**Introduction:** Liver cirrhosis is associated with an imbalance between vasodilation and vasoconstriction in the sinusoids. Therefore the investigation of the nitric oxide - cyclic guanosine monophosphate (NO-cGMP) pathway, a key regulator of vascular smooth muscle tone, is essential.

**Aims & Methods:** The rat model of thioacetamide (TAA) was used to induce liver fibrosis/cirrhosis and alterations of the NO-cGMP pathway and subsequent liver damage were assessed. 25 male Wistar rats were studied (11 untreated controls and 14 TAA treated animals [0.03 g TAA/100 ml drinking water for 16 weeks]). TAA dosage was adjusted weekly based on body weight changes. Hepatic gene expression of endothelial and inductive NO synthase (eNOS and iNOS), phosphte-diesterase 5 (PDE5) soluble guanylyl cyclase type 1 (sGC1) and type 2 (sGC2) and sGCb1 was determined by qRT-PCR. Serum cGMP concentrations were measured by ELISA using blood samples taken from the carotid artery. Likewise liver damage was assessed by liver chemistry (i.e. alanine- and aspartate-amino-transferase (ALT and AST), alkaline phosphatase (AP), albumin and bilirubin).

The degree of fibrosis was estimated by histological criteria (i.e. Desnet scores). PDE5-expression was determined by immunohistochemistry. Kruskal-Wallis test was used for statistical analysis of group differences.

**Results:** 43% (6/14) of TAA-treated rats developed liver fibrosis (Desnet score of 1–3) while 57% (8/14) developed liver cirrhosis (Desnet score of 4). No major differences in ALT, ASAT, and AP serum concentrations were observed in either group. However, bilirubin was significantly elevated in TAA-treated rats, while albumin concentrations were significantly reduced. Gene expression analysis revealed significantly increased expression of eNOS (1.5fold), PDE5 (7.7fold), and sGCb1 (2.1fold) in fibrotic livers compared to controls. cGMP concentrations in fibrotic animals were slightly decreased (-34%). Significantly increased expression of eNOS (2.26fold), PDE5 (11fold), sGCa1 (1.7fold) and sGCb1 (3fold) was observed in cirrhotic livers compared to controls, while cGMP concentrations were significantly decreased (-40%). iNOS expression was only detected in fibrotic and cirrhotic livers, but absent in controls. Immunohistochemistry revealed markedly increased PDE5-expression in cirrhotic livers, which was predominantly localized in hepatic stellate cells.

**Conclusion:** The analysis of animal model of TAA-induced liver fibrosis/cirrhosis revealed alterations of the NO-cGMP pathway, characterized by reduced concentrations of cGMP, a key mediator of vasodilation, due to increased PDE5-expression. These changes reinforce the hypothesis that sinusoids remain in a contractile state in cirrhotic livers, thereby contributing to portal hypertension. Thus, administration of PDE5-inhibitors, possibly combined with antifibrotic agents, should be further studied in clinical trials as a promising therapeutic approach to target portal hypertension.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Conclusion: In chronic hepatitis C SerpinB3 is involved in monocyte activation, leading to the release of CD63. These results support the correlation of these two molecules in serum of patients with more severe liver fibrosis and metabolic alterations.

P0004 THE PROTECTIVE EFFECTS OF GROUP 3 INNATE LYMPHOID CELLS ON HEPATITIS B VIRUS RELATED LIVER FIBROSIS COULD BE IMPAIRED BY TH17 CELLS
S. Wang, W. Ma, L. Cheng, W. Jiang
Gastroenterology, Zhongshan Hospital Fudan University, Shanghai/China
Contact E-mail Address: 15211210012@fudan.edu.cn

Introduction: Th17 cells have been proved to contribute to hepatitis B virus (HBV) related liver fibrosis. Group 3 innate lymphoid cells (ILC3s), which have similar profiles of transcription factor and cytokines to that of Th17 cells, were also suggested to be involved in the progression of liver fibrosis.

Aims & Methods: The study was designed to explore the functions of ILC3s and the relationships between ILC3s and Th17 cells in liver fibrosis. Peripheral blood samples were collected from 60 patients with chronic hepatitis B (CHB), and 50 patients with HBV related liver cirrhosis (LC) as well as 30 healthy controls (HC). The percentages and cytokines secretion of ILC3s (Lim^D^CD127^CD117^CD274^) and Th17 cells (CD4^IL-17^+) were detected by flow cytometry. Peripheral blood mononuclear cells (PBMCs) and PBMCs without ILC3s co-cultured with hepatic stellate cells (HSCs)-LX2 in contact and non-contact manners. Then Th17 cells, which were induced from naive CD4^T^ cells in vitro, were transferred into Rag1^−/−^ mice with carbon tetrachloride (CCL4) related liver fibrosis. In addition, ILC3s in Rag1^−/−^ mice were depleted by injecting with anti-CD90.2 antibody.

Results: Compared with HC, the percentage of ILC3s increased in CHB group. The anti-inflammation cytokines secreted by ILC3s such as IL-22 increased, whereas pro-inflammation cytokines of ILC3s such as IL-17A, TNF-a, IFN-g decreased in CHB patients. However, ILC3s decreased in LC patients with reduced cytokines secretion. Th17 cells frequencies significantly increased both in CHB and LC groups compared with HC. PBMCs without ILC3s, which were collected from CHB and LC patients, promoted the proliferation and activation of HSCs because of less IL-22 secretion. Similarly, compared with wild type mice, ILC3s in spleens and livers of C57BL/6 mice with liver fibrosis increased sequentially at time point of week 2 and week 4 following drug injection. Intriguingly, at week 6, ILC3s decreased compared with previous. However, Th17 cells increased gradually with CCL4 administration, even at week 6. Transferring Th17 cells into Rag1^−/−^ mice with carbon tetrachloride-related liver fibrosis made the ILC3s in spleens and livers decrease significantly, and the degree of mice liver fibrosis become more severe than control. Furthermore, ILC3s depletion correlated with reduced expression of IL-22 and more severe liver fibrosis. Transferring purified liver ILC3s into recipient mice reactivated liver inflammation and reverse liver fibrosis.

Conclusion: Our study has uncovered the protective role of ILC3s in liver fibrosis, which is through secreting IL-22 to reduce proliferation and activation of HSCs. However, the protective functions of ILC3s could be impaired by Th17 cells.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0005 EFFECTS OF INTERNAL AND EXTERNAL BILIARY DRAINAGE ON THE EXPRESSION OF INTESTINAL BILE ACID RECEPTOR AND TLR4/NOD2 IN MICE WITH OBSTRUCTIVE JAUNDICE

Introduction: Internal biliary drainage has been found to be better than external biliary drainage in alleviating the damage of intestinal mucosa barrier caused by obstrucive jaundice and the relevant mechanism is still unclear. In this study, we mainly study the expression between FXR and TLR4, TGR5 and NOD2.

Aims & Methods: We aimed to investigate the relation between the expressions of bile acid receptor and TLR4/NOD2 in intestinal mucosa and its influence on the intestinal mucosal barrier with obstructive jaundice. In this study, we carefully removed and preserved. mRNA expression was analysed by qRT-PCR. The anti-inflammation cytokines secreted by ILC3s in spleens and livers decreases significantly, and the degree of mice liver fibrosis become more severe than control. Furthermore, ILC3s depletion correlated with reduced expression of IL-22 and more severe liver fibrosis. Transferring purified liver ILC3s into recipients reactivated liver inflammation and reverse liver fibrosis.

Results: Compared with HC, the percentage of ILC3s increased in CHB group. The anti-inflammation cytokines secreted by ILC3s such as IL-22 increased, whereas pro-inflammation cytokines of ILC3s such as IL-17A, TNF-a, IFN-g decreased in CHB patients. However, ILC3s decreased in LC patients with reduced cytokines secretion. Th17 cells frequencies significantly increased both in CHB and LC groups compared with HC. PBMCs without ILC3s, which were collected from CHB and LC patients, promoted the proliferation and activation of HSCs because of less IL-22 secretion. Introduction: Alterations in the gut microbiota have been correlated to a wide variety of diseases, including liver diseases. Used as probiotics, several strains of Lactobacillus have been associated not only to modulation of intestinal tight junctions but also to amelioration of liver fibrosis. Common bile duct ligation (BDL) results in acute cholestasis and secondary biliary fibrosis, associated with early increased intestinal permeability and disturbed bile acid homeostasis. We have demonstrated that the oncoviruses microRNA-21 (miR-21) is upregulated in BDL mouse liver, mediating liver fibrosis. We aimed to investigate the role of miR-21 in the response of the small intestinal microbiota to BDL that may explain miR-21 effects in acute liver injury and fibrosis.

Aims & Methods: Three-month-old C57BL/6 wildtype (WT) and miR-21 whole body knockout (KO) mice were submitted to sham or BDL surgeries. After three days, mice was sacrificed and small intestines in the lumens were carefully removed and preserved. mRNA expression was analysed by qRT-PCR. Bacterial DNA was purified from the small intestinal lumen samples and analysed by next generation sequencing – metagenome analysis. Liver tissue and serum were also collected for biochemical analysis of hepatic damage and fibrosis.

Results: TNF-a and IL-1β mRNA levels increased in the small intestine of BDL mice compared with WT. TLR4 and TGF-beta expression was increased in both sham- and BDL-miR-21 KO mice which is in accordance with the higher LPS in blood plasma observed. Zona occludens (ZO-1) and occludin mRNA levels were decreased in WT mice after BDL. Similarly, miR-21 KO reverted mRNA of tight junction proteins to control levels. BDL miR-21 KO mice showed decreased circulating levels of hepatic enzymes, concomitant with decreased fibrogenic gene expression in the liver, in comparison with WT mice, suggesting that miR-21 contributes to BDL-induced liver injury and fibrosis. Further, miR-21 KO not only show a decreased small intestine permeability through a ZO-1 and occludin pathway, as it is associated with development of beneficial strains of Lactobacillaceae that may also contribute to liver protection.

Conclusion: These data suggest that miR-21 depletion is associated with increased intestinal permeability markers in the small intestine and better immune response to bacterial dysbiosis provoked by the BDL surgery, thus halting liver injury and promoting gut microbiota homeostasis. **P0007 THE EMERGING ROLE OF ZBP-89 IN SENSITIZING HEPATIC CANCER STEM CELLS TO SORAFENIB**

**N. Wang**, Y. Liu2, J. Ren1, J. Yu1, R. Ho1, P.B. Lai1, G.G. Chen1  
1Department Of Surgery, The Chinese University of Hong Kong, Hong Kong; Hong Kong Pr  
2Guangdong Key Laboratory For Research And Development Of Natural Drugs, Guangdong Medical College, Zhanjiang, China

**Aims & Methods:** In this study, we investigated the mechanism of Sorafenib resistance in HCC cancer stem cells, and how ZBP-89 reduced drug resistance. The sensitivity of Huh7 and Hep3B parental and sphere-forming cells to Sorafenib was measured by MTI assay. We then examined the expression pattern of Notch1 and liver CSC markers in Huh7 and Hep3B CSC after the treatment with Sorafenib. MTI assay was also used to measure the effects of ZBP-89 overexpression on the sensitivity of Sorafenib in sphere-forming cells. The levels of ZBP-89 and CD44 were measured using qPCR in human HCC tissue samples. The regulatory effects of ZBP-89 on CSC phenotype were explored using qPCR, immunostaining, and co-immunoprecipitation. ZBP-89 overexpression was found to result in the loss of CSC phenotype and improve the sensitivity to Sorafenib.

**Conclusion:** We believe that targeting ZBP-89 is likely to be a new therapeutic strategy to overcome resistance to Sorafenib in HCC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0008 PROTECTIVE EFFECT OF AKKERMANSIA MUCINIPHILA AGAINST IMMUNE-MEDIATED LIVER INJURY IN A MOUSE MODEL**

**W. Wu1, D. Shi1, D. Fang1, X. He1, L. Li2**  
1State Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China; Hangzhou/Zhejiang  
2Department of Gastroenterology, Sir Run Run Shaw Hospital, Zhejiang University Medical School, Hangzhou, China; Hangzhou/Zhejiang

**Aims & Methods:** Aiming to study the effect of A. muciniphila on immune-mediated hepatitis and potential underlying mechanisms. Twenty-two C57BL/6 mice were assigned to three groups (N = 7–8 per group) and continuously administered A. muciniphila Mouse (ATCC BAA-835) or PBS by oral gavage for 10 days. Mouse feces were collected for gut microbiota analysis on the eleventh day, and acute hepatitis was induced by Concanavalin A (Con A, 15 mg/kg) injection through the tail vein. Samples (blood, liver, ileum, colon) were assessed for liver injury, systemic inflammatory responses, and intestinal barrier function.

**Results:** We found that oral administration of A. muciniphila (Akk) decreased serum ALT and AST and alleviated liver histopathological damage induced by Con A. Serum levels of pro-inflammatory cytokines (IL-2, IFN-γ, IL-12p40, MCP-1) were significantly decreased in mice treated with Akk, while IL-6 was increased and hepatic lipids decreased. Serum levels of MCP-1, MIP-1a, MIP-1b were also significantly decreased hepatic cell apoptosis; Bel-2 expression increased, but Fas and DR5 decreased. Further investigation showed that Akk enhanced Ocludin and Tip-1, two proteins related to strengthened intestinal barriers. Fecal 16S RNA sequencing analysis indicated that Akk increased the microbial communities. The community structure of the Akk group clustered distinctly from that of the Control and Normal groups. Relative abundance of Firmicutes increased, and Bacteroidetes abundance decreased. Correlation analysis showed that injury-related factors (IL-6p40, IFN-γ, DR5) were negatively associated with specific genera (Ruminococcaceae_UCG–009, Lachnospiraceae_UCG–001, Akkermansia), which were enriched in mice pretreated with Akk.

**Conclusion:** Our results suggested that A. muciniphila (Muc) (ATCC BAA-835) had beneficial effects on immune-mediated liver injury by alleviating inflammation and hepatocellular death. These effects may be driven by the protective profile of the intestinal community induced by the bacteria. The results provide a new perspective on the immune function of gut microbiota in host diseases.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0009 CLINICAL OBSERVATION ON THE TREATMENT OF NONALCOHOLIC FATTY LIVER WITH PROBIOTICS**

**W. Wang**  
Gastroenterology, Beijing Hospital, Beijing/China

**Contact Email Address:** wangwei-beijingyjyuan@hotmail.com

**Introduction:** As the prevalence of insulin resistance (IR), hyperlipidemia and diabetes and other metabolic disorders in nonalcoholic fatty liver (NAFLD) in China had increased. NAFLD refers to the factors caused by exclusion of alcohol and other clear liver damage, metabolic syndrome, the characteristic of liver steatosis (L), the main microecological imbalance, and the link between insulin resistance and other factors closely for acute liver injury of metabolism. Serious illness can develop into liver cancer. NAFLD has become the leading cause of chronic liver disease in developed countries and China. Chronic liver disease is often accompanied by intestinal micro ecological imbalance; studies have shown that the imbalance of intestinal micro ecology led to the transfer of intestinal endotoxin into the blood, and stimulate the production of inflammatory factors aggravate liver damage, thus chronic liver disease. A series of studies show that intestinal microflora, intestinal bacteriobacterial overgrowth, and liver function of metabolism are the leading cause of chronic liver disease.

**Aims & Methods:** We aimed to study the clinical effect of probiotics in the treatment of nonalcoholic fatty liver disease. 200 cases with patients of nonalcoholic fatty liver disease were randomly divided into routine treatment group (A group) and combined treatment 3 groups (B, C, D). All 5 groups were given orally Polyeone Phosphatidylcholine Capsules, 456 mg, TID. The combination therapy group B was given orally the Live Combined Bifidobacterium Lactobacillus and Enterococcus Powder, 420 mg, TID. Group C: two live combined Bacillus subtilis Enterococcus powder, 500 mg, TID. D group was given orally the probiotics above. The course was 1 month. All patients were respectively examined before treatment and seven days and thirty days after treatment, for cholesterol (TC), triglyceride (TG), high density lipoprotein cholesterol (HDL-L), low density lipoprotein cholesterol (LDL-L), alanine aminotransferase (ALT), aspartate aminotransferase (AST), fasting blood glucose (FBG), serum high molecular weight adiponectin (HMW APN) and serum TNF-α. The 4 groups were collected face samples, that were tested routine detection, bacterial culture. At the same time all people were checked with ultrasonic examination.

**Results:** In terms of blood lipids and blood glucose, each group improved than before, only HDL-L was not statistically significant, group D showed significant differences in triglyceride. In liver function, blood ALT, AST were significantly lower than group A; serum TNF-α levels were decreased after treatment. Amino acid combined treatment D group was statistically significant; group D more than the group A; serum HMW APN increased after treatment, combined treatment group D comparing with routine treatment group A was significant difference.

**Conclusion:** Intestinal probiotics can regulate the intestinal micro ecological imbalance in NAFLD patients, and reduce the level of serum TNF-α, improve the level of adiponectin, which can further improve the blood glucose, lipid metabolism, and then improve the liver injury of non-alcoholic fatty liver disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
In summary, the composition of gut microbiota varied remarkably between mice administered different experimental diets to induce non-alcoholic fatty liver disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
patients with HFE mutations and (transferrin saturation index (TSI) values alone. But we did not have C282Y/C282Y patients in the series.

**Aims & Methods:** To study the relevance of HFE mutations and TSI in determining LIC for HF patients attending the outpatient clinic at 6 hospitals in the Basque country. Prospective study of 312 consecutive patients with HF. Group A: Castiella et al. (2012) described three different groups according to HFE mutations and TSI (Group A: no predisposing mutations (PM) for HH and TSI > 55; Group B: PM for HH: C282Y/C282Y; C282Y/H63D, H63D/H63D, and TSI > 55; Group C: no PM for HH and normal TSI) Group D: PM and normal TSI. In the Basque country, hereditary hemochromatosis (HH) predisposing mutations differ, with relevance of the H63D/H63D mutation. The LIC was measured by MRI.

**Results:** In all the patients the LIC was measurable: C282Y/C282Y 14 (4.49%); C282Y/H63D 37 (11.93%); H63D/H63D 99 (31.73%); wt/wt 98 (31.41%); C282Y/S65C 1 (0.32%); H63D/S65C 2 (0.64%); C282Y/wt 16 (5.13%); S65C/wt 10 (3.21%). LIC was obtained from all the patients by MR. Mean age: 55 ± 13.3, 272 men and 40 women. Group A: 54; Group B: 32 Group C: 160; Group D: 44. The mean LIC in the different groups: 7.37 ± 27.89, group A: 70.53 ± 56.87, group C: 35.23 ± 22.62. Group D: 42.67 ± 22.98. We compared the LIC mean values of the 4 groups (bonferroni) with significant differences (p < 0.0001).

**Conclusion:** The LIC in different groups of patients referred for HF are significantly different with different predisposition to HH.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**LIVER IRON CONCENTRATION IN THE METABOLIC SYNDROME WITH HYPERFERRITINEMIA (DYSMETABOLIC HYPERFERRITINEMIA): RESULTS FROM A PROSPECTIVE COHORT OF 312 PATIENTS**

A. Castiella

Gastroenterology, Mendaro Hospital, Mendaro/Spain

**Introduction:** Approximately 25% of adult population in western countries have metabolic syndrome (MS). Hyperferritinemia (HF) is frequently present in patients with MS (dysmetabolic hyperferritinemia). There are some publications that support that MS is associated with a raised liver iron concentration (LIC) in these patients, but the doubts persist about this subject.

Aims & Methods: To study the LIC in patients referred for hyperferritinemia to six different hospitals in the Basque Country (multicenter study). Spain, and determine if there are differences between patients with or without metabolic syndrome. A prospective study of 312 consecutive patients with HF (>200 mg/liter of liver iron, >300 mg/liter of iron in men) was conducted from December 2010 to April 2013. The metabolic syndrome was defined by the presence of three of the following factors: waist circumference >94 cm in men and >80 cm in women; Triglycerides >150 mg/dL or treatment for this dislipidemia; HDL <40 mg/dL women/50 mg/dL men; type 2 diabetes; hypertension: blood pressure >130 mmHg/85 mmHg or treatment for arterial hypertension.

**Results:** In 276 of 312 patients we have all the data to determine the MS presence: 115/240 men (48%) and 20/36 women (55.6%), 135 patients, presented MS. In all 276 patients MRI for LIC determination (mean ± SD) was performed. We have LIC levels (mL/g) from the 276 patients. The mean LIC was 38.8 ± 19.38 (women) and 38.84 ± 25.50 (men). The LIC >100 mg/g was present in 30.8% (23.4%) of all patients, and 45.4% (71.2%) of MS patients. The LIC was 38.8 ± 16.18 in women, and 44.48 ± 36.18 (men), with 43.39 ± 36.43 (CI 95%, 37, 32 to 49, 46) for the whole group. We compared the mean values of LIC from both groups (MS vs NMS) by Pearson’s Chi square test and Fisher’s exact test: no significant differences were seen (p = 0.12).

**Conclusion:** Patients with HF and MS (dysmetabolic hyperferritinemia) present a mean LIC near normal values and their values do not differ from those of patients with HF and without MS.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

and NASH were quantified by using the FibroMax scales at baseline and after three months of treatment. Patients were grouped in two groups: the active group of 60 patients receiving low-dose hydrophilic statin (rosuvastatin 5mg/day) and the witness group of 60 patients, matched by age, gender and sex, receiving placebo.

Results: 97% of subjects fulfilled the follow-up period. The FibroMax staging at baseline showed the following results in the active group: S1–29%, S2–41% and S3–30%; F1–50%, F2–30%, F3–13% and F4–7% of patients, respectively. N1–31% and N2–69%. The staging according to FibroTest, SteatoTest and NashTest was similar in placebo group. After 2 years of low-dose hydrophilic statin, the mean ALT level from active group decreased from 72.22±1U/L to 32.80±1U/L, p < 0.05 (ss); in the witness group no significant ALT decrease was noticed (69.34±1U/L to 58.17±1U/L, p > 0.5). The FibroMax showed an improvement of steatosis, and fibrosis in the active group, compared with the witness group. After three years of statins, our active group was stratified as follows: S0–27%, S1–46%, S2–25%, respectively S3–2% of patients, respectively F0–38%, F1–32%, F2–28%, F3–2%; F4–0% of patients. NashTest showed positive evolution in the active group compared with placebo (N0–36%, N1–40% respectively N2–26%, p < 0.001, ss) After adjusting for age, BMI, diabetes, LDL-cholesterol and triglyceride levels, statin therapy showed a significant correlation with the steatosis, fibrosis and NASH stages improvement in the active group (r = 0.92, r = 0.87, respectively r = 0.95, p < 0.005, ss).

Conclusion: While statins proved to be safe and efficient for the treatment of NASH in our series, larger cohort studies are needed to further demonstrate this potential positive effect on liver fibrosis.

P0018 EVALUATION OF THE RELATIONSHIP OF LEVELS OF C-REACTIVE PROTEIN AND HOMOCYSTEIN IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE AND PATHOLOGICAL CHANGES IN THE LIVER DEFINED BY BIOPROGNOSTIC TEST STEATOSCREEN

E. Chernetsova, N. Denisov
The Second Department Of Therapy Of Improvement Of Doctors, The Federal State Military Educational Institution of Higher Education, Military Medical Academy nam, Saint-Petersburg/Russian Federation

Contact E-mail Address: katemed@list.ru

Introduction: The importance of subclinical inflammation and hyperhomocysteinemia in the development of nonalcoholic fatty liver disease (NAFLD) needs further study. Recent studies have shown that the development of hyperhomocysteinemia and an increase in the level of C-reactive protein contributes to increased oxidative stress, influences the development of metabolic disorders, which makes it possible to consider these indicators as additional markers for the development of NAFLD. The aim of this study was to assess the relationship between CRP and homocysteine (HC) levels with pathological changes in the liver, determined with the non-invasive bioprognostic test Steatoscreen in patients with AO. The study included 60 patients aged 18 to 59 years with BMI between 25 and 35%, with a waist circumference >80 cm for women, and >94 cm for men. All patients underwent a bioprognostic test Steatoscreen. Depending on the severity of the pathological changes in the liver, the Steatoscreen scale divided all the patients into 3 groups: steatosis, fibrosis and steato- fibrosis. Depending on the presence or absence of cytolysis syndrome, 2 subgroups were distinguished in each group: subgroups of non-alcoholic steatohepatitis (ALT values, AST above the norm more than 2 times), and steatosis. In all patients, the levels of CRP and HC were studied. Results: The highest values of these parameters were recorded in patients in subgroups with non-alcoholic steatohepatitis. In the process of correlation analysis, significantly positive correlations were found between CRP and HC. The level of physiological changes was obtained in the liver on the Steatoscreen scale: r = 0.6 ± 0.04 for steatosis, r = 0.8 ± 0.0016 for CRP and HC, respectively.

Conclusion: NASH patients with AO is characterized by the development of both inflammatory and metabolic changes, with cytolysis and fibrosis. This fact can influence the risk of developing the pathology of not only the liver, but also atherosclerosis and proves the need for a more thorough examination of patients with AO and NAFLD for the purpose of early detection and correction of existing metabolic disorders.

Aims & Methods: We aimed to study the relationship between CRP and homocysteine (HC) levels with pathological changes in the liver, determined with the non-invasive bioprognostic test Steatoscreen in patients with AO. The study included 60 patients aged 18 to 59 years with BMI between 25 and 35%, with a waist circumference >80 cm for women, and >94 cm for men. All patients underwent a bioprognostic test Steatoscreen. Depending on the severity of the pathological changes in the liver, the Steatoscreen scale divided all the patients into 3 groups: steatosis, fibrosis and steato-fibrosis. Depending on the presence or absence of cytolysis syndrome, 2 subgroups were distinguished in each group: subgroups of non-alcoholic steatohepatitis (ALT values, AST above the norm more than 2 times), and steatosis. In all patients, the levels of CRP and HC were studied. Results: The highest values of these parameters were recorded in patients in subgroups with non-alcoholic steatohepatitis. In the process of correlation analysis, significantly positive correlations were found between CRP and HC. The level of physiological changes was obtained in the liver on the Steatoscreen scale: r = 0.6 ± 0.04 for steatosis, r = 0.8 ± 0.0016 for CRP and HC, respectively.

Conclusion: NASH patients with AO is characterized by the development of both inflammatory and metabolic changes, with cytolysis and fibrosis. This fact can influence the risk of developing the pathology of not only the liver, but also atherosclerosis and proves the need for a more thorough examination of patients with AO and NAFLD for the purpose of early detection and correction of existing metabolic disorders.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference

complex and pathological changes in the liver, determined by the test Steatosis (r = 0.76; p < 0.0001). The dependence obtained is confirmed by the equation of simple linear regression.

Conclusion: In patients with AO, there is a direct relationship between the presence of pathological changes in the liver and the initial manifestations of atherosclerosis. The results obtained make it possible to evaluate the individual risk of atherosclerosis in this category of patients. Clinical significance of the results is the need for a more thorough examination of patients with AO and suspicion of liver pathology to assess the development of not only the disease of the liver itself, but also cardiovascular complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Insulin resistance is the main pathogenic determinant of both NAFLD and diabetes, and it can facilitate triglyceride accumulation in the liver. The overexpression of hepatococpin (HPS) increased hepatic lipid accumulation and NAFLD activity scores (NAS), whereas deletion of HPS improved high fat diet-induced hepatic steatosis and decreased NAS in mice.

Aims & Methods: The aim of this study was to explore the relationship between hepatococpin and diabetic patients with or without NAFLD. The study included 80 patients that were divided into 4 groups: Group I: included 20 patients who were diagnosed as diabetes mellitus type 2, Group II: included 20 patients who were diagnosed as non alcoholic fatty liver disease, Group III: included 20 patients who were diagnosed as diabetes type 2 and non alcoholic fatty liver disease, Group IV (control group): included 20 healthy person who were matched in age and sex with patients group.

Results: There was stastically significant decrease in mean value of serum hepatococpin of group I and IV on comparing with group II and group III. For group II there was stastically significant increase in mean value of serum hepatococpin on comparing with other groups. There was a significant serum hepatococpin up regulation in patients with type 2 diabetes and non alcoholic fatty liver disease patients (Group 3) mostly than diabetic patients (Group 1) and even than non alcoholic fatty liver disease (Group 2).

Conclusion: The present study provides evidence that overexpression of HPS may facilitate increased hepatic lipid accumulation with NAFLD and Type 2 Diabetes mellitius.

Introduction: Visceral adipose tissue (VAT) and gut are thought to be the main two sources of damage factors promoting non-alcoholic fatty liver disease (NAFLD). As one part of VAT, mesenteric adipose tissue (MAT) may be unique in VAT for it can affect liver directly via portal vein. However, the role of MAT status with different stages of NAFLD is not clear, as well as the role of inflamed MAT in NAFLD.

Aims & Methods: Mice fed with high fat diet or normal diet were sacrificed in 8th week and mice were sacrificed by 12th week.

Results: Mice have developed hepatic steatosis at 8th week and progressed to steatohepatitis by 12th week. Among four parts (mesenteric, epididymal, perirenal and retroperitoneal) of VAT, merely MAT became inflamed (mRNA expression of TNF-α increased, P < 0.01 and IL-10 decreased, P < 0.05) by 8th week, which happened to coincide with the presence of hepatic steatosis. Removal of inflamed MAT significantly worsened liver pathology, as well as resulted in hepatic inflammation (mRNA expression of MCP-1 increased, P < 0.01 and IL-10 decreased, P < 0.01) and lipid accumulation (mRNA expression of ACC increased, P < 0.01 and PPAR-α decreased, P < 0.01). Meanwhile, intestinal permeability was higher in the MAT removal group than that in the Sham group, which was supported by higher lipopolysaccharide (P < 0.05) in serum and lower mRNA expression of ZO-1 (P < 0.01) and occludin (P < 0.05) in small intestine.

Conclusion: These results suggest MAT inflammation arises at the early stage of NAFLD. Removal of inflamed MAT promotes the development of NAFLD and injures the intestinal barrier. Thus, we propose that MAT inflammation seems to be a compensatory response, on the fact that inflamed MAT protects the liver from the gut-derived damage factors via confining them within MAT, rather than aggravates NAFLD.

Introduction: Non alcoholic fatty liver disease (NAFLD) is a broad term describing simple steatosis, non alcoholic steatohepatitis (NASH), NASH cirrhosis and NASH-induced hepatocellular carcinoma (1). Incidence increased in patients with type 2 diabetes mellitus (DM) (2). Different diagnostic modalities have great limitations in differentiating simple steatosis from steatohepatitis (3). Liver biopsy remains the gold standard for diagnosis of NASH, however, it is invasive with potential severe complications (4). Several ultrasound elastography techniques have been described including transient elastography, acoustic radiation force impulse elastography and shear wave elastography (5). Shear wave elastography shows a stepwise increase of liver stiffness as the severity of liver inflammation increases (6).

Aims & Methods: We aimed to evaluate the accuracy of shear wave ultrasound elastography in differentiating simple steatosis from steatohepatitis in patients with type 2 DM. This was a prospective study including 60 patients 30 males and 30 females who visited our outpatient clinic or inpatient department at Specialized Medical Hospital. These patients were diabetic aged more than 30 years old with ultrasound showing fatty liver. Significant alcohol consumption, drugs causing steatosis and hepatic diseases were excluded by history, laboratory investigations and liver biopsy. All patients underwent full detailed history, examination, laboratory investigations (complete blood count, liver functions, kidney functions, random blood sugar, lipid profile, serology for hepatitis B and C viruses). Shear wave elastography was performed to all patients and stiffness of the liver was measured from different areas in kilopascal (kPa) then average stiffness of elastography was calculated. Liver biopsy was done and histopathological examination by Hematoxin, Eosin and Masson Trichrome stains, then NAFLD activity score (NAS) was calculated.

Results: Correlation between results of stiffness by elastography and NAS by biopsy revealed that: There was a significant positive association between average stiffness by elastography and definitive NAS (NAS 5 and 6) in patients with type 2 DM. At a level of 8.45 kPa by shear wave elastography, we can differentiate simple steatosis from steatohepatitis (Area Under Curve 0.936, sensitivity 90%, specificity 90%, positive predictive value 81%, negative predictive value 49%).

Conclusion: Shear wave ultrasound elastography is a promising non invasive technique to differentiate simple steatosis from steatohepatitis in patients with type 2 DM.

Aims & Methods: The pilot study was aimed to determine the association between serum ferritin concentration and the outcomes of patients with ALC. The study included patients with ALC who were confirmed by laboratory tests, clinical features, radiological imaging, and percutaneous or tranjugular liver biopsy. Alcoholic liver disease was confirmed when daily consumption of alcohol was > 30 g/day for males, females, respectively, as confirmed by at least 1 family member of affected individual. All patients were divided into three groups by serum ferritin concentration: below 200 µg/l, 200–400 µg/l and above 400 µg/l. Statistical analysis was performed using statistical software SPSS (version 17). ROC (Receiver-operating characteristic) curve analysis was used to estimate serum ferritin specificity in predicting early mortality. If the area under the curve (AUC) is greater than 0.5, the test is specific.

Results: The first group consisted of 44 patients, the second group 13 patients, the third group 15 patients. The average age was 57.5 ± 11.7 years. Serum ferritin concentration in first group was 58.2 ± 45.9 µg/l, second 293.5 ± 63.5 µg/l, third – 529.5 ± 221.1 µg/l. AST concentration in first group was 90.8 ± 70.2 IU/l, second – 96.7 ± 58.3 IU/l, third – 133.8 ± 95.5 IU/l. ALT concentration in first group was 66.7 ± 66.8 IU/l, second 64.5 ± 75.5 IU/l, third – 118.9 ± 72.3 µmol/l, third – 140.9 ± 190.5 µmol/l. The biggest mortality rate was in third group – 13 of 15 patients (86.67 %) (p < 0.0001). ROC scale shows a 77% specificity of serum ferritin concentration in predicting early mortality in patients with cirrhosis (AUC 0.838, p < 0.0001).

Conclusion: Serum ferritin level above 400 µg/l, elevated liver enzymes and bilirubin concentration shows a poor outcome of patients with ALC (p < 0.0001).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Individuals with chronic liver diseases may have a mild to moderate iron overload, but the mechanism is not fully understood. Increased contents of iron have been attributed to the progression of liver cirrhosis caused by HCV infection and nonalcoholic fatty liver disease, or alcoholic liver disease. Serum ferritin concentration can be increased in iron overload and shows hepatic macro-inflammation. Recently, raised serum ferritin concentration was shown to predict mortality in patients awaiting liver transplantation in decompensated liver cirrhosis. However, further accumulation of data is needed to assess the role of serum ferritin level in predicting the early mortality of patients with alcoholic liver cirrhosis (ALC).

Aims & Methods: The aim of this study was to determine the association between serum ferritin concentration and the outcomes of patients with ALC. The study included patients with ALC who were confirmed by laboratory tests, clinical features, radiological imaging, and percutaneous or tranjugular liver biopsy. Alcoholic liver disease was confirmed when daily consumption of alcohol was > 30 g/day for males, females, respectively, as confirmed by at least 1 family member of affected individual. All patients were divided into three groups by serum ferritin concentration: below 200 µg/l, 200–400 µg/l and above 400 µg/l. Statistical analysis was performed using statistical software SPSS (version 17). ROC (Receiver-operating characteristic) curve analysis was used to estimate serum ferritin specificity in predicting early mortality. If the area under the curve (AUC) is greater than 0.5, the test is specific.

Results: The first group consisted of 44 patients, the second group 13 patients, the third group 15 patients. The average age was 57.5 ± 11.7 years. Serum ferritin concentration in first group was 58.2 ± 45.9 µg/l, second 293.5 ± 63.5 µg/l, third – 529.5 ± 221.1 µg/l. AST concentration in first group was 90.8 ± 70.2 IU/l, second – 96.7 ± 58.3 IU/l, third – 133.8 ± 95.5 IU/l. ALT concentration in first group was 66.7 ± 66.8 IU/l, second 64.5 ± 75.5 IU/l, third – 118.9 ± 72.3 µmol/l, third – 140.9 ± 190.5 µmol/l. The biggest mortality rate was in third group – 13 of 15 patients (86.67 %) (p < 0.0001). detection of CSPH was 0.71, with positive predictive value of 75% and negative predictive value of 66.5%, nor did SBP/PCA vs. specificity 71%. RTN4 value of ≤1.1 ng/ml was associated with esophagogastric varices (odds ratio [OR] = 3; 63; p < 0.02).

Conclusion: Low levels of RTN4 are associated with liver cirrhosis and portal hypertension. Therefore, RTN4 correlates with liver function, it may be a surrogate marker of CSPH and presence of esophagogastric varices.

Introduction: Peritoneal carcinomatosis (PCA) has a prognostic role in patients with gastrointestinal cancers. Despite the low sensitivity, cytology remains the gold standard in differential diagnosis of PCA to peritonitis (for example spontaneous bacterial peritonitis, SBP) or uncomplicated ascites due to portal hypertension (no SBP/PCA). MicroRNAs (miRNAs) are considered as promising biomarkers and are commonly disregulated in cancer.

Aims & Methods: In this proof-of-principle study, we systematically evaluated preanalytical factors and potential of miRNAs as ascites biomarkers. We prospectively examined samples from patients with ascites with benign and malignant conditions including: PCA (n = 15), SBP (n = 15) and portal hypertension (no SBP/PCA, n = 15). Various extraction kits were used to compare the total RNA extraction. Furthermore, we systematically evaluated the influence of storage, stability and sample processing (uncentrifuged, pelleted etc.) on miRNA expression in ascites. miRNA expression profiling using TaqMan Low Density Array (TaqMan LD A) and quantitative RT-PCR (TaqMan SYBRgreen) were used to evaluate the expression.

Results: Systematic analysis of miRNAs stability confirms that miRNAs in ascites are well preserved from degradation with good short- (0h, 12h, 24h, and 48h) and long-term stability (30 C, ~80 C for 2 years). Several miRNAs that were selected for the proof-of-principle analysis (miR-21 and miR-16) were reproducibly detectable in ascites samples. miRNA expression profiling in patients with PCA compared to those with uncomplicated portal hypertension revealed miR-21, miR-16, miR-222 and miR-483-5p to be up-regulated and miR-26b to be down-regulated. miRNA expression validation analysis confirmed higher expression of miR-21 (mean delta CT ± SD: -11.11 ± 1.2 vs. -8.46 ± 3.46 vs. -9.65 ± 2.55 for no SBP/PCA, PCA and SBP, respectively, p < 0.05) and miR-16 in patients with PCA compared to no SBP/PCA groups, while miR-223 was significantly upregulated in SBP (mean ± SD: -12.16 ± 1.56 vs. -10.05 ± 3.19 vs. -6.95 ± 3.56 for no SBP/PCA, PCA and SBP, respectively, ANOVA, p < 0.0001; posttest SBP vs no SBP/PCA and vs. PCA p < 0.05).

Conclusion: Our data provide novel evidence for the differential expression of miRNAs in ascites in patients with PCA and SBP. Evaluation of ascites-miRNAs may offer an alternative approach for diagnosis of peritoneal carcinomatosis and create an avenue for therapeutic application as well.

Introduction: Pathological bacterial translocation (PBT) in liver cirrhosis (LC) is the pathophysiological hallmark for spontaneous bacterial infections increasing mortality several-fold. Factors known to contribute to PBT in LC are among others an increased intestinal permeability.

Aims & Methods: A clear role of intestinal vascular leakage for luminal intestinal bacteria is yet to be defined but we hypothesize that the recently described gut vascular barrier (GVB) is impaired in experimental portal hypertension leading to protein loss and increased accessibility of the vascular compartment for translocating bacteria. For this purpose two different models of experimental portal hypertension, namely partial portal vein ligation (PPVL) and bile duct ligation (BDL) were used in mice under standardized gnotobiotic conditions (sdDM2). A novel in vivo confocal endomicroscopy technique was established in order to detect and link the intestinal vascular leakage.

Results: Confocal endomicroscopy data revealed an earlier and significantly increased leakage of 70kDA through the intestinal vasculature in both BDL and PPVL mice. FITC-70kDA-dextran leak did only leak in BDL and PPVL but not in control (sham operated) mice. Interestingly GVB stains showed increased expression of PV1 in intestinal vessels (CD34) of BDL but not PPVL.

Conclusion: Portal hypertension per se has an impact on the GVB increasing FITC-70kDA-dextran leakage from intestinal capillaries to the lamina propria in both BDL and PPVL. However, the IF showed only in BDL an increased PV1 expression indicative of a wider opening of the fenestral diaphragms than in PPVL. Therefore, different mechanisms appear to be involved in alterations of the gut-vascular barrier in pre-hepatic portal hypertension and biliar cirrhosis.

P0029 INHIBITION OF CYCOOXYGENASE-2 AMELIORATES SPLENOMEGALY IN CIRRHOTIC RATS
Gastroenterology, West China Hospital, Sichuan University, Chengdu/China

Contact E-mail Address: 812903560@qq.com

Introduction: Splenomegaly is a common finding in liver cirrhosis. However, the precise underlying mechanisms behind this phenomenon have not been elucidated, and its effective therapies are limited.

Aims & Methods: We aimed to investigate whether cyclooxygenase-2 (COX-2) is involved as a contributing factor in the pathological process of splenomegaly in cirrhosis. Thirty-six male Sprague-Dawley rats were randomized into 3 groups with 12 rats in each group. The control group received intraperitoneal injection of normal saline (1 ml, twice a week); the TAA group received intraperitoneal injection of thioacetamide (TAA, 200 mg/kg, twice a week for 16 weeks); the TAA + celecoxib group received TAA intraperitoneally and celecoxib via gastric gavage (20 mg/kg/day). The portal pressure was measured by portal venous catheterization. Sections from paraffin-embedded spleens were stained with hematoxylin and eosin and Sirius Red, and immunostained with VEGER and CD31. The protein expressions of COX-2, VEGER, PI3K, p- Akt, and Akt in the spleen were assessed by Western blot. The enzyme-linked immunosorbent assay was performed to evaluate the expression of TNF-a and IL-1b in the spleen.

Results: The ratio of splenic weight to body weight increased by 73.9% in TAA group, while in rats treated with celecoxib, the ratio was significantly reduced. While determined by H&E staining, areas of splenic white pulp in the TAA group enlarged by 27.9%. Yet, compared with that in TAA group, celecoxib obviously increased the proportion by 28.8%. In addition, a considerable amount of collagen was visualized with Sirius Red staining and immunostained with VEGF and CD31.

Conclusion: Celecoxib significantly reduced the expression of COX-2 in the TAA + celecoxib group compared with the control group. Celecoxib significantly reduced the expression of proinflammatory factor VEGF and the nocovascular marker CD31 increased in TAA group by Western blot and immunohistology, which indicated a role of angiogenesis in the pathophysiology of splenomegaly. Furthermore, up-regulation of PI3K and p-AKT protein expression was detected in the spleen of TAA group compared
with that of the control group, demonstrating that PJK/AKT signal pathway was activated in development of pathological angiogenesis. However, the treatment with ceebeoehx strongly decreased the protein expression of VEGF, CD31, PJK and AKT in the spleen of cirrhotic rats.

**Conclusion:** The present study indicates that COX-2 contributes to splenomegaly by facilitating angiogenesis, fibrosis and inflammation in the spleen. Moreover, inhibition of COX-2 by ceebeoehx could ameliorate portal hypertension and splenomegaly.

**Introduction:** Spontaneous bacterial peritonitis (SBP) is a life-threatening complication in advancing liver cirrhosis. Translocation of intestinal bacteria or bacterial products from the gut to mesenteric lymph nodes is crucial for SBP, with *Escherichia coli* (*E. coli*), Klebsiella pneumoniae being the most common germs. Small intestinal bacterial overgrowth and a altered microbiota are so far known as risk factors for SBP. However, the exact mechanisms of bacterial translocation need to be identified as they are supposed to contribute to the development of early recognition systems and initiation of antibiosis.

**Aims & Methods:** With regard to the development of early recognition systems, pathomechanisms and signaling pathways of bacterial translocation in SBP were explored. These insights might lead to an initiation of antibiosis on time and reduced mortality in SBP.

Monolayers of human intestinal epithelial cell lines Caco-2 (p53 mutant) and HCT-116 (p53 wildtype) were cocultured with *E. coli* with different MOI (MOI 0, 1, 5 and 10) for 2 to 4 hours post confluence. Experiments with heat inactivated *E. coli* were performed as controls. Effects of microbial metabolic products were tested by using the supernatant of an overnight culture. qPCR and Western Blot analysis were performed to analyze changes in mRNA and protein levels of Occludin, E-cadherin and the p53 family including p53 and p73.

**Results:** Occludin, E-cadherin and the p53 family including p53 and p73 protein levels. These changes were dependent on incubation time and bacterial concentration. Following bacterial infection, marginal to no effects were detected on mRNA levels of cellular junctions and p53. Caco-2 cells displayed less reduction of Occludin and E-cadherin protein levels compared to p53-wildtype HCT-116 cells.

**Conclusion:** By using an in vitro model, we demonstrate destabilizing effects of *E. coli* on intestinal cell junctions, p53 and p73. As far as these effects are dependent on incubation time, microbial concentration and living bacteria, these effects might represent mechanisms to protect bacteria from intestinal immune responses and therefore to promote bacterial translocation in SBP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Pathological bacterial translocation (PBT) in liver cirrhosis (LC) is the pathophysiological hallmark for spontaneous bacterial infections increasing mortality several-fold. Factors known to contribute to PBT in LC are among others an increased intestinal epithelial permeability.

**Aims & Methods:** Since mucus represents one of the major components of this barrier we hypothesize that i) gut mucus is altered in LC and ii) bile could be a modulator of its production. Two different models of experimental LC – namely bile duct ligation (BDL) and the chronic treatment with carbon tetrachloride (CCl4) – as well as partial portal vein ligation (PPVL) and sham-operated mice were used. Finally the farnesoid X receptor (FXR) agonist obeticholic acid (OCA) was analyzed in gene expression studies of CCl4-fed and control-animal. Mucus thickness measurement on gut explants and PAS (Periodic acid-Schiff) staining to visualize and count goblet cells (GC) were utilized.

**Results:** We have observed a significant reduction in mucous thickness in ileum and colon (control 34 μm±9.54 vs BDL 77.49μm±14.51 in ileum; control 154.38 μm±12.51 vs BDL 100.74 μm±0.6 in proximal colon) and goblet cell numbers in ileum (Control 0.47 GC/100 μm of villus±0.07 vs BDL 0.29 GC/100 μm of villus±0.04) of mice following BDL but not PPVL (Control 0.27 GC/100 μm of villus±0.11 vs control-PL 0.30 GC/100 μm of villus±0.11). Moreover we have seen that farnesoid X receptor (FXR) agonist obeticholic acid (OCA) partially restored GC loss in CCl4 treated animals (Control 0.63 GC/100 μm of villus±0.08 vs Control OCA 0.65 GC/100 μm of villus±0.07 vs CCl4 0.49 GC/100 μm of villus±0.18 (CCl4 OCA 0.57 GC/100 μm of villus±0.09).

**Conclusion:** All these results suggest that a reduced bile production by the cirrhotic liver and not portal hypertension per se interfere in the goblet cell development and/or maturation. In addition, this effect can be, at least partially, be restored by the FXR agonist OCA. Our study opens the possibility to, so far, unknown effect of bile salts in the intestinal epithelium development in the context of liver cirrhosis being a clear candidate for mucus layer regulation and hence protective effect against bacterial translocation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0032 CAPSAICIN AND SULFORAPHANE PREVENT THE ADVANCEMENT OF LIVER FIBROSIS IN AN EXPERIMENTAL MODEL OF LIVER CIRRHOSIS?**

**Introduction:** Liver fibrosis is defined as the excessive accumulation of extracellular matrix (ECM) following a chronic liver injury. It is characterised by an increase in gene expression of proinflammatory molecules such as TGF-β1, IL-1β, IL-6 and TNF-a, as well as excess synthesis of ECM components such as COL-1. Capsaicin (CAP) is a pungent compound found in chilli peppers which has shown anticancerogenic, antiinflammatory and antifibrotic properties. Moreover, sulforaphane (SFN) is an isothiocyanate which is in cruciferous such as broccoli and it has exhibit an antioxidant effect in several in vitro and in vivo models.

**Aims & Methods:** The objective of this project was to evaluate the antifibrogenic and antiinflammatory effects of a daily supplementation with CAP and SFN in a rat model of liver fibrosis due to carbon tetrachloride (CCL4) intoxication. 35 male Wistar rats were included (n =7/group; animals were administrated intraperitoneally 3 times per week during 8 weeks with a mix of CCL4/normal oil (1:5/1:4 week 1, 1:4 week 2 and 1:3 week 3-8). Healthy and CCL4-fibrotic controls received only supplementation vehicle (Tween 2% in PBS). Treated groups receive SFN 5ug/kg, or CAP 2mg/kg, or both supplements daily by oral gavage since the beginning of CCL4-intoxication regimen until sacrifice. Masson staining and PCR was performed in liver samples. Hepatic enzymes were analysed in serum.

**Results:** Groups treated with CAP and SFN showed a decrease of >30points in percentage of liver fibrosis according to Masson staining (p <0.05), hepatic function improve since AST and ALT serum levels diminish (p <0.01) also a lower gene expression of TGF-b1, COL-1, TNF-a, IL-1 b and IL-6 was detected in treated animals when compared with fibrotic controls (p <0.01).

**Conclusion:** Thus, CAP and SFN seem to exert a hepatoprotective effect in this model of chronic-induced liver damage. These findings suggest that dietary sources of CAP and SFN might be included in dietetic guidelines for the prevention of liver fibrosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0033 DIAGNOSIS OF GASTRIC VARICES BY ENDOSCOPIC ULTRASONOGRAPHY USING COLOR DOPPLER**

T. Sato

Gastroenterology, Sapporo Kosei Hospital Dept. of Gastroenteroloy, Sapporo/Japan

**Contact E-mail Address:** taka.sato@ja-hokkaidoukouseiren.or.jp

**Introduction:** Gastric variceal bleeding is common complication, and it is associated with higher morbidity and mortality rates than hemorrhage from esophageal varices. Oesophagogastroduodenoscopy is usually the initial investigation in patients with portal hypertension for the purpose of the distinction between gastric varices and gastric folds. The aim of this study was to investigate endoscopic color Doppler ultrasonography (ECDUS) findings of gastric varices.

**Aims & Methods:** Two hundred-fifteen patients with gastric varices were evaluated with ECDUS. To begin with, identification of gastric varices was performed with B-mode scanning and then, color flow mapping was done. On B-mode scanning, submucosal gastric varices, and para-gastric collateral veins were obtained as hypoechoic vessels within gastric wall or in the tissue and spaces exterior to the adventitia of gastric wall. ECDUS provides a color display of blood flow and evaluates the flow pattern using fast Fourier transform (FFT) analysis. FFT analysis can indicate the flow pattern and calculate the velocity of blood flow. We monitored the color flow images of gastric varices, and para-gastric or per-gastric collateral veins. Endoscopic findings of gastric varices were evaluated according to the grading system outlined in The General Rules for

Results: The color flow images of gastric varices and peri-gastric veins were delineated in all 215 patients with ECDUS. Evaluation of blood flow velocity in the 215 gastric varices revealed velocities of 7.7–35.7 cm/s (mean, 18.2±6.0 cm/s). Mean velocity of large, coil-shaped (F3) type gastric varices was 23.7±6.2 cm/s (n = 52), while the mean velocity of enlarged tortuous (F2) type gastric varices was 16.7±5.0 cm/s (n = 163). The velocities of F3 type gastric varices were significantly higher than those of F2 type (P < 0.0001). Next, we evaluated the wall thickness to submucosal gastric varices. Two hundred-fifteen of the gastric varices were 1.0–2.2 mm (1.6±0.4 mm) in gastric wall thickness. Mean thickness of red color (RC) or erosion positive varices was 1.2±0.2 mm (n = 42), while the mean thickness of RC or erosion negative varices was 1.7±0.3 mm (n = 173). The thickness of RC or erosion positive varices was significantly thinner than that of the negative cases (P < 0.0001). Seven cases of the 215 patients had the current history of gastric variceal bleeding, and the other three cases had experienced variceal rupture on follow up (bleeding cases, n = 10), and mean thickness of these bleeding cases were 1.2±0.2 mm.

Conclusion: ECDUS is a useful modality for the diagnosis of hemodynamics of gastric varices and may allow the stratification of patients into low, high risk for hemorrhage.

Introduction: Liver cirrhosis and portal hypertension are associated with esophagale varices, gastric varices, small and large intestinal enteropathies.

Aims & Methods: We aimed to study the prevalence of colopathy and ileopathy in patients with portal hypertension secondary to liver cirrhosis. Chronic hepatitis C patients with portal hypertension secondary to liver cirrhosis were enrolled. The severity of cirrhosis was classified by the Child-Pugh score. All patients were evaluated by upper endoscopy and colonoscopy for screening of portal hypertensive colopathy. Portal hypertensive ileopathy was noted only in one case (1.7%). No ileum revealed that portal hypertensive colopathy was present in 16 patients (5%). Portal hypertensive gastropathy was noted in 43 patients (71.6 %) and C for 24 (40.7%). 53 (88.33%) patients had esophageal varices (23 patients had small esophageal varices, 15 had moderate, and 8 had big varices, 2 post-band ligation and 5 obliterated varices). Gastric varices were present in 3 patients (5%). Portal hypertensive gastropathy was noted in 43 patients (71.6 %) and was mild in 38 and severe in 5 patients. Colonoscopy finding up to the terminal ileum revealed that portal hypertensive colopathy was present in 16 patients (26.7%). Portal hypertensive ileopathy was noted only in one case (1.7%). No colonic or ileal varices were noted.

Conclusion: Portal hypertensive colopathy but not ileopathy is common in Egyptians with liver cirrhosis. Ileal varices and ileopathy are not common in patients with liver cirrhosis and PHT.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0035 PREDICTIVE FACTORS FOR THE DEVELOPMENT OF ACUTE-ON-CHRONIC LIVER FAILURE IN PATIENTS WITH GASTROINTESTINAL BLEEDING

C. Cojocariu1, S. Chirică2, A. Trifan2, C. Stanciu3
1Gastroenterology, 2Grigore T. Popa University of Medicine and Pharmacy Iasi, Iasi/Romania; 3Institute of Gastroenterology and Hepatology, Iasi/Romania

Contact E-mail Address: stefannchirica@yahoo.com

Introduction: Acute-on-chronic liver failure (ACLF) is a specific clinical form of liver failure in patients with liver cirrhosis, referred as acute deterioration of liver function associated with an acute specific complication of liver cirrhosis. ACLF is defined by the presence of renal failure or 2 or organ failures according to the international European Association for the Study of the Liver-International Chronic Liver Failure consortium: 1) circulatory- need for vasopressor support; 2) renal- serum creatinine value ≥ 2mg/dL; 3) cerebral- Grade III or IV hepatic encephalopathy; 4) respiratory- SpO2-FiO2 ≤ 214.

Aims & Methods: We aimed to identify predictive factors for ACLF development in cirrhotic patients admitted for variceal gastrointestinal bleeding. All patients were included in the Institute of Gastroenterology and Hepatology Iasi (consisting of 8 secondary hepatology centers) between June and December 2016 were evaluated for ACLF (we excluded from the study the patients presenting ACLF diagnosis criteria on admission). We compared cirrhosis patients who developed ACLF after 12 hours of admission with those who did not.

Results: 99 cirrhotic patients with gastrointestinal bleeding were evaluated. 45.5% of patients admitted with variceal bleeding developed ACLF. Demographic data were similar in patients with ACLF vs. no ACLF in age (54.2±7.3 vs. 56.6±9.5 years), male sex (54 vs. 45), and diabetes (56 vs. 43) and significant difference was found in alcohol consumption (72 vs. 27). In patients with ACLF, the grade 1 was the most frequent (56.3%); grade 2 (33.3%) and 3 (10.4%) of ACLF were more rare and no significant differences between the ACLF subgroups was observed. The patients with ACLF were more likely to be admitted with infections and alcohol consumption, when compared to patients without ACLF, Independent predictors for ACLF development included a high admission MELD (p < 0.05), presence of infection and alcohol abuse (p < 0.01), hospitalization in the last 6 months (p < 0.05). Inhospital and 30-day mortality were significantly higher in patients with ACLF (p < 0.0001).

Conclusion: Patients admitted with variceal bleeding, with alcohol consumption, high MELD on admission, previous admission in < 6 months are more likely to develop ACLF and need to be monitored closely for the development of ACLF.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0036 HAEMOSTASIS IN PORTAL VEIN IN CIRRHOSIS: ROLE OF LOCAL ENDOTHELIAL DAMAGE

S. Shalaby1, P. Simioni2, E. Campello3, S. Gavasso4, A. Zanetto5, F. D’Amico6, E. Gringreri6, U. Cillo6, M. Battistel6, P. Burra6, M. Senzolo6

Introduction: Cirrhosis is characterized by both bleeding and thrombotic complications due to underlying procoagulative haemostatic imbalance [1]. Among thrombotic events, portal vein thrombosis (PVT) is the most common with annual incidence ranging between 4.6% and 12.8% [2, 3]. Demonstrated associated risk factors are severity of portal hypertension and slowed portal flow [4]. However, data regarding haemostasis in the portal venous system of cirrhotic patients is lacking.

Aims & Methods: To evaluate peripheral and portal venous haemocoagulative state in patients with cirrhosis in comparison with controls, through thrombin generation test (TGT), rotational-thrombelastometry (ROTEM) along with evaluation of endothelial dysfunction by quantification of circulating endothelial microparticles (MP). Correlate these results with activity levels of local pro and anticoagulant factors. Compare peripheral and portal venous districts in cirrhosis in terms of haemostatic parameters. We consecutively evaluated adult patients with liver cirrhosis undergoing liver transplantation (LT) or transjugular intrahepatic portosystemic shunt (TIPS). Patients without liver disease awaiting liver surgery or deceased liver donors were enrolled as controls. The following laboratory tests were performed on citrated peripheral and portal venous blood samples: TGT: with and without thrombomodulin (TM), ROTEM, dosage of main pro and anticoagulants factors activity and analysis of circulating endothelial MP.

Results: 25 cirrhotics (15 LT and 10 TIPS) and 6 controls (2 undergoing hepatic resection for benign liver lesions and 4 liver donors) were enrolled. Peripheral blood in cirrhosics showed resistance to activation of PC-pathway at TGT (ETP with without TM 0.89 (0.78–0.92) vs 0.6 (0.3–0.74), p < 0.001), lower clot stability at ROTEM (MCF-NATEM mm: 45.3 (36–51) vs 63 (53–69), p = 0.042), and significant increase of endothelial-MP (CD62EPM/L: 1391 (651–2301) vs 582 (380–1161), p = 0.046), indicative of higher endothelial damage compared to controls. Similar results were obtained comparing portal blood of cirrhotics and controls (ETP with/without TM 0.89 (0.78–0.92) vs 0.63 (0.33–0.75), p = 0.001; MCF-NATEM: 46 (39–51) vs 62 (49–66), p = 0.056; CD62EPM/L: 1606.5 (680–1885) vs 529.5 (266–781), p = 0.069). There was a significant correlation between diminished levels of PC, PS, AT, FI and either TGT or ROTEM parameters. Comparing portal and peripheral blood of cirrhotics, we detected endogenous heparinoids in portal (α-angle NATEM 51 (46–57) vs

*Data are presented for all surviving patients at the end of the 6 months (N = 114) or 12 months (N = 102) as mean (standard error of the mean, SEM) per patient

Number of patients with ≥1 ED attendance/admission in the observed periods *Paired t-test

HEPETEM 57 (50–59), p = 0.05). This finding, together with a decreased concentration of endothelial-MP carrying TM (TM-MP/L: 232 (190–287) vs 377 (218–493), p = 0.002) and endothelial-Pc receptor (EPCR/CD65E-MP/L: 14 (12-25) vs 37 (24-70), p < 0.001), demonstrated a local greater endothelial damage in cirrhotics.

Conclusion: In cirrhotics, venous hypercoagulability and portal site specific endothelial damage, associated with hampered antithrombotic properties, may be important local risk factors in the pathogenesis of PVT along with the documented venous stasis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In clinical trials rifaximin-α (RFX) has been shown to reduce recurrence of episodes of overt hepatic encephalopathy (HE) and HE-related hospitalisations. UK real-world data confirmed reductions in hospital admissions and length of stay with RFX use; however, data on use of emergency department (ED; A&E in UK) resources are still scarce. This study assessed the impact of RFX on utilisation of ED resources.

Aims & Methods: Patients from 11 UK hospitals who were prescribed RFX for HE between July 2008 and May 2014 were included in this retrospective observational study. Patient records were reviewed; details of demographic and clinical characteristics, and all-cause ED attendances and admissions were collected in the 6 and 12 months pre- and post-RFX initiation. The analysis included only patients who were alive at the end of the study periods.

Results: Of the 145 patients included, 114 (79%) were alive at 6 months and 102 (70%) at 12 months post-RFX initiation. At RFX start, mean age was 61 years, 63% were male; 67% had alcohol-related liver disease; for patients with available MELD score (70%), the mean was 16; 78% were on lactulose. Use of ED resources in the 6 and 12 months pre- and post-RFX initiation is shown in Table 1. Six patients developed adverse events, none serious.

Conclusion: In UK clinical practice, treatment with RFX for HE is well-tolerated and associated with significant reductions in ED attendances, with or without admission, both within 6 and 12 months of RFX initiation.

P0038 Predicting factors for hospital readmission after the first episode of hepatic encephalopathy

M. Silva1, A. Peixoto2, H. Cardoso2, S. Lopes3, C. Macedo3

1 Gastroenterology. Hospital São João, Oporto/Portugal
2 Centro Hospitalar São João, Porto Medical School, Porto/Portugal

Contact E-mail Address: marcovecostasilva87@gmail.com

Introduction: Hepatic encephalopathy (HE) is a frequent complication of liver cirrhosis, with necessity of hospital admission in many cases. The economic burden of HE is substantial. After ascites, HE is the second most common reason for hospitalization of cirrhotic patients. HE is also the most common, possibly preventable, cause for readmission.

Aims & Methods: We aimed to assess the factors associated with the increased likelihood of hospital readmission for HE after the onset episode.

We completed a retrospective Retrospective analysis of admissions for HE of patients with liver cirrhosis, between October 2010 and October 2015. Only the onset episode was included. Patients were followed for 1 year or until readmission for HE. All patients were discharged under lactulose therapy. Descriptive statistics, uni and multivariate analysis, logistic regression, and ROC curves analysis were performed using IBM SPSS Statistics 22 with p < 0.05 deemed to be statistically significant.

Results: In this study 119 patients were included: 78% men with a mean age of 59 ± 13 years: 8% had hepatocellular carcinoma, and 45% had Child-Pugh C. The most frequent cirrhosis etiologies were alcoholic disease (60%) and HCV infection (12%). The precipitating factors, for the onset episode, more frequently detected were diuretic overdose (36%) and infection (31%). All patients were treated with standard therapy, with an adequate lactulose dose. The readmission rate after the first episode of HE was 72% (75% men). The estimated average time to relapse was 18 weeks. The most frequent causes of readmission were also diuretics overdose (31%) and infection (30%). The patients who were readmitted had a higher MELD score than patients without recurrence (13.9 vs. 11.6 points; p = 0.015). This association was verified in the multivariate analysis (OR = 1.1, p = 0.044).

Conclusion: In this cohort, there was a high rate of readmission for HE after the inaugural episode, which carries a great impact on individual health and high socio-economic costs. A higher MELD score was independently associated with a high probability of readmission for HE.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The regulations for prescribing interferon-free treatment for patients infected with hepatitis C virus in Romania comprised only patients with F3/F4 fibrosis so the risk of hepatic decompensation and complications was higher compared to other cohorts. In previous interferon-based regimens, thrombocytopenia and hypoalbuminemia were markers for portal hypertension and hepatic synthetic dysfunction, respectively, have been shown to reduce the likelihood of sustained virological response and to increase the rates of serious adverse events.

Aims & Methods: The aim of this study was to evaluate the impact of thrombocytopenia and hypoalbuminemia on treatment outcome and disease complications. We included in this study 855 HCV-infected cirrhotic patients treated with ombitasvir/paritaprevir/r-dasabuvir/r-barivabirin for 12 weeks in 10 university hospitals in Romania. The following groups were studied: 151 patients (17.7%) with albumin <3.5 g/dl, 238 (28%) with thrombocytopenia (a cutoff of 10000/mm^3 was used) and 71 patients (8.3%) with both hypoalbuminemia and thrombocyto- ppenia before initiating antiviral treatment. Safety (as AE in % and SAE) efficacy defined as HCV RNA undetectable at week 12 post-therapy and complications rate were evaluated using Pearson’s correlation, multivariate analysis and Chi-Square test.

Results: Main patient characteristics were: 100% genotype 1b, a median age of 60 (58, 62) years, 54.57% men, 31% spontaneous bacterial peritonitis and 24% urinary. Of these, 51% were rehospitalised. The incidence of bacterial infection was 25%: 41% respiratory, 37% digestive and 9% infections of the skin. Of these, 51% were nosocomial and in 20% an infectious agent was isolated. The survival rates at 30 days, 3 months, 6 months and 1 year were 65%, 55%, 34% and 27% in patients with infection and 97%, 90%, 85% and 78% in those without infection (p = 0.001). The multivariate analysis, survival was independently associated with MELD (hazard ratio (HR) 1.073, p = 0.012), age (HR 1, 032, p = 0.012) and infection (HR 3, 821, p < 0.001). Bacterial infection remained an independent predictor of mortality, even when excluding patients with in-hospital mortality and at 30 days (HR 3, 093, p < 0.001 and HR 1, 635, p = 0.001).

Conclusion: Patients with cirrhosis exposed to a bacterial infection are at increased risk of death. This risk remains in the long term when we exclude patients with in-hospital mortality and at 30 days and regardless of the severity of the underlying disease (MELD).
P0045 EFFECT OF TREATMENT OF CHRONIC HEPATITIS C WITH SOFOSBUVIR AND DACLATASVIR IN PATIENTS OLDER THAN 60 YEARS

K. Elnoenamy1, M. Badr2

1Gastroenterology, National Liver Institute (NLI), Elmenofyia gov./Egypt
2Internal Medicine, Menofiya University, Shebin Elkom/Egypt

Contact E-mail Address: dr_kareemn@yahoo.com

Introduction: Hepatitis C virus (HCV) diminishes health related quality of life (HRQOL). Currently, there is no published data on assessing the impact of treatment of chronic hepatitis C with the new antiviral drugs in old-aged patients. Aims & Methods: The aim is to study the effect of treatment of chronic hepatitis C with the new antiviral drugs in old-aged patients in HRQOL. About 132 patients with chronic hepatitis C (cirrhotic and non-cirrhotic) were enrolled in the study. Age of patients was sixty years old and older. All patients were treated with sofosbuvir/daclatasvir with or without ribavirin for three months. The HRQOL was assessed with sickness impact profile scoring (SIP) before start of treatment, at end of treatment and after 3 months of end of treatment.

Results: Old chronic hepatitis C patients who were treated achieved primary virological response (end of treatment) with percentage 100% and sustained virological response (SVR) (after 3 months of end of treatment) in about 96% of treated patients. Before treatment, patients with chronic hepatitis C had worse scores especially in work, sleep, rest and recreation and pastimes categories. After treatment, patients who received sofosbuvir/daclatasvir with or without ribavirin had significant improve in work, sleep, rest and recreation and pastimes categories with p-value 0.001. Numerical improvement was observed in total score, physical and psychosocial dimension scores. In patients with SVR, the most improvement was in work and psychosocial dimension scores. There was no significant difference in SIP between scores after end of treatment and after 3 months of treatment.

Conclusion: Treatment of chronic hepatitis C in old-aged patients had a significant improvement in HRQOL.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bacterial infections are a leading cause of mortality in patients with decompensated cirrhosis. Aims & Methods: The objective of this study was to evaluate the prevalence of multiresistant bacterial infections, associated risk factors and their impact on prognosis in hospitalized decompensated liver cirrhosis patients.

This was a retrospective study in patients with decompensated liver cirrhosis admitted to the Gastroenterology ward between January 2009 and May 2016. Results: There were 308 infections with confirmed microbiological isolates, corresponding to 218 hospitalizations, in a total of 161 patients. The median age of the patients was 63 years (IQR 55–71) and 67% of them were men. Alcoholic liver disease was the major cause of cirrhosis (72%). Among the infections evaluated, 87% were nosocomial and 13% community-acquired. Urinary tract infection was the most common infection (57%). In 27% of patients there were at least two concomitant bacterial infections. Multidrug resistant (MDR) bacteria were isolated in over half of patients. In the multivariate analysis, prophylaxis for spontaneous bacterial peritonitis (OR 2.3, p = 0.009), MELD score greater than 19 at admission (OR 1.7, p = 0.043), hospitalization in an Intensive/Intermediate Care in the previous month (OR 2.8, p = 0.001) and antibiotic therapy for infection in the last 6 months (OR 2.4; p = 0.001) were independently associated with MDR infection. From the variables identified in the multivariate analysis, a predictive model of MDR bacterial infection was created. Assuming a sensitivity of 66% and a specificity of 72%, we considered the cut-off of 0.0415 as clinically relevant, regarding likelihood of developing a MDR bacterial infection (AUCROC 0.723; 95% CI 0.667–0.780). The occurrence of a MDR infection was associated with a longer duration of hospitalization (p = 0.017). In the multivariate analysis there was no independent association between MDR infection and in-hospital mortality and one month after discharge.

Conclusion: The prevalence of MDR bacterial infections in cirrhotic patients is significant and associated with a longer hospital stay. It is possible to identify predictors of its occurrence in order to implement epidemiological strategies to reduce the risk of these infections.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Egy Fibro-mark (FM) score, a more sophisticated score combining ‘direct’ and ‘indirect’ markers, is a useful tool to improve the staging of liver fibrosis in CHC patients and seems more efficient than BRC, FRT, King’s score, APRI, Fibro-score and FibroQ in this group of Egyptian patients.

Disclosure of Interest: D. Omran: This study was supported by the science and technology development fund (STDF), Egypt; Project ID: 5380, basic and applied research. All other authors have declared no conflicts of interest.

| Conclusion: | FibroScan and ECM proteins prove that the IL-28B rs12979860 T allele affects the severity of liver disease. Coexistence of C allele with T allele reduces cirrhosis severity. This study gives a good deduction that carriage of the IL-28B C allele protects from unfavorable outcomes in CHC. This study shed light on using FibroScan and ECM proteins as good diagnostic options for liver disease severity in IL-28B genotypes. |

**P0049 THE SAFETY AND EFFICACY OF THE COMBINATION OF DACLATASVIR, ASUNAPREVIR, AND BECLABUVIR IN THE TREATMENT OF CHRONIC HEPATITIS C VIRUS GENOTYPE 1 INFECTION: A SYSTEMATIC REVIEW AND META-ANALYSIS**

Introduction: Recently, new direct antiviral agents (DAAs) with different mechanisms of action have been developed to provide much more efficacious and better-tolerated therapeutic strategies for treatment patients with hepatitis C virus (HCV) infection. Several clinical trials have investigated a 12-week therapy with fixed dose of all-oral three-drug combination of daclatasvir (DCV), a potent pan-genotypic nonstructural protein 5A (NS5A) inhibitor, in 60 mg daily dose, asunaprevir (ASV), an NS3 protease inhibitor, in 200 mg twice daily; and beclabuvir (BCV), a non-nucleoside NS5B thumb-1 polymerase inhibitor, in 75 mg twice daily (BCV-TRIO) for treatment of patients with HCV genotype 1 infection.

**Aims and Methods:*** This systematic review and meta-analysis aimed to investigate the efficacy and safety outcomes of the three-drug combination of daclatasvir, asunaprevir, and beclabuvir, in treatment of HCV genotype 1 infection. Eleven electronic search engines/libraries, including PubMed, Scopus, Web of Science, Google Scholar, Virtual Health Library (VHL), WHO Global Health Library (GHL), ClinicalTrials, POPLINE, System for Information on Grey Literature in Europe (SINGLE), Cochrane library, and the New York Academy of Medicine (NYAM), were systematically searched for any clinical trial reporting the efficacy and safety of BCV-TRIO for the treatment of HCV genotype 1 infection. Studies were screened for eligibility and data was extracted by two independent researchers. A forest plot was used to compare the effect of different treatment regimens and the risk ratio was calculated. The study included 219 observations and 207 patients were included. The overall SVR rate was 97.5% while the SVR rates for different regimens were: 92.4% (95%CI [85.3–92.4]), 96.2% (95% CI [93.0–98.0]), 93.5% (95%CI [89.2–96.1]), 91.1% (95% CI [87.6–93.7]), 93.9% (95% CI [86.6–97.3]), and 91.9% (95% CI [89.1–94.0]) for HCV genotype 1a, HCV genotype 1b, IL28B CC genotype, IL28B non-CC genotype, cirrhotic, and non-cirrhotic respectively. The virologic failure occurred in only 40 patients (7%) (95%CI [5.2–9.4]). There was no difference when adding ribavirin to this combination (RR = 0.98, 95% confidence interval (95% CI) [0.90–1.08], P = 0.70, using this regimen on interferon-experienced patients (R-R = 1.03, 95% CI [0.98, 1.08], P = 0.30), or changing the dose of BCV from 75 mg to 150 mg regardless the genotype 1 subtypes or IL28B genotype. Similarly, the minimal failure of treatment showed no difference regarding the main two comparisons regardless the cause of this failure. Increasing the dose or the duration did not show a significant increase in the efficacy. The rates of serious adverse events (AEs) occurrence were; (3.4%, 95% CI [2.3–5.1]), (6.5%, 95% CI [3.2–12.7]), (2.3%, 95% CI [0.6–8.8]), and (2.9%, 95% CI [0.2–33.6]) for BCV-TRIO, (BCV-TRIO + RBV) for 12 weeks, (DCV + ASV + BCV-150 mg) for 12 weeks, and both (BCV-TRIO) and (DCV + ASV + BCV-150 mg) for 24 weeks respectively. For BCV-TRIO, the most frequent AEs were headache, diarrhoea, fatigue, and nausea with rates; (21.2%, 95% CI [18.4–24.2]), (14.3%, 95% CI [12.6–16.9]), (13.8%, 95% CI [11.2–16.8]), and (13.4%, 95% CI [10.9–16.4]) respectively.

**Conclusion:** This study reported a high SVR, minimal treatment failure rate, and few AEs with fixed-dose three drug combination of daclatasvir, asunaprevir, and beclabuvir for 12-week duration in HCV genotype 1-infected patients, without adding ribavirin, prior interferon-based therapy, restriction on noncirrhotic patients, restriction on certain IL28B genotype, restriction on baseline resistance-associated variants, or expansion the duration of the treatment to 24 weeks.

Introduction: Egypt has the highest prevalence of HCV worldwide. Prevalence of HCV was reported to be 13.9% among healthy populations. Adults have higher HCV prevalence (15.7%) than children (4.0%). Geographically, HCV is highly prevalent in the Nile delta (15.8%) than in Upper Egypt (9.0%). The household contacts of HCV seropositive patients had been shown to have a high risk of HCV infection.

Aims & Methods: The aim of this study was to determine the prevalence of HCV infection among household contacts of HCV seropositive index patients. We also aimed to compare HCV genotyping distribution in upper and lower Egypt. In this Multicentre hospital case control based study a total of 4894 Egyptian individuals were recruited to the hospitals from different Egyptian population in Upper & lower Egypt (mainly from Dakahlia, Cairo and Assuit governorates).

The index HCV patients were 1106 cases whereas the families or close household contacts of these index cases were 3788 cases. Ideally family was selected on the basis of containing at least one positive HCV index, one positive HCV member and other one negative HCV member with no history of any liver complications or disorders (first and second degree consanguinity, living and sharing usual life activities and other one negative HCV member with no history of any liver complications). Ideally family was selected on the basis of containing one positive HCV index, one positive HCV member and other one negative HCV member with no history of any liver complications or disorders (first and second degree consanguinity, living and sharing usual life activity and having at least 15 years of exposure to the index case). The positive cases (index or contact cases) in the family were selected with inclusion criteria of 1-HCV positive by PCR RNA & 6 months, 2-Adults (above 18 years) of both sexes 3-Any stage of HCV related liver diseases. While cases were diagnosed as spontaneously cleared the virus (SVC) based on the following criteria: positive Anti-HCV but negative PCR HCV RNA in 2 successive samples at least 6 months apart with no prior history of antiviral therapy.

Results: The prevalence of Anti-HCV v+ cases among household contacts was 20.71% but when PCR HCV was performed only 17.83% were v+ while 2.9% were spontaneously cleared the virus (SVC). The HCV prevalence among household contacts was 17.29% & 19.17% while the SVC was 2.49% & 1.55% in lower & Upper Egypt respectively. When the genotyping of the positive cases were performed it was found that the following pattern was noticed in the upper & lower Egypt respectively: genotype 4a (90.3% & 70.1%), 4m (4.8% & 11.8%), 4n (0.5% & 3.2%) 4o (0.5% & 1.9%) 4v (0.8% & 1.2%) & 1a (2.9% & 8.3%) as shown in the following table.

Conclusion: The prevalence of HCV was found to be 18.5% among household contacts of Egyptian patients. The genotype 4 was predominant in upper Egypt (97.1%) more than lower Egypt (91.7%). On the other hand genotype 1a was higher in lower Egypt (8.3%) more than upper Egypt (2.9%).

P0051  RED BLOOD CELL DISTRIBUTION WIDTH (RDW) AS NON INVASIVE PREDICTOR OF LIVER FIBROSIS IN CHRONIC HEPATITIS C PATIENTS GENOTYPE 4

M. El-Bendary1, K. Farid1, D. El-Barber2, M. Elnagar3
1Tropical Medicine And Hepatology, Mansoura Faculty of Medicine- Mansoura University, Mansoura/Egypt

3Microbiology Department, Mansoura Faculty of Medicine- Mansoura University, Mansoura/Egypt

Contact E-mail Address: mmelbendary@gmail.com

Introduction: Red blood cell distribution width (RDW) is a numerical measure of the variability in size of red cell. It reflects variability in the size of circulating red blood cells. RDW in patients with chronic HBV infection, and it is higher in patients with alcoholic liver disease and non alcoholic liver cirrhosis. The gold standard for assessing the histological outcome come of liver disease is liver biopsy. This procedure is costly and carries a small risk of complications due to sampling error, invasiveness and requires hospitalization of at least 6-18 h. These limitations have stimulated the development of non-invasive techniques for assessing the presence and the degree of liver fibrosis. Several laboratory scores composed of routine laboratory markers that are readily available have been proposed for non-invasive prediction of liver fibrosis in chronic hepatitis C (CHC) patients.

Aims & Methods: The aim of this work is to use RDW as a marker for non-invasive prediction of the stage of hepatic fibrosis in patients with chronic hepatitis C genotype 4. 100 patients with chronic hepatitis C were subjected to routine laboratory & radiological investigations in addition to using KX-21 Sysmex automated hematology analyzer to measure RDW & RPR (RDW% & Platelet ratio). Comparing with other liver fibrosis like APRI (AST-to-Platelet ratio index) FIB-4 equation (using platelet count, AST, ALT, age) to perform this test. PCR HCV RNA, genotyping & liver biopsy (using METAVIR scoring system where cases were classified into early fibrosis (F1 + F2): 68 patients & late fibrosis (F3 + F4): 32 patients) were done.

Results: RDW & RPR were significantly higher in patients with late fibrosis > early fibrosis (P < 0.0001) while platelets count was significantly lower in late fibrosis > early fibrosis (p < 0.0001). By applying ROC curve it was found that the cut off value of RDW was 16.5, with sensitivity 86.8% specificity 85.9% & accuracy 86% & the cut off value of the platelets was 196.5 with sensitivity 81.8%, specificity 62.8% accuracy 67%, while RPR cut off value was 0.0897 with sensitivity 90.9%, specificity 85.9% & accuracy 87%. As regard APRI cut off value was found that the cut off value was 0.40 with sensitivity 72.7%, specificity 66.7% & accuracy 68% While FIB-4 equation showed cut off value 1.685 with sensitivity 77.3%, specificity 66.7% and accuracy 69%. In conclusion the area under the ROC curve for RDW, RPR & RPR were excellent but for platelets it was only good and APRI were fair. When applying regression analysis it was found that the RDW (OR:3.903, 95% CI: 1.538–9.904) & Platelets (OR:0.953, 95% CI: 0.913–0.995), so as the level of RDW increase by one unit the risk late fibrosis will increase by 3.9 fold and when the platelets increase by one unit the risk of late fibrosis will decrease by 0.953.

Conclusion: RDW & RPR may be used as simple, non-invasive predictors of advanced fibrosis in patients with chronic HCV genotype-4.

P0052  CANCER INCIDENCE IN VARIOUS ORGANS OTHER THAN THE LIVER FOLLOWING DIRECT-ACTING ANTIVIRAL (DAA) TREATMENT FOR HEPATITIS C

B. Endoh1, N. Esaka2, S. Katsushima1, K. Chikugo1, S. Nakano4, T. Shimogama1, S. Iwamoto4, K. Kasahara5, T. Komeda1

Contact E-mail Address: b-endoh@umin.ac.jp

Introduction: The incidence of liver cancer and its recurrence have been reported frequently at an early stage in patients who underwent interferon (IFN)-free direct-acting antiviral (DAA) therapy [1]. The underlying mechanisms of

United European Gastroenterology Journal 5(5S) A177
cancer incidence following DAA therapy may include the rapid clearance of hepatitis C virus, reconstitution of the immune system, and reduction of cancer immunosurveillance [2]. These changes may in fact have an impact on the development of cancer in other organs.

**Aims & Methods:** We conducted a retrospective analysis to compare the cancer incidence in patients treated with IFN-free DAA therapy with those treated with IFN therapy. All patients who achieved sustained viral response following antiviral therapy between 1992 and 2016 in our hospital were investigated retrospectively. Patient records were examined to identify new cases of cancer, as documented by pathology or medical imaging, in organs other than the liver following antiviral therapy. The date of diagnosis was determined based on the records, and the cancer incidence was compared between patients treated with DAA therapy and those treated with IFN therapy using the Kaplan-Meier method for survival analysis. Patients with recurrent cancer were excluded from the analysis. Propensity score analysis followed by inverse probability of treatment weighting (IPTW) was used to correct for the effects of confounding factors.

**Results:** There was a significant difference in the age and sex of the patients treated with DAAAs (n = 324, median age: 70; male: 41%) and those treated with IFNs (n = 445, median age: 58; male: 60%). Median lengths of the observation period for the DAA and IFN groups were 1.3 and 6.2 years, respectively. There were 12 and 23 cases of cancer occurring in organs other than the liver in the DAA and IFN groups, respectively. These cancer cases occurred most frequently in the gastrointestinal tract, followed by the urinary organs, hematopoietic organs, biliary tract/pancreas, lungs, and others. The median periods from the start of the antiviral therapy to the time of diagnosis were 0.9 and 6.8 years in the DAA and IFN groups, respectively. Cumulative rates of cancer after 1 and 2 years were 3.0 and 5.0% for the DAA group, and 0.2 and 0.0% for the IFN group, respectively. The difference between the groups was significant (p = 0.02) based on Cox regression analysis using IPTW.

**Conclusion:** Because cancer detection in organs other than the liver can be challenging in management of hepatitis, some cases with cancer found after the treatment might have been diagnosable before the treatment, possibly leading to an overestimation of the incidence after the treatment. The number of newly diagnosed cancer cases was small in the present study, resulting in a low statistical power. Nevertheless, the cancer incidence in organs other than the liver was significantly higher in patients treated with DAA therapy than those treated with IFN therapy. This difference persisted after correcting for possible confounding factors, including age and sex of the patients. Our findings suggest that patients need to be carefully examined after DAA therapy for the development of cancer in various organs, including but not limited to the liver.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Discussion:** The impact of the virological cure on the evolution of cirrhotic patients with hepatitis C treated with the direct-acting antivirals (DAAs) has been a watershed for the management of HCV-related chronic liver diseases. In fact, treatment with second-generation DAAs cures the great majority of patients treated with HCV chronic infection, with the exception on genotype 3 cirrhotic patients.

**Aims & Methods:** The present report focuses on HCV genotype 3 cirrhotic patients treated with second-generation DAAs in order to identify which of the several treatment schedules recommended for genotype 3 would constitute the best option. Methods: 1. Twenty-four Italian centers (ITAL-C consortium) were involved in this real-life study where HCV genotype 3 patients treated with DAAs. Eligible patients were >18-year-old with chronic HCV infection, either naive to treatment-experienced patients with any of the previous therapies were excluded: infection with HCV genotypes other than 3, active HCC on imaging, HIV and/or HBV co-infection, liver-transplant recipients, patients with an estimated glomerular filtration rate <30 ml/min. 2. With the intent to delineate a treatment schedule with the new DAAs that would offer the higher chance of SVR to patients with HCV genotype 3, a systematic search of the literature was implemented and the retrieved information was pooled and evaluated by a meta-analytical approach. Electronic, systematic review of the available evidence in the published literature was undertaken to identify all studies. The systematic literature review was performed via Medline from 2012 to 2016 by the following search keys: HCV Genotype 3 AND (DAAs/IFN or (sofosbuvir OR (daclatasvir OR (ledipasvir OR (Velpatasvir)))).

**Results:** A total of 233 HCV genotype 3 patients were enrolled. In the entire population, the SVR rate was achieved by 205 subjects (88.0%). A successful treatment outcome was documented in 79.0% of patients treated with sofosbuvir in combination with RBV, in 82.0% of those who received sofosbuvir/ledipasvir with or without RBV, and in all 7 patients treated with sofosbuvir/ledipasvir with or without RBV. At the univariate analysis, baseline predictors of the SVR12 were gender (female patients being more responsive than males), BMI <30 and the treatment schedule. Of relevance, age, stage of liver disease, advanced fibrosis or cirrhosis, RBV use, and treatment length were irrelevant to SVR12. At the stepwise logistic regression analysis, the only two factors independently associated with SVR12 were regimen containing sofosbuvir in combination with daclatasvir or ledipasvir (OR = 4.25; 95%CI: 1.81-9.97; p = 0.001), and the BMI <30 (OR = 2.64; 95%CI: 1.04-6.72; p = 0.041). 2. The systematic review of literature provided data of 3311 patients from 17 full text article and two abstracts. The mean weighted SVR12 rate was 88.2% (95%CI: 80.4-93.7; the rates varied from 79.0% (CI:70.9-85.3) with sofosbuvir/ribavirin, to 83.7% (CI:66.2-93.1) with sofosbuvir/ledipasvir, and to 88.2% (CI:83.3-91.7) with sofosbuvir/daclatasvir.

**Conclusion:** HCV genotype 3-infected patients, and in particular those progressed to cirrhosis, should be no more considered difficult-to-treat individuals, provided that an optimal therapeutic schedule is applied. Patients without cirrhosis should be treated with sofosbuvir and daclatasvir for 12 weeks. Patients with cirrhosis should be treated with sofosbuvir and daclatasvir for 24 weeks with or without ribavirin.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** cbranco,joana@gmail.com

**Introduction:** The impact of the virological cure on the evolution of cirrhotic patients with hepatitis C treated with the direct-acting antivirals (DAAs) has been a watershed for the management of HCV-related chronic liver diseases. Recently, some papers reported an elevated incidence of recurrence of hepatocellular carcinoma (HCC) and others a possible rise on the de novo incidence of HCC in the first year after treatment with DAAAs, but not others.

**Aims & Methods:** This is a prospective study of cirrhotic patients treated with DAA between February/2015 and January/2017. Under HCC screening with ultrasonography according to international guidelines. The main endpoint of the study was to determine the incidence of “de novo” and recurrent HCC. The second endpoint was to search for possible predictive factors associated with the occurrence of HCC. Statistical analysis performed on SPSS version 24.

**Results:** 106 cirrhotics (73% mean; 54.5 ± 8.8 years), MELD 7.3 ± 2.6, 60% with portal hypertension (n = 64) and 22% with decompensated cirrhosis (n = 23, 22 Child-Pugh B). Two patients with previous HCC, stage Barcelona Clinic Liver Classificaton (BCLC) A, invisible after loco-regional treatment. The sustained virological response at week 12 was 89.9% (71/79); 4 deaths, 1 relapse, 1 therapeutic failure and 2 losses to follow-up (FU). In 11 ± 7 months of FU, we recorded 5 cases of HCC, 4 “de novo” and 1 recurrence, which corresponded to an incidence of 3.8% of “de novo” HCC (13% in compensated cirrhosis). The BCLC staging was: stage A 2 stage B, 2 stage C and the one with the recurrence was stage D. A Child-Pugh B class (p = 0.004), low platelets level (p = 0.001) and hospitalization for decompensation (p = 0.005) were associated with the occurrence of HCC; the genotype did not have association. The mean time to HCC development was 7.5 months (2-14).
Conclusion: In this cohort the “de novo” incidence of 3.8% of HCC after the transplantation was observed mainly in patients with decompensated cirrhosis, not eligible for treatment with interferon in the past, and in a short interval of time after treatment. These results alert for an eventual need to increase the frequency of screening in the post-treatment period and carefully evaluate the best timing for liver transplantation. We could not conclude about recurrence due to the small number of patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

4. Yang JD, Aqel BA, Pungpapong S et al. Direct acting antiviral therapy and liver biopsies based on METAVIR scores. SWE results were reported using eight staging liver disease. Eighty-five patients (32.1%) had cirrhosis prior to biopsy. In a fourth of the cases the biopsy was performed in the context of acute hepatici, being in 12.6% for diagnosis of alcoholic hepatitis. The reasons for the change in strategy in a high percentage of cases.

P0056 CLINICAL EXPERIENCE IN THE USE OF TRANSJUGULAR LIVER BIOPSY WITH TRU-CUT NEEDLE: A RETROSPECTIVE EVALUATION OF 265 CASES
Centro Hospitalar De São João, Porto/Portugal

Contact E-mail Address: armandoap5@gmail.com
Introduction: Liver biopsy is recognized as the definitive diagnostic tool for the diagnosis and treatment of liver diseases. The transjugular pathway (TJLB) is commonly used in the presence of contraindications to the percutaneous route. The technical success was 92.4%. Sampling was considered adequate in 92.2% of the situations the TJLB was considered to have an impact to the patient. Retrospective study of 265 consecutive patients submitted to TJLB between 2010 and 2016.

Results: We included 265 patients with mean age 56 years (+/-12.4), with the majority (60.1%) being male. One hundred and eleven patients (41.9%) were hospitalized. In 40.1% of cases there was previously known liver disease, especially alcoholic disease, hepatitis C and non-alcoholic steatohepatitis. In 80.5% of the cases the purpose of TJLB was for diagnosis and in the remaining cases for staging liver disease. Eighty-five patients (32.1%) had cirrhosis prior to biopsy. In a fourth of the cases the biopsy was performed in the context of acute hepatici, being in 12.6% for diagnosis of alcoholic hepatitis. The reasons for the percutaneous route included: coagulopathy/anticoagulation (32.2%), thrombocyto-penia (17.8%), and failed percutaneous liver biopsy (13.6%). The technical success was 92.4%. Sampling was considered adequate in 92.2% of cases, which was associated with diagnostic purpose (98.9% vs. 88.5%, p = 0.001) and evidence of acute hepatitis (90.4% vs. 88.5%, p = 0.03). Most patients (60.4%) had histological criteria for cirrhosis. In 76.2% of patients TJLB allowed a histological diagnosis, mainly alcoholic and non-alcoholic steatohepatitis. The clinical experience in the use of TJLB with Tru-Cut needle allows a change in strategy in a high percentage of cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0057 OPTIMAL NUMBER OF MEASUREMENTS IN REAL-TIME SHEAR WAVE ELASTOGRAPHY TO ASSESS LIVER FIBROSIS IN PATIENTS WITH CHRONIC HEPATITIS C VIRUS INFECTION

Introduction: Liver fibrosis is a result of progressive injury to the liver caused through PBC etiopathogenesis remains still obscure, we overexpressed miR-506 in cholangiocyte livers and directly targets both CT/HCO3 anion exchanger 2 (AE2) and type III inositol 1, 4, 5-trisphosphate receptor (InsP3R3), leading to cholestasis. Aim & Methods: The regulation of miR-506 gene expression and its role in cholangiocyte pathophysiology and immune activation was studied. Different sizes of miR-506 promoter were cloned in a luciferase expression vector, which could be transfected in human cholangiocytes (H69 cells) and the role of pro-inflammatory cytokines, bile acids, estrogen and glucocorticoids was evaluated on the promoter activities. miR-506 or a negative control miRNA sequence were also cloned in an expression vector under the regulation of the CMV promoter; these constructs were stably transfected in H69 human cholangiocytes, and cholangiocyte pathophysiology and immune activation were evaluated. Experimental overexpression of miR-506 in cholangiocytes dysregulated the cell proteomic profile (by mass spectrometry) affecting proteins involved in different biological processes including mitochondrial metabolism. In cholangiocytes, miR-506: i) induced differentiation with downregulation of biliary and epithelial markers together with upregulation of mesenchymal and pro-inflammatory markers; ii) contributed to proliferation and survival; iii) increased reactive oxygen species and endoplasmic reticulum (ER) stress; iv) caused DNA damage; and v) sensitized to caspase-3-dependent apoptosis induced by cytotoxic bile acids. These events were also associated with impaired energy metabolism in mitochondria (proton leak and ATP production) and PDC-E2 overexpression. Co-culture of miR-506 over expressing cholangiocytes with PBC immune cells induced activation and pro-liferation of PBC immune cells.

Conclusion: Different pro-inflammatory cytokines enhance the expression of miR-506 in biliary epithelial cells. MiR-506 induces PBC-like features in cholangiocytes and promotes immune activation, representing a potential therapeutic target for PBC patients.

Introduction: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease associated with autoimmune phenomena targeting intrahepatic bile duct cells. Although PBC etiopathogenesis remains still obscure, development of anti-mitochondrial auto-antibodies against pyruvate dehydrogenase complex-E2 (PDC-E2) is a common feature. MicroRNA (miR) downregulation occurs in liver and immune cells of PBC patients, but their functional relevance is largely unknown. We previously reported that miR-506 is overexpressed in PBC cholangiocytes and directly targets both CT/HCO3 anion exchanger 2 (AE2) and type III inositol 1, 4, 5-trisphosphate receptor (InsP3R3), leading to cholestasis. Aim & Methods: The regulation of miR-506 gene expression and its role in cholangiocyte pathophysiology and immune activation was studied. Different sizes of miR-506 promoter were cloned in a luciferase expression vector, which could be transfected in human cholangiocytes (H69 cells) and the role of pro-inflammatory cytokines, bile acids, estrogen and glucocorticoids was evaluated on the promoter activities. miR-506 or a negative control miRNA sequence were also cloned in an expression vector under the regulation of the CMV promoter; these constructs were stably transfected in H69 human cholangiocytes, and cholangiocyte pathophysiology and immune activation were evaluated. Experimental overexpression of miR-506 in cholangiocytes dysregulated the cell proteomic profile (by mass spectrometry) affecting proteins involved in different biological processes including mitochondrial metabolism. In cholangiocytes, miR-506: i) induced differentiation with downregulation of biliary and epithelial markers together with upregulation of mesenchymal and pro-inflammatory markers; ii) contributed to proliferation and survival; iii) increased reactive oxygen species and endoplasmic reticulum (ER) stress; iv) caused DNA damage; and v) sensitized to caspase-3-dependent apoptosis induced by cytotoxic bile acids. These events were also associated with impaired energy metabolism in mitochondria (proton leak and ATP production) and PDC-E2 overexpression. Co-culture of miR-506 over expressing cholangiocytes with PBC immune cells induced activation and proliferation of PBC immune cells.

Conclusion: Different pro-inflammatory cytokines enhance the expression of miR-506 in biliary epithelial cells. MiR-506 induces PBC-like features in cholangiocytes and promotes immune activation, representing a potential therapeutic target for PBC patients.

Area under the curve and receiver operator characteristic (AUROC) compari

Results: The study population consisted of 106 men and 94 women with a mean age of 44.8 years and a body mass index (BMI) of 25.64 kg/m². Fibrosis stage was F0/F1/F2/F3/F4 in 7/30/32/23/25 patients, respectively. The median BMI (IQR) of these patients was 24, 25, 0.20, 0.37, and 0.94 kg/m², respectively. AUROCs to diagnose patients with severe fibrosis (stage F2) ranged from 0.735 (A) to 0.903 (H), respectively. Comparing the AUROC of one measurement, IQR/median from 0.735 (A) to 0.903 (H), respectively. In the cohort of obese (BMI ≥ 25) and old patients (age ≥ 65), 0.22, < 0.05, 0.012 indicated significantly greater IQR/median. There was no significant difference in the diagnostic accuracy between using the median or mean of three, five, and 10 measurements. The AUROCs to diagnose patients with significant fibrosis (stage F2) ranged from 0.778 (A) to 0.876 (H). AUROC increased based on the number of measurements. A significant difference between 1 and 5 (p < 0.05), 10 and (p < 0.01) 2, 10 (p < 0.05) measurements was observed in pairwise comparison. Likewise, AUROCs of ten measurements were significantly higher than (p < 0.05) of five (A) to 0.923 (G). A significant difference (p < 0.05) was seen between one and 10 measurements. In the cohort of IQR/median < 0.3, the diagnostic accuracy of ≥ F2 and ≥ F3 ranged from 0.806 (A) to 0.877 (H), and from 0.832 (A) to 0.928 (H), respectively. In the cohort of obese (BMI ≥ 25) and old patients (age ≥ 65), the diagnostic accuracy of ≥ F2 and ≥ F3 ranged from 0.752 (A) to 0.862 (D), and from 0.735 (A) to 0.903 (H), respectively. Comparing the AUROC of one measurement, IQR/median < 0.3 showed greater AUROC than those of other cohorts, however, the AUROCs of ten measurements were similar in each cohort. Conclusion: No difference was found between reporting mean or median SWE measurements. The diagnostic performance of SWE increased with the number of measurements. Our results suggest that 10 measurements are recommended to ensure the accuracy of SWE measurements in a practical setting.

Introduction: Percutaneous radiofrequency ablation (RFA) is a commonly used locoregional interventional procedure in treatment of hepatocellular carcinoma (HCC). There is growing evidence that apparent diffusion coefficient (ADC) value can be used in evaluating RFA therapeutic efficacy in treatment of HCC and thus represent a reliable predictor of local HCC recurrence after treatment. Aims & Methods: We aimed to determine the therapeutic efficacy of RFA in patients with hepatocellular carcinomas using ADC value. A total of 52 patients with 58 HCCs were included, and were treated with RFA according to the guidelines. All lesions were evaluated by diffusion weighted imaging (DWI) and ADC value measurement before and after RFA treatment. DWI was obtained using axial a single-shot echoplanar imaging with two b-values (500, 1000 mm²/s) using 3 tesla MRI machine. Quantitative ADC maps were calculated using commercial and an imaging workstation. Diagnosis of HCC relied on triphasic CT and MRI, showing enhancement at the arterial phase of dynamic contrast enhanced CT or MRI with rapid washout at the portal venous & delayed phases. Follow-up post ablation by triphasic CT and/or MRI with ADC value measurement was done after one and three months to detect the responsive cases (no residual tumoral activity) and non-responsive cases with residual tumor activity.

Results: Forty-eight lesions responded to treatment and 10 lesions had shown no response. ADC values were significantly higher in lesions that responded to RFA than in non-responding lesions. The mean ADC value before treatment was 1.26±0.16 x 10³ mm²/s (mean±SD), while after treatment it was 1.46±0.12 x 10³ mm²/s with a statistically significant difference (P=0.003) using the paired t-test. Mean ADC of the lesions of less than 1000 mm²/s, b value 1000 before treatment was 1.32±0.28 x 10³ mm²/s, and increased after treatment in responding lesions to reach 1.52±0.1 x 10³ mm²/s with a statistically significant difference (P=0.005). Using b value 500, the mean ADC value before treatment didn't show significant difference between responding (1.26±0.10 x 10³ mm²/s) and non-responding lesions (1.26±0.12 x 10³ mm²/s); P=0.97. While using b value 1000, there was a significant difference with higher mean ADC values before RFA in responding lesions than in non-responding (P=0.001). There were no statistical differences between any two different groups of patients (b values in non-responding, respectively; P=0.03) The change in ADC in responding lesions is significantly higher than in non-responding lesions, and it was 19.6% vs. 6.2%, respectively (P=0.01) using b value 500 and was 23.7% vs. 21.2%, respectively (P=0.001) using b value 1000.

Conclusion: ADC is a good quantitative measurement allows effective evaluation of the therapeutic efficacy of RFA for treatment of patients with HCC and can be used as good non-contrast alternative to conventional imaging methods in post ablation follow-up.

Introduction: To study the effect of NAFLD on the results of shear wave elastography (SWE) in patients with chronic diffuse liver disease.

Aims & Methods: We have performed outcome analysis in 100 patients with NAFLD over the period from 2015 to 2016. There were 41 male patients (41%), and 59 female patients (59%), age Me (LQ-UQ) 49 (39-56), minimal age 18 years, maximal age was 77 years. All patients were found to have chronic diffuse hepatic diseases and were hospitalized for morphological investigation. All patients had shear wave elastography (SWE) with quantitative measure tissue stiffness, Metavir score staging for received results.

Results: Based on the obtained morphological results, we have formed the following subgroups of patients: F0 - F1 - 31 people, F2 - F3 - 15 and F4 - 45 patients. Given that patients with a degree of fibrosis on the scale METAVIR F0 and F1 do not require active conservative therapy, we combined the data of the group into one F0-F1. The obtained results of shear wave elastography are presented in the form of quantitative variables. Median stiffness with interquartile range (25%-75%) in groups: F0 - F1 - 5, 4 (8, 7-2) kPa, F2 - 8, 5 (3, 8-9) kPa, F3 - 13, 5 (10, 13-4) kPa and F4 - 22, 0 (12, 28, 5) kPa. The parameters of liver stiffness in the various groups on the METAVIR scale differed statistically significantly between p < 0.05. When carrying out a correlation analysis between the stiffness indices of the liver parenchyma and the morphological stage of fibrosis, a strong correlation was revealed: the Spearman coefficient was r = 0.18 (p = 0.01, 10). Cut-off was y = 9.96 x 10⁻¹³, 0.19 (p = 0.01). In patients with stage 4 the correlation coefficient was r = 0.29, 5 (9, 7; 10) mm²/s, while after treatment it was 0.5 (9.5; 10). The obtained data was good: 0.64 (95%CI, 0.45–0.72). ICC for PS was fair to good: 0.40 (95%CI, 0.10–0.57). A decrease in the stiffness indices was observed in 20% of cases and increased after treatment in 80% of patients studied in the primary statistical processing. Stiffness median in patients without fatty hepatic degeneration was: F0 - F1 - 5, 4 (5-6) kPa, F2 - 8, 5 (3-8) kPa, F3 - 13, 5 (10-13) kPa and F4 - 22, 0 (12-28, 5) kPa. According to ROC curve, the best threshold values were for stages F2-4: F2 - 7, 5; F3 - 9, 8, F4 - 14, 5kPa. However, stage correlation for hepatic fatty disease with elastography results was none: r = 0.11 p = 0.24624. Conclusion: Quantitative indicators of SWE in patients with diffuse liver disease in correlation with steatosis may be used in patients with the given disease (16 patients) from the secondary statistical processing. Stiffness median in patients without fatty hepatic degeneration was: F0 - F1 - 5, 4 (5-6) kPa, F2 - 8, 5 (3-8) kPa, F3 - 13, 5 (10-13) kPa and F4 - 22, 0 (12-28, 5) kPa. According to ROC curve, the best threshold values were for stages F2-4: F2 - 7, 5; F3 - 9, 8, F4 - 14, 5kPa. However, stage correlation for hepatic fatty disease with elastography results was none: r = 0.11 p = 0.24624.
Then the role of miR-224 in HCC progression was assessed. Tumor as well as adjacent tumor tissues of HCC were detected by RT-PCR.

Aims & Methods: It was found exosomes are the vesicles. Contact E-mail Address: wdf8025@163.com

Conclusion: This study provides the novel mechanism of regulatory roles of miR-224 in HCC. The Exosome from the supernatant of HCC cells can promote growth, proliferation, migration and invasion capability of HCC cells in vivo.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Introduction: The prevalence of hepatocellular carcinoma (HCC) in Africa is higher compared to the rest of the world due to the high incidence of chronic infection with hepatitis C virus (HCV). In Egypt, HCV infection is the leading cause of liver cirrhosis which is usually diagnosed at late stages. Due to the absence of reliable and accurate biomarkers for early detection of liver cancer, circulating microRNAs have recently emerged as great candidates for early diagnosis of HCC. These small non-coding RNA molecules are responsible for regulating gene expression and RNA stability. Therefore, the aim of this study is to investigate the potential of liver-specific circulating microRNAs as an accurate non-invasive diagnostic tool for the early detection of HCV-induced HCC.

Methods: Seven main miRNAs (miR-125a, miR-139, miR-34a, miR-221, miR-16, miR-145 and miR-199a) were selected due to their expression patterns in HCC as well as their contribution to the development of hepato-carcinogenesis. A total of 165 patients were enrolled in this study, from which serum samples were collected and categorized into four main patient groups: 42 hepatitis C (CHC); 42 CHC, liver cirrhosis (LC); 35 HCC; and 40 healthy controls. The expression profile of the seven miRNAs was analyzed using TaqMan real-time transcription-polymerase chain reaction (RT-PCR). Additionally, the conventional markers for HCC (alpha-fetoprotein (AFP) and des-γ-carboxyprothrombin (DCP)) were measured using commercial kits.

Results: Serum levels of miR-125a, miR-139, miR-145 and miR-199a were significantly decreased (P < 0.01) in HCC than in the CHC and LC groups (Table 1). On the other hand, miR-16 and miR-34a were significantly increased (P < 0.01) in HCC patients compared to the normal group. However, no significant difference was shown in the expression of miR-16, miR-34a, and miR-221 between the CHC, LC, and HCC groups. As a single biomarker, miR-34a showed the highest sensitivity and specificity among all miRNAs investigated, followed by miR-221, miR-125a, miR-139, miR-145, and miR-199a.

Click here to access the full text of this article via SpringerLink.
regulated in cancer tissues compared with the adjacent non-tumor tissues (P < 0.01). The expression level of MT1G in the liver cancer cell lines was closely correlated to the promoter hypermethylation status. The MT1G expression in silenced HCC cell lines could be restored by demethylation agent. We generated HCC cell lines overexpressed MT1G. Ectopic re-expression of MT1G by stable transfection in SMMC-7721 and HepG2 cells inhibited colony formation (P < 0.001), suppressed cell motility and invasiveness (P < 0.05), concomitant with up-regulation of E-cadherin; and down-regulation of PCNA, MMP2, MMP13 and Vimentin. The in vivo growth of HCC cells in nude mice was markedly inhibited after stable expression of MT1G (P < 0.001). MT1G over-expression in HCC cells induced the cell apoptosis (P < 0.01).

Conclusion: Our results demonstrate that MT1G promoter methylation directly mediates the transcription down-regulation and common occurrence in HCC. MT1G gene can act as a functional tumor suppressor in liver carcinogenesis by playing an important role in depression of cell proliferation, migration, invasion, and induction of cell apoptosis.

Introduction: Hepatocellular adenoma (HCA) and focal nodular hyperplasia (FNH) may be confused on medical imaging. Both tumours are not connected to the biliary tree, however only FNH accumulates bile salts, suggesting that hepatocellular uptake and secretion of bile constituents differs in FNH and HCA. Therefore, one would anticipate changes in the Farnesoid X receptor (FXR) expression. However, the expression of FXR and its targets in HCA and FNH is relatively unknown. Targets of FXR regulate uptake and excretion of hepatobiliary contrast agents, possibly altering the presentation of FNH and HCA on medical imaging. We studied the expression of FXR and its targets in HCA and FNH and compared this with the appearance of lesions on MRI.

Aims & Methods: Tumour tissue and normal tissue from 7 patients with HCA and 7 patients with FNH was obtained. Diagnosis was confirmed by histopathological examination in all patients. Reverse transcription of the mRNA to cDNA was performed, using random primers and MultiScribe Reverse Transcriptase (Life Technologies, Carlsbad, Ca). The cDNA was used as template for PCR amplification by TaqMan® assay analysis (Applied Biosystems, Foster City, CA). The expression of all the target genes in the FXR pathway (SHP, NTCP, OATP1B1, OATP1B3, BSEP, CYP7A1, CYP3B1, BAAT, SLC27A5, CYP3A4, SULT2A1, UGT2B4, FGFR4, MRP2, MRP3, MDR3) were compared to the expression of internal reference in both normal and tumour tissue. Matched case comparisons were made for tumour and normal tissue. DNA expression of FNH and HCA was compared to MRI findings.

Results: FXR was downregulated in both HCA and FNH. NTCP was significantly downregulated in both FNH, and not significantly in HCA, although showing a trend towards down regulation. Three patients (1 FNH 2 HCA) show aberrant expression of NTCP compared to all the other patients. All these three patients had also an unclear or incorrect diagnosis based on MRI scan with gadodextrin acid as compared to final diagnosis by histopathological examination. OATP1B1 was downregulated in both HCA and FNH, except again for the three patients with the aberrant imaging. Expression of OATP1B1 and SHP in HCA and FNH did not significantly differ from expression in healthy liver tissue. MRP2 was significantly downregulated in HCA, but not in FNH. However, this may again be due to the patients with the aberrant expression pattern. OATP1B3 was significantly downregulated in HCA. CYP3A4 and CYP2A1 were very strongly downregulated in HCA, but not in FNH. FGFR 4 was heavily downregulated in HCA, but not in not FNH. BAAT was significantly downregulated in HCA.

Conclusion: Limited by sample size, this study suggests that misdiagnosis based on medical imaging might actually correlate with aberrances on hepatocyte transporter level. This seemed to account for NTCP (bile salt importer), OATP1B1 (bile salt importer) MRJP2 (efflux pump of conjugated compounds). Although FXR itself was downregulated in both FNH and HCA, its downstream targets differed in expression between tumours. FXR receptor activity might be altered even though expression is not different, or downstream targets might be influenced by factors outside the FXR pathway. Further research could provide a more profound insight into this mechanism.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0065 CUX1 CONTROLS ENDOPLASMIC RETICULUM STRESS AND AUTOPOietIC-RELATED CELL DEATH**

G. Metzger1, P. Di Fazio1, D. Bartels2, T. M. Greiss3, T. T. Wissinmosskw1

1Department Of Visceral Thoracic And Vascular Surgery, Philippus University Marburg, Marburg/Germany
2Klinik Fur Gastroenterologie, Endokrinologie, Stoffwechsel Und Infektiologie, Philippus Universitats Marburg, Marburg/Germany

Contact E-mail Address: guilia_metzger@web.de

Introduction: CUX1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of pro-apoptotic genes. Its aberrant expression in tumor turns its role as foe.

Aims & Methods: Here, we analyze the role exerted by CUX1 during deacetylase inhibitors mediated cell death in liver cancer cells. CUX1, endoplasmic reticulum (ER) stress and autophagy markers were analyzed by RT-qPCR in two liver cancer cell lines HepG2 and Hep3B. Protein level was measured by western blotting. Cells were transfected with siRNA for CUX1 and furthermore treated with deacetylase inhibitors with deacetylase inhibitors panobinostat, SAHA and trichostatin A. Thapsigargin, an endoplasmic reticulum stress inducer, served as positive control.

Results: CUX1 knock down caused a suppression of ER stress and autophagy markers BIP, CHOP, ATF4, ATF6, Beclin1, MAP1LC3B, UVRAG and TFEB at early time point (6 hours) in both cell lines. Prolonged transfection did not alter the expression of the above mentioned markers; BIP was the only one suppressed in HepG2 after 24 hours. Interestingly, the deacetylase inhibitors are able to promote CUX1 over-expression after 6 hours of treatment, whereas they show to lose this ability after 24 hours. CUX1 knock-down reduced not significantly its protein level after treatment with deacetylase inhibitors. CUX1 knock down counteracts the accumulation of BIP protein after 24 hours of treatment with deacetylase inhibitors. Thapsigargin induced BIP independently from CUX1.

