADA were detected in 27 (45%) patients and AAA proved to be more frequent in subjects treated with IFX rather than those in therapy with ADA (n = 14, 66.6% vs 13, 33.3%, P = 0.017). EIM were observed in 26 (43.3%) patients, without any significant difference between ADA and IFX patients (n = 17, 51.5% vs n = 9, 42.9%, P = 0.1). We found that ADA treated patients with EIM were more likely to develop AAA (n = 9, 52.9% versus n = 4, 18.2%, P = 0.039) while no statistically significant association between EIM and AAA development was observed in IFX treated patients (n = 5, 55.5% versus n = 9, 75%, P = 0.64).

Conclusion: We found that ADA-treated patients with EIM tend to develop more frequently AAA. Assuming that the presence of AAA reduces the effectiveness of biological therapy, the presence of EIM may be considered a predictive factor for loss of response to biological therapy with anti-tumor necrosis factor alpha drugs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Anaemia is one of the most common extraintestinal manifestations in inflammatory bowel disease (IBD), with iron deficiency being the most frequent cause.

Aims & Methods: To characterize anaemia in a population of patients with IBD and to evaluate the efficacy of anti-TNF and carrier therapy. We retrospectively analyzed 169/1166 patients with IBD followed in a tertiary center between 2010-2016. All the patients received replacement therapy with ferric carboxymaltose, ferric saccharum or transfusional support. We analyzed the effect of immunosuppressive therapy with and without anti-TNF: group 1 and 2 respectively. Active disease was defined as C-reactive protein (CRP) ≥0.5 mg/dL, faecal calprotectin (FC) ≥50 μg/g or presence of ulcers in colonoscopy. Anaemia was defined according to ECOO criteria (iron deficiency anaemia (IDA), anaemia of chronic disease (ACD) and mixed anaemia (MA)). Multifactorial anaemia (MFA) was diagnosed when there was also vitamin B12 or folate deficiency.

Results: 169 patients were included: 111 with Crohn’s Disease (CD), 54 with Ulcerative Colitis (UC) and 4 with unclassified IBD. 44.4% were male and the mean age was 32.2 years (range 7-82). 98.2% had anaemia and 1.8% had only iron deficiency; 3.5% and 18.3% had a deficit of vitamin B12 and folate. The mean anaemia assessed in CD and UC were IDA (54.1% and 46.3%) according to MFA (19.8% and 24.1%), ACD (15.3% and 24.1%) and MA (8.1% and 5.6%). Female gender (OR 3.743 95% CI 1.554–9.018, p = 0.003), previous surgery (OR 2.845 95% CI 1.111–7.284, p = 0.02) and pene-trating perianal disease in CD (OR 8.252 95% CI 1.289—52.919, p = 0.026) were predictors of normal hemoglobin (Hb). CRP was associated with highest ferritin values (294.85 ± 302.00 vs 102.10 ± 127.75, p < 0.001). Hb and CRP had a negative correlation (p = 0.176, p = 0.022). In UC, CRP and FC normalization was associated with an improvement of transferrin saturation (13.63 ± 1.66 vs 12.47 ± 1.38, p = 0.005 and 51.33 ± 2.60 vs 27.63 ± 9.66, p = 0.048). There was no difference in the parameters evaluated comparing groups 1 and 2. There was also no significant difference in the variation of Hb and iron values after treatment with ferric carboxymaltose versus ferric saccharum.

Conclusion: In a population of patients with IBD, iron deficiency was the main cause of anaemia and the two forms of intravenous iron replacement were equally effective. In the group of patients with UC, elevated CRP was associated with higher Hb and transferrin saturation (13.63 ± 1.66 vs 12.47 ± 1.38, p = 0.005 and 51.33 ± 2.60 vs 27.63 ± 9.66, p = 0.048). There was no difference in the parameters evaluated comparing groups 1 and 2. There was also no significant difference in the variation of Hb and iron values after treatment with ferric carboxymaltose versus ferric saccharum.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aim of this study was to evaluate costs comprehensive of biological treatments and hospitalizations in a series of patients with ulcerative colitis (UC) and Crohn’s disease (CD) and their correlation with demographic and clinical variables. Disease severity was evaluated by clinical scores (partial Mayo score for UC, Harvey Bradshaw Index for CD). We analyzed retrospectively patients treated by biologics referred to our IBD Unit between May 2015 and April 2016 who underwent at least six months follow-up (last visit October 2016). As regards biological therapies costs burdened by our Centre pharmacy for each drug (Infliximab, Adalimumab, Golimumab, Vedolizumab) and for single patient were evaluated. About hospitalizations the average costs of hospitalizations of patients i.e. Diagnosis-Related Group (DRG) were collected. The mean overall monthly expenditure for each case was then evaluated.

Results: We collected clinical-economical data of 142 patients in biological treatment in the selected period (52 UC, mean age 43.3 years and male 40.4%; 90 CD, mean age 38.8 years and male 56.7%). About half of CD patients (48.9%) underwent percutaneous intestinal surgery. The disease severity was higher in UC group vs CD one. In UC group Infliximab was the most prescribed biologic (51.9%), followed by Golimumab (29.9%) and Adalimumab (21.2%). While CD patients were treated with Adalimumab in 54.4% and Infliximab in 45.6%. The average cost for month of treatment was 1253.41 ± 358.38 € for UC and 1148.92 ± 337.36 € for CD. No statistically different between the two groups. In both groups expenditure due to biologics amounts for more than 80%. We analyzed costs in groups different for sex, age and disease activity (only the last one was associated with increased costs with R² = 0.84 for UC and 0.95 for CD). The cost increases in patients with more lines of therapy in UC (not in CD) but the difference wasn’t significative.

Conclusion: In our study the main cost is due to biological therapy but the subjects enrolled were the most severe in comparison to the whole IBD population under conventional therapy. No differences were found between the type of biologic administered and the way of administration (intravenous or subcutaneous) so the therapeutical choice could be driven by clinical reasons and not only economic ones.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: We aimed to evaluate all these issues in Sicily through a web-based network of all prescribing centers. The Sicilian Network for Inflammatory Bowel Disease (SN-IBD) is composed by a super Hub coordinator centre and 20 peripheral centers. As clinical end-point, we set remission (corresponding to a Mayo Partial Score ≤ 2 for CD and Mayo Partial Score ≤ 5 for UC–12 WEEKS Naive to biologics 2.188 p = 0.001, and 79.8% vs. 47.2%, p = 0.001). At week 12, there was a higher rate of response/remission for adalimumab (ADA) compared with infliximab (IFX) and vedolizumab (VDZ) (71.8% vs. 56.6%, p = 0.002). However, IFX was superior to golimumab (GOL) (71.8% vs. 56.6%, p = 0.002). However, at week 52, IFX had a higher rate of response/remission compared to GOL (58.2% vs. 38.2%, p = 0.003) and ADA (58.2% vs. 33.9%, p = 0.002). However, IFX was superior to GOL in naïve patients only (60.2% vs. 26.7%, OR 4.165, p = 0.018). There was no significant difference between the two drugs when patients were stratified in naïve and non-naïve, while ADA was superior to IFX in patients with ileo-colic disease (68.8% vs. 48.4%, OR 2.282, p = 0.001). UC: there was a higher proportion of patients naïve to biologics among those on adalimumab (ADA) compared with infliximab (IFX) and vedolizumab (VDZ) (89.3% vs. 53.3% vs. 30.6%, p < 0.001). At week 12, there was a higher rate of response/remission for adalimumab (ADA) compared with infliximab (IFX) and vedolizumab (VDZ) (79.8% vs. 71.8%, p = 0.005, and 79.8% vs. 47.2%, p < 0.001, respectively), and a higher efficacy of IFX compared with VDZ (71.8% vs. 38.2%, p = 0.001). The superiority of ADA over IFX remained significant in naïve patients (81.5% vs. 73.7%, OR 1.581, p = 0.002), but not in non-naïve. At week 52, ADA had a higher rate of response compared to IFX (65.4% vs. 56.5%, p = 0.001), while IFX was superior to ADA in CD (58.2% vs. 44.1%, OR 1.581, p = 0.001). For both CD and UC, no significant difference in efficacy was observed between IFX originator and biosimilars. Several factors were identified as predictor of response - independently of the drug employed - at multivariable logistic regression analysis (Table 1).

Conclusion: In one of the largest “real-life” series of IBD patients on biological therapy reported to date, ADA in CD had a higher success compared to IFX at both 12 and 52 weeks; however, this results could be influenced by the preference of ADA as first-line anti-TNF drug in CD. IFX in UC was superior to GOL and ADA at 52 weeks; once again, this result could be influenced by the preference of IFX as first-line anti-TNF agent in UC; no difference was found between GOL and ADA in UC. Being naïve to biologics is a relevant predictor of response in both CD and UC at any time point. No significant difference in efficacy was observed between IFX originator and biosimilars.

Introduction: Recent studies have shown that FODMAPs (Fermentable Oligosaccharides, Disaccharides, Monosaccharides, and Polyols)-free diet is effective in subjects with Irritable Bowel Syndrome (IBS). Patients with Inflammatory Bowel Diseases (IBD), and celiac disease (CD) can experience functional gastrointestinal symptoms unrelated to inflammation, but data about the use of low FODMAPs diet in these settings is still scarce.

Aims & Methods: To evaluate the usefulness of a low FODMAPs diet on patients with IBS, non-active IBD, and CD on strict gluten-free diet (GFD), we performed a dietetic intervention on patients with IBD compared with baseline with a concomitant reduction of steroids dosage at week 10, and complete discontinuation at week 24.

Results: 127 subjects were enrolled: 56 with IBS, 30 with IBD and 41 with CD. The analysis of the IBS-SSS survey showed that abdominal symptoms improved after 1 month and 3 months of low FODMAPs diet in all subjects, with statistically significant difference within each group at T0 (average score in IBS: 293.3 ± 137 SD, average score in IBD: 206.6 ± 86 SD, average score in CD: 222.7 ± 65 SD, p < 0.001). Furthermore, by analysing the SF-36 questionnaire, while we did not observe any significant difference between the three groups, in terms of response to diet (p = NS), we observed a clinical improvement from T0 to T3, after the start of the diet, for most of the questionnaire’s domains.

Conclusion: A low FODMAPs diet could be a valid option to counter abdominal symptoms in patients with IBS, non-active IBD or CD on GFD, and, thus improve their quality of life and social relations.

Introduction: Vedolizumab (VDZ) is a new biologic agent approved for the treatment of adult patients with moderately to severely active ulcerative colitis (UC) and Crohn’s disease (CD).

Aims & Methods: The Sicilian Network for Inflammatory Bowel Disease (SN-IBD) is a network composed by all Sicilian centres prescribing biologics. These centres continuously enter in a web based software all real-life data about prescriptions and outcomes of biological therapy in patients with inflammatory bowel disease (IBD). Herein we report data on efficacy of VDZ on intestinal activity (Mayo Endoscopic Score, 0/1/2/3 and Mayo Partial Score) and on extraintestinal manifestations (extraintestinal manifestations IBD-associated SpA, peripheral arthritis, axial arthritis) in all subjects after 10 and 24 weeks of treatment. As clinical endpoint, we set steroid-free remission (corresponding to a Mayo Partial Score < 2 for UC, and to a Harvey-Brudhaw Index < 5 for CD), and clinical response (reduction of Harvey-Brudhaw Index ≥ 3 for CD and Mayo Partial Score ≥ 2 for UC compared with baseline with a concomitant reduction of steroids dosage at week 10, and complete discontinuation at week 24).

Results: From July 2016 to April 2017, 163 patients (84 with CD and 79 with UC) were included (table 1). At week 10, a steroid-free remission was obtained in 71 patients (43.6%), while a clinical response in 37 (22.7%). Out of 71 patients reaching 24 weeks of follow-up, 29 (40.8%) were in steroid-free remission, and 10 (14.1%) had a clinical response. No significant difference in terms of clinical benefit (rate of remission plus clinical response) among patients with UC and CD was reported at week 10 (68.4% vs. 64.3%, respectively; p = 0.58) and at week 24 (54.3% vs. 55.6%, respectively; p = 0.91), and no difference was observed comparing naïve and non naïve patients, neither at week 10 (61.5% vs. 67.7%, respectively; p = 0.48) nor at week 24 (30.0% vs. 59.0%, respectively; p = 0.11).

At multiple logistic regression analysis, a longer duration of disease (OR 0.96, 95% CI: 0.94-0.98, p = 0.037) and to a Harvey-Bradshaw Index /C21 S.D. C-Reactive Protein, mean S.D. (n.v. < 5mg/L) 5.0 ± 1.6 5.6 ± 1.6 5.0 ± 1.6 8.2 ± 1.6 8.3 ± 1.6 8.1 ± 1.6

Conclusion: In this large cohort of Sicilian IBD patients, VDZ showed good efficacy after 10 and 24 weeks of treatment, particularly in those with a shorter duration of disease and a limited inflammatory burden. A subset of patients reported improvement also on articular symptoms, probably as a consequence of the concomitant control of gut inflammation.

Introduction: Combined immune suppression of anti-tumour necrosis factor (antiTNF) biologicals and thiopurines is superior to respective monotherapies in remission induction and maintenance of response in inflammatory bowel disease (IBD). One of the putative mechanism of this clinical benefit is mutual positive pharmacokinetic effect of thiopurines on antiTNF levels and vice versa. It has been suggested that for this synergistic effect, reduced dose of thiopurines might be sufficient but the data supporting this hypothesis are still limited.

Aims & Methods: The aim of the study was to assess the differences of infliximab trough levels according to the dose of concomitantly used thiopurines. All IBD patients treated with infliximab (Remicade®) in two IBD centres between November 2015 and April 2017 were eligible. Infliximab trough levels were routinely measured in all patients with maintenance infliximab therapy using commercially available ELISA kit (Ridascreen®, R-Biopharm). All patients in remission with stable dose regimen of 5mg/kg every 8 weeks at the time of the first assessment of infliximab trough levels were identified retrospectively from the medical records. The differences in the proportion of patients with adequate trough levels (3–12 µg/mL) between patients on infliximab monotherapy, reduced (below 2 mg/kg) azathioprine (AZA) dose vs. full (2 to 2.5 mg/kg) AZA dose were analyzed statistically.

Results: Out of a total of 214 IBT patients treated with infliximab, there were 154 in remission at the time of the first assessment of infliximab trough levels. After excluding patients with previously intensified dose regimen, 125 patients were further analyzed. Among these 125 pts, 41 (33%) were on infliximab monotherapy, 58 pts (46%) were using combined immune suppression with a reduced dose of AZA and 26 (21%) were using the full AZA dose concomitantly with infliximab. Both groups, patients with infliximab monotherapy as well as patients using the reduced AZA dose had significantly lower percentage of patients with therapeutic levels of infliximab compared with the group using the full dose of AZA co-medication (41% vs. 64% vs. 81%; infliximab monotherapy, reduced AZA dose and full AZA dose, respectively; p < 0.001 for both comparisons, infliximab monotherapy, reduced AZA dose vs. full AZA dose. Conclusion: The proportion of patients with adequate infliximab trough levels is significantly higher in patients with full dose of concomitant azathioprine compared with the patients using a reduced dose of azathioprine. Thus, in order to maintain the therapeutic benefit of infliximab maintenance treatment, the combined immune suppression should comprise full dose of azathioprine.

Introduction: UC is a potentially severe disease that carries an increased risk of complications and colectomy. Immunosuppressant and biological therapies are relevant tools for complex patients. The ACCENT study showed that in Crohn's disease (CD), scheduled IFX infusions vs. episodic are associated with greater effectiveness. However, clinical difficulties of economic access in IFX and the necessity to conditioned to our IBD center, to use IFX in moderate to severe UC as a bridge to thiopurines in pts with IFX induction followed by thiopurines (re-induction when available for moderate to severe relapse) vs. scheduled IFX (inpts with 0.2,6,8 and 12 weeks interval infusions maintenance). Optimization (by frequency of intervals) was allowed in both modalities. Comparisons: Kaplan Meier/Log rank test: a) Cumulative incidence of colectomy, b) survival times relapse free, c) survival times corticosteroid free. Introduction: This independent study was described for CD pts, in the CU, the scheduled IFX treatment strategy regimen, after a moderate-severe outbreak, seem to be associated with better long-term outcome regarding colectomy requirement, relapses, and need for corticosteroids, compared with a bridge IFX strategy followed by thiopurines.

Results: KC per patients receiving IFX for moderate to severe UC (M 60, F 75, Age (mean ± SD) 35.9 ± 13.2, UC duration 5.8 ± 5.9 yrs,Extent: extensive 58.5%, Left-sided 41.5%, Activity: severe 78.5%, moderate 21.5%, mean Mayo score: 10.1 ± 1.8. Primary no responders at week 12 (n= 25). 10 months in maintenance treatments, which were performed in 110 out of the 135 pts. (Follow-up 37.5 ± 24.0 months) Groups: IFX bridge (n = 51) and scheduled IFX (n = 59), which were different in extent, and mean age, UC duration, Mayo score. Cumulative incidence of colectomy was significantly lower in the bridge strategy (HR 1.01; 95% CI 1.00–1.02, p = 0.034), survival times free of relapse (HR 3.1026, 95% CI 1.038 to 5.2405, p < 0.0001) and free of corticosteroids (HR 2.6057, 95% CI 1.5516 to 4.3757, p = 0.0003). A proportion of UC significantly higher within the re-induced pts (HR 1.08; 95% CI 1.04–1.12) required a shift of biological drug compared with the scheduled strategy (p = 0.016, Fisher), despite of similar rates of optimization. Infusion reactions needing definitive IFX suspension were more frequent as a trend (p < 0.006) in re-induced pts.

Conclusion: Same as described for CD pts, in the CU, the scheduled IFX treatment strategy regimen, after a moderate-severe outbreak, seem to be associated with better long-term outcome regarding colectomy requirement, relapses, and need for corticosteroids, compared with a bridge IFX strategy followed by thiopurines.

Introduction: CT-P13, the first biosimilar monoclonal antibody to infliximab (IFX) has previously been confirmed to be efficacious in inducing mucosal healing in ulcerative colitis (UC) patients. Aims & Methods: The aim of this study was to evaluate the efficacy of CT-P13 therapy in maintaining mucosal healing in UC. Patients diagnosed with UC, who were administered CT-P13 from June 2014 at 4 Hungarian and one Czech IBD Centre were prospectively enrolled. Sigmoidoscopy was performed at week 14 and week 54 to assess mucosal healing. Mucosal healing was defined as Mayo endoscopic subscore of 0 or 1. Complete mucosal healing was defined as Mayo endoscopic subscore of 0. CT-P13 trough levels, antibody positivity, serum inflammatory markers as CRP level, fecal calprotectin at weeks 14 and 54, compliance with antibiotic therapy at the time of sigmoidoscopy and at weeks 14 and 54, previous use of anti TNF drug and the need of dose intensification as possible predictive factors for mucosal healing at week 54 were evaluated. Results: Seventy-five UC patients were included in the study of which 74 patients completed the induction therapy and 54 patients had already completed the 54-month treatment period. Mucosal healing was shown in 55.4% of the patients at week 14 and 61.7% at week 54 (p = 0.033). Complete mucosal healing was patient in 24.3% at week 14, but in 17.7% at week 54. The proportion values of CRP (p = 0.017), leukocytes (p = 0.0001), thrombocytes (p < 0.0001), and albumin (p = 0.002) showed significant difference at baseline and week 54. Mean trough level of CT-P13 was 5.02µg/ml and 4.4µg/ml at week 14 and 54. Serum antibody positivity was assessed in 7.7% and 26.2% of patients at week 14 and 54, respectively. Dose escalation was necessary in one third of patients. None of the patients need surgery who completed week 54, however 4 subjects who stopped CT-P13 therapy after induction regimen required colectomy.

Conclusion: Sustained mucosal healing was achieved in one third of the patients during CT-P13 maintenance therapy. Our study confirmed the long-term efficacy of CT-P13 therapy on mucosal healing in UC. Disclosure of Interest: All authors have declared no conflicts of interest.

P1695 THE USE OF ANTI-TNFs IN INDUCING CLINICAL RESPONSE AND REMISSION IN ULCEARATIVE COLITIS: A COMPARATIVE ANALYSIS IN THE REAL-LIFE EXPERIENCE OF A SINGLE REFERRAL CENTER

B. Scriver, M.G. Cillofuo, G.C. Morreale, V. Calvaruso, M. Mendolaro, A. Vitello, S. Peralta, M. Cappello

Introduction: Anti-tumor necrosis factor (anti-TNF) agents, infliximab (IFX) and more recently adalimumab (ADA) and golimumab (GOL), have been shown effective and safe in the treatment of moderate-to-severe ulcerative colitis

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Anti-TNF is used for treatment of Crohn’s disease (CD) and ulcerative colitis (UC). Lack of head-to-head RCTs makes the choice among the three anti-TNFs difficult and indirect comparisons by network metanalyses lead to discrepant results.

Aims & Methods: Our aim was to compare efficacy of IFX, ADA and GOL in inducing clinical response and remission in a prospective cohort of patients with moderate to severe UC. From June 2015 to October 2016, 61 consecutive UC patients were treated with anti-TNFs: 19 with IFX, 25 with ADA and 17 with GOL. Disease activity was assessed by Mayo Score. Clinical response and/or remission were evaluated at week 8 and at week 16. We also recorded: indications to biologic therapy, previous immunosuppressive or anti-TNF therapy and rate of anti-TNF discontinuation.

Results: Among the 61 patients, 36 were males; mean age was 43.6 ± 15; no significant difference was present in baseline characteristics (extent and disease activity). 39 patients were thiopurine failure; 38 were naive to anti-TNFs, most were treated with IFX (p = 0.001). ADA and GOL were more often used as a second-line or third-line. The principal indication for steroid resistance patients was IFX. No significant difference was observed between IFX and ADA both at week 8 and at week 16 (p = 0.08 and p = 0.02, respectively). At week 16, IFX seems to be more effective than GOL in inducing clinical response (p = 0.048) but not remission. No significant difference among the three drugs was observed in patients naive to anti-TNFs. Treatment was discontinued in 2 patient in IFX group and in 6 patients in GOL group and in 6 patients with ADA because of persistent disease activity.

Conclusion: This single-center study shows that IFX is more effective than GOL both in the induction (8 weeks) and in the maintenance of response (16 weeks). ADA is more effective in inducing remission at 8 weeks but no significant difference is observed in the medium-term. However, GOL was used mainly as a second or third-line. In naïve patients, efficacy among anti-TNFs is comparable. Our results may help clinicians in the choice of an anti-TNF in UC. The superiority in steroid-resistant patients to get a faster response, ADA and GOL should be the first option in steroid-dependent patients naïve to anti-TNFs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Vedolizumab (VDZ), a gut-selective monoclonal anti-α4β7-integrin antibody, is used for treatment of Crohn’s disease (CD) and ulcerative colitis (UC). Data from large real-world cohorts can further characterise safety events not fully elucidated in a clinical trial setting, such as the risk of serious infections, as identified with anti-tumour necrosis factor-alpha (TNF) inhibitors.

Aims & Methods: We conducted a systematic review and meta-analysis of real-world VDZ safety outcomes reported for VDZ in UC and CD. MEDLINE-, Cochrane-, and EMBASE-indexed publications and conference abstracts (n ≥ 10) from May 1, 2014–January 10, 2017 were searched for studies reporting real-world VDZ safety outcomes. Reports for patients < 18 years of age or for off-label VDZ use were excluded. A meta-analysis was conducted using the DerSimonian-Laird random effects method to obtain a weighted mean of adverse event (AE) rates.

Results: Two hundred and eighty published studies were identified, with 33 reporting safety rates on 2857 VDZ-treated patients (CD: 1532; UC: 829; unspecified/other: 36, three studies [n=460] did not report individual UC/CD data) over a VDZ exposure/follow-up period ranging 0.5–18 months (20 studies). Among included studies, the mean age of patients ranged from 21 to 67 years, with mean disease duration ranging from 7 to 16 years. Most VDZ-treated patients (62–100%) had prior exposure to ≥1 anti-TNF therapy and 6–64% of VDZ-treated patients were receiving concomitant corticosteroids and immunomodulators. The most common non-infectious AEs were acne or acne-like lesions (5%; 95% confidence interval [CI] 3–11%), fatigue (6%; 95% CI 3–15%) and arthralgia (5%; 95% CI 3–10%) (Table 1). The most common infectious AEs were upper respiratory tract infections (7%; 95% confidence interval [CI] 5–11%), fatigue (6%; 95% CI 3–10%) and sinusitis (4%; 95% CI 1–19%) (Table 1). Infusion-related reactions occurred in 2% (95% CI 1–4%) of patients (n = 811), and maladies were reported in <1% of patients (<1–4%; 2 studies). Overall, the pooled AE rate reported in VDZ-treated patients was 21% (95% CI 14–32%); 10% (95% CI 6–16%) for infections, 8% (95% CI 6–10%) for serious AEs and 7% (95% CI 3–13%) for serious infections (Table 1).

"Includes pneumonia, lower respiratory tract infections, respiratory tract infection (not specified).

Conclusion: Pooled analysis of AE rates across multiple studies support the favourable, long-term benefit-risk profile of VDZ in real-world clinical practice, with low rates of infusion-related reactions, serious infections and malignancies reported, and no identification of new safety signals. These results are consistent with integrated safety data reported for VDZ in six clinical trials (>4000 patient-years), despite the selection of complex patients failing previous immunosuppressive or biologic therapies. Limitations of incidental reporting in real-world studies include potential underestimates of AE rates and the reporting of AEs not regularly observed in clinical trials; for example, due to the variability in medication use and sub-optimal screening of prior infections.

P1697 COST-UTILITY ANALYSES OF BIOLOGICS FOR REFRACTORY ULCERATIVE COLITIS

S. Campbell\textsuperscript{1}, C. Inserra\textsuperscript{1}, R. Salerno\textsuperscript{1}, A. Cassinotti\textsuperscript{1}, G. Muserra\textsuperscript{1}, M. Piazzella\textsuperscript{1}, A. Ardizzzone\textsuperscript{2}
\textsuperscript{1}Pharmacy, ASST Fatebenefratelli Sacco, Milan/Italy
\textsuperscript{2}Gastroenterology, ASST Fatebenefratelli Sacco, Milan/Italy

Contact E-mail Address: seccambellavics@gmail.com

Introduction: Although many biologies (Bs) have been approved for the treatment of refractory-to-severe Ulcerative Colitis (UC) in patients who have responded inadequately to conventional therapy, the selection of Bs is controversial due to the lack of head-to-head trials. Indirect economic comparisons of these costly drugs are available from National Healthcare perspectives that are not the Italian ones.

Aims & Methods: The objective is to evaluate cost-utility of Bs for the treatment of refractory ulcerative-to-severe UC both in Italy and in the Lombardy Region. A Markov model (considering 3 transition states: remission, clinical response, relapse) was constructed using the software R 3.3.1 markovchain-package to evaluate incremental cost-utility ratios (ICUR) of adalimumab (ADA), infliximab (IFX), infiximab biosimilar (IFX-B), golimumab (GOL) and vedolizumab (VED) treatments of patients over a 10-year time horizon from the perspective of the Italian (N) and Lombardy Region (R) healthcare system. Clinical parameters were derived from clinical trials. Costs (actualised by –1.5%) were obtained from the National database and Regional public tender. Utility was expressed as QALY (Quality Adjusted Life Years).

Results: Costs per treatment were different from a N and R perspective (ADA –55%; IFX –16.7%; IFX-B –29.6%; GOL –9.6%; VED –10%). Direct healthcare costs (treatment cost, visits, lab tests, hospital admissions) were calculated over 10 years of treatment per patient: ADA (N: €114,227, R: €68,314, –40.2%), IFX (N: €130,955, R: €103,081, –23%), IFX-B (N: €110,438, R: €78,852, –28.6%), GOL (N: €118,602, R: €96,922, –18.3%), VED (N: €113,852, R: €102,932, –9.6%) with associated QALY respectively of 6.68, 6.66, 6.66, 6.70, 7.02. From a N perspective, IFX-B was dominating compared to all other treatments. The ICUR of VED/IFX-B was €9,483 for 10 years (willingness to pay €94/8 QALY). From a R perspective, ADA was dominating compared to all other treatments. The ICUR of VED/ADA was €101,818 for 10 years (WTP = €182/2 QALY).

Conclusion: National and Regional cost-utility analyses produced different results. As Regional price discounts can occur, local analysis is needed to estimate the economic impact of therapies to ensure optimal choice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1698 ENDOSCOPIC SUBMUCOSAL DISSECTION OF ULCERATIVE COLITIS-ASSOCIATED DYSPLASIA: A SINGLE CENTER-BASED EXPERIENCE

D. Yang\textsuperscript{1}, S. Lee\textsuperscript{2}, K. Chang\textsuperscript{1}, E.M. Song\textsuperscript{1}, S.W. Hwang\textsuperscript{1}, S.H. Park\textsuperscript{1}, B.D. Ye\textsuperscript{1}, J.Y. Park\textsuperscript{1}, H.Y. Myung\textsuperscript{1}, S. Kang\textsuperscript{1}

Contact E-mail Address: gi.dry.yang@gmail.com

Introduction: Dysplasia is considered as the precursor of colitis-associated cancer in the long standing ulcerative colitis (UC). Although endoscopic submucosal dissection (ESD) has been suggested as an endoscopic resection technique for non-polyoid dysplasia, only a few studies investigated the feasibility of ESD as a treatment option of non-polyoid dysplasia.

Aims & Methods: We aimed to investigate the feasibility of ESD for the resection of ulcerative colitis dysplasia in UC. From August 2009 to February 2017, 19 UC patients with low grade dysplasia (LGD), high grade dysplasia (HGD) or early colon cancer were admitted for ESD and their medical records were retrospectively reviewed.

Results: Mean age of the 19 patients was 55.5±15.4 years and mean duration between UC diagnosis and dysplasia detection was 13.7±6.5 years. Nine were male. Five of 19 patients directly underwent colectomy without ESD trial due to non-lifting sign (n = 4) or surface ulceration (n = 1). Of these, preoperative single HGD (n = 3) or ECC (n = 1) patients showing non-lifting sign were diagnosed as invasive cancer and a single preoperative LGD case with non-lifting sign had multifocal LGDs in the colectomy specimen. As a result, ESD was performed for 14 of 19 patients. Major and minor axes of the lesion was 23.4±9.0mm and 18.1±9.1 mm, respectively. The lesions were located at the rectum (n = 9), sigmoid colon (n = 2), descending colon (n = 1), and transverse colon (n = 1). The gross morphology showed Paris IIa (n = 7), IIb (n = 4), Is (n = 1), and Iib + Is (n = 2). No lesions contained ulcerations. The borders were distinct in 6 and vague but endoscopically assumable in 8 cases. Mean UC endoscopic index of severity of the preoperative descending mucosa was 0.3±0.1. Mean resection time was 54.8±25.7 minutes. En bloc resection and R0 resection rates were 92.9% and 71.4%, respectively. There was no perforation or clinically significant bleeding. Mean hospitalization period after ESD was 1.14±0.36 days. Final histology of ESD specimens revealed 1 indefinite for dysplasia (IND), 1 sessile serrated adenoma/poly, 7 LGDs, 3 HGDs, and 1 intramusosal adenocarcinoma. Synchronous lesions were present in 5 patients. Synchronous dysplasia in 4 patients were removed endoscopically. However, colectomy was done in one patient suffering synchronous colorectal cancer and endoscopically unresizable dysplasia diagnosed by the surveillance biopsy specimens taken during ESD. Metachronous or recurrent dysplasia was identified in 2 of 9 patients who underwent follow-up colonoscopy after ESD (median follow-up period 12.3 months, range: 1.1–22.2 months). One developed metachronous LGD at 18 months after ESD and the other developed both metachronous and recurrent LGDs at 8 months after ESD.

Conclusion: According to our ESD series for dysplasia, ESD seems to be feasible for the selective resection of UC-associated dysplasia. However, meticulous surveillance colonoscopy is mandatory to monitor local recurrence and metachronous dysplasia. Non-lifting sign and surface ulceration are highly suggestive of invasive colitic cancer.

P1699 EVALUATION OF ADHERENCE TO INFlixIMAB THERAPY IN IBD PATIENTS

A. Cios\textsuperscript{1}, G. Corrales\textsuperscript{2}, F. Cunéte\textsuperscript{1}, T. Labatton\textsuperscript{1}, M. Larrain\textsuperscript{1}, L. Maria\textsuperscript{1}, M. Mosli\textsuperscript{1}, E. Cahén\textsuperscript{2}, E. Doménech\textsuperscript{2}
\textsuperscript{1}Gastroenterology, Hospital Germans Trias i Pujol, Badalona/Spain
\textsuperscript{2}Gastroenterology, ASST Fatebenefratelli Sacco, Milan/Italy

Contact E-mail Address: ariadna.closparals@gmail.com

Introduction: Biological therapies are effective treatments for inflammatory bowel disease (IBD) but represent an important economic burden to the healthcare system. Adherence surveillance is necessary to optimize the efficacy of treatment and its costs. This issue has been evaluated just in a few studies.

Aims & Methods: We aim to describe the adherence to infliximab in patients with IBD and identify causes and factors associated with poor adherence. We identified all IBD patients treated with infliximab in a single center since 2009. Fulfillment of the prescribed schedule was assessed for every single infliximab infusion. For every patient, we grouped infusions in “courses of treatment” defined as the administration of infliximab at the same dose and schedule for a minimum of six months. Therefore, restarting the treatment after a holiday of more than 4 months, or changing the interval of doses were considered as a new course of treatment. We defined “infusion well administered” when it was done within seven days before or after the date prescribed.

Results: We included a total of 147 courses of treatment, administered to 100 patients. Seventy-four percent of courses were Crohn disease patients, and 25% in ulcerative colitis patients. In 89% of courses combo therapy with immunosuppressants was used. The prescribed regimes were: every 8 weeks (76.2%), every 4 weeks (10,182/QALY).

Conclusion: National and regional cost-utility analyses produced different results. As Regional price discounts can occur, local analysis is needed to estimate the economic impact of therapies to ensure optimal choice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1700 TNF-EXPRESSION OF MONOCYTES IS A PREDICTIVE MARKER FOR RESPONSE TO ANTI-TNF TREATMENT

D. Lissner, B. Jessen, E. Sonnenberg, F. Schmidt, A. Kuehl, B. Siegmund
Department For Gastroenterology, Infectious Diseases And Rheumatology, Charité–Universitätsmedizin Berlin, Campus Benjamin Franklin, Berlin/Germany

Contact E-mail Address: domata.lissner@charite.de

Introduction: One-third of all patients with inflammatory bowel diseases (IBD) do not respond to initial treatment with the anti-TNF-antibody Infliximab. Thus, predictive markers for response to anti-TNF treatment are required.

Aims & Methods: The study was designed to investigate whether levels of TNF produced by peripheral blood mononuclear cells (PBMCs) can predict response to anti-TNF treatment. Fourteen patients with proven Crohn’s disease (CD) or ulcerative colitis (UC) without treatment with biologics in the past six months were included prior to first Infliximab infusion. Disease activity was measured by the use of Harvey-Bradow Index (HBI) or partial Mayo Score, C-reactive protein (CRP) and ultrasound (Limberg Score). TNF-expression of LPS-stimulated PBMCs was measured by ELISA before treatment. Additionally PBMCs’
intraacellular TNF-expression was analysed by flow cytometry. According to a current belief, TNF is principally produced by CD14⁺ and high-producer cells. Primary endpoint was clinical response, secondary endpoints were decrease in CRP and Limberg Score. Clinical response was defined as a decline in Score of ≥2 (HBI) or ≥3 (partial Mayo Score). A HBI <5 or a partial Mayo-Score <2 were defined as remission. Results were analysed using the Fisher’s exact test.

Results: Nine patients reached the endpoint at week 6 and were available for further analysis (5 patients with CD, 4 patients with UC). The median TNF-expression was 653.84 pg/ml (49.53–1154.78 pg/ml). TNF was mainly produced by CD14⁺ and monocytes. Four patients were identified as low-producers and five as high-producers. All high-producers responded well to the treatment regarding clinical scoring as compared to only half of the low-producers, but statistical significance was not reached due to the small number of patients (high: 100% vs. low: 10% clinical response, p = 0.167). However, remission rates after 6 weeks were significantly higher in high-producers compared to low-producers (high: 80% vs. low: 0% remission; p = 0.048). Secondary endpoints showed no significant difference in the two groups.

Conclusion: Quantification of TNF-expression in PBMCs and the resulting classification in low- and high-producers could be a potential predictive marker for response to anti-TNF-treatment in IBD patients.

Introduction: Corticosteroids (CS) are often used concomitantly with biologics in treatment of inflammatory bowel disease (IBD). However, their side-effect profile causes significant clinical and economic burden in long-term treatment. In this study, we investigated the impact of concomitant CS use on vedolizumab treatment persistence in patients with Crohn’s disease (CD) and ulcerative colitis (UC).

Aims & Methods: This was a nationwide (Finland), retrospective, non-interventional, multi-center chart review. From 27 centers, we included adult (≥18 years of age) IBD patients who received at least one vedolizumab infusion since 2014. Data were retrieved from patient charts in a standardized case report form. The key data collection points were at baseline, week 14 and month 6 of vedolizumab treatment. The main aim of the study was to analyze vedolizumab treatment persistence among IBD patients using CS in real-world clinical setting.

Results: 247 patients (CD 108, UC 139) were included. At baseline, 47 (43.5%) CD and 84 (60.4%) UC patients were using CS. Higher percentage of patients using CS at baseline discontinued vedolizumab during the 6-month follow-up compared to CS non-users (CD, 14/47 (29.8%) vs. 13/61 (21.5%); UC, 31/84 (37.3%) vs. 16/55 (29.1%). CS users had less vedolizumab discontinuations due to primary inefficacy (p = 0.04) and more discontinuations due to adverse events (p = 0.04), than CS non-users. Over half of the patients on CS at baseline and who persisted on vedolizumab able to continue CS before 6 months. Among CD patients, CS users had higher baseline disease activity than non-users. Such difference was not observed in UC. CS users had similar disease duration in both CD and UC. There was no difference in the number of prior TNF-alpha inhibitors between CS users and non-users.

Conclusion: Use of CS at the time of initiating vedolizumab treatment was more common in UC than in CD. Vedolizumab treatment persistence was lower in CS users than in non-users in both CD and UC. The data suggests that CS users have less vedolizumab discontinuations due to primary inefficacy and more discontinuations due to adverse events, than CS non-users. The majority of patients on CS at baseline who persisted on vedolizumab were steroid-free by 6 months, potentially relieving the burden of CS-induced side-effects for both patients and society.

Introduction: Strictures in Crohn’s disease (CD) may occur in different segments along the gastrointestinal (GI) tract. In contrast to ileocecal strictures, endoscopy demonstrates dilation (EDB) for CD-associated strictures of the upper gastrointestinal (UGI) tract is rarely reported. We therefore performed a comparison of efficacy safety and analysis of EDB for UGI CD-associated strictures in this multi-centre cohort study.

Aims & Methods: Individual patients characteristics were retrieved from electronic case report forms. Upper GI tract was defined as oesophagus, stomach and duodenum up to the ligament of Treitz. Time-to-event analysis was performed to assess symptom recurrence, re-dilation or surgery. Kaplan-Meier estimates were used to calculate event rates. For the multivariable Cox regression models, all variables that were available for at least 85% of subjects were considered for inclusion and the score method was used to choose the best model with two factors for each outcome.

Results: A total of 73 CD patients and 127 performed dilation procedures were included. Stricture locations were: duodenum n=46, stomach n=14; esophagus n=9; stomach and duodenum n=4. Technical success rate was 94.1% resulting in clinical efficacy in 88.9% of patients. Major complications, defined as perforation, bleeding or dilation-related surgery, occurred in 2.9% of all procedures. During a median follow up period of 36 months, 89.4% of patients underwent re-dilation and 29.8% required surgical intervention. The multivariable Cox regression models, all variables that were available for at least 85% of subjects were considered for inclusion and the score method was used to choose the best model with two factors for each outcome.

Conclusion: The goal of maintenance therapy in Ulcerative Colitis (UC) is to keep clinical and endoscopic steroid-free remission. 5-aminosalicylate (5-ASA) represents the first line maintenance therapy. Non-adherence to 5-ASA is associated with an increased risk of disease relapse, colorectal cancer and worsening of quality of life. Adherence rate has been analysed in several studies with controversial results.

Contact E-mail Address: Fatima.Bhayat@takeda.com

Introduction: Systemic immunosuppressive treatment, such as anti-tumour necrosis factor-alpha (TNFα) therapy, can reactivate latent hepatitis virus. VDZ is a humanised monoclonal antibody, blocks gut-specific lymphocyte trafficking by binding to α4β7 integrin and is approved in moderately to severely active ulcerative colitis or Crohn’s disease. The gut selectivity of VDZ may be associated with lower risk of virus reactivation than anti-TNFα agents. The VDZ European Product Label advises caution regarding VDZ use in patients with controlled chronic severe infection or a history of recurring severe infection. As VDZ clinical trials excluded patients with chronic viral hepatitis B or hepatitis C infection, there are no clinical trial data available in this patient population.

Aims & Methods: Here, we describe the safety experience of VDZ use in patients with pre-existing hepatitis B or hepatitis C in the post-marketing setting. Adverse events (AEs) were identified from the VDZ Global Safety database (data-cut May 20, 2014 to Nov 19, 2016) and included if patients’ medical history or concurrent conditions included a Medical Dictionary for Regulatory Activities (MedDRA) preferred term suggestive of hepatitis B or hepatitis C infection.

Results: In the context of ~77,382 patient-years of VDZ exposure and a total of 36 events (event rate: 0.47 event per 100 patient-years) in the VDZ database (n=13 participants, 9 non-serious) occurred in 15 patients with pre-existing viral hepatitis B (n=5, including 2 chronic cases) or hepatitis C (n=10). Of the 15 patients, six had ulcerative colitis, seven had Crohn’s disease, and in two the indication was not specified (NI). Eight patients received prior/concomitant anti-TNFα therapy. NI rate = 2. Events reported were reflective of the general VDZ safety profile in patients without viral hepatitis. Liver-related events were reported in two patients with hepatitis C—one patient who was a smoker reported hepatic neoplasms; the other related hepatitis macular Arnold–Cherubini syndrome, bladder tumour removal and right radical orchidectomy. Both events resulted in VDZ discontinuation. Of events with a reported outcome, 22/26 (84.6%) were resolved or resolving at the time of reporting and 4/26 (15.4%) were unresolved; NI rate = 25. VDZ treatment was continued in 10/14 (71.4%) patients and discontinued in 4/14 (28.6%); NI rate = 1.

Conclusion: In the post-marketing setting, there was no evidence of increased risk of virus reactivations in patients with hepatitis B or hepatitis C receiving VDZ. Limitations associated with post-marketing safety reporting (e.g. nature of reporting and incomplete patient medical history) and currently limited availability of VDZ in regions with endemic hepatitis B and hepatitis C infection should be considered when interpreting these results.

Introduction: Randomized controlled trials provide efficacy data of novel IBD drugs. The majority of patients included in these trials however, especially for novel biologics, are highly selected patients from referral centres and are included in a variety of countries with very different health care systems. Inclusion criteria and follow-up protocols are strict and do not reflect routine care. Long-term country specific effectiveness and safety data for novel drugs are therefore warranted. Development and implementation of a novel protocol and electronic case reporting registry for every new compound is however time consuming and expensive. Therefore, the Initiative on Crohn and Colitis (ICC) aimed to develop a web-based registry suitable for capturing, managing, and reporting data for all drugs and all IBD phenotypes in everyday practise in all centres.

Aims & Methods: Here, we aim to test the feasibility of the web-based registry in patients starting vedolizumab. With a structured iterative process with IBD-specialist from the ICC, case report forms and lab-evaluation forms were developed. A total of 230 IBD (4 IBD-U) patients starting vedolizumab were included in this retrospective study. Two hundred and fifty-seven patients were evaluated, 143 (55.6%) with CD and 114 (44.4%) by ulcerative colitis (UC). One hundred and forty-two (55.2%) were male. Median age at start was 39 (21.2–69.8) and are reported in table 1. The registry automatically reminds the treating physician or nurse prior to novel follow-up visits. Feasibility of the ICC-case series was assessed in 6 centres. Table 1 shows clear differences between baseline characteristics of real-life Dutch patients and patients in the GEMINI studies underlining the importance of country specific post-market data.

Introduction: Azathioprine (AZA) and thiopurine are widely used for induction and maintenance of remission in patients steroid-resistant or dependent with inflammatory bowel disease (IBD). The treatment must be withdrawn in 5–30% of patients due to the occurrence of adverse events.

Aims & Methods: Aim of this study has been to investigate its efficacy and safety in maintaining steroid-free remission in steroid dependent IBD patients six year after the institution of treatment. Data from consecutive IBD outpatients referred in our Institution, between 1985–2015, were reviewed and all patients treated with AZA were included in this retrospective study. AZA was administered at the recommended dose of 2–2.5 mg/kg. Blood chemistry was analysed before administration of the drug, every 10–15 days for the first 3 months and then every 1–2 months following the institution of treatment.

Results: Out of 2722 consecutive IBD outpatients visited in the index period, AZA was prescribed to 415 patients, 227 (54.7%) were affected by Crohn’s disease (CD) and 188 (45.3%) by ulcerative colitis (UC). One hundred and fifty-eight patients with a follow-up <72 months were excluded from the study. Two hundred and fifty-seven patients were evaluated, 143 (55.6%) with CD and 114 (44.4%) with UC. One hundred and forty-two (55.2%) were male.

Conclusion: The ICC developed a uniform web-based registry to study post-marketing safety and effectiveness of novel IBD-drugs. A feasibility study with 230 patients starting vedolizumab showed successful data-capture, managing, and reporting with the ICC-case series in 6 centres. Table 1 shows clear differences between baseline characteristics of real-life Dutch patients and patients in the GEMINI studies underlining the importance of country specific post-market data.
and 115 (44.8%) female (average age of 35.68±14.22 SD years, range 14–74 y.). Six years after the institution of treatment, 130 (50.6%) patients still were in steroid-free remission (85 CD vs 45 UC, 59.5% and 39.5%, respectively, p = 0.0017), 71 (27.6%) had a relapse requiring retreatment with steroids (29 CD vs 24 UC, 20.3% and 36.6%, respectively, p = 0.0048), 56 (21.8%) discontinued the treatment due to side effects (29 CD vs 27 UC, 20.2% and 23.7%, respectively). Loss of response from 1st to 6th year of follow-up was low, about 20%.

Conclusion: Six years after the onset of treatment 56% of patients did not require further steroid courses. After the first year loss of response was low in five subsequent years. In the present series the maintenance of steroid-free remission was significantly higher in CD than in UC patients. The occurrence of side effects leading to the withdrawal of AZA treatment has been low.

**P1708 CLINICAL EFFICACY AND SAFETY OF ANTI-TNF THERAPY IN INFLAMMATORY BOWEL DISEASE IN THE ELDERLY: A UK TERTIARY REFERRAL CENTRE EXPERIENCE**

J. Digby-Bell
Dept. Of Gastroenterology, St. Thomas’ Hospital, London/United Kingdom

Contact E-mail Address: jdlgbbell@doctors.org.uk

Introduction: Many patients, especially the elderly or those with comorbidities, are excluded from clinical drug trials and little real-life data exists on the safety and efficacy of anti-TNF.

Aims & Methods: We aimed to compare the clinical efficacy and safety of anti-TNF therapy in patients over 60 years in a tertiary IBD centre in London, UK. We interrogated our IBD biologic database from January 2009 to November 2015 and performed retrospective data analysis until end of follow up in April 2017. Data was collected on demographics, endoscopy, calprotectin, CRP, clinical scores, serious infections, malignancy, drug levels and anti-drug antibodies. Patients with an age of ≥60 when starting anti-TNF therapy were identified and ≥60 comparators were selected at random in a 1:2 ratio. Primary endpoints: week 14 and week 54 steroid free clinical remission (Harvey Bradshaw Index < 5 or Simple Colitis Activity index < 3) Secondary endpoint: proportion of patients remaining on anti-TNF at the end of follow up

Results: See table.

Conclusion: Only a small number of ≥60 patients started anti-TNF (29 out of greater than 650). This may reflect our local population or that clinicians favour anti-TNF therapies in this older group. Overall there was similar clinical efficacy at weeks 14 and 54 of anti-TNF therapy between the ‘young’ and ‘old’ groups. There was a higher discontinuation rate after 1 year of therapy in the older group (p = 0.043). There were more adverse events in the older group (7/29) including 3 new cancer diagnoses compared with the younger group (3/58), 4 patients had detectable anti-drug antibodies in the older group despite 2 of them having therapeutic thiopurine suggesting that the elderly may have more immunogenicity than the young. Further studies with more patients across multiple sites are required to clarify safety and efficacy in the elderly.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1709 TACROLIMUS IN REFRACTORY ULCERATIVE COLITIS–12 MONTH OUTCOME IN A SINGLE-CENTRE UK DISTRICT HOSPITAL**

N. Jayasooriya, L. Everson, S. Mann
Gastroenterology, Barnet and Chase Farm Hospital, Royal Free Trust NHS, Barnet/United Kingdom

Contact E-mail Address: nishami.jayasooriya@nhs.net

Introduction: Rescue therapy is required for patients with moderate - severe ulcerative colitis (UC) who have failed to respond to steroids and thiopurines. Anti-Tumour Necrosis Factor agents (Anti-TNFs) are widely used before considering a colectomy. Calcineurin inhibitors such as ciclosporin and Tacrolimus may be considered as alternatives to biologics. There have been some case series in assessing the use of Tacrolimus in such patients although the United Kingdom experience is limited. (1, 2)

Aims & Methods: We aimed to review the outcome of patients who received Tacrolimus as rescue and subsequent maintenance therapy for refractory symptoms of UC. This was a retrospective single-centre case review series. All patients who were refractory to standard medical therapies and being considered for a colectomy were reviewed by a Gastroenterologist with an interest in Inflammatory Bowel Disease. Demographic data, indications for treatment, clinical course and outcomes were reviewed from Electronic Patient Records (EPR).

Results: Fourteen patients (F = 6; mean age of 54 years) received Tacrolimus. 8 patients (57%) had evidence of pancolitis and six patients (43%) had distal colitis. All patients had previously received thiopurines and 11 patients (78.6%) had also received anti-TNFs. Three patients declined Anti-TNF treatment. All patients were steroid-dependent prior to commencing Tacrolimus. One patient received ciclosporin before the switch. The remaining 13 patients were initiated on Tacrolimus in the out-patient setting at a staring dose of 0.1 mg/kg/day in 2 divided doses. Patients took Tacrolimus for a mean period of 18.8 months (range: 2 months to 49 months). Eight patients (57%) achieved a steroid-free remission within 6 months. An additional 3 patients (23%) had a clinical response within 6 months, but required one course of steroids during this time period. Three patients (23%) failed to respond to Tacrolimus; 1 patient remains steroid-dependent and does not wish to proceed to surgery, 1 patient was switched to infliximab and 1 patient proceeded at 10 months to have an elective subtotal colectomy. Tacrolimus was withdrawn in all 3 non-responders. Of the 13 (78.6%) initial responders, 12-month outcome included withdrawal of Tacrolimus in 7 patients (63.6%). Reasons for withdrawal included: n = 1 renal impairment; n = 1 started on infliximab; n = 3 referred for leucapheresis; n = 1 restarted on Azathioprine and n = 1 referred for proctocolectomy. Three patients (21.4%) remain in steroid-free clinical remission with a good quality of life and

</tbody>
</table>
no adverse effects on maintenance treatment with Tacrolimus. 11 patients (47% of the population) had to stop treatment due to adverse effects within the first 12-months of follow-up.

**Conclusion:** Tacrolimus should be considered as an alternative treatment for patients with refractory UC in the out-patient setting. This is particularly useful if the patient is unwilling to consider a colectomy. With close monitoring and regular visits to the clinic, it is safe and feasible allowing patients an alternative immunosuppressant which may either avoid the need for a colectomy or, give some time to adjust to its implications.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**PI710 A REAL LIFE COMPARISON OF THE EFFICACY OF ADALIMUMAB VERSUS GOLIMUMAB IN MODERATE-TO-SEVERE UC: A MULTICENTER EXPERIENCE FROM THE SICILIAN NETWORK FOR INFLAMMATORY BOWEL DISEASE (SN-IBD)**

**Aims & Methods:** We reported the Sicilian Network experience on the comparative efficacy of ADA and GOL in patients (pts) with moderate-to-severe UC. From June 2015 until April 2017, 197 consecutive pts with moderate to severe UC were treated with ADA or GOL. The efficacy was evaluated at 8 week and at the end of the follow up considering “clinical response” (reduction of at least 2 points of Partial Mayo Score with concomitant steroid reduction or discontinuation) and “clinical remission” (Partial Mayo Score <2 without steroids). The presence of clinical response or clinical remission was defined as “clinical benefit”.

**Results:** 118 pts were treated with ADA and 79 with GOL for a median follow up of 40.21 (20.32, 69.14) weeks for ADA and 34.00 (17.43, 54.79) weeks for GOL (p = 0.08). Eighty-eight pts were naïve to anti-TNFα (59 ADA, 29 GOL, p = 0.09). No difference in Mayo Score value was observed between the 2 groups at the time of first drug injection (p = 0.92). After 8 weeks clinical benefit was achieved in 93/118 (78.8%) pts treated with ADA and 50/79 (63.3%) pts treated with GOL (p = 0.026). Clinical remission was achieved in 48/118 (40.7%) pts treated with ADA and 20/79 (25.3%) pts treated with GOL (p = 0.038). At the end of the follow up clinical benefit was achieved in 79/118 (66.9%) pts treated with ADA and 37/79 (46.8%) pts treated with GOL (p = 0.008). Clinical remission was achieved in 50/118 (42.4%) pts treated with ADA and 23/79 (29.1%) pts treated with GOL (p = 0.089). No difference was observed in clinical outcomes at 8 weeks and at the end of the follow up between naïve and non naïve pts (p = 0.187). At the end of the follow up the median Endoscopic Mayo Score was 3.00 (0.00, 5.00) in pts treated with ADA and 4.00 (1.00, 7.00) in pts treated with GOL (p = 0.025). Univariable analysis revealed that age ≥ 40 years at the time of first drug injection and age < 40 years at the diagnosis were associated with higher remission rate in pts treated with ADA respect to pts treated with GOL at 8 weeks and at the end of the follow up (p = 0.016 and p = 0.036). Disease duration > 5 years was associated with a higher remission rate in pts treated with ADA respect to pts treated with GOL at 8 weeks and at the end of the follow up (p = 0.037).

**Conclusion:** This is the first study where the comparable efficacy of ADA and GOL was evaluated. These real life data confirmed the efficacy of subcutaneous anti-TNFα in the treatment of moderate to severe UC. ADA resulted to be more effective than GOL in inducing and maintaining clinical benefit.

Larger prospective studies with longer follow up are warranted to confirm this data.

**PI711 REAL-LIFE STUDY (GORE-UC) EVALUATING THE EFFECTIVENESS OF GOLIMUMAB FOR THE TREATMENT OF UC: AN INTERIM ANALYSIS FROM ITALIAN GROUP FOR THE STUDY OF INFLAMMATORY BOWEL DISEASE (IG-IBD)**

**Aims & Methods:** An observational, non-interventional, retrospective, phase IV study, enrolling all patients starting golimumab from March to December 2015, from 21 IG-IBD centers. This study consists of two different parts: 1) retrospective, regarding data until December 2016 and 2) a prospective one, still ongoing, that will be concluded at the end of 2017. The co-primary outcomes were the overall durability of treatment with golimumab, defined as persistence on golimumab therapy because of sustained clinical benefit, and safety. Results for the first 54-week period are reported.

**Results:** 121 patients (47% female; median age of 45.7 years (IQR 14.3) and a median duration of disease of 8 years, (range 0–28) were included. Sixty-seven patients (55.4%) had severe endoscopic activity (Mayo 3). Clinical activity was defined as moderate (Partial Mayo Score (PMS) 5–6) in 55 patients (45.5%) and severe (PMS 7–9) in 66 patients (54.5%). Percentage of patients exposed to anti-TNFα was reported in 52% of patients (38 Infliximab, 4 Adalimumab, 21 both). Steroid-dependence and refractoriness were reported in 78.5% and 16.5% of patients, respectively. After 54 weeks, the cumulative persistence on golimumab therapy was 35%. Seventy-seven patients withdrew from treatment, without significant difference among anti-TNFα naïve vs exposed patients (55.2% vs 71.4%, p = 0.11 Chi-Square test). Among 90% of patients who completed week 8, 48% of patients were still on golimumab therapy at week 54. Thirty patients (24%) were withdrawn within the first 4 weeks. Among the remaining patients, at week 54 the persistence on golimumab therapy was 57.1%. Ten patients reported an adverse event, but only 6 of them withdrew from treatment. Four patients reported paradoxical skin lesions, unresponsive to topical therapy. Fifteen patients (12.4%) underwent surgery within the first 54 weeks, with a greater percentage among anti-TNFα exposed (20.6% vs 3.4%, p = 0.02 Chi-Square test).

**Conclusion:** This preliminary real-life data study endorses golimumab’s promising results, showing 57.1% of durability treatment at week 54 in those patients.
who completed first 14 weeks of treatment and confirming it as a safe drug. Anti TNF-α naïve patients were more likely to avoid colonoscopy.

Introduction: Ciprofloxacin is one of the most frequently used antibiotics in hospitalized inflammatory bowel disease (IBD) patients. Also discrepancies between clinical guidelines and real clinical situations are observed in terms of antibiotics use in patients with IBD. In the last few years an emerging resistance to ciprofloxacin, ranging from 43% to 82%, has been described in extended spectrum beta-lactamase producing bacteria (ESBL-E) colonizing the gut.1,2

Aims & Methods: The objective of this study was to evaluate the gut colonization with ESBL-E in IBD patients, determine the resistance to ciprofloxacin and bacterial plasmid genes associated with that. Rectal swabs were collected from all consecutive patients with confirmed ulcerative colitis (UC) and Crohn’s disease (CD) colonized with gut ESBL-E during a 7-year period (2010–2016). Enterobacteria were cultured and analyzed for ESBL presence according to EUCAST guidelines, resistance to ciprofloxacin and bacterial plasmid genes CTX-M, TEM and SHV were detected.

Results: A total of 148 patients with confirmed IBD diagnosis were included in the study–101 (68%) with UC, 47 (32%) with CD. We found that 12 (12%) of the UC patients and 5 (11%) of the CD patients were colonized with ESBL-E. The isolated ESBL producing strains from UC patients included Escherichia coli (n = 10), Klebsiella oxytoca (n = 1) and Escherichia hermanii (n = 1). The isolated ESBL producing strains from CD patients included only Escherichia coli (n = 5). The isolated bacterial plasmid genes associated with ESBL production in UC included CTX-M (n = 11; 92%), TEM (n = 4; 33%), SHV (n = 1; 8%), in CD–CTX-M (n = 4; 80%) and TEM (n = 3; 60%). In UC 6 (50%) and in CD 1 (20%) of the isolated ESBL producing strains from CD patients included only Escherichia coli (n = 5). In 1 case of the ciprofloxacin resistance CTX-M, TEM and SHV gene combination was observed, in 1 case CTX-M and TEM gene combination was observed, in 4 cases only CTX-M gene was present and in 1 case only TEM gene was present. Colonization rate with ESBL-E in IBD patients, mostly with Es. coli, expressing CTX-M gene was found comparing with the literature. 2. Higher resistance to ciprofloxacin was found in ESBL-E isolated from UC patients, compared to UC patients. 3. CTX-M and TEM genes are associated with resistance to ciprofloxacin.

Introduction: Ano-perineal fistulas (APF) are a common location of Crohn’s disease (CD). Their treatment is still disappointing. Identifying the predictive factors of response could guide the practitioner to adapt the anti-TNF α treatment of each patient.

Aims & Methods: We performed a descriptive, longitudinal and retrospective study over a period of 14 years. We included all patients with a definite diagnosis of complex APF of CD treated with anti-TNF α with a minimum follow-up of one year. Patients less than 16 years of age or over 70 years were excluded and non-observing patients were also excluded. A univariate and multivariate statistical analysis was then carried out using the SPSS software to identify the predictive factors of response to the treatment.

Results: A total of 49 patients had complex APF treated with anti-TNF α. 10% of the patients had also recto-vaginal fistulas. The mean age was 31 years. The sex ratio women/men was 1.35. All of the patients had an MRI at diagnosis. Patients had concomitant antibiotics and seton drainage in all cases. 76% of the patients received azathioprine. After the induction phase, 53% of the patients

Disclosure: The general sample of health insurance beneficiaries’ database provides a unique representative sample to analyze and describe real-life usage of anti-TNF in Crohn’s disease patients in France. All authors have declared no conflicts of interest.