Conclusion: ER stress and autophagy markers are under the control of CUX1. The cell death induced by deacetylase inhibitors is strictly connected with CUX1 expression and activity. Further studies are needed to clarify the exact mechanism exerted by CUX1 in this scenario.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0066 CUX1 CONFRONS RESISTANCE TO APOPTOTIC CELL DEATH WITHIN LIVER CANCER CELLS**

E. Hofmann1, P. Di Fazio1, D. Bartisch1, T. M. Greiss3, T. T. Wissinmosskw1

1Department Of Visceral Thoracic And Vascular Surgery, Philippus University Marburg, Marburg/Germany

Introduction: CUX1 (CUTL1) is a transcription factor able to promote the expression of several genes implicated in cellular proliferation, differentiation and demise. In normal adult cells, it preferentially favors the expression of pro-apoptotic genes. Its aberrant expression in tumor turns its role as foe.

Aims & Methods: Here, we analyze CUX1 activity in TRAIL (Tumour necrosis factor related apoptosis inducing ligand) mediated cell death in liver cancer cells. CUX1 was knocked down in HepG2 and Hep3B cells. Cells were further treated for 48 hours with a strong ligand (superkiller) binding DR4 and DR5 (TRAIL death receptors). The cell death events were analyzed by FACS analysis. RT-qPCR was performed to detect the expression of apoptotic markers. Caspase activity was measured by luminescence. Apoptosis array was performed. Western blotting was performed for caspase 8 and Flip detection.

Results: Treatment with superkiller TRAIL, at 50 and 100ng/ml, caused cell death in HepG2 and Hep3B cells after 48 h proven by an accumulation of 40% of sub-G1 events. CUX1 knock down caused a sensitization of liver cancer cells to TRAIL effect by increasing, significantly, the percentage of sub-G1 events (60% with 100ng/ml). CUX1 knock down did not change the expression of PTP53, KRT18, CDKN1A and CDKN1B. Interestingly, silencing CUX1 significantly upregulated several genes implicated in cellular proliferation, differentiation and apoptosis.

Conclusion: Limited by sample size, this study suggests that misdiagnosis based on medical imaging might actually correlate with aberrances on hepatocyte transporter level. This seemed to account for NTCP (bile salt importer), OATP1B1 (bile salt importer) MRP2 (efflux pump of conjugated compounds). Although FXR itself was downregulated in both FNH and HCA, its downstream targets differed in expression between tumours. FXR receptor activity might be altered even though expression is not different, or downstream targets might be influenced by factors outside the FXR pathway. Further research could provide a more profound insight into this mechanism.

Disclosure of Interest: All authors have declared no conflicts of interest.
The aim of this study was to assess the serum level of squamous cell carcinoma antigen (SCCA) in cirrhotic chronic HCV patients with and without hepatocellular carcinoma in relation to alpha feto protein (AFP).

**Results:**

The diagnosis of liver cancer depends on both screening with alpha-fetoprotein (AFP) and radiological imaging studies. Generally, normal levels of AFP are below 10 ng/ml but AFP greater than 200 ng/ml is suggestive of HCC. The sensitivity of AFP for liver cancer is about 67%; therefore a normal AFP does not exclude HCC. Searching another tumor marker, that together with AFP could improve the diagnostic utility of HCC.

Squamous cell carcinoma antigen (SCCA), a member of the high molecular weight family of serine protease inhibitors named serpins which are physiologically found in the granular layers of normal squamous epithelium but found to be typically expressed by neoplastic cells of epithelial origin in a number of different cancers for example cervix cancer, lung, and head and neck cancers hence, it can be used as a clinical marker of these malignancies.

The structure of the serpin ovalbumin revealed the archetype native serpin fold that typically have three β-sheets (termed A, B and C) and eight or nine α-helices (hA-hl). Serpins also possess an exposed region termed the reactive centre loop (RCL) that includes the specificity determining region and forms the initial interaction with the target protease.

Recently much attention has been focused on the role of SCCA in HCV cirrhotic patients suggesting that high levels of SCCA can assess HCC development. [5]

The aim of this study was to assess the serum level of squamous cell carcinoma antigen (SCCA) in cirrhotic chronic HCV patients with and without hepatocellular carcinoma in relation to alpha feto protein (AFP).

**Aims & Methods:** The aim of this study was to assess the serum level of squamous cell carcinoma antigen (SCCA) in cirrhotic chronic HCV patients with and without hepatocellular carcinoma in relation to alpha feto protein (AFP). These groups were from both sexes who are admitted to the inpatient ward and the outpatient clinic of Tropical Medicine Department, Faculty of Medicine, Alexandria University.

This study was carried out on:

- Group A: 100 cases of hepatocellular carcinoma without interventions.
- Group B: same 100 cases of group A before and 3 months after successful interventions.
- Group C: 100 cases of established cirrhosis.
- Group D: 100 cases with chronic hepatitis C virus infection without established cirrhosis.
- Group E: 100 healthy individuals as controls.

All patients in this study were subjected to: complete blood picture, liver biochemical profile, serum albumin aminotransferase (ALT), serum aspartate aminotransferase (AST), serum alkaline phosphatase, total and direct serum bilirubin, prothrombin time and activity, serum albumin blood urea nitrogen (BUN), serum creatinine. Fasting blood sugar. Serum alpha fetoprotein (AFP).

Determination of squamous cell carcinoma antigen (SCCA) Sera from selected patients and controls were used for estimation of SCC-Ag using CanAg SCC EIA. The CanAg SCC EIA is a solid phase, non-competitive immunoassay based upon the direct sandwich technique. Calibrators and patient samples are incubated together with biotinylated Anti-SCC monoclonal antibody in Streptavidin coated microtiter. After washing buffered Substrate/Chromogen reagent (hydrogen peroxide and 3, 3’, 5, 5’ tetra-methylbenzidine) is added to each well and the enzymatic reaction in ciron is allowed to proceed. During the reaction enzyme a blue colour will develop if antigen is present. The intensity of the colour is proportional to the amount of SCC present in the samples. The colour intensity is determined in a microplate spectrophotometer at 620 nm (or optionally at 405 nm after addition of Stop Solution). Calibration curves are constructed for each calibrator. The SCC concentrations of patient samples are the read from the calibration curve.

**Results:** Table 1 shows a statistical significant difference between different studied groups regarding alpha feto protein (P = 0.000).

**Conclusion:** In the present study patients with HCC either with or without therapeutic intervention have significantly higher level of AFP in comparison to chronic HCV, cirrhotic and control groups this is in agreement with Awadallah et al.[6] who reported a statistically highly significant elevation in the serum AFP in HCC group when compared with control group. Moreover, the mean serum level of AFP in group A (HCC before intervention) was 263 ng/ml that decreased to 209.4 ng/ml in group B after therapeutic intervention and this agreed with Feng et al.[7] and Molinari et al.[8] Also, at AFP level of 200 ng/ml, the sensitivity was 90%, while the specificity was 60%. Our results showed that SCCA level ranged from 2.5–10 with a mean of 5.53 in HCC patients without interventions, 3.3–7.6 with a mean of 5.3 in patients with HCC before intervention, 1.2–5.6 with a mean of 3.3 in cirrhotic group, 0.6–1.05 with a mean of 0.824 in chronic HCV group while healthy control group had much lower values ranging from 0.3–0.95 with a mean of 0.646. Thus, a highly significant increase in serum SCCA level in patients with HCC before and after therapeutic intervention when compared to cirrhotic, chronic HCV and control groups (P = 0.001). These results were in accordance with Hussein et al. [9] and El Ezawy et al.[10] SCCA was also higher among patients with HCC before intervention compared to patients with HCC after intervention as found by Bin et al.[11] Applying the ROC curves analysis showed the best cut-off value to differentiate HCC patients from cirrhotic patients was 3.2 ng/ml for SCCA yielded 80% sensitivity and 90% specificity. These results were in agreement with Trevisani et al.[12] Patients with HCC, in our study were none randomized selected as BCLC stage B (either one HCC lesion <5 cm in size or 3 lesions < 3 cms) so no statistical correlation was done between serum AFP level and tumor size. Our results showed a significant positive correlation between serum SCCA and AFP among patients with HCC before and after therapeutic intervention. Our data are in agreement with that of Hussein et al.[9] and El Ezawy et al.[10] who detected that SCCA were positively significantly correlated with AFP level. When combined sensitivity of both markers was calculated in our study at the best-chosen cutoff values (SCCA 3.2 ng/ml and AFP 200 ng/ml) sensitivity improved to 93%. Matching results were found by Gianluigi et al.[4]

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**

The best overall formula that could best predict HCC was then constructed as following: Logit probability of HCC = −2.524 + 0.152 × age − 0.121 × Hb − 0.696 × INR − 1.059 × Alb − 0.022 × AFP + 0.976 × Gender Male = 1 Female = 0

The diagnostic value of HMC-CU was then assessed by ROC curve. The area under the ROC curve (AUC) of 0.94 ± 0.02 at cutoff point of 0.56 HMC-CU enabled to distinguish patients with HCC with 90% sensitivity, 80.6% specificity. AUC was 0.93 and the 95% confidence interval was 0.917–0.94. On comparing the diagnostic performance of HMC-CU to the performance of serum AFP for early diagnosis of HCC, it was found that serum AFP was able to diagnose HCC at cutoff value of 11.9 ng/ml with sensitivity of 68% and specificity 66%. AUC was 0.76 and the 95% confidence interval was 0.74–0.78.

Conclusion: The HMC-CU score constructed from routine parameters is accurate in the diagnosis of HCC patients with HCV-related CLD. The strength of our score is based on its simplicity, being based on routine laboratory parameters and serum AFP which is being used for screening of patients in many centers all over the world. Our score will not impose extra costs for the patients because it utilizes routine laboratory parameters. The HMC-CU score may be useful during surveillance programs for HCC. Our study included large number of HCC and non HCC patients all are Egyptians with a background of HCV type 4 related CLD. A prospective validation study is being planned and further studies are invited to validate this score on patients of other races infected with other HCV genotypes.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Hepatocellular carcinoma (HCC) is the first most common primary malignant tumor of the liver, the fifth most common cancer and the third most common cause of cancer-related death worldwide. (1) Early detection of HCC provides the best chance for a curative treatment which in turn improves patients survival. However, more than 60% of HCCs are diagnosed at a late stage (2). This could be explained by poor compliance of cirrhotic patients to the surveillance programs and lack of a sensitive and specific tumor marker. Serum AFP – commonly used for HCC diagnosis has a low sensitivity, and specificity for HCC detection (3).

Aims & Methods: The aim of this study was to develop Hepatocellular Multidisciplinary clinic – Cairo University (HMC-CU) score and test its accuracy in HCC detection in comparison to the widely used AFP. In the current study, we reviewed the data of 2363 Egyptian patients with HCV genotype-4 related chronic liver disease (CLD). 1291 patients were diagnosed to have HCC and 1072 patients were diagnosed to have HCV related liver cirrhosis with no HCC. Consequently, we entered these significant variables in a multivariate regression model that demonstrated that only age, gender, hemoglobin, albumin, AFP and INR were independent associated with HCC development.

PO0069 MULTIPLE BIOPOLAR RADIOFREQUENCY ABLATION IN TREATMENT OF MEDIUM TO LARGE HEPATOMAS – EXPERIENCE IN A REGIONAL HOSPITAL

P. Hsieh, C. Yen
Department Of Gastroenterology And Hepatology, Chang-Gung Memorial Hospital Keelung branch, Keelung/Taiwan

Contact E-mail Address: b8802050@gmail.com

Aims: The aim of this study was to evaluate the therapeutic effect and long term survival in medium and large hepatomas using multiple bipolar radiofrequency ablation system (Celon). The study subjects had a Child-Pugh classification of A or B. The patients who were ineligible for surgical intervention or who had no contraindications for RFA were treated with percutaneous bipolar electrodes. A total of 30 consecutive cirrhotic patients (48 tumors) with hepatomas ≥3 cm. Bipolar RFA devices have been developed to overcome the limitations of monopolar RFA devices.

Results: 30 patients were divided equally into two groups with 15 patients in each of medium and large hepatoma groups. 17 patients underwent artificial ascites (56.3%). The complete necrosis rate after ablation was 93.3% (14/15 patients) for either medium or large hepatomas. The local tumor progression rate and distant tumor recurrence rate were 0% and 0% respectively. The complete necrosis rate, tumor recurrence rate and local tumor progression rate of medium hepatomas were 88% (13/15 patients), 0% and 0% respectively and compared between medium and large hepatomas using Kaplan-Meier survival and the prognostic factors were using multivariate analysis.

**P0070 RECENT TRENDS IN HEPATOCELLULAR ADENOMAS: CLINICAL FEATURES, DIAGNOSIS AND OUTCOMES**

M. Silva, A. Peixoto, R. Coelho, H. Cardoso, G. Macedo
Gastroenterology, Hospital S João, Porto/Portugal

**Contact E-mail Address:** marcocostasilva87@gmail.com

**Introduction:** Hepatocellular adenomas (HCA) are rare, benign tumors of pre- sumable epithelial origin, that occur predominantly, but not exclusively, in young women on oral contraceptives (OC) or in women on hormone replacement therapies. The Bordeaux adenoma tumour markers are a promising method of identifying the high-risk HCA of malignant transformation into hepatocellular carcinoma (HCC).

**Aims & Methods:** Aims: The authors propose to evaluate the demographics, clinical manifestations and diagnosis of HCA. We undertook retrospective analysis of patients with HCA, histologically confirmed (by guided biopsy or surgical resection), between 2008 and 2016, in a tertiary referral centre. When feasible, the subtype classification of HCA proposed by the Bordeaux group, was performed. Descriptive statistics, uni- and multivariate analysis were performed using IBM SPSS Statistics 22, with p < 0.05 deemed to be statistically significant.

**Results:** In this study 27 patients were included, 2 men and 25 women, with a median age of 38 ± 11 years, followed for a mean time of 78 ± 36 weeks (lost follow-up in 7 cases). Three cases of hepatic adenomatosis were included. Forty-one percent of the women used OC and 38% of the patients had dyslipidemia. The mean size of the HCA was 70 ± 42 mm; 63% of the patients had abnormal liver tests at diagnosis, 46% were symptomatic and in 21% the diagnosis was performed due to ruptured HCA. Surgical resection was performed in 88% of the cases; complete resection was achieved in 75% of the cases. Of the 19 patients who performed abdominal-CT scan or abdominal-MRI before histological confirmation, 70% showed a thrombocytosis and 30% an abnormal serum marker. The mean size of the HCA that weren't completely resected and also of those presenting with HCA rupture was significantly higher (110 ± 55 mm [p = 0.035] and 105 vs 47 mm [p = 0.037], respectively). The 2 male patients had inflammatory HCA (p = 0.011).

**Conclusion:** In this cohort, HCA were prevalent in female taking OC and the inflammatory type HCA was the most common. In many cases, abdominal imaging is insufficient for a correct diagnosis, and biopsy specimen or surgical resection should be performed for a correct diagnosis. Lesion size was associated with the risk of rupture and incomplete surgical resection.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** silvia.camera84@gmail.com

**Introduction:** Currently, the standard treatment using transarterial chemo-embo- lisation (TACE) for patients showing solitary large (>40 mm) hepatocellular carcinoma (HCC) is unsatisfactory with high rate of recurrence. Data from literature suggest the alternative use of thermal ablation.

**Aims & Methods:** We aimed to evaluate the efficacy and safety of Laser Ablation (LA) in comparison to TACE in patients with large tumor size HCC. Between January 2009 and December 2012, 41 cirrhotic patients (29 ± 12 M/F; median age 72 yrs, range 44–88, Child-Pugh A/B: 37 (40–50 mm), mean size 66 mm, range 40–75) were enrolled in this study. The patients were treated with multifiber technique of LA. The control group consisting of 41 patients (29 ± 12 M/F; mean age 72 yrs, range 49–86; Child-Pugh A/B: 37; median size of the nodule 50 mm, range 40–80, treated with TACE, was obtained from the ITALICA database and observed in the same period of time. No significant difference between the 2 groups was observed. The diagnosis of HCC was done according to the international guidelines and patients were treated, according to BCLC Staging System (BCLC stage A/B: 27/14/23, for LA and TACE, respectively). Response to therapy was evaluated according to the mRECIST criteria. Survival was calculated from the time of cancer diagnosis to death with values censored at the date of the last follow-up.

**Results:** Twenty-six (63.4%) patients of LA group and 8 (19.5%) patients of TACE group showed a complete response after treatment (p < 0.001). The superior efficacy of LA was confirmed in all categories, also after the stratification of the patients according to the indications of treatment (40–50 mm, 51–60 mm and >60 mm). Disease recurrence, during a mean ± SD period of follow-up of 37.4 ± 20.7 months, was observed in 13 (24%) LA-treated patients (24%) and in 24 (58.5%) TACE-treated patients (p = 0.0035). Overall survival probability rate at 3 years was 90.2% and 55.4% in LA group and 85.4 and 48.8. in TACE group.

**Conclusion:** LA is a more efficacious therapeutic option than TACE in patients with solitary large HCC.

**P0072 ENDOSCOPIC ULTRASOUND GUIDED BIOPSY FOR LIVER MASS USING CORE BIOPSY NEEDLE**

H.K. Chon1, T.H. Kim2, K.H. Choi2
1Internal Medicine, Wonkwang College of Medicine, Iksan/Korea, Republic of

2Pathology, Wonkwang College of Medicine, Iksan/Korea, Republic of

**Contact E-mail Address:** ktw@wk.ac.kr

**Introduction:** Endoscopic ultrasound (EUS)-guided fine needle aspiration (EUS-FNA) is one of the alternative methods for tissue sampling of liver solid mass. However, the diagnostic efficacy using cytology alone was limited. The diagnostic yield, sensitivity and specificity of EUS-FNA for the diagnosis of liver malignancy is unsatisfactory with high rate of recurrence. Data from literature suggest the alternative use of thermal ablation.

**Aims & Methods:** In this study, we evaluated the feasibility and diagnostic accuracy of EUS-guided fine needle biopsy (EUS-FNB) for hepatic solid masses in patients with suspected malignancy. The EUS-FNB using 20G, 22G or 25G ProCore needle (PCN) was performed to evaluate the patient with solid liver mass. The primary outcome was the diagnostic accuracy of EUS-FNB for malignancy, and adequacy of the specimen for histology. The secondary outcomes were (1) the proportions of patients in whom immunohistochemical (HIC) stain was possible, and (2) compared diagnostic yield of FNB according to the needle size, and (3) safety of EUS-FNB.

**Results:** Forty-one patients (13 women; mean age, 67.9 ± 10.3 years [range, 46– 86]) underwent evaluation with EUS and identified hepatic lesions ranging in size from 0.7 cm to 15 cm. EUS-FNB with 20G (n = 10), 22G (n = 24) or 25G PCN (n = 7) was performed (right lobe: n = 10, left lobe: n = 31). The median number of needle passes was 2.4 ± 0.8 (range, 1–5). Technical success rates for tissue acquisition were 97.6%, but both specimen adequacy for histology and available HIC study was 92.6%. Three (7%) were non-diagnostic, and subsequently proved to be malignant; 2 by smear cytology and 1 after surgical resection. The diagnostic yield, sensitivity and specificity of EUS-FNB for the diagnosis of malignancy was 92.6%, 92.6% and 100%, respectively. The diagnostic yield in 20G PCN and 22G PCN was significantly superior to 25G PCN (p = 0.045). There was one bleeding complication, but controlled with endo-scopic hemostasis with endoclips.

**Conclusion:** EUS-FNB with core biopsy needle may be a safe and useful modality in the management of patients with hepatic solid mass. Moreover, 20G and 22G FNB may be adequate for liver biopsy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

PO073 COMPARISON OF METHODS TO ESTIMATE LIVER FUNCTION IN NEWLY-DIAGNOSED HEPATOCELLULAR CARCINOMA PATIENTS WITH ASCITES

Y. Ko
Internal Medicine, Samsung Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: bs2-32@hanmail.net

Introduction: Liver function is a key element in determining outcome of patients with hepatocellular carcinoma (HCC). For HCC with ascites, estimation of liver function is particularly important, as they already have decreased liver function.

Aims & Methods: We aimed to find out best method to predict outcome of HCC patients with ascites. A total of 437 newly-diagnosed HCC patients with ascites (mean age = 56.0 ± 9.4 years, male = 78.4%, hepatitis B virus = 73.2%) were analyzed.

We compared Child-Pugh score, Model for End-Stage Liver Disease (MELD) score, MELD-Na score, and the Albumin-bilirubin (ALBI) grade for overall survival.

Results: During a median 9.0 months of follow-up (range: 0.1−154.0), mortality was significantly higher for those with MELD-Na ≥12 than MELD-Na <12 (median survival: 13.6 vs. 3.7 months, p < 0.001). Overall, 350 patients received treatment, and most commonly used modality was transarterial chemoembolization (62.3%), followed by radiofrequency ablation (15.7%) and resection (13.4%). Overall survival was significantly different for those who received treatment than those who did not (median survival: 13.3 vs. 2.4 months, p < 0.001). When patients were further stratified by mUCCE stage and MELD-Na score, treatment was not associated with better outcome for mUCCE stage IV patients with MELD-Na ≥12 (median survival: 2.2 vs. 1.8 months for treatment vs. best supportive care, p = 0.15), while treatment was associated with better outcome in other subgroups.

Conclusion: In HCC patients with ascites, treatment was associated with better survival, except for subgroup with advanced tumor with decreased liver function, indicating that ascites treatment was associated with better outcome in other subgroups.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO074 DIAGNOSTIC AND PROGNOSTIC ROLE OF SQUAMOUS CELL CARCINOMA ANTIGEN IN HEPATOCELLULAR CARCINOMA: SEROLOGICAL AND TISSUE DETERMINATION

F. Pelizzaro1, L. Ferrari1, R. Cardin2, M. Piciocchi1, G. Peserico1, P. Todesca1, A. Angelini1, C. Forlani1, F. Foffani1
1Department Of Surgery, Oncology And Gastroenterology, University of Padova, Padova/Italy
2Gastroenterology, Ospedale dell’Angelo, Venezia-Mestre/Italy

Contact E-mail Address: filippo.pelizzaro@gmail.com

Introduction: The ideal serological marker in hepatocellular carcinoma (HCC) has not been identified yet since Alphafetoprotein (AFP) has unsatisfactory characteristics. Squamous Cell Carcinoma Antigen (SCCA) is expressed in tissue and serum of HCC patients and when determined immunocomplexed with IgM (SCCA-IgM) has satisfactory diagnostic and prognostic performance.

Aims & Methods: Aim of our study was to evaluate, in HCC patients, the diagnostic and prognostic role of SCCA determination in tissue and in serum samples. SCCA-IgM levels were determined in 409 sera obtained from 196 HCC patients and 213 cirrhotics. SCCA tissue expression was analyzed in a subgroup of 62 patients with biopsy available at diagnosis. Sensitivity, specificity, correlation with clinical and tumor parameters, response to treatment and survival were evaluated.

Results: HCC patients had SCCA-IgM levels significantly higher than cirrhotics (P < 0.0001). Sensitivity, specificity, positive and negative predictive values were 76%, 52%, 60% and 76%, respectively. In comparison, sensitivity and specificity of AFP together with clinical and tumor parameters, SCCA-IgM levels and SCCA-IgM in SCC were 76%, 52%, 60% and 70%, respectively. A cut-off of 130 AU/mL (validated in literature) was used for the prognostic analysis: patients with SCCA-IgM levels ≤130 AU/mL showed a slightly better survival (p = ns), in long-term survivors (>24 months) and in Child A patients the difference in survival was statistically significant (p = 0.036 and p = 0.01, respectively). A drop in SCCA-IgM levels after TACE correlated with mRECIST response to treatment. Child-Pugh status was the only independent predictor of survival at Cox multivariate analysis. A better survival trend in HCC with low serum tissue expression was documented (31 vs 24 months, p = ns).

Conclusions: A higher SCCA-IgM levels showed an opposite behavior in the prognostic prediction: in males a better survival was documented with levels <130 AU/mL while in females with SCCA-IgM >130 AU/mL. In HCC patients, SCCA-IgM levels and SCCA tissue expression were identified as independent predictors of survival. SCCA-IgM levels were directly correlated with tumor size and BCLC stage in females and with etiology in males.

Disclosure: SCCA-IgM is a sensitive marker of HCC but lacks in specificity. As SCCA-IgM levels, SCCA tissue expression may identify patients with better prognosis (especially in long-term survivors) and the marker confirms its ability in detecting treatment responders. Lower levels of tissue SCCA seem to be related with less aggressive tumors, given that the longer survival of these patients. The gender-based differences observed in our patients, especially with respect to the SCCA-IgM prognostic role and correlation with clinical and tumor parameters, are intriguing and focused studies on the point are needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The BCLC algorithm is the standard system for clinical management of HCC. Data on adherence to this therapeutic paradigm are scarce. The aim of this field-practice study is to provide a description of HCC patients in Southern Italy, to evaluate the adherence to BCLC guidelines and its impact on patients’ survival.

Aims: We analyzed the region-wide Italian database of Progetto Epatocarcinoma Campania, which includes data of HCC patients, prospectively collected from January 2013 to December 2015 in 16 central regions.

Results: Overall 1008 HCC patients were enrolled: 70.6% patients received therapy according to BCLC algorithm, while 29.4% underwent different treatment. Among patients who were treated in adherence to guidelines, a higher rate of diagnosis on surveillance programs, better liver function, lower rate of AFP >200 ng/ml, more early stage and monofocal HCC, lower frequency of nodules >5cm, portal vein thrombosis and metastases were observed. The multivariate analysis showed that non-adherence to treatment guidelines was independently associated to the BCLC stage B, Child-Pugh classes B-C, and to the presence of neoplastic thrombosis and metastases. The mean overall survival in patients treated according to BCLC indications was 35.5 months, while in patients managed differently was 31.9 months (p < 0.0001).

Conclusion: Adherence to BCLC algorithm in field-practice was high in early and end stage HCC patients, but it was poor in intermediate and advanced patients. This may be due to the wide heterogeneity of intermediate-stage patients, and to the limited use of sorafenib in advanced-stage patients. Strategies to improve treatment and stratification of HCC patients are required.

PO076 A QUESTIONNAIRE SURVEY ON QUALITY OF LIFE WITH ANXIETY AND DEPRESSION SELF-RATING IN PATIENTS OF LIVER CIRRHOSIS

Y. Zhang1, X. Li1, X. Cui2, Y. Liu1
1Dept. Of Gastroenterology, Peking University People’s Hospital, Beijing/China
2Dept. Of Respiratory, Beijing Hospital of Chinese Traditional and Western Medicine, Beijing/China

Contact E-mail Address: medicalyun@qq.com

Introduction: Liver cirrhosis is a great public health burden for Chinese health system. The most common cause are HBV, HCV, alcohol consumption and non-alcoholic fatty liver disease, et al. The quality of life of liver cirrhosis patients is impacted by the physical symptoms and psychological symptoms such as anxiety as depression.

Aims & Methods: We aimed to investigate the quality of life of patients with cirrhosis, as well as depression and anxiety. A questionnaire survey was carried out in 95 patients in our gastroenterology department, Peking University People’s Hospital from May to August in 2016. The patients were divided into two groups, cirrhosis group and control group. The patients in cirrhosis group...
were diagnosed liver cirrhosis without complications. The control group included the digestive polyps patients without other diseases. The questionnaire included the World Health Organization Quality of Life (WHQOL)-BREF, Self-rating Anxiety Scale (SAS) and Self-rating Depression Scale (SPS). The questionnaire scores of the two groups were analyzed.

Results: A total of 95 valid questionnaires were collected and divided into cirrhosis group (n = 40) and control group (n = 45). In the cirrhosis group, there were 22 males and 18 females, average age 57.97 ± 10.448 years. In the control group, there were 45 males, 23 males and 22 females, with an average age of 61.47 ± 13.081, showing no difference from cirrhosis group. WHQOL includes four domains: physiological domain, psychological domain, social relationship domain, environment domain. The scores of liver cirrhosis group: physiological field (22.23 ± 3.312), psychological field (19.59 ± 3.925), social relationship field (9.64 ± 2.497), environment domain (26.23 ± 7.534) and control group (22.96 ± 3.275 in physiological field, 19.87 ± 3.152 in psychological field, 10.58 ± 2.061 in social relation field and 28.36 ± 5.091 in environmental field), they had no significant difference between the two groups (P > 0.05). The depression Self-rating score of cirrhosis group (47.86 ± 11.917) and control group (37.00 ± 12.521) (P > 0.05) (Table 1).

P0079 EARLY DIAGNOSTICS OF NAFLD: ANALYSIS OF RISK FACTORS USING NON-INVASIVE BILIRUBIN ASSOCIATION BETWEEN THE PREVALENCE STEATOSIS AND COMPONENT COMPOSITION OF THE BODY

I. Bakalin1, L. Belousova1, L. Evdokimova2, M. Serkova1, S. Ivanovs1, D. Korostovets2
1Chair of The Propedeutics Of Internal Diseases, Gastroenterology And Dietology, North-Western State Medical n.a. I.I. Mechnikov, Saint-Petersburg/Russian Federation
2North-Western State Medical n.a. I.I. Mechnikov, Saint-Petersburg/Russian Federation
3Pavlov First Saint Petersburg State Medical University, Saint-Petersburg/Russian Federation

Contact E-mail Address: liya73@mail.ru

Introduction: Non-alcoholic fatty liver disease (NAFLD) is liver disease with histological signs of accumulation of cholesterin excessive amount in hepatocyte in person without excessive alcohol consumption by patient (due to causes other than). The search for accessible, non-invasive and effective methods of screening for this pathology, allowing to detect NAFLD at early, potentially reversible stages of development is relevant. The purpose of the work was frequency estimation of the prevalence steatosis according to elastometry with controlled attenuation parameter (CAP®) among young people and associated with them specific body composition.

Aims & Methods: 59 volunteers (students of medical university) at the age of 19–28 years (the median age of 20.5) have participated in research. There were 22 (37.3%) men and 33 (62.7%) women among them without verified liver diseases. The survey was conducted in order to exclude or detect risk factors. Determining the level of liver steatosis and the degree of liver fibrosis was performed with the apparatus FibroScan 502 Touch. The final figures of elasticity of the liver were estimated in kPa (META VIR). The controlled attenuation parameter (CAP®) in dB/m was used for the severity of steatosis. Moreover, there was the body electrical impedance analysis of body (BIA), evaluated: body mass index (BMI), body fat.

Results: The signs of violations of the structure of the liver were diagnosed in 15 people out of 59 (25.4%). The signs of steatosis were found in 12 (20.3%) students. The signs of liver fibrosis were found in 7 (11.9%) people (E = 5, 8 kPa). At the same time the combination of liver fibrosis and steatosis was diagnosed in 4 (6.8%). After analyzing data of BIA it was revealed that body weight above normal in 23 (40, 3%); wherein fat body composition above normal value in 19 (33, 4%). Results of binary regression analysis showed that the chance of development of hepatic steatosis in case of excess adipose tissue increase 28 times (p = 0.045), influence of BMI, gender, age was statistically insignificant.

Conclusion: Based on the obtained results, it can be concluded that there is high enough level of distribution of liver steatosis among young people. Transient elastography (TE) with controlled attenuation parameter (CAP®) is a fast, reliable, repeatable non-invasive method for the assessment of NAFLD. The development of hepatic steatosis among practically healthy young persons was mainly associated with the increase the amount of adipose tissue in the body. Confirmed the importance of evaluation of body composition and lack of information of using only BMI when evaluating the chances of development of NAFLD.

P0080 SALVAGE TECHNIQUE USING A MICRO GUIDEWIRE FOR DIFFICULT BILIARY CHOLANGIOPANCREATOGRAPHY

Ishimomiya Nishi Hospital Dept. of Gastroenterology, Ishimomiya/Japan

Contact E-mail Address: a-mori@anzu.or.jp

Introduction: Biliary cannulation is indispensable for therapeutic endoscopic retrograde cholangiopancreatography (ERCP) in patients having biliary disease. Selective biliary cannulation is often difficult due to anatomical constraints. Numerous techniques have been attempted to overcome such problems. Although a wire-guided selective cannulation technique into the bile duct may be a useful approach, conventional guidewires (0.025 or 0.035 inch) are relatively rigid to pass through the long curved narrow distal segment (NDS) or malignant stricture and sometimes get flicked off the NDS in such cases. It may be better to pass through the long curved narrow distal segment (NDS) or malignant stricture and sometimes get flicked off the NDS in such cases. It may be better to pass through the long curved narrow distal segment (NDS) or malignant stricture.

Aims & Methods: We aimed to assess usefulness of GTWt for salvage technique in biliary cannulation. We studied 240 consecutive ERCP-naive patients between August 2014 and February 2017. We have tried to perform GTWt to ERCP-difficult-cases that was defined as patients of unsuccessful cannulation despite attempts over 15 min with conventional techniques including wire-guided cannulation, endoscopic retrograde cholangiopancreatography (ERCP) in patients having biliary disease. Selective biliary cannulation is often difficult due to anatomical constraints. Numerous techniques have been attempted to overcome such problems. Although a wire-guided selective cannulation technique into the bile duct may be a useful approach, conventional guidewires (0.025 or 0.035 inch) are relatively rigid to pass through the long curved narrow distal segment (NDS) or malignant stricture and sometimes get flicked off the NDS in such cases. It may be better to pass through the long curved narrow distal segment (NDS) or malignant stricture.

Results: Among 240 ERCP-naive patients, 40 were ERCP-difficult-cases (success rate with conventional technique: 200/240; 83%). Among 40 ERCP-difficult cases, GTWt was successful in 32 patients (success rate with GTWt: 32/40; 80%). Overall success rate of ERCP-naive patients improved from 80% to 97% (p < 0.001). Among eight patients who failed with GTWt, seven were successful performing precut papillotomy or endoscopic ultrasound-guided biliary drainage and one was interrupted because of developed serious condition.

Conclusion: GTWt as a salvage technique for unsuccessful selective biliary cannulation cases improves the success rate of ERCP, and could be attempted before performing a precut papillotomy, endoscopic ultrasound-guided techniques or other cumbersome procedures.

Introduction: To evaluate the safety and effectiveness of this procedure (ERCP) in patients age 85 years and older.

Methods: From first January 2010 until end December of 2016 in our digestive unit 3153 patients underwent ERCP, including 351 (11.13%) people over 85. Characteristics of these patients: The mean age was 89 (range 85–99); 117 males and 234 females. 43 (12.2%) were in treatment with antithrombotic drugs. The initial diagnosis in 218 patients (62.1%) was cholangitis, malignant CBD stenosis in 92 patients (25.9%), postoperative leak in 11 patients (3.1%) and unknown CBD stenosis in 31 patients (8.83%). All patients underwent the following clinical evaluation before and after ERCP. 34 patients (9.4%) were sedated with Propofol and anesthetists assisted. The rest of the patients 90.6% were sedated with the intravenous combination of midazolam and Fentanyl with standardized monitoring (pulse oximetry, heart rate, non invasive blood pressure measurements) during the procedure. Drug infusion was performed by the nursing staff and an attending endoscopist.

Results: Deep biliary cannulation was successful in 330 patients (94%). In 127 patients (36.18%) Vater papilla was associated with duodenal diverticula. The post-ERCP complication rates were as follows: Heperamulasia in 28 patients (7.38%), Mild pancreatitis in 12 patients (3.4%), Minor bleeding in 10 patients (2.8%), Major bleeding in 2 patients (0.6) and cholangitis in 6 patients (1.7%).

Conclusion: ERCP is an acceptable procedure in patients of 85 or older in terms of safety, success and complication rates.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0082 ALCOHOL CONSUMPTION CAN REDUCE THE RISK OF GALLSTONE DISEASE: A SYSTEMATIC REVIEW WITH DOSE-RESPONSE META-ANALYSIS OF CASE-CONTROL AND COHORT STUDIES

B.H. Cha1, M. Jang2
1Sheikh Khalifa Specialty Hospital, Ras Al Khaimah/United Arab Emirates
2Medical Research Collaborating Center, Seoul National University Hospital, Seoul/Korea, Republic of

Contact E-mail Address: doctorhyo@gmail.com

Introduction: Gallbladder stone (GBS) is a common gastrointestinal disease can progress to severe cholecystitis and is a strong risk factor for gallbladder cancer (GBC). Recently, clinical epidemiologic studies revealed that the alcohol consumption has a preventive effect for development of gallstone diseases.

Aims & Methods: To evaluate the relative risks of alcohol consumption for the gallstone diseases study development. Systematic searching was performed using MEDLINE, EMBASE and Cochrane library from January 1st, 1996, to December 31st, 2016 for studies assessed the relationship between alcohol consumption and gallstone development risk. The eligibility criteria was included: 1) studies involving the patients with gallbladder stone or without cholecystitis; 2) cohort or case-control studies investigated the association between alcohol consumption and gallstone disease development. Newcastle-Ottawa Scale was used to assess the methodological quality of each studies. Data was obtained from each selected studies regarding: 1) baseline characteristics of the study (cohort, case-control); 2) number of participants; 3) participants’ clinical features; 4) country; 5) publication year; 6) Risk or odds ratio (RR) and 95% confidence interval (CI); 7) alcohol consumption and risk of gallstone. The random effect model was used to estimate the pooled relative risks (RR) with 95% confidence intervals (CIs).

Results: Twenty-five cohort and case-control studies were included, and total 12, 581 cases with gallstone diseases among those 172, 590 controls. Alcohol consumption indicated a decreased risk of GSD development (Pooled RR = 0.84 [0.79-0.90], P < 0.001). Subgroup analyses according to the alcohol doses (g/d) confirmed a gradual risk-reduction effect on GSD compared to non-drinkers (Light: RR = 0.97 [0.94, 1.00], p = 0.864; Moderate: RR = 0.82 [0.79, 0.86], p = 0.777; Heavy: RR = 0.70 [0.62, 0.80], p < 0.01).

Disclosure of Interest: None.
Introduction: Patients undergoing endoscopic retrograde cholangiopancreatography (ERCP) and duct clearance for common bile duct stones (CBDS) should be followed up with an early choledochoscopy to prevent recurrent biliary complications (1, 2) and acute gallstone pancreatitis. Recently the National Confidential Enquiry into Patient Outcome and Death (NCEPOD) recommended that definitive eradication of gallstones by choledochoscopy prevents the risk of a recurrent attack of acute pancreatitis (AP). For patients with an episode of mild acute pancreatitis, early definitive surgery should be undertaken, either during the index admission or within three months (3, 4).

Aims & Methods: 1) To determine time frame between ERCP/duct clearance and cholecystectomy (CCX) in non-pancreatitis group. 2) To determine time frame between ERCP/duct clearance and CCX in pancreatitis group. 3) To determine re-admission rate while awaiting CCX. All patients who underwent ERCP for CBDS between 01/01/2014 to 31/12/2014 were included in the study. Patients who had previously undergone CCX (de novo stones) were excluded. All patients were followed up for a minimum period of 2 years following their ERCP.

Results: A total of 273 patients underwent ERCP for CBDS. Out of these 21.2% (n = 58) had previously had CCX and were excluded. Out of the remaining 215 with gall bladder (GB) in situ, 87.4% (188/215) underwent successful duct clearance at index or subsequent ERCP. Of these, 47.3% (89/188) underwent CCX within 27 days (range 0–85 days). Patients who had gall stone pancreatitis (GSP) on presentation and the median time between ERCP and CCX in the GSP group was 136 days (range 35–287 days); 12 of these had mild pancreatitis with a median time to CCX of 140 days (range 60–287 days). 4 patients re-presented with CBDS while awaiting CCX after duct clearance; 1 had pancreatitis on readmission, 51.6% (97/188) patients who did not undergo CCX after duct clearance are referred as non-cholecystectomy (non-CCX) group. This was mainly secondary to high ASA grade. We compared patient demographics and presentation with the CCX group and the results were as follows:

<table>
<thead>
<tr>
<th></th>
<th>CCX group (n = 97)</th>
<th>Non-CCX group (n = 91)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Value</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Median Age</td>
<td>61 years</td>
<td>79 years</td>
</tr>
<tr>
<td>Median ASA grade</td>
<td>1</td>
<td>2.8</td>
</tr>
<tr>
<td>Female patients</td>
<td>67%</td>
<td>56%</td>
</tr>
<tr>
<td>Male patients</td>
<td>33%</td>
<td>44%</td>
</tr>
<tr>
<td>Pancreatitis on presentation</td>
<td>17%</td>
<td>11.4%</td>
</tr>
<tr>
<td>Readmission with CBDS</td>
<td>4.5%</td>
<td>5.4%</td>
</tr>
</tbody>
</table>

In 27 patients duct clearance was not achieved: 26% (7/27) underwent surgical management (CBD exploration on table cholangiogram and CCX). The remaining 74% (20/27) patients were deemed unsuitable for invasive intervention and were either for symptomatic stent change only or conservative management. The time period between duct clearance and CCX was longer than anticipated, especially in patients with mild acute pancreatitis as none of them underwent CCX during index admission or within 2 weeks of ERCP/duct clearance. Some patients re-presented with CBDS while awaiting CCX. We looked into potential causes of delay in CCX – delayed referral to surgery, long waiting time for elective CCX and patient choice. We propose to develop a local pathway for patients with CBDS and gallstones and induct a robust system for referring patients for CCX following duct clearance. This would help to minimize readmission and potential complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aim of current study is to develop the multi-layer drug eluting membrane using ultrasonic spray coating method, which have uniform capacity of drug and be able to control the drug-release capacity.

Methods: The drug eluting membrane was made using ultrasonic spray coating machine (MediCoat-2JX). The membrane consists with two kinds of coating material. One is silicone (MED-6604), that was used to basic structure of membrane and the other coating agent is polyurethane (tecoflox, tecothane, Tefoflex and pellethene). The gemicatine was used as antitumor drug, and coated to membrane by mixed form with polyurethane (gemicatine, 250ug/ml; polyurethane, 500ug/ml). The thickness of membrane and the capacity of drug in membrane were measured at the proximal and distal end, and mid portion. The drug release capacity and duration was measured by using drug releasing test in vitro for 3 days.

Results: The mean thickness of membrane was 50um. The mean capacity of drug per unit area was 100 ug/cm², and the amount was constant in all tested area (Standard deviation, 5 ug/cm²). In drug release test, the capacity of releasing drug was different depended on the kinds of polyurethane. The total amount of released drug mass in 24 hours was 919 ug, 933 ug, 859 ug in tecophilic coating, tecothane coating, tecoflox coating, and pellethene coating. The total of released drug amount depended on polyurethane was described in table 1.

Table 1: The total of releasing drug amount in 72 hours

<table>
<thead>
<tr>
<th>Drug release amount</th>
<th>Gemicatine (ug)</th>
</tr>

Conclusion: The ultrasonic spray coating technique could be applied to make multi-layer drug eluting membrane with regular thickness. The membranes contained the uniform capacity of drug in all tested area. The releasing drug capacity is able to control by applying different kind of polyurethane.

Disclosure of Interest: All authors have declared no conflicts of interest.

1. Meredith C, Baird, P. Diagnostic yield of SurePath (SP) and conventional smear preparations (CSP) for brush cytology obtained from the common bile duct (CBD) in patients undergoing endoscopic retrograde cholangiopancreatography (ERCP). Gastroenterology, Vol 150, Issue 4, S516, 2016.

A087 ADVANCES IN CYTOLOGY FOR THE EARLY DIAGNOSIS OF PANCREATICO-BILIARY MALIGNANCY

C. Meredith1, P. Irandoost2, P. Baird3
1Gastroenterology And Hepatology, Bankstown-Lidcombe Hospital, Bankstown, Australia/NSW
2Cytology, Lavery Pathology, Ryde/Australia/NSW

Contact E-mail Address: drcmeredith@gmail.com

Introduction: Liquid-based sample preparations for cytology have improved the cellular yield in pancreatico-biliary (PB) malignancy.1 The SurePath (SP) method-ology produces a pellet of concentrated cellular material which enables addi-tional slides for immunohistochemical (IHC) staining for tumour markers Ki67, p53 and CDX2. The presence of the mitosis-related marker, Ki67, in high con-centration is considered to indicate the presence of PB malignancy. We aimed to assess the utility of SurePath (SP) in the diagnosis of pancreatico-biliary malignancy.

Methods: We aimed to assess the cancer cell morphology and the presence of tumour markers, p53 and CDX2, in SurePath (SP) samples from patients with pancreatico-biliary malignancy.

Results: A total of 100 SurePath samples were assessed for the presence of cancer cells and the expression of p53 and CDX2. The presence of cancer cells was detected in 96 out of 100 samples, with a sensitivity of 96% for the detection of cancer cells. The expression of p53 was detected in 52 out of 100 samples, with a sensitivity of 52%. The expression of CDX2 was detected in 48 out of 100 samples, with a sensitivity of 48%.

Conclusion: SurePath (SP) is a valuable tool for the diagnosis of pancreatico-biliary malignancy, with a high sensitivity for the detection of cancer cells and the expression of p53 and CDX2. The presence of cancer cells in SurePath (SP) samples is a reliable indicator of pancreatico-biliary malignancy.

Introduction: The current study aims to evaluate the anti-tumor effect of paclitaxel, gemcitabine, and mitomycin C eluting polyurethane membrane in an animal model. The eluting membrane was made using ultrasonic spray coating method, which have uniform capacity of drug and be able to control the drug-release capacity.

Methods: We aimed to evaluate the antitumor effect of the paclitaxel, gemcitabine, and mitomycin C eluting polyurethane membrane in a tumor model. The tumor model was created by implanting human pancreatic cancer cells into the abdominal cavity of nude mice. The tumor cells were stained with Ki67 as well as the pattern of intracellular staining adds a level of confidence for the cytopathologist to diagnose malignancy, particularly when there is no clinical or scan evidence of a tumour mass. Early diagnosis is the key for curative surgery and specific cell tumour markers &or their pattern may impact significantly on the outcome.

Disclosure of Interest: All authors have declared no conflicts of interest.

1. Meredith C, Baird, P. Diagnostic yield of SurePath (SP) and conventional smear preparations (CSP) for brush cytology obtained from the common bile duct (CBD) in patients undergoing endoscopic retrograde cholangiopancreatography (ERCP). Gastroenterology, Vol 150, Issue 4, S516, 2016.

A089 IMPACT OF PALLIATIVE BILIARY DRAINAGE BETWEEN METAL STENT AND PLASTIC STENT ON SURVIVAL RATE IN UNRESECTABLE DISTAL MALIGNANT BILIARY STRICTURE IN SOUTH OF THAILAND

T. Pattarapuntakul, B. Ovartlanporn, N. Netinatsunton
Faculty Of Medicine, Prince Of Songkla University, NCI Institute of Gastroenterology and Hepatology, Hatyai/Thailand

Contact E-mail Address: tanawat_kuey@hotmail.com

Introduction: Palliative biliary drainage was used to improving obstructive jaundice, nutritional status, quality of life along with survival rate in unresectable distal malignant biliary stricture patients. The ERCP with biliary drainage with or without systemic chemotherapy are mainstay of treatment in these patients. The benefits of biliary stents are much different in cost on survival rate, nutritional status and efficacy of biliary drainage in DBSs patients are still questionable in limit health budget country.

Methods: We aimed to assess the impact of endoscopic palliative biliary drainage stents on survival rate, nutritional status and efficacy of biliary drainage of patients in distal biliary malignant stricture patients. All of the computerized medical records of distal biliary malignant stricture patients, who were undergoing to endoscopic biliary drainage from January 01, 2012 to December 30, 2015 in Songklanakarin hospital were retrospectively review. ERCP with biliary drainage stent was undertaken at the discretion of attending physicians. The overall survival rate, nutritional status (body weight), efficacy of biliary drainage (level of total bilirubin) after biliary drainage between the metal stent group, plastic stent group and plastic stent followed with metal stent group were compared.

Results: Sixty eight patients (45 males, mean age 63.7 ± 14.8 years) were enrolled, 35 patients were classified into the plastic stent group, 18 patients were classified into the metal stent group and 15 patients were classified into the plastic stent followed to metal stent group. Demographic data, primary malignancy, tumor staging and ECOG score, initial total bilirubin and stricture length were similar between 3 groups. The median survival time was 5.4 months 95%CI (3.2–8.5) and overall survival rate was lowest in the metal stent group (median 3.2 months 95%CI 1.8–6.9). Mean weight reduction and the declining of total biliary after biliary drainage were not significantly different between biliary
stent types. The plastic stent group had lowest cost of total ERCP statistically
significant. The complications rate was not different between biliary stent types.
Conclusion: Palliative biliary drainage with plastic stent in unresectable distal malignant biliary stricture was slightly better on survival rate and was not dif-
ferent in nutritional status, efficacy to drainage and complication rate compared with metal stent or plastic followed with metal stent. But the plastic stent group had lowest cost of total procedure.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Patients with unresectable perihilar cholangiocarcinoma (PHC) typically present with obstructive jaundice. They require percutaneous or endo-
toscopic biliary drainage for symptom relieve and eligibility for palliative systemic chemotherapy. However, biliary drainage in unresectable PHC is complex with a high failure and complication rate even in tertiary referral centers.

Aims & Methods: The aim of this study was to investigate the failure and compo-
lization rate of the initial drainage procedure in patients with unresectable PHC. Consecutive patients with unresectable PHC on imaging in two tertiary referral centers between 2002 and 2014 were identified. Patients were included if a biliary drainage procedure was performed. Baseline patient and tumor characteristics

and data on the biliary drainage procedure were collected from medical records. Definitions of failure of drainage or other severe biliary related complications are shown in Table 1.

### Results

In total, 187 patients were included. Initial drainage was performed in a non-referral center in 125 patients (66.8%). The initial drainage procedure was endoscopic in 158 patients (84.5%) and percutaneous in 29 patients (15.5%). A stent was placed in 91 patients (63.5%) at the initial drainage procedure. The highest bilirubin level in the 2 weeks prior to drainage was 248 (IQR: 138–377) μmol/L. Only 14 (8.1%) patients had cholangitis prior to the initial drainage procedure. Failure of drainage or other severe complications related to the initial drainage procedure were noted in 117 (62.6%) patients. Failure of drainage or re-intervention was most common and was noted in 85 patients (50.8%). Bile duct injury occurred in 3 (1.6%) patients, acute pancreatitis in 5 (2.7%) patients and cholangitis in 11 (5.9%) patients. Two (1.1%) patients had cardiopulmonary complications and 1 (0.5%) patient had a duodenal perforation. The median period of the initial and second drainage procedure was 13 (5-31) days and the bilirubin level dropped below 50 μmol/L in 27 patients (14.4%). After initial drainage, 20 patients (10.7%) died within 30-days and 66 patients (35.3%) within 90 days. The median OS after initial drainage was 6.6 (95% CI: 2.0–15.2) months.

### Conclusion

Patients with unresectable PHC on imaging have a very high failure and complication rate after initial biliary drainage.

P0091 BRUSH CYTOLoGY GUIDED BY ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY OF BILiARY STRICTURES
Centro Hospitalar De Sao Joao, Porto/Portugal

**Contact E-mail Address:** armandoap5@gmail.com

**Introduction:** Endoscopic retrograde cholangiopancreateography (ERCP)-guided brush cytology has become the most widely used method, although with limitations, in the initial diagnostic evaluation of patients with biliary strictures.

**Aims & Methods:** The objective of the study was to evaluate if the systematic use of 10 brush passes improves the diagnostic yield of brush cytology guided by ERCP of bile strictures. ERCPs between 2012 and 2015 involving brush cytology of bile strictures for suspected malignancy were included in the study. Cytologies were obtained using the Brush Master V (Olympus Medical System). Histological evaluation was performed by two experienced cytopathologists.

**Results:** In total, 62 patients underwent cytology of biliary strictures, with a median age of 69 years (IQ: 55–81). The cytological analysis was compatible with adenocarcinoma in 30.6% of the cases, low grade dysplasia in 3.2%, high grade dysplasia in 1.6% and adenoma in 1.6%. In 26 patients the cytology was negative (41.9%) and in 13 cases it was considered inconclusive (21%). Fifteen patients were subsequently submitted to surgery (24.2%). In 34 cases (54.8%) there was a correlation between the cytology and the final diagnosis. In the univariate analysis, previous history of cholecystectomy (73.7% vs. 26.3%, p = 0.047), cytology suggestive of malignancy/adenocarcinoma (89.5% vs. 10.5%, p = 0.001) and final non-equivocal diagnosis (14.3% vs. 85.7%, p = 0.002) were associated with positive correlation. If the cytology and final diagnosis are coded as "malignant," "benign," or "inconclusive," the correlation increases to 67.7%. In this situation, the univariate analysis showed that the presence of malignancy in cytology (87.5% vs. 10.5%, p = 0.009) and final non-equivocal diagnosis (57.5% vs. 64.3%, p = 0.012) were associated with a positive correlation. If the cases identified as undetermined cytology were excluded, there was no increase in correlation with the final diagnosis (56.5%).

**Conclusion:** The systematic use of 10 passes in the cytology of the biliary tract mostly increases the accuracy of the detection of malignant versus benign situations.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
9 patients had the fast and medium degradation stents respectively and 12 had the slow degradation stents implanted. All stents were 3-mm in diameter and the length ranges from 60 to 120 mm depending on the level of obstruction. It took an average of 29.6 minutes to complete each procedures, and the mean stent deployment duration was 6.0 minutes. It ranges from 13.5 minutes in the initial phase and improved to 1.5 minutes in the later phase. Biliary sphincterotomy was not more than single biopsy, in the fast-degradable stents, but however, all patients with biliary stone had sphincterotomy to facilitate retrieval of the stones. Serum bilirubin level (SBL) showed reduction of 52% from the mean SBL of 54.9 μmol/L prior to stenting to 26.2 μmol/L at Day 7. Quality of life score improved from 2.0 up to 8.5 after stenting. The BBS ranks high in terms of loadability, tractability over guide-wire, and pushability with push catheter. There was minimal force required to implant it and it has good visibility by fluoroscopy. The BBS is as flexible as the conventional plastic stents and can be accurately deployed under fluoroscopy. Technical success or completion of the ERCP and stent deployment was achieved in all 30 patients.

**Conclusion:** This pilot study has shown encouraging results. It benefit the patient to avoid the burden of a second ERCP procedure for plastic stent removal. However, these results should be interpreted with caution as this is a pilot study to assess the safety and efficacy of the biodegradable stent on limited number of volunteers with symptomatic jaundice. We plan to conduct a phase 2 study involving a larger number of cohorts with a more specific indication of benign and malignant biliary stricture.

**Introduction:** The cystic fibrosis transmembrane conductance regulator (CFTR) has a major role in pancreatic ductal secretion and its genetic defects damage the pancreas. It is known that intracellular Ca2+ homeostasis is disturbed in bronchiolar epithelial cells in cystic fibrosis (CF), but the connection of CFTR and the intracellular Ca2+ signaling has never been suggested in pancreatic damage in CF patients.

**Aims & Methods:** Our aim was to characterize the Ca2+ homeostasis of CFTR-deficient PDC. Wild type (WT) and CFTR knockout (KO) mouse pancreatic ductal and acinar cells and iPSC (induced pluripotent stem cell) derived human organoids from 2 CF patients and controls, human CF pancreatic cell line (CFPAC-1; ΔF508 mutant) were used for intracellular Ca2+ measurements. Mitochondrial membrane potential (ΔΨm) and mitochondrial morphology was assessed in isolated pancreatic ducts. Immunofluorescent staining and quantitative PCR measurements were performed to detect changes of mRNA and protein expressions.

**Results:** The plateau phase of the agonist-induced Ca2+ signal was elevated in CFTR-deficient PDC, which was caused by decreased function of the plasma membrane Ca2+ pump (PMCA). The functional inhibition of both WT and KO PDC showed no effect on the PMCA activity. Human CF organoids have shown decreased PMCA function compared to control while the 24 h treatment of the CF organs (CFPAC-1; ΔF508 mutant) showed the same PMCA dysfunction. Viral transfection of CFPAC-1 with CFTR gene completely restored PMCA function. Sustained [Ca2+]i levels decreased ΔΨm and induced cytophrome c release in CFTR KO PDEC without significant alterations in mitochondrial morphology.

**Conclusion:** Dysfunction of PMCA leads to disturbed Ca2+ homeostasis in CFTR-deficient PDC and the consequent cellular Ca2+ overload impairs mitochondrial function contributing to the pancreatic damage in CF.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Given their capability to differentiate to every cell type of the human body, human induced pluripotent stem cells (hiPSCs) provide a unique platform for the platform for developmental study and regenerative medicine. The generation of a pancreatic progenitor (PP) cells from pluripotent stem cells follows the sequential induction of virtually pure definitive endoderm (DE), foregut endoderm (GTE) and pancreatic endoderm (PE). We have recently reported the generation of a novel three-dimensional pancreatic organoid culture system that generates functional acinar-/ductal-like structures from pluripotent stem cells (Hohlw6ier et al, *GUT*, 2016).

**Aims & Methods:** In the current study we implemented this culture system to understand the role of exocrine differentiation and proliferation factor (Expd2), a signalling molecule proposed to be involved pancreatic differentiation in zebrafish. CrispCas9 technologies were used to ablate Expd2 in human embryonic stem cells, while a piggy bac engineering approach allowed us timed expression to study the role of both loss and gain of Expd2 function during pancreatic differentiation.

**Results:** First, a limited role of Expd2 was observed until the PE stage, while PP formation was strongly diminished. Moreover, a dramatically altered organoid morphology was observed in the Expd2 knock-out lines, leading to mostly cystic structures. Phenotyping for ductal and acinar lineage allowed to investigate these
**Conclusion:** Thus, we report a novel signalling molecule playing a critical role during human pancreas development based on a pluripotent stem cell differentiation platform.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Reference**

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Conclusion:** Our result confirmed the functional activity of the TRPM2 channel in pancreatic acinar cells. In further investigations we aim to clarify the pathogenetic role of TRPM2 in AP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Pancreatic duct fluid and HCO₃⁻ secretion are crucially important in the physiology and pathophysiology of the exocrine pancreas. However, the role of human pancreatic secretory processes is great challenge due to the limited access to human pancreatic ductal cells. The recently developed three-dimensional pancreatic organoid cultures (OC) may help to overcome this limitation. However, the ion secretory processes in pancreatic OC is not known.

**Aims & Methods:** Our aim was to characterize the ion transport processes in mouse pancreatic OCs. Mouse pancreatic ductal fragments were isolated by enzymatic digestion. The isolated ducts were grown in Matrigel on 37°C for a week in OC medium. Changes of the intracellular pH was measured to characterize the ion transporter activities of the epithelial cells in OC.

**Results:** Basolateral administration of 20mM NH₄Cl in standard HEPES or CO₂/HCO₃⁻ buffered solution resulted in rapid intracellular alkalization, but not in the regeneration phase. Removal of NH₄Cl induced rapid acidification followed by regeneration to the resting pH levels. The regeneration phase was inhibited by the removal of extracellular Na⁺. The administration of 10mM CFTRinh-172, a selective inhibitor of cystic fibrosis transmembrane conductance regulator decreased the HCO₃⁻/H⁺ exchange with a recovery phase. Basolateral administration of 20mM amiloride and 20mM H₂DIDS decreased the intracellular pH suggesting the activity of Na⁺/H⁺ exchanger and Na⁺/HCO₃⁻ cotransporter on the basolateral membrane.

**Conclusion:** The ion transport activities in mouse OC are similar to those observed in freshly isolated primary tissue. This suggest that OC will be suitable to study human ductal epithelial ion transport.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0101 INVESTIGATION OF THE ORAI1 MEDIATED CA2⁺ ENTRY IN MOUSE PANCREATIC DUCTAL CELLS**

**Introduction:** Acute pancreatitis (AP) is the most common inflammatory disorder in the gastrointestinal tract with an overall mortality of 20–30% in severe cases. The treatment of AP is not resolved yet, urging the identification of novel drug targets. Toxic cellular Ca²⁺ overload was highlighted as a key event in pancreatic acinar and ductal cells during the pathogenesis of AP. In addition, the inhibition of Orai in pancreatic acinar cells markedly decreased the Ca²⁺ toxicity and the severity of AP. However, we have no information regarding the role of Orai in pancreatic ductal physiology or pathophysiology.

**Aims & Methods:** Wild type FVB/N mice were used for the isolation of pancreatic ductal fragments. The intracellular pH and Ca²⁺ level of the pancreatic ductal cells (PDC) were measured by microfluorimetry. The effect of selective Orai inhibitors provided by CalcMedica was evaluated.

**Results:** The tested compounds dose-dependently inhibited Ca²⁺ influx during the carbachol induced Ca²⁺ signal in PDC. Inhibition was complete at a concentration of 10µM (CM-B: 99.87%, CM-C: 95.29%). Next, endoplasmic reticulum Ca²⁺ stores were depleted with cyclopiazonic acid and the inhibition of store-operated Ca²⁺ entry (SOCE) was investigated after the re-addition of extracellular Ca²⁺. Under these conditions CM-B and CM-C significantly, but not completely, decreased SOCE in PDC (55.96% and 55.03% respectively). The removal of extracellular Na⁺ to abolish activity of the Na⁺/Ca²⁺ exchanger had no effect on the inhibition of SOCE by CM-B or CM-C. We also showed that the inhibition of Orai has no effect on the basal secretion of HCO₃⁻ by PDC, which is the main physiological function of these cells.

**Conclusion:** We showed that Orai has a significant role in the Ca²⁺ signaling of PDC. In the next step we will evaluate the pathophysiologival relevance of the channel.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Acute pancreatitis (AP) is among the most difficult diseases faced by gastroenterologists and surgeons. In some cases it is difficult to understand etiology of AP. Hereditary pancreatitis (HP) is an autosomal dominant genetic disorder characterized by recurrent attacks of acute pancreatitis.

Aims & Methods: We analyzed medical records of patients who were diagnosed with juvenile pancreatitis and pancreatitis of unknown etiology (PUE) at the Center for Digestive Diseases at Karolinska University Hospital from January 2008 to December 2016.

Results: During the observation period, 44 patients (17 male and 27 female) were registered with the ICD code chronic or relapsing pancreatitis, and onset of symptoms before the age of twenty. At time of first visit, the mean age was 36.7±26.9 years, range 24–57. The average period between the occurrence of first symptoms and diagnosis was 14.0 years (range 1–39 years). All patients (100%) clinically presented with recurrent acute pancreatitis. There were 28 (63.7%) patients with genetic mutations. Five out of 28 genetic positive patients (17.9%) had a definitive diagnosis of genetic etiology of pancreatitis. Seven out of 26 genetic negative patients (25%) had complications; in five patients endoscopic treatment due to pancreatic duct stenosis was performed; one patient had pancreatic and bile duct stenosis and one patient (female, age 28, CFTR heterozygous mutation) a pancreatic tumor (mucinous cystadenoma with high dysplasia that was successfully surgically treated with R0 resection). One patient died due to non-pancreatic related disease (kidney cancer). None of the patients reported alcohol overconsumption. Four out of 28 genetic positive patients (14.3%) were active smokers. Fecal elastase-1 (FE-1) was tested in 28 (63.6%) patients: 16 (57.1%) in genetic positive and 12 (75%) in genetic negative group of patients. Pancreatic exocrine insufficiency (PEI) was found in 5 out of 12 (41.7%) of genetic negative patients and in 5 out of 16 (31.2%) genetic positive patients. Average age at onset of PEI was 38 years (range 27–53). Diabetes mellitus (DM) was diagnosed in one patient in group with genetic alterations and 2 patients in group without genetic alterations.

Conclusion: We found high proportion of genetic alterations in patients with juvenile pancreatitis and PUE. In patients in whom pancreatitis remains unexplained after excluding of the most often etiologies and presence of chronic alteration, hereditary pancreatitis seems as reasonable explanation even in patients with mutations in other genes than PRSS1. Routine follow-up of patients with regular testing on pancreatic exocrine insufficiency and diabetes mellitus and pancreatic cancer surveillance is necessary.

Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: No conflicts of interest.
and their evolution after 24 h were evaluated. Accuracy was measured using different operating characteristics and analyses.

Results: Of the 817 eligible patients, 118 were excluded, most for a previous episode before admission. We analyzed 699 patients with a median age of 57.5 years (IQR: 45.2–72.7), 57.4% males. Most frequent comorbidities were: diabetes (19.9%), hyperlipidemia (9.9%) and COPD (7.7%). Median length of stay was 7 (5–10) days. Most common causes were: biliary (53.9%), idiopathic (21.8%) and alcoholic pancreatitis (14.3%). A CT scan was performed in 56.1% identifying local complications in 36.2% of them, acute fluid collections in 16.1%. There were 42 (6%) severe and 196 (28%) moderately severe cases. Overall mortality was 2.4% (1.5–3.9), 93.5% (23–50.8%) among severe cases. BUN at admission AUC: 0.88 (0.85–0.90), BISAP score (AUC: 0.88 [0.85–0.90]) and APACHE II (AUC: 0.87 [0.84-0.90]) were the other all-cause mortality predicting death. APACHE II presented the highest sensitivity, 100% (81.1–100%), while the BISAP score presented the highest specificities, 93.1% (90.6–94.8%). BUN at admission (AUC: 0.89 [0.86–0.91]) and the BISAP score (AUC: 0.87 [0.84–0.89]) also presented the best predictive performance.

The BISAP score significantly decreased the highest area under the ROC curve (94.2% [92.2–95.8%]), although with a low PPV, 32.1% (21.4–45.2%). On the other hand, diagnostic accuracy for mild AP was poor, as all predictors presented an AUC < 0.7. The HAPS score reached the highest specificity, 87.8% (83.9–91.4%), but presented a very poor sensitivity (28.9% [24.3–33.9%]).

Conclusion: The revised Atlanta classification accurately identifies those patients at higher risk of death. Among the available predictors of severity, BISAP and BUN at admission presented an excellent performance, with an AUC of nearly 0.9. New scores are needed to predict a mild course, as none of the available indexes presented an AUC > 0.7.

P0106 PANCREATIC DUCT ASCARIASIS

P. Somani, M. Sharma
Department Of Gastroenterology, Jayvant Bai Speciality Hospital, Meerut/India

Contact E-mail Address: dr_piyushsomani@yahoo.co.in

Introduction: Although uncommon in the West, Ascaris lumbricoides is a common cause of acute pancreatitis in developing countries. The mechanism of acute pancreatitis in ascariasis may be due to obstruction of papilla of Vater, invasion of common bile duct (CBD) or pancreatic duct (PD). The invasion of pancreatic duct occurs rarely owing to its smaller calibre. Ultrasonography (USG) is an effective tool for the diagnosis of biliary and pancreatic ascariasis; however, the diagnosis may be false negative in up to 30% of cases. Pancreatic ascariasis remains an unsolved problem. Only case reports have been described in the literature. We present our retrospective data of last 10 years of 15 cases of pancreatic ascariasis.

Aims & Methods: During a study period of 10 years, 15 cases of pancreatic ascariasis were diagnosed by USG or endoscopic ultrasonography(EUS). EUS was performed with a linear or radial echosondeoscope. 13 patients presented with symptoms of acute pancreatitis. Out of 13 patients, 9 presented with first episode of idiopathic pancreatitis while 4 presented with idiopathic recurrent acute pancreatitis. Out of 15 patients, 2 cases were diagnosed with USG while 13 patients were diagnosed with EUS. The patients underwent side-viewing endoscopy/ERCP under conscious sedation. EUS showed dilated common bile duct (CBD) or the PD. The serpentine movements of worms inside the duct. Live roundworms were removed from PD without undertaking sphincterotomy. In endemic areas, sphincterotomy facilitates the risk of migration of worms into the CBD or PD. Patients with severe acute pancreatitis (SAP) and idiopathic acute pancreatitis (IAP) are usually cold and EUS is the investigation of choice. The recurrence is rare and treatment is side-view endoscopy with removal of worms. EUS significantly improves the diagnostic yield for idiopathic acute pancreatitis (IAP). Our retrospective study shows that EUS is a highly sensitive and specific diagnostic method to diagnose the etiology of SAP with reference to biliary and pancreatic ascariasis. Although USG is quite sensitive for diagnosing BPA, its sensitivity significantly falls when the worm is thin, in the PD, or the CBD is non-dilated. EUS is more sensitive for diagnosis of ascariasis in the pancreatic duct than other radiological investigations. The probable reasons are excellent imaging of pancreas by EUS and in and out movement of ascaris which might be missed by other investigations. Endoscopic retrograde cholangiopancreatography, considered the gold standard for diagnosis of biliary ascariasis, should be reserved for therapeutic rather than diagnostic circumstances as sphincterotomy can lead to reentry of the worm into the common bile duct. EUS should be used early in the work-up of IAP after the first episode. We propose EUS to be investigation of choice for PD ascariasis. Most of the episodes are of mild pancreatitis with no mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

COTTON VS. REVISED ATLANTA CRITERIA TO DEFINE SEVERITY OF POST-ERCP PANCREATITIS

Introduction: The Cotton criteria (1) and the revised Atlanta classification (2) are advocated to define post-endoscopic retrograde cholangiopancreatography (ERCPC) pancreatitis (PEP) severity (3). Whereas Cotton puts the emphasis on length of hospitalisation, Atlanta focuses on the presence of local (necrosis) and systemic (organ failure) complications. The number of hospitalization days may not be a proper representation of PEP severity, because it is influenced by other diagnoses such as ERCPC complications and comorbidity. The goal of this retrospective cohort study is to compare the Cotton and Atlanta criteria for the severity of PEP.

Aims & Methods: All ERCPC procedures from a Dutch university medical centre and a teaching hospital between 2012 and November 2016 were checked retrospectively for patients with PEP. Patients were eligible if they met the Cotton criteria or Atlanta criteria for acute pancreatitis. All records were checked up to 48 hours after ERCPC to capture delayed PEP. Patients were excluded if they had acute pancreatitis prior to ERCPC or had chronic pancreatitis. In the primary analysis, mild/moderate and severe PEP were compared between Cotton and Atlanta with Fischer’s exact test. Atlanta was regarded as the golden standard.

Results: Out of a total 2156 ERCPCs, 66 patients (3%) had PEP. Two patients died within 10 days of early multiple organ failure. Two patients died of documented mesenteric ischemia during the early phase (<8 days) and 3/10 patients during the late phase (>8 days). IPN was present in 62 patients (43%), all requiring an intervention (i.e. radiological, endoscopic, and/or surgical). 35% of patients (22/62) had only one modality of drainage (radiologic or transgastric) and did not require any necrosectomy. For 30 patients (48%), additional necrosectomy was needed because of lack of improvement after drainage alone. 10 patients (17%) had only necrosectomy without prior drainage procedure. Complications such as hemorrhage and perforation of visceral organs occurred more frequently in the IPN group (14% vs 19.4%, p < 0.001 and 9% vs 8.5%, p = 0.02 respectively). The late phase mortality (>8 days) was significantly higher in the IPN group (14.5% vs 14%, p < 0.01). In multivariate analysis, factors associated with IPN were number of OF and postsplenomenosenteric venous thrombosis (table 1). 39 patients (68%) received anticoagulants with a median time of 6 [3–6] months and among them, 25 patients developed cavernoma, irrespective of whether or not they receive systemic anticoagulants (p = 0.31).

Conclusion: In conclusion, this study performed in routine practice conditions showed that IPN occurs in almost half of patients hospitalized in ICU for severe AP, and is associated with increased mortality and complications rates. Overall mortality was 17.6%, and factors associated with mortality were a high BMI, CTSI and persistent OF. Those results are consistent with previous studies1–3, but we reported a high rate of mesenteric ischemia (7/26 patients deceased) while this complication is occasionally described. IPN patients required an intervention for drainage of infected tissue removal, which was performed using minimally invasive techniques in the vast majority of cases, with no complication or severe side effect. 35% of patients were treated with drainage alone without any additional necrosectomy. Finally, PSMVT and early OF appeared to be associated with the risk of developing an IPN but anticoagulation for PSMVT did not protect for cavernoma occurrence and can expose to intestinal bleeding. Our results also suggest that the optimal and early management of OF and detection of PVSMT might prevent IPN and/or its complications. Such hypothesis will need to be tested in large multicentre prospective studies.

RISKS FACTORS AND OUTCOMES OF INFECTED PANCREATIC NECROSIS: RESULTS FROM A COHORT OF 148 PATIENTS ADMITTED IN ICU FOR SEVERE ACUTE PANCREATITIS

Introduction: The identification of risk factors for severe acute pancreatitis (SAP) may help to identify factors associated with IPN and to describe outcomes and mortality related to IPN.

Aims & Methods: This was a retrospective study of collected data from all patients admitted in Intensive Care Unit (ICU) in a single centre from 2012 to 2015 for a severe AP. Baseline characteristics of the overall population were expressed as frequencies (percentages) for categorical variables, and as mean±standard deviation (SD) for continuous data. For the analysis of mortality, multi-variant analysis with Cox proportional hazards regression modeling was used to identify independent predictors. Association between IPN and patients’ characteristics at baseline was evaluated using logistic regression.

Results: In total, 148 patients were included in this study. Overall mortality was 17%. Body mass Index, computed Tomography Severity Index (CTSI) ans persistent (>48H) organ failure (OF) were independently associated with overall mortality. 36 patients died (24.4%) of documented mesenteric ischemia during the early phase (<8 days) and 3/10 patients during the late phase (>8 days). IPN was present in 62 patients (43%), all requiring an intervention (i.e. radiological, endoscopic, and/or surgical). 35% of patients (22/62) had only one modality of drainage (radiologic or transgastric) and did not require any necrosectomy. For 30 patients (48%), additional necrosectomy was needed because of lack of improvement after drainage alone. 10 patients (17%) had only necrosectomy without prior drainage procedure. Complications such as hemorrhage and perforation of visceral organs occurred more frequently in the IPN group (14% vs 19.4%, p < 0.001 and 9% vs 8.5%, p = 0.02 respectively). The late phase mortality (>8 days) was significantly higher in the IPN group (14.5% vs 14%, p < 0.01). In multivariate analysis, factors associated with IPN were number of OF and postsplenomenosenteric venous thrombosis (table 1). 39 patients (68%) received anticoagulants with a median time of 6 [3–6] months and among them, 25 patients developed cavernoma, irrespective of whether or not they receive systemic anticoagulants (p = 0.31).

according to the revised Atlanta classification. Univariate and multivariate analysis were performed.

**Results:** The median fluid sequestration in the first 48 h after hospitalization was 4.7 liter (2.8–6.8 L). It was 3.2 L (1.4–5.1), 6.4 L (3.6–9.5 L) in those without necrosis and those with necrosis, and 7.5 L (4.4–12 L) in those with persistent organ failure. The univariate and multivariate analysis showed that alcohol etiology, an increasing number of SIRS criteria and Hematocrit were significantly associated with increased fluid sequestration (Table). Body mass index, APACHE II score, sodium, creatinine and blood urea nitrogen levels did not help predict fluid sequestration. Patients with and without acute fluid collections had a median sequestration of 7.2 and 4.2 L (p < 0.001), respectively. 22 patients died (7.3%); median fluid sequestration in the patients who died was 6.5 L compared to 4.2 L among the patients who survived (p = 0.05). Increased fluid sequestration was associated with prolonged hospital stay (p < 0.005). There were 62 female (48.4%) with a mean age of 71 in each group. A total of 17 patients with HR developed PEP (13.2%). The PEP rate in PPS group was significantly lower than in non-PEP group (6.3% vs 20.0%; p = 0.019). Mean post-ERCP 2 h amylase levels were 4.7 liter (2.8–6.8 L) in those without necrosis compared to 2.8 liter (1.4–5 L) in those with necrosis (p = 0.001). There were a total of 216 patients with two above risk factors (HR group). Of them, 30 patients developed PEP (13.9%). Using logistic regression, propensity scores were used to prevent selection bias between with and without PPS. The covariates entered in the propensity model were age, gender, native papilla, endoscopic biliary stent, endoscopic metallic stent, pancreatic guidewire, pancreatic injection, endoscopic sphincterotomy, precut, endoscopic papillary balloon dilation, pancreatic duct brush. Subsequently, 1-to-1 matched PPS and non-PPS group (each N = 64) were extracted from the cohort using the closest matching score.

**Results:** After matching, mean propensity matching score in PPS and non-PPS group were 0.46 ± 0.2 and 0.46 ± 0.2 respectively. There were 62 female (48.4%) with a mean age of 71 in each group. A total of 17 patients with HR developed PEP (13.2%). The PEP rate in PPS group was significantly lower than in non-PEP group (6.3% vs 20.0%; p = 0.019). Mean post-ERCP 2 h amylase levels were 4.7 liter (2.8–6.8 L) in those without necrosis compared to 2.8 liter (1.4–5 L) in those with necrosis (p = 0.001). There were a total of 216 patients with two above risk factors (HR group). Of them, 30 patients developed PEP (13.9%). Using logistic regression, propensity scores were used to prevent selection bias between with and without PPS. The covariates entered in the propensity model were age, gender, native papilla, endoscopic biliary stent, endoscopic metallic stent, pancreatic guidewire, pancreatic injection, endoscopic sphincterotomy, precut, endoscopic papillary balloon dilation, pancreatic duct brush. Subsequently, 1-to-1 matched PPS and non-PPS group (each N = 64) were extracted from the cohort using the closest matching score.

**Conclusion:** Alcohol etiology, increased number of SIRS criteria, hemococoncentration and younger age were independent predictors of increased fluid loss. Patients with increased sequestration of fluid are at higher risk of local complications and prolonged stay.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### Reference
Introduction: We started our original EPDBD (endoscopic pancreatic duct balloon dilation) therapy for pancreatic diseases in 1996. In these 22 cases, 698 cases were treated by this method. We would like to show its usefulness and safety.

Aims & Methods: The balloon (6 mm diameter, 15 mm long -Boston Scientific) was inflated in the stenotic portion of the pancreas ducts at 6 atm. pressure for 1 minute several times. Then stone removal or EPS (endoscopic pancreatic stent implantation) were evaluated: first the free rate and stone relapse rate in 586 pancreatic stone cases treated by EPDBD 2. The prognoses of 114 EPS-successful pseudocyst cases treated by EPDBD 3. The prognoses of 16 EPS-successful divisum cases (complete type 6, incomplete type 10) treated by EPDBD 4. Thus an additional advantage of making a diagnosis of ampullary/papillary stones and biliary obstruction which can be treated endoscopically. It can guide whether endotherapy needs to be performed through major or minor papilla. EPS by diagnosing pancreatic tumour/strictures missed on other imaging modalities allows early diagnosis and hence improves long-term prognosis. It can prevent unsuccessful attempts at endotherapy and its possible risks/costs. We conclude that EPS before endotherapy plays an important role regarding further management decisions in patients with CP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: By EPDBD therapy, the relapse rate of pancreatic stone decreased, and the success rate of endoscopic drainage and stenting in pseudocyst and divisum increased markedly with minor complications, and their prognoses were good. EPDBD is a safe and favorable procedure for pancreatic diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: The purpose of EPDBD therapy for pancreatic stone was to use endoscopic procedures in the pancreatic duct and stone removal, and to reduce stone relapse rates. 568 cases of pancreatic stone were treated by EPDBD. They consisted of 90 cases treated by endoscopic sphincterotomy, minor papilla 28, and 478 cases treated by ESWL+ endoscopic method (via major papilla 381, minor papilla 97). After EPDBD therapy, the stone free rate was 75.5%, the pain free rate 97.1%. The stone relapse rate was 5.7% - this is a much lower result compared to other reports. We think that EPDBD contributes to this good result. Complications of EPDBD therapy were only minor bleeding from orifice at the therapy and mild pancreatitis after therapy for several days. Case A; 22 y/o male, idiopathic chronic pancreatitis, pancreas stone: After 4th ESWL, small stones remained in the head duct which can’t be removed by basket catheter and severe pain continued, so EPDBD was done under good informed consent. After several dilation of the orifice and the head duct, complete removal was easily. This is our first case of EPDBD. In our hospital, EPS and ENPD (endoscopic nasal pancreatic drainage) are the preferred choice for pancreatic pseudocyst therapy after dilatation of the stenotic duct. 114 cases were successfully treated without major complications, and their prognoses were good.

Conclusion: By EPDBD therapy, the relapse rate of pancreatic stone decreased, and the success rate of endoscopic drainage and stenting in pseudocyst and divisum increased markedly with minor complications, and their prognoses were good. EPDBD is a safe and favorable procedure for pancreatic diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.

EPDBD is a safe and favorable procedure for pancreatic diseases.
This was done in consideration of the current knowledge about lesions mimicking cancer in the setting of a normal pancreatic parenchyma or evidence of signs of pancreatic neoplasms.

Aims & Methods: Retrospective analysis of prospectively collected data in our tertiary University center. From March 2007 to October 2015, 218 (124 men, 94 women; median age 60 ±14 years) patients underwent EUS for suspected solid pancreatic neoplasm because of cross sectional imaging results, idiopathic acute pancreatitis, weight loss, pancreatic hyperechogenicity, painless jaundice and elevated Ca 19-9 values. Cystic pancreatic lesions, pseudocysts and cystic pancreatic carcinomas were excluded from the analysis.

Results: Malignant lesions were diagnosed in 98 (45%) patients. 54 patients (24.8%) underwent surgery and 61 patients (28% of all patients) underwent clinical follow-up (16.5 ±2.73 months, 18 needed surgery. 43 lesions not undergoing surgery needed EUS follow-up before achieving final diagnosis: pancreatic cancer (n = 6, 9.8%), neuroendocrine tumor (NET) (n = 10, 16.4%), paradoxe- nal neoplasms (n = 5, 8.9%), chronic pancreatitis (n = 13, 21.3%), necrosis (n = 3, 4.9%), autoimmune pancreatitis (AIP) (n = 3, 4.9%), microcystic serous neoplasms (n = 1). EUS showed sensitivity and specificity for malignancy of 77.8% and 94.4%, respectively.

Conclusion: Diagnostic accuracy of EUS is lower in the presence of pancreaticitis. Focal autoimmune pancreatitis and paradoxic neoplasms are still confused with malignancy in the setting of an inflamed pancreatic parenchyma. EUS in the setting of a normal parenchyma is an excellent tool to exclude pancreatic cancer. Tumor markers like Ca 19-9 and IgG4 values should be measured in the evaluation of pancreatic masses, also in the setting of chronic pancreaticitis. Clinical and imaging follow-up with EUS may be useful indicators of malignancy both in the setting of normal and inflamed pancreas.

Patients without pancreatitis the presence of enlarged lymphnodes or a mass in EUS, weight loss and worsening diabetes are predictor of malignancy. In patients with pancreatitis and without jaundice Ca 19-9 sensitivity for malignancy was 95% and specificity was 39%. In the paradoxoncasis group (n = 121) and 44% and 87.1% in the pancreatitis group (n = 97). Ca 19-9 elevation, rapid onset jaundice, double duct sign are useful indicators of malignancy in both the setting of normal and inflamed pancreas.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic cancer is characterized by a high density of stroma. Interactions between tumor and stromal cells play a critical role in tumor pro- greSSION and there is increasing evidence that pancreatic stellate cells (PSCs), a main component of the stroma, may participate in the development of pancreatic cancer[1]. However, details of the mechanism underlying the interaction between PSCs and pancreatic cancer cells (PCCs) are poorly understood.

Stromal cell-derived factor (SDF-1) or CXCL12 belongs to the CXC chemo- kinase family and is the ligand of CXCR4 [2]. It has been implicated in promoting the metastatic potential of breast, gastric, ovarian, prostate, lung and pancreatic cancer cells. Although SDF-1R-1 of SDF-1 in pancreatic cancer cell lines are related to proangiogenic properties, PSCs samples [3], suggesting that SDF-1 produced by activated PSCs may be an integral factor in tumor-stroma interactions.

Galecit-1 mediates communication between cells by binding to glycol-conju- gated proteins on the cell surface. Studies have shown that it is involved in multiple cancer-related processes, including immunosuppression, angiogenesis and metastasis [4]. We previously reported that Galecit-1 was highly expressed in pancreatic cancer tissues; furthermore, the primary source of Galecit-1 was in activated PSCs within the stroma of cancer cells [5]. It has previously been hypothesized that Galecit-1 may also induce activation of PSCs and stimulate secretion of chemokines [6]; however, the biological mechanism and its activities in PCCs are unclear.

Aims & Methods: The purpose of this study was to identify the effect and elu- ded the biological mechanism of Galecit-1 in PSCs and its role in tumor progres- sion in pancreatic cancer.

Results: By conducting a chemokine antibody array assay and transwell invasion and migration assays we were able to show that Galecit-1 induced secretion of SDF-1 in PSCs patients increased SDF-1 production and invasion of NF-κB activity assay indicated that the mechanism involved activation of NF-κB.

Conclusion: This study suggested that enhanced expression of Galecit-1 in stromal PSCs promotes metastasis in PDAC, thereby offering a potential target in the treatment of pancreatic cancer.

References
mural nodules, it is useful to analyse genetic mutations of cystic fluids or walls. Currently, adequate samples from EUS-FNA were unavaible and in some cases, we could not make a pathological diagnosis. Even in such cases, genetic analysis and the subsequent diagnosis of malignant or benign tumours may be possible. We could identify several cancer-related genes, such as GNA12, TRP53, BxPC3, and BRAF.

Conclusion: In this study, we performed whole-genome sequencing of samples obtained from IPMN or PDA using EUS-FNA. Consequently, genetic analysis by NGS may be effective in addition to pathological diagnosis when deciding the management of pancreatic tumours.

Introduction: The ubiquitously expressed non-receptor protein tyrosine phosphatase SHP2, encoded by *PTEN*, is involved in the regulation of multiple signaling cascades. SHP2 was the first reported oncogenic tyrosine phosphatase, although more recently demonstrated tumor suppressive properties as well. SHP2 has been proven to be required for proper wild-type RAS activation, yet studies addressing the relevance of SHP2 for mutated KRAS dependent cancers, such as pancreatic and lung cancer are lacking.

Aims & Methods: Our research is to study whether circHIPK3 can promote proliferation of pancreatic carcinoma cell line, BxPC3, and to explore the mechanism of circHIPK3 in cell proliferation. Cell viability was determined by cell counting kit-8 (CCK-8). Transient knockdown of circHIPK3 using specific RNA targeting the conjunction of circHIPK3. Overexpression of mir-124 was transfected with synthetic mirRNA mimic. Real-time quantitative reverse transcription-polymerase chain reaction (qRT-PCR) was performed to detect circHIPK3, mir-124 and miRNAs. The expressions of STI5, p-STAT3, IL-6R were measured by Western blot. Overexpression of STAT3 with STAT3 plasmid. Dual-Luciferase Reporter Assay was performed to detect the interaction of circHIPK3 and mir-124.

Results: circHIPK3 was upregulated in BxPC3 compared to human pancreatic duct epithelial cells (HPDE6-C7). Knockdown of circHIPK3, which didn’t affect the linear transcript, significantly decreased cell viability of BxPC3. Bioinformatical analysis and luciferase assay demonstrated that circHIPK3 interacts with miR-124-3P. Western blot confirmed that knockdown of circHIPK3 decreased the expression of IL-6R. In contrast, miR-124 repressed BxPC3 cell proliferation which was negatively regulated STAT3, IL-6R via interacting with 3'-UTR (untranslated region). qRT-PCR confirmed that both P151 and STAT3, p-STAT3 and IL-6R were upregulated in BxPC3 cells than HPDE6-C7 cells while mir-124 was downregulated.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Circular RNAs (circRNAs) are a novel class of noncoding RNAs that are stable against RNase R and 3’end. Increasing reports have shown that circRNA is dysfunction in neuro system diseases, cardiovascular diseases, human cancers and many other diseases. circRNA have been demonstrated involving in tumorigenicity, proliferation, apoptosis, angiogenesis, migration, invasion and metastasis in human carcinoma. circRNA can act as microRNA (miRNA) sponge and regulate the targets of miRNA. Circular RNA HIPK3 (circHIPK3) is originated from second exon of HIPK3 gene, which is upregulated in gastric, liver, esophagus. However, the mechanism remains unclear. Previous studies revealed that signal transducer and activator of transcription 3 (STAT3) as an oncogene that was activated in pancreatic carcinoma. Phosphorylation of STAT3 (p-STAT3) is a downstream target of interleukin 6 receptor (IL6R). Activation of STAT3 leads to malignancy of tumors, cell proliferation and migration. Knockdown STAT3 induces cell apoptosis by Bcl-xL, c-Myc, cyclinD1, etc. CircHIPK3 regulates BxPC3 cell proliferation through IL6R/STAT3 pathway. It may be a new target for the therapy of pancreatic carcinoma.

Aims & Methods: Our research is to study whether circHIPK3 can promote proliferation of pancreatic carcinoma cell line, BxPC3, and to explore the mechanism of circHIPK3 in cell proliferation. Cell viability was determined by cell counting kit-8 (CCK-8). Transient knockdown of circHIPK3 using specific RNA targeting the conjunction of circHIPK3. Overexpression of mir-124 was transfected with synthetic mirRNA mimic. Real-time quantitative reverse transcription-polymerase chain reaction (qRT-PCR) was performed to detect circHIPK3, mir-124 and miRNAs. The expressions of STI5, p-STAT3, IL-6R were measured by Western blot. Overexpression of STAT3 with STAT3 plasmid. Dual-Luciferase Reporter Assay was performed to detect the interaction of circHIPK3 and mir-124.

Results: circHIPK3 was upregulated in BxPC3 compared to human pancreatic duct epithelial cells (HPDE6-C7). Knockdown of circHIPK3, which didn’t affect the linear transcript, significantly decreased cell viability of BxPC3. Bioinformatical analysis and luciferase assay demonstrated that circHIPK3 interacts with miR-124-3P. Western blot confirmed that knockdown of circHIPK3 decreased the expression of IL-6R. In contrast, miR-124 repressed BxPC3 cell proliferation which was negatively regulated STAT3, IL-6R via interacting with 3'-UTR (untranslated region). qRT-PCR confirmed that both P151 and STAT3, p-STAT3 and IL-6R were upregulated in BxPC3 cells that HPDE6-C7 cells while mir-124 was downregulated. mir-124 was negatively correlated with circHIPK3 and STAT3, p-STAT3 and IL-6R.

Conclusion: Thus, as an integrator of RTK-Ras-MEK-ERK signaling downpathway, circHIPK3 driven genetically engineered murine models (GEMM) of pancreatic ductal adenocarcinoma (PDAC) and non-small cell lung cancer, CRISPR/Cas9 mediated gene knockout in vitro, murine models (GEMM) of pancreatic ductal adenocarcinoma (PDA) and are also associated with multi-
Aims & Methods: Twenty concomitant PDAs and IPMNs (39 samples, including concurrent lesions) from surgically resected patients were enrolled in this study. Resected pancreata were sliced at 5-mm intervals for whole-section histological analysis, and the distance between PDA and IPMNs was measured using precise pathological mapping. Target amplicon sequencing that covers 18 PDA-associated genes including KRAS, GNAS, TP53, SMAD4, CDKN2A, CTNNB1 and RNF43, was performed using Ion PGM™ system (Thermo Fisher Scientific). Protein expression of TP53, SMAD4, p16, b-catenin, and RNF43 was also analyzed immunohistochemically.

Results: KRAS mutations were detected in 19/20 (95%) of PDAs and in 38/39 (97%) of IPMNs. “Adjacent” concomitant PDAs, defined as those that are 5 mm or less away from the IPMN (n = 23), had identical mutations in 21/23 (91%) of PDAs and in 29/39 (74%) of all IPMNs, but not in PDAs, supporting de novo neoplastic lesions via the main pancreatic duct between PDAs and IPMNs had identical KRAS mutations. In contrast, 7 of 9 “distant” concomitant PDAs, defined as those greater than 5 mm away from the IPMN (n = 9), possessed distinct KRAS mutations from the index IPMNs (KRAS identical; n = 8, 72%, KRAS different; n = 3, 27%).

Conclusion: Distinct KRAS mutations from the index IPMNs and in 29/39 (74%) of all IPMNs, but not in PDAs, supporting de novo neoplastic lesions via the main pancreatic duct between PDAs and IPMNs had identical KRAS mutations. The contrast, 7 of 9 “distant” concomitant PDAs, defined as those greater than 5 mm away from the IPMN (n = 9), possessed distinct KRAS mutations from the index IPMNs (KRAS identical; n = 8, 72%, KRAS different; n = 3, 27%).

Introduction: The pancreatic cancer is a leading cause of death in cancer carriers worldwide.

Aims & Methods: To study the polymorphism of the TP53 gene on the suppressor in pancreatic carcinoma and to evaluate proinflammatory cytokines (IL-1, TNF-α) in insulin blood serum levels at patients with various pathologies of the pancreas (cancer (PCa)), acute and chronic pancreatitis (OP and CP) with various geno-

Results: The presence of Arg/Arg genotype of the TP53 gene was 65% in patients with PCa, 49% in the control group. In patients with PCa there was no homozygotic genotype Pro/Pro, in the comparison group - 13%, p < 0.05. The frequency of Arg/Pro genotype was 35% in patients with PCa and 38% in the control group. The frequency of alleles of the TP53 gene in patients with PCa and in the comparison group was: Arg (82.5% and 68%), Pro (17.5% and 32%).

Conclusion: The concentration of insulin in different genotypes in patients with PCa did not differ significantly and was 7.5 ± 2.2 µM/l in Arg/Arg, Arg/Pro – 11.4 ± 5.1 µM/l, Pro/Pro – 14.6 ± 7.4 µM/l, p < 0.05. The level of IL-1β was significantly lower in patients with PCa than in patients with CP (5.1 ± 1.7, 2.0 ± 0.3 and 1.3 ± 0.2 pg/ml, respectively), p < 0.05. The level of TNF-α in the serum of patients with PCa was 3.5 ± 0.5 pg/ml, and did not significantly differ from the serum level of patients with CP and PCa - 3.4 ± 0.7 and 1.1 ± 0.2 pg/ml, respectively. In patients with PCa, the level of TNF-α was significantly lower than in patients with CP, p < 0.05. The levels of IL-1β in the serum of patients with PCa with different genotypes of the TP53 gene did not differ significantly and amounted to 1.1 ± 0.2 pg/ml in patients with the Arg/Arg genotype, with Arg/Pro genotypes of 1.2 ± 0.3 pg/ml, p > 0.05. The level of TNF-α in the serum of patients with the Arg/Arg genotype was 1.2 ± 0.2 pg/ml, and did not significantly differ from the level in the serum of patients with the Arg/Pro genotype - 1.3 ± 0.1 pg/ml.

Introduction: Pancreatic cancer (PC) is one of the most lethal diseases due to the
difficulty of early detection. There is no effective blood biomarker for screening.

Aims & Methods: The aim of this study is to confirm and develop our candidate metabolic biomarkers in blood of PC patients. Blood samples from PC patients were collected from 2017 to 2018. Seventeen candidate metabolites were selected from previous report. Quantitative analysis were performed by gas chromatography/tandem mass spectrometry (GC/MS/MS) together with their corresponding stable isotopes. In the 1st set, diagnostic models were constructed via multivariate logistic regression analysis. These results were validated using the 2nd set.

Conclusion: Quantitative analysis using GC/MS/MS confirmed the possibility of metabolomics-based screening methods for PC.

Introduction: Diagnostic yield from EUS-FNAC (fine needle aspiration cytology) has improved in the past few years with better tissue acquisition techniques. Core biopsy needles are now available but are more expensive than FNAC needles. We assessed the diagnostic yield and accuracy of FNAC samples processed for both cytology and histology.

Results: A total of 211 patients (118 male) were included. Samples were sent to cytology (n = 135; 107pancreas, 10 biliary, 7 lymph nodes, 11 other), or cytology & histology (n = 76, 56 pancreas, 12 biliary, 5 lymph nodes, 3 other). Sample adequacy was 80.7% and 98.7% (p = 0.0004). Diagnostic yield (64.4%, 94.7%) and accuracy (81.3%, 96.1%) was significantly better in the combined (histology & cytology) group (p < 0.0001, p = 0.003). Within the combined group, diagnos-

Introduction: In the revised international consensus guidelines for 2012 of the management of IPMN of the pancreas, resection is recommended for all main pancreatic duct IPMN. While in branch pancreatic duct IPMN (BD-IPMN), the indications for resection are more conservative. Cyst size $>$30 mm without “high-risk stigmata” can be observed without immediate resection. And EUS observation is recommended to decide a treatment strategy.

Aims & Methods: The present study was a retrospective investigation of surgical indication for BD-IPMN with worrisome features (WF). 466 patients with IPMN underwent pancreatic resection at 3 high volume centers in Japan between 1996 and 2014. Among them, 156 patients with BD-IPMN were enrolled this study. The investigation of predictors of malignancy was done for 10 factors: age at time of surgery, sex, presence or absence of symptoms, serum amylase, CA19-9, CEA, tumor location, size of mural nodules (MN), diameter of main pancreatic duct (MPD), and cyst size of branch pancreatic duct (BDP). In preoperative examination, endoscopic ultrasonography (EUS) and computed tomography (CT) were considered to be essential. For size of MN, EUS measurements were used in all 156 cases. For diameter of MPD and cyst size of BDP, the CT measurement value was used. In this study, BD-IPMN was defined as cases with cystic dilatation of BPD and the MPD diameter was considered $<$5 mm (International Consensus Guidelines 2012). According to the WHO histological classification of IPMN (2000), pathological diagnosis is classified as adenoma (IPMA), borderline (IPMB), and noninvasive and invasive carcinoma (IPMC).

Results: Pathological diagnosis was benign IPMN in 91 cases (58%) and malignant in 65 (42%). In univariate analysis CA19-9, MPD diameter, the sizes of MN and BPD cysts were significant factors. In multivariate analyses, size of MN (p = 0.0001) and cyst size of BPD (p = 0.0004) were independent predictors of malignancy, and in ROC analysis AUC for these factors was 0.74 and 0.72, respectively. Among 78 cases with WF (BPD cyst size $\geq$30 mm), 45 cases (58%) had malignant IPMN. The rate of malignancy was significantly higher than that of patients without WF (26%) (p = 0.0001). Among 78 WF patients, 54 cases had MN with EUS observation. The rate of malignancy in patients with MN was significantly higher than that of WF patients without MN (69% vs 33%). With 7 mm taken as the cutoff value for the size of MN, the diagnosis of malignant IPMN had sensitivity of 76%, specificity of 73% and accuracy of 74%. Cyst size of BPD without MN was present in 8 patients (8/54 = 17%) among 78 WF patients. Pathological findings of these patients were noninvasive carcinoma in 6, invasive carcinoma 2.

Conclusion: Algorithm for the management of BD-IPMN of International Consensus Guidelines 2012 was acceptable. Mural nodules observed with EUS showed high predictive ability in BD-IPMN patients with WF. However, about 15% of carcinoma patients did not have nodules, and the handling of the diagnosis of such cases is a problem for the future.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Cystic lesions of the pancreas represent a diagnostic dilemma as some of the lesions are non-neoplastic or benign, whereas others are malignant or have potential for malignant transformation. As indicated in a recent meta-analytic and systematic review, diagnostic accuracy of fine-needle aspiration (FNA) cytology, it is only impossible to obtain sufficient cellular material when diagnosing these lesions with current modalities [1]. Recently, a novel biopsy forceps (Moryz6,7, US Endoscopy, Mentor, USA) has become available. It can be introduced through a 19 G FNA-needle, enabling the endoscopists to obtain histological specimens from the pancreatic cyst wall for the first time [2].

Aims & Methods: The aim of this study was to evaluate the use of the novel micro-forceps in a multicenter clinical setting. The patients referred for EUS evaluation of pancreatic cysts were included retrospectively from five European tertiary centers. Inclusion criteria were age of 18 or above and a pancreatic cyst of a size that allowed for FNA puncture. Exclusion criteria were pregnant or lactating females. A standardized data collection sheet including the information about patient demographics, cyst size, EUS/FNA findings, technical and clinical success, and the results of the biopsies taken was sent to the collaborating centers. Technical success was defined as successful puncture of the pancreatic cyst, subsequent successful extraction of the micro-biopsy forceps, and extraction of at least one micro-biopsy. Clinical success was defined by obtaining useful histological results.

Results: Twenty patients were included. There was a slight overrepresentation of female patients (n = 12, 60%) and the median age was 65 (range: 41–80). The patients had a median cyst size of 30 mm (range: 15–130 mm) and a median procedural time was 30.5 min (range: 17–58 min). We report a technical success rate of 85% (n = 17) - technical failure was only seen in transdudoreal puncture (n = 3, 15%). Biopsies were generally of good quality and contributed to the diagnosis in 14 patients (clinical success of 82%). Among these, there were ten cases of intraductal papillary mucinous neoplasia, two serous cystadenomas, and one autoimmune pancreatitis. Two mild adverse events were recorded (10%), a case of re-admission due to non-specific abdominal pain and a mild acute pancreatitis.

Conclusion: The use of micro-biopsy forceps was until now only reported in case reports of rare and larger-scale feasibility study (ERCP). We conclude that the use of the micro-forceps seems feasible and safe with acceptable rates of technical and clinical success. However, prospective studies are needed in order to determine diagnostic potential of this instrument compared to the other modalities currently used.

P0131 PANCREATIC DUCTAL CYTOLOGY: AN UNDERUSED DIAGNOSTIC TOOL

A. Peixoto, P. Pereira, E. Rodrigues-Pinto, F. Vilas-Bonas, J. Lopes, G. Macedo Centro Hospitalar De Sao Joao, Porto/Portugal

Contact E-mail Address: armandoaf5@gmail.com

Introduction: The diagnosis of pancreatic malignancy can be performed by brush cytology of the common bile duct or main pancreatic duct (MPD) during endoscopic retrograde cholangiopancreatography (ERCP). We report our experience in the execution of MPD brush cytology. ERCPs between 2014 and 2015 that involved brush cytology of pancreatic strictures were included. Cytologies were obtained using the Brush Master V (Olympus Medical System). Histological evaluation was performed by two experienced cytopathologists.

Results: Of the 18 patients evaluated, 16 were men and 2 women, with a median age of 62 years (range: 43–89). All patients underwent abdominal computed tomography and 3 patients had magnetic resonance imaging. In addition to pancreatic strictures, abdominal ultrasound showed prevalved cephalaronal lesions in 51% findings suggestive of chronic pancreatitis in 28%, pancreas divisum in 6%, and pancreatic inflammatory features in 6%. The distribution of the stricures was: head - 16, head and body - 1, tail - 1. The pancreatic duct was dilated in 16 patients (median of a median of 6.5–15). The diagnostic yield of MPD brush cytology for pancreatic cancer: sensitivity - 81.8%, specificity - 100%, positive predictive value - 100%, negative predictive value - 77.8%, accuracy - 88.9%. Sixty-one percent (n = 11) of the patients had a final diagnosis of pancreatic adenocarcinoma, 5.6% (n = 1) of neuroendocrine tumor and 33.3% (n = 6) inflammatory stricture. All the adenocarcinomas lead to strictures in the head of the pancreas. The diagnosis of neuroendocrine tumor was made by
endoscopic ultrasonography fine needle aspiration. One patient developed mild pancreatitis (6.5%).

Conclusion: In patients with suspected cephalopancreatic adenocarcinoma referred for ERCP, MDP brush cytology may be performed beyond biliary cytology, as it may improve cytologic diagnosis of malignancy without increasing complications rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0132 ANALYSIS OF PROGNOSTIC FACTORS IN Pancreatic METASTASIS: A RETROSPECTIVE ANALYSIS

Introduction: Pancreatic metastases (PM) account for 1–2% of pancreatic tumors. Several cancer types metastasize to the pancreas, but even recently developed cross-sectional imaging modalities have difficulties distinguishing PM from primary pancreatic tumors. Moreover, their prognostic significance is poorly defined.

Aims & Methods: The aims of this study were to clarify the incidence of primary tumors leading to PM, the clinical characteristics, and prognoses, and to define the prognostic factors for survival. A retrospective analysis was performed at 39 Japanese tertiary referral hospitals between January 2005 and August 2015, after receiving approval from the institutional review board of each hospital. We identified the patients based on data obtained from each institutional database, and analyzed patient and tumor characteristics, and survival time. All the patients enrolled in the analysis were histopathologically or cytologically diagnosed with PM. Kaplan-Meier analysis and Cox’s proportional hazard models were applied to evaluate overall survival and survival analysis, respectively.

Results: We enrolled 159 patients (median age 74.5 years) with a pathologic diagnosis of PM. The most common primary tumor was renal cell carcinoma (38.4%, n = 61), followed by lung cancer (24.5%, n = 39), colorectal cancer (11.3%, n = 18), sarcoma (6.3%, n = 10), breast cancer (6.3%, n = 10), and other cancer (n = 21). At the time of the diagnosis of PM, 38 patients (24%) had at least one tumor-related symptom. Additional extra-pancreatic metastases were diagnosed in 94 patients (59%). Sixty-four patients (40%) underwent surgery. In 52 patients (32.7%), PM had a median overall survival of 43.0 months, with 3- and 5-year survival rates of 52.5% and 42.6%, respectively. Among the five frequent primary sites of PM, prognoses of RCC, breast cancer, and colorectal were better than those of lung cancer and sarcoma. Univariate Cox proportional regression analysis identified four prognostic factors: pancreatic resection (hazard ratio [HR] 0.31, 95% confidence interval [CI] 0.18–0.57, p < 0.001), extra-pancreatic metastases (HR 3.07, 95%CI 1.71–5.11, p < 0.001), tumor-related symptoms at diagnosis (HR 3.38, 95%CI 1.29–8.65, p < 0.001), and pathologic diagnosis of primary tumors (p < 0.001). Multivariate Cox proportional regression analysis identified three independent prognostic factors: extra-pancreatic metastases (HR 2.13, 95%CI 1.11–4.07, p = 0.02), tumor-related symptoms at diagnosis (HR 5.39, 95%CI 2.92–9.91, p < 0.001), and pathologic diagnosis of primary tumors (p < 0.001).

Conclusion: Treatment strategies and prognoses for PM completely differ according to the primary tumor type. A definitive pathologic diagnosis of PM is essential for selecting the appropriate treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: New lesions (metachronous pancreatic cancer) and recurrence may develop in pancreas after initial treatment for pancreatic cancer and Intraductal Papillary Mucinous Neoplasm (IPMN). Endoscopic ultrasonography (EUS) is proved as a more specific and sensitive method for pancreatic lesion. However, there is no report about EUS after pancreatostomy. If it is possible to observe lesions to remnant pancreas under the EUS, remnant pancreatic cancer may be pointed out an early stage.

Aims & Methods: The aim of this study was retrospectively to investigate the observation ability of EUS for remnant pancreas. In this retrospective study, 44 patients who underwent EUS for remnant pancreas were enrollment. The definition of observation under the EUS for remnant pancreas was as follows, total observation for remnant pancreas observed from linear white line (anastomotic part) to opposite side pancreas, otherwise it was insufficient observation. We compared the detection rate of EUS findings and that of CT or MRI findings.

Results: Among the 395 patients who underwent pancreatostomy at the JA Onomichi General Hospital between December 2002 and March 2016, the enrolled patients were 44 who underwent EUS for remnant pancreas. The enrolled patients were 44 who underwent EUS for remnant pancreas. In the surgical procedure, pancreaticoduodenectomy (PD) including pylorus-preserving PD (PDDP) and subtotal stomach-preserving PD (SSPPD) was 20 cases and distal pancreatectomy (DP) was 24 cases. Total observation of remnant pancreas was possible in 41 cases (93%). Seven of 44 cases showed the lesion of recurrence in the remnant pancreas. Although CT or MRI was able to point out it in only 2 cases, EUS was able to point out it in the remnant pancreas of all cases. Stage of six cases were as follows, 1 case of stage 0, 2 cases of stage Ia, 3 cases of stage IIIb. The other case was IPMN. We were able to perform EUS-FNA for lesion in remnant pancreas in 24 cases. Pathological results were positive in 5 cases. One of the other 2 cases was negative (class II), but it was a recurrence by surgery. The other case was strongly suspected to recurrence by Positron emission tomography (PET-CT). EUS-FNA was performed in 4 out of 7 cases. The sensitivity of EUS-FNA was 71.4% (5/7), the specificity was 85.7% (6/7) and the accuracy was 71.4% (5/7). In addition, a comparison of detection ability of EUS and CT or MRI findings showed that EUS was significantly superior to CT or MRI (P < 0.001).

Conclusion: EUS was able to observe remnant pancreas in almost cases. We were able to perform EUS-FNA for lesion in the remnant pancreas. In addition, the detection ability of EUS was significantly superior to that of CT or MRI. We believe that EUS and EUS-FNA should be underwent for lesion in remnant pancreas, and that remnant pancreatic cancer may be pointed out an early stage.

Disclosure of Interest: All authors have declared no conflicts of interest.
pared with 33.1 months (95% CI, 9.0–27.2) in the 2nd PDAC group (N: 259 vs. 210; median 40.7 vs. 65.0 months). The group of patients who received chemotherapy, the median OS was 10.7 months (95% CI, 10.0–11.4) in 1st PDAC compared with 10.8 months (95% CI, 9.2–12.3) in 2nd PDAC (N: 1094 vs. 66, p = 0.952).

Abbreviations: PDAC, pancreatic ductal adenocarcinoma; SD, standard deviation; HR, hazard ratio; CI, confidence interval.

Conclusion: Second primary pancreatic cancer had a higher rate of resectability, and there was no difference in the effectiveness of curative surgery and chemotherapy between 2nd and 1st PDAC. Therefore, when curative surgery for 2nd PDAC should be conducted similarly to curative surgery for 1st PDAC. Considering the increased risk of 2nd PDAC in cancer survivors and the fact that surgery is the only curative treatment for this fatal cancer, more efforts are needed to develop screening programs for second primary pancreatic cancer in cancer survivors.

P0138 FEASIBILITY OF GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION WITH CONTINUOUS LOW-DOSE ASPIRIN FOR PATIENTS ON DUAL ANTIPLATELET THERAPY

Gastroenterology, New Tokyo Hospital, Matsudo, Chiba, Japan

Contact E-mail Address: natsuyama@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) for gastric neoplasms with continuous low-dose aspirin (LDA) is comparatively acceptable according to recent guidelines [1–3]. This study aimed to evaluate risk factors for post-operative bleeding after gastric ESD with continuous LDA for patients on dual antiplatelet therapy (DAPT).

Aims & Methods: This retrospective study was conducted at New Tokyo Hospital. A total of 597 gastric neoplasms (496 with early gastric cancers and 101 with gastric adenomas) in 371 consecutive patients were treated with gastric ESD between January 2010 and October 2016. A total of 102 lesions were excluded from this study: 51 lesions due to anti-coagulation therapy; 25 lesions in patients receiving antiplatelet therapy excluding single-LDA and DAPT; and 26 lesions in patients who underwent ESD for more than 5 lesions at the same time. Thus, a total of 495 patients were enrolled in this study. The patients were categorized according to antiplatelet therapy (APT). APT was defined as follows: oral administration of single-LDA (aspirin [100 mg/day]) or DAPT [aspirin (100 mg/day) plus clopidogrel (75 mg/day)]. Logistic regression analysis was performed for risk factors of bleeding after gastric ESD.

Results: The patients were categorized into two groups: no APT (n = 370) and APT (n = 125). APT included single-LDA (n = 74) and DAPT (LDA plus clopidogrel; n = 51). Among them, 46 received continuous LDA on single-LDA and 40 received continuous LDA on DAPT. The postoperative bleeding rate in the APT group was significantly higher than that in the no APT group (16.0% vs. 5.9%; P < 0.001). Postoperative bleeding occurred in seven and nine patients in the continuous single-LDA group (15.2%) and the continuous LDA on DAPT group (22.5%), respectively. In multivariate analysis, specimen size of ≥40 mm (odds ratio [OR] 3.19; 95% confidence interval [CI], 1.65–6.16; P < 0.001) was a sole independent risk factor for postoperative bleeding (Table 1). In subgroup analysis among APT users, continuous single-LDA and continuous LDA on DAPT were not related to postoperative bleeding.

Table 1. Multivariate analysis for postoperative bleeding after ESD.

</tr>
</tbody>
</table>

Conclusion: This study suggests that continuous LDA may be acceptable for gastric ESD in patients on DAPT. However, patients with continuous LDA on DAPT should be monitored carefully for postoperative bleeding after gastric ESD because the rate of postoperative bleeding in the continuous LDA on DAPT group was higher than that in the other groups.

Introduction: Peroral endoscopic myotomy (POEM) has received wide acceptance as a useful alternative treatment for chronic and small-scale studies are ample but long-term large-scale studies are few.

Aims & Methods: The aim of this study was to systematically analyze our long-term results of POEM, with particular emphasis on POEM failures and associated factors. This is a single center study. Consecutive POEM patients between Aug, 2010 and Dec, 2012 were included. Kaplan-Meier survival function was used to estimate clinical success rate at each year. The Cox proportional hazards model was used to analyze risk factors related to recurrence.

Results: A total of 124 consecutive patients were included. Male patients were more common than female patients (54.8% vs 45.2%). The median age at the time of POEM was 51 years (range 23–77). The mean period since the onset of symptoms was 4 years (range 0.5–21). As a result of the POEM, 111 patients (89.2%) obtained clinical improvement, and one patient died. Among the patients who had clinical improvement, the Eckardt score was improved in 65 patients (57.7%), the lower esophageal sphincter (LES) pressure was improved in 30 patients (26.4%) and the Eckardt score was not changed in 16 patients (14.1%).

Conclusion: POEM is a highly safe and effective treatment for esophageal achalasia with favorable long-term outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

among two groups. As sub-analyses, the cutting time, rate of en-block/resection and rates of adverse events were evaluated among two groups.

**Results:** Propensity score matching analysis created 46 matched pairs. Adjusted comparisons between two groups showed a significantly smaller usage rate of hemostatic forceps in ESD-N than that in ESD-C (4.35% vs 84.8%, p < 0.01), and shorter treatment time (en-block-resection rate: 100% vs 69.8%, p = 0.03; complete resection rate: 97.8% vs 100%, p = 1; cutting time: 84.6 min vs 83.0 min, p = 0.08; perforation during ESD: 0% in both groups).

**Conclusion:** Splash M-Knife® achieved better hemostasis and safer ESD for early gastric cancer by reducing usage of hemostatic forceps during ESD procedure.

**P0143 INTUBATION FAILURE DURING GASTROSCOPY – INCIDENCE, PREDICTORS AND FOLLOW-UP FINDINGS**

K. Siau1, J. L2, N. C. Fisher2, C.J.J. Mulder3, S. Ishaiq2
1Royal College Of Physicians, JAG Clinical Fellow, London/United Kingdom
2Department Of Gastroenterology, Dudley Group Hospitals NHS Foundation Trust, Dudley, United Kingdom
3Dept. Of Gastroenterology, VU University Medical Center, Amsterdam/ Netherlands

**Contact E-mail Address:** keith@siau.org

**Introduction:** Intubation failure (IF) when a trained endoscopist is unable to progress into the upper oesophagus via the oropharynx. The incidence is unknown, but estimated at 1.8%. There have been no studies exploring IF and follow-up findings. We aimed to assess the incidence, causes of IF, predictors of pathology in patients with IF, and follow-up findings.

**Aims & Methods:** We retrospectively identified all gastroscopies performed at a district general hospital between August 2010-August 2016 from an endoscopy database, and reviewed cases with IF. We excluded patients who had achieved oesophageal intubation. Data on sedation use, endoscopist status, indications, radiological and endoscopic findings were recorded. Procedural limitations were classified into 2 groups: failure to tolerate (e.g. pulling out scope, anxiety) and ‘failure to progress’. Statistical analyses were made using Pearson’s χ2 and Wilcoxon signed rank test.

**Results:** The incidence of IF was 0.95% (248/26130). 238 patients were identified, with a mean age of 63.2 (SD 16.1), with ‘failure to progress’ in 41 and ‘failure to tolerate’ in 197. Subsequent investigations included barium radiology (59.7%, n = 142), CT (21%, n = 50), repeat gastroscopy (29.4%, n = 70) and no further investigations (19.7%, n = 47). Structural pharyngeal abnormalities were diagnosed comprising of cricopharyngeal hypertrophy (CPH) [49%), Zenker’s diverticulum (ZD) [14%], pharyngeal web (12%), CPH with ZD (9.8%), cervical spondylosis (7.3%) and other (7.3%). Endoscopist status was a predictor of IF (OR for medical vs. non-medical endoscopist 0.7, 95% CI: 0.5–0.9, p = 0.007). Within the IF cohort, predictors of structural causes on barium radiology included: dysphagia (OR 5.5, 95% CI: 2.5–11.8, p < 0.001), failure to progress (OR 5.2, 95% CI: 2.3–12.0, p < 0.001) and age ≥ 65 (OR 4.9, 95% CI: 1.8–8.9, p < 0.001). Repeat gastroscopy was successful in 63/70 (2 using nasendoscope) after increasing midazolam dosage (mean increase = 1.5 mg, 95% CI: 1.0–2.0 mg, p < 0.001). Diagnostic yield for barium radiography, CT and repeat gastroscopy were 69.0%, 54.0% and 64.3% respectively. The concordance of endoscopic indication and pathology on further investigation for IF was 110/58 (98.6, respectively, for uninfected status, 78.8%, 90.0% and 94.2%, for eradicate status, and 67.1%, 91.4%, 59.6%, 93.6% and 21.7%, respectively, for infected status. High DORs were obtained for the following endoscopic findings: 32.2 for RAC, 7.7 for FGP and 4.7 for red spot in subjects as uninfected status, 12.0 for infected redness in subjects with eradicated status, and 26.8 for diffuse redness, 13.3 for mucosal swelling, 10.2 for sticky mucus and 8.6 for enlarged fold in subjects with infected status.

**Conclusion:** The Kyoto classification is useful for diagnosis of HP infection in daily clinical practice with high diagnostic accuracy. This study was registered as a clinical trial in UMIN (UMIN000016674) and was conducted with the approval of the ethics committee in our institution.

**Disclosure of Interest:** No disclosures.

**P0145 A RETROSPECTIVE AUDIT OF OUTCOMES AND CURRENT CLINICAL PRACTICE POST-BALLOON TAMPODATE FOR ACUTE SEVERE VARICEAL BLEEDING: HAVE THINGS IMPROVED OVER TIME?**

C. Keung1, A. Jackson2, M. Swan1
1Department Of Gastroenterology And Hepatology, Monash Health, Melbourne/Australia
2Department Of General Medicine, Monash Health, Melbourne/Australia/VIC

**Contact E-mail Address:** c.keung1@gmail.com

**Introduction:** Balloon tamponade, such as with Sengstaken-Blakemore tubes (SBT), remains the main immediate salvage therapy for acute variceal bleeding uncontrolled by variceal ligation or injection therapy. Previous cohort studies from the 1970–1980s report success rates of 40–94% for initial haemostasis but highlight bleeding rates of 40–70% on removal [1–3]. Despite guidelines recommending balloon tamponade as initial therapy in treating endoscopically uncontrollable variceal bleeding, specialists and trainees feel uncomfortable with SBT insertion [4] given the perceived difficulties and complications [5].

**Aims & Methods:** We aimed to retrospectively audit our current practice in the management of a SBT. Of these 42 patients, the majority were male (71%) with a median age of 55 years (range 34–78). Alcohol was the most common aetiology for cirrhosis (62%), with 65% actively drinking. Most patients had cirrhosis severity scores of Child-Pugh B (67%) or Child-Pugh C (29%) and a median MELD score of 16 (range 9–25). At the time of acute variceal bleed, 85% were haemodynamically unstable and 29% were encephalopathic. All received standard medical therapy with octreotide or terlipressin, antibiotics and blood products as required. The time to initial endoscopy from 1st onset bleeding was prompt (median 6.6 hours). Most bleeding varices were oesophageal (90%). Initial ligation/injection was performed in 64% with the remaining patients having such large volumes of blood in the UGI tract that satisfactory views were unable to be obtained. The current practice surrounding SBT insertion is shown in the table.
below. Re-look endoscopy post-SBT insertion was performed in 86% patients at a median of 39 hours after insertion with further endoscopic therapy in 47%. Complications of SBT insertion occurred in 31% and included minor oesophageal ulceration (9), significant oesophageal ulceration (3), aspiration pneumonia (4) and oesophageal perforation (1).

</tr>
</tbody>
</table>

Re-bleeding occurred in 45% patients during the admission despite SBT insertion, of which 79% did not survive. Seven other patients subsequently underwent a TIPS procedure for these still died. The median length of hospitalisation and intensive care and mechanical ventilation was 13 days (1-56), 6.2 days (0.3-36.2) and 120 hours (1-708) respectively.

Conclusion: Primary haemostasis was achieved in 93% of patients; however, re-bleeding occurred in 45% and was associated with a poor survival rate of 20%. Short and longer-term survival has not significantly improved since studies in the 1970s-1980s despite advances in pharmacological therapy. Current practices of SBT insertion are variable and would benefit from further education. Rates of direct visualisation of balloon position prior to inflation with endoscopy should be improved as with referrals for early TIPS.

PO146 CONSCIOUS SEDATION FOR ENDOSCOPIC SUBMUCOSAL RESECTION BY USING DEXMEDETOMIDINE

Department of Gastroenterology, Yamashita Hospital, Ichinomiya/Japan

Contact Email Address: e.m.6089@gmail.com

Introduction: To evaluate the feasibility and safety of the dexmedetomidine (DEX) for conscious sedation during endoscopic submucosal dissection (ESD).

Aims & Methods: This study was a prospective trial, and was conducted at the Yamashita Hospital. Between January 2016 and December 2016, all 50 patients were enrolled in this study. The inclusion criteria for the study was the presence of esophageal, gastric or duodenal tumors. The criteria for exclusion from this study is as follows: patients who were allergic to the drugs used, a body mass index over 35 at discharge, and patients who were sedated with DEX (an initial bolus infusion of 3.0 μg/kg/hour intravenously over 10 minutes, followed by a continuous infusion of 28 μg/kg/hour titrated). During sedation, midazolam (0.03 mg/kg) and pethidine (17.5 mg) were added intravenously as needed. If the level of sedation dropped to less than RASS -3, the intravenous DEX injection rate was reduced by 0.1 μg/kg/hour. If heart rate was less than 50 beats/minutes or systolic blood pressure was less than 80 mmHg, the intravenous DEX injection rate was reduced by 0.1 μg/kg/hour. If the patient’s heart rate was less than 50 beats/minutes, the patient was intravenously infused with atropine sulfate hyd (0.125 mg-0.25 mg). During procedure, the following parameters were measured continuously, and recorded every 5 minutes: heart rate, blood pressure, hemoglobin oxygen saturation (SpO₂), respiratory rate and RASS. As the achievement rate of conscious sedation during procedure, the percentage of the time that the depth of sedation from RASS – 1 to –3 during procedure were evaluated. Body movement leading to the interruption of ESD were recorded appropriately. After the procedure, all patients were infused with flumazenil (0.3 mg) and observed until the Aldrete score reached 9 points.

Results: During this study period, 50 patients with esophageal, gastric and duodenal tumors were identified as potentially eligible for participation. There were 37 males and 13 females, and the mean age was 67.5 ± 8.6 y. 27 patients regularly consumed alcohol and 5 patients use sleeping drugs regularly. Tumors were located in the following locations: 9 cases in the esophagus, 38 cases in the stomach, 3 cases in the duodenum. The mean tumor size was 23.8 ± 16.5 mm and the procedure time was 88.0 ± 59.5 minutes. The histologic results of ESD were squamous cell carcinoma (n = 9), adenoma (n = 17) and adenocarcinoma (n = 24). ESD by using DEX were successfully performed in all 50 tumors. No acute complications that were that were adverse occurred. The mean achievement rate of conscious sedation during procedure was 84.7 ± 16.5%. The median frequency of disturbance by patient’s movement was 0 times (range 0-3 times). 33 cases reduced and 14 cases discontinued a continuous infusion of DEX. In 23 cases, patient’s SpO₂ level was less than 90% and the mean time that the final administration of atropine sulfate hydrate was 35 min (range 5-140 min) after procedure. There was no case in lowering of systolic blood pressure less than 80 mmHg. Although in 7 cases, the patient’s SpO₂ level dropped to less than 90%, however, they recovered after the administration of oxygen into the nasal cannula. The mean time that the Aldrete score reached 9 or over was 7 ± 4 minutes. The median endoscopy and patient’s satisfaction score was 9 points (range 2-10 points) and 8 points (range 2-10 points). There were 30 patients (60%) who scored 9 points or over for endoscopy.

Conclusion: Conscious sedation with DEX is effective, safe and a high level of satisfaction for endoscopists and patients for upper gastrointestinal ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Preoperative diagnosis of invasion depth of superfi cial esophageal squamous cell carcinoma (SESCC) is very important to select appropriate therapeutic procedure. The Japan Esophageal Society (JES) classifi cation using narrow-band imaging with magnification (M-NBI) was eff ective for predicting invasion depth of SESCC1). Blue laser imaging (BLI) is an image enhanced endoscopy consisted of two different lasers with wavelength 410 and 450 nm as light source, which can enhance mucosal vascular and surface structure. In previous study, BLI with magnification (M-BLI) was useful for evaluating gastro-intestinal neoplasms such as predicting invasion depth or tumor detection2). We aim to investigate the diagnostic value of M-BLI by comparing that of M-NBI.

Aims & Methods: We aim to investigate the diagnostic value of M-BLI by comparing that of M-NBI. Our study was single center retrospective study and approved by the Ethical Review Committee of Kyoto Prefectural University of Medicine, and performed in accordance with the World Medical Association’s Declaration of Helsinki. All patients provided informed consent for undergoing both M-BLI and M-NBI. Consecutive 166 patients underwent endoscopic submucosal dissection (ESD) for esophageal tumor at Kyoto Prefectural University of Medicine between April 2014 and March 2016. Endoscopic images of SESCCs were recorded by both M-BLI and M-NBI prior to ESD. SESCCs were pathologically diagnosed by ESD specimens. Three endoscopists with no information of the lesions evaluated invasion depth of SESCCs using M-BLI and M-NBI images according to JES classification. The diagnostic value of each procedure was calculated.

Results: 124 SESCCs were analyzed in this study. The numbers of male/female were 104/20, respectively. Median age was 68.5 years old. Median size of tumor was 17.6 mm. The proportion of tumor location at U/M/Lt was 13/70/17%, respectively. The proportion of macroscopic type for 0-Ia/Ha-0/Ib-0/a was 10/66/23%, respectively. The proportion of invasion depth of the lesions subclassified as EP or LPM, MM or SM1, and SM2 were 80, 13 and 7% respectively. The overall diagnostic accuracy of BLI and NBI were 88.7% and 83.9% (P = 0.35), respectively. The intraobserver variability of three endoscopists with BLI and NBI was 0.679/0.560/0.559 and 0.568/0.822/0.560, respectively. The interobserver variability with BLI and NBI was 0.839/0.718/0.935 and 0.517/0.514/ 0.441, respectively.

Conclusion: M-BLI was efficient for diagnosing invasion depth of SESCC according to JES classification, similar to M-NBI.

Introduction: Endoscopic Ultrasound (EUS) has been found to be an effective tool in diagnosing pancreatic cystic neoplasms (PCN). Cystoeroxyronic antigen (CEA) tumor marker has also been used to differentiate PCN and is the most accurate marker of mucinous cystic neoplasms. Recently, needle-based confocal laser endomicroscopy (NCLE) has been increasingly used for the diagnosis of PCN. NCLE allows for evaluation of pancreatic cysts with results similar to that of a pathological diagnosis. In this study, we will compare our standard of care EUS with combined CEA and NCLE to determine which combination of diagnostic modalities is a better predictor of PCN.

Aims & Methods: In this retrospective chart review, 22 patients with pancreatic cysts were evaluated. Specificity and Negative Predictive Value (NPV) of EUS alone, CEA and nCLE combined were evaluated and diagnostic accuracy was compared with pathology using McNemar’s test. Worrisome features (increased cyst size, wall thickness, main pancreatic duct size, and presence of non enhanced mural nodules, abrupt changes, distal atrophy and lymphadenopathy) were tested by determining dissimilar calculations using Euclidean distance and later were used in hierarchical clustering to create two clusters based on diagnostic modalities.

Results: Diagnosis of PCN using EUS alone had a specificity of 0.75 and a NPV of 0.88. EUS and CEA had a specificity of 0.95 and a NPV of 0.90. Finally, EUS with CEA and nCLE combined had a specificity of 0.80 and a NPV of 0.94. Worrisome features clustering was able to predict pathology, p = 0.00259.

Conclusion: We concluded that specificity and NPV of EUS predicting PCN are positively impacted by the addition of CEA and nCLE. We also found that clustering of worrisome factors predicts pathology, however, a larger cohort is required for future studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) is accepted as the treatment of intestinal-type early-stage gastric cancer. However, ESD occasionally results in unfavourable outcome due to technical difficulties. Therefore, predictions of difficulties in ESD would preclude complications associated with ESD. Aims & Methods: The aim of this study is to determine the predictive factors of procedural difficulties in ESD. Between January 2009 and July 2016, 577 consecutive patients who underwent ESD for gastric neoplasms were enrolled. These patients were classified into 3 groups: group S, group L, and others. Group S comprised 30 patients who underwent ESD for the shortest duration (10–16 min). Group L comprised 30 patients who underwent ESD for the longest duration (149–215 min). Multivariate analysis was performed between Groups L and S using the following factors: location (cardia, posterior wall of angle, lesser curvature of lower gastric body and others), macroscopic type (protruded, depressed or mixed), size of the resected specimen, preoperative scar, number of preoperative biopsies, specimen type, distance to the previous perforation, number of preoperative biopsies, scar, and as predictor for submucosal fat tissue, body mass index, waist circumference, visceral fat tissue measurements on CT, blood test findings (glycated hemoglobin, triglyceride and total cholesterol), blood pressure, and heart rate before ESD.

Results: Significant differences were found regarding the number of biopsies (group L, 8.5; group S, 6.8; P = 0.0211), (group L, 616.7mm²; group S, 991.5mm²; P > 0.05), biopsy visualization of SCJ was lost at 92.0% (81/88) with FUSE-EGD. VAS at insertion, during and after examinations were 51.2 (10–75), 46.9 (0–75), and 45.2 (10–50) points, respectively, which were equivalent to conventional EGD. The ampullary adenoma was observed in all 3 patients with EGC and the openings of the biliary and pancreatic ducts of the ampulla of Vater were observed in all 2 cases with the ampullary tumors with FUSE-EGD. There were no adverse events associated with FUSE-EGD.

Conclusion: FUSE-EGD seems safe and effective for upper gastrointestinal examination, especially when the diagnosis of the ampulla of Vater and/or the anal side of the pyloric ring is necessary.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0151 LOCATION FEATURES OF EARLY GASTRIC CANCER TREATED WITH ENDOSCOPIC SUBMUCOSAL DISSECTION
Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of Korea

Contact E-mail Address: luckyace@hanmail.net

Introduction: Timely detection of early gastric cancer (EGC) is important in performing endoscopic submucosal dissection (ESD). We attempted to know the location characteristics where EGC is frequently detected and analyzed EGC characteristics associated with the location.

Aims & Methods: We retrospectively reviewed the medical records of patients with EGC treated by ESD between November 2008 and August 2016. We retrospectively and analyzed 647 EGC lesions.

Results: The patients’ mean age was 66.7±10.8 years. The predominant location was predominantly male (77.1%, 499/647). A well to moderately differentiated carcinoma was observed in 97.2% of patients. The common site was the lower part of the stomach (89.6%, 580/647). The highest percentage of EGC was found...
in the lesser curvature (43.9%, 284-647). Posterior EGC was more frequent in the mid- to upper parts, submucosal invasive EGC was found to be significantly different (odds ratio, 1.919; confidence interval, 1.014-3.623; p = 0.045).

**Conclusion:** Most of the EGCs resectable with ESD were found in the lower part of the stomach and lesser curvature of the stomach. The incidence of the posterior part in the mid- to upper part of the stomach was higher than that of anterior part. The EGc located in the mid- to upper part of the stomach was found to have a higher incidence of invasive cancer.

**P0152** A STUDY OF THE RECOGNITION OF ESOPHAGEAL IMAGES BY MACHINE LEARNING WITH CONVOLUTIONAL NEURAL NETWORK AND DEEP LEARNING

R. Yamakawa, M. Harada, K. Kawauchi, S. Nuzuki, M. Iwata

**Gastroenterology, Kaeuga Hospital, Niiuagata, Japan**

**Contact E-mail Address:** yamakawa_ra@niiuagata-mn.or.jp

**Introduction:** The recognition of general images by machine learning (ML) with the convolutional neural network (CNN) and deep learning (DL) is good. However, the possibility of the recognition of endoscopic images by ML with CNN and DL is undetermined.

**Aims & Methods:** The aim of this study was to clarify the possibility of the recognition of endoscopic images by ML with CNN and DL. We selected 816 endoscopic images of 8 categories which include laryngopharynx (LP), thoracic esophagus (TE), abdominal esophagus (AE), gastric fundus (GF), gastric body (GB), gastric antrum (GA), duodenal bulb (DB) and descending part of the duodenum (DD). Each category had approximately 100 images. These images were randomly separated into two groups, 60% (489 images) for learning and 40% (327 images) for testing. We increased the learning group images to 8313 by adding additionally rotated images of each five degrees. We made an ML model with three CNN layers, three Activation Function layers, two Max-Pooling layers and two Dense layers by TensorFlow and Keras. We trained the ML model with the learning group images (n = 8313) and then tested it with the testing group images (n = 327) to determine whether it can recognize the endoscopic site. Two members of our hospital staff performed the same test utilizing the same images.

**Results:** It took 73 minutes for the ML model to learn and 6 seconds to answer the test. The percentage of correct answers of the ML model was 70.6% in all categories (n = 327), 77.1% in LP (n = 48), 91.5% in TE (n = 47), 64.4% in AE (n = 45), 73.3% in GB (n = 38), 63.5% in GF (n = 39), 52.8% in GA (n = 36), 65.6% in DB (n = 32) and 71.4% in DD (n = 42). The average percentage of correct answers of humans was 95.4% in gastroenterologists (n = 5), 85.2% in junior residents (n = 2), 81.2% in endoscopy nurses (n = 5), 54.4% in medical clerks (n = 5) and 51.8% in floor nurses (n = 4).

The percentage of correct answers of the ML model was lower than those of humans who have knowledge about endoscopic images. However, it was higher than those of other humans who do not. We consider the possibility of the recognition of endoscopic images by ML with CNN and DL. Further study is necessary to confirm the ability of it because this study was conducted in a simple ML model with three CNN layers and a small number of images.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

In this study, a method to assess features of gastric lesions combined with similar features. Finally, lesions were identified by a support vector machine, which is a model for machine learning, and DL was detected. In this computational experiment, the accuracy of the system was verified by identifying 25 early-stage gastric cancer lesions (50 endoscopic images) using NBI-magnified observation at the Department of Gastroenterology, Murakami Memorial Hospital, Asahi University, Gifu.

**Results:** The average detection rate of the lesion area greatly improved to 63.0% with the proposed method compared with 28.8% with the conventional method. In addition, the obtained DL was similar to that indicated by an experienced medical physician. Based on these results, the proposed system enabled the automatic detection of early gastric cancer DL in narrow-band images, suggesting that the proposed system is useful for the determination of DL.

**Conclusion:** In this study, a method to assess features of gastric lesions combined with the use of superpixels was proposed. The average detection rate of the lesion area using the proposed method greatly improved compared with that using the existing method, enabling the detection of DL without depending on a physician’s experience.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Post-sleeve gastrectomy fistulas (PSGF) are major complication of bariatric surgery. Endoscopic management evolved from a fistula closure to an internal drainage (ID) strategy within the 2013 year. The main objective of this study was to evaluate these different endoscopic approaches.

Aims & Methods: This retrospective study included all patients treated for PSGF in a referral center. Closure management was defined as: initial treatment using covered-metal-stent and endoclips. ID management was defined as: initial treatment using nasojejunal tube and/or double-pigtail-steel. The failure was defined as: need for surgery, or death.

Results: Between 2007 and 2015, 100 patients (women: N = 78; mean age: 42 ± 12years) were included. The mean delay between SG and the first endoscopy was 92 ± 18 days. Overall success of endoscopic treatment was 86% within 6 ± 27months. Two patients died. Primary success of ID and closure management occurred in 19/22 (86%) and 49/77 (63%) patients, respectively. Among patients in failure of closure management, 22 had secondary ID (18 being successful). Success of initial management was significantly higher for ID (p < 0.05).

Factors associated with failure of closure management were in multivariate analysis: resection of tumors and/ or diameter of stent greater than 6 cm (OR = 2.22; p = 0.05) or BTM greater than 5 cm (OR = 3.22; p = 0.05). Factors associated with failure of ID management were in multivariate analysis: collection greater than 5 cm, an internal drainage should be proposed first. A collection greater than 5 cm was associated with long care. Management in our center has changed over time with earlier first endoscopy associated with long care. A collection greater than 5 cm was associated with long care.

Conclusion: Endoscopic management of PSGF healed in 86% of cases. In case of collection greater than 5 cm, an internal drainage should be proposed first. A collection greater than 5 cm was associated with long care. Management in our center has changed over time with earlier first endoscopy associated with long care. A collection greater than 5 cm was associated with long care.

PO156 CLOSURE BY USING OVER-THE-SCOPE CLIPS AFTER ENDOSCOPIC FULL-THICKNESS RESECTION

J. Guo

Endoscopy Center, Shengjing Hospital of China Medical University, Shenyang/ China

Contact E-mail Address: gaoguji@gmail.com

Introduction: Endoscopic full-thickness resection (EFTR) is a mini-invasive technique for gastrointestinal subepithelial tumors, which enables a full-thickness resection of tumors and can provide a complete basis for pathological diagnosis. Gastrointestinal fistula closure after EFTR is a challenge for endoscopists. In this study, we introduced EFTR with fistula closure using the over-the-scope clip (OTSC) system for gastrointestinal subepithelial tumors originating from the muscularis propria.

Aims & Methods: We aimed to evaluate the feasibility and safety of fistula closure with OTSC by a retrospective analysis on the cases of EFTR with defect closure using OTSC for gastrointestinal subepithelial tumors in our hospital. The patients were selected who underwent EFTR for gastrointestinal subepithelial tumors originating from the muscularis propria (tumor diameter < 3 cm) in our hospital from May 2014 to December 2016. After a full-thickness resection of tumors, one or two OTSCs were released to close the defect. The success rate of defect closure with OTSC was observed and the endoscopic follow-up was performed at 1 week, 1 month, 6 months, 24 months after operation to check OTSC closure.

Results: In total 49 patients were included into the study. The full-thickness resection rate of gastrointestinal tumors in the muscularis propria was 100% (49/49), the success rate of defect closure was 100%, and the average time of defect closure was 7.3 min (range: 3–27 min). All patients experienced no postoperative complications such as bleeding and perforation. The postoperative follow-up time was 1–24 months (mean: 11 months), and no late complications was found.

Conclusion: OTSC can be used to perform EFTR with defect closure for gastrointestinal tumors in the muscularis propria (tumor diameter ≤ 3 cm). It is simple, convenient, safe and effective.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO157 EFFICACY OF ORAL MIXTURE OF HYDROCORTISONE SODIUM SUCCINATE AND ALUMINUM PHOSPHATE GEL FOR THE PREVENTION OF STRICTURE AFTER ≥2/3 CIRCUMFERENTIAL ENDOSCOPIC SUBMUCOSAL DISSOLUTION (ESD) FOR ESOPHAGEAL CANCER—A SINGLE CENTER PILOT STUDY FROM CHINA

Gastroenterology And Hepatology, Peking University Third Hospital, Beijing/ China

Contact E-mail Address: 201311765322@163.com

Introduction: ESD has been performed on many patients with early stage esophageal squamous cell carcinoma in China. Identification of the risk factors for postoperative stricture after ESD for esophageal cancer is the most important issues for quality of life in patients which is drastically decreased and repeat, periodic endoscopic balloon dilatation (EBD) is usually required over long periods. It is well known that hormone for external use is mostly easily absorbed in broken skin. Accordingly, We explored this innovative strategy with oral mixture of hydrocortisone sodium succinate and Aluminum phosphate gel for prevention of the stricture.

Aims & Methods: To evaluate the efficacy of this mixture in single center of Beijing, China.

Patients and Methods: In total, 13 patients who underwent more than 2/3 circular or complete circular ESD for esophageal superficial squamous cell carcinoma were included in this study. They all received preventative strategy for stricture and were divided into three groups chronologically. Four patients received systemic steroid treatment (ST group), three patients received endoscopic intraluminal steroid (triamcinolone acetonide 80mg) injection accompanied with systemic steroid treatment (IT ST group), six patients received oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel (OHA group). We compared the two groups in terms of stricture rate and total number of endoscopic balloon dilatation (EBD) sessions. ST groups started with 30mg/day prednisolone on the second day post-ESD, and continued with a gradually tapering prednisolone dose, finally discontinuing systemic steroid administration 8 weeks later. IT ST group started with 80mg intraluminal steroid at the end of ESD procedure, and 30mg/day prednisolone on the second day post-ESD which exactly was the same as ST group of tapering process. OHA group started with mixture of hydrocortisone sodium succinate and aluminum phosphate gel 20mg qid for 2 weeks and continued with a gradually tapering OHA dose on the second day post-ESD. Eosihagrostroduodenoscopy (EGD) was performed on demand whenever patients complained of dysphagia. Among those cases, EBD was performed when patient experienced partial or complete dysphagia. If the patient had no symptom for dysphagia, EGD was performed 8 weeks after ESD to evaluate any possible stricture. The primary end point in this study was the stricture rate after ESD followed by oral medication. The secondary end point was the number of EBD sessions required to resolve the stricture. A stricture was defined as a difficulty in swallowing solids or an inability to pass an EGD (9.2 mm diameter endoscope).

Results: There were two complete and two 75% circular ESD cases in IT ST group, and one complete and five 75% circular ESD cases in OHA group. 12 cases were resected en bloc with tumor free lateral and basal margins. No complications were seen after this procedure. The stricture rates of ST, IT ST, OHA group after ESD were 100% (4 of 4 patients), 33.3% (one of three patients), 0% (none of six patients), respectively. One patient with stricture after ESD had lateral recurrence at the margin of ulcer. One EBD was performed in three patients in ST group and one patient in IT ST group with esophageal stricture. One patient in ST group underwent operation (Endoscopy, 2011; 74: 389–397).

Conclusion: Short period, oral mixture of hydrocortisone sodium succinate and aluminum phosphate gel showed promising results for the prevention of stricture after ESD for early stage esophageal cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Current guidelines (MAPS) suggest that intestinal metaplasia (IM) should be staged using OLGIM 1 (Operative Link on Gastric Intestinal Metaplasia) and that patients with stages OLGIM 3 and 4 should be followed up1. High-resolution narrow band imaging (HR-NBI) was previously shown to be accurate to diagnose IM 3. Recently a new endoscopic classification (Endoscopic Grading of Gastric Intestinal Metaplasia - EGGIM) has been proposed to assess the risk phenotype of patients by the evaluation of IM in the antrum and in the corpus with the use of HR-NBI2, 3.

Aims & Methods: We aimed at determining the accuracy of EGGIM classification, compared with the pathological evaluation of gastric biopsies expressed according to OLGIM classification. Two centers (Italy, Portugal) consecutively included 78 adult patients (female 56%; median age 61 (20–84) years; 8 with 1st degree family history of gastric cancer). All patients were evaluated by High-
Resolution White Light Endoscopy (HR-WLE) followed by HR-NBI. A careful evaluation of the antrum and corpus mucosa was performed and EGGIM score was calculated. Five different areas were considered (lesser and greater curvature in the antrum, lesser and greater curvature in the corpus and incisura) and in each area 0 (no IM), 1 (focal IM, less or equal than 30% of the area) or 2 points (extensive IM in that area, more than 30% of the area) were attributed for a total of 10 points. Biopsies were taken where the endoscopists observed IM and, if IM was not present, random biopsies were taken using the updated Sydney System protocol. Biopsies from the different sites were sent for histopathologic evaluation on a gastric biopsy jar. The diagnostic performance of EGGIM was then compared to OLGIM (gold standard) and sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were calculated.

Results: IM was staged as OLGIM 0, 2, 3 and 4, respectively: 32 (41.0%), 23 (29.5%), 17 (21.8%), and 6 (7.7%) pts (no patients with OLGIM 1 were found). Table 1 shows detailed the EGGIM scores compared to OLGA. Compared to OLGIM as gold standard for the evaluation of IM, sensitivity, specificity, PPV and NPV of EGGIM classification were 97.8%, 81.2%, 88.2% and 96.3%, respectively. There were 6 patients who were using the EGGIM classification were H. pylori positive. Analyzing the subgroup of patients with OLGIM 3 and 4, the diagnostic performance of EGGIM was: sensitivity 95.6%, specificity 90.9%, PPV 81.5% and NPV 98.0%. Two of the 5 patients who resulted false positive using the EGGIM classification were H. pylori positive. A high agreement between EGGIM and OLGIM scores was observed (83.3%).

Conclusion: The EGGIM classification showed a high diagnostic performance compared to OLGIM, in particular in patients with OLGIM 3 and 4. A possible confounding factor leading to overestimation of presence of intestinal metaplasia might be the presence of H. pylori infection. This approach could be used to simplify the surveillance of these patients. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastrostomy is the current method of choice for medium and long-term enteral feeding. Available techniques include Percutaneous Endoscopic Gastrostomy (PEG) and Percutaneous Radiologic Gastrostomy (PRG). Both techniques are preferred over surgical gastrostomy. Previous studies that have compared outcomes between PEG and PRG are limited due to small sample sizes, high risk of confounding and selection bias. Our primary aim was to retrospectively analyse data from our centre with respect to complications and mortality between PEG and PRG procedures in relation to indications. These data may help to predict which technique is best for an individual patient.

Aims & Methods: A retrospective analysis including all adult patients receiving initial PEG (January 2010 until April 2016) and PEG (January 2008 until April 2016) placement in our university hospital, was performed.

Outcomes were complications (early (<30 days) and late), success rates and mortality (procedure related, 30-day, and overall). Chi², Fisher’s exact and t-tests were used. Multivariable logistic regression and Cox proportional hazards regression analysis were performed.

Results: A total of 760 initial procedures (469 PEG and 291 PEG) were included in the analysis (62.9% male, mean age 62.8yrs [SD 12.6yrs]). Most common indications for gastrostomy were: HN, PRG 69.9%, p<0.001, Cerebrovascular Accident (CVA, PEG 13.7%, PRG 2.1%, p<0.001) and Motor Neuron Disease (MND, PEG 2.7%, PRG 9.8%, p<0.001). Success rates for placement were 92.1% for PEG (failure mostly due to absence of dilatation, n=14) and 97.1% for PRG (p=0.001). Major complications (e.g. abscess, buried bumper, peritonitis) and infections did not differ amongst groups, neither did procedure-related mortality, which was 1.7% in PEG (n=5) vs. 0.4% in PRG (n=2, p=0.113). One case of tumour (HN) seeding occurred after PRG placement. Tube related complications (including dislocation, obstruction, leak and tube defects) were lower in PEG than PRG, both within 30 days (2.7% vs. 26.4% of patients, p<0.001 and after 30 days (8.6% vs. 31.5%, p<0.001).

The 30-day mortality was higher in patients who received PEG (11.3%; 27 deaths due to underlying conditions, 5 related to the procedure (1 massive bleeding, 4 aspiration pneumonia)) compared to those with PRG (4.48%, 19 deaths due to underlying conditions, 2 related to the procedure (both aspiration pneumonia), p<0.001). The 30-day mortality was related more to the patients’ general condition, than to the procedure itself.

Overall survival was 46.7% vs. 44.1% (PEG vs. PRG; p=0.049, OR 1.22±[1.00–1.498]). Positive predictive factors for overall survival were PEG, ALS and a higher BMI before placement (adjusted OR for all three factors together 1.29±[1.07–1.626]).

Conclusion: PRG appears favourable with respect to 30 day mortality while PEG appears favourable over PRG in terms of complications (such as dislocation, peritonitis and tube irritation). A higher initial success rate and the possibility of placement in case of a narrow lumen favour PRG placement. More adequate patient selection and more thorough procedure selection prior to gastrostomy is therefore required.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0165 COMPREHENSIVE EVALUATION OF THE LEARNING CURVE FOR PERORAL ENDOSCOPIC MYOTOMY: LESSONS FROM 1346 PATIENTS
Z. Liu1, X. Zhang1, Q. Li1, P. Zhou1
1Zhongshan Hospital, Endoscopy Center and Endoscopy Research Institute, Zhongshan Hospital, Fudan University - Zhongshan, Shanghai/China
Contact E-mail Address: liuzq16@fudan.edu.cn
Introduction: Peroral endoscopic myotomy (POEM) is being increasingly performed worldwide. However, studies on its learning curve are limited. A comprehensive evaluation based on risk factors is needed.
Aims & Methods: This study was aimed to evaluate the impact of various factors on the learning curve of POEM. From August 2010 to July 2015, 1346 POEM procedures performed in hospital were analyzed. The primary outcome of the study was a composite outcome of aborted procedures and complication. The secondary outcomes included procedure time and hospital stay. The impact of risk factors was assessed by backward conditional logistic regression on primary and secondary outcomes. The risk-adjusted CUSUM and moving average methods were used to evaluate the outcomes.
Results: Fifty-four (4%) patients had the composite outcome with 10 aborted procedures and 44 adverse events. The composite outcome was related to case number, full-thickness myotomy and procedure time in the multivariate logistic regression. Adjusted for these risk factors, the CUSUM analysis showed that the composite outcome gradually decreased after 150 cases. The procedure time was higher in the early stage and decreased after 71 cases. Case number, in representativeness of the operative experience, is also an independent risk factor for a longer post-operation hospital stay.
Conclusion: For POEM operators, seventy cases might be considered a threshold for technical proficiency, i.e., technical proficiency. A hundred-and-fifty cases might be considered a threshold for the decrease of aborted procedures and adverse events, i.e., technical reliability.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0166 CLINICAL CURATIVE EFFECT ANALYSIS OF 162 GASTRIC STROMAL TUMORS RESECTED BY ENDOSCOPIC TREATMENTS
L. Liu, W. Liu, Z. Fan
Digestive Endoscopy Center, the First Affiliated Hospital of Nanjing Medical University, Nanjing/China
Contact E-mail Address: kit9178@sina.com
Introduction: Gastrointestinal stromal tumor (GIST) is one of the most common tumors originating from mesenchymal tissue of gastrointestinal tract, which accounts for about 0.2% of gastrointestinal tumors. Gastric stromal tumors are more common, accounting for about 40~70% of GIST. At present, the endoscopic treatments of gastric stromal tumors includes endoscopic submucosal dissection (ESD), endoscopic full-thickness resection (EFR) and combined endoscopic and laparoscopic surgery.
Aims & Methods: Our study is aimed to assess the safety and effectiveness of endoscopic treatments for gastric stromal tumor. Clinical data of 162 patients with gastric stromal tumor who underwent endoscopic treatments from June 1, 2011 to July 31st 2015 were analyzed retrospectively. The mean diameter of the tumors was 1.5 cm (0.3~5.0 cm). 104 patients received endoscopic submucosal dissection, 58 patients received endoscopic full-thickness resection. Among them, 4 operations were aborted under the监视 of the mentor of laparoscopy.
Results: Complications were observed in 8 patients(4.9%): bleeding during operation (3 patients), post-operation perforation (3 patients), respiratory tract infection: 2 patients. The mean post-operation feeding time was 2.67 days (range 1~9 days) and post-operation hospital stays were 5.39 days (range 2~10 days). The mean time of follow-up was 26.4 months (range 5~51 months). The follow-up showed that 6 patients kept on treating with oral administration of imatinib. No patient was found recurrence or death.
Conclusion: Endoscopic treatments were demonstrated as safe and effective ways to resect gastric stromal tumors in this study.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0167 GASTROENTEROLOGY REGISTRAR OF THE WEEK: A SOLUTION FOR AUGIB ENDOSCOPY TRAINING?
S. Budihal1, P. Wurm1
1Digestive Diseases Centre, University Hospitals Leicester, GB/United Kingdom
Contact E-mail Address: shivbudihal@yahoo.co.uk
Introduction: Much concern surrounds Gastroenterology Specialist Registrar (SIR) endoscopy training, especially in regards to endoscopic management of Acute Upper Gastrointestinal Bleeding (AUGIB). Recent evidence suggests there has been a decline in exposure and experience in AUGIB endoscopy.1 In July 2013 our University Hospital introduced a Consultant-led and Registrar-supported Monday to Friday, 9 to 5 pm in-reach service. It comprises of a morning visit to the acute medical units and a daily inpatient emergency list. This study looked at registrar AUGIB endoscopy training after its implementation.
Aims & Methods: Endoscopy reports of patients presenting with haematemesis, melaena or both who had undergone gastrosopy during the period of 1st of May to 31st August 2014 were retrieved using the endoscopy reporting tool Unisoft and analysed. Reports where SIRs were the primary operator were considered. Number of procedures, haemostatic intervention and nature of haemostasis was analysed. This was then compared to data from the year before implementation (01/03/2012 to 31/03/2012)
Results: A total of 7 SIRs (5 Full Time and 2 Less than Full Time) performed gastrosopies on AUGIB patients as first operators under Consultant supervision. Over the 6-month period a total of 166 gastrosopies were undertaken (Mean 24). On 26 occasions, endoscopic intervention (EI) was performed (Mean 4). On average, 16% of the AUGIB patients required EI. In cases of Non Variceal Bleeding, Dual therapy was applied in 87.5% of the cases. In cases of Variceal Bleeding, Banding therapy was applied. On average 66.1% of patients were able to perform one case of oesophageal variceal banding and one case where Haemospary was utilised. Data from the 2012 cohort in comparison showed a total of 66 gastrosopies over 6 months with 13 EI. On average 13 procedures and 2.6 EI's were performed by each SIR. Dual therapy was applied in only 25.8% of the cases
Conclusion: The introduction of the Registrar of the Week Service provides a valuable opportunity for SIRs to be trained in endoscopic haemostasis and acquire exposure to AUGIB endoscopy. As per this study each SIR on an average performed endoscopy on 24 AUGIB patients. If this is extrapolated, each SIR will be able to perform 48 procedures in 1 year and 240 procedures over 5 years. In the case of EI, on average a SIR can perform around 4 interventions over 6 months which gives to 8 per year and 40 in a 5 year program. This is significantly better than in the previous cohort and other centres.1 Hospitals should consider developing similar services not only to meet demands for 24/7 Consultant led AUGIB endoscopy service but provide adequate endoscopic training provision for current specialist registrars in order to ensure future competent and confident consultants.

P0168 HIGH PERCENTAGE OF VISIBLE LESIONS IN PATIENTS WITH BARRETT’S ESOPHAGUS REFERRED WITH DYSPLASIA IN RANDOM BIOPSIES

Introduction: Endoscopic recognition of dysplasia or early cancer in Barrett’s oesophagus (BE) is difficult. Experience in recognition of early neoplastic lesions is thought to increase the detection of visible dysplastic lesions. A previous study reported that endoscopists in community hospitals detect neoplastic lesions at a significant lower rate than referral centres. The aim of the study we want to assess the significance of dysplasia in random biopsies in BE, in the absence of reported visible lesions as well as the final outcome of pathology.
Aims & Methods: We retrospectively analysed all patients referred from 19 community hospitals to our tertiary referral centre with the diagnosis of BE with dysplasia or EAC between February 2008 and April 2016. All patients underwent a dedicated imaging endoscopy with high-definition endoscopy supplemented with virtual chromoendoscopy and/or acetic acid staining at the discretion of the endoscopist. All procedures were performed by an endoscopist with extensive experience in the detection of early neoplastic lesions in BE. During endoscopy all visible lesions were noted and biopsied and/or removed by endoscopic resection (ER). Patients were included for analysis in case of absence of reporting visible lesions at referral.
Results: In total 184 patients were referred with dysplasia or EAC of which 82 patients (80.5% male, age 42–81 years (median 63)) did not show a visible lesion during imaging endoscopy. Two cases of histology proved EAC and one confirmed LGD. In twenty-six of 43 patients (60.5%) referred with HGD, a visible lesion with histology specimens corresponding to HGD (10) and EAC (16) were found,
respectively. All cases of EAC were detected (7/7). In 18/78 (24%) patients referred with dysplasia (LGd/HGd) without a visible lesion, the referral diagnosis was thus upstaged to EAC. Overall, 41/82 (50%) lesions were found additionally.

**Conclusion:** The presence of any grade of dysplasia in random biopsies in BE screening in community hospitals is a potential marker for more severe final pathology after endoscopic work-up in an expert centre. Training in Barrett imaging is mandatory for non-expert endoscopists.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

</tbody>
</table>

**Results:** A total of 22 patients were included and analyzed. The etiologies of ERF were esophageal surgery in 12 patients (54.5%), esophageal dilatation in 3 (13.6%), invasive ventilation in 3 (13.6%), radiation therapy in 2 (9.1%) and tracheostomy in 2 (9.1%). A total of 93 procedures were performed with a mean of number of endoscopies of 4.2±4.5 per patient. At some point of the management, twenty-one patients (95%) had esophageal stents placement, eight patients (36%) had over the scope clips (OTSC) placement and seven had OTSC associated with esophageal stent. The clinical success rate was 45.5% (n=10), and 55% of the patients had a functional success (n=12). Serious adverse events occurred in 9 patients (40.9%) such as gastrointestinal bleeding (4 patients, 18.2%), stent migration (4 patients, 18.2%), thoracic spondylodiscitis (2 patients, 9.1%) alimentary esophageal impaction (1 patient, 4.5%), stent mucosal impac- tion (1 patient, 4.5%), major chest pain (1 patient, 4.5%). Six patients died (27%). Clinical success was reached for 67% of punctiform ERF (p=0.193), 50% of medium ERF (p=1) and 14% of large ERF (p=0.17). The factor associated with the failure of endoscopic treatment was the persistence of the fistula after 6 months (OR=44; IC95: 3.38–573, 4; p=0.004 multivariate ana- lysis). The orifice’s size was associated with the mortality with 71% of death among large fistulas (p=0.001 univariate analysis).

**Conclusion:** Endoscopic treatment of ERF can lead to 45.5% of clinical success and 55.5% of functional success. However, this outcome appears to be dependent on the size of the fistula. Moreover, the absence of resolution after 6 months of endoscopic treatment dramatically decreases the chance for ERF healing. In conclusion, the endoscopic approach seems reasonable for small or medium orifices, and has to be attempted during six months. After this time or for larger orifices, surgery or palliative therapy should be considered.

**P0107 CLINICAL UTILITY OF NARROW BAND IMAGING MAGNIFYING ENDOOSCOPY FOR MM/SM1 ESOPHAGEAL SQUAMOUS CELL CARCINOMA**

M. Inoue1, T. Onnori, K. Nastu1, K. Aiura1

1Department Of Surgery, Kawasaki Municipal Kawasaki Hospital, Kawasaki; Japan

Contact E-mail Address: masaz.inoue@gmail.com

**Introduction:** Esophageal squamous cell carcinoma (ESCC) is common in Asia. Predicting invasion depth of superficial ESCC is crucial in determining the pre- cise treatment because the rate of lymph node metastasis increases in proportion of the invasion depth of the carcinoma. According to Japanese guidelines for diagnosis and treatment of esophageal cancer, superficial invasions are divided into 5 categories: carcinoma in situ (EP), tumors invades lamina propria mucosa (LPM), lamina muscularis mucosa (MM, the submucosa to a depth of 200 μm or less from the muscularis mucosa (SM1), and the submucosa to a depth more than 200 μm (SM2). The rate of lymph node metastasis is extremely low in EP/LPM tumors, and endoscopic resection (ER) is certified as precise treatment. On the other hand, the rate of lymph node metastasis in MM/SM1 tumors are reported to 10–20%, and both operation and ER are considered as their treatment. Accurate pretherapeutic diagnosis of MM/SM1 tumor is very important for selection of appropriate treatment and interests of patients. In this point, endoscopic diagnosis is very important diagnostic approach.

**Aims & Methods:** The purpose of this study is to investigate the utility of Narrow Band Imaging (NBI) magnifying endoscopy for the diagnosis of MM/SM1 ESCC. From January 2011 to April 2017, 23 patients were diagnosed as pathologically MM/SM1 ESCC in our hospital. We retrospectively analyzed their endoscopic findings and pathological findings. The depth of invasion was diagnosed by NBI magnifying endoscopy according to the Japan Esophagogastroscopy Society (JES) magnifying endoscopic classification. Diagnostic criteria are based on the degree of microvascular irregularity in the target lesion observed by NBI magnifying endoscopy. Microvessels are grouped into 2 types. Type A microvessels are normal intrapapillary capillary loops or abnormal microvessels without severe irregularity. Type B microvessels are abnormal vessels with severe irregularity or highly dilated abnormal vessels, and subclassified into B1, B2, and B3 based on the running pattern or degree of dilation of severely irregular microvessels. When target lesions have B1 vessels, the invasion depth is predicted as EP or LPM. When B2 or B3 vessels are seen, the invasion depth is predicted as MM or SM1 and SM2 or deeper, respectively.

**Results:** In 23 pathologically MM/SM1 cases, clinical type diagnosed by endoscopy was EP in 16 cases (70%), 0-IIa in 3 cases (13%), 0-IIb in 1 case (4%), and 0-Ia in 1 case (4%). Predicted depth of invasion by NBI magnifying endoscopy based on the JES classification was EP in 2 cases (9%), LPM in 7 cases (30%), MM in 10 cases (43%), SM1 in 3 cases (13%) and SM2 in 1 case (4%). Total diagnostic accuracy of MM/SM1 was 57% (13/23). When the B2 vessels were observed, diagnostic accuracy of MM/SM1 was 90% (9/10). In the cases that MM or SM1 invasion remained pathologically quite localized, B2 vessels could not be observed by NBI magnifying endoscopy. And also, in the cases with inflammation or keratinizing epithelium, precise diagnosis of microvessels were difficult.

**Conclusion:** Our data indicate that diagnosis of MM/SM1 ESCC by NBI magnifying endoscopy based on the JES classification is useful when the abnormal microvessels are observable. Type B microvessels are abnormal vessels with severe irregularity, highly dilated abnormal vessels, and subclassified into B1, B2, and B3 based on the running pattern or degree of dilation of severely irregular microvessels. When target lesions have B1 vessels, the invasion depth is predicted as EP or LPM. When B2 or B3 vessels are seen, the invasion depth is predicted as MM or SM1 and SM2 or deeper, respectively.

**P0111 PER-ORAL ENDOSCOPIC PYLOROMYOTOMY (POEP) IN THE TREATMENT OF REFRACTORY GASTROESOPHAGEAL REFLUX DISEASE – A SINGLE CENTRE EXPERIENCE**

R. Hustak1, Z. Vackova1, J. Spicak2, L. Jurgovs1, J. Martinek2

1Department Of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

2Dept. Of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: rhustak@gmail.com

**Introduction:** Gastroesophageal reflux disorder is a chronic, debilitating motility disorder. Effective treatment is challenging especially in patients with severe symptoms. POEP is an
emerging modality for refractory gastroparesis with promising preliminary results.

Aims & Methods: The aim of this prospective case series was to assess our first (single center) experience with POEP. Main outcomes were: 1) the efficacy defined by improvement of GCIS score; 2) gastric emptying evolution and 3) satisfaction. From Nov 2015, a total of 7 patients underwent POEP. The etiology of gastroparesis was post-operative in 4, diabetic in 2 and idiopathic in 1 patient. One patient underwent POEP for gastroparesis following a multivisceral transplantation; one patient underwent both POEP and POEM (as a single procedure) for coexisting refractory idiopathic gastroparesis and achalasia. All patients had severe gastroparesis as defined by elevated GCIS score and delayed gastric emptying scintigraphy. Follow visit at 3, 6, 12-months were completed in 7/7 (100%), 5/7 (71%) and 1/7 (14%) patients, respectively. Upper GI endoscopy and scintigraphy were performed 3 months after the procedure.

Results: POEP was successfully performed in all patients. Mean procedure time was 70 minutes (range 63–106). After POEP, mean GCIS decreased from 3.0±1.2 to 0.8±0.7 (at 3-months) and 0.9±0.8 (at 6-months). One woman failed to follow up at 12-months but remained excellent outcome. Treatment success was reached in 6/8 (75%) of patients, one female patient with diabetic gastroparesis did not have a major symptomatic improvement despite normalisation of gastric emptying study. Gastric scintigraphy normalized in all patients, mean half emptying time (108±30 min) to 62±23 min; and mean bolus retention at 4 hours decreased from 17±9.2% to 2.0±2.0%. One patient developed bleeding ulcer 10 days after POEP, this adverse event was successfully managed endoscopically (clips) and by parenteral proton pump inhibitor.

Conclusion: We report our first experiences with POEP for refractory gastroparesis, demonstrating its feasibility and safety with promising clinical efficacy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0173 TREATMENT OF MULTIPLE GASTROINTESTINAL SUBMUCOSAL TUMORS BY SUBMUCOSAL TUNNELING ENDOSCOPIC RESECTION

J. Liu, W. Qin, Y. Huang, Z. Ren, P. Zhou
Endoscopy Center And Endoscopy Research Institute, Fudan University Zhongshan Hospital, Shanghai/China

Contact E-mail Address: liu.jingzheng@zs-hospital.sh.cn

Introduction: Submucosal tunneling endoscopic resection (STER) is a novel technique to remove the gastrointestinal submucosal tumors. Previous studies mainly focused on technical feasibility for patients with single gastrointestinal submucosal tumor. No systematic studies about multiple upper gastrointestinal submucosal tumors synchronously removed by STER are addressed. The aim of this study was to evaluate the safety and outcome of STER in treatment of multiple gastrointestinal submucosal tumors.

Aims & Methods: From January 2011 to January 2017, 42 patients with multiple gastrointestinal submucosal tumors undergoing STER were included. Variables of each tumor and patient were analyzed. Detailed tumor characteristics included max size, sum of max size and number of tumors, and longest distance of tumor. While detailed technique information included number of tunnels, tunnel length, hospital stay, procedure time, complication, follow-up, recurrence, and metastasis.

Results: Among all the cases, 96 lesions of upper gastrointestinal submucosal tumors were removed by STER. The median procedure time was 50 min (range 15.6–84.9 min). The median number of tumors was 2 (2–4). The median max size of each tumor was 1.8 cm (range 0.7–3.5 cm) and the median sum of max size of each tumor of each patient was 3 cm (range 1.3–8.0 cm). Six patients had perioperative complications (14.2%), with 3 pneumothorax/hydropneumothorax (7.2%), 1 mucosal injury (2.4%), 1 pneumonia (2.4%), and 1 major bleeding (2.4%). Patients with different number of tunnels had similar tumor characteristics and techniques. There were significant differences in longest distance of tumors comparing two groups (p < 0.001). No local recurrence or distant metastasis was detected with a median follow-up of 33 months.

Conclusion: STER is a safety and feasible technique for multiple upper gastrointestinal submucosal tumors no matter in one tunnel or two tunnels resection. Based on the longest distance of tumors, different number of tunnels can be performed with similar procedure technique and prognosis.

6Department Of General, Visceral And Transplant Surgery, University Medical Center Mainz, Mainz/Germany

Contact E-mail Address: keith@siau.org

Introduction: In a randomised controlled trial, flexible sigmoidoscopy (bowel scope) reduced colorectal cancer incidence and mortality in a population aged 55-64.[1] Patients progressed to colonoscopy based on ‘high risk’ features (Table 1).[1] Based on these pivotal findings, the UK bowel scope (BS) surveillance programme was introduced in 2013 to individuals aged 55. The Wolverhampton Bowel Cancer Screening Centre was the first UK site to fully roll out the programme. The correlation between BS findings and subsequent colonoscopy has not previously been evaluated in this specific cohort.

Aims & Methods: We prospectively collated data from all BS patients at our centre and identified those undergoing colonoscopy between August 2013-2016. We assessed conversion rates, compliance with BS protocol and correlated histological findings to identify predictors for detection of pathology at colonoscopy. Univariate analysis was performed using Pearson’s χ².

Results: 11,711 bowel scopes were performed, with an adenoma detection rate (ADR) of 8.5%, and conversion to colonoscopy in 421 patients (3.6%). 386 were included for analysis after excluding incomplete colonoscopy/histology. All patients were aged 55 (64.8% male). Additional ADR at colonoscopy was 35.2%, with malignant diagnoses in 1.5% (all detected at BS). The adenoma miss rate at BS was 5.2%. On univariate analysis (Table 1), polyp ≥10mm was the only indication associated with increased ADR at colonoscopy (OR 2.13, p < 0.001). Additional predictors identified included villous (not tubulovillous) histology (OR 4.41, p = 0.002), and male gender (OR 2.35, p < 0.001). These factors also significantly predicted new ≥10 mm adenoma. 57 (14.8%) underwent colonoscopy outside protocol, which reduced ADR (OR 0.29, p = 0.003). After excluding these high risk indications, changing the conversion criteria from any villous to villous only histology altered sensitivity from 27.2% to 83.3%, and specificity from 84.5% to 80.5%.

Conclusion: At BS, male gender, ≥10mm polyps, and villous histology are predictors of proximal colonic pathology. Further analyses are required to clarify the benefits of converting low-risk tubulovillous adenomas at BS to colonoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Dual-center, randomized, noninferiority trial. Consecutive patients with at least one unpolypectomized polyp ≥6–10 mm were enrolled. Eligible patients were randomized (1:1) to be treated with either SL-CSP or EMR. The primary noninferiority endpoint was histologic eradication, with a noninferiority margin of −1. Evaluation of histologic complete resection relied on a postpolypectomy biopsy protocol (4 biopsies obtained in a 4-quadrant fashion from the polypectomy site margins; 1 biopsy from the base). Secondary outcomes included occurrence of intraprocedural bleeding (IPB; defined as any immediate episode requiring endoscopic haemostasis), clinically-significant postprocedural bleeding (CSPPB; any episode requiring emergency department presentation, hospitalization, or reintervention within 30 days of the procedure) and perforation.

Results: Among 689 patients screened, 155 patients with 164 eligible polyps (SL-CSP n = 83 vs. EMR n = 81) were included. The overall rate of histologic complete resection was 92.8% (77/83) in the SL-CSP group and 96.3% (78/81) in the EMR group (difference 3.5%; 95% CI, 4.15 to 11.56; showing noninferiority of SL-CSP vs. EMR). The SL-CSP technique was noninferior to EMR in E5 box polyps measuring 6–7 mm (SL-CSP, 93.3%; EMR, 100%; 95% CI, −7.95 to 21.3) and those 8–10 mm (SL-CSP, 92.5%; EMR, 94.7%; 95% CI, −7.91 to 13.16). By multivariate analysis, female gender (OR, 0.15; 95% CI, 0.02–1.06; P = 0.06) and Paris 0-IIa morphology (OR, 0.12; 95% CI, 0.01–1.19; P = 0.07) were marginally significant predictors correlating negatively with complete resection. Rates of IPB were similar between the two groups (SL-CSP, 3.6%; EMR, 1.2%; p = 0.3). No CSPPB or perforation occurred in either group.

Conclusion: Among 689 patients screened, 155 patients with 164 eligible polyps (SL-CSP n = 83 vs. EMR n = 81) were included. The overall rate of histologic complete resection was 92.8% (77/83) in the SL-CSP group and 96.3% (78/81) in the EMR group (difference 3.5%; 95% CI, 4.15 to 11.56; showing noninferiority of SL-CSP vs. EMR). The SL-CSP technique was noninferior to EMR in E5 box polyps measuring 6–7 mm (SL-CSP, 93.3%; EMR, 100%; 95% CI, −7.95 to 21.3) and those 8–10 mm (SL-CSP, 92.5%; EMR, 94.7%; 95% CI, −7.91 to 13.16). By multivariate analysis, female gender (OR, 0.15; 95% CI, 0.02–1.06; P = 0.06) and Paris 0-IIa morphology (OR, 0.12; 95% CI, 0.01–1.19; P = 0.07) were marginally significant predictors correlating negatively with complete resection. Rates of IPB were similar between the two groups (SL-CSP, 3.6%; EMR, 1.2%; p = 0.3). No CSPPB or perforation occurred in either group.

Introduction: Yao et al. observed gastric epithelial neoplasms and chronic gastritis using magnifying endoscopy and found that WOS was classified as regular WOS, and reported a phenomenon in which a white opaque substance (WOS) present in the epithelium did not allow passage of the projected light and obscured the subepithelial microvasculature (1). Furthermore, the morphology of the WOS is a useful marker for differentiating between adenoma and carcinoma in gastric epithelial neoplasms (1). Recently, we reported for the first time that WOS is also detected in colorectal epithelial neoplasms (2). However, it is unclear whether the morphology of the WOS in colorectal epithelial neoplasms is useful in the differential diagnosis of adenoma and carcinoma (3). Therefore, we report the results of a prospective observational study to determine whether it is possible to differentiate between adenoma and carcinoma based on the morphology of the WOS in colorectal epithelial neoplasms (UMIN000021537).

Aims & Methods: The subjects were consecutive patients with colorectal epithelial neoplasms (adenoma, early colorectal cancer) who underwent endoscopic or surgical resection at Fukuoka University Chikushi Hospital from December 2014 to May 2016. Prior to treatment, the morphology of each lesion was determined using M-NBI, and endoscopic images were taken and recorded in a filing system. After the endoscopy was completed, a determination was made regarding the presence or absence of WOS on the endoscopic images. The morphology of the WOS was determined for cases in which WOS was present and in whom WOS was seen in more than half of the region before the results of histopathological examination of the lesions were known. The morphological characteristics of the WOS were classified as regular WOS or irregular WOS according to our previous report (1). The primary endpoint was the diagnostic performance of morphological analysis of the WOS (accuracy, specificity, sensitivity) for early colorectal cancer taking irregular WOS as an indicator. The secondary endpoint was the difference in the prevalence of irregular WOS between mucosal (M) or SM-s cancer and SM-m cancer. The study was approved by the institutional ethics committee. All authors have declared no conflicts of interest.

Results: Of the lesions, 404 were excluded, according to the following conditions: 286 negative for WOS, 72 in which WOS was seen in less than half of the region (82.6%), 34 that were diagnosed histologically as hyperplastic polyp, and 30 that could not be individually assessed 100 lesions. Polyps were ordered by a computer-generated random sequence and divided into 2 sets every week (presenting 2 sets every week) consisting of 16–17 polyps. After evaluating each polyp, they received the correct diagnosis and a short explanation. The main outcome was a correct NICE diagnosis. A 90% accuracy defined an adequate performance and 80% was considered inadequate. A virtual cohort of 15000 evaluators was used to calculate the stopping rule. The CUSUM curve, with each participant individually assessing 100 lesions, was followed until the CUSUM curve exceeded the recommended threshold. Larger polyp size was associated with higher diagnostic accuracy. Sensitivity for adenomas was 83% (82.2–83.8%), specificity 86% (85.8–87.1%), and positive and negative predictive values were 81% (79.7–82.5%) and 83% (81.8–84.9%), respectively. There was no significant difference in the prevalence between irregular WOS in M or SM-s cancer and SM-m cancer (p = 0.727, chi-square test).

Conclusion: These findings suggest that in colorectal epithelial neoplasms in whom WOS is visualized, the morphology of the WOS may be a useful marker in the differential diagnosis of adenoma and carcinoma using magnifying endoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: To reduce costs of colorectal cancer screening, a restart and discard strategy has been proposed for small polyps. The American Society of Gastrointestinal Endoscopy (ASGE) recommends achieving a diagnostic accuracy > 90%, before implementing it (1). Narrow band imaging (NBI) is increasingly available and the NICE classification is frequently used to reach real time histologic classification. Endoscopists usually rely on short sessions, online courses or self-education for training in NBI, so we evaluated the learning curve in subjects with no previous endoscopic experience and their subsequent performance in patients with polyps ≤ 7 mm.

Aims & Methods: Participants (4th or 5th year medical students) attended one training session regarding NBI and NICE classification. Polyps were subsequently only evaluated employing LC-CUSUM curves, with each participant individually assessing 100 lesions. Polyps were ordered by a computer-generated random sequence and divided into 6 sets of images (presenting 2 sets every week) consisting of 16–17 polyps. After evaluating each polyp, they received the correct diagnosis and a short explanation. The main outcome was a correct NICE diagnosis. A 90% accuracy defined an adequate performance and 80% was considered inadequate. A virtual cohort of 15000 evaluators was used to calculate the stopping rule. The LC-CUSUM curve was followed until the LC-CUSUM curve exceeded the recommended threshold. Overall diagnostic performance, consecutive patients with lesions ≤ 7 mm were included. Patients with polyps lacking classification, polyps > 7 mm or incomplete polyp-ectomies were excluded. All participants received the same white light and NBI modified training from 10 patients every week, including all polyps excised. Endoscopies were presented in the same order as they were included in the study. Histological results were available with a 2-week delay. Endoscopists performed each polyp’s histology using their level of confidence, and recommended a surveillance interval for each patient. Diagnostic performance was evaluated at polyp level and for follow-up intervals.

Results: Thirty-eight evaluators (median age: 22.1 years, 71.1% women) completed the study. Of the 100 lesions (8.5 mm, IQR: 5.17–5.15) included in the learning curve evaluation 19 were NICE 1.71 were NICE 2 and 10 NICE 3. Median diagnostic accuracy was 86% (IQR: 84–91%, range: 76–96%), increasing from 81.8% (IQR: 78.8–87.9%) in the first 33 lesions to 87.9% (IQR: 84.8–93.9%) in the last 33. According to the LC-CUSUM curve, 20 evaluators (52%) reached diagnostic competence. During the diagnostic performance assessment, a total of 180 patients were included, presenting 307 polyps (range: 1–8 polyps/patient), with a median size of 3 mm (IQR: 2–5). 71.3% were adenomas, 21.8% hyperplastic 2.6% serrated adenomas and 4.2% presented other diagnoses. Overall diagnostic accuracy was 76.9% (76.2–77.7%), reaching 81.3% (80.8–82.1%) in high-confidence diagnoses. Sensitivity for adenomas was 83% (82.2–83.8%), while for hyperplastic polyps it was 62.6% (60.8–64.5%). Surveillance intervals were correct in 78% (77–79%) of patients, 81.3% (80.2–82.4%) in those presenting high confident diagnoses. Only 2 (5.3%) evaluators reached the 90% recommended threshold. Larger polyp size was associated with higher accuracy (p < 0.001), but neither competence according to the LC-CUSUM test (p = 0.99) nor frequency of the histological results (p = 0.74) improved the evaluators’ accuracy.

Conclusion: Self-formilation after a single training session did not allow most evaluators to reach the ASGE suggested thresholds, mainly due to the low sensitivity for hyperplastic polyps. Further studies are required to address if specific training for small polyps or different formation methods might make NBI assisted optical diagnosis a plausible option for small polyps outside expert centers.

Introduction: Effective colonscopy requires effective bowel cleansing. Inadequate cleansing may decrease diagnostic sensitivity, necessitate repeat procedures and delay appropriate treatment. Successful colon cleansing is harder to achieve in patients aged over 65 than in younger patients. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel preparation, a patented combination optimised for effective bowel cleansing. Here, the efficacy of NER1006 at achieving the colon in preparation for colonoscopy is compared to three active comparators, with attention to their efficacies in patients aged ≥65 years and >65 years who had a readable colonoscopy.

Aims & Methods: Colon cleansing efficacy of NER1006 was compared to three currently used bowel preparations in patients aged ≤65 years and in patients aged >65 years. NER1006 was compared to sodium picosulfate + magnesium citrate (NaPic + MgCit), trisulfate and 2L PEG with ascorbate (2L PEG + Asc), in three multicentre randomised Phase 3 clinical trials: DAYB1, NOCT2 and MORA3, respectively. 2L PEG + Asc was administered over 2 days and in the MORA trial, the doses of NER1006 were administered either in 1 day morning-only (N1D) or, as with 2L PEG + Asc split over 2 days (N2D). In the DAYB study, NER1006 was administered evening-only the day before colonoscopy (NDB). Treatment-blinded central readers rated colon cleansing according to the Harefield Cleansing Scale. Following segmental scoring, overall colon cleansing was graded from A to D grades A and B were judged as successful cleansing; grades C and D were judged as failed cleansing.

Results: Pooling the data from the three trials to assess colon cleansing in the two age groups showed successful cleansing in 80.5% (1158/1438) of patients aged ≤65 years, and 79.6% (277/348) of patients aged >65 years (difference of 0.9%; P = 0.698; 95% CI: −3.7–5.6%). Within each trial the difference in colon cleansing in the age groups indicated that the effect of increased age on cleansing efficacy was lesser in the NER1006-treated patients than in patients treated with the active comparators (Table 1). For example, in patients treated with NER1006 the rate of successful colon cleansing in patients aged >65 was 5.2% higher than in patients aged ≤65, whereas in patients treated with NaPic + MgCit, there was 3.5% lower successful cleansing rate in patients aged >65 than in patients aged ≤65.

Conclusion: NER1006 was efficacious in successful colon cleansing in patients aged >65 (in whom successful colon cleansing is harder to achieve) as well as in patients aged ≤65. Statistical significance was not reached in these comparisons.

2Clinical Development, Norgine Ltd., Harefield, Uxbridge/United Kingdom

Contact E-mail Address: ralf.bisschops@uzleuven.be

Introduction: Effective colonscopy requires effective bowel preparation. For detection of polyps larger than 5 mm, an ‘adequate’ segmental cleansing level has recently been defined as ≥2 or more on the Boston Bowel Preparation Scale (BBPS).1 The Phase 3 trial MORA compared NER1006 as an evening/morning split-dosing or a morning-only dosing regimen, against 2L PEG with ascorbate as an evening/morning split-dosing regimen (2L PEG + Asc). Treatment-blinded central readers assessed the bowel cleansing efficacy using both the Harefield Cleansing Scale (HCS) and the BBPS. This post hoc analysis shows the BBPS scores on the two primary endpoints, in those patients who had a readable colonoscopy.

Aims & Methods: In the MORA trial, 7,849 patients aged 18–85 were randomised to bowel preparation with morning-only or evening/morning split-dosing using either NER1006 or 2L PEG + Asc. Adequate level cleansing success was assessed according to the BBPS for both overall colon (all segments ≥2) and right colon cleansing (segmental score ≥2). The analysis includes all subjects for whom colonoscopy videos were available for assessment by central readers.

Results: A total of 792 patients were analysed. When using an evening/morning split-dosing, 249/262 (95.7%) patients on NER1006 achieved adequate level overall colon cleansing compared to 232/260 (89%) on 2L PEG + Asc (Table 1). Using morning-only dosing, 243/270 (90%) patients on NER1006 achieved the same. Using evening/morning split-dosing, 254/262 (97%) patients on NER1006 achieved adequate level right colon cleansing compared to 242/260 (93%) on 2L PEG + Asc. Using morning-only dosing, 253/270 (94%) patients on NER1006 achieved adequate level right colon cleansing. Adequate level cleansing success was achieved significantly more often with NER1006 evening/morning split-dosing than 2L PEG + Asc, both in the overall colon (P = 0.013) and in the right colon (P = 0.042). The slight improvement seen with NER1006 morning-only dosing in the cleansing rate of the overall colon and right sided colon was not statistically significant. Table 1: Adequate cleansing level of the overall colon and right colon (BBPS segmental scores 2–3) as determined by treatment-blinded central readers

N.B. successful cleansing defined here as a Harefield Cleansing Scale grade of A or B (overall colon)
Abstract No: P0184

**Aims & Methods:** To assess the quality of colonoscopy in current clinical practice, through the use of online questionnaires, compared with recently published ESGE performance indicators. The development of the online practitioner and procedure questionnaires has been previously described. Data collection is an ongoing process. We analysed data collected between 2/6/16 and 17/4/17 and compared with the ESGE performance measures.

**Results:** 40 of 50 practitioners completed the practitioner questionnaire. 2094 colonoscopies were documented across 8 European countries by 47 practitioners. The ESGE sets a minimum standard of ≥90% of patients with adequate bowel preparation, defined as Boston Bowel Preparation Scale score ≥3. From our data, 81% (n = 1692) of procedures had adequate bowel cleansing (data unavailable for 96.4%). The ESGE recommends a minimum standard of ≥90% of all diagnostic and screening colonoscopies visualize the whole caecum (excluding those that have no indication to reach the caecum). Only 55% of practitioners routinely record caecal intubation rate. The caecum was the intended endpoint in 66% of procedures. For those diagnostic and screening colonoscopies where the caecum was the intended endpoint (n = 1390), 93% reached the endpoint but only 70% had this endpoint photo-documented. The ESGE recommends that adenoma detection rate (ADR) should be used as a measure of adequate inspection at screening or diagnostic colonoscopy in patients aged 50 years or more. ADR was routinely recorded by only 18% of practitioners. Polyp removal rate is routinely recorded by 30% of practitioners, and polyp retrieval rate by 23%.

**Conclusion:** Our findings indicate that some important performance measures recommended by ESGE are not currently being achieved in practice. By providing self-assessment tool and as a next step, by individual consultations with the ESGE performance measures.

**Introduction:** When it comes to gastrointestinal endoscopy, considerable heterogeneity is observed between gastroenterologists regarding the use of sedation and the preferred sedative agents. The sedation protocol used by a gastroenterologist may have a significant effect on endoscopic quality, patient cooperation and both the doctor’s and the patient’s satisfaction with the procedure.

**Aims & Methods:** The aim of this study was to document current endoscopic practices of Greek gastroenterologists and investigate whether they use sedation to perform gastrointestinal endoscopy and which pharmaceutical agents are usually involved. A 39-item online questionnaire was devised, addressing demographic data, use of sedation in endoscopy and monitoring practices. It was subsequently made available to 509 Greek gastroenterologists by e-mail.

**Results:** A total of 195 questionnaires were successfully completed (38.3%). 49 gastroenterologists did not use sedation to perform esophagogastroduodenoscopy (EGD) or colonoscopy (25.1%). The younger gastroenterologists were more likely to use sedation (p = 0.005). Among those using sedation, midazolam was the most frequently used agent in EGD (50%) and the combination of midazolam/fentanyl was the most frequently used in colonoscopy (24.6%), followed by midazolam (21.9%). Out of 137 physicians using benzodiazepines (midazolam, diazepam) as part of their endoscopic sedation regimen, 91 (66.4%) routinely used flumazenil to facilitate pharmacological antagonism after the completion of the endoscopy. In total, 45 physicians, 23.1% of the participants and 30.8% of those using sedation, used propofol or a combination of propofol and other agents. 30 gastroenterologists routinely administered propofol without the aid of an anesthesiologist (66.6%). Medicolegal issues (33%), inadequate training in the use of propofol (26.4%) and risk of cardiorespiratory complications (23.6%) were cited as the main reasons for not using propofol. As far as monitoring practices go, the majority of gastroenterologists observed heart rate and oxygen saturation (96% and 97% respectively). Regarding the safety equipment available to the gastroenterologists, 160 (82%) reported having access to regimens of pharmaceutical resuscitation, 145 (74%) to oropharyngeal airway devices and laryngeal airway masks, 92 (47%) to endotracheal intubation equipment and 86 (44%) to a defibrillator. When asked to rate their level of satisfaction with their preferred sedation regimen (or with not using sedation) in a scale of 1 to 10, 72 physicians rated their satisfaction level as 9 or 10 (36.9%) and 92 as 7 or 8 (47.1%). While there was no significant difference in terms of satisfaction between the doctors that used sedation and those who did not, there was a statistically significant difference between the gastroenterologists that used propofol (alone or in combination with other agents) and those who used other sedative agents (p = 0.003). When asked on their preferred method of sedation, if they were themselves subjected to gastrointestinal endoscopy, 104 physicians opted for propofol-based sedation regimens (53.3%).

**Conclusion:** Gastrointestinal endoscopy is performed with the use of sedation by the majority of Greek gastroenterologists. Propofol-based regimens are seldom used in everyday clinical practice, despite a vast number of Greek gastroenterologists identifying them as their preferred regimen, in case they themselves should undergo endoscopy. Compared to a past survey, Greek gastroenterologists are still hesitant about using propofol. However, an increasing tendency towards administering propofol without the aid of an anesthesiologist is observed. Also, physicians using propofol seem to be more satisfied with their sedation practices than the doctors using other sedation regimens. Absence of a distinct legal framework, inadequate training and fear of cardiorespiratory complications are identified as the main reasons preventing Greek gastroenterologists from using propofol.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Indicators for colonoscopy quality assessment were developed and promoted during this last decade. However technical and human resources constraints limit local implementation of continuous recording of endoscopic quality indicators (QI). Automatic system of data extraction and presentation could help endoscopy units in their quest for quality improvement. We hereby report our experience in implementing colonoscopy QI record trough an automatic data extraction system from separate databases (DB), and assess the colonoscopy quality at unit and individual levels.

Aims & Methods: We locally adapted a company reporting system for colonoscopy by adding in a dedicated tab, selected procedure indicators. Endoscopic QI data from reporting system DB and pathological results from another DB were extracted and merged together in a separate DB. On a regular period basis or on request, key QI are calculated and extracted. It includes adenoma detection rate (ADR), polypt detection rate, caecal intubation rate, quality of bowel preparation (using the Boston bowel preparation scale) and type of sedation. During a first period of 6 months starting in January 2016, endoscopists were encouraged to fulfill the dedicated tab on a voluntary basis. In a second period, filling of QI was made mandatory for all endoscopists. The completeness of QI recording was evaluated across both periods, and results from second period are presented. Performance measures of all endoscopists were compared to global results of our department and to published targets.

Results: During the 6 months "mandatory-filling" period (July-December 2016), 1802 colonoscopies were performed with a QI tab fully filled in 100% of cases compared to 63.1% after the “free-filling period” (p = 0.0001). The global caecal intubation rate for screening colonoscopy was 92.9%. Mean Boston bowel preparation score was 7.2 ± 0.76 with 86.9% of cases with adequate preparation (Boston score > 5; 89.9% among outpatients and 81.9% among inpatients). Colonoscopies were performed under propofol sedation in 94.1%. During this second period, the global ADR was 32.4% (range: 0%-55.7%). The polypt detection rate was 44.4% with a mean of 1.19 polypt removed by colonoscopy.

Conclusion: This study illustrates that quality indicators for colonoscopy assessment in a Belgian tertiary hospital endoscopy unit could be easily implemented with limited human resources by adapting a company reporting system and link it to an institutional database. Moreover, a mandatory filling of QI items was necessary for system implementation success. Our results are consistent with goals required by international guidelines. This system allows giving feedback to individual endoscopists for self-performance assessment and might be easily adapted in the future following guidelines updates.

Introduction: There has been a growing interest in the detection of colorectal cancer (CRC) using a computer-aided detection system (CAPS). However, the current CAPS are not widely used in clinical practice due to the high cost and complexity of these systems. A recent advance in deep learning technology is convolutional neural networks (CNNs), which can be used to automate the detection of colorectal adenomas from colonoscopy images. This technology has the potential to improve the accuracy and efficiency of colon cancer detection, which is a critical public health issue worldwide.

Aims & Methods: We aimed to develop and evaluate an automated polyp detection system using deep learning technology. We collected a dataset of high-resolution colonscopic images and used a CNN to automatically detect polyps in these images. The performance of our system was evaluated using standard metrics such as sensitivity, specificity, and precision. We also compared our system to a manually annotated set of polyp images to assess its accuracy.

Results: Our automated polyp detection system achieved an accuracy of 85% in the detection of polyps, with a sensitivity of 80% and a specificity of 88%. The system was able to detect a wide range of polyp sizes and shapes, and had an excellent false positive rate. A comparison with the manually annotated set of polyp images showed that our system had a high level of agreement with the human assessors.

Conclusion: Our study demonstrates the feasibility of using deep learning technology for the automated detection of colorectal adenomas from colonoscopy images. This technology has the potential to significantly improve the accuracy and efficiency of colon cancer detection, which is a critical public health issue worldwide. Further research is needed to evaluate the performance of this system in real-world clinical settings.
Aims & Methods: The aim of this study was to develop a computer-aided detection (CAD) algorithm for colonoscopy using deep learning. To evaluate the developed CAD algorithm, we retrospectively viewed colonoscopy videos from a previous randomized controlled study (UMIN000017083) conducted from April 2015 to October 2015. All examinations were performed using CF-H290ZI (Olympus Corp., Tokyo, Japan). In this study, two endoscopists (M.M. Y.M.) manually annotated 43 colonoscopy videos with 238 min of 17,903,967 frames. These videos included 75 polyps (48 neoplasms, 27 non-neoplasms), and annotations were made on the presence or absence of polyps in every frame. Forty-three videos were divided into 300 short video for machine learning and validation process. Among 300 short videos, 246 were used for the machine-learning process. The remaining 54 (33 included a lesion) were used to validate the CAD algorithm (Group A). A modified version of Caffe with 3-Dimensional Convolutional Networks (a kind of deep learning) was used for the CAD algorithm. The validation samples were analyzed using the CAD algorithm and its output as the probability of the presence of a lesion in each video. To verify their operating characteristic (ROC) analysis was performed to evaluate the efficacy of the CAD algorithm.

Results: The mean probability of a poly-positive video was 62.1 ± 27.9%, whereas that of a poly-negative video was 18.1 ± 24.6% (P < 0.001). The area under ROC was 0.887, and the positive predictive value of the present CAD algorithm could detect a poly with 90.9% sensitivity and 76.2% specificity.

Conclusion: Our preliminary results showed that state-of-the-art artificial intelligence has the potential for achieving automatic detection of colorectal polyps. A prospective study is now planned after more machine-learning sessions'.

P0192 TREATMENT OUTCOMES OF COLD FORCEPS POLYPECTOMY FOR PATIENTS WITH DIMINUTIVE POLYPS: A PROSPECTIVE FOLLOW-UP STUDY

H. Hasegawa1, S. Bambu1, H. Ban1, H. Imaeda1, A. Nishida1, O. Inatomi1, M. Sasaki1, M. Sugimoto1, A. Andoh1
1Dept. Of Gastroenterology, JCHO Shiga Hospital, Otsu,Japan

Contact E-mail Address: hirohase@belle.shiga-med.ac.jp

Introduction: The results of the National Polyp Study are premised on the removal of all adenomatous lesions. Cold forceps polypectomy (CFP) using jumbo biopsy forceps is a simple and safe technique used for diminutive polyps (≤5 mm). The recurrence rate after CFP for patients with diminutive polyps has not been elucidated.

Aims & Methods: We have prospectively enrolled patients with diminutive polyps treated with CFP from June 15 to March 2017. Minuscule polypectomy was used for all procedures. The location, size, endoscopic findings and procedures were recorded. The patients who have undergone CFP had their follow-up colonoscopy in one year after CFP.

Results: CFP was performed for total 515 polyps from 277 patients. The size of the polyps was <3 mm/4 mm/5 mm: 379/101/35. The rate of one-bite polypectomy for adenoma was <3 mm/4 mm/5 mm: 79%/54%/33%. There was no significant difference in the one-bite rate between endoscopists’ experience. No cancer was observed in histology. Rates of delayed bleeding after CFP was 0.19% (1/515). Concomitant use of anticoagulation use of antiplaudelets was found in 14% (7485), and none of them experienced delayed bleeding. No perforation occurred. Seventy-five patients had their follow-up colonoscopy so far. There are no polys without suspicion residual or recurrent lesion. Among 75 patients, 62 patients had less than two polyps removed at their first colonoscopy (Group A). On the other hand, 13 patients had more than three polyps removed at their first colonoscopy (Group B). Follow-up colonoscopy revealed that the rates of newly discovered polyps in the same segment were 8% and 23% in groups A and B, respectively. The rates of newly discovered polyps in the different segment were 27% and 61% in groups A and B, respectively. When the initial CFP was performed by the endoscopist with the experience of <5 years/5–9 years/10 years/more than ten years, the rates of newly discovered polyps found at follow-up colonoscopy was 54% (14/26)/42% (8/18)/37% (11/30), respectively.

Conclusion: The rate of one-bite polypectomy was significantly higher for diminutive polyps especially less than 5 mm. Importantly there are no polyps suspicious residual or recurrent lesion. CFP is a safe and effective option for diminutive polyps (≤5 mm). Although the rate of one-bite polypectomy was not related to the endoscopists’ experience, adenoma detection rate is seemed to be low in young endoscopists. Since achievement of “clean colon” is critical with a single colonoscopy, multiple colonoscopy examination are necessary to achieve “clean colon” especially if the patients have more than two polyps at the first examination.

P0193 EFFICACY OF CIMETROPRIUM BROMIDE ON POLYP DETECTION DURING COLONOSCOPIC WITHDRAWAL: A DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED, CLINICAL TRIAL

Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of

Contact E-mail Address: sulsupul@naver.com

Introduction: Colonoscopy is the most effective method for preventing colorectal cancer, as it offers easy detection and resection of polyps. Cimetropium bromide...
results in colonic spasmylosis and may improve polyp detection. We studied the effect of cimetropium bromide on polyp detection during colonoscopic withdrawal.

**Aims & Methods:** Patients undergoing colonoscopy for screening examinations were included and randomized to cecal intubation to receive either 5 mg cimetropium bromide or placebo. We evaluated the polyp detection rate (PDR), adenoma detection rate (ADR), and advanced ADR (AADR) in the right side colon as well as in the colon resection.

**Results:** A total of 181 patients were analyzed in this study. Cimetropium group consisted of 90 patients and control group consisted of 91 patients. PDR, ADR, and AADR were not significantly different in cimetropium and control groups (62.6% vs. 66.6%, P = 0.571; 51.6% vs. 47.7%, P = 0.060; 3.2% vs. 7.7%, P = 0.187; respectively). Similarly, PDR and ADR in the right side colon were not significantly different between the groups (46.1% vs. 47.7%, P = 0.827; 32.9% vs. 35.5%, P = 0.714; respectively).

**Conclusion:** Cimetropium bromide does not improve the PDR or ADR in the right side colon or the colon resection. Thus, administration of cimetropium bromide can be used in the colonoscopy procedure.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0194 ADHERENCE TO EUROPEAN SOCIETY OF GASTROENTEROLOGY ENDOSCOPY (ESGE) POLYPECTOMY GUIDELINES: AN IRISH EXPERIENCE**

O. N’Moura, Y. Parhil, O. O’Dwyer, P. Maheshwari, L. Kumar, S. Fennessey, N. Breslin, B. Ryan, D. McNamara

1Gastroenterology & Hepatology, Tallaght Hospital, Dublin/Ireland
2Gastroenterology Tráitory Academy Academic Gastroenterology Group (T4GEG), AMNCH Tallaght, Dublin/Ireland

**Contact E-mail Address:** neil.moran@amnch.ie

**Introduction:** Colorectal cancer (CRC) accounts for up to 11% of all cancers in women and 14% of men in Ireland, and is the second most common cancer across sexes. The adenoma-carcinoma sequence of colorectal carcinogenesis lends itself to screening with the aim of complete excision of polyps. It has been estimated that incomplete resections of polyps are involved in 19–31% of interval cancers. ESGE guidelines state that polyps 5 mm or greater should be removed by snare resection. Previous studies report inappropriate resection techniques in up to 46% of cases. The aim of this study was to investigate polypectomy techniques and to assess adherence to guidelines in a tertiary referral, University teaching hospital in Dublin, Ireland. We also investigated the differences between subspecialty and consultants versus trainees.

**Aims & Methods:** The study included all patients who underwent colonoscopy in Tallaght Hospital (Dublin, Ireland) between January 2012 and December 2015 for any indication. From this, a list of patients with colon polyps was compiled. Demographics and other information including number and site of polyps, resection and retrieval rates, method of resection and speciality of endoscopist were included.

**Results:** 11,400 colonoscopies were performed during the study period. To date, the records of approximately 7000 (61%) procedures have been reviewed. 2337 (22.5%) patients were identified with polyps, with 1027 females (43.4%), 1310 males (56.6%) and a mean age of 60.6 years. The indication for colonoscopy included symptoms (47.2%), polyp surveillance (22.3%), CRC cancer screening (12.9%) and CRC cancer surveillance noted in 12.9%. The mean number of polyps per patient was 2.2. 47.7% of polyps were resected by forceps and not by snare resection. Non-adherence to guidelines was observed in 12–18% amongst trainees and Consultants. The effect of gender aspects should be taken into account upon polyp induced sedation for gastrointestinal endoscopy. That includes adequate dosing for female as well as cautionness regarding potential overdosing of male patients.

**Conclusion:** ClinicalTrials.gov (Identifier: NCT02687568). Data were presented at a national meeting (DGEBV) in Germany.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** ariphau@web.de

**Introduction:** Sedation for colonoscopy by using intravenous propofol has become standard in many Western countries.

**Aims & Methods:** While gender-specific differences have been shown for general anaesthesia used in dentistry, no such data exist as yet for gastrointestinal endoscopy. In a prospective observational study at an Academic teaching hospital of Hannover Medical School 219 patients (108 women and 111 men) scheduled for colonoscopy were included. Invasive sedation using EEG monitoring during a constant level of sedation depth (D0 to D2) performed by trained nurses or physicians after bodyweight adjusted loading-dose.

**Main outcome measures:** Primary endpoint was the presence of gender-specific differences in wake-up time (time from end of sedation to eye - opening and the complete orientation of the patient); secondary outcome parameters analysed were total dose of propofol, sedation associated complications (bradycardia, hypotension, hypoxia, apnoea), patient cooperation and patient satisfaction. Multivariate analysis was performed to correct confounding factors such as age and BMI.

**Results:** Women awake significantly faster compared to men with a time to eye opening of 26.26 ± 3.69 versus 34.93 ± 3.81 min. (p = 0.005) and time until complete orientation 9.14 ± 3.38 versus 10.4 ± 3.71 min (p = 0.008); propofol dosage was not significantly different, with some trend towards more propofol per kg body weight in women (3.98 ± 1.81 mg versus 3.72 ± 1.75 mg, p = 0.232, n.s.).

The effect of gender aspects should be taken into account upon polyp induced sedation for gastrointestinal endoscopy. That includes adequate dosing for female as well as cautionness regarding potential overdosing of male patients.

**Trial registration:** ClinicalTrials.gov (Identifier: NCT02687568). Data were presented at a national meeting (DGEBV) in Germany.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Cold snare polypectomy (CSP) has grown in popularity worldwide due to its ease and safety with a low incidence of adverse events, such as hemorrhage and post-polypectomy syndrome. However, there are concerns regarding tumor residue with CSP because it does not use electrocautery, thereby increasing the rate of adequate lymph node harvest. Further studies and methods are needed to harvest adequate lymph nodes in colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0198 EFFICACY OF PLATELET-RICH PLASMA (PRP) ON ENDOSCOPIC RESECTION TECHNIQUES: CLINICAL STUDY IN 15 PATIENTS

Lorenzo-Zúñiga García1, V. Moreno De Vega2, I. Marín3, N. Caballero3, R. Bartoll3, I. Ben3, J. Boix3

Introduction: Prevention of complications secondary to endoscopic resection techniques (ER or ESD) requires avoiding deep thermal damage and increase mucosal healing. Platelet-rich plasma (PRP) has demonstrated efficacy in pre-clinical endoscopic resection models [1]. The EndoPRP study was a prospective single-center study to assess the efficacy of PRP on endoscopic resection of large sessile lesions (larger than 35 mm). (Study registered at ClinicalTrials.gov: NCT02931149)

Methods: In the EndoPRP study 15 patients (males and females, aged 52–80) were assigned to receive PRP (6–16 mL). i) Endoscopic Shielding Technique (EST, n = 4), applying PRP as a shield after standard resection technique, or ii) Submucosal injection (SMI, n = 11), performing a submucosal injection of PRP prior to ER or ESD. Patients were informed and accepted to participate with a written consent. PRP was obtained from a sample of patient’s blood (18–36 mL) drawn at the time of endoscopy. Patients underwent endoscopic follow-up at 4 weeks. The efficacy of PRP was assessed by the incidence of adverse events (delayed bleeding or perforation). Mucosal healing rate (MHR) was defined as a percentage of mucosal restoration after 4 weeks.

Results: Shielding technique with PRP was performed in 4 lesions at rectum (Æ 55.7 ± 20.6 mm, range 35–80 mm). Submucosal injection of PRP was used in 11 lesions (2 at antrum, 3 at rectum, and 8 at colon) (Æ 41.6 ± 9.9 mm, range 35–70 mm). Delayed bleeding occurred after ER of 1 lesion (no required blood transfusion or endoscopic treatment; 6.6% of all lesions: 1 patient at EST group, 0 patients at SMI group). MHR was significantly higher in patients treated with SMI than EST (87.5% vs. 78.6%; p = 0.03).

Conclusion: PRP applied as a shield over the scar or as submucosal fluid cushion has proved clinical efficacy in endoscopic resection of large lesions. Submucosal injection of PRP has showed better mucosal healing rate as comparison with shielding technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: rhodri@coreva-scientific.com

Introduction: Procedural sedation is commonly used during gastrointestinal endoscopic procedures. It comes, however, with the risk of sedation-related adverse events (AEs) as defined by World SIVA. The cost of AEs and their impact on healthcare resource use and efficiency is currently unknown.

Aims & Methods: The aim of our study is to quantify and compare the costs of AEs during procedural sedation in France, Germany, Italy, UK, and USA. Online interviews were conducted with providers (nurses, physicians, and anesthesiologists) and payers. Respondents were screened to ensure that they had the expertise and experience to complete the survey. The provider surveyed covered topics such as guidelines, sedation agents, monitoring, and patient outcomes following AEs. Each provider reported on current clinical practice, the incidence of AEs, and the standard treatment and outcomes for 100 hypothetical patients screened for eligibility between September 2015 and August 2016. Three hundred and ninety-four lesions were assigned to the CSP group and 402 lesions were assigned to the HSP group. One hundred and nine lesions (56 in the CSP group and 53 in the HSP group) were excluded for FPS analysis. Background characteristics of the lesions (size, location, morphology, and institution) were similar in both groups. The complete resection rate for CSP was 99.6%, compared to 99.4% for HSP. The between group difference in complete resection rate was 0.6% (95% CI. of ± 0.5–2.7; p < 0.0001). Resection time, overall, was significantly shorter with CSP than with HSP (60 vs. 83 s, respectively; p < 0.001). Postoperative bleeding requiring endoscopic treatment occurred in 2 HSP (5.2%) and 4 CSP (10.6%) lesions. Subgroup analysis according to the size of the polyp (4–5 mm and 6–9 mm) showed a comparable complete resection rate for CSP and HSP for both subgroups of polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

nontattooing group, both side injection group was better result (96.2% vs. 95.6%, p-value = 0.229). Most results did not have statistical association with higher lymph node yield in colorectal cancer. But in T1 cancer, the rate of adequate lymph node harvest was higher in the both side injection group, statistically (94.7% vs. 81.0%, OR 4.235, p-value 0.0047) Conclusion: CSP was associated with a higher lymph node harvest in colorectal cancer, especially in T1 cancer. And both side injection of ICG increased the rate of adequate lymph node harvest. Further studies and methods are needed to harvest adequate lymph nodes in colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.
with a defined AE. Treatment options, including none required, were taken from StGChI-defined lines. Reponses examined included: 1.) unplanned hospital admission, and death. Payers were surveyed about costs for interventions, provider time, hospital administration, and admissions. Outliers were identified using Dixon’s Q test. The mean treatments and outcomes per AE for the CR procedures were calculated, with responses weighted by the AE frequency reported by physicians and the outliers replaced by global means. Mean costs were calculated per utilization and outcome, with outliers removed.

Results: 101 providers and 26 payers completed the surveys, with a minimum of 20 providers for each country. The overall mean responses were 52.3% (SD 17.4%); 62% of providers were gastroenterologists and anaesthesiology nurses. Local guidelines determined practice in most cases, and propofol and midazolam were the main sedation agents employed. The most common AEs reported were hypotension and bradycardia, with 9% and 4% of respondents, respectively, estimating each curve to occur during >10% of procedures. Mean provider time required to treat AEs ranged from 1.7 minutes for mild desaturation in Germany to 3.10 minutes for cardiac arrest in the USA. Accounting for interventions and provider time, the median direct cost per range from EUR 1.12 for bradycardia in Germany to USD 3.877 for cardiac arrest in the USA (Table). When costs were “fully loaded” these became EUR 39 and USD 19, 722, respectively. Although of low direct cost, bradycardia in Germany was reported to cause procedure termination or substantial delay in 3.8% of cases. In Euro countries, the median of mean direct costs for an AE was EUR 40 (IQR: 29.67). When costs of outcomes of AEs were included the median “fully loaded” cost reached EUR 301 (IQR: 115-738).

Table: Costs of select adverse events by country. FL: Fully-loaded (costs including hospital administration, time, inpatient stays, delays, and cancellations, but excluding legal costs)

Conclusion: Costs of sedation-related AEs can be substantial regardless of country of origin. Disruption of patient flow and provider efficiency may add to the cost burden. Even relatively minor events may prompt additional intervention, increasing the overall cost of care.

P0200 COLORECTAL ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD), KNIFE-ASSISTED SNARE RESECTION (KAR) AND SPARENESS: A WESTERN EUROPEAN EXPERIENCE IN SPAIN

J. C. Marin-Gabriel1, J. B. Diaz Tasende1, P. Canezas-Nava2, S. Rodriguez-Muñoz1, A. J. De Pozo-Garcia1, M. Alonso-Riano2, Y. Rodriguez-Gil1, C. Berruezo-De Andrade3, G. Castellano-Tortajada4

2Research Institute "11-12", Hospital Universitario "12 de Octubre", Madrid, Spain
3Gastroenterology, Endoscopy Unit, Hospital Ruber, Madrid, Spain
4Pathology, University Hospital "12 de Octubre", Madrid, Spain

Introduction: Performing CR-ESD remains challenging in Western countries and surveillance studies in this setting are not fully described. KAR has been advised as a reasonable strategy for non-expert endoscopists and difficult lesions. However, some KAR eventually requires a piecemeal resection (p-KAR). A direct comparison between these two techniques is lacking. Additionally, when the specimen is resected en bloc regardless of what procedure is used, and the only pathological risk factor for recurrence is lateral margin (LM) involvement, its implications concerning the recurrence rate should be assessed.

Aims & Methods: 1.) To compare the recurrence rate after R0 and R1/Rx endoscopic resection (ER), on an ESD “intention-to-treat” basis, in a Western European setting where CR-ESD is performed by non-experts. 2.) To evaluate the impact of LM involvement on local recurrence when neoplasms without risk factors for lymph node metastasis are resected en bloc. We prospectively included 89 consecutive CR neoplasms planned for ESD from September 2008 to December 2015. When technical difficulties arose or for patient’s safety reasons, we performed a KAR. Kaplan-Meier survival curves were used to assess the recurrence rate over time. The end of follow-up was considered when a local recurrence occurred or at the end of the surveillance period in those patients who did not develop the event. Comparisons were made using the log-rank test. The recurrence rate during follow-up was stratified considering advanced histology, en bloc resection and R0 resection.

Results: The ER was aborted in 5 cases (perforation n = 3; technical difficulties n = 2). Surgical intervention was needed after ER because of submucosal or linfovascular invasion in 4 patients. Five out of the remaining 80 cases, were lost to follow-up. Finally, 75 CR neoplasms were included in 74 patients (43 male; 58.1%). Median age was 71 years (range: 37–93). Median size of the lesions was 32 mm (range-10–100). Histology was 26 (34.7%) Vienna category 3; 46 (61.3%) Vienna 4 and 3 (4%) sm1-Vienna 5. En bloc resections were obtained in 44 cases (58.7%); 33 ESD (48%) and 11 KAR (14.7%). The ER finished as p-KAR in the 31 remaining lesions (41.3%). R0 resections (n = 23; 30.7%) were achieved in 18/33 ESD and 5/42 KAR (OR = 8.9, CI 95%: 2.8–28.3; p < 0.0001). The median follow-up period was 16 months (1–91). Local recurrence occurred in 11 cases: 9 of the latter throughout the first year (81.8%). No surgery was needed because of recurrence. The overall recurrence rate at 36 months was 15%. The recurrence rate at 3 years showed a statistical significant difference when R0 resections were compared with R1/Rx: 0% vs. 21.5% (p = 0.03). When results were stratified according to histology and en bloc resection, no significant differences were found in the recurrence rate. When en bloc resections in pTa/T1b (sm1); –; +; pV60 (lesions n = 44) were analysed separately, LM distribution was 80%, LM0 (52.3%); 18 LM1 and 3 LMx (6.8). There was a non-significant trend concerning the recurrence rate when LM0 (n = 23) lesions were compared with LM1/LMx (n = 21%): 0% vs. 14.8% at 3 years; p = 0.06.

Conclusion: ESD R0 resections were 9 times greater than that of KAR on an ESD “intention-to-treat” basis. R0 resections were associated with lower recurrence rates in comparison with R1/Rx resections. LM involvement increased the recurrence rate but without a statistical significance when it was the only pathological risk factor for recurrence and the specimen was resected en bloc.

P0201 ASSOCIATION BETWEEN SIZE, LOCATION AND HISTOLOGICAL CHARACTERISTICS OF COLORECTAL LATERALLY SPREADING TUMORS

F. L. Mota1, J. F. Loureiro2, L. S.N, Da Costa2
1Digestive Endoscopy, Hospital Sirio Libanes, Sao Paulo/Brazil
2Digestive Endoscopy Department, Hospital Sirio Libanes, Sao Paulo/Brazil

Contact E-mail Address: lucasnde@gmail.com

Introduction: LATERALLY SPREADING TUMORS (LST) are important precursors of colorectal cancer (CRC). The endoscopic characteristics of the LSTs, such as size and location, appear to correlate with the histological findings2, which is an essential data for the decision of the best therapeutic procedure to be carried out.4

Aims & Methods: To determine the association between size, location and the histological characteristics of colorectal LSTs by reviewing of the colonoscopy and histopathological reports of the LSTs endoscopically removed between October 2013 and June 2015 at the digestive endoscopy department of a tertiary hospital. The Vienna revised classification was used for the adenomatous lesions4, and the World Health Organization (WHO) classification for the “sessile serrated adenomas” (SSA)5. The regions of the colon were referred to
as either “proximal” or “distal” colon. Thereafter the division into six anatomical segments was considered (cecum, ascending, transverse, descending, sigmoid and rectum).

Results: A total of 218 LSTs were included in this study. Most patients (59.4%) were female. The mean age was 66.1 years, and the average size of the LSTs included was 1.69 cm. Larger than the other classifications. This association, however, is not observed in the proximal colon. However, when the subdivision of the colon into anatomical type (p = 0.005), the adenomas with low grade dysplasia were most prevalent in the proximal colon. However, when the subdivision of the colon into anatomical segments was considered, the SSA without dysplasia was the most common type at the ascending colon.

Conclusion: There is association between the size and the histological characteristics of colorectal LSTs. Adenomas with high grade dysplasia were found to be larger than the other classifications. This association, however, is not observed between location and histology; there is association between location and histology; with the SSAs without dysplasia being the predominant type at the ascending colon.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0202 SAFE AND SUCCESSFUL RESECTION OF DIFFICULT GI LESIONS USING A NOVEL SINGLE-STEP FULL-THICKNESS RESECTION DEVICE (FTRD)

P.V. Valli, J. Mertens, P. Bauerfeind
Division of Gastroenterology And Hepatology, University Hospital Zurich, Zurich/Switzerland

Introduction: Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are well-established and effective techniques for the endoscopic resection of mucosal neoplasms along the gastrointestinal (GI) tract. However, these procedures are limited to superficial lesions. In the case of deeper ingrowth into the gut wall as well as anatomic sites prone to perforation, the novel full-thickness resection device (FTRD) offers a new dimension of possibilities for endoscopic resection.

Aims & Methods: Sixty patients underwent therapeutic endoscopic full-thickness resection (eFTR) at our institution. The procedures were carried out as follows: First, the target lesion is marked with electrocautery and the endoscope is then retracted. The full-thickness resection device (FTRD, Ovesco® Endoscopy AG, Tübingen), is fitted onto a therapeutic endoscope. The endoscope with the FTRD® is advanced to the previously marked lesion. Grasping forceps are used to take hold of the target lesion and carefully push it into the plastic cap of the FTRD®. Immediately after deployment of the OTSC®, eFTR is performed using the hyperthermic snare within the plastic cap. The full-thickness specimen is retrieved and processed for histopathological examination. Safety, learning curve, R0 resection rate and clinical outcome of all 60 interventions were studied.

Results: eFTR was performed for the following indications: 1. Recurrent adenomas (n = 22.5%), with a non-lifting sign after previous incomplete polypectomy and adenomas with a primary non-lifting sign on saline injection (n = 2.3%). 2. Non-lifting base after extensive piecemeal resection of a spreading adenoma (n = 4.7%). 3. Diverticular polyps (n = 2.3%). 4. Polyps the cecal appendix (4.7%). 5. Submucosal lesions (n = 5.8%). 6. Early carcinoma (n = 7.1%). 7. Follow-up resection of a malignant polyp (n = 10%). 8. eFTR over endoloop resection (n = 2.3%). In 97% (38/40) of the interventions, the FTRD®-mounted endoscope reached the previously marked lesion and eFTR was performed (technical success). Full-thickness resection was achieved in 88% of the cases, with an R0 resection on histological examination in 79%. The clinical success rate based on follow-up history was even higher (88%). The following adverse events occurred: Appendicitis of the cecal appendix after eFTR of an appendiceal adenoma (1/58.2%). Minor bleeding at the eFTR site (2/58.3%). eFTR performed accidentally without proper prior deployment of the OTSC® (1/58.2%). There was no secondary perforation or eFTR-associated mortality.

Conclusion: In conclusion, after specific training, endoscopic full-thickness resection is a feasible, safe and promising resection technique. It allows complete resection of lesions affecting layers of the gut wall beneath the mucosa, without the risk of perforation. In the future, eFTR may become a valuable alternative to a surgical approach in cases where endoscopic resection was previously thought impossible.

P0203 VASCULAR AND PIT-PATTERN ANALYSIS ACCORDING TO KUDO, SANO AND NICE CLASSIFICATIONS: IMPROVES AFTER AN IMAGE-BASED TRAINING PROGRAM

F. Desideri1, G. Esposito2, S. Angelletti1, F. Iacopini1, M. Haefner1, E. Di Giulio1
1Gastroenterology, S. Maurizio Hospital, Bolzano/Italy
2Endoscopy Unit, S. Andrea Hospital, Rome/Italy

Contact E-mail Address: federico.desideri@gmail.com

Introduction: Narrow Band Imaging (NBI) and chromoendoscopy with methylene blue are enhancing techniques which are helpful in differentiating vascular and pit patterns of colorectal neoplasms. Therefore, they have a key-role for the adequate management of the lesions which might be candidates for endoscopic resection.

Aims & Methods: The aim of our study was to measure the interobserver agreement and the diagnostic accuracy in an endoscopy unit using methylene blue and NBI for the evaluation of the pit and vascular pattern according to the Kudo, Sano and NICE classifications of colorectal neoplasms, before and after the image-based training program. We retrospectively collected consecutive endoscopic images (NBI and with methylene blue) of colorectal neoplasms from the internal database. The image set was then evaluated by our gold standard composed by two expert endosofts. Their evaluation resulted confident with histology reports in 88% of cases. The images set was then evaluated by the 9 endoscopists of the unit, before and after a 30-minutes image-based training program on enhancing techniques and surface colorectal patterns. NBI and colorectal neoplasms’ surface and vascular patterns. Interobserver agreement was calculated using the kappa statistic by Cohen. By using the gold standard evaluation as criterion standard, the accuracy of colorectal neoplasms’ evaluation before and after the training was also calculated using the McNemar test. A value of p < 0.05 and good statistical significance.

Results: A total of 30 images were obtained (see Table). Before the training process, the interobserver agreement was minimal for Kudo (0.10 ± 0.03) and Sano (0.12 ± 0.04), and poor for the NICE classification (0.24 ± 0.05). Diagnostic accuracy was 0.33 ± 0.07, 0.54 ± 0.12 and 0.60 ± 0.10 for Kudo, Sano and NICE classifications, respectively. After the image-based training program, interobserver agreement moved to moderate for the Kudo classification (p < 0.0001) and to good for Sano and NICE classifications (p < 0.0001). Diagnostic accuracy increased significantly, too, with values of 0.60 ± 0.05, 0.76 ± 0.05, 0.80 ± 0.05 for Kudo, Sano and NICE classifications, respectively (p < 0.0001).

Conclusion: To the best of our knowledge, we present the first study on the ability of an image-based training program in increasing the interobserver agreement and diagnostic accuracy in differentiating pit and vascular patterns of colorectal neoplasms using all the available endoscopic classifications (Kudo, Sano and NICE classifications). Such training seems mandatory for endoscopists using enhancing techniques especially when advanced lesions are planned to be treated endoscopically.

P0204 YIELD OF 2ND SURVEILLANCE COLONOSCOPY IN “INTERMEDIATE RISK” PATIENTS. COULD SURVEILLANCE INTERVALS BE REDEFINED?
M. Balakrishnan, B. Adeoti, S. Cerys, S. Catnach, A. King, B. Macfarlane, J. Landy
Gastroenterology, West Hertfordshire Hospitals NHS Trust, Watford/United Kingdom
Contact E-mail Address: jonathan.landy@whht.nhs.uk
Introduction: Data regarding the yield of 2nd surveillance colonoscopy after index procedure findings of advanced colonic neoplasia (ACN) are limited. The yield of ACN at 2nd surveillance is associated with high risk index or surveillance findings (1). However, previous studies are heterogeneous and definitions of ACN include characteristics of both "intermediate" (IR, >3 adenomas or any adenoma >10 mm) and "high risk" groups (HR, >5 adenomas or >3 adenomas with at least 1 >10 mm) as defined by BSG guidelines.
Aims & Methods: We aimed to evaluate the differences in yield of advanced colonic neoplasia at 2nd surveillance colonoscopy (S2) between “intermediate” and “high” risk patients at index colonoscopy in our unit. ACN was defined as ≥5 adenomas, any adenoma ≥1 cm, tubulovillous histology or high grade dysplasia, or cancer. Patients with HR or IR index procedures undertaken by 3 experienced, accredited bowel cancer screening colonoscopists and at least 2 surveillance colonoscopies, were identified from our local database between 2008 and 2016. Findings at 1st and 2nd surveillance procedures were assessed for the presence of ACN. Statistical analysis was undertaken using Graphpad Prism 5 using Fisher’s exact test. All tests were two tailed and a p value of <0.05 was considered significant. ORs with a 95% CI were calculated for significant findings.
Results: 218 patients meeting inclusion criteria were identified. 53% of patients had IR index findings. The median time to S2 was 49 months (IQR 48–49.4) for HR index patients and 72 m (IQR 70–73) for IR index patients. 11% of all patients had ACN at S2. 4% of IR patients v 18% of HR patients had ACN at S2. 0.4% (95% CI 0.2–0.6%) of IR patients without ACN at S1 had ACN at S2 v 15% of IR patients with ACN at S1 (ns). 11% of HR patients without ACN at S1 v 37% with ACN at S1 had ACN at S2; OR 0.2 (95% CI 0.07–0.6). Conclusion: Stratification of high-risk index findings into HR and IR groups facilitates a low-risk group at second surveillance colonoscopy. The second surveillance interval for IR patients without ACN at first surveillance might be increased as ACN is infrequently detected in this group.
Disclosure of Interest: J. Landy: Educational support from Norgine.

Introduction: Cold snare polypectomy (CSP) has been increasingly used in recent years because post-polypectomy bleeding is less common with this technique than with conventional polypectomy. According to the 2012 update of the Japanese guideline for periprocedural management of antithrombotic medications, the Food and Drug Administration issued the warning to stop taking aspirin 3 days before CSP. This guideline was followed by Japanese Gastroenterological Endoscopic Society (JGES) classification for optical diagnosis of colorectal polyps following standardized and continued training. Endoscopy 2015; 47: 200–206

was indicated for non-pedunculated polyps smaller than 10 mm, excluding lesions with potential invasion and suspected of being cancers at the preprocedural diagnostic evaluation.
Results: CSP was performed to remove 2466 polyps in 1003 patients; cancerous lesions accounted for 0.2% of them, but all had negative margins. There were 549 polyps in 294 patients who had been taking antithrombotic medication before CSP (antithrombotic group), and 1917 (77.7%) in 817 patients not taking antithrombotic medication (non-antithrombotic group). In the antithrombotic group, 106 patients with 283 polyps continued taking the antithrombotic medication; specifically, aspirin in 41 patients with 113 polyps, clopidogrel in 13 patients with 17 polyps, dual antiplatelet therapy (DAPT) in 13 patients with 18 polyps, antiplatelet agents other than clopidogrel in 17 patients with 68 polyps, antiangioplasty agents in 20 patients with 56 polyps, and antplatelet plus anticoagulant combination therapy in 2 patients with 11 polyps. Heparin bridging was used in 13 patients with 38 polyps. Post-CSP bleeding occurred in 0.54% (3/549) of the interventions in the antithrombotic group and in 0.10% (2/1917) of those in the non-antithrombotic group, showing no significant difference (p = 0.08). Endoscopic hemostasis was successful in all cases of bleeding, without requiring blood transfusion. As for the 3 cases of post-CSP bleeding in the antithrombotic group, the specific antithrombotic medication being used was aspirin in 1 patient with 1 polyp (0.88%, 1/113), and aspirin and clopidogrel in a patient with 2 polyps (11.1%, 2/113). No post-CSP bleeding occurred in patients on other antplatelet or anticoagulant agents, or on heparin bridging. Clipping after CSP was more likely used in the antithrombotic group (i.e., 13.5% vs. 4.6%; p < 0.01). No significant difference in post-CSP bleeding rate was observed between lesions with and without clipping (0% with clipping vs. 0.34% without clipping; p = 0.55).
Conclusion: CSP is a safe procedure even in patients on antithrombotic medication. The risk of post-polypectomy bleeding is lower with CSP when compared with the biopsy method in patients on antithrombotic medication (post-procedural bleeding rate, 0.09–0.61%), suggesting that CSP can be virtually categorized as a procedure with a low risk for hemorrhage in the guideline for periprocedural antithrombotic medication management.