Conclusion: The general sample of health insurance beneficiaries’ database provides a unique representative sample to analyze and describe real-life usage of anti-TNF in Crohn’s disease patients in France.
achieved clinical remission, 31% a partial clinical response and 12% a primary failure. The patients maintained a clinical remission after a year of anti-TNF therapy. After a mean time of 13 months, 42% of the patients had a loss of response. The analytical study found that the absence of recto-colic involvement, CRP negativity and normalization of platelet count under treatment and achievement of clinical remission after the induction phase were predictive factors of long-term good response to anti-TNF therapy. Clinical remission after the induction phase was the only independent predictive factor of long-term remission under maintenance treatment after multivariate analysis. However, presence of recto-Vaginal fistula as well as the presence of a recto-vaginal fistula and young age at diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The management of chronic inflammatory bowel disease (IBD) has experienced significant advance with the development of biologic therapy. Infliximab (IFX) was the first monoclonal antibody approved for IBD. The patent expiry of biologics and their relatively high costs that result in a significant financial burden on the healthcare system, led to the development of biosimilar agents. The biosimilar IFX has been authorised for use in all the indications as the reference IFX. The demonstration of biosimilar IFX efficacy and safety equivalence was based on two pivotal clinical trials in rheumatic diseases. As a result of the extrapolation to IBD, there is growing controversy regarding the appropriate use of biosimilar IFX. The efficacy and safety of infliximab reference in inducing and maintaining remission in IBD has been extensively proven in clinical trials. However, the role of biosimilar IFX, has not been systematically investigated in clinical practice.

Aims & Methods: We aimed to compare the safety and efficacy in inducing and maintaining remission in IBD, between the reference IFX group and biosimilar IFX group. This retrospective, multicenter study was carried out at 4 tertiary hospitals, from January 2013 to December 2016. The analysis included 2 cohorts of consecutive IBD patients. One cohort composed of patients who were started original IFX since 2013. The second cohort included patients who were treated from the introduction of biosimilar IFX. Adverse events (AEs), demographic, clinical, endoscopic and laboratory data were collected on all patients. Efficacy was assessed according to response and remission at 14th, 54th week. For CU, response was defined as a decrease in partial Mayo score of 2 or more from baseline and a partial Mayo score of 1 or less was used to remission. For CD, response was defined as a decrease in Harvey-Bradshaw score of 3 or more from baseline, and a Harvey-Bradshaw score of 4 or less was used to remission. We used Student’s t for independent samples and Chi-square test. Time to withdrawal due to adverse effects was estimated using Kaplan-Meier survival analysis, and the log rank test was used to test for treatment group differences.

Results: The analysis included 346 consecutive IBD patients, 104 treated with original IFX and 242 with biosimilar IFX. 103 patients were diagnosed with CU, 238 with CD and 5 with indeterminate colitis. Overall median follow-up was 21 months. Baseline clinical activity scores were not significantly different among the 2 groups. Frequency of coexisting azathioprine and systemic steroids were not different among both groups. Patients in biosimilar infliximab group were more likely to experience previous biologic treatment failure (29.2% versus 20.2% in the original IFX, p = 0.0163). There were no significant differences in patients achieving response and remission at weeks 14 and 54. There were no significant differences in rate of withdrawals among the 2 groups (37.1% versus 38.8% for biosimilar IFX, p = 0.811). There were no significant differences in cumulative discontinuation rate due to AEs in original IFX and biosimilar IFX (42.42, (95% CI 39.49–45.34) months versus 44.61 (95% CI 42.66–46.56) months, log-rank test p = 0.292).

Conclusion: Our clinical experience showed similar efficacy and safety profile of biosimilar IFX compared to original IFX.

Introduction: The prevalence of Crohn’s disease is important for planning of health care and allocation of clinical resources. In 2005, a National Patient’s Registry in Poland was established to collect demographic and clinical data. To quantify efficacy of medications in real-life treatment during the study period, data regarding medical treatment were collected from Registry.
Aims & Methods: The aim of the study was assess the efficacy and tolerance of different medications in reference to demographic data and disease location and behaviour.
Results: 60/630 of patients have been enrolled to the Polish National CD Patient’s Registry, conducted in 9 gastroenterology centers in Poland. Patient’s phenotype according to: Montreal classification, demographics, smoking, alcohol consumption, extraintestinal manifestation and medical treatment have been evaluated. The impact of demographic factors on the use of drugs from different groups (mesalamine, prednisone, azathioprine, methotrexate, anti-TNF), and medications efficacy and tolerance was assessed. The efficacy assessment was evaluated according to subjective 4-step scale. Similarly treatment tolerance was assessed according to 2-step scale.
Results: No gender effects were observed on the use or efficacy of individual drug classes, although greater tolerability of prednisone and azathioprine was observed in men (respectively 95.56 vs 93.82 and 93.4 vs 91.65, both p < 0.05). Smoking did not affect the effectiveness and tolerability of the used medications. However surprisingly fewer smokers were treated with azathioprine, methotrexate, and anti-TNF in comparison to non-smokers (38 vs 45%, 0.5 vs 1.55%, 0.5 vs 11%, all p < 0.05) In patient’s declaring casual alcohol use, the efficacy and tolerability of prednisone was significantly better than in patients declaring abstaining (89 vs 84 and 96 vs 93%; p < 0.05). Referring to the Montreal classification, efficacy of mesalamine, prednisone and azathioprine was significantly higher in A1 group with the lowest in A2 patients (A1: 90, 56% and 14, 40%); adalimumab (n = 14, 40%), etanercept (n = 10, 29%), vedolizumab (n = 7, 20%), and certolizumab pegol (n = 4, 11%). Combination therapy with an immunomodulator and a biologic agent was administered in 57% of cases (n = 20). All patients were treated for LTBI and the majority (83%) was treated prior to

P1719 EFFICACY OF VEDOLIZUMAB INDUCTION THERAPY IN PATIENTS WITH SEVERE, THERAPEUTIC RESISTANT INFLAMMATORY BOWEL DISEASE

Introduction: Vedolizumab (VDZ) is the first gut-specific monoclonal antibody alternative to anti-tumor necrosis factor alpha therapy in patients with moderate- to-severe inflammatory bowel disease (IBD). It has been registered since 2016 in Hungary, but currently the high treatment costs are considerably limiting the availability of VDZ. All newly initiated VDZ therapy is individualized, it should be approved by the steering committee of five Hungarian IBD-specialists. This results in that VDZ therapy is available exclusively for patients in whom conventional treatment was ineffective or contraindicated.
Aims & Methods: The aim of our non-interventional retrospective study was to assess the efficacy of induction VDZ therapy. 41 patients with Crohn’s disease (CD) and 25 with ulcerative colitis (UC) received VDZ induction therapy between September 2016 and April 2017 in Hungary. Efficacy of induction therapy was assessed based on the changes of activity indices on week 14.
Results: Of 41 enrolled IBD patients, 24 patients were therapeutic failure or intolerant for infliximab and/or adalimumab therapy. The mean age was 38.6 years (range 18–67; median 40) and the average disease duration was 11.7 years (range 1–36; median 10). In 16 cases moderate and in 25 cases severe disease activity was observed. Extraintestinal manifestations occurred in 19 patients, and in 13 cases the IBZ was associated with primary sclerosing cholangitis (PSC). Rate of the therapeutic responders for VDZ induction therapy was 80.49% (N = 33). Complete clinical remission was observed in 19 cases (46.34%) and 8 cases (19.51%) of which were steroid-free remission. In one case VDZ therapy had to be interrupted due to development of IBD associated colorectal cancer and in one case due to MCV infection.
Conclusion: Our results suggest that induction VDZ therapy is effective and it is a safe therapeutic option in anti-tumor necrosis factor alpha failure or intolerant IBD patients with moderate or severe disease activity.

Introduction: Tuberculosis (TB) reactivation is of particular concern in patients with inflammatory bowel disease (IBD) treated with biologic therapies. Screening for latent tuberculosis infection (LTBI) is indicated prior to initiating treatment. Between January 1996 and August 2016, data extracted included 41 IBD patients diagnosed with LTBI following a tuberculin skin test (PPD) or interferon gamma release assay (IGRA) and who received biologic therapy between January 1996 and August 2016. Data extracted included patient demographics, TB risk factors, chest x-ray findings, biologic agent used, prior and concomitant therapy used were biologic therapy and the timing of biologic therapy initiation has not been extensively studied.
Aims & Methods: In order to evaluate the effectiveness of LTBI treatment in IBD patients receiving biologic, we conducted a retrospective review of all IBD patients diagnosed with LTBI following a tuberculin skin test (PPD) or interferon gamma release assay (IGRA) and who received biologic therapy between January 1996 and August 2016. Data extracted included patient demographics, TB risk factors, chest x-ray findings, biologic agent used, prior and concomitant therapies, and LTBI treatment regimen. TB reactivation after completion of LTBI treatment was the primary outcome of the study. Risk of TB reactivation was calculated using McGill University’s ‘The Online TST/IGRA Interpreter.'
Results: A total of 35 IBD patients (27 Crohn’s; 8 ulcerative colitis) were included in the study. Their mean age was 38.3± 14.4 years and 68.6% were male (Table 1). The median time from diagnosis of IBD to LTBI was 9 years (0–48 years). Prior IBD therapies included corticosteroids (86%), aminosalicylates (83%), other immunosuppressants (69%). At least 43% of patients have been previously exposed to at least 1 biologic agent. The most common LTBI treatment regimen was isoniazid (INH) for 9 months (n = 26, 74%). Biologic therapy used were infliximab (n = 14, 40%), adalimumab (n = 10, 29%), vedolizumab (n = 7, 20%), and certolizumab pegol (n = 4, 11%). Combination therapy with an immunomodulator and a biologic agent was administered in 57% of cases (n = 20). All patients were treated for LTBI and the majority (83%) was treated prior to
starting biologic therapy. The median time from initiation of LTBI treatment to biologic was 43 days (IQR: 23–40). The median duration of follow-up was 2.9 ± 3.3 years. The median calculated annual risk of developing active TB without treatment was 0.52% (0.08%–1.3%). Of the cohort studied, only one patient taking adalimumab monotherapy after completing 6 months of INH therapy developed reactivation of TB. The estimated TB reactivation rate in our cohort was 0.98 cases per 100 patient-years of follow up.

Conclusion: Treatment for LTBI in patients with IBD treated with biologics is effective, but does not eliminate the risk of reactivation, which occurred at a rate of 0.98 cases per 100 patient-years in our cohort. Additional studies with extended follow-up are warranted to further characterize the efficacy of LTBI treatment in these patients.

Introduction: Resection in Crohn’s disease (CD) intends to be a curative surgery, but in 40%–50% of cases it is not possible to remove completely the lesions of the damaged gut. The aim of our study was to describe the characteristics and management of patients with residual disease after surgery (RD) and to compare these with patients with curative surgery (CS) in post operative CD patients.

Aims & Methods: PRACTICROHN was a retrospective study that included adult patients from 26 Spanish hospitals who underwent CD-related ileocolonic resection with ileocolic or ileorectal anastomosis between January 2007 and December 2010. Clinical data was retrospectively collected from clinical charts. RD was defined when lesions were still present after surgical resection. Postoperative recurrence (POR) was defined by clinical symptoms (diarrhea, abdominal pain) and endoscopic Rutgeerts score ≥2, and/or CT or MRI confirmation of disease activity. Categorical variables were compared with the χ2 test or Fisher’s exact test. Kaplan-Meier method was used to assess time to clinical recurrence and a log-rank test to obtain statistical significance. Results: Three hundred and sixty-four patients were analyzed (mean age 40 years [SD 13], 50% men). Of these, 27 (7.5%) had RD after surgery. Median age at diagnosis was shorter in patients with RD than CS: 23 (IQR 19–34) years vs 29 (IQR 23–40), p = 0.02. At the time of resection B1+ (p+), behavior was more frequent in RD than in CS: 6 (22%) vs 26 (8%), p = 0.05; and location was mainly L1±(±)L4 in CS (190, 57%) and L3±(±)L4 in RD (190, 70%), p = 0.02. Four (16%) patients in RD were receiving immunomodulators at the time of surgery vs 132 (41%) of CS, p = 0.002. More patients in RD vs CS presented postoperative complications (12 (44%) vs 87 (26%), p = 0.06) as well as hospitalizations the first year after surgery (30 (37%) vs 42 (12%) p = 0.001). No differences in smoking habit, perianal disease or length of resection were found between the two groups. More patients were performed an endoscopy within the first year after surgery in the RD vs CS: 16 (39%) vs 122 (36%), p = 0.03 but no difference in prophylactic treatment were found in RD vs CS groups. POR was more frequent among patients with RD (69% vs 29%, p = 0.001). Median time to POR was longer in patients who received prophylaxis vs those who didn’t received it (698 vs 392 days; p = 0.41).81/275 (29%) in the CS presented POR with median time to POR being longer in patients who received prophylaxis (no median found vs 1529 days) p = 0.04. Table 1. Table 1

Conclusion: Residual disease is a rare situation after intestinal resection in CD. Patients with residual disease after surgery are more likely followed-up endoscopically within the first year. Conversely, similar proactive recurrence prevention was observed compared to curative surgery. In the case of residual disease although prophylactic treatment is useful, most of the patients will present POR. RD is a factor of poor postoperative in post-operative CD patients.

Introduction: Bile acid malabsorption (BAM) is a common cause of diarrhoea in Crohn’s disease (CD) patients with ileal resection and can lead to complications such as renal and biliary stone disease. BAM is usually diagnosed by selenium labelled homotauricolic acid test (75SeHCAT) but its availability is limited. Thus, a large proportion of resected CD patients either remain undiagnosed or subject to empirical therapy. There is a paucity of studies examining the correlation between length of ileal resection and severity of BAM which will be of particular use to clinicians with no recourse to diagnostic testing for BAM.

Aims & Methods: We identified all CD patients with a prior surgical resection who underwent 75SeHCAT testing at our institute. Testing was based on the treating clinician’s discretion. The length of resected ileum was recorded from histopathology report. We conducted a Spearman’s correlation test to check for correlation between length of resected ileum and percentage retention on 75SeHCAT. Response to treatment with bile salt sequestrant and 75SeHCAT retention values was tested using Mann-Whitney test.

Results: A total of 97 patients were identified with a mean age of 46.4 (SD 14.5). The median length of resected ileum was 22.5 cms (range 1.5–95 cms) with a median of 1 resection (range 1–4). Overall, 90 patients (92.8%) had 75SeHCAT retention values of <5%, 5 (5.2%) patients between 5–10% and only 2 patients had values of >15%. There was moderate correlation between 75SeHCAT retention and length of ileal resection (Spearman’s rho: 0.4041, P < 0.001). Data on response to treatment was available for 60 patients, of whom 41 (42%) responded and 19 (19%) failed to respond to bile salt sequestrants. The 75SeHCAT retention values was comparable among responders (median 0.02%, range 0.1–6.6) and non-responders (median 0.02%, range 0.1–6.6, Mann-Whitney test, P = 0.72).

Conclusion: There was moderate correlation between length of ileal resection and severity of BAM as defined by 75SeHCAT retention values. Response to bile salt sequestrant therapy was not dependent on 75SeHCAT retention values.

CLOSTRIDIUM DIFFICILE
Medical Center, Boston, MA, USA, Boston/United States of America

whether SB enhances transformation to ‘protective’ secondary BA in human.
'pro-germination' primary BA including CA in human stools B) Describe primary BAs (cholic acid and chenodeoxycholic) into secondary (deoxycholic acid) in human.

Group 1 (n = 12) received AC for 7 days and SB for 14 days. Group 4 (n = 12) did not receive any treatment. Group 1, 2, 3 had successive stool samples at D-28, 0, 7, 10, 13, 21. Group 4 had stool samples at D0, 7 and 21. The fecal concentrations of 28 BAs were measured by HPLC-MS, and expressed as % of total BA concentration.

Results: AC alone (group 2) significantly reduced the rate of fecal secondary BA at day 7 compared to control (group 4) (54.8 ± 10.1 vs 83.1 ± 7.4%, p = 0.017). In group 3 (AC plus SB), the decrease in secondary BA rate was significantly less than for AC (71.23 ± 7.4 vs 63.40 ± 8.9%, p = 0.04), and this decrease was prolonged over time. Similarly, the AC + SB group showed a significantly lower (and sustained) increase in CA than in the AC alone group. Conclusion: Antibiotics alter the transformation of BA by microbial enzymes into secondary BA. This transformation is a spore germination in vitro, increases in stool during antibiotic therapy. The concomitant administration of SB during AC treatment significantly reduces this CA peak. These results highlight new human data on a potential mechanism for post-antibiotic spore germination by the microbiota can encourage germination of the microbiota.

Microbiota Signature Associated With Severity of Irritable Bowel Syndrome.
Microbiota-Gut-Brain Axis in Visceral Pain: Relevance to Irritable Bowel Syndrome.

Thirty-one patients (65%) showed psychological distress, 22 (31%) anxiety, and 10 depression (21%). Psychological variables significantly segregated gut microbial dysbiosis. Correlational analysis and comparisons in bacterial abundance among subgroups defined by thresholds in psychological variables.

Conclusion: A microbial signature accurately predicted the presence of psychological distress. Psychological variables significantly segregated gut microbial dysbiosis, underlining the role of brain-gut-microbiota axis.

Aims & Methods: We assessed the abundance of Fusobacterium in CRC, colorectal mucosa and saliva. We extracted DNA from mucosal biopsies and measured bacterial levels by quantitative PCR of the 16S rRNA ribosomal RNA gene. We also investigated the homology of F. nucleatum in oral cavity and CRC.

Results: In 51 CRC cases, Fusobacterium positivity was significantly higher in CRC compared to controls (p < 0.05). Fusobacterium was more detected in CRC (12.9%) than in normal tissue (2.9%) respectively. The detection rate of F. nucleatum was 96% in saliva and 93% in CRC by next-generation sequencer.

A total of 15 patients with CRC were included to check the homology of F. nucleatum in saliva and CRC. From these patients who were F. nucleatum-positive in saliva and CRC, we next looked for the results of AP-PCR and 6 patients have shown common band patterns.

Conclusion: The results support a link between the abundance of F. nucleatum in oral cavity and CRC. Our data also indicate that there may be a route from the oral cavity to the CRC in F. nucleatum positive cases. We are now identifying DNA sequences, specific for the objective strains.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Saccharomyces boulardii (SB) CNMC I-745 demonstrated clinical efficacy in the secondary prevention of post-antibiotic Clostridium difficile infection (CDI), but the mechanism remains unclear. Cholic acid (CA) is a primary bile acid (BA), synthesized by the liver which triggers the germination of C. difficile spores in the intestine. Physiologically, the gut microbiota transforms primary BAs (cholic acid and chenodeoxycholic) into secondary (deoxycholic and lithocholic). CA loses its germinating properties after transformation and appears to become protective against CDI. The goals of this work in healthy volunteers (HV) were to: A) Describe the effect of CA on thresholds of distress, anxiety, depression and stress perception. 16s rRNA faecal microbial analyses (ILuminis Miseq, V1-v2 amplified from total DNA) in 48 IBS patients (Rome-III criteria, mean age 42 years, 35 female subjects, 25 diarrhoea-dominant, 5 constipation-dominant and 18 alternating-type IBS). Assessment of psychological and clinical variables with validated questionnaires, microbial analysis via QIIME. Machine learning to predict psychological distress through a composite model of bacterial features. Correlational analysis and comparisons in bacterial abundance among subgroups defined by thresholds in psychological variables.

**P1727** HUMAN MILK OLIGOSACCHARIDES: A NEW STRATEGY AGAINST POST-ANTIBIOTIC CLOSTRIDIUM DIFFICILE INFECTION?

L. K. Vignaes

Business Development, Glycom A/S, Hørsholm/Denmark

**Contact E-mail Address:** louise.vignaes@glycom.com

**Introduction:** Human Milk Oligosaccharides (HMOs) are a family of complex carbohydrates found in high concentrations in human milk and which are now becoming commercially available. In clinical studies, in both infants and adults, HMOs powerfully and specifically modulate the gut microbiota by increasing bifidobacteria and reducing certain pathogenic bacteria (1,2). Also, HMO bacterial consumption results in the production of beneficial metabolites such as short chain fatty acids and the lowering of pH. Hence, the selective growth of bifidobacteria on HMOs can create an ecological niche that is more colonization resistant against pathogens. Bifidobacteria may also have a direct impact on microbial toxins by reducing their level and cytotoxic effect (3). Antibiotics, especially broad-spectrum antibiotics, dramatically impact the microbiota and its balance, and have been implicated in the pathogenesis of many health conditions including gastrointestinal symptoms such as diarrhea (4). The most commonly cited mechanism for antibiotic-associated diarrhoea is intestinal overgrowth of the pathogenic bacterium, *Clostridium difficile*.

**Aims & Methods:** The aim of this study is to investigate, in *in vitro* models of *C. difficile* infection, (i) the impact of HMOs on the microbial community and activity (e.g. bacterial metabolites and pH), and (ii) the anti-pathogenic activity of HMOs against *C. difficile*, with a focus on preventing recurrence of the infection. Two *in vitro* models, each using human faecal microbiota infected with *C. difficile*, were used to examine the impact of HMOs on bacterial metabolism and *C. difficile* infection. One model is a 48 hour batch fermentation model, while the other is a simulated gut model, run for 3 weeks post infection, which simulates the infection cycle of *C. difficile* after antibiotic treatment.

**Results:** The study revealed that the HMOs increase the level of bifidobacteria, increase the level of beneficial bacteria in general, such as short chain fatty acids and decrease pH compared to a control with no added HMOs. Additionally, HMOs reduced the level of *C. difficile*; in some cases completely eradicating *C. difficile* below detection limits. This antimicrobial effect of HMOs on *C. difficile* was pH-independent, hence another mechanism is causing the anti-pathogenic activity of HMOs.

**Conclusion:** Conclusively, the results show that HMOs can impact *C. difficile* infection in an *in vitro* system, which suggests HMOs as a potential approach to reduce risk of antibiotic associated diarrhoea and post-antibiotic *C. difficile* infection.

**Introduction:** It has been reported that the composition of human gut microbiota changes with aging, body mass index (BMI), diet and other environmental factors. In particular, the relationship between gut microbiota and obesity has been widely reported. It has been reported that the composition of human gut microbiota differs between obese and normal group. Some previous researches observed differences of composition of gut microbiota between obese and normal group, but many of the researches did not take aging into consideration. Our study indicated that different intervention stratified with age could be needed.

**Introduction:** Due to its high incidence, sporadic colorectal cancer (CRC) remains a major public health problem across the world. In many countries colorectal cancer is the second most common new cancer diagnosis, and the third most common cause of cancer death worldwide (1). The exact contribution of large intestinal bacteria to the pathogenesis of CRC has not been elucidated yet, still the mucosal, not the luminal, microbiota seem to play the crucial role. Bacteriocins are small proteins, which are produced by probiotic bacteria, and inhibit growth of other bacteria. Bacteriocins split up into single group, colicins and microcins are the most important ones. Bacteriocins possess antibacterial, antineoplastic, pro-apoptotic and probiotic effect.

**Aims & Methods:** The aim of this prospective study was to evaluate bacteriocin production by mucosal large intestinal bacteria in colorectal neoplasia. We used an original methodology reported by our group (1). Mucosal biopsies were taken in the caecum, transverse colon and rectum within the colonoscopy in patients with non-advanced colorectal adenoma, non-a-A (11 men, 10 women, mean age 65±10), advanced colorectal adenoma, a-A (which was defined as neoplasia larger than 10 mm and/or containing villous component and/or containing high grade dysplasia; 13 men, 7 women, mean age 67±10) and in the controls (average risk population with normal findings on colonoscopy and with negative history of colorectal neoplasia and/or inflammatory bowel disease; 7 men, 13 women, mean age 68±10). The study protocol was approved by the local ethical committee.

**Results:** A total of 249 mucosal biopsies were taken (60 controls, 63 non-a-A, 60 a-A, 66 CRC) and samples were further investigated. Colcin producing strains were detected in 22% (13/60) controls, 59% (37/63) non-a-A, 55% (33/60) a-A and in 76% (50/66) CRC. Significantly higher production of colicins was observed in non-a-A, a-A and CRC group when compared to controls, p<0.001. Significantly higher production of colicins was confirmed in patients with CRC compared to patients with a-A, p=0.016. Microcin producing strains were isolated in 23% (14/60) controls, 56% (35/63) non-a-A, 78% (47/60) a-A and in 62% (41/66) CRC. Significantly higher production of microcins was observed in non-a-A compared to controls, p<0.002, in a-A and CRC group when compared to controls, p<0.001. Microcins were produced more frequently in patients with a-A compared to those with non-a-A, p=0.008.

**Conclusion:** Strains isolated from large bowel mucosa in patients with colorectal neoplasia produce bacteriocins more frequently compared to those with normal findings on colonoscopy. We presume, that mucosal large intestinal microbiota with their products including bacteriocins play an important role during the development of colorectal neoplasia.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

*Br J Nutr* 2014; 111: 733.
in DNA of both probiotic strains. Sequencing of these fragments showed differ-
ences in the nucleotides compared to the reference DNA of DPC 4571 strain (A instead of G at position 46, C instead of T at position 249 and A instead of T at position 537), but all these replacements do not lead to changes in the amino acid sequence of a bacteriocin. For Lactobacillus acidophilus D76 another bacteriocin gene fragment of 283 bp was identified (in addition to 537 bp fragment). The latter had 95% homology with the helveticin J gene of Lactobacillus helveticus R0052 (R0052_09025 gene). In NCBI BLASTX database the sequences homo-
logous to the helveticin gene of Lactobacillus helveticus DPC 4571 were found in 14 different Lactobacillus species, related to Lactobacillus acidophilus, Lactobacillus crispatus, Lactobacillus gallinarum, Lactobacillus helveticus and Lactobacillus kitasatosii. The addition of the carboxylic and amino acids mixture (Actoflor®-S) results in 2:2-5-fold enhanced antimicrobial activity of both tested probiotic strains. The test pathogens Lactobacillus helveticus O75 and Salmonella Enteritidis 209, most likely due to an increase in bacteriocin gene expression.

Conclusion: Study shows that there are at least two bacteriocins in Lactobacillus helveticus D76 and one bacteriocin in Lactobacillus helveticus D75. Carboxylic acid and amino acids mixture identical to the metabolites of the probiotic Escherichia coli strain M17 probably induces bacteriocin synthesis in probiotic strains Lactobacillus helveticus D75 and Lactobacillus helveticus D76 and enhances their antimicrobial activity against test pathogens Escherichia coli O75 and Salmonella Enteritidis 209, most likely due to an increase in bacteriocin gene expression.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Fecal microbiota transplantation (FMT) has been shown to be effective treatment for recurrent Clostridium difficile infection. Concern has been raised about the long-term safety of FMT.

Aims & Methods: The aim of this study was to determine the long-term safety of fecal microbiota transplantation (FMT), and its effect on gastrointestinal symptoms (GI) in Clostridium difficile (CDI) patients. We studied 84 patients of which 45 received an FMT treatment via colonoscopy and 39 as controls receiving antibiotic treatment (AB) for the recurrent CDI and followed their recurrent CDI recurrence for an average of 3.8 yrs. All together 130 patients (55 patients in the FMT group and 75 patients in the AB group were sent in a 45-item questionnaire collecting information about the patient demographics, their physical and mental health, including allergies, infections, gastroenterological conditions such as IBD and IBS, diabetes, autoimmune diseases, neurological disorders, mental wellbeing and malingerances. Response rate for the questionnaire was 64.6%.

Results: There were no differences in the incidence of severe diseases between the groups including the incidence of IBD, diabetes, diseases of the nervous system, autoimmune diseases, incidence of colon polyps and cancer. Change of weight was neither different between groups (kg/SD): FMT = 2.5 (5.6) and AB = 1.3 (5.6), p = 0.51. The AB treated subjects recorded more frequently that their bowel function had become worse and more irregular after the treatment (Δ4,5.6%, P<0.001) compared to FMT group. 77.8% of the patients treated with FMT experienced GI symptoms related to IBS whereas 92.3% of antibiotic-treated patients recorded these symptoms (Δ=0.06). AB patients experienced more symptoms of the upper intestinal tract than the FMT patients (Δ=15.9%, P=0.001). In this cohort 97.6% of the FMT-treated patients and 60% of AB treated patients would prefer in the future that their initial treatment to be FMT instead of antibiotics.

Conclusion: FMT is a rational, durable, safe, and acceptable treatment option for patients with recurrent CDI. No severe diseases appeared after FMT and FMT seem to relieve GI symptoms better than antibiotic treatment. FMT and AB treated patients would prefer in the future that their initial treatment for recurrent CDI to be FMT instead of antibiotics.

P1732 CLOSTRIDIUM DIFFICILE–ASSOCIATED DISEASE IN A PORTUGUESE HOSPITAL CENTER

T. Gago, A. Antunes, A.M. Vaz, P. Queirós, J. Roseira, A. C. Cunha, A. Ramos, H. Guerreiro
Servico De Gastroenterologia De Faro, Centro Hospitalar do Algarve, Faro/Portugal

Contact E-mail Address: taniagago@gmail.com
Introduction: Clostridium difficile–associated disease (CDAD) is an infection caused by Clostridium difficile, gram-positive, anaerobic, spore-forming and toxin-producing bacteria. Infection is recognized as the leading cause of diarrhea associated with health care services in the developed countries. In Portugal epidemiological data are limited.

Aims & Methods: Characterize Clostridium difficile–associated disease episodes in a Portuguese Hospital Center. Retrospective analysis of 250 hospitalized patients with CDAD, in Centro Hospitalar do Algarve, between 2011 and 2015. The data was obtained from clinical processes and statistical analysis was performed with SPSS version 23.

Results: The patients were mostly women (52%). The mean incidence of CDAD was 0.21% and the patients had an associated mortality of 28%. The year with the highest incidence was 2015 (0.53%) but with a lower associated mortality rate. CDAD was mostly acquired at the hospital level (75.6%) and the mean length of hospital stay was 33 days. About 82.4% of the cases were first occurrences and the remaining (18.6%) were recurrences of CDAD. The majority of the population under study performed Proton Pump Inhibitors-IBP (52.8%) and antibiotic therapy (74.6%) (26.8% made a single antibiotic, and 23.6% 2 or more distinct antibiotics). Penicillin antibiotic class was the most used, followed by Cephalosporins (21.5%), Fluoroquinolones (11.4%) and Macrofides (10.1%).

Conclusion: A significant increase in the incidence of CDAD was observed in this study. This increase may be related to several factors, such as the improvement of laboratory diagnostic methods, increased antibiotic prescription, hospital contamination with Clostridium difficile spores or with the appearance of new and more virulent Rybotypes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1733 THE EFFICACY OF SELECTIVE ARTERIAL EMBOLIZATION IN THE MANAGEMENT OF DIVERTICULAR BLEEDING

1Digestive Disease Center, Yokohama city Minato Red Cross Hospital, Yokohama/Japan
2Gastroenterology, Tokyo Medical and Dental University, Graduate School of Medical Science, Tokyo/Japan

Contact E-mail Address: yfukami.gast@gmail.com
Introduction: Colonic diverticular bleeding is the most common cause of lower gastrointestinal bleeding. Persistent bleeding or acute massive bleeding of pre-
senting with hemodynamic disorders requires an intervention trial. The question of what is the best treatment for acute diverticular bleeding remains
The aim of this study is to clarify the efficacy of TAE for unanswered. In our institution, we gastroenterologists perform interventional radiology for the study of transmural embolization (TAE) for colonic diverticular bleeding was performed.

Aims & Methods: The aim of this study is to clarify the efficacy of TAE for colonic diverticular bleeding. 229 patients were diagnosed as diverticular bleeding from Jan 2010 to Dec 2016 in our institution. Bleeding stopped spontaneously in 126 patients. 103 patients were performed colonoscopy. Overt bleeding occurred in 8 patients after colonoscopy, and those were eligible for this study who underwent TAE. Conservative management or endoscopic procedure were not successful in all the patients. 7 patients were male and 1 was female with a median age of 62.6 years (range 39–85 years). The average opportunity for enhanced CT was 2.1, 7 patients were in shock, and all of 8 the patients were treated with blood transfusion. Those who were extravasation-positive in enhanced CT underwent angiogram from the recta near the extravasation at least 3 times. In case radiopaque clips were placed at the bleeding site via colonoscopy to mark embolization site, regardless of whether or not active extravasation was identified on angiogram, coil embolization was performed using 0.010 inch coils in vasa recta. Technical success and complications were evaluated. Technical success was defined as immediate complete cessation of bleeding confirmed by digital subtraction angiography showing no further contrast extravasation at the end of each TAE. Clinical success was defined as no recurrent bleeding in observation period.

Results: Technical success rate was 88%/7(8), and clinical success was also 88%/7(8). 6 patients were extravasation-positive in enhanced CT, and 5 patients were extravasation-positive in angiogram. Although 3 patients were extravasation-negative in angiogram, 2 patients underwent TAE. After TAE, no recurrence of bleeding was observed. Severe adverse events such as bowel infraction did not occur in all cases.

Conclusion: As the microcatheter technique has improved further, adverse events are rare. Therefore superselective coil embolization could be first choice for diverticular bleeding with extravasation-positive in enhanced CT.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1734 ACCURACY OF THE NASOGASTRIC TUBE AND THE BUN/CREATININE RATIO FOR DISTINGUISHING BETWEEN UPPER AND LOWER SOURCES OF GASTROINTESTINAL BLEEDING. A SYSTEMATIC REVIEW

S. Machlab1, E. Martinez-Bauer2, P. Garcia-Iglesias3, A. Lira1, C. Marmol1, G. Llibre1, J.P. Da Costa1, M. Gallach1, L. Melcarne2, V. Puig-Divi4, F. Junquera5, R. Campo6, X. Calvet1
Gastroenterology, Hospital Universitari Parc Taulí, Sabadell/Spain

Contact E-mail Address: stmachlab@taulit.cat

Introduction: The insertion of a nasogastric tube (NGT) and assessment of the BUN/creatinine ratio were recommended as initial measures to distinguish between upper and lower gastrointestinal bleeding (American College of Gastroenterology 2016). As the nasogastric tube is one of the most bothersome interventions for the patient, we evaluated the evidence supporting these recommendations.

Aims & Methods: The aim of the study was to identify the diagnostic accuracy (sensitivity, specificity, positive predictive value, negative predictive value and likelihood ratios) of the NGT and the BUN/creatinine ratio for distinguishing between upper and lower sources of gastrointestinal (GI) bleeding. We conducted a systematic review of the literature in order to identify studies assessing the diagnostic accuracy of the NGT or BUN/creatinine in patients with melena, hematochezia or rectorrhagia without hematemesis. The search was performed in November 2016 in five data bases (PubMed, Scopus, Web of Science, Cochrane Plus Library and Open Grey).

Results: Four studies met the selection criteria (two evaluating the NGT, one BUN/creat and one both). The two methods had a low sensitivity for detecting upper GI bleeding source. Both a positive NGT aspiration and BUN/creatinine ratio above 30 markedly increased the probability of an upper GI source with a positive likelihood ratio ranging from 2 to 11. Unfortunately, the sensitivity of both tests for upper GI bleeding was very low (negative likelihood ratios around 0.6). Characteristics and results of the studies selected are shown in table 1.

Conclusion: For patients with gastrointestinal bleeding without hematemesis, BUN/creat ≥30 indicates a high probability of an upper GI source. Nasogastric tube aspiration provides little additional information and so is not indicated. Neither test reliably rules out an upper GI source of bleeding.

Introduction: Acute lower gastrointestinal bleeding (ALGB) occurs in patients taking anticoagulants either warfarin or non-Vitamin K oral anticoagulants (NOACs). The use of NOACs has been increasing compared with warfarin in recent years. We investigated patients with ALGB on anticoagulation therapy and we analyzed characteristics, management and clinical outcome in patients treated with NOACs versus warfarin.

Aims & Methods: All patients with ALGB on anticoagulation therapy treated in our hospital during a seven-year period were evaluated. Characteristics and clinical outcome were compared between patients on warfarin and patients on NOACs.

Results: Out of 587 patients with ALGB, 43 (7.3%) were on NOACs and 68 (11.6%) on warfarin with an age 75.9±9.5 vs 77.1±7.9. The bleeding site was in the small bowel in 2/43 and 6/68 respectively. Causes of bleeding were not different between two groups except for polyps/neoplasia (8/43 vs 6/68, p=0.003).

Endoscopic hemostasis was more commonly needed in patients on NOACs 17/43 (40%) vs 14/68 (20%) (p=0.049), while they required less hospitalisation days (6.1±4.2 vs 4.5±3.6, p=0.04). Blood transfusions and need for other interventions (embolization and/or surgery) were not different. Also recurrence of bleeding (4/43 vs 11/68) and mortality (3/43 vs 6/68) were low and not statistically different between the two groups.

Conclusion: ALGB in patients on NOACs although presents some differences it has a similar clinical outcome to patients with ALGB on warfarin.

Disclosure of Interest: All authors have declared no conflicts of interest.

NOBLADS - THE NEW RISK SCORE TO PREDICT THE SEVERITY OF ACUTE LOWER GASTROINTESTINAL BLEEDING

M. Patita, G. Nunes, R. Barosa, L. Ramos, C. Fonseca
Gastroenterology, Hospital Garcia de Orta, Almada/Portugal

Contact E-mail Address: martapatita21@gmail.com

Aims & Contact Method: We aimed to evaluate the accuracy of the NOBLADS score to predict severe LGIB and the outcome of patients admitted by LGIB. We performed a retrospective, observational and unicentric study. Including patients admitted for acute LGIB and submitted to endoscopic evaluation between January/2015 and March/2016. LGIB was classified as severe if ≥2 units of erythrocyte concentrate (UCE) were required and/or if hematocrit drop >20%. Total score ranges from 0–8; when total score is ≥2, it is considered high risk for severe LGIB.

Introduction: A new risk score for acute lower gastrointestinal bleeding (LGIB) has recently been validated, based on 8 admission criteria–nonsteroidal anti-inflammatory drugs use, absence of diarrhea, absence of abdominal tenderness, age over 75 years, female gender, hemoglobin <10 g/dl, platelet count ≥150,000 and creatinine ≥1.5 mg/dl, disease score ≥2 (Charlston comorbidity index) and syncope (NOBLADS). Results: 173 patients were included (male: 50.3%, mean age: 69 ± 17 years), with LGIB manifested by hematochezia (91.9%) or melena. Endoscopic evaluation was performed 1.7 ± 2 days after admission, with the most frequent findings being diverticular hemorrhage (n = 53) and ischemic colitis (n = 29); no lesions were found in 8.3% of cases. Thirty-three patients required intervention (endoscopic n = 27, radiological n = 2, surgical n = 4) and 36 (20.8%) repeated endoscopic intervention. 28.9% of patients presented severe LGIB and NOBLADS score determined the severity of LGIB with an area under the curve value of 0.92 ± 0.018. Overall, higher score values were associated with a requirement for transfusion support, intervention and longer hospitalization (p < 0.001 for trend test). Patients at high risk for severe LGIB (score ≥ 2, n = 39) presented a significantly higher number of transfused UCEs (3.6 vs 0.08, p < 0.001), intervention (38% vs 13%, p < 0.001) and days of hospitalization (12.8 vs 3 days, p < 0.001).

Conclusion: The NOBLADS score is simple and quick to apply. It predicts with high accuracy the risk of severe LGIB and allows to identify patients that are more likely to require transfusional support, intervention and prolonged hospitalization. In clinical practice, NOBLADS score may be useful to select on admission patients who will benefit from hospitalization or from earlier intervention.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1740** RISK OF COLORECTAL CANCER IN ASYMPTOMATIC INDIVIDUALS WHOSE FIRST DEGREE RELATIVES WERE AFFECTED BY CRC AT DIFFERENT AGES OF ONSET: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 9.28 MILLION SUBJECTS

J.L. Huang, M. C. Wong, C. Chan, J. Lin, W. W. Cheung, M. Liang, Y. Fang, C. Yu, E.F. Chung
Chinese University of Hong Kong, Hong Kong/Hong Kong Prc
Contact E-mail Address: martin_wong@cuhk.edu.hk

*Introduction:* The current literature is mixed regarding whether first-degree relatives (FDRs) of asymptomatic colorectal cancer (CRC) at much earlier age are at substantially increased risk of CRC.

*Aims & Methods:* The present systematic review and meta-analysis evaluated the risk conferred by family history of CRC in FDRs according to their age of onset. We searched Ovid Medline, EMBASE and grey literature from their inception to December 2016, and included all screening studies that investigated the presence of family history of CRC in FDR and incidence/prevalence of CRC. Two reviewers independently worked on selection, assessment and data extraction of eligible articles. A random effects meta-analysis was employed to pool relative risks (RR) and odds ratios. Subgroup analyses were performed according to the age of onset of CRC in FDRs of asymptomatic subjects (<40 vs. ≥40; ≤50 vs. ≥50; <60 vs. ≥60 years). Statistical heterogeneity was assessed by the I² statistic. Publication bias was evaluated by an inverted funnel plot analysis with Begg’s regression model.

**Results:** Fifty-six case-control and seven cohort studies involving 9.28 million subjects were included in the analysis. A family history of CRC in FDRs of asymptomatic subjects conferred a significantly higher risk of CRC (RR = 1.76, 95% CI = 1.57–1.97; p < .001, I² = 95.7%). Earlier age of onset of CRC in FDRs was associated with significantly higher risk of CRC in index subjects (RR = 3.29, 95% CI = 1.67–6.49 for <40 years vs. RR = 1.42, 95% CI = 1.24-1.62 for ≥40 years; p = 0.017; RR = 2.81, 95% CI = 1.94-4.07 for <50 years vs. RR = 1.47, 95% CI = 1.28-1.69 for ≥50 years; p = 0.001). The Begg’s test did not identify any publication bias (Kendall’s tau = 0.122, p = 0.159).

**Conclusion:** A family history of CRC in FDRs whose age of onset is earlier than 40 or 50 years conferred a significantly higher risk of CRC to asymptomatic individuals, implying that age of onset could potentially enhance the discriminative capability of CRC prediction scores.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1741** IS THERE ANY DIFFERENCE IN RISK OF COLORECTAL CANCER AMONG ASYMPTOMATIC SUBJECTS WHOSE SIBLINGS VS. PARENTS WERE AFFECTED? A SYSTEMATIC REVIEW AND META-ANALYSIS

J.L. Huang, M. C. Wong, C. Chan, J. Lin, W. W. Cheung, M. Liang, Y. Fang, D. Fung, C. Yu
Chinese University of Hong Kong, Hong Kong/Hong Kong Prc
Contact E-mail Address: martin_wong@cuhk.edu.hk

*Introduction:* Few studies compared the risk of colorectal cancer (CRC) among individuals with probands who were parents, siblings, and those with two or more probands.

*Aims & Methods:* This systematic review and meta-analysis tested the hypothesis that the risk of CRC conferred by family history of CRC in parents vs. siblings vs. ≥2 first-degree relatives (FDRs) was similar. The Ovid Medline, EMBASE and grey literature were searched from their inception to December 2016, and all screening studies that investigated the association between detection of CRC and family history of CRC in FDR were included. Two reviewers independently searched, assessed and extracted data from eligible studies. The relative risks (RR) and odds ratios were pooled based on a random effects meta-analysis. We conducted subgroup analyses according to the identity of FDRs affected (parents vs. siblings vs. ≥2 FDRs), and examined statistical heterogeneity by the I² statistic. Potential publication bias was explored by funnel plot analysis with Begg’s regression test.

**Results:** We identified 56 case-control and 7 cohort studies, consisting of 9.28 million subjects who were finally included in the meta-analysis. Asymptomatic individuals with siblings affected (RR = 2.44, 95% CI = 1.90–3.13); parents affected (RR = 2.18, 95% CI = 1.95–2.45) and ≥2 FDRs affected (RR = 2.68, 95% CI = 1.53–4.53) had statistically similar risk of CRC. We did not identify any publication bias based on the Begg’s regression test (p = 0.199).

**Conclusion:** The risk of CRC was similar among subjects whose siblings; parents or ≥2 FDRs were affected by CRC. Information on the identity of the FDRs affected does not seem to be necessary when the risk of CRC in asymptomatic individuals is predicted.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1742** GILBERT SYNDROME IS NOT THAT INNOCENT

N. Arber1, M. Menachem1, L. Ari,2 G. Lion1, B. Ezra1, H. Gil1, H.G. Amir1, J. Mizrahi1, S. Shapira1
1Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
2Tel-Aviv Sourasky Medical Center, Tel Aviv/Israel
Contact E-mail Address: nadira1@tfmc.gov.il

*Introduction:* Gilbert’s syndrome is considered to be entirely benign. Some studies have shown a reduced risk for cardiovascular disease (CVD). There is conflicting data regarding cancer risk among Gilbert patients.

*Aims & Methods:* We aimed to evaluate the association of Gilbert syndrome with CVD and cancer. Clinical and epidemiological data was obtained from consecutive healthy subjects undergoing annual screening at the Integrated Cancer Prevention Center in Tel Aviv. The annual check-up includes: thorough examination by specialists in internal medicine, surgery, dermatology, plastic surgery, OB/GYN, urology, oncology, oral surgery, gastroenterology. Blood work (smac 24, blood count, TSH, CRP, PSA), vaginal, P&SA and mammography (>40ys), LDCT in heavy smokers and all needed imaging when clinically indicated. Peripheral blood DNA was extracted from all subjects. Gilbert syndrome was determined by clinical criteria (normal liver function tests but to mild elevation in unconjugated bilirubin <3 mg/dl without any hemolysis). In the majority of the cases the diagnosis was confirmed genetically by the homozygous mutation (TA)7TA in the promoter region of UGT1A1 enzyme. Prevalence of CVD and cancer were compared between subjects with/without Gilbert syndrome.

**Results:** A total of 6258 (49%) men and 6461 (51%) women, mean age 47.0 ± 11.5 years, were included of which 1.019 had clinical Gilbert. Gilbert was significantly more common among men (11.5% versus 4.6% P < 0.001). The prevalence of gilbert disease was equal in Sephardic and Ashkenazi Jews. Malignancy and CVD were diagnosed in 678 (5.3%) and 1.837 (14.4%) subjects respectively. The prevalence of any CVD was significantly higher in the Gilbert group (OR 1.23 95% CI 1.04-1.46 p = 0.017), and incidence of hypertension (OR 1.37 95% CI 1.12–1.80 p = 0.003) and CVA (1.1% versus 0.6% p = 0.06). Higher rate of kidney and bladder cancers (2.64, 1.22–5.70, p = 0.019) was also observed in the Gilbert group. In contrast, the prevalence of breast cancer was much lower among Gilbert patients with Gilberts (OR 0.36, CI 0.13–0.97, P = 0.034).

**Conclusion:** In Israel Gilbert syndrome is not that innocent. In a large cohort it seems to be associated with increased risk of hypertension, CVD and CVA. Bladder cancer is higher but females are protected from breast cancer. Further studies are mandated in order to better understand these findings and determine proper screening and surveillance practices in Gilbert disease.

**P1743** CHARACTERISTICS AND PREDICTORS OF INTERVAL CANCER: A CASE-CONTROL STUDY

I. Laiš1, J. Mizrahi2, F. Konikoff1
1Meir Medical Center, Kfar Saba/Israel
2Stony Brook University Hospital, New York/United States of America
Contact E-mail Address: ido.laiishi@gmail.com

*Introduction:* Interval colorectal cancer is largely related to a poor endoscopic performance (missed lesions, incomplete polyp resection) or different biology in the development of the polyed (accelerated growth). Thus, quality endoscopic measures and Lynch syndrome were highly investigated for their association with interval cancer. However, most reports come from the Western world and not the Middle East, and differences in ethnicity or environmental factors might potentially have impact on the biology of tumor progression. In addition, patient-related factors were less investigated for their association with interval cancer. The aim of this study was thus to assess tumor and patient characteristics and predictors of interval cancer in a population from Israel.

*Aims & Methods:* This retrospective cohort study included all patients that were diagnosed with colon cancer in our institution between 2005–2014. Cases included patients with a previous colonoscopy within 1–10 years before the diagnosis of cancer, with either negative findings or benign polyps. Only full colonoscopies with at fair or good preparation were included. Interval cancer was defined on an individual basis, when cancer occurred within the recommended surveillance interval according to accepted guidelines. Cases were further stratified according to time since previous colonoscopy (<3 years, 3–7 years). Positive controls were cancer patients without previous colonoscopy, and “negative” controls were sex- and age-matched patients with two negative colonoscopies within the study period who were randomly selected on a 1:5 ratio. Tumor characteristics (location, staging) and patient-related features (age, gender, positive family history of colon cancer, aspirin use, diabetes, diverticulosis) were compared between cases and control groups.
P1745 THE RELATIONSHIP BETWEEN QUANTITATIVE FIT RESULTS AND NEOPLASTIC FINDINGS

J.S. McGrath, M. Bogaarnd, D. Pace, A. Antile, S. Stone, E. Randell, J. Quinlan Dept. Of Gastroenterology, Memorial University, St. John's/Canada

Contact E-mail Address: jm McGrath@m.u.n.ca

Introduction: Fecal Immunochemical Testing (FIT) is currently used in most Canadian provinces to screen for colorectal cancer. Newfoundland and Labrador have a provincial population based colorectal cancer screening program over the past five years. Newfoundland and Labrador selects participants for colonoscopy if one of two FIT values ≥100 ng/mL.

Aims & Methods: The goal of this study is to assess the effectiveness of different FIT cut-offs and number of FIT tests for detecting adenomas and colorectal cancer.

Results: Data for this study were obtained in a prospective fashion using the Newfoundland and Labrador Colon Cancer Screening Program. 21,371 participants enrolled in the study between the ages of 50–74 and at average risk for colorectal cancer between July 1, 2012 and June 30, 2016. 16,152 participants returned their FIT tests. 1831 were positive on at least one FIT kit and underwent colonoscopy. The positive FIT values ranged from 100.0 to 54,017. The mean FIT was 942.3 (25th percentile: 145, 50th percentile: 260, 75th percentile: 576). Of the 1831 participants who had a colonoscopy 73 (4.0%) were found to have colorectal cancer. 845 patients were diagnosed with a colon cancer within the study period, 574 (68%) were found to have an adenoma. By using only one FIT test at a cut off of 100, our program would have missed 8.2% of cancers. An additional 541 colonoscopies were required to detect these cancers. If we stratified patients according to number of FIT tests we found that 83.5% of colon cancers detected were positive on both FIT kits at a quantitative cut off of 100. If a FIT cut off of 200 was used and applied to our patients our program would have missed 20% of cancers on based on both FIT kits being positive. An additional 1133 colonoscopies were required to detect the additional cancers by using two FIT kits as opposed to one. There was no significant difference in the detection of cancer, advanced adenomas or colorectal cancer as FIT cut off was increased and with a reduction in FIT kits completed from two to one. The positive predictive value for cancer increased as the quantitative cut off was increased but this was not at the expense of case detected.

Conclusion: Two FIT tests are more effective than one at screening. Participants with two FIT positive results are more likely to have: colon cancer, an advanced adenoma and a simple adenoma. Further triaging of colonoscopy wait lists could be considered based on quantitative FIT values and number of positive tests. Provinces and health authorities need to be cautious when determining the number of FIT kits a participant should complete as well as setting the quantitative cut off. Increasing the FIT cut off results in a higher probability of colon cancer or adenoma but there are overall less cases detected.

P1746 PREVALENCE OF SERRATED POLYPSYNDROME IN AVERAGE-RISK SCREENING COLONOSCOPIES IN GERMANY

C. Schramm, K. S. Jahnhausen, J. Dinter, F. Kuetting, T. Goeser, H. Steffen
1University Hospital Cologne, Cologne/Germany
2St. Katharinen-Hospital, Prechen/Germany

Contact E-mail Address: christoph.schramm@uk-koeln.de

Introduction: Serrated polyps (SPs) have been recognized as precursors of colorectal cancer (CRC), accounting for up to 30% of CRCs via the serrated neoplasia pathway. SPs are classified into hyperplastic polyps (HPS), sessile serrated polyps (SSPs) with or without dysplasia and traditional serrated adenomas (TSAs). The serrated polyp syndrome (SPS) is characterised by multiple SPs throughout the colorectum. CRC screening is based on detection of CRC risk factors, and colonoscopic pathologic findings were assessed in patients with metabolic syndrome: a multicentre cohort study.

Aims & Methods: The aim of the study was to determine the prevalence of SPS in average-risk individuals participating in the German CRC screening programme. We retrospectively analyzed screening colonoscopies performed by 11 gastroenterologists in 4 medical practices and 1 tertiary academic hospital between 01/01/2011 and 14/12/2016. Individuals <50 years with an increased risk of CRC (i.e. family history of CRC, colorectal cancer, or adenomas) or those with a previous or incomplete colonoscopy (i.e. procedures not reaching the cecum) were included in colorectal cancer screening standards. SPs are: I) ≥2 SPs proximal to the sigmoid colon, of which two ≥10 mm, II) any number of SPs proximal to the sigmoid colon, individual who has a first-degree relative with SPS, or III) ≥20 SPs of any size distributed throughout the colon.

Results: A total of 3089 individuals were analyzed. 47.5% were male, median age was 62 years (interquartile range 57–67). Of all individuals with detected SPs none fullfilled the diagnostic criteria for SPS. Hence, we determined a prevalence of SPS of 0% in our cohort.

Conclusion: In our study, the prevalence of SPs in average-risk individuals undergoing screening colonoscopy was 0%. Because overall ADR was above the recommended values for screening colonoscopies, we conclude that this low prevalence might be attributed to a lack of awareness for SPS rather than to low-quality procedures. However, this was not able to be confirmed due to the lack of information on first-degree relatives of SPS from medical records of individuals with SPs to check the second diagnostic criterium for SPS. We also included only one colonoscopy per individual. It has been shown that prevalence increases when follow-up colonoscopies are included in SPS. Both facts might have caused an underestimation of the true prevalence of SPS in our cohort.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: togrega@gmail.com

Aims & Methods: Screening for colorectal cancer is focused on the population with average risk of this disease. Individuals with metabolic syndrome represent a population with a higher risk of developing colorectal cancer, but they are not included in colorectal cancer screening standards.

Methods: To identify the number of patients with colorectal neoplasia (advanced adenomas and cancers) and evaluated their impact in colorectal cancer screening. Prospective, multicenter study was performed from January 2013 to December 2015 at eight high-quality colonoscopy centers. Baseline characteristics, demographic measures, and negative findings at index colonoscopy (51 patients) had higher prevalence of diabetes (33% vs. 15%, p = 0.002) but the same rate of family history, aspirin use and diverticulosis. There were no significant differences in all these characteristics between patients with interval cancer and those without.

Conclusion: Interval cancer tends to be older and have proximal tumor location than patients with primary colon cancer, and have higher prevalence of diabetes. A close surveillance or the use of better endoscopic techniques (e.g. use of NBH for longer retrieval time) should be considered for patients with these characteristics.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Early onset gastroenterological cancers lacking a positive family history are an increasingly worrisome entity. On one hand, early onset is the cornerstone of genetically determined oncological problems, but on the other negative family history does not support the suspect of familial syndromes.

Aims & Methods: We addressed the contribution of germline mutations to non familial early onset cancers. Patients with pancreatic, gastric, esophageal, duodenal and colorectal cancers were enrolled from 2015 to 2017 at the Gastrointestinal Personalized Medicine unit. Eligibility criteria were the juvenile onset and the negativity for clinical criteria of hereditary cancer syndromes. Early onset colorectal cancer was defined as <45 yrs. For the other cancers, the threshold was defined at 50. Eligible patients provided informed consent. Genes were sequenced by means of a validated Next Generation Sequencing panel of oncological susceptibility genes and confirmed by means of Sanger sequencing.

Results: Among 12 colorectal cancer patients (7F, 5M), NGS analysis showed 2: MSH2 (clone C6 in C20), MSH6 occurring de novo, given the absence of family history; 3 variants of unknown significance (VUS) (2 MSH2 and 1 MLH1); and 7 were negative. Age-stratification revealed that, among those <35 years (n=4), 1 had MSH2 gene mutation and 3 were negative. In the 36–40 age group (n=3), 1 had MSH2 mutation, 1 had VUS and 2 were negative. In the age group 41–45 (n=5), MSH6 mutation and 2 VUS were found, alongside 2 negative results. Among the colorectal cancers, 17% of patients had a de novo mutation of Lynch Syndrome, 5% had a VUS and 38% were negative.

Among 2 pancreatic cancer patients (<50 yrs, 2 F), 1 tested positive and the other had a VUS on PMS2.

NGS analysis performed on 1 esophageal cancer (46 yrs, M) was negative. 1 duodenal cancer (46 yrs, F) has a MSH2 mutation and 2 VUS (MSH6 and PMS2).

Conclusion: A significant percentage (17%) of early onset colorectal cancers resulted in Lynch Syndrome even when family history is not suggestive of hereditary cancer. We reliably infer the determinant role of genetics, even when the family history does not support the hypothesis. Elsewhere, our results suggest that neutrophils can be one of the immune cells implicated in this process. This work shows a link between immune microenvironment, pathogenic E. coli and tumor development.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1748 IMPACT OF COLIBACTIN-PRODUCING ESCHERICHIA COLI ON MICRO ENVIRONMENT AND CANCER PROGRESSION IN PRECLINICAL COLORECTAL CANCER MODEL

Aims & Methods: Min mice were per os inoculated with a CRC-colibactin-producing E. coli strain (11G5), non pathogenic E. coli (K-12 MG1655) or PBS. Using optical in vivo imaging (IVIS spectrum), we evaluated oxidative stress induction with a bioluminescent inflammation probe in Min mice chronically infected. After 7 weeks, number and volume of polyps were evaluated and colonic samples were histologically analysed. Detection of immune cells was quantified by immunofluorescent labelling using a specific and innovative algorithm created with Tissue Studio software. Then, the density and localization of immune cells were performed in the three colon regions of interest: lymphoid follicle, mucosa and tumor.

Results: Using optical imaging, we detected a significant increase of luminescent intensity in the CRC carcinogenesis process. C57BL6/J mice carrying the ApcMin mutation developed ~24.3±3.7 adenomas and several carcinomas in the small intestine by the age of 16 weeks compared to the ~7±1.7 polyps that ApcMin/CD24 +/- (double KO) mice developed. Mice colonoscopy showed a significant reduction in the number and size of polyps upon depletion of CD24 alleles. The ApcMin mice displayed severe splenomegaly (355±68 mg) compared (141±49 mg) in double KO mice similar to WT mice. Hb level in the ApcMin was 5.8±2.5, significantly lower than in the double KO mice (8.2±0.9) and their WT littermate.

Aims & Methods: We aimed to study the cellular interactions between CD24 and beta-catenin, and effects of their interaction on intestinal tumorigenesis. CD24-inducible 293T-Rex cells previously developed in our lab (Shapira et al., 2011) and SW480 CRC cells stably transduced with CD24 (Naumov et al., 2014) were used to study this interaction in vitro. Co-immunoprecipitation and immunofluorescent staining were used to investigate the interaction between the two proteins. Far western blotting (FBW) analysis was used to confirm this direct interaction by probing the standard WB membrane with the purified CD24 protein.

Results: In vitro: Western blotting analyses showed that expression of CD24 in 293T-Rex cells induced the activation of beta-catenin, while down-regulation of CD24 in SW480 cells caused a decrease in the level of active beta-catenin. Cytoplasmic/nuclear fractionation showed that more active beta-catenin entered the nucleus in cells that expressed compared to control (clone 4). In addition, in both cell lines, TOP/FOP luciferase reporter assay showed a significant increase in Luciferase activity upon CD24 expression induction. Co-immunoprecipitation studies of CD24 and beta-catenin indicated that these two proteins might be interacting. In addition, in HEK-293T cells and SW480 cells, immunofluorescent staining of CD24 and beta-catenin showed that these two proteins co-localize on the cellular membrane. Furthermore, far western blotting analysis suggests that a direct interaction between the proteins exist.

Conclusion: 1. CD24 plays a major role in intestinal tumorigenesis. 2. CD24 interacts with the Wnt pathway by activating beta-catenin. 3. CD24 interacts directly with beta-catenin. 4. Down-regulation of CD24 may be an important aim in the therapy of CRC.