P0206 OPTICAL ENHANCEMENT FOR THE IN VIVO PREDICTION OF COLORECTAL POLYPS
E. Klenšek, C. Neufert, A. Näge1, S. Zöpf, M. F. Neurath, T. Rath
Department Of Medicine V/University Hospital of Erlangen, Erlangen/Germany
Contact E-mail Address: enichko.klenseks@uk-erlangen.de
Introduction: Diminutive polyps are a common finding among surveillance colonoscopies without having high prevalence of advanced histology, making their detection challenging. Filter technologies, such as optical enhancement (OE), enable the detection of features of diminutive colorectal polyps in vivo in real-time and meet the PIVI thresholds of diagnostic or surveillance colonoscopies. OE in vivo histology prediction using OE was compared to results of histopathology as a reference standard.
Aims & Methods: In this study we aimed to assess whether OE can accurately predict the histology of diminutive colorectal polyps according to the ASGE PIVI criteria. A total of 106 colorectal polyps from 49 patients undergoing diagnostic or surveillance colonoscopy were included. The in vivo histology prediction using OE was compared to results of histopathology as a reference standard.
Results: The overall accuracy of OE for real-time prediction of polyp histology was 94.3% with a sensitivity, specificity, positive (PPV) and negative prediction value (NPV) of 100%, 95.3%, 85.4% and 100%, respectively. When including only high confidence (HC) predictions, the accuracy of OE increased to 96.5%. Sensitivity, specificity, PPV and NPV were 100%, 94.5%, 91.2% and 100%, respectively. In distal colorectal polyps the accuracy was 93.3% with sensitivity, specificity, PPV and NPV being 100%, 91.3%, 80% and 100%, respectively. The post-polypectomy colonoscopy surveillance intervals were predicted correctly in >90% of patients with OE.
Conclusion: Optical enhancement allows to accurately predict the histology of diminutive colorectal polyps in vivo in real-time and meets the PIVI thresholds for diagnostic and discarded diminutive polyps without histological assessment and for leaving distal diminutive colorectal polyps in place. Hence, optical enhancement can potentially reduce time, risk and costs associated with removal and histopathological assessment of diminutive polyps.

Introduction: Blue Laser Imaging (BLI) is a new image-enhanced endoscopic technique, meant, in association with magnification endoscopy, to help differentiating between neoplastic and non-neoplastic colorectal polyps. A variety of endoscopic classifications have been developed to guide optical diagnosis of colorectal polyps and the aim of our study was to evaluate NICE, WASP and Sano classifications for the optical diagnosis of colorectal polyps using Blue Laser Imaging and magnification.

Aims & Methods: Between May 2014 and December 2015, 181 colorectal polyps in 65 patients were imaged and resected in our single center study. Each polyp was evaluated using white light endoscopy, BLI with and without magnification. An independent expert reviewed the pictures and the videos of the polyps and staged them using NICE, Sano and WASP classifications: his conclusions were compared with the actual histology of the polyps. Diagnostic performances of BLI and magnification were calculated with each endoscopic classification.

Results: 181 polyps were studied, among which 125 adenomas, 24 sessile serrated adenomas/polyps, 25 hyperplastic polyps, 2 adenocarcinomas and 11 normal colorectal mucosal samples. The median polyp size was 7 mm. Overall, the NICE, Sano and WASP classifications were comparable in terms of diagnostic performances for the optical diagnosis of colorectal adenomas (p = 0.7). However, staging provided the maximum benefit of this study. The best results were obtained with the NICE classification. Specificity, positive and negative predictive value, and diagnostic accuracy for the diagnosis of adenoma of 0.93 (95% CI 0.86 to 0.97), 0.80 (95% CI 0.66 to 0.91), 0.93, 0.80 and 0.9. In the rectosigmoid, negative predictive value for the diagnosis of adenoma were 0.77; 0.91; and 1.0 using NICE, Sano and WASP classifications.

Conclusion: Our work suggests that BLI with magnification is a promising technique for the optical diagnosis of colorectal polyps with a diagnostic accuracy of 80%. Our study did not establish significant difference between the three classifications. However, the ASGE criteria for the implementation of the "resect and discard" strategy were met for the classifications of Sano and WASP with a negative predictive value for the diagnosis of adenoma beyond 90% in the rectosigmoid.

Introduction: Colonoscopy is difficult procedure, largely due to unpredictable looping during insertion. If the endoscopist is able to see the colonoscope on the image display, fewer attempts are needed to straighten the shaft of the scope. A prototype Fiber Brag Grating (FBG) scope guided endoscopy provides a facility for continuous viewing on a monitor of the position of the colonoscope during examination.

Aims & Methods: The aim of this study was to evaluate the accuracy and feasibility of the innovative 3D Colonoscope using FBG. In the first part of the study, the FBG sensor was inserted into the working channel of a routine colonoscope in the first 70 cm from the tip of the scope. Then, the scope was placed in front of the monitor to confirm movements in three-dimensions. We evaluated loop formation such as N loop, alpha loop, reverse alpha loop, with the 3D imaging monitor. In the second part of the study, 5 patients underwent colonoscopy with a FBG sensor, the colonoscope can be displayed in anteroposterior or lateral view, or in both positions together. Fluoroscopy was used in all investigations for comparison.

Results: In the first part of the study, the results showed that the shape sensor was successfully inserted to the working channel of 80 mm². The average tip error was 1.722 ± 1.678 mm, which corresponds to 1.50 ± 1.46% of the total length of the sensor. Scope movement and loops were detected correctly in all cases through the monitor. The prototype used in the second part of the study showed high correlation and little discrepancy with the comparative findings at fluoroscopy.

Conclusion: Scope-guided endoscopy using FBG sensor can be successfully used to display colonoscopy configuration. This flexible, thin and almost weightless prototype, FBG sensor would be a novel technique for identification of colonoscope shape.

Disclosure of Interest: All authors have declared no conflicts of interest.
permeability process after IRE by providing the real-time images. Additionally, Magnetic resonance spectroscopy can be applied as a diagnostic tool to measure the amount of chemical formulas with prokinetic effect. Pralocalcine is a serotonin (5-HT4) receptor agonist which stimulate colonic mass movements and provide main prokinetic force for defecation.

P021 LARGE (>30MM) POLYP ENDOSCOPIC MUCOSAL RESECTION: OUTCOMES AND PREDICTORS OF SUCCESS

Introduction: Endoscopic mucosal resection (EMR) is an established therapeutic option for large (>30 mm) colonic polyps. We aimed to assess characteristics and outcomes of this cohort. Primary outcomes consisted of rates, predictors and durability of EMR success, whilst secondary outcomes included complications, malignant risk, and conversion to surgery.

Aims & Methods: We prospectively identified patients referred for large polyp EMR from a polyp multidisciplinary team meeting between August 2008–2016 in a district general hospital with tertiary EMR expertise. Data on demographics, polyp site, morphology, size, accessibility (SMAA), histology and follow-up endoscopy were retrospectively collected. Binary logistic regression modelling was performed using SPSS, with components comprising of year, individual SMAA components, and histology. The Kaplan-Meier approach was used to measure durability of EMR success.

Results: Large polyp EMR was performed in 91 patients out of 125 MDT referrals (73%). Patients had a median age of 72 (interquartile range [IQR] 14.4), and were predominantly male (60%). Polyps were sessile (46%), flat (49%) or pedunculated (4%), with a median size of 40 mm (IQR 20.5 mm), and were left-colon in 81%. Bleeding occurred in 16.5%, all of whom achieved haemostasis. The 30-day complication rate was 11% (delayed bleeding in 1 patient), 54 (59%) were fully resected in one session, with overall EMR successful in 75 (81.5%) after an average of 1.5 sessions. On multivariable analysis, significant predictors of complete resection at first attempt (Table 1) included: increasing year, sessile vs. flat morphology, and non-malignant histology. Malignant histology (p < 0.001) predicted overall EMR failure, but not age, gender, year of EMR, SMSA score, or concomitant argon plasma coagulation. Of the EMR failure group, 11/16 (69%) underwent surgical resection, of which 7/11 (64%) harboured malignant risk, and non-malignant histology. Malignant histology was fully resected in one session, with overall EMR successful in 75 (81.5%) after an average of 1.5 sessions. Significant predictors of complete resection at first attempt (Table 1) included: increasing year, sessile vs. flat morphology, and non-malignant histology. Malignant histology (p < 0.001) predicted overall EMR failure, but not age, gender, year of EMR, SMSA score, or concomitant argon plasma coagulation. Of the EMR failure group, 11/16 (69%) underwent surgical resection, of which 7/11 (64%) harboured malignant risk, and non-malignant histology. Malignant histology was fully resected in one session, with overall EMR successful in 75 (81.5%) after an average of 1.5 sessions.

Conclusion: Large polyp EMR is a safe and effective alternative to surgical resection of large polyps. Endoscopist experience, polyp morphology, and benign histology are predictors of complete resection at index EMR. Further data are required to evaluate the long-term outcomes of malignant polyps.

Introduction: Endoscopic mucosal resection (EMR) is an effective and safe treatment for large (>20mm) laterally spreading colorectal lesions. Although colon EMR has been established as a minimally invasive technique for treatment of large colorectal lesions, risk of adenoma recurrence is the main limitation. Current guidelines recommend first follow-up at 3–6 months; however, there are no well-designed prospective-studies published establishing an optimal follow-up interval. Our aim was to measure the current scheduling process and developing strategies to standardize our endoscopy center practices.

Aims & Methods: Single tertiary referral center quality improvement project started in January 2017 and currently still in progress. We present here the interim data. Consecutive patients who had undergone or would have EMR of lesions ≥20mm were eligible for inclusion. The process of following-up patients after EMR was divided at two levels: A dedicated team member generated a monthly report identifying patients who underwent colon EMR using our endoscopy procedure documentation program. The appropriate time frame for follow-up was established as either 3 months or 6 months. A dedicated team member reviewed the status of patients who underwent colon EMR and scheduled the colonoscopy follow-up. Evaluation of follow-up: A dedicated team member reviewed the status of patients who underwent colon EMR and scheduled the colonoscopy follow-up. Evaluation of follow-up: A dedicated team member reviewed the status of patients who underwent colon EMR and scheduled the colonoscopy follow-up.

Conclusion: These preliminary results suggest significant improvement in SC1 compliance with our intervention. We believe that continuing these efforts and further refining the intervention process, requiring less personnel resources, may be helpful to improve the follow-up time until 3–6 months interval while also enduring as a sustainable change for our practice.

P0214 META-ANALYSIS SUGGESTS: INSPECT TWICE TO INCREASE RIGHT COLON ADR DETECTION RATE

K. Triantafyllou, P. Gkolfakis, G. Tzatzios, G. D. Dimitriadis
2nd Dept Of Internal Medicine And Research Institute, National and Kapodistrian University of Athens, Medical School, Athens/Greece

Contact E-Mail Address: kritiani@med.uoa.gr

Introduction: Missed adenomas in the right colon are of major concern for interval colon cancer (CRC) development. There is evidence from cohort and randomized controlled studies (RCTs) that a second examination of the right colon – either in direct view or in retroflexion- increases the diagnostic yield of the procedure. However, data are not accepted unanimously.

Aims & Methods: The aim of this meta-analysis was to examine the effect of a second, back-to-back mucosa inspection on the diagnostic yield of colonoscopy in the cecum and the ascending colon. We performed literature searches in MEDLINE to identify studies evaluating the effect of a second pass endoscopic examination on adenoma detection rate (ADR) and advanced adenoma detection rate (AADR) in the right colon. Study outcomes effect sizes were calculated using RevMan 5.3 software fixed or random effect model, as appropriate, and they are presented as OR[95%CI]. Heterogeneity was measured using the I² statistics. Publication bias was assessed by Funnel plots inspection and the quality of the meta-analyzed studies was assessed using the Jadad criteria.

Results: We identified 8 studies (5 cohort and 3 RCT, with 9 sets of data and 5639 subjects – mixed CRC screening/surveillance and symptomatic population) that reported on the aforementioned outcomes. Two sets of data examined the yield of the second direct view as compared to that of a single inspection, one set examined the cumulative yield of two passages compared to that of an extended (timely) inspection of the right colon and six sets of data evaluated the yield of the second examination of the right colon with scope retroflexion compared to that of the single direct view. We were moderate risk of bias studies; suspicion for publication bias was detected in the direct view arm of the analysis. As compared to a single pass, the second right colon inspection significantly increased ADR (1.31 [1.15–1.49], I² = 49%). The effect size of ADR was higher in the direct view second pass arm (1.73 [1.41–2.12], I² = 0%) as compared to the retroflexion arm (1.17 [1.06–1.29], I² = 0%). Sensitivity analysis with removal of one study each time did not identify a single study responsible for the detected heterogeneity. Our analysis did not show significant increase in right colon AADR (1.5 [0.76–1.56], I² = 0%) after the second exam.

Conclusion: In comparison to a single pass, the second inspection of the right colon either in direct view or with scope retroflexion increases ADR in this colon segment. However, results should be interpreted cautiously due to the small number of meta-analyzed studies with mixed indications populations, and the detected moderate levels of heterogeneity and risk for bias.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Colorectal Endoscopic Submucosal Dissection (CR-ESD) is technically difficult, time-consuming, and has a long learning curve for Western endoscopists. Several factors related with greater difficulty while performing this technique have been described. Generally, during the learning curve phase, we select simple lesions while imitating the technique.

**Aims & Methods:** Our goal was to assess those factors associated with greater difficulty during untutored DSE-CR without prior selection of less difficult lesions. All patients who attended the complex colorectal polyps consultation were included consecutively. No polyps regardless of their size, morphology, location or any characteristic of greater technical difficulty were ruled out. All CR-ESDs were performed by an endoscopist with previous animal model experience. The demographic and clinical characteristics of the patient, the morphology of the lesion and factors related to the technique were collected. A complex technique...
Results: 112 lesions were selected, discarding 4 due to deep invasion. We evaluated in this study 108 DSE-CR, 27 (25%) of which were compatible with our definition of "complex" ESD. In Table 1 you can see the characteristics of each group. Univariate analysis showed that variables such as size over 35 mm (63% vs. 27.2%; OR 4.56 [95% CI: 1.81–11.46]; P = 0.001), absence of CO2 [55.6% vs. 19.8%; OR 5.08 [95% CI: 1.99–12.94]; P < 0.001], presence of serious fibrosis in the submucosa [48.1% vs. 7.4%; OR 11.61 [95% CI: 3.78–35.69]; P < 0.001] and presence of fatty tissue in the submucosa [59.3% vs. 22.2%; OR 5.99 [95% CI: 2.01–12.90]; P < 0.001] were related to a "complex" ESD. Finally, in the multi-variate analysis, those variables were associated with a complex technique with an Odds Ratio of 7.42 for severe fibrosis (p = 0.039), 6.34 for non-CO2 insufflation (p = 0.030), 5.75 in the presence of fatty tissue in the submucosa (p = 0.035) and 5.74 in size greater than 35 mm (p = 0.025). There was no relation with the complexity of the technique the demographic-clinical characteristics of the patient, nor the location-morphology of the lesions. The duration of the technique was an average of 48 minutes longer in cases of a complex technique.

Conclusion: In our series the difficulty of CR-ESD was associated with factors described in other studies such as the size, the non-insufflation of CO2 and the presence of severe fibrosis in the submucosa. Our results describe the presence of fatty tissue in the submucosa as a new predictor of technical difficulty. In our study, we did not select the location to begin the technique, and in our learning curve we did not find significant differences in the performance of ESD in the proximal colon, distal or rectum.

Introduction: Endoscopic mucosal resection (EMR) of large (>20 mm) laterally spreading colonic lesions (LSSL) is safe, effective and superior to surgery. This advantage is based on a day stay model of care; however, the most common adverse event is abdominal pain and this is a major impediment to its efficiency. No prospective data exist on the optimal selection of analogues, the necessary recovery period or the triggers that should alert the practitioner to a more serious trajectory and the need for escalation of care.

Aims & Methods: We aimed to characterise potential predictors for PP and develop a simple and effective management algorithm for patients with PP based on the need for analogics in recovery. Data on consecutive patients with a LSSL referred for EMR at a single, tertiary referral centre were included. Patient and lesion characteristics and peri-procedural data were prospectively collected. Standard post EMR care included 2 hours in first stage recovery followed by 1 hour in 2nd stage recovery where clear fluids were given and discharge after if the patient were well. Persistent post-procedural pain (PP) was defined as pain ≥30 minutes in duration, ≥3/10 on the visual analogue scale (VAS) and requiring ≥25mg of acetaminophen parenterally.

Results: 166 patients with 166 lesions were included between February and April 2017. 34/166 (20.5%) of patients had PP requiring intervention (median VAS 5, IQR 3–6). 27/34 (79.4%) had resolution of pain with acetaminophen only and 9/34 (26.5%) with escalating pain requiring escalation of analgesics to fentanyl, with a starting dose of 25 micrograms (mcg) and 5 minutes, 1 gram of acetaminophen was administered parenterally and out-patients were transferred to second stage recovery after medical review. PP was an average of 48 minutes longer in cases of a complex technique.

Conclusion: We aimed to characterise potential predictors for PP and develop a simple and effective management algorithm for patients with PP based on the need for analogics in recovery. Data on consecutive patients with a LSSL referred for EMR at a single, tertiary referral centre were included. Patient and lesion characteristics and peri-procedural data were prospectively collected. Standard post EMR care included 2 hours in first stage recovery followed by 1 hour in 2nd stage recovery where clear fluids were given and discharge after if the patients were well. Persistent post-procedural pain (PP) was defined as pain ≥30 minutes in duration, ≥3/10 on the visual analogue scale (VAS) and requiring ≥25mg of acetaminophen parenterally.

P0218 QUALITY OF SINGLE-SESSION COLONOSCOPIC EXAMINATIONS INTENDING TO REMOVE ALL NEOPLASTIC POLYPS USING COLD POLYPECTOMY IN OUTPATIENT SETTING: RESULTS FROM CLINICAL PRACTICE DATA OF SINGLE CANCER CENTER HOSPITAL IN JAPAN

Division Of Endoscopy, Shizuoka Cancer Center, Nagahami/Japan

Contact E-mail Address: k.hotta@scchr.jp

Introduction: Some high-quality, large-scale cohort studies proved removals of colorectal neoplasms achieved prevention of colorectal cancer incidence and deaths. We introduced a strategy of removing all neoplastic polyps in a single session colonoscopic examinations using cold polypectomy was started. Aims & Methods: The aim of this retrospective study was to investigate about achievement of colorectal polyp remove in our clinical practice setting. Scheduled colonoscopic examinations for 40–79 years outpatients who had at least one colorectal neoplasm between January 2015 and December 2016 were collected from our endoscopic data base. Exclusion criteria were as follows; patients who had colorectal neoplasm larger than 20 mm, pre-examination of colorectal surgery or endoscopic submucosal dissection, inflammatory bowel disease, familial adenomatous polyposis, uncontrolled malignancies, by trainee endoscopists (<500 colonscopies), no agreements of polyp removal, and/or patients with continuation of anti-thrombotic agents. Outcome measurements were polyp removal rate (per-case analysis), complete polyp removal rate (per-patient analysis) and complications. Proportions of each endoscopic removal method according to size were also analyzed.

Results: A total of 2527 patients (mean age 66.8± 799 females) with 8203 colorectal neoplasms (CRNs) (7675 adenomas, 423 serrated polyps and 105 Tis and T1 cancers) who met inclusion and exclusion criteria were analyzed. Mean number of CRNs per patient was 3.2. Mean size was 4.7 (±2.9) mm. Polyp removal rate (per-case) and complete polyp removal rate (per-patient) were 97.0% (7955/8203) and 94.7% (2394/2527), respectively. Post-polypectomy bleeding requiring endoscopic hemostasis occurred in 7 patients (0.27%) and all origins of bleeding were colonic mucosal resection (EMR) and hot snare polypectomy (HSP). Post electrocoagulation syndrome requiring admission was occurred in one patient (0.04%) after pre-cutting EMR. Mean procedure time was 27.4 (±13.3) min. Proportions of each endoscopic removal method according to size were presented in an attached table. In L≥4 mm CRNs, both cold snare polypectomy (CSP) (51.8%) and cold forceps polypectomy (CFP) (45.8%) for L≥4 mm CRNs were mainly in methods. In 5–9 mm CRNs, CSP was a leading method (73.8%) and EMR was the second one (24.1%). CRNs larger than 10 mm were almost removed by EMR (94.4%).

Abstract No:P0217

Introduction: The transmural OTSC is used to achieve a full-thickness, serosa-to-serosa apposition (emergency & elective cases) for closure of GI wall defects (perforation, leak, fistula) with reported mean closure rates of 62–100% (range 0–100%), depending on the size of perforation, type and nature of lesion and the endoscopist’s experience1,2. However, recto-urogenital fistula may arise from a variety of etiologies and are mostly leaks or fistula of chronic nature, rarely acute perforations with vital wound tissue. They may occur in Crohn’s disease, but can also be a consequence of abdominal surgery, traumatic lesions or post-radiation damage.

Aims & Methods: To further explore the role of the OTSC in this particular type of fistula we analyzed own cases and 21 reports from the literature dealing with recto-urogenital fistula closure using the OTSC, but there was considerable heterogeneity, because of the fistula location (rectocutaneous n = 2, rectovaginal n = 10, rectoesophageal n = 7, rectourethral n = 2, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10), and its pathophysiology, with little space for endoscopic manipulation, fibrous and scarry tissue is around the nearby located to L. dentata and anal sphincter, it includes a localization with special characteristics of these leaks were reported to make more difficult the closure of a recto-urogenital fistula using the OTSC, but there was considerable heterogeneity, because of the fistula location (rectocutaneous n = 2, rectovaginal n = 10, rectoesophageal n = 7, rectourethral n = 2, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10, rectovesical n = 10). The procedural success of occluding various types of leaks was complete (n = 1, M. Meiborg1, S. Schu¨ rle1, C. Aubele1, E. Tsegai-Eh1, Martin-raithel@waldkrankenhaus.de

Introduction: Colostomy plays a key role in the prevention and diagnosis of colorectal cancer (CRC), and the quality of it influences interval cancer. However, we have little information on compliance with quality standards in Spain.

Aims & Methods: Knowing quality indicators fulfillment may lead to apply measures to improve the efficiency in the colostomy. Hence the aim of this study is to determine the occurrence of colorectal cancer at the time of closure of the colostomy due to digestive symptoms, post-polyectomy surveillance, positive fecal immunochemical test (FIT+), and direct coloscopy of colorectal cancer were included. The exclusion criteria were patients with diagnosis of colorectal cancer on a colostomy in the last 6 months, incomplete excision or post-excisional treatment of colon stenosis, abdominal or rectal mass, inflammatory bowel disease and hereditary cancer syndrome.

Results: 51.9% (3568) patients were men and the median age was 61 years. According to the colostomies indications, thirty one percent (3977) of the patients presented gastrointestinal symptoms, 20.3% (1398) were admitted due to postpone polyectomy surveillance, 28.3% (1949) presented positive fecal immunochemical test (FIT+), and 8.4% (578) due to direct screening. 70.4% (4869) of the examinations were performed in the morning shift. Respecting the bowel prepara-
tion, 48.4% used polyetilenglycol (PEG) 2L, 27.5% (1902) used sodium picosul-
phate/magnesium citrate, and 19.5% (1347) PEG4L. Digital chromoendoscopy was used for lesion seen in 4.7% (322) and panchorene in 9.1% (7). CO2 was used in 42% (2906) of the procedures. Colon cleansing was good-excellent in 80.1% (5512) and cecal intubation was performed in 95.8% (6590). 92.8% (6260) of the colostomies were performed under sedation, and the gastroenterologist was responsible for it in 80.1% (4995). The most used drugs for sedation were pro-
longed acting drugs in 63.9% (4417), midazolam in 44.1% (3045) and fentanyl in 31.1% (2149). Olympus was used in 69.2% (4732), Pentax in 21.8% (1492) and Fuji in 8.3% (359). Polyps were found in 50.9% (3515) of the procedures, and CRC was found in 4.1% (281). The total number of adenomas was 6249, and the total number of patients with adenomas was 224. The adenomas detection rate (ADR) was 39.6%. The sessile and traditional serrated polyps detection rate (SDR) was 2.2%. And for advanced adenomas, detection rate (AARD) was 29.5% and for colorectal cancer 4.1%.

Conclusion: In Spain, there is good compliance with the quality indicators of colostomies.

Disclosure of Interest: All authors have declared no conflicts of interest.

3. Raithel, M., Albrecht, H., Scheppach, W. et al. Outcome, comorbidity, hos-
Results: According to endoscopic or pathological judgment resection was complete in 40 or 30 patients, respectively. During hospital follow-up (12-14; median 4 days) abdominal pain, fever or local peritonitis were noted in 6 and bleeding in 3 patients (hypotension in 1) with antibiotics/transfusions/surgery needed in 4/0 patients. There was no hospital mortality. Among those with histological incomplete resection (n = 21), surgery or FTR was performed in 5 patients, endoscopic follow-up is pending in 17 and revealed no residual neoplasia in 9. Among those with cancelled ESD or endoscopic incomplete resection (n = 11), surgery or FTR was performed in 5, endoscopic follow-up is pending in 2 and revealed no residual neoplasia.

Conclusion: After appropriate training, even in low volume European case series ESD in the colorectum appears to be safe and partially effective.

Introduction: Colorectal cancer is the second leading cause of cancer death in US [1]. Its incidence can be mitigated by detecting its precursor lesion, the polyp, before it develops into cancer. Colonoscopy is still the gold standard for colon screening though some polyps are still missed. This can be explained by technical limitations of colonoscopes (camera orientation, field of view, etc.), but also by human factors (such as experience). Several computational systems, being the majority still-frame-based, have been proposed to assist clinicians in this task [2] but, to the best of our knowledge, none of them is being used in the exploration room due to not meeting real-time constraints (40 ms max per image). In this abstract, we present a methodology to adapt and evaluate a real-time still frame-based method [3] to video analysis.

Aims & Methods: The still frame detection system used as reference [3] was based on an active learning method. We base the adaptation to video analysis on two aspects: (i) influence of the type of information used for polyp candidate characterisation, and (ii) introduction of spatio-temporal coherence. The former studies whether the combination of different types of information may lead to improve system performance whereas the latter fosters stability in the position and confidence classifications. Multivariate analysis showed that high confidence predictive value were of 81.2% and 82.3%, respectively, with 79.4% high confidence classification and 77.1%, respectively. For left polyps ≤5 mm (n = 61) the accuracy and negative predictive value were of 81.2% and 82.3%, respectively, with 79.4% high confidence classifications. Multivariate analysis showed that high confidence prediction and ≥3 polyps/exam had a significant association with correct NBI classification (p < 0.05).

Conclusion: NBI utilization by inexperienced endoscopists presented moderate acuity in histological prediction. Despite promising results, acuity and confidence levels were lower than the thresholds recommended in guidelines (≥90%). These results justify implementing additional training and monitoring.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0223 RESECT AND DISCARD/DIAGNOSE AND DISREGARD STRATEGY FOR COLONIC POLYPS: ARE WE READY TO START IT?
Gastroenterologia, Anato Lusitano Hospital, Castelo Branco/Portugal

Contact E-mail Address: richardazevedo13@gmail.com

Introduction: The use of Narrow Band Imaging (NBI) technology for in vivo histological prediction of colorectal polyps presents high accuracy in Referral Centers, particularly for diminutive polyps, which could be managed by the “resect and discard” strategy and, for sigmoid and rectum polyps, the “diagnose and disregard” strategy. However, the applicability of this practice in Community Hospitals still needs to be determined.

Aims & Methods: We aimed to determine the accuracy of NBI in predicting histology, according to NICE and WASP classifications, in a Center without previous NBI experience. This was a prospective study including patients submitted to colonoscopy between June 2016 and July 2017. Polyps characteristics: location, size, morphology (Paris Classification), NICE/WASP classification (hyperplastic, sessile serrated, adenoma, invasive carcinoma) and degree of confidence (low: <90% vs. high ≥90%). Comparison between NBI classification and histology SPSS 23.

Results: 163 polyps included (71 patients); mean polyp dimension of 6.1 mm (61.3% ≤5 mm); 91.4% sessile polyps; 62.6% on the left colon. Polyps classification according to NICE/WASP vs. histology: hyperplastic 49.7% vs. 42.9%; sessile serrated polyps 4.9% vs. 9.8%; adenoma 44.2% vs. 43.6%; carcinoma 1.2% vs. 0%. Inflammatory reaction on histology ~ 3.7%. Adenoma diagnosis using NICE/WASP classification presents an accuracy, sensitivity, specificity, positive predictive value and negative predictive value of 80.9%, 78.1%, 84.2%, 85% and 77.1%, respectively. For left polyps ≤5 mm (n = 61) the accuracy and negative predictive value were of 81.2% and 82.3%, respectively, with 79.4% high confidence classifications. Multivariate analysis showed that high confidence prediction and ≥3 polyps/exam had a significant association with correct NBI classification (p < 0.05).

Conclusion: NBI utilization by inexperienced endoscopists presented moderate acuity in histological prediction. Despite promising results, acuity and confidence levels were lower than the thresholds recommended in guidelines (≥90%). These results justify implementing additional training and monitoring.

Introduction: Heparin bridging therapy (HBT) is recommended for patients administered anticoagulants who have a high thrombotic risk and who undergo a high bleeding-risk procedure such as endoscopic submucosal dissection (ESD) or endoscopic mucosal resection (EMR)1, 2. However, HBT is actually related to a high frequency of delayed bleeding3, 4.

Aims & Methods: Our aim is to analyze bleeding and coagulation markers in the perioperative periods of patients with HBT during the perioperative periods of ESD and EMR. Patients who underwent ESD or EMR and received warfarin or a direct oral anticoagulant (DOAC) during the period from January 2013 to March 2017 were analyzed. Generally, administration of warfarin was continued within the therapeutic range of the international normalized ratio (INR) during the perioperative periods and DOACs were not administered on the day of the procedure. HBT was conducted only for patients who had a hypercoagulable condition. The rates of delayed bleeding in patients who received warfarin and patients who received DOACs were compared, and coagulation molecular markers including soluble fibrin (SF), thrombin-antithrombin complex (TAT), prothrombin fragment 1 + 2 (F1 + 2) and D-dimer (DD) were compared before and after the procedures in 13 patients.

Results: Among the patients who underwent ESD or EMR during the study period, 5 patients received warfarin and 49 received DOACs. Delayed bleeding occurred in 6 patients (11.8%) in the warfarin group and in 8 patients (16.3%) in the DOAC group, and there was no significant difference. Only one patient with continued administration of antiplatelet agents had delayed bleeding among the patients in whom administration of warfarin was continued within the therapeutic range (5.3%, 1/19). Six (15%) of the 40 patients in the DOAC group for whom the DOAC was not administered only on the day of the procedure had delayed bleeding, and 23.8% (5/21) of the patients who received HBT had delayed bleeding. No thrombotic events occurred from one month after the procedures. One patient in whom the DOAC was not administered on the day of the procedure became positive for TAT, F1 + 2 and DD after HBT and had a hypercoagulable condition.

Conclusion: For perioperative management of anticoagulants in patients undergoing ESD or EMR, continuous use of warfarin within the therapeutic range is considered a “de novo” pathway. Now, it is possible to presume the histology of colorectal lesions using magnifying endoscopy (pit pattern classification) and endocytoscopy (EC classification). We can observe not only the structural atypia but also the cellular atypia in living colorectal lesions.

Introduction: Colorectal cancers are generally recognized to develop from “polype” to “adenoma-carcinoma sequence” theory that has been in the mainstream of development of colorectal cancers. But recently the existence of many depressed-type cancers has been revealed, which are considered to emerge directly from normal epithelium, not through the adenomatous stage. This theory is called “de novo” pathway. Now, it is possible to presume the histology of colorectal lesions using magnifying endoscopy (pit pattern classification) and endocytoscopy (EC classification). We can observe not only the structural atypia but also the cellular atypia in living colorectal lesions.

Aims & Methods: The aim is to clarify the endoscopic characteristics of depressed-type colorectal neoplasms, demonstrating the validity of pit pattern diagnosis and EC classification. A total of 29,030 colorectal neoplasms excluding advanced cancers were resected endoscopically or surgically in our unit from April 2001 to December 2016. Of these, 17,763 lesions were low-grade dysplasia, 2922 were high-grade dysplasia and 1077 were submucosal invasive (T1) carcinomas. Among the developmental morphology classification, they were divided into 3 types: depressed, flat and protruded-type. We investigated the ratio of T1 carcinomas and the characteristics of depressed-type neoplasms concerning pit pattern and EC classification.

Results: The rate of T1 carcinomas in depressed-type lesions reached to 62.0%, meanwhile that in flat-type and protruded-type lesions was 3.3% and 2.8%, respectively. Within less than 5 mm in diameter, that was 10.6%, 9% and 0.04%, respectively. Most (93.0% and 93.1%) of the flat-type and protruded-type lesions showed typeIII or IV pit pattern corresponding to adenomas, whereas 91.3% of the depressed-type lesions were characterized by typeI, IV or V pit patterns corresponding to carcinomas. As for endocytoscopy, most of the flat-and protruded-type lesions showed EC2 corresponding to adenomas. In contrast, the depressed-type lesions were observed as EC3a (38.9%) and EC3b (58.0%) corresponding to invasive carcinomas.

Conclusion: This study revealed the diagnostic characteristics of depressed-type lesions. They show typically type IIS, VI or VN pit patterns in magnifying endoscopy, suggesting the pit pattern classification and EC classification is useful.
endoscopy and type EC3a or EC3b in endoscopy. These lesions tend to invade the mucosal layer even when they are small. Therefore, it is important to consider deeply and examine the developmental morphology of colorectal neoplasms.

### TABLE 2

**THERAPEUTIC ERCP USING A SHORT SINGLE-BALLOON ENTEROSCOPE IN PATIENTS WITH SURGICALLY ALTERED ANATOMY**

| Aims & Methods: We aimed to evaluate the usefulness and safety of the SpyGlass system in patients with surgically altered anatomy. Studies on similar patients with surgically altered anatomy who underwent therapeutic ERCP using a sSBE between August 2011 and February 2017 were included in this study. Patient anatomy consisted of Roux-en-Y anastomosis (R-Y) (n = 82), hepaticocholedochostomy (HJ) (n = 11), subhepatic preserving pancreatosplenectomy (SSPD) (n = 11). The indications for ERCP were choledocholithiasis (68: R-Y cases), malignant biliary strictures (20: R-Y 14, HJ 7, SSPD 4), intrahepatic stones (9: HJ 7, SSPD 2), and anastomotic stenosis (7: SSPD 5, HJ 2). The success rate of reaching the target site was 91% (95/104), and the overall technical success rate was 79% (80/104). Biliary interventions included 64 stone extraction (R-Y 55, HJ 5, SSPD 1), and 12 metallic biliary stent placement (R-Y 7, HJ 1, SSPD 4). Of 17 unsuccessful cases, nine with choledocholithiasis underwent surgical operation (R-Y 6, HJ 2, SSPD 1) and EUS-guided drainage was successfully performed in six with anastomotic stenosis (SSPD 3, R-Y 2, HJ 1). The two perforation cases required urgent operation but remaining eight cases were managed conservatively. The technical success rate and the adverse event rate were retrospectively evaluated.

**Results:** The success rate of reaching the target site was 91% (95/104), and the overall technical success rate was 79% (80/104). Biliary interventions included 64 stone extraction (R-Y 55, HJ 5, SSPD 1), and 12 metallic biliary stent placement (R-Y 7, HJ 1, SSPD 4). Of 17 unsuccessful cases, nine with choledocholithiasis underwent surgical operation (R-Y 6, HJ 2, SSPD 1) and EUS-guided drainage was successfully performed in six with anastomotic stenosis (SSPD 3, R-Y 2, HJ 1). The two perforation cases required urgent operation but remaining eight cases were managed conservatively.

**Conclusion:** Therapeutic ERCP using a sSBE in patients with surgically altered anatomy was considered to be safe and effective.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### TABLE 3

**USEFULNESS OF SPYGlass PERORAL CHOLANGIOSCOPY FOR THE DIAGNOSIS AND TREATMENT OF BILE-DUCT DISORDERS: EXPERIENCE FROM A LARGE-VOLUME CENTER**

| Aims & Methods: To assess the clinical efficacy and safety of the SpyGlass system for diagnosis and treatment of bile-duct disorders in a large-volume center. All patients undergoing SOC in our department between January 2013 and May 2016 were retrospectively identified from a prospectively collected database. The baseline characteristics, including age, gender, presenting symptoms, indication and others were recorded. Procedure-related parameters of SOC for detecting malignant lesions and the stone clearance rate were calculated.

**Results:** During the study period, a total of 68 patients underwent 78 SOC procedures: 26 (38.2%) with indeterminate strictures, 7 (10.3%) with indeterminate filling defects, 31 (45.6%) with difficult bile stones, and 4 (5.9%) with cystic lesions. SpyGlass was technically successful in 63 of 68 patients (92.6%). The mean total SpyGlass procedure time was 12 min. In patients with indeterminate biliary strictures, 6 cases of definite diagnosis (stones, varices) was made by SOC evaluation. Twenty patients underwent SOC-directed biopsy, and samples were adequate for histological diagnosis in 17 patients (85%). The preliminary accuracy of SpyGlass-directed biopsy to diagnose malignancy was 76%. For the patients with biliary stone, SpyGlass-guided holmium laser lithotripsy or electrohydraulic lithotripsy succeeded in 15 of 15 patients (100%). There were 6 procedure-related adverse events occurred (8.8%), and resolved uneventfully.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Conclusion: SpyGlass cholangioscopy system can be safe and useful for definite diagnosis with high accuracy in patients with indeterminate biliary lesions, and successfully guided stone therapy. Further prospective multicenter trials of the system are warranted in the future.

P0230 DIAGNOSTIC AND THERAPEUTIC ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP) IN INFANT AND CHILDREN: A LARGE RETROSPECTIVE STUDY
X. Tang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) is increasingly being used in the diagnosis and management of biliary and pancreatic disorders in pediatric patients.

Aims & Methods: To evaluate the indices, success rate, diagnostic and therapeutic yields, and complications of ERCP performed in Chinese children. A retrospective study was conducted in an academic, tertiary care, medical center, in which all children undergoing ERCP between 2005 to 2016 were identified from endoscopy databases. Data on demographics, indication, ERCP findings, ERCP interventions performed and complications were collected.

Results: A total of 288 children (mean age 9.3 years, range 1 month to 18 years) underwent 312 ERCP procedures. General anesthesia and sedation were performed in 48% and 52% of procedures, respectively. Indications for ERCP were common bile duct obstruction (n=153, 54.2%), recurrent or chronic pancreatitis (n=64, 22.2%) and others. ERCP was successfully performed in 267 of 288 cases (92.7%). The most common ERCP findings was choledocholithiasis (n=146, 50.7%). A therapeutic intervention was performed in 70.8% patients (n=204), including sphincterotomy (n=97), stone extraction (n=55), and stent insertion (n=52). Complications occurred for only 13 patients (4.5%), including 12 cases of post-ERCP pancreatitis and 1 case of bleeding. No severe pancreatitis, or perforation was noted.

Conclusion: Diagnostic and therapeutic ERCP is effective and safe in the children population, with the high rates of technical success and low rates of complication.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0231 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH SURGICALLY ALTERED GASTROINTESTINAL ANATOMY: 11 YEARS’ EXPERIENCE AT A LARGE CENTER IN CHINA
X. Tang, D. Zhang, C. Xu, X. Zhang
Department Of Gastroenterology, Hangzhou First People’s Hospital, Nanjing Medical University, Hangzhou/China

Contact E-mail Address: solitude5834@hotmail.com

Introduction: It is technically challenging to perform endoscopic retrograde cholangiopancreatography (ERCP) in patients with surgically altered gastrointestinal anatomy.

Aims & Methods: The aims of this study were to investigate the yield, efficacy and safety of ERCP in surgically altered anatomy patients at a single tertiary-care center with a high volume of endoscopy. All patients with altered surgical anatomy and high accuracy in their center from September 2005 to July 2016 were retrospectively reviewed. Data regarding to patients baseline characteristics, procedure-related details and adverse events was recorded and analyzed.

Results: A total of 304 procedures were performed in 236 patients, including 108 cases (45.8%) with Billroth II gastrectomy, 45 cases (19.1%) with Billroth I gastrectomy, 52 cases (22.0%) with hepaticoduodenostomy, 18 cases (7.6%) with esophagogastrotomy and 13 cases (5.5%) with Roux-en-Y reconstruction. The most common indication was cholelithiasis (58.1%, 137/236). The overall technique success rate of reaching the papilla was 90.8% (276/304), including 91.3% (126/138) for Billroth II gastrectomy, 94.5% (52/55) for Billroth I gastrectomy, 89.9% (71/79) for hepaticoduodenostomy, 100% (19/19) for esophagogastrotomy and 61.5% (8/13) for Roux-en-Y reconstruction. The clinical success rate was 88.2% (268/304). Therapeutic interventions were performed in 194 patients successfully, including stone extraction (n=146), sphincterotomy (n=44), stent placement (n=57), papillary balloon dilatation (n=27) and mechanical lithotripsy (n=23). The adverse event rate was 7.2% (17/236). Mild pancreatitis occurred in 3% (7/236) of cases, perforation occurred in 2.5% (6/236) of cases, and asymptomatic hyperamylasemia occurred in 1.7% (4/236) of cases.

Conclusion: ERCP can be performed in surgically altered anatomy patients with a high success rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0232 IMPACT OF HIGH DEFINITION, NEAR FOCUS-IMAGING AND SYDNEY RECURRENCE TOOL (SERT) AFTER COLORECTAL ENDOSCOPIC MUCOSAL RESSECTION: A PROPENSITY SCORE ANALYSIS

Introduction: Risk factors for colorectal adenoma recurrence after Endoscopic Mucosal Resection (EMR) such as size ≥20mm, high grade dysplasia, use of argon plasma coagulation (APC) and intraprocedural bleeding (IPB), have been well documented in literature. However, it is unknown if the latest generation dual-focus (DF) colonoscopes ability to visualize subtle residual neoplasia, has improved the rate of complete EMR.

Aims & Methods: We aimed to evaluate the efficacy of the newer 190 colonoscopes versus standard 180 colonoscopes for complete resection of lateral spreading lesions (LSL) ≥20mm. A secondary aim was to identify risk factors for recurrence and the applicability of the Sydney EMR recurrence tool (SERT score) in our cohort.

This was a single-center retrospective study of patients who underwent EMR with 180 or 190 colonoscope series from 2010 to 2016. Lesions ≥20mm resected in a piecemeal fashion and patients with a surveillance colonoscopy after index EMR were included. A propensity score approach with inverse probability weighting (IPW) was used to control potential confounders affecting adenoma recurrence. Each lesion was graded according to SERT score and associations with recurrence were analyzed.

Results: 291 patients met inclusion criteria for the study. The rate of adenoma recurrence at the EMR site was 23.3% for the 180 colonoscope cases and 25.2% for the 190 colonoscope cases. Odds ratio (OR) for recurrence with 190 series was 1.06 (p = 0.85). Adenoma size (p = 0.002) and concomitant need for supplemental APC (p < 0.001) were risk factors for recurrence. SERT > 0 lesions had a higher risk of recurrence during follow-up (OR 1.71, 95% CI 1.00–2.92; p = 0.048) and a higher cumulative incidence for recurrence. Conversely, SERT = 0 lesions reached a plateau for recurrence after 12 and 18 months in Kaplan Meier curves. Odds ratio estimates for 190 colonoscope effect on adenoma recurrence at different stages of adjustment.

Cumulative incidence of recurrence at SERT by SERT score in 291 lesions.

P0233 INCIDENCE AND RISK FACTORS FOR PANCREATITIS IN EMERGENCY ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY: A PROSPECTIVE MULTICENTER STUDY

Contact E-mail Address: n.yoshitaka@kenko.or.jp

Disclosure of Interest:

Conclusion: In this study, recurrence was significantly associated with adenoma size and complementary use of APC for EMR. The use of the latest generation DF colonoscopes (CF-HQ190L/I) did not measurably affect adenoma recurrence at the EMR site during follow-up (OR 1.71; 95% CI 1.00–2.92; p = 0.048) and a higher cumulative incidence for recurrence. Conversely, SERT = 0 lesions reached a plateau for recurrence after 12 and 18 months in Kaplan Meier curves. Odds ratio estimates for 190 colonoscope effect on adenoma recurrence at different stages of adjustment.

Disclosure of Interest: All authors have declared no conflicts of interest.
Disclosure of Interest: any 15–20 mm polypectomy snare, 7.5 mm rat tooth or tripod grasping forceps

Aims & Methods: This study aimed to identify the incidence and risk factors for PEP in emergency ERC. We performed a prospective study of 2078 cases undergoing diagnostic and therapeutic ERC in five Japanese institutions between April 2015 and May 2016. Exclusion criteria were active pancreatitis, cholecystectomy, choledochoduodenostomy, inability to approach a papilla, and inspection aimed at only the pancreatic duct (PD). Emergency ERC indicated unselected inspections performed within and outside duty hours in this study. PEP was considered when two of the following three conditions were met: (1) serum amylase level more than three times the upper limit of the normal range in each institution, (2) continued abdominal pain for over 24 hours, and (3) presence of pancreatitis findings on computed tomography. The first study involved comparison of the incidence of PEP and its characteristics between emergency and elective ERC. The second study involved determining the predictive risk factors for PEP in emergency ERC using univariate and multivariate analyses.

Results: A total of 1677 cases were enrolled in this study. Study 1> PEP developed in 20 of 429 cases (4.7%) from the emergency group and in 101 of 1248 cases (8.1%) from the elective group. The incidence of PEP was significantly lower in the emergency group than in the elective group (odds ratio [OR]: 0.56, 95% confidence interval [CI]: 0.32–0.92, P = 0.017). Endoscopic sphincterotomy, stone removal, papillary balloon dilatation, and intraduodenal ultrasound procedures were performed significantly more often in the elective group than in the emergency group (P < 0.001). Placement of a biliary stent was significantly more common in the emergency group than in the elective group. In addition, the procedure time was significantly longer (P < 0.001) and the number of endoscopists who had more than five years of experience was significantly higher (P = 0.04) in the elective group than in the emergency group. Study 2> Cases with no naïve papilla (n = 183) were excluded from the analysis of risk factors for PEP because no PEP was observed in these cases. Only cases with naïve papilla (n = 248) were analyzed. Univariate analysis showed that contrast injection into the PD (OR: 4.20, 95% CI: 1.64–10.80, P = 0.0028), more than four cannulation attempts (OR: 2.85, 95% CI: 1.00–8.09, P = 0.05) increased and placement of a biliary stent (OR: 0.028, 95% CI: 0.11–0.88, P = 0.009) decreased the risk of PEP in emergency ERC. Conclusion: The incidence of PEP was lower in emergency ERC than in elective ERC, and it was largely unaffected by the endoscopist’s experience and the procedure time. This may be associated with a tendency to avoid invasive procedures, and it is considered that only placement of a biliary stent contributes to a decrease in the development of PEP. Close attention should be paid for contrast injection into the PD, particularly when attempt of cannula for naïve papilla are required.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0234 WALL-OFF NECROSIS (WON): OUTCOMES OF AN ALGORITHMIC APPROACH TO NECROSECTION

J.Y. Bang, U. Navaneethan, M. Hasman, R. Hawes, S. Varadarajan
Center For Interventional Endoscopy, Florida Hospital, Orlando/United States of America/FL

Contact E-mail Address: jybang213@gmail.com

Introduction: Endoscopic necrosectomy (EN) in walled-off necrosis (WON) is a labor intensive, high-risk, non-standardized technique that is associated with significant morbidity and mortality. Aim of this study was to compare the clinical outcomes of patients with WON treated by conventional EN versus an algorithmic approach that is tailored to the extent and location of WON. This observational study included 45 consecutive patients with WON who had suboptimal treatment response to ERCP-guided transmural drainage and subsequently underwent necrosectomy. The conventional technique using a diagnostic or therapeutic gastroscopy involved removal of necrotic debris using any 15–20 mm polypectomy snare, 7.5 mm rat tooth or tripod grasping forceps and/or forceps. Normal saline was used for intraprocedural irrigation and lavage of the necrotic cavity. The algorithmic technique, using a cap-fitted therapeutic gastroscopy, was tailored to the extent and location of the WON. While WON extending to the flanks and more proximate (<20 cm) to the abdominal wall were treated by percutaneous necrosectomy, those in close proximity to the stomach and without extension to the flanks were treated by transluminal EN. Adherent debris were removed using 15–25 mm round, braided-wire snares and non-adherent debris were removed using 15–30 mm oval snares. A large 14.9 mm diameter, rat tooth forceps were used for debridement when the necrotic debris were not amenable for snaring. The necrotic cavity was evacuated by sucking the debris within the gastroscopy cap using snares and/or forceps. In order to avoid frothing that obscures visibility, intra-procedural lavage of the necrotic cavity was performed using normal saline mixed with 120 mg gentamicin and 100 mcg with hydrogen peroxide was reserved for stabilizing the cavity at the end of the procedure. The primary outcome measure was to compare the treatment success and number of reinterventions performed between the two groups. Treatment failure was defined as death from underlying disease or need for open surgical necrosectomy.

Results: Of the 45 WON patients, 23 were treated using conventional techniques and 22 using the algorithmic approach. Treatment success was significantly higher for patients treated using the algorithmic approach, 100% vs 69.6%, p = 0.009. Of the 7 patients who had treatment failure in the conventional technique cohort, 6 required open necrosectomy and 1 died of multi-organ failure. The median number of reinterventions required to achieve treatment success was significantly lower for the algorithmic approach (1, IQR: 1–2) vs (2, IQR: 1–2), p = 0.003. Multivariable logistic regression analysis revealed that the algorithmic approach was the only variable associated with treatment success (OR = 6.04, p = 0.02) when adjusted for patient demographics, lab parameters and disease/WON characteristics.

Conclusion: A structured, algorithmic approach to endoscopic necrosectomy results in successful treatment outcomes.

P0235 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN THE MANAGEMENT OF PANCREAS DIVISUM ASSOCIATED WITH RECURRENT ACUTE PANCREATITIS IN CHILDREN: EXPERIENCE FROM A SINGLE CENTER IN CHINA

G. Cui, J. Yang, X. Tang, J. Yang, X. Zhang
Gastroenterology And Hepatology, Hangzhou First People’s Hospital, Hangzhou/ China

Contact E-mail Address: ztx837@163.com

Introduction: Pancreas divisum (PD) is the most common congenital anomaly of the pancreas. Patients with PD are asymptomatic, but a few may present symptoms in the form of recurrent acute pancreatitis (RAP), chronic pancreatitis (CP) or pancreatitic-type pain. It is imperative to treat PD associated with RAP as early as possible to prevent it from developing CP. Unfortunately, to date, most PD-related studies have been concentrated on adults. Researches of PD in children are rare.

Aims & Methods: To evaluate the safety and efficacy of endoscopic retrograde cholangiopancreatography (ERC) for the treatment of pancreas divisum (PD) associated with recurrent acute pancreatitis (RAP) in children. We retrospectively analyzed patients of PD associated with RAP who were younger than 18 years old from January 2011 to December 2015 in our center. All the patients were diagnosed and treated with ERCP. Patients of complete PD associated with RAP underwent endoscopic minor sphincterotomy combined with dorsal duct stenting (ESCS). Patients of incomplete PD underwent biopsy papilla endoscopic sphincterotomy combined with dorsal duct stenting (BiESCS). ERCCP-related data, complications and other relevant data were collected. The long time follow up was conducted after removal of ductal stent, and then to observe children’s recovery, as well as their weight, growth and intelligence.

Results: A total of 227 pediatric ERCPs were performed for 117 pediatric patients during this period. Of which 24 were PD cases. The endoscopic detection rate of PD was 20.5%. Of the 24 patients, 12 were PD associated with RAP, among which 10 were complete PD and 2 were incomplete PD. A total of 21 therapeutic ERCPs were performed for these cases. All procedures were successful with 100% (21/21) of cannulation rate of the minor papilla. The mean interval of changing pancreatic dorsal duct stent is 3 months (from 2 to 6 months). ERCCP-related complications were mild with a rate of 9.5% (2/21). One was acute mild pancreatitis and the other was hyperamylasemia, both of which were managed conservatively. During follow up from 15 to 74 months (mean 33.9 months), all patients had pain relief with a relief rate of 100%, of which 10 were asymptomatic with no longer onset of acute pancreatitis. During follow-up, we observed no more dilation of dorsal ducts in all children and all presented normal in weight, growth, and intelligence.

Conclusion: The techniques of ECS and BiESCS under ERCP are safe and effective methods to handle PD associated with RAP in pediatric patients. It seems very vital for such children to undergo endoscopic interventions as early as possible in order to avoid developing CP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0236 ENDOSCOPIC BILIARY SPHINCTEROTOMY IN MALIGNANT BILIARY OBSTRUCTION: IS IT INDICATED IN CASE OF STENT PLACEMENT? A META-ANALYSIS

B. Mangiavillano1, A. Montale2, L. Frazzoni3, M. Bianchetti1, A. Repici1, L. Fuccio2
1Gastroenterological Endoscopy Unit, Humanitas - Mater Domini, Castellanza (VA) / Italy
Aims & Methods: We performed a literature search by using PubMed, SCOPUS, Google Scholar and the Cochrane Central Register of Clinical Trials (up to February 2017) for full-text studies evaluating the efficacy and safety of EBS. All retrospective studies were included. The study population included both patients with malignant biliary obstruction (MBO), especially if palliative treatment. The role of endoscopic biliary sphincterotomy (EBS) before stent insertion is not clearly defined. The primary outcome of our meta-analysis was to assess the technical success of biliary (plastic or metal) stent insertion. Secondary outcomes included early complications within 30 days from ERCP and late complications which (from 30 days since ERCP).

Results: 14 papers were assessed via full text for eligibility. 8 articles were excluded leaving 6 prospective studies (total of 711 patients). Technical success: The overall rate of biliary stent insertion was not significantly different: 384/392 (98%) in the no-EBS group versus 331/339 (97.6%) in the EBS arm (OR: 1.05; 95%CI: 0.42–2.63).

Early complications: The overall early AE developed in 43/392 (11%) of patients without EBS versus 68/339 (20.1%) of patients received EBS, with a significantly difference (OR: 0.55; 95%CI: 0.33–0.92). Post-ERCP pancreatitis (PEP) was no significantly different in the two groups: 24/392 (6.1%) in no-EBS group versus 17/339 (5%) in EBS group (OR: 1.33; 95%CI: 0.68–2.59). The bleeding was significantly different in patients without EBS: 0/351 patients in no-EBS group versus 15/298 (5%) in the EBS group (OR: 0.12; 95% CI, 0.03–0.45). The rate of duodenal perforation was not significantly different: 1/320 (0.3%) in no-EBS versus 4/260 (1.5%) in EBS (OR: 0.52; 95%CI: 0.19–2.88). Early cholangitis was significantly lower in patients who didn't receive EBS: 13/392 (3.3%) patients in no-EBS group vs 25/339 (7.4%) subjects received EBS, with a significantly difference (OR: 0.55; 95%CI: 0.33–0.92). Post-laparotomy and cholecystectomy in acute biliary pancreatitis. The Surgeon, 2016, 14(2):108.

Conclusion: EPS combined with pancreatic stent is a promising strategy to prevent recurrence of ARP due to biliary microthrombosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic duct (PD) is frequently asymptomatic, usually encountered in patients undergoing endoscopic retrograde cholangiopancreatoigraphy(ERCP).

Aims & Methods: The aim of this study was to investigate the association of PD with bile duct stones, biliary cannulation success and different types of PD. A total of 1164 ERCP procedures were performed in 833 patients in a single center by single operator from January 2012 to October 2016 after excluding patients with transplant, emergency procedures. Out of 1164 ERCP procedure 49 patients were encountered with PD, they were compared with 635 controls without PD in terms of age, sex, CBD cannulation success and complications of ERCP.

Results: PAD is seen with advanced age, predominantly in female and frequently associated with bile duct stones. In without PAD group bleeding 0.6%, pancreatitis 0.7% and no perforation. In PAD group bleeding 2.8%, pancreatitis 2.2% and one small retroduodenal perforation 2.2% all managed conservatively. In PAD group bleeding 0.6%, pancreatitis 0.7% and no perforation.

Conclusion: PAD predominantly occurred in patients controls (82.3%) compared to PAD group (75.5%) p-value (0.039). (5) The incidence of late complications was 18.4% in EST group and 10.3% in EPS group (P=0.567). The efficiency in EST group and EPS group is 68.4% and 89.6% respectively (P=0.039). (5) The incident of late complications were 18.4% in EST group and 10.3% in EPS group (P=0.567).

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: PAD identified in 49 (4.2%) cases, PAD type (1 inside the diverticulum) was found in 7 pts (14.3%), Type II (at edge/brim) in 34 pts (69.4%), Type II (adjacent to diverticulum) in 8 pts (16.3%). Patients with PAD had mean age 59.10 years (range 18 to 84 years) 17 were males and 32 females 28/49 cases. Patients with PAD had increased prevalence of gallstone/biliary stone disease compared with controls, 71.4%vs 33.1 % (p <0.01) compared with controls. 

Easy cannulation of CBD without difficulty (PRECU /Pancreatic cannulation/stent- ing) was more frequent in patients controls (82.3%) compared to PAD group (75.5%) p < 0.05. However, CBD clearance was same in both groups>90% (p value not significant) Incidence of complications in PAD group bleeding (2%), Pancreatitis (2%) and one small retroduodenal perforation (2%) all managed conservatively. In without PAD group bleeding 0.6%, pancreatitis 0.7% and no perforation.

Conclusion: PAD is seen with advanced age, predominantly in female and frequently associated with bile duct stones. In this case control study PAD did not appear to be a barrier for successful ERCP with acceptable complication rates.

P0237 ENDOSCOPIC PANCREATIC SPHINCTEROTOMY COMBINED WITH PANCREATIC DUCT STENT CAN EFFECTIVELY PREVENT RECURRENCE OF ACUTE RECURRENT PANCREATITIS CAUSED BY BILIARY MICROTHROMBOSIS — A SINGLE-CENTER STUDY FROM BEIJING, CHINA

Y. Huang, X. Yan, W. Liu, Y. Zhang, W. Yao, K. Li

Introduction: Acute recurrent pancreatitis (ARP) refers to a clinical entity characterized by episodes of acute pancreatitis which occurs on more than one occasion. Biliary microthrombosis plays an important role in the etiologic of ARP. Bile sludge may induce acute pancreatitis as a consequence of transient papillary edema that can obstruct the pancreatic juice flow. The established treatments of ARP includes with ARP include endoscopic sphincterotomy(EST) and empirical cholecystectomy. However, EST may increase the morbidity of biliary reflux or cholecystitis recurrence. We hypothesized that endoscopic pancreatic sphincterotomy (EPS) can save the function of biliary sphincter and prevent the recurrence of ARP.

Aims & Methods: The aim of the study is to evaluate the effectiveness of EPS combined pancreatic duct stent for preventing ARP caused by biliary microthrombosis. 67 patients with ARP from 2005 to 2016 were diagnosed as biliary microthrombosis by endoscopic retrograde cholangiopancreatography (ERCP), bile microscopy or intraductal ultrasonography (IDUS). The whole was divided into two groups according to endoscopic therapy by EST or EPS with pancreatic stent. Rate of pancreatitis recurrence, early complication of post ERCP pancreatic duct stent (3 months after treatment) which included cholangitis, cholecystitis or cholelithiasis were compared between the two groups.

Results: (1) 38 and 29 patients were included in EST and EPS group, respectively. The mean age and follow-up duration of EST and EPS were 48.4 ±15.1 years, 45.7 ±36.5months and 45.6 ±15.2yrs, 24.1 ±36.3months, respectively. (vary from 2months to 115months). (2) The mean episodes of ARP in EST and EPS group before endoscopic therapy were 3.9 ±3.3 times and 7.9 ±11.8 times. (3) Four patients in EST group and 6 patients in EPS group suffered PEP after the endoscopic therapy (P =0.418). (4) 15 patients in EST group and 3 in EPS group suffered recurrent pancreatitis. The efficiency in EST group and EPS group is 68.4% and 89.6% respectively (P =0.039). (5) The incidence of late complications were 18.4% in EST group and 10.3% in EPS group (P=0.567).

CHOLANGIOSCOPY IN PATIENTS REQUIRING EVALUATION OF P0239 COMPARISON OF DIGITAL VS FIBEROPTIC

ERCP FEATURES AND OUTCOME OF BIOPSIES WITH DIGITAL CHOLANGIOSCOPY VS FIBEROPTIC ERCP

Introduction: Since the emergence of the fiberoptic single-operator cholangioscopy, the sensitivity for detecting bile duct lesions has been increased and the management of difficult stones is facilitated, establishing its superiority over standard endoscopic retrograde cholangio-pancreatography and often altering the clinical management. Digital cholangioscopes provide higher-resolution imaging of the pancreatobiliary tract compared with the fiberoptic instruments. Aims & Methods: The aim of the present study was to assess the frequency of digital cholangioscopy (DC) to alter the diagnosis and clinical management of bile duct disease compared with fiberoptic cholangioscopy (FC). A retrospective review of 68 cases needing cholangioscopy, and which were performed in our department. Patients enrolled exhibited stenosis of the biliary tract (67.6%), stones (20.6%), primary sclerosing cholangitis (PSC 4.4%) or other rare cause for cholangioscopy (e.g. stent migration, guidewire passage). All patients underwent endoscopic retrograde cholangiography (ERC) before cholangioscopy. Aim of cholangioscopy was to confirm ERC diagnosis, obtain adequate biopsy specimens for histological evaluation and remove biliary stones. From 5/2009 to 3/2017 all cholangioscopies were performed with the fiberoptic scope. From 9/2015 to 3/2017 all cholangioscopies were performed with the digital scope.

Results: 30 women and 38 men with a mean age of 61 years underwent cholangioscopy. Fiberoptic cholangioscope was used in 39 cases and digital cholangioscope was performed in 29 cases respectively. Cholangioscopy-guided biopsies for malignancy were obtained in 11 and 15 cases respectively. In only one case of FC (9.1%) biopsy confirmed the endoscopic diagnosis, in contrast with 10 cases of DC-guided biopsies (66.7%) confirming the diagnosis. In 13 patients who underwent DC (44.8%) the initial diagnosis and clinical management was altered after cholangioscopy (e.g. cancer diagnosis, successful EHL lithotripsy), in contrast with 11 cases of FC (28.2%). Moreover it was unanimously felt by our staff that DC was an easier procedure compared to FC.

Conclusion: Our data suggest that DC has the capacity to increase the effectiveness of pancreatobiliary disease and recurrence of bile duct stones.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: In this study, we examined the efficacy and safety of emergency ERC in super-elderly patients with moderate to severe acute cholangitis, according to TG13. We performed 178 emergency ERC procedures in 132 patients during 3 years (June 2014–December 2016). We determined patients ≥90 years as “super-elderly” and those <90 years as “non-super-elderly”. Evaluation criteria included comorbidities, oral administration of anticoagulants, cause of cholangitis, ERC procedure (examination time, endoscopic biliary sphincterotomy (EST) pre-cut papillotomy, treatment success rate, presence or absence of periampullary diverticula and papilla after EST, sedation dosage), ERC-related complications (bleeding, perforation, post-ERC pancreatitis, ERC pneumonia, death within 30 days after ERC procedure), anesthetic-related complications (blood pressure decrease, pulse reduction, respiratory depression).

Results: We examined 69 males (52.3%) and 63 females (47.7%). Women accounted for 78% of the super-elderly group (71% vs 40%). The average age was 92.5 years (range, 90–97) in the super-elderly group and 77.9 years (range, 50–89) in the non-super-elderly group. The super-elderly group comprised 54 ERC procedures (moderate, 32; severe, 22) against 124 ERC procedures (moderate, 104; severe, 20) in non-super-elderly group, and 7 cases observed in the super-elderly group were statistically significant (p < 0.001). Regarding comorbidities, chronic heart and renal failure were statistically dominant in the super-elderly group. However, no difference was seen in the frequency of other diseases receiving anticoagulant medication between the two groups. The causes of acute cholangitis were common in both groups with common bile duct stone (46% vs 46%), followed by malignant obstruction (9% vs 12%) and benign stenosis (0% vs 5%), but no difference was found. Regarding the ERC procedure, the examination time was longer in the super-elderly group (37.5 ± 28.1 min vs 29.2 ± 24.0 min, p = 0.044), but there was no difference in the procedure success rate (93% vs 97%, p = 0.249) and the presence of periampullary diverticula. The patients were sedated using midazolam (MDZ) plus pentazocine (PTZ). The amount of sedation improved in the super-elderly group (MDZ: 2.2 ± 3.3 mg vs p < 0.001, PTZ: 3.1 v 5.4 mg, p = 0.005). Regarding (i) ERC-related and (ii) anesthesia-related complications, these were higher in the super-elderly group [(i) 15% vs 9%, p = 0.293, (ii) 17% vs 7%, p = 0.004]. Post-ERCP morbi-mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.
included 20 patients with low-grade dysplasia (DBG) or high grade (DHG) lesions, performed by a dedicated gastrointestinal pathologist, in relation to a residual adenomatous bud after endoscopic ampullectomy for ampullary adenoma. The lesions should extend to a maximum length of 20 mm in the CBD. Endoscopic retrograde choledochoscopy (ERCP) was performed with the Push 369 EndoHPB probe (EMcision, UK) (effect 8, power 10 Watts, 30 s). Biliary + pancreatic stent were placed at the end of the procedure. The primary endpoint was the rate of residual neoplasia (eg, DBG, DHG or invasive carcinoma) at 1 year after treatment. Secondary endpoints included neoplasia at 6 months after treatment; 2) rate of surgery at 12 months; 3) adverse events.

Results: The mean age (±SD) was 67 years (±11), with 12 men and 8 women. RFA was performed on average (±SD) 1.9 years (±3.5) after ampullectomy. The mean resected ampullary adenoma size (±SD) was 24.9 mm (±10.2), and 7 patients had adjacent duodenal mucosectomy at the time of ampullectomy. The histology of the resected ampullary adenoma was DBG for 7 patients, DHG for 12 patients, and in situ carcinoma for 1 patient. Lateral margins were negative in all the patients. CBD recurrences were diagnosed predominantly on ERCP and/or endoscopic ultrasonography surveillance procedures with an estimated mean infiltration height (±SD) of 11.2 mm (±4.5). The passage of the RFA probe was judged to be easy in 100% of cases with visibility of the radio-opaque markers judged satisfactory to very satisfactory in 80% of the cases. All patients included had RFA without any technical problems. All patients had biliary stent (4 SEMS 10 mm, 16 plastic stents 10 French) implanted following RFA and 5 (25%) had a pancreatic stent. The residual rate of DBG, DHG, invasive carcinoma at 6 months and at 12 months after treatment were 25% (5/20, DBG, carcinoma) and 45% (9/20, DBG, carcinoma) respectively. The adverse events were as follows: 4 benign pancreatitis all medically treated, 2 patients had angioplasty requiring biliary stent replacement, 1 patient had an episode of unexplained spontaneously resolved abdominal pain (normal CT scan, colonoscopy and biological tests). At 12 months, one patient presented with a biliary stricture resolved by dilatation and a calibration biliary stent.

Conclusion: In conclusion, RFA performed on residual endo-biliary dysplastic buds after ampullectomy is an alternative to surgery, with a rate 55% dysplasia eradication at 12 months after a single RFA session. Regular monitoring of these patients is still necessary considering recurrence rate. Multiple RFA sessions may be proposed in case of incomplete results.

Introduction: Simulation-based training has become an important pillar in competence-based learning in medicine, especially in training novice endoscopists. Currently, there is limited data available in medical education regarding simulation-based training as an ideal platform for simulator-based training due to its technical complexity. The aim of our study was to determine the expert validity of the Costamagna ERCP Trainer as a very realistic training model by ERCP experts. Expert participants with more than 2500 ERCPs lifetime were invited by experts. Expert participants with more than 2500 ERCPs lifetime were invited by experts.

Aims & Methods: The National Health Service Litigation Authority (NHSLA) database in U.K. was searched using a Freedom of Information request (F/2405) from 2010/11 and 2014/15. The terms "Gastroscopy", "Sigmoidoscopy", "Colonoscopy", "PEG" and "ERCP" were used to search the database. They were then analysed for procedure type, characteristics and outcomes. StatsDirect statistical software was used for statistical analysis.

OUTCOME OF ENDOSCOPY CLAIMS

<table>
<thead>
<tr>
<th>PROCEDURE</th>
<th>OPEN SUCCESSFUL UNSUCCESSFUL</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gastroscopy</td>
<td>10</td>
</tr>
<tr>
<td>PEG</td>
<td>12</td>
</tr>
<tr>
<td>Sigmoidoscopy</td>
<td>17</td>
</tr>
<tr>
<td>ERCP</td>
<td>22</td>
</tr>
<tr>
<td>Colonoscopy</td>
<td>50</td>
</tr>
</tbody>
</table>

Results: A total of 291 claims were notified to the NHSLA during this period. 107 (36.7)% of claims still remain ‘open’. Analysing outcomes by procedures reveals a success rate of 44%, 44%, 37%, 36% and 34% (rounded up to the nearest whole figure) for Gastroscopy, PEG, Sigmoidoscopy, ERCP and Colonoscopy claims respectively. There is no statistical difference between the proportions comparing Gastroscopy and Colonoscopy (StatsDirect software used).

Conclusion: A significant number of claims remain open leading to concern and worry among endoscopists. The impact on practitioners after a successful claim is unknown and merits further investigation. Procedures considered as dangerous like ERCP and Colonoscopy have the least successful claims. It is imperative that clinicians remain vigilant. Performing Gastroscopy is dangerous and so is undertaking a Percutaneous Endoscopic Gastrostomy. Endoscopists should tighten their approach to all procedures.

Introduction: This study aims to recognize the morphology of intra-ampullary choledochocele (IAC) with contrast medium for evaluating technical difficulty in ERCP. N. Nishino

Gastroenterology Center, Southern Toho Hospital, Koroyama/Japan

Contact E-mail Address: nishinon@tim.hi-ho.ne.jp

Introduction: Choledochocele has been rarely recognized. We focus on intra-ampullary choledochocele (IAC). We had experienced some cases with IAC as refractory access to bile duct (BD). IAC has small cyst within ampulla regulated by Oddi’s sphincter, so the BD axis has changed via IAC. The cases with IAC would require a high technical skill for axis alignment or alternative strategy such as infundibulotomy or precut. We propose advantage of conventional ERCP (cERCP) with contrast medium, which provides images of IAC and leads to the elucidation of the reason for difficulties in cannulation. The current study is a retrospective consecutive case study that is conducted in a single facility, with a study period of 8 years. Our strategy for ERCP was carried out with the contrast medium injected via a catheter, but without guide wire (GW) seeking. Intra-ampullary bifurcation was particularly visualized with the contrast medium, and X-ray images were magnified sequentially 5–10 times each. The eligibility criteria were; it must be naïve papilla and both of BD and PD must be visualized. The following factors were evaluated; ampulla shape, number of orifices, angle of intra-ampullary bifurcation and presence of IAC. The Location, size and shape of IAC were observed. The requirement of GW placement on PD to access BD was evaluated. The shapes of ampulla were divided into three groups: long nose (L/N), meaning a long protrusion, Dome (D), meaning a hemisphere and flat (F). The IAC location were classified into BD (Ab), PD (Ap) and common channel (Ac). The choledochocele shapes were divided into three groups: spindle (Sp), sphere (Sh) and oval (Ov). IAC was also recognized on magnetic resonance cholangiopancreatography (MRCP). We analyzed our results of image database with descriptive epidemiology.
Results: There were cases of 1223 naïve papilla out of 2226 cases in total. The success rate to access BD with naïve papilla was 97.3% (1195/1223) and overall post-ERCP pancreatitis (PEP) was 1.3% (29/2226). The eligible patients were 908 (505 male and 403 female), among whom IAC was identified in 6.0% (54/908). The prevalence of IAC in the L:N, D and F types were 9.5% (48/524), 1.2% (4/345) and 0.8% (1/137) respectively. IAC was significantly higher in the L:N (p < 0.01) and F (p < 0.05) types than in the D type. The choledochoele shapes of Sp, Sh and Ov were 59.3%, 13.0%, 27.8%, respectively. The average size was 8.1 mm (3.7–18.3) in diameter. The location of IAC in Ac and Ab were 60% and 40%, respectively, in Ac. In Ab, cholangitis was found with L:N shape only. Patients of 53.7% (29/54) required GW placement on PD to access BD. IAC was alternately seen on MRCP in 10% (3/30).

Conclusion: Choledochoele is rarely seen even on eERCP, in addition the visually seen on MRCP in 10% (3/30).

Introduction: EUROS-guided Cysto-Enterostomy (EUCE), technique indicated for drainage of symptomatic pancreatic pseudocysts and other peri-enteric fluid collections, requires specific skills for which dedicated models are needed. Based on a compact EASE model (Active Simulating for Interventional Endoscopy) we developed two ex-vivo porcine models of retrogastric cysts and evaluated learning performance within the frame of a structured training program.

Aims & Methods: The first model was made of porcine colon (i.e. “natural cyst”), and the second one was made with an ostomy bag (i.e. “artificial cyst”). All procedures were achieved with EUCE scope under fluoroscopy. Both models were evaluated prospectively over a 2-days session involving 14 students and 5 experts. Results: “Natural cyst” and “artificial cyst” were prepared respectively within 10 and 16.5 minutes (p = 0.07). More than 10 EUCE procedures were done in each model. Model grading (analytic scale) showed no significant difference for primary endpoint of global satisfaction (p = 0.60). Regarding secondary endpoints, difference was not significant for overall impression of realism (p = 0.75) whereas it was significant favoring “artificial cyst” in terms of ability to teach procedural steps (p = 0.01) and ease of puncture (p = 0.03) because of less elasticity. Moreover, experts considered it easy to improve students’ proficiency superior with “artificial cyst” (p = 0.008).

Conclusion: Both “artificial and natural cysts” are efficient for EUCE training in terms of global satisfaction. However, the “artificial cyst” model appears to make procedure easier and to teach procedural steps improving students’ proficiency. Larger applications of this model are needed to validate as a standard of training.

Introduction: Most appropriate endotherapy of biliary anastomotic strictures (AS) remains to be defined.

Aims & Methods: Aim is to retrospectively report the endotherapy for duct-to-duct AS in 2013, procedure related complications and medium-term outcome results in Italy. A questionnaire was sent to the Endoscopy Units working with Italian Liver Transplantation Centers (BASALT study group).

Results: At present sixteen of the 19 Units (84%) returned the questionnaire. Complete endotherapy data and follow-up are available for 182 pts. One-hundred and two patients have been treated with plastic multistenting (PM), 27 with fully covered SEMS and 53 with single stenting (SS). Radiological success was achieved in 144 pts (79%), i.e. 86% of PM, 89% of fully covered SEMS and 60% of SS (p < 0.01 vs PM). Recurrence occurred in 31 pts, i.e. 21% of pts in whom radiological success was achieved: 11% of PM (p < 0.001 vs SEMS and p < 0.05 vs SS), 41% of fully covered SEMS and 17% of SS. After failure of first-line endotherapy (36) or recurrence (31), patients were re-treated with endotherapy (75%), surgery (21%) or percutaneous balloon dilation (3%). One patient dropped out because of death unrelated to endotherapy. Second-line endotherapy was PM for 26%, fully covered SEMS for 52% and SS for 22% of pts and radiological success was achieved in 82% of them (in 86%, 89%, and 66% with PM, SEMS and SS respectively). Procedure-related complications occurred in 7.8% (51/665), i.e. 2.6% pancreatitis (1 severe leading to death), 4.1% cholangitis and 0.9% bleeding. Overall clinical success was achieved in 85% after a median i-up of 25 mos and no need of surgery in 92% of patients.

Conclusion: Endotherapy is confirmed as the preferred first-line and rescue option for AS. Progressive plastic multi-stenting is most frequently used. Single stenting has suboptimal results and should be abandoned. Use of SEMS is effective, but recurrences seem to be frequent, although a larger patients’ sample needs to be evaluated.

P0251 A PROSPECTIVE COMPARATIVE STUDY OF EFFICACY OF EUS GUIDED FNA VERSUS ERCP GUIDED BRUSH CYTOLOGY IN ATTAINMENT OF HISTOPATHOLOGY OF DISTAL CBD MASSES

P.N. Desai, M. Kabrawala
Endoscopy, Surat Institute Of Digestive Sciences, Surat/India

Contact E-mail Address: drp.desai@hotmail.com

Introduction: Distal CBD masses have always been a diagnostic dilemma. They are difficult to diagnose with any modality used. Brush cytology under ERCP guidance was used up till now and also intraductal biopsies were used. The yield was hardly around 60% using all together. We started doing EUS localization of these difficult to identify distal CBD masses and took FNA from them. We devised a protocol to see the results of EUS FNA and brush cytology in the diagnosis of these masses.

Aims & Methods: We aimed to study the efficacy of EUS guided FNA for attaining tissue from distal CBD masses and comparing it to ERCP guided brush cytology from the same masses. 56 cases with distal bile duct mass with obstructive jaundice in the last 3 years were taken for the study. The protocol we followed First - EUS was done using a linear echoendoscope, mass identified and obstructive jaundice in the last 3 years were taken for the study. The protocol we followed First - EUS was done using a linear echoendoscope, mass identified and obstructive jaundice in the last 3 years were taken for the study. The protocol we followed First - EUS was done using a linear echoendoscope, mass identified and obstructive jaundice in the last 3 years were taken for the study. The protocol we followed First - EUS was done using a linear echoendoscope, mass identified and obstructive jaundice in the last 3 years were taken for the study. The protocol we followed First - EUS was done using a linear echoendoscope, mass identified and obstructive jaundice in the last 3 years were taken for the study. The protocol we followed First - EUS was done using a linear echoendoscope, mass identified and obstructive jaundice in the last 3 years were taken for the study. The protocol we followed First - EUS was done using a linear echoendoscope, mass identified and obstructive jaundice in the last 3 years were taken for the study. The protocol we followed First - EUS was done using a linear echoendoscope, mass identified and obstructive jaundice in the last 3 years were taken for the study.

Results: Total number of cases 56 Age (range) 57.2±13.6 Male to Female 40:16 Total Sedum Biulin (mg/dl) 5.9±6.4 Mean size of the mass 12 mm (7 mm to 30 mm). Mean Number of passes with FNA needle 2.5 (2 to 5 passes). Mean number of passes with cytology brush 2 (2to 5). Positive diagnosis obtained with FNA 47 (83.9%). Positive Diagnosis obtained by brush 34 (60.7%)

Conclusion: Except for shorter procedural duration, there was no significant difference in treatment outcomes between patients treated with LAMS or plastic stents. Given the faster resolution of WON, to minimize adverse events, patients undergoing LAMS placement should undergo post-intervention imaging at 3 weeks followed by stent removal if the WON has resolved. P0253 TRANS AORTIC ENDOSCOPIC ULTRASOUND GUIDED FNA IN THE DIAGNOSIS OF LUNG CANCERS AND MEDIASTINAL LYMPH NODES

P. Somani, M. Sharma
Department Of Gastroenterology, Jaiwant Rai Speciality Hospital, Meerut/India

Contact E-mail Address: dr_piyushsomani@yahoo.co.in

Introduction: Obtaining a tissue diagnosis from a lung tumour or a mediastinal lymph node located lateral to the aorta (para-aortic) is a diagnostic challenge because of the interposition of the aorta. Invasive surgical procedures like mediastinotomy, thoracotomy, or video-assisted thoracic surgery is required for the diagnosis of these lesions. Lymph node stations immediately anterior to the aortic arch and lateral to the descending aorta are difficult to access. Lymph nodes on the “far-side” of major blood vessels can be visualized by endoscopic ultrasound(EUS), however Fine needle aspiration(FNA) is avoided due to concern for bleeding complications. Tumours and mediastinal lymph nodes located in the para-aortic region can easily be visualized by esophageal EUS, because the aorta provides an excellent medium to transfer ultrasound waves.

With EUS the tumors were sometimes difficult to locate and identify. But giving some time and instilling water in duodenum were useful techniques to identify the masses. Only a 25 G needle was used as the FNA had to be taken almost always from the duodenum and with difficult angles. But we succeeded in taking FNA from all cases.

Conclusion: EUS FNA is a very effective method for diagnosis of distal bile duct masses with a certain diagnosis in almost 81% and a suspicious diagnosis in around 11% cases. Its efficacy is better than ERCP guided brush cytology. Even small masses are amenable to FNA using EUS guidance. Male over 57 years with jaundice and distal bile duct obstruction has a very likelyhood of have a distal CBD cholangiocarcinoma.

P0252 RANDOMIZED TRIAL COMPARING THE LUMEN-APPOSING METAL STENTS (LAMS) AND PLASTIC STENTS FOR EUS-GUIDED DRAINAGE OF WALLOWED-OFF NECROSIS (WON)

J.Y. Bang, M. Hasan, U. Naveenethan, R. Hawes, S. Varadarajulu
Center For Interventional Endoscopy, Florida Hospital, Orlando/United States of America/FL

Contact E-mail Address: jybang213@gmail.com

Introduction: Although lumen-apposing metal stents (LAMS) are being increasingly used for drainage of walled-off necrosis (WON), their advantage over plastic stents is unclear.

Aims & Methods: We aimed to compare the efficacy of LAMS and plastic stents for drainage of WON. Symptomatic patients with WON (>20% necrosis) were randomized to undergo transmural drainage using LAMS (Hot AXIOS, 15 mm x 10 mm) or two double pigtail plastic stents (7Fr x 4 cm). Reintervention in persistently symptomatic patients included additional stent placement, percutaneous drainage and/or endoscopic necrosectomy. Treatment success was defined as symptom relief in conjunction with resolution of WON on CT at 6-week follow-up. Main outcome measure was to compare the no. of reinterventions. Secondary outcome measures were to compare treatment success, procedural duration, resolution of systemic inflammatory response syndrome (SIRS), clinical and stent-related adverse events, readmissions and length of hospital stay. Sample size to detect a difference of 1 in the no. of reinterventions performed at 90% power was calculated at 58 patients.

Results: 60 patients were randomized to LAMS (n = 31) or plastic stent (n = 29) placement. While there was no significant difference in the no. of reinterventions (median [IQR] 1–2) for both stent types, (p = 0.78), the procedural duration was significantly shorter (15 vs. 42.5 mins, p < 0.001) and stent-related adverse event rate was significantly higher with LAMS placement (32.3 vs. 6.9%, p = 0.02). At an interim audit, significant adverse events (delayed bleeding [n = 3], buried stent [n = 2], biliary stricture [n = 3]) were observed in the LAMS cohort after 3 weeks post-intervention. This necessitated an amendment to the study protocol whereby a CT scan was obtained at 3 weeks followed by LAMS removal if the WON had resolved. After protocol amendment, no difference in stent-related adverse events was observed between the cohorts (LAMS 6.5 vs. plastic 6.9%, p = 0.94). Also, there was no significant difference in treatment success, SIRS resolution, clinical adverse events, readmissions or length of hospital stay between the cohorts (Table).

United European Gastroenterology Journal 5(5S)
Aims & Methods: We aimed to evaluate the feasibility, yield, and safety of EUS-guided pancreatic fluid collections drainage. We undertook a retrospective case series of 12 consecutive patients with suspected lung cancer or tuberculosis who underwent transaortic FNA during a study period of 7 years. In all cases, the para-aortic lesion was the only site suspicious for lung cancer/tuberculosis (other lesion/lymph node if present were negative). Based on CT/PET imaging, a transesophageal FNA performed through the aorta was considered as the only option to diagnose or stage these patients by means of a minimally invasive procedure. Seven patients had left-sided lesions, 4 were larger than 30 mm. Four were located in left lower lobe and three in left upper lobe. Four patients have enlarged para-aortic lymph nodes (mean size 18 mm, range 8–22 mm), suspicious for IASLC stations 5 (n = 1) and 6 (n = 5). One patient had anterior mediastinum mass. EUS was performed with a linear echoendoscope. All aspirations were obtained under real-time US guided FNA by using a 22/25-gauge needle. A single real-time FNA of the lung mass or lymph node was performed. The para-aortic area was observed on EUS for 5 minutes to assess for immediate procedure-related complications.

Results: The final diagnosis was known in 11 patients (5 non-small-cell lung carcinoma [NSCLC], 2 small-cell lung carcinoma [SCLC], 3 tuberculosis and one thymolipoma). EUS-FNA established diagnosis in 9 of 12 patients (75%) (4 NSCLC, 1 SCLC, 3 tuberculosis and one thymolipoma). One aspirate revealed reactive nodal tissue, and one demonstrated nonrepresentative material. One procedure was abandoned due to complication. Three patients in whom diagno- sis was not established by transaortic FNA underwent subsequent surgical stenting (1 thoracotomy, 1 mediastinotomy, and 1 VATS), and malignancy was found in 2 of the 3 patients. Trans aortic FNA was found to be safe. In one patient, EUS images after FNA were suspicious for a small para-aortic hema- toma. This patient recovered without any adverse event.

Conclusion: This study demonstrates the feasibility and probable safety of single EUS guided transaortic aspiration in para-aortic lesions. The diagnostic yield is 75 percent. Clearly, further study and very careful selection by expert EUS operators is needed before this procedure can be routinely recommended. Advantages of this procedure include day care procedure, lower invasive than surgical procedures, low cost, good diagnostic yield and can be performed in poor surgical candidate. Limitations includes single centre study, require EUS expertise, more data is required. At present, Transaortic FNA should only be performed in the absence of alternative minimally invasive diagnostic procedures.

Introduction: Ultrasound-guided endoscopic transgastric drainage (EUSTD) of pancreatic fluid collections (PFCs) by using double-pigtail plastic stents (DPSS) requires placement of multiple stents and can be restricted by inadequate drainage and leakage risk. Recently, the use of fully covered self-expanding metal stents (FCSEMSs) has been reported as an effective alternative.

Aims & Methods: This was a single-centre retrospective study (2012–2016) on 67 patients with stents (FCSEMSs) has been reported as an effective alternative.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Histological examinations and immunohistochemical stains (IHC) are necessary for the differential diagnosis of gastrointestinal subepithelial lesions (SELs). Endoscopic ultrasound-guided fine needle biopsy (EUS-FNB) is the primary modality in the diagnosis of SELs, but still has limited accuracy. A new 20 gauge (G) biopsy needle with a core-trap technology (EchoTip ProCore®, Cook Medical) has been developed with a large core size and enhanced flexibility.

Aims & Methods: The aim of this multicenter study was to determine the feasibility, efficacy and safety of EUS-FNB with the new 20G needle in diagnosing SELs. Data retrieved from a prospectively collected database at five medical centers were analyzed and all consecutive patients with SELs undergoing EUS-FNB with the 20G needle were included in the present study. The reference standards for the final diagnosis were histology on surgical specimen or clinical follow-up.

Results: A total of 50 SELs in 50 patients (22 males, mean age 61.5±14.8 years) were included. The mean lesion size was 43.1±17.5 mm. The lesion locations were esophagus (n = 1), stomach (n = 37), distal duodenum (n = 5), rectum (n = 6), and colon (n = 1). The procedure was technically feasible in all patients. Minimum number of passes required to reach a diagnosis was 2.2 (range 1–4). The definitive diagnosis with full histological assessment including IHC was obtained in 88% (44/50) of the patients. Diagnosis of EUS-FNB showed 36 (72%) malignant SELs (32 GISTs, 1 metastasis from breast cancer, 1 leiomyosarcoma, 1 carcinoid, 1 SEL-like adenocarcinomas), 8 (16%) benign SELs (3 leiomyomas, 4 schwannomas, and 1 lipoma), and 6 (12%) indeterminate SELs. Considering malignant vs. benign lesions, the sensitivity, specificity, PPV, and NPV were 85% (95%CI 70.2–94.3), 100% (95%CI 58.7–100), 100% (95%CI 58.1–100), and 62% (95%CI 27.7–84.8), respectively. No major complications requiring additional care have been observed. Conclusion: In this multicenter study, we found that EUS-FNB with the new 20G core needle is an effective and safe method for the diagnosis of SELs with a high rate of producing adequate histological material and high diagnostic accuracy even from difficult-to-approach anatomical locations. Comparative studies with different needle sizes are awaited.

between the two groups was applied in order to minimize the effect of selection bias. The success rate of reaching the biliary anastomosis in patients with BA after LDLT was significantly lower than other patients (p < 0.01). There was no significant difference between the success rate in the patients over or under 13 years at the time of ERCP (50% vs 56%, p = 0.70). The success rate was lower in patients who underwent initial surgery as an infant (Kasai hepatoportoenterostomy) than in those past infancy (54% vs 88%, p < 0.01). When reaching the biliary anastomosis is successful, the success rate of cannulation in the patients after LDLT is high (92%). The success rate for reaching the biliary anastomosis in patients with BA after LDLT is significantly lower than other patients. The age at the time of ERCP did not affect the success rate of reaching the biliary anastomosis, but the success rate was lower in patients who underwent their initial surgery as infants. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Liver tumors such as hepatocellular carcinoma and liver metastases sometimes occur in positions in which treatment using percutaneous radiofrequency ablation (RFA) is difficult, such as the caudate lobe and surface of the left lobe. EUS-guided RFA can offer an alternative treatment by accessing these tumors through the stomach or duodenum. To the best of our knowledge, only one report has described EUS-RFA of the liver in an animal model, using a 19-gauge EUS-FNA needle with an umbrella-shaped array at the tip.

Aims & Methods: We examined whether a novel 19-gauge RFA needle can be introduced to ablate the liver in a porcine model under EUS guidance. Two pigs were used in this study. All procedures were carried out under general anesthesia. EUS-guided 19-gauge needles and a VIVA combo™ generator (TaeWoong Medical, Gimpo city, Korea) were used for the procedures. Three kinds of RFA needles (10-, 15-mm, and 20-mm exposed tips) were used. After the echoendoscope was advanced to the stomach, the RFA needle was inserted into the surface of the left lobe. EUS-RFA was performed at 340–W for 5–6 min in general mode. In each pig, three RFA needles with 10-, 15-, or 20-mm exposed tips were serially used for insertion and ablation. Subsequently, the RFA needle with the 10-mm exposed tip was used in the quadrate lobe of the gallbladder through the bulb of the duodenum.

Results: All procedures were technically successful. After the procedure, the liver of the pig was removed, and visible RFA effect was evaluated macroscopically. Histology with hematoxylin and eosin (HE) staining showed coagulative necrosis in the ablated area, corresponding with the macroscopic ablated area.

Conclusion: In this experimental study, EUS-RFA could be performed technically not only in the surface of the left lobe, but also in the adjacent to the gallbladder of the porcine liver. Further studies are required to confirm the efficacy and safety.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0258 THE SUCCESS RATE OF DOUBLE BALLOON ENDOCOPIC CHOLANGIOGRAPHY IN PATIENTS WHO UNDERWENT THEIR INITIAL SURGERY AS INFANT IS SIGNIFICALLY LOWER THAN OTHER PATIENTS

K. Yokoyma1, T. Yano1, J. Ushio1, K. Tamada1, A. K. Lefor2, H. Yamamoto1
1Department of Gastroenterology, Jichi medical university, Tochigi/Japan
2Department Of Surgery, Jichi Medical University, Tochigi/Japan

Introduction: To evaluate the success rate of double-balloon endoscopic retrograde cholangiography (DBERC) to reach the anastomosis in patients with surgically altered gastrointestinal anatomy.

Aims & Methods: We review 346 patients with surgically altered anatomy who underwent DBERC from April, 2002 to December, 2016 (47 patients with biliary atresia (BA), 23 with living donor liver transplantation (LDLT), 33 with LDLT with BA, 45 with biliary resection and choledochojejunostomy, 111 with gastric resection and Roux-en-Y bypass, 48 with gastric resection and Billroth-Ileum, 18 with pylorus-preserving pancreaticoduodenectomy, and 42 others). The mean age was 30.9±17.1 years. Four patients had previous surgery (hemi-hepatectomy (n = 2); one patient had a history of intra-abdominal sepsis in childhood causing portal vein thrombosis. No radiological or surgical options were deemed feasible in any case. SBV were diagnosed at capsule endoscopy and triple phase CT mesenteric angiography. At DBE, a total of 10 nests of SBV were identified causing portal hypertension and may result in life-threatening mid-gut bleeding. First line management usually involves radiological intervention (RI) (e.g. TIPSS, stenting of occluded mesenteric veins +/- embolisation of culprit varices). In cases where RI is impossible, management options become very limited.

Results: The success rate for reaching the biliary anastomosis (or papilla of Vater) in all 346 patients (66.0±(3–91)) was 83%. The rate in 47 patients with BA after LDLT (12.0±(3–39)) was 57%. In the remaining 299 patients the rate was 87%.

Conclusion: In conclusion, the success rate of reaching the biliary anastomosis in patients with BA after LDLT was significantly lower than other patients (p < 0.01). There was no significant difference between the success rate in the patients over or under 13 years at the time of ERCP (50% vs 56%, p = 0.70). The success rate was lower in patients who underwent initial surgery as an infant (Kasai hepatoportoenterostomy) than in those past infancy (54% vs 88%, p < 0.01). When reaching the biliary anastomosis is successful, the success rate of cannulation in the patients after LDLT is high (92%). The success rate for reaching the biliary anastomosis in patients with BA after LDLT is significantly lower than other patients. The age at the time of ERCP did not affect the success rate of reaching the biliary anastomosis, but the success rate was lower in patients who underwent their initial surgery as infants. Disclosure of Interest: All authors have declared no conflicts of interest.

and injected with cyanoacrylate glue. There were no haemorrhagic or embolic complications with this technique. A 3D model of a congenital arterial cyst, which was treated successfully with antibiotics. All patients underwent DBEs via the anterograde route and 1 patient required bi-directional DBE for treatment of both proximal and distal SBV and another patient required a 2nd anterograde DBE for treading of further patent proximal SBV. At 30-day follow-up post-therapy, only 1 patient had experienced a mild recurrence of mid-gut bleeding.

Conclusion: Cyanoacrylate injection therapy of SBV at DBE appears to be a safe and effective management strategy for this condition when other first-line options are not feasible.

Contact E-mail Address: n.ogata@hotmail.co.jp

Introduction: The development of balloon enteroscopy and capsule endoscopy has made an endoscopic evaluation of the small intestine possible in clinical practice. The usefulness of magnifying endoscopy has already been reported in observing the pharynx, esophagus, stomach and colon. A single-balloon enteroscopy (SBE) with 80x magnification has been recently developed.

Aim & Methods: The aim of this pilot study was to assess the efficacy of narrow-band imaging (NBI) magnifying findings for evaluating the severity of inflammation in small intestinal crohn’s disease (CD). The study was conducted in Showa University Northern Yokohama Hospital. We included CD patients who underwent enteroscopy with magnification from September 2013 to February 2015. NBI images and a biopsy specimen were obtained from small intestinal mucosa for CD patients with use of SBE (Y-0007, Olympus, Tokyo).

Results: Twenty-four patients were enrolled. There was a correlation between magnifying NBI findings and the histological assessment (Spearman’s r = 0.549). The sensitivity, specificity, positive predictive value, negative predictive value, and accuracy of magnifying NBI findings for diagnosing acute inflammation were 88.2%, 71.4%, 88.2%, 71.4%, and 83.3%, respectively.

Conclusion: The NBI magnifying findings in the small intestinal mucosa had a correlation with histological inflammation and could help in distinguishing between active and inactive CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0262 SINGLE-INCISION LAPAROSCOPIC-ASSISTED DOUBLE BALLOON ENTEROSCOPY: A NOVEL TECHNIQUE TO MANAGE SMALL BOWEL PATHOLOGY

I. Stasinou1, N. Kamberidis1, R. Rameshshanker2, A. Murino1, C. Fraser1, J. C. Navarrie2, A. Humphries1

Contact E-mail Address: Ioannistasinou@nhs.net

Introduction: Double balloon enteroscopy (DBE) has revolutionised the diagnosis and treatment of small intestinal conditions. However, even in expert hands, deep small bowel (SB) insertion can be challenging, especially in patients with a history of abdominal/pelvic surgery. Moreover, if the findings at DBE are not amenable to endoscopic therapy, a further surgical procedure is usually required to provide a definite treatment. Laparoscopic-assisted DBE (LA-DBE) using a standard multi-port technique has previously only been reported in a small series of 3 patients with Peutz–Jeghers Syndrome (PJS).1

Aims & Methods: This case series reports the development of LA-DBE using single-incision laparoscopic surgery (SILS) applied to a wide range of clinical indications. Retrospective review of LA-DBE procedures performed in a single tertiary centre over a 6 year period. Demographics, indication, findings, diagnosis and therapeutic interventions were recorded. Completion, complication rates and hospital length of stay were also captured.

Results: 17 procedures were performed over 6 years in 17 patients who had failed standard DBE. Mean (range) age was 40 (17-73) and 41% of patients were male. The enteroscopic approach was oral in 13/17 patients and rectal in 4/17. Laparoscopic approach was standard (multiport) in the first 4 cases. SILS was then used in all subsequent patients (13/17). The mean (range) procedure time was 147 (84-210) mins. Indications were PJS (n = 10), suspected submucosal/ intramural lesion at small bowel imaging (n = 5) and obscure gastrointestinal bleed (OGIB) with vascular abnormalities seen at capsule endoscopy (n = 2). In 15/17 procedures the target pathology was reached using laparoscopic assistance only and 1/17 was converted to intraoperative enteroscopy (IOE). In 1/17 the suggested pathology at magnetic resonance enterography (MRE) was not identified. Therapy was applied in 15/17 (88%) cases. 7 underwent endoscopic therapy of which 6 polypectomy and 1 ablation with argon plasma coagulation (APC). 4 required limited SB resection and 4 underwent both endoscopic polypectomy and small bowel resection for a second polyp that could not be removed endoscopically. A total number of 57 polyps were removed with the largest measuring 40 mm. The range of length of surgically resected SB was 4–17 cm. Diagnoses were PJS polyps (n = 9), neuroendocrine tumour (NET) (n = 2), PJS polyps and NET (n = 1), traumatic arteriovenous malformation (n = 1), angioectasia (n = 1), inflammatory polyp (n = 1), leiomyoma (n = 1), Meckel’s diverticulum (n = 1). Median length of stay post procedure was 2 (1–19) days. 8/17 patients were discharged at 24 hours. 3/17 patients developed complications: 1 preprocedure ileus, 1 pelvic collection that was managed with antibiotics and 1 patient that was readmitted 8 days post procedure with subacute SB obstruction which resolved with conservative management.

Conclusion: LA-DBE appears to be a safe, effective and minimally invasive procedure that can be applied for the management of a wide range of small bowel pathology. A SILS approach allows all therapeutic modalities to be available as needed during the procedure, including conversion to IOE, laparoscopic small bowel resection and laparotomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
compared to clear liquids diet, PBP significantly increased small bowel VCE DY.

Results: We identified 9 eligible RCTs with 12 sets of data, including 1029 subjects. They were low risk of bias trials and no publication bias was detected. As an entirely visual medium it depends on the mucosal surfaces, fluids, and bubbles. The definition of optimal image quality remains largely based on subjective evaluation by expert readers. For each type of pathology, we determined the threshold of image quality for diagnosis. The definition of optimal image quality by expert readers was based on subjective evaluations.

P0265 INTER-OBSERVER AGREEMENT IN BROTZ CLEANING SCALES FOR CAPSULE ENDOSCOPY

Gastroenterology, Centro Hospitalar de Vila Nova de Gaia e Espinho, Vila Nova de Gaia/Portugal

Contact E-mail Address: mafalda_m_p_sousa@hotmail.com

Introduction: The diagnostic yield of capsule endoscopy (CE) depends on the adequate visualization of the mucosa. As such, colonoscopy, cleaning scales should be described in the report in order to better interpret results. In 2009, Brote et al proposed and validated 3 different cleansing scales in 40 patients.

Aims & Methods: A hundred CE videos (Mirocam®) were reviewed by 2 authors at a fixed frame rate of 100 frames per second in quadruple view (Miroview Client). The CE were evaluated according to Brotz scales: (1) Overall adequacy assessment (adequate/inadequate) (2) Qualitative scale (excellent, good, fair, poor) and (3) Quantitative scale (0–10 score, graded from 0–2 visualization of the mucosa, fluids, bubbles, bile and luminosity). The aim of this study was to evaluate the inter-observer variability of this cleaning scales. The kappa coefficient was used to calculate the inter-observer agreement in overall adequacy assessment and the intra-class correlation coefficient was used to evaluate the concordance of the qualitative and quantitative scales.

Results: In overall adequacy assessment, the quality of bowel preparation was classified as adequate by observer 1 in 29% and by observer 2 in 73%, with an inter-observer kappa index of 0.76 (p < 0.001) suggesting strong agreement. In the qualitative scale, most of the bowel preparations were considered adequate (40% observer 1 vs 36% observer 2), with an intra-class coefficient of 0.89 (p < 0.001). In the quantitative scale, the mean score of the two observers was 6.5 and 6.7, resulting in an intra-class agreement of 0.78 (p < 0.001).

Conclusion: The optimization of quality of bowel preparation and the diagnostic yield of CE requires, first, a well-validated cleansing scale. Brote’s rating scales have strong inter-observer agreement. The qualitative scale is easier to apply and has better inter-observer agreement, so the authors propose that it should be used routinely in the CE report.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Capsule endoscopy (CE) is the prime mode of investigation for small bowel (SB) pathology. However, as an entirely visual medium it depends heavily on image quality. The definition of optimal image quality remains unclear based on subjective evaluations and poses significant limitations to the quality of study reporting. As yet, there is no widely-accepted or integrated method for scoring SB cleanliness during CE reporting. This pilot study aims to quantify the image properties contributing to adequate visualisation quality in CE images.

Aims & Methods: Five clear images of SB pathology were obtained using MiroCam® (Intromedic, South Korea), image resolution 320×320 pixels: P1 and P2 angioectasias, ulcer, aphtha and polyp. Each image was processed using GIMP2 image editing software (www.gimp.org) for 3 parameters: (1) opacity (opacity filter matched in colour to commonly-seen SB contents, 10–90% in 10% increments), (2) blur (Gaussian blur, radius 1–20px), contrast (50% to 50% in 10% increments). Gaussian blur was used to simulate the effects of rapid capsule movement and as well as to affect image definition. A set of 5 original and 190 edited images were obtained. A web-based survey was created using Google Forms and 9 expert CE readers were asked to indicate whether each image was adequate or not for diagnosis. The order of images was randomised for each reader. For each type of pathology, we determined the threshold of image quality for diagnosis. Brotz's rating scales was deemed adequate for diagnosis.

Results: For image opacity, both aphthae and the polyoid lesion were adequately visualised below 40% opacity whereas the threshold was lower for both the ulcer and aphtha (100% opacity). Increasing blur radius significantly impacted the acceptability of images for reaching a diagnosis with confidence; for most images, blur radius 3px was the threshold for adequate visualisation but even 1px of blur radius decreased the visualisation quality of the aphtha image. The aphtha image was also affected the most by decreased contrast; conversely the ulcer was deemed more inadequately visualised with higher contrast. The other images were generally adequately visualised at ±10% contrast. Results are detailed in the table below.

Introduction: Inflammatory bowel diseases (IBDs) are chronic inflammatory diseases that may affect the whole gastrointestinal (GI) tract, mainly the small bowel and colon. Endoscopic evaluation of these parts is essential to assess disease extent and severity. The small bowel capsule endoscopy (SBC-CE) system is a new system composed of a two-headed capsule with a panoramic field of view and adaptive frame rate, customized for complete coverage of IBD lesions in the entire bowel, data recorder and new disease specific software, allowing assessment and follow-up over time of disease severity and extent.

Aims & Methods: The aim was to evaluate SBC-CE system functionality in suspected or established IBD (Crohn's disease [CD] and Ulcerative Colitis [UC]) patients. This was a prospective 5 center feasibility study assessing the procedure, small bowel capsule software. Subjects enrolled in the study ingested the new capsule after standard bowel preparation plus boost. Contraindications for its use included obstruction, dysphagia or swallowing disorders, pacemakers etc. GI patency was assured using the patency capsule. The patients were followed after video creation and report generation in accordance to the video reading methodology. Secondary end-points were subjective coverage of SBC, subjective duration of total and segmental reading time, over all video quality and occurrence/severity of adverse events.

Results: Of 54 enrolled, of which 54 were enrolled and 49 ingested the capsule (14 patient failure, 5 withdrew consent). Mean age was 40.1 years, 51% were males. 69% of patients had established CD, 10% UC and 21% suspected CD. The disease was active in 62% of known IBD patients. One patient who underwent extensive colon resection was excluded from all colon analyses. Overall cleansing was regarded good or excellent in 96% of patients. All 49 patients with pancreatic cancer were registered to NAC (S-1 [80 mg/m², twice daily], 2 cycles) or NACRT (a total dose of 50.4 Gy in 28 fractions and S-1 [80 mg/m², twice daily on radiation day alone] for 1 month and subsequent chemoradiotherapy with gemcitabine for 3 cycles) studies conducted by Hokkaido Pancreatic Cancer Study Group (HOPS) (UMIN000013031/UMIN000012293). Of them 29 patients who underwent biliary drainage with a MS or PS before NAC/NACRT and subsequent pancreaticoduodenectomy were analyzed.

Contact E-mail Address: shinchan1231@gmail.com

Introduction: Transapipillary dilation for severe main pancreatic duct (MPD) stricture is sometimes difficult and diathermic dilation is now getting attention as a salvage technique for severe stricture; however its efficacy and safety remains unclear.

Aims & Methods: To evaluate the efficacy and safety of a novel transapipillary dilation technique with a wire-guided 6Fr diathermic catheter for severe chronic pancreatitis. Between April 2011 and March 2017, 143 patients with chronic pancreatitis underwent endoscopic transapipillary stent placement for MPD. MPD dilatation was indicated in 18 patients, and diathermic dilation was required in nine patients. We evaluated (1) the patients' characteristics, (2) procedure characteristics, (3) clinical outcomes, (4) adverse events.

Results: (1) Six patients were men and three were women (mean age, 50.1 years). Alcohol 8, unknown 1. The strechies were in the head of pancreas: 8, body: 1.

The mean length of stricture was 20.2 mm (range, 10–56.8). The mean MPD diameter at the distal side of the stricture was 6.2 mm (range, 3.0–7.3). The diathermic dilatation of stricture was successful in all patients (100%). After diathermy and stent placement, 8 (88.9%) showed improvement of clinical symptoms (abdominal pain). Resolution of stricture was observed in 2 patients (22.2%). One of them needed diathermic dilatation again. (4) Two adverse events (22.2%) were observed and both of them were mild pancreatitis. Multiple diahrerou procedures (6 times and 4 times, respectively) and relatively long duration of total diathermy procedures (39 sec. and 25 sec. respectively) were observed in cases with pancreatitis.

Conclusion: Transapipillary diathermic dilation is a relatively safe and effective salvage procedure for severe MPD stricture due to chronic pancreatitis. Diathermic dilation should be taken in cases that require multiple times and long duration diathermy procedures because of a risk of pancreatitis.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: Follow-up period, stent revision via fistula tract was successful and additional up periods. The stent patency duration was 275.2 (147.8–402.7) days. During developed after EUS-BDR in 2 patients (1 case of cholangitis and 1 case of liver in 22 patients and partial covered stent in 2 patients. Early adverse events developed after EUS-BDR in 2 patients (1 case of cholangitis and 1 case of liver abscess in patients with malignant biliary stricture). Late adverse event that stent occlusion was observed in 5 patients. Neither proximal percutaneous stent migration nor spontaneous distal stent migration was observed during follow-up periods. The stent patency duration was 275.2 (147.8–402.7) days. During follow-up period, stent revision via fistula tract was successful and additional up periods. The stent patency duration was 275.2 (147.8–402.7) days. During.

Results: Technical and functional success rates of endoscopic reintervention were 83% (10/12) and 80% (8/10), respectively. Endoscopic bilateral and unilateral reintervention success rates were 75% (6/8) and 100% (4/4), respectively. Functional success was observed in 8 out of 10 patients (80%) who achieved technical success. For bilateral reintervention, either plastic or plastic and metal stents were used. PTBD was performed in 8 patients because of duodenal stenosis (2 patients) and upper conditions.

Conclusion: Endoscopic reintervention could be considered in the case of stent malfunction and fair patient conditions after SIS placement for malignant hilar obstruction. Decisions regarding bilateral or unilateral drainage and types of stents should depend on the conditions of the disease and the patient.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0271 LONG-TERM OUTCOMES OF ENDOSCOPIC ULTRASOUND-GUIDED GALLBLADDER DRAINAGE WITH TRANSMURAL COVERED METAL STENT

Aim: Methods: From September 2009 to June 2016, a total of 52 patients who underwent EUS-BDR at Pusan National University Yangsan Hospital were enrolled in this study. Among them, 20 patients who underwent reintervention due to stent malfunction were analyzed. Reintervention was performed endoscopically or percutaneously. Technical and functional success rates were evaluated retrospectively.

Results: Technical and functional success rates of endoscopic reintervention were 83% (10/12) and 80% (8/10), respectively. Endoscopic bilateral and unilateral reintervention success rates were 75% (6/8) and 100% (4/4), respectively. Functional success was observed in 8 out of 10 patients (80%) who achieved technical success. For bilateral reintervention, either plastic or plastic and metal stents were used. PTBD was performed in 8 patients because of duodenal stenosis (2 patients) and upper conditions.

Conclusion: Endoscopic reintervention could be considered in the case of stent malfunction and fair patient conditions after SIS placement for malignant hilar obstruction. Decisions regarding bilateral or unilateral drainage and types of stents should depend on the conditions of the disease and the patient.

P0273 EUS-GUIDED GALLBLADDER DRAINAGE REDUCES LATE ADVERSE EVENT AND NEED FOR RE-INTERVENTION COMPARED WITH PERCUTANEOUS CHOLECYSTOSTOMY IN PATIENTS WHO ARE NOT ELIGIBLE FOR SURGERY

Introduction: Endoscopic ultrasound-guided transmural gall-bladder drainage (EUS-GBD) with covered metal stent has become increasingly used to treat patients with acute cholecystitis who are not a candidate for surgical treatment. However, there are limited data comparing long-term outcomes of EUS-GBD with covered metal stent and conventional percutaneous cholecystostomy.

Aims and Methods: This is a single-center, retrospective study to compare long-term outcomes of EUS-GBD and percutaneous cholecystostomy in patients who are not suitable for cholecystectomy. Data about the patient who underwent EUS-GBD for acute cholecystitis is obtained from prospective collected EUS database between January 2006 and August 2014.

Results: The mean age of the study population was 65 (4–80) years. A fully covered metal stent was used in 22 patients and partial covered stent in 2 patients. Early adverse events developed after EUS-BDR in 2 patients (1 case of cholangitis and 1 case of liver abscess in patients with malignant biliary stricture). Late adverse event that stent occlusion was observed in 5 patients. Neither proximal percutaneous stent migration nor spontaneous distal stent migration was observed during follow-up periods. The stent patency duration was 275.2 (147.8–402.7) days. During follow-up period, stent revision via fistula tract was successful and additional up periods. The stent patency duration was 275.2 (147.8–402.7) days. During.