P1750  YM155 AS AN INHIBITOR OF CANCER STEMNESS SIMULTANEOUSLY INHIBITS AUTOPHOSPHORYLATION OF EGFR AND G9A-MEDIATEDSTEMNESS IN EGFR-POSITIVE CANCER CELLS
C. Cheng1, A. Ho2
1Hematology And Oncology, Mackay Memorial Hospital, Taipei/Taiwan
2Division Of Gastroenterology, Chang Gung General Hospital, Taipei/Taiwan
Contact E-mail Address: aisheng49@gmail.com
Introduction: Cancer stem cells survive as the leading reason to tumor recurrence after tumor repressive treatments. Therefore, it is worth discovering specific and efficient inhibitors against cancer stemness for applications in reducing tumor recurrence. Previously, literature has indicated that YM155 can significantly reduce the number of tumorsphere formation of gastric cancer cell lines, but the mechanism of YM155 activity is not completely clear.
Aims & Methods: The aim of this study attempted to investigate the potential mechanism of YM155 against cancer stemness in EGFR-positive cancers. The tumorspheres derived from EGFR-mutant HCC827 and EGFR-wild-type HCT116 and A549 cells expressing higher cancer stemness markers, CD133, were used as cancer stemness models.
Results: We found that higher EGFR autophosphorylation (Y1068) in HCC827, A549, and HCT116-derived tumorspheres compared to the parental cells, which induced tumorsphere formation through activating G9α-mediated stemness property. YM155 was demonstrated to inhibit the tumorsphere formation by unexpectedly blocking the autophosphorylation of EGFR and G9A-mediated stemness pathway. The chemical and genetic inhibitions of EGFR and G9a revealed the significant role of EGFR-G9α pathway in maintaining the cancer stemness property.
Conclusion: In conclusion, this study not only revealed that EGFR triggered the formation of tumorspheres through elevating the G9α-mediated stemness, but also demonstrated that YM155 inhibited the formation of tumorspheres by simultaneously blocking autophosphorylation of EGFR and activity of G9α as a potent anti-stemness agent against EGFR-positive cancers.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Promoter hypermethylation-induced epigenetic silencing of tumor related genes played a key role in the initiation and development of colorectal cancer (CRC). Using Methylated DNA Immunoprecipitation (MeDIP), we identified that Fibroblast Growth Factor 14 (FGF14) was preferentially methylated in CRC.
Aims & Methods: We aimed to investigate the epigenetic regulation and biological function of FGF14 in CRC. The expression of FGF14 in 10 CRC cell lines and 24 pairs of CRC tissues and adjacent normal tissues by real-time PCR. CRC cells were treated with DNA demethylating agent 5-aza-2′-deoxycytidine (5-Aza). The methylated status of FGF14 in CRC cell lines and tissues were determined by real-time MSP. The biological function of FGF14 in CRC was interrogated by cell viability assay, colony formation, immunofluorescence and flow cytometry, as well as in vivo study.
Results: FGF14 was downregulated or silenced in all (10/10) CRC cell lines, while it was readily expressed in normal colonic tissues. The expression of FGF14 was significantly lower in primary CRCs as compared to their adjacent normal tissues (P < 0.01). The loss of FGF14 gene expression was restored by treatment with DNA demethylating agent 5-Aza. Re-expression of FGF14 in CRC cell lines inhibited colony formation, suppressed cell viability, and induced cell apoptosis via AMPK/mTOR pathway, accompanied with enhanced protein expression of cleaved caspase-3, cleaved caspase-7, cleaved caspase-9 and PARP. In xenograft mouse model, overexpression of FGF14 significantly reduced tumor growth (P < 0.001).
Conclusion: FGF14, which induces cell apoptosis via AMPK/mTOR pathway, is a novel tumor suppressor down-regulated by epigenetic inactivation.

Introduction: A cancer with a number of somatic mutations is defined as “hypermutator”, and shows therapeutic features, such as high sensitivity to immune checkpoint inhibitor. However, to date, analyses of hypermutator have not been done with a large number of cases.

Aims & Methods: The aim of this study is to analyze the incidences and characteristics of hypermutator in digestive system cancers. We analyzed somatic mutations in digestive system cancers in 1145 cases (age: 67.4±11.3 yrs, M:F = 755: 390), those underwent surgery after full informed consent during 2014 to 2015. Genomewide sequencing was performed on 47 inherited cancer-associated genes and 411 cancer-associated genes using next generation sequencer (Illumina HiSeq 2500). Tumors were not different by the hypermutation. Hypermutator was recognized in 6.2% (66 cases (5.8%)). Age and gender differences in the somatic DNA.

Results: The 1145 subjects included 583 colorectal cancers (CRC), 229 gastric cancers (GC), 103 metastatic liver tumors, 100 hepatocellular carcinomas (HCC), 45 pancreatic cancer, 23 GISTS, 15 esophageal cancers and 14 neuroendocrine tumors, etc. Hypermutator was recognized in 66 cases (5.8%). Age and gender were not different by the hypermutation. Hypermutator was recognized in 6.2% (36 cases) of CRCs, 11.8% (27 cases) of gastric cancers, 2% (2 cases) of HCCs, and one case of small intestinal cancer. Within the hypermutator group, multiple cancers developed in 13.9% of CRC patients and 25.9% of GC patients. Mutations were detected in 33.9% (22 cases), that of mismatch repair genes (either of MLH1, MSH2, MSH6, PMS2) in 13.6%, POLE in 9.1%, and POLD1 in 4.5%, respectively, in the hypermutator group.

Conclusion: Hypermutator was recognized in 5-10% of digestive system cancers, predominantly seen in CRCs and GCs. Cases of hypermutator sometimes develops multiple cancers, associated with a somatic mutation of mismatch repair genes. Further research must be needed to clarify the characteristic of hypermutator of the digestive organs in the therapeutic aspects.

Introduction: Location and somatic gene signature of CRCs may impact prognosis and response. A relative specific CRC-related dysbiosis has been characterized.

Aims & Methods: The aim was to characterize colon microbiota in CRC patients regarding location, gene markers and outcome. Patients (N = 173) signet consensus for whole metagenome (shot gun sequencing on Illumina HiSeq2500) analysis of tumor DNA: 72 CRC (35 sporadic-S, 19 Lynch-L), 87 asymptomatic subjects (normal colonoscopy), 14 first degree healthy relatives from Lynch families. 6MOCA1 pipeline was used, library sorted (Pared quality score 20 Allintelli) and RMA was done of < 35 A, human genes or phage sequences. Quality sequences were aligned (REFMG.V13) and most abundant genes constructed (MBMA program v.0.1). The Shimab program (shaman.cbi.pasteur.fr) was used. The number of bacteria was estimated (REFMG). The linear model (GLM) was implemented in the DESeq2 R kit. Differences between Control (N = 87) and CRCs (N = 69), between L (N = 19) and S CRCs(N = 50), and between LCRC (N = 19) and Healthy Lynch relatives were obtained after interaction of age, BMI and gender was considered (GLM model). The p value was retention by correction (Benjamini and Hochberg). The specific taxonomic composition of the control and CRC groups was subjected to random analysis (Caret’s R package) with two optimization parameters (precision and kappa) in the model.

Results: There was no difference for gender, age (p = 0.08) and BMI (p = 0.187) in the L and S CRCs. Significant differences were observed between Normal and CRCs, C-CRC and L-CRC, L-CRC and first degree relatives based on the common component (similarity of sequences): 13 species differentiated Normal and CRCs, two were more prevalent in L-CRCs. The panels of bacteria linked with location, MSI, Ras mutations, methylation phenotypes and survival were identified. No significant link was observed with TNM Staging: I (N = 17, 2L and 15S), II (N = 12, 5L and 7S), III (N = 20, 10L, 10S), IV (N = 21, 2L and 2S), DFS might be dysbiosis dependent. Conclusion: CRC dysbiosis is location-dependent. Several bacteria are associated with Ras mutation, MSI, and methylation status. They may directly or through their metabolites contribute to the prognosis. Microbiota signature should be taken in consideration in trials.

Introduction: Colorectal serrated lesions (SLS) include hyperplastic poly (HP), traditional serrated adenoma (TSA) and sessile serrated adenoma polyp (SSA/P). SSA/Ps are well-known precursors of colorectal cancer (CRC) characterized by BRAF mutation and microsatellite instability (MSI), whereas the molecular characteristics of TSAs are not fully understood.

Conclusion: Using an unbiased transcriptomics approach we identified transcription factors that are lost on protein level upon ER stress. Furthermore, our data suggests that the significant loss of the transcriptional regulator CtBP2 contributes to intestinal epithelial stem cell differentiation.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Aims & Methods: We aimed to identify epigenetic alterations associated with the development of TSAs and to clarify the associations between clinical, pathological and molecular characteristics in colorectal lesions. The genome-wide DNA methylation status in TSAs consisting of protruding and flat components was analyzed using an Infinium HumanMethylation450 BeadChip, and changes in DNA methylation during the development of TSAs were identified. Methylation of identified genes and CIMP markers (MINT1, 2, 12, 31, p16 and MLH1) and BRAF/KRAS mutations were analyzed in 847 colorectal lesions and 61 samples of normal colonic tissue. Effects of epictotic expression on CRC cell growth in a population study were assessed in vitro and in vivo.

Results: BeadChip analysis revealed 11 genes in which methylation levels were progressively increased during development of TSAs. Among them, SMOC1 was prevalently methylated in TSAs, but was rarely methylated in SSA/Ps (p = 0.001). RT-PCR revealed that SMOC1 is abundantly expressed in normal colon and SSA/Ps, but is significantly downregulated in TSAs. Immunohistochemical analysis showed that SMOC1 was expressed in the epithelium of normal colonic tissues and SSA/Ps, but that expression is significantly reduced in TSAs. The expression of SMOC1 was associated with proliferative activity and cell cycle progression, and in vivo tumor formation by CRC cells. Analysis of colorectal lesions revealed that SMOC1 is frequently methylated in TSAs and CRCs, and that SMOC1 methylation is strongly associated with KRAS mutation and CIMP-low.

Conclusion: Methylation of SMOC1 is associated with TSA development but is rarely observed in SSA/Ps. Immunohistochemical analysis of SMOC1 may be a useful marker to discriminate between SSA/Ps and TSAs. Our data suggests SMOC1 methylation may play a role in the neoplastic pathways arising in TSAs.

Introduction: The number of individuals partaking in colorectal cancer (CRC) screening still remains to be low even after the implementation of the Korean Government’s National Cancer Screening Program for CRC. The aim of this study is to identify factors associated with partaking in CRC screening.

Aims & Methods: The Korean National Health and Nutrition Examination Survey (KNHANES) 2007 ~ 2010 datasets were used to develop a CRC screening participation screening score. 10,527 individuals aged ≥20 who completed the survey and not previously diagnosed with CRC were selected. Both logistic regression (LR) analysis and artificial neural network (ANN) were used to develop predictive models. Multilayer perception ANN was constructed based on 16 clinical variables. We then validated the models using the KNHANES 2011 and 2012 (n = 9968) datasets and compared them with each other.

Results: Out of 10,527 individuals selected, 57.0% (n = 6005) responded unscreened for CRC. Among various demographic and socioeconomic factors, factors influencing CRC screening, including age, household income, education level, private health insurance, self-reported depression, self-reported health status, and residence were found to be independently associated with CRC screening. LR analysis produced screening score (range 0–10.3), and a cutoff point of ≥5.5 defined 49% as unscreened for CRC and yielded area under the curve (AUC) of 0.626. When validated with KNHANES 2011 and 2012 datasets, the AUC of the defined LR model was 0.663, meanwhile the AUC of ANN based predictive model was 0.743.

Conclusion: The ANN produced better performing model than LR analysis based model in identifying population with low CRC screening participation. Sensible and 2012 datasets, the AUC of the defined LR model was 0.663, meanwhile the LR analysis produced screening score (range 0–10.3), and a cutoff point of ≥5.5 defined 49% as unscreened for CRC and yielded area under the curve (AUC) of 0.626. When validated with KNHANES 2011 and 2012 datasets, the AUC of the defined LR model was 0.663, meanwhile the AUC of ANN based predictive model was 0.743.

Introduction: Background: CD24, a mucin-like cell surface molecule, highly expressed in solid tumors and hematological malignancies (HM) (Gastro 2006, Clin Can Res 2007, Can Res. 2008). mAb CD24 were found to inhibit the growth CD24 cancer cells (Gastro 2009). We have shown that a simple non-invasive blood test evaluating CD24 levels on PBL had good sensitivity and specificity for detecting colorectal neoplasia in subjects undergoing screening colonoscopy (Kraus et al., 2009).

Aims & Methods: We aimed to improve a simple, noninvasive blood test that could simultaneously identify individuals with different types of cancer. Blood was taken from patients with various malignancies (CRC, Pancreatic Cancer (PC), gastric cancer (GC), sarcoma and HM), that was confirmed by history. Age, gender and ethnic matched healthy individuals served as controls. Hemoglobin levels were measured. They underwent a thorough and extensive workout at the Integrated Cancer prevention center at Tel Aviv Medical Center (Ear J Intern Med. 2013) All samples were collected and processed identically. For each sample, 20,000 leukocytes were analyzed by flow cytometry for the expression of SMOC1 and CD24. An initial template has been generated using gates within the software to create a hierarchical population tree at the beginning of the screen. All additional analyses were accomplished after data acquisition has been completed. The template file include compensation adjustment, which is uniformly applied to all the data collected in order to minimize fluorescence overlap between detection channels.

Results: The novel assay was improved significantly, distinguished healthy from CRC (Fig 1a) (P < 0.013), PC (Fig 1b) (P < 0.018), biliary tract (P < 6.4E-12), Gastric Cancer (GC) (P < 0.003), Lung (P < 0.003), MDS (P < 0.01), and Lymphoma (P < 2.1E-07) patients. CD24 expression levels were higher by up to 25% in cancer cases as compared to normal subjects. The sensitivity and specificity for CRC were 79.2% and 74.7%, and for PC 70.0% and 75.9%, respectively.

Conclusion: The positive (PPV) and negative predictive (NPV) values of CD24 for the detection of CRC was 38% and 94.8%, and for PC 17.1% and 97.3%, respectively. Specificity and sensitivity for HM were also statistically significant (data not shown). The CD24 test could not discriminate between patients with cervical, stomach and lung cancers and healthy subjects.

Introduction: Colonoscopy is considered the gold standard for prevention and early detection of colorectal cancer (CRC), however its effectiveness is directly related to quality of bowel preparation. Two of the quality measures of colonoscopy, cecal intubation rate and adenoma detection rate, are both associated with adequate bowel preparation. Data on factors associated with quality of preparation using Picolax® are limited.

Aims & Methods: We aimed to evaluate factors associated with a good bowel preparation using Picolax® (Sodium picosulfate/magnesium citrate) in the Israeli heterogeneous population. Consecutive outpatient referred for colonoscopy were prospectively assessed by a nurse practitioner filling out a questionnaire. Hemoglobin levels were measured. The time between sachets of Picolax was prospectively assessed by a nurse practitioner filling out a questionnaire.

Results: Out of 452 patients included in the study (M = 54%, mean age 56.5 ± 16.3 yrs), 366452 (81%) achieved a “good” bowel preparation, and 86 (19%) were classified as “not good.” No significant difference was observed between genders and in terms of achieving a good bowel preparation (p = 0.77, p = 0.054). There was a significant difference among diabetics (n = 93, 20.6%) and non-diabetics (n = 359, 79.4%) in quality of the bowel prep. While 69.9% of diabetics achieved a good bowel preparation only 83.8% of non diabetics achieved a good bowel preparation (p = 0.004). In the univariant analysis, Bisacodyl had no effect on bowel preparation (p = 0.83) except in the diabetics, where those who took an average of 1.3 ± 1.9 (median = 6) vs. 4.3 ± 1.5 (median = 4) tablets fared better (p = 0.018). Other chronic diseases had no effect on bowel preparation. Drinking 3–7 vs 8–15 glasses of water achieved good preparation in 72.7% vs 83.8% of cases, respectively (p = 0.01). Time from end of preparation to colonoscopy -75% achieved significantly better prep vs >8 hrs (p = 0.002). In the multivariant model for prediction of quality of bowel preparation that included the time between sachets of picolax, number of water cups consumed, diabetes, gender, and age we found that all, excluding age, were good predictors of bowel preparation. Women had a higher chance of achieving a good adequate bowel preparation (OR1.68, p = 0.045, 95%CI = 1.01–2.79). Patients without diabetes had a higher chance of achieving an adequate bowel preparation (OR = 2.05, p = 0.014, 95%CI = 1.16–3.69). Patients who had 5–9 hours between the 2 sachets of picolax had a lower chance of achieving an adequate bowel preparation as compared to those who had 9 to 24 hours between the 2 sachets (OR = 0.375, p = 0.009, 95%CI = 0.180–0.785). Lastly, drinking fewer than 8 cups lowers the chance of achieving an adequate bowel preparation (OR = 0.461, p = 0.003, 95%CI = 0.278–0.775).

Contact E-mail Address: dr.szalai.milan@gmail.com

Introduction: Colonoscopy is the gold standard method of colorectal cancer and polyp screening, but polyps are missed during a colonoscopic examination at a rate that varies from 6% to 27%. Improved adenoma detection rates can be achieved with advanced colonoscopic visualization methods. A recently developed new Fujinon endoscope system, Eluxeo, carries a new function of electronic chromoendoscopy, Linked Color Imaging (LCI), that enhances the coloring and contrast of mucous membranes and blood vessels which are difficult to see with the conventional endoscopes. In our prospective randomized study, we evaluated the effectiveness of LCI, a new endoscopic visualization technique that may enhance image quality to improve colonic adenoma detection.

Aims & Methods: Up till now 247 eligible patients, older than 45 years, admitted for screening outpatient colonoscopy were randomly enrolled to undergo high-definition white-light colonoscopy (WLC) or LCI colonoscopy during instrument withdrawal. The colonoscopic procedures were performed by three experienced endoscopists with Fujinon LF-7000 processor and with either the conventional high-definition Fujinon EC902 or a new EC7602 VS Eluxeo colonoscope. All of the colonoscopic procedures were made under Propofol deep sedation guided by an anesthesiologist. The minimum withdrawal time was defined as more than 6 minutes. All colonoscopies were routinely assisted with pure CO2 insufflation. The primary outcome parameter of our study was to assess and compare the polyp and adenoma detection rate with the two endoscopic techniques.

Results: A total of 247 patients were randomized (mean age 58.7 years). 101 patients were enrolled in the WLC group and 146 patients in the LCI group. No significant differences have been observed in the patient demographics and colonoscopy withdrawal time between the two groups. Patients having both colonic polyps and adenomas were detected more frequently in the LCI group than in the control group: 60.9% and 43.3% versus 55.4% and 33.6% respectively, however, this was not statistically significant (p = 0.32 and 0.16). In contrast, the total number of adenomas relative to the total number of polyps detected with LCI withdrawal were significantly higher than with conventional WLC: 105 vs. 75 (p < 0.001) respectively (p = 0.008).

Conclusion: The LCI enhancement of the Fujinon Eluxeo colonoscopy system was superior to the conventional HD-WLC in detecting patients with colonic adenomas, which was mainly due to the ability of the more sensitive detection of minute (less than 5 mm) adenomas. (Study was supported by ECT grant GINOP-2.1.1.-15.-2015-00128.)

Introduction: Serine protease inhibitors (Serpins) play an important role in the regulation of enzymes involved in proteolytic cascades. Members of the family are: alpha-1-antitrypsin, alpha-1-antichymotrypsin, C1 inhibitor, antithrombin and neuroserpin. Kallikrein-related peptidases (KLKs) are involved in proteolytic cascades of different tissues. KLK14, acting via PAR-2, represents an auto- crine/paracrine regulator of colon tumorigenesis and alpha1-antitrypsin is a natural inhibitor of KLK14. Therefore its role in regulating the proteolytic cascade in colorectal tumorigenesis is of great importance.

Aims & Methods: The aim of this study was to analyze AI-antitrypsin (AAT) expression in tissue samples at different stages in the process of colorectal cancer development. We examined a total of 245 colon samples. Of these, there were 101 colorectal carcinoma tissues, for 70 of which paired normal mucosa was also examined. A total of 74 colorectal adenomas were examined. Quantitative real time PCR was used to measure AAT expression. Clinical evaluation of AAT levels was demonstrated in terms of disease-free survival (DFS) and overall survival (OS).

Results: Alpha-antitrypsin expression was found to be significantly associated with categorical to advanced stages of disease (p = 0.028). In univariate analysis revealed that high status alpha-antitrypsin expression is a significant factor for disease-free survival (DFS) (p = 0.002) and overall survival (OS) (p = 0.026) in patients with colorectal cancer. Kaplan-Meier survival curves demonstrated that low alpha-antitrypsin expression is significantly associated with longer DFS (p = 0.001) as well as OS (p = 0.021).

Conclusion: Our data suggests that alpha-antitrypsin expression could be considered as a potential biomarker of unfavorable prognosis for colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Real-time differentiation between neoplastic and non-neoplastic colorectal lesions may be crucial during colonoscopy. While adenomas are compared to normals. 42% of lncRNAs upregulated in CRC samples showed elevated expression in adenomas (p < 0.05). A total of 10 lncRNAs were upregulated and 8 lncRNAs (e.g. LINC00350) were underexpressed compared to adenomas (p < 0.05). In CRC samples 8 lncRNAs (e.g. AC12032.1) were overexpressed and 9 lncRNAs (e.g. RP1-3497K6.1) were downregulated
neoplastic, and therefore should be resected, hyperplastic polyps never turn malignant and do not require specific endoscopic therapy. The aim of our prospective, randomized study was to distinguish subcentimetric hyperplastic and adenomatous polyps based on Fujinon FICE versus Eluxeo BLI electronic chromoendoscopic technology with high-definition colonoscopy with and without optical amplification.

Aims & Methods: In order to create a video and digital picture library of polyps, patients undergoing screening or diagnostic colonoscopy were considered for inclusion. Patients with at least one histologically verified <10mm polyp were included. A video-capture module was added to the Fujinon EC480Z and EC760Z endoscopes and stored in an anonymized database. Once the video-library was constructed, each of our 5 colorectal experts (ML, SZM, OL, DZS, and SZA) independently and randomly reviewed all of the cases with a standardized electronic questionnaire. In each case, all of the observers had to assess the color, the vascularization and the surface of the polyps, and the pit pattern was also assessed. Kudo classification. Finally, with the definition of confidence (low/medium/high on VAS), the histological prediction and the final decision has been clarified on each lesion as neoplastic or non-neoplastic (hyperplastic).

Results: Up till now 115 polyps were enrolled and recorded into our digital web-based library, 59 were assigned into the FICE and 56 into the BLI group. Of the all detected 115 polyps were endoscopically removed and histologically analyzed and this was regarded as gold standard. The overall accuracy with WLI versus FICE versus BLI technology of the 5 experts without zoom and with 50x times magnification to differentiate between hyperplastic and adenomatous lesions were 77.62% and 84.51%, vs. 74.58% and 83.90% and 88.84%, respectively. There was an excellent correlation between the histopathological results and our KUDO classification with both FICE and BLI technology. Both 50x times optical zoom and BLI technology were independently and significantly improved our confidence rate that was associated with a more precise histopathologic prediction as compared to non-zoom, WLI or FICE endoscopic polyp assessment.

Conclusion: The new electronic chromoendoscopic technology with Eluxeo BLI significantly improved the reliability of the histology prediction as compared to Fujinon EC480Z. Furthermore, Fujinon high-confidence predictions for the differentiation of neoplastic and non-neoplastic polyps with Eluxeo BLI electronic chromoendoscopy provide a potential for real-time endoscopic diagnosis of hyperplastic polyps to support restect and discharge strategy. (Study was supported by ECT grant GINOP 2015-015-2.1.1.-15-2015-00128)

Introduction: Till now, narrow-band imaging (NBI) could make it possible to analyze the surface microvessels of colorectal lesions for differentiating neoplasms from non-neoplasms and for predicting the histopathological diagnosis. Endocytoscopy (EC) is the next generation of ultramagnification endoscopy that allow visualization of the glanular structure and cellular atypia. EC has visualized living tumor cells in vivo and obtained a ultra-magnification pathological image simply by applying the scope to the target mucosa during an endoscopic examination. However, in colorectal, the impression of the microvessel (i.e. morphology and volume) is always required. Since dyne staining complications the procedure, new endocytoscopic way of use without of dye has been strongly desired. On the other hand, EC with NBI (EC-NBI) allows ultra-magnified microvesel observation without using any dye solution.

Aims & Methods: The aim of this study was to validate the evidence whether the observation of surface microvessels using EC-NBI was useful in predicting the histopathology of colorectal lesions. The study included 438 patients who underwent complete colonoscopy and endoscopic or surgical treatment between April 2006 and June 2015. A total of 576 lesions (45 Non-neoplastic polyps, 304 adenomas, 71 intramuscular cancer, 21 slightly invasive submucosal cancer (SMCs) and 135 massively invasive submucosal cancer) were retrospectively evaluated. We used the Kudo classification for the degree of submucosal invasion and classified cancers accordingly. SM cancer without vessel permeation does not metastasize. In contrast, SMM lesions show a substantial proportion (~10%) of lymph node metastasis. We named the ultra-magnified microvesel findings as endocytoscopic vascular feature (ECV) pattern and classified into the following 3 groups: ECV-1, the surface microvessels were very fine obscure; ECV-2, the surface microvessels were more clearly seen and showed regular vessels network, and their caliber and arrangement were uniform; and ECV-3, the surface microvesel were thick, and their caliber and arrangement were heterogeneous.

Results: The sensitivity, specificity and accuracy of ECV-1 diagnosis of hyperplastic polyp were 85.9%, 98.5% and 97.7%, respectively. As regards the sensitivity, specificity and accuracy of ECV-3 for diagnosis of SMM were 82.2%, 98.0% and 94.3%, respectively.

Conclusion: Endocytoscopic vascular pattern was helpful in predicting the histopathology of colorectal lesions.

P1768 CONSIDERATION OF RECTAL NEUROENDOCRINE TUMORS IN OUR HOSPITAL
M. Akita
1Internal Medicine, Mitoyo General Hospital, Kanonji City/Japan

Introduction: The diagnostic criteria and treatment indications for rectal neuroendocrine tumours (NETs) are recommended to undergo endoscopic therapy, those with a tumour diameter of >10 mm and up to the deep submucosal layer. However, no clear guideline has been established on the radical criteria and early surgical treatment. Furthermore, colorectal investigations have the potential to miss the diagnosis of bowel cancer screening. However not all patients are eligible for this.

Contact E-mail Address: m_akita1976@yahoo.co.jp

Contact E-mail Address: m_akita1976@yahoo.co.jp

Results: The mean age of the patients was 65.2 years (range, 49–88 years); male-to-female ratio, 15:7; diagnosis opportunity, 21 asymptomatic cases and 1...
symptomatic condition (lumbago); lesion site (Rs/Ra/Rb), 1/2/19 cases; mean tumor diameter of 10 mm in diameter. Among the treatment options, EMRL is considered useful and well tolerated. However, follow-up observation and case accumulation seem necessary to determine the long-term prognosis in NET, which may recur after years.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1769  SELECTIVE ERADICATION OF K-RAS MUTATED CANCER CELLS BY DELIVERY OF BACTERIAL TOXINS

N. Arber1, I. Ilana2, D. Kazarov1, S. Shapira1
1Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
2Tel-Aviv Sourasky Medical Center, Tel Aviv/Israel

Introduction: Inactivation of TP53 is the most frequent genetic damage in human cancer. In addition, hyperactivation of the RAS pathway is common in many human malignancies (Lung (LC)—40%, pancreatic (PC)—95%) and colorectal cancer (CRC)—50%). Despite multiple attempts, targeting these pathways for the treatment of cancer, for example through the development of RAS pathway inhibitors has not proven to be effective thus far. Herein, we propose to exploit the hyperactive RAS pathway and TP53 mutation status of human cancer to deliver targeted antitumor therapy. We have previously reported that a recombinant adenovirus, carrying a pro-apoptotic gene (PUMA) under the regulation of RAS signaling (AP-2) can improve the efficacy of this system (Shapira et al, 2015).

Aims & Methods: We aimed to establish a tight regulated dual system by expressing a toxin under the control of the RAS pathway in cancer cells, while sparing normal cells by expressing the anti-toxin under the control of RAS in non-malignant cells. Adenoviral vectors carrying the toxin (P4-MafF-acc) and the anti-toxin (INS-acc-AP-2) were used. Humanized Anti-CD24 antibody fragment (scFv) was engineered and fused to the lentivirus envelope. Cell death was measured qualitatively by using fluorescent microscopy and was quantified by the enzymatic MTT assay.

Results: We found that 40% of pancreatic cancer cells, 60% of colorectal cancer cells, and 75% of breast cancer cells harboring mutated Ras after co-infection with the toxin and the anti-toxin genes. The antitoxin was able to protect ~70% of the cells that were affected by background low level expression of the toxin construct, due to promoter leakage [Fig.1]. Similar results were obtained in a colony formation assay and FACS analysis of co-infected LC cells. A549 harboring mutated Ras showed greater sensitivity (~82% early apoptotic cells) compared to H1650 cells harboring WT Ras (~27% early apoptotic cells) [Fig.2]. These results indicate that the antitoxin indeed actively protects cells with WT p53.

Conclusion: Exploiting the activated RAS pathway and mutation in p53 holds promise for specific and effective therapy that could specifically target tumor cells while sparing normal tissues.

card. All other authors have declared no conflicts of interest.

P1770  USE OF A COMBINATION OF LENTIVIRUS PARTICLES AND A SPECIFIC PEPTIDE FOR ERADICATION OF CD24-
EXPRESSING

N. Arber1, F. Eynat1, L. Abraham1, S. Shapira1
1Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
2ACPalm Medical Center, Hadassah-Hebrew University, Rehovot/Israel

Contact E-mail Address: nadira@tlvmc.gov.il

Introduction: Lentiviral replication is driven by a molecular motor consisting of two viral motor proteins, such as the reverse transcriptase, protease and integrase (IN). The genomic RNA of the virus is used to produce a copy of viral DNA by reverse transcription, and the integrase catalyses the covalent insertion of this DNA into the chromosomes of the infected cells. Integration of the viral DNA—which is driven by the RIGOR SgnLTR sequences—results in a combination of cleavage and ligation resulting in the appearance of double-stranded breaks in the host genome that eventually leads to apoptosis. CD24 is a heavily glycosylated cell-surface GPI-anchored protein. We have previously shown that CD24 is an important player in the multistep process of GI carcinogenesis (Gastro 2006, Clin Can Res 2007, Can Res 2008) as well as in many other human malignancies (Cervical, Bladder, Epithelial squamous cell carcinoma, Glioma, Breast etc.).

Aims & Methods: We designed and developed specifically directed lentiviruses expressing a C24-specific therapeutic (engineered Anti-CD24) and a control peptide. Humanized Anti-CD24 antibody fragment (scFv) was engineered and fused to the lentivirus envelope. Cell death was measured qualitatively by using fluorescent microscopy and was quantified by the enzymatic MTT assay. Human colorectal, pancreatic, lung and triple negative breast cancer cells were used for testing the potency of the lentiviral-based system.

Results: INS was able to stimulate the viral Integrase enzyme in test tubes and in vivo infected cells. The anti-CD24 antibody fragment has a high affinity and specificity toward CD24, allowing targeted precision of viral transduction (Figure 1). These Lentivirus particles contain DNA molecules with flanked LTRs allowing their integration into the CD24-expressing target cells DNA and formation of double-stranded breaks into the DNA of the target cells irrespective of the activation status of their gene which was stimulated by the INS derived peptides. Massive cell death was induced upon exposure of the infected cells to the INS peptide compared to the control peptide.

Conclusion: The use of INS derived peptides together with the CD24-targeted lentiviruses is a novel strategy to specifically promote death of CD24-expressing cancer cells.

card. All other authors have declared no conflicts of interest.

P1771  ILF3 STABILIZES AND ACTIVATES EGFR-MEDIATED G9A PATHWAY FOR MAINTAINING CANCER STEMNESS PROPERTY IN EGFR-POSITIVE CANCERS

C. Cheng1, A. Ho2
1Hematology And Oncology, Mackay Memorial Hospital, Taipei/Taiwan
2Division Of Gastroenterology, Cheng Hsin General Hospital, Taipei/Taiwan

Contact E-mail Address: aisheng49@gmail.com

Introduction: A specific inhibitor of interleukin enhancer binding factor 3 (ILF3), YM155, suppresses EGFR phosphorylation and significantly reduces the formation of cancer stemness tumorspheres in vitro, suggesting that ILF3 as an oncogene participates in the maintenance of cancer stem cell property through stabilizes EGFR-mediated stemness pathway. Since cancer stemness cells is the leading reason for tumor recurrence in the tumor repressive treatments, and EGFR enhances the formation of cancer stemness, it is worthy of investigating the function of ILF3 for maintaining the cancer stemness property in the EGFR-positive cancers.

Aims & Methods: The tumorspheres derived from EGFR-wild-type and KRAS-mutant colorectal HCT116 and lung A549 cells expressing higher cancer stemness markers, CD133, were used as cancer stemness models in this study. ILF3 was utilized to select the putative growth in the formation of tumorspheres as the cancer stemness markers. Meanwhile, the differentiating stemness markers were also compared between ILF3-knockdowned and the control shLuc cells. Then, the protein level and phosphorylation of EGFR were investigated in the YM155-treated and ILF3 inhibited ILF3-knockdowned cells. ILF3-knockdowned cells were also transplanted into SCID mice for evaluating the function of ILF3 in vivo.

Results: We found that higher EGFR autophosphorylation (Y1068) in HCC116- and A549-derived tumorspheres compared to the parental cells. The results of RNAseq evaluated that CD133 was a positive stemness marker, whereas MARCH4 as a negative marker. Knockdown of ILF3 reduced the cell proliferation in A549 cells in vitro and in vivo, demonstrating that ILF3 was an oncogene involving in cancer cell survival. Moreover, inhibition of ILF3 by YM155 blocked the autophosphorylation of EGFR and inhibited the EGFR-downstream G9a activation, leading to a reduction of stemness property. Moreover, Knockdown of G9a reduced the ILF3 expression and increased MARCH4 expression, revealing that G9a was essential for maintaining for cancer stemness property in the EGFR-positive cancers.

Conclusion: In conclusion, this study demonstrated that ILF3 played an important role in maintaining the EGFR-positive cancer stemness property in HCC116- and A549-EGFR-positive cancer cells. We demonstrated that ILF3 stabilized and phosphorylated EGFR to enhance the activation of G9a, leading to increasing CD133 and decrease MARCH4 expressions. Therefore, we suggested that the ILF3 inhibitor, YM155, was potential for utilization in cancer therapy against the EGFR-positive cancers.

P1772 EFFICACY AND SAFETY OF TWELVE CHEMOPREVENTIVE REGIMENS FOR THE RECURRENTNESS OF COLORECTAL ADENOMAS: A NETWORK META-ANALYSIS
H. Chen
Jiangsu Province Hospital, Nanjing/China

Contact E-mail Address: chenhanchen068@hotmail.com

Introduction: Although various pharmacological agents have been trialed for recurrent colorectal adenomas, their comparative effectiveness remains unknown. We conducted both direct and indirect comparisons of twelve chemopreventive agents for recurrent colorectal adenomas.

Aims & Methods: MEDLINE, EMBASE, Scopus, Web of Science, and Cochrane Central Register of Controlled Trials, and ClinicalTrials.gov were searched up to May 1, 2016. RCTs were assessed by a random-effects model within a Bayesian framework. Agents for each outcomes were ranked by surface under the cumulative ranking area (SURCA). This study is registered with PROSPERO, number CRD42016041923.

Results: 33 RCTs were eligible, enrolling 44,447 participants treated by twelve regimens: 9 aspirin and other NSAIDs, 11 antioxidants, 4 dietary supplements, 3 NSAIDs (SUCRA = 65.9%), but none reached statistically significance when compared with placebo. We measured EPA in CRC patients and other novel agents (e.g.metformin) in the chemoprevention of CRC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal cancer (CRC) is the third most common cancer world-wide. The Glasgow Prognostic Score (GPS) system was also widely studied, but the results were controversial. Which are indicators of systematic inflammatory response and nutritional status respectively. Growing evidence suggested that GPS was served as an independent prognostic index in a variety of malignant cancers. For patients with CRC, the GPS system was also widely studied, but the results were controversial.

Aims & Methods: To investigate the correlation between GPS and prognosis of patients with CRC to further clarify its clinical significance. A comprehensive literature search was performed. Embase, Web of Science, and Chinese National Knowledge Infrastructure was performed to identify eligible studies, from which the risk of overall survival (OS) and cancer-specific survival (CSS) were extracted. A random-effect model was adopted to combine hazard ratio (HR) and 95% confidence interval (CI).Heterogeneity and publication bias among studies were assessed.

Results: 25 articles with a total of 5660 participants were included. The pooled results indicated that elevated GPS was associated with poor OS (HR = 2.33, 95%CI: 2.00–4.00, P < 0.01) and CSS (HR = 1.94, 95%CI: 1.51–2.49, P < 0.01). This correlation was confirmed both in primary operable and advanced inoperable patients. Increased GPS was also closely related to advanced tumour-node-metastasis (TNM) stage (odds ratio [OR] = 1.44, 95%

P1775 COST EFFECTIVENESS OF THE FIRST SURVEILLANCE COLONOSCOPY IN POPULATION WITH ADVANCED COLORECTAL POLYPS OR MULTIPLE POLYPS FROM COLORECTAL CANCER SCREENING PROGRAM

L. Carot1, M. Gonzalez2, M. Battile3, A. Buron3, X. Besa Casserras4, M. Andreu Garcia1, A. Alvarez-Urturi5, L. Carot1, L. Carot1, M. Gonzalez1, M. Battile3, A. Buron3, X. Besa Casserras4, M. Andreu Garcia1, A. Alvarez-Urturi5

Contact E-mail Address: l.carot.1@partedesalut.cat

Introduction: The implementation of the CRC screening program has generated an increase in surveillance colonoscopies. However, the intermediate-high risk group that included advanced lesions (size ≥10mm, villous component or high grade dysplasia) or the presence of 3 or more polyps, has a low incidence of metachronous risk lesions when performing colonoscopy at 3 years according to the current recommendations. Identifying predictors of metachronous lesions would provide a better risk stratification and improve the efficiency of surveillance programs.

Aims & Methods: We aimed to identify the cost effectiveness of the first surveillance colonoscopy and the predictive factors of metachronous lesions at 3 years in individuals with advanced lesions or ≥3 polyps detected at baseline screening colonoscopy. This was an analysis of all cases with advanced polyps and/or multiplicity from CRC screening program population of Barcelona detected at baseline colonoscopy during the years 2010–2011 and with a performed colonoscopy after 3 years. Epidemiological and clinical data of all individuals were collected as well as the morphological data of all polyps. For the statistical analysis, a bivariate analysis and logistic regression were performed.

Results: 638 cases were identified, with mean age of 64 years. 342 were men (62.6%). 23.8% required more than one colonoscopy for the complete removal of the polyps. A complete surveillance colonoscopy at 3 years was performed in 518 cases (82%) with an average surveillance time of 38 months [15–75]. Mean fecal hemoglobin was 440 ng/ml. 51.8% suffered from hyperthermia, 15% from diabetes mellitus, 46.5% from dysplasia and 12.3% from chronic obstructive pulmonary disease. 45.8% of individuals were overweight (BMI ≥ 25) and 34.7% were obese (BMI ≥ 30). Surveillance colonoscopy was normal or with low-risk polyps in 420 cases (80.1%); and advanced polyps or multiplicity were identified in 98 cases (18.3%) 73 advanced adenoma in 59 cases (11.4%), ≥3 adenomas in 62 cases (11.5%), at least one adenoma and/or serrated polypla in 71 cases (13.7%). The presence of ≥3 adenomas and/or serrated polyps was the only variable that was associated with increased risk of the diagnosis of advanced adenomatous or serrated lesions in surveillance colonoscopy (p < 0.001)

Conclusion: Identifying individuals with advanced polyps and/or multiplicity the incidence of metachronous risk lesions at 3 years is low. Assessment a baseline colonoscopy with complete removal of all the polyps could allow to increase the interval of surveillance, maintaining and ensuring the compliance of the surveillance in 3 years in the cases with multiplicity in the basal colonoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal Endoscopic Submucosal Dissection (ESD) is recommended for superficial neoplastic lesions at high risk of submucosal invasion. ESD allows an en-bloc resection but ESD experience is still limited in Western countries.

Aims & Methods: The aim of this retrospective study was to evaluate technical and clinical outcomes of colorectal ESD, in a single tertiary European center. We retrospectively analyzed all consecutive patients treated by ESD for colorectal lesion at Humanitas Research Hospital (Milan, Italy) from January 2011 to September 2016. The primary outcomes were technical success, defined as en-bloc resection and clinical success, defined as curative resection (R0) without need for surgery. Secondary study outcomes were complication rate and adenoma/carcinoma recurrence. Complications were divided in early (<24 hours) and delayed (>24 hours) and included bleeding and perforation. Recurrences were identified as the presence of adenoma or carcinoma at the endoscopic follow-up performed at 6 months, 1, 3 and 5 years. Data were analyzed by STATA 14 statistical software.

Results: A total of 185 lesions in 185 patients (M: F 79/56, mean age 67.6 ± 11.5). Lesions were located in the rectum (64.3%), left colon (9.7%), transverse (11.9%) and ascending colon (14%). Mean size was 39.3 ± 24.4 mm. In 94 lesions (49.7%) local recurrence was observed. Ligation was performed in 27 cases (14.1%). 205 ESD were performed, 58 were ended with a near-total closure of the lesion (28%). 91 ESD were performed with a total closure of the lesion. Recurrence rates (grade dysplasia) or the presence of 3 or more polyps, has a low incidence of metachronous risk lesions when performing colonoscopy at 3 years according to the current recommendations. Identifying predictors of metachronous lesions would provide a better risk stratification and improve the efficiency of surveillance programs.

Main aim was to assess the impact of the first 30 months of the organized non-population based National Colorectal Cancer Screening Program in the Czech Republic–FIRST RESULTS OF THE NEW PROGRAM SETTINGS

3Department Of General Practice, Department of GP First Faculty of Medicine Charles University, Prague/Czech Republic

Contact E-mail Address: stepan.suchanek@uvn.cz

Introduction: The organized non-population based National Colorectal Cancer (CRC) Screening Program in the Czech Republic has been running since year 2000. In January 2014, the transition to population based settings has been implemented. Currently, the annual immunochromochromic FIT (FIT) is offered at the age 50-54, followed by FIT+ colonoscopy, if positive. In age of 55, there is a choice of either FIT biannually or screening colonoscopy in 10 years’ interval.

Main aim was to assess the impact of the first 30 months of the population-based CRC screening program on the target population participation and colorectal neoplasia detection. The data from National Reference Center (health insurance companies database) and Preventive Colonoscopies Registry in years 2013 (non-population based settings) and 2014–2015 (population-based settings) were evaluated and compared. Participation in the target population participation at 33.1%. This has influenced the increase of number of detected adenomas (by 42%) and cancers (by 20%) detection in year 2014. In year 2015, all the results remained stable (detailed results in the table).

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: The transition to population-based program resulted in the improve-
ment of target population participation followed by increase in colorectal neo-
plasia detection.
Disclosure of Interest: All authors have declared no conflicts of interest.
Supported by the projects MO1012 and PRVOUK-P271LF1/1

P1778 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY CANCER AND HIGH GRADE DYSPLASIA IN COLORECTUM
P. Zhou1, T. Chen1
1Endoscopy Center, Zhongshan Hospital, Fudan University, Shanghai/China
Contact E-mail Address: chentao66@yahoo.com
Introduction: Although endoscopic submucosal dissection (ESD) is a widely accepted treatment for colorectal neoplasm, little is known about large consecutive studies evaluating long-term outcomes of early cancer and high grade dys- plasia. We aimed to evaluate the efficacy and safety of ESD for early cancer and high grade dysplasia in colorectum and evaluated the long-term outcomes, including local recurrence and metastasis.
Aims & Methods: We performed a retrospective analysis of data collected from 5 consecutive patients with 520 colorectal early cancer and high-grade dyspla-
tasia treated with ESD between January 2007 and December 2013. Histology and patient data were collected during an average follow-up time of more than 5 years to determine tumor stage and type, resection status, complications, tumor recurrence, and distant metastasis.
Results: The overall rates of en bloc resection, complete resection, R0 resection, major complications were 94.4%, 91.3%, 89.2% and 2.1%, respectively. Large tumors and snare-assisted ESD were independent factors of piecemeal resection. ESD of colon tumors increased the risk for complications. During the follow-up period, all patients remained free from metastasis. However, local recurrence occurred in 4 patients (0.8%); large tumors and piecemeal resection were risk factors.
Conclusion: ESD is effective and safe for resection of early cancer and high grade dysplasia in colorectum and long-term outcomes are favorable. ESD is indicated for the treatment of colorectal early cancer and high grade dysplasia to obtain curative resection and prevent the local recurrence.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1779 LOW UPTAKE OF PSYCHOLOGICAL THERAPIES AMONG PATIENTS WITH IRRITABLE BOWEL SYNDROME IN SECONDARY CARE
O. Craig1, C. Black1, L. Houghton2, A.C. Ford1
1Leeds Gastroenterology Institute, St. James’s University Hospital, Leeds/United Kingdom
2Leeds Institute Of Biomedical & Clinical Sciences, St.James’s University Hospital, Leeds/United Kingdom
Contact E-mail Address: ofcraig@gmail.com
Introduction: Patients with irritable bowel syndrome (IBS) often have co-existent mood disorder and psychological illness. Meta-analyses of randomised con-
trolled trials consistently demonstrate that psychological therapies, such as cog-
nitive behavioural therapy (CBT) and hypnotherapy, are effective treatments for IBS. In the UK the National Institute for Health and Care Excellence (NICE) recommends considering the use of these in patients with no response to pharma-
cological therapies, and for refractory symptoms.
Aims & Methods: We performed a cross-sectional survey to examine willingness of patients with IBS to engage with psychological therapies. We collected com-
plete symptom data from consecutive, unselected referrals to secondary care seen in a specialist IBS clinic. All participants completed the validated Rome IV questionnaire for IBS, the IBS severity scoring system (IBS-SSS), the hospital anxiety and depression scale (HADS) to assess mood, and the patient health questionnaire-12 (PHQ-12) to examine somatof orm-type behaviour. They also provided their opinion on possible treatment options, and were asked to rank medical therapies, dietitian input, psychological therapies, including CBT and hypnotherapy, and explanation of the condition and/or reassurance in order of preference.
Results: Among 93 adults with confirmed IBS (74 (79.6%) female, mean age 36.0 years (range 16 to 77 years), 35 (37.7%) had high levels of anxiety, 22 (23.7%) had high levels of depression, and 23 (24.7%) had severe levels of somatof orm-type behaviour. Despite this, only 10 (10.8%) of 93 patients ranked psychological therapies as their first-choice treatment option. In total, 8.8% of patients with high levels of anxiety ranked psychological therapies as their first-choice treat-
ment option, versus 13.2% without (P = 0.64), 9.5% of those with high levels of depression, versus 12.1% of those without (P = 0.91), and 17.4% of patients with severe somatoform behaviour, versus 9.2% of those without (P = 0.26). Those with severe symptoms according to the IBS-SSS were no more likely to select psychological therapies as their first-choice treatment option than those with mild or moderate symptoms (7.7% versus 21.7%, P = 0.10).
Conclusion: Despite high levels of psychological comorbidity and NICE recom-
mandations, patients with IBS in a specialist clinic were generally reluctant to consider psychological therapies such as CBT or hypnotherapy. Those with anxiety, depression, somatof orm-type behaviour, or severe symptoms were no more willing to consider these therapies than those without.

P1780 GUT SYMPTOMS AND TRANSIT DISTURBANCE IN PARKINSON’S DISEASE ARE NOT ÜBIQUITOUS: A WIRELESS MOTILITY CAPSULE STUDY
V. Passamanti, N. Zarate Lopez, R. Sweis, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom
Contact E-mail Address: valentinapassamanti@gmail.com
Introduction: Symptoms of gastrointestinal dysfunction are among the most common non-motor complaints in Parkinson’s patients. These may involve mus-
cles from the oropharynx to the anorectum, and the autonomic and enteric nervous system are often involved, resulting in secondary bowel dysmotility.
Aims & Methods: The objectives of this study were to evaluate a technology measuring the spectrum of gut dysfunction, the Wireless Motility Capsule (WMC), in Parkinson’s disease. We also wanted to correlate transit measures with gastrointestinal symptoms. Fifteen PD patients and 7 controls (table1) were included. PD severity were scored with the modified Hoehn and Yahr (H&Y) staging score. GI symptom severity were scored with the Wexner constipation score and Gastroparesis Cardiographic Symptom Index (GCSI). Acidity, motility and transit data were obtained, as standard, by WMC. All medications affecting pH and motility, including L-dopa, were discontinued for 5 days before and for the duration of the study. Were analyzed data about gastric emptying time (GET), small bowel transit time (SBTT), colonic transit time (CTT) and whole gut transit time(WGTT).
Results: One patient could not swallow the capsule, and of the 14 patients com-
pleting the study, 8 reported GI symptoms. Compared to non-symptomatic patients, those with GI symptoms showed significant delayed transit in the stom-
mach, colon and whole gut (table 1). However, small bowel transit did not significantly differ. GI dysfunction was not correlated with H&Y score in this small study, used the risk lower constipation scores were correlated, suggesting a pan-enteric problem in symptomatic individuals. There was a significant correla-
tion between the Wexner constellation score and CTT in all patients (p < 0.01) but not GCSI and GET (p > 0.10). The results of Wireless Motility Capsule did not differ between non-symptomatic PD and controls.

P1781 OUTLET DYSFUNCTION IS PREVALENT IN SEVERE FUNCTIONAL BLOATING: PRELIMINARY REPORT FROM A MULTICENTER ITALIAN STUDY

the handling of gas is a relevant underlining mechanism in FGID patients with bowel incontinence. 

Aims & Methods: Our aim is to study the relationship between the defecation pattern, the severity of bloating and the abdominal girth measurements in FGID patients consulting for bloating as primary complaint with/without visible abdominal distension and without obvious obstructive or dysmotility signs.

We performed a prospective, multi-center study of patients with severe abdominal bloating (VAS score >24 on a 100-mm scale) as primary complain with/without visible abdominal distension. Patients were recruited at 4 gastroenterology outpatient clinics in Italy. Comorbid FGID were grouped according to Rome III criteria. All patients were prescribed a lactose-free diet supplemented by dietary advice according to the NICE guidelines for two weeks. A belt around the abdomen at standardized abdominal girth measurements. During the 2-week run-in period patients completed a daily diary log including abdominal bloating and pain/discomfort scores (100-mm VAS), Bristol Stool Form and stool frequency, the severity of bloating and the abdominal girth changes (r= .53 and .52, p < .0001, respectively).

Results: 76 patients (66 female, 39.6 ± 12.2 mean age, 6 IBS-D, 6 IBS-M, 30 IBS-C, 9 IBS-U, 6 FC, 16 FB, 3 FD) completed the 2-week run-in period. A significant negative correlation was found between adequate relief and both bloating and abdominal girth changes (r = .53 and .52, p < .0001, respectively). 53 / 76 (70%) patients reported inadequate relief (worse or no improvement). Among the non-responders the vast majority (68%) failed the BET. Multiple regression analysis showed that BET (successful or failed) was a dependent variable related significantly to bloating severity. No relationship was demonstrated for abdominal girth changes, FGID diagnosis and straining questionnaire.

Conclusion: In this prospective, multichannel trial simple diet advise was of benefit in approximately 30% of FGID patients consulting for severe bloating. In the non-responders outlet dysfunctio was prevalent and correlated with subjective bloating perception. The study is ongoing, but our data may support bowel retraining as potential treatment option for functional bloating.

Introduction: Fecal Incontinence (FI) is a common and socially disabling condition, more prevalent among females over 50 years old. Detailed anatomical and physiological assessment of each patient is important to determine the correct diagnosis, and abdominal sphincters and rectum.

Aims & Methods: To evaluate symptoms and anorectal function of patients affected by FI, we included 358 patients with FI (77% female) and 23% men (M), mean age 63 (range 22–92 year) referring to the outpatient unit of Digestive Pharmacothy of S. Giovanni-Addolorata Hospital, Rome from January 2006 to December 2016. Clinical presentation (history, symptom profile and severity) and anorectal physiological evaluation (digital examination, manometry, rectal sensory testing, bulon evacuation test) were analyzed. The manometric parameters included with conventional and HR-ARM were: resting pressure, squeeze pressure, rectal compliance, rectal sensibility and the anorectal pattern during the defecatory maneuvers.

Results: 114 out of 358 patients (32%) reported both FI and difficulty evacuating stools and also urinary incontinence (2%); Proctological surgery (n=12, 34%), pelvic surgery (n=7, 21%) and traumatic anial or vaginal history (n=4, 11%) were statistically associated with FI (p<0.05). Normal manometric parameters were found in 16 patients (4%). Manometric alterations observed were: internal anal sphincter (IAS) dysfunction: 228 (64%); isolated external anal sphincter (EAS) dysfunction: 274 (76%); combined sphincter dysfunction IAS and EAS: 198 (55%); isolated dysynergic defecation: 100 (28%); rectal hypersensibility: 130 (36%).

Conclusion: In our study, in accordance with the literature, we observed a female prevalence in FI. FI is significantly associated with previous proctological/pelvic surgery and traumatic anal/vaginal delivery. Furthermore, patients with FI referred difficulty evacuating stools, too. In fact in patients with dyssynergic-type constipation, the FI may be confused with an encopresis. Finally we observed these prevalent manometric alterations: combined dysfunction IAS and EAS, and rectal hypersensivity. Manometric findings could help physicians to identify approprate patients for a biofeedback therapy.

Introduction: Bile acid malabsorption (MAB) is a common and frequently under-investigated cause of chronic diarrhea. Most of the cases of chronic diarrhea after excluding organic disorders are labelled as functional diarrhea or irritable bowel syndrome (IBS). The most commonly used diagnostic test is Selenium hexalinum acid taumine (SeHCAT) scan due to its sensitivity, specificity, safety and low cost. However this test is not frequently used in the algorithm for the diagnosis of chronic diarrhea.

Aims & Methods: We aimed to evaluate the usefulness of SeHCAT scan in evaluating patients with chronic diarrhea and identify potential risk factors associated to MAB. We retrospectively reviewed all patients who had SeHCAT scan between June 2014 and October 2016 in a University Hospital. BAM was defined as SeHCAT retraction of less than 15%. We collected the following variables: demographic characteristics, IBS-D Rome III criteria, duration of diarrhoea (months), stool culture, parasitic investigation of stool specimens, background of comorbid gastrointestinal and other comorbid conditions, positive HLA-DQ2 and DQ8 haplotype.

Results: 137 patients referred to clinic for chronic diarrhea underwent SeHCAT testing over the reviewed period. 42M: 95F, median age 46 y (95% CI 44.0–50.1), median BMI 25.34(kg/m2) (95% CI 24.0–27.00), 70.4% of patients met IBS-D Rome III criteria, median duration of diarrhea 48 months (95% CI 43.10–59.24). Background of co-morbid gastrointestinal conditions 45.3% (62/136), other co morbid conditions 55.3% (75/136). History of previous positive stool culture (30.1%) and parasitosis (20.8% of stool specimens). Percentage of positive HLA-DQ2 and DQ8 haplotypes were 27.8% (35/126) and 10.2% (13/127), respectively. SeHCAT test was positive for BMA in 48.9% (67/137); 25.4% (mild 10–15%); 31.3% (moderate 5–10%), and 43.3% (severe < 5%). Patient characteristics between positive and negative SeHCAT test were similar (Table 1). Interestingly, patients with SeHCAT test exhibited longer periods of diarrhea.

Patients who exhibited MAB (confirmed by SeHCAT test) were treated with colestyramine. 27.1% (23/85) exhibited partial response, 33.9% (21/62) exhibited total response, 3.2% (2/67) exhibited no good tolerance, we had no information in 21% (13/67).

Conclusion: SeHCAT scanning must be considered as a diagnostic tool for the diagnosis of chronic diarrhoea, specially in those patients with long-standing diarrhoea.

Introduction: The cause of IBS is uncertain; however, food intolerance shares many features with this condition. Consumption of FODMAPs has been shown to induce IBS-type symptoms (Shephard 2008) and clinical trials have shown that a low FODMAP diet can improve symptoms in this patient group (Halmos 2014). However, FODMAP intake is not higher in IBS than in health (Bohn 2013) and it is not proven that the outcome of low FODMAP diet is better than standard dietary advice in this condition (Bohn 2015). Recent, experimental research has shown that psychological factors are associated with increased postprandial symptoms in IBS patients (Zhu 2013, Van Oudenhove 2016). This study was designed to assess the relative importance of, and interaction between, psychiatric disease, social stress and diet in the aetiology of IBS in the general community.

Aims & Methods: This population based study tested the hypothesis that high FODMAP intake increases the risk of IBS more in individuals with psychiatric disease and/or life event stress than other members of the community.

Subjects aged 16–74 were randomly selected from five South-Chinese communities. All subjects completed questionnaires by face-to-face inquiry with investigators including demographic information, gastrointestinal symptoms (Rome III), dietary intake (food frequency chart validated in Chinese community), psychiatric disease (HADS), life event stress (LES) and quality of life (SF-8).

Results: From 1999/2115 (94.7%) members of the community that completed study questionnaires, 117 (5.9%) had IBS by Rome III criteria. The IBS group attended a university hospital-based outpatient clinic specialized in functional GI disorders between 2005 and 2015. The patients underwent examinations to investigate oro-anal transit time (OATT) and visceral sensitivity (rectal balloon distension and a lactulose challenge test), and they also completed questionnaires to assess anxiety and depression (HAD), overall IBS symptoms (IBS-SSS), bowel habits (BSF), quality of life (IBSQOL), extraintestinal somatic symptoms (PHQ-12), sense of coherence (SOC), fatigue (MFI), GI-specific anxiety (VSI) and physical and sexual abuse. OATT was similar between groups, as was stool form and frequency. Visceral sensitivity tended to be higher in patients with anxiety, and depressed patients reported more severe pain during the lactulose challenge.

Conclusion: FODMAP intake was similar in IBS and No-IBS groups in the community (lactose intake was lower in IBS subjects, likely due to avoidance of dairy products (Long 2017)). However, as expected, IBS patients in the community had a greater likelihood of psychiatric disease, life event stress and clinical co-morbidity. Joint effects analysis demonstrated that high FODMAP intake alone was not associated with abdominal symptoms; however, IBS was more common in those with a high FODMAP intake and concomitant psychosocial factors known to increase visceral sensitivity to digestive function (Zhu 2013). (ClinicalTrials: NCT0126597)

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A large proportion of patients with irritable bowel syndrome (IBS) suffer from anxiety or depression, but the associations with pathophysiological findings and overall symptom reporting are not clear.

Aims & Methods: We included 772 patients with IBS (Rome III criteria) who attended a university hospital-based outpatient clinic specialized in functional GI disorders between 2005 and 2015. The patients underwent examinations to investigate oro-anal transit time (OATT) and visceral sensitivity (rectal balloon distension and a lactulose challenge test), and they also completed questionnaires to assess anxiety and depression (HAD), overall IBS symptoms (IBS-SSS), bowel habits (BSF), quality of life (IBSQOL), extraintestinal somatic symptoms (PHQ-12), sense of coherence (SOC), fatigue (MFI), GI-specific anxiety (VSI) and physical and sexual abuse.

Results: Based on validated HAD cut-off levels (≥5), anxiety and depression were present in 55% and 26% of the IBS patients, respectively. More women were anxious (p = 0.001), but for depression no gender differences were detected (p = 0.76). IBS patients with anxiety or depression were younger (p < 0.001), and more commonly reported sexual and/or physical abuse (p < 0.001) than IBS patients without anxiety or depression. The presence of anxiety or depression did not differ between IBS subgroups based on the predominant bowel habit (p = 0.41, p = 0.18). For an overview of comparisons of data from questionnaires and pathophysiological examinations, see table 1. Both the presence of anxiety and of depression were associated with reports of more severe GI and extraintestinal symptoms, GI-specific anxiety, fatigue, and lower sense of coherence. Regarding pathophysiological examinations, the findings were more inconsistent. OATT was similar between groups, as was AATT. No differences were found in the stool form and frequency. Visceral sensitivity tended to be higher in patients with anxiety, and depressed patients reported more severe pain during the lactulose challenge.

Table: Joint effects of psychiatric disease, life stress & total FODMAP intake on relative risk of IBS in community

P1786 THE ASSOCIATION BETWEEN IRRITABLE BOWEL SYNDROME AND LACTOSE INTOLERANCE

R. Dakab1, T. Arslan Kucuk1, S. Tunus1, H. Cetin1, E. Ahsual2, C. Dolapcoglu1

1Family Medicine, Dr. Lutfi Kardar Kartal Research And Training Hospital, Istanbul/Turkey
2Gastroenterology, Dr. Lutfi Kardar Kartal Training and Research Hospital, Istanbul/Turkey

Contact E-mail Address: resat_dakab@hotmail.com

Introduction: Irritable bowel syndrome (IBS) and lactose intolerance may co-exist and readily cause diagnostic confusion due to similar symptomatology (1,2).

Aims & Methods: This study aims to examine the incidence of lactose intolerance in healthy controls and in subjects diagnosed with IBS based on Rome III criteria, as an effort to investigate the association between IBS and lactose intolerance. The patient population consisted of individuals between 18 and 80 years of age who attended between June-December 2013. Patients diagnosed with IBS based on Rome III criteria comprised the IBS group, and subtypes of IBS. Control subjects were healthy volunteers over 18 years of age with no IBS-like symptoms. All participants ingested 25 g of lactose dissolved in 250 ml of water within 5 minutes after 8 hours of fasting, in order to evaluate the lactose intolerance via hydrogen breath test (0, 15, 30, 60, 90, and 120 minutes). Additionally, symptoms arising during the test were assessed.

Results: Of the total 200 participants, 100 (50%) were in IBS and 100 (50.0%) were in control group. There were 153 females (66.5%), and the mean age was 40.5±12.3 years. Of the total 70 patients (35.0%) with lactose intolerance, 47 (47.0%) were in IBS and 23 (23.0%) were in control groups (p = 0.001). Symptoms related to IBS were more common in participants with lactose intolerance in both groups (p = 0.001, p = 0.001 respectively). A comparison of the two groups with regard to symptomatology after the test showed the presence of complaints in 35 (35.0%) patients in IBS group as compared to 24 (24.0%) subjects among controls (p = 0.092). The incidence of lactase intolerance in patients with IBS subtypes of diarrhea-predominant IBS, constipation-predominant IBS, mixed IBS, and unspecified IBS were 27 (57.4%), 7 (4.9%), 10 (21.3%), and 3 (6.4%), respectively, with no significant differences (p = 0.161, p = 0.124, p = 1.000, and p = 0.661 respectively).

Conclusion: A significantly increased frequency of lactose intolerance was found among IBS patients than in controls. In additional, symptoms associated with lactase intake occurred at a higher frequency in IBS patient, although the difference was insignificant.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The population prevalence of Rome IV functional gastrointestinal disorders (FGIDs) and their cumulative effect on health impairment is unknown. We sought to address this issue.

Aims & Methods: An Internet-based health survey was completed by 5931 of 6300 general population adults from three English-speaking countries (2000 each in US, Canada, and UK). The survey included questions on demographics, medication, surgical history, somatisation, quality of life, doctor-diagnosed organic GI disease, and criteria for the Rome IV FGIDs. Comparisons were made between those with Rome IV FGIDs against non-GI and organic GI disease controls.

Results: The number of subjects having symptoms compatible with a FGID was 2083 (35%) compared to 3421 (57.7%) non-GI and 427 (7.2%) organic GI disease controls. The most frequently met diagnostic criteria for FGIDs was bowel disorders (n = 1665, 28.1%), followed by gastroesophageal reflux (n = 627, 10.6%), anorectal disease (n = 440, 7%), oesophageal diseases (n = 241, 7%), and gallbladder disorders (n = 104, 0.2%). On average, the 2083 individuals who met FGID criteria qualified for 1.5 FGID diagnoses, and 742 of them (36%) qualified for FGID diagnoses in more than one anatomic region. The presence of FGIDs in multiple regions was associated with increasing somatisation, worse mental and physical quality of life, greater use of medical therapies, and a higher prevalence of abdominal surgeries; all p < 0.001, see table. Notably, individuals with FGIDs in multiple regions had worse somatisation and quality of life scores than organic GI disease controls.

Conclusion: Roughly a third of the general adult population fulfills diagnostic criteria for a Rome IV FGID. Roughly a third of this subset have FGIDs in multiple regions and this overlap is associated with increased health impairment. Study Support: The Rome Foundation

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: The presence of anxiety and depression seems to clearly potentiate the already substantial disease burden in IBS patients. However, the association with other pathophysiological findings is less distinct. This group of patients with complex and severe symptoms will benefit from a holistic management approach.

**Introduction:** Although correlations between features of irritable bowel syndrome (IBS) have been reported, these were based on between-person rather than within-person variation. We investigated the longitudinal within-person correlations between features of IBS.

**Aims & Methods:** We used a longitudinal cohort of 276 IBS patients, who filled out online questionnaires once annually over five years. On the following features: gastrointestinal (GI) symptom severity (GSS), quality of life (QOL), GI specific anxiety (VSI), general anxiety and depression (HADS), coping resources (CRI), and sense of coherence (KASAM). For each participant, scores were centered on their own mean, and within-person correlations were computed for all pairs of features.

**Results:** Aggregate within-person correlations are shown in figure 1. Within-person correlations were strong for the triad GI symptom severity, GI specific anxiety, and QOL (r: 0.47 to 0.64). Another set of features was comprised of general anxiety, depression, coping resources, and sense of coherence (r: 0.39 to 0.57). Within-person correlations between the two sets were weak (r: 0.00 to 0.37). However, within-person correlations tended towards bimodal distributions across the population, especially for GI symptom severity and depression (r = -0.6 for half of participants, and r = -0.4 for the other half).

**Conclusion:** Here we show that, within individual IBS patients, GI symptom severity is strongly associated with GI specific anxiety and QOL, but not with four other psychological features. The presence of negative within-person correlations in some individuals may imply a lack of relation, but could also signal long-term causative processes.

**P1790 Irritable Bowel Syndrome with Constipation: Impact of Symptom Severity on Quality of Life: A Post hoc Analysis of Data from Two Phase 3 Trials of Linacotide**

A. Marciniak

1. Allergan plc, Marlboro/United Kingdom
2. Allergan plc, Jersey City/United States of America/NJ
3. Allergan plc, Bridgewater/United States of America/NJ

Contact E-mail Address: Anne.Marciniak@Allergan.com

**Introduction:** Irritable bowel syndrome with constipation (IBS-C) is a chronic gastrointestinal disorder associated with significant impairment in health-related quality of life (HRQoL). However, information on the impact of IBS-C symptom severity on patients’ HRQoL is lacking.

**Aims & Methods:** This post hoc analysis assessed the burden of IBS-C on HRQoL according to symptom severity among adult patients meeting the modified Rome III criteria for IBS-C based on baseline data from the two Phase 3 clinical trials of linacotide. These randomized, double-blind, placebo-controlled, parallel-group, placebo-dose-matched trials were Sienna-1 and Sienna-2. The clinical trials were conducted in the United States, Canada, and Europe. Patients were recruited from community practices and located across 33 countries (United States (n = 610), Canada (n = 608), and Europe (n = 763)). Participants who were 18 to 75 and met criteria for IBS-C according to Rome III were included. Assessments included validated quality of life instruments: IBS-QOL for IBS-C patients and EQ-5D for all patients. The primary endpoint was differences in mean total IBS-QOL score compared to those with GSS ≤ 3. Differences in overall and subscale scores between patients aged <65 and ≥65 years, and between sexes, were compared.

**Results:** A total of 1602 IBS-C patients were included for analysis. Compared to placebo, patients treated with linacotide had a lower HRQoL as indicated by lower mean IBS-QOL overall and subscale scores, with the greatest differences seen for body image (15-point difference), dysphoria and health worry (both 13-point difference) subscales (Table). Patients with GSS ≥ 3 also had a lower EQ-5D index score compared to those with GSS < 3 (0.67 vs 0.72) (Table). Women reported a slightly lower mean total IBS-QOL score compared to men, but had a notably lower score (14-point difference) on the body image subscale (Table). No difference in mean EQ-5D score was observed between sexes. IBS-QOL total and EQ-5D index scores were similar between patients aged <65 and ≥65 years, though the younger subgroup generally had lower scores on the IBS-QOL, including on the food avoidance and sexual subscales (Table).

**Conclusion:** Among this patient population, IBS-C patients with higher symptom severity reported greater impairments in HRQoL. These results indicate that symptom severity may be an important consideration for disease management and emphasise the need for IBS-C treatments that improve both symptom burden and HRQoL.

<td></td>
</tr>
</tbody>
</table>

Results: Significant differences were recorded in the levels of PT (median: 14.5 vs 13.1 sec, p = .0005) and aPTT (median: 28.7 vs 26.4 sec, p = .0005) between IC patients and controls, respectively. Prolongation over the upper limit of normal of PT (>14 sec) was most common in IC patients, 67.9% vs 18.2% (p = .0005) as well as the prolongation of aPTT (>35 sec), 12.2% vs 6.2% (p = .469). The presence of LA was characterized as weakly present in 5 of 6 patients with the aPTT prolongation (9.6%, normalized LAC ratio: 1.2–1.5) and moderately present in 1 patient (1.9%, normalized LAC ratio: 1.5–2.0).

Conclusion: Prolongation of PT and aPTT, possibly indicating a chronic Vitamin K deficiency state, may be implicated in the pathophysiologcal mechanisms of IC.

P1795 THE RISK PREDICTIVE VALUES OF ACG CLASSIFICATION IN A COHORT OF ISCHEMIC COLITIS: REFINING THE DEFINITION OF MILD DISEASE
1Gastroenterology, Hospital Central do Funchal, Funchal/Portugal
2Department of Gastroenterology and Hepatology, North Lisbon Hospital Center, University of Lisbon, Lisbon/Portugal
3Gastroenterology, Hospital São João, Oporto/Portugal

Introduction: Although most cases of colon ischemia (IC) are mild and self-limiting, when severe it implies high mortality rates. We aimed to evaluate the risk predictors of the classification of disease severity proposed by American College of Gastroenterology (ACG) guidelines (2015), created to provide a management algorithm for these patients and select the level of care.

Aims & Methods: A retrospective multicenter study was conducted on adult patients with definite IC (clinical, colonoscopic, pathologic and culture criteria), between 2013 and 2016. Data was collected on clinical presentation, comorbidities, organ failure, management and outcome. Each case was classified according to ACG guidelines after assessment of the number of risk factors (gender, systolic blood pressure <90 mm Hg, heart rate >100 beats per min, abdominal pain without rectal bleeding, BUN > 20 mg/dl, Hbg < 12 g/dl, LDH > 350 U/l, serum sodium < 136 mEq/l, WBC > 15 x 10^9 cmm). Patients were then classified as mild (0 risk factors (RF)), moderate (1–3 RF), and severe (3 RF or more) predictors of the following: perforation signs, pneumatosus or portal venous gas, gangrene on colonoscopic examination and pan-colonic or isolated right-colon ischemia involvement on imaging by colonoscopy or computed tomography.

Results: 349 cases with the clinical diagnosis of IC were analyzed. 193 patients met the inclusion criteria of definitive diagnosis of IC (62.7% females; mean age 72 years ±13). ACG classification of mild, moderate and severe disease was attributed respectively to 21% of patients (0 intra-hospital deaths), 45% (2 deaths) and 34% (12 deaths). The number of ACG RF was: 40% with 0 RF, 8% with 1, 9% with 2, 15% with 3, 16% with 4, 8% with 5, 4% with 6 and 1% with 7. No patient with 0 or 1 RF died. Only 1 patient with 2 RF died. The remaining 13 deaths were verified RF less than 3 RF. The univariate analysis revealed a statistical correlation between RF and intra-hospital or 30-day mortality as well as the need for surgery (mean = 4.06, sd = 1.85). ACG classification presented high predictive accuracy for in-hospital and 1-month mortality with an AUROC of 0.78 (95% CI: 0.71–0.85), respectively. For a cutoff of 2 ACG RF, the sensitivity (SE) for death was 100%, specificity (SP) 52%, with a positive predictive value (PPV) of 14% and negative predictive value (NPV) of 100%. For 3 ACG RF the results were: SE 93%, SP 61%, PPV 16% and NPV 99%, 3 or more risk factors had an odds ratio of 20.2 (confidence interval (CI) 2.59–158) for intra-hospital mortality and 18.42 for 1-month mortality (CI 2.34–144).

Conclusion: No patient in this cohort with less than 2 ACG RF died, suggesting that the ACG classification as mild disease may include 0 and 1 risk factor without changing the prognosis. Short-term mortality risk increases significantly in patients with at least 3 ACG RF.

P1796 HOW COST AFFECTS THE TREATMENT CHOICE FOR IRRITABLE BOWEL SYNDROME WITH DIARRHEA PATIENTS: A COST-EFFECTIVENESS ANALYSIS OF TRICYCLIC AGENTS AND RIFAXIMIN
E. D. Shah, E. Andraska, J. Li, S. Zhang, W.D. Chey
Division Of Gastroenterology, University of Michigan, Ann Arbor/United States of America

Contact E-mail Address: esrshah@med.umich.edu

Introduction: Drug pricing and third party payer coverage exert a profound effect on access to prescription therapies in patients with irritable bowel syndrome with diarrhea (IBS-D). We performed a cost-effectiveness analysis to assess the trade-offs associated with treating IBS-D patients with a tricyclic agent (TCA) or rifaximin.

Aims & Methods: We constructed a decision analytic model evaluating three treatment strategies for IBS-D in the United States healthcare system: first-line therapy with TCA-only, first-line rifaximin followed by second-line TCA for nonresponders, and first-line TCA followed by second-line rifaximin for nonresponders. This model accounted for direct and indirect costs of therapy (Medicaid NADAC database and Healthcare Book) and work-productivity loss (published literature and US Bureau of Labor) with a 3% per annum discount rate. Rifaximin was administered in 4-month treatment cycles based on physician clinical experience. Responder and discontinuation rates were derived from clinical trial data, and validated health utility values were assigned to terminal health states. Base-case analysis was performed to determine incremental cost-effectiveness ratios (ICER) for both rifaximin strategies. Threshold analysis assessed rifaximin pricing at contemporary willingness-to-pay (WTP) levels per quality adjusted life year (QALY). Appropriate sensitivity analyses were conducted. Analysis was performed with a 1-year time horizon from societal and payer perspectives.

Results: Based on the average acquisition cost of rifaximin (USD $29.78/pill), second-line rifaximin could be cost-effective from a societal perspective (Table 1). However, at contemporary WTP thresholds neither rifaximin strategy was cost-effective from a payer perspective despite greater effectiveness than TCA alone. Depending on WTP, a 12-62% price reduction (USD $18.46-$26.34/pill) would enable the first-line TCA followed by second-line rifaximin to be more cost-effective than a TCA-only strategy (Table 1). An 84-88% price reduction (USD $3.53-$4.71/pill) would enable first-line rifaximin followed by second-line TCA to be more cost-effective than TCA-only, though first-line TCA followed by second-line rifaximin would remain the more cost-effective strategy. Our model was robust to tornado analysis and most influenced by rifaximin treatment interval. Sensitivity analysis on rifaximin retreatment interval suggests that current pricing may be based on longer retreatment intervals than those found in clinical literature (Fig 1a). Sensitivity analysis with a lower TCA responder rate could enable first-line rifaximin to be the preferred strategy, albeit at a reduced price (Fig 1b).

Conclusion: Rifaximin is an effective therapy for IBS but is less cost-effective than TCA as currently priced. We propose an evidence-based pricing strategy which would maximize the cost-effectiveness of rifaximin in IBS-D patients.

Introduction: Colonoscopy has been widely used for diagnostic and therapeutic purposes. Although the incidence is very low, perforation is one of the most serious complications. It is important to decide whether to try endoscopic clipping or to perform prompt surgical management.

Aims & Methods: We retrospectively reviewed charts of all patients who experienced colonoscopy-associated perforation in a single center between May 2009 and July 2015, and totally 45 patients were enrolled.

Table: The risk factors surgical treatment in colonoscopy-associated perforation

</tr>
</tbody>
</table>

Results: Diagnostic cases in purpose, sigmoid colon in location and non-clipping status were significantly more common in surgery group than conservative group (Table). Endoscopic clipping was performed in 31 cases (immediate; 23, delayed; 8), and immediate clipping group had significantly lower rate of operation (p = 0.013) and better clinical outcome (duration of antibiotic: p = 0.006, hospital stay: p = 0.001). Among 18 surgical cases, 13 patients had primary closure and 5 patients had complex surgery (2; segmental resection, 3; Hartmann’s procedure). The early (<24hr) surgical management significantly decreased the possibility of complex surgery (p = 0.002), as well as had better clinical outcomes such as duration of antibiotic use, fasting time and length of hospital stay (p = 0.003, p = 0.001, p = 0.005, respectively). In therapeutic cases, all five perforated patients who had surgery within 1 day could be managed by simple primary closure, but all four patients who had surgery after 1 day required complex surgery.
Conclusion: In colonoscopy-associated perforation, immediate endoscopic clipping decreases the possibility of operation and shows better clinical outcomes, and early surgical approach decreases complex operation rate. Especially, early operation need be considered in diagnostic perforation regardless of endoscopic clipping.

P1798 PATIENTS’ AND CLINICIANS’ VIEWS OF AND EXPERIENCE WITH A NOVEL CLINICAL PATHWAY FOR FUNCTIONAL GASTROINTESTINAL DISORDERS

E. C. Linedale1, A. Mikodas-Walas1, P.R. Gibson2, J. M. Andrews3
1Department Of Medicine, The University of Adelaide, Adelaide/Australia/SA
2Gastroenterology, Monash University, Melbourne/Australia/VIC
Contact E-mail Address: ecubslinedale@adelaide.edu.au

Introduction: Despite diagnostic criteria and effective management options for functional gastrointestinal disorders (FGID), confidence in managing these disorders in primary care is low, and long waiting lists for specialist care are common. New models which efficiently transfer specialist-held expertise to primary care practitioners is needed.

Aims & Methods: We aimed to explore and describe the patient and primary healthcare provider (PHCP) experience of a novel non-specialist-dependent algorithm-based approach to the diagnosis and management of FGID (ADAM-FGID). Consecutive patients triaged to the ‘routine waitlist’ of an Australian public hospital Gastroenterology Department over 2 years, with non-specific gastrointestinal symptoms (no alarms) were randomised to waitlist control or the algorithm (2:1). Algorithm patients were screened for organic disease with an alarms-based questionnaire and panel of routine blood/stool tests. When patients had clinical alarms or abnormal tests, data were reviewed by a gastroenterologist and, if appropriate, prompt gastroenterologist appointment offered. All others were classified using Rome III criteria. and received a letter explaining their FGID diagnosis and dietary/psychological management options. Waitlist control patients were not screened. All participants completed follow-up surveys at 6, 26 and 52 weeks. Referring doctors of the algorithm group were sent a feedback survey at study completion.

Results: 89 participants were screened (42 years [SD 14], 62% female). 35 had clinical alarms or abnormal tests, data were reviewed by a gastroenterologist and, if appropriate, prompt gastroenterologist appointment offered. All others were classified using Rome III criteria. and received a letter explaining their FGID diagnosis. As a result, 45 were diagnosed with functional gastrointestinal disorders (FGIDs), in primary care is warranted. New models which efficiently transfer specialist-held expertise to primary care practitioners is needed.

P1799 ANNUAL FECAL IMMUNOLOGY TESTING IS LESS COSTLY THAN COLONOSCOPY EVERY 5 YEARS AND REDUCES MORTALITY IN FAMILIAL COLONORECTAL CANCER SCREENING

Introduction: Colonoscopy every 5 years, starting at the age of 40 years, is considered the first-choice screening strategy in first degree relatives (FDR) of patients with colorectal cancer CRC, as these individuals are considered at higher risk of developing CRC than average-risk individuals. However, this practice has a low adherence and remains opportunistic. Recently, it has been suggested that annual fecal immunochemical testing (FIT) might be a valid alternative to colonoscopy in this setting. However, there are scarce data regarding cost-effectiveness of these strategies from the perspective of healthcare services.

Aims & Methods: This study was aimed to compare the cost-effectiveness of annual FIT and colonoscopy every 5 years, to reduce CRC mortality, in FDR of patients with CRC. A Markov model was constructed to simulate the efficacy and cost of annual FIT (cut-off 10 µg Hb/g feces) or colonoscopy every 5 years of
previously unscreened FDR, starting at age 40 years and ending at age 75. A 5 g Hemoccult test was used for each strategy as was assumed. The model was adjusted to the incidence of CRC in Spain and real prevalence of advanced adenoma and CRC in the familial-risk population (http://dx.doi.org/10.1371/journal.pmed.1002080.g001). The main outcomes were quality-life-year (QALY) gained compared to baseline, lifetime burden of colorectal cancer, lifetime costs, relative risks of colonoscopy complications, and the incremental cost-effectiveness ratio (ICER). We applied a willingness-to-pay threshold of €25,000 per QALY gained. Data from a prospective EuroQol survey carried out on 920 Spanish patients at different disease stages were used for QALY measurement. Sensitivity analysis was performed to evaluate the robustness of the model.

Results: In a hypothetical cohort of 10,000 asymptomatic FDR, annual FIT and colonoscopy every 5 years were cost-effective over no screening. Taking no screening as the baseline, the ICER for annual FIT and colonoscopy every 5 years was 1989 and 4472 euros/QALY, respectively. Compared to no screening, annual FIT and colonoscopy every 5 years reduced CRC mortality by 59% and 81%, respectively. The annual FIT strategy saved 33% of colonoscopies and was assumed to be the number of complications compared to colonoscopy every 5 years. The results were robust in sensitivity analyses.

Conclusion: Assuming a 50% adherence, annual FIT is less costly than colonoscopy every 5 years for CRC screening and reduces mortality in the familial-risk population. These data suggest that FDR of patients with CRC could be included in organized nationwide FIT-based screening programs.

Introduction: Faecal occult blood test (FOBT) is a non-invasive and easily performed test which has demonstrated to reduce CRC incidence and mortality in the populations. Faecal calprotectin (FCP) has good evidence for detecting inflammatory bowel disease but its value in CRC and adenoma detection remains unassessed. This study was aimed to evaluate the diagnostic accuracy of the combination of FOBT plus FCP versus each test alone in asymptomatic patients referred for diagnostic colonoscopy. A total of 171 patients who completed colonoscopic investigations and returned stool samples were prospectively recruited and included in the final analysis. FOBT was performed by SENTRY FIT 270 test (Sentinel Diagnostics, Milan, Italy) and FCP by the ELISA Calprotectin immunoassay (Thermo Fisher Scientific, Waltham, United States). Reference cutoff levels were 117 ng/ml for FOBT and 90 μg/g for FCP respectively. The diagnostic accuracy of FOBT and FCP were evaluated by logistic regression model. CRC, advanced adenoma, IBD and angiodyplasia were considered as relevant pathology. Positive and negative predictive values, sensitivity and specificity were calculated. MedCalc was used for the ROC curve analysis.

Results: 171 patients (42.7% female; median age 62 years, IQR: 51–68) were included. 37 (21.6%) had relevantcolonic pathology. The most frequent indications for colonoscopy were previous episode of rectal bleeding in 71 (42%) patients, change of bowel habits in 28 (16%) and anaemia in 22 (13%). Diagnostic accuracy of FOBT, FCP and combination of both are summarized in table 1.
P1802 PERFORMANCE OF THE MOTUS PURE-VU SYSTEM - A NOVEL DEVICE FOR ACHIEVING ADEQUATE BOWEL PREP IN POORLY PREPPED PATIENTS

P.D. Siersma1, K. Van Keulen1, H. Neumann2, M.C.W. Spaander3

Introduction: The success of colonoscopy depends on the quality of the bowel preparation, which is estimated to occur in as many as 25% of colonoscopy procedures. The MOTUS G Pure-Vu system (Tirat Carmel, Israel) is an FDA cleared device designed to improve visualization in an inadequately prepared colon by facilitating intra-procedural cleaning.

Aims & Methods: This study aims to evaluate the performance of the Pure-Vu System in cleaning a poorly prepared colon, assess the system’s usability, patient satisfaction and safety. Forty-seven cases were planned to be enrolled at three clinical sites, of which 32 had completed the study so far. Pure-Vu was used in subjects with a partially prepped colon after 2x10 mg Bisacodyl, diet restrictions (no dried fruit, seeds or nuts) starting 2 days before the procedure and a 24-hour fast. Subjects with a partially prepped colon after 2x10 mg Bisacodyl, diet restrictions and a 24-hour fast were included in the analysis. Indications for colonoscopy included family history of CRC (56%) and poly surveillance (44%). No serious adverse events were reported. The Pure-Vu significantly increased the number of subjects with an adequate cleansing degree (BBPS > ≥ 2 for all 3 colon segments) from 25% to 67.2% (CI 95% [11%, 43%]) at baseline to 100%; CI 95% [89%, 100%] after Pure-Vu and the colon was reached and visualized in all study cases (i.e., 100%; CI 95% [89%, 100%]). Mean post-treatment BBPS score was 8.5 ± 0.8 vs. 3.38 ± 2.3 prior to Pure-Vu use. Physicians were satisfied with the device’s general use of ease and found it in most cases acceptable to good or excellent to insert and to angulate the colonoscope. No major difficulties were experienced when performing polypectomy. Thirty of 32 (94%) patients reported that they would recommend Pure-Vu to their friends and family members who need a colonoscopy. Thirty (94%) of the patients found the overall bowel preparation as very tolerable (55%) or acceptable (39%). Seventy-nine percent of patients who had a previous colonoscopy procedure reported that the Pure-Vu bowel preparation was more tolerable as compared to their previous colonoscopy preparation and 14% of the patients reported it to be about the same.

Conclusion: The Pure-Vu System was found to be safe and effective in cleaning inadequately prepared colons to an adequate level for a thorough exam. Based upon these early results it is expected that the device may play a role in patients with an inadequately prepared colon which may help to improve the overall quality of colonoscopy.

Introduction: Recently, the European Society of Gastrointestinal Endoscopy (ESGE) published guidelines on key performance measures for colonoscopy (1). We analyzed feasibility of monitoring these measures and whether the proposed standards were met in the Polish Colonoscopy Screening Program (PCSP).

Aims & Methods: We analyzed database records for 40,644 participants aged 55 to 64 years, who between 2014 and 2015, underwent screening colonoscopy in 24 centers of population-based PCSP. We used the ESGE guideline definitions to calculate values of all seven key performance measures. We compared key performance measures within the PCSP against proposed standards on the program and center level. Data on adequacy of bowel preparation was routinely assessed with the Boston Bowel Preparation Scale, whereas data on patient experience with the validated Gastronet questionnaire (2). Data on complication rates were collected from the National Health Fund database and Personal Identification Number Registry.

Results: Overall, on the program level, all minimum standards for colonoscopy key performance measures were met. Rate of adequate bowel preparation was 92.1% for the whole program, ranging 80.9–99.2% per individual center, with 7 centers (29.2%) not reaching minimum standard of 90% and 9 centers (37.5%) reaching the target standard of 95%. Cecal intubation rate was 97.4% (range 93.4–99.4%), with all centers reaching minimum standard of 90% and only one center not reaching target standard of 95%. Adenoma detection rate was 29.9% (range 19.1–39.1%), with 7 centers (29.2%) not reaching minimum standard of 25%. Appropriate polypectomy technique was applied in case of 90.9% 6 to 9 mm polyps (range 64.3–100%) with only 2 centers not reaching minimum standard of 80% and 48.2% of 4 to 5 mm polyps (range 0–100%) with only 6 centers reaching minimum standard of 80%. Target standard of 90% was reached in 15 centers for polyps 6 to 9 mm in diameter and only 2 centers for polyps 4 to 5 mm in diameter. For the whole program, 7-day hospitalization rate after screening colonoscopy was 0.3% (122 cases) and 30-day all-cause mortality was 0.02% (9 cases). Gastronet questionnaire coverage is assumed to be 100%, however the response rate was 65.3% (range 7.6%–81.8%), with painful colonoscopy rate of 19.2%. No minimum standard is set, however target standard of 90% of procedures with measured patient’s experience was not met. Appropriate post-polypectomy surveillance, based on the European guidelines, was proposed in 95.4% of cases (range 84.9–99.7%). Target standard of 95% was met in 15 centers, the minimum standard is not set.

Conclusion: Monitoring ESGE performance measures for colonoscopy is feasible in colonoscopy programmatic screening setting. 6 of 7 performance measures were easy to monitor with PCSP database, however monitoring complications needs further development to avoid extracting data from external registries. PCSP meets proposed minimum standards on program level, however some centers need additional interventions to meet the quality standards. Applying appropriate polypectomy technique for polyps ranging 4 to 5 mm in diameter
is currently the biggest issue in PCSP and further training is needed to reach minimum standards for this performance.

P1805 VALIDATION OF THE "FAILURE TO PROVIDE ADEQUATE RELIEF" (F-PAR) SCALE IN A SPECIALIST CLINIC SETTING

V. Passananti, N. Zarate Lopez, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Treatment of chronic idiopathic constipation is somewhat empiric, but based on step-wise approach[1]. If first-line conservative treatment (lifestyle advice and laxatives) do not relieve symptoms sufficiently, secondary approaches with prokinetic or secretagogue drugs are used before considering hospital-based care (biofeedback, psychosocial support, transanal irrigation (TAI), surgery). Nevertheless, patients are often dissatisfied with care[2] and fail to progress to adequate levels of therapy. The 5-point Failure to Provide Adequate Relief (F-PAR) scale[3] was developed to facilitate the recognition of when to move from one step to the next.

Aims & Methods: The aim of this study was to validate F-PAR in a tertiary clinic setting. We studied 403 consecutive consultations of 331 patients (262 women, mean age 41) in our specialist clinic. All fulfilled Rome III/IV diagnostic criteria for chronic constipation. Immediately prior to each face-to-face clinical assessment by one of 2 experienced physicians, participants completed the F-PAR scales: patients were blind to the F-PAR result. Standard clinic assessment was undertaken to identify efficacy of the current management as the gold standard.

Results: Of the 403 consultations, clinical assessment identified inadequate relief with current therapy was identified in 200. Neither duration nor type of treatment were correlated with relief. The table stratifies, by clinical gold standard, each item of the F-PAR and in the lower panel the total number of F-PAR items replied to positively.

Table: Positive F-PAR items correlated to clinical assessment of relief

<table>
<thead>
<tr>
<th>Adequate relief (Clinical)</th>
<th>Inadequate relief (Clinical)</th>
</tr>
</thead>
<tbody>
<tr>
<td>n = 203</td>
<td>n = 200</td>
</tr>
</tbody>
</table>

Bowel frequency inadequate | 5 | 71
Strain most occasions | 6 | 89
Stool hardness | 3 | 21
Onset other symptom | 2 | 57
Current therapy poor tolerable | 8 | 80
0 FPAR replies | 187 | 1
1 FPAR replies | 10 | 41
2 FPAR replies | 4 | 67
3 FPAR replies | 2 | 22
4 FPAR replies | 0 | 8
5 FPAR replies | 0 | 9

Conclusion: Our findings showed that the F-PAR with only five questions can be considered sufficient to provide clinical evidence of treatment failure. The use of standardized process to investigate the efficacy of treatment may reduce the time and improve the quality of managing for the chronic constipation patients.

P1806 ADHERENCE WITH TRANSANAL IRRIGATION USING THE NAVINA™ SYSTEM IS ASSOCIATED WITH PERSONALITY TRAITS EVEN WHEN THERE IS IMPAIRED HAND FUNCTION

V. Passananti, J. Storrice, N. Zarate Lopez, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Transanal irrigation has become a key therapeutic modality in managing patients with neurological diseases who experience constipation and/or fecal incontinence. Such neurogenic bowel dysfunction (NBD) complicates over three quarters of patients with spinal cord injury (SCI) and multiple sclerosis (MS). Approximately 60% of patients who start TAI continue with long-term treatment. A common cause of treatment cessation is impaired hand function [1]. Training of the patient is a key aspect of TAI therapy and requires patients to be willing to manage their health themselves: self-efficacy.

Aims & Methods: We wished to study whether use of a novel TAI system, Navina™ Smart, which has an electronic pump component allows patients with impaired levels of hand function to adhere to TAI therapy, to be able to self-administer the device. We also wished to identify if there were physiological or psychological correlates of adherence. Twenty-eight consecutive patients (19 SCI and 9 MS; 17 male, mean age 42) were studied. All patients scored greater than 18 on the Cohn Hand Function Questionnaire (HFQ) indicating they were completed to assess anxiety/depression and locus of control respectively. Anorectal physiology (manometry, sensation and rectal compliance) was undertaken at baseline. Training in TAI was undertaken by the same experienced nurse, with weekly follow up until a stable regime was established. Adherence with therapy at 12 weeks was identified.

Results: At 12 weeks, 16/28 (57%) of patients were still using Navina TAI, similar proportions with SCI (11/19) and MS (5/9). There was no difference in baseline scores for HAD-anxiety (6.0 ± 3.9 vs 5.9 ± 2.9; p = 0.37) or HAD-depression (8.6 ± 3.9 vs 8.8 ± 4.2; p = 0.46) and were similar in both those who were and were not still using TAI (mean ± SD respectively). The Rotter score for non-adherers was significantly greater than adherers (14.2 ± 6.7 vs 10.6 ± 5.9 respectively; p = 0.0008). There was no difference in any of the anorectal parameters between those who did or did not adhere with TAI.

Conclusion: Navina Smart TAI is an effective therapy in 57% of NBD patients with significant hand dysfunction. Anorectal physiology, anxiety and depression scores do not predict likelihood of treatment adherence. An external locus of control, reflecting a belief that health events occur because of outside forces (such as fate, chance, or powerful others), is associated with reduced treatment success. The results suggest that future studies of TAI should consider locus of control as an important potential predictor of outcome.

Disclosure of Interest: All authors have declared no conflicts of interest.

OESOPHAGEAL, GASTRIC AND DUODENAL DISORDERS III - HALL 7

P1807 THE DUODENAL MUCOSA RETAINS A DIVERSE MICROBIOTA FOLLOWING BOWEL PREPARATION

E. Shanahan1, A. Shah1, A. Do2, P. Ghasemi3, T. Hansen1, N. Koloski3, M. Morrison2, G. Holtmann1

3University of Queensland, Diamantina Institute, Microbial Biology and Metagenomics, Brisbane/Australia

Contact E-mail Address: e.shanahan@uq.edu.au

Introduction: The microbiota inhabiting the gastrointestinal (GI) tract plays an essential role in gut health. Although mucosal biopsies are increasingly used for microbiota studies, these are subject to variations introduced through sampling technique and patient preparation. The impact of bowel preparation on the microbiota-associated microbiota (MAM) is of particular interest given it results in complete emptying of bowel contents via laxative ingestion. Although bowel preparation does not appear to induce long term changes to stool microbiota [1], it can induce short-term changes to the colonic MAM [2]. While improvements in clarity of the small intestine after bowel preparation have been reported [3], the impact on the upper GI microbiota is currently unknown. Given patients may undergo both upper GI endoscopy and colonoscopy consecutively, a subset of endoscopy patients will have consumed bowel preparation prior to their procedure, representing a potential bias in MAM analyses. Therefore, this study aimed to assess the impact of bowel preparation on the duodenal MAM.

Aims & Methods: Individuals undergoing upper GI endoscopy, with or without concurrent colonoscopy, were recruited consecutively with ethical approval. Individuals who underwent upper GI endoscopy following overnight fast (n = 58), or both upper endoscopy and colonoscopy following polyethylene glycol bowel preparation (n = 48). Participants were undergoing screening for iron deficiency anaemia or GI symptoms with no evidence of mucosal disease/inflammation (n = 58), or with diagnosed Crohn’s disease (n = 18). Duodenal biopsies were obtained and gDNA extracted. Amplicon libraries of the 16s rRNA gene were sequenced (Illumina MiSeq). Sequencing of reagent controls enabled exclusion of
non-duodenal sequences. Bioinformatics and statistics were performed in QIIME and Calfyso.

**Results:** A diverse microbeota was observed in duodenal mucosal samples from all subjects, following overnight fasting or bowel preparation. Overall the duodenal microbeota was dominated by the genus Streptococcus, followed by Prevotella, Veillonella and Neisseria. Microbial diversity within samples was not significantly different with and without bowel preparation (Chao1 metric). Principal coordinates analysis (weighted UniFrac) revealed substantial overlap between the two groups, and no significant clustering was observed (ADONIS) based on whether patients had undergone overnight fasting or bowel preparation. Similar findings were obtained when these analyses were repeated with exclusion of the Cronh’s disease population.

**Conclusion:** This study reveals a diverse duodenal MAM is retained following bowel preparation. The comparison of overnight fasting and bowel preparation indicates these differences in patient preparation do not substantially alter the duodenal MAM. Thus patients undergoing concurrent upper GI endoscopy and colonoscopy can be included in study cohorts investigating the upper GI MAM without risk of a substantial confounding effect.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact Email Address:** mcvaughtfranco@gmail.com

**Introduction:** Upper gastrointestinal bleeding (UGIB) in patients with cancer presents a unique and difficult challenge as these patients are at higher risk for rebleeding and mortality.1 Currently available prognostic scoring systems for UGIB for the general population have produced variable accuracy in their validation studies.2 An effective method of stratification for cancer patients to identify the high-risk group for early hospital-based intervention and death could enhance the outcomes of this specific population.

**Aims & Methods:** The primary aim of this study was to compare the Glasgow-Blatchford score (GBS), Rockall score (RS) and AIMS65 score for predicting ICU admission, blood transfusion, hemostatic therapy, rebleeding, and in-hospital mortality in cancer patients with UGIB. The secondary aim was to assess the above cited scores in correctly identifying low-risk patients that can be effectively managed as an outpatient. An IRB-approved, prospective study was conducted at the Cancer Institute of Sao Paulo, Brazil. Consecutive patients with known cancer admitted with UGIB were enrolled. Pre-endoscopic clinical parameters pertinent to the scoring systems, hemostasis techniques, and outcomes were collected into a prospective registry. Patients were followed for at least 30 days or until the day of discharge, whichever was longer. The low-risk group was defined as those without blood transfusion, hemostatic therapy (by endoscopy, radiotherapy, angiographic or surgical intervention), rebleeding or mortality in 30 days. Multiple logistic regression with receiver operating characteristics analysis was done to assess the predictive ability of each scoring system for the above outcomes.

**Results:** From April 2015 to May 2016, 394 consecutive patients were screened, while 259 patients met the inclusion criteria. A total of 243 patients were considered for the final analysis, after excluding 16 patients due to missing data or lost to follow up (Table 1). Predicting outcomes: The AIMS65 score (area under curve) significantly better predicted ICU admission than GBS (AUC 0.79; p = 0.04), both the total and clinical RS (AUC 0.71 and 0.66; p < 0.001 for both). The GBS best predicted the need for blood transfusion (AUC 0.82, sensitivity 71% and specificity 80% for GBS ≥ 12) compared with the other prognostic scores. All scores performed poorly in predicting the need for hemostatic therapy and risk of rebleeding. The AIMS65 score best predicted in-hospital mortality (AUC 0.84) compared to the GBS (AUC 0.75; p = 0.004), both the total and clinical RS (AUC 0.70 and 0.69; p < 0.001 for both). Among patients bleeding at EGD, there was no difference in 30-day mortality if the etiology of bleeding was tumoral or non-tumoral disease (38.1% vs 31.9%; p = 0.46). Identifying low-risk group: With GBS score of 0 as the cut-off value, its specificity was 100% with sensitivity of 5.8%. When GBS ≥ 2, its specificity was maintained at 100%, while sensitivity increased to 23.5%. This change increased the proportion of the patients from 1% to 5% without erroneously discharging high-risk patients. In comparison, when an AIMS65 value of 0 was chosen as definition for low-risk, this tool misclassified 20 patients who needed hospital interventions (specificity of 53% and sensitivity of 89.5%). Finally, head-to-head comparison between GBS vs. RS, and GBS vs. AIMS65 scoring system revealed GBS to be superior to both the clinical RS (p < 0.001) and AIMS65 (p = 0.001) in correctly identifying low-risk patients.

</tr>
</tbody>
</table>

**Conclusion:** The AIMS65 score was superior to other scoring systems in predicting in-hospital mortality and ICU admission in patients with cancer and UGIB, whereas the GBS was superior for predicting the need for blood transfusion. All scores performed poorly in prediction of hemostatic therapy and rebleeding. The GBS was superior in accurately identifying low-risk patients. Furthermore, the cut-off ≤ 2 in GBS score displays increased sensitivity without compromising specificity, effectively increasing the number of patients who can be safely managed as an outpatient.

**Contact Email Address:** ken.namikawa@jfcr.or.jp

**Introduction:** Endoscopists are more frequently performing endoscopic resection (ER) in patients on antplatelet or anticoagulant therapy and nowadays patients have increasingly started taking direct oral anticoagulant (DOAC) therapies, including direct anti-Xa and thrombin inhibitors. Major guidelines recommend the cessation of anticoagulants before ER and heparin bridging therapy (HBT) for high thrombotic risk cases, although these are still controversial. A recent study has suggested that HBT may be associated with a higher post-endoscopic resection bleeding (PERB) rate in patients on anticoagulants.

**Aims & Methods:** This study aimed to evaluate the effect of anticoagulants on PERB rate in patients. This was a retrospective study based on medical records from three leading Japanese ER centers. PERB was defined as bleeding that occurred 6 h to 10 days after ER, which required endoscopic hemostasis. We reviewed 108 gastric tumors including adenoma and early cancer in 97 patients on anticoagulant therapy who underwent endoscopic submucosal dissection (ESD) in our hospitals between June 2008 and February 2016. Further, we reviewed 69 colorectal polyps including adenoma and early cancer in 69 patients on anticoagulant therapy who underwent ER in our hospitals between October 2013 and September 2016. ER included polypectomy, endoscopic mucosal resection (EMR), and ESD. Patients were divided into two groups: those prescribed warfarin and patients prescribed DOAC. The management of antithrombotics was based on the Japanese Gastroenterological Endoscopy Society guidelines published in 2005 and 2012. The anticoagulants used during the study period were warfarin, dabigatran, rivaroxaban, apixaban, and edoxaban. Warfarin was discontinued 4–5 days before ER, whereas the others were stopped 24–48 h prior to the procedure. For patients at a high thrombotic risk, intravenous unfractionated heparin was administered after ceasing anticoagulants.

**Results:** Warfarin and DOAC were prescribed to 73 (75%) and 24 (25%) patients, respectively. Apixaban was administered to 1 (1%), dabigatran to 12 (12%), rivaroxaban to 11 (11%) patients. There were no significant differences between the DOAC and warfarin groups in terms of clinical characteristics or...
P1811 CLINICAL FEATURES OF DELAYED BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC NEOPLASMS IN HIGH-RISK AND LOW-RISK PATIENTS

Gastroenterology, Osaka General Medical Center, Osaka/Japan

Contact E-mail Address: tampakatakkun@gmail.com

Introduction: Antithrombotic drugs are administered to patients undergoing endoscopic treatment at high risk for thromboembolism. However, antithrombotic drugs have been also known as a cause of delayed bleeding associated with endoscopic treatment, including endoscopic submucosal dissection (ESD). We previously reported the clinical features of post-polypectomy bleeding associated with heparin bridge therapy (1), and then various risk factors of delayed bleeding after endoscopic treatment have been reported.

Aims & Methods: The aims of the present study are to investigate the risk factors of delayed bleeding after gastric ESD and to clarify the clinical features of delayed bleeding in high-risk and low-risk patients. High-risk patients were defined as patients who underwent ESD for gastric neoplasms in Osaka General Medical Center between January 2009 and December 2016 were retrospectively investigated. Independent risk factors of delayed bleeding were analyzed by using a multivariate analysis by logistic regression model, and three predictors of delayed bleeding were selected. Patients were categorized into a high-risk group or low-risk group for bleeding, and the clinical features of post-procedural bleeding in each group were investigated.

Results: A total of 717 patients with 781 gastric neoplasms were identified. Mean age was 74.6, and 71.6% was male. With regard to comorbidity, the proportion of hypertension, diabetes, chronic liver disease, and hemodialysis was 50.2%, 19.2%, 2.7%, and 6.1%, respectively. Total 188 patients have taken oral antithrombotic drugs, and of them, 50 patients treated by gastric ESD under heparin bridge therapy. Two-thirds lesions were located in gastric body and median tumor size (range) was 15 (3–80) mm. En-bloc resection was achieved in 751 lesions (96.2%), and no uncontrollable bleeding occurred. Forty-nine patients (6.8%) experienced delayed bleeding after gastric ESD. Hospital stay was significantly longer in bleeding cases than in non-bleeding cases [median hospital stay (range) 11 (3–20) vs. 9 (2–25), p<0.007]. Multivariate analysis of delayed bleeding included age (>75 years), number of bleeding episodes (without heparin bridge therapy) and antithrombotic treatments as independent risk factors for delayed bleeding.

Conclusion: Blending high-risk patients with heparin bridge therapy, antithrombotic therapy, and hemodialysis should be carefully observed after gastric ESD while early hospital discharge is acceptable for bleeding low-risk patients.

P1810 ENDOSCOPIC ALLPICATION OF MUCOADHESIVE POWDER (NEXPOWDER®) FOR HEMOSTASIS IN PATIENTS WITH GASTROINTESTINAL BLEEDING

1Division Of Gastroenterology, Department Of Internal Medicine, Inha University School of Medicine, Incheon/Korea, Republic of
2Digestive Disease And Research Institute, SoonChungHyang University School of Medicine, Bucheon/Korea, Republic of
3Department of Internal Medicine, Bucheon St. Mary’s Hospital, Bucheon/Korea, Republic of

Contact E-mail Address: bangbyoung@naver.com

Introduction: Although endoscopic hemostasis is usually effective in controlling gastrointestinal (GI) hemorrhage, some have difficulty in achieving successful hemostasis depending on the location and severity of hemorrhage. NEXPOWDER® (Next Biomédical, Incheon, South Korea) is a biocompatible and biodegradable powder and the hemostatic effects are accomplished by physical-barrier when this powder immediately forms mucoadhesive hydrogel after contacting blood or water. It shows high adhesiveness and persistency of gel on contactal barrier when this powder immediately forms mucoadhesive hydrogel after contacting blood or water. It shows high adhesiveness and persistency of gel on ulcer base. And new powder delivering device shows low contact clogging rate of catheter during spraying powder. The endoscopic application of NEXPOWDER® depending on the location and severity of hemorrhage.

Aims & Methods: The aims of this study were to confirm 1) success rate of hemostasis using NEXPOWDER® for endoscopic treatment, including endoscopic submucosal dissection (ESD). We previously reported the clinical features of post-polypectomy bleeding associated with heparin bridge therapy (1), and then various risk factors of delayed bleeding after endoscopic treatment have been reported.

Conclusion: Patients on HBT, rivaroxaban, and antiplatelet agents plus antithrombotic therapy at an increased PEB risk after ESD for gastric tumors. We suggested that the PEB rate differs among DOACs because each drug has its own blood concentration and metabolization. Most clinicians have a limited knowledge on PEB during DOAC treatment because these are relatively new drugs, and because PEB has a low prevalence. Therefore, comparative data on larger patient series are needed to address this issue.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: gisela tv@hotmail.com

Introduction: There are few studies of the efficacy of parenteral ferric carboxymaltose (FCM) treatment in acute gastrointestinal bleeding (GIB) of different origins. Few data are available on its use to treat anemia post-acute haemorrhage.

Aims & Methods: To determine the efficacy and safety of FCM treatment in patients with acute GIB not associated with portal hypertension. A retrospective descriptive 3-year study of patients with acute GIB (anaemia with evident bleeding and/or haemodynamic instability) treated with FCM as part of our hospital’s habitual clinical practice.

Results: Analysis of 84 patients admitted with acute GIB (69.0% male, mean age 68.0 years [SD 6.9]), with a Charlson index ≥3 in 67.1% of cases (≥5 in 31.6%). 15.5% had previously suffered acute GIB due to peptic ulcer. There were 86 hospital admissions for acute GIB; 93.8% were upper GIB (above the angle of Treitz). The most frequent clinical presentation was melena, in 76.7% of cases. 25.6% presented hemodynamic instability at admission. The mean Glasgow-Blatchford index score was 16.1 (SD 2.7) and the mean Rockall score post-endoscopy was 4.2 (SD 1.7). The most common causes of bleeding were: 36.0% duodenal ulcer, 29% gastric ulcer, 9.3% gastritis/erosions, and 7.3% angiodysplasia of the colon. The mean Hb at admission was 9.0 g/dL (SD 2.2)
and the mean of the lowest Hb during admission was 7.6 g/dL (SD 1.3). The most common total dose of FCM administered was 1000 mg. During admission, a mean Hb increase of 8.9 g/dL (SD 2.3) was observed in a mean period of 5.7 days (median: 4.0) after treatment with FCM, with an increase of 4.2 g/dL (SD 2.6) 30 days after acute GIB. After FCM administration, the mean Hb increased significantly (p < 0.0001) in patients ≥75 years (2.12 g/dL [SD 1.7]), in patients with Charlson index ≥3 (1.9 g/dL [SD 1.6]), and when Hb level during admission was <10 g/dL (2.0 g/dL [SD 1.7]). No adverse reactions were observed.

**Disclosure of Interest:** In patients with acute GI bleeding the administration of ferric carboxymaltose improves Hb levels promptly and safely, especially in patients of advanced age and with associated comorbidities.

P1815 PREDICTIVE FACTORS FOR IN-HOSPITAL MORTALITY IN PATIENTS WITH PEP TIC ULCER BLEEDING

D. Matei1, S. Pasca1, I. Groza2, D. Negruti2, A. David1, M. Nedal2, M. Tantau1

1University of Medicine and Pharmacy Iuliu Hatieganu, Cluj Napoca/Romania

2Regional Institute of Gastroenterology and Hepatology Prof. Dr. Octavian Fodor, Cluj Napoca/Romania

Contact E-mail Address: dmatei68@gmail.com

**Introduction:** Peptic ulcers are the most frequent cause of upper gastrointestinal bleeding. In different population based surveys regarding all-cause UGIB, mortality ranges between 3% and 14%.

**Aims & Methods:** The aim of this study was to assess in-hospital mortality in patients with peptic ulcer bleeding and to evaluate the risk factors associated with mortality. In this prospective study we enrolled all patients diagnosed with peptic ulcer bleeding in a tertiary care center over a period of 24 months (January 2015–December 2016). Patients were divided into two groups - those who died and those who survived - and the following parameters were compared: age, signs of hemodynamic instability (hypotension, tachycardia), presence of comorbidity, details provided by Charlson score, presence of risk factors (age >75 years vs ≤75 years; male vs female; diabetes vs no diabetes; hypertension vs no hypertension; hypercholesterolemia vs no hypercholesterolemia). The study included 431 patients. In-hospital mortality rate was 7.9%.

**Results:** The following differences have been observed by comparing patients who died and those who survived: age ≥75 years 41.2% vs 23.4% (p = 0.036); hypotension 17.6% vs 2.3% (p < 0.001); tachycardia 47.1% vs 21.4% (p = 0.001); one or more comorbidities 94.1% vs 63.5% (p = 0.001); high risk endoscopic stigmata 79.4% vs 62.2% (p = 0.070); multiple ulcers 41.2% vs 33.5% (p = 0.473); Rockall score ≥5 points 94.1% vs 46.9% (p = 0.001); Blatchford score ≥10 points 91.2% vs 66.2% (p = 0.005); hemoglobin <9.5 g/dl 70.6% vs 41.1% (p = 0.002); INR ≥2.5 17.6% vs 5.8% (p = 0.022); creatinine ≥1.5 mg/dl 38.2% vs 10.8% (p = 0.001); INR >2.5 20.6% vs 10.3% (p = 0.123); need for blood transfusion 82.4% vs 56.4% (p = 0.006); need for surgery 11.8% vs 3.5% (p = 0.063). In most cases (88.2%), the cause of death was other than hemorrhagic shock. Using multivariate analysis, three of these factors were identified as representing independent factors significantly associated with the age over 75 years old: oral anticoagulants use (OR = 2.40, 95%CI:1.24–4.62, p = 0.009), antiplatelet use (OR = 2.33, 95%CI:1.43–3.81, p = 0.001) and in-hospital mortality (OR = 2.09, 95%CI:1.27–3.47, p = 0.048).

**Conclusion:** The use of oral anticoagulants and antiplatelet was significantly higher in older patients, compared to the younger group. Elderly patients with peptic ulcer bleeding do not have a different rebleeding, need for surgery, need of transfusion or hospitalization or in-hospital mortality was higher in elderly patients due to more frequent association of comorbidities.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P1816 ANAEMIA AND UPPER GI BLEEDING: A LOCAL EXPERIENCE
M. Ding, R. Prasraddadja, Z. Arasta, H. Sabri, M. Smith
Gastroenterology, Royal shrewsbury hospital, Shrewsbury/United Kingdom
Contact E-mail Address: michaeldjw@gmail.com
Introduction: There has been significant research recently on the use of blood transfusions in upper GI bleeding (UGIB) [1] with recent evidence advocating a restrictive approach to blood transfusions as well as the use of iron therapy[2] for anemia management. We conducted a local retrospective analysis of patients admitted with UGIB over a six month period and analysed the use of blood transfusions at our trust which consists of two District General Hospitals.
Patient data over a period of up to 12 months post discharge was collected to monitor their anaemia.
Aims & Methods: Our aim was to monitor the appropriateness of transfusions in Upper GI Bleeding as well as monitoring the response to iron therapy following discharge. All inpatients that had an Upper GI endoscopy for UGIB were analysed. Electronic patient records were obtained from our endoscopy software and hospital database. Patients were selected over a time period of six months from 1/6/2015 to 31/12/2015. A Student’s T Test was used to compare the average hospital database. Patients were selected over a time period of six months from 1/6/2015 to 31/12/2015. A Student’s T-Test was used to compare the average hospital database. Patients were selected over a time period of six months from 1/6/2015 to 31/12/2015. A Student’s T Test was used to compare the average hospital database. Patients were selected over a time period of six months from 1/6/2015 to 31/12/2015. A Student’s T Test was used to compare the average hospital database.
Results: There were 148 patients, 81 male and 67 female. The mean age was 69.3, minimum 20 and maximum 98. The average Hb on admission was 103 g/L (min – 32 g/L, max – 178 g/L). 78 out of 148 (52.7%) patients presenting with UGIB received a blood transfusion. The mean amount of blood received for those transfused was 3.7 units. 48 out of 78 (61.5%) of blood transfusions were given when Hb was below 70 g/L. 30 of 78 (38.5%) were transfused as an emergency. 37 patients with Hb above 70 had cardiac risk factors. The mortality rate in those transfused above Hb of 70 was 13.3% (n = 4) vs 10.4% (n = 5) 41.5% (n = 44) patients who were anemic post-UGIB were discharged with iron therapy. The average rise in Hb was 15 g/L. This equated to 7.5% for those who did not take iron. There was a statistically significant rise in Hb for those discharged with iron therapy (p < 0.005) on follow-up versus those who did not receive it (n = 62). The anaemia related readmission rates were similar for patients discharged on iron or not (91.9% vs 9 vs 9.7% n = 6).
Conclusion: The data obtained supports a restrictive transfusion policy (mortality rate of 13.3% vs 10.4%). 58.5% of patients who were anaemic on discharge did not receive any iron therapy. On follow up, there was a statistically significant rise in Hb in those who received iron for those who did not. There was a statistically significant rise in Hb for those discharged with iron therapy (p < 0.005) on follow-up versus those who did not receive it (n = 62). The anaemia related readmission rates were similar for patients discharged on iron or not (91.9% vs 9 vs 9.7% n = 6).

P1817 THE RELATIONS AMONG SERUM GHELIN, MOTILIN, CIRCULATING ANTIMYENTERIC ANTIBODIES AND GASTRIC EMPTYING IN PATIENTS WITH AUTOIMMUNE GASTRITIS
Ç. Kalkan, F. Karakaya, I. Soykan
Gastroenterology, Ankara University, Ankara/Turkey
Contact E-mail Address: mf.karakaya@yahoo.com
Introduction: Autoimmune gastritis (AIG) is an organ-specific autoimmune disease of the stomach marked by autoantibodies directed to hydrogen/potassium-ATPase and intrinsic factor. Gastric emptying of solids is delayed and autonomic nervous system dysfunction leading upper gastrointestinal symptoms. Delayed gastric emptying leading upper gastrointestinal symptoms.
Aims & Methods: The aim of this study was to: (i) compare serum levels of ghrelin and motilin in patients with delayed gastric emptying and (ii) investigate whether circulating antimyenteric antibodies, serum levels of ghrelin and motilin and gastric emptying are related. Fourty-one patients with AIG were included into this study. Autoimmune gastritis was diagnosed depending upon histopathological findings in gastric biopsy specimens.
Results: Forty-one patients (27 women), mean age 56.61 ± 11.79 years with AIG were included into the study. Overall, 22 (53.6%) patients showed delayed GE and 19 patients showed normal GE (GET ½: 241.19 ± 190 ± 19 mins, p < 0.05). Serum ghrelin and motilin levels of patients with delayed GE were significantly decreased compared to patients with normal GE, respectively (67.55 ± 8.81 vs 126.79 ± 25.81 pg/mL, p < 0.001 and 279.59 ± 111.12 vs 500.42 ± 155.95 pg/mL, p < 0.001). In all, 26 (63.4%) patients showed autonomic nervous system dysfunction and, 15 (36.5%) patients had normal autonomic nervous system test findings (total autonomic test score: 0.8 ± 0.25 vs 5.65 ± 1.74, p < 0.001). Serum ghrelin and motilin levels of patients with delayed autonomic nervous system function were significantly decreased compared to patients with normal autonomic nervous system function (140.88 ± 49.50 vs 280.73 ± 48.63 pg/mL, p < 0.0001 and 316.92 ± 160.47 vs 490.20 ± 141.02 pg/mL, p < 0.001). In multivariate analysis, plasma motilin level was found as an independent factor that affected serum ghrelin level (r = 0.623, p = 0.019). However, serum ghrelin (r = 0.70, p < 0.001) levels were found as independent factors that affected plasma motilin level. We also investigated the presence of antimyenteric antibodies, however all the patients were negative by means of antimyenteric antibodies therefore, no further relationship was sought.
Conclusion: Mean fasting serum ghrelin and plasma motilin levels in autoimmune gastritis patients with delayed GE and delayed autonomic nerve function were significantly decreased. Novel finding was the presence of circulating antimyenteric antibodies. These decreased serum ghrelin and plasma motilin levels in patients with autoimmune gastritis suggest a potential role for ghrelin and motilin in explaining the finding of the delayed gastric emptying in autoimmune gastritis patients. We believe that these new observations supply more insight into the pathophysiology of autoimmune gastritis.

P1818 EFFECTS OF FAECAL MICROBIOTA TRANSPLANTATION ON NEUROGENIN 3, MUSASHI 1 AND ENTEROENDOCRINE CELLS IN THE DUODENUM OF PATIENTS WITH IRREGULAR BOWEL SYNDROME
T. Mazzawi, M. El-Salhy2, G.A. Lied3, T. Hausken3

Introduction: The interaction between gut microbiota and enteroidendocrine cells alterations is believed to play an important role in the pathophysiology of irritable bowel syndrome (IBS). The densities of the duodenal enteroendocrine cells are abnormal in IBS patients, which appears to be caused by a reduced stem cells density and their differentiation into endocrine cells (1).
Aims & Methods: The aim is to investigate the effects of faecal microbiota transplantation (FMT) on the differentiation of the stem cells into enteroendocrine cells as detected by neurogenin 3, the stem cells as detected by Musashi 1 and the enteroendocrine cells in the duodenum of patients with IBS. The study included 16 IBS patients according to Rome III criteria and four patients were excluded. The remaining patients (n = 12, 4 females and 8 males, age range 20-44 years) were divided according to the cause of IBS into PI-IBS patients (n = 6) and idiopathic IBS (n = 6) and received FMT donated from their relatives. The patients completed the IBS-symptom severity scoring system (IBS-SSS) before and 3 weeks after FMT. The patients underwent pastscopies with biopsies taken from the descending part of the duodenum at baseline and 3 weeks after FMT. The biopsies were immunostained for neurogenin 3, Musashi 1 and all types of duodenal enteroidendocrine cells, and quantified by computerized image analysis.
Results: The score of IBS symptoms as assessed by IBS-SSS was significantly reduced 3 weeks after (240.2 ± 33.6) compared to before (326.6 ± 22.3) receiving FMT, P = 0.0009. The scores of IBS-SSS before and 3 weeks after FMT for PI-IBS were 326.6 ± 27.8 and 210.4 ± 41, respectively (P = 0.025), and for idiopathic IBS are 352.5 ± 34 and 270.3 ± 54, respectively (P = 0.034). The densities of neurogenin 3, Musashi 1 and enteroidendocrine cells in the duodenum of IBS patients before and 3 weeks after receiving FMT are presented in Table 1.
Conclusion: Faecal microbiota transplantation improved the symptoms in IBS patients, both PI and idiopathic. This improvement was associated with a change in the enteroendocrine cell density. The changes in the enteroendocrine cell density does not appear to be caused by changes in the stem cells or their early progenitors, but rather by changes in the differentiation progeny as detected by changes in neurogenin 3.

Introduction: Neuronal plasticity has been reported to develop following nociceptive emotional experience in prefrontal cortex (PFC) and hippocampus. The N-methyl-D-aspartate receptor (NMDAR) and D-serine, the endogenous co-agonist of NMDAR1, may mediate the neural plasticity. However, whether the neural plasticity participates in the mechanism of esophageal visceral hypersensitivity is little known.

Aims & Methods: This study aims to investigate the expression of NMDAR and the alteration of D-serine after neonatal and adult esophageal acid exposure. All rats were exposed to esophageal acid or saline at postnatal days 7–15P7–P15, and most rats underwent acute acid or saline exposure again as adult time (P60). All rats were randomly distributed to 5 groups, including P5S, P7H, P7H + P60H, P7S + P60H(P7; postnatal 7–15 days; P60; adult at postnatal 60 days; H; 0.1N HCL infusion; S; saline control). The tissue harvest was conducted at P60. We examined the expression of subunits of NMDAR (including NR1, NR2A, and NR2B), c-fos, and serine racemase in PFC, dorsal hippocampus(DH) and ventral hippocampus(VH). We also determined the D-serine in PFC and hippocampus by LC-MS analysis. Statistical comparisons were performed by General Linear Model and one-way ANOVA in SPSS.