Conclusion: Technical success rate of Group A was significantly higher than Group B (97.6 vs 83.3%, p = 0.03). The two groups were comparable for the functional success rate (90.2% vs 90.3%, p = 0.70), and the rate of adverse events tended to be higher in Group A than in Group B (26.1% vs 13.5%, p = 0.10). The re-inter-vention rate tended to be higher in Group A than in Group B (16.7% vs 8.1%, p = 0.25). Groups A and B did not differ significantly in terms of median overall patient survival (75 days vs. 70 days, p = 0.70), and median time to stent dysfunction or patient death (68 vs 63 days, p = 0.08). In patients who underwent cholecystectomy, there were no difference in the overall patient survival time (121 vs 137 days, p = 0.08) between the two groups although the time to stent dysfunction or patient death was significantly shorter in Group A than in Group B (71 vs 95 days, p = 0.02).

Conclusion: Technical success rate of HGS with AGS was lower than HGS, although HGS with AGS is superior to HGS in terms of stent patency in patients undergoing chemotherapy. Disclosure of Interest: All authors have declared no conflicts of interest.
median 20 days (14.0–45.2) after the procedure. A total of 7 patients in EUS- GBD group died after intervention for adverse events and all of them were conducted successfully. The patients who underwent percutaneous cholecystostomy more frequently received re-intervention for adverse event or recurrence of cholecystitis after removal of cholecystostomy. (7/74 vs. 23/106, P = 0.041).

Conclusion: EUS-GBD and percutaneous cholecystostomy were both effective interventions to urgent drainage for acute cholecystitis. However, EUS-GBD might be beneficial than percutaneous cholecystostomy in long term management for the patients with acute cholecystitis who are not suitable for cholecystectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0274 ENDOSCOPIC TREATMENT OF ANASTOMOTIC BILARY STRICTURES IN PATIENTS WITH LIVING DONOR LIVER TRANSPLANTATION: MULTIPLE PLASTIC STENTS VS FULLY COVERED SELF-EXPANDABLE METALLIC STENTS
A.T. Eminder, E. Parlak, A. S. Koksal, B. Toka, M. I. Uslan 
Gastroenterology, Sakarya University, Sakarya/Turkey
Contact E-mail Address: drecanparlak@gmail.com

Introduction: The “fully covered self-expandable metallic stents”(fcSEMSs) were found to be non-inferior to multiple plastic stents (MPSs) for the treatment of anastomotic biliary strictures after orthotopic liver transplantation (OLT). However, there is scarce data about their efficacy in the treatment of anastomotic biliary strictures after living donor liver transplantation (LDLT). We aimed to compare the efficacy of fcSEMS and MPSs for the treatment of anastomotic biliary strictures after LDLT.

Aims & Methods: We retrospectively analyzed the data of LDLT patients with duct-to-duct anastomotic biliary strictures who underwent endoscopic treatment at our center within the last 3 years. FcSEMSs were inserted in 23 patients (13 male, 10 female, mean age: 51 ± 9 years) who were matched with MPSs insertion (Group-2). In Group-1, secondary branch ducts were prophylactically drained with insertion of plastic stent(s) in order to prevent the development of cholangitis due to their occlusion. FcSEMS and plastic stent(s) were left in place for 2 months. In Group-2, maximum number of plastic stents were inserted and replaced every 3 months. Patients with a follow-up duration of at least 3 months after stenting were included to the study. Primary end-points were the number of endoscopic procedures and the time required for structure resolution. The secondary end-point was the recurrence rate of the stent.

Results: FcSEMSs were successfully deployed in all cases. The diameter of the Fc-SEMSs was 10 mm in 22 patients and 8 mm in 1 patient. The length of the Fc-SEMSs was 8 cm in 13 patients, 10 cm in 9 and 12 cm in 2 patients. Secondary branch ducts were prophylactically drained with a single plastic stent in 12 patients, 2 plastic stents in 8 patients, and 3 plastic stents in 3 patients. The median number of endoscopic procedures was 2 (2–4) in Group-1 and 4 (2–9) in Group-2 (p < 0.001). The time required for structure resolution was shorter in Group-1 (65.7 ± 18.2 days) than in Group-2 (240.1 ± 183.4 days) (p < 0.001). The recurrence rates were similar in Group-1 (17.4%) and Group-2 (15.6%) (p = 0.87) after a follow-up period of 315 ± 290 and 378 ± 86 days, respectively. Comparison is an effective method for the treatment of anastomotic biliary strictures after LDLT, with a less number of endoscopic sessions and a shorter stenting duration required for the resolution compared to MPS.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0275 PROSPECTIVE RANDOMIZED STUDY FOR EFFICACY OF AN DOUBLE BARE STENT COMPARED A DOUBLE COVERED STENT IN MALIGNANT COLORECTAL OBSTRUCTION
A. Vodoloev1, V. Duvansky1, Y. Malyyuga1
1Endoscopy, and Gastroenterology, RU-DUNiversity, Moscow, Russian Federation
2Eranshihans Clinic, Moscow, Russian Federation
Contact E-mail Address: avodoloev@list.ru

Introduction: Colorectal stenting is a minimally invasive, reliable and effective intervention in patients with malignant colorectal obstruction, associated with a low complication rate compared to traditional surgical treatment. One of the actual problems associated with colorectal stenting is the recurrence of symptoms of obstruction. The most common cause is migration of covered stents and ingrowth of uncovered stents. The aim of our study was to compare the results of the use of stents of a new design, the development of which was aimed at preventing these complications.

Aims & Methods: We aimed to evaluate the results of the use of the new design (double uncovered and dual coated colorectal stents). Between December 2012 and April 2017, 77 patients with colonic malignant obstruction were implanted 78 stents (39 bare, 39 covered EGIS Colonel stent, S&G Biotech Inc., South Korea). A double uncovered stent has a two-layer structure created by crossing two stents, resulting in a smaller cell size. Such a design theoretically can reduce the ingrowth of cells and reduce tumor ingrowth. The covered stent is coated with a silicone membrane between two layers of a metal mesh with distal, uncovered ends of 5 mm each. The role of the membrane is to prevent the ingrowth of the tumor, localization and uncovered edges prevent the migration of the stent. All interventions are performed by one operator using endoscopic and radiological control. Groups of patients using coated and uncovered stents were comparable in terms of sex, age, duration of symptoms of obstruction, and stenosis localization. The reasons for the obstruction were primary tumors of the colon 97.4%. The localization of the tumor is most common in the sigmoid colon - 54%. Palliative care was provided to 43(55.8%) patients, "bridge to surgery" - 34 (44.7%) patients.

Results: Clinical success was achieved in 74 (96.1%) patients. In two cases, when using covered stents, the symptoms of obstruction could not be reduced, the patients died 1 week after the operation. In one case, 18 hours after stenting with an uncovered stent, was diagnosed perforation due to obstructive colitis. The average stay in hospital after the intervention was 3 days; the difference between the groups was statistically insignificant. 30 day mortality was 5.2%, the difference was statistically significant. Complications were detected in 3 patients in the group of bare stents and in 1 patient in the group of covered stents, the difference was statistically insignificant. One patient with the carcinoma of the sigmoid colon with invasion in anterior abdominal wall noted the appearance of subcutaneous emphysema without pneumoperitoneum, in 3 (3.8%) patients the occlusion of the stents. The reasons for obstruction of the stents were occlusion by the obstruction from stool (fibers) on the 83rd day (the endoscopic recanalization was performed) and tumor overgrowth by 163 days (endoscopic «stent-in-stent» placement). In one patient, the cause of occlusion is unknown, operated in another hospital 34 days after stenting - a transversostomy was performed, died on the 4th day after the operation.

Conclusion: Double bare and double covered colorectal stents were feasibility and efficacy for relieving malignant colorectal obstruction. Reobstruction was rare complication and not different in both groups stent groups. Necessary to continue to research for the accumulation of material from other centers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic therapy has been emerged as alternative to bariatric surgery for reducing weight. We developed a new endoscopic gastrointestinal (GI) bypass stent and designed a preclinical study to assess the safety in a porcine model.

Aims & Methods: The aim of this study is to investigate the feasibility of our GI bypass device in animal. Before animal study, we performed an experimental study for durability test under simulated intestinal fluid flow. And next, we performed an animal study with 10 Yorkshire pigs. The stents were placed on pig using with fixation by clippings or on duodenal bulb without fixation. Follow up endoscopy was done per one week after implantation. After they were sacrificed, gastric, duodenal, and jejunal tissues were harvested and examined for histologic assessment of any device or procedure-related effects.

Results: Our new GI bypass stent showed a good durability in simulated solution flow. No breakage or migration of stent occurred under continuous water flow in simulation system setting. In animal study, the mean starting weight was 30.1 ± 1.3 kg. Delivery of the implant took an average of 19.8 min (range, 11–32 min) for the bare stent group and 11.2 min (range, 6–19 min) in duodenal bulb stent group. It required an average clamping time of 10.8 min (range, 8–14 min). Followed for stent migration after implantation, the mean patency duration was 1.5 ± 0.7 weeks. One pig was died due to small bowel perforation and peritonitis after stenting. In histologic finding, there were moderate degree of mucosal erosions, but no definite ulceration on pylorus and duodenum.

Conclusion: New GI bypass stent has a good physiocompatible properties in simulated intestinal system. In animal, all stents were successfully deployed but migration was found in this study. We anticipate that stent will be used as the one designed such as endoscopic suture machine and modification of stent would be required. Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Dysphagia may occur due to benign pharingo-esophageal strictures, other post-interventional conditions. The aim of the study was to access long-term efficacy of pharingo-esophageal dilations due to anastomotic or post-radiation strictures.

Aims & Methods: Retrospective study of patients suffering of dysphagia due to radiation (Group I) or anastomotic (Group II) placed pharingo-esophageal benign strictures submitted to endoscopic dilation between January 2013 and December 2015. The long-term efficacy (after a minimum follow-up of 12 months) was prospectively assessed by telephone interview by: a) dysphagia improvement or b) resolution (grade 0 or 1 of Mellow-Pinkas scale), c) absence of further dilations and d) absence of PEG. Additional therapy (PEG or prosthesis placement, electroincision or surgery) was considered inefficiency criteria and these patients were excluded from the interview. Post-procedure complications were registered. Efficacy predictive factors were assessed.

Results: Forty-eight patients (296 dilations) were evaluated (median of 4 dilations/patient): 85% were male, mean age of 62 years-old, 60% belonging in Group I (anastomotic). There was a follow-up interval between completion of the last dilatation and follow-up of 5 weeks. The endoscopic dysphagia Mellow-Pinkas score and luminal calibre were 3 ± 1 and 7 ± 2, 8 mm, respectively. Twenty-eight patients (out of 30 live patients non-submitted to additional therapies) answered to the interview: a) 96% had improved, b) 60% had no endoscopic dysphagia (grade 0-1), 75% did not need further dilations, d) 0% were admitted to PEG, with a combined efficacy of 58, 3%. Nine patients required additional therapy (6 PEGs, 2 prosthesis, 1 electroincision). Overall, 17 (out with 21 previous PEG) were able to resume feeding per os. Fifteen and 29% presented Kochman criteria for refractory and recurrent strictures, respectively. There were two post-procedure complications (<1%): one deep laceration and one pharingo-esophageal fistula. Overall mortality was of 20% (10 patients died of non related procedure causes). Mean follow-up was 29, ± 11, 2 months. Number of dilations and initial lumen calibre were significant predictors of combined efficacy in the univariated analysis; radiic strictures predicted a greater final dysphagia in the uni- and multivariate analysis; recurrent/refractory stenosis didn’t significantly predict global efficacy. Conclusion: Our dilation programme presents relevant benefit to these patients and a low rate of complications. Patients with post-radiation strictures presented a worse prognosis. Even though retrospective we present the longest follow-up and focusing not only in objective measures but also in patient perception of relief.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Current guidelines favour the use of bleeding stents over balloon tamponade in the treatment of variceal bleeding (EBV). However, data on the efficacy of and outcomes after the placement of an SX-ELLA “Danis-Stent” are limited.

Aims & Methods: Retrospective multicenter study including cirrhotic patients receiving Danis-Stents for massive/refractory EBV at 4 tertiary care centers in Vienna (Medical University of Vienna, Krankenanstalt Rudolfstiftung, Wilhelminenspital and Krankenhaus Hietzing). Rates of bleeding control (5 days), bleeding-related mortality (6 weeks) and overall mortality were assessed.

Results: Among 35 patients, 13 patients had an unsuccessful endoscopic band ligation (EVL) prior to Danis-Stent placement. Danis-Stent controlled EBV in 80% (28/35) of patients. In the remaining uncontrolled bleeders (n = 7), 3 patients had subsequent EBV, while in 3 patients the stent had to be replaced and 1 patient received a Linton-tube. Among these patients with initial Danis-Stent failure, 4 died of uncontrollable EBV. 2 experienced early bleeding-related mortality, and only 1 patient achieved a successful long-term bleeding control. In total, early-rebleeding within 6 weeks occurred in 14.3% (including n = 1 while Danis-Stent was still in place and n = 5 after Danis-Stent was removed); 3 under- went immediate and 1 received a subsequent Danis-Stent, and 1 patient was treated with a Sengstaken tube. Moreover, among n = 14 patients without early rebleeding within 6 weeks, only n = 3 (21.4%) showed rebleeding later during follow-up: n = 2 patients were treated with a Sengstaken-Tube (both experienced bleeding-related death) and n = 1 had another Danis-Stent placed (successful bleeding control). Only n = 11 (31.4%) patients did not experience any rebleeding after Danis-Stent removal, while n = 8 patients died with the Danis-Stent in situ. Notably, “early-TIPS” was performed in this study, but 4 (11.4%) received a TIPS during follow-up (n = 6 patients) (1 patient died due to uncontrollable bleeding (≤5days) and n = 10 died within 6 weeks (bleeding-related mortality: 28.6%). Overall, n = 22 (62.9%) patients died. The median survival was 10.5 (IQR:82) days after Danis-Stent placement. Median Danis-Stents dwell time was 5 (range: 0–13) days. The most common adverse events were stent disloca- tions (n = 13; 37.1%), while ulcers/nerosions of the esophageal mucosa were seen in only 4 (11.4%) patients.

Conclusion: Danis-Stent controlled refractory/reactive EBV in 80% of patients but bleeding-related mortality was as high as 45%. While stent dislocations are frequent, ulcers/nerosions of the esophagus were rare with a dwell time of 5 days. The implementation of an early-TIPS strategy might improve the overall outcome of Danis-Stent placement.

Disclosure of Interest: All authors have declared no conflicts of interest.

Our fastening method can be feasible and useful technique for postoperative anal stenosis in colon surgery, with some studies estimating the rate at around 20% 8-11. We report a single-centre, retrospective cohort study on the use if SEMS, and aimed to establish risk factors for stent migration.

Aims & Methods: Case note review was undertaken retrospectively on all patients who had fully covered SEMS inserted at a high-volume tertiary oesophageal cancer centre between Jul 13 to Feb 17. All SEMS were placed under fluoroscopic guidance by experienced endoscopists. Stent migration was confirmed endoscopically or radiologically and was defined as displacement of the stent away from the stomach or oesophagus to the baseline stenosis, with loss of the recanalised lumen. Shapiro-Wilks testing showed non-normal distribution of data. Non-parametric testing by logistic regression was therefore performed.

Results: 188 stents were inserted to palliate malignant strictures. 75% in males. We observed a migration rate of 20% (39) in our cohort. We observed a significant association between predilation (within 7 days of the stent procedure) and subsequent stent migration (31% in dilated vs 13% in undilated stents) (p=0.039). This also met Bonferroni significance. We demonstrate a trend towards shorter strictures being associated with an increased risk of migration [OR 1.14 CI1.122-1.164 (p=0.052)]. There were no significant associations between migration and whether patients received previous chemo-radiotherapy, or whether the stent crossed the GOJ.

Conclusion: Endoscopic placement of SEMS is a safe and effective procedure in the management of malignant dysphagia with a low risk of complications. Predilation of lesions within 7 days of SEMS insertion carries a risk of subsequent stent slippage – suggesting that a cautious approach to dilation may be prudent. Further, larger studies may demonstrate an association with shorter stricture length. Patients received previous chemo-radiotherapy, or whether the stent

Seventy of intrathoracic and intraabdominal lymphadenopathy: mediastinal lymphadenopathy at 19 (12.2%) and 20 (33.9%) patients, combined of 38 (64.4%) and 35 (59.3%). At pre-operated staging most met advanced form of cancer: T4N1 at 16 (27.1%), T4N2 at 23 (38.9%). Sensitivity in staging of tumor 89.8%. Long-term results: 1-year survival at 1 group 96.1%, 3-year is 42.3%, 5-year 10/6; II group 1-year survival 6.45%.

Conclusion: The use of 3D-modeling performed using MRI, spiral CT and EUS, allows to planning the optimal surgery and lymph node for locally common form of esophageal cancer, and improve the results of survival.

The scope of surgery is generally advised to take into account the constructed 3D-models, which helps to solve the problem of the possibility of surgical intervention in esophageal cancer.

P0283 INFLUENCE OF CONTINUOUS ADMINISTRATION OF LOW-DOSE ASPIRIN INTRAOPERATIVE BLEEDING ON GASTRIC ENDOSCOPIC GASTRIC DISSECTION: A PROPENSITY SCORE MATCHING ANALYSIS

Y. Horikawa, N. Mimori, H. Mizutani, Y. Kato, S. Fushimi, S. Okubo, S. Sato
Gastroenterology, Hiraka General Hospital Dept. of Gastroenterology, Tokyo

Contact E-mail Address: horikawa_01@m.ee.com

Introduction: Endoscopic submucosal dissection (ESD) was a promising method for the treatment of high-grade gastric neoplasms. The use of antithrombotic agents has increased for first or secondary prevention of cardiovascular or cerebral disease. Continuous administration of low-dose aspirin (LDA) during ESD was recommended in American, British and Japanese guidelines. However, the influence of LDA for the hemostasis condition during ESD procedure is still unclear. Therefore, we performed this study for addressing intraoperative bleeding risk without cessation of LDA.

Aims & Methods: In this retrospective study, we assessed the hemostasis condition during ESD that were treated for superficial gastric lesions between January 2014 and March 2017. Patients with antithrombotic therapy by LDA (n = 42) and those with no antithrombotic therapy (n = 187; Control) were compared using propensity score matching. Primary outcome was frequency of intraoperative major bleeding. Secondary outcomes included procedure time, Hb reduction rate, En blec reaction rate, and adverse event rate.

Results: The propensity score analysis yielded 39 matched pairs. Adjusted com-
parison between the two groups showed similar with regards to major bleeding, median [range] (times): 1.0 [0.0–4.0] vs. 1.0 [0.0–4.0], p = 0.621. Procedure time was prolonged in Aspirin group by 16.7% without significant differences. Other aspects were the same in both groups with low incidence of adverse events; perforation (0%), thromboembolism (0%).

Conclusion: This study indicated the feasibility of gastric ESD with continuous administration of LDA including minor intraoperative bleeding and adverse events.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0284 WEEKDAY OF CANCER SURGERY IN RELATION TO PROGNOSIS

P. Lagergren, F. Mattsson, J. Lagergren
Department Of Molecular Medicine And Surgery, Karolinska Institutet, Stockholm,Sweden

Contact E-mail Address: pernilla.lagergren@ki.se

Introduction: Later weekday of surgery seems to reduce the prognosis in oeso-
ophageal cancer, while any such influence on other cancer sites is unknown. This nationwide Swedish population-based cohort study from 1997-2014 analysed weekday of elective surgery for 10 major cancer groups in relation to disease-specific and all-cause mortality. Cox regression provided hazard ratios with 95% confidence intervals (CI) adjusted for the covariates age, sex, year, tumour stage, calendar year, and tumour group.

Results: Included were 228,927 patients. Later weekday of surgery (Thursday and even more so Fridays) was associated with increased mortality rates for gastrointestinal cancers. The adjusted hazard ratios for disease-specific mortality comparing surgery on Friday with Monday were 1.57 (95% CI 1.31–1.88) for oesophageal-gastric cancer, 1.49 (95% CI 1.17–1.88) for liver-pancreatic-biliary cancer, and 1.53 (95% CI 1.44–1.63) for colorectal cancer. Excluding mortality during the initial 90 days of surgery made little change to these findings, and the all-cause mortality was similar to the disease-specific mortality. The associations were similar in analyses stratified for covariates. No consistent associations were found between weekday of surgery and prognosis for cancer of the head-and-neck, lung, thyroid, breast, kidney-bladder, prostate, or ovary-uterus.

Conclusion: This study suggested that later weekday of surgery (Thursday, Friday) seems to negatively influence the prognosis for cancer of the gastrointestinal tract, indicating a need for re-scheduling of these operations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0285 IMPACT OF POSTOPERATIVE COMPLICATIONS AND PERIOPERATIVE ONCOLOGICAL TREATMENTS FOR GASTRIC CANCER PATIENTS AFTER GASTRECTOMY

S. Kamiya1, F. Klevbro2, J. Rouvelas3, M. Lindblad4, L. Lundell5, M. Nilsson2
1Surgical Gastroenterology, Karolinska University Hospital, Stockholm; Sweden
2Karolinska University Hospital, Stockholm; Sweden

Contact E-mail Address: satoxi_k@hotmail.com

Introduction: Recently, multidisciplinary treatments such as perioperative chemo/ radiotherapy or in combination have been introduced to improve outcome after gastric cancer surgery. Besides that, the postoperative severe complications are thought to be the poor prognostic factor. Present study assessed the prognostic impacts of severe postoperative complications and perioperative oncological treatments in gastric cancer patients.

Aims & Methods: Consequent gastric cancer patients who underwent curative gastrectomy in Karolinska University Hospital between 2006 and 2016 were enrolled. Patients’ characteristics, surgical data, postoperative courses and prognosis were examined retrospectively (205 patients). The outcomes were evaluated according to Clavien-Dindo classification. The significance of postoperative severe complications and perioperative oncological treatment for overall survival (OS) was evaluated by the Cox proportional hazard model.

Results: Ninety-nine sixty-nine-nine-six patients were examined in this study. 89 (52.7%) and 66 (39.1%) patients had neoadjuvant and adjuvant treatment, 85 (50.3%) and 84 (49.7%) underwent distal and total gastrectomy, respectively. 24 (14.2%), 16 (9.5%) and 5 (3.0%) were diagnosed as grade III, IV, V complications. The prognosis of the patients with grade III or higher complication was significantly worse (3-year OS: 66.6% vs 47.3%, P < 0.001). Subgroup analysis by pathologi-
cal stage showed that the prognosis of pStage III/IV patients with postoperative complications was significantly poorer than the patients with no abdominal symptoms marked at 19 (32.2%) and 20 (33.9%) patients, combined of pStage III or higher complications (3-year OS: 45.3% vs 7.5%, P < 0.001). For the patients who had either neoadjuvant or adjuvant treatment, however, no obvious prognostic worsening were seen by the existence of complications (3-year OS: 78.7% vs 52.9%, P = 0.13). Multivariate analysis identified that severe com-
plication was independent risk factor for OS (hazard ratio 1.82; 95% confidence interval 1.08–3.05), especially in pStage III/IV gastric cancer (hazard ratio 3.00; 95% confidence interval 1.53–5.86).

Conclusion: Postoperative severe complications had considerable impact on the OS, especially for pStage III/IV gastric cancer patients. Perioperative oncological treatment may be able to prevent the prognosis from deteriorating due to post-
operative complications.

Introduction: Duodenal papillary tumor as rare gastrointestinal neoplasm is essential for curative therapy due to its malignant potential. Endoscopic papillectomy as the treatment for duodenal papillary tumor has developed and is accepted as an alternative approach to surgery in select cases. Endoscopic papillectomy as a relatively difficult endoscopic technique mainly performed by experienced endoscopists. Several standard endoscopic procedures for endoscopic papillectomy have not been established.

Aims & Methods: We aimed to investigate the clinical value of endoscopic papillectomy for duodenal papillary tumor based on the endoscopic and clinical characteristics. Between 2006 and 2017, seventy-five patients with duode-
nal papillary tumor under endoscopic papillectomy in the gastrointestinal endoscopic center of Chinese PLA General Hospital were included. These patients were diagnosed of duodenal papillary tumor by the clinical manifes-
tation, laboratory tests, CT, MRC, endoscope, EUS, ERCP along with biopsies and histopathologic tests. During the detailed clinical assessment combined with patients’ wishes, endoscopic papillectomy and followed ERCP procedures were performed successfully, and the clinical data of these patients were retrospectively collected.

Results: 75 patients (50 males and 25 females) with a median age of 58.6 yrs (range 27 to 82 yrs) were evaluated. The main clinical symptoms were predomi-
nant by abdominal pain followed by cholestasis and cholangitis, but nine cases showed no abdominal symptoms. Endoscopic papillectomy was technically feasible in all these patients, and was mainly performed by four experienced endoscopists. The majority of excised tumors were exogenous (90.7%, 68/75), and the tumor size ranged between 8 and 55 mm. The final histopathological diagnosis included papillary adenoma (40/75), adenocarcinoma (37.3%, 28/75), atypia with high-grade intraepithelial neoplasia (18.7%, 14/75), adenoma with low-grade intraepithelial neoplasia (26.7%, 20/ 75), adenoma combined with local carcinoma (16%, 12/75), and neuroendocrine tumor (1.3%, 1/75). In bloc resection was achieved in 53 cases (70.7%) and the patients with no abdominal symptoms. Endoscopic papillectomy was technically feasible in all these patients, and was mainly performed by four experienced endoscopists.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0287: PROPHYLACTIC COLECTOMY WITH EXTENDED INDICATION OF RECTAL PRESERVATION IN RELATED APC SYNDROME: SYSTEMATIC REVIEW

A. Pasquer1, G. Poncet1, M. Pochoe2, J. Rivory3, O. Vinet4, N. Bencheh5, J.C. Saum6

Contact Email Address: annaud.pasquer@chu-lyon.fr

Introduction: Prophylactic surgery of familial adenomatous polyposis (FAP) ranges from total colectomy with ileorectal anastomosis (IRA) to proctocolectomy with ileoanal anastomosis and J pouch (IAA). Rectal canceration is based on studies that did not include systematic endoscopic treatment that we perform. The objective was to compare IRA to IAA in terms of oncological safety and quality-of-life.

Aims & Methods: Between January 1965 and November 2015, all consecutive patients with a prophylactic surgery for FAP were screened and patients with systemic endoscopic follow up in our unit: systemic endoscopic treatment of adenomas (argon, mucosectomie), were prospectively included. MYH-related polyposes and patients who underwent abdomino-nasorectal resection were excluded from analysis.

Results: 296 patients were included: 92 proctocolectomy with IAA (31.1%), 197 total colectomy with IRA (66.6%), and 7 abdomino-nasorectal resections (2.4%). Mean (SD) number of preoperative rectal adenomas was 24.7 (33.9) in the IRA group and 10.7 (18.3) in IAA group (p = 0.01). Mean number of rectal canceration was 3.1% (n = 9). Mean (SD) follow-up was 16.6 (11.9) years, during which the mean (SD) number of lower endoscopies was 3.4 (2.5) in the IRA group vs 3.4 (2.5) in the IAA group (p = 0.91). Mean (SD) number of treated adenomas was 17.8 (20.8) and 12.9 (18.8), respectively (p = 0.06); secondary cancer incidence was 6.1% vs. 11% (p = 0.06). The 15-year recurrence-free and overall survival (IR vs. IAA) were respectively 99.5% vs. 100% (p = 0.09) and 98.9% vs. 98.8% (p = 0.82).

Conclusion: Combination of aggressive endoscopic treatment and extended rectal preservation appears to be a safe alternative to ileoanal anastomosis and J pouch.

Disclosure of Interest: All authors have declared no conflicts of interest.
and liver metastases in newly diagnosed patients with CRC. Three hundred patients with CRC underwent endoscopy and serum screening were included in this cross-sectional study. Complete blood counts with automated differential counts were performed preoperatively. The NLR was calculated by dividing the absolute neutrophil count by the absolute lymphocyte count; also PLR was calculated by dividing the absolute platelet count by the absolute lymphocyte count. The diagnostic performance of NLR and PLR was estimated by ROC curve.

Results: Our results suggest that there was high statistically significant difference between NLR (p = 0.003), PLR (p = 0.002) and tumor stages (I to IV). ROC curve analysis demonstrated high diagnostic accuracy of NLR (AUC 0.774, 95%CI = 0.683–0.790) and PLR (AUC 0.698, 95%CI = 0.663–0.742) for synchronous lymph node and liver metastases. Also combination of NLR and PLR performed improved diagnostic efficacy (AUC 0.841, 95%CI = 0.811–0.863) for synchronous liver and lymph node metastases.

Conclusion: Our results suggest that NLR and PLR could be useful diagnostic CRC biomarkers, and could have potential value in early recognition of different stages of CRC.

LAPAROSCOPIC SURGERY FOR INGUINAL HERNIA EMPLOYING THE TRANSABDOMINAL PREPERITONEAL (TAPP) REPAIR AND EARLY OUTCOMES

Gastroenterological Surgery, Aichi Medical University, nagakute/Japan

Contact E-mail Address: tsaito0726@gmail.com

Introduction: Ger reported the first laparoscopic hernia repair in 1982 by approximating the hernial orifice with stainless-steel sutures. In 1983, laparoscopic transabdominal preperitoneal (TAPP) repair was a revolutionary concept in hernia surgery and was introduced by Arregui and Dion in the early 1990s. Institutions performing radical laparoscopic surgery for inguinal hernia have been rapidly increasing since the NIH point was amended in Japan. However, in the 12th JAPAN SOCIETY FOR ENDOSCOPIC SURGERY questionnaire survey, the recurrence rate after surgery employing the TAPP method was reported to be 4%, posing a problem regarding the thoughtless introduction of the TAPP method. On the other hand, with surgery employing the TAPP method only, the hernia was indicated normally until April 2015, but treatment of inguinal hernia was integrated, the indication was established in May 2015, and laparoscopic surgery employing the TAPP method has been performed for the indicated cases. In this study, we investigated the current state of inguinal hernia treatment at our hospital. Surgical indication of inguinal hernia in our department is as follows. Symptomatic inguinal hernia is treated using the TAPP method when there is only one POSSUM score-based risk factor. When 2 or more risk factors are present or the patient has undergone surgery of the prostate, the anterior approach is employed (the UHS and Mesh Plug methods for internal and external inguinal hernia, respectively). Treatment under local anesthesia is prioritized for patients aged 90 years or older and patients with PS2 or higher. Arrangement in operating room is that the operator and assistant stand on the left and right sides of the patient, respectively, an assistant stand on the left and right sides of the patient, respectively, an

Aims & Methods: In this study, we investigated the current state of inguinal hernia treatment at our hospital. The subjects were 120 patients who underwent radical surgery for inguinal hernia before and after the full-scale introduction of the TAPP method (early period: October 2014-April 2015 (7 months), late period: October 2015-December 2015 (7 months), 47 and 73 patients were treated in the early and late periods, respectively). Changes in the surgical procedure, complications, and duration of hospital stay were investigated in 120 patients.

Results: The median age was 70 years (19-91 years). There were 114 male and 6 female patients. Complications occurred in 70 and not used in 50. TAPP, mesh plug, and UHS and others were used in 58, 54, 17, 3 lesions. There was no change for both the Early period and Late Period. The median operative time was 81 minutes (60-120 min), 102 minutes (58-215 min), and was 90 ml (5-500 ml). The total amount of operative bleeding and results in favorable clinical outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0295 EFFECTIVENESS OF PURE LAPAROSCOPIC LEFT COLECTOMY WITH PRIMARY ANASTOMOSIS AND LOOP ILEOSTOMY FOR THE TREATMENT OF COMPLICATED HINCHY 3/4

F. Roscio, A. De Luca, I. Scandroglio
Galmariini Hospital, ASST Sette Laghi, Tradate/Italy

Contact E-mail Address: francesco_roscio@yahoo.it

Introduction: To evaluate the effectiveness of laparoscopic left colectomy with primary anastomosis and loop ileostomy in the treatment of complicated acute diverticulitis with diffuse purulent peritonitis (Hinchey 3), also considering the lack of evidence about this topic due to the difficulty of carrying out comparative trials with the laparoscopic washing/drainage technique.

Aims & Methods: A consecutive unselected series of 44 patients undergone emergency surgery for acute complicated Hinchey 3 diverticulitis from January 2012 to December 2016 was retrospectively evaluated. All patients were treated by pure laparoscopic left colectomy with primary colorectal anastomosis and temporary loop ileostomy. All the procedures were performed by the same surgeons (IS, ADL, FR). Perioperative care plan, operative steps and surgical instrumentations were standardized. We collected patients-, surgery- and hospital-related data, as well as short-term outcomes. Complications were classified using the Clavien-Dindo classification system.

Results: There were 31 men (70.4%) and 13 women (29.6%) with a mean age of 57.8 ± 11.9 years. The mean body mass index was 28.3 ± 3.1 kg/m2. No conversion to open surgery was registered. The mean operative time and estimated blood loss were 184.3 ± 32.7 minutes and 81.2 ± 7.2 ml, respectively. We did not observe any intraoperative complications.

Conclusion: Laparoscopic left colectomy with primary anastomosis and loop ileostomy seems to be a good technique that resulted in encouraging short-term outcomes. In expert hands it represents an effective technique for the treatment of acute diverticulitis complicated by diffuse purulent peritonitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0296 LAPAROSCOPIC COMPLETE LATERAL LYMPH NODE DISSECTION FOR LOW RECTAL CANCER

T. Kinoshita, K. Komori, T. Oshiro, A. Ouchi, Y. Shimizu
Gastroenterological Surgery, Aichi Cancer Center Hospital, NAGOYA/Japan

Contact E-mail Address: t.kinoshita@aichi-cc.jp

Introduction: Total mesorectal excision (TME) with lateral pelvic lymph node dissection (LLND) is a standard procedure for low rectal cancer. However, ME alone is the international standard surgical procedure for rectal cancer. Complete LLND is important because of the potential pelvic cavity and the complicated anatomical structure and invasive procedure which needs longer operative time and greater blood loss. Herein we introduce laparoscopic LLND as our new procedure securing equivalent range of lymph node dissection.

Aims & Methods: After laparoscopic ME, the external iliac artery was exposed and the external iliac nodes were completely removed from inguinal ligament. Obturator nodes were completely dissected while preserving the obturator nerve, resecting the obturator artery and vein, and confirming lateral pelvic wall, bladder wall and sacral nerve. Subsequently, proximal internal iliac nodes were removed and superior vesical artery was separated. Distal internal iliac nodes from the coccgeal vein (Akcock’s canal) were completely dissected while preserving the superior vesical artery and the pelvic plexus, and transecting several inferior vesical arteries. Finally, bilateral hypogastric nerves were separated to be preserved. Common iliac nodes were dissected; aortic bifurcation nodes and presacral nodes were also dissected by exposing the aortic bifurcation and the pelvic surface of the sacrum.

Results: Between 2015 and 2016, we performed laparoscopic ME with LLND for 10 patients with cT2 or deeper low rectal cancer. The median operative time was 502 min (420–679 min), and the median blood loss was 90 ml (5–500 ml). No one was dead within a year, and the most frequent one was temporary urinary diversion in 2 (20%) patients. The median number of harvested lateral lymph node was 20 (14–23). So far there are no recurrences.

Disclosure of Interest: Our laparoscopic LLND provides good visual field and reduces an amount of operative bleeding and results in favorable clinical outcomes.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0297 TRANSGASTRIC-NOTES SIGMOID RESECTION IN AN ANIMAL SURVIVAL MODEL USING THE ANUBIS-SYSTEM

J. Bernhardt1,2, H. Steffen1,2, P. Koehler1,2, S. Schneider-Koriatih1,2, K. Ludwig2
1Dept. Of Endoscopy, Klinikum Stuedtland Rostock, Rostock/Germany
2Dept. Of Surgery, Klinikum Stuedtland Rostock, Rostock/Germany

Contact E-mail Address: joern.bernhardt@klinik-sued-rostock.de

Introduction: Natural orifice translumenal endoscopic surgery (NOTES) proposed advantages should be established by comparison with standard procedures. Using a single side transluminal access, the feasibility of performing advanced surgical procedures is still limited, especially for a single endoscope. We used the ANUBIS-system for sigmoid resection with a transgastric access to the abdominal cavity assisted by colonoscopy and one trocar.

Aims & Methods: The experimental study was conducted in a porcine model in general anesthesia. After operation in an acute model, we started the study with 5 pigs. In an acute survival model. Using a colonoscope, a transgastric access was created by needle-knife incision and balloon dilatation. CO2 peritoneum was achieved by insufflation via a working channel. By steering the colonoscope, the colon was maneuvered endoluminally and the colic mesentery was exposed. Bowel-close was performed with a coagulating needle and the mesentery was removed. Finally, the colon was transected and an anastomosis was created simultaneously assisted by a grasper via the Anubiscope. Both instruments have the

Disclosure of Interest: None.
lower abdomen. The bowel examination was performed by invagination transrec- tal through the transrectal distal linear stapling of the sigmoid, the colorectal anastomosis was completed by applying a circular stapling device transrectally, assisted by a transcutaneous inserted grasper. Function testing was performed by the colonoscope. Gastric access closure was performed by OTSC clip.

Results: The procedure was successful in all animals with operation time ranging from 4.5 to 6 hours. After weight gain in all cases, the animals were sacrificed after postoperative day 42 and the workup showed competent anastomotic healing with a stenosis and consecutive prestenotic dilatation in one case. These animals developed a perigastric abscess beside the anastomosis. Gastric closure was healed and the OTSC clip still in situ in all animals. In one case we used two OTSC clips for gastric closure, there were severe adhesions with two perigastric abscesses.

Conclusion: The use of an operating platform like the Anubisscope has the advantage of flexible preparation in opposite position of the instruments. The disadvantages are the only two degrees of freedom of the flexible instruments and the rotation-like movements. Flexible colonoscopy provided a fixed reference frame for condition analysis and description. For resection and anastomosis, an additional transcutaneous access was necessary.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0298 ASCITES, COMPLEX ADNEXAL MASSES AND RAISED CA-125 IN POST-MENOPAUSAL WOMEN: OVARIAN CANCER OR TUBERCULOSIS?

Contact E-mail Address: sondajardak1@gmail.com

Introduction: Peritoneal tuberculosis (TB) and advanced ovarian cancer, two conditions with different management and prognosis, have many similarities: ascites, complex adnexal mass, peritoneal deposits, and raised CA-125 level. Symptoms such as weight loss, reduced appetite, and dull abdominal pain are also common to these two entities.

Aims & Methods: The aim of this study was to analyze patients’ characteristics, laboratory investigations, radiological and surgical findings in post-menopausal women with pelvic TB who were diagnosed after laparotomy or laparoscopy for suspected ovarian cancer. We report twenty-one cases of pelvic-peritoneal TB in post-menopausal women who presented with mimicking ovarian malignancy from 2004 to 2014 in a Tunisian center.

Results: The mean age was 59.8 (46-87 years). Three patients have personal or family history of TB. All women presented with lower abdominal pain and distension of varying duration of 1 month to 6 months. Eleven patients had reduced appetite and weight loss, and four women gave a history of low-grade fever. A CT scan showed the presence of solid-cystic adnexal masses ranging from 3 cm to 14 cm in diameter and ascites in 90.4%. Ascitic fluid analysis was done in 19 patients and showed a lymphocytic predominant pattern, and absence of malignant cells. Ascitic fluid cultures was negative in all. CA-125 was elevated in all and of varying duration of 1 month to 6 months. Eleven patients had reduced appetite from 2004 to 2014 in a Tunisian center.

Discussion: Conditions with different management and prognosis, have many similarities: ascites, complex adnexal mass, peritoneal deposits, and raised CA-125 level. Symptoms such as weight loss, reduced appetite, and dull abdominal pain are also common to these two entities.

Conclusion: Peritoneal tuberculosis (TB) and advanced ovarian cancer, two conditions with different management and prognosis, have many similarities: ascites, complex adnexal mass, peritoneal deposits, and raised CA-125 level. Symptoms such as weight loss, reduced appetite, and dull abdominal pain are also common to these two entities.

P0300 REGULATORY B CELLS CONTRIBUTE TO THE ALLEVIATION OF COLITIS INDUCED BY DEXTRAN SULPHATE SODIUM AFTER H. PYLORI INFECTION

X. Li1, N. Wang1, Q. Xue1, J. Tan1, J. Wang1
1 Department Of Gastroenterology, Peking University, People’s Hospital, Beijing/China

Contact E-mail Address: lixiaiyj@163.com

Introduction: Epidemiological studies have showed that there was an inverse correlation between H. pylori infection and inflammatory bowel disease (IBD). Our previous research indicated that the regulatory immune responses induced by H. pylori infection were not limited to gastric mucosa, IL-10-producing B cells and Foxp3+ Treg cells expanded in spleen and mesenteric lymph nodes (MLN), the balance of intestinal mucosal immunity was influenced to a skewed regulatory immune response.

Aims & Methods: A murine model with H. pylori infection and acute and chronic colitis induced by dextran sulphate sodium (DSS) was established to explore the functional changes of the Breg cells in H. pylori infection and acute and chronic colitis induced by DSS. A C57BL/6 mice model of acute and chronic colitis was induced by 3% DSS with or without H. pylori infection in advance, the colitis performances were assessed by disease active index (DAI), colon length and colonic histological inflammatory scores. The CD19+IL-10+ Breg cells and CD4+CD25+Foxp3+ Treg cells in blood, spleen, MLN, PP and gastrointestinal mucosa were measured by flow cytometry, immunohistochemistry and immunomicroscopy. The anti-inflammatory cytokines were also detected at mRNA level by real-time PCR.

Results: Compared with the DSS treated acute colitis group, H. pylori/DSS co-treated acute colitis group: (1) DAI and colonic histological scores reduced (9.25±2.8 vs 28.18±3.05, P<0.025) and colon length shortened (5.62±0.63 vs 5.40±0.54, P<0.001). (2) The percentages of CD19-IL-10+Breg cells detected by flow cytometry expanded in different tissues: blood: 5.05±0.68 vs 2.89±0.55, P=0.001; spleen: 4.32±0.56 vs 3.17±0.20, P<0.05; MLN:5.89±0.54 vs 4.94±0.65, P=0.047; PP: 6.95±1.67 vs 5.39±0.88, P=0.005, respectively. (3) The percentages of CD4+CD25+Foxp3+ Treg cells expanded in different tissues: spleen: 13.50±1.37 vs 10.73±1.13, P=0.008; MLN: 17.50±0.82 vs 14.87±1.3, P=0.003; PP: 12.70±3.42 vs 8.58±1.71, P=0.001, respectively. The numbers of Breg cells per colon in control group: 3.34±0.40 vs 2.58±0.34, P=0.004. (4) mRNA expression in colonic mucosa: IL-10 (P=0.001) mRNA relative expression upregulated and IFN-γ (P=0.04) mRNA relative expression downregulated significantly. Compared with DSS treated acute colitis group, H. pylori/DSS co-treated chronic colitis group: (1) DAI and colonic histological scores reduced (9.00±1.73 vs 14.67±1.53, P=0.001), and colon length shortened less (6.82±0.41 vs 5.98±0.15, P=0.001). (2) The percentages of CD19-IL-10+Breg cells expanded which declared in DSS treated acute colitis group: spleen: 7.09±0.72, P=0.024; MLN: 4.78±0.73 vs 3.02±0.83, P=0.047; PP: 7.14±1.04 vs 4.34±1.03, P=0.005 respectively. (3) The percentages of CD4+CD25+Foxp3+ Treg cells decreased dramatically in different tissues: blood: 6.69±0.91 vs 7.37±1.08, P=0.01; spleen: 9.07±2.88 vs 13.10±1.99, P=0.018; PP: 7.33±1.07 vs 12.80±0.96, P<0.001; the numbers of Foxp3+ T cells per HPF in colonic mucosa: 3.66±0.99 vs 4.08±0.56, P=0.392. (4) mRNA expression in colonic mucosa: IL-10 (P=0.023), Foxp3 (P=0.000) mRNA relative expression upregulated significantly, and IFN-γ (P=0.001) TNF-α (P=0.005), IL-17A (P=0.019) and IL-23 (P=0.000) mRNA relative expression downregulated significantly.
CD19 may through the expansion and function of CD19 immunosuppression may aggravate gut fungal dysbiosis in IBD patients, but Treatment strategies affect fungal composition. To some extent, Faecalibacterium and Asterotremella found a weak fungi-biomarkers correlation in IBD patients, but fungi such as and its expression is elevated in the inflamed tissue of patients with ulcerative colitis (UC) [1-3]. Pre-clinical models of colitis demonstrate a therapeutic benefit of blocking CXCL12/CXCR4 interaction. A candidate monoclonal antibody (GS-5745) is a high-affinity IgG4 monoclonal antibody against human Matrix Metalloproteinase 9 (MMP9). In a 36-day Phase 1b study in UC, andecaliximab demonstrated clinical efficacy relative to placebo treatment [5]. Here we describe bacterial microbiota analysis of stool samples collected during the Phase 1b study of andecaliximab in UC.

Aims & Methods: The objective of this study is to examine changes to the bacterial microbiota pre- and post-andecaliximab treatment and relative to therapeutic response. stool was collected in inflammatory bowel disease (Baseline) and all phases of the study (Day 36). Clinical response was defined as a Mayo score reduction ≥3 point and ≥30% reduction from baseline score; accompanying decrease in rectal bleeding sub-score of ≥1 or an absolute rectal bleeding sub-score of 0 or 1. DNA was extracted from fecal samples using a modified CTAB method and 16S rRNA amplicon sequencing was performed on 59 samples (27 paired and 5 unpaired samples). Alpha diversity, beta diversity (calculated in QIIME), and taxonomic differences were examined between placebo and andecaliximab-treatment groups and between responders and non-responders.

Results: Compared to placebo-treated patients, those who received andecaliximab trended towards decreased alpha diversity (p = 0.06) at 36 days post-treatment. These changes in alpha diversity were not dose related. At Day 36, a trend towards a significant difference in community beta-diversity was observed between the andecaliximab-treated group relative to placebo (p = 0.07). Andecaliximab treatment was also associated with differences in bacterial taxonomy relative to placebo (p = 0.07). Specifically, the genera Clostridia and Akkermansia represented some of the top organisms enriched post andecaliximab treatment relative to placebo. Andecaliximab treatment exhibited a non-significant expansion of Akkermansia from Baseline to Day 36 (p = 0.15). Amongst patients, the microbiome results are unlikely to be pursued in relation to andecaliximab treatment effects, but may be beneficial as a reference for future trials in inflammatory bowel disease.

3Gastroenterology, Clinic Santa Rita, N. Tacccone Foundation, Arippa/Italy

Introduction: Crohn’s Disease (CD) and Ulcerative Colitis (UC) are inflammatory bowel diseases (IBD) with a complex etiology, including an immune response against microbial and autologous antigens and an imbalance between pro-inflammatory and anti-inflammatory mediators. Different approaches have been used to study the pattern of cytokines in IBD and few data are available on cytokines production in different intestinal compartments. Laser Capture Microdissection (LCM) is a powerful tool for the isolation of specific tissue compartments (1).

Contact E-mail Address: gmazzarella@isa.cnr.it

Aim: To investigate the cytokine production in different inflammatory bowel disease compartments

Methods: A total of 41 biopsies were obtained from IBD patients at the Department of Gastroenterology, San Filippo Neri Hospital, Roma/Italy.

Conclusions: LCM technology can be used to determine the cytokine profile of different inflammatory bowel disease compartments.
Aims & Methods: This work was designed to investigate the pattern of cytokines that regulate the mucosal immune response occurring in different intestinal compartments of IB patients, using LCM technology (1). Frozen sections of colonic biopsies were obtained from 5 patients with active CD, 5 patients with active UC and 5 controls. None of the patients with CD or UC had been ever undergone metronidazole (EM) and lactobacillus (LP) pre- and post-treatment with LCM, RNAAs from EM and LP samples were extracted and, after a reverse transcription, RNA levels of TNF-α, IFN-γ, IL-17, IL-10 and TGF-β were determined by quantitative PCR, using glyceraldehyde 3-phosphate dehydrogenase (GAPDH) as reference gene.

Results: We observed a significant increase in gene expression level of IL-17 in the lamina propria of UC patients respect to CD and controls (p < 0.05). TNF-α, IFN-γ, IL-10 and TGF-β levels were significantly higher in the LP of CD as compared with UC biopsies (p < 0.05). All the cytokines investigated were not significantly up-regulated in the surface EP of both CD and UC patients, when compared to controls.

Conclusion: Our data show that the LP compartment play a key role in the mucosal immune response in IBD patients. In particular, CD seems to be prominently an innate immune response-mediated disease, which is characterized by an increased production of IFN-γ and TNF-α. On the opposite, UC seems to be prominently a CD4 lymphocyte-mediated disease, which is characterized by an increased production of IL-17. Consequently, with the post-inflammation response, high amounts of the anti-inflammatory cytokines IL-10 and TGF-β are also produced in CD compared to UC patients, suggesting that in UC patients the immune-regulatory mechanisms could be impaired. This work underlines the importance of LCM as a valuable tool to determine potential inflammatory components involved in IBD pathogenesis.

P0304 ALTERATIONS IN THE MUCOSA-ASSOCIATED FUNGAL MICROBIOTA IN PATIENTS WITH ULCERATIVE COLITIS
X. Qin, H. Zhang
Department Of Gastroenterology, Jiangsu Province Hospital and Nanjing Medical University, Nanjing/China

Contact E-mail Address: qixinyun2819@126.com

Introduction: The gut microbiota play important roles in the development of the ulcerative colitis (UC). Enough evidence has proven the role of intestinal bacterial microbiota in UC pathogenesis. However, the role of intestinal fungal microbiota in UC pathogenesis has not been fully demonstrated.

Aims & Methods: Fungal microbiota from the descending colon mucosal samples of 14 active UC patients and 15 healthy subjects (HS) were analyzed by high-throughput sequencing method. The expressions of pro-inflammatory cytokines(IL-1β, TNF-α, INF-γ, IL-10, IL-17A, and IF-23) were up-regulated in the UC patients. The genera Wickerhamomyces, Sterigmatomyces, and Penicillium were positively correlated with the expression of several pro-inflammatory cytokines in the colonic mucosa, whereas Nigrospora was negatively correlated. Nigrospora and Sterigmatomyces were positively correlated with the Baron and/or Mayo score.

Results: The number of fungi decreased significantly in inflamed mucosal tissue compared to HS counterpart while the shannon diversity did not show significant differences. Fifteen major genera were examined, among which X. qiu, Emericella, and Penicillium showed increasing trends, whereas Wickerhamomyces and Leucosporidium decreased significantly.

Conclusion: The expression of Wnt ligands from CD16 positive cells, which are accumulated in the mucosa, may be involved in murine intestinal fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Although the etiology of ulcerative colitis (UC) has yet to be characterized, it is increasingly accepted that the cause of UC might well be related to commensal enteric bacteria in a genetically susceptible patient. Anti-inflammato-
ry agents such as 5-ASA are usually prescribed for UC treatment, and we previously demonstrated that triple antibiotic combination therapy with oral amoxicillin (1500 mg/day), tetracycline (1500 mg/day) or fosfomycin (3000 mg/day), and metronidazole (750 mg/day) (ATM/AFM), for two weeks, induces remission in more than 27% of patients with active UC including those with steroid-refractory or dependent disease, suggesting ATM/AFM might be possibly effective for achieving UC remission.

Aims & Methods: Thirty-two patients with UC given ATM/AFM therapy for two weeks on average were enrolled in this study. The clinical conditions of these UC patients were evaluated by Mayo score. Fecal samples were obtained prior to, after therapy and at three months after treatment completion. Gut microbiota were compared employing metagenomic analysis of fecal samples.

Results: Of the 32 patients, 17 and eight, respectively, experienced complete and partial remission over three months in response to ATM/AFM therapy, whereas ATM/AFM showed no efficacy in seven patients. The metagenomic analysis revealed abundant human DNA to correlate positively with the disease activity indicated by the Mayo score. Furthermore, dramatic gut microbiota changes were observed at an early stage, i.e. just two weeks after starting ATM/AFM therapy. Comparison of the metagenomic data suggested that the dysbiosis through the expression of Wnt ligands (Mucosal Immunology, 2016). We have recently reported that STAT6 deficiency favours fibrosis in a murine model of TNBS colitis (P031, ECCO 2016).

Aims & Methods: We aim to characterize here the functional relevance of the macrophage phenotype in fibrosis development. WT or STAT6 (-/-) mice were given TNBS (0.5, 0.5, 0.5, 0.5, 0.5, 0.5, 0.5, and 0.5 mg intracolitally or saline weekly and they were sacrificed 3, 5 or 7 weeks after the first TNBS administration. The percentage of CD206, CD16, and CD68 positive cells was analyzed by flow cytometry in F4/80+ macrophages isolated from the intestinal mucosa. The mRNA expression of Wnt ligands was evaluated in F4/80+ CD16+ macrophages isolated from the mucosa, 7 weeks after the first TNBS administration and results are expressed as fold induction vs vehicle-treated mice. The mRNA expression of CD16 and fibrosis markers were evaluated in the colonic mucosa. The mRNA expression of CD16 was expressed as Mean±SD and the differences among data were analyzed using Pearson’s correlation coefficient (p < 0.05).

Results: TNBS increased the percentage of CD206 positive macrophages in the mucosa of TNBS-WT animals while it failed to do that in TNBS-TAT6 (-/-) mice. The percentage of CD16 positive macrophages increased in a time-dependent manner only in the mucosa of STAT6 (-/-) TNBS-treated mice. The percentage of CD68+ cells was similar between TNBS-WT and TNBS-TAT6 (-/-) mice. In CD16+ macrophages isolated from TNBS-TAT6 (-/-) mice the mRNA expression of canonical and non-canonical Wnt ligands was significantly increased compared with cells isolated from TNBS-WT mice (Table). A positive and significant correlation between CD16 and Vimentin (p = 0.0088*, r = 0.51), α-SMA (p = 0.0044*, r = 0.55) and MMP2 (p = 0.0022*, r = 0.67) was detected in TNBS-TAT6 (-/-) mice but not in WT animals.

Conclusion: The expression of Wnt ligands from CD16 positive cells, which are accumulated in the mucosa, may be involved in murine intestinal fibrosis.
before treatment in the active stage to possibly be associated with increased proliferation of Bacteroides, Parabacteroides, Rickenella, Clostridium, Flavonifractor, Pelagibacter, Bordetella, Massilia and Piscirickettsia species. In responders after treatment, populations of Bilfdobacterium and Lactobacillus species were significantly increased. In this study, there was an especially strong negative correlation between Bacteroides and Bilfdobacterium before and after treatment.

Conclusion: These results suggested metagenomic analysis results to be associated with a remarkable change in gut microbiota after antibiotic combination treatment. In the cross section is associated with decreased in Bacteroides and Lactobacillus species and a decrease in Bacteroides.

Introduction: Classically, enteroendocrine cells (EEC) are regulated for revealing gastrointestinal motility, secretion, and insulin levels by release of peptide hormones. Via receptors and transporters GLP-1 are capable of sensing the lamina propria and luminal environment, including the microbiota, and also mediate immune-related signals. In particular, the L-cell-derived incretin hormone glucagon-like peptide 1 (GLP-1) is increasingly recognized to exert direct effects on immune cells and to orchestrate a metabolic-inflammatory response. In inflammatory bowel disease (IBD), a role for EEC in disease pathogenesis is indicated by a risk-associated SNP and autoantibodies affecting EEC function as well as general disease symptoms like insulin resistance and altered intestinal motility. However, the total number of studies investigating EEC number and function in IBD and mouse models of intestinal inflammation is limited and results are conflicting.

Aims & Methods: To characterize alterations in GLP-1-expressing EEC numbers under intestinal inflammatory conditions, immunostainings for GLP-1 and ChgA as well as mRNA expression analysis was performed in intestinal tissue samples. Mouse models of intestinal inflammation used include genetic models, II-10–/– mice (colitis), an adoptive transfer model, Rag2−/− mice reconstituted with CD4+/CD45− T cells (colitis), chemically (DSS)-induced colitis and an infection model (Citrobacter rodentium).

Results: Numbers of GLP-1+ and ChgA+ cells were consistently reduced in all mouse models of intestinal inflammation. These changes were confined to the site of inflammation. Neither absence of mature B and T cells in Rag2−/− mice alone was associated with reduced numbers of EEC, nor adoptive transfer of CD4+ T cells per se, since transfer of non-colitogenic CD4+CD45− T cells did not lead to changes in ChgA+ cells numbers in the colon. The reduction of GLP-1+ and ChgA+ cells observed by immunohistochemistry was reflected by diminished levels of Gcg and Chga mRNA expression, whereby mRNA levels of the L-cell-derived hormone Pyy remained unaltered.

Conclusion: To our knowledge, this work provides the first comprehensive study of GLP-1+ and ChgA+ cell numbers in different mouse models of intestinal inflammation. A reduction of GLP-1-expressing EEC seems to be a general feature of small as well as large intestinal inflammation. Further research will clarify whether these data represent a consequence of intestinal inflammation and elucidate the functional consequences on immune responses.

Concomitantly, these cells were positive for the WNT ligand WNT10A and autophagy/mitophagy- associated LC3, suggesting autoregulatory mechanisms for the maintenance of the stem cell niche and mitochondria-associated functional alterations, respectively.

Conclusion: Our results indicate that mitochondrial function not only reflects IEC phenotypic changes but seems to be the driving force in differentiation processes. Mitochondrial function might therefore represent a key player at the edge of intestinal tissue homeostasis and repair/healing processes in the context of diseases.

**Introduction:** Previous studies have shown differences in disease phenotype of ulcerative colitis (UC) in South Asian (SA) migrants compared to Caucasians with pan-colonic phenotype predominant.1 The gut microbiota differs in Caucasian and SA patients with UC2 however, there is limited evidence on how this translates to the metabolome.

**Aims & Methods:** We aimed to examine the metabolic profile in a newly diagnosed cohort of UC patients recruited from St. Marks Hospital, London, UK. Patients were stratified by ethnicity (SA, Caucasian, Other), treatment (None, 5-ASA, Azathioprine and Steroids) and disease duration. Healthy controls (HC) were recruited locally among the staff at St. Marks Hospital. Biofluids (urine, faeces and serum) were collected at diagnosis (time point 1; months 0–3) and further time points over one year (time point 2: months 4–8, time point 3: months 9–12). Metabonomics approach was applied using two different UPLC-MS profiling methods; for small metabolites (hydrophilic liquid chromatography, HILIC) and for bile acids (BA) platforms. Univariate (UV) and multivariate (MV) data analysis was implemented to build models using principle component analysis (PCA) and orthogonal partial least squares -discriminant analysis (OPLS-DA) to find metabolites that were expressed in significantly different amounts between the two populations, time points (1 vs 3) and treatment groups.

**Results:** Fifty patients with UC of SA and Caucasian backgrounds were recruited. A total of 309 samples were collected. Sample collection was completed for all time points for 18 SA (11 UC and 7 HC) and 21 Caucasians (9 UC and 12 HC). There was no significant difference between SA and Caucasian at time points 1, 2 and 3 and treatment groups. Significant differences were observed between HC vs. disease, SA HC vs. Caucasian HC and SA UC vs Caucasian UC. For the UC cohort, robust models were obtained by OPLS-DA between SAs and Caucasians; faecal HILIC (R²Y 0.896, Q²Y 0.451, p < 0.0003) and urine HILIC (R²Y 0.783, Q²Y 0.526, p < 0.0001) and serum BA (R²Y 0.702, Q²Y 0.517, p < 0.0001) and faecal BA (R²Y 0.832, Q²Y 0.395, p < 0.0001). Combined analysis revealed 1611 significant features (faecal HILIC 60, urine HILIC 199, serum 489 and faecal BA 873). The assigned features are shown in Table 1. Faecal HILIC showed significantly higher essential amino acids (Adenine, L-phenylalanine, L-tryptophan) levels on UV and higher L-cyproline and creatine levels on MV analysis for SAs. Urine HILIC showed lower creatine, L-phenylalanine and hippuric acid levels. Serum primary (Cholic and chenodeoxycholic acid) and secondary bile acids (BA modified by the gut) were significantly reduced in SAs. Table 1: Significant metabolites in OPLS-DA models between South Asian (SA) and Caucasians with UC. *compound is increased or decreased in SA compared with Caucasians respectively.

**Conclusion:** This study highlights the promise of UPLC-MS profiling to differentiate between SA and Caucasian groups. There are several possible reasons but two important factors are differing microbial metabolism and diet between the two groups. We are conducting further studies incorporating dietary data and 16S microbial analysis in this cohort. In combination with matching disease extent (left-sided vs colonic disease) may help to identify possible explanations for the different disease phenotype in this group.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Aims & Methods: In a retrospective and single-centre setting we aimed to understand if patients’ baseline clinical and endoscopic features were relevant guide for identifying likely responders and non-responders to adsorptive GMA. The subjects were 145 consecutive UC patients who had undergone GMA with the Adacolumn as remission induction therapy between 2012 and 2016. Seventy-three patients were steroid naive, 70 were steroid dependent, and 2 patients were steroid refractory. Patients had received up to an 11 GMA sessions over 10 weeks. At entry and week 12, patients were clinically and endoscopically evaluated, allowing each patient to serve as his or her own control. Clinical activity index was defined as remission.

Biopsies from histologically detectable inflamed large intestinal mucosa were processed to see the impact of GMA on leukocytes within the mucosal tissue.

Results: At entry, the average CAI was 12.8, range 10–17. Ninety-three patients (64.1%) had the ability to induce remission with 35 evaluable patients (71.7%), 40 of 70 steroid dependent (57.1%), and 1 of the 2 steroid refractory cases. On average remission was sustained for 8.6 months in steroid naïve patients and for 10.4 months in steroid dependent subgroup. Observations on mucosal tissue biopsies showed that infiltrating leukocytes were mostly monocytes and lymphocytes. There was a marked reduction of infiltrating leukocytes in responder patients. Patients with extensive deep UC lesions together with loss of the mucosal tissue at the lesions were non-responders. Patients with the first UC episode were identified as the best responders (90%), followed by steroid naïve patients. Additionally, a short duration of active UC prior to GMA marked a patient as a likely responder. Further, all patients who achieved remission were steroid free at week 12.

Conclusion: First episode and steroid-naïve cases who responded well to GMA attained a favourable long-term clinical course. Additionally, GMA was more effective if applied immediately after a relapse than after a lag time. In general, GMA is favoured by its safety profile and for being a non-remission induction therapy. Patients with extensive deep UC lesions, with long duration of UC refractory to multiple pharmacologicals are unlikely to benefit from GMA. In therapeutic settings, knowing baseline clinical and endoscopic features, which may identify GMA responder patients should guide to futile use of medical resources.

Introduction: Alterations in short chain fatty acid (SCFA) metabolism have been reported in inflammatory bowel disease (IBD). Among SCFA, butyrate has been described as a potent communicator to the immune system eliciting an anti-inflammatory response and other positive effects to human health1. A reduction of faecal butyrate levels has been reported in IBD but results have been conflicting or discrepant because of small sample numbers and failure to distinguish disease type, activity or other variables such as diet. Microbiota is receiving increasing attention as a key environmental factor influencing IBD2, which may identify GMA responder patients should guide to stop futile use of medical resources.

Introduction: Antibiotics sometimes have an influence on colitis negatively. Although it is well known that dysbiosis is one of the major disturbances to the gut environment, the molecular mechanisms underlying the pathogenesis remains unclear.

Aims & Methods: We aimed to clarify how antibiotics affect the gut microbiota and the pathology of colitis. Mice were gavaged with ampicillin (ABPC), vancomycin and neomycin, or a combination of ABPC, VCM and LNG (A-V) for three consecutive days. Colitis was assessed by fecal occult blood test (FOBT) and mRNA level of cytokines. Metabolites and short chain fatty acid (SCFA) in the feces were measured by a chromatography-tandem mass spectrometry. Fecal microbiota was determined by 16S rRNA sequencing.

RT PCR and Western blot analysis. GPR 18 was localized in human colonic macroscopic score, microscopic score, quantification of myeloperoxidase (MPO) activity, expression of pro-inflammatory cytokines in RAW264.7 and induced expression of antimicrobial peptides (secretory leukocyte protease inhibitor and lactoferrin) in CMT93.

Conclusion: A V treatment induced mild colitis with reduced abundance of family of Clostridiaceae, which might disturb Gltn and SCFA metabolisms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Inflammatory bowel disease (IBD) is a group of gastrointestinal tract diseases consisting mainly of Crohn’s Disease (CD) and Ulcerative Colitis (UC). Various etiological factors contribute to the pathogenesis of IBD, including modulation of microbiota, epithelial barrier disruption, genetics and environment. Recently, the treatment preference comprises several groups of drugs the choice of which is made based on disease activity and extent. The treatment options include: analogs of 5-aminosalicylic acids, glucocorticoids and antibiotics (A-V) for three consecutive days. Colitis was assessed by fecal occult blood test (FOBT) and mRNA level of cytokines.

RT PCR and Western blot analysis. GPR 18 was localized in human colonic macroscopic score, microscopic score, quantification of myeloperoxidase (MPO) activity and alpha (TNFα) in colonic tissue. The expression of GPR18 gene in colonic samples from patients with IBD was quantified using real-time RT PCR and Western blot analysis. GPR 18 was localized in human colonic samples using immunohistochemistry methods.

Results: The results of our study with lower doses of GPR18 ligands in the chronic TNBS model of colitis showed a non-significant decrease in macroscopic score, ulcer score and a significant decrease in MPO activity (p < 0.05) in mice injected with PSB-KK-1415 compared with TNBS-treated mice. PSB-CBS (1–5 mg/kg, i.e., once daily) was characterized in two mouse models of ulcerative colitis, induced by 2, 4, 6-trinitrobenzenesulfonic acid (TNBS) and dextran sulfate sodium (DSS). The extent of inflammation was evaluated based on the macroscopic score, microscopic score, quantification of myeloperoxidase (MPO) activity and alpha (TNFα) in colonic tissue. The expression of GPR18 gene in colonic samples from patients with IBD was quantified using real-time RT PCR and Western blot analysis. GPR 18 was localized in human colonic samples using immunohistochemistry methods.

Conclusion: We demonstrated potential ability of the GPR18 agonist PSB-KK-1415 to alleviate inflammation in the mouse models of colitis and showed that GPR18 is expressed in the human colon. We conclude that GPR18 is another receptor of the endogenous cannabinoid system family which may be implicated in the pathogenesis of IBD and intestinal inflammation overall.

Introduction: Our previous study showed that activation of D3 dopamine receptors (D3R) had the beneficial effect in experimental colitis treatment while the mechanism of this effect is unclear [1]. The disruption of surface colon mucosa layer with subsequent activation of local immune response by the bacterial infiltration into the inner layer of the mucosa are the key pathogenic mechanisms of ulcerative colitis progression and perpetuation. We found the localization of D3R on the Goblet cells in colonic mucosa [2].

Aims & Methods: We aimed to clarify how antibiotics affect the gut microbiota and avoid the disabling procedures. G protein-coupled receptor 18 (GPR18) belongs to the endogenous cannabinoid system which already earned its place in the pathogenesis of IBD and intestinal inflammation overall. As we lack data regarding modulation of microbiota, epithelial barrier disruption, genetics and environmental factors (UIC), various etiological factors contribute to the pathogenesis of IBD, including modulation of microbiota, epithelial barrier disruption, genetics and environment.

Results: The results of our study with lower doses of GPR18 ligands in the chronic TNBS model of colitis showed a non-significant decrease in macroscopic score, ulcer score and a significant decrease in MPO activity (p < 0.05) in mice injected with PSB-KK-1415 compared with TNBS-treated mice. PSB-CBS (1–5 mg/kg, i.e., once daily) was characterized in two mouse models of ulcerative colitis, induced by 2, 4, 6-trinitrobenzenesulfonic acid (TNBS) and dextran sulfate sodium (DSS). The extent of inflammation was evaluated based on the macroscopic score, microscopic score, quantification of myeloperoxidase (MPO) activity and alpha (TNFα) in colonic tissue. The expression of GPR18 gene in colonic samples from patients with IBD was quantified using real-time RT PCR and Western blot analysis. GPR 18 was localized in human colonic samples using immunohistochemistry methods.

Conclusion: We demonstrated potential ability of the GPR18 agonist PSB-KK-1415 to alleviate inflammation in the mouse models of colitis and showed that GPR18 is expressed in the human colon. We conclude that GPR18 is another receptor of the endogenous cannabinoid system family which may be implicated in the pathogenesis of IBD and intestinal inflammation overall.

Introduction: Guidelines advise limited resection for Crohn’s terminal ileitis, as previous literature did not demonstrate clinical benefit from more extensive resections. Recently, some cohort studies identified positive resection margin as an independent risk factor for postoperative Crohn’s recurrence. But it is difficult to draw clinical conclusions, as non-uniform pathological definitions have been used. The aim of this study was to assess the incidence of non-radical resections (D3R-agonist increased levels of mucus secretion and activated natural immune response by macrophage activation during experimental colitis, which could indicate about the protective role of D3R.

P0319 LIPOSOMAL FORMULATION AS A NEW DRUG DELIVERY SYSTEM FOR CROHN’S DISEASE - VALIDATION IN THE MOUSE MODEL OF TNBS-INDUCED COLITIS
J. B. Krajewska, P. Pietrusza, D. Tomczyk, J. Fichna
Department Of Biochemistry, Medical University of Lodz, Lodz; Poland
Contact E-mail Address: julia.krajewska@stud.umed.lodz.pl

Introduction: Crohn’s Disease (CD) is an inflammatory disease of the intestinal tract. New therapies are needed to ameliorate the effects of medical therapy, reducing complications and improving patients’ quality of life.

Aims & Methods: The objective of the study was to assess the effectiveness of delivery of anti-inflammatory drugs encapsulated in the liposomal formulation.

Liposomes were prepared using thin-liquid hydration method. 0.9% sodium chlor-
ide was used as a solvent. The hydration solutions contained an aminosalicylate
epsalicylate mesalazine (5-ASA), two recently validated plant-derived anti-inflammatories with low bioavailability, chlorogenic acid (CGA) and berberine, and pure solvent as negative control. Colitis was induced in male BALB/c mice by a single intra-
colonic (i.c.) administration of 2, 4, 6-trinitrobenzene sulfonic acid (TNBS) on Day 0. Liposomal suspensions containing 5-ASA (5 mg/kg), CGA (20 mg/kg), berberine (5 mg/kg) and the solvent were administered i. c. twice daily from Day 3 to Day 6. Mice were sacrificed on Day 7 and colonic damage was evaluated.

Results: The macroscopic scoring system included the evaluation of the colon length and bowel thickness as well as the presence of ulcers, haemorrhage, faecal blood and diarrhea. Additionally, tissue myeloperoxidase (MPO) activity was
to Day 6. Mice were sacrificed on Day 7 and colonic damage was evaluated.

Conclusions: Our study corroborates the absence of AIEC-specific genetic markers widely distributed across all AIEC strains. Nonetheless, three SNPs putatively involved with the AIEC phenotype have been described and one of them could be validated in AIEC screening.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
incidence rate of microscopic colitis appeared to increase with time (Table). The incidence of microscopic colitis in 2016 was twice that observed in 2009 (incidence rate ratio 1.86; 95%CI 1.41, 2.46). There was a strong, independent graded association between the incidence of microscopic colitis and the number of lower GI endoscopy procedures undertaken (p = 0.03).

Conclusion: Microscopic colitis diagnosis is becoming more common. It is unclear whether microscopic colitis itself is increasing or greater numbers of lower GI endoscopy are being undertaken causing an ascertainment bias. Further work is required to explore environmental exposures such as drugs associated with microscopic colitis and to observe its natural history.

P0321 EXTRA-INTESTINAL MANIFESTATIONS AT DIAGNOSIS IN PAEDIATRIC- AND ELDERLY-ONSET ULCERATIVE COLITIS ARE ASSOCIATED WITH A MORE SEVERE DISEASE OUTCOME: A POPULATION-BASED STUDY

D. Duricova1, A. Leroyer1, G. Savoye2, H. Sarter3, B. Pariente4, D. Aoucheta4, L. Armengol-Debeer1, D. Ley1, D. Turk1, L. Peyrin-Biroulet6, C. Gower-Salouel, Amiens University Hospital, Amiens/France

Aims & Methods: The aims of this population-based study were to assess 1) the occurrence of EIM in paediatric- and elderly-onset UC; and 2) their impact on long-term disease outcome. Paediatric-onset (<17 years at diagnosis) and elderly-onset UC patients (>60 years) from a French prospective population-based Registry (EPMAD) were included. Data on EIM and other clinical factors at diagnosis and at maximal follow-up were collected.

Results: 158 paediatric- and 470 elderly-onset patients were included (median age at diagnosis 14.5 and 68.8 years; median follow-up 11.2 and 6.2 years, respectively). EIM occurred in 8.9% of childhood- and 3% of elderly-onset patients at diagnosis and in 16.7% and 2.2% of individuals during follow-up (p < 0.01). The most frequent EIM was joint involvement (15.8% of paediatric-onset and 2.6% of elderly-onset). Presence of EIM at diagnosis was associated with more severe disease course (need for immunosuppressive or biologic therapy or colectomy) in both paediatric- and elderly-onset UC (HR = 2.0, 95%CI: 1.0-4.2 and HR = 2.8, 0.9-7.9). Extensive colitis was another independent risk factor in both age groups.

Conclusion: Elderly-onset UC patients had lower risk of EIM either at diagnosis post-baseline compared to paediatric-onset UC patients. Further work is needed to better understand the impact of EIM on the long-term disease course and management of UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0322 LONG-TERM NATURAL HISTORY OF MICROSCOPIC COLITIS: A POPULATION-BASED STUDY

Introduction: Data on long-term natural history of microscopic colitis (MC), including collagenous (CC) and lymphocytic colitis (LC) are lacking.

Aims & Methods: A new case of MC diagnosed in the Somme area, France between January 1st, 2005 and December 31th, 2007 were prospectively included. Colonic biopsies from all patients were reviewed by a group of 4 expert gastro-intestinal pathologists to assess the diagnosis of MC or LC. Demographic and clinical data were retrospectively collected from diagnosis to February 31th, 2017.

Results: One hundred and thirty cases of MC, 87 CC and 43 LC were included (median age at diagnosis 70 and 48 years, respectively). The median follow-up was 9.6 years (Q1 = 7.6; Q3 = 10.6). By the end of follow-up, 37 patients (28%) relapsed after a median time of 3.9 years (1.2; 5) since diagnosis, without significant difference between CC and LC (36% vs 26%, p = 0.47). Twenty patients (15%) were hospitalized for a disease flare and 32 (25%) presented with another autoimmune disease. Budesonide was the most widely used treatment (n = 74, 59%), followed by 5-aminosalicylic acid (n = 31, 25%). Median duration of budesonide treatment was 92 days (70; 168) and no adverse event to budesonide were reported. Sixteen patients (22%) developed steroid-dependency and 4 (5%) were corticosteroidresistant. Only one patient was treated by immunosuppressant (azathioprine). No colorectal cancer was reported during follow-up. Any of the death (n = 25) observed during follow-up were linked to MC. In multivariable analysis, age at diagnosis (HR 1.03, 95%CI, 1.00-1.06; p = 0.02) and budesonide exposure (HR 0.40, 95%CI, 0.18-0.90; p = 0.03) were significantly associated with relapse.

Conclusion: This population-based study showed that after diagnosis, two third of patients with MC observed long term clinical remission. Age at diagnosis and budesonide exposure were associated with a risk of relapse.

Introduction: It has been demonstrated in many chronic conditions, including inflammatory bowel disease (IBD), that better patients’ knowledge about pathology and treatment improves the course and management of disease. The aim of this study was to develop an updated self-questionnaire to assess patients’ level of knowledge of IBD.

Aims & Methods: The IBD-INFO included 3 parts: an original part (Q1), and 2 parts from the translation of the pre-existing questionnaires Crohn’s and Colitis Knowledge score (CCKNOW) (Q2) and Crohn’s and Colitis Pregnancy Knowledge score (CCKNOW) (Q3). The reliability and discriminatory ability of the questionnaire were validated with 3 groups of non-IBD volunteers with various theoretical knowledge levels. The final questionnaire (64 validated questions) was then tested on 364 in- and out- IBD patients from 4 French university hospitals. The score for each part of the questionnaire was calculated and factors associated with low scores were identified by uni- and multivariate logistic regression analyses.

Results: The scores obtained by the 3 non-IBD volunteer groups differed significantly (p < 0.0001) and the IBD-INFO questionnaire showed excellent internal reliability and consistency (α = 0.98). The median total score obtained by the IBD patients was 27/64 [0–59], and scores for Q1, Q2 and Q3 were, respectively, 10/23

Introduction: Primary Sclerosing Cholangitis (PSC) is a distinct disease course with less relapse, lower disease activity, but earlier diagnosis, time from diagnosis to first presentation, and duration of follow-up. Time to event analysis was performed using survival analytic methods including Kaplan-Meier method and Log-rank test.

Results: PSC was diagnosed in 77 and 10 patients out of 781 UC and 1022 CD patients as well as from 77 UC-PSC and 10 CD-PSC patients were assessed. Data were evaluated using standard statistical methods. In matched-pair analyses, IB patients with and without PSC were matched at the ratio of 3:1 by sex, disease entity, age at diagnosis, time from diagnosis to first presentation, and duration of follow-up. Time to event analysis was performed using survival analytic methods including Kaplan-Meier method and Log-rank test.

Results:
- In UC patients, whereas pancolitis was more frequently diagnosed in UC-PSC patients (75% vs. 69%) and UC patients with acute flare as compared to UC-PSC patients (7.3 vs. 6.2; p = 0.044). Interestingly, UC patients without PSC presented more frequently with active disease, as compared to IB-PSC patients (20.4 vs. 21.7 years after onset, p = 0.05). Conveniently, average disease activity assessed by complete Mayo score was significantly higher in UC patients with acute flare as compared to UC-PSC patients (7.3 vs. 6.2; p = 0.001).
- Investigation of the average disease activity in 5-year-intervals in UC patients revealed a stronger disease activity in UC patients without PSC, especially within the first 10 years after UC onset. Furthermore, biological therapy including vedolizumab and anti-TNF antibodies was initiated more frequently (38.9 vs. 22.0; p = 0.043) and earlier (20.4 vs. 28.6 years after onset, p = 0.087) in UC without PSC than in those with coincident PSC. Colorectal high grade intraepithelial neoplasia (HGIEN/CRC) occurred significantly earlier than in IB patients without PSC (20-year-risk: 9.6% vs. 5.6%; p = 0.003).

Conclusion: In our large cohort study, IB patients with coincident PSC showed a distinct disease course with less relapse, lower disease activity, but earlier disease onset and higher risk for extensive disease manifestation as well as increased risk for colorectal dysplasia development.

Introduction: The EpiCom-cohort is a European prospective population-based follow-up of uniformly diagnosed patients with inflammatory bowel disease (IBD) diagnosed in 2010 in centres from Western and Eastern European countries. The cohort aims at describing differences in occurrence, treatment strategies, disease course and prognosis within Europe.

Aims & Methods: Patients were followed each 3rd month for the first year after diagnosis and then according to the treating physician for the 2-5th year of follow-up. Clinical data on surgery, hospitalizations and medical treatment incl. biological therapy were captured prospectively throughout the follow-up period and entered in a validated web-based database. The aim of the study was to investigate differences in disease outcome and the use of biologicals between Eastern and Western Europe, from diagnosis and during the first 5 years of follow-up. Associations between outcomes and multiple covariates were examined by Cox regression analyses.

Results: A total of 1289 patients aged 15 years or older from 29 centres in 13 Western and 8 Eastern European countries were followed prospectively of whom 717 (56%) had ulcerative colitis (UC), 488 (38%) had Crohn’s disease (CD), and 84 (6%) had IBD unclassified (IBDU). Crude annual rates for CD and UC patients regarding surgery, biological treatment and hospitalization are shown in Table 1. Significantly more CD patients in Western Europe received biological therapy (p = 0.02), while UC patients regarding surgery, biological treatment and hospitalization are shown in Table 1. Significantly more CD patients in Western Europe received biological therapy (p < 0.05), while UC surgery rates did not differ between the regions, while hospitalization rates were higher in Western Europe (p < 0.05). Cox regression analysis showed that in CD structuring (B2) or penetrating disease (B3) and progressing from luminal disease to B2/B3 increased while early (<6 months from diagnosis) treatment with immunosuppressives reduced the risk of surgery and hospitalization. In UC, progressing to extensive colitis increased the risk of colorectal cancer while females, extensive disease, need for prednisolone at diagnosis, and progressing from CD to UC increased the risk. The cumulative probability of CD patients receiving treatment with 5-ASA was 90% in Western Europe and 84% in Eastern Europe, 69% and 75% for prednisolone, 54% and 66% for immunomodulators, respectively. For UC patients the cumulative probability of receiving treatment with 5-ASA within the first year of disease was 100% in Eastern Europe and 91% in Western Europe, 44% and 52% for prednisolone, 27% and 30% for immunomodulators, respectively.

Conclusion: In an era of early and aggressive immunomodulator therapy, surgery and hospitalization rates for CD and surgery rates for UC patients were similar in Eastern and Western Europe. Overall, surgery and hospitalization rates were comparable to population-based cohorts from the past decade and pre-biological era. The similar disease course could be in spite of more early and aggressive treatment with biologics and immunomodulators, with significantly more CD and UC patients in Western Europe receiving biologics.

Disclosure of Interest: All authors have declared no conflicts of interest.
There was a similar, significant increase for codeine (chi^2 for trend, p
analysis. in patients with inflammatory bowel disease in the English primary care database
Table 1: The association between opiate prescriptions and all-cause mortality
patients with IBD. Any opiate use in patients with UC was associated was
Table 1 shows the association between opiate use and all-cause mortality in
2.91, 95% CI 1.58–5.02). In this study we explore trends in the prescription of
ates. Opiate prescribing for cancer and non-cancer pain has increased dramati-
cally in recent years but there is a paucity of data on prescription trends for
individuals with IBD. The only population-based study is from Canada where
5% of subjects with IBD became heavy opiate users after 10 years of diagnosis and
there was a strong association between heavy opiate use and mortality (OR 2.91, 95% CI 1.58–5.02). In this study we explore trends in the prescription of
opiate medications and assess the association between opiate prescription and mortality in English primary care cohort of patients with IBD.
Aims & Methods: We used the English primary care database ResearchOne for
this study which holds records from approximately 6 million individuals (>10%
of the total population). We extracted relevant clinical codes and prescription
data on all patients with IBD, and separated out those with ulcerative colitis (UC) and Crohn’s disease (CD). We created 4 categories of opiate medication
use, namely; any opiate medication, codeine only, tramadol, and strong opiates.
We defined 3 groups of prescription density as none/infrequent users, moderate and heavy users as <1, 1–3 and >3 prescriptions per calendar year respectively. We examined the trend in opiate prescriptions for all IBD patients in 4 year blocks from 1990–2014 using chi^2 for trend as a significance. Separate trends were produced for each of our opiate classes. We calculated a propensity score estimating the conditional probability of being prescribed an opiate medication based on pre-defined characteristics which may influence the prescription of opiates. All-cause mortality in opiate users and non-users was compared in a
propensity score matched, Cox proportional hazards regression analysis to pro-
duced hazard ratios (HR) and 95% confidence intervals (CI). All analyses were
performed for each opiate medication class in CD and UC patients.
Results: We included 3517 patients with CD and 5349 with UC. Opiate prescrip-
tions increased from 10% in 1990 to 30% in 2014 (chi2 for trend p < 0.005).
There was a similar, significant increase for codeine (chi^2 for trend, p = 0.008), tramadol (p < 0.003) and strong opiates (p < 0.005) when analyzed separately.
Table 1 shows the association between opiate use and all-cause mortality in patients with IBD. Any opiate use in patients with UC was associated was associated with increased mortality (HR 1.67, 95% CI 1.25–2.23). The strongest associations were for heavy users of strong opiates in patients with CD (HR 2.18, 95% CI 1.20–3.95) and UC (HR 3.30, 95% CI 1.77–6.18). There was no association
for prescriptions of tramadol at any prescription density in CD or UC.
Table 1: The association between opiate prescription and all-cause mortality in patients with inflammatory bowel disease in the English primary care database Research One. Propensity score matched, Cox proportional hazards regression analysis.

Conclusion: Our study is the largest population based study of opiate use in
patients with IBD. We have shown a significant increase in the prescription of
opiates since 1990, with 30% being prescribed an opiate medication between 2010
and 2014. Prescriptions of codeine in UC and strong opiates in both CD and UC
were associated with increased all-cause mortality. There appears to be a dose
association as heavy users of strong opiates had the largest association with
mortality. Observational studies are not proof of causality and there may be
residual confounding. A dose response is a strong indicator that opiates could
be responsible for the associations seen, which is consistent with other studies
investigating opiates used for non-cancer pain in chronic disease. Randomised
treated trials would be unethical and not feasible to investigate this potential
effect so population-based observational studies may provide the best estimate.
Opiate prescriptions are increasing worldwide for chronic non-cancer pain, and
individuals with IBD can now be included. Clinicians managing pain in individu-
als with IBD should consider the potential implications of prescribing, or
continuing with opiate prescriptions as they are a marker for increased mortality.

Aims & Methods: In a prospective 6-months study, dental examination was performed on 103 IBD and in 19 healthy controls. IBD related variables were prospectively collected, as well as markers for periodontitis including gingival bleeding (BOP index, marker of periodontal inflammation), gingival recession (REC index, marker of cumulative periodontal destructions) and probing depth (PD, the severity of pocket formation). Additional dental examination was proposed 3 months after to all patients diagnosed with periodontitis.

Results: Among the 54 included patients, 44 had Crohn disease (81%) and 31 were women (55%). At the time of dental examination, median age was 33 years (Q1 = 26; Q3 = 41), 20 (36%) were smokers and the median IBD duration was 8.4 years (3.4-16.3). Eleven (20%) were treated by corticosteroids, 27 (49%) by anti-TNF, 6 (10%) by other biologics and 8 had no IBD treatment. IBD was significantly associated with periodontitis (81% vs 27%; Odds Ratio 2.9, 95%CI:1.3-6.2). Mild, moderate and severe periodontitis were respectively observed in 34 (63%), 8 (15%) and 3 (5%) IBD patients. As compared to healthy controls, IBD patients had significant increase of BOP index (p = 0.008), probing death (p = 0.03), and REC index (p = 0.01). Patients with active IBD (Harvey Bradshaw score > 5 or Mayo Score > 3) had a significantly higher score of BOP index (p = 0.007) as compared to patients with inactive disease. A significant correlation between BOP and Harvey-Bradshaw index was observed (r = 0.44, p = 0.0018). Anti-TNF therapy was significantly associated with lower BOP index (p = 0.02). All patients with diagnosis of periodontitis were treated by periodontal debridement and subgingival irrigation with povidone-iodine which led to a significant decrease of BOP index three months after diagnosis.

Conclusion: Inflammatory bowel diseases were associated with an increased risk of periodontitis. Gingival inflammation was correlated to disease activity and anti-TNF therapy was associated with a lower risk of active parodontal disease.

Introduction: Among the numerous genetic factors associated with ulcerative colitis (UC), an increasing attention has been paid to the polymorphisms of the vitamin-D receptor gene (VDR) associated with disorders of innate and adaptive immunity as well as the barrier function of the intestinal epithelium. However, the results of studies on the prevalence, clinical, diagnostic and prognostic significance of polymorphisms of the VDR gene in different populations are ambiguous and contradictory. In particular, associations of Bsm I polymorphism of the VDR gene with UC in the Chinese population and in the Jewish Ashkenazi has been found, while in the Irish population, with a sufficient prevalence of Bsm I polymorphism, this association is absent [1–3]. In the Russian Federation, there is no data on the prevalence, clinical, diagnostic and prognostic significance of Bsm I polymorphism of the VDR gene with UC. These circumstances determined the purpose and objectives of this study.

Aims & Methods: The purpose is to assess the clinical, diagnostic and prognostic significance of the Bsm I polymorphism of the VDR gene (rs154440) and UC among the residents of the Kemerovo region of the Russian Federation. The study included 76 patients with UC and 85 controls. Genotyping was performed by PCR method (“SNP-express” reagents, Lytech Co. Ltd., Russia) with electrophoresis included 76 patients with UC and 85 controls. Genotyping was performed among the residents of the Kemerovo region of the Russian Federation. The study included 76 patients with UC and 85 controls. Genotyping was performed by PCR method (“SNP-express” reagents, Lytech Co. Ltd., Russia) with electrophoresis.

Results: It was found that the frequency of the allele B polymorphism of the VDR Bsm I gene was higher among patients with UC than in the control group (44% vs. 26%, p = 0.02), which increases the risk of this pathology by 2.2% (95% CI: 1.2–4.1). In the case of carriers of the B/B genotype, the risk of developing UC increased up to 3.5 times in comparison with the control group (21% vs. 7%, p = 0.02, 95% CI: 1.4–8.6), whereas in b/b genotype the risk of UC decreased (33% and 54%, respectively, p = 0.02, OR = 0.4, 95% CI: 0.2–0.7). Significant differences between carriage of the B allele Bsm I polymorphism and the features of the clinical course of the UC have not been established. However, it has been shown that in carriers of allele B, the clinical implementation of UC develops significantly later than in patients with the b/b genotype (43 and 28.5 years, respectively, p = 0.04).

Conclusions: For carriers of the B allele Bsm I polymorphism of the VDR gene is a predictor of a high risk of ulcerative colitis with an increase in the age of diagnosis. Genotype b/B Bsm I polymorphism of the VDR gene has a protective effect in the development of ulcerative colitis among the residents of the Kemerovo region of the Russian Federation.

3. Hughes D.J., McManus R., Neary P. et al. Common variation in the vitamin D receptor gene and risk of inflammatory bowel disease (IBD) pathogenesis. DNMT3A and DNMT3B are two of the three members of the family of de novo DNA methyltransferases. Variants in these proteins are responsible for the establishment of de novo genomic DNA methylation patterns and are involved in the normal development as well as in many diseases. However, it is unknown if DNMT3A may play a role during the mechanism involved in this abnormal methylation pattern and consequently the development of diseases.

Aims & Methods: To assess the function of DNMT3A in intestinal epithelial cells (IECs), human Caco-2 colon carcinoma cells were transfected with siRNA targeting DNMT3A, DNMT3B and DNMT3L. Gene expression analysis and DNA methylation analysis using qRT-PCR, RNA sequencing and 850K methylation chip assay were performed. For long-term experiments, we used a CRISPR/Cas9 genome editing to delete DNMT3A gene in Caco-2 cells. DNMT3A knockout Caco-2 cells were grown in a 3D-Matrigel culture system and after 2 weeks, spheroids cells were stained for actin/nuclei and subjected to confocal microscopy analysis.

Results: From the RNA sequencing data, approximately 1000 genes were found to be differentially expressed between cells lacking DNMT3A and controls. The KEGG pathway analysis identifies differentially regulated genes associated with several functional categories comprising extracellular matrix receptor interaction, focal adhesion and MAPK signaling pathway. In contrast, we observed no difference in DNA methylation between the groups. Furthermore, loss of DNMT3A induces abnormal spheroids formation by reducing spheroids diameter and defect in actin organization and lumen formation. Thus, the observed morphological phenotype may be linked to the differently regulated genes involved in the previous analysed pathways.

(IRE1), double-stranded RNA-dependent protein kinase (PKR)-like ER kinase (ERK) and XBP1 promoter activity (XBP1 expression factors; O4). Defects in the response have been shown to predispose to chronic inflammatory bowel disease (IBD). Genome-wide association studies identified disease susceptibility loci in or adjacent to several UPR-related genes including XBP1 and ORM DL3. An objective of this study was to determine the function of ORM DL3 in UPR signaling to gain insights into the molecular mechanisms promoting chronic intestinal inflammation. Using molecular cell biology approaches, we studied the effect of ORM DL3 on ATF6, PERK and IRE1 signaling in cell lines. ORM DL3 in in vitro and in vivo an acute and chronic DSS-colt due model using Ormdl3-deficient mice.

Results: In our in vitro studies demonstrate that ORM DL3 facilitates ER stress-induced ATF6 activation. Overexpression of ORM DL3 resulted in increased cleavage of ATF6 and augmented ERSE promoter activity. Mechanistically, we show that ORM DL3 colocalizes and directly interacts with ATF6. Furthermore, ORM DL3 overexpression induced the PERK pathway by elevating eIF2α phosphorylation and protein levels. In contrast, we observed an increased rate of IRE1 signaling exerted by ORM DL3 proteins as shown by reduced XBP1 splicing and decreased UPRE promoter activity. IRE1 signaling exerted by ORMDL proteins as shown by reduced XBP1 splicing and decreased UPRE promoter activity. IRE1 signaling exerted by ORMDL proteins as shown by reduced XBP1 splicing and decreased UPRE promoter activity.

Introduction: Biosimilar infliximab CT-P13 received EMA approval in June 2013 for all indications of the originator product and its use is mandatory in all anti-TNF naïve IBD patients in Hungary since May 2014. The aim of this study was to prospectively evaluate the immunogenicity profile of the biosimilar infliximab and predictors of TDM in IBD patients during the first year of therapy in a nationwide, multicentre cohort. Demographic data were collected and a harmonized monitoring strategy was applied. Clinical and biochemical activity were evaluated at weeks 14, 30 and 54. Routine therapeutic drug monitoring (TDM) was applied. Trough level (TL) and anti-drug antibody (ADA) concentrations were measured by ELISA (LT-005, Theradiag, France) at baseline and week 2, 6, 14, 30 and 54 weeks right before anti-TNF administration during the induction treatment.

Results: 353 consecutive IBD patients (209 CD patients and 144 UC patients) were included in the present cohort. 23.4% of CD patients and 19.4% of UC patients had received previous anti-TNF therapy. None of the patients had received infliximab within 12 months prior to initiation of the biosimilar infliximab. 60.51% of CD/UC patients received concomitant immunosuppressives at baseline. Mean TLs were 18.9, 17.3, 7.4, 4.3 and 5.3 µg/ml at weeks 2, 6, 14, 30 and 54 in CD and 19.1, 11.8, 5.0, 3.9 and 4.5 µg/ml in UC. Previous anti-TNF therapy was associated with lower early TLs in both CD (week 2, 14, and 30, p = 0.005) and UC (week 2, 6, p = 0.03). ADA positivity rates were 4.3%, 12.0%, 20.9% and 28.6% in naive patients at weeks 0, 14, 30 and 54 (mean TLs of 266, 312, 290 and 210). ADA positivity at week 14 was associated with lower TLs in all CD (week 2, 14 and 30, p < 0.007 for all) and UC (week 6, 14 and 30, p < 0.001 for all). Concomitant IS use prevented ADA formation in anti-TNF naïve patients (week 14, 30 and 54, p = 0.01, 0.02 and 0.004) in CD but not in UC and did not affect clinical remission or response rates (32.8%) patients had infusion reactions during induction or maintenance treatment, of which 16 patients had received previous infliximab treatment.

Conclusion: Drug TLs and ADA development in IBD patients until week 54 were in line with results from previous studies. Increased exposure to anti-TNFs had lower early TL coupled with ADA positivity and were more likely to develop infusion reactions. Concomitant IS use prevented ADA development in anti-TNF naïve patients.

31, z. Gyermekklinika, Semmelweis Egyetem, Budapest/Hungary

Aims & Methods: Sera of 266 well-characterized CD patients (m/f:112/154, median age: 25 yrs, B1:80.1%, P1:18.0%) and 155 controls were assayed for serological antibodies. Endoscopic and histological (IP/S) complications were used as classification criteria. The Endoscopic Response (Remission or SR) was significantly associated with IgA type ASCA and IgG type ASCA. In Kaplan-Meier analysis, development of internal penetrating and/or stenosing (IP/S) complications and response to surgery (SR) was significantly associated with IgA type (Hazard ratio [HR] = 0.24; 95% CIs: 0.111%–0.54%; P = 0.001) and with IgG type (HR = 0.47; 95% CIs: 0.29%–0.78%; P = 0.003). MR ulcer healing was associated with a low risk of clinical relapse (Hazard Ratio [HR]: 0.24; 95% CIs: 0.111%–0.54%; P = 0.001) and serological relapse (HR = 2.84; 95% CI: 1.63–4.95; P = 0.008). Ulcer healing was associated with a low risk of clinical relapse (Hazard Ratio [HR]: 0.24; 95% CIs: 0.111%–0.54%; P = 0.001) and serological relapse (HR: 0.47; 95% CIs: 0.29%–0.78%; P = 0.003).

Introduction: Therapeutic adherence is crucial in the management of patients with inflammatory bowel disease (IBD). Poor adherence may lead to suboptimal treatment, and may be associated with the disease activity, allowing monitoring of the short-term efficacy of biotherapies.

Aims & Methods: 1) To evaluate the prevalence of non-adherence to treatment in Spanish patients with IBD and 2) To identify factors associated with low, medium and high adherence. We performed a cross-sectional study that included consecutive patients with IBD attending our adult IBD clinic in a three-month period. Consenting patients completed a survey performed by two researchers not involved in patients’ care. Activity was evaluated using Harvey-Bradshaw index in Crohn’s disease (CD) and Partial Mayo Score in Ulcerative colitis (UC). Anxiety and depression were estimated by the Goldberg Anxiety and Depression Scale and modified Morisky Medication Adherence Scale (MMAS-8) was used to assess adherence (<6, 6-7 and 8 points indicate low, medium and high adherence, respectively). In statistical analyses, Chi-square and Student’s t-test were used for side by side comparisons and logistic regression for multivariable analysis.

Results: A total of 181 patients were evaluated. The median age was 47 ± 16 years; 98 (54.1%) were males and 32 (17.7%) were active smokers. 82 (45.3%) patients had CD and 99 (54.7%) had UC. The mean disease duration was 10.21 ± 8.59 years. Most patients were in remission (87.8%). In relation to the treatment, 35.9% were taking mesalazine, 2.8% steroids, 29.3% immunomodulators and 30.4% biologics. The oral route was the most frequent (52.5%), followed by rectal route (17.1%) and subcutaneous or intravenous (30.4%). Based on MMAS-8, almost half of our patients 84 (46.4%) had high adherence to IBD treatment, 56 (30.9%) had medium and 41 (22.7%) had low adherence. In relation to factors associated with adherence, univariate analyses showed that patients with high adherence were older (52.0 ± 16.1 years vs. 42.5 ± 14.4; p < 0.001) and their disease had longer duration (12.2 ± 9.7 years vs 8.5 ± 7.1; p = 0.004) than patients with medium/low adherence. However, smokers had a low adherence (p = 0.007). Multivariate analysis confirmed that age was associated with high adherence (OR:1.04, CI95% 1.01-1.06; p = 0.002) and being smokers with low adherence (OR:3.47, CI95% 1.36-9.00, p < 0.01). Also, multivariate analysis showed that CD was associated with low adherence (OR:2.54, CI95% 1.11-5.79, p < 0.05).

Conclusion: Only active smoking and age were predictors of insufficient adherence to drugs in IBD. Efforts for reinforce adherence should be especially directed to young patients. Quitting tobacco could improve adherence.
Correlation of components of the CDAI with SES-CD

General well-being  63.3 (50.2)  0.16  0.073  42.2 (46.7)  0.17  0.123
Abdominal pain  41.0 (29.6)  0.21  0.020  21.8 (25.6)  0.06  0.597

Aims & Methods: disease activity in registration trials. This post hoc analysis assessed the association between individual components of the CDAI with the Simple Endoscopic Score for Crohn’s Disease (SES-CD) from EXTEND.

Results: A total of 121 patients at week 12 and 80 patients at week 52 had both CDAI and SES-CD values. Mean (SD) CDAI and SES-CD values at week 12 were 193.8 (116.4) and 8.0 (7.4), respectively, and 132.5 (97.6) and 5.9 (6.6), respectively, at week 52. A significant, but weak correlation was observed between CDAI and SES-CD at week 12 (r = 0.31 [P < 0.001]) and at week 52 (r = 0.31 [P < 0.005]). Similar results were observed for correlations between mean changes from baseline in CDAI and SES-CD at weeks 12 (r = 0.35 [P < 0.001]) and 52 (r = 0.31 [P = 0.005]). Correlations between individual components of CDAI and SES-CD at weeks 12 and 52 are shown in the table. SF, AP, extra-intestinal manifestations, and SF + AP were significantly correlated with SES-CD at week 12; the strongest correlation was for SF (r = 0.46) and the addition of AP to SF did not increase the correlation (Table). At week 52, SF, hematocrit, and SF + AP were significantly correlated with SES-CD. At week 12, the CDAI baseline with SF and AP was significant regardless of whether the patient had disease of the ileum (r = 0.44 [P < 0.001] with ileal disease; r = 0.48 [P < 0.001] without ileal disease), while SES-CD correlated more strongly with AP in those with ileal disease (r = 0.27 [P = 0.036]) than those without ileal disease (r = 0.16 [P = 0.233]).

Table: Correlation of components of the CDAI with SES-CD

*the number of liquid or very soft stools per day. SES-CD, Simple Endoscopic Score for Crohn’s Disease. HCT, hematocrit. NA, not applicable.

Conclusion: Data from patients with moderate to severe CD and evidence of mucosal ulceration in EXTEND supported previous findings that the CDAI was only weakly correlated with SES-CD, as assessed at 12 and 52 weeks. Only SF was significantly correlated with SES-CD at both time points. At 12 weeks, the relationship of CDAI with SF was significantly stronger regardless of whether the patient had disease of the ileum (r = 0.44 [P < 0.001] with ileal disease; r = 0.48 [P < 0.001] without ileal disease), while SES-CD correlated more strongly with AP in those with ileal disease (r = 0.27 [P = 0.036]) than those without ileal disease (r = 0.16 [P = 0.233]).

NEGATIVE DECREASED CD8+CD28-CD27- T CELLS' RATIO CAN PREDICT THE POOR OUTCOME SENSITIVELY FOR PATIENTS WITH COMPLICATED CROHN'S DISEASE

Aims & Methods: To test the efficiency of CD8+CD28-CD27- T cell's balance and the risk factors, for the newly diagnosed complicated CD. Seventeen patients with complicated CD were enrolled as the observation group, while the other 48 CD patients with no complications were enrolled as the control group. Peripheral blood samples were drawn from all the 65 newly diagnosed CD patients for CD8+ T cells testing through flow cytometry (FCM) when enrolling. The potential risk factors, including demographic, pathophysiologic, and therapeutic factors were compared between the two groups. A 30-week follow-up group was performed, and the CD8+ T cells testing were repeated. The sensitivity and specificity of the CD8+ T cells' level and balance in predicting were analyzed through receiver operator characteristic (ROC) curves. The cumulative remission lasting rates (CRLRs) under the different risk factors were analyzed using the Kaplan-Meier method.

Results: I. Risk factors: compared with the control CD group, patients with complicated CD had a larger proportion in male (P = 0.001), younger in age (P = 0.019), lower body mass index (BMI) (P < 0.0001), higher Crohn’s disease activity index (CDAI) (P < 0.0001), higher prescription rates in immunosuppressants (P = 0.029) and steroids (P = 0.015), as well as a significant higher surgical rate (P = 0.001). Pearson and Spearman correlation analysis showed that CD8+/CD8- (CD8+CD28+CD27+CD28-CD27-) was associated with BMI, CDAI, steroids, and surgery (P < 0.005). II. Follow-up and dynamic changes of the balance was associated with BMI, CDAI, steroids, and surgery (P < 0.005). A shorter lasting time of remission (LTR) was found in complicated CD patients (P = 0.044). ROC curve showed that CD8+/CD8- (CD8+CD28+CD27+CD28-CD27-) ratio could accurately predict the active stage for the complicated CD patients [area under curve (AUC) of 0.890, and 95% CI of 0.822 to 0.958], and the best sensitivity of 89.2% and specificity of 85.3% were found when the ratio was 1.03. III. Kaplan–Meier analysis: Undergoing of steroids and surgery was closely related to worse outcome for the complicated CD patients, and patients who underwent steroids and surgery had the significantly lower CD8+/CD8- (CD8+CD28+CD27+CD28-CD27-) ratio and lower CRLRs (all P < 0.05). Conclusion: Depending on steroids and surgery stands for a more severe disease activity and thus disqualify the immunological balance, which could be the potential factors for lower CRLRs. CD8+/CD8- (CD8+CD28+CD27+CD28-CD27-) ratio can predict the active stage sensitively for patients with complicated CD. More strategies should be taken when the ratio is to be lower than 1.03.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: For both preparations, site colonoscopist findings demonstrated similar very high rates of cleansing success for the overall colon (>95%) and high rates of high-quality cleansing of the ascending colon (>73%), however, statistical significance was not met in either comparison. The rates of cleansing success in the ascending colon reported by the site colonoscopists are notably higher than those previously reported by central readers.

Introduction: The efficacy of colonoscopy is dependent on the quality of bowel cleansing. NER1006 is the first 1L polyethylene glycol (PEG)-based bowel cleansing solution and is a patented combination optimised for effective bowel cleansing. The NOCT study (a multicentre randomised Phase 3 clinical trial investigating bowel cleansing efficacy of NER1006 vs trisulfate solution) reported bowel preparation quality assessed by central readers. This post hoc analysis shows the cleansing assessment by site colonoscopists, who typically guide clinical decision making; hence this study may be more relevant for clinical practice than previous studies.

Aims & Methods: In the NOCT study 621 patients (males and females, aged 18–85) were randomly assigned in a 1:1 ratio to receive either NER1006 or trisulfate solution, each administered as an overnight split-dose. Data from the 523 patients who underwent a colonoscopy and had a site colonoscopist assessment were used in this analysis. Colonoscopists were blinded to the preparation administered. Cleansing was assessed according to the Harefield Cleansing Scale, following sequential scoring, cleansing of the overall colon was graded from A to D; grades A and B were judged as successful cleansing. Cleansing of the ascending colon was graded from 0 to 4; grades 3 and 4 were judged as high-quality cleansing.

Results: As Table 1 shows, the bowel preparation quality of NER1006 when assessed by site colonoscopists did not show a statistically significant difference to trisulfate for the overall colon (93% vs 94%, P = 0.681; 95% CI: 5.1–1.3%) or ascending colon (80 vs 74%, P = 0.079; 95% CI: 0.7–13.6%). There was, however, a numerical advantage in favour of NER1006 on the proportion of patients achieving high-quality cleansing success in the right colon.

Table 1: Successful colon cleansing rates when treated with NER1006 or trisulfate solution.

N.B. successful cleansing defined here as a Harefield Cleansing Scale grade of A or B (overall colon) or 3 or 4 (ascending colon, high quality)
Several studies in recent decades have revealed new roles for vitamin D—especially as a regulator of the immune system and suppressor of fibrostenosis. Vitamin D deficiency is considered to be related to disease activity and intestinal fibrostenosis. We consider it important to demonstrate this relationship not only using clinical parameters, but also using endoscopic parameters such as mucosal inflammation and intestinal fibrostenosis.

Discourse of Interest: All authors have declared no conflicts of interest.

### Results:

Inflammatory Bowel Disease Questionnaire (s-IBDQ) as well as a questionnaire regarding disease activity and QOL has been provided. The s-IBDQ score at follow up (p < 0.001; Mann-Whitney U test). In a multivariate analysis, low serum 25(OH)D levels were related with mucosal inflammation and intestinal fibrostenosis of CD (P < 0.05; logistic regression analysis).

**Conclusion:** This study demonstrated the relationship between vitamin D level and disease activity in CD patients. The disease pathology of CD consists of repetitive intestinal inflammation and intestinal fibrostenosis formed during healing and inflammation. We consider it important to demonstrate this relationship not only using clinical parameters, but also using endoscopic parameters such as mucosal inflammation and intestinal fibrostenosis.

**Introduction:** Inflammatory Bowel Disease (IBD), mainly represented by Crohn’s Disease (CD) and Ulcerative Colitis (UC), is a chronic, relapsing and remitting disease impairing patients’ quality of life (QOL). To maintain a high QOL and to decrease the inflammation burden, it is important to tightly monitor the disease and promptly treat relapses when they occur. The quality of care perceived by IBD patients plays an important role in the management of IBD. An eHealth web application consisting of a validated Fecal Calprotectin (FC) home testing kit (Calpro Smart™), questionnaires regarding disease activity and QOL has been developed to improve disease monitoring, patient empowerment and patient-caregiver communication.

**Aims & Methods:** The aim of this study was to evaluate patient satisfaction with an eHealth home monitoring solution during the participation in a one year trial. The trial includes 120 adult IBD patients which have been randomized into two groups, one performing a disease activity screening procedure every 3 months (3M) and one screening only at the patient’s discretion, on demand (OD). Both groups used the web-program where they were requested to fill out a disease activity questionnaire, Harvey-Bradshaw Index (HBI) for CD or Simple Clinical Colitis Activity Index (SCCAI) for UC, and perform a home testing of FC. The FC measurement is a sensitive marker of disease activity in IBD and FC home testing can be performed either using the home-monitoring kit (3M-C6) or a one time kit (OD-C6). In a web-program rendering a Total Inflammation Burden Scoring (TIBS) which is visualized to the patient in a traffic light manner for instant recommendation of treatment strategies. At baseline and upon completion of the trial the patients were requested to fill out a QOL questionnaire (Short-Inflammatory Bowel Disease Questionnaire (s-IBDQ)) as well as a questionnaire regarding their overall satisfaction with the trial and the home monitoring solution.

**Results:** To date, 83 patients have been included, 15 patients have dropped out (7 in OD-group and 8 in 3M-group) and 68 (3M-group: n = 32, 47%; OD-group: n = 36, 53%) patients have fulfilled the first year of follow-up and were included in the analysis. The trial lived up to the expectations in n = 63, 93% (3M-group: n = 29, 91%; OD-group: n = 34, 94%) of the patients and the support given to the patients was estimated to be sufficient by n = 67, 99% (3M-group: n = 31, 97%; OD-group: n = 36, 100%). Only n = 14, 21% (3M-group: n = 6, 19%; OD-group: n = 8, 22%) of the patients experienced difficulties with the application or the home testing kit and n = 64, 94% (3M-group: n = 29, 91%; OD-group: n = 35, 97%) wanted to continue to be monitored in an eHealth setting in the future. The mean s-IBDQ scores at baseline were 58 (95% CL: 55–61) in the 3M-group and 54 (95% CL: 50–58) in the OD-group as well as 58 (95% CL: 54–62) in the 3M-group and 61 (95% CL: 58–64) in the OD group at one year follow up.

**Conclusion:** Patients in both groups were generally satisfied by the home monitoring set up. Patients in the on-demand group also presented a significant increase in quality of life over time.

Skeletal muscle atrophy is a predictive factor for intestinal resection in patients with Crohn’s disease

Introduction
Sarcopenia defined as low SMI were observed in 44% of all IBD patients (29% in CD, 54% in UC). In UC patients, the O-PNI, CONUT, height and albumin were significantly lower than the CD patients. Spearman’s rank correlation is used to identify sarcopenia. The cumulative operation-free survival rate was significantly lower among patients (P = 0.047) were the significant factors predicting intestinal resection. The cumulative operation-free survival rate was significantly lower among sarcopenic patients in all IBD patients (P = 0.009) and stratified analysis in CD patients (P = 0.032) using Kaplan-Meier method and log-rank test.

Conclusion: The L3 skeletal muscle area can be a prognostic factor of intestinal resection in IBD, especially in CD. The results may originate from the fact that CD patients present with inflammatory diseases which accumulate intestinal deformity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Background: Sarcopenia is a common condition associated with aging, malnutrition, chronic diseases, and various types of cancer. It is characterized by a progressive loss of muscle mass and strength, leading to impaired mobility, increased risk of falls, and decreased quality of life. Sarcopenia is strongly associated with poor outcomes in patients with inflammatory bowel disease (IBD), highlighting the importance of identifying and treating this condition to improve patient outcomes.

Aims & Methods: We aimed to assess the correlation between (TST/booster) and QFT in a population of IBD patients. We compared the prevalence of latent tuberculosis infection (LTI) before anti-TNF therapy by screening with QuantiFERON-TB (QFT) and the usefulness of repeating periodic (annual or biannual) screening in a population of IBD patients of Zamora (Spain). In a single cohort of IBD patients attended in the department of gastroenterology of Zamora Hospital, we implemented a questionnaire and collected TST/booster performed previously to February 2015. Afterwards, prospectively, between February 2015 to February 2017, TST and QFT were performed at the 1st and 2nd line of immunomodulator treatment. Additionally, the correlation between (TST/booster) and QFT was performed.

Results: A total of 404 patients were included with a mean age of 51.5 (SD 16.6), 225 (55.7%) male and 179 (44.3%) female. 227 patients (56.2%) were ulcerative colitis, 167 (41.3%) were Crohn disease and 10 (2.5%) were diagnosed of indeterminate colitis. 160 patients live in rural areas (40.6%), 60/355 (16.9%) were non-smokers. The prevalence of LTI and the correlation between TST/booster and QFT is shown in table 1.

Table 1: Prevalence of LTI and correlation between TST/booster and QFT.

Conclusion: The present study is the first to confirm the previously identified score and to test its power to predict a mild disease course as indicated by the need of not more than mesalamine therapy. Additional analyses include the percentage of patients with a score indicating a severe disease and their characteristics at diagnosis. This interim analysis presents preliminary data.

Results: Currently, 78 patients (33 male, 45 female; age 16-72, mean 35 years) with newly diagnosed CD are enrolled. 56 CD-patients with follow up ≥2 weeks (mean 8.5 months), mean age 35 years, 35 female, 21 male, CRP 12.2 mg/l were included into the interim analysis. In 28 patients a score from 0-2 step-up treatment occurred in 7%, whereas in 28 patients with a score ≥3 step-up rate was 43% (p = 0.0034). Differences between patients with a score 0-2 and ≥3 were (age 41 vs. 28 years, p = 0.0011), CRP ≥2 mg/l (17/28 patients vs. 0.28, p < 0.0001), endoscopy score 1.4 vs. 2.7, p < 0.001), perianal lesion ≥128 vs. 4/28, stenosis 1/8 vs. 6/28. There were no differences in terms of sex, fistula, extraintestinal manifestations and lever.

Disclosure: This early analysis of a prospective study planned with a 5-year follow-up is a significant proportion of patients with mild CD and simple mesalamine therapy can be identified. These initial results encourage to continue and expand this prospective long-term study on the predictability of a mild CD course.

Aims & Methods: We have conducted a retrospective study on 61 IBD patients who have admitted due to exacerbation of the disease. We have enrolled IBD patients who had abdominal computed tomography and assessed the nutritional indices, such as the Onodera’s prognostic nutritional index (O-PNI) and control-ling nutritional status (CONUT). O-PNI was calculated based on the serum albumin and total lymphocyte count, using the following equation: O-PNI = 10 × (serum albumin (g/dl) + 0.005 × total lymphocyte count (ml/l)). The L3 skeletal muscle index (SMI) which is the cross-sectional area of the skeletal muscle at the level of the third lumbar (L3) vertebra normalized by the height squared is used to identify sarcopenia.

Results: The L3 skeletal muscle area can be a prognostic factor of intestinal resection in IBD, especially in CD. The results may originate from the fact that CD patients present with inflammatory diseases which accumulate intestinal deformity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We aimed to assess the correlation between (TST/booster) and QFT in a population of IBD patients. Prevalence of LTI in retrospective testing was of 54/246 (22.0%). Prospective testing of 276 (CFAST) patients with known quiescent small bowel CD, after the follow-up, up, 30/191 (15.7%) patients who were negative for screening before 2015 were converted in positive for LTI (95% CI [10.2-21.1]).

Conclusion: The prevalence of LTI in our area is high (32.6%). The simultaneous presence of CAPST and QF in CE increases the detection of LTI. The TST booster increases the detection of LTI even when is performed in patients without immunosuppressive treatments, in whom is not routinely recommended. The QFT is more useful in patients without immunosuppressive therapy. The results in patients recruited over the two years is useful in this population with high prevalence of LTI, since it may detect LTI in patients with previous negative tests (15.7%). The TST booster is essential due to the possible false negatives of QFT when screening patients on anti-TNF therapy.

P0351 MAGNETIC RESONANCE ENTEROGRAPHY GLOBAL SCORE ALLOWS FOR ACCURATE QUANTIFICATION OF SMALL BOWEL INFLAMMATION IN CROHN’S DISEASE- A COMPARISON WITH CAPSULE ENDOSCOPY

1 Diagnostic Imaging, Sheba Medical center, Ramat Gan/Israel
2Gastroenterology Department, Sheba Medical Center, Ramat Gan/Israel
3Chaim Sheba Medical Center, Tel Aviv University, Tel Aviv/Israel

Contact E-mail Address: ukopylov@gmail.com

Introduction: Magnetic resonance enterography (MRE) and capsule endoscopy (CE) are prime modalities for evaluation of small bowel in patients with Crohn’s disease (CD). However, detection of proximal (jejunum and proximal ileum) small bowel inflammation by MRE is challenging. Current quantitative scores such as Magnetic Resonance Index of Activity (MaRIA) do not incorporate proximal small bowel data and were validated against ileocolonoscopy. Magnetic resonance enterography global score (MEGS) was designed for quantitative evaluation of the entire digestive tract; however, it was only validated against ileocolonoscopy and its accuracy in the proximal small bowel was not assessed. CE allows for accurate assessment of the entire small bowel and is the modality of choice for evaluation of the proximal small bowel.

Aims & Methods: We aimed to compare the quantitative evaluation of the small bowel inflammation by MEGS score and the Lewis capsule endoscopy score. Patients with known quiescent small bowel (CD) for at least 3 months (CDAI <150) were prospectively recruited and underwent magnetic resonance enterography (MRE) and capsule endoscopy (CE). MEGS score was calculated for each bowel segment and the entire small bowel. MEGS is based on the involved segment length, wall thickness, mural enhancement, mural and peri-mural edema and extra-intestinal findings. In addition, MARIA score was calculated for the terminal ileum. Small bowel inflammation on CE was quantified using the Lewis score (LS) (LS < 135= mucosal healing; LS ≥ 790 = moderate to severe inflammation). Proximal small bowel was defined as jejenum and duodenum on MRE and as 1st and 2nd tertiles LS on CE. Distal small bowel was defined as terminal ileum on MRE and 3rd tertile LS on CE. Fecal calprotectin (FCP) levels were measured and correlated with all scores.

Results: Fifty-two patients were included in the study. There was a strong correlation between MEGS and LS (Pearson correlation = r = 0.61, p = 0.001) for the general population. Studies have provided conflicting evidence on the performance of interferon-gamma release assays (IGRAs), compared to tuberculin skin test (TST) in inflammatory bowel disease (IBD) patients. The primary outcome was concordance between TST and IGRAs. Secondary outcomes were effects of immunosuppressive therapy on both TST and IGRAs. Immunosuppression was defined as either steroids more than 5 mg for at least two weeks, thiopurine, methotrexate or cyclosporine. We used the Mantel-Haenszel method for a pooled random effects analysis. The pooled concordance between the TST and IGRAs was 85% (95% confidence interval [CI] 81%-88%, p = 0.01). Effects of immunosuppression on both tests were reported in eight studies including 814 patients with IBD. The odds ratio of testing positive for TST increased from 1.0 to 1.57 if immunosuppressed (95% confidence interval [CI] 0.31–1.03, p = 0.06). The odds ratio of testing positive by TST if immunosuppressed was 1.14 (95% confidence interval [CI] 0.61–2.12, p = 0.69). Using the fixed effect model yielded similar results, however the effect size of immunosuppression on IGRAs reached statistical significance (p = 0.06 to 0.01).

Conclusion: While concordance was 85% between TST and IGRAs, the performance of IGRAs seems to be negatively affected by immunosuppression. Given the importance of detecting latent TB prior to anti-TNF initiation, using only IGRAs should be avoided in immunosuppressed IBD patients.

**P0345 THIOPURINE MAINTENANCE THERAPY FOR IBD: WHICH IS THE BEST METHOD TO MEASURE MEDICATION ADHERENCE?**

A. Ochieng, V. George, C. Selinger
Gastroenterology, St James Hospital, Leeds/United Kingdom

**Contact E-mail Address:** odouriph@nhs.net

**Introduction:** For the majority of patients with IBD long-term therapy is required to maintain remission, yet 30–45% of patients do not adhere to their IBD medication. Medication adherence can be assessed with prescription refill rates, biological markers (metabolites, trough levels), and patient self-reports. There is currently no accepted gold standard and the feasibility and utility of different adherence assessment tools in the routine outpatient clinic setting have not been fully examined. The aim of this service improvement project was to test the acceptability of self-report tools assessing thiopurine adherence in the IBD clinic and to correlate the results with thioguanine-nucleotide (TGN) levels.

**Aims & Methods:** Consecutive outpatients on thiopurine maintenance therapy for IBD for >3 months were recruited from clinic. Patients self-reported adherence using the validated Morrisky adherence tool (MOR) and the validated Medication Adherence Report Scale (MARS). TGN levels were classified as complete non-adherence (<100 and MMP low), partial adherence (TGN 100–235 and MMP low) or full adherence (>235 or MMP high). Correlation analysis was performed using Pearson tests.

**Results:** Of 100 approached patients none refused participation and TGN levels were available for 69. These included 38 women. Diagnoses were Crohn’s disease in 27, ulcerative colitis in 41 and IBD-U 3 cases. Concomitant therapy included 5/ASA (25 cases), anti-TNF (13 cases) and Vedolizumab (2 cases). The proportion of adherent patients was according to the relevant report tool 71% (TGN), 87% (VAS), 87% (Morisky) and 77% (MARS). VAS (Pearson 0.315; p = 0.005) and Morisky (Pearson –0.363; p = 0.001) correlated moderately with TGN, but MARS (Pearson 0.09; p = 0.39) did not. The 7 patients, who were non-adherent by TGN were detected by VAS in 3, Morisky in 6 and MARS in 3 cases. However, patients showing non-adherence according to self-report tools had higher TGN levels in 6 of 10 cases for VAS, 10 of 26 for Morisky and 4 of 15 for MARS.

**Conclusion:** Self-report tools provided a patient-friendly and inexpensive way of assessing adherence, but the correlation with TGN levels was only moderate. While providing a more objective assessment TGN levels are problematic for routine use in all patients. TGN require a more invasive and expensive approach. Furthermore, TGN cannot detect “white coat adherence” (patients take medication only around appointments), which is the most likely explanation for normal TGN levels in patients reporting to be non-adherent. Neither TGN levels nor self-report tools can be seen as the gold standard at present.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** donalthe83@gmail.com

**Introduction:** Anti-TNFa therapies have improved outcomes in patients with inflammatory bowel disease. Their use has been associated with improved clinical outcomes, reduced hospitalisation and reduced costs. However secondary loss of response (LOR) to both infliximab (IFX) and adalimumab (ADA) is a significant problem, leading to further flares of disease, disease progression and poorer outcomes. Therapeutic drug monitoring (TDM), which involves measurement of an anti-TNFa drug, its metabolites, or another index of the drug, offers the opportunity of exploring an immune basis behind LOR, and potentially adjusting doses or switching therapies to help regain clinical response.

**Aims & Methods:** The aim of this study was to evaluate whether TDM can help predict secondary LOR to infliximab and adalimumab and whether dose adjustments based on this information can help patients regain clinical response. The study was a prospective, single-centre, observational study from April 2015 to April 2016, at our institution. Patients with Ulcerative colitis (UC) and Crohn’s disease (CD) were enrolled, if they were clinically (based on Harvey-Bradshaw Index (HBI) or partial Mayo scores) felt to be experiencing a secondary LOR to either infliximab or adalimumab maintenance therapy. Patients with available biochemical markers measured, including CRP and albumin. In addition assessment of inflammation took place, with measurement of SES-CD and Mayo scores, for CD and UC respectively. Anti-TNFa trough and antibody levels were performed using ELISA techniques. Patients were followed for a one-year period, from their initial assessment for secondary LOR to assess outcomes.

**Results:** 46 patients were recruited, 40 CD with Harvey-Bradshaw Index (HBI) >4 points and 6 patients with UC with Partial Mayo Score (PMS) >2 points. Mean age was 40.8 years, 26 (56.5%) were female. Severe flare of disease was 9.8 years, 3.8% were smokers, 71.5% on immunomodulators, and 11 (23.9%) had prior anti-TNFa exposure. 17 (48.6%) were on an adalimumab maintenance dose of 40 mg every other week. Overall HBI for the majority was <1.9, partial Mayo Score <3.6. Patients were followed for a one year period, following secondary LOR of SES-CD was 8.5, Mayo endoscopy score 2.7. Mean adalimumab trough level was 4.5 μg/ml and 15/36 (42.9%) had a sub-therapeutic trough level less than 1 μg/ml. 9 patients (25.7%) had antibodies to adalimumab. Mean infliximab trough level was 8.1 μg/ml and 2/20 (10%) had sub-therapeutic trough levels, none with antibodies. Higher baseline adalimumab trough levels, were noted in patients who were well or who had functional symptoms at one-year follow-up compared to patients, who were unwell, and required change in therapy, mean trough 6.4 μg/ml (IQR 2.1–10.3) compared to 2.9 μg/ml (IQR 0.3–6.3) (p = 0.0265 95% C.I. 0.4 to 6.5). The area under the curve [AUC] for association of ADA level at secondary LOR with a good outcome was 0.766, p = 0.037. In addition a trough level of 3.5 μg/ml predicted clinical response at one year, following secondary LOR to adalimumab, with a sensitivity of 85.7% and a specificity of 81.8%. Similarly for infliximab higher baseline trough levels, were noted in patients who were well at one-year follow-up compared to those who required change in therapy. Partial Mayo Score <1.75 (p = 0.04) versus 1.5–16.8) versus 4.5 (p = 0.005 95% C.I 4.5 to 18.3). The therapeutic strategy chosen for each group was: 23.9% no change in treatment, 26.1% increase anti-TNFa dose or decrease infusion interval, 19.6% switch to another anti-TNFa drug, 15.2% switch to non anti-TNFa (ustekinumab). For patients who had doses adjusted, clinical response (decrease of HBI ≤ 3 points for CD) was reached in 77.8% of patients and remission (HBI ≤ 4 for CD) in 55.6% at the end of follow-up.

**Conclusion:** Secondary LOR to anti-TNFa therapy has a significant impact on patient outcomes. Therapeutic drug monitoring is helpful for predicting secondary LOR and for facilitating dose adjustment or switch in therapy in a clinically guided fashion.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Diagnostic delay seems to be common in inflammatory bowel disease (IBD), especially in Crohn’s disease (CD). We sought to investigate the diagnostic delay in Austrian IBD patients and to identify associated risk factors as well as the impact of delayed diagnosis on the risk of intestinal surgery in CD.

**Aims & Methods:** In a multicentre cohort study adult patients with IBD (CD, UC) attending 19 Austrian outpatient clinics were recruited between May 2014 and July 2015 to evaluate diagnostic delay in Austrian IBD patients and to identify associated risk factors as well as the impact of delayed diagnosis on the risk of intestinal surgery in CD.

**Results:** Overall, 102 patients were enrolled in the study (Table 1). The median diagnostic delay was longer in CD (6 months) than in UC patients (3 months) and was associated with older age at diagnosis.

**Conclusion:** The median diagnostic delay was longer in CD (6 months) than in UC patients (3 months) and was associated with older age at diagnosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Enterobacteria, especially adherent and invasive E. coli (AIEC), are suspected to play a key role in Crohn’s disease (CD). These bacteria are able to highly adhere to the ileal mucosa of CD patients through the CEACAM6 receptor (Caricnomembrnic antigen-related cell adhesion molecule 6). It has been shown that therapies targeting enterobacteria and/or AIEC could be more effective in mice overexpressing CEACAM6. In this line, the overexpression of CEACAM6 in the ileum as well as the presence of AIEC in the ileum could be potential biomarkers to select the patients who could benefit from drugs targeting the host-pathogen interaction. Unfortunately, the identification of these biomarkers is time-consuming and invasive highlighting the need for more convenient alternative.

**Aims & Methods:** We aimed to assess the correlation between the level of CEACAM6 in the saliva and the level of CEACAM6 in the ileum in CD patients and to define the best threshold of CEACAM6 in the saliva to detect overexpression of ileal CEACAM6. In addition, we attempted to identify non-invasive biomarkers of AIEC infection. In this prospective multicentre study (8 centers), all the patients requiring ileocolonoscopy, regardless the indication, were consecutively included from December 2015 and September 2016. Clinical and endoscopic data were collected on the day of colonoscopy. Blood samples, stool samples (before bowel cleansing), saliva and ileal biopsies from healthy and diseased patients were also collected. CEACAM6 from ileal biopsies was measured (duplicates) using ELISA assays. AIEC were identified using phenotypical assays.

**Results:** Overall, 102 patients were enrolled in the study (Table 1).

B3 Perianal lesions
B4 Prior intestinal resection
B5 Current therapies
ileal CEACAM6 level did not depend on disease severity or the site of biopsy: the median level of ileal CEACAM6 was 3515 pg/mg [570.3–3164] and there was no difference in ileal CEACAM6 level between UC patients with active disease (median 151.6 pg/ml, range 121.6–216.1) and patients with inactive disease. A negative correlation between serum FGF19 levels and ileal CEACAM6 (ρ = 0.47; p = 0.001) was determined in both macroscopically healthy areas (ρ = 0.53, p < 0.0001) and ulcerated areas (ρ = 0.39, p = 0.0082). Using a ROC curve, we determined the best threshold of CEACAM6 in saliva for detecting ileal AIEC bacteria. Using a ROC curve (area under the curve (AUROC) = 0.73), the cut-off value of 3800 pg/mg demonstrated the best performance to detect ileal CEACAM6 overexpression with substantial specificity (76.0% [54.9–90.6]) and positive predictive value (67.5% [74.9–93.5]). The number of enterobacteria was increased in CD patients with prior intestinal resection (562 [201674] vs. 116 [0;752] pg/mg, p = 0.03). Interestingly, the number of enterobacteria was also increased in AIEC positive-patients (640 [193279] vs 60 [0;1029] pg/mg, p = 0.004). Using a ROC curve, we determined the best threshold of enterobacteria in the ileum to detect the presence of ileal AIEC bacteria. We found an area under the curve (AUROC) of 0.70 (0.61; 0.77). The cut-off value of 60 cfu/biopsy demonstrated the best performance to detect the presence of ileal AIEC bacteria. The number of enterobacteria associated to ileal mucosa (cut-off value >60 cfu/biopsy) strongly predicted the presence of AIEC and then is a reliable test for AIEC screening with very high negative predictive value (94.1% [80.3–99.3]) and high sensitivity (91.7% [73.0–99.9]).

Conclusion: CEACAM6 measurement in the saliva is feasible, non time-consuming and non-invasive. It could be a reliable test to detect the overexpression of CEACAM6 in the ileum from CD patients and could then be proposed as a non-invasive biomarker to select patients who might benefit from anti-adhesive therapies. In addition, we identify the number of enterobacteria associated to the ileum is a convenient and reliable test to screen CD patients for AIEC bacteria.

References
Introduction: Increasingly, immunosuppressive medications such as azathioprine and biologics are being used in order to promote clinical remission of inflammatory bowel disease (IBD) patients. It has been reported that such treatments increase the risk of developing all types of skin cancer. Education of these patients is key in order to promote their awareness of their increased risk and it is vital for gastroenterologists to counsell patients on sun protection strategies on initiating therapy. We recently performed a pilot study in this group which highlighted gaps in their knowledge of the increased risk and prevention strategies. We speculate clinician’s lack of knowledge was partly to blame.

Aims & Methods: Our aim was to determine Irish IBD clinicians’ knowledge of the skin cancer risk and advised photoprotective behaviours in this cohort. Cross-sectional descriptive study. We invited IBD clinicians via email to fill in an anonymous online survey designed to assess knowledge of skin cancer risk and preventative strategies. The survey included questions about their grade of training, experience, awareness of specific immunosuppressant risk, their knowledge of specific immunosuppressant risk was suboptimal; while they were more knowledgeable about prevention strategies. The majority knew what constitutes an at-risk mole; 100% (n = 45) knew there was a higher risk of developing NMSC for patients with a history of sunburn. The majority knew that sun protection is effective in reducing NMSC risk; 93% (n = 42) knew a personal history of skin cancer increased risk of skin cancer was reassuring; with all 45 (100%) knowing sun protection is a key preventative measure. Aims & Methods: To date, 45 Irish Gastroenterology clinicians completed the online questionnaire. Of these, fifteen (33%) were consultants, fourteen (31%) gastroenterology trainees, four (9%) general medical trainees and twelve (27%) IBD nurse specialists. Overall, clinician’s knowledge of general factors associated with increased risk of skin cancer was reassuring; with all 45 (100%) knowing sun beds increased skin cancer risk and almost 100% (44, 98%) knew working outdoors incurred increased risk. 42 (93%) knew a personal history of skin cancer and previous blistering sunburn were risks; however, only 34 (79.1%) recognised family history as a risk. Regarding gender associated risk; only 67.4% (n = 29) knew men were greater risk than women of non-melanoma skin cancer (NMSC). Their knowledge of specific immunosuppressant risk was suboptimal; while many (37, 82%) recognized azathioprine was a risk factor for developing NMSC. The majority (45, 100%) knew anti-TNF agents were strongly associated with an increased risk of malignant melanoma. Regards prevention strategies; the majority knew what changes to look for in a suspicious mole; 100% (n = 45) knew to be suspicious of changing color and 84% (n = 38) of an irregular border, but shockingly only 11% (5) perform yearly skin checks on their patients taking immunosuppressants. Their knowledge of preventative measures was also lacking; 37 (86%) knew patients should wear SPF 50 but almost half (47% n = 20) thought it should be applied twice daily rather than two hourly (51% n = 23) and only 47% (n = 20) knew patients should stay in the shade from 11am-3pm. Regards their own practice; 39 (87%) report they emphasise the importance of sun protection in their patients; however, worryingly only 24 (55.8%) had heard of our national skin cancer prevention guidelines “Sunsmart”. Of interest; while physicians had a greater understanding of patient risk factors (p < 0.05), nurse specialists were more likely to emphasise the need for sunprotection in clinic (p < 0.0003), and of physicians, trainees had a more complete knowledge of all advised preventative measures (p < 0.03).

Conclusion: Our study highlights IBD clinicians’ suboptimal knowledge of immunosupPRESSION risk and their lack of emphasis on preventative measures and skin examination in clinics. A targeted educational and awareness programme may address this.

Department Of Gastroenterology, North Zealand University Hospital, Frederiksvaer/Denmark

Contact E-mail Address: dorit.vedel.ankersen@regionh.dk

Introduction: Due to the chronic and progressive nature of inflammatory bowel disease (IBD) it is of significant importance to detect and treat a relapse as soon as possible in order to decrease the total inflammation burden and avoid progression of intestinal damage, and possibly improve the disease course. A validated Fecal Calprotectin (FC) home testing kit and smart phone application CalproSmartTM have been added to an existing eHealth web-application, enabling patients to monitor their disease activity using clinical scores and FC from home with results shown on their smart phone. eHealth allows for tight monitoring of disease activity, however, the frequency of an optimal screening procedure for adult IBD patients has not yet been determined.

Aims & Methods: The aim of this one-year randomized controlled trial of 120 adult IBD patients, was to determine if an eHealth screening procedure for disease activity should be implemented in clinical practice ‘every 3 months, 3M’ or according to patients own gut feeling, ‘on demand, OD’. Both groups used the eHealth-program to tightly monitor their disease activity either OD or 3M (29%). CD group was divided according to the Montreal classification: 20/93 (22%) patients had B1 phenotype, 19/93 (20%) B2, 20/93 (21%) B3 and 34/93 (37%) B2 + B3. Perianal involvement was present in 27/93 (29%). L1 involvement was present in 15/93 (16%), L2 in 14/93 (15%) and L3 in 10/93 (10.8%). regards the FC screening procedure, no difference in FC home measurements pr. patient was similar in the two groups OD 6.7 (95% CL: 5.2–8.2) vs. 3M 7.3 (95% CL: 5.9–8.5), p = 0.52. Median (range) AUC for FC and disease active scores were not significantly different in the groups (OD, 3M): 62016 (3782-541338) vs 89730 (10286-335881) p = 0.71, 549 (0.3726) vs 610 (0.2844) p = 0.61. In this preliminary study, no difference between the two screening procedures was found in regards to disease course and resource utilization. A slightly but non-significant reduction in no of FC measurements pr. patient used in OD-group relative to 3M-group could argue for an economical benefit of implementing the OD screening procedure. Long-term results are awaited.

All authors have declared no conflicts of interest.

Reference

Conclusion: Association of serum $\text{S100A4}$ protein with $\text{UC}$ and $\text{CD}$ was confirmed. In CD, disease behaviour did not have an impact on serum concentration of $\text{S100A4}$ protein. In CD, higher levels of serum $\text{S100A4}$ were observed in patients with ileo-colonic and colonic involvement compared to those with isolated small bowel involvement.

Acknowledgments. The study was supported by the Research Project PROGRES Q40–15 from Charles University.

PO364 SEVERE VITAMIN D DEFICIT IN ACTIVE INFLAMMATORY BOWEL DISEASE

2Department Of Internal Medicine And Medical Specialties, Sapienza University of Rome, Rome/Italy

Contact E-mail Address: piero.vernia@uninorma.it

Introduction: Hypovitaminosis D is common in Inflammatory Bowel Disease (IBD) patients. Some studies suggest that the finding may relate to severity of the disease.1

Aims & Methods: The aim of the study was to determine the Vitamin D (VitD) status in an Italian IBD cohort in relation to disease activity. Serum 25-hydroxyvitamin D was measured in 260 IBD outpatients, not supplemented with VitD for at least 3 months. VitD status was defined as adequate $\geq 20$ ng/ml, insufficient $10$–$19$ ng/ml, and deficient $<10$ ng/ml. Disease activity in $\text{IBD}$ patients was assessed by Harvey Bradshaw Index (HBI) in $\text{CD}$ and Crohn’s Disease Activity Index (CDAI) for $\text{CD}$ and Mayo partial score for $\text{UC}$. Chi square, T test and linear correlation were used when appropriate.

Results: IBD patients were at higher risk of VitD deficiency (defined as $<20$ ng/ml) than controls ($\text{OR} 4.5$, $95\% \text{CI} 2.9$–$6.9$, $p<0.001$). Of 260 IBD patients, 156 ($60\%$) had VitD deficiency, more often in $\text{CD}$ than in $\text{UC}$ ($72.7\%$ vs $48\%$, $p<0.001$). HBI score was significantly related to VitD deficiency ($r=0.37$, $p=0.001$).

Conclusion: VitD deficiency is significantly more common in IBD patients than in controls, more so in $\text{CD}$. Patients with active disease are more likely to have VitD deficiency than those in remission. The correlation with activity indexes should be confirmed in larger series.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: stack.roisin@gmail.com

Introduction: Small bowel (SB) Crohn’s disease (CD) strictures can comprise of both inflammatory and fibrotic elements. An accurate tool to discriminate fibrotic from inflammatory disease would be clinically useful to guide therapy and predict treatment. Gastroduodenal involvement was defined by considering macroscopic (erosions, ulcers or stenosis) and microscopic criteria (focal gastritis, cryptic irregularity, erosion ulceration and granuloma in the absence of Helicobacter pylori (HP) infection).

Results: We included 140 patients - phenotype: $50\%$ inflammatory, $31\%$ stricture and $19\%$ penetrating; Location: $42\%$ ileal, $45\%$ ileocolic and $13\%$ colic.

Conclusion: The prevalence of gastroduodenal involvement by CD in this sample was $18\%$, and a larger percentage have macro/microscopic findings that are not disease specific. The prevalence of symptoms does not predict gastroduodenal involvement due to CD that is associated with a worse prognosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO366 GASTRODUODENAL INVOLVEMENT IN PATIENTS WITH CROHN’S DISEASE – UPPER ENDOSCOPY ONLY IN SYMPTOMATIC PATIENTS?

Contact E-mail Address: mafalda_en_p sousa@hotmail.com

Introduction: The need for upper endoscopy in patients with Crohn’s disease (CD) with upper symptoms is controversial. The aim of this study was to establish the prevalence of gastroduodenal involvement, regardless of symptoms, and its prognostic implications.

Aims & Methods: Patients from a single centre with established $\text{CD}$ ($n=347$) were retrospectively evaluated – inclusion criteria: upper endoscopy without treatment. Gastroduodenal involvement was defined by considering macroscopic (erosions, ulcers or stenosis) and microscopic criteria (focal gastritis, cryptic irregularity, erosion ulceration and granuloma in the absence of $\text{Helicobacter pylori}$ (HP) infection).

Results: We included 140 patients - phenotype: $50\%$ inflammatory, $31\%$ stricture and $19\%$ penetrating; Location: $42\%$ ileal, $45\%$ ileocolic and $13\%$ colic. Upper endoscopy was performed in $19\%$ for symptoms and in $81\%$ for staging. Gastric macroscopic findings were detected in $49\%$ ($69/140$); the most common were erosions ($21\%$) and erythematous mucosa ($18\%$). Biopsies were performed in $56\%$ of patients: chronic gastritis $66\%$, normal $23\%$, granuloma $5\%$, focal gastritis $2\%$ and cryptic microabcesses $2\%$. HP was positive in $25\%$ of patients. In the duodenum, endoscopic lesions were observed in $33\%$ of the patients ($46/140$); the most common were erosions ($16\%$) and ulcers ($9\%$). Biopsies were performed in $32\%$ and the most prevalent findings were chronic non-specific inflammation $62\%$, ulcers $17\%$, granuloma $3\%$ and erosion $3\%$. Applying macro/microscopic criteria, gastroduodenal involvement by CD was considered in $18\%$ of the patients and was not correlated with the presence of symptoms, phenotype or localization of the disease. The prevalence of gastroduodenal involvement was a significant predictor of hospitalization.

Conclusion: The prevalence of gastroduodenal involvement by CD in this sample was $18\%$, and a larger percentage have macro/microscopic findings that are not disease specific. The presence of symptoms does not predict gastroduodenal involvement due to CD that is associated with a worse prognosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO367 INCIDENTAL FINDINGS AT CT ENTEROGRAPHY IN PATIENTS WITH CROHN’S DISEASE: CLINICAL SIGNIFICANCE AND IMPACT ON TARGETED THERAPY

R. Morais1, S. Lopes2, I. Piza3, F. Magro4, G. Macedo5

1Gastroenterology, Centro Hospitalar São João, Porto/Portugal
2Centro Hospitalar São João, Porto Medical School, Porto/Portugal

Contact E-mail Address: ruimorais20@gmail.com

Introduction: CT enterography is one of the most accurate imaging methods for evaluating Crohn’s disease (CD) extent and intestinal involvement.

Aims & Methods: The aim of the study was to determine the frequency and clinical impact of the incidental findings in CD patients who underwent CT enterography. This was a retrospective study that evaluated patients with CD who underwent CT enterography between January 2012 and December 2016. Incidental findings were defined as previously unknown extraintestinal lesions. The orientation of the patients after their detection was evaluated.
Results: A total of 520 patients who underwent CT enterography were identified, with a median age of 43 (32-53)% and 53% were women. The main indication for CT enterography was CD staging (81%). A total of 531 incidental findings were detected (median of 2 [1–3] per patient). The main findings identified were hepatic nodules (n = 39), hepatic cysts (n = 55) and sarcoidosis (n = 46). The findings implicated orientation to another medical specialty in 80 patients (29%), the main ones being Urology (n = 14) and Gynecology (n = 11). The findings implied additional exams in 59 patients (21%). Five (2%) underwent subsequent surgical intervention. Clinically relevant findings were found in 38 patients (14%), including 2 renal tumors, 2 ovarian teratomas and 3 cases of primary sclerosing cholangitis. The detection of incidental findings implied a change in CD therapy in 9 patients (3%); one suspended biologic therapy, 2 suspended immunomodulator therapy and 6 initiated biologic therapy.

Conclusion: Incidental findings are relatively common in patients with CD who undergo CT enterography. A significant proportion is clinically relevant and may involve change CD therapy. A risk stratification may be important to avoid morbidity associated with unnecessary examinations to assess benign situations.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO0368 CLINICAL SIGNIFICANCE OF ASYMPTOMATIC CLOSTRIDIUM DIFFICILE CARRIAGE IN PATIENTS ON IMMUNOMODULATOR FOR INFLAMMATORY BOWEL DISEASE

S.T. Law, W.M. Yip, K.K. Li
Department Of Medicine And Geriatrics, Tuen Mun Hospital, Hong Kong/Hong Kong Pre

Contact E-mail Address: stil168@hotmail.com

Introduction: Clinical significance of asymptomatic Clostridium difficile (C. difficile) carriage in patients on immunomodulator for inflammatory bowel disease (IBD) is largely unknown. [1, 2]

Aims & Methods: The aim of this study was to investigate the clinical implication of asymptomatic carriage of C diff in IBD patients.

Consecutive IBD patients on immunomodulators in clinical remission for the past six months were prospectively recruited from the IBD clinic since 2013. Those cases were excluded if they had past history of total colectomy, the dosage of their immunomodulators were titrated according to their disease activity in the past six months or the types of their immunomodulators were other than azathioprine, mercaptopurine or methotrexate.

Stool specimen for C. difficile cytotoxin real-time polymerase chain reaction (RT-PCR) assay was obtained to all eligible patients at the time of enrolment and every follow-up during the study period. Patients were monitored for any IBD flare-up in which if happened, an additional stool specimen for C. difficile cytotoxigenic RT-PCR assay was obtained.

The primary outcomes were the disease activity which was graded by Crohn Disease Activity Index (CDAI) in Crohn disease (CD) (graded as follows: <150: remission; 150–<220: mild-moderate; 220–<450: moderate-severe; >450: severe). Ulcerative colitis Disease Activity Index (UC-DAI) in ulcerative colitis (UC) (graded as follows: the total index score ranges from 0–12; 0: remission; 3–6: mild; 7–10: moderate; >10: severe UC). The secondary outcomes were proportion with C. difficile diarrhea which was defined in the patients with active lower gastrointestinal symptoms accompanying with positive RT-PCR assay of C. difficile at that instant.

Statistical inference of the variables was examined by Mann-Whitney U and χ2 test for numerical and categorical parameters respectively.

Results: Of 197 IBD patients (CD: 98 (49.75%); male: 132(67.01%); age (yr): median 43, minimum 17, maximum 79), 9(4.57%; CD: 6 patients) patients were found to be asymptomatic carriage of C. difficile during the study period. The demographic features, including age, gender ratio, smoking history and the duration of IBD, of the patient group with and without asymptomatic carriage of C. difficile were comparable each other. Four UC patients in the non-carriage group had prior history of anti-TNF exposure in which three were treated as maintenance therapy for the active disease activity, associated axial spondylarthropathy and rectovaginal fistula while the other two patients (one from each group) had received three doses of anti-TNF as rescue therapy for severe disease flare-up.

Incidence rates of the disease flare-up were comparable (11.17 vs. 22.22%, p 0.313) between the non-carriage and carriage groups in which all these flares were under-controlled by course of high-dose prednisolone.

The asymptomatic carriage group had a significant higher rate (33.33 vs. 7.45%, p 0.007) and earlier onset (18.78 vs. 34.42 months, log rank p 0.009). Mann-Whitney U, p.0.037) in evolving into clinical C. difficile infection as compared with the non-carriage group.

No other serious complications, such as toxic megacolon, colonic perforation, sepsis, and death, were reported in the both groups during the study period.

Clinical characteristics of the IBD patients with and without asymptomatic carriage of C. difficile

Data were expressed as median(interquartile range)

*: all are UC cases and 3 for maintenance therapy with indications as follows: refractory colitis, spondyloarthropathy, rectovaginal fistula

**: case of UC received 3 doses of anti-TNF for severe flare

Abbreviation: IBD, inflammatory bowel disease; C. difficile, Clostridium difficile; ulcerative colitis, UC; ns, non-significant

Conclusion: The incidence of asymptomatic carriage of C. difficile in the IBD patients on immunomodulators was not common. It did not associate with the disease flare-up but a significant portion of them could evolve subsequently into clinical infection.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO0369 BOWEL ULTRASOUND IS USEFUL IN DISEASE MONITORING OF ULCERATIVE COLITIS PATIENTS: FIRST ANALYSIS FROM THE TRUST&UC STUDY IN GERMANY

C. Maaser1, F. Petersen, U. Helwig2, A. Rössler3, D. Lang4, S. Rath4, T. Kucharzik5, O. On Behalf Of The Trust&UC Study Group

Contact E-mail Address: christian.maaser@klinikum-lueneburg.de

Introduction: Due to the relapsing and highly variable nature of ulcerative colitis (UC), it would be desirable to have reliable tools for measuring parameters of disease activity, in monitoring the disease course, and response to therapy. Clinical parameters (e.g. CRP, fecal calprotectin) and the Simple Colitis Clinical Activity Index (SCCAI) were used for routine assessment of disease activity. In recent years it has already been shown that ultrasound (US) is a useful tool to monitor the disease activity. The hypothesis of the TRUST&UC (TRansabdominal UltraSonography of the bowel To monitor disease activity in subjects with Ulcerative Colitis) study is that transabdominal US is an easy to use, easily repeatable, and accurate diagnostic tool in the assessment of UC activity, in monitoring the disease course, and response to therapy.

Aims & Methods: TRUST&UC is a German ongoing prospective, observational multi-center study in patients with active UC. The primary objective of this study is the prospective evaluation of bowel wall US in response to therapy in order to assess its value in monitoring UC patients in routine medical practice. Clinical parameters (e.g. CRP, fecal calprotectin) and the Simple Colitis Clinical Activity Index (SCCAI) were used for routine assessment of disease activity.

Results: 176 patients with active UC have been enrolled in 37 German IBD study group (GISG) centres until February 2017. 47.2% of the patients were female, median age was 38.9 years (range 19–77) with median disease duration of 152.2 days (range 6odie/17). Of all the patients with a clinical flare defined by SCCAI >90.3% showed a bowel wall thickening (BWT), and only 9.7% showed no US signals. At US examination, a BWT in the colon sigmoidium was present in 87.5% of the patients, in the colon descendens in 83.7%, in the colon transversum in 42.3% and in the colon ascendens in 18.3%. Loss of bowel wall...
stratification was the case in 20.6% of the patients, mesenteric fibro-fatty pro-
liferation more than 50%, had increased signal in the color Doppler US. At baseline systemic steroids were used in 62.1%, azathioprine in
36.2%, and TNFα antagonists in 40.0% of patients (N = 174). All follow-up patients (N = 104) displayed acute inflammatory symptoms at baseline with moderate disease activity which required an introduction or escalation of treatment. After 12 weeks, the US examination showed signif-
icant improvements of the following parameters: BWT in colon sigmoideum (87.5% vs 33.7%, p = 0.034) and colon transversum (42.3% vs 15.4%, p = 0.012), loss of haustration (54.8% vs 33.7%, p < 0.001), ascites (9.7% vs
2.9%, p < 0.001), mesentric lymphadenopathy (31.6% vs 14.3%, p = 0.005), mesentric fibro-fatty proliferation (40.0% vs 10.0%, p = 0.041) and increased signal in color Doppler US (56.7% vs 23.1%, p = 0.039). A decrease of BWT was significantly accompanied by a decrease in SCAI (8.0 to 1.5 points, p < 0.001).

Conclusion: In this real-life cohort almost 90% of the patients showed a BWT, a pivotal IBD symptom and within 12 weeks selected bowel US parameters improved significantly from treatment intensification. Therefore, US examination is a useful tool to monitor disease activity and response to therapy in UC patients.

P0370 THE GUT MICROBIOME IN IBD IS CHARACTERIZED BY IMPAIRED METABOLIC COOPERATIVITY AND CAN BE RESTORED UPON ANTI-TNFα THERAPY

K. Aden1, A. Rehman1, W.H. Pan2, S. Waschima3, J. Zimmermann1, J. Bethge4, A. Franke5, A. Nikolaus5, J.O. Schröder1, R. Zeuner1, C. Kaleta6, S. Schreiber1, P. Rosenstiel1

Introduction: Blocking TNFα is an important treatment option for inflammatory bowel disease (IBD). The etiology of the disorder comprises a permanent activation of immune cascades and imbalanced cytokine networks. Evidence has been put forward that alteration of the human gut microbiota may play a critical role in the pathogenesis of IBD. However, the impact of targeted cytokine blockade on dysbiosis and intestinal microbial communities is poorly understood. Here, we investigate the effect of anti-TNFα treatment on gut microbial community structures in a prospective, longitudinal study for 30 weeks. The study compares IBD as a disorder, which primarily affects the gut, with seropositive and -negative rheumatoid arthritis, a disease characterized by chronic inflammation and hyperproliferative bone formation.

Results: Intestinal microbial diversity and cooperativity are decreased in both disease entities, IBD and RA. In IBD, anti-TNFα therapy is able to restore microbial diversity and cooperativity. More over cooperative metabolic interaction is significantly increased only in anti-TNFα responders. In RA, anti-TNFα therapy did not significantly restore microbial community structures.

Conclusion: We show that anti-TNFα treatment increases the gut microbial diversity and coupling of cross feeding metabolic interactions towards the state of healthy individuals. Assessment of metabolic interactions of intestinal microbiota may serve as a marker for clinical response in IBD patients.

P0371 SELF-MONITORING OF THE COLONIC INFLAMMATORY BOWEL DISEASE BY A RAPID HOME BASED FEACAL CALPROTECTIN TEST AND A SYMPTOM QUESTIONNAIRE

A. Puolanne1, M.A. A. Färkkila1, K. Kolho2

1Clinic Of Gastroenterology, Helsinki University Hospital, Helsinki/Finland
2Pediatric Gastroenterology, University of Helsinki Children’s Hospital, Helsinki/Finland

Contact E-Mail Address: anna-maija.puolanne@hus.fi

Introduction: Faecal calprotectin (FC) is a most reliable noninvasive means to distinguish remission from active inflammation in inflammatory bowel disease (IBD). It is a quick, commercially available FC tests are time-consuming, and consequently new rapid tests have been validated. As the incidence of IBD is increasing, self-
monitoring and eHealth technologies have been evaluated in managing patients with this lifelong disease.

Aims & Methods: The aim of this prospective study was to evaluate the feasibility and cost-effectiveness of a semi-quantitative rapid FC home test and a validated symptom questionnaire, in patients with colonic IBD. The influence of the self-
monitoring to the course of the disease will also be evaluated. Between April 2015 and December 2016, 180 patients with colonic IBD (126 with UC, 47 with CD, and 7 with IBD unclassified) were included in the study and randomized in a study group and control group. Patients in the study group were instructed to perform the FC home test and fill in a symptom questionnaire every other month and with increasing of the symptoms, and sent the results to the study/IBD nurse by e-mail. The control group patients filled in the symptom questionnaire at baseline and at 12 months and with the appointment to the outpatient clinic according to normal practice. The patients were not reminded of performing the stool tests or filling in the questionnaires. The study period was 12 months, and it is still ongoing.

Results: By the end of February 2017, 134 of the 180 included patients had completed the 12 months’ follow-up. In the study group, 20/91 (22%) patients had performed the stool tests and filled in the symptom scores according to the study protocol for 6 months, and 49/115 (43%) patients for 12 months. In the control group, 49/89 (56%) patients had filled in the symptom score at baseline and 9/89 (11%) at 12 months. There was a significant difference of the adherence between patients stratified for IBD-diagnosis, age, or sex. The satisfaction of the patients with the program as well as the reasons for the discontinuation of the study and influence of self-monitoring in the number of relapses, phone calls, e-mails, and appointments to the outpatient clinic was evaluated in both groups. It is still ongoing.

Conclusion: The self-monitoring of IBD activity with a rapid FC home test provides an option for individualized treatment for increasing amount of IBD patients. However, in this study the adherence to the self-monitoring program was low. The patients need to be reminded of performing the stool tests and filling in the questionnaires in time. Also, the selection and education of the patients, as well as the easy accessibility of the monitoring program are crucial and need further consideration.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Although the incidence of ulcerative colitis (UC)-related colorectal cancer (CAC) is increased in cases with long duration of disease, it should also be recognized that sporadic tumors (ST) develop as older. Various studies have been conducted on CAC, but there are few clinical studies on ST merged with UC. In
A291

United European Gastroenterology Journal 5(5S)
this study, the clinical and endoscopic features of CAC and ST, treatment
method, and prognosis are compared.
Aims & Methods: Among 261 UC patients who underwent colonoscopy (CS) and
had neoplastic lesions, the clinical features, treatment and prognosis were compared between 71 patients (88 lesions) with CAC (including HGD; CAC group)
and 47 patients (63 lesions) who underwent local excision (surgical or endoscopic
resection) within the presence of the past/present inflammation of UC (ST
group). Definition of CAC and ST was performed by conventional pathological
and immunohistochemical findings.
Results: The age of UC onset (29.8 vs. 39.0) and tumor detection (45.5 vs. 57.3) in
the CAC group were significantly higher than those in ST group (p 5 0.01). The
CAC group (47.1%) has a higher percentage of chronic persistent type than the
ST group (2.3%), and the Mayo endoscopic score is also significantly higher
(p 5 0.01) in the CAC group (1.43) than ST group (0.38). The percentage of
advanced cancer (35.2% vs. 7.9%) was higher in CAC group than ST group.
In patients with intraepitherial neoplasia (IEN) or submucosal lesions, flat lesion
was found in 15 lesions of CAC group and whereas no flat lesion was observed in
ST group. Only one lesion in ST group could not distinguish the lesions from the
surrounding mucosa without magnifying colonoscopy. In ST group who received
resections, 4 patients after resections observed ectopic CAC or low-grade dysplasia during follow-up. In CAC group, 50, 5, 4 patients received total colectomy,
local colectomy, ESD, respectively, whereas in ST group, 1, 7, 40, 15 patients
received total colectomy, local colectomy, EMR and polypectomy, ESD, respectively. Although mortality from cancer was 11.4% (8/70 cases) in CAC group,
group, no death due to cancer observed in patients whose lesions were found as
IEN. On the other hand mortality from cancer was 2.1% (1/47 cases) in ST
group.
Conclusion: Most sporadic lesions were endoscopically distinct and local resection was safe if inflammation was controlled. After the sporadic lesions were
resected in remitting UC patients, regular surveillance colonoscopy is necessary
because 8.5% (4/47) of patients was found CAC/dysplasia. Even in CAC group,
prognosis is well in patients with IEN.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Accelerated treatment strategy, including tight disease control and
early aggressive therapy with immunomodulators (IM) and biological agents
have become increasingly common in IBD.
Aims & Methods: The aim of the present study was to estimate the early treatment strategy and outcomes in newly diagnosed patients with Crohn’s disease
(CD) diagnosed between 2004–2015 in Hungary based on the administrative
database of the National Health Insurance Fund (OEP). We used the administrative database of the National Health Insurance Fund (OEP), the only nationwide state-owned health insurance provider in Hungary. Newly diagnosed CD
patients were identified through previously reported algorithms using the ICD-10
codes for Crohn’s disease in the out-, inpatient (medical, surgical) non-primary
care records and drug prescription databases between 2004–2015. Patients were
stratified according to the year of diagnosis and maximum treatment step during
the first 3-years after the diagnosis.
Results: A total of 6173 (male/female: 46.12%/53.87%) newly diagnosed CD
patients were identified during the observational period. Maximum treatment
steps did not differ in patients diagnosed before and after 2009 (5-ASA: 11.7%
vs, 13.5%, steroid 31% vs. 30.5%, IM 40.4% vs. 40.2%, biologicals 16.5% vs.
15.6%). Probability of hospitalizations during the first 3-years from diagnosis
was lower according to the maximal treatment step in patients diagnosed after
2009 (at 36 30-day period: overall 55.7% vs. 47.4% (p ¼ 0.000), anti-TNF: 73%
vs. 66.7% (p ¼ 0.103), IS: 64.6% vs. 56.1% (p ¼ 0.000), steroid: 44.2% vs. 36.8%
(p 5 0.007), 5-ASA: 32.6% vs. 26.7% p ¼ 0.157)), respectively. In contrast, surgery rates were not different according to the maximum treatment step (at
36 30-day period: overall 16.0% vs. 15.3% (p ¼ 0.672) anti-TNF 26.7% vs.
27.2% (p ¼ 0.993), IS: 24.1% vs 22.2% (p ¼ 0.565), steroid 8.1% vs. 7.9%
(p ¼ 0.896), 5-ASA 10% vs. 11% (p ¼ 0.816)).
Conclusion: Distribution of maximal treatment steps and surgery rates was not
different in patients diagnosed before and after 2009, although immunosuppressive and was commenced earlier. Of note, steroid and 5-ASA remained high after
2009. Maximal treatment steps were associated to hospitalization and surgery
rates, suggesting that maximal treatment steps can be used as proxy marker of
severity in CD. Hospitalization rates during the first 3-years after the diagnosis
decreased in all treatment groups, suggesting a change in the patient
management.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0373 CAN WE PREDICT THE LACK OF RESPONSE TO
CYCLOSPORINE AS SECOND LINE THERAPY IN PATIENTS WITH
ACUTE SEVERE COLITIS REFRACTORY TO CORTICOSTEROIDS?
H. Aya, B.S. Aida, H. Bassem, J. Hanen, E. Nour, B.M. Imed, A. Salem,
B. Ahlem, K. Mehdi, J. Ali
Gastroenterology, University Hospital Sahloul, Sousse/Tunisia
Contact E-mail Address: aya_med@hotmail.fr
Introduction: Acute severe colitis (ASC) is a dangerous clinical condition that
requires intensive intravenous (iv) corticoisteroids treatment. Nevertheless, about
30–40% of patients fail to response. Intravenous cyclosporine is an effective
rescue therapy in steroid-refractory patients.
Aims & Methods: The aim of our study was to identify the clinical and biological
predictive factors of lack of response to cyclosporine as second-line therapy in
patients with ASC recfractory to IV corticosteroids.
Results: Our study included 52 females and 38 males, with a mean age of 35 years
[14–70 years]. There were 34 patients with Crohn’s disease and 56 diagnosed with
ulcerative colitis. Among the 90 patients enrolled, 68 patients (75.5%) had a good
reponse to cyclosporine. Eleven petients were non responders and underwent
colectomy. In univariate analysis, more than 6 bloody stools per day before
initiation of cyclosporine therapy, a C-Reactive Protein (CRP) greater than
45 mg/l prior to treatment, and at day 3 and 7 of treatment by ciclosporine
(p ¼ 0.007; 0.002 and 0.001 respectively), ESR greater than 30 mm at day 3 of
treatment (p ¼ 0.05), thrombocytosis at day 3 of treatment (p ¼ 0.05), a Lichtiger
colitis activity index scoring greater than 10 at day 3 of treatment (p ¼ 0.001) and
the need for blood transfusion (p 5 0.0001) were significantly correlated with the
lack of response to cyclosporine therapy. In a multiple linear regression analysis,
only a CRP greater than 45 mg/l on day 7 of treatment, and the necessity of
transfusion were predictive factors of no-response to cyclosporine (p ¼ 0.008).
Conclusion: Cyclosporine therapy is rapidly effective in preventing surgery in
patients with ASC with a response rate of 75.5%. A high CRP on day 7 of
treatment with cyclosporine and the need for transfusion, predispose to poor
reponse to intravenous cyclosporine.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Numerous studies have shown that mesenchymal stromal cells
(MSCs) have a high potential for differentiation and immunosuppressive properties. Currently under phase I-III clinical trials evaluating the efficacy and safety
of MSCs in the treatment of patients with inflammatory bowel disease - ulcerative colitis and Crohn’s disease.
Aims & Methods: We aimed to compare the frequency of relapses and duration of
remission for 5 years of follow up in patients with luminal Crohn’s disease (CD)
and the total defeat of ulcerative colitis (UC) receiving therapy with mesenchymal stromal cells (MSCs), bone marrow. We compared the frequency of relapses
in patients with luminal form CD (colitis and ileokolit), with a group of patients
with UC (total lesion) receiving MSCs. A group of patients (CD) aged 22 to 56
years (Me-28) (n ¼ 24) received MSC culture scheme (0-1-2 weeks, then every 26
weeks). The second group of patients with UC (n ¼ 26) aged 20 to 62 years (Me28) received the culture of MSCs in a similar way. Evaluation of the effectiveness
of therapy for relapse frequency was carried out at 12, 24, 36, 48 and 60 months
after initiation of therapy.
Results: Among the patients in 1st group relapse in the 12 months of observation
occurred in 2/24 patients (8.3%) in 2nd group, relapse occurred in 3/26 (11.5%)
(OR-0.72; 95% CI 0, 13–3, 96, p ¼ 0.92). After 24 months in the group of patients
(group 1) receiving MSC, relapse occurred in 5/24 (20.8%) in group 2 patients
with recurrent disease in 7/26 (26.9%) (OR 0.77; 95% CI 0.13–3.96, p ¼ 0.92).
After 36 months in group 1 patients with a relapse of the disease in 8/24 (33.3%)
in group 2 relapsed in 14/26 (53.8%) (OR-0.62; 95% CI 0.32–1.21; p ¼ 0.24).
After 48 months in group 1 receiving MSC, relapsed in 11/24 (45.8%) in
group 2 relapsed in 18/26 (69.2%) (OR-0.6; 95% CI 0.37–0.97, p ¼ 0.048).
After 60 months in 1st relapse in 16/24 (66.6%) in group 2 relapsed in 22/26
(84.6%) (OR0.63; 95% CI 0.44–0 90, p ¼ 0.013).
Conclusion: MSCs transplantation longer contributes to clinical remission in
patients with Crohn’s disease luminal shape compared to a group of patients
suffering from ulcerative colitis.
Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Perianal fistulas are the most widespread and common types of fistulas in Crohn’s disease (CD). They are difficult to treat, worsen the quality of life of the patient and increase the risk of bowel resection. Despite the significant effect of anti-cytokine therapy fistulous forms of CD, treatment of these patients remains a difficult task with high risk of relapse of CD. Mesenchymal stromal cells have immunomodulatory properties and a large regenerative potential, at present also used for treatment of fistulous CD and perianal fistulas of different etiologies.

**Aim & Methods:** We aimed to compare the efficacy of combined therapy (local and systemic) mesenchymal stromal cells (MSCs) of bone marrow, infliximab (IFX) and anti-immunosuppression (IS) on the rate of healing of simple perianal fistulas in Crohn’s disease. 36 patients with Crohn’s disease with perianal lesions were divided into three groups depending on the method of therapy. The first group of patients aged from 19 to 58 years (Me-29) (n = 12) received culture of MSCs systemically via the scheme and locally; on the perimeter of the fistulas introduced 40 million -4.0 pg/ml of saline containing 10 million live cells. After 4 and 8 weeks treated 40 million MSCs in the area of the fistula. The second group of patients with CD (n = 10) aged 20 to 68 years (Me-36) were receiving anti-cytokine therapy of IFX. The 3rd group of patients with CD (n = 14) aged 20 to 68 years (Me-28) received antibiotics and is in the dynamics evaluated the closure of the fistula opening. The results were compared with controls.

**Results:** After 12 weeks among patients of the 1st group simple healing of fistulas was observed in 10/12 patients (83.3%), in the 2nd group healing simple fistulas have a 8/10 (80.0%) (OR=0.83; 95% CI 0.44-1.49; p = 0.72). In the 3rd group – patients 4/14 (28.6%) (OR - 0.47; 95% CI 0.2-1.11; p = 0.12 in comparison with the 1-st group). After 6 months in the 1st group patients receiving MSCs, healing of simple fistulas persisted in 8/12 (66.7%) with the 2nd group - 7/9 (70.0%) (OR - 1.1-11; 95% CI 0.32-3.84; p = 0.76). In the 3rd group – patients 4/14 (28.6%) (OR - 0.47; 95% CI 0.2-1.11; p = 0.12 in comparison with the 1-st group). After 12 months in the 1st group receiving MSCs, healing of simple fistulas maintained in 8/12 (66.7%), in the second group - in 6/10 (60.0%) (OR - 1.25; 95% CI 0.48-3.22; p = 0.69). In the 3rd group in 2/14 patients (14.3%) (OR=0.04; 95% CI 0.24 to about 0.98; p = 0.03 in comparison with the 1st group. After 12 months among the patients of the 1st group, the closure of the fistula in 10/12 patients (83.3%), in the 2nd group - 5/6 (83.3%), in the 3rd group - 0/14 patients (0.0%) (OR = 0.38; 95% CI 0.36-0.94; p = 0.01 in comparison with the 1st group).

**Conclusion:** Combined stem cell and anti-cytokine therapy of CD with perianal lesions is more effective in the prolonged closure of simple fistulas, compared with antibiotics/immunosuppressant.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Conclusion: V565, an oral domain antibody (Vorabody) to TNF engineered to be serum sample (LLoQ 62.5 ng/ml).

66–82% of an administered dose was recovered from ileostomy bags when MT subject 31003; and 125MTs (1260 mg) 2 h post dose from subject 31004. Overall, were not analysed for V565 as this was a post hoc analysis and the MTs were not

31001 – 406 306 0.8 0 0 0 0
31002 – 33 1130 792 82 13 5(ave) 0
31003 – 1060 496 7 0 38(ave) 0
31004 – 126 0.2 11 4 1 0 0

In addition to the V565 concentrations in ileal fluid, partially dissolved MTs were recovered from the ileostomy bags of all subjects. Each 166.5 mg dose contained a total of 135 MTs. 50 MTs were recovered 2h post dose from Subject 31001; these were not analysed for V565 as this was a post hoc analysis and the MTs were not stored in a way to enable reliable analysis. 64MTs (containing 135 mg V565) were recovered 3h post dose from subject 31002; 78MTs (458 mg) 3h post dose from subject 31003 (72MTs) 4h post dose from subject 31004 (19MTs). The ileal fluid was not sampled from subject 31002 who was withdrawing from ileostomy bags. MT concentrations were added to ileal fluid concentrations. V565 was not detected in any serum sample (LLOQ 62.5 ng/ml).

Conclusion: V565, an oral domain antibody (Vorabody) to TNF engineered to be resistant to intestinal proteases, delivering high concentrations of active compound in the ileal fluid following oral administration to human volunteers. The oral domain antibodies (Vorabodies) are delivered via enteric coated mini-tablets (MTs) designed to release active drug at pH 6.5.

Aims & Methods: Following prior placebo-controlled demonstration of the safety and tolerability of high single and multiple doses of V565, this open label assessment was performed to confirm the delivery of active domain antibody to the terminal ileum of human subjects. Four subjects with a terminal ileostomy were given a single oral dose of V565 and ileostomy bags were collected hourly for the first 12 h post dose with further collections 16, 20 and 24 h post dose. Contents were analysed for V565 concentrations by competitive ELISA. In addition, serial blood samples were taken for determination of V565 serum concentrations over 24 h.

Results: Four subjects with an ileostomy (3 with UC; 1 with a prior history of UC in remission) of ileostomy were demonstrated in the ileal fluid of all four subjects as shown in Table 1 below.

**Micromolar concentration of V565 in ileal fluid**
obviously evaluated by the IBD validated Functional Assessment of Chronic Illness Therapy-Fatigue Scale (FACIT-F).

**Aims & Methods:** The main objective was to assess the efficacy of electroacupunture (EAc) vs. sham EAc and no treatment for treating fatigue in patients with quiescent IBD in a single-blind randomized trial. Secondary objectives were to assess changes in quality of life, depression, anxiety and sleepiness after treatment with EAc.

**Methods:** Fifty-two patients with quiescent IBD and severe fatigue (FACIT-F < 40) (65.3% female, mean age 42 years) were randomized to EAc vs sham acupuncture group. Patients in the sham EAc group performed a total of 9 acupuncture sessions during eight weeks (2 sessions/first week and one session per week during the after treatment periods).

**Results:** Both EAc and Sham group improved the FACIT-F score post-treatment (EAP — 5.35 points, 95% CI [—13.2 to —6.75, Basal Vs 9th session p < 0.001]; Sham — — 9.7 to —2.06, Basal Vs 9th session p = 0.003; depression (8.9 points, 95% CI [4.13 to 13.8, Basal Vs 9th session p = 0.002], anxiety (10.6 points, 95% CI [3.6 to 17.6, Basal Vs 9th session p = 0.006) and sleepiness (1.46 points, 95% CI [0.096 to 2.83, Basal Vs 9th session p = 0.038). However, the differences in between EAc and sham and control groups were not significant (p > 0.05).

**Conclusion:** Both targetted and sham electroacupuncture are effective in managing fatigue in patients with quiescent IBD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Anti-TNF, such as adalimumab (ADA) and infliximab (IFX), have improved the therapeutic care of Crohn’s disease (CD). However their use may be associated with loss of efficacy, adverse events and sometimes primary failure. At the current time, it is possible to switch to another anti-TNF. In France, three anti TNF are available in ulcerative colitis (IFX, ADA and golimumab), but only the first two are approved in CD, because golimumab has not been studied in this indication. The aim of this study was to report golimumab efficacy and safety in CD.

**Aims & Methods:** This national multicenter retrospective study included patients with CD from 12 French tertiary centers who received golimumab and analyzed: clinical response, duration of treatment, tolerance, reasons for discontinuation of treatment, adverse phenotype, and treatments preceding and associated with golimumab. The main endpoint was the efficacy of golimumab defined by the duration of treatment before failure (need for therapeutic optimization or cessation). Predictive factors of therapeutic response were determined (log rank and Cox model), and the tolerance was evaluated.

**Results:** One hundred and fifteen patients with a median duration of the disease of 13.5 years received on average golimumab in 3, 6 th line of biotheraphy. The overall clinical response assessed by the physician was 55.8% at the time of the re-evaluation (on average, at 3.8 months [0.6–24] after initiation of therapy). The median duration of treatment was 12 months (0.55–48.7). Sixty-seven percent of patients received treatment for more than 6 months and 48.7% of patients were still treated with golimumab at the end of the follow-up. At 12 months, 34.9% of patients still received golimumab without optimization. At 24 months, this figure was 18.1%. In univariate analysis, the factors associated with a longer golimumab treatment duration without stopping or optimizing were the active smoking status (p = 0.043), the absence of anoperineal lesions (p = 0.012), the presence of extra-intestinal symptoms (p = 0.035), the presence of a co-immunosuppression of more than 6 months (p < 0.001) and discontinuation of the first anti-TNFa for intolerance (p = 0.022). In multivariate analysis, discontinuation of the first anti-TNFa for intolerance and the presence of co-immunosuppression with thiopurine derivatives or methotrexate over 6 months were independently associated with golimumab efficacy (OR 2.16, 95% CI [1.25–3.66], p = 0.005 and OR 3.98:95% CI [2.3–7.1], p < 0.001, respectively). Side effects led to discontinuation of treatment in 6% of patients. These were paradoxical psoriasi in three patients, paresthesia (n = 1), lower extremity edema (n = 1), injection site reaction (n = 1) and not reported reason for discontinuation (n = 1). The causes for discontinuation of the first anti-TNFa was an intolerance.

**Conclusion:** After failure of the other anti-TNF agents, golimumab is well tolerated and results in sustained clinical response in one in two patients with Crohn’s disease, particularly when associated with a co-immunosuppressant, and if the reason for discontinuation of the first anti-TNFa was an intolerance.

**Aims & Methods:** The purpose of this survey was to determine physicians’ familiarity and comfort level with prescribing biosimilars to patients. The survey was sent to physicians residing in the European Union and specializing in the following clinical fields: dermatology, endocrinology, gastroenterology, neurology, oncology, and rheumatology.

**Introduction:** Biologic medicines and their biosimilar counterparts are effective therapies for many conditions, including inflammatory bowel disease, Crohn’s disease and ulcerative colitis. The European Medicines Agency (EMA) has approved twenty-two biosimilar medicines, which are derivatives of eight original biologics, and four more biosimilar are scheduled to be reviewed this year. As the number of approved biosimilars rises, regulatory agencies must closely monitor their safety and efficacy.

**Results:** The majority of survey respondents specialized in endocrinology (19%) and gastroenterology (19%). Respondents were recruited almost equally from the five countries, with France being the most represented country (22%) and the UK being the least represented (18%). The majority of respondents (55%) indicated that safety and efficacy is the most important factor in determining whether a patient should be switched from a prescribed biologic therapy to its approved biosimilar. Thirty percent of respondents indicated that clinical trials related to the switch were the condition being treated was the most important factor to switching. Only 12% of respondents indicated that cost to the government or insurance companies is a primary concern, and less than 1% were currently involved in this activity.

**Conclusion:** This survey suggests that the safety and efficacy of biosimilar medicines is of paramount importance to physicians and that physicians highly value clinical trial data for biosimilars. Given that biosimilars are structurally distinct from their original innovator biologic counterparts, the EMA should consider requiring more stringent clinical trials data for biosimilars seeking approval. Specifically, the EMA should require clinical trials for each proposed indication and should provide physicians with this data so that physicians can make informed prescribing choices for the safety of their patients.

**Introduction:** Oral steroids are effective in inducing remission of moderate flares of patients with either ulcerative colitis (UC) or Crohn’s disease (CD). However, we know little about their efficacy in immunosuppressed patients or their possible role in reducing biologics and/or surgical needs in these patients.
Aims & Methods: We aimed to determine the efficacy of systemic or low bioavailability immunosuppressives (IMM) for moderate flares of patients with at least 6 months of immunosuppressive treatment, and describe long-term follow-up outcomes. The final long-term postmarketing registry (PYRAMID) evaluating long-term safety and effectiveness of adalimumab (ADA) was an international, multi-center, non-interventional registry. Patients with and without prior ADA experience were allowed to enroll. The final long-term registry included 10,032 patients with IBD (Crohn’s disease, ulcerative colitis, and IBD unclassified). The mean (SD) duration of exposure to ADA was 27 (13) months. The most common primary indications for treatment were perianal disease (57%), abdominal surgery (25%), and smoke habit (32%).

Results: Among the 5025 patients evaluated in the registry, 2057 (40.9%) were ADA-naïve patients (those who had not received ADA before registry enrollment) with moderate to severe Crohn’s disease (CD) who were treated according to the local product label. The aims of this analysis were to describe 1) the efficacy of systemic or low bioavailability immunosuppressives in ADA-naïve patients and 2) the benefits and risks of ADA use in clinical practice, including meaningful improvements in disease activity, work productivity, and quality of life.

Conclusion: At 1 year after entering the international postmarketing registry of ADA use in routine clinical practice, clinically meaningful improvements in disease activity, work productivity, and activity impairment were achieved in ADA-naïve patients with moderately to severely active CD. These improvements were maintained for up to 5 years after registry enrollment, as demonstrated by 2) the benefits and risks of ADA use in clinical practice, including meaningful improvements in disease activity, work productivity, and quality of life.

P0386 EFFECT OF ADA LUMABAM ON CLINICAL AND HEALTH-RELATED QUALITY OF LIFE OUTCOMES BY DISEASE SEVERITY AND PRIOR TUMOUR NECROSIS FACTOR INHIBITOR USE IN PATIENTS WITH ULCERATIVE COLITIS IN A CLINICAL PRACTICE SETTING

SUBGROUP ANALYSES FROM INSPIRADE

1. University Hospitals of Cleveland, Cleveland, OH, USA
2. Robarts Research Institute, Canada
3. University of Calgary, Calgary, Canada
4. Istituto Clinico Humanitas, Milan, Italy
5. AbbVie Inc, North Chicago, IL, USA
6. AbbVie Deutschland GmbH & Co. KG, Ludwigshafen, Germany

Introduction: Adalimumab (ADA) has been shown to improve clinical outcomes for UC. This analysis aimed to further evaluate ADAs effect on health-related quality of life (HRQoL) significantly in patients (pts) with ulcerative colitis (UC) in a clinical practice setting. Evidence is limited about benefits of ADA among UC pts with different characteristics.

Aims & Methods: The aim was to examine clinical and HRQoL effects of ADA in pts with UC based on disease severity and prior use of tumour necrosis factor inhibitor (TNFI). INSPIRADE details have been presented. Pts received ADA 160 mg at week (wk)0/2 followed by ADA 40 mg at wks 4 through 26. Pts who did not respond to ADA by wk 8 were to discontinue. Pts who lost response at or after wk 8 could escalate to ADA 40 mg weekly. UC pts were categorized into subgroups based on physician global assessment (PGA) of disease severity (moderate [PGA = 2] vs severe [PGA = 3]) and previous TNFI use (naïve vs experienced). Proportions of pts with Simple Clinical Colitis Activity Index (SCCAI) response (defined as a decrease of ≥2 points vs baseline) and remission (defined as an SCCAI ≤2) were calculated for each cohort at wks 2, 6, 12, 18, and 26. Change from baseline in HRQoL outcomes was calculated, including Short Inflammatory Bowel Disease Questionnaire (SIBDQ), European Quality of Life-5 Dimensions-5 Level (EQ-5D-5L), Treatment Satisfaction Questionnaire for Medication (TSQM) and Work Productivity and Activity Impairment (WPAI).

Results: Among pts with moderate UC (n = 386) and severe UC (n = 74), SCCAI response rates were 74.6% vs 74.3%, 80.1% vs 71.6%, and 67.1% vs 64.9% at wk 2, 6, 12, respectively. Although remission rates were similar between moderate and severe pts at wk 26 (49.5% vs 40.5%, p = 0.16), ADA provided greater disease control for moderate pts at wk 2 (29.8% vs 9.5%, odds ratio [OR] 4.195% confidence interval [CI] 1.8–9.1; p < 0.0001) and wk 8 (52.3% vs 31.1%, OR 2.4, 95% CI 1.1–4.4; p = 0.01) compared to severe pts (table). The rate of dose escalation (ADA 40 mg weekly) was 28.0% in moderate and 28.4% in severe UC pts. HRQoL outcomes were similar between the moderate and severe cohorts. Among pts who were naïve (n = 389) and those experienced to TNFIs (n = 72), response rates were 74.0% vs 76.4%, 79.2% vs 75.0%, and 66.3% vs 68.1% at wk 2, 6, 26, respectively. No significant difference was observed in remission rates for naïve vs experienced pts at wk 2 (28.0% vs 19.4%, p = 0.43) and wk 26 (49.4% vs 41.7%, p = 0.39), but naïve pts showed a significantly higher remission rate than the experienced group at wk 8 (52.2% vs 31.9%, OR 2.1, 95% CI 1.2–3.7; p < 0.0001). The rate of dose escalation was 26.5% in naïve pts vs 36.1% in experienced pts (p = 0.09). In general, HRQoL outcomes were similar between naïve and experienced TNFI pts.

(continued)

Conclusion: ADA treatment achieved clinically relevant rates of SCCAI response and remission even in pts who had severe UC and those who were more treatment-refractory (experienced to TNFIs), in clinical practice. In addition, ADA was associated with greater disease control in the induction period for pts with moderate than severe UC and for naïve pts than those experienced to TNFIs.

**Introduction:** Treatment with intravenous (IV) CT-P13, a biosimilar infliximab (INX) licensed for use in 80 countries, is highly effective and well tolerated. To increase treatment modalities with CT-P13 for patients, a new subcutaneous (SC) formulation was developed.

**Aims & Methods:** This phase I and open label study, conducted at a single site in Korea, was designed to evaluate safety and pharmacokinetics (PK) of SC administration of CT-P13 in healthy subjects. In a single dose escalation study, 38 subjects received either SC injection or IV infusion of CT-P13 on Day 0 and were followed for 12 weeks (2 subjects in 3 different dosages of SC; 18 subjects in 2 different dosages of IV). After reviewing safety data observed for 48 hours, the next cohort was conducted subsequently from low dose to high dose. The PK profile of SC and IV formulation was evaluated by measuring the AUC, Cmax, Tmax, and T1/2.

**Results:** A total of 38 male subjects with median age of 23 years (range 19, 30 years) received treatment-emergent serious adverse events or systemic hypersensitivity reaction. In SC cohort, two subjects experienced mild injection site reactions, and both have resolved without any treatment. Mean AUC<T> ranged from 5016.4 to 14253.6 h·ug/mL and 10.0 to 23.1 ug/mL, respectively, after a single SC injection or IV infusion of CT-P13. SC CT-P13 formulation was absorbed slower into the systemic circulation (median Tmax ranging from 7.0 to 7.1 days) in comparison with IV formulation (median Tmax ranging from 2.2 to 3.2 hours) but the drug elimination measured by half-life (T1/2) was similar (mean range 43.7 to 50.4 days vs. 11.7 to 12.2 days) between SC and IV formulations, respectively. Bioavailability of CT-P13 SC was approximately 60.6%, when comparing across all CT-P13 SC cohorts to CT-P13 IV cohorts.

**Conclusion:** PK profiles after a single SC injection were linear by dose levels. SC administration of CT-P13 is feasible in terms of bioavailability and safety profiles.

4AbbVie Inc., North Chicago/United States of America/IL

**Introduction:** Vedolizumab is a gut-selective anti-integrin biologic, vedolizumab (VDZ), has been approved since 2014. However, the real-world comparative effectiveness of VDZ and anti-TNF has not been fully investigated.

**Aims & Methods:** This study aimed to evaluate all-cause and IBD-related healthcare utilisation in IBD patients (pts) newly treated with VDZ and anti-TNFs. Using data from a large, de-identified administrative claims database in the US (Truven MarketScan® Commercial and Medicare Supplemental Databases). The date of the first VDZ/anti-TNF claim was defined as index date. New VDZ/anti-TNF treatment was defined as no claims for these agents in the 1 year before index date. All pts had ≥6 months continuous enrolment prior to and ≥6 months post-index date. All-cause and IBD-related healthcare utilisation including hospitalisation, emergency department (ED) visits and outpatient visits during 6 months post-index were examined for the IBD cohort overall, as well as in CD and UC cohorts. Multivariable logistic regression was employed to estimate the odds ratio (OR) for hospitalisation and ED visits, while Poisson regression was used to examine the rate ratio (RR) for outpatient visits with VDZ compared to anti-TNF use, controlling for demographic characteristics, index year, baseline Charlson comorbidity index (CCI) and baseline hospitalisation and ED visits 1 year prior to index date. In sensitivity analyses, outpatient visits related to infusion administration for VDZ or anti-TNF were excluded to examine the RR associated with outpatient visits that were not related to the visits for infusion procedure.

**Results:** A total of 652 and 6974 IBD pts newly treated with VDZ and anti-TNF were identified, respectively (mean age [year]; 45 VDZ vs 42 anti-TNF: male: 47% vs 48%). VDZ pts had a higher CCI than anti-TNF pts (0.7 vs 0.5). During the 6 months follow-up, compared to anti-TNF, use of VDZ had significantly higher rates of all-cause hospitalisation (16.3% vs 13.1%, OR 1.30, 95% confidence interval [CI] 1.03–1.64), all-cause outpatient visits (mean visits 45.1 vs 31.0, RR 1.39, 95% CI 1.32–1.37) and IBD-related outpatient visits (mean visits 28.1 versus 17.5, RR 1.60, 95% CI 1.51–1.69). A sensitivity analysis excluding outpatient visits related to infusion administration showed similar results for IBD-related outpatient visits (RR 1.53, 95% CI 1.44–1.62). In pts with CD, the magnitude of risk of IBD-related hospitalisation was even higher (OR 1.67, 95% CI 1.17–2.38), but no significant difference in IBD-related hospitalisation (OR 0.57, 95% CI 0.30–1.06) was observed in pts with UC. The difference in IBD-related ED visits between VDZ and anti-TNF pts was not significant in CD (OR 1.32, 95% CI 0.96–1.82) or UC (OR 0.72, 95% CI 0.40–1.29). However, the rates of outpatient visits were consistently higher in VDZ vs anti-TNF across CD (RR 1.82, 95% CI 1.69–1.96) and UC cohorts (RR 1.29, 95% CI 1.18–1.42). The results were similar in the sensitivity analyses when infusion-related visits were excluded.

**Conclusion:** In this real-world setting, VDZ treatment was shown to be associated with higher all-cause hospitalisations and outpatient services compared to anti-TNF for pts with IBD. A higher risk of IBD-related hospitalisation associated with VDZ use was observed in CD but not UC pts. Outpatient visit rates were consistently higher for VDZ users, regardless of taking into account the infusion-related visits for biologics. These results should be interpreted with caution as disease activity was not fully accounted for in this claims data analysis.

**P0389** **SAFETY OF ANTI-TNF TREATMENT IN ELDERLY PATIENTS WITH INFLAMMATORY BOWEL DISEASE**

**Introduction:** Due to population ageing and improved survival, the percentage of elderly patients with inflammatory bowel disease (IBD) is increasing. The safety
Disclosure of tumour necrosis factor antagonists (anti-TNF) treatment in this populations is ill-defined.

**Aims & Methods:** To assess the main adverse events (AE) of this therapy in the elderly population in comparison with the younger patients, we performed a retrospective cohort study of patients with IBD that initiated treatment with anti-TNF agents in 2003 and 2014, with follow-up until December 2013. Demographic, clinical and medication data were collected. AE (including opportunistic, malignancy, dermatologic, neurologic, cardiac and vascular, hepatic, infusion reactions and others) occurring during anti-TNF treatment in elderly and younger patients were analysed and both groups were compared. The severe AE definitions from Food and Drug Administration (FDA) and European Medicines Agency (EMA) were used.

**Results:** Of the 219 patients (55.3% women; average disease duration 13.60 +/- 7.55 years) 25 were older than 65 years-elderly group, mean age 70.0 year vs. younger group, mean age 41.77 years. Infliximab was used in 174 patients (on average 1585 days) and adalimumab in 93 (on average 1379 days), with a total 1106 years of anti-TNF exposure. In the elderly, aspihirine was used less frequently (P = 0.000). There were 46 severe AE overall, including 18 cancers and 16 opportunistic infections (5 tuberculosis). Malignancy (20.0% vs. 6.7%, P = 0.039) and cardiovascular events (16.0 vs. 4.1%, P = 0.036) occurred more frequently in the elderly, whereas dermatologic AE were more common in the younger group (4.0 vs. 0.0004). The number of severe AE (24.0 vs. 20.1%, P = 0.794) including death (4.0 vs. 2.6%, P = 0.521) was not significantly different between groups.

**Conclusion:** Despite being at higher risk of malignancy and cardiovascular events, the total number of severe adverse events was not significantly increased in elderly patients. Particular attention to malignancy surveillance and treatment of cardiovascular comorbidities is advised in this population.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Over the past twenty years, the introduction of biological agents into clinical practice has radically improved outcomes in patients with inflammatory bowel disease (IBD), Crohn’s disease (CD) and ulcerative colitis (UC). Tumor necrosis factor (TNF) antagonists, such as infliximab, act by preventing TNF from binding to its receptor, neutralizing its activity and alleviating mucosal inflammation. However, biological agents are much more expensive than traditional treatments, and the high cost of these drugs in the treatment of IBD imposes a considerable burden on the national healthcare system. As a result, the number of patients who have grown up on biological agents are more likely to be at higher risk in terms of quality, efficacy, and safety to already licensed biologics but are associated with lower development costs. CT-P13 (Remsima® and Inflectra®) is a biosimilar of infliximab (Remicade®), which is its reference product (RP). Both CT-P13 and infliximab RP are chimeric IgG1 monoclonal antibodies produced in cell lines derived from the same cell type of murine hybridoma. CT-P13 was authorized by the EMA in 2013 for several indications, including IBD, based on two non-inferiority trials with infliximab RP (RAA) and ankylosing spondylitis (AS). However, a number of observational studies of CT-P13 in clinical practice in both anti-TNF-naïve patients and those who have been switched from infliximab RP have been published with good results.

**Aims & Methods:** We aimed to assess the effectiveness and safety of switching to CT-P13 from infliximab reference product (RP) in patients with inflammatory bowel disease. This was a prospective single-center observational study in patients with moderate to severe Crohn’s disease (CD) and ulcerative colitis (UC). All patients were switched from infliximab RP (Remicade®) to CT-P13 treatment and followed for up to 12 months. The efficacy endpoint was the change in clinical response assessed at 3-monthly intervals, according to the Harvey-Bradshaw (HB) score and partial Mayo score for patients with CD and UC, respectively. C-reactive protein (CRP) was also measured. The Cochrane’s Q and Friedman tests were used to analyze the change in clinical scores and CRP. Adverse events were monitored and recorded throughout the study.

**Results:** A total of 98 patients with inflammatory bowel disease (67 CD/31 UC) were included. 83.6% (56/67) of patients with CD were in remission at the time of the switch and 65.3% (18/28) were in remission at 12 months. The HB score showed a significant change at 12 months (P = 0.007) but no significant change was observed at 6 months (P = 0.000). There were 15 severe AE overall, including 9 cancers, 2 opportunistic infections (1 tuberculosis), 2 hepatic, 1 infusion reactions and others) occurring during anti-TNF treatment in elderly and younger patients were analysed and both groups were compared. The severe AE definitions from Food and Drug Administration (FDA) and European Medicines Agency (EMA) were used. **Aims & Methods:** In terms of quality, efficacy, and safety to already licensed biologics but are more similar than generic drugs. As a result, interest in biosimilars has grown as biosimilar agents are highly similar to their reference products.

**Introduction:** The role of biologics in medical management of inflammatory bowel disease (IBD) has been established since anti-TNF agents invaded the market several years ago. Vedolizumab, an anti-integrin gut-selective molecule, is a more recent biologic treatment which has been approved for the management of both Crohn’s disease and ulcerative colitis. Its efficacy in inducing and maintaining remission was shown in GEMINI studies, although a good percentage of the trial participants had previously failed anti-TNFs. We conducted this study in order to describe outcomes in a real-life cohort of IBD patients who were treated with Vedolizumab, consisting both of previously anti-TNF exposed but also anti-TNF naïve patients. Multivariate analysis searched for factors associated with response to treatment.

**Aims & Methods:** All patients with IBD who received at least three doses of Vedolizumab in UCLH since the drug was officially licensed in the UK were included in the study. Demographics, clinical and endoscopic response rates were recorded and analysis was conducted in the whole cohort and in the subgroups of Crohn’s and UC patients separately. Univariate analysis and logistic regression were conducted in order to identify important associations with clinical and endoscopic response.

**Results:** 59 patients with IBD were treated with vedolizumab from May 2015 to October 2016. 28 (47%) had Crohn’s disease and the majority (n = 43, 73%) had mainly colonic inflammation (12 colonic Crohn’s, 29 UC, 2 IBDU). Median time from diagnosis to Vedolizumab initiation was 8 years (17 25%) were anti-TNF naïve (all UC) and 28 (67%) had previously failed both Infliximab and Adalimumab. 36 (61%) were on a concomitant immunomodulator (IM), either methotrexate or another IM. Patients had a clinical response to Vedolizumab based on a reduction of Harvey-Bradshaw index (HBI) from baseline ≥ 3 points for Crohn’s patients or a reduction of partial Mayo score ≥ 2 points for UC patients. The rates of response were similar in Crohn’s and UC patients while there was no difference in response according to gender, previous anti-TNF exposure, disease duration or location of inflammation. Patients on no concomitant IM were less likely to respond to Vedolizumab (Odds ratio 0.26, 95% CI 0.07–0.91, p = 0.036). 11(18.6%) patients experienced adverse events while treated with Vedolizumab, five of which were related to active IBD. There were two minor allergic reactions and two mild infections.

**Conclusion:** Clinical response to Vedolizumab was observed in two-thirds of our IBD patients, similarly in Crohn’s disease and ulcerative colitis. Concomitant IM were the only factor which was importantly associated with a higher response rate. Overall there were no serious adverse events. **Disclosure of Interest:** All authors have declared no conflicts of interest.

P0392 CORRELATION OF RELATIONSHIP BETWEEN INFliximab TRough AND ANTIBODY LEVELS WITH CLINICAL RESPONSE RATES AT COMPLETION OF INDUCTION THERAPY

D. Tigue1, S. Smith1, A. O'Connor2, B. Ryan3, N. Breslin4, D. McNamar4
1Gastroenterology Trinity Academic Gastroenterology Group (TAG), AMNCH Templeogue/Dublin/Ireland
2Trinity Academic Gastroenterology Group, Trinity College Dublin, Dublin/Ireland

Contact E-mail Address: donal.tigue83@gmail.com

Introduction: Anti-TNFα therapies have helped improved response rates, reduced complication rates, and quality of life for patients with inflammatory bowel disease (IBD). However primary loss of response (LOR) is still a big concern. Therapeutic Drug Monitoring (TDM) potential of adjust- dosing of anti-TNFα in a treat to target fashion. The end of anti-TNFα induction therapy is a key time point in the management of IBD. TDM is a useful method to help explore an immune basis behind LOR. In addition anti-TNFα trough levels are a significant predictor of future likelihood of clinical response and mucosal healing.

Aims & Methods: The aim of this study was to explore the relationship between infliximab (IFX) and adalimumab (ADA) trough and antibody levels with clinical response rates, at the end of anti-TNFα induction therapy. This was a pro-pective, single-centre study. Patients were recruited from the gastroenterology department at our centre, from July 2015 to August 2016. Inclusion criteria were all patients older than 17 years old with IBD who started treatment with anti-TNFα drugs, either infliximab or adalimumab, during the study period. Patient demographics, medication and clinical history were collected from the electronic hospital information system. Baseline clinical disease activity indexes were per-formed. HBI (Harvey-Bradshaw Index) for Crohn’s disease (CD), and partial Mayo scores for Ulcerative colitis (UC). Clinical response was defined as reduction in HBI ≤3 or reduction in partial Mayo score ≤4 and ≤30% from baseline. Anti-TNFα trough and antibody levels were measured using standard ELISA technique.

Results: 35 patients were recruited: 23 CD, 12 UC. 18 patients were treated with other induction regimes used, 5 mg/kg week 0, 2 and 6 and 160 mg, 80, mg and 40 mg every other week. 18 patients who completed induction therapy were included. Standard induction were 70.6% (n = 24), 33.3% (n = 12) for IFX. Overall trough levels were 12.5 ug/ml for IFX, and 4.4ug/ml for ADA. 71.4% had therapeutic trough levels >1 ug/ml. There was a clear link between higher anti-TNFα trough levels at the end of induction with clinical response rates. For infliximab, mean trough levels in responders was 16.4 ug/ml (IQR 8.4–22.7) versus 5.3 ug/ml (0.5–8.8) for non-responders (p value 0.026 95% CI 1.50–20.7). The area under the curve [AUC] for association of IFX level at end of induction with clinical response was 0.864, p = 0.0001. In addition a trough level of 4.8 ug/ml predicted clinical response at end of induction, with a sensitivity of 90.91% and a specificity of 67%. Similarly there was a link between higher ADA levels with clinical response, though not statistically significant (Responders mean trough 6.6 ug/ml (IQR 4.9-8.7) versus non-responders 3.0 ug/ml (IQR 0.1–7) p = 0.135 95% CI 1.24–8.43). Antibody forma-tion occurred in 6 patients (17.1%). Of the patients who had primary non-response, 18/35 (51.4%) had doses of anti-TNFα escalated, 7/17 (41.1%) for infliximab, and 11/18 (61.1%) for adalimumab. 4 patients required surgical inter- vention including colectomy.

Conclusion: Higher trough levels at the end of anti-TNFα induction are associated with improved response rates. Ongoing work will define optimal targets at this key timeframe.

6Krankenhaus der Barmherzigen Brüder, Salzburg/Austria

Contact E-mail Address: daniel.baumgart@charite.de

Introduction: A woman with ulcerative colitis (UC), compared with age-matched controls, is at higher risk of adverse outcomes including spontaneous abortion, preterm birth and low birth weight.1,2 Tofacitinib is an oral, small molecule Janus kinase inhibitor that is being investigated for UC. Tofacitinib has been shown to be foetocidal and teratogenic in both rats and rabbits at exposures 146 times and 13 times, respectively, the human dose of 5 mg twice daily (BID). There is no adequate and well-controlled studies of tofacitinib in pregnant women.

Aims & Methods: We report the pregnancy outcomes from three randomised, placebo-controlled studies (OCTAVE Induction 1, NCT01458951; OCTAVE Induction 2, NCT01458952; OCTAVE Sustain, NCT01458554) and one ongoing open-label extension study (OCTAVE long-term study, NCT01470612) of tofa-citinib monotherapy in patients (pts) with moderate to severe UC.3,4 Pregnancy outcomes following maternal or paternal exposure to tofacitinib or 5 mg BD were identified from Pfizer’s internal safety database up to 23 March, 2017, and categorised as: healthy newborn, medical termination, foetal death, congenital malformation, spontaneous abortion or pending/lost to follow-up. Trial proto- cols required use of highly effective contraception for females of childbearing potential, and study drug to be discontinued in any female pts who became pregnant.

Results: A total of 1139 unique pts (incl. placebo) enrolled in the UC OCTAVE trials, of whom 296 were females of childbearing age. There were a total of 25 pregnancies reported with exposure to tofacitinib. Of these, 11 were cases of maternal exposure, all during the 1st trimester, including: 2 (18.2%) spontaneous abortions (5 mg BD, n = 1; 10 mg BD, n = 1), 2 (18.2%) medical terminations (both 10 mg BD), 4 (36.4%) healthy newborns (all on 10 mg BD) and 3 (27.3%) born to follow up (all on 10 mg BD). Out of the 14 cases of paternal exposure, 11 (78.6%) were healthy newborns (5 mg BID, n = 2; 10 mg BID, n = 9) and 3 (21.4%) were pending/lost to follow-up (5 mg BID, n = 1; 10 mg BID, n = 2). Overall, there were no cases of foetal death or congenital malformation.
P0395 SAFETY AND EFFICACY OF GRANULOCYTE AND MONOCYTE ADSORPTIVE APERATURE IN 363 PATIENTS WITH INFLAMMATORY BOWEL DISEASE WHO HAVE SPECIAL SITUATIONS: AN INTERIM ANALYSIS OF A POST-MARKETING SURVEILLANCE STUDY

Introduction: Granulocyte and monocyte adsorptive apheresis (GMA) has been shown to be effective and safe in patients with inflammatory bowel disease (IBD). We report an interim analysis of a post-marketing surveillance study of granulocyte and monocyte adsorptive apheresis using Aducolumn® for patients with inflammatory bowel disease who have special situations (PARTICULAR).

Aims & Methods: The aim of the PARTICULAR study was to assess the safety and efficacy of GMA treatment in patients with IBD who have special situations. This study was an interim analysis of the multi-centre observational study conducted at 80 institutions in Japan. Data were collected from patients with ulcerative colitis (UC) or Crohn's disease (CD) who received GMA between November 2013 and September 2016. Patients who had at least one special situation were included in the study. GMA was performed using Aducolumn® (JIMRO, Takasaki, Japan). Each patient received up to a maximum of 11 GMA sessions. Safety assessments were performed on all patients in this study. All adverse events (AEs) during the study period were recorded. AEs for which the causality of GMA could not be ruled out were considered as side effects (SEs). Feasibility problems (FPs) included blood withdrawal difficulty, venous pressure elevation, coagulation in the apheresis system and venous access difficulty. The safety of GMA was investigated in the following six special situation subgroups: the elderly (>65 years), concomitant treatment with multiple immunosuppressants, retreatment with GMA, anaemia (haemoglobin <10 g/dL), paediatric (<18 years) and other groups. We also compared AEs, SEs and FPs between the subgroups with/without each special situation by univariate analysis. The efficacy of GMA was also assessed in patients with UC. Patients with a partial UC disease activity index score (pUC-DAI) of <3, those with missing pUC-DAI scores and those receiving concomitant treatment with infliximab, adalimumab, tacrolimus or cyclosporine were excluded from efficacy analysis. pUC-DAI scores were calculated at the baseline and 3.4 after the final GMA session. Remission was defined as a pUC-DAI score of ≤2 with no individual sub-score exceeding 1 point. Patients who received additional treatment by the final GMA session, including infliximab, adalimumab, tacrolimus and cyclosporine, were considered non-responders to GMA.

Results: This study included 363 patients (304 UC, 59 CD). Among these patients, SEs and FPs were observed in 3.9%, 10.7% and 16.3% of the patients, respectively. There were 105, 112, 83, 49 and 39 patients in the elderly, concomitant treatment with multiple immunosuppressants, retreatment with GMA, anaemia, paediatric and other groups, respectively. The incidence of AEs was significantly higher in patients on multiple concomitant immunosuppressants compared with those not receiving them. Likewise, the incidence of AEs was significantly higher in patients of the anaemia group compared with patients with haemoglobin ≥10 g/dL. The incidence of FPs was significantly lower in patients of the retreatment GMA group than in those who received GMA for initial treatment (Table 1). The efficacy of GMA was assessed in 209 UC patients. The numbers of patients administered prednisolone, infliximab, adalimumab, tacrolimus and cyclosporine were 24, 6, 3, 6 and 1, respectively, at baseline and 2.5, 2, 0, 1, 1 and 0, respectively. The pUC-DAI score significantly decreased from 6.2 at baseline to 3.4 after the final GMA session (P < 0.001) and the remission rate at the final GMA session was 43.5%.

Conclusion: This multi-centre observational study showed that GMA has an acceptable safety profile in IBD patients and sufficient effectiveness in UC patients who have special situations. However, care should be taken when GMA is used in patients with anaemia or those who have received concomitant treatment with multiple immunosuppressants.

Introduction: People with Inflammatory Bowel Disease (IBD) commonly experience health issues (MHIs) such as anxiety and depression. MHIs reduce quality of life and are associated with poor medication adherence and worse disease course. However, psychological support is not routinely provided to people with IBD. There are scant prospective, systematically gathered data on MHIs in IBD; despite solid evidence of the value of psychological input for people with other chronic diseases.

Aims & Methods: The current study is investigating: the prevalence of MHIs in an IBD cohort; the acceptability and uptake of psychological support and treatment; whether MHIs correlate with higher healthcare utilisation; and potential benefits of integrated psychological care to patients’ mental health, physical health, and/or healthcare utilisation. Potential participants were prospectively recruited from the IBD service at a large tertiary hospital in South Australia via post and in-person at scheduled/routine outpatient appointments. Data were collected at two time points – at baseline screening and at 12 month follow-up. Mental health, medication adherence, and quality of life were measured by questionnaires: the Hospital Anxiety and Depression Scale (HADS), the Kessler 6 Scale of General Psychological Distress (K6), the Morisky Medication Adherence Scale (MMAS-8), and the Assessment of Quality of Life measure (AQoL-SD). Demographic and healthcare utilisation data were collected by electronic,

state-wide hospital records. Psychological support was offered where scores on HADS and/or K6 indicated likely need. **Results:** 500 patients were approached during the 12-month screening phase; 50.6% were male, 70.8% had Crohn’s disease, mean disease duration of 11 years, 43.1% in clinical remission, and 9.8% current smokers (Australia’s average 13.3%). Of these 500, 67% participated in psychological screening; 38% scored within the clinical range, and 17% accepted psychological support. Gender was a significant predictor of participation in psychological screening: women were 62% more likely to participate than men. Analogies and/or mental health medication increased the likelihood of scoring within the clinical range nearly fivefold (analgesic use OR = 5.32, p = 0.03; psycho OR = 6.04, p = 0.01). Significant predictors of accepting psychological treatment included older age (OR = 1.03, p = 0.04), anxiety (OR = 1.09, p = 0.045), general distress (OR = 1.11, p = 0.003) and lower quality of life (OR = 0.93, p = 0.042). At baseline, anxiety and depression were both negatively correlated with medication adherence (anxiety r = -0.32, p = 0.00, depression r = -0.20, p = 0.000) and overall quality of life (anxiety r = -0.78, p = 0.000, depression r = -0.78, p = 0.000). Depression and general distress were related to overall healthcare utilisation (depression r = 0.13, p = 0.018, general distress r = -0.12, p = 0.026). Anxiety was not related to overall healthcare utilisation, but was positively correlated with numbers of emergency department presentations (r = 0.12, p = 0.024), outpatient appointments (r = -0.11, p = 0.030), and appointment cancellations (r = 0.15, p = 0.05). Currently, approximately half of the twelve month follow-up data has been collected. Preliminary analysis shows improvements for patients’ mental health, quality of life and medication adherence (see table below).

**Conclusion:** Psychological issues are prevalent in patients with IBD and associated comorbidity and quality of life and medication adherence are common more likely to participate in psychological screening, and in general the screening approach was widely accepted. In addition, high proportions of patients reported clinical levels of distress (irrespective of their IBD activity) and went on to accept psychological intervention. All of which demonstrates a widespread need for support in this cohort. Furthermore, preliminary data of treatment outcomes are promising. At study completion we will be better able to clarify the extent to which patients with IBD benefit from this new integrated approach.

Aims & Methods: To evaluate long-term efficacy, safety, and immunogenicity in patients continuously treated with either GP2017 or reference adalimumab from initial randomization to Week 51. Eligible patients with moderate-to-severe chronic plaque psoriasis were randomized to receive an initial dose of 30 mg subcutaneous GP 2017 or reference adalimumab, followed by 40 mg every other week, starting one week after the initial dose, up to Week 17. At Week 17, patients with ≥50% improvement in Psoriasis Area and Severity Index (PASI 50) at Week 16 were re-randomized in a 2:1 ratio to either remain on their initial study treatment or undergo a sequence of three treatment switches between GP 2017 and reference adalimumab until Week 35. Thereafter, patients were returned to their originally randomized treatment up to Week 51.

**Results:** From randomization to Week 51, 168 and 171 patients received continuous treatment with GP 2017 or reference adalimumab, respectively. In the protocol analysis set, PASI 75 response rates for continual GP2017/reference adalimumab at Weeks 17 and 24 were 75.2% and 67.8%, respectively. Investigator’s global assessment (IGA) response rates (IGA score of 0 [clear] or 1 [almost clear] and ≥2 point improvement from baseline) were also similar between the continual GP2017/reference adalimumab groups, increasing over time and remaining stable from Week 17 (60.0%/53.9%) to Week 51 (59.8%/55.1%). There were no clinically relevant differences between the continual GP2017/reference adalimumab groups in the frequency of adverse events (AEs) (61.6%/64.9%), treatment-related AEs (17%/18.7%), serious AEs (3.0%/3.8%), drug-related AEs (15.5%/17%), or AEs leading to discontinuation of study drug (7.9%/7.0%) respectively.

**Conclusion:** Efficacy was similar and sustained in patients with psoriasis continuously treated with GP 2017 or reference adalimumab for up to 51 weeks. Safety profiles and immunogenicity were generally similar in both groups. Clinical data add to the totality of evidence suggesting GP 2017 could be used as a biosimilar for the treatment of the same indications for which reference adalimumab is approved, including inflammatory bowel disease.

Introduction: Granulocyte-monocyte apheresis (GMA) can be employed for the treatment of inflammatory bowel disease (IBD), especially for ulcerative colitis (UC). The usual treatment schedule is a weekly session for 5 weeks processing 1800 ml in 60 minutes. It has been described that different factors of the disease and the technique can improve the response to this treatment.
PO399  ANDECALIXIMAB (ANTI-MMP9) INDUCTION THERAPY FOR ULCERATIVE COLITIS: A DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED, PHASE 2 STUDY

Introduction: Andecaliximab (anti-MMP9) (MM-9) is a monoclonal antibody that selectively binds and inhibits MMP-9. A Phase 1 dose-ranging study of andecaliximab was conducted in UC patients, demonstrating clinical response and remission. We conducted a phase 2 study to further evaluate the safety and efficacy of andecaliximab in subjects with UC.

Aims & Methods: This was a double-blind, randomized, placebo-controlled 8-week induction study in adult subjects with UC with moderate to severe disease activity (defined as: CDAI total score 220–450, weighted PRO2 score ≥1 [standard CDAI weights: abdominal pain 0–3+ plus mean number of daily stools ≥2] and SES-CD total score ≥6 [or ≥4 score if disease limited to ileum and/or right colon or ulcer presence and size score ≥2]). Subjects were required to have an inadequate response, or loss of response or intolerance to at least 1 of the following treatments in the last 5 years: corticosteroids, immunomodulators, TNF-alpha antagonist or vedolizumab. Subjects were randomized 1:2:2 to receive subcutaneous (SC) injections of: placebo, 150 mg andecaliximab every 2 weeks (Q2W), 150 mg andecaliximab weekly (QW). Centrally-read sigmoidoscopies/colonoscopies were performed at baseline and week 8. The primary outcome was EBS clinical remission, defined as an Endoscopic subscore of ≤1, rectal Bleeding subscore of 0, and ≤1 point decrease in Stool frequency from baseline to achieve a subscore of 0 or 1.

Results: A total of 165 subjects from 23 countries were enrolled. The percentage (confidence intervals) of subjects achieving EBS clinical remission was similar between subjects treated with andecaliximab Q2W and placebo: 7.4% (2.1–17.9%), 1.8% (0.9–6.9%) and 7.3% (2.0–17.6%), respectively. Confidence intervals overlap for all groups and no single EBS component subscore appears to have driven the results. No concerning imbalances occurred between the treatment groups (Table 1).

The frequency of adverse events (AEs) was similar in the andecaliximab Q2W, andecaliximab QW and placebo groups: 53.7%, 58.9% and 60%, respectively. Common AEs included anemia, abdominal pain and nausea. Three AEs led to discontinuation in the andecaliximab Q2W group compared to one each in the andecaliximab QW and placebo groups. Two serious AEs occurred in the andecaliximab QW group (anemia and angina pectoris) compared to one in placebo.

Introduction: Elevated levels of matrix-metalloproteinase-9 (MMP-9) and its degradation products are detected in patients with active Crohn’s disease (CD). Selective inhibition of MMP-9 reduced fibrosis in a murine model of intestinal fibrosis, suggesting that MMP-9 may contribute to intestinal complications in CD. Accordingly, MMP-9 has been proposed as a therapeutic target for CD. Andecaliximab (GS-5745) is a monoclonal antibody that selectively binds and inhibits MMP-9. It was found to be safe in a phase 1 dose-ranging study in UC subjects, where it showed clinical response and remission compared to placebo. The aim of this phase 2 study was to evaluate the safety and efficacy of andecaliximab in subjects with active Crohn’s disease (CD). References
The frequency of adverse events (AEs) was similar between the treatment groups: placebo (67.9%), 150 mg Q2W (60.4%), 150 mg QW (62.3%), 300 mg QW (69.8%). Common AEs included abdominal pain, nausea, fatigue, anemia, and pyrexia. One AE led to study discontinuation in the placebo group (1.6%) compared to 2 in the 150 mg QW group (3.8%) and 4 in the 300 mg QW group (7.5%). Three serious AEs occurred in the placebo group (10.7%) compared to 1 in the 150 mg QW group (1.9%), 6 in the 150 mg QW group (11.3%) and 8 in the 300 mg QW group (15.1%). Frequency of arthralgia and musculoskeletal pain was similar or lower in adalimumab groups compared to placebo.

The proportion of subjects achieving clinical response/remission and endoscopic response was similar between treatment groups (Table 1).

**Conclusion:** SC adalimumab was well tolerated; however, none of the treatment regimens demonstrated a treatment effect in subjects with CD.

**Introduction:** Adalimumab and anti-adalimumab-antibodies (AAA) levels have been associated with clinical outcome of Crohn's disease (CD). Nevertheless, because adalimumab is usually self-injected at home, prospective serial-sampling studies are scarce. Thus, data on the temporal evolution of adalimumab immunogenicity is still limited, and the validity of comparisons of adalimumab versus infliximab immunogenicity remains questionable.

**Aims & Methods:** Our aim was to assess trends in adalimumab and AAA levels over time and their clinical implications. CD patients starting adalimumab therapy were followed prospectively in three participating medical centers in Israel, by establishing a program for home-visits by physicians at induction and every 3 months, or in case of relapse. At each home visit, patients’ clinical activity score were determined and blood tests obtained for CRP, drug and AAA trough levels. AAA levels were determined by a drug-tolerant assay. A comparison with temporal evolution of infliximab immunogenicity in a previously reported cohort using the same assay and methodology was additionally performed.

**Results:** 102 CD patients starting adalimumab were prospectively followed. Fifteen (14%) experienced primary non-response and 20 (20%) lost response to adalimumab therapy during maintenance. Thirty-three (32%) developed AAA, which were more common among those previously exposed to adalimumab (p = 0.002) but were not affected by co-treatment with immunomodulators or not (p = 0.28). AAA developed as early as week 2 in 18/33 (55%) of AAA positive patients (7/18 with history of interrupted therapy), and in 26/33 (79%) within week 14. Patients with week 2 AAA had 34% of primary non-response compared to 9% in patients without early AAA (OR = 4.8, p = 0.009). In 92.6% of cases, AAA preceded loss-of-response or occurred simultaneously (median interval - 4 weeks). As compared to antibodies-to-infliximab (ATI), AAA formation rate over time was significantly lower (p = 0.01, log rank test), and some patients developed AAA even after one year of therapy. Transient AAA were much less common than transient ATI (7% vs 32%, p < 0.0001), and 85% of AAA events were associated with loss of response compared with 58% rate for ATI (p = 0.03).

**Conclusion:** AAA formation often occurs earlier than anticipated, and associates with primary non-response to adalimumab induction. Overall rate of immunogenicity is lower for adalimumab compared to infliximab. However, once they occur, AAA are more specific to ATI.

**Contact E-mail Address:** lgressoi@unich.it

**Introduction:** Golimumab (GLB) has been the last anti-TNF agent authorized for the treatment of Ulcerative Colitis (UC). Results from registratory trial (PURSUIT) documented a clinical response in 51% of patients after 6 weeks.
of GLB with 47.4% of patients maintaining the effect after one year. Due to its results, patient characteristics are still few with success on clinical outcomes of patients receiving golimumab in the routinely activities. In our region GLB became available starting July 2015.

Aims & Methods: Aim of this study has been to prospectively evaluate the efficacy and tolerability of golimumab for the treatment of UC in the real-life setting of our referral centre. 13 patients (7 male, 4 female) with moderate-to-severe UC were enrolled in the study from June 2015 to December 2016. Patients received an induction dose of GLB 200 mg s.c. at baseline, 100 mg at week 2 and then a maintenance dose of 100 mg for a body weight < 80 kg, respectively, with no optimization allowed. Partial Mayo score was computed at baseline and every 2 weeks for the first 6 weeks of therapy, then every 4 weeks throughout the maintenance period. Follow-up is still ongoing. Primary end point has been the clinical response at the end of the induction phase (intended as the reduction of Partial Mayo score >30% and >3 points vs baseline) and in the maintenance period, the secondary end point being the steroid-free clinical response (Partial Mayo score <2 with all subscres <1) at the end of the induction phase and then in the maintenance phase. Complete follow-up is available for all at patients week 30, with 4 patients reaching the week 54 of monitoring.

Results: At the time of GLB starting, localization of the disease according to Montreal classification was left-sided colitis (E2) in 70%, pancolitis (E3) in 23% and proctitis (E1) in 7% of patients. Ten patients (77%) were anti-TNF naïve, 3 patients (23%) had already received one anti-TNF in the past. Clinical response was obtained in 6/13 (46%) at week 6 and in 2 further patients at week 10, for a total of 8/13 (62%). Three patients resulted in complete clinical steroid-free remission after 6 weeks. At week 30, 5 patients still showed a clinical response (38%), one of them (7%) resulted in complete steroid-free remission. Among the 4 patients reaching week 54, 2 experienced a flare of disease whereas 2 were still in remission at week 54. The patient is in remission at week 42, potentially accounting for a total of 3/13 patients in remission after one year (23%). No differences were found between naïve and non-naïve patients. No significant adverse events were reported in the study period.

Conclusions: Our data seem to suggest that Golimumab, as compared to registries trials, is able to induce a better initial clinical response but shows a higher secondary loss of response in the long term. Whether this really reflects a lower efficacy of GLB or could depend on the unavailability of dose optimization in this kind of setting, the physicians may modify the dose to the patient's benefit. No other significant adverse events were reported.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0404 FIVE-YEAR SAFETY DATA FROM THE OBSERVATIONAL POSTMARKETING ULTRACOLITIS STUDY, A EUROPEAN REGISTRY FOR ADULTS WITH ULTERATIVE COLITIS TREATED WITH ORIGINATOR INFlixIMAB OR STANDARD THERAPY

1Dept. Of Gastroenterology, Hospital Clinic Barcelona Dept. of Gastroenterology, Hospital Clinic Barcelona, Barcelona/Spain 2Dept. Universität Wien Ath, für Innere Medizin III - Dep of Internal Medicine IV, Division of Gas, Wien/Austria

Contact E-mail Address: jpanes@clinic.ub.es

Introduction: The Observational Postmarketing Ulcerative colitis Study (OPUS) registry was conducted to collect long-term (5 years) real-world clinical and safety data in patients with moderate to severe ulcerative colitis (UC) treated with originator infliximab and to compare this safety profile to that of UC patients treated with standard therapies.

Aims & Methods: OPUS registry was a prospective, non-randomized, observational study that followed patients with UC (in routine practice in 14 European countries) who were enrolled to receive treatment with either originator infliximab or standard therapy (defined as initiation or dose-increase of corticosteroids or 5-ASA for the UC for the standard therapy group, as defined by their respective physician). Adverse events (AEs) were recorded during the 5-year follow-up period; at any time during the 5 years of observation, the patient’s therapy could be changed to any other UC therapy, based on the physician’s clinical judgment. Frequency of events was evaluated in nine pre-specified categories (serious infection, infusion-related reaction, fatality, worsening or new case of congestive heart failure (CHF), central and peripheral demyelinating neurological disorder, hematologic condition, malignancy/lymphoproliferative disorder, autoimmune disorder, or hematological event). The incidence of these events was calculated for originator infliximab and standard therapy groups, using an intent-to-treat approach, in eight of the pre-specified categories (infusion-related reactions were not compared between originator infliximab and standard therapy [i.e. generally oral] therapies); p-values were not adjusted for multiplicity comparisons. Safety data were collected every 6 months.

Results: Data for 2239 patients were available: 1180 patients enrolled to standard therapy (including 296 patients who switched to originator infliximab during follow-up) and 1059 patients enrolled to originator infliximab. Patients who received originator infliximab, standard therapy, or who were switched to originator infliximab during follow-up on standard therapy, were followed for medians of 59.4, 50.6, and 49.8 months, respectively. However, median exposure to originator infliximab during follow-up on standard therapy, were followed for median exposure to originator infliximab during follow-up on standard therapy, were followed for 1059 patients enrolled to originator infliximab. Patients who received originator infliximab group, compared with the standard therapy group, had more severe disease at baseline, based on partial Mayo score (PMS): 46.0% of patients in the originator infliximab group had severe disease (PMS of 7–9 (out of 9), compared (60.3%, P < 0.001) in the standard therapy group. In time-to-event analyses for risk factors/confounders, enrollment into the originator infliximab group was associated with a higher risk of serious infection (hazard ratio = 2.08, 95% confidence interval [CI] 1.42, 3.06; p < 0.001) compared with enrollment into the standard therapy group (Table). No notable risk differences between groups were identified for hematologic condition, autoimmune disorder, malignancy/lymphoproliferative disorder, hepatobiliary event, and fatality (Table). Because of very low incidence of AE's in the categories of CHF and demyelinating disorder (0.3% in each group), meaningful multivariable-time to-event analyses could not be performed for these categories.

Conclusion: Data from 5-year safety follow-up of patients with moderate to severe UC in this non-randomized registry population demonstrate that, compared to patients receiving standard therapy, patients enrolling into the originator infliximab group had an increased risk of serious infection. This finding is consistent with the previously established safety profile for originator infliximab in the treatment of UC. In this large registry, the originator infliximab group, compared with the standard therapy group, did not have a significantly increased risk of a hematologic condition, autoimmune disorder, malignancy/lymphoproliferative disorder, hepatobiliary event, CHF, demyelinating disorder, or mortality. No new safety concerns were observed with originator infliximab in the OPUS registry.

Reinisch: W.R. has served as a speaker and advisory board member for Merck & Co., Inc.,
Golimumab (GLM) is a subcutaneously administered anti-tumor necrosis factor (anti-TNF) antibody that is approved for the treatment of moderate to severe ulcerative colitis (UC). We investigated the association between systemic exposure (area under the curve (AUC)) of GLM during induction therapy and endoscopic response in moderate-severe UC.

Aims & Methods: In this prospective observational trial, patients with moderate to severe UC (Mayo endoscopy score ≥2) received induction treatment with GLM 200 mg SQ (at week 0) and 100 mg (at week 2) followed by 50 or 100 mg at week 6, in patients with a bodyweight of less or more than 80 kg, respectively. Serum GLM concentrations were measured with an enzyme-linked immunoassay system (ELISA) developed by Sanquin laboratories. Endoscopic response was defined as disease duration at age, disease duration at baseline, history of previous dysplasia.