Results: In PFC, compared with adult saline treatment (AS, including P7H + P60H and P7S + P60H group) and without adult treatment (A-, including P7S and P7H group), adult acid exposure (AH) increased the expression of NR1 (P = 0.052, P = 0.298), NR2B (P = 0.035, P = 0.045), and serine racemase (P = 0.022, P = 0.017) significantly. In ventral hippocampus, compared with adult treatment absence, adult acid exposure caused increasing expression of NR1 (P = 0.012) and NR1 (P = 0.024) significantly. In PFC, the expression of serine racemase in the P7S + P60H group was obviously higher than that of other groups (P = 0.008). See Table1. In dorsal hippocampus, there was statistical significance on the level of c-fos between the P7S + P60H group and other groups (P = 0.008). Table1. In PFC, the LC-MS analysis results that D-serine (AH vs A-: P = 0.000, AS vs A-: P = 0.042, AH vs AS: P = 0.081) and serine racemase(AH vs A-: P = 0.000, AS vs A-: P = 0.015, AH vs AS: P = 0.082) decreased in the AH and AS group, comparing with A- group.

The expression of serine racemase in PFC and c-fos in VH

Conclusion: Acute esophageal acid exposure may increase the expression of NMDAR in PFC and ventral hippocampus. We also found the first acid exposure at adult stage may enhance the expression of serine racemase in PFC and c-fos in ventral hippocampus, but this phenomenon may be absent in those rats having the experience of acid exposure in early life. Those long-term and intrinsic molecular alterations may mediate the development of acid exposure related esophageal visceral hypersensitivity.

Introduction: Globus pharyngeus, a sensation of a lump or tightness in the throat, is a well-defined clinical symptom that is usually long-lasting, difficult to treat, and has a tendency to recur. More than half of globus patients suffered from probable psychological disorders, such as anxiety and depression 3. Antidepressants are used in the treatment of functional gastrointestinal disorders (FGIDs) and showed a promising efficacy. Our study manifested that low-dose amitriptyline is well tolerated and effective for general globus pharyngeus patients 2. Our anterior study had ever speculated that AMT could modify brain-gut axis function, up-regulating brain-gut peptides, reducing the visceral sensitivity and regulating the secretory and motor functions of the gastrointestinal tract 1, so that gastrointestinal symptoms as well as emotional well-being could be significantly improved. As we known, serotonin (5-hydroxytryptamine, 5-HT) is an important factor in gut function, playing key role in intestinal peristalsis, secretion, and sensory signaling in the brain-gut axis 4. Several studies have investigated the association between SLCOA4 and functional gastrointestinal disorders, including IBS and FD. Besides, the association between various complex behavioral traits and disorders were also studied, including anxiety, major depression, suicide, smoking behavior, alcohol dependence. A single gene (SLCO4A4), located on the human chromosome 17q11.2, 17q12, is coded by serotonin transporter (5-HTT). The polymorphism of this gene is characterized by the insertion or deletion of the 44-bp sequence and this is related to the different transcriptional activity of the gene. Allele with 44-bp deletion (short allele) is characterized by a three times lower transcriptional activity than allele with 44-bp insertion (long allele). Compared to other FGIDs, the researches about globus are rare. The pathogenesis of globus pharyngeus is still unknown.

Reference
To the best of our knowledge, our findings are the first to establish an association between SLC6A4 polymorphism and globus pharyngeus.

Aims & Methods: 84 patients diagnosed with globus according to Rome III and 160 healthy controls were genotyped for 5-HTTLPR polymorphism by PCR amplification and agarose gel electrophoresis. All globus patients were studied with high-resolution manometry. Globus patients were randomized into paroxetine group; amitriptyline group for 6-week treatment, and were asked to complete the following questionnaires pre- and post-treatment: Glasgow Edinburgh Throat Scale (GETS), Pittsburgh Sleep Quality Index, Hamilton Rating Scale Anxiety/Depression. Treatment response was defined as a > 50% reduction in GETS scores.

Results: The significant difference was shown in globus performed S/S genotype with anxiety when compared to without (X² = 14.579, P = 0.006). The S genotype was associated with higher pressure between high upper esophageal sphincter pressure (>104 mmHg) and non-high upper esophageal sphincter pressure patients (X² = 14.433, P = 0.006). There was significant association between the S/S genotype and the response to antidepressants treatment, while patients with sleep disorders or depression not.

Conclusion: A significant association was observed between S/S genotype of SLC6A4 polymorphism and globus pharyngeus, suggesting that SLC6A4 is a potential candidate gene involved in the pathogenesis of globus pharyngeus.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Multiple rapid swallows (MRS) and rapid drink challenge (RDC) are provocative tests that can enhance the diagnostic value of esophageal HRM. The discriminatory characteristics of these provocative tests were evaluated in symptomatic patients referred for esophageal HRM.

Aims & Methods: Consecutive patients presenting for esophageal HRM were evaluated for a 2-month period and provocative testing with MRS and RDC in addition to standard manometric protocol. Integrated relaxation pressure >15 mmHg identified outflow obstruction; those without outflow obstruction were further analyzed using software tools (IRP, distal contractile integral, DDI, intrabolus pressure, IBP) for peristaltic reserve (MRS or RDC DCI > mean DCI from wet swallows), and obstruction (IBP > 30 mmHg during MRS or RDC). All patients completed symptom questionnaires addressing reflux symptoms (GERD-Q), dysphagia (Savo Dysphagia Questionnaire), and globus symptom severity (GSS) on a 100 mm visual analog scale (VAS). Univariate and multivariate analyses were performed to evaluate overall yield (proportions with MRS/RDC findings not seen with the standard HRM protocol) and to assess association of presenting symptoms with results of MRS and RDC in patients without outflow obstruction.

Results: 149 patients (55.4 ± 1.2yr, 68.8% F) fulfilled inclusion criteria and had no outflow obstruction on HRM. Of these, 91 (61%) had peristaltic reserve on MRS, 19 (12.6%) on RDC (p < 0.001), only 10 were concordant. Obstruction was noted in 16 (9.8%) on MRS, 8 (4.9%) on RDC (p = 0.09), and 5 were concordant; of these, only 2 patients had panesophageal compartmentalization of pressure, and only 1 had elevated IRP during provocative measures. Within ineffective esophageal motility, peristaltic reserve was noted in 59.3%. Within dysphagia presentations, obstruction was noted in 7.7%, and absent peristaltic reserve in 50%. Thus, the overall yield of MRS was 80.5%, and RDC 19.8% (p < 0.001). 131 patients had adequate questionnaire data. Findings on provocative tests did not predict presenting symptoms (GERD-Q or MDQ). Obstruction on RDC predicted higher GSS (odds ratio 5.56, 95% CI 1.04-29.72).

Conclusion: MRS identifies peristaltic reserve better than RDC and has higher overall clinical value. While both MRS and RDC identify outflow obstruction, only RDC obstruction predicts higher symptom burden. Neither MRS nor RDC findings correlate with presenting symptoms.

Introduction: Achalasia is an uncommon condition of failed lower oesophageal sphincter relaxation. Data regarding the incidence and prevalence are limited. The aim of this study was to provide accurate, contemporary epidemiological data utilising two national databases.

Aims & Methods: Hospital Episode Statistics (HES) includes demographic and diagnostic data for all English hospital admissions. The Health Improvement Network (THIN) database includes primary care records of 7% of the UK population, representative of national demographics. Both were searched for incident cases and THIN for prevalent cases of achalasia.

Results: There were 10,509 and 711 new achalasia subjects in HES and THIN respectively. The incidence per 100,000 population in HES was 1.99 (95% CI 1.87-2.11) and 1.53 (1.42-1.64) per 100,000 person years in THIN. The prevalence measured in THIN was 27.1 (25.4-28.9) per 100,000 population.

Conclusion: The incidence of oesophageal achalasia was approximately 15 to 20 per 1 million population. There were approximately 17,500 patients with achalasia in UK in 2015. The above data represents the largest published epidemiological investigation of achalasia. The variation of findings between the databases likely results from differences in coding practice and marginally different population structures.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1823 ACHALASIA DESPITE NORMAL INTEGRATED RELAXATION PRESSURE WITH SMIL WATER SWALLows

Introduction: The resistance to bolus flow across the lower oesophageal sphincter (LES) is a hallmark of achalasia. Presently the gold standard of diagnosis is by high-resolution manometry (HRM) demonstration of raised integrated relaxation pressure (IRP) following ten 5 mL water swallows; however, this does not negate normal swallowing behavior. It has been demonstrated that the addition of adjunctive tests improves sensitivity of identifying relevant dysmotility. Such tests include multiple water swallows (MWS; 200 mL water drunk freely) and solid swallows. In addition, the timed barium esophagram (TBE) measures esophageal emptying. This study describes a cohort of patients who have been treated as having achalasia based on resistance to flow not exhibited with single water swallows.

Aims & Methods: Inclusion criteria were all patients between October 2014–2016 with normal mean and median IRP with 5mL water swallows but considered to have achalasia due to resistance to flow demonstrated by pan-oesophageal presurization (PEP) during MWS or solid swallows and/or a persistent column at 5 minutes during TBE. Outcome following treatment was based on the Eckardt symptom score (E5).
Results: 14 patients (9 male) fulfilled inclusion criteria. 7 were treatment-naïve and 7 were treatment-experienced (3 myotomy, 3 pneumatic dilatations). Mean resting LES pressure was 14.6 ± 7.4 mmHg. In all patients, and mean median IRP values for ten 5 mL water swallows were non-raised (mean 9.1 ± 4.3 and 8.7 ± 4.5 mmHg respectively). Of the 7 treatment-naïve patients, 5 demonstrated PEP on MWS, 3 on solid swallows and 6 had a positive TBE at 5 minutes. In treatment-experienced patients, 5 had PEP on MWS, 1 on solid swallows and all had a positive TBE. Of the 13 who had resistance to flow on TBE, 10 (77%) also had resistance demonstrated during MWS and/or solid swallows. Mean height of the 5-minute column in treatment-naïve patients was 16.5 ± 8.9 cm. In treatment-naïve patients, 8 had (so far) undergone therapy based on these findings: one per oral endoscopic myotomy and 7 pneumatic dilations. The median baseline ES was 7.5 (IQR: 5–8). The median ES at minimum 3 months (range 3–15 months) following treatment was 1 (IQR 0–3; P < 0.001 cf. baseline). Similarly, there was significant improvement in TBE findings post-therapy (mean 5-minute column height 3.5 ± 4.1 cm; P = 0.04 cf. baseline).

Conclusion: A normal IRP for water swallows does not preclude a diagnosis of achalasia. The addition of free drinking/swallowing during HRM or the TBE can identify pathology that might have been missed with standard 5 mL water swallows alone as normal, clinically relevant swallowing behavior is reproduced. Patients treated based on this algorithm exhibit excellent treatment outcomes, validating this approach. Further, the close correlation of HRM adjunctive testing with TBE supports its routine inclusion in clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The timed barium esophagram (TBE) is an objective measurement of oesophageal transit treated during the assessment of achalasia. Post-therapy correlation of the maximum height of the residual barium column has been found to correlate imperfectly with short-term symptomatic outcomes, but carries long-term prognostic implications. We hypothesize that the size of the surface area (SA) of the barium column may be more accurate than height, firstly, because the observed improvement in esophageal width that often occurs post-therapy, but also by correcting for artificially higher height values due to esophageal (longitudinal) contraction occurring during a single image. We aimed to compare the correlation of TBE outcome measures of height and SA with symptom improvement post-therapy.

Aims & Methods: Inclusion criteria were achalasia patients who underwent therapy between August 2015–6 and had TBE and Eckardt score (ES) performed at pre- and post-therapy. With TBE upright single images were acquired at 1.2 and 5 minutes following ingestion of 100–200 mL of low-density barium sulfate. Barium height was measured between the gastro-esophageal junction and the superior extent of any residual barium column. After manually defining the column boundaries, software was used to calculate SA (AGFA IMPAX surface area tool (Figure)). Adequate symptom relief was defined as reduction in ES ≤ 3. On TBE, metrics of adequate emptying evaluated were i) post-therapy column height <5cm, ii) >50% reduction in column height from pre to post-therapy and iii) >50% reduction in column SA from pre to post-therapy. Associations between symptom improvement and TBE measures of emptying were assessed using Pearson’s correlation (R). Paired t-tests compared TBE measures before and after therapy.

Results: 18 patients (9 male; 6 Type I, 11 Type II, 1 Type III) were included. 11 had dilatation and 7 endoscopic myotomy. Reductions with therapy of both mean 5-minute barium column height (14.7 ± 8.7 to 7.9 ± 6.0 cm; P = 0.01) and mean ES (5.27 ± 4.35 to 24.5 ± 26.28 cm²; P = 0.02) were noted. Symptoms also improved with treatment; median baseline ES of 7 (IQR 5.25–8) improved to 0 (IQR 0–1) post-therapy. Only 2 patients had inadequate symptom relief and are awaiting further treatment. However there was poor concordance between post-therapy barium column height and symptomatic relief (i.e. post-therapy column height >5 cm despite ES ≤ 3 or vice versa), and the correlation (R) between these two variables was poor (Table). Similar poor concordance was seen when adequate emptying was defined by >50% reduction in column height, but >50% reduction in SA paralleled symptom improvement.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Measuring the effect of naso-gastric (NG) feeding on oesophageal motility in patients with dysphagia and achalasia is challenging. To overcome this, we aimed to compare NG feeding with a comparison group of patients with achalasia swallowing water.

Methods: In patients with symptoms of oesophageal outflow obstruction and no evidence of underlying motility disorder, NG feeding was performed at the same time as a 10 minute barium swallow study. 17 dysphagic patients (9 male; 11 Type I, 4 Type II) were included. Baseline and NG feeding studies were performed as described above. The barium swallow study was reviewed by an independent radiologist (DS) and standardised to assess the effect of NG feeding on oesophageal motility.

Results: Addition of NG feeding altered oesophageal motility in dysphagic patients in all areas measured. NG feeding resulted in significant improvement in oesophageal motility (p ≤ 0.04 cf. baseline).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastric nutrients may influence the GEA, making NEC more effective at an earlier stage, increasing the likelihood of successful NEC and reducing the risk of NEC complications. We aimed to assess the effect of NG feeding on the GEA in patients with dysphagia and achalasia.

Results: NG feeding improved the GEA in all patients with dysphagia and achalasia, including those with a normal GEA at baseline.

Disclosure of Interest: All authors have declared no conflicts of interest.
stop. Gastric nutrients reduced significantly rectal gas evacuation (45% vs saline, increased the number of defecation (3.3 ± 1.3 belches; p = 0.018 vs saline), and increased greater epigastric perception (score 2.7 ± 0.6; p = 0.030) that decreased during the 30 min following infusion stop (score 1.6 ± 0.7; p = 0.042 vs infusion stop). By contrast to epigastric perception, abdominal perception was only somewhat higher during gas infusion with nutrients (score 2.6 ± 0.5) than during saline (score 2.1 ± 0.5; p = 0.100 vs nutrients).

Conclusion: Gastric nutrients modulate transit of gastric gas, by reducing gas perception to the distal gut, and enhancing retrograde gas evacuation via belching.

Disclosure of Interest: All authors have declared no conflicts of interest."

**P1827 MODIFICATIONS OF THE ECKARDT SCORE PARAMETERS AFTER PERORAL ENDOSCOPIC MYOTOMY**

Introduction: Peroral endoscopic myotomy (POEM) is a recently developed technique or the treatment of lower esophageal sphincter achalasia. POEM could be as efficient as surgical Heller myotomy, while associated with lower morbidity. Currently, the Eckardt score is the clinical score that is the most widely used to assess outcome after POEM. Although a number of studies have been performed on this matter, a uniform evaluation was possible. The full analysis set (FAS) score (GIS) [1], as well as the therapeutic dose (37%,47%/32% of cases, and esophagectomy in one case. Median Eckardt score varied from 7 (6–8) MMHg. At last follow-up visit, 86% of patients had bleeding complications despite only 3 having had variceal eradication. This reports 13 patients from international centres who have had gular intrahepatic portosystemic shunt (TIPSS) before endoscopic dilation. All varices were identified endoscopically in 7 patients, radiologically in 5 and in 1 patient varices were first noted during surgical myotomy. 2 patients had grade 3 varices, 7 had grade 2 and 3 had grade 1 varices (grading not provided for the rest). Cirrhosis was due to alcohol in 7 patients, non-alcoholic steatohepatitis in 3, was sought through the International Manometry Working Group.

Introduction: Well-proven therapeutic options for the therapy of functional gastrointestinal diseases are rare and therefore gain high attention. One of these is STW 5 (Iberogast), for which more than five decades of therapeutic experience in more than 73 Mio patients are available. For determining whether its efficacy in functional dyspepsia proven by meta-analyses is comparable in male and female as well as patients of different age groups, sub-group analyses were conducted. Aims & Methods: Data-analyses of patient placebo-controlled double blind trials with STW 5 have proven compliance to modern standards for a proof of efficacy, now sub-group analyses were conducted. The analyses (ANCOVA) were based on the original single patient data from the trials, including demo-graphic data and primary endpoints.

Results: As the primary outcome variable, the validated gastrointestinal symptom score (GIS) [1], as well as the therapeutic dose (3 × 20 drops/day) were identical in all trials, a uniform evaluation was possible. The full analysis set (FAS) included 557 patients (272 resp. 285 for placebo resp. verum). The mean age (44 ± 11 years) was the same (both groups 168.7 cm), between body weight (72.0 resp. 72.2 kg), the BMI (25.35 resp. 25.54), the gender distribution (67.3% resp. 69.5% females), the duration of the disease at the time of inclusion and the baseline of the GIS (11.6 resp. 11.5 points) were very comparable between both groups. For the primary variable GIS the difference between placebo and verum after 28 days of treatment showed a highly significant (p < 0.0001) difference between placebo and verum (5.6 resp. 4.7 points). The analyses in different age groups (up to 30, 30–40, 40–50, 50–60, above 60) in male and female patients did show a comparable efficacy in all these groups.

Conclusion: These meta-analyses therefore clearly show the efficacy of STW 5 (Iberogast) and its therapeutic usefulness irrespective of age and gender. Given also its good tolerability, POEM could be the treatment of lower esophageal sphincter achalasia. POEM could be as efficient as surgical Heller myotomy, while associated with lower morbidity. These meta-analyses therefore clearly show the efficacy of STW 5 (Iberogast) and its therapeutic usefulness irrespective of age and gender. Given also its good tolerability, POEM could be the treatment of lower esophageal sphincter achalasia. POEM could be as efficient as surgical Heller myotomy, while associated with lower morbidity.

Introduction: Achalasia is a chronic condition presenting with dysphagia, regurgitation, chest pain and/or weight loss. Management options include Heller’s myotomy, Botox, pneumatic dilatation and Per-Oral Endoscopic Myotomy (POEM). Treatments carry risks of bleeding and perforation. Concomitant portal hypertension with varices is very rare and achalasia treatment in this context has only been described in single case reports.

Aims & Method: Experience from physicians/surgeons treating these disorders was sought through the International Manometry Working Group.

Results: 13 patients with portal hypertension from 6 international centres have been collected; mean age 61 ± 9 years. The median pre- treatment Eckardt score was 7 (IQR 6–9), 9/13 (69%) patients had a barium swallow and 12/13 (92%) had oesophageal physiology studies performed. There were 3 Type I, 6 Type II, 2 Type III achalasia and 2 with oesophageo-gastric outflow obstruction. Varices were identified endoscopically in 7 patients, radiologically in 5 and in 1 patient varices were first noted during surgical myotomy. 2 patients had grade 3 varices, 7 grade 2 and 3 had grade 1 varices (grading not provided for the rest). Cirrhosis was due to alcohol in 7 patients, non-alcoholic steatohepatitis in 3, cryptogenic in 2 and 1 had hepatitis C cirrhosis. 75% were Child-Pugh A and 25% were Child-Pugh B. Patients had diverse treatments for their achalasia. 4 were treated with Botox injections (1 with EUS), 4 had dilation alone, 3 received a POEM, another had POEM then dilation and 1 patient had Botox followed by Heller’s myotomy. 3 patients underwent variceal eradication in advance; all had banding first but in 2 patients superficial eradication was followed by a transjugal intrahepatic portosystemic shunt (TIPSS) before endoscopic dilation. All patients had symptomatic improvement with median Eckardt score post intervention = 1 (IQR 0–2) p < 0.0001 compared to baseline. A matched group of 20 patients who underwent treatment for achalasia (all subtypes) but without varices had median Eckardt score post intervention = 1 (IQR 0–2) p < 0.0001 compared to baseline. None of these patients had complications of bleeding or perforation; however both patients who had TIPSS had temporary hepatic decompensation.

Conclusion: This reports 13 patients from international centres who have had interventions for achalasia on the background of oesophageal varices. None had bleeding complications despite only 3 having had variceal eradication. Symptom response mirrored those who undergo standard achalasia therapy,
PI830 THE NATURAL HISTORY OF ACHALASIA: EVIDENCE OF A CONTINUUM–THE PATTERN-EVOLUTIVE STAGING THEORY

Dept. Of Surgical, Oncological And Gastroenterological Sciences, University Hospital of Padova, Padova/Italy

Contact E-mail Address: m.costantini@unipd.it

Introduction: Esophageal achalasia is classified into three clinically relevant patterns at High Resolution Manometry (HRM) and according to Chicago Classification. Currently, it is unclear whether they represent distinct entities or are part of a disease continuum.

Aims & Methods: The aims of this study were: a) to test the hypothesis that the three manometric patterns represent different stages in the evolution of esophageal achalasia and b) to investigate whether manometric patterns change after Laparoscopic Heller-Dor (LHD). We evaluated the patients who had a diagnosis of achalasia and underwent LHD as first treatment from 1992 to May 2016. Symptoms were scored using a detailed questionnaire for dysphagia, food-regurgitation, and chest pain; barium swallow, endoscopy, and esophageal manometry (conventional or High Resolution technique) were performed, before and 6 months after surgical treatment. All conventional manometric tracings, before 2010, were reviewed and re-classified according to the manometric-pattern classification, whereas after 2010 the HRM data were prospectively collected.

Results: Five-hundred and eleven consecutive achalasia patients (M:F = 283:228) represented the study population. Based on their manometric findings, 231 patients (45.2%) were classified as having pattern I, 241 (47.2%) had pattern II, and 39 (7.6%) had pattern III. Demographic and clinical data showed that pattern III cases had a shorter duration of symptoms, a more incidence of chest pain, and a less dilated gullet (p<0.001). Further, all patients with a sigmoid-shaped mega-esophagus (radiological grade IV) had pattern I achalasia. One patient with diagnosis of pattern III achalasia, who refused any treatment evolved to pattern II at a follow-up manometry performed for a progressive worsening dysphagia after 36 months. At a median follow-up of 30 months (IQR 12–56), the outcome of surgery was positive in 479 patients (91.7%). The only predictor of final outcome was the prooperative manometric pattern (p<0.001). All patients (42) whose surgical treatment failed underwent one or more endoscopic pneumatic dilations using Rigiflex balloons (30, 35 or 40 mm). The overall success rate of the combined treatment (LHD plus endoscopic dilations where necessary) was 98%. All patients with pattern I prooperatively had the same pattern after LHD, whereas more than 50% of patients with pre-treatment pattern III had patterns I or II after surgery. There were no cases showing the opposite trend (Table 1). Five patients showed signs of a partial recovery of peristalsis (all patients had a pattern II before LHD).

Table 1: Changing manometric patterns after LHD. *5 patients had a recovery of peristalsis (all patients had a pattern II before LHD).

Introduction: The development of non-invasive methods to detect the presence of H. pylori, and to estimate the extent and severity of gastritis, have reduced the need for diagnostic endoscopy in asymptomatic individuals. However, it is not known whether the use of non-invasive diagnostic methods is effective in dyspeptic patients.

Aims & Methods: To use a non-invasive blood test with four stomach-specific biomarkers to assess the prevalence of different stomach conditions: gastroesophageal reflux disease (GERD), H. pylori (HP) infection, chronic atrophic gastritis (CAG), and the efficacy of proton pump inhibitor (PPI) therapy in a primary care population. A cohort of 2583 dyspeptic patients (male 56%, mean age 44.0 yrs, range 6–95) was selected in a primary care population and examined with a panel of biomarkers (Pepinogen-I (PG-I) and -II (PG-II), imidazol gastrin-17 (G-I7), and HP IgG (Biost, Finland)). A standard questionnaire, including upper gastrointestinal symptoms and PPI use, was administered. Exclusion criteria were dysphagia, anemia, weight loss and vomiting. CAG patients underwent to endoscopy and histological examination.

Results: Healthy stomach was found in 21.2% patients. Prevalence of CAG increased with patient’s age in both sexes as well as the use of PPIs (p=0.0001). Table 1 shows the serum biomarkers values divided according to five categories: healthy stomach (H), GER, HP, HP+CAG, and HP+PPI therapy.

Conclusion: The combination of data on the levels of PG-I, PG-II, G-I7 and HP IgG allow to diagnose different pathological conditions such as HP, and non-HP-related gastritis, the appropriateness of PPI administration, GERD and CAG, a precancerous condition.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Functional dyspepsia (FD) is one of the most common functional gastrointestinal disorders characterised by chronic or relapsing symptoms without structural or biochemical abnormalities that can be identified in the routine clinical setting. Thus, treatment targets symptoms. Very little is known about prolonged treatment for more than 4 weeks.

Aims & Methods: The aim of the additional data analysis of a previous randomized placebo-controlled trial was to explore post-treatment effects that occurred after continuation of therapy for a 4-week randomized placebo controlled treatment with Menthacarin1 with regard to disease-specific symptoms and QoL in FD patients. After the 4-week randomised placebo-controlled treatment period, patients were allowed to continue the treatment. The treatment was given in a double-blind fashion and allocation of treatment followed the original randomization. The results of these 54 patients are reported here. Outcomes were assessed utilising the self-rating Nepean Dyspepsia Index (NDI). Intra-individual differences between baseline and week 4/week 12 for NDI sub-scores for pain (sum of the NDI items 'pain or ache in upper

Introduction: The introduction of proton pump inhibitors (PPIs) into clinical practice has revolutionized the management of acid-related diseases. Studies in primary care and emergency settings suggest that PPIs are frequently inappropriately prescribed or used in clinical conditions with little benefit.

Aims & Methods: To evaluate the role of Gastropanel in relation to the appropriateness of PPI-therapy prescription. 2583 dyspeptic patients (male 36%, mean age of 44.0 yrs, range 6-95) with no alarm symptom (i.e., dysphagia, anemia, weight loss and vomiting) from a primary care population were included in the study. For each patient a blood sample was collected for serum Pepsinogen I (PG-I) and II (PG-II), Gastrin 17 (G-17) and IgG HP (Biohit, Oyj, Finland); the values of PG-I and G-17 values according to the response to PPI therapy. 68 (6.7%) presented HP infection. Table 1 shows the values of PG-I and G-17 and IgG HP (Biohit, Finland). 38 patients under PPIs therapy (3.7%) were confirmed histologically). 68 (6.7%) presented HP infection. Table 1 shows the values of PG-I and G-17 values according to the response to PPI therapy.

Results: After the initial 4 weeks, 54/114 patients opted for an extension of therapy. Interestingly, 34 out of 52 patients had been on active therapy while only 20 had received placebo. Until week 4, the ND1 sub-score for pain had decreased by 7.5±3.9 points during Menthacarin treatment as compared to 5.1±3.8 points during placebo treatment (p = 0.0371). After the follow-up, over-all reduction for Menthacarin (8.7±4.9 points) was also significantly better as compared to placebo (5.1±4.9 points, p = 0.005). The ND1 sub-score for discomfort had decreased until week 4 by 3.5±2.1 points during active therapy as compared to 1.2±2.1 points during placebo treatment (p = 0.0003). For the 12-week therapy, the score had declined by 3.7±2.5 points and 1.3±2.6 for Menthacarin and placebo, respectively (p = 0.0014). Overall QoL improvement was better for active medication for 4 and 12 weeks as compared to placebo.

Conclusion: After 4 weeks of randomized double-blind, placebo-controlled treatment with either Menthacarin or placebo, patients who received active medication are more likely to opt for a continuation of therapy as compared to patients on placebo. The gain over placebo remained significant even after 12 weeks of treatment. Menthacarin® is a proprietary combination of essential oils of specified quality from Mentha x piperita L. (90mg Peppermint oil WSN® 1340) and Carum carvi (50mg Caraway oil WSN® 1520).

Introduction: Gastric acid secretion is believed to decrease in the aging stomach, but the number of elderly patients on proton pump inhibitor (PPI) therapy is unknown. This study aimed to evaluate the role of GastroPanel in relation to the appropriateness of PPI-therapy prescription. It was performed.

Results: IGP was significantly lower during acid perfusion compared with saline perfusion (p = 0.003). Acidification also resulted in decreased TEER (p = 0.005), increased passage (p = 0.001) and lower protein expression of claudin 3 (p = 0.0006). No difference in mast cell (p = 0.34) and eosinophil (p = 0.34) counts were detected, but an increased protein expression of tryptase (p = 0.0008) was found after acid perfusion. In the placebo and the DSCG group, acidification induced a similar drop in IGP (p = 0.68). There was also no difference in TEER (p = 0.70) and passage (p = 0.21) after acid perfusion between both pretreatments.

Conclusion: Duodenal acid perfusion in healthy volunteers disrupts epithelial integrity and activates an inhibitory duodenogastric reflex. Although this effect seems to be independent from increased duodenal acid exposure in functional dyspepsia is a potential pathophysiological mechanism contributing to abnormalities in duodenal and gastric structure and function observed in patients with functional dyspepsia.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI834 DUODENAL ACID PERFUSION INCREASES DUODENAL TISSUE PERMEABILITY AND ACTIVATES THE DUODENOGASTRIC REFLEX, INDEPENDENTLY FROM MAST CELL ACTIVATION

H. Vanheel1, R. Farre1, D. Beeckmans1, M. Vicario1, J. Tack1, T. Vanuytsel1

Introduction: We recently reported that functional dyspepsia patients show impaired duodenal integrity, associated with low-grade inflammation (Vanheel, Gut 2014). A potential cause underlying this phenomenon may be the increased duodenal acid exposure that has been demonstrated in some of these patients. Aims & Methods: Our aim was to evaluate the effect of duodenal acid perfusion on duodenal permeability in healthy volunteers and to investigate whether mast cell activation is required for acid-induced impairment of mucosal integrity. As it has already been shown that duodenal acid activates duodenogastric reflex pathways, we also assessed intragastric pressure (IGP). This study consisted of 2 parts, each including 10 healthy volunteers. 1) An infusion tube was positioned in the second part of the duodenum and a high resolution manometry probe was positioned in the stomach to measure IGP. HCI 0.1N or saline was infused in the duodenum during 30 min (5mL/min) in a randomised, double-blind manner. Duodenal biopsy specimens were obtained after infusion to measure transepithelial electrical resistance (TEER) and paracellular passage (fluorescein-labeled dextran, 4KDa) in Ussing chambers. Expression of cell-to-cell adhesion proteins (claudin 1–4, occludin, zonula occludens 1-3, β-catenin, E-cadherin, desmocollin-2, desmoglein-2) in biopsies was evaluated by PCR, western blot and/or immunofluorescence. The number of mast cells and eosinophils was counted using immunohistochemistry for tryptase and eosinophilic major basic protein respectively, and by evaluating the expression of these proteins using PCR and Western blot. 2) The participants were orally treated with placebo or with the mast cell stabilizer disodiumcromoglycate (DSCG) 200mg qid for 2 weeks. After treatment, the study design was as described above (although only acid perfusion was performed).

Results: IGP was significantly lower during acid perfusion compared with saline perfusion (p = 0.003). Acidification also resulted in decreased TEER (p = 0.005), increased passage (p = 0.001) and lower protein expression of claudin 3 (p = 0.0006). No difference in mast cell (p = 0.34) and eosinophil (p = 0.34) counts were detected, but an increased protein expression of tryptase (p = 0.0008) was found after acid perfusion. In the placebo and the DSCG group, acidification induced a similar drop in IGP (p = 0.68). There was also no difference in TEER (p = 0.70) and passage (p = 0.21) after acid perfusion between both pretreatments.

Conclusion: Duodenal acid perfusion in healthy volunteers disrupts epithelial integrity and activates an inhibitory duodenogastric reflex. Although this effect seems to be independent from increased duodenal acid exposure in functional dyspepsia is a potential pathophysiological mechanism contributing to abnormalities in duodenal and gastric structure and function observed in patients with functional dyspepsia.

Abstract No: P1834
increasing. Pepsinogen I (PGI) <30μg/L, PGI/PGII <3 and gastrin-17 (G17) >10 pmol/L are non-invasive serological markers to explore gastric function, with a negative predictive value for chronic atrophic gastritis (CAG) of 96%.

Aims & Methods: Aim of the study was to evaluate gastric function by means of serology (PGI, PGII, G17-1 and IgG-antibodies against Helicobacter pylori) in very elderly patients, including centenarians. A total of 379 patients were prospectively enrolled (M = 126, F = 253, mean age = 83.6 ± 6.7, range 70–106). They were divided in four groups: 132 subjects with an age between 70 and 79 years old (first group), 146 subjects between 80 and 89 (second group), 76 subjects between 90 and 99 (third group) and 25 subjects between 100 and 106 (fourth group). Demographics and drug intake, particularly the PPI intake, were collected. For all patients, serological markers were determined in fasting blood samples by using GastroPanel® (Biohit Oyj, Finland; normal values: PGI: 30–120 μg/L; PGII: 2–15 μg/L; PGI/PGII ratio: > 3; G17: 1–9 pmol/L; H2: IgG: < 30 EU).

Results: In the first group (age 70–79), 18.2% of the subjects showed H. pylori infection (PGI > 10 μg/L, G17 against H.p. > 30 EU), 22.7% had CAG (PGI > 30 μg/L and PGII < 35%) and 53.8% were under PPI therapy. 16.9% of the patients on PPI therapy had CAG. In the second group (age 80–89), 32.9% of the subjects showed H. pylori infection, 8.9% had CAG and 48.6% were under PPI therapy. 8.5% of the patients on PPI therapy had CAG. In the third group (age 90–99), 22.4% of the subjects showed H. pylori infection, 10.5% had CAG and 48.7% were under PPI therapy. 8.1% of the patients on PPI therapy had CAG. In the fourth group (age 100–106), 44.0% of the subjects showed H. pylori infection, 16.0% had CAG and 72.0% were under PPI therapy. 16.7% of the patients on PPI therapy had CAG.

Conclusion: Acid secretion is preserved in most of the elderly and very elderly subjects, even in centenarians. Serological markers may be helpful to identify patients affected by CAG in which the administration of PPI is inappropriate, especially in the elderly.

P1836 THE PSYCHOLOGICAL CHARACTERISTICS OF REFLEX HYPERSENSITIVITY-A PILOT STUDY BASED ON SCL-90 QUESTIONNAIRE AND 24 HOUR PH-IMPEDANCE MONITORING

K. Wang, Z. Xu, Z. Xia, Y. Ge, L. Duan
Department Of Gastroenterology, Peking University Third Hospital, Beijing/China

Contact E-mail Address: duanlp@bjmu.edu.cn

Introduction: Reflux hypersensitivity (RH) was lately defined as a functional esophageal disorder based on the HP-24h study. The clinical and psychological characteristics are still unknown.

Aims & Methods: The aim of this study was to assess the reflux and psychological characteristics of RH. Patients who underwent 24h pH-impedance monitoring were selected from January 1st 2011 to November 30th 2015. The patients with heartburn or chest pain ≥2 days/week for more than 6 months were enrolled. Healthy volunteers (HV) were enrolled too. All subjects fulfilled the SCL-90 questionnaire, underwent gastroscopy to exclude upper gastric diseases and underwent HRM test to exclude motility disorders. The patients for normal esophageal mucosal but overload acid, weakly acid or non-acid reflux were diagnosed as non-erosive reflux disease (NERD). The patients with normal esophageal mucosal and normal reflux but positive symptom index (SI) or symptom association probability (SAP) were diagnosed as RH. The patients with normal mucosal, normal reflux, normal SI or SAP and negative PPI test results were enrolled in functional heartburn (FH) group. The reflux and psychological characteristics were compared among NERD, RH and FH.

Results: Total 231 patients were enrolled. 107 were NERD (48.25±1.27yrs, M:F=58:49), 92 were RH (48.30±1.27yrs, M:F=9:83), 32 were RH (48.41±2.63yrs, M:F=42:28). 28 HVs (47.21±2.27, M:F:8:20) were enrolled as controls. NERD presented significantly higher acid exposure time (pH < 4.2) than those of FH, RH and HV (6.55±0.71, 12.5±0.1209, 0.33, 2.9±0.53, respectively, p<0.005). The acid reflux and weakly acid reflux were both higher in NERD than that in FH, RH and HV (p<0.01). The total scores of SCL-90 of the fourth group of patients were significantly higher than HV (NERD/HV, 58.1±5.1; RH/HV, 111±7.6; FH/HV, 142±1.5; M:F=58:49).

Conclusion: Significant differences were recorded in most of the considered parameters obtained by the two RH systems. This is particularly relevant in the evaluation of the LES relaxation, the cardinal point in the hierarchical approach of the Chicago Classification, probably due to different analysis used by the two systems (the lowest residual pressure vs IRP). Furthermore, the differences found in the measurement of the LES resting pressure and abdominal length may rely either on the different technology (3-D vs linear transducers) or on the different algorithms and thresholds used. The latter may probably also apply to the differences found with the two systems in the duration of the esophageal contractions and in the new contractile parameters (i.e.: DCI and DL) introduced by the Chicago Classification. This study emphasizes the need for a careful validation of any new motility disorderful manometry. The acquisition of new sets of normal values, to be used to compare the data measured in patients, is therefore mandatory. The results of our study may represent the reference normal values for other esophageal laboratories that are using the HRM systems and devices we tested here.

Introduction: High-Resolution Manometry (HRM) has recently became the gold standard for the evaluation of esophageal motility. A new classification of esophageal motility disorders (Chicago Classification, v. 3.0) has been developed, based on the findings from a given hardware and software. Different systems for HRM and new features of the existing ones have recently been developed.

Aims & Methods: In this study we aimed to evaluate a new solid-state HRM system and a new 3-D catheter and system for the study of lower esophageal sphincter (LES). Fifteen healthy volunteers (7m, 8f, median age 27) underwent two consecutive Esophageal HRM studies by using two different solid state systems (ManoScan, Medtronic, Minneapolis, USA and Medica SpA, Italy with Unisensor AG, Atikon, Switzerland catheter). The studies were performed in a random order using the standard protocol. Furthermore, a new 3-D catheter for the study of sphincters was evaluated in 12/15 volunteers.

Results: Table 1 reports the findings obtained with the Medica system compared to the consolidated Medtronic system. The data of the 3-D evaluation are also reported. The data are expressed as medians (and 5th-95th percentiles).

Conclusion: Significant differences were recorded in most of the considered parameters obtained by the two HRM systems. This is particularly relevant in the evaluation of the LES relaxation, the cardinal point in the hierarchical approach of the Chicago Classification, probably due to different analysis used by the two systems (the lowest residual pressure vs IRP). Furthermore, the differences found in the measurement of the LES resting pressure and abdominal length may rely either on the different technology (3-D vs linear transducers) or on the different algorithms and thresholds used. The latter may probably also apply to the differences found with the two systems in the duration of the esophageal contractions and in the new contractile parameters (i.e.: DCI and DL) introduced by the Chicago Classification. This study emphasizes the need for a careful validation of any new motility disorderful manometry. The acquisition of new sets of normal values, to be used to compare the data measured in patients, is therefore mandatory. The results of our study may represent the reference normal values for other esophageal laboratories that are using the HRM systems and devices we tested here.

Introduction: Proton Pump Inhibition-response esophageal eosinophilia (PPI-REE) is a condition characterised by symptoms of esophageal dysfunction in the setting of eosinophilic inflammation on esophageal biopsies responding to a course of 5 weeks of PPI therapy. Recent data collected by using esophageal high resolution manometry (HRM) documented that patients with PPI-REE present frequently motility abnormalities, mostly weak peristalsis and hypertensive esophaegogastric junction (EGJ). Data on the effect of PPIs in improving these motor abnormalities are lacking.

Aims & Methods: The aim was to retrospectively compare HRM features of patients with PPI-REE before and after a course of PPI therapy. Consecutive patients with symptoms suggestive of EoE underwent upper endoscopy to assess the presence of at least 15 eos/hpf on esophageal biopsies at mid/proximal esophagus and, therefore, were treated with twice-daily PPIs for at least 8 weeks. Thereafter, patients repeated upper endoscopy and PPI-REE was identified in case of less than 15 eos/hpf and a 50% decrease from baseline. Patients with PPI-REE underwent HRM at the time of the diagnosis (off-PPI) and after the course of PPIs (on-PPI). Patients with achalasia and absent peristalsis were excluded (Chicago Classification v.3).

Results: Twenty-eight patients [23M:5F; mean age 33] reporting dysphagia (93%), bolus impaction (68%) and chest pain (25%) were diagnosed with PPI-REE. After a secretory therapy, most of the patients reported complete resolution of esophageal symptoms directly linked to esophageal infiltration (p < 0.001), namely dysphagia, bolus impaction and chest pain. Compared to HRM features at baseline, HRM after PPI therapy showed that patients with PPI-REE had higher median EGJ resting pressure [baseline 11 (1–34) vs. post-PPI 17 (1–34); p < 0.05], greater mean distal contraction integral [1094 (483–5281) vs. 2634 (495–6450); p < 0.01], and less frequent panesophageal pressurization [6 (21%) vs. 0 (0%); p < 0.02]. No differences were observed in terms of distal latency and rate of different EGJ subtypes (p > 0.05). As to the manometric diagnoses, after PPI therapy patients with PPI-REE showed a reduced rate of ineffective motility or fragmented peristalsis [16 (57%) vs. 7 (25%); p = 0.02] and increased frequency of normal peristalsis [9 (32%) vs. 18 (64%); p = 0.03]. No differences were observed in terms of frequency of distal esophageal spasm and outflow obstruction diagnoses (p > 0.05).

Conclusion: In most PPI-REE patients, PPI therapy restores the impairment of esophageal motility expressed by ineffective and fragmented peristalsis, thus favouring the return to a normal motility pattern. This finding, paralleled with symptoms improvement in the same subjects, seems to emphasize the important role of inflammation linked to the eosinophilic infiltration of the esophageal wall in inducing motor dysfunction and related symptoms.

Introduction: In recent years, new guidelines and recommendations have been published regarding the diagnostic criteria and therapeutic management of eosinophilic esophagitis (EoE). Aims & Methods: The aim of this study was to assess the diagnostic and therapeutic management of patients diagnosed with EoE in daily clinical Dutch practice and whether this was according to guidelines and recommendations. A population-based, retrospective cohort study was conducted using data from the Dutch national pathology registry (PALGA), medical records, and telephone interviews of patients diagnosed with EoE in two academic and two non-academic hospitals in the period 2004–2014. Data regarding demographics, clinical manifestations, endoscopic results, histologic samples and therapeutic strategies were collected. Standard statistical analyses were performed to summarize the patient characteristics.

Initial treatment after diagnosis EoE

Results: In total, 119 patients were diagnosed with EoE and included in this study. The median age at onset of symptoms was 29 years (IQR, 15–42) and the median age at diagnosis was 38 years (IQR, 23–51 years), leading to a median diagnostic delay of 6.5 years (IQR, 2–14 years). The median delay in diagnosis between first contact in the hospital and diagnosis was 1.0 year (IQR, 2–14 years). The incidence of patients newly diagnosed with EoE increased steadily over a period of 11 years. Criteria for the microscopic diagnosis of EoE varied between pathologists in each hospital. Initial treatment included topical corticosteroids (30.3%), proton pump inhibitors (PPIs) (29.4%) or a combination of the two (10.1%). A follow-up interview to prospectively compare HRM features of patients with PPI-REE before and after a course of PPI therapy revealed the importance of inflammation linked to the eosinophilic infiltration on esophageal biopsies responding to PPI therapy. Remarkably, the diagnostic entity PPI-responsive EoE was only used in one center, follow-up endoscopy was performed in less than half of patients and all pathologists used different criteria for the microscopic diagnosis of EoE. Moreover, therapeutic strategies were not always utilized in the participating centers. Our results show that apart from developing guidelines, efforts should be undertaken to implement them in daily clinical practice.

Introduction: Eosinophilic Esophagitis (EoE) is a chronic immune disease of the esophagus characterized by a histologically characterized by a predominant eosinophilic infiltration. EoE is mainly found in patients with atopic conditions. However, recently an association with IgG4 but not with IgE has been reported. Gastroesophageal reflux disease (GERD) is the most important differential diagnosis of EoE. In this study we measured systemic serum IgG4 and IgE levels of EoE patients before and after a topical steroid therapy, correlated them to esophageal IgG4-positive plasma cells and compared them to GERD patients.

References
Aims & Methods: Serum levels of IgG4 and IgE of 19 EoE patients were measured before and after eight weeks of therapy with budesonide (1 mg twice a day). Biopsies were taken from the esophagus before and after therapy for histological and immunohistochemical evaluation. 14 patients with GERD without histological proof of eosinophilic granulocyte infiltration were taken as a control group. Serum levels of IgG4 and IgE of 19 EoE patients were measured before and after eight weeks of therapy with budesonide (1 mg twice a day). Biopsies were taken from the esophagus before and after therapy for histological and immunohistochemical evaluation. 14 patients with GERD without histological proof of eosinophilic granulocyte infiltration were taken as a control group.

Results: Serum IgG4 levels of EoE patients were significantly higher than in GERD patients (mean: 121.0 mg/dL vs. 71.2 mg/dL, p = 0.034). In contrast, no significant difference of IgE levels in EoE and GERD patients was observed. In EoE patients, the number of eosinophiles/hpf in histology was decreased at a significant level after topic steroid therapy (mean: 51.9 eosinophiles/high power field (hpf) vs. 6.4 eosinophiles/hpf, p < 0.001). After therapy lower levels of IgG4-serum-levels could be measured (mean: 121.0 mg/dL vs. 104.2 mg/dL; p = 0.034). In contrast, no significant difference was determined in the number and severity of symptoms, which manifests in the normal development of their daily activities, their physical health state. An up-to-date systematic review will provide a useful resource for practice and research of EoE. Further validation studies in several languages and populations are required to support the use of disease-specific HRQoL measures.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: In this study, we aimed to systematically assess the nature of subepithelial histologic alterations, analyze their relationship with epithelial histologic findings, endoscopic features, and symptoms, and evaluate the diagnostic impact of subepithelial eosinophilic counts in patients with an epithelial peak eosinophil count of <15/hpf. We prospectively included in this cohort study adult EoE patients who underwent assessment of clinical, endoscopic, and histologic disease activity using scores.

Results: We included 200 EoE patients (mean age 43.5 ± 15.7 years, 74% males) with a median peak count of 36 intraepithelial eosinophils/hpf [IQR 14–84]. The following histologic features were identified in the subepithelial layer: eosinophilic infiltration (median peak count of 20 eosinophils/hpf [IQR 10–51]), eosinophil degranulation (43%), fibrosis (82%), and lymphoid follicles (56%). Peak intraepithelial eosinophil counts were higher, identical, and lower when compared to the subepithelial layer in 62.5%, 7%, and 30.5% of patients, respectively. Subepithelial histologic activity correlated with epithelial histologic activity (rho 0.32, p < 0.001), endoscopic severity (rho 0.208, p = 0.003), and symptom severity (rho 0.179, p = 0.011). Forty percent (21/52) of patients with <15 intraepithelial eosinophils/hpf had subepithelial peak counts of ≥15/hpf.

Conclusion: In one third of patients subepithelial peak eosinophilic counts are higher than epithelial eosinophil counts. Systematic assessment of subepithelial eosinophilic counts can aid in diagnosing EoE in additional 40% of all patients with epithelial eosinophils <15/hpf.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1844 GASTROESOPHAGEAL REFLUX DISEASE PATIENTS REFUXATE TYPE INFLUENCE ON MACROPHAGE PHENOTYPE

Aims & Methods: We aimed to assess the influence of refluxate type on macrophage phenotype programming and paradigm of Th1/Th2 cytokines due to the recurrent exposure to acidic and nonacidic refluxate of gastric contents in GERD patients. Macrophage phenotype was assessed in vitro by adding acidic and nonacidic refluxates of patients with GERD and Barrett’s esophagus were included in the study. Macrophage phenotype was assessed by adding acidic and nonacidic refluxates of patients with GERD and Barrett’s esophagus were included in the study. Macrophage phenotype was assessed by adding acidic and nonacidic refluxates of patients with GERD and Barrett’s esophagus were included in the study. Macrophage phenotype was assessed by adding acidic and nonacidic refluxates of patients with GERD and Barrett’s esophagus were included in the study. Macrophage phenotype was assessed by adding acidic and nonacidic refluxates of patients with GERD and Barrett’s esophagus were included in the study.

Results: We included 100 GERD patients (mean age 43.5 ± 15.7 years, 74% males) with a median peak count of 36 intraepithelial eosinophils/hpf [IQR 14–84]. Analysis of cytokine macrophage production revealed the prevalence of Th1 and Th1/Th2 bivalent (IL-2, IL-6) cytokines as compared to Th2. The most significant changes due to the influence of refluxate pH were observed in Th1 cytokine IL-8, TNFα and TNFβ. In the acidic refluxate increased production of IL10: 3.13 pg/ml in group I vs 27.7 ± 8.65 pg/ml in group II (p < 0.005). The expression of surface M1/M2 macrophage CD markers significantly varied depending on the acidity of refluxate. Mild-alkaline pH (III group) resulted in increasing expression of M2 markers CD163/CD206 as compared to M1-CD80/CD25, but changing M1/M2 index of CD80/CD163 ratios significantly changed in different refluxate pH conditions.

Conclusion: Pooled analysis of GERD patients refluxate type influence on macrophage phenotype showed the prevalence of M1 phenotype activity activated macrophages (Th1) with increased expression of M1 surface markers and predominantly increased production of Th1 cytokines (IL-8, TNFα, TNFβ). The changes were more expressed in macrophages exposed to acidic refluxate. The effect of the different refluxate on the macrophage phenotype was more significant in the acidic refluxate.

P1845 THE LOCATION OF OESOPHAGEAL MUCOSAL AFFERENT NERVES IS MORE SUPERFICIAL IN PATIENTS WITH NERD THAN IN HEALTHY VOLUNTEERS AND PATIENTS WITH BARRETT’S OESOPHAGUS

Aims & Methods: To test the hypothesis that differences in peripheral esophageal nerve fiber innervation may be related to the distribution of mucosal nerve fibers in patients with NERD and BE and compared the results with that of healthy subjects. 13 patients with NERD undergoing reflux testing and 16 patients with BE undergoing endoscopic surveillance were prospectively recruited. Biopsies were obtained from the proximal and distal esophageal mucosa in NERD patients and the distalmost squamous epithelium in BE patients, then examined immunohistochemically for presence and localization of calcitonin gene-related peptide (CGRP)-immunoreactive nerve fiber. The results were compared with those from 10 healthy volunteers (HV) previously studied by our group.

Results: The distribution of mucosal CGRP-immunoreactive nerve fibers is equidistant from the distal esophageal lumen in HV and BE (median 25.5 cell layers to surface [IQR 21.4–28.8]) vs 21.5 [16.1–27.5] respectively, p = 0.055). Mucosal innervation is significantly more superficial in NERD both distally (9.5 cell layers to surface [IQR 21.4–28.8] vs 21.5 [16.1–27.5] respectively, p = 0.0098 vs HV).

Conclusion: The acid hypersensitivity seen in NERD may be partially explained by the increased proximity of mucosal afferents to the esophageal lumen, and therefore greater exposure to noxious substances in refluxate. Conversely, the relative acid hyporesponsiveness in BE may be attributed to the deeper location of mucosal afferents.

Disclosure of Interest: All authors have declared no conflicts of interest.
Belching is a commonly occurring symptom in patients with gastroesophageal reflux disease (GERD). Belching may elicit reflux. It is unknown whether GERD patients with isolated pathological upright reflux (UP) have belching patterns that are different from GERD patients with pathological biphasic reflux (BIP).

**Aims & Methods:** Aim of this study was to therefore examine the belching patterns of UP reflux patients as compared with BIP reflux patients. We included 50 consecutive patients with pathological reflux and typical symptoms who underwent 24-h pH-impedance monitoring at the Maastricht University Medical Centre from 2015 to 2017. Patients referred for excessive belching were excluded.

A group of 25 UP reflux patients (10 male, mean age 52.9 years (range 22–77)) and 25 BIP reflux patients (11 male, mean age 47.9 years (range 18–78)) were examined. Results of pH-impedance tracings were analysed manually. We classified belches according to: a) physiological mechanism: supragastric vs. gastric; and b) their temporal relationship with a liquid reflux episode: isolated belch, preceding or during a liquid reflux episode. Symptom-association analysis was performed to assess a relationship between reported symptoms and reflux episodes.

**Results:** BIP patients showed higher acid reflux time (17.8 ± 2.4% vs. 7.3 ± 0.6%, p < 0.001) and higher number of total reflux episodes (121 ± 9 vs. 97 ± 8, p = 0.05) than UP patients. Notably, both the proportion of reflux episodes with belches of any type and the proportion of belches preceding liquid reflux were higher in UP patients than in BIP patients (51.7 ± 3.6% vs. 32.1 ± 3.7%, p < 0.001 and 27.3 ± 3.1% vs. 17 ± 2.9%, p = 0.03, respectively). No difference was found in the proportion of both supragastric and gastric belches between groups. During 24-h pH-impedance monitoring UP patients reported more symptoms (21 ± 6 vs. 12 ± 3, p = 0.16) and had more positive symptoms with belches (60.2 ± 7.1% vs. 39.0 ± 6.6%, p = 0.03) than BIP patients. Of the total number of belches that were detected using 24-h pH-impedance, more belches were detected in UP patients than in BIP patients (24.8 ± 6.4% vs. 11.1 ± 2.5%, p = 0.06).

**Conclusion:** In our study, GERD patients with isolated pathological upright reflux had more often (symptomatic) belches than GERD patients with pathological biphasic reflux. Therefore, examination of belching patterns can assist diagnostic and therapeutic strategic planning in GERD patients who are refractory to medical therapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Aims & Methods: The aim of the study was to evaluate the effect of the menthol infusion into the esophagus on the esophageal peristalsis and lower esophageal sphincter pressure in healthy volunteers. High-resolution manometry and the parameters of esophageal pressure topography were used to quantitatively evaluate the certain components of esophageal motility. 13 healthy volunteers without out esophageal symptoms were enrolled. High-resolution manometry, whether with a thin silicon tube attached or placed transnasally so that the distal end of the tube was 5 cm above the LES. After a 5 min. adaptation period the measurement was performed in the supine position according to the protocol as follows: after the baseline recording 10 water swallows of 5 ml and 3 s with water swallows of 10 and 15 ml after. At a 20 min. infusion challenge with 3 mM menthol 8 ml/min. was carried out and subsequently the water swallows in order described above were repeated. HRM tracings were manually analyzed using ManoScan software and parameters used in the Chicago classification (v3.0) were evaluated. Integrated relaxation pressure (IRP), nadir LES pressure and distal contractile integral (DCI) values from 5ml, 10 ml and 15 ml swallows were obtained. These were compared before and after the menthol infusion.

Results: None of the subjects had any motility disorder defined by the Chicago Classification v3.0. Few volunteers reported only mild cold sensation during infusion presumed to be of the esophageal origin. The nadir LES pressure before and after menthol infusion was 7.5 ± 0.5 mmHg vs. 7.3 ± 0.7 mmHg, respectively (p = 0.7). IRP of 5 ml swallows was 2.8 ± 0.6 mmHg vs.2.1 ± 0.5 mmHg showed significance (p = 0.01). However, difference of IRP of 10 ml and 15 ml swallows was not significant (p > 0.1, p > 0.5, respectively). Average DCI pressure (5 ml swallows) was 11.3 ± 1.8 mmHg before and after menthol infusion, respectively (p > 0.5).

Conclusion: We found no significant difference in the reflux burden in the distal esophagus/hypopharynx between the groups of symptomatic LPR patients with and without using 24h channel pH/impedance. Other factors, e.g. visceral hypersensitivity might play a role in the development of symptoms, even in patients with objectively established LPR.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Sliding hiatal hernia (HH) is a frequent diagnosis during upper endoscopy performed in patients with GERD-related symptoms. Recently, high resolution manometry (HRM) allowed an accurate evaluation of the esophageal-gastric junction (EGJ) and its sub-types (Chicago Classification V3.0; CCV3). Few data are available comparing the diagnostic accuracy of HRM and UE to detect HH.

Aims & Methods: The aim of this study was to compare the prevalence of HH obtained with UE and HRM and to determine the role of this finding by diagnosing gastroesophageal reflux disease (GERD) on the basis of impedance and pH (MII-pH) monitoring. We enrolled consecutive patients with heartburn and HH diagnosed with UE. After UE, all patients underwent HRM and MII-pH to investigate GERD. All tests were performed previous a 20-day wash-out from proton pump inhibitors. Erosive esophagitis (ER) was diagnosed according to Los Angeles Classification, and HH was diagnosed when the separation between the squamo-columnar junction and the diaphragmatic impression was greater than 2 cm. Patients with achalasia or major disorders of peristalsis or previous surgery were excluded. MII-pH monitoring allowed to subgroup patients with non-erosive GERD in: NERD (normal AET), AET (%) 7.7.

Introduction: In patients with symptoms suggestive of gastroesophageal reflux disease (GERD) candidate to anti-reflux surgery or in those refractory to medical therapy, it is recommended to perform function tests in order to objectively diagnose GERD. Esophageal manometry is currently considered the gold standard method to assess esophageal motility. However, it has been shown limited capability to diagnose GERD. With the advent of high-resolution manometry (HRM), new metrics have been developed to investigate esophageal motor function, esophagogastric junction (EGJ) morphology and their function. In particular, the antireflux barrier function of EGJ can now be assessed evaluating the contraction integral of the EGJ.

Aims & Methods: Our aim was to assess the differences in terms of HRM characteristics between patients with typical reflux symptoms with GERD and those with functional heartburn (FH), classified by means of upper GI endoscopy and impedance-pH (MII-pH) monitoring off-medication. We also aimed to develop a predictive model for distinguishing FH from GERD by using the prevalence of these HRM features. Consecutive patients with heartburn and/or regurgitation and a recent endoscopic assessment were enrolled. All patients underwent HRM to assess the EGJ and 10 single water swallows to evaluate esophageal peristalsis and EGJ function and one multiphase swallow (MRS). The tracings were analyzed according to the Chicago Classification 3.0. EGJ pressure, EGJ contractile integral (EGJ-CI), EGJ morphology, mean and peak distal contractile integral (DCI). MRS DCI/mean DCI ratio and motility pattern were measured. Moreover, all patients underwent MII-pH off-thrapy. We measured the esophageal acid exposure time (AET), number of total impedance reflux episodes and symptoms association analysis using both symptom association probability (SAP if >95%) and symptom index (SI if <50%). GERD was diagnosed in case of one or more abnormal parameters at MII-pH. To analyze the differences between patients with MII-pH positive and negative for GERD, Mann-Whitney’s U test for continuous variables was used and significance was set at P < 0.05. A multivariate logistic regression analysis was then carried out to identify factors independently associated with MII-pH positivity for GERD, significance settled at P < 0.05. According to Hosmer’s purposeful selection of covariates on automated predictive model, based on HRM variables was built by logistic regression analysis. The model was tested for discriminative performance by computing the area under ROC curve (AUROC), and calibration was assessed by Hosmer-Lemeshow goodness-of-fit test. The bootstrap re-sampling method was used to evaluate the internal validity of the model and to correct for over-fitting.

Results: Overall, 68 patients (39 F/29 M, median age 42.3) underwent HRM and MII-pH. HRM findings stratified according to MII-pH positivity for GERD are provided in Table 1. At univariate analysis, statistical differences were found in EGJ pressure, EGJ-CI, mean DCI and MRS DCI/mean DCI ratio between GERD and FH. Based on logistic regression analysis and according to Hosmer’s purposeful selection of covariates, we developed a predictive model which ultimately encompassed five HRM variables, the EGJ pressure (OR 1.614, 95% CI 0.993–2.895) and EGJ-CI (OR 0.952, 95% CI 0.913–0.985). The model had a fair discriminative performance (AUROC = 0.798, 95% CI 0.650–0.934) between MII-pH positivity and negativity for GERD and was well calibrated according to Hosmer-Lemeshow goodness-of-fit test (p = 0.769). The internal validation of the model by bootstrap method showed AUROC = 0.779. Considering that the predicted cut-off of MII-pH for GERD was 0.5, the model, which maximized sensitivity and specificity (i.e. 67.4%), sensitivity and specificity of the predictive model in predicting GERD against FH were 80.8% and 76.2%, respectively.

Introduction: Randomized controlled trials report about 30% of GORD patients complain of bothersome remaining symptoms (heartburn, regurgitation) despite PPI. The LOPA (Lost Patients) Study of 333 GORD patients seen in general practice revealed 46% of patients experienced heartburn or regurgitation symptoms at least twice per week despite PPI. A total of 20% were dissatisfied with their treatment. Few patients had received specific GORD diagnostics or recommended other options (<10%).

Aims & Methods: The LOPA II study is a prospective, multicenter, observational study conducted in 17 general practice clinics. Patients with chronic GORD, taking PPI therapy for at least 1 year, and not satisfied with their treatment were asked to complete a questionnaire. Patients were asked the duration of their PPI therapy, satisfaction with their current condition, frequency of symptoms in the last week, whether they had previously received diagnostic evaluation or surgical consult related to GORD, whether they plan to consult a reflux specialist, all common anti-reflux medications, and reasons for dissatisfaction with their current medication treatment. “Lost Patients” were defined as those with a satisfaction score of 1 or 2 on a 5-point Likert scale (1: very dissatisfied; 2: dissatisfied; 3: neutral; 4: satisfied; 5: very satisfied). GerdQ score at least 8, and have not received specialized GORD diagnostics.

Results: 310 consecutive patient responses were collected within one year. Patients suffered from GORD an average of 9.6 years and prescribed PPI therapy for an average duration of 7.9 years. 78% were dissatisfied or very dissatisfied on the GerdQ score at the last visit (score of 1 or 2). 83% reported heartburn or regurgitation at least 2 days in the prior week (53% 4-7 days). 94% reported additional medication other than their prescribed PPI at least 2 days per week (34% 4-7 days). In patients dissatisfied on PPI, most cited insufficient symptom control for dissatisfaction (31% cited heartburn). 31% cited concerns with long-term use of drugs and 27% the need for daily medication. 92% of patients had an upper endoscopy, 12% had a pH-metry, 7% manometry, and 9% received prior surgical consult for GORD. Of patients who never received surgery, 48% were not aware of any surgical anti-reflux methods, 25% were concerned about possible complications, 18% felt their condition is not serious enough, 6% were recommended against anti-reflux procedure or therapy by their doctors.

Conclusion: Chronic GORD patients who are dissatisfied with their PPI therapy are rarely offered specialized GORD diagnostic procedures or treatment alternatives. Half of the patients took medication in addition to PPI to control their symptoms. In addition to persistent symptoms, concerns of long-term PPI use and burden of daily medication play a role in patient dissatisfaction with PPI therapy.

Introduction: Gastroesophageal reflux disease (GERD) is a common disorder commonly overlapping with several functional or allergic immunological disorders, whose symptoms are related to food intake. Awareness of health care costs and potential side effects of long-term acid suppression has increased the attention in non-pharmacologic treatment for alleviating reflux symptoms.

Aims & Methods: The aim of our prospective study was to evaluate the non-inferiority of a controlled diet compared to antacid compounds in relieving reflux symptoms in patients suffering from mild GERD. We considered 500 consecutive patients referred to the Division of Allergy and Clinical Immunology of Azienda ISPIC-San Martino di Genua for gastrointestinal symptoms associated to food intake. Patients with a clinical and instrumental diagnosis of food allergy, food intolerance, Irritable Bowel Syndrome (IBS) and Small intestinal Bacterial Overgrowth (SIBO) were excluded. Patients with a diagnosis of GERD based on clinical history represented our study population. Basal metabolic rate and calorie needs of patients was assessed by means of a validated questionnaire (RDQ administered at baseline, after antacids course (1 month) and after diet (1 month)). A treatment was considered effective if a 50% improvement in the symptomatic score was recorded.

Results: After investigations 261 patients out of 500 (52.2%) were included because of IBS (140), celiac disease (6), nickel allergy (25), lactose intolerance (60), SIBO (10), and allergy to other foods (20). The remaining 239 patients were diagnosed as affected by mild GERD (median age 47; BMI 24; 132F/107M; no erosive reflux disease) and were included in our interventional prospective study. At the end of elimination diet on the RDQ score, patients achieved a 50% improvement in their symptoms, based on their calories need. Efficacy of the two treatments was evaluated by means of a validated symptom questionnaire (RDQ administered at baseline, after antacids course (1 month) and after diet (1 month)). A treatment was considered effective if a 50% improvement in the symptomatic score was recorded.

2Evangelisches Krankenhaus Herne, Herne/Germany
3Aarhus University Hospital, Aarhus/Denmark

Conclusion: A structured diet regimen, tailored on the metabolic need of the patients, appears more effective than antacids alone in relieving reflux symptoms in patients with mild GERD. Further controlled studies are mandatory to confirm these preliminary data.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1858 ANTI-REFLUX MUCOSECTOMY (ARMS) FOR REFRAC'TORY GERD—INITIAL CLINICAL EXPERIENCE

A. Bapaye1, M. R. Mahadik1, R. Pujari1, T. K. Bharadwaj1, S. G. Vare1, N. Dubale1, S. Date2, J. A. Bapaye1
1Shrivardhan Desai Center For Digestive Disorders, Deenanath Mangeshkar Hospital Digestive Diseases & Endoscopy, Pune/India

Contact E-mail Address: amolbapaye@gmail.com

Introduction: It remains the mainstay for treatment of gastroesophageal reflux disease (GERD), however laparoscopic fundoplication is recommended in refractory patients. Various endoscopic methods have been attempted with variable success. Anti-reflux mucosectomy (ARMS) is a recently introduced option for temporary palliation of refractory patients.

Aims & Methods: The current study describes initial clinical experience of ARMS. Data from a prospectively maintained database of consecutive patients undergoing ARMS for refractory GERD was abstracted. Inclusion criteria—

- Duration of disease > 3 years
- Prior PPI usage > 6 months

- Presence of hiatus hernia > 3 cm on EGD and normal esophageal body motility on high-resolution manometry (HRM). Exclusions—hiatus hernia > 3 cm, poor or absent esophageal body motility, poor-risk candidates for anesthesia or invasive procedure.

- Pre-ARM mucosal healing (EYD) to assess Hill's grade of flap valve, esophageal mucosectomy, 24-hour ambulatory esophageal pH studies, PPI requirement and GERD-HRQL questionnaire.

Results: N = 15, duration—12 months. Mean age 40.8 years (Range 22-69): M: F = 11: 4. HI: RM-normal esophageal body motility in all. Mean GERD-HRQL score improved significantly from pre-ARMS 4.04 to post-ARMS 7.6 (p < 0.05). Mean Deemester score decreased from 85.8 pre-ARMS to 5.9 post-ARMS (p < 0.001). Mean Hill's valve grade decreased from pre-ARMS 2.8: post-ARMS 1.6 (p < 0.05). Three AE's—mucosal injury—2 (treated by endocylps), grade I dysphagia—1. At 4 weeks follow up, 11/15 patients (73.3%) had discontinued PPI, 4/11 (36.3%) had > 50% reduction in PPI dosage.

Conclusion: Current study shows impressive short-term results for ARMS. Significant symptom resolution and acid exposure reduction occurred in all patients. 100% patients could discontinue or reduce PPI usage. AE's were minor. Larger randomized studies with longer term follow up are recommended.

P1859 EFFECTIVENESS OF SELECTIVE SEROTONIN REUPTAKE INHIBITORS IN PATIENTS WITH NON-EROSIVE REFUX DISEASE: A RANDOMIZED TRIAL

I. Birichenko, N. Bondarenko, A. Svintsitsky
National Medical University, Kyiv/Ukraine

Contact E-mail Address: doctor.gastro@yahoo.com

Introduction: To date a large quantity of 5-HT1 receptors were found in esophageal mucosa that on an important role of this neuromediator in pathogenesis of non-erosive reflux disease (NERD) and gastroesophageal reflux disease (GERD). Antidepressants seems to be effective, as they have central and psychologic effect and show a placebo response. Objective: To compare the antidepressant effect with placebo in patients suffering from NERD. Material and Methods: 156 patients were randomized into two groups: patients of the first group received PPI (pantoprazole) 40 mg once a day plus escitalopram as follows: initial dose - 5 mg/day for the first two weeks of treatment; depending on individual response the dose was increased to 10 mg/day. The second group received only PPI 40 mg once a day. Data were collected at visits at baseline, 6, 12, and 24 months. In addition, patients were divided into two subgroups: patients of the first group received PPI (pantoprazole) 40 mg once a day plus antipsychotic drug with comparison with PPI for patients with NERD. Methods: In this randomized superiority study adult patients (18–65 years) with confirmed diagnosis of NERD were eligible to participate. Exclusion criteria: the presence of “red flag” signs and other comorbidities that could explain the symptoms. Patients were assessed in clinically and psychologic way. Psychologic testing was done using validated short-form version of the depression anxiety stress scales (DASS-21) and Toronto alexithymia scale (TAS). All the patients were randomly divided into two arms: patients of the first arm received PPI (pantoprazole) 40 mg once a day plus escitalopram as follows: initial dose - 5 mg/day for the first two weeks of treatment; depending on individual response the dose was increased to 10 mg/day. The second arm received only PPI 40 mg once a day. Patients were assessed on the 4th and 8th week of treatment. The superiority was shown if there was more lasting decrease in heartburn severity, reduced anxiety (A), depression (D) and alexithymia levels. Results: Of 75 randomized patients 39 were allocated to the first arm and 36 to the second one. The groups were statistically comparable in age and sex. Treatment results showed reduction of heartburn severity in both groups on the 8th week, however more significant in the first group (1group-89.7%, 2group-61.1%, P < 0.001). Also both A and D levels were much lower in the first group compared to the second one (P < 0.001). Comparing the levels alexithymia between two arms on the 8th week after the initiation of treatment we found that alexithymia type of personality prevailed in patients that received PPI only (P < 0.001).

Conclusion: The combination of PPI plus antidepressant demonstrates superiority to PPI therapy alone, showing more lasting symptoms regression and improved psychological and emotional condition of patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1860 QUALITY OF ESOPHAGEAL MUCOSAL HEALING IN EROSI VE REFUX DISEASE: A RANDOMIZED COMPARATIVE TRIAL WITH LANSOPRAZOLE ALONE OR COMBINED WITH REBAMIPIDE

Contact E-mail Address: post22@daum.net

Introduction: The quality of histologic healing or inflammatory cytokine-related change in erosive reflux disease (ERD) had been verified in few studies. The aim of the current study is to evaluate the quality of histologic healing in patients with lower gastro intestinal motility.

Aims & Methods: We conducted double-blinded comparative study to assess histologic, histologic quality of mucosal healing in ERD, following 4-week medical treatment with lansoprazole combined with rebamipide or not. The patients with ERD in modified LA classification grade A-D were enrolled via four referral institutes, regardless of GERD related symptoms. The enrolled subjects were randomly allocated to ingest 30 mg lansoprazole alone or ingest lansoprazole 30 mg with rebamipide 100 mg three times in a day for 4 weeks. In addition, follow up endoscopy was performed to assess endoscopic healing (regressed into minimal change or normal), and to obtain esophageal biopsy specimens (at 3 o’clock direction, 3 cm proximal area from squamocolumnar junction). Additional tissue samples were obtained to measure tissue inflammatory cytokines (IL-8, PAF, at 9 o’clock direction, 3 cm proximal area from squamocolumnar junction).

Results: Overall 109 patients were enrolled and randomly allocated to lansoprazole group (N = 54) or combination group (N = 55). Demographic data, smoking or drinking habits were not significantly different between both groups. The endoscopic healing rate at 4-week was not different significantly (75.0% vs 89.7%, P = 0.686, Difference 3.95%, 95%CI [-15.24, 23.13]). The histologic changes of basal layer thickness, intraepithelial infiltration of inflammatory cells (eosinophils, neutrophils) were normalized in subsets of patients regardless of the fate of endoscopic healing, and were not different in both groups. In contrast, papillary length, intraepithelial infiltration of T lymphocyte and the dilated intercellular space (DIS) was normalized significantly in endoscopically
healed combination group. When both group were pooled in a group (proton pump inhibitor administration), the papillary length and DIS was significantly improved in endoscopically healed patients. Tissue level of IL-8, but not Lyso-PAF, was significantly decreased in lansoprazole alone group.

**Conclusion:** Adjunctive therapy of rehampidie to lansoprazole failed to reveal additional esophageal healing effect by endoscopic or histologic evaluation. Papillary length and DIS was more evident parameter of quality of mucosal healing in patient of erosive reflux disease treated with proton pump inhibitor. Long term follow-up data are needed on whether these histologic parameters of mucosal healing can help predict the prognosis of gastroesophageal reflux disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Radiofrequency ablation (RFA) with or without endoscopic resection (ER) is an established endoscopic treatment of early Barrett’s esophagus (BE) related neoplasia (BORN). After successful treatment, follow-up is still required as recurrences may occur. The aim of this prospective single-center case series was to assess the long-term efficacy of endoscopic treatment (RFA with or without ER) for BORN. Main outcomes were complete remission of neoplasia (CR-N) and intestinal metaplasia (CR-IM) and recurrence of IM (R-IM) and neoplasia (R-N).

**Aims & Methods:** A total of 99 consecutive patients with BORN have been treated since 2009. Of those, 87 patients (75 men, mean age 64, range 22-91) completed the treatment and were included into this analysis. The patients had been followed up during 296 patient-years (mean 3.4 years, range 0.5-6). Thirty-three patients were diagnosed with adenocarcinoma (35%), 24 patients with high-grade dysplasia (28%) and 30 patients with low-grade dysplasia (34%). Prior to RFA, ER for visible lesions was performed in 57 patients (66%). Mean length of the Barrett’s esophagus (BE) was 4.6 cm (range 1.13 cm). At treatment, the patients have undergone regular endoscopic surveillance with multiple biopsies. Remission: Complete remission of IM (CR-IM) and complete remission of neoplasia (CR-N) were achieved in 54 patients (54.3%, 54.3–74.5) and 82 patients (98.8%; 95% CI 92.8-99.9), respectively. All patients who did not achieve CR-IM had macroscopic normal neo-Z-line without visible abnormality. A complete remission of neo-Z-line was achieved in one patient where microscopic eradication of BE was not possible due to giant hiatal hernia and who was referred for anti-reflux surgery. During the follow-up, 18 patients (13.3%, 18/54 pts) experienced a recurrence of IM and 3 patients (2.5%, 3/120 pts) had a recurrence of neoplasia (LGD 2x, HGD 1x). We did not encounter any patient with a subsquamous neoplasia. All recurrences occurred at the level of neo-Z-line and 6 patients with recurrent IM had also macroscopic recurrence of BE. A total of 13 patients underwent endoscopic retreatment: 7x probe-based re-RFA, 5x esoph agen plasma coagulation (APC) and 1x ER. After retreatment, we achieved 100% CR-N and 54% (7/13 pts) CR-IM. Treatment-related adverse events occurred in 22 patients (25%) vs 12 chest pain and 10x stricture. Two patients with a stricture had to undergo surgical resection - first patient due to perforation during balloon dilatation of a post-RFA stricture, the second because of refractory post-RFA stricture after 20 sessions of dilatation.

**Conclusion:** RFA combined with ER for patients with BORN achieves a high success rate of CR-N with durable results. Recurrence of IM occurs in approxi- mately one-third of patients and supports continuous endoscopic surveillance even after complete eradication. Nonetheless, the majority of recurrent IM occurs within a normally appearing neo-Z-line with questionable clinical relevance.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P1863 SEVEN-YEAR PROSPECTIVE FOLLOW-UP RESULTS OF RADIOFREQUENCY ABLATION FOR BARRETT’S ESOPHAGUS WITH HIGH-GRADE DysPLASia AND EARLY CANCER

K. Belghazi1, B. L.A.m. Weusten1, S. L. Meijer2, J. J. G.h.m. Bergman3, R. E. Pouw4
1Gastroenterology And Hepatology, Academic Medical Center, Amsterdam/Netherlands
2Pathology, Academic Medical Center, Amsterdam/Netherlands

Contact E-mail Address: k.belghazi@amc.uva.nl

Introduction: Radiofrequency ablation (RFA) of Barrett’s oesophagus (BE), with or without prior endoscopic resection (ER) of focal lesions, results in complete eradication of intestinal metaplasia (CE-IM) and complete eradication of neoplasia in 96–100% respectively.

Aims & Methods: The aim of this study was to assess if the excellent results after successful RFA for BE with high-grade dysplasia (HGD) or early cancer (EC) are sustained on the long term. We screened all patients treated with RFA, and ER for Barrett’s oesophagus, for BE with histologically proven HGD, EC, which were previously enrolled in 5 consecutive cohort studies in a tertiary referral center in the Netherlands. All patients who had reached endoscopic and histologically confirmed CE-neo and CE-IM after RFA were included for evaluation of long-term follow-up (FU). Primary outcome: recurrence of HGD-EC, recurrence of endoscopically visible Barrett’s mucosa. Secondary outcomes: Burden Barrett’s glands, IM in biopsies obtained distant to a normal appearing neo squamous-columnar junction (neo-SCJ); need for retreatment; sustained CE-IM and CE-neo at last FU.

Results: 68 patients were included (55 men, median 64 yrs, median BE C5M6). In 53/68 patients ER was performed (worst pathology: low-grade dysplasia (LGD) (n = 34), HGD (n = 19), EC (n = 9), LGD and HGD (n = 2)). Worst pathology pre-RFA (after ER) was: non-dysplastic IM (n = 9), LGD (n = 27), HGD (n = 32). Median FU was 58 months (IQR 58–96) with a median of 7 FU endoscopies per patient. Recurrence of HGD-EC was found in 2 patients (3%): one patient with a T1m2 EAC 3 cm above the neo-SCJ after 44 months and one patient had a visible lesion at the neo-SCJ with HGD after 22 months, both were treated successfully with ER. Recurrence of endoscopically visible Barrett’s mucosa was seen in 22 patients (32%) after a median of 20 months: small Barrett island (n = 10), BE tongue (n = 6), CE neo (n = 5), circumferential BE ≤2 cm (n = 2). In 3 patients Buried Barrett’s glands were detected (overall 3/448 FU endoscopies, 0.7%). IM in a normal appearing neo-SCJ was found in 19 patients (28%), and this was not reproduced in 84%. In 2 patients LGD without IM was found in the neo-SCJ. Eleven patients required retreatment: APEC for small areas of visible Barrett’s mucosa (n = 5), six patients had additional ER (ex 1x T1m2, 1x HGD, 2x LGD, 2x visible Barrett’s islands), RFA for LGD without IM in the neo-SCJ (n = 1). CE-neo and CE-IM (excluding IM in the neo-z-line) at the last FU examination was found in 23% of patients, however it was confined to small islands or tongues ≤1 cm in the vast majority of patients.

Conclusion: With 7-years of follow-up, this study presents the longest published follow-up data on RFA for BE with HGD-EC to date. Our long-term outcomes show that after successful RFA recurrence of HGD-EC is rare (3%). Recurrence of endoscopically visible BE was found in 32% of patients, however it was confined to small islands or tongues ≤1 cm in the vast majority of patients.

All other authors have declared no conflicts of interest.

P1864 ACTION IS REQUIRED TO IMPROVE UNDERSTANDING AND REDUCE ANXIETY LEVELS AMONGST PATIENTS IN THE BARRETT’S SURVEILLANCE PROGRAMME

2Gastroenterology, Homerton University Hospital, NHS Foundation Trust, London/United Kingdom

Contact E-mail Address: vsehgal@doctors.org.uk

Introduction: Barrett’s oesophagus (BE) is the only identifiable pre-cursor condition for oesophageal adenocarcinoma. Endoscopic surveillance is performed in BE to detect dysplasia as it is likely to be amenable to curative therapy. There is debate as to whether a diagnosis of BE has a negative impact on the quality of life of patients. To our knowledge, no guidance exists on the counselling of patients who are understandably anxious about their diagnosis. Further efforts need to be made to address this and help empower a group of patients who are understandably anxious about their diagnosis.

Aims & Methods: We aimed to study the association between circulating inflammatory and metabolic biomarkers and Barrett’s esophagus (BE) are scant and conflicting.

Table 1: A 14-point based questionnaire which was used to check the understanding amongst patients with Barrett’s Oesophagus (BE–Barrett’s Oesophagus, OAC–Oesophageal adenocarcinoma PPI: Proton pump inhibitor).

3Boston University Medical Center and Boston University School of Medicine, Boston/United States of America/MA

Contact E-mail Address: manol.jovani@email.harvard.edu

Introduction: Data on the association between inflammatory and metabolic biomarkers and Barrett’s esophagus (BE) are scant and conflicting.

Aims & Methods: We aimed to study the association between circulating inflammatory biomarkers (interleukin-6 [IL-6], high-resolution C-reactive protein [hCRP], intra-cellular adhesion molecule [ICAM], tumor necrosis factor receptor-2 [TNF-R2]) and metabolic biomarkers (leptin, adiponectin, C-peptide, insulin-like growth factor 1 [IGF-1], and insulin-like growth factor binding proteins -1, -2, and -3 [IGFBP1, -2 and -3]) with BE. This was a case-control study, nested within two female-only prospective cohort studies (Nurses’ Health Study 1 and 2) and one male-only prospective cohort (Health Professional Follow-up Study). Participants of provided biennial detailed information on demographic, lifestyle, dietary and medical factors, including endoscopy use. Overall, 80,437 participants completed in these cohorts provided a prediagnostic blood specimen between 1989 and 1995. Among these participants, through 2012, we identified 283 cases of BE (163 females and 120 males). Two study physicians, blinded to biomarkers results, reviewed the medical records of patients reporting BE. We matched BE participants to reference, and assessed linear trend across exposure categories using the median of each quintile as a continuous variable.

Results: In women, plasma adiponectin was significantly associated with BE (p<0.001). When compared to the lowest quintile (Q1), the multivariate odds ratio (OR) for the highest quintile (Q5) of adiponectin was 0.39 (95%CI 0.17, 0.88). This association was not materially altered after further adjustment.
P1866 OUTCOMES OF TREATMENT OF PATIENTS WITH EARLY-STAGE ADENOCARCINOMA OF THE ESOPHAGUS WITH INCIDENTAL SUBMUCOSAL INVASION, RETROSPECTIVE ANALYSIS OF 19 CASES FROM A TERTIARY REFERRAL CENTER IN THE UK

Contact E-mail Address: xenobab@yahoo.it

Introduction: Endoscopic mucosal resection (EMR) is an established diagnostic and treatment tool in the management of Barrett’s oesophagus (BO) with early neoplasia. The goal is to improve the survival of patients with BO, in whom the EMR’s histologic assessment identifies early-stage adenocarcinoma of the oesophagus with incident submucosal invasion (pT1b sm1).

Aims & Methods: We have conducted a retrospective analysis using our electronic database for endoscopic procedures for patients with BO, who underwent EMR from October 2010 to December 2016. We investigated the size of the EMRs, the complication rates of the EMRs, the histological features and the resection margins of the EMR specimens and also the outcomes with the mortality.

Results: A total of 99 patients underwent 134 EMR procedures, and the histology identified early adenocarcinoma with incident invasion of the submucosa in 25 patients. 23 (92%) were male, the mean age at the EMR was 71 years (SD: 8.1). In all 25 EMRs 7 (28%) patients had a single piece, 7 (28%) patients had a piece 2, 7 (28%) patients piece 3 and 4 (16%) patients 4 piece EMR. The median length of the circumferential and maximum extent of the BO segments were 2 and 5 cm respectively (interquartile range (IQR) 2–4). We observed 6 (24%) intra-proce-dural bleedings and 2 (8%) patient needed admissions with post procedural bleeding and 1 (4%) of them required transfusion. Stricture was endoscopically detectable but not causing any symptoms in 1 (4%) patient and another patient (4%) had slight dysphagia post EMR, but did not need dilatation. Histology showed lymphovascular invasion in 6 (25%) patients and vascular invasion in 1 (4%) patient. Of all 25 early adenocarcinomas 7 (28%) were reported as poorly differentiated, 11 (44%) as moderately differentiated and 3 (12%) as well differentiated. In 4 (16%) cases differentiation was not reported. All resection margins were reported as being clear from dysplasia or cancer. There were 7 (28%) cases, radial resection margins were reported with dysplasia in 3 (12%) cases and with cancer in 15 (60%) cases, but this included the multiple piece EMRs. The deep margin was reported as being clear in 18 (72%) cases, with dysplasia in 1 (4%) case and with cancer in 6 (24%) cases. There were 14 (50%) patients with carcinoma on the radial and/or deep margin of the EMR specimen, of these patients 9 (60%) had oesophagectomy and in the histologic assessment of these specimens, lymph node involvement was observed in 2 cases (22.2% of all oesophagectomies and 9.5% of all surviving and currently cancer-free patients). There was no residual cancer in 3 (33.3%) of the surgical specimens. Radical radio-chemotherapy was given in 1 (6.7%) patient and 3 (33.3%) patients did not have radical treatment for clinical reasons. There were 10 (40%) patients without cancer invasion of the EMR resection margins, of these 4 (40%) had oesophagectomy and 1 (10%) radical radio-chemotherapy. The histologic assessment of these surgical specimens showed residual cancer in 3 (30%) cases and high-grade dysplasia in 1 (10%) case. Of the 25 patients 5 (20%) met the criteria and had radio frequency ablation of the residual Barrett’s oesophagus. Of the 13 (52%) patients who have had oesophagectomy 1 (7.7%) patient died of the deterioration precipitated by the oesophagectomy, and sadly in this case the oesophagectomy specimen did not show residual cancer. Of the 12 (48%) patients who had not had oesophagectomy 3 (25%) died since their EMR, 1 (8.3%) of cardiac arrest, 1 (8.3%) of chronic obstructive pulmonary disease and 1 (8.3%) of advanced oesophageal cancer, 18 months after the EMR, and the 9 (75%) surviving patient are all cancer free on follow up investigations, one after radical chemo/radiotherapy. The median survival of all 21 (84%) patients currently alive is 25 months (range: 2–68 months; SD: 22.2).

Conclusion: In this retrospective analysis we have found that the clinical outcomes are very difficult to predict for patients with early adenocarcinoma and incident invasion of the submucosa. Clinical decision making remains very challenging and has to be individualised for all patient, until further in depth studies gives us more useful prognostic factors.

Contact E-mail Address: shannomehan@surgery.cuhk.edu.hk

Results: From July 2015 to March 2017, forty-four patients were included in the study. Seventeen of the forty-four (38.6%) patients had histological confirmed cancer of the esophagus. There were sixteen patients who had normal finding and nine patients with esophagitis. The positive predictive value for malignancy (ECA 4 and 5) was 89.5%; the negative predictive value was 100%. Sensitivity was 100% and specificity was 92.6%. Similar findings were noted with IPCL on magnifying NBI. The positive predictive value for malignancy (IPCL 4 and 5) was 100%; the negative predictive value was 100%. Sensitivity was also similar at 100% and specificity 92.6% respectively. To compare the diagnostic accuracy of endocystoscopy and magnifying NBI, the McNemar test was performed. The McNemar chi-squared statistic is NaN, and the McNemar chi-squared statistic with continuity correction 0.5 is infinity, meaning that the two tests have the same diagnostic accuracy.

Conclusion: Endocystoscopy had a high positive predictive value and specificity for esophageal malignancy. Its diagnostic accuracy was comparable with magnifying NBI. It may be helpful as an adjunct for better characterization of esophageal lesions. However, further studies on interobserver variability is required.

P1868 CLINICAL OUTCOMES OF ENDOSCOPIC RESECTION FOR ACHALASIA-ASSOCIATED SUPERFICIAL ESOPHAGEAL CANCER

Gastroenterology, Showa University Koto-Toyosu Hospital, Tokyo/Japan

Contact E-mail Address: nishikawab@med.showa-u.ac.jp

Introduction: Esophageal achalasia is considered to be a high-risk factor for superficial esophageal cancer. But there are few reports of endoscopic resection for this cancer, and the outcome is unclear. In our hospital, we have performed over 1300 Per-Oral Endoscopic Myotomy procedures for esophageal achalasia and related airway aspiration use. We aim to evaluate clinicopathological findings and outcomes of endoscopic resection for 10 achalasia-associated superficial esophageal cancer. This is a case series study at our hospital. Between August 2010 and February 2017, 10 achalasia patients with superficial esophageal cancer underwent endoscopic resection. We performed in all cases upper gastrointestinal endoscopy, using lugeo’s solution and narrow band imaging, and we included all patients that had early cancers that were eligible for endoscopic resection in this series. At 2 and 12 months after treatment, we performed follow-up endo-scopy in all cases. After this, we performed long-term endoscopic follow-up every year. In the case that the tumor invasion depth is to the muscularis mucosa(MM), we performed endoscopic resection for all cases and report relatively long-term outcome. Aims & Methods: We aimed to evaluate clinicopathological findings and outcomes of endoscopic resection for 10 achalasia-associated superficial esophageal cancer. We performed endoscopic resection for all cases and report relatively long-term outcome. Aims & Methods: We aimed to evaluate clinicopathological findings and outcomes of endoscopic resection for 10 achalasia-associated superficial esophageal cancer. We performed a retrospective analysis of 19 cases from a tertiary referral center in the UK.

Results: There were 6 men and 4 women and their average age was 61.7 years. 8 patients were diagnosed with lesions before POEM. We performed endoscopic submucosal dissection (ESD) and EMR in all cases after POEM. None of the patients had a severe adverse event. The mean tumor diameter was 30mm (range: 5–80mm). The pathological diagnosis was 8 SCC, 2 high grade intraepithelial neoplasia. Out of the SCC cases, 7 were found with superficial lesion with depth of Tis-EP to T1a-LPM, and 1 with depth of T1a-MM, without lymphatic invasion(T0) or venous invasion(V0). Follow-up surveillance mean term was 32 months (range: 1–
P1869 USEFULNESS OF TRIAMCINOLONE INJECTION TO PREVENT STRicture AFTER SEMIFORMALIN ISOLAR DISSECTION (ESD) FOR PHARYNGEAL SCC

T. Oyama1, A. Takahashi2
1Endoscopy, Saku Central Hospital Advanced Care Center, Nagano/Japan

Contact E-mail Address: oyama@cerc.ocn.ne.jp

Introduction: ESD is a standard treatment for superficial esophageal cancer in Japan. Stricture is one of important complications of esophageal ESD, and it makes quality of life of the patient worse. Usefulness of Triamcinolone (TA) injection to prevent stricture after semi-circumferential ESD has been reported. However, usefulness of TA injection after circumferential esophageal ESD is still unclear.

Aims & Methods: The aim of this study is to clarify the usefulness of triamcinolone injection to prevent stricture after circumferential ESD. A total of forty-four patients treated by circumferential esophageal ESD from 2004 to 2016 in Saku Central Hospital Advanced Care Center were enrolled in this retrospective study. The patients treated from 2004 to 2009 were followed up without TA injection (Non-TA group). TA injection was performed for the patients after 2009 (TA group). The number of patient in Non-TA and TA group was 16 and 28, respectively. Age of both groups was 65 (30–83) and 61 (42–82) years old. The length of circumferential resection was 75 (50–100) and 76 (55–111) mm, respectively. There was no significant difference in the background of both groups. Fifty mg TA was injected into submucosal layer just after ESD, and TA injection was repeated in two-weeks interval. Fifteen mm endoscopic balloon dilatation (EBD) was performed when the scope couldn’t pass the ESD ulcer. The primary endpoint was the number of balloon dilatation. The secondary endpoints were duration from ESD to ulcer healing, and the difference between Barrett’s esophagus adenocarcinoma (EAC) and squamous cell carcinoma (SCC).

Results: 1. Number of EBD in Non-TA and TA group were 20 (13–33) and 5.1 (0–23), respectively (p = 0.01). Duration from ESD to ulcer healing were 10 (3–25) days, and 11 days (p = 0.07). Complications, (p = 0.047) 3. Mortality rate due to ESD was 6.3% (1/16) and 3.6% (1/28). Both patients were treated by conservative therapy. 4. Difference between EAC and SCC: There were four EAC and 24 SCC patients in TA group. The number of EBD were 5.3 (5–11) and 4.4 (3–11), respectively. Duration of ulcer healing were 10 (6–14) and 6.5 (5–24), respectively. There was no significant difference between two groups.

Conclusion: Triamcinolone injection is safe and effective treatment to prevent stricture after circumferential ESD, not only for SCC but also for EAC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1871 SHOULD ANTIITHROMBOTIC AGENTS BE DISCONTINUED PRIOR TO ESOPHAGEAL ENDOSCOPIC SUBMUCOSAL DISSECTION?

Division Of Endoscopy, Shizuka Cancer Center, Shizuka/Japan

Contact E-mail Address: n.kawata@schr.jp

Introduction: Endoscopic submucosal dissection (ESD) has been widely performed as a minimally invasive treatment for superficial esophageal squamous cell neoplasms (ESCs) in Japan and Asian countries. According to the current guidelines[1], ESD is classified as a high bleeding risk procedure. However, these guidelines have not been fully validated.

Aims & Methods: The aim of this study was to identify the risk factors of bleeding associated with esophageal ESD, and to clarify whether antithrombotic agents should be discontinued before ESD. A forensic pathological review was conducted for 413 patients who underwent ESD at our hospital from January 2013 to October 2016 were analyzed in this retrospective study. ESD was performed using an IT knife (Olympus, Tokyo, Japan). Hemostatic forceps (Coagrasper, Olympus, Tokyo, Japan) were used when hemostasis during ESD proved difficult with the IT knife nano. Longer hemostatic time during ESD was defined as more than 120 secs required for hemostasis with hemostatic forceps. We analyzed the relationship between risk factors for longer hemostatic time during ESD and the following factors using univariate and multivariate analyses: age (<75 or ≥75 years), sex, body mass index (<25 or ≥25), treatment for synchronous multiple ESCNs, previous radiation therapy, antithrombotic agents, lesion location (upper or middle or lower), lesion size (<2 cm or ≥2 cm), lesion circumferential extent (<1/3 or ≥1/3), and the endoscopist’s experience of esophageal ESD (<40 or ≥40 procedures).

Results: Twenty-nine ESCNs (6%) were treated by ESD without discontinuation of antithrombotic agents. Hemostatic forceps were used for 116 lesions (25%), median forceps use time was 73 secs (range: 8–120 secs), and the median number of forceps application during procedures was 2 (range: 1–9 times). Of these, 41 lesions (9%) met our definition for longer hemostatic time. Univariate analysis revealed that lesion size (≥2 cm), lesion circumference (≥3/4), and the endoscopist’s experience (≥60) were strongly associated with longer hemostasis time. Multivariate logistic regression analysis revealed that a lesion size ≥2 cm (OR 2.4 [95% CI 1.1–5.1], P = 0.02) was an independent risk factor for longer hemostatic time. Postoperative bleeding occurred 20 days after ESD in one patient (0.2%) receiving the continuous administration of warfarin and aspirin.

Conclusion: Our results suggest that continuous use of antithrombotic agents does not increase the risk of bleeding during esophageal ESD, and that postoperative bleeding was a rare occurrence. Discontinuation of antithrombotic agents may therefore not be necessary prior to esophageal ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: While definitive chemoradiotherapy (CRT) showed high efficacy for esophageal cancer (EEC), the potential contribution of curative endoscopic treatment of early EEC underwent endoscopic resection (ER) or endoscopic submucosal dissection (ESD). Based on histopathological staging, patients with ‘high-risk’ EEC have been referred for endoscopic treatment. Complete local remission in continued endoscopic treatment consisting of further sessions of ER and/or radiofrequency ablation if necessary. The patients have been followed up for a median of 39 months (range 2–156).

Results: Of 56 patients with ‘high-risk’ EEC underwent endoscopic treatment: 21 patients (41%) had T1a cancer with ‘high-risk’ features and 35 patients (59%) had T1b cancer with sm invasion (sm1: 15, sm2: 9, sm3: 11); 45 patients had adenocarcinoma (EAC), 11 patients had squamous carcinoma (SCC); 19 (34%) were referred for endoscopic treatment (all patients were treated with endoscopic submucosal dissection). Complete local remission (CLR) of neoplasia was achieved in 35/37 patients (95%). Two patients without CLR continued endoscopic therapy with palliative intent. Tumor generalization occurred in 2 patients (one of them achieved CLR 24 months after endoscopic treatment) (both patients had sm3 invasion, A+, L+) and these patients are undergoing oncological treatment. All remaining patients with CLR (n = 33) have experienced neither local relapse nor generalization. One patient had to undergo surgery due to endoscopic relapsed perforation. Tumor-free survival was 89% (CI 79–99%) in patients treated endoscopically and endoscopic related mortality was 0% (0/37). Among 19 patients who were referred for endoscopy, one patient presented with tumor generalization revealed during the operation. The remaining patients underwent esophagectomy; local residual of malignancy were present in 5/18 patients (28%). Lymph node (LN) metastases have not been detected in any patient among the 337 examined LNs. Surgery related mortality was 6% (1/18).

Conclusion: Endoscopic treatment provides long-term remission or cure in a considerable number of patients with ‘high-risk’ EEC and it may thus represent a valid alternative to surgery. Broadening of indications for radical endoscopic treatment of early EEC should be reconsidered.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI874 DIAGNOSTIC ACCURACY OF ENDOSCOPIC ULTRASONOGRAPHY FOR ESOPHAGEAL SUBMUCOSAL GLAND DUCT INVOLVEMENT ACCOMPANIED BY EARLY ESOPHAGEAL CANCER
Y. Jie, L. Ying
Digestive Department, The Affiliated Drum Tower Hospital, Nanjing University Medical School, Nanjing, Jiangsu Province, CH

Contact Email Address: 13770755008@126.com

Introduction: Normally, resided within the submucosal layer of esophagus, each submucosal glandular wall will culminate in a single duct. The esophageal submucosal gland ducts (ESMGDs) can traverse the subepithelial connective tissue and muscularis mucosa, and deliver the acinar secretions to the esophageal lumen. However, the clinicopathological features of the esophageal submucosal gland duct involvement (ESMGDI) and its precursor lesion have not been comprehensively evaluated so far, and the series study focusing on endoscopic features of this lesion has not been reported widely. Compared with the 1990s, the esophageal lesions presumed to originate from ESMGDs had been described constantly in various case reports. Currently, in addition to the gold standard of histology, almost no more useful modality could be applied to this lesion. In our study, we considered that the ESMGDDI had a correlation with early esophageal cancer, and we noted that the ESMGD DI had special features under the endoscopic ultrasonography (EUS). The typical ultrasonic images of EUS could help diagnose ESMGD.

Aims & Methods: In order to investigate the clinical value of EUS for diagnosing ESMGD DI accompanied by early esophageal cancer, which were suggested by clinicopathological endoscopy or histology, this study retrospectively analyzed the consecutive patients with early esophageal cancer diagnosed in the Endoscopy Center at the Affiliated Drum Tower Hospital, Nanjing, China from September 2009 to November 2016. The clinical data of 519 patients were included in this study, and all of them had already underwent EUS combined with Endoscopic Submucosal Dissection(ESED). The EUS preoperative diagnosis were compared with the results of postoperative pathology from ESD.

Results: According to the pathological results, all patients (371 males and 148 females, with a mean age of 67.5 ± 4.5 years) had been diagnosed with early esophageal cancer with different invasive depth. Out of 519 patients, about 478 patients were not found ESMGD DI by both examinations. Besides, postoperative pathology confirmed that 40 patients were identified with ESMGD DI, 34 patients of which were completely consistent with the preoperative diagnosis of EUS. Approximately 98.7% (512/519) of ESMGD DI were diagnosed exactly by EUS. Another six cases were estimated as false negative inaccurately, including two squamous cell carcinoma and four high-grade intraepithelial neoplasia. One case was considered as ESMGD DI. The pathological confirmation confirmed not by pathology, the EUS values for sensitivity and specificity for the diagnosis of ESMGD DI were 85.0% (34/40) and 99.8% (478/477) respectively. Furthermore, the positive predictive value was 97.1% (34/35), and the negative predictive value was 98.8% (478/480).

Conclusion: The esophageal submucosal gland duct involvement is a kind of lesion performed as a hypoechoic sonographic pattern located in the thickened mucosa. EUS has a satisfactory diagnostic accuracy for ESMGD DI as well as its histological sensitivity and specificity.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI837 ENDOSCOPIC TREATMENT OF PATIENTS WITH HIGH-RISK EARLY ESOPHAGEAL CANCER

Contact E-mail Address: marek.kollar1@seznam.cz

Introduction: Endoscopic treatment is a standard therapeutic approach for patients with T1a early esophageal cancer (EEC). In patients with ‘high-risk’ T1a cancer (especially grading or invasion of blood/lymphatic vessels) and in patients with any submucosal (sm) invasion (Tib), surgery is recommended as a standard of care. However, recent data suggest, that endoscopic treatment might be curative in selected patients with ‘high-risk’ EEC.

Aims & Methods: The aim of this study was to assess outcomes of endoscopic treatment in patients with ‘high-risk’ EEC. ‘High-risk’ cancer was defined as any cancer with sm invasion or mucosal cancer with at least one of following: poor differentiation (G3/G4), invasion to blood (A+) or lymphatic vessels (L+), high tumor cell dissociation (TC3D). The main outcome measurement was tumor-free survival. A single-center, retrospective analysis of prospectively collected data. Patients with EEC underwent endoscopic resection (ER) or endoscopic submucosal dissection (ESD). Based on histopathological staging, patients with ‘high-risk’ EEC have been referred for endoscopic treatment. Complete local remission in continued endoscopic treatment consisting of further sessions of ER and/or radiofrequency ablation if necessary. The patients have been followed up for a median of 39 months (range 2–156).

Results: Of 56 patients with ‘high-risk’ EEC underwent endoscopic treatment: 21 patients (41%) had T1a cancer with ‘high-risk’ features and 35 patients (59%) had T1b cancer with sm invasion (sm1: 15, sm2: 9, sm3: 11); 45 patients had adenocarcinoma (EAC), 11 patients had squamous carcinoma (SCC); 19 (34%) were referred for endoscopic treatment (all patients were treated with endoscopic submucosal dissection). Complete local remission (CLR) of neoplasia was achieved in 35/37 patients (95%). Two patients without CLR continued endoscopic therapy with palliative intent. Tumor generalization occurred in 2 patients (one of them achieved CLR 24 months after endoscopic treatment) (both patients had sm3 invasion, A+, L+) and these patients are undergoing oncological treatment. All remaining patients with CLR (n = 33) have experienced neither local relapse nor generalization. One patient had to undergo surgery due to endoscopic relapsed perforation. Tumor-free survival was 89% (CI 79–99%) in patients treated endoscopically and endoscopic related mortality was 0% (0/37). Among 19 patients who were referred for endoscopy, one patient presented with tumor generalization revealed during the operation. The remaining 18 patients underwent esophagectomy; local residual of malignancy were present in 5/18 patients (28%). Lymph node (LN) metastases have not been detected in any patient among the 337 examined LNs. Surgery related mortality was 6% (1/18).

Conclusion: Endoscopic treatment provides long-term remission or cure in a considerable number of patients with ‘high-risk’ EEC and it may thus represent a valid alternative to surgery. Broadening of indications for radical endoscopic treatment of early EEC should be reconsidered.

Introduction: Preoperative Neutrophil to Lymphocyte Ratio (NLR) has been proposed as a prognostic marker in several solid tumors (Templeton 2014). A retrospective prospective study of 60 patients showed the prognostic relevance of NLR as a predictor of response in esophageal cancer patients treated with chemoradiotherapy. The aim of this study is to assess the NLR prognostic strength in a retrospective series of two high-volume centers.

Aims & Methods: A retrospective review of two prospective esophageal cancer databases was conducted. Neutrophil to lymphocyte ratio was defined as the prechemoradiotherapy serum neutrophil count divided by lymphocyte count. We dichotomized the NLR data using as cut-off values 2.5 and 3 respectively. Univariable logistic regressions were performed to determine the effect of NLR on response after neoadjuvant treatment. Survival curves were constructed with Kaplan Meier method and compared with the long rank test.

Results: We included 280 patients. The analysis of NLR as predictor of pathologic complete response (pCR) showed a OR of 0.963 (95% CI 0.531–1.746, p = 0.901) and 1.161 (95% CI 0.647–2.081, p = 0.617) considering as cut-off values 2.5 and 3 respectively. In our large series, NLR did not result as a predictor marker neither in terms of Overall Survival nor in terms of Disease Free Survival (p = 0.997 and p = 0.672 respectively).

Conclusion: Our results did not confirm NLR as a significant marker of pCR. Moreover, the survival analysis did not reveal significant differences using NLR as a stratifying variable. The heterogeneity of treatments, the comorbidity of the disease, the absence of a validated and pre-defined NLR cut-off value in the available literature are the main limits to our analysis. Further studies are needed to assess the clinical relevance of NLR as a predictive marker of response to neoadjuvant treatment.

ACCELERATION OF HEALING OF PREEXISTING GASTRIC ULCERS BY CARBON MONOXIDE RELEASING MOLECULE -2 (CORM-2), INVOLVEMENT OF HEME OXGENASE, OXIDATIVE STRESS AND PROINFLAMMATORY MARKERS

Physiology, Jagiellonian University Medical College, Cracow/Poland

Contact E-mail Address: katarzyna.magierowska@uj.edu.pl

Introduction: Carbon monoxide (CO) is produced endogenously in the body as a by-product of heme degradation via activity of the enzyme heme oxygenase (HO-1). This gaseous mediator with multidirectional biological activity exerts antioxidant, anti-inflammatory and immunomodulatory properties. In newly discovered class of compounds, named CO-releasing molecules (CORMs), is capable of liberating CO gaseous molecule that can be useful as pharmacological tool to assay the physiological role of CO under experimental conditions. CORM-2 was implicated in gastroprotection against formation of acute gastric lesions but the contribution of CO to the mechanism of ulcer healing has not been fully elucidated.

Aims & Methods: We determined the effect of daily treatment with vehicle or CORM-2, on healing of preexisting gastric ulcers induced by aerosol application of acetic acid (ulcer area = 28 mm2) in rats. Our second goal was to examine the mechanism of CO released from its donor by the determination of the CORM-2-induced alterations in gastric blood flow (GBF) at ulcer margin, the parameters of oxidative stress and the gastric mucosal expression of pro-inflammatory and anti-inflammatory factors. Groups of seventy rats with gastric ulcers (A-D) received daily treatment with A) vehicle (saline), B) CORM-2 in doses from 1 to 10 mg/kg i.g., C) the HO-1 inducer, hemin (5 mg/kg i.p.), D) the HO-1 activity inhibitor, zinc protoporphrin IX (ZnPPIX) (5 mg/kg i.p.). After 9 days of treatment, the ulcer area was measured by planimetry, the gastric blood flow (GBF) at ulcer margin was determined by Laser Doppler technique, plasma TNFα and IL-1β levels were measured by ELISA and ZnPP IX significantly reduced the area of gastric ulcers and raised GBF at ulcer margin but the treatment with ZnPPIX IX significantly increased the area of gastric ulcers and significantly decreased the GBF at ulcer margin. The decrease in gastric ulcer healing by

CORM-2 was accompanied by a significant decrease in plasma levels of IL-1β and TNF-α receptor 1 (R1), comparing to vehicle-control group. The expression of EL-10, TNF-α, COX-2 and iNOS mRNA was strongly upregulated in vehicle-treated gastric mucosa but expression of these factors was significantly attenuated in CORM-treated animals. The increased mucosal expression of mRNA for HO-1 but not HO-2 was detected in vehicle control group and these effects were ameliorated by treatment with CORM-2. The gastric mucosal MPO activity and thernocural content of MDA + 4HNE in gastric mucosa were elevated in vehicle-control group and these effects were significantly inhibited by CORM-2. Contact E-mail Address: ktrianti@med.uoa.gr

Introduction: There is evidence of proton pump inhibitors (PPIs) misuse in the community and in the hospitals causing significant direct and indirect costs burden for the health care system. Aims & Methods: We aimed to evaluate the frequency of inappropriate PPIs administration in hospitalized patients, to measure the direct in-hospital costs of PPIs misuse and to calculate the number of patients exposed to the risk of upper gastrointestinal (UGI) complications due to medication underuse. This was a prospective, cross-sectional, prescription-indication drug-utilization, chart-review study in hospitalized patients with follow-up until discharge, in a tertiary hospital in Athens, Greece. We recorded data of all patients admitted (intensive care, cardiac, psychiatric, obstetrics and day clinic admission were excluded) during three consecutive on-call days of the hospital in March 2017 regarding PPIs utilization before admission, during hospitalization and at discharge. We calculated average daily cost per hospital cost per PPIs overuse and the number of patients at risk of UGI complications due to PPIs underuse for 1 year period, using a simulation model. Results: We included data from 470 patients aged 67 ± 19 yrs; 32.5% were pre-served and 67.5% were admitted due to hospitalization and 22.8% at discharge. PPIs overutilization was detected in 15.7%, 41.3% and 12.6% of the patients before, during and after the admission, while medications under-utilization was detected in 10.2%, 8.1% and 9.5% of them, respectively. Admission at internal medicine and orthopedics clinics was associated with the highest underutilized ORs (1.68 [95%CI 1.63–1.72] and 1.68 [1.59–1.78]) for PPIs misuse. 80% of the 193 over treated patients received PPIs (80% of them od, 20% bid) while the rest were treated with PPIs per os (80% of them od, 10% bid) during hospitalization. This accounts for 1480 PPI doses and 344 PPI per os doses inappropriately given during the observation period. Taking into account in our simulation model that there are 90 on-call days of our hospital annually, the cost of each PPI dose is 3.435 and 0.235 euros for iv and per os preparations and assuming a similar to that of our sample case distribution the number of attempts, and in the absence of recurrence. All patients under went endoscopic follow-up. Early and late complications were registered. Results: We included 84 patients, 56 patients (67%) had an adenoma confined to the ampulla (ACA), 17 patients (20%) had a LSA and 11 patients (13%) were treated for adenomas that demonstrated growth pattern with intraductal extension. Fifty-five percent of the patients were men and the median age was 65.4 years (range 32–89). The median lesion size was 24.6 mm (range 5–80) for ACA, 34.9 mm (CI 12.4–49.9) and 42.2 (CI 15.7–113.1) mm for LSA. Endoscopic resection of an ampullary lesion were retrospectively identified. Cases were selected by using ENDOBASE and we provided a search in the our local PALGA database. We included patients with a histological diagnosis of adenoma. Endoscopic resection was performed by 5 experienced endoscopists. Endoscopic success was defined as complete excision of the adenoma, irrespective of the number of attempts, and in the absence of recurrence. All patients underwent endoscopic follow-up. Early and late complications were registered.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1880 ENDOSCOPIC RESECTION OF ADVANCED AMPULLARY ADENOMAS: A SINGLE-CENTER 14-YEAR RETROSPECTIVE COHORT STUDY

S. E. Van Der Wiel, J.W. Poley, M.J. Bruno, A.D. Koch
Gastroenterology And Hepatology, Erasmus University Medical Center, Rotterdam/Netherlands

Contact E-mail Address: s.e.vanderwiel@erasmusmc.nl

Introduction: Adenomas of the ampulla of Vater are rare. Endoscopic ampullectomy has been recognized as a safe and reliable treatment of selective tumors of the ampulla of Vater and is associated with lower morbidity and mortality rates than surgical resection. However, the success rates for endoscopic ampullectomy have been reported from 61 to 92 percent, with recurrence described in up to 33 percent of patients. Despite the increasing number of studies concerning endoscopic resection of ampullary tumors, data evaluating endoscopic resection of the more advanced ampullary adenomas are limited. Methods: The aim of our study was to evaluate the technical success, complications and recurrence of endoscopic resection for treating patients with ampullary adenomas with intraductal extension (AIE), and patients with lateral spreading adenomas (LSA). Between January 2002 and November 2016, all patients referred to the Erasmus Medical Center, Rotterdam, for endoscopic resection of an ampullary lesion were retrospectively identified. Cases were selected by using ENDOBASE and we provided a search in the our local PALGA database. We included patients with a histological diagnosis of adenoma. Endoscopic resection was performed by 5 experienced endoscopists. Endoscopic success was defined as complete excision of the adenoma, irrespective of the number of attempts, and in the absence of recurrence. All patients underwent endoscopic follow-up. Early and late complications were registered.

Results: We included 84 patients, 56 patients (67%) had an adenoma confined to the ampulla (ACA), 17 patients (20%) had a LSA and 11 patients (13%) were treated for adenomas that demonstrated growth pattern with intraductal extension. Fifty-five percent of the patients were men and the median age was 65.4 years (range 32–89). The median lesion size was 24.6 mm (range 5–80) for patients with ACA, 34.9 mm (range 23–50) for LSA and 16.3 mm (range 10–47) for patients with an AIE (P = 0.039). Complications occurred in 26 patients (30.9%), of which hemorrhage was most seen in 17.9%, followed by perforation in 5.9% of the patients. Complications were equally divided over these three groups (P = 0.775). The mean follow-up duration was 31.1 months (range 0–129) for ACA, 23.1 months (range 0–127) for LSA and 11.9 months (range 0–37) for IAE (P = 0.136). Endoscopic resection was curative in 87.5% of patients with a localized adenoma, 82.3% in patients with a lateral spreading adenoma and in only 9.1% of patients with an intraductal extended tumor (P < 0.000). Recurrence occurred in 9 patients (10.7%), 5 of them had a localized adenoma, 3 patients with a lateral spread adenoma and 1 patient with an intraductal extended adenoma (P = 0.875).

Conclusion: Endoscopic ampullectomy is a safe and successful treatment in patients with an adenoma with or without a lateral spreading growth pattern. In case of an intraductal extended adenoma endoscopic success rates are significantly lower.

Introduction: There are few reports about the technical difficulty of gastric endoscopic submucosal dissection (ESD) which were investigated through the prospective trial.

Aims & Methods: The aim of this study was to evaluate the factors associated with the technical difficulty of ESD for early gastric cancer (GC) which met expanded indication criteria using data from JCOG0607. The major inclusion criteria of JCOG 0607 were as follows: 1) histologically proven intramuscular adenocarcinoma; 2) cT1aN0M0; 3) lesion without finding of ulcer (UL negative) and >2 cm in size, or UL positive and ≤3 cm in size; 4) age > 75. ESD were performed by certified endoscopists or under the supervision of certified endoscopists who had experienced 100 cases or more. The difficult case was defined as the ratio between the number of significant findings detected by EUS tissue aspiration, EUS-FNA and the total number of EUS examinations performed for a given indication.

Results: During the study period 1487 EUS procedures were performed in our clinic. Thirty patients with gastric submucosal lesions were enrolled to participate (35 patients were followed). 66% were female, mean age was 62 years (range 31–88). Mean lesion size was 27 mm (range 12–60 mm). Twenty-two-gauge needles were used in 14 cases (55%) and twenty-five-gauge needles were used in 12 cases (45%). Overall diagnostic yield for 3 needle passes was higher for FNB vs. FNA for gastric submucosal lesions (78% [9/12] vs. [44% [4/12], P = 0.04). Among the different indications for ESD, the diagnostic yield was: 61%, 67% and 78% with the first, second, and third FNB pass, respectively. In evaluation of tissue quantity and quality of FNB specimens, the mean tissue length was 7.3 ± 5.2 mm, with a median number of tissue pieces of 5 ± 75% of the total tissue procured (determined as the percent of the surface are occupied by lesion over the surface area of the entire tissue on one side). No complications occurred during the study period.

Conclusions: FNB using a novel core needle system is effective for diagnosis of gastric submucosal lesions. When performed without on-site cytologic evaluation, EUS-FNB has a higher diagnostic yield than FNA and may represent an advance for endoscopic ultrasound guided gastrointestinal biopsies.

P1882 COMPARATIVE EFFECTIVENESS OF NOVEL FINE-NEEDLE BIOPSY DEVICE VS CONVENTIONAL FINE-NEEDLE ASPIRATION FOR ENDOSCOPIC ULTRASOUND DIAGNOSTIC OF GASTRIC SUBMUCOSAL LESIONS

M. Marrahi1, A. Yee1, I. Nasr1, J. Cohen1, J. Sheridan1, R. Chuttani1, T. Berzin1, M. Sawhney1, D. Pleskow1

Introduction: Endoscopic ultrasound with fine-needle aspiration (EUS-FNA) is commonly used for the diagnosis of various gastrointestinal lesions. Recently, a novel fine-needle biopsy (FNB) system (SharkCore, Medtronic) was developed to acquire cohesive units of tissue to increase the diagnostic yield of EUS. Aims & Methods: Our study objective was to compare the diagnostic yield of EUS-FNA using a conventional needle vs. EUS-FNB using the novel needle for gastric submucosal lesions. We conducted a prospective analysis of patients undergoing diagnostic EUS from November 2014 to October 2015. Each patient underwent 3 FNA passes followed by 3 FNB passes, without onsite cytologic evaluation. Data gathered included demographics, size and location of the lesion, needle size, and complications. Pathology and cytology were reviewed separately by two blinded, expert gastrointestinal pathologists. Diagnostic yield was defined as the ratio between the number of significant findings detected by EUS tissue aspiration and the total number of EUS examinations performed for a given indication.

Results: A total of 43 patients were enrolled, and 15 of them received submucosal tunneling endoscopic resection, while the other 28 cases received endoscopic full-thickness resection. There was no significant difference between the two groups in terms of gender, age, tumor size, en bloc resection rate, operation time, pathohistological results, hospital stay and cost (p > 0.05). However, patients who received endoscopic full-thickness resection had a longer suture time and needed more clips to close the gastric wall defect (p < 0.05). No recurrence was noted in the submucosal tunneling endoscopic and endoscopic full-thickness resection groups during a mean follow-up of 12.1 and 22.8 months, respectively.

Comparison of clinical characteristics and therapeutic outcomes between STER and EFR

(continued)
Comparison of clinical characteristics and therapeutic outcomes between STER and EFTR

STER (n=15)  EFTR (n=28)  P
No. of clips for suture  5.8 ± 1.4  7.6 ± 1.6  0.001
Complications, %  6.7% (1/15)  14.3% (4/28)  0.643
En bloc resection, %  6.7% (1/15)  3.6% (1/28)  1.000
GIST/Leiomyoma/ Schwannoma  11/4.0  25/2.1  0.173
Length of stay, d  6.1 ± 1.5  6.2 ± 2.0  0.856
Cost, USD  615.8 ± 168.3  3237.5 ± 615.8  0.906
Follow-up time, mon  12.1 ± 12.2  22.8 ± 18.4  0.052

Conclusion: The treatment efficacy between submucosal tunneling endoscopic resection and endoscopic full-thickness resection for treating gastric fundus submucosal tumors was comparable, but submucosal tunneling endoscopic resection offers advantages over endoscopic full-thickness resection in terms of shorter suture time and smaller number of clips needed to close the gastric wall defect.

P1884 COMPARISON OF THE DIAGNOSTIC YIELDS OF ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION FOR DUODENAL AND GASTRIC SUBEPITHELIAL LESIONS
K. Nakamura
Gastroenterology, St.Luke’s International Hospital, Chuo-ku/Japan

Contact E-mail Address: nakamen@luke.ac.jp

Introduction: The propagation of diagnosis and treatment for gastrointestinal subepithelial lesions (SELs) have been remarkable by the wide use of Endoscopic Ultrasound-Guided Fine Needle Aspiration (EUS-FNA) and the development of Laparoscopy and Endoscopy Cooperative Surgery. EUS is used widely for SELs that occur in the digestive tract. There are many reports on gastric SELs, but there are no studies on a large group of patients focusing on duodenal SELs.

Aims & Methods: The aim of this study was to investigate the usefulness and safety of EUS-FNA for duodenal SELs, comparing them with gastric SELs. Cross-sectional study was conducted using 41 patients who underwent EUS-FNA at tertiary medical center in Tokyo between April, 2012 and February, 2017. We divided into 2 groups: 6 patients with duodenal SELs (group D) and 35 patients with gastric SELs (group G), who were diagnosed as SELs located on the 4th layer by pre-operative EUS and were performed EUS-FNA consecutively. We retrospectively evaluated the patient characteristics and outcome of the technique on the subjects.

Results: Age (median, range): D: 61 (42–63), G: 60 (32–85); male:female ratio: D: 1/5, G: 18/17; tumor size (median, range)(mm): D: 16, [14–45], G: 24, [13–67]; type of needle (22-gauge/19-gauge): D: 5/1, G: 30/6 (One case was used two type of needles); number of needle passes: D: 5, [4–5], G: 4, [7–]); procedure time (median, range)(min): D: 34, [22–52], G: 42, [20–67]; diagnostic yield: D: 100%, G: 91.4%; complication: D: 0%, G: 2.9%. There were no significant differences into 2 groups, but the size of duodenal SELs tended to be smaller than gastric SELs. Histological diagnosis of EUS-FNA using immunohistochemical analysis showed duodenal SELs were 5 GIST, 1 neuroinflammatory, and gastric SELs were 25 GIST, 4 ectopic pancreas, 3 neuroinflammatory, 3 indeterminate. Two of the indeterminate were followed up by CT, one was SEL like cancer diagnosed by conventional biopsy.

Conclusion: Although five of the six cases of duodenal SELs were small lesions of less than 20 mm, immunohistochemical staining was performed for all the cases, and diagnosis was made. EUS-FNA for duodenal SELs was as useful and safe as gastric SELs.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
published guidelines regarding appropriate surveillance of patients with GIM and how this is wide disparity in the management of this premalignant condition.

**Aims & Methods:** This study aimed to analyze surveillance practice and characterize the natural history of this premalignant condition by identifying all patients with GIM on an upper GI surveillance programme and reviewing follow-up data. This is a retrospective study of patients with GIM who are currently enrolled in an upper GI surveillance programme. Patients with a history of GIM identified at any time during an 18 year surveillance period (from 1998 to 2016) were included in the study. Patient characteristics, endoscopy data including histology, rates of Helicobacter pylori infection, Barrett’s oesophagus association and outcomes were reviewed.