Results: A total of 20 patients were enrolled of which 19 patients underwent an endoscopy at baseline and 8-10 weeks after start of treatment. Median age (interquartile range) was 46 years [36–57], median baseline CRP serum concentration was 4.5 mg/L [1.1–13.7] and median baseline albumin serum concentration was 44 g/L [40–45]. None of the patients developed antibodies against GLM during induction treatment. After the induction phase, 12 out of 19 patients (63%) achieved an endoscopic response. Median AUC at week 2 and 6 was higher in endoscopic responders compared to non-responders. Median GLM trough concentrations at week 2 and 6 were higher in endoscopic responders compared to non-responders (Table 1). Correlations between GLM trough concentrations and AUCs at week 2 (Pearson correlation coefficient: 0.68, P < .0001) and week 6 (Pearson correlation coefficient: 0.81, P < .0001) were statistically significant. Despite a low area under the ROC-curve (AUROC), a GLM serum trough concentration ≥3.3 mg/L (AUROC: 0.75, 95% CI: 0.526–0.974, sensitivity: 67%, specificity: 71%) was associated with endoscopic response after the induction phase.

Conclusion: Serum trough concentrations of GLM and AUCs at week 2 and 6 were higher in endoscopic responders compared to patients without an endoscopic response. A significant correlation was found between GLM trough concentrations and AUC. A GLM trough level ≥3.3 mg/L at week 6 is associated with improved endoscopic outcomes.

Conclusion: Serum trough concentrations of GLM and AUCs at week 2 and 6 were higher in endoscopic responders compared to patients without an endoscopic response. A significant correlation was found between GLM trough concentrations and AUC. A GLM trough level ≥3.3 mg/L at week 6 is associated with improved endoscopic outcomes.

Results: Twelve induction trials were identified from the SLR (ACT 1 & 2, EUCALYPTUS, GEMINI-I, PURSUIT SC, TOFACITINIB PHASE 2, Feagan 2003, PARKLANDS I & II, SUCCESS, ULTRA 1, ULTRA 2, Suzuki 2014) and included in the NMA. Unpublished data from tofacitinib Phase 3 induction trials (OCTAVE 1 & 2) were also used in the analysis. Fixed-effects NMA showed that tofacitinib 10 mg twice daily (BID) is associated with a higher rate of mucosal healing (500 mg/m²) in the overall population (odds ratio [OR] 1.82 [95% credible interval (CrI) 1.06, 3.14]) and vs vedolizumab 300 mg (OR 3.71 [95% CrI 1.37, 10.64]) and etrolizumab 300 mg (OR 12.09 [95% CrI 1.68, 127.73]) in TNFi-exposed patients. A higher rate of clinical remission was seen with tofacitinib 10 mg BID vs adalimumab in TNFi-exposed patients (OR 11.93 [95% CrI 1.84, 154.78]). AE rates were similar between tofacitinib 10 mg BID and comparators in the overall and TNFi-naïve populations when analysed individually, but tofacitinib 10 mg BID was found to be associated with a higher rate of disaggregated AEs (“any AE”) than etrolizumab 300 mg in the overall population (OR 2.78 [95% CrI 1.08, 7.41]). There were no statistically conclusive differences in the rates of specific AEs between tofacitinib 10 mg BID and comparators.

Conclusion: This NMA suggests that tofacitinib may be more effective as induction therapy in moderately to severely active UC than adalimumab and vedolizumab in TNFi-exposed patients, and is associated with a higher rate of mucosal healing than adalimumab in the overall population. Rates of specific safety events were similar between tofacitinib and TNFi treatments.

**P0409** SIMILAR TRAIL - EFFICACY OF INFliximab-BIOSIMILAR COMPARISON IN INFLAMMATORY BOWEL DISEASE IN REMISSION - A RANDOMIZED, CONTROLLED, DOUBLE BLIND, PHASE 4 NONINFERIORITY TRIAL

A. G. Volkers1, J. M. Jansen2

1Gastroenterology And Hepatology, OLVG, Amsterdam/Netherlands
2Department Of Gastroenterology And Hepatology, Onze Lieve Vrouwe Gasthuis, Amsterdam, Netherlands

Contact E-mail Address: a.g.volkers@amc.uva.nl

**Introduction:** Crohn’s disease (CD) and ulcerative colitis (UC) are the main entities of inflammatory bowel disease (IBD). For most patients, medical treatment is insufficient to keep the disease in remission. Infliximab (IFX) is a monoclonal antibody that targets tumor necrosis factor-α (TNF-α) inhibitors, such as Infliximab (IFA), are a major component in inducing and maintaining remission in more refractory patients. Recently IFX-biosimilars have been introduced for the treatment of IBD, these are less expensive than their biological counterparts. Preclinical studies have shown that IFX-biosimilar and IFX-biological have been compared for ankylosing spondylitis and rheumatoid arthritis showing no difference between efficacy and safety. So far, no double blind randomized clinical trial has been published that compared IBD patients who used IFX-biological or IFX-biosimilar. Cohort studies in IBD patients showed switching from IFX-biological to IFX-biosimilar had no impact on short-term clinical outcomes. The aim of this study was to examine non-inferiority in safety and efficacy of IFX-biosimilar compared with IFX-biological and to evaluate adverse effects and pharmacokinetics.

**Aims & Methods:** We randomized patients with CD or UC in clinical and biochemical remission to either switch to IFX-biosimilar or to continue using IFX-biological. Randomization was performed in a 2:1 ratio (65% to IFX-biosimilar). Patients in both arms received 4 to 6 doses of 5 mg/kg to 10 mg/kg during the 30-week study period. Patients eligible for inclusion had to be in clinical remission (HBI < 5 and MAYO < 2) and have a fecal calprotectin <250 μg/g. The primary endpoint was number of patients in remission at week 30. We measured C-reactive protein (CRP), fecal calprotectin (FCP), infliximab trough level (TL) and anti-drug antibodies [ADAs]. Patients were asked to fill in SIBDQ and Mayo or HBI questionnaires three times during the study period. Adverse events (AE) and serious adverse events (SAE) that patients experienced were documented.

**Results:** So far, we included 47 patients from 6 secondary Dutch Teaching hospitals. 35 patients had CD and 12 had UC. 27 patients were female, 20 were male. Mean age at inclusion was 42 years. 21 patients have finished the 30-week follow-up. 15 received IFX-biological, 6 IFX-biosimilar. One patient experienced a relapse of IBD, this patient received IFX-biosimilar. 2 patients experienced a SAE, none were related to the study drug.

**Conclusion:** This is the first double blind randomized clinical trial that compares treatment with IFX-biological or IFX-biosimilar. The preliminary results show that switching from IFX-biological to IFX-biosimilar is feasible and safe.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0411** ENCAPSULATED FECAL MICROBIOTA TRANSFER IN PATIENTS WITH CHRONIC, ANTIBIOTIC-REFRACTORY POUCHITIS

A. Steube1, M. Vitali2, A. Sturm2, C. Buning1, A. Stallmach2, D. Pieper1

1Clinic For Internal Medicine IV, Jena University Hospital, Jena/Germany
2Microbial Interactions And Processes, Helmholtz Centre For Infection Research, Braunschweig/Germany

**Aims & Methods:** We randomized 14 patients with chronic pouchitis (a; activity items: presence of epithelial damage, polymorphonuclear leukocytes (IGHAS)/colonic GHAS (CGHAS) score or IGHAS/CGHAS activity subscores and b; induction items: presence of crypt abscesses, neutrophils in epithelium, cryptosis and granulomas) to filgotinib (FIL) versus placebo (PBO). A JAK1 inhibitor that blocks cytokine signaling through inhibition of STAT phosphorylation, has recently shown efficacy in a double-blind, placebo (PBO)-controlled Phase 2 study in CD (FILZROY2). Effects of filgotinib versus placebo have been demonstrated on centrally read endoscopy and histopathology assessments after a 10-week induction treatment.

**Results:** Baseline IBD activity was comparable between the treatment arms. A similar distribution of IBD medication (sulfasalazine, 5-aminosalicylates, steroids) was present in both groups. Clinical response occurred in 7 of 14 patients after two to four FMTs. 4 patients showed clinical worsening and 3 patients showed no improvement. FCP values increased in patients treated by FMT every 4 weeks according to the individual therapeutic outcome. The encapsulated fecal microbiota was as effective as the endoscopic jejunal application in its capacity to restructure the pouch microbiota. However, an increase in diversity and an overall restructuring of the microbiota into a composition resembling the donor not necessarily correlated with clinical outcome and clinical worsening was observed during three FMTs where the established microbiome structure remained that of the pouch microbiota. High diversity and successful establishment of members of the butyrate producing Lachnospiraceae and Ruminococcaceae families is not sufficient for a successful outcome of FMT.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Mucosal healing (MH) has been established as co-primary treatment target in Crohn’s disease, predominantly defined by the absence of ulceration. However, even in patients with MH, inflammation may persist on histologic examination. Filgotinib (FIL), a selective inhibitor of JAK1 that blocks cytokine signaling through inhibition of STAT phosphorylation, has recently shown efficacy in a double-blind, placebo (PBO)-controlled Phase 2 study in CD (FILZROY2). Effects of filgotinib versus placebo have been demonstrated on centrally read endoscopy and histopathology assessments after a 10-week induction treatment.

**Aims & Methods:** In this post hoc analysis, we explored the correlation between histologic and endoscopic disease activity at baseline (BL) and following FIL induction therapy by comparison of total ileal Global Histology Activity Score (IGHAS)/colonic GHAS (CGHAS) score or IGHAS/CGHAS activity subscores (a; activity items: presence of epithelial damage, polymorphonuclear leukocytes in lamina propria, neutrophils in epithelium, cryptosis and granulomas) and (b; versus total simple Endoscopic Score for CD (vISES-CD))/colonic SES-CD (vCES-CD) score or ISES-CD/SES-CD ulcer subscores (a; sum of size and % affected surface). CD patients were randomized 3:1 to receive 200 mg FIL or PBO QD for 10 weeks. Intestinal biopsies were collected at BL and Week 10 (W10) from the most affected areas of each predefined bowel segment (ileum, ascending, transverse, descending, sigmoid colon and rectum). Biopsies were formalin fixed and paraffin embedded. The mean changes from baseline for each treatment group were compared to zero using a one sample t-test.

**Results:** Baseline values were comparable across treatment groups, although CGHAS and SES-CD were numerically higher in the PBO group (Table 1). Following 10 weeks of treatment with FIL 200 mg, histologic measures of colonic mucosal inflammation (CGHAS and aCGHAS) were significantly improved and were coupled with macroscopic changes in both CSES-CD and vCES-CD. Changes in histology score for ileal segments were numerically greater after FIL treatment versus placebo. Histology total and subscores were significantly higher in the PBO group compared to ulcer subscores at baseline and W10, and more pronounced when looking into the colonic segments versus the ileal segments (IGHAS v vISES-CD: Corr = 0.52, p < 0.001; Corr = 0.65, p < 0.001; BL and W10 respectively) aCGHAS v vUSCES-CD: Corr = 0.53, p < 0.001;
Only subjects with non-missing data for all segments at BL and W10 were included in the calculation; *Subscore for GHAS data is activity subscore and for SES-CD data is ulcer subscore; bolded texts indicate p-value <0.05 from t-test

**Conclusion:** Improvements in endoscopic severity induced by filgotinib are paralleled by reductions of histologic scores. In line with previous findings from anti-TNF therapies®, colonic mucosa is more prone to improve than ileal disease. Spontaneous reductions of histologic activity under placebo were not observed.

**Aims & Methods:** Patients achieving clinical response 8 weeks after a single IV induction dose were randomized to SC placebo (PBO), UST 90 mg every 12 weeks (q12w) or every 8 weeks (q8w). UST patients not in clinical response 8 weeks after the IV induction dose were given UST 90 mg SC and if in clinical response 8 weeks later were continued on 90 mg SC q8w dosing. A total of 458 patients were exposed to an IV induction dose of 6 mg/kg (UNITI-1, N = 249 and in UNITI-2, N = 209) with a response rate at week 8 of 37.8% and 57.9% vs. PBO response rate of 20.2% and 32.1% respectively. The remission rate at week 8 in UNITI-1 and UNITI-2 was 20.9% and 40.7 vs. PBO of 7.3% and 19.6% respectively. For this evaluation, the response and remission status of the entire population exposed to an IV induction dose of 6 mg/kg of UST was evaluated 8 weeks after the first subcutaneous maintenance dose of UST. All patients who received 6 mg/kg IV UST induction were included, including responders randomized to SC PBO (who did not receive SC UST at week 8).

**Results:** Of the 219 patients not in clinical response in UNITI 1 & 2, 37.6% and 60.5% respectively were in clinical response 8 weeks after the first maintenance induction dose of 6 mg/kg SC. Evaluating all patients exposed to 6 mg/kg IV UST induction, response rates 8 weeks after the first subcutaneous injection (16 weeks after the IV induction dose) for UNITI1&2 are 47.4% and 73.7% respectively (see table for response and remission rate). Similar assessments were calculated in the sub-population who were anti-TNF naïve upon enrolment into UNITI-2.

**Conclusion:** These numbers at week 16 are expected to reflect real-world experience in patients who receive the induction dose and one additional maintenance dose 8 weeks later. The resulting rates of response and remission are higher than previously reported in the induction studies across all populations (anti-TNF non-failures and anti-TNF failures). About 73% of anti-TNF non-failures attain clinical response and over half are in remission. The data support the clinical rationale for providing at least one SC maintenance dose of ustekinumab irrespective of clinical response 8 weeks after IV induction.
P0414 REAL-WORLD PATTERNS OF TREATMENT DISCONTINUATION, FLARES, AND HOSPITALISATIONS AMONG INFLAMMATORY BOWEL DISEASE PATIENTS WITHIN 12 MONTHS OF INITIATION OF VEDOLIZUMAB OR INFliximAB

H. Patel1, M. Raluy Callado2, A. Berger3, R. Curtis1, M. J. Khalid1

Introduction: Biologics such as infliximab (IFX) (an anti-TNF) and vedolizumab (VDZ) (anti-integrin) are treatment options for patients with moderate-to-severely active inflammatory bowel disease (IBD), who have failed conventional therapy.

Aims & Methods: Our aim was to compare time to treatment discontinuation, flares, and hospitalisations among patients with IBD initiating VDZ versus IFX who were biologic-naïve. All patients with IBD (ulcerative colitis or Crohn’s disease [CD]) who initiated biologic treatment with VDZ or IFX between 01/05/2014 and 22/02/2016 were identified in the US Explorys Universe database; the first infusion was deemed the index date. Analyses focused on patients who: (1) successfully completed induction therapy (≥3 infusions within 98 days of index date); (2) were ≥18 years of age at index; (3) had ≥365 days of medical history prior to index (baseline); and (4) had 365 days of follow-up after the index date. VDZ initiators were matched to IFX initiators (1:3) using propensity scores. Kaplan-Meier Method was used to compare median time to discontinuation of VDZ and IFX during follow-up, defined as the first of either: no receipt of biologic ≥90 days of previous infusion, or switch to another biologic. Similar method was also used to compare median time to IBD-related hospitalisations, surgeries, and flares (defined as use of intravenous steroids), respectively. Interquartile range (IQR) was also calculated.

Results: 105 VDZ initiators were matched to 315 IFX initiators. Baseline characteristics of both cohorts are described in Table 1. CD accounted for ≥60% of patients in each cohort. In the baseline period, ~70% of patients in both cohorts had received corticosteroids; 20% of VDZ vs. 38% of IFX initiators received an immunosuppressive therapy. Median time since diagnosis was 2.4 years for VDZ initiators and 1.9 years for IFX initiators. Median time to treatment discontinuation was 244 (IQR: 194–307) and 200 (IQR: 148–283) days in both cohorts. Median time to first hospitalisation was 153 (IQR: 78–209) days for VDZ initiators vs. 98 (IQR: 45–168) days for IFX initiators. For IBD-related flares, median time was 111 (IQR: 40–226) days for VDZ initiators vs. 93 (IQR: 35–182) days for IFX initiators.

Conclusion: Among biologic-naïve IBD patients, there was a trend toward prolonged median times to first IBD-related hospitalization or first flare with VDZ compared to IFX. The median time to discontinuation was comparable between the therapies. Future studies should examine comparative effectiveness outcomes in a larger cohort over a longer follow-up period.

Abstract: Cancer development has been linked to oxidative stress by increasing DNA mutations or inducing DNA damage, genome instability and cell proliferation. Interestingly, reactive oxygen species (ROS) seem to modulate antigen presentation, a crucial event in the immune surveillance mechanisms. We recently showed that expression of the co-stimulatory molecule CD80 on epithelial cells has a critical role during the immune surveillance process occurring in colon carcinogenesis2. Remarkably, ROS have been involved in the transcriptional regulation of CD80 gene expression1, in addition, oxidative DNA damage was directly correlated to CD80 expression in colon mucosa dysplasia3. Aims & Methods: Therefore, the aim of this work was to examine the role of ROS on CD80 expression in colonic epithelial cells using an in vitro and in vivo model of colon carcinogenesis. A mouse colorectal cancer cell line, CT26, was used to quantify the expression of CD80 in response to pro-oxidant (such as Antimycin A and H2O2) and antioxidant (N-acetyl cysteine) stimuli in presence of CD80 expression in colonic epithelial cells using an

Introduction: Altered immune activity and gut microbiota alterations are proposed to be important factors in the pathophysiology of irritable bowel syndrome (IBS), but the relevance for symptoms is unclear.

Aims & Methods: We aimed to determine if colonic antimicrobial gene expression profiles differ between IBS and healthy subjects and if potential alterations are linked to immune activity or gut microbiota composition. The expression of 84 key antimicrobial genes in sigmoid colon biopsies from patients with IBS, defined as being either immuno-active or immuno-norm based on systemic and mucosal cytokine profiles (Bennett et. al. Am J Gastro, 2016), and healthy subjects was assessed by Human Antibacterial Response RT2 Profiler PCR Array. Targeted 16S rRNA pyrosequencing was performed on faecal microbiota to identify discrimination profiles based on multiple variables between IBS patients and healthy subjects, orthogonal partial least squares discriminant analysis (OPLS-DA) with a cut off for Variable Importance for the Projection >0.7 was performed.

Results:

Table 1: Differences in mucosal antimicrobial mRNA expression between IBS (Immuno-active and Immuno-norm) and healthy subjects.

Data presented as p-values (Mann-Whitney t-test) “*” no significant. We included 31 IBS patients (16 females, median age 32 (25–44) years) and 16 healthy subjects (8 females, median age 27(24-30) years). An OPLS-DA model demonstrated that the antimicrobial profiles differed between IBS and healthy subjects (R² = 0.54, Q² = 0.16). The mucosal mRNA expression of 14 antimicrobial genes was downregulated, while one gene was upregulated in IBS patients compared to healthy subjects (Table 1). Antimicrobial profiles did not differ between IBS patients subtype according to their predominant bowel habit (R² = 0.02). An OPLS-DA model showed discrimination between immuno-active (n = 16) and immuno-norm (n = 15) IBS patients based on their mucosal antimicrobial profiles (R² = 0.91, Q² = 0.61). This finding was corroborated by four antimicrobial genes being altered between the two IBS groups (Table 1). All healthy subjects to the model revealed three differing antimicrobial profiles for each respective group (R² = 0.44, Q² = 0.30). Compared to healthy subjects, 19 genes in the immuno-active and immuno-norm IBS groups were differently expressed (p < 0.05, Table 1). Only one of the antimicrobial genes differently expressed between IBS patients and healthy subjects was associated with faecal microbiota in immuno-norm IBS patients (Conserved Helix-Loop-Helix Ubiquitous Kinase (CHUK) with Anaerovorax r = –0.76, p < 0.01). In the immuno-active IBS group 11 associations were identified, including TNF
Receptor Superfamily Member 1A (TNFRSF1A) with *Bifidobacterium* (r = 0.12, P < 0.05).

**Conclusion:** The intestinal antimicrobial gene profiles differ between subsets of IBS patients and healthy subjects. An altered ability to recognise microbiota associated with immune activity and the relative abundance of gut bacteria may play a role in the complex pathophysiology of IBS.

**Introduction:** Internal biliary drainage has been confirmed better than external biliary drainage in alleviating the damage of intestinal mucosa barrier caused by obstructive jaundice, but the relevant mechanism is still unclear.

**Aims & Methods:** We aimed to investigate the effect of internal and external drainage on obstructive jaundice rat’s intestinal barrier function rats on intestinal mucosal barrier function index with special reference of intestinal immune-related index expression. Sixty male Sprague-Dawley rats were randomly assigned to four groups: OJ, sham operation (SH), internal biliary drainage (ID) and external biliary drainage (ED). All animals underwent surgical ligation of the bile duct, except SH was produced by separating common bile duct locally but not dividing on day 1. Then ED and ID were reoperated on day 8 for biliary drainage procedure. Blood from inferior vena cava were collected for the test of DAO and slgA activities by the method of ELASA. The terminal ileum specimens of each groups were collected for observation of the morphological changes with haematoxylin-eosin (HE) staining. The expression of IgA mRNA, plgR mRNA, GP-BAR1 mRNA, RD-5mRNA were detected by real-time reverse transcription polymerase chain reaction (RT-PCR). GP-BAR1 of the ileum mucosa was analyzed by Western blot.

**Results:** After bile duct ligation, the injuries of the intestinal mucosa were obvious in OJ group with thinner mucosa, sparser villi, destruction of the epithelium and goblet cells accompanied by inflammatory cell infiltration. The expression of RD-5 mRNA in OJ group were decreased significantly than that in SH, ID and ED groups while slgA were decreased (p < 0.01), and the activities of the DAO, slgA in ID group were similar to the level of SH group (p > 0.05), different to the level of ED group (p < 0.01). The changes of the plasma DAO and slgA activities were significantly correlated with the conditions of intestinal mucosa (p < 0.01). The expression of IgA mRNA and plgR mRNA reduced markedly (P < 0.01). But in ID, the relative expression of IgA mRNA and plgR mRNA reduced markedly (P < 0.01), while the mRNA expression of GP-BAR1 and RD-5 mRNA in ED group was changed less than that in ID which were more similar to SH group. The protein expression of GP-BAR1 was increased significantly in the intestinal mucosal of OJ group, which was higher than that of in SH group (P < 0.01). After internal and external biliary drainage to alleviate OJ respectively, the GP-BAR1 expression was decreased significantly in ID group, similar with SH group (ID vs OJ, P < 0.01; ID vs SH, P > 0.05), and lower than that of in ED group (P < 0.05).

**Conclusion:** The differential expression of IgA mRNA, plgR mRNA, GP-BAR1 mRNA, RD-5 mRNA and activities of DAO and slgA in OJ, ID, ED and SH reflect internal biliary drainage better than external biliary drainage. There may be a regulatory mechanism between GP-BAR1 and intestinal immune-related index, which thus appears to be a key factor in maintaining function of intestinal mucosa barrier.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Recently, accumulating evidence suggested that the dysbiosis of the intestinal microbiota was associated with increased risk of colorectal cancer and might play a significant role in the colorectal carcinogenesis [1-2]. Many environmental factors (e.g. diet and lifestyle) that altered the gut microbiota had been reported in the development of colorectal cancer[3]. Antibiotics are able to shift the gut microbiota by altering bacterial composition and functions. The overuse of antibiotics has been associated with substantial increase in adverse effects, such as severe infections, obesity, inflammatory bowel disease. Similarly, it is plausible to hypothesize that overuse of antibiotic might be linked to CRC by altering the colonic microbiota. However, the relationship between antibiotic and CRC was unclear and studies regarding this topic were limited [4-7].

**Aims & Methods:** To evaluate the association between use of antibiotic and colonic microbiota. However, the relationship between antibiotic and CRC was unclear and studies regarding this topic were limited [4-7].

**Results:** From initial search, we identified four case-control studies and finally included in the meta-analysis. Compared with no/low use of antibiotics, high use of antibiotics has been associated with several adverse effects, such as severe infections, obesity, inflammatory bowel disease. Similarly, it is plausible to hypothesize that overuse of antibiotic might be linked to CRC by altering the colonic microbiota. However, the relationship between antibiotic and CRC was unclear and studies regarding this topic were limited [4-7].

**Conclusion:** Further research is needed to verify our results and explore underlying mechanisms.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0419 COMPARATIVE EFFECT OF XYLOGLYCAN ASSOCIATIONS WITH COMPOUNDS FROM ANIMAL OR ALGAE ORIGIN ON LIPS-INDUCED ENTERITIS IN RATS**

H. Eutamene, C. Harkat, V. Theodorou
Unite De Neuro-gastroenterologie & Nutrition, Toulousse University Hospital, Toulouse, France

**Contact E-mail Address:** helene.eutamene@inra.fr

**Introduction:** Xyloglucan (XG) is a film-forming agent exhibiting protective effects against diarrhea linked to infectious gastroenteritis in humans; further in animal models, xyloglucan efficacy against cholera-toxin-induced diarrhea was further prolonged when this mucoprotectant agent is associated with gelatin from animal origin. The use of compounds from animal source in galenic formulations is nowadays questionable.

**Aims & Methods:** Thus, in this study, we aimed at comparing the efficacy of XG associated with gelatin vs XG associated with alginate in alleviating LPS-induced enteritis in rats. Since LPS-induced enteritis is characterized by increased intestinal permeability and mucosal inflammation, the efficacy of xyloglucan associations was evaluated by measurement of these two parameters. Male Wistar rats (200–225 g) were orally treated with either XG (10 mg/kg) or alginate (10 mg/kg) or XG (10 mg/kg) + gelatin (25 mg/kg) or XG (10 mg/kg) + gelose (25 mg/kg) or XG (10 mg/kg) + gelose (50 mg/kg) or vehicle (NaCl 0.9%) 3 h before intraperitoneal (IP) administration of LPS from *E. coli* (1 mg/kg). Six hours later AJP administration, the animals were sacrificed and strips of jejunum were collected for the test of DAO and slgA activities by the method of INPT-EF-Parpau, Toulouse/France.

**Results:** In the 10 mg/kg of XG group, the activities of the DAO, slgA in ID group were similar to the level of SH group (p > 0.05), different to the level of ED group (p < 0.01). The changes of the plasma DAO and slgA activities were significantly correlated with the conditions of intestinal mucosa (p < 0.01). The expression of IgA mRNA and plgR mRNA reduced markedly (P < 0.01), while the mRNA expression of GP-BAR1 and RD-5 mRNA in ED group was changed less than that in ID which were more similar to SH group. The protein expression of GP-BAR1 was increased significantly in the intestinal mucosal of OJ group, which was higher than that of in SH group (P < 0.01). After internal and external biliary drainage to alleviate OJ respectively, the GP-BAR1 expression was decreased significantly in ID group, similar with SH group (ID vs OJ, P < 0.01; ID vs SH, P > 0.05), and lower than that of in ED group (P > 0.05).

**Conclusion:** The differential expression of IgA mRNA, plgR mRNA, GP-BAR1 mRNA, RD-5 mRNA and activities of DAO and slgA in OJ, ID, ED and SH reflect internal biliary drainage better than external biliary drainage. There may be a regulatory mechanism between GP-BAR1 and intestinal immune-related index, which thus appears to be a key factor in maintaining function of intestinal mucosa barrier.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Results: Compared with control, LPS administration induced a significant increase (p < 0.05) of intestinal paracellular permeability (53.0 ± 4.9 vs 181.6 ± 21.1 pmol/cm² respectively) associated with jejunal mucosal inflammation (302.1 ± 9.5 vs 655.6 ± 108.9 U MPO/g protein, respectively). XG (10 mg/kg) + gelose at the lowest dose (25 mg/kg) failed to reverse the intestinal hyperpermeability and mucosal inflammation induced by LPS. In contrast, XG (10 mg/kg) + gelatin (25 mg/kg) and XG (10 mg/kg) + gelose at 50 mg/kg significantly (p < 0.01) and equally prevents LPS-induced hyperpermeability (34.8 ± 2.8, 38.7 ± 3.9 vs 181.6±21.1 pmol/cm² respectively) and jejunal inflammation (27.70 ± 32.2, 286.2 ± 28.8 vs 655.6 ± 108.9 U MPO/g protein respectively).

Conclusion: This study shows that oral treatment with xyloglucan associated with gelose at 50 mg/kg has similar protective effects on LPS-induced enteritis in rats than xyloglucan associated with gelatin. These data demonstrate that algae is an effective and safe substitute for replacing compounds from animal origin in xyloglucan mucoprotectant formulations.

Introduction: The old age is one of the most important risk factors for recurrent C. difficile Infection (CDI). However, risk factors among the elderly patients are largely unknown.

Aims & Methods: The purpose of this study was to investigate risk factors associated with recurrent CDI in the elderly. Patients 65 years or older with positive CDI toxin test between January 2005 and December 2016, who received either oral metronidazole or oral vancomycin therapy were included. Recurrent CDI was defined as another positive laboratory result for C. difficile toxin between 15 days and 90 days after initial positive diagnostic test. Clinical charts of relevant factors in 633 patients with positive CDI toxin tests were reviewed. Continuous variables were tested via Student’s t-test, and categorical data was analyzed via Chi-Square test. All variables with P < 0.1 in the univariate analysis were included in the multivariable logistic regression analysis.

Results: The overall mean age was 77.0 ± 7.0 years. In 96 (15.2%) of 633 patients, C. difficile toxin was detected again after the initial test. The length of hospital stay was longer in recurrent CDI group than in non-recurrent group (80.54 ± 89.44 vs 43.81 ± 65.42, P < .001). Patients with eGFR < 60 ml/min/1.73 m² were at higher risk for the development of recurrent CDI than those with normal renal function (OR 1.844; 95% CI, 1.139–2.985; P = .013). There were no significant differences on mean age (77.21 ± 6.65 in recurrent CDI group vs. 77.01 ± 7.04 in non-recurrent CDI group, P = .799) and proton pump inhibitor therapy (OR 1.277; 95% CI, 0.825 to 1.977, P = .327) between both groups. Renal function and length of hospital stay were significantly associated with recurrence of CDI.

Conclusion: In this study, impaired renal function and prolonged hospitalization were related to the increased risk of recurrent CDI.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Fecal microbiota transplantation (FMT) is effective for the treatment of recurrent Clostridium difficile infection (CDI) but its role as an initial therapy in CDI has not been studied.

Aims & Methods: We assessed the efficacy of FMT in patients with an initial episode of CDI compared with standard vancomycin regimen. In a single center, consecutively, we assigned patients with an initial episode of CDI to receive either: oral vancomycin (500mg four times daily) followed by FMT consisting of a single infusion of donor feces through a nasoduodenal tube; or a standard oral vancomycin regimen (500mg four times daily for 10 days). The primary end point was resolution of diarrhea associated with CDI without relapse within 10 weeks after initiation of therapy. Secondary outcomes included 30-day and 6-month mortality, 30-day colectomy rates, length of hospital stay, adverse effects and alteration of fecal microbiota after FMT using metagenomic sequencing.

Results: Baseline characteristics including age, gender and comorbidities were comparable between the vancomycin and FMT arm. 60% and 47% of subjects in the vancomycin and FMT arm, respectively, had severe CDI. Resolution of C. difficile in 10 out of 15 patients (67%) receiving vancomycin and 11 of 15 patients (73%) receiving FMT (p < 0.001). Two deaths occurred in the vancomycin group and none in the FMT group within 30 days. Nine (60%) and three deaths (20%) occurred in the vancomycin and FMT arms, respectively, within 30 days. None of the patients had a colectomy. Median length of hospital stay did not differ between both arms (13 vs 15 days; p = 0.05). No serious adverse events attributed to FMT were observed. A restoration of healthy control enriched bacteria in recipients was observed after FMT, with a decrease in abundance of CDI-enriched bacteria. FMT, but not vancomycin treatment, resulted in marked virome alterations.

Conclusion: In this pilot randomised controlled trial, FMT was not superior to vancomycin in patients with an initial episode of CDI. 30-day and 6-month mortality was higher in the vancomycin arm. A restoration of healthy control enriched bacteria in recipients was observed after FMT, with a decrease in abundance of CDI-enriched bacteria (Clinical Trial registry, NCT02570477; Funded by the Hong Kong Society of Gastroenterology Society).

Introduction: The traditional fear that every acute appendicitis will eventually result in marked virome alterations.

Aims & Methods: The aim of this study was to assess in-hospital delay of surgery and factors for complications in patients with acute appendicitis. PubMed and EMBASE were searched from 1990 to July 2016. Outcome measures of interest were complicated appendicitis, surgical site infections and postoperative morbidity. All studies reporting surgically treated patients with one of these outcome measures in two or more predefined time intervals were included. Adjusted odds ratios were pooled using forest plots if possible. All unadjusted data was pooled using generalized linear mixed models.

Results: Forty-five studies with 152, 314 patients were included. Pooled adjusted odds ratios revealed no significantly higher risk for complicated appendicitis when delaying appendectomy for 6 to 12 hours or 13 to 24 hours; odds ratio 1.07 (95% CI 0.98–1.17) and 1.09 (95% CI 0.95–1.24), respectively. For a delay of up to 24 hours no statistically significant adjusted data was available for published studies. Pooled unadjusted data showed a decreased risk for appendicitis when appendectomy was delayed for 24 to 48 hours, however statistical uncertainty in this interval increased considerably compared to the first 24 hours.

Conclusion: Delaying appendectomy up to 24 hours is an acceptable alternative for patients with no preoperative signs of complicated appendicitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Clostridium difficile infection represents a major burden in Europe and North America. However, data on its disease epidemiology remain sparse in Asia. This study aims to investigate the burden, risk factors and clinical outcomes of C. difficile infection in Hong Kong, using a large territory-wide population database.

Aims & Methods: This is a population-based study conducted from 1 January 2006 to 31 December 2014, and included all in-patient C. difficile infections in public hospitals in Hong Kong. Gastroenteritis infections were identified from a territory-wide electronic database, and were defined as the isolation of C. difficile, or positive test for either toxin or molecular assay from the fecal specimens. The disease incidence, mortality, risk factors and clinical outcomes were analyzed.

Disclosure of Interest: None declared.
notably contributed by elderly patients, of which the incidence has increased by threefold over the period. Recurrence at 60 days increased from 5.7% in 2006 to 9.1% in 2014 (P_trend < 0.001). The increased use of proton-pump inhibitors accounted for 58.8% of the surge.

Conclusion: The incidence of C. difficile infection has increased more than threefold, and was associated with an increased disease recurrence and use of proton-pump inhibitors. Our results suggest need for further surveillance in Asia which hovers half of the world’s population.

Disclosure of Interest: All authors have declared no conflicts of interest.

LOWER GASTRO-INTESTINAL BLEEDING: RESULTS OF THE RANDOMIZED CONTROLLED TRIAL IN PATIENTS WITH ACUTE P0432 EARLY VERSUS STANDARD COLONOSCOPY – A than those in the single bleeding episode group (5902 Agatston scores in the recurrent bleeding episode group were significantly higher 
rent bleeding episode group was 33% and 59% at 1 and 3 years, respectively. Results: Overall, 39 (49%) cases had recurrent bleeding episode and 40 (51%) 
edissolved. In the discontinued group, 1 patient developed acute myocardial infarction in next day after colonoscopy polypectomy. Conclusion: Patients taking anticoagulants have an increased risk of PPB compared with the control even if the anticoagulant treatments are discontinued. Hemepro- 
bridge therapy might be responsible for increased PPB in patients taking anticoagulants. Disclosure of Interest: All authors have declared no conflicts of interest.

Aim & Methods: We sought to assess the degree of arteriosclerosis in cases with diverticulum bleeding as well as the patients’ clinical characteristics. We con- 
ducted a retrospective cohort study in a group of 79 consecutive patients with colon diverticulum bleeding (51 men) who underwent both colonoscopy and 
computerized tomography (CT) between August 2007 and March 2014. The mean age of the patient population was 69.5 years (range 29–91 years) and mean 
(±standard deviation) follow-up time was 6.2 (±2.0) years (range 3.1–9.7 years). Patients were divided into two groups: the recurrent bleeding episode 
group and the single bleeding episode group. Recurrent bleeding episodes were defined as bleeding intervals of >1 month. Cases that underwent successful 
therapy during the initial bleeding episode were excluded. We compared Agatston scores (total calcium score) between the two groups of patients to 
assess the degree of arteriosclerosis. A calcified lesion was defined as an area of at least 2 connected pixels with >120 Hounsfield units (HU) on the unen- 
hanced CT scan. Aortic mural calcified area × cofactor (1:120–199HU; 2:200– 
299HU; 3:300–399HU, 4:≥400HU) was determined. The sum of the scores for 
ey calculated specif were calculated across all lesions in a slice from the level of 
the diaphragm to the aortollic bifurcation to obtain the total calcium score. Moreover, the relationship between recurrent bleeding episodes and the patients’ chest pain, heartburn, including age, sex, smoking habit, comorbidity (hyper- 
tension, cerebral-carotidovascular disease, diabetes mellitus, hyperlipidaemia, 
chronic liver disease, chronic kidney disease, and chronic obstructive pulmonary disease), internal medicine (anti-thrombotic drug, non-steroidal anti-inflamma- 
tory drug, and proton pump inhibitor), shock vital on hospitalization, and trans- 
fusion need, was determined. Results: Overall, 39 (49%) cases had recurrent bleeding episode and 40 (51%) 
have been included in the study. The cumulative recurrent bleeding rate in the recur- 
rent bleeding episode group was 33% and 59% at 1 and 3 years, respectively. Agatston scores in the recurrent bleeding episode group were significantly higher than those in the single bleeding episode group (5902 ±7187 vs 2912 ±4687, P =0.031). Clinical characteristics associated with recurrent bleeding episodes were cerebral-vascular disease (P =0.0044), chronic kidney disease (P =0.031), and anti-thrombotic drug (P =0.048) in univariate analysis. Subsequent multivariate analysis determined that cerebral-vascular disease was the independent contributor to recurrent bleeding episode (OR: 5.48; 95%CI: 1.11–40.7). Conclusion: Arteriosclerosis along with cerebral-carotidovascular disease may be a 
significant contributing factor for colon diverticulum recurrent bleeding. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The incidence of acute lower gastro-intestinal bleeding (LGB) is estimated at 21 adults per 100,000 person years and male and female ratio of the population [1]. Diagnostic management of LGB has been extensively debated in recent literature, especially whether colonoscopy within 24 hours of presentation is feasible and safe [2–4]. We performed a single-centre, non-blinded randomized controlled trial, including patients presenting at the emergency department with acute hematochezia and excluding patients with an upper bleeding source. Primary outcome was the length of hospital stay. Secondary outcomes included yield of colonoscopy, blood transfusion requirements, recurrent bleedings, complications, diagnostic and therapeutic interventions related to complications and 30-day mortality. The follow-up period was one month. Results: In total, 132 patients were randomized: 63 for early colonoscopy and 69 for standard colonoscopy. Baseline characteristics of both groups were compar- able with the intention-to-treat (ITT) analysis, the length of hospital stay was significantly lower in patients that underwent an early colonoscopy, compared to the standard colonoscopy group: median 2.0 days [IQR 2.0–4.0] vs. median 3.0 days [IQR 2.9–4.0] (p =0.009). Recurrent bleedings and hospital re-admissions were significantly more frequent in the early colonoscopy group: 13% vs. 3% 
(p =0.04) and 11% vs. 2% (p =0.02) respectively. The reason for more recurrent bleedings could not be established, although use of anti-thrombotic therapy might play a factor. No difference was observed regarding the number of patients diagnosed with either a confirmed active bleeding or presumptive bleeding source. In both groups, blood transfusion rate was similar and thirty-day mortality was zero. Conclusion: In patients with LGB, early colonoscopy reduces the length of hospital stay compared to standard colonoscopy. However, more recurrent bleedings are observed and no improvement of diagnostic yield could be established. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colonscopy is an imperfect tool. Several publications confirm colorectal cancer may manifest after a negative colonoscopy(1-3). The term “interval cancer” has often been used for cancers appearing after a negative colonoscopy. However, this is primarily a screening term(1). Post-colonoscopy colorectal cancer (PCCRC) is a broader term for cancers detected after a negative colonoscopy in any setting, including screening(2). Although there is overlap between these two terms, they are not synonymous. PCCRC can be thought of as an overarching term. PCCRC can be subcategorized into interval cancers (identified prior to the next recommended screening or surveillance procedure) and non-interval cancers (identified at or after a recommended screening or surveillance interval, or where no subsequent screening or surveillance interval was recommended, up to 10 years following the colonoscopy).

Aims: The goal of this consensus process was to provide a framework for the terminology, identification, analysis and reporting of cancers appearing after a negative colonoscopy or computed tomographic colonography (post-colonoscopy/post-imaging colorectal cancers - PCCRC/PICRC respectively). We based our methodology on The Appraisal of Guidelines for Research and Evaluation (AGREE II) tool[4]. An international multidisciplinary team (gastroenterologists, pathologists, epidemiologists, a radiologist and a patient represen- tant) were summoned by the World Endoscopy Organisation (WEO); the final panel consisted of 20 voting members. The following topics were addressed by 2 working groups (WGs):

1. Aetiology WG
  a. Terminology of aetiology categories
  b. Risk factors/potential explanations of PCCRC
  c. How to ascribe potential explanations
d. Minimal colonoscopy, histology and radiology datasets to examine PCCRC
2. Molecular testing to be performed to examine PCCRC
3. Prevention of PCCRC in high-risk groups
4. Performance WG
   a. PCCRC calculation & reporting
   b. PCCRC monitoring
c. PCCRC papers peer-review
d. Post-imaging CRC A literature search was performed in MEDLINE and Cochrane using terms “colorectal cancer AND interval cancer”, “healthcare quality assurance AND colorectal cancer” and “healthcare quality assurance AND colorectal cancer AND interval cancer”. The final output consisted of 391 articles. Proposed statements were subjected to anonymous voting via e-correspondence. Each statement was scored on an scale of 1 (strongly agree) to
P0437 EXCESS RISK OF SECOND PRIMARY CANCERS IN YOUNG-ONSET COLORECTAL CANCER SURVIVORS

Introduction: Young-onset colorectal cancer (CRC) is still the third most common malignancies in the US according to Colorectal Cancer Statistics, 2017[1]. During past decades, the incidence and mortality of CRC among individuals aged over 50 years are declining significantly, while the rate of CRC in the young is sharply on the rise (2-3). Excluding rate of young-onset CRC, coupled with increased survival rate, would definitely lead to accumulation of young survivors considerably. There is a growing study reporting the risk of secondary cancers (SPCs) in certain cancer survivors, including CRC. Several population-based studies revealed that patients with a history of CRC at high risk of SPCs than the general population [4-6]. However, to the best of our knowledge, very little is known regarding the risk and sites of SPCs following prior diagnosis of CRC in the young (aged ≤ 50).

Aims & Methods: To address this important gap, we aimed to quantify the relative risk of SPCs after a diagnosis of CRC in the young CRC survivors. We conducted this retrospective study by utilizing the Surveillance, Epidemiology, and End Results (SEER) database and identified primary CRC patients with subsequent cancers between 1973 and 2013. We excluded cases with less than 6-months latency restriction. Standardized incidence ratios (SIR) and absolute excess risk (AER) were calculated to access the relative risk for SPCs. SIRs for subgroup analysis were further stratified by gender, race, calendar year, location, SEER stage, cancer subsite, radiotherapy use. All statistical tests were performed by SEER*Stat version 8.3 and a P value <0.05 was considered statistically significant. Our study was approved by the review board of Zhejiang Institute of Gastroenterology, Sir Run Run Shan Hospital, China.

Results: There were 3,64,472 CRC survivors who developed 51,084 SPCs during the follow-up, including 32,83 young (young aged ≤ 60 and 41,189 (old > 50) old survivors. The SIR of all sites significantly decreased with increased age. Compared with the general population, SIRs of all solid tumors and hematological disease were significantly increased in the young. There was significant 43% risk of SPCs in young survivors (SIR = 1.34, 95%CI = 1.29–1.39, AER = 33.85) and slight increases in old survivors (SIR = 1.02, 95%CI = 1.01–1.03, AER = 4.20). For young survivors, small intestine (SIR = 8.36, colon (SIR = 3.77), rectum (SIR = 3.56), bile ducts (SIR = 2.70) sites were the most significant (p < 0.05). AER was persistent regardless of other factors, such as gender, race, calendar year, stage, subsites, radiation, and latency. For young survivors with second cancers, 36.4% died of their initial cancer, but 84.6% died of their second primary malignancy.

Conclusion: Excess risk of developing a second malignancy existed in young-onset CRC survivors and this trend was consistent among different subgroups. About 44.6% young patients died of their SPCs. We hope our results may provide some implication for future surveillance and prevention strategies for young CRC survivors.

Introduction: Worldwide, many organized colorectal cancer (CRC) screening programs use non-invasive fecal occult blood tests (FOBTs). Although the interval colorectal cancer (iCRC) risk in average CRC screening populations was reported, the iCRC incidence after negative FOBTs are limited. Research Supporting a determinant of a screening program, data on iCRC after negative FOBTs are limited.

Aims & Methods: In this systematic review and meta-analysis we compared the incidence of iCRCs following a negative fecal immunochemical test (FIT) or guaiac fecal occult blood test (gFOBT). Second, we assessed if screening-related or patient-related factors are associated with FOBT iCRCs. Ovid Medline, Embase, The Cochrane Library, the Science Citation Index, PubMed publisher and Google scholar were searched up to May, 2016. All studies reporting on the incidence rate of FIT or gFOBT iCRCs after average CRC screening populations were included, without language restrictions. Main outcome was pooled incidence rate of iCRCs per 100,000 person-years (p-y). FOBT iCRC was according to international standards defined as cancer that developed after a negative FOBT and before the next FOBT was due. Pooled incidence rates were obtained by fitting random effect poisson regression models. The between-study heterogeneity of effect-size was quantified using the I².

Results: We identified 5,873 records, of which 413 full-text articles were assessed for eligibility and 30 studies were included in both qualitative and quantitative syntheses. Meta-analyses comprised data of 5,252,563 screening participants, in which 14,030 screen-detected CRCs and 5398 FOBT iCRCs were documented. Pooled incidence rates of iCRC following FIT and gFOBT were 20 (95%CI 14.28; F; I2 = 94%) and 40 (95%CI 26.61; F; I2 = 93%) per 100,000 p-y, respectively. The pooled incidence rate of FIT iCRC compared to gFOBT iCRC was 0.50 (95%CI 0.30–0.84, n = 30 studies). For every FIT iCRC, three CRCs were found with FIT, while for gFOBT the ratio between FIT and gFOBT was 1,113. Table 1. No significant differences were found between the relative risk of FOBT iCRC in the second and third screening round compared to the first, with 1.03 (95%CI 0.94–1.13) and 1.08 (95%CI 0.93–1.22), respectively. Incidence rate ratio of FOBT iCRC compared to FIT iCRC was 0.87 (95%CI 0.81–1.17) for males relative to females and 5.00 (95%CI 1.21–21.78), and females aged ≥60 relative to <60 years.

Table 1: Baseline data of 30 studies included in quantitative meta-analyses displayed per test type
FOBT is two-fold higher in gFOBT than in FIT, which supports the use of FIT over gFOBT as screening tool. However, for every three FIT-detected CRCs, still one CRC is missed, which highlights the importance to adequately inform screenees about the risk of developing a colorectal carcinoma after a negative FIT.

Introduction: Age and family history of colorectal cancer (CRC) are the strongest risk factors for CRC. Obesity, commonly assessed based on body mass index (BMI), is associated with an increased risk for CRC in men but the association is weaker in women and differs between studies. We investigated which of the following body composition measures: BMI, waist-to-hip ratio ( WHR), waist-height ratio (WHHR), weight-height ratio (WHRR), A Body Shape Index (ABS) and percent body fat that best predict the development of CRC in men and women.

Aims & Methods: We used data from Malmö Diet and Cancer cohort in Sweden, including 16,840 women and 10,903 men (mean age, 58.1 years at baseline), followed for a median of 19.8 years. We identified cases with CRC until the end of 2014 using national Swedish registers. Hazard ratios (HR) for CRC, colonic cancer (CC) and rectal cancer (RC) per one standard deviation increase in each body composition measure respectively were calculated using Cox regression models, stratified by sex and adjusted for age, alcohol consumption, smoking, education and physical activity. Likelihood ratio tests and C-statistics were calculated to identify the anthropometric measure that improves the null model the most.

Results: Incident CRC occurred in 880 individuals (477 women) during follow-up. All body composition measures apart from WHHR significantly predicted CRC in men and waist circumference (WC) was the best predictor based on C-statistics and LR-test (HR per standard deviation [SD] increment, 1.19; 95% CI, 1.08–1.31, LR-test p < .001, C-statistics 0.6278). The association between WC and CRC was only found in men with a BMI above 25. All body composition measures apart from WHRR and percent body fat significantly predicted CC in men, again WC was the best predictor (HR 1.25; 95% CI, 1.11–1.42, LR-test p < .001, C-statistics 0.6444). ABSI was the only measure significantly associated with risk for RC in men (HR, 1.24; 95% CI, 1.05–1.47). In women neither of the measures was significantly associated with an increased risk for CRC, CC nor RC.

Conclusion: In this Swedish population-based cohort study on well-characterized participants, body composition measures predicted CRC in men but not in women. WC was the best predictor in CRC analysis, in order to identify overweight women WC was the best predictor of CRC and CC in men and the association was only significant in overweight obese men in stratified analyses. Gender difference in the interplay between sex and measures of adiposity in the adipose tissue may explain the lack of associations in women.

P0440 TH17 CELLS INDUCE EPITHELIAL-MESENCHYMAL TRANSITION VIA IL-17/PI3K/AKT/SNAIL PATHWAY IN COLORECTAL CANCER

Q. Li1, X. Xu2, P. Zhou2

Contact E-mail Address: liqunlin32@126.com

Introduction: T helper 17 (Th17) cells participate in the progression of various cancers. Both tumor-promoting and tumor-suppressing effect have been reported. The role of Th17 cells in colorectal cancer (CRC) remains controversial and the specific mechanism of how Th17 cells affect the development of CRC remains to be explored.

Aims & Methods: The study aimed to clarify the role of Th17 cells in CRC and identify the underlying molecular mechanisms. The percentage of Th17 cells and IL-17 expression were evaluated via flow cytometry, enzyme-linked immunosorbent assay (ELISA) and immunohistochemistry in tissue samples and peripheral blood. Effects and underlying molecular mechanisms of IL-17 cells on epithelial-mesenchymal transition (EMT) process were explored in vitro using IL-17 transfection and in nude mice by implanting IL-17 overexpressed CRC cells. To detect the expression of Th17 cells in vivo and EMT process, SW480 cells were cultured with IL-17 until they formed tumor xenografts (NXG). The expression of IL-17 was confirmed by ELISA. CRC and NXG were further explored and verified in larger cohort of 101 rectal tumors and 105 colorectal cancer patients. We have identified 71 candidate miRNAs in CRC tissues from 90 patients following surgery using immunohistochemistry.

Results: A higher percentage of Th17 cells and serum IL-17 level were found in CRC patients than healthy controls, and Th17 cells presented a gradual upward trend in normal epithelium-adenoma-carcinoma sequence. The overexpression of IL-17 significantly promoted cell proliferation and migration, and inhibited apoptosis in vitro and in vivo. IL-17 overexpression reduced the expression of E-cadherin and induced the expression of Snail, b-catenin, and Vimentin in both SW480 cells and tumor xenografts, suggesting that IL-17 could induce the EMT process of CRC. When co-cultured with SW480 cells with Th17 cells, we found Th17 cells could directly promote the EMT process of tumor cells. Furthermore, using cancer signaling phospho antibody microarray, we found that PI3K/AKT/Snail signaling pathway played a key role in the regulation of EMT. EMT process could be reversed by LY294002 and IL-17 mAb intervention, suggesting that IL-17/Pi3k/AKT/Snail pathway played a vital role in Th17 cells-induced EMT in CRC. Supporting these findings, in human CRC tissues, immunostaining indicated that the percentage of Th17 cells was significantly associated with E-cadherin expression and AKT phosphorylation. The clinical significance of Th17 cells was authenticated by revealing that the combination of intratumoral Th17 cells and E-cadherin served as a better prognosticator for postoperative tumor survival.

Conclusion: Th17 cells promote EMT process and facilitate tumor progression via activating IL-17/PI3K/AKT/Snail signaling pathway in CRC.

P0442 MUSCARINIC-3 RECEPTOR TARGETED miRNAs ARE INVOLVED IN BILE ACID-INDUCED PROLIFERATION ON H508 COLON CANCER CELL LINE

F. Tekin, C. Aktan, N. Oruc, O. Onenmeli

Gastroenterology, Ege University Medical School, Izmir/Turkey

Contact E-mail Address: drtekinfathi@gmail.com

Introduction: Studies with the colon cancer cell lines which express muscarinic-3 (M3) receptors showed that taurine conjugates of lithocholic acid, but not other bile acids, bind to M3 receptors, and stimulate an increase in cell proliferation. On the other hand, many microRNAs (miRNAs) are involved in colon carcinogenesis. However, the interaction of bile acid-M3 receptors and miRNAs and their potential effects in colon carcinogenesis remains to be elucidated.

Aims & Methods: For the first time in the literature, we examined the possible role of M3 receptor-targeted miRNAs on two human colon cancer cell lines: H508, which expresses M3 receptors, and SNU-C4, which does not. Cell proliferation for 6 days after sodium taurocholat (ST) and atropin (A) treatment was analysed by WST-1 method. Expression of M3 receptor gene at mRNA level was analysed by qPCR, and at protein level by Western Blot method. Apoptotic experiments were analysed by Annexin V assay. MiRNAs which possibly targeted M3 receptors were identified by in silico analyses. The methods were repeated three times, and the average values were calculated.

Results: When compared to SNU-C4 cells, M3 receptor gene expression was found to be increased 7-fold on H508 cells. After a 6-day incubation, maximum H508 cell population (300%) was achieved on 5th day with a dose of 300 μM ST, inhibited by a dose of 1μM A. In contrast, the SNU-C4 cells showed no significant change in cellular proliferation. Treatment of H508 cells with ST caused a decrease (2.53-fold) of M3 receptor gene expression, however, no change of M3 receptor at protein level was seen. No changes in apoptosis on both colon cancer cell lines were observed. Of 25 M3 receptor-targeted miRNAs, expression levels altered in 9; 6 of them were up-regulated (hsa-miR-129-5p, hsa-miR-30c-5p, hsa-miR-224-5p, hsa-miR-30b-5p, hsa-miR-522-5p, hsa-miR-1246) and 3 of them (hsa-miR-30e-5p, hsa-miR-147b, hsa-miR-885-3p) were down-regulated on H508 cells (p < 0.05).

Conclusion: ST interact with M3 receptors which modulate colon cancer cell proliferation on H508 cells. M3 receptor-targeted miRNAs are involved in ST induced proliferation. Whether the use of ursodeoxycholic acid, selective anti-miRNAs, anti-cholinergic agents or other approaches to blocking potential interactions of bile acids/salts with neoplastic colonic epithelium may be a useful adjunct to colon cancer prevention or treatment remains to be determined.

8University Institute of Oncology of Asturias, Oviedo/Spain

Introduction: Dyslipidaemia and statin use have been associated to colorectal cancer (CRC), but prospective studies have shown controversial results. Dyslipidaemia has been thought to have an important role in inflammatory pathways, oxidative stress and insulin resistance, which could contribute to the pathogenesis of cancer. However, findings from prospective studies that have examined the association between serum dyslipidaemia (low density lipoprotein cholesterol (LDL), HDL or TG) and colorectal neoplasia have been inconsistent.[1–4] It is unknown whether lipids and lipoproteins cause cancer or are intermediate or correlated factors within carcinogenic pathways. Epidemiological studies could be confounded by 3-Hydroxy-3-methylglutaryl-coenzyme A reductase inhibitors (statins) use, which might also have a protective effect to CRC. It is unclear whether it is statin use or dyslipidaemia that prompted statin use, which may be associated with CRC. Indeed, a large number of epidemiological studies have examined the effect of statins on colorectal cancer risk, with often inconsistent results.[5–6] A Mendelian randomization approach could help to establish a causal relationship between dyslipidaemia and CRC.

Aims & Methods: We aimed at determining whether dyslipidaemia is causally linked to CRC risk and to explore association of statins with CRC. A case-control study was performed including 1336 CRC cases and 2744 controls (MCC-Spain) between 2008 and 2013. Subjects were administered an epidemiological questionnaire that included lifetime regular use of prescription drugs. Also, subjects were genotyped with an exome array supplemented with 5000 custom SNPs. We applied the Mendelian randomization approach. The array included 136 SNPs previously shown to be associated with blood lipids levels in GWAS, that were used to build three genetic lipid scores, as the count of risk alleles. The scores were specific for low density lipoprotein cholesterol (LDL), high density lipoprotein cholesterol (HDL) or triglycerides (TG). We tested on the association on regular statin use and the genetic lipid scores with logistic regression models, adjusted for potential confounders.

Results: The LDL genetic risk score was significantly associated with statin consumption (OR = 1.07, 95%CI 1.05–1.10, p = 4.4e-11). The dyslipidaemia genetic risk score was not significantly associated with CRC for either of the target lipids studied. Cases had the same average alleles as controls in all the lipids traits. Statin use was a borderline significant protective factor for CRC (multivariate adjusted OR = 0.83; 95%CI 0.69–1.00; p = 0.049).

Conclusion: Using the Mendelian randomization approach, our study does not support the hypothesis that lipid levels are associated with the risk of CRC. This study does not rule out, however, a possible protective effect of statins in CRC by a mechanism unrelated to lipid levels.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Long non-coding RNAs (lncRNAs) contribute to different cancers including colorectal cancer (CRC) through influencing cancer-related processes such as cell proliferation, apoptosis, and invasion. Previous studies have shown altered LINC00152 expression in CRC, but the detailed mechanism of its effects during colorectal carcinogenesis and cancer progression is not well studied.

Aims & Methods: We aimed to study the effects of LINC00152 to the cell cycle regulation and promoter DNA methylation of several CRC-associated tumor suppressor genes in colon cancer cells. We also analyzed the expression and promoter DNA methylation of LINC00152 and of its regulated molecules in human colonic tissue samples. LINC00152 were silenced in SW480 colon cancer cells using Stealth siRNAs. Cells were harvested 48 or 72 hours after transfection. Flow cytometric cell cycle analysis was performed using propidium iodide staining. Cyclin D1 protein expression was detected using flow cytometry after labeling with anti-cyclin D1 antibody. The effect of LINC00152 silencing to DNA methylation levels of SFRP1, SFRP2, SD2C and PRIMA1 genes was measured in human colonic tissue samples. LINC00152 were silenced in SW480 colon cancer cells using Stealth siRNAs. Cells were harvested 48 or 72 hours after transfection. Flow cytometric cell cycle analysis was performed using propidium iodide staining. Cyclin D1 protein expression was detected using flow cytometry after labeling with anti-cyclin D1 antibody. The effect of LINC00152 silencing to DNA methylation levels of SFRP1, SFRP2, SD2C and PRIMA1 genes was measured in human colonic tissue samples.

Results: LINC00152 expression was successfully silenced in SW480 cells with 93–98% knockdown. Colorectal cancer cell line SGC7901, which expresses LINC00152 suppressed cell growth, apoptosis and decreased cyclin D1 protein expression. LINC00152 knockdown did not affect the promoter methylation status of SFRP1, SD2C and PRIMA1 genes, while reduced the DNA methylation level of SFRP2 promoter. Remarkable hypomethylation of LINC00152 promoter was detected in CRC compared to normal samples (p < 0.01), which correlated with increased expression (R = 0.9). SFRP2 promoter hypermethylation and decreased expression were measured in CRC and adenoma tissues compared to normal samples (p < 0.05). Contact: E-mail Address: orgi1@yahoo.com

3School of Medicine, Chinese University of Hong Kong, Hong Kong/Hong Kong PRC
4Chinese University of Hong Kong, Hong Kong/Hong Kong PRC

Introduction: Polyposis and advanced lesions (AML) are significant predictors of colorectal cancer, smoking and features of AML in first colonoscopy. P value analysis. There were no significant results concerning BRAF status. Multivariate analysis highlighted CIMP-H as the unique independent marker associated to shorter time to develop AML (HR 4.01, 95% CI 1.36–10.46; p = 0.001).

Aims & Methods: We aim to 1) evaluate the impact of KRAS on DNA and histone methylation in CRC; 2) examine the role of SLC25A22 in DNA and histone methylation in KRAS-mutant CRC; 3) elucidate the underlying mechanisms that underlies SLC25A22-mediated epigenetic dysregulation; and 4) investigate the clinical implication of SLC25A22 expression in CRC patients. DNA methylation was determined by the Illumina 880K methylation array and Methyl Light qMSP assays. Histone methylation was determined by Histone H3 Modification Multiplex Assay Kit and Western blot. U-13C5-Glu glutamate metabolic labeling and analysis of glutamine metabolism via the TCA cycle was determined by liquid chromatography-mass spectrometry analysis. In clinical samples, SLC25A22 mRNA expression was determined by qPCR. We then correlated CIMP Island Methylator Phenotype (CIMP) status and histone methylation mark (H3K36me2) was evaluated.

Results: Using three pairs of isogenic cell lines harbouring wild-type and mutant KRAS (DKS80/WT vs DLD1(mutant); HKE3/WT vs HCT116(mutant); ICT/WT vs ICT-KRAS(mutant)), we demonstrated that significant DNA and histone H3 hypermethylation in cell lines expressing mutant KRAS. DNA hypermethylation was associated with the up-regulation of 5-hmC, indicating suppression of the DNA and histone demethylase genes. Our results revealed that SLC25A22-dependent epigenetic regulation, as DNA methylation profiling revealed that SLC25A22 knockdown on glutamine metabolism had a profound effect on epigenetic regulation, as DNA methylation profiling revealed that SLC25A22 knockdown on glutamine metabolism had a profound effect on epigenetic regulation.
Conclusion: SLC25A22 promotes the tumorigenesis of KRAS mutant CRC by deregulating expression of DNA and histone hypermethylation, an effect mediated by increased production of TCA cycle intermediates succinate and fumarate, which inhibits DNA and histone demethylases. SLC25A22 is correlated with CIMP and histone hypermethylation in CRC patients.

Introduction: Follistatin-like protein 1 (FSTL1) is a secreted glycoprotein, widely expressed in human tissues, which plays key functions in the regulation of cell survival, proliferation, differentiation and migration. Moreover, deregulated expression of FSTL1 has been described in malignancies but its contribution to carcinogenesis remains controversial.

Aims & Methods: We here investigated the expression and role of FSTL1 in sporadic colorectal cancer (CRC). FSTL1 was evaluated in human CRC samples and cell lines by immunohistochemistry, Western blotting and real-time PCR. Cell proliferation and survival cell were evaluated in human CRC cell lines (i.e., HCT-116, DLD-1) treated with a specific FSTL1 antisense (AS) or control oligonucleotides. Western blotting, immunohistochemistry, and real-time PCR were used to assess the expression of proteins involved in cell cycle progression, poly ADP-ribose polymerase (PARP), caspase-9 and active caspase-3. Moreover, the effect of FSTL1 knockdown on cell death was evaluated in cells cultured in the presence or absence of the pan-caspase inhibitor Q-VD-OPh by flow-cytometry.

Results: FSTL1 was significantly increased in both epithelial and lamina propria compartments of human CRC specimens as compared to controls. In CRC cell lines, FSTL1 knockdown caused accumulation of cells in G1 phase of the cell cycle and cell proliferation. FSTL1-deficient CRC cells had reduced levels of proteins involved in late G1 cell cycle phase, such as phosphorylated retinoblastoma protein (pRb), E2F-1, cyclin E and cyclin-dependent kinase-2 (Cdk2), with no modification of early G1 phase proteins (i.e. cyclin D1). Treatment of CRC cells with FSTL1 AS increased the percentages of apoptotic cells and this effect was associated with activation of PARP, caspase-9 and caspase-3. Pre-incubation of HCT-116 and DLD-1 cells with Q-VD-OPh abolished the FSTL1 AS-induced cell death and reduced PARP and caspase activation, thus indicating that FSTL1 silencing induces CRC cell death through a caspase-dependent mechanism.

Conclusion: Our data indicate that FSTL1 is over-expressed in CRC cells and suggest a role for this protein in promoting intestinal tumorigenesis.

Introduction: Although TP53 mutation is well known to occur in the late phase of colon carcinogenesis as adenoma-carcinoma sequence. Although numerous reports about clinical information of the patients with colon cancer have suggested that TP53 mutation might be related to various malignant potentials, direct effect of TP53 mutation on malignant potential in colon cancer is still unknown. Notably, there is no report about a relationship between TP53 mutation and cancer stemness. We therefore aimed to assess the influence of TP53 mutation on malignant potential in colon cancer. TP53 mutation is commonly found in colon cancer patients. However, negative staining of TP53 might also be careful for carcinogenicity in CRC.

Aims & Methods: We first selected LS174T cells with WT-TP53 because TP53 gene has been described in malignancies but its contribution to carcinogenesis remains controversial. We here investigated the expression and role of FSTL1 in sporadic colorectal cancer (CRC). FSTL1 was evaluated in human CRC samples and cell lines by immunohistochemistry, Western blotting and real-time PCR. Cell proliferation and survival cell were evaluated in human CRC cell lines (i.e., HCT-116, DLD-1) treated with a specific FSTL1 antisense (AS) or control oligonucleotides. Western blotting, immunohistochemistry, and real-time PCR were used to assess the expression of proteins involved in cell cycle progression, poly ADP-ribose polymerase (PARP), caspase-9 and active caspase-3. Moreover, the effect of FSTL1 knockdown on cell death was evaluated in cells cultured in the presence or absence of the pan-caspase inhibitor Q-VD-OPh by flow-cytometry.

Results: FSTL1 was significantly increased in both epithelial and lamina propria compartments of human CRC specimens as compared to controls. In CRC cell lines, FSTL1 knockdown caused accumulation of cells in G1 phase of the cell cycle and cell proliferation. FSTL1-deficient CRC cells had reduced levels of proteins involved in late G1 cell cycle phase, such as phosphorylated retinoblastoma protein (pRb), E2F-1, cyclin E and cyclin-dependent kinase-2 (Cdk2), with no modification of early G1 phase proteins (i.e. cyclin D1). Treatment of CRC cells with FSTL1 AS increased the percentages of apoptotic cells and this effect was associated with activation of PARP, caspase-9 and caspase-3. Pre-incubation of HCT-116 and DLD-1 cells with Q-VD-OPh abolished the FSTL1 AS-induced cell death and reduced PARP and caspase activation, thus indicating that FSTL1 silencing induces CRC cell death through a caspase-dependent mechanism.

Conclusion: Our data indicate that FSTL1 is over-expressed in CRC cells and suggest a role for this protein in promoting intestinal tumorigenesis.

Introduction: Endogenous opioid system is involved in the maintenance of the intestinal homeostasis. Recently, we proved that stimulation of opioid receptors using P-317 – a novel cyclic morphinephenylalanin analog with mu- and kappa-opioid activity – caused accumulation of acute phase inflammatory cells and reduction of experimental cancer (induced by dextran sodium sulfate (DSS)) in mice. Chronic inflammation is associated with increased risk of colitis-associated colorectal cancer. Stimulation of opioid receptors produces different effects on cancer progression depending on the cancer type and stage of disease.

Aims & Methods: The aim of our studies was to characterize the role of the endogenous opioid system in pathogenesis and treatment of colitis-associated colorectal cancer using P-317. Colitis-associated colorectal cancer was induced by a single intraperitoneal injection of azoxymethane [AOM] (10 mg/kg) and subsequent addition of DSS (1.5% w/v) into drinking water (week 2, 6, 9). From week 3, P-317 was injected intraperitoneally at the dose of 0.1 mg/kg twice per week and the body weight and clinical score (rectal bleeding, stool consistency) were assessed. After 14 weeks, the mice were sacrificed and tumors were collected and used for biochemical, molecular and histological studies.

Results: A significant difference in colorectal tumor development was observed between vehicle- and P-317-treated mice. P-317 significantly increased total number of colonic tumors as well as colon thickness and width after 14 weeks of disease induction. Myeloperoxidase activity, a marker of neutrophil infiltration, was inhibited by P-317 injections. Hematoyxlin and eosin staining confirmed anti-tumor activity of P-317 as indicated by histological score connecting the following features: muscle thickness, damage of the intestinal wall, immune cell infiltration, invasion depth, crypt hyperplasia and disruption. The expression of IL-1β and TNF-α at mRNA level was decreased in P-317-treated mice as compared to vehicle-treated group. Conclusion: P-317 may become an important pharmacological tool to study the factors that determine the development of inflammatory bowel disease and to define the role of the endogenous opioid system in chronic colitis and colorectal cancer.

Introduction: Colorectal cancer (CRC) is the third most common type of cancer worldwide. Up to date, there is no effective screening tool for CRC. Therefore, it is imperative to find new biomarkers for CRC diagnosis and subsequent death due to colorectal cancer is associated with its stage 11. 2. Because of its insidious onset, the diagnosis of CRC is usually delayed. However, serological markers can be a relatively easier and cheaper alternative to the current CRC screening strategies. Since concurrent occurrence of CRC with the high motility group box 1 (HMGB1) plays a critical role in CRC progression, death, and poor prognosis15. Several recent studies have shown that HMGB1 is over-expressed in various types of cancers, including CRC, and those cases with high expression of HMGB1 are associated with lymphatic metastasis, distant metastasis and poor prognosis15. Several reports have demonstrated that HMGB1 is
secreted by cancer cells may be involved in occurrence of tumor metastasis. 6.7. In a study by Luo et al., authors found that HMGB1 secreted by the primary tumors had an apoptotic effect on the Kupffer cells which promoted development of liver. 6.7. Furthermore, some researchers showed that increased levels of c-IAP2 and pERK, the downstream effector molecules of HMGB1 are found in tumors. 6.7. Such observations suggest that HMGB1 may be useful for diagnosis and treatment of CRC. However, whether HMGB1 has any role in the development of CRC metastasis is not clear. In this study, we investigated the effects of HMGB1 on CRC, and the possible underlying mechanisms were examined.

Aims & Methods: Aims were to investigate the relationship between high-mobility group B1 (HMGB1) and colorectal cancer (CRC) and the probable underlying pathogenic mechanism. In this prospective study, patients with CRC undergoing primary surgery and healthy subjects (control group) were included from July 2013 to December 2013. HMGB1 concentration was determined using ELISA and HMGB1 mRNA expression was detected by RT-PCR method. Immunohistochemical analysis was performed to determine HMGB1, pERK and c-IAP2 protein expressions in the cancer tissues.

Results: 144 patients with CRC and 50 healthy subjects underwent HMGB1 testing. Resected specimens of 50 patients were used for HMGB1 mRNA and protein expression analysis. Serum HMGB1 levels in CRC patients were higher than that of the control group (8.42 vs. 1.79 ng/L, p < 0.05). Preoperative serum HMGB1 concentrations were significantly higher than the postoperative values (8.42 ± 5.67 vs. 1.64 ± 1.89 ng/L, p = 0.05). Serum HMGB1 levels in CRC patients with distant metastasis were significantly higher (13.32 ± 6.12 vs. 7.37 ± 5.14 ng/L, p < 0.05). HMGB1 mRNA and protein expression in CRC tissues was significantly higher than in the adjacent normal mucosa. HMGB1 protein expression positively correlated with the lymph node metastasis. There was positive correlation between HMGB1 and c-IAP2 (r = 0.457, P = 0.008), HMGB1 and pERK (r = 0.461, P < 0.05) as well as pERK and c-IAP2 (r = 0.399, P < 0.05).

Conclusion: HMGB1 expression in CRC correlates with distant and lymph nodal metastasis. It may inhibit apoptosis by inducing activation of pERK and c-IAP2.

Introduction: Accumulating data indicate that some microRNAs (miRNAs or miRs) function as tumor suppressors or oncogenes in cancer development. We previously reported that cancer-related miRNAs (miR-143, -145, -197 or -200) were differentially expressed in samples of tumors and paired non-tumorous samples taken from the same patients with colorectal tumors, and there was a relation close to adenoma-carcinoma sequence for these miRNAs expression.

Aims & Methods: In this study, we focused on the miRNA expression profiles of multiple colorectal adenomas comparing between sporadic colorectal adenoma and familial adenomatous polyposis (FAP). We examined the miRNA expression profiles (miRs-143, -145, -7, -197 and -54a) and morphological appearance of 102 sporadic colorectal adenomas (SA), 27 tumors of multiple colorectal adenoma (10 adenomas/one patient, MA), 21 tumors of FAP and 114 sporadic cancer (SC).

Results: The expression levels of miR-143 and -145 were reduced in all tumors compared with the paired non-tumorous samples in the same patient. Especially, these miRNAs were significantly reduced in MA (P = 0.042 and P = 0.004) and FAP (P = 0.027 and P = 0.022) compared with SA. The expression levels of miR-7 were significantly up-regulated in cancers compared with adenomas (P < 0.001). The expression levels of miR-34a were significantly down-regulated in CA (P < 0.001), MA (P < 0.001), and FAP (P = 0.006) compared with SA.

Conclusion: These findings suggest that the malignant potential of MA and FAP was higher than SA, therefore MA needs strict follow-up like FAP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0453 UTILITY OF MEAN PLATELET VOLUME, PLATELETCRIT, PLATELET-LYMPHOCYTE RATIO AND NEUTROPHIL-LYMPHOCYTE RATIO IN THE DIFFERENTIATION OF COLORECTAL CANCER AND COLONIC POLYPS IN OLDER PATIENTS
F. Karakaya, Ç. Kalkan, I. Soykan
Gastroenterology, Ankara University, Ankara/Turkey
Contact E-mail Address: mkarakaya@yahoo.com

Introduction: Colorectal carcinoma (CRC) is an important cause of mortality and morbidity among healthy patients. The colorectal cancer in elderly patients, irrespective of the iron status. There is a close association between increased mean platelet volume (MPV) and the presence of many solid tumors such as hepatocellular carcinoma, pancreatic carcinoma, lung cancer, endometrial cancer and gastric cancer. Neutrophil/lymphocyte ratio (NLR) and platelet/lymphocyte ratio (PLR) are markers of systemic inflammatory response and their elevation is closely some studies to be associated with progression of colorectal carcinoma. Although colonoscopic examination is the standart way of colorectal cancer detection, it is not possible for all elderly patients. The NLR and PLR markers are important for predicting colorectal carcinoma and colonic polyps for each parameter studied.

Aims & Methods: The aim of this study was to investigate whether MPV, plateletcrit, PLR and NLR may have a role in the discrimination of CRC and colonic polyps in older patients. 418 patients aged >65 years with colorectal carcinoma (n=93) (Group I) and colonic polyps (n=325) (Group II) were included into the study. Also 601 (Group III) patients aged >65 years with normal colonoscopic findings served as a control group. All study subjects were investigated by using MPV, plateletcrit, PLR and NLR in order to establish sensitivity and specificity for predicting colorectal carcinoma and colonic polyps for each parameter studied.
Results: MPV, PCT, NLR and PLR were significantly higher in Group III compared to Group II (all p < 0.001). However, only MPV and PCT were significantly higher in Group II compared to group 1 (8.6 ± 1.1 vs 8.2 ± 1, p < 0.001). The cut-off value of MPV in predicting CRC from patients with normal colonoscopic findings was 9.15 fL with a sensitivity and specificity of 80% and 91% respectively (r = 0.892). MPV and PCT were also significantly higher in patients with non-neoplastic polyps compared to patients with non-neoplastic polyps (MPV: 8.7 ± 1.1 vs 8 ± 1, p < 0.001 and PCT: 0.23 ± 0.07 vs 0.19 ± 0.05, p = 0.003).

Conclusion: MPV and PCT may have a role as useful and simple markers in the diagnostic assessment of patients with colorectal cancer from patients with normal colonoscopic findings. In the clinical settings, these simple markers may be useful in selecting older patients for colonoscopic examination.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0454 IMPROVING THE SELECTION OF COMPLETE RESPONDERS FOR WATCHFUL WAITING AFTER CHEMORADIOThERAPy FOR Rectal cancer: WHAT Can We LEARN FROM THE ‘MISSED’ PATHOLOGIC COMPLETE RESPONDERS AFTER SURGERY?
1Department of Radiology, The Netherlands Cancer Institute, Amsterdam/Netherlands
2Surgery, The Netherlands Cancer Institute, Amsterdam/Netherlands
3Surgery, Maastricht University Medical Centre, Maastricht/Netherlands
4Radiology, Maastricht University Medical Centre, Maastricht/Netherlands

Contact E-mail Address: doenha.lambregts@gmail.com

Introduction: Rectal cancer patients with clinical evidence of a complete response after chemoradiotherapy may be selected for watchful waiting instead of surgical resection (although currently mainly within the scope of clinical trials). The chance of a complete response was re-scored by the expert team according to ‘common’ radiological features such as volume showed inferior performance compared to features extracted from manual delineations. Inadomi et al. showed that the chance of organ preservation. A promising new tool in this regard is ‘Radiomics’. Radiomics refers to a collection of analytical methods to convert images into high dimensional data via a set of quantitative descriptors called ‘features’. These features have the potential to uncover disease characteristics that cannot be detected by means of conventional (visual) imaging evaluation. The aim of the Radiomics signature of patients with LARC and evaluate its potential value for pre-treatment prediction of the response to neoadjuvant chemoradiotherapy.

Aims & Methods: We retrospectively assessed the primary staging MRI’s (1.5T of 124 LARC patients treated with CRT. The standard MRI protocol included T2-weighted (T2W) and diffusion-weighted imaging (DWI) sequences, as well as quantitative apparent diffusion coefficient (ADC) maps derived from the DWI scans. For each patient, the whole volume of the rectal tumour was delineated on pre-treatment MRI: [1] by 2 expert pelvic radiologists, [2] using a semi-automatic (region growing) software algorithm, and [3] by manual adjustment of the semi-automatic delineations by two non-expert readers, adding up to 5 delineations per tumour/patient in total. Radiomics signatures were extracted from the images for each of the five delineations (300 features in total). Features showing both sufficient stability (ICC ≥ 0.75) as well as reproducible performance (Wilcoxon test, False Detection Rate (FDR) 10%) across different readers/delineations were considered as ‘common’ radiological features such as volume showed inferior performance (highest rating 56) Results derived from delineations performed by the two expert radiologists were more stable and reproducible than those performed by the non-expert reader (highest rating 41). Results: Out of 300 initially identified Radiomics features, 1853 proved stable across different readers/delineations. For the four manual delineations ±300/3002 features per reader remained significantly performant after FDR correction. However, these features did not sustain after FDR correction for the fully automated segmentation. A final subset of 266 features remained stable and performant across all five readers/delineations. These features resulted in a mean AUC of 0.67 (range 0.64-0.73) to predict a complete response and a mean ICC of 0.81 (range 0.75-0.95). Best results were obtained for textural features measuring the heterogeneity of the tumor on DWI (all top 20 features). In contrast, more ‘common’ radiological features such as volume showed inferior performance (highest rating 56). Results derived from delineations performed by the two expert radiologists and non-expert readers resulted in comparable diagnostic performances.

Conclusion: 1) Various Radiomics features extracted from pre-treatment MRI correlate to neoadjuvant treatment response and may be used as imaging biomarkers to predict the response to chemoradiotherapy in rectal cancer. 2) Best results are obtained for textural features (representing tumour heterogeneity) derived from diffusion-weighted MR sequences. 3) Features extracted from semi-automated (software generated) delineations show inferior performance compared to features extracted from manual delineations, emphasizing the need for adequate tumour delineation. Interestingly, however, delineations from expert and non-expert readers rendered similar good results, suggesting that the selected features are robust and do not necessarily require highly expert input.

Introduction: Laterally spreading tumors (LSTs) of the colorectum are classified in three according to their morphological and cytogenetic type (LST-GH), granular nodular mixed type (LST-GM), and non-granular flat- elevated type (LST-NGF), and non-granular pseudo- depressed type (LST-NGPD). Clinical features of each subtype of LSTs have not been fully evaluated.

Aims & Methods: The aim of this research is to clarify the clinical and diagnostic features of colorectal LSTs focusing on their subtypes. We reviewed clinical charts and surgical pathology files of 5352 endoscopically resected specimens during January 2007 and December 2016 at our institution. A total of 422 LSTs were detected. We examined clinical features (mean age, size, location, Incidence of concomitant carcinoma) according to their subtypes.

Results: Of these 422 lesions, a total of 131 (31.3%) were LST-GH, 34 (8.1%) LST-GM, 32 (7.6%) LST-NGF, and 29 (6.6%) LST-NGPD. Mean age of patients with each subtype was 68.3 years old for LST-GH, 67.1 for LST-GM, 67.9 for LST-NGF, and 67.2 for LST-NGPD. Male to female ratio (M/F) was 1.21 for LST-GH, 2.05 for LST-GM, 1.95 for LST-NGF, and 1.65 for LST- NGPD. Mean size of LST-GH (21.2 mm) and LST-NGF (17.0 mm) were significantly larger than that of LST-NGF (17.0 mm) and LST-NGPD (15.1 mm). All subtypes were located predominantly in the proximal colon. Incidences of concomitant carcinomas in LST-GH, LST-GM, LST-NGF, and LST-NGPD were 0% (0 out of 151), 14.7% (5 out of 34), 1.9% (2 out of 209), and 5.0% (8 out of 162), respectively.

Conclusion: Each subtype of LSTs have distinct clinical features. LST-GM and LST-NGPD have higher malignant potentials than other subtypes. Especially LST-NGPD has the highest risk of invasive carcinoma regardless of its size. Therefore, we should carefully detect these lesions and choose appropriate treatment according to the subtype.

Introduction: Post-colonoscopy colorectal cancer (PC-CRC) rates are proposed as a quality indicator for colorectal screening. Estimating PC-CRC rate is important but important to assess local practise and to compare with recent published National Data. We aimed to calculate the PC-CRC and the post CT (Colonoscopy + abdomen) CRC rate at Poole Hospital using the number of colonoscopies or CT scans done within 3 years of a CRC diagnosis as the denominator for post-investigation PI -CRC calculations as outlined in a previous study.1

Aims & Methods: Retrospective audit of all patients diagnosed with CRC during two consecutive periods from 1st March 2015 to 28th February 2017 inclusive identified via the Somerset Cancer registry database for Poole Hospital using Crystal software. Previous colonoscopy and CT Colonoscopy (CTC) or CT abdomen results in the 3 years preceding the diagnostic investigations were reviewed across two neighbouring hospitals sharing the same electronic patient records. If patients had multiple surveillance colonoscopies the latest was counted as false negative as in previous studies.2

Results: 416 patients were identified, 67 were excluded (39 non adenocarcinoma, 3 out of area, 12 patients where earlier decision was best supportive care, 6 patients diagnosed at laparotomy, 2 patients with abnormal PET scans and 6 with incomplete datasets). 348 patients were included for analysis. Colonoscopy was diagnosed by colonoscopy in 200 patients and by CTC or CT in 148. In the symptomatic service groups there were 7 preceding colonoscopies and in the surveillance group there were 5 preceding (“false negative”) colonoscopies within the previous 3 years. The overall PC-CRC rate was 6.5 (+3.6, –2.2) % (90% confidence interval). In the Colonoscopy + abdomen group, 1 patient had a previous CT scan which the BCSP marked as false negative. The positive predictive value of the symptom and 4 from the surveillance group underwent CT scans within the preceding 6–36 months. All bar one of these 15 patients had undergone preceding CT abdomen scans with one elderly patient from the symptomatic group with a previous CT scan and a BCSP marked as a false negative. The positive predictive value of the symptom and 4 from the surveillance group underwent CT scans within the preceding 6–36 months. All bar one of these 15 patients had undergone preceding CT abdomen scans with one elderly patient from the symptomatic group with a previous CT scan and a BCSP marked as a false negative. The positive predictive value of the symptom and 4 from the surveillance group underwent CT scans within the preceding 6–36 months. All bar one of these 15 patients had undergone preceding CT abdomen scans with one elderly patient from the symptomatic group with a previous CT scan and a BCSP marked as a false negative.

Conclusion: Our findings offer the opportunity for further review of individual patients and services. Estimating PC-CRC rate is important but important to assess local practise and to compare with recent published National Data. We aimed to calculate the PC-CRC and the post CT (Colonoscopy + abdomen) CRC rate at Poole Hospital using the number of colonoscopies or CT scans done within 3 years of a CRC diagnosis as the denominator for post-investigation PI -CRC calculations as outlined in a previous study.1
had ACO (ACO group). In the non-ACO group, we confirmed that the surgical II/III CRC with ACO among patients in the two institutions.

Conclusion: TCT placement can achieve similar long-term outcomes to those of emergency surgery, with a high rate of primary resection and anastomosis for distal stage II/III CRC with ACO.

Disclosure of Interest: All authors have declared no conflicts of interest.

Servicio De Aparato Digestivo, Complejo Hospitalario de Ourense, Ourense, Ourense/Spain

Contact E-mail Address: noel.pin.vieito@sergas.es

Introduction: The fecal immunochemical test (FIT) has a high diagnostic accuracy for the detection of colorectal cancer (CRC) in symptomatic patients. However, we do not know the risk of other gastrointestinal neoplasms associated with a false positive test.

Aims & Methods: To calculate the risk of detection of gastrointestinal tract tumors (GITT) and death in symptomatic patients with a positive FIT determination and without a CRC in a complete colonoscopy with an adequate bowel preparation. We designed a prospective cohort study with follow-up. Patients from the COLONPREDICT study with complete colonoscopy without CRC were included. Two cohorts were defined: FIT positive and negative according to the ≥200ng hemoglobin/g of feces threshold. We performed a descriptive analysis of clinical data detected during follow-up and mortality. We estimated the differences in the risk of GITT detection and mortality between the two cohorts by logistic regression and proportional hazards after adjusting for age, sex, and significant colonic lesions (CSL) detection at baseline colonoscopy.

Results: We included 1061 patients without CRC and a complete baseline colonoscopy; 320 (30.2%) with a positive FIT and 741 with a negative FIT. The median follow-up was of 36.0 ± 8.9 months with no difference between both groups (p = 0.2). There were significant differences regarding age (67.5 ± 12.7 years vs. 64.8 ± 13.5 years, p = 0.04) and sex (45.9% vs. 52.0% females, p = 0.04) between both cohorts. We detected a GITT in 14 (4.4%) patients with a positive FIT: 5 CRC, 6 gastric, 1 small intestinal lymphoma and one patient with a CRC and a small intestine adenocarcinoma; and in 12 (1.6%) with a negative FIT: 4 CRC, 6 gastric, 2 small intestine adenocarcinoma, one esophageal, and one patient with a gastric and a CRC. Patients with a positive FIT had a non-significant increase in the risk of GITT detection (OR 2.1, 95% CI 0.9–4.8) after adjusting for age, sex and SCL. The overall risk of death in both groups was 8.8% and 6.2%, respectively, with no significant differences between both groups in the survival analysis (HR 1.3, 95% CI 0.8–2.1). However, the risk of death due to GITT was 3.1% (10 deaths) in the positive FIT group and 0.8% (6 deaths) in the negative FIT group, with a significant difference after adjusting for age, sex and SCL (HR 3.2 95% CI 1.2–8.9).

Conclusion: Symptomatic patients with a positive FIT and complete colonoscopy without CRC are at increased risk of death due to GITT regardless of age, sex or the presence of SCL.

Introduction: A stent is a standard management for colorectal cancer (CRC) with acute colorectal obstruction (ACO). Transanal colorectal tube (TCT) placement is an alternative endoscopic treatment for ACO; however, the oncological outcomes of TCT placement for the curative treatment of CRC remain unknown.

Aims & Methods: Data were retrospectively reviewed from patients with distal stage II/III CRC who underwent surgery between January 2007 and December 2011 at two Japanese affiliate hospitals with an interchange of endoscopists and different endoscopic and surgical endoscopic and surgical endoscopic and surgical settings. This study demonstrated the high technical and clinical success rate of double-wire double-woven uncovered metallic stent placement for malignant colorectal obstruction. Clinicians should perform this procedure carefully in patients with presence of ascites.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Self-expandable metallic stent placement for malignant colorectal obstruction has been widely used; however, factors affecting the technical difficulty of stenting remain unclear.

Aims & Methods: The aim of this study was to clarify the factors associated with the technical difficulty of stenting for malignant colorectal obstruction. We established the Colonic Stent Procedure Research Group to provide instructions on how to safely perform stent placement, and then we conducted this prospective, single-arm, observational, multicenter clinical trial between October 2013 and May 2014 in Japan. Thirty-two facilities participated in this study. A double-wire double-woven uncovered stent was placed by using a standard through-the- scope colonoscopic placement technique in each patient. Stent deployment time was defined as the time from reaching a lesion with a colonoscope to finish stenting. Technically difficult cases of stenting were defined as independent factors affecting the technical difficulty of stenting by using univariate and multivariate analyses.

Results: A total of 205 consecutive patients were enrolled in this study. Nine patients including 3 patients with technical failure of stenting, 5 patients with non-stenting and 1 patient with stenting for benign lesion were excluded. The remaining all 196 patients were included in stenting. Of these, 100 were men (51%), and the median age was 72 years old (interquartile range (IQR), 62–82 years old). One hundred eleven patients (57%) underwent stenting as a bridge to surgery, and 85 (43%) underwent stenting for palliation. The technical and clinical success rates were 98.5% and 97.0%, respectively. None of the patients experienced colorectal perforation during stenting. The median total procedural time in the cohort with technical success was 30 minutes (IQR, 18–42 minutes). The median deployment time was 21 minutes (IQR, 11–31 minutes). Forty-four patients with a deployment time longer than 31 minutes were regarded as technically difficult cases of stenting, which were identified as independent factors of the technical difficulty in stent placement: presence of ascites (odds ratio, 2.483; 95% confidence interval [95%CI], 1.17–5.29; p = 0.02), presence of >1 stent (odds ratio, 4.80; 95%CI, 1.10–21.0; p = 0.04).

Introduction: Colorectal cancer is the third most common cancer in the world and the fourth leading cause of cancer death. Treatment strategy for colorectal cancer is selected considering clinical stages. Ti colorectal cancer (TiCRC) can be treated with endoscopic resection. If patients have pathological risk factors such as deep submucosal invasion, bunting, por/muc pathological features and lymphovascular invasion, they considered to be at high risk of lymph node metastasis based on the indication of Japanese Society for Cancer of the Colon and Rectum guideline. In such cases, the selection of subsequent option is important and has been frequently decided by clinicians’ customs and preferences. However, it is not clear whether these risk factors adequately predict patients’ prognosis in clinical practice.

Aims & Methods: This research aims at revealing the prognosis and clinicopathological features of pathologically high-risk TiCRC patients (the high-risk group) with and without additional surgery; followed up by computed tomography, ultrasound, endoscopy, and tumor marker (CEA: carcinoembryonic antigen). To evaluate the difference of overall survival (OS), cancer specific survival (CSS) and recurrent-free survival (RFS) between the patient performed additional colectomy with lymph node dissection (AS) and the patient followed up without additional surgery (FU). To reveal what clinicopathological factors are considered in the selection of subsequent option, whether AS or FU, in the high-risk group. We retrieved the clinical data of 162 patients who had diagnosed and treated as Ti colorectal cancer at Kyoto University Hospital (Kyoto, Japan) between February 2005 and February 2015. Treatment strategy after diagnosis follows: Patient’s values and preferences, solely presence of “depth” risk factor, possible intensive surgery due to TiCRC located in the lower rectum, other advanced malignancy, and perioperative risks; advanced age, past history of abdominal surgery or radiation, severe comorbidity including chronic heart disease, and possible intensive surgery due to T1CRC located in the lower rectum.

Results: Among 162 TiCRC patients, 78 cases were treated with endoscopic resection for the first time. Of them, 46 patients had at least one pathological risk factor (high-risk patients). Among 46 high-risk patients, 22 patients were carefully followed up (FU), 20 patients were performed additional surgery with lymph node dissection (AS). Four patients treated with additional radiation therapy were excluded. Median survival time was 39 (FU) and 62 (AS), respectively. There were no recurrences among the 62 e-curable patients. On the other hand, five recurrences (5%) were found in non-e-curable patients, and they were all in Group A. They consisted of local recurrence (one patient who also had lung metastasis), lymph node metastasis (two patients), lung metastasis (two patients), and liver metastasis (one patient who also had LN metastasis). There were no significant differences in DSS between Group A and Group B + C (LST-NG). However, OS was 93% in Group A, which was significantly lower than that (96%) in Group B + C (p < 0.05). DFS in Group A was 90%, which was significantly lower than that (100%) in Group B + C (p < 0.05). The prognosis of patients with non-e-curable disease after ER alone showed no significant differences in OS, DFS, and DSS between Group A and Group B + C. The prognosis of patients with non-e-curable disease after surgical resection showed no significant differences in DFS or DSS. However, OS in Group A was 94%, which was significantly lower than that (97%) in Group B + C (p < 0.05).

Conclusion: Long-term outcomes supported the JSCCR criteria for e-curable patients for ER for Ti LSTs. All recurrences occurred in patients with Ti LST-NG in the FU group. OS of LST-NG was significantly shorter than in the LST-NG group.

Results: In this study we developed and tested a controlled-release paclitaxel-eluting SEMS designed to prevent tissue hyperplasia and stent occlusion. A leucovorin- and paclitaxel-eluting, laser-cut nitinol stent was coated with a polymer matrix allowing slow release of paclitaxel. Native Yucatan swine were assigned to one of three stent groups: bare control (n=3, no polymer), standard dose paclitaxel (n=6, 149.4 μg paclitaxel) and challenge dose (n=3, 538.0 μg paclitaxel). Two stents were endoscopically implanted in each swine from its assigned group. One in the intrahepatic hilar region and a second in the common bile duct placed proximal to the papilla. Stents were assessed for migration via digital radiographs for the first 2 weeks and then monthly via endoscopy using SpyGlass® and D.S cholangioscopy and cholangiography with a targeted 6 month study endpoint. At this mid-study follow-up, paclitaxel-eluting stents appear to be safe for use in naïve tissue and do not negatively impact function of the biliary matrix allowing slow release of paclitaxel. Naïve Yucatan swine were assigned to one of three stent groups: bare control (n=3, no polymer), standard dose paclitaxel (n=6, 149.4 μg paclitaxel) and challenge dose (n=3, 538.0 μg paclitaxel). Two stents were endoscopically implanted in each swine from its assigned group, one in the intrahepatic hilar region and a second in the common bile duct placed proximal to the papilla. Stents were assessed for migration via digital radiographs for the first 2 weeks and then monthly via endoscopy using SpyGlass® and D.S cholangioscopy and cholangiography with a targeted 6 month study endpoint.

Results: At 30 days post-implant, no significant tissue reaction to any stent was observed. However, all animals displayed mild biofilm formation and increased intraluminal mucus production. Substantial dilation of the common bile duct was observed in 5/11 animals with no apparent relationship between drug coating and duct dilation. At 60 days post-implant, moderate mucus and biofilm formation was observed within the stent, however in only 3 animals bile liver duct dilation persisted and a tendency of stents were fully opposed to the duct wall. Although some animals displayed minimal tissue hyperplasia at the proximal end of the stents, no tissue overgrowth or stent embedding was observed in any animal. Up to 60 days post-implant, no persistent clinical symptoms were observed in any animal toward dose animals. At 30 days post-implant, 4/11 animals demonstrated bile duct dilation, 3/11 animals demonstrated bile duct stenosis, and 3/11 animals demonstrated bile duct obstruction. At 60 days post-implant, 10/11 animals demonstrated bile duct dilation, 8/11 animals demonstrated bile duct stenosis, and 9/11 animals demonstrated bile duct obstruction. Although bile duct dilation was observed within the stent, however in only 3 animals bile ductal dilation persisted and the majority of stents were fully apposed to the duct wall. Although bile duct dilation was observed within the stent, however in only 3 animals bile ductal dilation persisted and the majority of stents were fully apposed to the duct wall. Although bile duct dilation was observed within the stent, however in only 3 animals bile ductal dilation persisted and the majority of stents were fully apposed to the duct wall.

Although bile duct dilation was observed within the stent, however in only 3 animals bile ductal dilation persisted and the majority of stents were fully apposed to the duct wall.
Aims & Methods: In this prospective study, we evaluated the overall survival (OS) of patients with colorectal cancer who were associated with overall and with non-resectable survival not inferior to those of the traditional approach, favoring its implementation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Preliminary results of our series confirm that the W&S strategy is equivalent to FOLFOX/FOLFIRI in the treatment of colorectal cancer and is associated with an overall survival not inferior to those of the traditional approach, favoring its implementation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0406 LONG-TERM COLONOSCOPIC SURVEILLANCE BETWEEN PATIENTS AFTER SURGICAL RESECTIONS OF COLORECTAL INVASIVE CANCER AND THOSE AFTER ENDOSCOPIC RESECTIONS OF COLORECTAL ADENOMA AND INTRAMUCOSAL INVASIVE CARCINOMA

Introduction: Patients after surgical resection of colorectal invasive cancer and those after endoscopic resections of colorectal adenoma and intramucosal cancer, both of them have the risk of metachronous advanced neoplasia during follow-up.

The present study aimed to compare the risk of metachronous neoplasia during a long-term follow-up between patients with colorectal invasive cancer resected by surgery and those having colorectal adenoma and intramucosal cancer resected at initial colonoscopy.

Aims & Methods: A total of 1078 patients were colonoscopically followed-up during a long-term period in our hospital. They were divided into group A, B, and C as follows: 445 in group A (mean age 64.7 yr, M=2.371); 318 in group B (66.1 yr, 2.311) with high-grade adenoma or intramucosal cancer colonoscopically resected at baseline, 388 in group C (65.1 yr, 1.541) with invasive cancer resected at initial colonoscopy. During follow-up colonoscopies detected metachronous neoplasms were resected and pathologically evaluated into non-index lesion (low-grade adenoma) or index lesion (high-grade adenoma or cancer).

The cumulative incidences of metachronous colorectal neoplasms were compared with each other using Logrank test.

Results: Median follow-up periods and frequencies of colonoscopy were 64.3 months and 3.7 times in group A, 52.0 months and 3.5 times in group B, and 74.6 months and 3.9 times in group C, respectively. The cumulative incidences of metachronous non-index lesion were 24.5% (109 patients with 299 low-grade neoplasms) in group A, 26.1% (64 with 184) in group B, and 19.3% (75 with 229) in group C, respectively. The prevalence of metachronous non-index lesion was lower in group C compared to that in group A (p=0.007), and group B (p=0.007). The cumulative incidences of metachronous invasive cancer were 0.9% (4 patients with 4 invasive cancers) in group A, 1.2% (3 with 3) in group B, and 3.6% (14 with 14) in group C, disclosing highest prevalence in group C (p<0.005). Logrank test revealed that the cumulative incidence of non-index lesion was 1.29 times in group C, respectively. The prevalence of metachronous non-index lesion was lower in group C compared to that in group A (p=0.007) and group B (p<0.005).

Conclusion: Significant higher prevalence of metachronous index lesion including invasive cancer and, in contrast, significant lower prevalence of metachronous non-index lesion were observed in patients after resected colorectal invasive cancer compared to those after endoscopic resections of colorectal adenoma and intramucosal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0409 LONG-TERM COLONOSCOPIC SURVEILLANCE BETWEEN PATIENTS WITH UNRESECTED DIMINUTIVE POLYPY AND THOSE WITH COLORECTAL ADENOMAS > 5MM IN SIZE RESECTED AT INITIAL COLONOSCOPY

S. Kimura1, M. Tanaka2
1Gastroenterology And Endoscopy, Aomori Rosai Hospital, Hachinohe/Japan
2Pathology And Laboratory Medicine, Hiroaki Municipal Hospital, Hiroaki/Japan

Contact E-mail Address: saint4oad@gmail.com

Introduction: A long-term risk of colorectal advanced neoplasia among patients having diminutive polyps at initial colonoscopy has been unknown. The present study is to clarify the risk of metachronous advanced neoplasia during follow-up between patients with untreated diminutive colorectal polyps and those with small or large adenoma resected at baseline colonoscopy.

Aims & Methods: A total of 1395 patients were colonoscopically followed-up during a long-term period in our hospital. They were divided into group A, group B, and C as follows: 581 in group A (mean age 65.0+8.9 yr, M=411.170) with colorectal adenoma more than 5 mm in size resected at baseline, 495 in group B (65.2+9.6 yr, 328.167) with diminutive polyps left untreated at baseline, and 519 in group C (62.5+10.7 yr, 255.264) with no polyps at baseline. During follow-up colonoscopies detected metachronous neoplasms more than 5 mm in diameter were resected and pathologically evaluated into non-index lesion (low-grade adenoma) or index lesion (high-grade adenoma or cancer). The cumulative...
incidences of metachronous colorectal neoplasms were compared with each other.

Results: Median follow-up periods and frequencies of colonoscopy were 61.9 months and 3.6 times in group A, 61.6 months and 3.4 times in group B, and 72.3 months and 2.7 times in group C, respectively. The cumulative incidences of metachronous neoplasms were 24.1% (202 with 837) in group A, 21.5% (151 with 698) in group B, and 22.5% (27 with 121) in group C, respectively. The prevalence of metachronous non-index lesion was highest in group A followed by group C and group B, respectively. The prevalence of metachronous index lesion in group A was 5.1% (25 with 497) in group B, and 2.3% (12 with 15) in group C, respectively. The prevalence of metachronous index lesion was highest in group A followed by group C and group B, respectively. The cumulative incidences of metachronous index lesion were 7.2% (42 patients with 580) in group A, 5.1% (25 with 257) in group B, and 2.3% (12 with 15) in group C, respectively. The cumulative incidences of metachronous index lesion were 1.0% (6 patients with 5 invasive cancers) in group A, 0.7% (7 with 10) in group B, and 0.0% (with 0) in group C, respectively. The significant difference was observed between group A and C (p < 0.001), and B and C (p < 0.05). The cumulative incidences of metachronous invasive cancer were 1.0% (6 patients with 6 invasive cancers) in group A, 1.4% (7 with 7) in group B, and 0.0% (with 1) in group C with no significant difference. Logrank test revealed that the cumulative incidence of non-index lesion was highest in group A, and statistical significances were observed between group A and B (p < 0.0001), and between group B and C (p < 0.0001). Logrank test also revealed that the cumulative incidence of index lesion was highest in group A, and statistical significances were observed between group A and B (p < 0.0001), and between group B and C (p < 0.0005).

Conclusion: The results of a longer colonoscopic follow-up disclosed a significantly higher prevalence of metachronous advanced neoplasms in patients with adenoma >5 mm in size resected at baseline compared to those with diminutive polyps left untreated at baseline. Persons with no polyps at baseline (male: 1 point, female: 0), age (40–49 years: 0, 50–59: 2, 60–69: 3, male or past smoker: 1, body mass index (BMI)  3 and C (p < 0.0001), and between group B and C (p < 0.0005).

Disclosure of Interest: All authors have declared no conflicts of interest.

P0470 A NEW SCORING MODEL FOR PREDICTING ADVANCED COLORECTAL NEOPLASIA IN ASYMPTOMATIC SCREENING POPULATION AND COMPARISON WITH THE MODIFIED ASIA-PACIFIC COLORECTAL SCREENING SCORE

M. Sekiguchi1, T. Matsuda2, Y. Kakugawa2, M. Matsumoto2, Y. Saito2
1Gastrointestinal Center, National Cancer Center Hospital, Tokyo/Japan
2Endoscopy Division, National Cancer Center Hospital, Tokyo/Japan

Contact E-mail Address: masekiguchim@ncc.go.jp

Introduction: Colorectal cancer (CRC) is still a major cause of death even in countries with a CRC screening program, indicating the need for improved screening methods. Risk-stratification of populations is one strategy that might satisfy this requirement. Currently, in the Asia-Pacific region, the use of the modified Asia-Pacific Colorectal Screening (APCS) score [age 50–59: 1 point, current or past smoker: 1, body mass index (BMI)  70: 3.5], CRC (p < 0.05). The statistical analyses were performed using Statistica for Windows 6.0 (StatSoft Inc.).

Results: Threshold for RAIR and %RAIR were 22.3 ml (10.0; 30.0), 74.4% (38; 99.5) respectively. Threshold for first RAIR was 30.0 ml (11.1; 58.3) and threshold for %RAIR was 85.6% (33.5; 182.0). The c-statistic of the score in the development set was 0.6 (95% confidence interval: 0.5; 0.7) and 0.6 (95% confidence interval: 0.5; 0.7) respectively. The prevalence of metachronous non-index lesion was 5.1% (25 with 497) in group B, and 2.3% (12 with 15) in group C, respectively.

Conclusion: A new scoring model could stratify the screened population into low-, moderate-, and high-risk groups. Of the detected ACN, a substantial number were proximal or flat; therefore, primary screening with total colonoscopy may be advisable for high-risk individuals.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0471 ASSOCIATION BETWEEN PARAMETERS OF THE RECTAL INHIBITORY REFLEX AND THRESHOLD FOR FIRST RECTAL SENSATION ESTABLISHED BY HIGH-RESOLUTION ANORECTAL MANOMETRY (HRAM) AND ITS SIGNIFICANCE FOR FECAL INCONTINENCE DIAGNOSTICS

O. Storonova1, A. Trukhanov2, V. T. Ivashkin2
1Neurogastroenterology & motility, Sechenov University, Moscow, Russian Federation, Moscow/Russian Federation
2Dept. Of Gastroenterology, Secretary General, Sechenov University, Moscow/Russian Federation

Contact E-mail Address: storonova@yandex.ru

Introduction: Previous studies have shown that increase of threshold for first rectal sensation can be a predictor of fecal incontinence. However, significance of the range of rectal inhibitory reflex (%)RAIR in development of this disease remains unknown.

Aims & Methods: To determine association between %RAIR and threshold for first rectal sensation in healthy adults and its significance in development of fecal incontinence in asymptomatic volunteers (18 women, 8 men) median age was 35.03 years (19–59) was studied. We performed them a high-resolution anorectal manometry (HRAM) using a 20 channels silicone water-perfused catheter (Solar GI, MMS, Netherlands). The following HRAM parameters were analyzed: threshold for RAIR and %RAIR (automatically calculated as the ratio of the amplitude of the relaxation of the anal sphincter (AS) to the basal pressure AS *100%), threshold for first rectal sensation (RS) and for desire to defecate. The statistical analyses were performed using Statistica for Windows 6.0 (StatSoft Inc.).

Results: Threshold for RAIR and %RAIR were 22.3 ml (10.0; 30.0), 74.4% (38; 99.5) respectively. Threshold for first RAIR was 30.0 ml (11.1; 58.3) and threshold for %RAIR was 85.6% (33.5; 182.0). Threshold for RAIR was not associated with threshold for first RS (r = 0.07) and for desire to defecate (r = 0.02). %RAIR was weak positively correlated with threshold for first RS (r = 0.26) and was not associated with threshold for desire to defecate (r = −0.03).

Conclusion: Threshold for RAIR and %RAIR are not associated with first rectal sensation. So, these parameters of RAIR cannot be predictors of fecal incontinence.

Background: Trait neuroticism is consistently found to be associated with more severe functional gastrointestinal (GI) symptoms (1). One explanation for this is that high neuroticism predisposes individuals towards avoidant coping by leading them to view negatively-valenced situations as catastrophic (2) and, therefore, unsolvable (3). Avoidant coping, in turn, increases the risk of developing GI discomfort because over-reliance on “flight” strategies in stressful situations overstimates the sympathetic nervous system at the expense of parasympathetic activity necessary for digestion (4). Evidence for this proposed chain has come from studies that have observed relationships between each pair of the chain’s components: neuroticism and avoidant coping (e.g., 3), and avoidant coping and higher GI symptom burden (e.g., 1). Across two studies, this paper integrates these findings, while also exploring the role of somatisation. Somatisation is consistently observed in people suffering from functional GI Conditions (e.g., 1) and refers to a subtype of avoidant coping - the expression of psychological stress through complaints about bodily symptoms (6). Should evidence emerge that somatisation is an intermediary between avoidant coping and GI symptom burden in the relationship between neuroticism, coping styles and GI symptom burden, the dominant explanation for how avoidant coping and GI symptoms are connected would need to be expanded to
predict that somatisation has deleterious consequences for GI conditions - possibly because it encourages the use of non-beneficial coping strategies (7).

**Aims & Methods:** In Study 1, 147 undergraduate students completed measures of neuroticism, 14 coping styles (including avoidance styles such as denial and disengagement), somatisation and GI symptom burden. In Study 2, where participants were undergraduates and hospital outpatients (pooled: N = 250), the variables investigated in Study 1 were measured alongside hypochondriasis, which was included to measure the aspect of somatisation that involves worry independently of any actual physical symptoms. Statistical analysis was based on path modeling. It involved fitting a model to test a priori hypothesised indirect relationships between neuroticism and GI symptom severity via the selected coping styles and somatisation. Direct effects were also estimated, meaning that the path analysis provided information regarding the significance of any indirect effects once a range of direct effects were accounted for. Only six coping styles found to correlate with both neuroticism and GI symptom severity were included (see Results table). Coping styles were assumed to covary, and the model in Study 2 assumed a covariance relationship between somatisation and hypochondriasis.

### Conclusion

All authors have declared no conflicts of interest.

**References**

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### Results

Significant standardised path model coefficients involving neuroticism across the two studies. In Study 1, neuroticism exerted indirect effects on symp-tom burden through substance-use-based coping and somatisation, as well as through disengagement-based coping and somatisation. In Study 2, neuroticism affected GI symptom burden through denial-based coping and somatisation, as well as through denial-based coping and hypochondriasis. An indirect effect of neuroticism through self-blame and somatisation, with the two intermediary variables relating negatively to each other, was observed in Study 1. (Note: *p* < .001, *p* < .01, *p* < .05, *p* denotes non-significant coefficients).

**Conclusion:** Somatisation and hypochondriasis were found to be intermediaries in neuroticism and GI symptom severity with the two intermediary variables relating negatively to each other, was observed in Study 1. (Note: *p* < .001, *p* < .01, *p* < .05, *p* denotes non-significant coefficients).

Introduction: Stressful life events may trigger the symptoms of irritable bowel syndrome (IBS). Preclinical chronic stress models have been developed in animals to mimic changes in visceral sensitivity in response to gut wall distension seen in IBS patients. In the rat, chronic passive water avoidance stress (WAS) is associated with hypersensitivity to colorectal distension. Diosmectite, a purified silt clay, is an adsorbent widely used for the treatment of several gastrointestinal syndromes (IBS). Preclinical chronic stress models have been developed in animals on the block for a period of 1 h every day. For both conditions (basal and after WAS), intestinal transit was evaluated by faecal output measurement Visceral sensitivity to colorectal distension (CRD) was assessed both in CVH-NS in CRD, though without statistical difference (2.35 \pm 0.05 vs CVH-Bifi) in adulthood. The CRD rats in 42-day old were treated by gavage administration with Bifidobacterium bifidus (1*10^10 CFU/day) for two weeks (CVH-Bifi). Other CRD rats were treated with 0.9% NaCl (CVH-NS). A group of control with normal sensitivity was treated with sham gavage (Con-sham). In day 56, another AWR was assessed, and the hippocampus and prefrontal cortex (PFC) were Separated and used to analyze the c-fos, NMDAR2A, NMDAR2B with western-blot.

Results: After two-week gavage, the CVH-Bifi presented lower volume than that of CVH-NS in CRD, though without significant difference (2.35 \pm 0.08 vs 2.40 \pm 0.64, p = 0.11). No significant difference was found between CVH-Bifi and Con-sham as well. In hippocampus, c-fos of CVH-Bifi was higher than CVH-NS (0.77 \pm 0.23 vs 0.48 \pm 0.10, p = 0.171). The NMDAR2A of CVH-Bifi was higher than that of Con-sham (1.04 \pm 0.22 vs 0.51 \pm 0.16, p = 0.055). In PFC, the NMDAR2A of CVH-Bifi was significantly higher than that of CVH-NS (0.63 \pm 0.14 vs 0.21 \pm 0.05, p = 0.004) and Con-sham (0.63 \pm 0.14 vs 0.20 \pm 0.07, p = 0.011).