**Results:** 160 patients (including those with Barrett’s oesophagus, GIM and family history of gastric cancer) were enrolled on the surveillance programme. 42 patients with GIM were identified—20 females (47.6%) and 22 males (52.3%). The mean age at which GIM was first diagnosed was 60.6 years (range from 17.9 to 71.5 years). 15/42 patients (35.7%) had co-existent Barrett’s oesophagus and Helicobacter pylori was identified in 6/42 (14.3%). The follow-up period ranged from 5.7 to 17.3 years. 27 patients had repeated gastroscopies following initial diagnosis. 15 patients are still awaiting a repeat gastroscopy. A large degree of variability in the number and frequency of follow-up gastroscopies was observed. The average interval of follow-up gastroscopies was 3.3 years per person. 14/27 patients (51.8%) had no evidence of GIM on most recent gastroscopy. 7/27 patients (26%) had repeat findings of persistent focal GIM, 5/27 patients (18.5%) progressed to extensive GIM. No cases of dysplasia were recorded but 1 patient (3.7%) developed gastric cancer.

**Conclusion:** This study suggests a low apparent risk of progression of gastric intestinal metaplasia in a small western cohort. Further studies may be necessary to address if the applicability of published surveillance guidelines can be generalized to regions with low gastric cancer prevalence.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** tsm3wa@naver.com

**Introduction:** Previously we reported that direct family history of gastric cancer (GC) as a risk factor of and genetic polymorphisms of TGFBI (transforming growth factor-β) was associated with the development of GC in the first-degree relative of GC. The aim of this study is to investigate relationship between stage of gastric cancer and genetic polymorphism of TGFBI regarding first-degree relative of GC.

**Aims & Methods:** From January 2006 to March 2017, 1090 gastric cancer patients were enrolled at Seoul National University Bundang Hospital in whom stage of GC was obtained from surgery, endoscopic submucosal dissection (ESD), endoscopic mucosal resection (EMR), and computed tomography (CT) and positron emission tomography (PET-CT) images. 203 patients (18.6%) had direct family history GC and 887 (81.4%) did not have. Genotype of TGFBI-S409 was measured by the polymerase chain-restriction fragment length polymorphism (PCR-RFLP). Relationship between TGFBI polymorphism and stage of GC or familial history in GC was analyzed.

**Results:** Proportion of stage 1 & 2 was statistically higher in the group with direct family history GC (170, 83.7%) than without direct family history (600, 74.4%). (P=0.005). When GC stage was analyzed regarding direct family history and TGFBI genetic polymorphism the ratio of gastric cancer stage I to TGFBI-S409 T carrier was significantly higher than that of stage II or higher (P=0.008), only in male. However, this difference was not found in female. In addition no significant difference was found in GC patients without direct family history. Lauren classification and TGFBI genotype did not show any statistically significant results even in the group with direct family history.

**Conclusion:** Family history of GC affects the stage of GC and the genotype of TGFBI-S409 could be underlying mechanism in case of male. Survival analysis is undergoing.

**Table:** Differences of gastric cancer stage according to TGFBI-S409 polymorphism and family history (Hx) of gastric cancer

**Contact E-mail Address:** tacheei@gmail.com

**Introduction:** Gastric adenocarcinoma and proximal polyposis of the stomach (GAPPS) has to been described recently only in a few families worldwide (only one in Europe so far). Three different point mutations in promoter 1B of the APC gene were identified as causal (c.-191T>C, c.-192A>G, and c.-195A>C). We diagnosed GAPPS in the second Czech white family (not related to that one published previously-ref. 1).

**Aims & Methods:** We diagnosed GAPPS across 3 generations in a new Czech white family. A genetic analysis of the family was performed.

**Results:** The Proband (a 43-year-old male) was endoscopically regularly surveyed from his 34 years of age because of fundic-gland polyposis with predominant involvement of the gastric fundus and body (with relative sparing of the lesser curve) and microcytic anaemia. Polyposis slowly progressed with the intestinal differentiated low-grade dysplasia in polypectomy specimens 10 years after the diagnosis. As the GAPPS criteria were fulfilled (ref. 2), he and his family under went genetic testing and b-directional Sanger sequencing of promoter 1B revealed a point mutation (c.-191 T>C). The same type of mutation was described in his father (63 years old), sister (41 years old), nephew (son of his sister, 6 years old), uncle (father’s brother, 51 years old) and 2 cousins (uncle’s daughters, 23 and 27 years old), all have been asymptomatic. No gastric cancer in the family history was mentioned. The Proband underwent preventive total gastrectomy, histology of the surgical specimen confirmed severe involvement of gastric body with fundic gland polyposis, low-grade and focal high-grade dysplasia. The microcytic anaemia improved rapidly after surgery. The rest of family is scheduled for gastroscopy. The fundic-gland polyposis of similar distribution (with significantly lower number of polyps, without any dysplastic changes) was recently diagnosed in the 23-year-old cousin.

**Conclusion:** The second European family with GAPPS is presented. The recently described mutations in promoter 1B of the APC gene does not automatically mean a faster progression of the disease as suggested earlier. GAPPS can be presented with various phenotypes with a different course of disease, the prevalence can be higher than previously reported. Acknowledgement: The study was supported by the Research Project PROGRES Q40–15.

Introduction: ESD is the one of the options of treatment even for lateral spreading (non-muscle invasive) esophageal squamous cell carcinoma (ESCC). Lymph node metastasis is not high. However, endoscopic diagnosis is difficult compared to the stomach or colon. The aim of this study is to evaluate the clinical value of EUS for diagnosing and treating ESCC.

Aims & Methods: All 60 cases were resected by surgery or ESD. The EUS preoperative diagnosis was compared with the results of postoperative pathology from ESD. The EUS values for sensitivity and specificity for the diagnosis of ESMGDI were 98.7% (42/43) and 99.5% (278/280) respectively. Furthermore, the positive predictive value was 97.1% (34/35), and the negative predictive value was 98.8% (478/484).

Conclusion: The actual LN metastasis in the EUS preoperative diagnosis is low compared to other cancers. The EUS predictive accuracies of ESMGDI and ESCC are high. The EUS should be accepted. G-17 does not seem to provide any additional benefit.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Few major international guidelines consider pepsinogen tests as the best available non-invasive tests to detect precancerous lesions (in particular, - corpus atrophy) in the stomach mucosa. Gastrin-17 (G-17) has been discussed as an alternative biomarker for atrophic gastritis and precancerous lesions in Japan and Asia. Recommendations from the European Commission expert group consider the need for additional studies before any screening with biomarkers can be recommended for implementation.

Aims & Methods: Generally healthy 40-65 years aged participants of the GISTAR pilot study referred for upper endoscopy according to the pilot study protocol were enrolled. Pepsinogen (Pg) I and II were assessed from plasma samples by two methods-ELISA (Biohit Plc.) and latex-agglutination (Eiken Chemical Co.) test systems. G-17 and IgG group antibodies to H. pylori infection were assessed by Biohit Plc. ELISA test systems. The following cutoff values were considered characteristic for atrophy: Pg I/II < 1 mg/l or 3 for ELISA, Pg I/II < 1 and Pg I < 0.7 for latex-agglutination, and G-17 < 1 pmol/l (in a plasma sample obtained in fasting condition). Biopsies were sampled and read by two independent pathologists according to the updated Sydney system. OLGA and OLGIM scoring systems were also applied. Cancer, dysplasia, OLGA/OLGIM III-IV taken together were considered high-risk lesions.

Results: Altogether 1044 subjects (55% females, mean age 52, 67.7% with positive H. pylori antibodies) were included to the study. The sensitivity and specificity for detecting moderate to severe atrophy in the corpus for Biohit ELISA test was 47.2% and 92.3%, but for Eiken latex-agglutination test 81.1% and 62.1%, respectively. The corresponding values for G-17 to detect atrophy in the antrum were 29.2% and 58.9%. High-risk lesions were detected by Biohit ELISA pepsinogen test system with 22.8% sensitivity and 91.6% specificity, but with Eiken latex-agglutination test with 67.4% and 62.5% sensitivity and specificity.

Conclusion: Due to the high specificity, pepsinogens (e.g. ELISA) could be potentially used for screening of precancerous lesions if relatively low sensitivity could be accepted. G-17 does not seem to provide any additional benefit.

miR-211-5p could suppress melanoma proliferation, migration, and invasion [4]. Growing evidence show that miRNAs can act as either tumour onco-genes or suppressors in different types of cancers. Previous studies revealed that miR-211-5p could suppress gastric cancer cell lines by targeting FoxC1 in gastric cancer and miR-211-5p might be a potential target for the treatment of gastric cancer. We demonstrate that miR-211-5p acted as a tumour suppressor by downregulation of FoxC1. Bioinformatics and quantitative analysis revealed that FoxC1 might be a target of miR-211-5p. Downregulation of FoxC1 inhibited proliferation, migration and induced apoptosis in gastric cancer cell lines in vitro.

Results: The expression levels of miR-211-5p were significantly decreased in gastric cancer and low expression of miR-211-5p correlates with poor prognosis in gastric cancer patients. Ectopic expression of miR-211-5p suppressed proliferation, migration and induced apoptosis in gastric cancer cells in vitro.

Aims & Methods: We aimed to investigate and characterize the biological role of miR-211 in the development of gastric cancer. The expression level of miR-211-5p was measured in paired primary gastric cancer with corresponding adjacent gastric mucosa by RT-PCR. Furthermore, we investigated the biological role of miR-211-5p in proliferation, apoptosis, migration of gastric cancer cell lines in vitro.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1893 CONGENITAL OR METAPLASTIC: EVALUATION OF GASTROESOPHAGEAL NEO-JUNCTIONS TO ASSESS CARDIAC TYPE EPITHELIAL ORIGIN
J. Castela, D. Vina Pereira, S. mão De Ferro, R. Casaca, R. Fonseca, P. Chaves, A. Dias Pereira
Núcleo Regional do Sul da Liga Portuguesa Contra o Cancro, Lisboa/Portugal

Introduction: The dramatic rise in the incidence of gastroesophageal junction (GEJ) adenocarcinoma in the Western countries, has promoted an increased interest about the etiopathogenesis and natural history of GEJ. The cardiac epithelium (CE), which integrates the morphological spectrum of Barrett’s esophagus, is frequent target in endoscopy and surgery of children and adults. Its congenital versus metaplastic origin still needs to be clarified. The endoscopic CE defined by the presence of circular pattern with NBI in the neo-junction was evaluated with white light and Narrow band imaging (NBI); under endoscopic diagnosis of CMET and CE confirmed in 18/20 patients; additionally identified oxyntocardiac epithelium (OC) and cardia-type metaplasia arising in the remnant esophagus after fundoplication. Gastrointest Endosc. 2004 Jun; 59(7):810–7.

Results: The mean size was 14.4 mm and 28.9 mm for lesions resected en-bloc and piecemeal, respectively. Histopathological findings were: low-grade dysplasia (n = 27, 36%), high-grade dysplasia (n = 34, 45.4%), high-grade dysplasia with focal adenocarcinoma (n = 12, 16%), intramuscular adenocarcinoma (n = 2, 2.6%). Pre-EMR biopsy tended to downgrade the lesion in 25% (n = 34, 45.4%), high- grade dysplasia (n = 12) or percutaneous (n = 1). There was no procedure-related mortality. Follow-up was scheduled after 3, 6 and 12 months for the first year, and then yearly for up to 5 years.

Conclusions: Endoscopic mucosal resection (EMR) of non-ampullary sporadic duodenal adenomas: long term results
G. Valeri1, A. Tringali1, I. Boskoski1, P. Familiari1, V. Boive1, R. Landi2, V. Perelli3, G. Costamagna3

Department Of Gastroenterology, Sir Run Run Shaw Hospital, hangzhou/China

Introduction: Duodenal adenomas are rare epithelial tumors and represent 25% of the benign lesions diagnosed in the small bowel. Non-ampullary sporadic duodenal adenomas (NASDA) are usually asymptomatic and their diagnosis is mostly incidental. NASDA are benign epithelial tumors with a potential for malignant transformation via the adenoma–carcinoma sequence; nevertheless this risk is lower compared to ampullary or duodenal adenomas in the context of genetic syndromes. Results of Endoscopic Mucosal Resection (EMR) of NASDA are not presented in a large series.

Aims & Methods: Consecutive patients undergoing EMR of NASDA between May 2002 and December 2016 were identified from an electronic database. Patients with a genetic polyposis syndrome (FAP or Peutz-Jeghers) and/or adenoma of the major or minor duodenal papilla were excluded. Preoperative biopsy was performed at operator discretion, considering that the majority of the patients were referred from other centers. In case of doubt for a possible involvement of the ampulla of Vater, duodenoscopy with a side-viewing scope was also performed. EUUS was not systematically done before duodenal EMR. Size, site of the lesion, pre- and post-EMR histology, adverse events, local recurrence and survival rates were retrospectively analysed. En-bloc resection was preferred, when possible, for lesions >20 mm; bigger lesions were removed piecemeal. Blended “endocut” current was used in all the cases. All resected specimens were retrieved for histological examination. CO2 insufflation was routinely used during duodenal EMR after 2013. Argon plasma coagulation was used to eradicate residual adenomatous tissue at discretion of the operator. Endoscopic follow-up was scheduled after 3, 6 and 12 months for the first year, and then yearly for up to 5 years.

Results: EMR of 75 NASDA was performed in 68 patients (56% en-bloc resec-tion, 44% piecemeal). The mean size was 14.4 mm and 28.9 mm for lesions resected en-bloc and piecemeal, respectively. Histopathological findings were: low-grade dysplasia (n = 27, 36%), high-grade dysplasia (n = 34, 45.4%), high-grade dysplasia with focal adenocarcinoma (n = 12, 16%), intramuscular adenocarcinoma (n = 2, 2.6%). Pre-EMR biopsy tended to downgrade the lesion in 44.4% (16/36). Retropertioneal perforations occurred in 3/75 (4.0%) procedures and were treated by surgical (n = 2) or percutaneous (n = 1) drainage; delayed bleeding was reported in 17/75 (23%) resections and was successfully managed in 12/17 (71%). Two (2%) patients had a procedure-related mortality. Follow-up was available in 61/68 patients (89.7%) after a median time of 39 months (range 3–147) from resection. Residual and recurrent adenoma were diagnosed in 9 and 6 cases, respectively; all but one were successfully fully retreated endoscopically.

Conclusion: The present series reports the results of duodenal EMR for NASDA after more than 4-year median follow-up. When biopsies had been performed before duodenal EMR for NASDA, the lesion was recorded more than 40% cases in our series, suggesting that biopsies are not routinely necessary before EMR. EMR for NASDA is effective for favorable long-term outcomes. The main limitation of duodenal EMR is the high incidence of residual/recurrent adenoma which was 27.3% in our series. Piecemeal EMR was
associated, in our series, with a higher incidence of residual/recurrent adenoma, when compared to other recent results. These results are similar to those reported in the literature. Residual and recurrent duodenal adenomas were successfully retreated by EMR in all of them but one. Mortality related to NASDA was absent in our series after a median follow-up of 59 months (range 1–147). Management of adverse events after EMR for NASDA requires the availability of interventional radiologists and surgeons with experience in percutaneous surgery. In our experience colorectal adenomas was correlated to NASDA (33.3%), colonoscopy is considered part of the pre-EMR assessment when NASDA is diagnosed. A recalled system and patient’s compliance to endoscopic follow-up are mandatory to detect recurrences and their prompt treatment.

Introduction: NSAIIDs have demonstrated chemopreventive activity against gastric adenocarcinomas and limit their use in the prevention. Oxaliplatin is a 5-fluorouracil (5-FU) and folinic acid (5-FU/L) antineoplastic drug infusional. Treatment with 5-FU/L antineoplastic drug and infusional oxaliplatin in CRC is a standard treatment. We have now postulated as possible adjuvants to surgery chemotherapy in order to prevent the formation of new lesions and reduce disease progression. Cancer cells enhance their resistance to the cytotoxic action of antineoplastic drugs by activating autophagy, which is a catabolic process that degrades superfluous and damaged organelles in the lysosome. We previously showed that indomethacin inhibits autophagy in gastric cancer cells by acting at a late stage in this catabolic process.

Aims & Methods: The aim of this study is to analyze whether indomethacin modulates lysosomal function and oxaliplatin-induced cell death in these cells. Gastric AGS cells were treated with increasing concentrations of indomethacin for 2, 6 and 20 hours. Lysosomal pH was assessed by using Lysotracker Red and Acridine orange fluorescent probes (static cytometry). Cathepsin activity was determined by using Omnicathepsin fluorescence substrate. In cells treated with indomethacin for 2 hours LAMP2 immunostaining was also carried out. In another set of experiments AGS cells were treated with increasing doses of the antineoplastic drug oxaliplatin. Cell viability was measured using an MTT assay, the rate of apoptosis/necrosis was analyzed by means of the Apoptosis Detection Kit, and autophagy by p62 immunoblotting.

Results: Treatment of AGS cells with indomethacin decreased Lysotracker fluorescence in AGS cells after 2, 6 and 20 hours. Indomethacin also produced an acute reduction in lysosome-derived fluorescence of acridine orange after 2 and 6 hours of treatment. In addition, we observed a significant reduction of cathepsin enzymatic activity in cells treated with indomethacin for 6 or 20 hours. Furthermore, we observed an increased expression of LAMP-2 positive dots from the perinuclear position observed in control cells to a peripheral position in cells treated with indomethacin. Taken together, these data suggest that indomethacin inhibits the activity of lysosomal acidic enzymes by increasing lysosomal pH. On the other hand, oxaliplatin decreased cell viability in a dose-dependent manner after 48 hours of treatment, and treatment of cells with indomethacin during the last 24 hours further decreased cell viability. In addition, indomethacin also increased the rate of apoptosis and necrosis in AGS cells treated with oxaliplatin. Finally, indomethacin blocked the autophagic degradation of p62 protein induced by oxaliplatin.

Conclusion: Indomethacin inhibits lysosomal function in gastric cancer cells. This could explain the inhibitory action on autophagy and the resultant increase in susceptibility to cytotoxic drugs.

Results suggest that ENS may be a new actor in gastric carcinogenesis. The expression of CSC markers (CD44, ALDH) and EMT markers (Snail, Zeb1) in gastric cancer cells is associated with the inhibition of ACh effects. Therefore, the study of ENS modulation may contribute to the understanding of gastric cancer and to its potential therapeutic approach.

Aims & Methods: Our aim was to study the effect of ACh on gastric cancer cells, and in particular its capacity to induce the stem cell phenotype, and to study the mechanisms involved. Adenocarcinoma gastric epithelial cells MKN-45 were first cultured in adherent conditions in the presence of ACh (0.1-10 μM), before being cultured in non-adherent condition in order to favour expansion of CSC and formation of tumorspheres (T). The effect of ACh on T formation was evaluated under microscope by quantifying the number and size of T using the System snapshot file in INCell analyzer 2200/6000. The involvement of different cholinergic (muscarinic and nicotinic) receptors in ACh-induced responses was studied by pharmacological approach using selective agonists and antagonists. The expression of L-NMMA (NO donor) and L-NAME (nitric oxide synthesis inhibitor). Finally, the effect of ACh on the expression of CSC and epithelial-mesenchymal transition (EMT) markers was studied by immunofluorescence, RT-qPCR and flow cytometry. Statistical analysis was performed using a metric ANOVA test, Kruskal-Wallis test, or two-way non-parametric ANOVA test using SPSS16.0 F software.

Results: ACh at concentrations of 0.1 and 1 μM significantly increased the number and size of T as compared to control conditions (p < 0.001). Bethanecol, a selective muscarinic receptor agonist, increased the number and formation of T. Conversely, SNAP (NO donor) and L-NAME (nitric oxide synthesis inhibitor) significantly inhibited the stimulatory effect of ACh on T (p < 0.001 as compared to ACh-stimulated cells). Importantly, L-NAME significantly inhibited the effects of ACh on the number of T. Conversely, SNAP, at 0.1 and 1 μM, increased the number and size of T. Finally, ACh induced the expression of CSC markers (CD44, ALDH) and EMT markers (Snail, Zeb1) and Vimentin) on gastric cancer cells.

Conclusion: This study shows that ACh induces CSC properties of gastric cancer cells of diffuse type via activation of muscarinic and nicotinic pathways. It also shows that ACh effects are, at least in part, mediated by nitric pathway. These results suggest that ENS may be a new actor in gastric carcinogenesis.

Introduction: Linked color imaging (LCI), a recently developed endoscopic tech-nique, emphasizes diffuse redness, which is a characteristic of Helicobacter pylori (Hp) infection. However, the diagnosis of Hp infection does not have objective indicators; it depends on medical doctors’ experience. Therefore, it is necessary to construct objective indicators to diagnose Hp infection.

Aims & Methods: The aims of this study are to determine objective indicators for the presence or absence of Hp infection to support medical doctors’ diagnoses by constructing an automatic diagnostic system. In the proposed system, first, a region with a high hue in LCI images is defined as a region of interest (ROI). Images with a wide ROI and images with a narrow ROI are classified as high and low hue images, respectively. As a result, LCI images are classified into two types in which inflammation due to Hp infection presents as red and purple. Then, the presence or absence of Hp infection is learned by machine learning for each type of LCI image. The feature values used in the learning process are the ratio of the ROI, the average and median hue values in high hue images, and the mode saturation value and the median and variance of the hue in low hue images. Then, the trained classifiers diagnose the presence or absence of Hp infection automatically. In this paper, the constructed system was evaluated using 128 images (32 patients) in which endoscopic examination (LCI observation) and Hp infection diagnosis were performed at Murakami Memorial Hospital of Asahi University. Furthermore, support vector machines were used as classify learners for diagnosis.

Results: In the previous system [1], 29 out of 32 cases were automatically diagnosed correctly. In contrast, all cases were automatically diagnosed correctly with the proposed system. This result demonstrates that classifying LCI images into two types based on color improves the accuracy of this system.

Conclusion: The proposed system can automatically diagnose the presence or absence of Hp infection with the same precision as medical doctors with sufficient experience. Therefore, the proposed system can support the diagnosis of medical doctors with less experience.

Introduction: γ-glutamyltranspeptidase (GGT) is a cell surface-associated enzyme that is not highly expressed in normal cell. However GGT is overexpressed in various type of human cancers. It is known that Helicobacter pylori (H. pylori) also produce GGT. Urano et al have developed an enzymatically activatable fluorescent probe, γ-glutamyl hydroxymethyl rhodamine green (γGlu-HMRG), which is fluorescent under a pH of 7.4 and normal cellular environ-ment, but turns to be highly fluorescent upon reaction with GGT [1]. Aim of this study is to consider if γGlu-HMRG can be useful for diagnosing infection H. pylori.

Aims & Methods: In this study, we investigated whether activation of γGlu-HMRG fluorescence detects a wild-type of H. pylori (WT) and a ggt gene-disrupted mutant of H. pylori (ggt mutant). In addition, we investigated whether activation of γGlu-HMRG fluorescence was suppressed in H. pylori culture solution which was co-incubated with an inhibitor of GGT (GGsTop). Furthermore, we applied γGlu-HMRG to biopsy specimens which were taken from antrum and corpus of stomach in H. pylori positive patients (n = 13) and H. pylori negative patients (n = 14). We then observed the increase of fluorescence intensity over time (1 min, 5 min, 10 min, 15 min). Fluorescence intensity was quantified by Image J2 software (National Institutes of Health, Rockville, Maryland).2

Results: Activation of γGlu-HMRG fluorescence was detected in WT strain, but was not in ggt mutant strain. Activation of γGlu-HMRG fluorescence was inhibited by GGsTop. There was significant difference of the increase of fluorescence intensity between H. pylori positive and negative both in antrum corpus of stom-ach (antrum p = 0.0008, corpus p = 0.047).

Conclusion: GGT-activated fluorescent probe can be useful for H. pylori infection diagnosis.

P1903 SEROLOGICAL CHANGES AFTER EQUIVOCAL HELICOBACTER PYLORI-SEROLOGY TEST FINDINGS DEPEND ON THE GASTRIC SECRETING ABILITY

Internal Medicine, Gastroenterology, Konkuk University Hospital, Seoul/Korea, Republic of

Contact E-mail Address: kjhcess@gmail.com

Introduction: The serum anti-Helicobacter pylori (H. pylori) IgG and serum pep-sinogen (PG) assays are widely used for gastric cancer screening. An equivocal serology test finding indicates IgG titer between the positive and negative test findings.

Aims & Methods: The study aim was to evaluate the long-term, follow-up result after an equivocal test finding on the serum anti-H. pylori IgG assay. Koreans above 18 years-old with an equivocal serum anti-H. pylori IgG assay finding were included. Subjects were excluded if they did not undergo H. pylori serology test, serum PG assay, and upper gastrointestinal (UGI) endoscopy on the same day at our center. Annual test findings were followed up using the same methods.

Results: Of the 7,178 subjects who underwent the serum assays and UGI endo-scopy on the same day, 274 (3.8%) subjects showed an equivocal H. pylori serology test finding. Of the 98 followed-up subjects, 59 (59.2%) showed sero-positive finding at the mean follow-up period of 30.6±12.4 months. Subjects with seroconversion showed a higher initial serum PG I (p = 0.023) and PG II (p = 0.036) levels than the subjects without seroconversion.

Conclusion: An equivocal H. pylori serology test finding is not rare (3.8%) in Korean adults, and 60% of the equivocal subjects show seroconversion within 3 years. Higher seroconversion rates in the subjects with high PG I and PG II levels suggest that intact gastric secreting ability play a role for the survival of H. pylori. Therefore, equivocal subjects with increased serum PG levels should be consid-ered as a potential seropositive subjects.

Disclosure of Interest: All authors have declared no conflicts of interest.

2Department PJ Gastroenterology, Satsuma Kyudo Hospital, KagusuchI/Japan

**Contact Email Address**: takusan.yamasan@gmail.com

**Introduction**: Several *H. pylori* (HP) infection related cardiac findings (mucosal atrophy, metaplastic change, diffuse redness, spotted redness and nodular change of the antrum etc.) are so important sign of HP infection on endoscopic examination. On the other hand, we have confused with various newly endoscopic findings (patchy redness and map-like redness etc.) were seen on all cardia eradicated stomach. On this time, we have found out a new other ultimate useful finding showing HP infection related gastritis at gastric cardia (EG junction) including present and post HP infection. The endoscopic image of gastric cardia is the first gastric view through the esophagus on each endoscopic examination.

**Aims & Methods**: Our aim of this study is to elucidate possibility of judgement with only this cardiac endoscopic view about presence or absence with HP infection. We have found out so useful and specific cardiac image (We call Whole Shark Sign: WSS) closely related to HP infection. We have examined the presence of WSS on 4,268 cases that have been able to overviewed on their endoscopic profiles. We have judged the presence of HP infection with serum HP antibody titers on each case. The 3,233 cases their serum HP antibody titers were measured from Jan. 2012 to Oct. 2016. A total of 2,810 patients (HP positive) were enrolled. Fisher’s exact test was used in all statistical analyses. The judgement of HP present or past infection was done more than serum HP antibody 3 U/ml to avoid false negative results.

**Results**: Mean age of patients was 52.4 years old. In case of WSS positive, all their serum HP antibody titers showed more than cut-off level (3 U/ml). This means that the presence of WSS closely related to HP related gastritis. The positive predictive value (PPV) of WSS was surprisingly high (95%). According to this high PPV, we can think WSS positive cases are high risk of HP related gastritis.

**Conclusion**: We have been able to judge the presence of HP infection with only cardiac endoscopic images (WSS), we should take care of seeing the presence of WSS sign. Since this sign is very easy and simple, everyone will be able to judge the presence of HP infection as a gastric cancer risk.

**Disclosure of Interest**: All authors have declared no conflicts of interest.

2Faculty Of Health Sciences, Trinity College Dublin - Faculty of Health Sciences, Trinity College Dublin; Dublin IE; Dublin/Ireland

Contact E-mail Address: dbrenna90@tcd.ie

Introduction: The Urea Breath Test (UBT) is considered the gold standard non-invasive test for detection of Helicobacter pylori infection in Ireland. In Ireland, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment. With this in mind, it is important to optimise management of H. pylori infection. It has been suggested that the DOB value is reflective of the amount of bacteria present in the stomach and could predict whether the infection is eradicated.

Aims & Methods: The aim of this study was to determine whether there is an association between DOB and eradication of H. pylori infection in an Irish cohort. Treatment naive adult patients undergoing UBT were included. Patients were deemed to be H. pylori positive if a Delta Over Baseline (DOB) value of > 40% was obtained. Positive patients were categorised into low (< 16%), intermediate (16-35 %), and high (>35 %) DOB groups. A random subset of positive patients was given clarithromycin-based triple therapy for 7 days. A follow-up breath test was performed at least 4 weeks post-treatment to confirm eradication of H. pylori in all patients. The three DOB groups were compared with respect to age, gender and eradication rates.

Results: Out of 860 of UBTs assessed (mean age 43.3 ± 15.2 years, 39% male), 283 patients were positive (mean age 43.1 ± 14.9 years). 41.9% of the total positive patients, 91 (31.5%) returned for a follow-up UBT to confirm eradication of H. pylori. When patients were categorised into low, intermediate and high UBT groups, there was no significant difference in age and gender between groups (p=0.06 for age, p=0.3 for gender). Eradication rates in the low, intermediate and high UBT groups were 70.5%, 63.0% and 50.0% respectively (p=0.3). Patients were then categorised according to eradication status. When eradication was successful, the average DOB value was significantly lower (20.6% ± 9.7%) compared to unsuccessful (29.8% ± 10.7%) (p=0.03). The DOB value could be a useful value in stratifying patients with H. pylori infection; especially as histology and antimicrobial resistance information is unavailable in patients undergoing non-invasive testing for H. pylori infection.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1908 COMPARISON OF THE EFFICACY BETWEEN BISMUTH AND ALTERNATING RIFAXIMIN ON SECOND-LINE QUADRUPLE REGIMEN OF HELICOBACTER PYLORI ERADICATION

Dietetic Disease Center, Institute For Digestive Research, Soochunhyang University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: junsark@schmc.ac

Introduction: Bismuth is a heavy metal which has antimicrobial activity through binding to bacterial proteins. Rifaximin has been studied as a treatment for persistent H. pylori infection. Rifaximin has been prescribed for replacing the bismuth of the regimen concurrently uses PPI, metronidazole, and tetracycline in Soochunhyang University Hospital, Seoul for a while. So we reviewed the clinical outcomes of the 2 different regimens.

Aims & Methods: From May 1st 2003 to October 31th 2015, six thousand and five hundred ninety-five patients were treated their H. pylori infection in Soochunhyang University Hospital, Seoul. And their prescriptions and result of eradication were retrospectively reviewed on the medical records. The patients who had clari-drug-resistant HP infection, were then excluded. The average success rate of RIF regimen was 97.2% (789/851). On the other hand, the average success rate of RAC regimens (330/443=74.5%) (p<0.001). These results suggest that using rifaxime in APB (P-CAB) plus AMX regimen might be the strongest H. pylori eradication triple therapy regimen to overcome CAM resistance.

Introduction: Success or failure of Amoxicillin (AMX) and Clarithromycin (CAM)-based H. pylori (HP) eradication therapy mainly depends on sensitivity of CAM for HP. In Japan, we are permitted to prescribe AMX and CAM as antibiotics of 1st eradication. So far now, several proton pomp inhibitors (PPIs) have been used in HP eradication therapy. Most of reports said that the success rate of eradication approximately from 70 to 80% on AMX and CAM-based triple therapy regardless of CAM dose (400 or 800 mg/day) in Japan. Recently the ratio of CAM resistance in Japan comes up to over 30%, we have to overcome this problem.CAM resistance is considered that the stability of continuous gastric acid suppression is one of most important factors. At the point of gastric acid suppression, we expect stronger acid suppressive drug rather than PPIs. Since Feb. 2015 we have used P-CAB (Potassium-Competitive Acid Pump Inhibitor) and CAM-based triple therapy regimens (VAC, RAC). This study is a multicenter clinic (7 hospitals), prospective case study from Jan. 2012 to Oct. 2016. A total of 1,310 patients (HP positive) were enrolled. Mean age of patients was 52.4 years old. Fisher’s exact test was used in all statistical analyses. Regimen of VAC (400 or 800) was VPZ (400 mg bid, PPI bid (Rabeprazole 20 mg/ day) b.i.d.), AMX (1,500 mg/day) b.i.d. plus CAM (400 mg/ day) b.i.d. for 7 days. Regimen of RAC (400 or 800) was RPZ (20 mg/day) b.i.d., AMX (1,500 mg/day) b.i.d. plus CAM (400 or 800 mg/day) b.i.d. for 7 days. The judgement of success or failure on eradication was done with the HP breath test on 3 months later after eradication therapy to avoid false negative results.

Results: Success rate of VAC 800 showed significantly high (416/428=97.2%, PPS) rather than VAC 400 (373/423=88.2%, PPS) (p<0.001). The average success rate of VAC regimen was 89.7% (789/851). On the other hand, the average success rate of CAM dose (P-CAB) regimen was PPS) (p=0.125). The average success rate of CAM regimen was 74.5% (330/443, PPS). The average success rate of RAC regimens was 97.2% (789/851, PPS). The success rate of RAC regimen was 97.7% (789/851, PPS). These results suggest that using high dose CAM with VPZ (P-CAB) plus AMX regimen might be the strongest H. pylori eradication triple therapy regimen to overcome CAM resistance.

Introduction: Standard triple therapy (STT) has been widely used in Helicobacter pylori infection, but eradication rate is decreasing because of clarithromycin resistance. Recently, Levofloxacin-based therapy (LBT) has been evaluated to overcome the low eradication rate of standard triple therapy and reported eradication rate over 80%. Aims & Methods: We compared the efficacy and safety of SST group and LBT group for Koreans. Between April 2014 and April 2016, 49 patients in the SST group (amoxicillin 1 g bid, clarithromycin 500 mg bid and omeprazole 20 mg bid for 10 days) and 48 in the LBT group(levofloxacin 500 mg bid, amoxicillin 1 g

**Introduction:** In Ireland, Helicobacter pylori infection has become increasingly resistant to commonly used antibiotics, such as clarithromycin. Concurrently, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment.

**Aims & Methods:** The aim of this study was to compare eradication rates of standard clarithromycin-based triple therapy with those of tailored therapy based on antimicrobial susceptibility as a first-line treatment for *H. pylori* infection. Treatment-naïve adult patients undergoing endoscopy were prospectively recruited. Biopsies from *H. pylori*-positive patients (assessed by CLO test) were processed for sensitivity testing by E-testing and genotyping by the GenoType Helicobacter assay (Hain). Patients randomly received either clarithromycin-based standard triple therapy or tailored therapy based on antibiotic sensitivities, for 7-14 days. A follow-up breath test was performed at least 8 weeks post-treatment.

**Results:** To date 889 patients have undergone endoscopy and 186 (21%) were *H. pylori* positive. Infected patients were significantly younger (mean age 53 vs 49 years, p = 0.002) and tended to be male (43% vs 53%, p = 0.02). Of 186 *H. pylori*-positive patients, 112 (60%) were treatment naïve. Culture of *H. pylori* was successful in 57% (64/112) of samples and primary clarithromycin resistance was 47% (30/64) by E-test. Genotypic resistance data was available for 93% (92/99) of primary resistant strains. Of 71/140 patients who completed the study, 27 (49%) patients have received levofloxacin triple therapy; 14 (26%) a PPI and 2 antibiotics based on their sensitivities; 10 (18%) bismuth quadruple and 4 (7%) clarithromycin triple therapy. The efficacy of first-line treatment by intention-to-treat and per protocol analysis was poor, at 47.3% (26/55) and 59.1% (24/41) respectively. Patients who received one previous treatment were significantly more likely to achieve eradication than those who received >1 previous treatment (76.2% vs 43.5%, p = 0.004).

**Conclusion:** Eradicating *H. pylori* infection for the first time round, before more virulent or antimicrobial resistant strains are selected for.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Helicobacter pylori (Hp) successful eradication has been considered since it contributes to several gastrointestinal disorders. Sequential therapy has been used widely as the first approach in Hp eradication therapy (HpET). However, its failure in 10-45%. The addition of probiotics has been considered because of potential benefit in the improvement of efficacy and reduction of side effects during HpET.

**Aims & Methods:** We aimed to evaluate the effect of probiotics, as adjuvant to sequential HpET on treatment efficacy, side effects and patient compliance. The effect of probiotics was also assessed in HpET failure cases.

**Methods:** Of 265 HpET (22.9%) patients recruited in this study (47%). Those in which were sensitive to clarithromycin, prescribed a regimen based on antibiotic susceptibilities. The eradication rates for standard triple therapy and tailored therapy according to clarithromycin resistance status are as follows:

- **Standard Arm (n = 45)**
  - Resistant (n = 23):
    - Susceptible strains (n = 21)
    - Resistant strains (n = 2)

- **Tailored Arm (n = 54)**
  - Resistant (n = 26):
    - Susceptible strains (n = 24)
    - Resistant strains (n = 2)

**Eradication Rate**

**ITT (n = 12)**

- **Standard Arm:** 55% (23/42) vs 77% (32/42) for standard therapy (p = 0.03)
- **Tailored Arm:** 62% (31/50) vs 78% (39/51) for tailored therapy (p = 0.02)

**Conclusion:** In those who are sensitive to clarithromycin, standard clarithromycin-based triple therapy achieves an acceptable eradication rate of approximately 81%. However, a high primary clarithromycin resistant strain was observed in this study (47%). In those who are resistant to clarithromycin, prescribing a regimen based on antibiotic susceptibilities increases eradication rates to 83%, compared to those treated with standard triple therapy (57%, p = 0.09).

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: As a country with high incidence of gastric cancer, the elimination of Helicobacter pylori (HP) is useful strategy for the prevention of gastric cancer in Japan. And the eradication therapy for HP-infected gastritis was approved as an insurance indication since 2013, and virtually all HP-infected patients were treated in Japan, triple therapy using proton pump inhibitor (PPI)/amoxicillin (AMPC)/clarithromycin (CAM) has been used as a regimen for the primary eradication therapy. Since HP has rapidly acquired the resistant character against CAM, the eradication rate has gradually been decreasing. Recently, vonoprazan (VPZ), a novel potassium competitive acid blocker, has been approved for HP eradication therapy. Recently, higher HP-eradication rate by VPZþAMPCþCAM than PPI based triple therapy has been reported. However, there might be some concern for the use of VPZ, higher serum gastrin, decrease in the diversity of intestinal microbiota and increase in colitis. Therefore, PPI-based triple therapy is still used, and additive effect of probiotics has been reported in these therapy.

Aims & Methods: The aim of this study is to investigate the effect of probiotics, CLOSTRIDIUM BUTYRICUM Miyairi-588 (MBM) on PPI-based triple ther-

Introduction: The objective of this study is to compare, in Morocco, an African country, the efficacy rates of the concomitant versus the sequential H. pylori eradication therapy. Our prospective randomized study included 164 patients with newly diagnosed H. pylori infection, randomized to receive a 14-day concomitant or 10-day sequential therapy. Treatment outcome was assessed by 13-weeks after therapy. Intention to treat (ITT) and per protocol (PP) analysis of the eradication rates were performed. Secondary end points included patient compliance and safety. Results: The concomitant therapy group achieved statistically significant higher eradication rates when compared with the sequential treatment group, both in the ITT and in the PP analysis (86.6% versus 79.9%, p<0.002, and 90.6% versus 72.1%, p<0.001, respectively), after adjusting for age, gender, smoking status, residence, presence or not of ulcer or non-ulcer dyspepsia and BMI. The concomitant therapy group showed a significantly higher eradication rate of H. pylori (99.5% for the concomitant therapy group and 96.2% for the sequential therapy group, p=0.067). Regarding treatment safety, major adverse events that led to the discontinuation of both regimens were few, with no statistical difference between the two groups (6.2% for the concomitant therapy group and 3.1% for the sequential therapy group).

Conclusion: Concomitant therapy led to statistically significant higher eradication rates over sequential therapy. Both therapies showed excellent compliance and an acceptable safety profile. The high dose quadruple concomitant therapy scheme should be the adopted for first-line H. pylori eradication in Morocco.

Introduction: The Maastricht V/Florence Consensus Report recommends bismuth quadruple or non-bismuth quadruple concomitant therapies as first-line treatments for H pylori infection, in areas where clarithromycin resistance is high (>15%). Head-to-head studies between both therapies are needed.

Aims & Methods: We aimed to compare compliance, efficacy and adverse effects of two first-line H pylori eradication therapies in a high clarithromycin resistance

standard sequential therapy, and an experimental group receiving in addition to the standard therapy, 500mg of Ultralevures Saccharomyces boulardii, orally and daily during the ten days of regimen. All the patients were reviewed in the end of the therapy to evaluate the adherence to treatment and the incidence and severity of side effects. The eradication of Helicobacter pylori was evaluated by C-urea breath test 4 to 6 weeks after the end of the protocol. Statistical analysis was performed by the software SPSS 20.0. A model of logistic regression was performed to analyse the effects of Saccharomyces boulardii supplementation on eradication rate and side effects.

Results: There was no significant difference between the two groups on age (middle age = 44.3±13.8years vs 43±13.2years), gender (Sex ratio M/F = 1.15 vs 1.05), medical antecedents, smoking, endoscopic and histological datas. In Intention To Treat ITT and Per Protocol PP analysis, the eradication rate was significantly higher in the experimental group (86.6% ITT, 87.5% PP), compared to the control group (78.2% ITT 74.7% PP), p=0.02. Moreover, the Saccharomyces boulardii supplementation allowed a significant reduction of the incidence of overall side effects (RR =0.26, IC95%[0.14–0.47], p<0.001), and the incidence of antibiotic-associated diarrehea (RR =0.07, IC95%[0.02–0.26], p<0.001). The incidence of nausea and vomiting, dizziness, asthenia and metal-

We aimed to investigate the effects of the Saccharomyces boulardii supplementation to the sequential therapy on Helicobacter pylori eradication rate and associated therapy side effects.

Aims & Methods: One hundred ninety nine patients with Helicobacter pylori infection documented on a histological study of gastric biopsies were enrolled from May 2013 to May 2016, on a single center, prospective, controlled and randomized study, performed in the Gastro EnteroLOGY II department on the military hospital of Rabat. Using a permuted block randomization, our patients were assigned to one of the following groups: a control group receiving the

Contact E-mail Address: hanaeboutallaka@gmail.com

Introduction: The eradication of Helicobacter Pylori remains crucial because of constantly evolving data. The recent recommendations of Maastricht V stipulate that the concomitant quadritherapy and the bismuth quadruple therapy are more efficient than the sequential therapy because of a higher rate of eradication (90% vs 82%), but with more important side effects. The aim of our study is to investigate the effects of the Saccharomyces boulardii supplementation to the sequential therapy on Helicobacter pylori eradication rate and associated therapy side effects.

Aims & Methods: One hundred ninety nine patients with Helicobacter pylori infection documented on a histological study of gastric biopsies were enrolled from May 2013 to May 2016, on a single center, prospective, controlled and randomized study, performed in the Gastro EnteroLOGY II department on the military hospital of Rabat. Using a permuted block randomization, our patients were assigned to one of the following groups: a control group receiving the
area, and in clinical practice. A prospective study was performed in a Spanish center recruiting consecutive naive adult patients, candidates to *H. pylori* eradication. Omepraizole 40mg, Clarithromycin 500mg. Amoxicillin 1g and Metronidazole 500mg. all drugs b.i.d, for 14 days (OCAM); or Omepraizole 20mg b.i.d and 3-in-1 capsule with Bismuth 140mg + Tetracycline 125mg + Metronidazole 125mg. 3 capsules q.i.d. for 10 days (3–1–OBMT) were prescribed according to physician criteria. Compliance was assessed by striking the consumed doses in a patient filled template, and adverse effects using a specific questionnaire with a 1–3 intensity scale. Efficacy was determined by 13C-urea breath test. A descriptive study and analysis of efficacy by intention to treat (ITT) were performed. Cases with poor therapeutic compliance (<80%) or no available data were excluded in per-protocol (PP) analysis. Chi2, Student’s t, and Mann-Whitney U tests with significance level p < 0.05 were applied. The protocol was approved by the Ethics Committee. Results: 216 patients (63.43% women; age mean ±SD: 51.53 ± 3.41 years) were included. OCAM were prescribed in 103 and 3–1-OBMT in 113. No differences in age, sex and functional dyspepsia as indication to eradicate were observed. OCAM and 3–1-OBMT regimens achieve high and similar compliance and efficacy rates, but the rest were indicated after previous eradication treatment. Inappropriate indication to PCP compared to GS (36.4% vs 7.2%; p = 0.001). A significant increase in the adherence to appropriate treatment regimens (71% vs 35%; p = 0.001) and eradication rates (78% vs 57%; p < 0.0001) was observed in the PCP group after the implementation of specific counselling based on national guidelines.

Conclusion: Hp infection management at primary care level is appropriate with high eradication rates. The introduction of a specific counselling to PCP has significantly improved these outcomes. These data should encourage the implementation of interventional strategies in order to reduce the actual increase in antibiotic resistance.

Introduction: Radiation-induced gastrointestinal syndrome (RIGS) stems from the clonogenic loss of crypt cells and vill depopulation and results in mucosal barrier disruption, bacterial inflammation, and sepsis. Valproate (VPA) is the one of the popular anti-consulants, recently its Notch signal modulatory effect has been reported. Notch signalling pathway is known to maintain intestinal stem cells and to differentiate to secretory cells such as goblet cells. Moreover, it has been reported that combination of VPA and CHIR 99021 (GSK3ß inhibitor) has powerful proliferatory effect for intestinal stem cells, such as Lgr 5+ cells. One of the major difficulties for RIGS studies is the fact that crypts are not easily accessed and cultured with traditional means. Ex vivo culture techniques for single crypt or a stem cell derived enteroid, with essential features of the in vivo tissue architecture, have been recently developed. Thus, we have adopted the 3D-cultured enteroids for RIGS ex-vivo model, and proved the effect of VPA and SCFAs for RIGS.

Aims & Methods: We have adopted the 3D-cultured enteroids for RIGS ex-vivo model, and proved the effect of VPA and SCFAs for RIGS. To culture enteroid, ten centimeters segments of jejunum were procured from 9–13 week-old C57BL/6 mice. Crypts were isolated by EDTA chelation, suspended in Matrigel and grown in culture media containing epidermal growth factor, noggin, R-spondin 1. After 1 day in culture, the enteroids were treated (or not) with 3 mM CHIR 99021 (GSK3β inhibitor) and 1 mM VPA. On day 3, the enteroids were irradiated as a dose dependent manner. The evaluation of irradiated enteroids was performed by measuring MIT assay, budding efficiency of enteroid, and EdU staining. On post-irradiation Day 2 and Day 7, RT-PCR was performed.

Results: Enteroid from mouse had multiple crypts (‘budding’) with well-differen- tiated goblet, Paneth cells, + stem cells (quencia stem cells, BMII is expressed), Lgr5+ stem cells. In the response of radiation, irradiated enteroid decreased proliferation rate in a dose dependent manner, as measured by MIT assay, budding efficiency of enteroids. Irradiated enteroids with VPA +CHIR 99021 could maintain their + stem cells even in 10 Gy of irradiation, lethal dose of mouse intestinal epithelium, and they were able to proliferation. Combination of VPA + CHIR 99021 did not have an effect on paneth cells, enteroendocrine cells and goblet cells.

Conclusion: VPA and CHIR 99021 may ameliorate RIGS in ex-vivo mouse enteroid, through + reservoir stem cell preservation and stimulatory action for epithelial proliferation. Considering their clinical application such as safety, they could be possible strategy for prevention and treatment of RIGS.

Contact E-mail Address: lounesfadila@yahoo.fr

Introduction: Celiac disease (CD) is an important health problem worldwide. It is characterized by a high prevalence (1%), specific morbidity, long-term complications and epidemiological progression. However, mass screening is not recommended. Currently, the strategy of 'Targeted screening,' defined as screening of high-risk groups, is widely practiced and recommended by learned Societies, in contrast to the relatives of CD patients. In the world, targeted screening studies related to CD showed prevalence ranging from 4.2 to 10.3%.

Aims & Methods: The main aim of our study is to determine the prevalence of CD in the first degree relatives in Algerian population. This was a descriptive-transversal study with prospective recruiting. This is a screening of first-degree relatives of patients known and treated for CD. Relatives are screened by using anti-transglutaminase (tTG) antibodies in the serum. Upper digestive endoscopy and duodenal biopsy are performed in all sero-positive relatives and graded as per Marshall modified by Obertuber classification to confirm the diagnosis. The prevalence of CD in first-degree relatives of patients included in our study.

Results: Among the 546 first-degree relatives, we have 18.5% of parents, 57.5% of brothers and 23 sisters (9). The average age of screening cases is 31.8 years with CI at 95% [25.7–38.1]. The prevalence of CD in first-degree relatives with positive serology and positive duodenal biopsy is 7.3% with CI at 95% [5.2–9.4]. The age of screening cases is 31.8 years with CI at 95% [27.2 to 36.4] and extremes of [3–71] years. The mean duration of symptoms before diagnosis is 3.4 years, with CI at 95% [2.8 to 4.0] years. Among the 44 new cases detected by targeted screening, 14.4% are asymptomatic, 88.6% are symptomatic. This is a classical form in one case and atypical form in 86.4% of cases.

Conclusion: The present work entitled “Prevalence of celiac disease in relatives” is the first screening study of CD in the first-degree relatives carried out in Algeria. Among first-degree relatives, it is characterized by high prevalence which corresponds to the prevalence of CD in first-degree relatives of patients known and treated for CD. Our investigation supports the idea that the development of an extensive screening approach is needed to promote early diagnosis and to prevent complications of CD in first-degree relatives.

P1920 LONG-TERM HEALTH AND LIFESTYLE OUTCOMES IN ADULT CELIAC DISEASE PATIENTS DIAGNOSED IN CHILDHOOD BECAUSE OF CLINICAL SUSPICION OR BY SCREENING
L. Kivela1, S. Alin2, S. Kroger2, K. Kaukinen2, K. Kurppa2
1Tampere Center For Child Health Research, University of Tampere and Tampere University Hospital, University of Tampere/Finland
2School Of Medicine, University of Tampere, Tampere/Finland

Contact E-mail Address: laura.kivela@fimnet.fi

Introduction: Starting a gluten-free diet (GFD) and follow-up of celiac disease was sent to 564 adults with a childhood diagnosis. Further, the participants fulfilled validated Gastrointestinal Symptom Rating Scale (GSRS) and Psychological General Well-Being (PGWB) surveys for symptoms and quality of life. Clinical and histological presentation at diagnosis and other relevant medical data were confirmed from patient records. All variables were compared between screen-detected and clinically detected patients.

Results: Altogether 235 (42%) adults completed the questionnaires. At diagnosis, screen-detected patients (n = 49) were older (11.3 vs 8.8 yr, p = 0.016) and had less symptoms (44% vs 85%, p < 0.001) than clinically detected patients (n = 186). They also had a trend to have less often total villous atrophy (18% vs 32%, p = 0.075) and anemia (18% vs 32%, p = 0.072). The groups did not differ in gender, current age (median 26.5 vs 27.1 yr, p = 0.64) and were similar in the number of lifetime symptoms related to CD. A trend was noted among the group who experienced health concerns about health, clinical symptoms, strict GFD (74% vs 80%, p = 0.161), lifestyle restrictions caused by GFD, presence of celiac disease-related complications, physical activity, fertility or GSRS and PGWB scores. However, screen-detected patients smoked less (4% vs 15%, p = 0.037) and had more often celiac disease in relatives (78% vs 58%, p = 0.011).

Conclusion: Diagnostic approach and presentation of celiac disease in childhood do not seem to affect the long-term health outcomes or attitude towards the disease in adulthood. Lack of difference in the dietary adherence and lifestyle recommendations gives further support for active screening and early diagnosis of celiac disease.

P1921 REVIEW OF SERVICE PROVISION OF NATIONAL INSTITUTE OF HEALTH AND CARE EXCELLENCE (NICE) RECOMMENDED QUALITY STANDARDS FOR COELIAC DISEASE AT A BIG DISTRICT GENERAL HOSPITAL
F.K. Shaikh, D. Vani, M. Sprakes, F. Greenhalgh
Gastroenterology, Mid Yorkshire Hospitals NHS Trust, Wakefield/United Kingdom

Contact E-mail Address: shaikh177@yahoo.com

Introduction: In the UK, 1 in 100 people are affected with coeliac disease. NICE published quality standards (QS134) for coeliac disease in October 2016 based on NICE guidelines NG20 (September 2015). This quality standard covers the recognition, assessment and management of coeliac disease in children, young people and adults. The quality standard is expected to contribute to improvements in the diagnosis of coeliac disease, growth in children and young people, health-related quality of life, incidence of osteoporosis, intestinal lymphoma, vitamin D deficiency, and iron deficiency.

Aims & Methods: We audited our departmental practices against NICE quality standards for coeliac disease. It is a retrospective data analysis of patients, 16 years and above, with probable coeliac serology from April 2016 to September 2018. The adverse events were by referral, value of issue transglutaminase (tTG) antibodies, type of referral (new or follow up), timing of OGD (less than or more than 6 weeks), whether or not seen by dietician, offer of annual review, and DEXA scan.

Results: Out of 24 patients, 6 patients had new referrals (26%). 5 patients had follow-up (21%). New referrals, 3 (13%) had follow-up and 2 (9%) had screening. 2 (8%) patients had OGD in more than 6 weeks. 4 (17%) patients had DEXA scan.

Conclusion: The incidence and prevalence of coeliac disease in our study are 30.28 per 100,000 persons-years and 8 per 100,000 population respectively. The data demonstrates that Mid Yorkshire NHS Trust is not providing required service standards for optimum care of coeliac patients in the Mid Yorkshire region. We need to keep in mind that some gastroscopies would have been performed in the primary care sector, the records of which were not available on our system. This factor could have potentially affected our results. Due to several constraints in our service provision, time frames stipulated in the NICE guidance are challenging as evidenced by the audit results. In spite of our unique local access to endoscopy units in primary care, we are still not able to deliver the required standards of care. Given the potential disease sequelae of coeliac disease, such as osteoporosis and lymphoma, it is important that these issues are addressed by the development of local referral and management pathways to ensure that all coeliacs are captured, investigated, and followed up appropriately.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In nonresponsive celiac disease (NRCD) the symptoms and duodenal mucosal changes persist despite gluten-free diet (GFD). Recently, knowledge about dysbiotic microbiota is increasing (1). Furthermore, serum microbial antibodies to Saccharomyces cerevisiae (ASCA), Pseudomonas fluorescens-associated sequence (I2) and Bacteroides caccae TonB-linked outer membrane protein (OmpW) were found to be gluten-sensitive (2) and present already at early stages of CD development (3). We hypothesized that increased seroactivity to microbial antibodies is associated also with NRCD.

Aims & Methods: Serum ASCA, I2 and OmpW were measured in 20 CD patients with persistent villous atrophy and mucosal inflammation despite strict GFD and negative celiac serology (NRCD group). Corresponding GFD responsive patients served as CD controls (58 samples at diagnosis and 55 on GFD) and...
80 healthy blood donors as non-CD controls. Kruskal-Wallis test was used to compare antibody titers and Dunn-Bonferroni for post hoc pairwise comparisons.

**Results:** At least one serum microbial marker was positive in 80% of NRCD patients, in 97% of untreated and 87% of treated CD patients and in 44% of non-CD controls. NRCD patients had the highest frequency of ASCA positivity (64% vs 52%, 20% and 0%, respectively) and also significantly higher ASCA IgA (median 14.5 U/ml) and IgG (32.5 U/ml) titers than treated CD patients (7.0 U/ml, 13.0 U/ml) and non-CD controls (4.5 U/ml, 5.8 U/ml). There was no difference in ASCA between NRCD and untreated CD. The frequencies of 12 (65%) and OmpW (45%) were lower in NRCD than in untreated CD (86%, 59%, respectively), while 12 titers were higher in NRCD (median absorbance 0.76) and untreated (1.0) and treated (0.83) CD than non-CD controls (0.32). OmpW was elevated in untreated (1.1) and treated (0.94) patients compared with non-CD controls (0.79).

**Conclusion:** Seropositivity and high titers of ASCA were associated with NRCD and might thus serve as additional follow-up tool for histological recovery in CD.

**P1924 CIRCULATING EXTRACELLULAR VESICLES, A NOVEL MECHANISM OF ENDOCRINE CELLULAR CROSS-TALK, ARE INCREASED IN NEWLY DIAGNOSED CELIAC DISEASE PATIENTS**

**Contact E-mail Address:** efkan78@gmail.com

**Introduction:** Extracellular vesicles (EVs) have been recently hypothesized to represent a major peripheral mechanism of cellular cross-talk. EVs carry surface receptors and proteins characteristic of their cells of origin and shuttle molecules (proteins, RNAs, microRNAs) potentially controlling physiological and pathological systemic processes. Recent studies have demonstrated an increased number of circulating EVs in a variety of conditions characterized by multi-organ impairment and/or damage such as insulin-resistance, atherosclerosis and obesity. Celiac disease (CD) is an immune-mediated inflammatory enteropathy, triggered by gluten ingestion in genetically susceptible individuals. It is frequently associated with a variety of systemic conditions both autoimmune and potentially immune-mediated in nature.

**Aims & Methods:** The aim of this study was to assess and characterize patterns of circulating EVs in newly diagnosed CD patients. We enrolled consecutive adult anti-tTG positive, biopsy proven CD patients. Circulating EVs were identified untouched on whole blood samples by a no-lyse/no-wash method, combined with EVs volumetric count (FACSVerse, BD), based on a novel six-colour flow cytometry panel, in order to identify and enumerate both the whole EV compartment and different EVs subpopulations. Data are expressed as mean ± SD and statistical differences were evaluated by means of T-test.

**Results:** We evaluated 12 age- and sex-matched controls (mean age 42 ± 19.1 vs. 40.8 ± 15.9 years, F/M = 4:1) at diagnosis and 12 age- and sex-matched healthy controls. Histology was considered positive for lesions of grade ≥B1 according to the Corazza-Villanacci classification. Mean anti-tTG levels at diagnosis were 6.9 ± 3 units/L. Mean number of total circulating EVs was significantly higher in CD than in controls (5985 ± 72482 vs 14383 ± 10018 EV/microL, p < 0.035). Subgroup analysis showed that EpCAM + EVs, of epithelial origin, and CD44 + platelet-derived EVs were not significantly different between CD and controls (894 ± 1004 vs. 548 ± 1237 and 3052 ± 1563 vs. 1734 ± 1610 respectively, p > 0.05). On the contrary, CD45 + EVs, of leucocyte origin, showed a significantly higher number on CD patients vs. controls (460 ± 492 vs. 119 ± 150 p = 0.026).

**Abstract No: P1923**

Data on levels of ROS and oxidative damage biomarkers in sera of naïve patients (N-CD), coeliac patients on a gluten-free diet (GFD) including responders (CD-GFD) or non-responders (NRCD) to treatment.
Conclusion: Celiac disease patients at diagnosis show higher numbers of circulating cell-free DNA in peripheral blood when compared with matched controls. Phenotypical assessment suggests that this increase is not primarily driven by epifelial or endothelial damage. On the contrary, the increased numbers of leukocyte-derived EVs, suggest their potential implication in systemic signaling.

P1925 COELIAC DISEASE AND REPRODUCTIVE DISTURBANCES: IS THERE ANY CORRELATION

H. Boutallaka, I. Benbelrhadj, F.Z. Ajana
Medecine C, Ibn Sina University Hospital, Rabat/Morocco

Contact E-mail Address: haneaiboutallaka@gmail.com

Introduction: The coeliac disease is an autoimmune enteropathy induced by the ingestion of gluten in genetically predisposed individuals. The clinical phenotypes ranges varieted manifestations including reproductive disorders. The aim of our study is to evaluate the frequency of these disorders in the coeliac disease and their evolution under gluten-free diet.

Aims & Methods: It's a single-center, retrospective and descriptive study including 241 patients with coeliac disease enrolled within period of 17 years from 1995 to 2016 in the department of Gastroenterology « Medecine C » in Ibn Sina University Hospital. Results: About 241 patients suffering from coeliac disease,58 patients presented reproductive disorders, either 28.9%. Recruiting 53 women and 5 men, with a sex ratio M/F of 10/6. The mean age was 32.25years ranging from 13 to 59years old. The diagnosis of coeliac disease was based on: History (severe or partial Villous atrophy with intraepithelial lymphocytosis exceeding 30%), the antinomous antibodies and/or antitransglutaminase antibodies positive. The reproductive disorders were never isolated but always associated with digestive or extradigestive signs at the time of the diagnosis of coeliac disease. These disorders were mostly among puberty in 11 cases (19%), secondary amenorrea in 13 cases (22.4%), Metrorrhagia in 12 cases (20.6%), absence of development of secondary sexual characters in 8 cases (12.5%), spontaneous abortion in 7 cases (10.9%), menometrorrhagia in 4 cases (13.8%), primary sterility in 5 cases (8.6%), precocious menopause in 6 cases (10.3%), premature labour and/or IUGR in 3 cases (5%), primary amenorrea in 2 cases (3.4%), and intrauterine Fetal death IUFD in one case (1.7%). All our patients benefited from a gluten-free diet. 15 patients were excluded from the study, 2 patients died, and 12 patients were lost to follow-up. Of the 29 patients stayed, the evolution of the reproductive disorders under gluten-free diet was good in 26 cases (90%), with normalization of the cycles in 15 cases, The cycle was returned in 6 cases, development of secondary sexual characters in 2 cases, fertility was returned in one case. The 15 patients leveled her cycle after primary amenorrea, and one case was delivered a baby in term after a repeated premature deliveries. The evolution was good in 3 cases as regard missed abortion four years after the gluten-free diet in 1 patient, and amenorrea continued in 2 cases.

Conclusion: Reproductive disorders related to the coeliac disease were frequent and variable. In our study, these disorders well responded to the gluten-free diet. 15 patients were excluded from the study, 2 patients died, and 12 patients were lost to follow-up. Of the 29 patients stayed, the evolution of the reproductive disorders under gluten-free diet was good in 26 cases (90%), with normalization of the cycles in 15 cases, The cycle was returned in 6 cases, development of secondary sexual characters in 2 cases, fertility was returned in one case. The 15 patients leveled her cycle after primary amenorrea, and one case was delivered a baby in term after a repeated premature deliveries. The evolution was good in 3 cases as regard missed abortion four years after the gluten-free diet in 1 patient, and amenorrea continued in 2 cases.

Contact E-mail Address: ancatrifan@yahoo.com

Introduction: Celiac disease (CD) is a chronic imune-mediated enteropathy that occurs in genetically predisposed individuals. The clinical phenotypes ranges from classical gastrointestinal manifestations to only atypical signs, thus making the clinical diagnosis a challenge. The aim of the study was to investigate the relationship between duodenal histology, specific antibody levels and clinical presentation in adult CD Romanian patients.

Aims & Methods: Design: retrospective retrieval of information prospectively entered into a structured database including 81 adult patients diagnosed with CD hospitalized at the Institute of Gastroenterology and Hepatology, “St. Spiridon” Hospital, Iasi between January, 2012- December, 2016 admitted with symptoms of abdominal disturbances (diarrhoea, heartburn, nausea, vomiting, reurgitation, abdominal pain). Demographic, clinical, serological, and histological characteristics of individuals with CD were reviewed.

Results: The study group included 81 adult patients with a female: male ratio of 3: 1. 60 (71.1%) female patients, mean age 40.02 ± 12.14 years. A total of 46.1% patients presented with gastrointestinal (GI) complaints and 51.9% of patients presented mostly with non-GI manifestations, and advanced age of symptom onset in the latter category (38yrs vs 47yrs). Marhl-Obreuber classification was used to assess mucosal injury and Marsh 3c lesions were found in 25 (30.9%) cases. When assessing the serological parameters, IgA anti-tissue transglutaminase (IgA- TGt) antibody (61.45±7.458 u/mL vs 162.02±106.179 u/mL, P = 0.001) and IgA anti-gliadin antibodies (IgA-AGA) levels (61.83±69.41 u/mL vs 77.15±71.02 u/mL, P = 0.001) correlated with intestinal villous atrophy (Marsh 3a and 3c) in CD patients by Spearman rank correlation. Among symptomatic, abdominal distention and diarrhea were associated with abnormal histology. Hemoglobin levels were evaluated and anemia was diagnosed in 61.7% patients among patients with elevated IgA-tTG levels (r = 0.516, P = 0.004), IgA-AGA (r = -0.301, P = 0.006) and Marsh 3b-3c lesions (P = 0.0084). Among biological markers included in the statistical analysis, low iron levels (cut off 30 mg/dl), hypocholesterolemia and low protein levels were associated with Marsh 3 b lesions (P = 0.008) and elevated IgT-IgA titers (r = -0.384; P = 0.001). Coeliac disease IgA-tTG and AGA levels correlate with duodenal villous atrophy in adult CD patients. An IgA-tTG titer > 160 was nearly always associated with severe CD histopathology. GI and non-GI symptoms are not reliable predictors of CD.

Introduction: Celiac disease is an immunologically-mediated enteropathy that triggered by the intake of gluten-containing foods in genetically predisposed individuals. It causes intestinal and extraintestinal manifestations. Extranintestinal findings are observed in many systems. The prevalence of extraintestinal findings in CD patients is 30%, 10–25% higher than in the general population. We performed an echocardiography study to determine the frequency of accompanying cardiac findings in our patients with celiac disease. In this article, we aimed to share the frequency of the PFO detected in celiac patients with high results.

Aims and Methods: Between May-June 2015, 65 patients who applied to the gastroenterology clinic of Derince Education and Research Hospital and followed up with celiac disease were identified. The sociodemographic characteristics, celiac disease diagnosis duration, symptoms and complaints, accompanying diseases, drug use histories, hemogram and biochemical parameters of these patients were recorded. The patients underwent saline contrast transthoracic echocardiography in the cardiology clinic. Patients’ data were recorded. The obtained data were evaluated with appropriate statistical methods.

Results: Sixty-five celiac patients were included in the study, 21 (32.3%) male and 44 (67.7%) female. The mean age was 41.3 ± 14.1 years. PFO was detected in 39 (60%) of the patients. There was no difference in the incidence of PFO in between male and female patients. (61.9% and 59.1% respectively, p=0.829). Compared with the frequency of PFO in the general population, the incidence of PFO in patients with CD is even higher. (25% and 66% respectively, P<0.004). Conclusion: As a result, the incidence of PFO is more prevalent in celiac patients than in the general population. For this reason, the evaluation and treatment of the PFO, which may be the cause of cerebrovascular disorders in clinical follow-up of patients, are required. In addition, the high incidence of PFO in celiac patients suggests that celiac disease is a factor affecting the development of patients from intrauterine period. Because our patients did not undergo transesophageal echocardiography, this rate may be less than real exist. For this reason, further evaluation is required with a wider patient group and by transesophageal echocardiography.

Introduction: Celiac disease diagnosis (CD) guidelines recommend sampling of both the bulb and distal duodenum for diagnostics. This has been reinforced by the recent data on ultra-short CD [1]. However, it has been previously shown in pediatric CD that bulb samples are frequently of poor quality [2]. However, the bulb and the duodenal bulb in non-celiac patients also, and it can lead to false-positive diagnoses [2]. Our aim was to address the same issue in adult CD, using the same validated morphometric methods [3].

Aims and Methods: We prospectively recruited cases of clinically recommended upper GI endoscopy; all patients also had signs and symptoms of CD and were checked for CD serology (serum tissue transglutaminase 2 antibodies and endomysial antibodies) and biopsy sampled according with current
recommendations. Paraffin embedded biopsy samples were assessed for villous height (VH) and crypt depth (CD) and VH/CD ratio revealed a critically reduced sensitivity, due to a sensitivity problem with this serology in the pediatric population or secondary to a suboptimal IgA band expression of the POCT.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1929 QUALITY STANDARDS IN COELIAC DISEASE: A RETROSPECTIVE EVALUATION IN A SINGLE SPECIALIST CLINIC
M. Fitzpatrick¹, S. Nichols², E. Soilleux², S. Travis¹
¹Translational Gastroenterology Unit, St John’s Institute of Dermatology, London, United Kingdom
²Department Of Nutrition And Dietetics, John Radcliffe Hospital, Oxford, United Kingdom

Contact E-mail Address: mebfiz@gmail.com

Introduction: Quality standards in coeliac disease management were recently published by the National Institute for Health and Care Excellence. These specify a new 6-week target for the time from referral to endoscopy, which was previously covered by the 18-week referral to treatment (RTT) pathway. They also state that all newly-diagnosed patients should discuss a gluten-free diet with a specialist diettian. We retrospectively evaluated practice in the Oxford University Hospitals NHS Foundation Trust coeliac clinic against these criteria, and against national guidelines (duodenal bulb sampling at endoscopy and screening for nutritional deficiency).

Aims & Methods: The medical records of 110 patients referred to our clinic between September 2015 and September 2016 were examined. The date of referral and endoscopy were recorded, along with relevant demographic, clinical and laboratory data. Information was collected and analysed in Microsoft Excel.

Results: Eighty-five patients (68% female, median age 34) were seen within the waiting time of the 18-week referral to treatment (RTT) pathway. Six patients declined or delayed endoscopy, and endoscopy or referral information were not available for 4 patients. For the remaining 66 patients, mean time from referral to endoscopy was 12 weeks (SD 37 days), with 59 patients (89%) referred within 18 weeks, but only 11 patients (17%) within 6 weeks (Figure 1). Duodenal bulb biopsies were taken at endoscopy in 31 patients (44%). A diagnosis of coeliac disease was made in 74 (87%) of all patients referred, of whom 67 (90%) were referred to a specialist diettitian. Haematocrits (iron studies, vitamin B12 and folate) were measured in 67 patients (90%), bone densitometry was measured in 51 patients (69%) and all patients were offered a follow-up appointment in the coeliac clinic. Iron deficiency was found in 31 patients (45%) of patients tested, folate deficiency in 12 patients (18%) and vitamin D2 deficiency in 5 patients (8%) and vitamin D3 deficiency in 23 patients (38%). Osteoporosis was diagnosed in 5 patients (10%) and osteopenia in 10 patients (20%).

Conclusion: Appropriate dietitian referral, specialist follow-up and screening for nutritional deficiency and bone disease occur within the Oxford coeliac disease service. Compliance with recommended biopsy protocols was only 44%. Whilst most referrals met the previous 18-week RTT pathway, few would have met the new quality standards.

Introduction: We previously reported that small-bowel capsule endoscopy (CE) is effective in diagnosing small-bowel lesions with occult obscure gastrointestinal bleeding (OGIB) (Gastroenterol Res Pract. 2013). However, there is no consensus regarding the management of occult OGIB patients without bleeding source revealed by CE.

Aims & Methods: We aimed to consider management of occult OGIB patients based on the long-term outcomes. A total of 357 consecutive occult OGIB patients (203 men; mean age: 59.7 years) who underwent CE at Hiroshima University Hospital before March 2016 and whose entire small-bowel could be observed and followed-up by CE for at least 12 months, were enrolled. We examined each patient to confirm the positive CE findings rate, the detection rate of bleeding source lesions, the details of bleeding source lesions, the overt

Introduction: Celiac disease (CD) is a chronic inflammatory disorder triggered by the genetically susceptible people. The prevalence varies in between European countries and averages at 1% within whole Europe. It is anticipated that the number of undetected and therefore untreated cases is high. Since untreated CD is associated with a high morbidity, further diagnostic modalities to uncover undiagnosed coeliacs are currently explored. In this setting, we evaluated Simtossmax™, a POCT detecting deamidated gliadin peptide antibodies, with the goal to identify patients that need for duodenal biopsies prior to gastroscopy. Thus, the goal was to establish a test allowing to guide the endoscopist in his decision to collect duodenal biopsies.

Aims & Methods: Prospective investigator-initiated multi-center study in six adult gastroscopy and two pediatric gastroscopy centers in Berlin and Brandenburg, Germany, approved by the local ethical committees. Finger prick blood of patients registered for gastroscopy and eligible for the study (exclusion: defective coagulation, established celiac disease or on gluten-free diet) was analyzed by the POCT (IgA and IgG for deamidated gliadin peptides; Simtossmax™ test, Tillotts, Switzerland). Test results were compared with duodenal histology (Marsh classification). In POCT-positive individuals transglutaminase-IgA serology was performed.

Results: Analysis was performed in n=721 adult patients (average age: 48 yrs) and n=108 pediatric patients (average age: 11 yrs). In the adult cohort 45 POCT were judged as “positive”. Within the POCT positives, 6 Marsh III cases were detected. None of the 676 POCT-negative individuals revealed CD. Therefore, the prevalence of CD in this population was 0.8%. The POCT-specificity in this group was 94% (5%-CI 92-96%), the sensitivity was 100% (95%-CI 51-100%). In the pediatric cases 21 POCTs were judged as “positive” with 13 being true-positive. Of the 87 negative POCTs, 68 were true-negative, but 4 were false-negatives. Thus, the prevalence of CD in the pediatric gastroscopy was 16%. However, sensitivity in this group was only 76% (50-93%) and specificity 91% (91-93%). Examiners at various centers suggested, that “faint” bands in the POCT analysis might contribute to interpretation failures.

Conclusion: A screening test like a POCT in CD-needs to perform optimally especially in sensitivity. In the adult population all CDs were detected by the

POCT. However, the CD prevalence in this group was low. In the pediatric group the POCT revealed a critically reduced sensitivity, due to a sensitivity problem with this serology in the pediatric population or secondary to a suboptimal IgA band expression of the POCT.

Disclosure of Interest: All authors have declared no conflicts of interest.

bleeding rate with or without treatment, the rate of anaemia exacerbation (hemo-
globin levels decreased 45 ng/ml, p value 0.05 95% C.I 0.22–1.03 O.R. 0.05.

Results: The positive CE findings rate was 44% (157/357) and the decte-
tion rate of bleeding source lesions was 27% (98/357). All of the treated bleeding source lesions (Group A) were as follows: angioectasia 61 patients (Yano-
Yamamoto classification Type 1a 37 patients, Type Ib 24 patients), non-specific ulcer, diverticular anti-inflammatory drugs-induced ulcer, 6 patients, hemangiomia 5 patients, Crohn’s disease 3 patients, primary cancer 2 patients, metastatic cancer 2 patients, gastrointestinal stromal tumour 2 patients, malignant lymphoma 2 patients, others 3 patients. Lesions that were not regarded as bleeding source without treatment (Group B) were as follows: angioectasia 25 patients (Type 1a without oozing 25 patients), erythema 31 patients, others 3 patients. There were no patients with overt bleeding
in Group B. Although 6 patients (10%) had anaemia exacerbation in Group B (Type 1a) that were not a bleeding source lesion. OR in both Group A and Group B was 90%. DSS in Group A was 99% and in Group B 100%. One patient in Group A died of a primary small-bowel cancer.

Conclusion: Conclusion: Long-term outcomes with occult OGB patients were good except malignant tumor, because overt bleeding and/or anaemia exacerbation did not occur within the follow-up period. Thus, occult OGB patients without bleeding source lesions, including Type 1a angioectasia without oozing, and erythema, are unnecessary to follow-up with CE in occult OGB patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1932 A PILOT STUDY EXPLORING THE VALUE OF FAECAL IMMUNOCHEMICAL TEST (FIT) WHEN INVESTIGATING ANAEMIA OR OCCULT GASTROINTESTINAL BLEEDING WITH SMALL BOWEL CAPSULE ENDOSCOPY
D. Tighe1, C. Judge1, P. Walsh1, M. Kelly1, A. O’Connor1, N. Breslin2, B. Ryan1, G. Boran2, D. Menamara1
1 Department Of Gastroenterology Trinity Academic Gastroenterology Group (TAGG), AMNCH Tallaght, Dublin/Ireland
2 Department Of Clinical Chemistry, AMNCH Tallaght, Dublin/Ireland

Contact E-mail Address: donaltighe83@gmail.com

Introduction: Small bowel capsule endoscopy (SBCE) is a very useful method of investigating iron-deficient anaemia, or occult gastrointestinal (GI) bleeding. It can identify the causes of anaemia or bleeding, such as angiodysplasia, small bowel Crohn’s disease, polyposis, lymphoma, and malignant lesions. There is however a need to improve the diagnostic yield, particularly where resources and access to capsule endoscopy are restricted. Faecal immunochromat test (FIT) has an established role, in investigating large bowel bleeding, and is incorporated into a number of bowel cancer screening programmes.

Aims & Methods: The aim of our study was to investigate whether FIT could help predict likelihood of small bowel bleeding or other significant pathology at time of small bowel capsule endoscopy. This was a prospective pilot study, performed at our centre from September 2016-April 2017. Indications for enrolment were patients referred for SBCE with the indication of anaemia or occult GI bleeding. Baseline patient characteristics were obtained including age, gender, history of recent or distant diagnosis, and use of anti-platelet/anti-coagulants.

Patient haemoglobin (Hb) level was checked on the day of SBCE where possible. Patients were asked to return one completed FIT for further analysis. A cut of 50 ng/ml was chosen as this is the standard cut-off used, in the Irish National Bowel Cancer Screening programme.

Results: A total of 40 patients were enrolled, mean age 55.4 years (range 18–77), 64% were female. A total of 27.6% of patients were on anti-platelet agents or anti-coagulants. 34% of patients had a blood transfusion within the last year. Mean Hb for the cohort was 12.8 g/dL (range 7.8–15.9 g/dL). The average FIT reading was 459 ng/mL (range 0–4246 ng/mL). 30% of patients had a FIT level >50 ng/mL. 46% of patients, had positive findings at SBCE. 9/12 (75%) of patients with a FIT level >50 ng/mL had positive findings at capsule endoscopy, compared to 5/28 (17.8%) for FIT <50 ng/mL. p value = 0.002, 95% C.I. 0.29–0.86 O.R. 0.16. These included 4/12 (33%) cases of Crohns, 3/12 (25%) angiodysplasia, 3/12 (33%) non-HBD enteritis, 1/12 (16.7%) small bowel tumour and 1/12 (16.7%) melanoma, with no clear source. In addition there was a good correlation between FIT and Haemoglobin levels. 60% of patients with FIT >30 ng/mL were anaemic (Hb <11.5 g/dL), compared to 17% with FIT <30 ng/mL, p value = 0.02 95% C.I. 0.09–0.76 O.R. 0.14. Combining Hb and FIT levels, was also informative and predictive of small bowel pathology. 83% of patients, who were anaemic and had a FIT >50 ng/mL had clinically significant findings at SBCE compared to 21% pick up rate in patients with normal Hb and FIT levels, p value = 0.05 95% C.I 0.22–0.33 O.R. 0.05. Overall the sensitivity for a FIT >50 ng/mL for detecting small bowel pathology was 83% with a specificity of 92%, giving a positive predictive value of 83.3% (95% C.I. 56.9%–95%).

Platelet use was not predictive of a positive FIT, as 16.7% of patients with a FIT >50 ng/mL were on anti-platelet agents, compared to 83.3% who weren’t.

Conclusion: FIT is useful at predicting clinically significant small bowel pathology at the time of capsule endoscopy. It may help better identify and prioritise patients who would benefit from referral.

Table 1B
Conclusion: VCE detected small bowel lesions in 71% in our cohort. There is a high prevalence of PHE in patients with decompensated cirrhosis. Vascular lesions are the most common finding in the small bowel of this population.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Aim of this meta-analysis was to examine the differences in re-bleeding rates in patients with OGB after index VCE, as measured in Western and Eastern studies. A comprehensive literature search in MEDLINE was conducted to identify all studies examining re-bleeding rate after VCE for OGB. Meta-analysis assessed the pooled proportion of re-bleeding events after VCE for OGB according to study’s origin (Western vs. Eastern) as the primary end point. Possible ratios for re-bleeding after positive vs. negative index VCE and after long (>24 months) vs. short (<24 months) follow-up in the two studies origins, comprised the secondary endpoints. Study outcomes effect sizes were calculated using RevMan 5.3 software random effect model and they are presented as rate(95% CI) or OR(95% CI). Heterogeneity was measured using the I² statistics and publication bias risk was examined with Funnel plots inspection.

Results: Thirty-eight (14 Eastern and 24 Western) studies were included in the analysis with 5197 patients followed from 6 to 52 months. We detected significant heterogeneity with no evidence for publication bias in the meta-analyzed studies. While the overall, pooled rate of re-bleeding after VCE was 25%(21–29%), I² = 93%, similar re-bleeding rates were detected among Eastern and Western populations [22%(16–28%), I² = 93% vs. 28%(22–35%), I² = 95%]. The re-bleeding risk after positive compared to negative VCE index examination was higher [1.89(1.01–3.24), I² = 72%] in Eastern population studies, while a similar difference was not detected in the Western studies [1.46(0.72–2.94), I² = 88%]. When only studies with short-term follow-up were analyzed, the OR of re-bleeding after positive vs. negative VCE was 1.23(0.58–2.61), I² = 77% and 1.93(0.90–4.13), I² = 71% in Western and Eastern studies, respectively. For studies with long-term follow-up, no significant difference in the OR of re-bleeding after positive vs. negative index VCs was detected either in the East [2.03(0.96–4.29), I² = 71%] or in the West [2.04(0.82–5.08), I² = 99%].

Conclusion: Our analysis shows that patients undergoing VCE for OGB have similar re-bleeding rates in the East and in the West, regardless of the length of the follow-up. An increased re-bleeding risk after positive vs. negative index VCE was noted only in studies originating from the East.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1935 MULTICENTER PROSPECTIVE CASE-CROSSOVER STUDY ON THE ASSOCIATION BETWEEN OVERT SMALL-BOWEL BLEEDING AND DRUGS USING CAPSULE ENDOSCOPY

Introduction: Small-bowel capsule endoscopy (SBCE) have been useful in managing obscure gastrointestinal bleeding. We previously reported that the use of oxicams and diclofenac was associated with an increased risk of nonsteroidal anti-inflammatory drug (NSAID)-induced small-bowel injury (Aliment Pharmacol Ther 2014). However, the etiology and temporal development of drug injuries have been useful in managing obscure gastrointestinal bleeding. We previously reported that the use of aspirin-induced injuries, angiodysplasias, Meckel’s diverticula, and polyps. Loxoprofen-associated SBB was caused by mostly loxoprofen-induced injuries.

Conclusion: Enteric-coated aspirin, clopidogrel, and loxoprofen were identified as drugs causing overt SBB during the relatively short period after administration.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1936 LONG-TERM OUTCOMES AFTER NEGATIVE DOUBLE-BALLOON ENTEROSCOPY (OVERT SMALL BOWEL BLEEDING (OBSCURE-OVERT GASTROINTESTINAL BLEEDING)

R. Hashimoto1, T. Matsuda2, M. Nakahori3

1Dept. Of Gastroenterology, Sendai Kosei Hospital, Sendai/Japan

Contact E-mail Address: rinhashimoto@gmail.com

Introduction: There are very few reports about long-term outcomes in patients with negative balloon assisted enteroscopy for suspected overt small bowel bleeding (obscure-overt gastrointestinal bleeding).

Aims & Methods: The aim of this study is to evaluate long-term outcomes and risk factors of re-bleeding after negative double balloon enteroscopy (DBE) for suspected overt small bowel bleeding. We investigated 297 patients undergoing DBE for suspected overt small bowel bleeding between December 2004 and April 2016 at Sendai Kosei Hospital. Prospectively collected data were reviewed, and 83 patients (27.9%) showed negative results in the first antegrade and/or retrograde DBE. For these patients, letter and telephone interviews were conducted in April 2017. As a result, a cohort of 64 patients could be followed. The primary outcome measurement is overt rebleeding and necessity for clinical assessment after negative DBE.

Results: Overt rebleeding was observed in 19 of 64 patients (29.7%) with 76 months follow-up period. The mean period during the first DBE and the first rebleeding episode was 11.6 months(2day-48months). Three patients showed rebleeding after more than three years of the first DBE. At the time of rebleeding, emergent endoscopy including DBE (within less than 48 hours) and/or contrast-enhanced computed tomography (CCT) was performed in all patients. The bleeding source was identified in 17 of 19 patients (89.4%). The bleeding source were duodenum (n = 8), jejunum (n = 7) and colon (n = 2), respectively. One

Disclosure of Interest: All authors have declared no conflicts of interest.
patient died due to uncontrollable duodenal bleeding. Blood transfusion before the
first DBE was associated with rebleeding (odds ratio 22.5, 95% confidence interval
1.97–198). However, other factors, including sex, age, and discontinuation of antithrombotic
agents were not associated with positive CE findings. Conclusion: Discontinuation of antithrombotic
agents did not affect the diagnostic accuracy of PillCam SB 3.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Capsule endoscopy allows high-quality imaging of the small bowel. Newer capsule with a panoramic viewing mode is available and might increase the detection rate of bleeding lesions in patients with obscure gastrointestinal bleeding. Furthermore, an improved patient acceptance rate is expected.

Aims & Methods: In a randomized prospective comparative multi-center study, patients with obscure gastrointestinal bleeding were included and examined either with Capsocam SV-1 versus PillCam SB 3.

Results: One hundred eighty-one patients with obscure gastrointestinal bleeding were recruited into the study. After exclusion of 28 patients 153 patients were randomized and Capsocam SV-1 (n = 78) or PillCam SB 3 (n = 75) was administrated. Capsocam SV-1 detected more cases of bleeding (31/79, diagnostic yield 39.7%) compared to PillCam SB 3 (26/75, diagnostic yield 34.6%, n.s.). Transit time of both capsules was not different. Evaluation time with PillCam SB was reviewed. The trial was included 100 patients (50 cases in each group) received enteric-coated low-dose aspirin 100 mg. The Group PPI received LDA plus pantoprazole 40 mg, the Group RB received plus rebamipide 300 mg. Before starting therapy, we checked the background characteristics of each patient (H pylori, use of LDA, NSAID, bismuth, PPI, and endoscopic findings).

Gastroscopy and capsule endoscopy were performed, and the fecal occult blood reaction and fecal calprotectin levels were measured before, two and four weeks after drug administration. After the therapy, we asked physicians and patients about medication compliance and side effects. Capsule endoscopy was then repeated. The primary endpoint was the change in the number of mucosal breaks from baseline to 4 weeks. The secondary endpoints were the rates of side effects.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
3 was superior to CapsoCam SV-1 (27 min. vs. 40 min, p=0.01). 95% of the physicians were satisfied with each capsule system and evaluation software. The acceptance rate of the patients to retrieve the CapsoCam SV-1 was high. Adverse events/SAEs were 17.9%/1.3% with CapsoCam SV-1 and 16%/0% with PillCam SB 3. Re-bleeding rate was 28.75% within 3 months.

Conclusion: Both capsules allow high-quality imaging of the small bowel. CapsoCam SV-1 detected more lesions, however, relevant bleeding sources were visualized by both capsules. Physician's satisfaction was high with both capsule systems and evaluation software. Patient's acceptance with CapsoCam SV-1 was unexpectedly high. SAEs were 0% with PillCam SB 3 and 1.3% with CapsoCam SV-1.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI940 VALIDATION OF A SCORE CHART TO PREDICT THE RISK OF CHRONIC MESENTERIC ISCHEMIA: A DISCRIMINATIVE AND USEFUL TOOL IN CLINICAL DECISION-MAKING

7multidisciplinary study group, studygroup/Netherlands

Contact E-mail Address: l.vandijk@erasmusmc.nl

Introduction: Chronic mesenteric ischemia (CMI) is the result of insufficient mucosal perfusion of the gastrointestinal tract, mostly caused by atherosclerotic stenosis of the mesenteric arteries. Other causes of CMI are vasculitis, median arcurate ligament syndrome or non-occlusive ischemia (NOMI) due to decreased cardiac output or hypoxia-oxygenation. The diagnosis of CMI remains challenging as chronic abdominal pain is common and mesenteric artery stenoses are frequently observed in the general population but not necessarily related. Harki et al.(1) designed a score chart to predict the risk of CMI based on a cohort of CMI suspected patients. This score chart consists of patient characteristics (female 1 pt, weight loss 1 pt, cardio-vascular disease 1 pt) and radiologic evaluation (50-70% celiac artery (CA) stenosis 1 pt, >70% CA stenosis 4 pts, 50-70% superior mesenteric artery (SMA) stenosis 1 pt and >70% SMA stenosis 3 pts). A total score of 0-2 pts predicts an absolute risk of CMI of 0-21%, 3-6 pts a 22-70% risk and ≥7 pts a risk of ≥79%. We aimed to validate this prediction model in a prospective large multicenter patient cohort.

Aims & Methods: Patients suspected of CMI referred to our Dutch specialized CMI referral centers were included consecutively from January 2014 to August 2016. After diagnostic work-up of medical history taking, mesenteric CT-angiography and/or conventional catheter angiography, and a functional test for detecting mucosal ischemia using either tonometry or visible light spectroscopy. All cases were discussed in a multidisciplinary meeting attended by a radiologist, an intestinal surgeon and vascular surgeon. The primary outcome was clinical response to revascularization, defined as relief of presenting symptoms as experienced by the patient. The score chart for CMI based on patient characteristics and anatomy is a reliable tool to discriminate the risk of CMI and useful for clinical decision-making, for example to adopt a wait-and-see policy in patients with a low risk and immediate vascular intervention in patients with high risk of CMI.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Isolated stenosis of the celiac artery (CA) or the superior mesenteric artery (SMA) is frequently observed in patients with abdominal complaints. These patients may suffer from chronic mesenteric ischemia (CMI) causing nonspecific abdominal complaints as postprandial pain, nausea or diarrhea. However, the exact cause of single arterial mesenteric ischemia is a topic of continuous clinical debate and reports on the effectiveness of single mesenteric artery revascularization are scarce. We evaluated the long-term clinical success rates for single CA or SMA revascularization in patients with gastrointestinal symptoms and confirmed mucosal ischemia.

Aims & Methods: Data were collected from all 97 consecutive patients with gastrointestinal symptoms and a single mesenteric artery stenosis referred to the outpatient clinic of our tertiary care institution for analysis of CMI between January 2006 and October 2010. All patients underwent a standardized diagnostic work-up for CMI at baseline consisting of medical history taking and physical examination, imaging of the gastrointestinal arteries with either CT- or MR-angiography and/or conventional catheter angiography, and a functional test for detecting mucosal ischemia using either tonometry or visible light spectroscopy. All cases were discussed in a multidisciplinary meeting attended by a vascular surgeon, interventional radiologist and gastroenterologist, all specialized in CMI, leading to an expert based consensus diagnosis. Patients with consensus diagnosis of CMI underwent surgical or endovascular revascularization. The primary outcome was clinical response to revascularization, defined as relief of presenting symptoms as experienced by the patient.

Results: Consensus diagnosis of CMI was obtained in 62/97 patients and all consensus patients were revascularized. Isolated CA stenosis was present in 55/62 patients (89%) (31 vascular disease; 24 median arcuate ligament syndrome, MALS) and isolated atherosclerotic SMA stenosis in 7 patients. After a mean follow-up of 5.5 ± 3.0 years, 42/62 patients (68%) experienced sustained symptom relief. Responders to revascularization had a BMI increase during follow-up in contrast to the non-responders (+0.43 ± 2.5 versus −1.06 ± 2.4 kg/m², p = 0.033). Response to revascularization was not related to lesion localization (CA 67% versus SMA 71%, p = 0.825) or lesion etiology (MALS 63% versus vascular disease 71%, p = 0.483). See table.
CA = celiac artery; SMA = superior mesenteric artery; MALS = median arcuate ligament syndrome

Symptom relief No symptom relief
All patients 42/62 (68%) 20/62 (32%)
Vascular lesion
CA stenosis 37/55 (67%) 18/55 (33%)
SMA stenosis 5/7 (71%) 2/7 (29%)
Etiology
MALS 15/24 (63%) 9/24 (38%)
Vascular disease 27/38 (71%) 11/38 (29%)

Conclusion: Revascularization of the CA or SMA provides long-term symptom relief in 68% of patients with chronic gastrointestinal symptoms and confirmed mucosal ischemia due to single mesenteric artery stenosis. This provides the opportunity to help patients with otherwise unexplained, refractory abdominal complaints.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1942 UNDERUTILIZATION OF ENDOCOSCOPIC ARGON PLASMA COAGULATION FOR TREATMENT OF BLEEDING GASTROINTESTINAL ANGIODYPLASIAS: AN INTERNATIONAL MULTICENTRE COHORT STUDY

K. Groote1, M. Mathurewnez1, G. Holleran2, E. Van Geenen1, D. Maran2, L. B. Drenthe1
1Gastroenterology And Hepatology, Radboudumc, Netherlands, Nijmegen/Netherlands
2Department of Clinical Medicine, Trinity College, Dublin/Ireland

Contact E-mail Address: karingroote@gmail.com

Introduction: Endoscopic argon plasma coagulation (APC) is the first-line treatment in patients with iron deficiency anaemia or overt bleeding resulting from gastrointestinal angiodyplasias. In the minority of patients active bleeding angiodyplasias are seen during endoscopy, but in contrast non-bleeding angiodyplasias can be an incidental finding. This can make the decision whether to treat endoscopically detected angiodyplasias with APC difficult.

Aims & Methods: The aim of this study is to investigate the need for repeat endoscopies with APC in patients with angiodyplasias who were left untreated during the index endoscopy performed for iron deficiency anaemia or overt bleeding. We initiated an international, multicentre cohort study to collect clinical, laboratory and endoscopic data from angiodyplasia patients. Cases were identified through a systematic search in endoscopy reports from 2010–2015 with follow-up until July 2016. Inclusion criteria was endoscopic detection of angiodyplasia in the context of overt bleeding or iron deficiency anaemia. Exclusion criteria were other vascular anomalies and angiodyplasias as incidental finding. The primary outcome was repeat endoscopy with APC.

Results: A total of 197 patients with proven angiodyplasia as cause for anaemia or bleeding were included (mean age= 68 years; 58% male). Median follow-up was 37 months (range 18–57). In 52% of the cases (n = 103) APC treatment for bleeding angiodyplasia(s) was performed at the index endoscopy. Repeat endoscopy with APC was necessary in 17 patients (18%) in whom angiodyplasia were detected but left untreated during the index endoscopy. Median time between index and repeat endoscopy was 21 weeks. A total of 48 patients (51%) who received a purely diagnostic index endoscopy were in need of other treatment modalities (e.g. iron supplementation, blood transfusion, stop anti-coagulants). Anemia and/or overt bleeding resolved spontaneously in 24 patients (26%).

Conclusion: A substantial proportion of patients with clinical symptomatic angiodyplasia bleeding do not receive APC at the index endoscopy and continue to be dependent on iron supplementation, blood transfusion or undergo repeat endoscopy with APC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1943 DIGESTIVE INVOLVEMENT IN SYSTEMIC DISEASES: A UNIVERSITY HOSPITAL EXPERIENCE

W. Khannoussi1, K. Chita2, H. Bachir2, G. Kharraiss1, A. El Mekkaoui1, S. Hamza1, H. B. Aalou2, K. Serraj1, Z. Ismaili3, W. Khannoussi
1UNIVERSITY HOSPITAL EXPERIENCE

Contact E-mail Address: wkhannoussi@yahoo.com

Introduction: Digestive manifestations in systemic diseases including vasculitis and granulomatosis is broad and can affect any segment of the digestive tract and related organs. The clinical symptoms are not specific and it can be challenging for diagnosis. The other difficulty remains the interference of digestive side effects of medication used.

Aims & Methods: We aimed to review various digestive manifestations of systemic diseases. This was a retrospective study from Feb 2009 to Sep 2016 in internal medicine and gastroenterology departments. The exclusion criteria was incomplete data or regarding the diagnosis of the systemic disease.

Results: patients were included, sex ratio 0.38 (101 F/39 M), mean age at inclusion was 40 years old [13,79]. The following chart summarize the% of digestive manifestations by disease:

- Systemic Lupus erythematos 49 (10.36%)
- Systemic sclerosis 27 (8.33%)
- Behcet’s disease 27 (4.39%)
- Celiac disease 14 (7.37%)
- Wegener’s granulomatosis 2 (21.60%)
- Antiphospholid Anti body Syndrome 3 (22.58%)
- Amyloidosis 1 (45.16%)
- Churg-Strauss syndrome 2 (20.96%)
- Dermatomyositis 2 (25.80%)
- Microscopic Polyangiitis 1 (0%)
- Horton’s disease 1 (2.96%)
- Takayasu arteritis 3 (3.22%)
- Cryoglobulinaemic vasculitis 2 (0%)
- Henoch-Schönlein purpura 3 (30.10%)
- Leucocytoclastic vasculitis 2 (12.9%)
bariatric surgery, 52.3% of patients had VDD and 36.8% had VDI. After surgery, the number of VDD increased to 71.1% (p = 0.0079). The mean levels of 25(OH)D decreased significantly from 19.8 ng/mL before surgery to 16.6 ng/mL after surgery (p < 0.05). There was no correlation between the amount of weight loss and the changes in the levels of 25(OH)D in our study.

**Conclusion:** There is a high prevalence of vitamin D deficiency in obese patients eligible for bariatric surgery. The level of deficiency tends to increase after RYGB. This population of patients should, therefore, be offered an adequate level of vitamin D supplementation, especially after the procedure.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1946 INTRAGASTRIC BALLOON: A CRITICAL VIEW IN NON ELECTIVE BARIATRIC SURGERY PATIENTS**

1. *Dept. Of Bariatric Endoscopy, Endogastro Rio, Rio de Janeiro/Brazil*
2. *Dept. Of Gastroenterology, Usuy Clinic, Florianopolis/Brazil*
3. *Bariatric Endoscopy, Gastro Obeso Center, Sao Paulo/Brazil*

**Contact E-mail Address:** ricfittipaldi@hotmail.com

**Introduction:** Bariatric surgery is established as an excellent therapy for obesity. However, lower degrees of weight reduction without surgical indication also impact on patients’ health and quality of life, and the intragastric balloon (IGB) may be a treatment option.

**Aims & Methods:** We aimed to assess the efficacy of excess weight treatment with an IGB in patients with overweight and grade I obesity at EndogastroRio Clinic. A total of 717 patients were analyzed. A liquid filled IGB was used. The patients had an initial body mass index (BMI) between 27 and 34 kg/m². The level of significance was set at p < 0.05.

**Results:** 615 patients were women. 131 patients had overweight and 586 had grade I obesity. Mean age was 37.97 years (17-75). Weight loss results and the changes in the levels of 25(OH)D in our study.

**Conclusion:** Bariatric surgery is established as an excellent therapy for obesity, All other authors have declared no conflicts of interest.

---

**P1947 SPATZ3® ADJUSTABLE INTRAGASTRIC BALLOON TREATMENT: A BRAZILIAN MULTICENTRIC EXPERIENCE**

1. *Dept. Of Bariatric Endoscopy, Endogastro Rio, Rio de Janeiro/Brazil*
2. *Bariatric Endoscopy, Gastro Obeso Center, Sao Paulo/Brazil*
3. *Dept. Of Gastroenterology, Usuy Clinic, Florianopolis/Brazil*

**Contact E-mail Address:** ricfittipaldi@hotmail.com

**Introduction:** Intragastric balloons (IGB) are already used worldwide in the treatment of overweight and obesity, with established success. The Spatz3® adjustable balloon brings the possibility of balloon volume control during all the treatment, possibly reducing the risk of early removals due to intolerance and greater weight loss when compared to traditional IGBs.

**Aims & Methods:** We aimed to analyze the initial 25 months results regarding weight loss and complications with Spatz3® adjustable intragastric balloon in Brazil. In this retrospective longitudinal study were included patients submitted to Spatz3® adjustable IGB treatment between October 2014 to April 2017 in four private clinics in Brazil. The IGB Spatz3® was filled with a standard volume of 600 ml that was downward or upward adjusted when necessary. The patients presented a minimum body mass index (BMI) of 27 kg/m². Were analyzed the complications of Spatz3® treatment and BMI reduction, percent total body weight loss (%TBWL) and percent excess weight loss (%EWL). Data were analyzed using descriptive statistic and the Student t test. The level of significance was set at p < 0.05.

**Results:** 422 patients underwent implant Spatz3® balloon in the period. The complications (14.28%) at the present study were: early balloon removal (6.89%), gastric ulcer (3.94%), spontaneous deflation (1.48%), gas production inside the balloon (0.98%), gastric perforation (0.23%) and Malory Weiss Syndrome (0.23%). There was no death at the present study. Twenty-eight patients underwent downward adjustment due to intolerance (mean volume reduction: 162.86 mL) and all of them kept in the treatment (no early removals). 180 patients have completed the treatment (minimum 9 months of gastric balloon stay). The BMI decreased from 37.69 to 31.51 kg/m² (p < 0.0001), body weight decreased from 107.67 to 90.16 kg (p < 0.0001) and excess weight diminished from 36.79 to 19.27 kg (p < 0.0001). Eighty-six patients underwent upward adjustment. The adjustment resulted in a further mean weight loss of 4.2 kg (9 to 20 kg), the range of upward volume was 281.73 ± 66.58 ml (100-420 ml) and the moment of the procedure was 7.06 ± 1.64 months. The group of patients that did the upward adjustment don’t have a higher %TBWL, %EWL or a a higher BMI reduction when compared to the group that did not (p = 0.4413, p = 0.9245, p = 0.2729, respectively).

**Conclusion:** This study shows that Spatz3® IGB treatment is an effective procedure for weight reduction, without mortality but with higher morbidity rates when compared to traditional IGBs. Even more, the downward adjustment treatment and BMI reduction, percent total body weight loss (%TBWL) and percent excess weight loss (%EWL). Data were analyzed using descriptive statistic and the Student t test. The level of significance was set at p < 0.05.

*p < 0.0001 for all comparisons between values at baseline and at the end of the study. IGB = intragastric balloon; BMI = body mass index; TBWL = total body weight loss; EWL = excess weight loss. Success rates (criteria: ≥10% TBWL or ≥25% EWL).

**Conclusion:** Endoscopic treatment of obesity with an IGB shows to be an excellent therapeutic option to non elective patients for bariatric surgery according to BMI criterion.

**Disclosure of Interest:** M. Galvao Neto: I declare that I have received personal fees from FRACHTYL LABS, GI WINDOWS, APOLO ENDO SURGERY, GI DYNAMICS, ETHICON ENDO SURGERY, not related to the present study. All other authors have declared no conflicts of interest.
Patients' body mass distribution had a clear improvement, with a significant increase in the percentage of Fat-Free Mass. A significant reduction of the basal metabolic rate of 1893.24 to 1694.67 was noted. Endoscopic approach with gastric balloon provides a significant weight loss and helps patients acquiring healthy habits.

Introduction: Many factors contribute to the development of irritable bowel syndrome (IBS) including the altered visceral perception, intestinal low-grade inflammation and psychosocial factors. Recent research has revealed a relationship between intake of FODMAPs (Fermentable Oligosaccharides, Disaccharides, Monosaccharides, and Polyols) and abdominal complaints. A diet low in FODMAPs can reduce symptoms in patients with IBS but mechan- isms were poorly understood.

Aims & Methods: We aim to explore the role of FODMAPs in triggering IBS symptoms by investigating visceral sensitivity, intestinal inflammation and short chain fatty acid (SCFA) stress in induced IBS mice model. Fructo-oligosaccharide (FOS) as one of the most frequently exposed FODMAPs in daily life was used in this study. Mice were subjected to water avoidance stress (WAS condition; 1 h/day for 10 days) or sham stress (basal condition; 1 h/day for 10 days) with oral gavage of saline or FOS solution containing saline (8 g/kg) for 2 weeks. Then visceral sensitivity was measured by abdominal withdrawal reflex (AWR) in response to colorectal distension (CRD) and histological analyses were used to evaluate mucosal inflammation. Immunohistochemistry, reverse transcription, and gas chromatography were used to estimate mucosal mast cell, levels of cytokines (IL-6, IL-23, TNF-α) and IL-1β and SCFA, respectively.

Results: Colonic mucosal hyperalgesia and low-grade inflammation in WAS mice as a model of IBS. In WAS condition, increased visceral sensitivity and mucosal mast cell (12.3 ± 2.61 vs. 8.33 ± 3.55, P < 0.01) were observed in FOS-administered mice compared with saline-administered mice. In WAS condition, cytokine expression were mediated by FOS with increased IL-23 (3.17 ± 2.11-fold, P < 0.05) in ileum and IL-1β (2.45 ± 1.55-fold, P < 0.05) in colon compared with saline. In addition, the average concentrations of acetate (2.48 ± 0.62 vs. 1.04 ± 1.0, P < 0.01), propionate (0.48 ± 0.09 vs. 0.33 ± 0.09, P < 0.05), butyrate (0.10 ± 0.003 vs. 0.05 ± 0.003, P < 0.05) and total SCFA (3.61 ± 0.89 vs. 1.79 ± 0.17, P < 0.001) significantly increased in FOS-administered mice compared with saline-administered mice in WAS condition. Basal condition, no difference of visceral sensitivity, intestinal inflammation and SCFA were observed between mice treated with FOS or saline.

Conclusion: Oral gavage of FOS leads to both an increase in visceral sensitivity and gut inflammation in stress induced IBS mice. These effects are link with the production of SCFA in the gut which involved in the regulation of sensitivity and intestinal immune activation. These findings support the hypothesis that visceral hypersensitivity and intestinal inflammation aggravated by certain FODMAPs may be responsible for IBS symptom generation, and indicate an alternative mechanism of the efficacy of the low-FODMAP diet for IBS patients.

Introduction: Several formulations consisting of live lactobacillus acid bacteria, including bifidobacteria, are marketed as probiotic products. However, these products are often defined and thought into three main groups: ham- pers further application in treating diseases, limits comparative studies, and pre- vents predicting their efficacy. We have previously addressed this by providing genomic and functional characterization of single commercial strains (Kainkainen et al 2009, Douillard et al 2013, Tygart et al 2016). The multispecies probiotic VSL#3 is marketed globally for treating colitis ulcerosa, pouchitis, and irritable bowel syndrome. To provide a rational basis for understanding the function of VSL#3 and generate a baseline for future studies, the genomes of all 8 strains that make up this multispecies product were determined and used to predict their function. The strains were provided by the facility which is currently producing both the single strains and the blend mix (CSL-SACCO System, Zelo Buon Persico - Lodi-ITALY).

Aims & Methods: The individual strains of multispecies product VSL#3 were grown and total DNA was extracted using established methods. The DNA was subject to paired-end Illumina sequencing using a HiSeq2000 platform, assembled and annotated as previously described (Douillard et al 2013).

Results: The next generation sequencing provided high quality genomes of all 8 strains that are components of the multispecies product VSL#3. Detailed phylo- genetic and genomic analysis confirmed the species composition to be as indicated in the VSL#3 product specification and showed the 8 strains of this multispecies product to be the species Lactobacillus rhamnosus, Lactobacillus acidophilus, Lactobacillus casei, Lactobacillus plantarum, Lactobacillus helveticus, Bifidobacterium breve and B. animalis subsp. lactis (this species included two strains). The species L. paracasei and L. casei are highly related and in need for further official taxonomic resolution. The anno- tated genes of the assembled genomes were used to identify genes involved in potential probiotic functions. Full sets of genes for the production of tight adherence pili were observed in the Bifidobacterium spp. and are known to produce biofilms that we recently proved to mediate microbial adhesion to mucosal surfaces and promote intestinal integrity, and influence host cell development (O’Connell Motherway et al 2011). Moreover, a series of signaling proteins were identified in the genomes of the Lactobacillus spp., including surface layer proteins and sortase-dependent pili proteins that we showed to interact with the mucosal surfaces and dendritic cells (Konstantinov et al 2008; Kankainen et al 2008; Tygart et al 2016).

Conclusion: The genomic analysis of the VSL#3 strains confirmed the product specifications, defined the baseline genetic coding capacity, and predicted a number of probiotic mechanisms that could explain the efficacy of this multi- species product.

Introduction: Disease prevention and high public awareness are fundamental to reduce morbidity, mortality and health-related costs. Extensive research led to identification of causes of gastrointestinal (GI) diseases, which remain still difficult to get population involved. The goals of our pilot campaign are: (a) to raise awareness about GI diseases, risk factors, signs, symptoms, in order to convince people to change behavior and to prompt them with concerns to visit doctors as early as possible; (b) to facilitate communication between healthcare providers and population; (c) to determine the knowledge of health personnel about the appropriate diagnostic investigations. Any information we can share may also benefit patients and their families, in recognition of the many people who suffer with the pain and discomfort caused by GI disorders.

Aims & Methods: We organized population-based events, out of health facilities, during which: (a) giant inflatable anatomical models of GI organs that can be visited inside, were installed; (b) educational panels and brochures were set and exhibited both inside and outside the models; (c) videos illustrating endoscopic exams and histopathology examinations were projected and discussed; (d) clinical cases, also mimicking patient encounter, were simulated.

Results: We started an innovative strategy focused on the keywords: multidisci- plinary team, scientific rigor but simple words, people attraction, curiosity induc- ing communication, in Parma and neighbouring Cities. Specialists in Gastroenterology, Anatomic Pathology, Radiology, Surgery, Biochemistry, Nutrition, together with pre- and post-graduate Students, discussed various aspects of diagnostic and therapeutic strategies. Selected people were examined by ultrasonography, Municipal and civil society were also involved to ensure organiza- tional efficiency. The most discussed topics regarded dyspepsia, gastritis, helicobacter pylori infection, gastroesophageal reflux disease, alcohol abuse, cir- rhosis, hepatitis, intestinal bacterial dysbiosis, cancer, food allergy and intolerance, optimal nutrition in health and disease. The event performed in the main square of Parma lasted two full consecutive days and was attended by about 3,000 people, most of which also filled a ques- tionnaire. A total of 120 ultrasound examinations were performed. In neighbour- ing Cities the events were organized for one day; as a consequence, the number of participants was lower in proportion, but very satisfactory.
Conclusion: The events were educational and enjoyable for all age groups. The interactive approach and the environment out of health-care centres facilitated population to feel comfortable and eager to learn, as well as clinical cases simulation provided a valuable entertaining experience. This strategy of raising public awareness of GI diseases seems promising, we are refining the model for a national campaign.

P1955 LONG-TERM TRENDS IN HEMATOLOGICAL AND NUTRITIONAL STATUS AFTER GASTRECTOMY FOR GASTRIC CANCER

J. Kim
General Surgery, The Catholic University of Korea, Seoul/Korea, Republic of

Aims & Methods: This study investigated long-term trends in hematological and nutritional parameters after gastrectomy for gastric cancer and evaluated the influence of the reconstruction type on these trends. The medical records of 558 patients who underwent curative gastrectomy with standard lymph node dissection for stage I gastric cancer between January 2006 and December 2013 were reviewed. The hematological and nutritional parameters evaluated included albumin, total protein, albumin, total cholesterol, triglyceride, and calcium. The patients were followed up for 6 months postoperatively and then annually until death, cancer recurrence, or follow-up loss.

Results: In the long term, ferritin and triglyceride gradually decreased after gastrectomy while the other parameters decreased slightly or were stable. In the comparisons according to reconstruction type, the Roux-en-Y group had the lowest levels of hemoglobin, ferritin, vitamin B12, total protein, albumin, and total cholesterol beginning 6 months postoperatively compared with the Billroth I and II groups. However, only ferritin and vitamin B12 had significant differences in the 5-year cumulative incidences of deficiency according to the reconstruction type, whereas albumin, triglyceride, total cholesterol and calcium did not.

Conclusion: Although malabsorption and malnutrition are common in patients after a gastrectomy, most nutritional parameters were stable or decreased slightly in the long-term and were not markedly influenced by the reconstruction type or extent of gastrectomy. Therefore, for more accurate nutritional assessment after gastrectomy, multidirectional evaluation should be considered rather than simply measuring biochemical parameters.

P1956 EVOLUTION OF REPRODUCTIVE DISORDERS RELATED TO CELIAC DISEASE UNDER GLUTEN-FREE DIET

A. Asmar1, M. Frirvana1, A. Amjahdi1, E. Benbelrabhadi2

1 CHU Rabat, Rabat/Morocco
2 Rabat, Ibn Sina Hospital, Rabat/Morocco

Aims & Methods: Descriptive retrospective study of 173 patients with celiac disease followed in the department of digestive tract medicine of the Ibn Sina Hospital in Rabat, over a period of 18 years.

Results: In 173 patient with celiac disease, 58 patients had reproductive disorders. The frequency of these disorders in celiac disease and their evolution under gluten-free diet. Aims & Methods: Descriptive retrospective study of 173 patients with celiac disease followed in the department of digestive tract medicine of the Ibn Sina Hospital in Rabat, over a period of 18 years. Results: In 173 patient with celiac disease, 58 patients had reproductive disorders. There are 53 women and 5 men. The average age was 32.25 years; the diagnosis of celiac disease followed in the departement of diseases of the digestive tract medecine among others, reproductive disorders. The aim of our study is to assess the frequency of these disorders in celiac disease and their evolution under gluten-free diet.

OF RANDOMIZED CONTROLLED TRIALS
P1958 OPTIMAL NUTRITIONAL ROUTE FOLLOWING TOTAL GASTRECTOMY

Introduction: Total gastrectomy can profoundly influence patients’ nutritional status and recovery. Our objective was to evaluate the various nutritional options available postoperatively, namely total parenteral nutrition (TPN), or enteral nutrition (EN) either via the nasojejunal (NJ) or jejunal (JEJ) route. The aim of this review was to determine the optimal nutritional route after total gastrectomy for gastric cancer.

Methods: In a systematic review and meta-analysis of randomized controlled trials involving 353 patients (median age 62 years, 217 males, 170 females), patient characteristics were compared.

Results: VAD increased body weight significantly (p < 0.05) during feeding period irrespective of fat content of the diet. Fat content and VAD had no effect on 1 hr food intake after food deprivation. VAD decreased water intake (p < 0.001) but VAD blunted decreased faeces weight significantly (p = 0.0001 and p < 0.05 respectively) but there was no change in intestinal transit, HFD impaired short -term memory (p < 0.02), whereas VAD compromised spatial learning (p < 0.04). HFD rats were more anxious in OFT (p < 0.01).

Conclusion: HFD-induced alterations in memory and anxiety were not affected by VAD but VAD blunted effect of HFD on water intake and faeces weight, suggesting that their operating mechanisms are different. VAD by itself impaired spatial memory that requires further investigation.

P1959 TAUROLIDINE PREVENTS CATHERER-RELATED BLOODSTREAM INFECTIONS IN PATIENTS ON HOME PARENTERAL NUTRITION–A RANDOMIZED CONTROLLED TRIAL

Introduction: Patients on home parenteral nutrition (HPN) are exposed to a lifelong risk of catheter-related bloodstream infections (CRBSI), which threaten catheter and patient survival. Both taurolidine 2% and saline 0.9% solution are used as catheter lock solutions (CLS) to prevent CRBSI. The optimal agent however, remains unclear. We hypothesized that taurolidine as CLS is superior to saline in preventing CRBSI in HPN patients.

Methods: We hypothesized that taurolidine 2% as CLS is superior to saline 0.9% in preventing CRBSI in HPN patients. This multicenter double blind trial randomly assigned HPN patients to use either the CLS taurolidine 2% or saline 0.9% solution to prevent CRBSI. The optimal catheter and patient survival. Both taurolidine 2% and saline 0.9% solution were enrolled for this study.

Results: Of 105 randomized patients, 81 were used in the final analysis and were compared to the opening data. The primary outcome measure was the proportion of CRBSI-free patients after one year. The number of catheter removals due to CRBSI, number of catheter removals due to CRBSI, exit-site infections, catheter occlusions, and (serious) adverse events.

Conclusion: Taurolidine 2% was not superior to saline in preventing CRBSI in HPN patients. However, a trend towards greater mortality in patients who received TPN compared with NJ (odds ratio (OR) 1.95, 95% Confidence Interval (CI) 1.16-3.28, p = 0.01). There was a trend towards greater mortality in patients who received TPN compared with EN (OR 1.90, 95%CI 0.64-5.70, p = 0.25). When EN was sub-ana lyzed according to NJ or JEJ, morbidity was significantly greater in patients who received TPN compared with EN (p < 0.002 but not in patients who received NJ feeding (OR 1.23, 95%CI 0.64-2.36, p = 0.53). Conclusion: Enteral nutrition in the form of feeding jejunostomy was associated with lower morbidity compared with TPN following total gastrectomy for cancer.

P1960 REPAIR OF DAMAGED CENTRAL VENOUS CATHETERS SUBSTANTIALLY EXTENDS DEVICE SURVIVAL IN PATIENTS ON HOME PARENTERAL NUTRITION
Y. Wouters1, R. Vissers2, W. Kievet2, G. Wanten1
1Radboudumc, Nijmegen/Netherlands
2Radboud University Medical Center, Nijmegen/Netherlands

Contact E-mail Address: Yannick.Wouters@radboudumc.nl

Introduction: Patients with severe intestinal failure depend on lifelong home parenteral nutrition (HPN) support. Repeated central venous catheter (CVC) loss due to complications, including mechanical damage, compromises vascular access. It remains unclear whether repair of damaged CVCs is an effective strategy to extend catheter life, avoid surgical replacement and maintain venous access.

Aims & Methods: The objective of this study was to characterize patients who underwent catheter repair and to evaluate effects on catheter survival and describe complications. This study concerns a retrospective analysis of all catheter repairs that were performed in HPN patients at the Radboud University Medical Center between January 2000 and May 2017. Primary endpoint was the difference in catheter survival in the presence or absence of catheter repair. To this end, a non-parametric survival analysis was performed. Secondary outcomes included localization of catheter damage and frequency of repair-related complications within 1 month after catheter repair.

Results: A total of 50 repairs in 38 CVCs of 32 HPN patients were included in the analysis. 16 CVCs (32%) were damaged at the distal end, near the screw thread of the catheter, 25 CVCs (50%) at the junction between the rigid and flexible part of the catheter, and 9 CVCs (18%) at the tip of the catheter. The mean time to catheter repair after placement was 2.2 years (95% CI = 1.5–2.9 years). The mean catheter survival after repair was extended by 1.4 years to 3.6 years (95% CI = 2.69–4.46; p = 0.01). No repair-related complications occurred within 1 month after catheter repair.

Conclusion: Repair of damaged CVCs significantly extends catheter life in HPN patients with access to non-surgical repair of catheter is a safe procedure.

P1961 LONG-TERM CLINICAL OUTCOMES OF PATIENTS ON HOME PARENTERAL NUTRITION USING TAUROLIDINE CATHETER LOCKS
Y. Wouters1, B. Roosenboom2, W. Kievet2, G. Wanten2
1Radboudumc, Nijmegen/Netherlands
2Department Of Gastroenterology And Hepatology, Radboud University Nijmegen, Nijmegen/Netherlands

Contact E-mail Address: Yannick.Wouters@radboudumc.nl

Introduction: Catheter-related complications (CRCs) in home parenteral nutrition (HPN) patients are a threat to both catheter and patient survival. Taurolidine 2%, an antimicrobial catheter lock solution (CLS), is an effective agent for the prevention of catheter-related bloodstream infections (CRBSI).

Aims & Methods: The aim of this retrospective study was to evaluate long-term clinical outcomes of our HPN patient cohort that uses the CLS taurolidine. Between 2008 and 2016, all adult HPN patients requiring a central venous catheter (CVC) for home parenteral nutrition were included in this study. CRBSI and CRC rates were recorded. A total of 364 patients were included, who received taurolidine as CLS. CRBSI and CRC incidence rates were recorded and compared. Kaplan-Meier analysis was used to determine the time until a first CRC. Cox proportional hazard analysis was performed to identify risk factors for a first CRC.

Results: In 221 HPN patients, 658 CVCs (418 Hickmans, 172 PACs, and 28 non-tunneled CVCs) were inserted, comprising 261252 catheter days. Median survival for Hickmans, PACs and non-tunneled catheters was 175 (43–544), 310 (61–827) and 90 (29–406) days, respectively. In 47% and 32% of patients, at least one CRBSI and CRC occurred, respectively. Median time to first CRBSI or CRC was 246 (58–817) and 215 catheter days (5–2070). Numerically, but not significantly, CRBSI and CRC rates decreased over time. The sole use of intravenous fluids was associated with a significantly lower risk for CRBSI (RR 0.32). Meanwhile, use of an overtube while guiding the catheter into the stomach in pull technique succeeded the reduction of the bacterial implantation. It is still unclear if the modified introducer technique or the overtube assisted pull technique would reduce risks of adverse events.

Aims & Methods: In this study, we retrospectively investigated risks of adverse events associated with the modified introducer technique and the overtube assisted pull method. Outcomes of patients who underwent the PEG placement from Jan 2013 to Oct 2016 at Jikei University Hospital were analyzed. The following data were collected from clinical records: age, gender, technique of PEG, reasons for PEG, lab tests and prognostic nutritional index (PNI).

Results: During the study period, 236 PEG placements were done in 234 patients. The average age was 69.3 ± 12.5. The modified introducer technique was applied in 167 procedures (70.8%) and the overtube assisted technique was applied in 69 procedures (29.2%). The overtube assisted technique was placed aiming for the gastrostomy tube placement. Results supported for cancer patients in 132 procedures, cerebrovascular accident in 51 procedures, aspiration pneumonia in 32 procedures, and others such as infection and disuse atrophy in 21 procedures. Age (the overtube assisted pull technique > the modified introducer group), Gender and preoperative serum C-reactive protein level were significantly different between the two groups (p < 0.05). Overall, adverse events were observed in 19 (8.1%) procedures, although there was no procedure related mortality in the both groups. The risks of clinically significant adverse events were not different between the two groups. There was no significant difference in the types and the rate of adverse events between the two groups. However, severe peristomal bleedings were observed only in the modified introducer technique group. Four patients required suture placements and 3
patients required blood transfusion for the peristomal bleeding. In a univariate analysis, age, the rate of aspiration pneumonia as the reason for the PEG placement were higher in patients encountering adverse events (p < 0.05) (table 1). Also, serum platelet level, serum albumin and the rate of nutrition supports for cancer as the reason of the PEG placement was lower in patients encountering adverse events (p < 0.05). In a multivariate analysis, lower serum platelet level was solely recognized as a relevant predictive factor for adverse events (p < 0.05). The types of the technique used were not relevant to risks of adverse events.