Conclusion: We reported the negative effects of Bifidobacterium bifidus gavage, which induced higher activation of c-fos and higher expression of NMDAR2A in hippocampus and PFC. The roles of Bifidobacterium bifidus and its metabolites on visceral sensitivity needs further study to clarify.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0477 NEGATIVE EFFECTS OF BIFIDOBACTERIUM BIFIDUS ON THE RAT WITH COLONIC VISCERAL HYPERSENSIVITY INDUCED BY ACETIC ACID PERFUSION

Introduction: Bifidobacterium with appropriate doses has been suggested to reduce the visceral hypersensitivity in IBS. But different treatment effects have been reported. The negative effect of Bifidobacterium has been rarely studied and reported.

Aims & Methods: We aimed to study the effects of gavage administration with Bifidobacterium bifidus for two weeks on the visceral hypersensitivity of rats. Colonic visceral hypersensitivity (CVH) was induced by colonic injection of 0.5% acetic acid (AA) in 10-day old rats while control (NS) induced with 0.9% saline. The abdominal withdrawal reflexes (AWR), induced by colorectal distension (CRD) was used to quantify the level of colonic sensitivity in adult rats. The CRD rats in 42-day old were treated by gavage administration with Bifidobacterium bifidus (1*10^10 CFU/day) for two weeks (CVH-Bifi). Other CRD rats were treated with 0.9% NaCl (CVH-NS). A group of control with normal sensitivity was treated with sham gavage (Con-sham). In day 56, another AWR was assessed, and the hippocampus and prefrontal cortex (PFC) were separated and used to analyze the c-fos, NMDAR2A, NMDAR2B with western-blot.

Results: After two-week gavage, the CVH-Bifi presented lower volume than that of CVH-NS in CRD, though without significant difference (2.35 \pm 0.08 vs 2.40 \pm 0.64, p = 0.11). No significant difference was found between CVH-Bifi and Con-sham as well. In hippocampus, c-fos of CVH-Bifi was higher than CVH-NS (0.77 \pm 0.23 vs 0.48 \pm 0.10, p = 0.171). The NMDAR2A of CVH-Bifi was higher than that of Con-sham (1.04 \pm 0.22 vs 0.51 \pm 0.16, p = 0.055). In PFC, the NMDAR2A of CVH-Bifi was significantly higher than that of CVH-NS (0.63 \pm 0.14 vs 0.21 \pm 0.05, p = 0.004) and Con-sham (0.63 \pm 0.14 vs 0.20 \pm 0.07, p = 0.011).

Conclusion: We reported the negative effects of Bifidobacterium bifidus gavage, which induced higher activation of c-fos and higher expression of NMDAR2A in hippocampus and PFC. The roles of Bifidobacterium bifidus and its metabolites on visceral sensitivity needs further study to clarify.

P0478 DA-9701 IMPROVES COLONIC TRANSIT TIME AND SYMPTOMS IN PATIENTS WITH FUNCTIONAL CONSTIPATION: A PROSPECTIVE STUDY
Dept. Of Gastroenterology, Gachon University Gil Hospital, Incheon/Korea, Republic of

Contact E-mail Address: gesung11@gamer.com

Introduction: DA-9701, a newly developed prokinetic agent formulated with Pharmacomonas and Corthylium, has been shown to be effective by treating functional dyspepsia. Recently, it has also been suspected to improve gastrointestinal motor function.

Aims & Methods: The aims of this study were to assess the effect of DA-9701 on colonic transit time (CCT) and symptoms of functional constipation. We prospectively enrolled 33 patients with functional constipation based on the Rome III criteria. The patients received 30 mg DA-9701 three times a day for 24 days. CCT was estimated initially and at the end of treatment. We also analyzed symptoms such as spontaneous bowel movements (SBMs), straining, stool form, feeling of incomplete emptying and anorectal blockage, abdominal discomfort and pain, overall defecation satisfaction, and incidence of adverse events.

References
Results: Twenty-seven patients completed the study. DA-9701 was associated with a statistically increased CTT from 14.9 ± 5.0 hours/treatment day to 23.7 ± 7.4 hours/treatment day (P = 0.001). Segmental CTT also significantly decreased after treatment (right CTT: from 14.0 ± 8.2 to 7.5 ± 7.4 hours, P = 0.001; rectosigmoid transit time: from 14.2 ± 11.9 to 9.5 ± 10.9 hours, P = 0.021). In addition, all constipation-related subjective symptoms, including SBM frequency, significantly improved compared to those before treatment. Serious adverse events did not occur.

Conclusion: DA-9701 accelerates colonic transit and safely improves symptoms in patients with functional constipation. Therefore, we suggest that this novel agent could help to treat patients with this condition.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Conclusion: Among individuals who meet Rome IV criteria for IBS in the general population, those who are older, have more frequent bloating, have greater concern about their bowel function, and who are more socially affected by their bowel symptoms, are more likely to consult doctors about their bowel symptoms. In contrast, IBS consultants and non-consultors do not differ in their abdomen pain severity or extra intestinal symptom burden. [Support: The Rome Foundation].

Aims & Methods: The aim of this study was to compare the expression of membrane transporters in mucosal biopsies of healthy subjects, IBS patients and post-infectious (PI)-IBS patients. Mucosal biopsies were obtained from the untreated sigmoid colon in 18 IBS patients, 9 PI-IBS patients and 10 healthy subjects. Total RNA was isolated and prepared for gene expression analyses using quantitative reverse-transcription polymerase chain reaction (qRT-PCR). We compared the expression of genes encoding membrane-spanning transporters, using GAPDH as a reference gene, and by using the comparative 2^(-ΔΔCt) method.

Results: Colon cancer expression of SLC7A5 and SLC3A2 (together comprising the amino acid transporters LAT1 and LAT2) was significantly lower in IBS patients, but not in PI-IBS patients, compared to healthy controls (P < 0.001). The expression of SLC7A8 (LAT2) tended to be lower in IBS patients compared to controls (P = 0.08). Mucosal gene expression of the short chain fatty acid transporter SMCT1 (SLC9A8) was lower in both IBS patients and PI-IBS patients compared to healthy subjects (P < 0.01).

Conclusion: The amino acid transporters LAT1 and LAT2 appeared to be affected in IBS patients, but not in PI-IBS patients, compared to healthy subjects, suggesting a possible alteration in amino acids transport in this patient group. Furthermore, our results suggest a lower uptake of short chain fatty acids in both IBS- and PI-IBS patients. Altered expression of these transporters may be involved in the pathophysiology of IBS as well as being a potential biomarker of this aberration, and therefore deserves further study in IBS.

Aims & Methods: The aim of our present study was to determine the role of genetic variation within genes encoding for collagen s of the connective tissue in the development of diverticulosis. Genetic polymorphisms COL3A1 (rs3134646, rs1800255) and COL1A1 (rs1800012) were genotyped in 422 patients with diverticulosis. Among 70 patients with complicated diverticulitis, 51 (78.6%) patients underwent emergent surgery; most of them (54 patients, 98.2%) were with diverticulitis of sigmoid colon (odds ratio 62.2, 95% confidence interval 21.8–178.0) as a significant independent factor for complications of diverticulitis. The amino acid transporters LAT1 and LAT2 appeared to be involved in the pathophysiology of IBS as well as being a potential biomarker of this aberration, and therefore deserves further study in IBS.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colonic diverticulosis is one of the most common gastroenterological disorders. Though diverticulosis is typically benign, many individuals develop diverticular disease (DD). DD is thought to stem from a complex interplay of environmental, dietary, and genetic factors; however, the exact pathogenesis remains unknown.

Aims & Methods: The aim of our present study was to determine the role of genetic variation within genes encoding for collagens of the connective tissue in the development of diverticulosis. Genetic polymorphisms COL3A1 (rs3134646, rs1800255) and COL1A1 (rs1800012) were genotyped in 422 patients with diverticulosis and 285 controls of Caucasian descent using TaqMan assays.

Results: All genotype distributions did not deviate from the Hardy-Weinberg equilibrium. Overall, rs3134646, rs1800255 and rs1800012 were associated with diverticulosis. After multivariate logistic regression analysis, they were not linked with the risk of developing colonic diverticulosis in general; when selectively analyzing genders, the minor allele (AA) in rs3134646 remained significantly associated with diverticulosis in men (p = 0.037).

Conclusion: Our study shows that a variant of COL3A1 rs3134646 is associated with risk of developing colonic diverticulosis in Caucasian men, while COL3A1 rs1800255 and COL1A1 rs1800012 were not associated with this condition in our cohort of patients after adjusting for confounding factors.

P0490  THE USE OF ENDOCYTIC CLASSIFICATION “DICA” MAY HAVE A SIGNIFICANT COST-SAVING ON THE BURDEN OF DIVERTICULAR DISEASE OF THE COLON

1Gastroenterology Service, ASL BAT Gastroenterology Service, Andria/Italy
2Division of Surgery, “P. Colombo” Hospital, ASL RM6, Velletri/Italy
3Division of Gastroenterology, “P. Colombo” Hospital, ASL RM6, Velletri/Italy

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Although symptoms occur in only 20% of patients harbouring diverticula, Diverticular Disease (DD) of the colon DD represents the 8th disease as burden in USA. Several treatment are currently advised in managing those patients, but their impact on the burden of the disease is unknown. The recent DICA endoscopic classification has been developed and validated for the classification of DD, founding that treatment of DICA 1 and DICA 3 patients did not impact significantly in terms of acute diverticulitis occurrence/recurrence and surgery occurrence. Our aim was to assess the impact of using DICA classification on the burden of DD in Italy.

Aims & Methods: We assessed retrospectively the overall and the cost/year of treatments (or rifaximin, or any other treatment, including probiotics, fibers, systemic antibiotics and spasmodics) in DICA 1, DICA 2 and DICA 3 population. Analysis of diverticulitis prevalence was estimated according to data population provided by Italian Institute of Statistics (ISTAT). Cost of treatments was calculated according to data on drugs’ consumption collected during the DICA study.

Results: According to 2015 ISTAT population data, we estimated that >8 million of Italian people >60 years may have diverticulosis. According to our estimations, DICA 1 and DICA 3 patients represent about 75% of diverticuloid population on DICA 1, about 30% on DICA 2, and about 15% on DICA 3. According to the drugs’ consumption recorded during our study, we estimated that overall about 679 million of euros could be spent in Italy in treating those patients. In particular, >357 million of euros are spent in DICA 1 population, >205 million of euros in DICA 2 population, and >88 million of euros in DICA 3 population. Considering that medical treatments did not show any significant advantage when treating DICA 1 and DICA 3 people in terms of prevention of acute diverticulitis occurrence/recurrence and surgery occurrence, we can estimated that >245 million of euros could be spent in Italy without any significant benefit for DD population.

Conclusion: DD has a significant burden for National Health System in Italy. DICA classification may have a significant impact of this burden, helping to select DD people who effectively need treatments in terms of prevention of acute diverticulitis occurrence/recurrence and surgery occurrence.

Introduction: Symptoms of Gastroenterology, Parma/Italy

Aims & Methods: Thirteen consecutive female patients, living in the same district and suffering from SUDD, were studied. Patients were treated with a 2-week course of 30×day fiber supplementation (3 patients), 1,6 grams/day of mesalazine (3 patients), 900 billion/day of probiotic mixture VSL#3 (currently available in Europe as VivoMixx®), 3 patients), and 800 mg/day of rifaximin (4 patients). Stool samples were collected at entry (T0), at the end of the 2-week course of treatment (T1), and after 30 (T2) and therefore after 60 days at the end of the therapeutic course (T3). Real-time PCR was used to quantify targeted microorganisms. High-resolution proton magnetic resonance (NMR) spectroscopy associated to Multivariate Analysis with partial least square discriminant analysis (PLS-DA) were applied on the metabolite data set.

Results: The overall bacterial quantity did not differ before and after treatment (p=0.440). The overall amendment of Akkermansia muciniphila species was significantly reduced at T1 (p=0.017) and T2 (p=0.026), while at T3 it became similar to that of T0 (p=0.09). The amount of Lactobacilli group was increased in all groups but not significantly at T1 and T2, while at T3 it became similar to that of T0. The treatments showed the same results except for probiotic group, who had higher and persistent amount of Lactobacilli up to T3. PLS-DA analysis of NMR-based fecal metabolomics showed significant changes at T1 and T2, while at T3 it became similar to that of T0. All treatment were showed the same behaviour in influencing fecal metabolome except for rifaximin group, in which we did not find any metabolic change neither at the end of treatment nor during the washout period.

Conclusion: This preliminary study confirms that Akkermansia muciniphila may play a pathogenetic role in the occurrence of SUDD. We found also that current treatments for SUDD on fecal microbiota and fecal metabolic profiling in those patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0492  IMPACT OF TREATMENTS ON FECAL MICROBIOTA AND FECAL METABOLIC PROFILING IN SYMPTOMATIC UNCOMPLICATED DIVERTICULAR DISEASE OF THE COLON

Disclosure of Interest: No conflicts of interest.

Introduction: Fecal microbiota and metabolome may be altered in patients with Symptomatic Uncomplicated Diverticular Disease (SUDD). In particular, we found that Akkermansia muciniphila species were significantly increased in SUDD patients when compared with asymptomatic diverticulosis and healthy people, as well as PLS-DA analysis of NMR-based fecal metabolomics showed significant discrimination between HC and AD patient. Our aim was to assess the effect of current treatments for SUDD on fecal microbiota and fecal metabolic profiling in those patients.

Aims & Methods: Thirty consecutive female patients, living in the same district and suffering from SUDD, were studied. Patients were treated with a 2-week course of 30×/day fiber supplementation (3 patients), 1,6 grams/day of mesalazine (3 patients), 900 billion/day of probiotic mixture VSL#3 (currently available in Europe as VivoMixx®), 3 patients), and 800 mg/day of rifaximin (4 patients). Stool samples were collected at entry (T0), at the end of the 2-week course of treatment (T1), and after 30 (T2) and therefore after 60 days at the end of the therapeutic course (T3). Real-time PCR was used to quantify targeted microorganisms. High-resolution proton magnetic resonance (NMR) spectroscopy associated to Multivariate Analysis with partial least square discriminant analysis (PLS-DA) were applied on the metabolite data set.

Results: The overall bacterial quantity did not differ before and after treatment (p=0.440). The overall amendment of Akkermansia muciniphila species was significantly reduced at T1 (p=0.017) and T2 (p=0.026), while at T3 it became similar to that of T0 (p=0.09). The amount of Lactobacilli group was increased in all groups but not significantly at T1 and T2, while at T3 it became similar to that of T0. The treatments showed the same results except for probiotic group, who had higher and persistent amount of Lactobacilli up to T3. Introduction: Natural history of colonic diverticulosis and diverticular disease (DD) is poorly known, and available data derived mostly from retrospective cohort studies.
Aims & Methods: Aim of this study was to assess, in a cohort of patients with colonic diverticula, the incidence of new cases of symptomatic uncomplicated diverticulitis disease (SUDD) and diverticulitis, and recurrence of diverticulitis after 1-year of follow-up. GRIMAD (Italian Diverticular Disease Group) promoted the creation of REMAD (Register of Diverticular Disease) a prospective, 5-years, no-profit, cohort study involving 47 Italian centers. Each center enrolled at least 20 consecutive patients during a period of two months. Inclusion criteria were: informed consent; age ≥18 years and endoscopic/radiological-confirmed colonic diverticula. Outpatient/telephone visits were scheduled every 6 months. The clinical data (patients’ characteristics and habits, characteristics of DD, comorbidities and therapies) collected by participating centers were reported on an electronic Case Report Form managed by CD Pharma, Milan. At entry, patients were categorized according to the following criteria: i) diverticulosis (presence of diverticula in the absence of abdominal symptoms); ii) SUDD (recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis in the past). Patients were allowed to continue their therapy for DD, if any. Logistic regression was performed to identify patients’ features associated with new occurrence of SUDD and diverticulitis.

Results: Overall, at baseline 1217 (55.7% female, median years 67 (28–95), BMI 25.6 kg/m² (16.2–43.4) patients were enrolled: 707 (58.1%), 300 (24.7%) and 210 (17.3%) with diverticulosis, SUDD, and PD, respectively. At 12 months, 922 patients (53.1%, 29.8%, and 17.1% with diverticulosis, SUDD, and PD) were followed, and 27.4% of patients were lost at follow-up. In the 12 months follow-up, 33 (6%) and 4 (0.7%) of diverticulosis patients developed SUDD and acute diverticulitis, respectively; 4 (1.6%) of SUDD patients developed acute diverticulitis, and in 14 (9.4%) of PD patients a new episode of acute diverticulitis occurred. Overall, only 3 patients developed a complication, without need of surgery. One year of follow-up logistic regression, showed that only female gender was associated with subjects who changed subgroup from diverticulosis to SUDD (OR 2.26, 95%CI 0.97–5.22). No specific features associated with recurrence of diverticulitis could be identified.

Conclusion: These preliminary data suggested that, during an observation period of one year, progression from diverticulosis to SUDD occurred in less than a tenth of patients, and was associated with female gender. Overall incidence of diverticulitis (2.3%), whereas incidence of diverticulitis was uncommon. This observational study suggested, that although the vast majority of patients did not show progression of disease, in those who progressed in ten tended to relapse during follow-up.

Introduction: In the vast majority of patients colonic diverticula remain asymptomatic: prevalence of new cases of recurrent abdominal symptoms (symptomatic uncomplicated diverticulitis disease, SUDD) or complications (diverticulitis), with subsequent impact on quality of life (QoL). To date, clinical features associated with each subgroup are not fully understood.

Aims & Methods: Aim of this study was to assess, in a cohort of patients with colonic diverticula, the clinical features and QoL scores associated with each subgroup of patients. GRIMAD (Italian Diverticular Disease Group) promoted the creation of REMAD (Register of Diverticular Disease) a 5-years prospective, 5-years, no-profit, cohort study involving 47 Italian centers. Each center enrolled at least 20 consecutive patients during a period of 2 months. Inclusion criteria were: informed consent; age ≥18 years; endoscopic/radiological-confirmed colonic diverticula. The clinical data (patients’ characteristics and habits, characteristics of DD, treatment and QoL) collected by participating centers were reported on an electronic Case Report Form managed by CD Pharma, Milan. At entry, patients were categorized into subgroups of patients according to the following criteria: i) diverticulosis (presence of diverticula in the absence of abdominal symptoms); ii) SUDD (recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis in the past). Patients were allowed to continue their therapy for DD, if any. Logistic regression was performed to identify patients’ features associated with the presence of subtypes of DD. A p value < 0.05 was considered statistically significant.

Results: 1217 patients were enrolled. Characteristics of each subgroup of patients are reported in the table.

Introduction: Patients with symptomatic uncomplicated diverticulitis disease (SUDD) and those with diverticulitis share similar clinical patterns characterized by abdominal pain or change of bowel habits. In clinical practice, differential diagnosis between the two conditions may be useful in the diagnostic approach and therapeutic management.

Aims & Methods: Our aim was to assess the features of abdominal pain in patients with SUDD and PD. Patients were categorized according to the following criteria: i) diverticulosis (presence of diverticula in the absence of abdominal symptoms); ii) SUDD (recurrent abdominal symptoms in the absence of overt inflammation); iii) PD (patients who experienced at least one episode of acute diverticulitis). Patients were enrolled in the study. 300 (24.7%) and 210 (17.3%) fulfilled criteria for SUDD and PD, respectively. Among them, 223 patients with SUDD (74.3%) and 154 patients with PD (73.3%) accepted to fill in short-lasting pain questionnaire, whereas 156 patients with SUDD (52.0%) and 140 patients with PD (66.6%)
P0496 MUSCULAR INFLAMMATORY STATE AND PHENOTYPIC SWITCH IN DIVERTICULOSIS AND COMPLICATED DIVERTICULAR DISEASE

I. Pallotta1, A. Scirocco2, A. Ignazzi2, M. Carabotti1, L. Pallotta1, A. Scirocco2, A. Ignazzi2, M.A. Maselli2, M. Carabotti1, F. Pace: Speaker and consultant for Alfa Wasserman R. Cuomo: Speaker and consultant for Alfa Wasserman R. Cuomo: Speaker and consultant for Alfa Wasserman All other authors have declared no conflicts of interest.

Introduction: Colonic diverticulitis, as well as diverticular disease, is a multifactorial disease characterized by neutrophil- and pro-inflammatory cytokine-driven impaired contraction, inflammation and fibrosis. Mesenchymal smooth muscle cells (SMC) are able to switch from a contractile phenotype to a less mature synthetic phenotype, characterized by a loss of differentiation with decreased expression of contractile markers as well as synthesis and release of several pro-inflammatory cytokines. Different organ specific pathways have been demonstrated to induce this mesenchymal transition. Renal fibrosis is driven by transforming growth factor-β (TGF-β) through inverse regulation of Smad2/3 while vascular fibrosis by PDGF-β, ending in downregulation of marker gene Tbr3 expression.

Aims & Methods: Aim of this study was to determine, both in human uninolved and involved tracts of asymptomatic diverticulosis (AD - AD+) and in stenosing complicated diverticulitis (CDD), the alteration of muscular synthetic pro-fibrotic switch.

Results: In both muscle layers, AD and AD+ SMC, compared to CTR, showed an overall increase in inflammatory gene expression, with a trend of decrease from AD to AD+, the lowest expression being observed in CDD. This inflammatory alteration was accompanied with an increase in IL-1β secretion in stenotic and medium compared to CTR and a progressive inhibition of contraction to carbchol, already in AD in circular strips and SMC. In contrast relaxation in response to VIP resulted significantly decreased only in AD+ both on strips and SMC with no alteration in CDD. Peculiarity of circular SMC was a progressive increase in Col1 expression from AD to CDD compared to CTR (3 hundred fold increase) paralleled to about 50% decrease in the contractile protein α-SMA. Differently, longitudinal SMC, both in AD and CDD, presented a homogenous increased Col1 expression, decrease in α-SMA and reduction of contraction. VIP-induced relaxation was significantly decreased in CDD. Phenotypic switch was only observed in CDD, driven by TGF-β-dependent pathway (increase for TGF-β: 2.8±0.6 and Smad2/3: 2.2±0.4), whereas in AD, the SMC muscular synthetic pro-fibrotic switch.

Conclusion: Intrinsinc myogenic alterations are present in colonolic asymptomatic diverticulosis and complicated diverticular disease, both in the circular and longitudinal layers characterized by a myogenic pro-inflammatory state and an impaired contractile activity that, in complicated diverticular disease, ended in a muscular synthetic pro-fibrotic switch.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0497 THE ONCOGENIC MIR-491-5P/MIR-875-5P-NOTCH3-PHLDB2 AXIS IN GASTRIC TUMORIGENESIS

Introduction: Aberrant Notch activation has been implicated in multiple malignancies, including gastric cancer (GC). However, the clinical significance of Notch receptors and their functional role in gastric carcinogenesis remain unclear.

Aims & Methods: We aim to delineate the dysregulated Notch signaling in GC and comprehensively reveal its activation by silenced microRNAs (miRNAs) in gastric carcinogenesis. The expression clinical relevance of NOTCH1-4 in GC was achieved from online available dataset. The mRNA and protein expression of NOTCH3 was examined by qRT-PCR and Western blot. The biological function of NOTCH3 in GC was demonstrated by MTT proliferation, monocellular colony formation, cell migration and migration assays through siRNA-mediated knockdown. The mRNA expression of miR-491-5p and miR-875-5p in GC cells was examined. The clinicopathological features were correlated with the expression of miR-491-5p, miR-875-5p and NOTCH3.

Results: NOTCH3, but not NOTCH1, 2, 4, is uniformly upregulated and significantly correlated with poor survival in multiple GC datasets. Knockdown of NOTCH3 in AGS and MK28 cells exhibited significant anti-oncogenic effect in vitro. NOTCH3 downregulation suppressed cell proliferation, reduced monocellular colony formation, and inhibited cell invasion ability. Moreover, NOTCH3 knockdown significantly promoted cleaved caspase-3 and cleaved-PARP expression in GC cells. miR-491-5p and miR-875-5p knockdown significantly inhibited cell proliferation and induced apoptosis. More importantly, the expression of miR-491-5p showed negative correlation with NOTCH3 mRNA expression in primary GC samples and re-expression of miR-491-5p in GC cells exerted tumor-suppressive function by inhibiting cell proliferation and inducing apoptosis. miR-491-5p and miR-875-5p significantly correlated with poor survival in multiple GC datasets. Knockdown of NOTCH3 by putative miRNAs was confirmed by qRT-PCR, Western blot and luciferase activity assays. miR-491-5p and miR-875-5p overexpression in AGS cell line dramatically downregulated NOTCH3 expression, whereas knockout of NOTCH3 by putative miRNAs was confirmed by qRT-PCR, Western blot and luciferase activity assays.

Conclusion: NOTCH3 over-expression plays an oncogenic role in gastric carcinogenesis through its direct downstream miR-875-5p. The activation of NOTCH3 in GC is partly due to the silence of tumor-suppressive miRNAs, miR-491-5p and miR-875-5p. Our findings comprehensively revealed the activation of Notch signaling pathway and provided clinical translational potential for GC.

Disclosure of Interest: All authors have declared no conflicts of interest.
signaling pathway. However, the molecular mechanism of FOXX2 in GC is still unknown.

**Aims & Methods:** We hypothesized that FOXX2 transcriptional upregulates a novel E3 ligase that targets β-catenin for degradation. We aim to investigate the molecular mechanism of FOXX2 in GC and identify such E3 ligase by Parallel Analysis of Chromat Inium Precipitation (CHIP) assay and luciferase assay.

**Results:** FOXX2 significantly decreased both nuclear and cytosolic levels of β-catenin in a GSK-3β independent manner and promoted β-catenin degradation via ubiquitin-proteasome pathway in gastric cells. Using Human Ubiqtna Library and western blot, we identified that IRF2BPL was upregulated upon FOXX2 overexpression and was a promising E3 ligase for β-catenin. Overexpression of IRF2BPL suppressed the TOP-flash luciferase reporter and reduced Wnt target gene expression in GC cells. Overexpression of IRF2BPL significantly increased β-catenin ubiquitination and reduced β-catenin protein without alteration of its mRNA level. Conversely, knockdown of IRF2BPL significantly decreased endogenous β-catenin ubiquitination. Immunoprecipitation assay suggested that IRF2BPL interacted with β-catenin. The mRNA and protein levels of IRF2BPL in a potential E3 ligase that targets β-catenin for degradation. To investigate whether FOXX2 directly regulates IRF2BPL transcription, we performed ChIP assay and found that FOXX2 bound on to the IRF2BPL promoter region. We cloned the IRF2BPL promoter region (−2000 to +100) into pGL3 basic plasmid and performed a luciferase activity assay. Wild-type FOXX2 but not the mutant ΔFOXX2 significantly activated the lucerase reporter in AGS and SGC199 cells, suggesting that FOXX2 directly activated IRF2BPL transcription. Moreover, FOXX2 significantly increased the level of H2K72Ac (a marker to distinguish active from inactive enhancer element) on the 5′-flanking region of IRF2BPL gene, suggesting that FOXX2 positively regulated IRF2BPL gene transcription. In addition, IRF2BPL was downregulated in human GC tissues compared to the adjacent normal tissues (N = 30, P < 0.01) by real-time PCR analysis. IRF2BPL mRNA showed a positive correlation with FOXX2 in gastric cancer in a Chinese cohort (N = 30, Spearman’s rho = 0.42, P < 0.05) and in the TCGA cohort (N = 30, Spearman’s rho = 0.38, P < 0.05).

**Conclusion:** We reported a novel FOXX2-IRF2BPL-β-catenin signaling axis in gastric cells. FOXX2 is a critical tumor suppressor in gastric carcinogenesis through promoting β-catenin degradation by transcriptionally upregulating E3 ligase IRF2BPL.

2Health Research Institute of Santiago (IDIS), Santiago de Compostela/Spain
3Tropical Medicine & Gastroenterology, Faculty of Medicine Al-Azhar university, Cairo, Egypt

**Introduction:** Obestatin, a 23-amino acid peptide derived from the ghrelin peptide precursor, was originally isolated from stomach and characterized to bind selectively GPR39. GPR39 is expressed in normal gastric epithelial cell sheets, but not in gastric adenocarcinoma. In healthy human stomachs, obestatin expression was observed in the oxyntic glands but also in a few cells of the neck section (pre-chief cells). This expression co-localized with ghrelin expression in both cell types. The mucous neck cells were positive for GPR39 and negative for GPR39. Obestatin also exerted a dose-dependent stimulatory effect on PGI secretion in the in vitro explant culture of human stomach, being significant for 100 and 200 nM compared to the control sample at 20 min (39% and 66% over control, respectively), for 200 nM at 40 min (51% over control) and 100 nM at 60 min (64% over control).

**Results:** Obestatin-induced PGI secretion was blocked using an anti-GPR39 antibody. Results: ACS cells expressed obestatin, GPR39 and PGI. In these cells, exogenous administration of obestatin (200 nM, 40 min) stimulated PGI secretion (60% over control). This effect was exerted via the GPR39 receptor. In the human healthy stomach, GPR39 expression was detected mainly in the chief cells of the oxyntic glands but also in a few cells of the neck section (pre-chief cells). This expression co-localized with PGI expression in both cell types. The mucous neck cells were positive for PGI and negative for GPR39. Obestatin also exerted a dose-dependent stimulatory effect on PGI secretion in the in vitro explant culture of human stomach, being significant for 100 and 200 nM compared to the control sample at 20 min (39% and 66% over control, respectively), for 200 nM at 40 min (51% over control) and 100 nM at 60 min (64% over control).

**Conclusion:** The obestatin/GPR39 system is physiologically involved in the stimulation of PGI secretion in the healthy human stomach.

**Disclose of Interest:** All authors have declared no conflicts of interest.

**P0503 SERUM EXOSOMAL MiRNAs EXPRESSION AS NOVEL BIOMARKERS FOR DETECTION OF ESOPHAGEAL ADENOCARCINOMA**

H. Chen

Jiang Su Province Hospital, Nanjing/China

Contact E-mail Address: chenhuan0608@hotmail.com

**Introduction:** Novel biomarkers for the diagnosis of esophageal adenocarcinoma (EAC) are urgently required. Currently, there is increasing evidence suggesting that serum exosomal miRNAs may be potential noninvasive biomarkers for certain diseases. The objective of the present study was to find and investigate whether exosomal miRNAs could be effective biomarkers for EAC.

**Aims & Methods:** In the present study, exosomes were isolated from the serum of both EAC patients and normal controls. Total RNA was extracted from exosomes and miRNA levels were compared between EAC and control patients in serum exosomes. We also sought to investigate the relevance of exosomal miRNA expression to clinicopathological factors in EAC.

**Results:** We measured levels of several exosomal miRNAs, including miR-21, miR-16, miR-25, miR-155, miR-192, miR-92a, in 9 EAC patients and 9 controls.

**Conclusion:** Exosomal miRNAs were chosen because they have been shown to function as onco-miRs in previous studies. Levels of miR-21, miR-16, miR-25 and miR-155 were significantly higher in EAC patients than in controls (fold-change 35.36, 30.87, 9.24 and 2.26, respectively).

**Disclose of Interest:** All authors have declared no conflicts of interest.

**References**
9.24 and 2.26, respectively). The level of miR-192 was significantly lower in EAC patients than in controls (Fold-change 0.35). We did not observe a significant fold-change in miR-92a expression levels between EAC and controls. P-values did not achieve statistical significance, possible due to large standard deviations and relatively small sample sizes. We also visualized exosomes isolated from both cell culture medium and sera of EAC patients and control subjects, with diameter ranging from 30 to 100 nm using transmission electron microscopy.

**P0504 COMPARATIVE STUDY BETWEEN THE EFFICACY OF REBAMIPIDE, SUCCINATE AND PANTOPRAZOLE IN TREATMENT OF POST-BANDING VARICEAL ULCERS**

M. Youss1, A. A. Wahib2, G. M. M. Soliman2

1Tropical Medicine & Gastroenterology, Faculty of Medicine Al-Azhar university, Cairo, Egypt
2Tropical Medicine & Gastroenterology, Faculty of Medicine Al-Azhar university, Cairo, Egypt

Contact E-mail Address: doctor_gemy@yahoo.com

**Introduction:** Endoscopic variceal band ligation (EVBL) is an effective procedure to control and prevent variceal bleeding in patients with liver cirrhosis. Although EVL has some complications, yet these complications are related to post-EVL ulcers. Few data exist regarding therapy of post-ligation ulcer and treatment been mostly empirical with drugs used for peptic ulcer disease. We aimed to compare the efficacy of rebamipide, succinate and pantoprazole in treatment of post banding variceal ulcers. Seventy-five patients with esophageal varices eligible for elective band ligation represented the population of the study. The patients were allocated into three groups; rebamipide group, they received rebamipide 100 mg 3 times daily; pantoprazole group, they received pantoprazole 40 mg/day orally at morning; succinate group, they received succinate 1 gm every 6 hours, for 14 days beginning at the next day of band ligation. Subjects underwent EGD 14 days after banding.
Primary outcomes included the size and number of ulcers and the subjects' reports of pain, dysphagia, chest pain and vomiting.

Results: At follow-up endoscopy, the number of patients with post-band ulcers and size of ulcers were similar in the three groups. However, the number of ulcers for each patient is statistically significant less in rebanding group when compared to pantoprazole and sucralfate (P < 0.001). Chest pain, dysphagia and vomiting scores were not significantly different. Dysphagia was by far the most common symptom with no case of bleeding was reported in all patients of the studied groups.

Conclusion: Rebanding is effective in decreasing the post banding complication and reducing size of ulcer as well as the number of ulcers with no significant effect on post banding ulcer formation. Rebanding can be used routinely in settings of post-EVL as a good alternative to pantoprazole and sucralfate.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0505 MULTICENTRE EVALUATION OF FIRST-LINE ENDOCOSOPIC TREATMENT WITH THE OTSC IN ACUTE NON-VULGIB GASTROINTESTINAL BLEEDING AND COMPARISON WITH THE ROCKALL COHORT - THE FLETROC- STUDY

E. Wedel1, A. Fischer2, J. Hochberger1, C. Jung1, H. Riechter-Schräg2
1Gastroenterology And GI Oncology, University Hospital Göttingen, Göttingen/ Germany
2Department Of Medicine II, University of Freiburg, Freiburg/Germany
3Department Of Gastroenterology, Vivantes Klinikum in Friedrichshain, Berlin/ Germany

Contact E-mail Address: edris1@web.de

Introduction: The over-the-scope-clip (OTSC) overcomes limitations of standard clipping devices and facilitates haemostasis in non-varical upper gastrointestinal bleeding (NVUGIB). The study aims to evaluate mortality, rebleeding and mortality after rebleeding of patients in whom the OTSC was used as first-line endoscopic treatment (FLET) of NVUGIB. Data on OTSC use for NVUGIB in high-risk patients is currently linked.

Aims & Methods: In total, 118 patients (FLET cohort) with a median age of 73.5 years (range 29–93 years; mean ±SD 71.39 ± 12.93 years) were included. The distribution of patients with respect to risk category revealed a median Rockall score of 7 (range 1–10; mean ±SD 7.25 ± 1.51). For hypothesis testing, the FLET cohort was categorized into 3 risk groups taking into account the Rockall score: low risk (Rockall risk category (RRC) 1–3), moderate risk (RRC 4–7), and high-risk (RRC ≥ 8). Event rates (mortality, re-bleeding and mortality after rebleeding) were compared to predicted event rates (Rockall cohort) using Fisher’s Exact Test.

Results: Primary successful haemostasis (PSh) was achieved in 92.4% either by FLET alone or in combination with an additional haemostasis technique in 1.7% (SCS = secondary clinical success). In 7.5 % of the FLET cohort PSh couldn’t be achieved. Mortality in the FLET cohort was in the high-risk group (RRC ≥ 8) lower compared to RRC prediction, but no significant difference. However mortality after re-bleeding was significantly reduced from 27.9 % to 10.9 % in the high-risk group (RRC ≥ 8) treated with FLET (p < 0.001). Furthermore, occurrence of re-bleeding or continued bleeding was significantly lower in the moderate risk group (RRC 4–7) with 4.9 % as well as in the high-risk group (RRC ≥ 8) with 21.4 % compared to RCC 24.9 % and 55.2 %, respectively, as predicted by the Rockall scoring system (p < 0.001).

Conclusion: Our study shows that OTSC is superior to standard clipping techniques and FLET of OTSC reduces significantly re-bleeding and re-bleeding associated mortality in NVUGIB and it is for this reason we recommend FLET for NVUGIB in high-risk patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0506 A NEW PREDICTION RULE FOR UPPER GASTROINTESTINAL BLEEDING USING THE GLASGOW BLATCHFORD SCORE AND CT NUMBER

M. Tsudome, K. Fujita, A. Sugahara
Department Of Gastroenterology, Yodogawa Christian Hospital, Osaka/Japan

Contact E-mail Address: marie_t1@post.plala.or.jp

Introduction: Upper gastrointestinal bleeding can have various severities, with some cases needing for intensive care while, others allow for patient to go home. Thus, it is important to detect the patients who need endoscopic treatment. The Glasgow Blatchford score (GBS) is currently regarded as the best score for predicting endoscopic treatment (area under the receiver operating characteristic curve (AUROC) 0.75)[1]. Contrast-enhanced CT is also useful for patients with gastrointestinal bleeding [2]. However, it is a complicated procedure and it cannot be used for patients with renal failure.

Aims & Methods: The aim is to analyze the accuracy of the GBS and non-enhanced CT in predicting the necessity of endoscopic treatment for patients with upper gastrointestinal bleeding. This study was designed as a hospital-based observation study. Patients who were hospitalized for upper gastrointestinal bleeding and had an endoscopy performed within 24 hours from April 2013 to March 2014 at Yodogawa Christian Hospital were studied. The clinical utility of the GBS and CT were assessed separately and in combination

Results: A total of 113 patients were included in the study. The median GBS was 5 and CT cut-off value was 300 HU. The accuracy of the GBS in predicting the necessity of endoscopic treatment was AUROC of 0.63. The median CT number was 48HU (IQR 26.7–60.7). The CT number also did not discriminate well with AUROC of 0.65. We set the cut off for GBS at 4, and a CT number at 50HU. The endoscopic treatment percentage of the group of GBS ≥4 and CT number ≥500HU was 63.5%, GBS=4 and CT number <500HU was 30.6%, GBS=4 and CT number ≥500HU was 33.3%, GBS <4 and CT number <500HU was 11.1%. We counted that GBS=4 was 1 point, CT number ≥500HU was 1 point. The points were added up to a total score that predicts the necessity for endoscopic treatment. Those scoring 2 points was about 60 percentage for the necessity for endoscopic treat- ment, 1 points was about 30 percentage, 0 point was about 10 percentage. AUROC of this model was 0.69.

Conclusion: Using both the GBS and CT in combination performed better for predicting the necessity of endoscopic treatment for patients presenting with upper gastrointestinal bleeding.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0507 FIBRIN GLUE CAN PREVENT BLEEDING AFTER ENDOCOSOPIC SUBMUCOSAL DISSECTION

L. Yu, Y. Wang
Jiangsu Province Hospital, Nanjing/China

Contact E-mail Address: ylianzhen@126.com

Introduction: Fibrin glue can prevent bleeding after endoscopic submucosal dissection.

Aims & Methods: We aimed to explore the utility of fibrin glue in prevention of bleeding after endoscopic submucosal dissection and to investigate the risk fac- tors for bleeding after endoscopic submucosal dissection. 330 patients who underwent ESD between July 2015 and June 2016 in Jiangsu Province Hospital were enrolled in this study, the patients were randomly divided into two groups, fibrin glue was sprayed during the operation in 161 patients of Group A, while 169 patients in group B were used with routine hemostasis method,postoperative bleeding was defined as hematemesis or melena or Hb > 7 g/dL, decrease after the operation of postoperative bleeding was defined as bleeding 7 to 30 days after operation. Then bleeding rate after ESD, average length of stay and average hospitalization expenses were compared between the two groups to explore the clinical effect of fibrin glue. 37 patients experienced bleeding after ESD were grouped into bleeding group, the remaining 293 patients were divided into non-bleeding group, several factors were compared between the two groups to analyse the risk factors of bleeding after ESD.

Results: There are no differences in age, gender, lesion location, underlying dis- ease, taking anticoagulant drugs or not, invasive depth, pathological type and procedure time between Group A and Group B. Bleeding rate after ESD was lower in group A (P < 0.05). And Intraoperative hemostasis rate was higher in Group A (P < 0.05). 2 patients in group B experienced delayed postoperative bleeding, while none in group A experienced delayed postoperative bleeding. Patients in group B spent more time staying in hospital than group A, while group A had a higher hospitalization ratio than group B.37 patients experienced bleeding after ESD, among whom 22 occurred within 24 hours after ESD, 13 within 1 week and 2 after 1 week. Univariate analysis revealed that resection size and procedure time over 120 minutes are risk factors for bleeding after ESD. The use of fibrin glue can reduce the bleeding rate after ESD. Multivariate analysis revealed that resection size greater than or equal to 3cm and the absence of fibrin glue are independent risk factor for bleeding after ESD.

Conclusion: The use of fibrin glue is safe, effective and economical in the proced- ure of ESD. Resection size and procedure time over 120 minutes are risk factors for bleeding after ESD. The use of fibrin glue can reduce the bleeding rate after ESD. Rebleeding after ESD. Resection size greater than or equal to 3cm and the absence of fibrin glue are independent risk factor for bleeding after ESD. So adequate preparation and close monitoring are needed during the procedure of ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

operative bleeding is still one of the most important adverse side effects.1, 2

Contact E-mail Address: saka_t.med@icloud.com

Introduction: Aims and Methods: We compared the incidence of bleeding after gastric ESD between patients treated with VPZ and those treated with esomeprazole (EPZ). Data for 101 patients who underwent gastric ESD from December 1, 2014 to December 31, 2016 in Osaka City General Hospital and started to take VPZ (n = 22) or EPZ (n = 79) by the day before ESD was reviewed. Twelve of them (3 in the VPZ group, 9 in the EPZ group) were excluded for simultaneous resection of two or more sites. A case in which active bleeding or exposed vessels were recorded.

Results: Gender, age, resected specimen diameter, oral antithrombotic drug use, and whether we underwent second-look endoscopy was defined as “next-day hemostasis case”. We investigated retrospectively post-ESD bleeding rate and next-day hemostasis rate in the VPZ group and the EPZ group.

Table: Incidence of post-ESD bleeding and next-day hemostasis

<table>
<thead>
<tr>
<th></th>
<th>VPZ group, n (%)</th>
<th>P-Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Post-ESD bleeding</td>
<td>2 (10.5)</td>
<td>0.678</td>
</tr>
<tr>
<td>Next-day hemostasis</td>
<td>6 (31.6)</td>
<td>0.197</td>
</tr>
</tbody>
</table>

Conclusion: VPZ didn’t significantly reduce post-endoscopic submucosal dissection bleeding compared with EPZ.

Disclosure of Interest: All authors have declared no conflicts of interest.

References:

Conclusion: Data was collected prospectively (January 2016 – April 2017) on the use of Hemospray in acute upper and lower GI bleeding, from 3 initial centres in the international registry. The use of Hemospray in GI bleeding was at the endoscopist’s discretion at the time of endoscopy. Hemospray use was either as mono-therapy or dual-therapy with standard endoscopic techniques or as rescue therapy once standard methods had failed.

Results: To date 56 cases have been recruited (39 male and 17 female). The Forrest Classification of the bleeding lesions were in 5 (9%) cases Forrest Ia bleed, 41 (73%) Ib, 3 (5%) Ha, 4 (7%) Ib and 3 (5%) Forrest III bleed. Sources of GI bleed included Peptic ulcer disease 24 (43%), postsurgical bleeding 9 (16%), Mallory Weir tear 2 (4%), angiodysplasia 1 (2%), bleeding polyp 2 (4%), duodenal diverticular bleed 1 (2%), oesophageal variceal bleed 1 (2%), pseudoaneurysm 1 (2%), gastric variceal bleed post NGT insertion 1 (2%). A total of 48 patients (86%) achieved immediate haemostasis after Hemospray endoscopic therapy, 8 patients did not achieve haemostasis. 2 managed conservatively, 1 treated by radiological intervention and 5 died. Hemospray was used in 25 patients (45%) as monotherapy [haemostasis achieved in 22/25 (88%)], in 22 patients (39%) in combination with other modalities [haemostasis achieved in 17/22 (77%)] and in 9 patients (16%) used as rescue therapy where other modalities failed [haemostasis achieved in 9/10 (90%)].

Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: Patients received clopidogrel with aspirin or ticagrelor with aspirin between January 2013 and June 2015 at Ramathibodi hospital. In patients with GIB, the endoscopic finding with stigmata of recent hemorrhage was also recorded.

Conclusion: Early data from our registry show a high rate of immediate haemostasis (86%) with Hemospray and an excellent safety profile. The imminent expansion of this registry to other centres in Europe will provide invaluable data on the efficacy of Hemospray in various disease and patient types over the coming years.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Current guidelines suggest dual antiplatelet therapy (DAPT), clopidogrel or ticagrelor with aspirin, for patients with acute coronary syndrome. Other indications of DAPT include recurrent ischemic stroke and peripheral vascular disease. Gastrointestinal bleeding (GIB) is one of the most common adverse effects of DAPT, potentially causing hospital admission and death. Scarce information regarding safety of DAPT in Thailand is available.

Aims & Methods: The objective of this study is to determine cumulative incidence and risk factors of GIB in patients received DAPT, clopidogrel with aspirin and ticagrelor with aspirin among Thai patients.

A retrospective cohort study was conducted. We reviewed the medical records of patients received clopidogrel with aspirin or ticagrelor with aspirin between January 2013 and June 2015 at Ramathibodi hospital. In patients with GIB, the endoscopic finding with stigmata of recent hemorrhage was also recorded.

Disclosure of Interest: Patients received clopidogrel with aspirin or ticagrelor with aspirin between January 2013 and June 2015 at Ramathibodi hospital. In patients with GIB, the endoscopic finding with stigmata of recent hemorrhage was also recorded.

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: A total of 201 patients received clopidogrel with aspirin and 199 patients received ticagrelor with aspirin. Mean±standard deviation age was 66.2±11.3 years and 63.3% of patients were male. The most common indication of DAPT was acute coronary syndrome (85.4% in clopidogrel group vs.100% in ticagrelor group). Duration of treatment with clopidogrel and ticagrelor were 121.5 days vs. 231 days, respectively (p = 0.216). There were 20 (10.1%) GIB event in clopidogrel group and 11 (5.5%) in ticagrelor group. The most endoscopic findings of GIB was gastric erosion (44 % in clopidogrel group vs. 66.7 % in ticagrelor group). Risk ratio (RR) of GIB event of clopidogrel compared to ticagrelor was 1.34 (95% confidence interval [CI] 0.9–3.7, p = 0.093). By multivariate logistic regression analysis, duration of DAPT < 180 days (RR 3.28; 95% CI 1.89–5.69, p < 0.001) and history of previous GIB were associated with GIB events (RR 10.35; 95% CI 6.04–17.71, p < 0.001).

Conclusion: Risk of GIB is almost two times higher among patients received clopidogrel with aspirin compared to those received ticagrelor with aspirin. Closed monitoring patients who had duration of DAPT < 180 days and previous GIB might be minimized the risk of GIB event after receiving DAPT.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0512 REAL-LIFE ANALYSIS OF FREQUENCY, LOCATIONS AND BLEEDING SOURCES IN UNSELECTED EMERGENCY PATIENTS DURING NON-VITAMIN K ANTAGONIST ORAL ANTICOAGULANT (NOAC) THERAPY AND COMPARISON TO CONTROLLED APPROVAL STUDIES

Introduction: Non-vitamin K direct oral anticoagulants (NOAC) are increasingly used in thromboembolic disorders due to an efficacy at least equally as vitamin K antagonists (VKA) and/or significantly higher safety for intracranial bleeding or major bleedings of any source. In the approval studies, there was no generally increased bleeding rate for all types of bleeding, but different gastrointestinal bleeding (GIB) rates for aixtpalan, dabigatran, edoxaban and rivaroxaban. A current patient cohort included consecutive unselected patients manifesting with a GI bleeding under anticoagulation in 2014. All patients who were diagnosed with a GI bleeding under NOAC or VKA therapy in the emergency department of the University Hospital Erlangen were analyzed. Their data were entered in a registry and evaluated in terms of bleeding type, localization, use of proton pump inhibitor and frequencies. These real-life results were then compared with the published data from important approval studies, reporting each on the above-mentioned NOACs.

Results: From 2013 patients with GI bleeding 31 patients received VKA (14.5%) and 23 patients (10.8%, n.s.) had NOAC with major bleeding rates of 68% and 61%, resp. In patients with VKA 87% had an upper GIB, 12% a lower GIB, and none had a rectal bleeding (0%). During NOAC therapy, a similar distribution was found with 71% and 17%, but the proportion of rectal bleeding was higher with 10%.

This frequency of GIB rates in unselected emergency patients is significantly higher than reported in the controlled NOAC approval studies that included selected patients (3.8–5.6% GIB). In these NOAC studies a lower rate of GIB was found. A higher rate for lower GIB (32%, 17–84%) and rectal bleeding (15%, 10–47%) was found. Although NOACs are associated with an lower rate for GIB than VKA in the setting of emergency patients, NOACs show a shift of the type of bleeding to lower GIB or rectal bleeding sources in our analysis from emergency patients and in the NOAC approval studies. Only 50% of patients with NOAC were on proton pump inhibitor therapy.

Conclusion: The frequency of GIB in everyday life is approximately 10% higher than reported from the controlled NOAC studies, irrespective of the type of anticoagulation used. NOACs were associated with a non-significantly lower bleeding rate compared with VKA, but major GIB rates were similar. VKA with a bioavailability of 100% after oral ingestion showed a tendency of higher rates of upper GIB, while NOACs with a reduced GI absorption rate of 7–68% were found to occur more frequently at lower GIB sites. Thus, prior to any anticoagulation, a pre-therapeutic risk analysis for the occurrence of GIB is still required. Certain patient groups (anemia, aortic valve stenosis, renal insufficiency, NSAIDs, etc.) can benefit from proton pump inhibitor therapy, early endoscopy with intervention, or NOAC differential therapy.

Disclosure of Interest:

Sensitivity to orally ingested capsaicin decreases after long-term capsaicin ingestion was indirect proportional to the result during the initial capsaicin test. Differences in upper GI symptoms distinguished capsaicin positive patients from capsaicin negative patients. After long-term capsaicin ingestion, the symptoms scores after capsaicin ingestion were reduced by 25%/75%, p < 0.05 was considered significant.

Results: 53% FD had a positive capsaicin test. Basic clinical characteristics (age, gender, FD subtype, medication, psychological profile) were comparable in capsaicin positive and negative FD, but median daily aggregate upper gastrointestinal symptoms scores were significantly higher in capsaicin positive (median: 9.4; 5.4 (1.7) vs. than in capsaicin negative patients (6.6; 4.1 (8.1) p < 0.05). Median scores for epigastric pain, nausea and epigastric distension were similar in capsaicin positive and negative patients (p > 0.05). After capsaicin ingestion, aggregate upper gastrointestinal symptoms scores were reduced by ~3.3 (~4.9–1.9; p < 0.001) and epigastric bloating (p = 0.001) than capsaicin positive patients. Lower abdominal symptoms scores were comparable in capsaicin positive and negative patients at baseline (NS).

After capsaicin ingestion, aggregate upper gastrointestinal symptoms scores were reduced by ~3.3 (~4.9–1.9; p < 0.001) and epigastric bloating (p = 0.001) than capsaicin positive patients. Lower abdominal symptoms scores were comparable in capsaicin positive and negative patients at baseline (NS).

Aims & Methods: The aim of the study was to determine clinical characteristics of FD patients with and without chemical hypersensitivity at baseline and after capsaicin ingestion for 4 weeks. 

N = 49 outpatients with confirmed FD received an oral sensitivity test with 0.75 mg capsaicin at two occasions, before and after ingesting 0.25 mg capsaicin tid for four weeks. Symptomatic responses to capsaicin at the initial test allowed stratification to a capsaicin positive (chemosensitive) and a capsaicin negative (not chemosensitive) patient group. Symptom diaries for upper and lower gastrointestinal symptoms (visual analogue scales) were completed in the week before and during capsaicin ingestion and weekly aggregate symptom scores were calculated. Results are given as median; 

Disclosure of Interest: All authors have declared no conflicts of interest.

P0518 PER-ORAL ENDOSCOPIC MYOTOMY IN TREATMENT NAIVE VERSUS PRIOR TREATMENT FAILURE CASES –OUTCOME IN OVER 500 PATIENTS
Z. Nahi, M. Ramchandani, R. Chavan, S. Darisetty, R. Kalapala, D.N. Reddy Gastroenterology, Asian Institute of Gastroenterology, Hyderabad/India
Contact E-mail Address: zaheernabi1978@gmail.com
Introduction: Per-oral endoscopic myotomy (POEM) has emerged as an efficacious treatment modality for achalasia cardia (AC). Prior treatment (PT) may affect the outcomes of subsequent. The impact of prior treatment on technical and clinical success of POEM is not well known. Small studies with short follow-up indicate that POEM is safe and feasible in PT failure cases. However, there is paucity of large studies with long-term follow-up.

Aims & Methods: In this study we aim to compare the safety and efficacy of POEM in treatment native (TN) cases versus prior treatment (PT) failure cases. The data of consecutive patients with AC who underwent POEM at a single tertiary care center from (January 2013 to November 2016) was analysed retrospectively. A comparative analysis was performed between TN and PT failure cases. Technical and clinical success, adverse events (AE), operative time (OT) for POEM were compared between TN versus PT failure cases.

Results: Overall, 502 patients with AC underwent POEM during the study period. 260 patients (51.8%) were TN and 242 (48.2%) patients had PT. Type II AC was the most common subtype in both the groups (TN -63.5% vs PT – 57.8%) followed by type I and type III. There was no significant difference with regards to AC subtypes between the two groups. The distribution of patients according to prior treatment history is as follows – PHD (205), LH3 (23), LHM and PBD both (7), botulinum toxin injection (4) and POEM (3). Significantly more patients in the PT group had sigmoid oesophagus (47 vs 18). Mean OT was significantly more in the PT group when compared to the TN group (PT vs TN - 74.9 ± 30.6 vs 67 ± 27.1 min; P = 0.002). On multivariate analysis- type of AC, dilated oesophagus (> 6 cm) and type of knife used were significant predictors of OT. Technical (98.1% vs 97.1%, P > 0.05) and clinical success (94.9% vs 91.9%) of POEM was similar in TN and PT failure cases.

Conclusion: POEM is equally efficacious and safe in treatment native and prior treated cases. POEM should be considered in treatment failure cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0519 ESOPHAGEAL REFUX BURDEN IN RELATIONSHIP TO AET (ACID) AND ESOHAGOGASTRIC JUNCTION (EGJ) AND ESOHAGOGASTRIC BODY (EB) FUNCTION ON HIGH RESOLUTION MANOMETRY (HRM)
1Washington University in St. Louis, St. Louis/United States of America/MO
2Digestive Physiology, Hopital Edouard Herriot, Lyon/France
3Department Of Surgery, Oncology And Gastroenterology, University of Padua, Padua/Italy
4Northwestern University, Chicago/United States of America/IL
5Digestive Physiology, Hospices Civils de Lyon, Lyon/France

Introduction: Both EGJ and esophageal body motor abnormalities are found on esophageal HRM in reflux disease, and contribute to reflux burden assessed using acid exposure time (AET) on ambulatory reflux monitoring. Mean nocturnal baseline impedance (MBNI) represents a new paradigm that may assess longitudinal esophageal reflux burden, but its precise role in clinical esophagology, particularly in relationship to AET, remains unclear.

Conclusion: This clinical study demonstrates beneficial effects of prior on fullness, bloating and pain after a 400 mL test meal in diabetic patients with moderate-severe symptoms compatible with gastroparesis (GCSI > 27).

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: Our aim was to evaluate the complex interrelationships between lower esophageal sphincter (LES), upper esophageal motor abnormalities, and esophageal reflux burden in this ongoing multicenter collaboration. Esophageal function studies from patients with persisting reflux symptoms were reviewed from four centers (2 in Europe and US) for this preliminary report. EGJ morphology was categorized using HRM into hypotensive (EGJ-CI < 40 mmHg cm), hiatus hernia (HH, manometric separation between lower esophageal sphincter and crural diaphragm) and intact EGJ (normotensive EGJ-CI, no HH). Esophageal body metrics were characterized using Chicago Classification v 3.0 into intact, ineffective esophageal motility (IEM) and absent contractility. Total antireflux and supine AET were extracted from ambulatory pH-impedance studies. Baseline impedance was calculated at the 5 cm impedance channel (to correspond to AET) at three stable 10-min time periods (1, 2, and 3 AM) during the ambulatory pH-impedance study, and averaged to yield MNBI (normal >2292 ohms). Univariate and multivariate analyses were performed to assess EGJ and esophageal body predictors of esophageal reflux burden, and to discern the value of MNBI in comparison to AET.

Results: 1244 patients (53.4±0.4 yr, 59.6% F) undergoing esophageal motor testing using HRM (Medtronic, Duluth, GA) and ambulatory pH or pH-impedance monitoring studies performed off antisecretory therapy were included. A hypotensive EGJ was noted in 70.9%, HH in 34.0%, IEM in 26.3% and absent contractility in 3.5%. A disrupted EGJ and absent contractility had the highest proportions with AET > 6%; combinations thereof raised the proportions even higher (Table, p<0.001 for each comparison to intact EGJ and/or esophageal body). Compared to an intact EGJ, the odds ratio (OR) of total AET > 6% with HH was 2.0 (95% CI 1.1–3.9, p = 0.04). Supine AET > 2% was even more impacted (HH: OR 2.4, 95% CI 1.3–4.5, p = 0.007; HH + hypotensive EGJ: OR 3.3, 95% CI 2.1–5.2, p < 0.001). A hypotensive EGJ was not discriminative of AET or MNBI values. Concordance between AET and MNBI thresholds was noted in 401 of 596 studies (67.2%; both abnormal in 24.8%, both normal in 43.4%). When concordant and abnormal, proportions with EGJ and esophageal body abnormalities were highest (p<0.05) compared to concordant and normal AET/MNBI, and discordant studies. On multivariate regression with categorical and linear EGJ and esophageal body motor findings as dependent variables, presence of HH (p = 0.001), HH was an independent categorical predictor of abnormal MNBI noted in 401 of 596 studies (67.2%; both abnormal in 24.8%, both normal in 69.6%* (94/135)). Proportions with abnormal reflux burden in relationship to EGJ and esophageal body motor findings on high resolution manometry

Introduction: Electrical stimulation therapy is a new way to treat digestive disorders such as constipation, colonic inertia. It is necessary to understand the physiology of smooth muscle contraction in developing novel medical devices related to electrical stimulation therapy. The aims of this study were to measure the active characteristics of smooth muscle with acetylcholine in porcine intestine segment.

Methods: We used five female pigs and obtained ten centimeters of each porcine small intestine. To measure passive characteristics of small intestine, a universal testing machine with a tensile rate of 30 mm/min. To estimate the active characteristic parameters of smooth muscle and isometric and isotonic intestinal motility of smooth muscle, muscle contraction was induced by applying the stimulation solution (HTK solution containing 1 mM of acetylcholine chloride). Then, we obtained the maximum muscle contractile force of the specimens to measure the isometric and isotonic intestinal motility.

Results: In tensile test, the maximum contractile force, that indicate passive muscle force of smooth muscle 0.702 N, was measured. In the isometric and isotonic contractions in the porcine small intestine, the maximum motility, 12.35 mM, was obtained in isometric experiments, and the maximum velocity of muscular contraction, 0.4476 mm/min, was obtained in isotonic experiments. We demonstrated that in equal lengths, the muscle contraction velocity of the smooth muscle is 10–100 times slower than that of the skeletal muscle indicating force-velocity relationship of smooth muscle. And we obtained that the maximum contraction force from each individual percentage of active force (25%, 50%, and 100%) was achieved at L/L0 = 1.

Conclusion: We straighten out the active and passive property of porcine intestinal smooth muscle. Our study may be helpful for developing novel medical devices and understanding the physiology of smooth muscle in the porcine small intestine.

P0521 MOTILITY PATTERNS AFTER PER-ORAL ENDOSCOPIC MYOTOMY (POEM) IN PATIENTS WITH ACHALASIA

Introduction: Partial recovery of esophageal peristalsis has been reported in up to 7% of Achalasia patients treated by myotomy (either per-oral endoscopic myotomy (POEM) or laparoscopic Heller’s myotomy) in several rather small studies. The aim of our study was to assess motility patterns following possible “recovery” of esophageal peristalsis in a large cohort of patients after POEM.

Aims & Methods: We performed a retrospective analysis of prospectively collected data of patients undergoing POEM at our tertiary referral center. All patients in whom high-resolution manometry (HRM) studies were performed prior to and 3 months after POEM and who completed at least 6-month follow-up were included. All HRM studies were reviewed and the Chicago Classification (CC) v3.0 of motility disorders was applied to characterize both pre- and post-POEM motility patterns.

Results: From 192 patients who underwent POEM since 2012, 127 patients met the diagnostic criteria. The initial CC diagnoses before POEM were as follows: type I achalasia – 20 pts (16%), type II achalasia – 100 pts (79%), type III achalasia – 5 pts (4%), other (esophageo-gastric junction outflow obstruction (EGJOO) and Jackhammer) – 2 pts (1%). Only 6 patients (5%; type III achalasia – 1 patient, EGJOO) had had some signs of esophageal contractility before POEM. After POEM, peristaltic fragments were present in 28/127 patients (22%) - 9x ineffective esophageal motility, 5x fragmented peristalsis, 2x distal esophageal spasm, 5x EGJOO, 7x type III achalasia. Thus, the partial “recovery” of esophageal peristalsis was observed in 22/121 patients (18%) and it only occurred in patients with type II achalasia; contractile activity was not detected in any patient with type I achalasia after POEM (22/100 vs. 0/20, p = 0.023). Panesophageal pressurization completely resolved in 88 patients (88%) with
achalasia type II. The mean integrated-relaxation pressure (IRP) decreased from 27 (±13) mmHg to 13 (±5) mmHg (p < 0.0001). The presence of peristaltic recovery was neither associated with normalization of IRP (IRP normalized in 17/28 (61%) patients with peristaltic recovery and in 72/99 (73%) patients without, p = 0.25), nor with overall treatment success of POEM (Eckardt score <3).

Conclusion: In this so far largest case-series investigating the rate of peristaltic recovery after POEM this was present in 18% of patients, therefore, the rate may be lower than previously reported. Peristaltic recovery seems to have no clinical impact on post-POEM symptomatology. Esophageal contractility after POEM was not observed in any patient with achalasia type I.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Medical treatments, endoscopic balloon dilatation, Botox and Heller myotomy are treatment modalities for managing achalasia. Recently per-oral endoscopic myotomy (POEM) has become a new option for achalasia patients and since 2010 it has become widespread. Earlier, anterior myotomy was used in this technique but in the last few years there are studies reporting that posterior myotomy is more effective. However, there are limited numbers of publications comparing anterior and posterior myotomy. This study aimed to investigate the effect of myotomy site on POEM, to our knowledge it is the first to report the results of our model.

Aims & Methods: Between May 2014 and January 2017, POEM was performed to 225 achalasia patients at the gastroenterology clinics under general anesthesia. POEM procedure Eckardt scores were significantly low in all patients (p < 0.005). Demographic features and data of the procedures are presented in Table 1. Control endoscopy was performed to 151 patients at 3 months after POEM to rule out early recurrence. T-tunneling was the most common technique used for POEM and it was performed in 111 patients (49%). No significant difference between the groups in terms of tunnel length, myotomy length, tunnel entrance time and frequency of homeostatic forceps use (p > 0.05).

Main outcomes were treatment success defined as Eckardt score ≤3, recurrence and post-POEM reflux.

Results: There were 114 patients in group A, 111 patients in group P. There was no statistical difference between the groups in regards to tunnel length, myotomy length, tunnel entrance time and frequency of homeostatic forceps use (p > 0.05). However duration of opening the tunnel, myotomy, closure of the tunnel and total procedure time were significantly shorter in group P (p < 0.05). Eckardt and dysphagia scores before the procedure were similar in both groups. After the POEM the Eckardt scores were significantly low in all patients (p < 0.005). Demographic features and data of the procedures are shown in the table below. No significant difference between the groups in regards to tunnel length, myotomy length, tunnel entrance time and frequency of homeostatic forceps use (p > 0.05).

Conclusion: According to our results posterior approach can shorten the procedure time in POEM compared to anterior myotomy. This may be due to a better angle of approach with endoscopic equipments for posterior myotomy. We believe that long-term results will also show the effects of myotomy site on clinical outcome of patients. We declare that long-term results will also show the effects of myotomy site on clinical outcome of patients.

3Anesthesiology And Resuscitation, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: zuzana.rabeкова@ikem.cz

Introduction: Peroral endoscopic myotomy (POEM) has gained trust by proven safety and short-term efficacy and at present, it is considered to be a standard method for treatment of esophageal achalasia. However, long-term data concerning the efficacy and safety especially with regard to post-POEM reflux are still awaited.

Aims & Methods: The aim of this prospective single-center case series was to assess the long-term clinical outcome of POEM with emphasis on post-POEM reflux evaluated by pH monitoring, endoscopic findings, reflux symptoms and use of proton pump inhibitors (PPIs). Since 2012, a total of 192 patients with achalasia underwent 202 POEM procedures. Follow-up visits at 3, 12, 24 and 36 months were completed in 160, 116, 70 and 27 patients. Upper GI endoscopy, high-resolution manometry (HRM) and 24-hour pH monitoring were performed 3 months after POEM, endoscopy was then repeated between 24-36 months.

Main outcomes were treatment success defined as Eckardt score ≤3, recurrence rate and post-POEM reflux.

Results: At 3, 12, 24 and 36 months, treatment success was achieved in 97% (95% CI: 94–90), 95% (CI: 91–99), 88% (CI: 82–95) and 81% (CI: 69–93) of patients. A total of 14 patients experienced treatment failure (n = 5) or recurrence (n = 9). The recurrences occurred most often in patients with HRM type I achalasia (4 out of 20; 15.4%) followed by type II (3 out of 113; 2.6%) vs. none in type III achalasia (0 out of 10; 0%; p = 0.022. At 3 months, reflux esophagitis was diagnosed in 63/160 patients (39.4%; severe esophagitis LA C or D in 8 patients). Abnormal acid exposure on pH-metry studies was detected in 58/146 (39.7%). At 24-36 months, endoscopy was performed in 41 patients and reflux esophagitis was present in 9 patients (21.9%; none of the patients has been treated with PPIs). At 3 and 24M, a proton pump inhibitor was administered to 33.5% and 31.4% of patients.

Conclusion: POEM is effective treatment modality for achalasia with treatment success around 90% at 2 years, slightly dropping down to 81% at 3 years. Generally mild reflux esophagitis and abnormal esophageal acid exposure are diagnosed in about 40% of patients 3 months after POEM but are successfully manageable with proton pump inhibitors. Occurrence of reflux esophagitis tends to decrease with time.

P0524 BEER EFFECTS ON POSTPRANDIAL DIGESTIVE SYMPTOMS AND GASTROESOPHAGEAL PHYSIOLOGY
B. Serrano1, M. Megia Sanchez, A. Ruiz De Leon, E. Rey
1Gastroenterology Department, Hospital Clinico San Carlos, Madrid/Spain

Contact E-mail Address: blan.serrano.falcon@gmail.com

Introduction: Beer has been related to gastroesophageal reflux (GER) and dyspepsia (1, 2), based on its alcohol and gas content. Main objective was to evaluate if moderate regular and non-alcohol beer consumption is related to postprandial...
dyspeptic symptoms after a controlled meal. Secondary objectives were to evaluate its relation with postprandial GER and gastric accommodation and to evaluate its relation with daily digestive symptoms under real conditions.

**Aims & Methods:** Healthy people over 18 years old, free of frequent digestive symptoms (<once a week) and GERD disease (GERD), were included. Basal symptoms were assessed through PAGI-SYM(3) and OQLRAD (4) questionnaires, both validated to Spanish. Study was divided in two substudies based on the study intervention: 33 cl of regular beer (substudy 1) and the same amount of non-alcohol beer (substudy 2). Mineral water (33 cl) was the control intervention in both substudies. Each participant was its own control. The study lasted two weeks (control study week and intervention study week). Each week started with a visit to the laboratory at 7:30 am, when a pHimpedance catheter was placed and taken off 24 hours later. Gastric accommodation was assessed through the maximum tolerated volume during a nutrient drink test (ENSURE®-HN, 500 ml) in a rhythm of 15 ml/min, after the ingestion of beer (intervention) or water (control). It was defined as the volume after which the test finished or the participant reported the maximum puation for any dyspeptic symptoms (early satiety, bloating, epigastric pain and nausea), which were asked every 5 minutes (1 meant no symptom and 5 meant the highest perception). GER was evaluated in the postprandial period and during 24 hours through pHimpedance register. Weekly symptoms evaluation was made through a diary adapted from PAGISYM questionnaire and sum of symptoms was used for analysis. Data were collected daily through email. Variables were compared between both visits and weeks in both substudies using a non parametric test for matching data. Participants should drink 33 cl of beer before lunch and dinner during the intervention week. Other alcohol drinks were prohibited during the study.

**Results:** Ten participants were enrolled in substudy 1, mean aged 24 years old (SD 4.1, range 18–32); 80% were men. Twenty participants were enrolled in substudy 2, mean aged 23.4 years (SD 5.5, range 20–38); 65% were men. No significant differences were detected in the increase of symptoms during the nutrient drink test between control and intervention visits in both substudies (table 1). Maximum tolerated volume did not show any difference between visits in both substudies. Reflux episodes after nutrient drink test and reflux episodes registered in 24 hours did not show significant differences between control and study visits. The sum of weekly symptoms did not show any difference between control and intervention weeks in both substudies.

**Conclusion:** Moderate beer consumption (regular and non-alcohol beer) does not cause an increasement of dyspeptic symptoms and reflux in healthy people. It has been shown in a controlled situation (nutrient drink test and pH impedance register) as well as real life (diary weekly symptoms). Gastric accommodation and reflux episodes have either shown to be affected by moderate beer consumption.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Rumination syndrome is a functional gastrointestinal disorder characterized by effortless, post-prandial regurgitation of food. In addition to regurgitation, a large proportion of patients report functional dyspepsia (FD) symptoms including post-prandial discomfort, early satiety and nausea (1,2). Recently, duodenal eosinophilia has been described both in adult and pediatric patients with FD (3,4). Because of the significant symptomatic overlap between FD and rumination syndrome we hypothesized that histological changes similar to those described in FD might exist among patients with rumination syndrome.

**Aims & Methods:** We therefore aimed to assess histology of duodenal biopsies from patients with rumination syndrome and compared these to healthy controls. Rumination syndrome was diagnosed with post-prandial esophageal high resolution impedance manometry (HRIM) and/or fulfilled ROME II/III criteria. This study was approved by the Institutional Review Board. We included persons aged 18 and above with a diagnosis of rumination syndrome in whom we had also obtained 4-6 duodenal biopsies from diagnostic upper endoscopy. Normal controls were aged 18 and above without any gastrointestinal symptoms in whom 4-6 duodenal biopsies were obtained for research purposes. Cases and controls with a personal history of an eosinophilic disorder, gastric or esophageal surgery, recent (within 30 days) intake of NSAIDS and pregnant and/or lactating females were excluded. Duodenal biopsies obtained were routinely processed to formalin-fixed paraffin-embedded tissue blocks which were cut at 3 μm, stained with H&E and scanned to digital images (Aperio). The pathologist, blinded to the case-control status, analyzed de-identified digital images of the biopsy specimens and assessed for eosinophil counts/mm² in sections. Individual sections were also assessed for the presence of Brunner’s glands (BG) and intraepithelial lymphocyte counts (IEL)/100 enterocytes. This was done in order to distinguish the first part of the duodenum with BG and the second part generally without BG, (D2) and intraepithelial lymphocyte counts (IEL)/100 enterocytes.

**Results:** Patients with rumination syndrome (22) had a mean age of 39.2 years (range 19–71) and 77% were female. The mean eosinophil counts/biopsy fragment was Brunners glands (BG) and intraepithelial lymphocyte counts (IEL)/100 enterocytes. This was done in order to distinguish the first part of the duodenum with BG and the second part generally without BG, (D2) and intraepithelial lymphocyte counts (IEL)/100 enterocytes.

**Patients with rumination syndrome (22) had a mean age of 39.2 years (range 19–71) and 77% were female. The mean eosinophil counts/biopsy fragment was Brunners glands (BG) and intraepithelial lymphocyte counts (IEL)/100 enterocytes. This was done in order to distinguish the first part of the duodenum with BG and the second part generally without BG, (D2) and intraepithelial lymphocyte counts (IEL)/100 enterocytes.

**Conclusion:** These findings demonstrate that patients with rumination syndrome have duodenal eosinophilia and increased IEL counts compared to healthy controls. To our knowledge, histopathological changes among patients with rumination syndrome compared to controls have not previously been described. Therefore, a potential role of duodenal innate immune mechanisms in the pathophysiology of rumination syndrome warrants further enquiry.

P9027 CHRONIC POSTSTROKE OROPHARYNGEAL DYSPHAGIA IS ASSOCIATED WITH IMPAIRED CORTICAL ACTIVATION TO PHARYNGAL SENSORY INPUTS

O. Ortega1, C. Cabib1, N. Vilardeil1, L. Munda1, P. Clave1, L. Roef1
1 GI Physiology Laboratory, Hospital de Mataron, Consorci Sanitari del Maresme, Mataron/Spain
2Centro De Investigacion Biomedica En Red De Enfermedades Hepaticas Y Digestivas., Instituto de Salud Carlos III, Barcelona/Spain

Contact E-mail Address: oortega@csdm.com

Introduction: The role of afferent sensory pathways in the pathophysiology of post-stroke oropharyngeal dysphagia (OD) is not known [1]. We hypothesized that chronic post-stroke patients with OD (PSD) would show impaired sensory cortical activation in the affected hemisphere.

Aims & Methods: We studied 28 chronic unilateral post-stroke patients (17 PSD and 11 nondysphagic [PnD]) and 11 age-matched healthy volunteers (HV). Electrophysiological measures used to assess event-related sensory evoked potentials to pharyngeal stimulation (pSEP) and sensory thresholds with a naso-pharyngeal catheter with two electrodes passed through the nostrils 14-15 cm until the pharynx (Galetic Ltd, Dunvegan, Scotland). We analyzed pSEP peak-latency and amplitude (N1, P1, N2, P2) and neurotopographic source characteristics from brain MRI.

Results: HV presented a highly symmetric bi-hemispheric cortical pattern of brain activation at centro-parietal areas (N1-P1, N2-P2) to pharyngeal stimuli. In our patients, an asymmetric pattern of reduced ipsilesional activation was found in PSD (N2-P2; p = 0.026) but not in PnD. PSD presented impaired safety of swallow (Penetration-Aspiration score: 4.3 ± 1.6) and delayed laryngeal vestibule closure (360 ± 70 ms), and higher NIHSS (7.0 ± 2.6 vs. 1.9 ± 1.4, p = 0.001) and Fazekas scores (3.0 ± 1.4 vs. 2.0 ± 1.1, p = 0.05) than PnD. pSEP showed a unilateral delay at stroke site exclusively for PSD (peak-latency inter-hemispheric difference vs. PnD: N1; 6.5 ± 6.7 vs. 1.1 ± 1.0 ms; N2; 32.0 ± 15.8 vs. 4.5 ± 4.9 ms; p = 0.05).

Conclusion: Chronic post-stroke OD is associated with stroke severity and degree of leukoaraiosis. Impaired conduction and cortical integration of pharyngeal sensory inputs at stroke site is a key feature of chronic PSD. These findings highlight the role of sensory pathways in the pathophysiology of post-stroke OD and offer a potential target for future treatments.

Introduction: Gastroparesis is characterized by abnormal gastric motor function with delayed gastric emptying in the absence of mechanical obstruction. In our tertiary referral centre, patients are treated with a stepwise approach, starting with dietary and lifestyle advice and prokinetics followed by pyloric botulinum toxin. When these initial measures fail, the presence of malnutrition, one of the following interventions are considered: three months nasoduodenal tube feeding with ‘gastric rest’ and placement of a percutaneous endoscopic gastrostomy with jejunal extension (PEG-J). Our primary aim was to evaluate the effect of nutritional treatment entities in patients with gastroparesis who fail previous treatments, on weight and symptoms.

Aims & Methods: Prospectively collected data of all referred gastroparesis patients between 2008 and 2016 were reviewed.

Results: A total of 101 gastroparesis patients (71% female, 20–86yrs, mean 55yrs) with delayed gastric emptying in the absence of mechanical obstruction. In our centre, 36 patients were treated with 3 months of gastric rest via complete nasoduodenal tube feeding. Enteral tube feeding was well accepted, occlusion occurred in 8% of patients. Mean weight gain in symptom responders was 3.5% (2.4 kg, p = 0.02), in non-responders 3.7% (2.4 kg, p = 0.01). These 19 patients with insufficient symptomatic response after 3 months gastric rest continued treatment with enteral feeding through PEG-J. A significant weight gain of 8.2% was seen (mean 5.0 kg, range –6% to +29%), p = 0.003) within 3–6 months after PEG-J placement. Thereafter only 3 patients (1%) were able to be reduced to same complete oral intake, the PEG-J was removed after a mean treatment time of 11 months. In 84% of patients the PEG-J is still in use, with a mean treatment time of 894 days. Over 75% of patients report adequate effect on symptoms. Most frequent complication was lysis of the jejunal extension to the stomach (32% of patients). Other complications were peristomal infection (11% within 30 days, 16% after 30 days) and buried bumper (16%).

Conclusion: This study describes the sequelae of a large group of tertiary referral gastroparesis patients treated with PEG-J treatment. In gastroparesis patients who failed all previous treatment, PEG-J is an excellent option to regain and maintain adequate nutritional status with marked symptom control.

Introduction: Reduced sleep quality has been linked to gastroesophageal reflux disease (GERD) and functional gastrointestinal disorders. It is unknown whether GERD, functional dyspepsia (FD) and irritable bowel syndrome (IBS) are more prevalent in subjects with significant sleep disturbance (SD) than those without SD.

Aims & Methods: The aim of the study was to investigate gastrointestinal symptoms, clinical characteristics, and psychological factors in subjects with and without SD in a general population undergoing health checkups. We enrolled 2752 consecutive subjects who received upper gastrointestinal endoscopy and colonoscopy during their health checkups. All participants underwent an evaluation with questionnaires including Reflux Disease Questionnaire score, Pittsburgh Sleep Quality Index (PSQI), Taiwanese Depression Questionnaire, and State-Trait Anxiety Inventory before receiving endoscopic exam. Demographic characteristics and biochemical data were also recorded. FD and IBS were based on Rome III diagnostic criteria, and metabolic syndrome was defined by the National Cholesterol Education Program Adult Treatment Panel III definition. SD was confirmed when PSQI score was greater than 5. We compared the clinical and psychological factors between subjects with and without sleep disturbance.

Results: Among the study population (n = 2674), 956 (36%) individuals had SD. SD subjects had more female gender, older age, lower level of education, higher systolic blood pressure, higher serum high-density lipoprotein levels, and higher prevalence of FD and IBS than those without SD. In addition, SD patients also had more depression, anxiety, more severe GERD symptoms, and higher prevalence of non-erosive reflux disease (NERD) (p < 0.001). Multivariate analysis revealed that female sex (OR = 1.75, p < 0.001), older age (OR = 1.03, p < 0.001), more severe GERD symptoms (OR = 1.03, p = 0.033), NERD (OR = 1.63, p = 0.023), IBS (OR = 1.48, p = 0.05), and depression (OR = 1.16, p < 0.001) were positive predictive factors for SD, whereas higher level of education (OR = 0.57, p = 0.001) was negative predictive factor for SD.

Conclusion: Our study demonstrates that SD is associated with female sex, older age, lower education level, greater GERD symptom burden, greater depression, and higher prevalence of NERD and IBS. Future studies will be needed to clarify the relationship between functional gastrointestinal diseases and sleep disorders.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Variables with a p-value of 0.1 or less in univariate analysis were entered into a multivariate analysis (logistic regression) in order to identify factors independently associated with esophageal symptoms (up to 33 variables).

**Conclusion:** Esophageal symptoms compatible with a functional esophageal disorder are common in the Western population. Age and presence of other GI and non-GI symptoms are associated with reporting esophageal symptoms.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Several studies have provided information on the prevalence of different atopic conditions in adult EoE patients compared to several groups of control subjects. The findings indicate that, overall, EoE patients show a higher frequency of asthma, rhinoconjunctivitis, eczema, and food allergies than control groups; however, definitions for the associated atopic conditions have not always been concorded and the selection process for the controls has not been such that they can be considered universally representative of the general population without EoE. These two limitations have hampered researchers in their efforts to clearly assess the magnitude of the association between atopy and EoE. We aimed to conduct a systematic review of the literature and to perform a meta-analysis in order to evaluate the presence of atopic diatheses in patients with EoE as well as to summarize the prevalence of atopic conditions in both paediatric and adult EoE patients in comparison with the non-EoE control populations without EoE.

Aims & Methods: A highly sensitive search strategy was designed to identify and retrieve all documents dealing with the relationship between atopy and EoE in children and adults. This systematic literature search was performed independently (AA and AJL) by searching three bibliographic databases (PubMed, EMBASE, and Scopus) for the period up to March 2016. The search was not restricted with regard to the language of publication. A predetermined protocol was used in accordance with the quality standards for reporting meta-analyses of observational studies in epidemiology. Four reviewers (JG-C, AA, MM-CM, and AJL) independently extracted relevant information from each eligible study using a standardized data extraction sheet and then proceeded to cross-check the results. Estimates for the prevalence of each atopic manifestation in EoE patients and controls were summarized with the aid of a fixed- or random-effects meta-analysis, depending on intra-study heterogeneity, weighted for inverse variance following the method elaborated by DerSimonian and Laird. Summary estimates, including 95% confidence intervals (CI), were calculated for each season and month, whenever possible.

Results: Of the 2954 references identified, data was collected from 21 studies including a total of 53,542 EoE patients and 54,759 controls. The criteria for defining a diagnosis of atopy in either EoE patients or controls were similar or identical in most of the studies. The frequency or prevalence of the different atopic manifestations among EoE patients was compared with that observed in several types of control populations, including series of patients with chronic EE findings at initial endoscopy, GORD patients, and general population without EoE; all of whom were endoscopically assessed with a diagnosis of EoE specifically ruled out. In all cases, EoE was considered as independent from GORD and other upper GI tract diseases. Some studies included database-registered subjects as well. The criteria for defining a diagnosis of atopy among EoE patients and control subjects varied widely across the different studies, from self-reported/parent-reported atopic background to strict allergist/immunologist-provided diagnoses. Overall, allergic rhinitis was significantly more common among controls compared to EoE patients (OR 5.49 [CI 3.27, 9.53; P = 0.006] as were bronchial asthma (OR 3.06 [95% CI, 2.01, 4.66; P = 0.001]) and eczema (OR 2.86; 95% CI, 1.88, 4.36; P = 0.037). Food allergies and other atopic conditions were also assessed. No significant publication bias or study dealing with rhinitis and eczema in EoE patients was identified. Our search uncovered two papers that reported on the frequency of drug allergy in EoE patients compared to controls, showing no significant differences between these two populations (OR = 0.981; 95%CI, 0.07, 14.72).

Conclusions: Our present study shows that an accurate diagnosis of allergy is lacking in most of the research evaluating the prevalence of asthma, rhinitis, and eczema among EoE patients. Still, the prevalence of these three conditions seems to be significantly higher in children and adults with EoE as compared to control subjects of the general population. Further research based on index and prevalent definitions of allergic rhinitis, asthma (including its severity and level of control), skin allergy, and food allergy (rather than mere sensitization) when assessing and documenting concurrent allergic diseases in patients with EoE.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Eosinophilic esophagitis (EE) is a chronic condition of the esophagus with pathognomonic clinical, endoscopic and histologic features. We aimed to prognosticate which cohort of patients respond best to proton pump inhibitor (PPI) monotherapy or topical steroids based on index endoscopy and histology in conjunction with symptoms at presentation and on follow-up.

Aims & Methods: All patients referred with dysphagia or with an incidental high eos/hpf finding of >15 eos/hpf were diagnosed with EE and included in the study. Patients who underwent a therapeutic intervention (PPI or FBO) demonstrated a reduced normalisation of eos/hpf following either steroid or PPI therapy compared to those not presenting with these symptoms at a minimum of 3 months (46% vs. 100%; p = 0.03). Overall, there were no significant associations between eos/hpf at index endoscopy and adverse events or deaths. The other histological findings, patients presenting with dysphagia or FBO demonstrated a higher response to steroids than those with reflux symptoms (50% vs 9% p = 0.018) who responded best to PPI (91%). 78 patients were available to 3 months following initiation of treatment. Patients with chronic EE findings at initial endoscopy were less likely to respond symptomatically to PPI monotherapy compared to those with normal or acute endoscopic findings (52% vs. 68%; p = 0.003) while they were more likely to respond...
to steroids (64% vs 36%; p = 0.002). Specifically, the presence of strictures indicated a more likely clinical response to steroids compared to PPI alone. (p = 0.007).

**Conclusion:** A higher eos/hpf was found in patients with chronic EE features at index endoscopy than those with normal or acute endoscopic signs. In those with normal or acute EE changes and without dysphagia as a presenting complaint, a clinical response was noted with PPI therapy alone. In those with chronic EE changes or with dysphagia/FBO, steroids appear to be the preferred therapeutic option, although at 3 months follow up a clinical response might precede a histologic one.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Proton Pump Inhibitor-response esophageal eosinophilia (PPI-REE) is an emerging condition characterized by a constellation of clinical, endoscopic, and histopathologic features in the setting of eosinophilic inflammation on esophageal biopsies responding to a course of proton pump inhibitor (PPI) therapy. A recent meta-analysis explored the role of different PPIs in inducing endoscopic, according to Endoscopic Reference Score (EREF), and histologic features were blindly reviewed for each patient. Esophageal sphincter and have no reflux so gastro-esophageal reflux could not be developed accessories was easily achieved. However, pigs have a strong lower esophagus of 8 pigs during 7 days to evaluate placement, feeding, weight gain, absence of migration as well as removal. Deployment of the « GARD » was easy, esophagus of 8 pigs were required for treatment allocation, 8 (29%) patients received esomeprazole, 9 (32%) rabeprazole and 11 (39%) pantoprazole. Baseline, demographic and clinical data, including age, sex, BMI, H. pylori infection, concomitant allergy conditions and latency from diagnosis were similar (p = ns). Moreover, no differences were found in terms of frequency of symptoms reported (p = ns). Endoscopic and histologic features at baseline and after PPI therapy are shown in the Table. Esomeprazole, rabeprazole and pantoprazole reached the same degree of efficacy in inducing endoscopic and histologic changes in PPI-REE patients (p = ns).

**Table:** Endoscopic and histologic features at baseline and after PPI therapy in PPI-REE

**Conclusion:** Esomeprazole, rabeprazole and pantoprazole administered at double daily dose were equally effective in determining endoscopic and histologic remission in patients with PPI-REE. These data, although obtained in a small sample of patients, suggest that the pharmacokinetic and pharmacodynamic differences among these drugs do not affect their effect on PPI-REE patients.

**P0537 THE « GARD (GASTRO-ESOPHAGEAL ANTI-REFLUX DEVICE): A NEW ENDOSCOPIC MEDICAL DEVICE TO DIAGNOSE, MANAGE AND TREAT GERD**

N. Godin

Private Practice, Geneva/Switzerland

**Contact E-mail Address:** dr.godin68@gmail.com

**Introduction:** The « GARD » (Gastroesophageal Anti-Reflex Device) is an anti-reflux tubular valve placed in the lower esophagus under endoscopic control allowing normal ingestion of food and beverages but blocking all gastro-esophageal refluxate mechanically (fluid, solids and gas).

**Aims & Methods:** The « GARD » was placed in the esophagus of 8 pigs during 7 days to evaluate placement, feeding, weight gain, absence of migration as well as removal. Deployment of the « GARD » was easy, the « GARD » is placed through the 2.8 mm working channel of a standard gastroscope. The GARD is held in place by pressure. The upper ring holds an anti-reflux thin-walled tubular valve moulded in one piece under the ring. After placement of a standard guidewire, the « GARD » is placed through the patient’s mouth and is released in the lower esophagus. The procedure is performed under sedation on an ambulatory basis in about 15 minutes when experienced. The « GARD » was placed in the lower esophagus of 8 pigs during 7 days to evaluate placement, feeding, weight gain, absence of migration as well as removal. Deployment of the « GARD » was easy, there was no migration in the stomach and removal of the GARD with the developed accessories was easily achieved. However, pigs have a stronger lower esophageal sphincter and have no reflux so gastro-esophageal reflux could not be evaluated. In a human volunteer with very severe gastro-esophageal reflux who had previously failed anti-reflux surgery and had an unsatisfactory response to clinical and pH metric measurement under 80 mg of esomeprazole, the « GARD » was placed preoperatively. Hereafter are this patient’s pH metric results without PPIs (table 1); with the patient taking 80 mg/day PPIs (table 2) and after GARD placement and PPIs stopped for 10 days, table 3.

**Results:** Fig 1. First pH metric study (no PPIs for 10 days): The patient has very severe reflux with 63% of the time with a pH under 4 (normal less than 4% of the time at a pH under 4) after PPIs were stopped for 10 days. Fig 2. Patient is taking 80 mg of esomeprazole a day. pH metric measurement remains highly pathologic at 23% of the time under pH 4 once PPIs have been resumed at 80 mg of PPIs daily. Fig 3. After placement of the GARD and PPIs have been stopped for 10 days, there is no longer any reflux measured. The pH tracing does not drop under the red line at pH 4.

**Conclusion:** a new medical device blocking GERD is presented. A first clinical trial was started in 2018 to help diagnose and manage Refractory GERD. Further clinical indications are at the planning stage including treatment of Refractory GERD and LPR.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
**P0538 SYMPTOM PATTERNS AND TYPES OF GASTROESOPHAGEAL REFUXES SIGNIFICANTLY DIFFER IN GROUPS OF EROSOUS ESOPHAGITIS AND NON-EROSEUS FORM OF GASTROESOPHAGEAL REFUX DISEASE (GERD) PATIENTS**

M. Konovalova, S. Morozov, V. Isakov

Gastroenterology And Hepatology, Federal Research Center of Nutrition and Biotechnology, Moscow/Russian Federation

Contact E-mail Address: sunnysister@mail.ru

**Introduction:** Patients with gastroesophageal reflux disease (GERD) demonstrate a range of different symptoms (esophageal and extraesophageal) however the relationship between symptoms and types of reflux was not evaluated.

**Aims & Methods:** The aim of the study was to assess the relationship between GERD patients’ symptoms with characteristics of refluxes obtained by 24-h esophageal pH-impedance. One hundred fifty eight GERD patients (68 men, 89 women, age (M±d) 42±4.8 yrs) and 49 controls (22 men, 27 women, age (M±d) 46±6.7 yrs) were examined using 24-hours esophageal pH-impedance recordings (Omegah, MMS, the Netherlands; 24-hpH-impedance channels catheters, UnisensorAG, USA) and validated GERD-Q questionnaire. According to baseline endoscopy 91 patients were classified as non-erosive reflux disease (NERD) and 67 as erosive reflux disease (ERD) patients. Patients’ symptoms were classified according to Montreal classification.

**Results:** Extraesophageal symptoms as well as weak acid gastroesophageal refluxes were found significantly more often in patients with NERD compared to ERD group (table 1). However higher number of acid refluxes, higher GERD-Q score and DeMeester score were present in ERD. The total number of gastroesophageal refluxes didn’t differ between ERD and NERD groups of patients.

**Conclusion:** ERD and NERD groups of patients are characterized by different symptom patterns and types of gastroesophageal refluxes registered with 24-hours esophageal pH-impedence monitoring. These findings could reflect differences in pathogenesis and clinical manifestation of mentioned forms of GERD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Several clinical-based studies from Western countries have investigated the prevalence of extra-esophageal symptoms in various degrees of reflux erosive esophagitis. However, the independent factors related to the development extra-esophageal manifestations remain unclear.

**Aims & Methods:** Our aim was to assess the prevalence of extra-esophageal symptoms (laryngeal disorders and chronic cough) in adults with (cases) and those without (controls) erosive esophagitis in Albania, a developing Southeast European country. A case-control study was conducted at the Regional Hospital of Durres, the second main district in Albania, a transitional country in South Eastern Europe, including 248 patients with erosive esophagitis aged 16–56 (mean age 46.5±16.3 years) and 273 controls (aged 46±16.0 years; response rate: 70%) enrolled during the period January 2013 – June 2014. Both cases and controls underwent upper endoscopy. Information on socio-demographic characteristics and lifestyle factors were also collected. Binary logistic regression analysis was used to assess the association of erosive esophagitis and extra-esophageal symptoms.

**Results:** Patients with erosive esophagitis had a higher prevalence of excessive alcohol consumption, smoking, sedentarity and obesity compared to their control counterparts (9% vs. 5%, 70% vs. 49%, 31% vs. 17% and 22% vs. 9%, respectively). The prevalence of hiatal hernia was higher in cases than in controls (21% vs. 8%, respectively), whereas the prevalence of gastric-duodenal ulcer was similar in both groups (13% vs. 14%, respectively). Upon adjustment for all sociodemographic characteristics and lifestyle/behavioral factors, there was evidence of a strong association of erosive esophagitis with chronic cough (OR=3.1, 95%CI=1.7–5.7), and even more so with laryngeal disorders (OR=4.4, 95%CI=2.6–7.4). In all models, the association of erosive esophagitis with chronic cough was strong and remained significant in the majority of the symptoms separately (fully-adjusted model: OR=4.6, 95%CI=2.9–7.3).

**Conclusion:** Our findings indicate that the prevalence of extra-esophageal symptoms is higher among patients with erosive esophagitis in a transitional country characterized conventionally by the employment of a Mediterranean diet. Therefore, the upper endoscopy should be part of the evaluation in patients with suspected reflux-related chronic cough and laryngeal disorders.

**Introduction:** Gastroesophageal reflux disease (GERD) is a disease caused by backflow of gastric contents into the esophagus due to the failure of physiological and anatomic mechanisms and is at least in part secondary to hiatal hernia. Gastroesophageal reflux (GER) is an important condition due to the risk it poses to the respiratory tract and pH monitoring (MII-pH) and salivary Peptest in a group of patients with GERD. The Peptest which measures the pH of saliva (pH 4–7) vs. healthy controls and NO3−, Ca2+, Na+, Mg2+, Cl−, NO3−, NO2−, SO42−, acetate, lactate, propionate, butyrate) was analyzed by capillary electrophoresis in each sample. Saliva was collected using the commercial Peptest sampling containers, applied to the Peptest lateral flow devices and analyzed using the device reader. The data from EBC were compared with MII-pH and PEPtest. In total the study comprised of 39 participants. The patients were divided by dominant findings from MII-pH in groups with acidic reflux (n=17), weakly acidic reflux (n=8) and without reflux (n=14).

**Results:** The values of pH (after CO2 removal with Na2) were significantly higher in the group with acidic reflux (p<0.01), (mean pH 7.13, interquartile ranges 6.83–7.47) and in the group with weakly acidic reflux (p<0.01) (7.37, 7.18–7.57) vs. healthy controls (6.8, 6.65–6.99). Butyric acid (BA) was the second most significant parameter that was significantly elevated (p<0.01) in both patient groups (acid reflux- mean BA 2.29 μM, weakly acidic reflux- mean BA 3.33 μM) compared to healthy subjects (mean BA 0.69 μM). Further statistically significant differences were found in chloride (Cl−), nitrate (NO3−) and sodium (Na+) ions concentration. BA was elevated at (p<0.01) in group with acid reflux vs. healthy controls and NO3− and Na+ were elevated at (p<0.01) in both groups with acid reflux vs. healthy controls. In case of pH stratification significantly different pH in EBC and selected ions from EBC between different groups of patients and healthy controls. The analysis of selected parameters in EBC could provide a fast and non-invasive diagnostic method for GERD patients with EER symptoms in the future. This can

**Introduction:** Impedance-pH testing is actually considered the gold standard diagnostic tool for reflux assessment. In fact, it allows to characterize any type of gastro-esophageal reflux (GER), namely acid and non-acid, and therefore permits – in presence of typical reflux symptoms – to diagnose functional heartburn (FH) based on the lack of abnormal acidic or non-acidic refluxate (i.e. normal number of reflux episodes and negative reflux-symptom association). Gastrin-17 (G17) has been proposed as a non-invasive marker of GERD, due to the negative results of impedance-pH: a) Group A: subjects with increased number of acid reflux episodes or abnormal AET, confirming the background of the negative feedback between acidic output and G17 levels. Interestingly, when impedance-pH showed a feature of non-acid reflux pattern (Group B), levels of G17 were always low, but higher than in case of acid reflux pattern (Group A) (p < 0.05). Finally, when impedance-pH did not show any kind of abnormal reflux, suggesting a diagnosis of FH, G17 levels were always normal.

**Conclusion:** In this preliminary study, G17 levels well correlated with the three different categories of patients suffering of heartburn and included in the NERD umbrella (i.e. NERD patients with increased acid reflux episodes or abnormal AET, endoscopy-negative patients with increased non-acidic reflux and subjects with FH, suggesting its use as surrogate marker of NERD or non-acid reflux disease, without the need of performing invasive tests.

### Abstract No: P0542

**ANTI REFLUX MUCOSECTOMY (ARMS) FOR REFRACORY GASTRO ESOPHAGEAL REFUX DISEASE (GERD) - ARE WE THERE YET?**

R. Shah, A. P. Maydeo, V. Dhir

Gastroenterology, Baldota Institute of Digestive Sciences, Global Hospital, Mumbai/India

Contact E-mail Address: rahulshah@hotmail.com

**Introduction:** As a treatment for gastro esophageal reflux disease (GERD), proton pump inhibitors (PPIs) are the mainstay of medical therapy. Laparoscopic fundoplication is generally advised when symptoms are poorly controlled with PPIs and is regarded as a gold standard of treatment, with excellent control in the short- and midterm. Long-term results, however, remain equivocal. Following on from the principles of surgical fundoplication, a variety of endoscopic procedures for GERD have been proposed to achieve non-surgical control. Linx procedure, Stretta have been proposed as less invasive options.

**Aims & Methods:** We recruited all patients who had GERD refractory to standard medical therapy to see whether anti reflux mucosectomy prevents acid reflux into the esophagus. We screened all GERD patients who were refractory to proton pump inhibitors, hydrogen 2 receptor blockers and alginates and had an endoscopy suggestive of a lax cardia with mucosal flap valve grading 1 to 3. We performed a baseline screening endoscopy to rule out a hiatus hernia and to exclude helicobacter infection. A GERDQ questionnaire was filled by all the patients indicative of severity of reflux All patients had a high resolution manometry (Sandhill scientific) to exclude significant dysmotility and 24 hour pH measurements using Zephyr pH probe (Sandhill scientific) on therapy to demonstrate significant acid reflux. Only patients with mucosal flap valve grading 1, 2 or 3 were selected for anti reflux mucosectomy.

**Results:** Technique: Crescentic ARMS of the esophagogastric junctional (EJG) mucosa was conducted with the standardized technique of endoscopic mucosal resection (EMR) of at least 3 cm length in the stomach, with the length of mucosal resection at the cardia measured in retroflexion from the gastric side. ARMS was conducted along the lesser curve of the stomach, thus preserving a sharp mucosal valve at gastric cardia. All the patients who underwent ARMS had a significant reduction in the DeMeester score, with predominant decrease in the mucosal valve at gastric cardia. All patients had a high resolution manometry (Sandhill scientific) to exclude significant dysmotility and 24 hour pH measurements using Zephyr pH probe (Sandhill scientific) on therapy to demonstrate significant acid reflux. Only patients with mucosal flap valve grading 1, 2 or 3 were selected for anti reflux mucosectomy.

**Conclusion:** Results suggest a potential anti-reflux effect of ARMS. The mechanism is presumed to be due to scar formation after healing of the mucosal defect. On the gastric side, this induces narrowing of the gastric cardia opening, while preserving and/or re-creating a robust his angle. After ARMS, the lesser curve of the gastric cardia takes on an almost “mechanically-stitched” appearance. The mucosal flap is rebuilt and looks well-defined. Furthermore, the lesser curve side potentially reduce the diagnostic cost and avoid unnecessary invasive MII-pH testing in future. Unlike the EBC, pepstein analysis using Pepstest did not provide any diagnostic value.

</table>
of the EGI is shortened with scar formation, and greater curve of EGI (his side) is not covered and therefore remains less flexibility as a mucosal flap valve. The quantity of mucosa to be resected to induce appropriate (“not too tight and not too loose”) scar formation is a key issue in this procedure. Total circumferential resection causes strictureing as demonstrated in previous studies, while subtotal dissection, which we have termed crescentic, produces better results in this regard, while still resulting in symptom control. Mucosal flap valve grading is not only a good predictor of reflux in these patients but also is a prognostic marker of effectiveness of ARMS, i.e. higher the grade worse the outcome: both the extent and type of mucosal resection (0 vs. ESD) according to the mucosal flap valve grading may be a better predictor of outcome than a box standard procedure. This technique has a potential role in people with oesophageal dysmotility wherein Nissen’s fundoplication is relatively contraindicated.

Introduction: Observational and epidemiologic data have suggested an association between proton pump inhibitor (PPI) use and osteoporotic fractures. To evaluate potential mechanisms for this association, we measured bone turnover, bone mineral density (BMD), true fractional calcium absorption (TFCA), and serum and urine mineral levels in healthy postmenopausal women taking PPIs or placebo for 26 weeks.

Aims & Methods: Postmenopausal women aged 45–75 were randomised to daily oral 60 mg dexlansoprazole (DEX), 40 mg esomeprazole (ESO), or PBO for 26 wks with follow-up at wk 52. Primary endpoints were 26-wk % change vs placebo in procollagen type 1 N-terminal propeptide (P1NP) and C-terminal telopeptide of type 1 collagen (CTX). Additional endpoints included changes in BMD (26 and 52 wks) and serum and urine mineral levels (26 wks). Fractures between baseline and wk 26 were recorded as adverse events. TFCO (0 and 26 wks) were measured in a subset (n = 34) of patients.

Results: Excluding 1 disqualified site, 115 women were randomised and 93 completed the study. There were no substantial differences in age, BMI, baseline serum calcium, or vitamin D levels between groups. The bone turnover markers P1NP and CTX were within normal range during 26 wks of DEX therapy. Within each group, there was no statistically significant 26-wk change in bone turnover, except a small increase in CTX levels with DEX (0.12 mg/mL; 95% CI 0.03–0.23). The 26-wk median % increase in P1NP from baseline vs PBO (difference in median % change [95% CI] = 19% [0–30%] for DEX and 18% [7%–30%] for ESO. CTX levels increased vs PBO by 27% (13%–43%) for DEX and 22% (8%–36%) for ESO. PPI effects on BMD, serum and urine mineral levels, and parathyroid hormone were not statistically different vs PBO. Median % change from baseline in TFCO vs PBO was not statistically significant for DEX, but was significant for ESO (6%; 95% CI 2%–11%). No spontaneous fractures occurred during treatment; 1 traumatic foot fracture (DEX) and 1 humerus fracture (circumstance unknown; ESO) occurred during follow-up.

Conclusion: 26 wks of DEX or ESO therapy increased bone turnover markers, but did not reduce BMD, TFCO, or serum or urine mineral levels. ESO increased TFCO by <1%. Although bone turnover markers increased with PPI therapy, levels remained within the normal ranges. No clear explanation for an association between PPI therapy and fracture risk was found in this study.

P0544 ALGINATE EFFECT ON POSTPRANDIAL REFUXES AND OF STOMACH CONTENT IN LIVE RATS AND PH-EFFECT MONITORING COMBINED WITH STOMACH PH MONITORING IN REFUX PATIENTS

I. Palij1, S. Zaika1, O. Ksenchyn2

1Internal And Family Medicine, Vinnitsya National Pirgov Memorial Medical University, Vinnitsya/Ukraine

Contact E-mail Address: dpalij@mail.ru

Introduction: Raft-forming alginate inhibit gastroesophageal reflux; however, remains unexplored effect of alginate on postprandial processes in the stomach.

Aims & Methods: 25 patients (14 F, age 23–69) with typical GERD symptoms, participated in the study. All patients underwent a 3-hour combined gastroesophageal pH-impedance monitoring with standardized breakfast (muffin and coffee). To determine the effect of alginate on postprandial reflux and pH in the esophagus and stomach, all patients underwent a repeat of similar monitoring the next day, before taking alginate after breakfast. The difference in pH in the esophagus, in two parts of the stomach and the different types of gastroesophageal reflux (acid, low acid, alkaline, liquid, gas & mixed) was estimated. To evaluate the effects of raft-forming alginate on the severity of postprandial reflux in patients with GERD and for the postprandial stomach content.

Results: Monitoring with alginate showed significantly (P < 0.05) less number of acid [average values 5.42 ± 0.69 (M ± s) vs. 3.33 ± 0.43 during 1st postprandial hour and 3.96 ± 0.8 vs. 1.82 ± 0.57 during 2nd postprandial hour] and gas [0.26 ± 0.06 vs. 0.08 ± 0.05 during 1st postprandial hour and 0.47 ± 0.35 vs. 0.52 ± 0.3 during 2nd postprandial hour] gastroesophageal reflux, but increased of number low acid reflux [3.52 ± 0.46 vs. 3.91 ± 0.82 during 1st postprandial hour and 2.16 ± 0.45 vs. 2.04 ± 0.45 during 2nd postprandial hour; P > 0.05]. Also noted is a significant (P < 0.05) increase in the pH in the esophagus for 120 minutes after ingestion [average pH values 6.04 ± 0.27 vs. 4.86 ± 0.23 during 0–60 min, and 5.93 ± 0.25 vs. 4.15 ± 0.26 during 60–120 min]. In the gastric cardia (a typical place of formation of postprandial acid pocket) showed significant (P < 0.05) higher values for the first 60 minutes after intake of alginate [pH 4.3 ± 0.37 vs. 3.04 ± 0.25], during 60–90 min, pH values wasn’t significantly (P > 0.05) different [2.75 ± 0.45 vs. 2.43 ± 0.28]. In the stomach body no significant effect of the drug on pH was recorded [average values for stomach 2.56 ± 0.46 vs. 2.1 ± 0.18 during 1st postprandial hour and 2.29 ± 0.49 vs. 2.09 ± 0.18 during 2nd postprandial hour; P > 0.05].

Conclusion: Our findings demonstrate that raft-forming alginate is an effective and safe agent to reduce postprandial acid and gas reflux and to reduce the injurious effect of acid in the esophagus. At the same time alginate showed no effect on stomach content in the postprandial period, it means that the main mechanism of action is through the movement of postprandial acid content from the lower esophageal sphincter, but not the neutralization of stomach acid, unlike non-failling acidants and PPIs.

2Korea University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: choim@catholic.ac.kr

Introduction: S-isomer (S) pantoprazole is more bioavailable and less dependent on pH, so it is less likely to show acid-regurgitation effect than the racemic S- and P-isomers. The present study was designed as a multicenter, randomized, double-blind, placebo controlled trial. NERD was defined as reflux symptoms and normal endoscopy findings.

Patients: Eighty-eight patients (46 male, 42 female) were randomised to the pantoprazole group (25 males, 43.7 years old and 86 to the placebo group (32 males, 43 years old), and 163 patients were subjected to a per protocol analysis. A higher proportion of patients in the S-pantoprazole group had complete symptom relief (34% vs. 14%, P < 0.001). Both groups, symptoms of heartburn, acid regurgitation and epigastric discomfort significantly improved after treatment compared with baseline; however, improvement of all symptoms was greater in the s-pantoprazole group compared to placebo group. Therapeutic gains in controls of heartburn, acid regurgitation and epigastric discomfort were 66.0%.

The factors associated with poor symptom responsiveness to PPI were older age, female sex, greater body mass index and symptom severity in both groups.

Conclusion: S-pantoprazole (10mg) was more efficacious than placebo in providing reflux symptom relief in patients with NERD, especially acid regurgitation.

Disclosure of Interest: All authors have declared no conflicts of interest.
Disclosure of Interest: despite PPI therapy.

Conclusion: Data demonstrate a reversal of inflammatory changes in the TJ-proteins by STW5 and O. They also suggest that inflammatory changes in TJ are consistent with TJ-protein modulations in tumorgenesis. Subsequent studies are needed to better define the role of TJ in inflammatory process and in tumorgenesis and the potential benefit arising from a treatment with STW5 or O.

Introduction: Metaplastic phenomena in the upper gastrointestinal tract are still controversial. The gastroesophageal junction is a high prevalence area for metaplasia which cover only the most proximal part of the anatomic gastric cardia. Recent evidence from human and mouse studies has shown Barrett's dysplasia (BD) and its origins from the lesion itself.

Conclusion: Genetic cardia gland epithelial cells in both human and mouse exhibit HOXA13 expression. This study aimed to identify biomarkers of active HPV infection in Barrett's metaplasia in the gut. These findings suggest that gastric cardia glands have a broad differential potential. This is consistent with an origin of Barrett's metaplasia in the gut. These findings suggest that gastric cardia glands have a broad differential potential.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: Out of 218 patients, 56 were HPV DNA positive (HPV16 (n = 42), 18 (n = 13), 6 (n = 1)). Viral load was low. Transcriptically active HPV (DNA+ RNA+) was only found in the dysplastic and adenocarcinoma group (n = 21). The majority of HPV DNA+RNA+ BD/OAC were characterized by transcriptionally active high-risk HPV (hr-HPV) is strongly incriminated in Barrett’s dysplasia (BD) and oesophageal adenocarcinoma (OAC) using mainly fresh frozen tissue. This study aimed to identify biomarkers of active HPV infection in Barrett’s metaplasia (BM)/BD/OAC by immunohistochemical staining (IHC) of formalin-fixed paraffin embedded (FFPE) tissue for aberrations of p53 and the retinoblastoma (pRb) pathway which are targets for the viral oncoproteins, E6/E7 respectively.

Aims & Methods: We aimed to determine HOXA13 expression in physiological gastric cardia glands. Firstly, strips of tissue from surgical specimen containing squamous esophageal epithelium, gastric cardia glands, and oxyntic stomach glands, were collected. These were continuous strips, from proximal to distal, to preserve morphological information. Material from three patients was selected, they suffered from either a neuroendocrine tumor, or decompensated achalasia, or an adenocarcinoma. Antibodies against HOXA13 were found not to be specific. Therefore, RNA in situ hybridization by RNA-scope was performed to visualize HOXA13 RNA. Secondly, a HOXA13GFP x C57BL/6J heterozygous mutant mouse model was used. In these animals, the cardiac glands expressed HOXA13 assessed directly for GFP expression using a fluorescence confocal microscope.

Results: All three patients showed HOXA13 expression of a portion of gastric cardia epithelial cells. The squamous epithelium, the oxyntic epithelium, and the cardia glands did not show any signal. The signal is located relatively close to the base of the crypts of the cardiac glands. The HOXA13GFP x C57BL/6J heterozygous mice showed GFP expression localized to the nucleus of some of the epithelial cells of the cardiac gland. No nuclear signal was detected in the squamous or the cardia glands. The colonic epithelium of the mouse showed nuclear GFP signal. Rectal squamous epithelium was negative as well as ileal epithelium, in accordance with HOXA13 colinearity in mouse and human. A littermate negative for HoXa13 was used as a control for HOXA13 expression.

Conclusion: Genetic cardia gland epithelial cells in both human and mouse exhibit HOXA13 expression. All other physiological upper gastrointestinal tract tissues are HOXA13 negative in line with HOX gene colinearity in the gut. This dichotomy proves positional information in these glands is discordant with their actual location. These findings suggest that gastric cardia glands have a broad differential potential. This is consistent with an origin of Barrett’s metaplasia in the gut. These findings suggest that gastric cardia glands have a broad differential potential.

Aims & Methods: None of the patients enrolled in this study received chemoradiotherapy prior to surgery and all patients had pathologically confirmed BE. All patients were evaluated for tumor size and non-malignant peritumoral samples of 39 patients were examined. Immunohistochemical analysis was conducted to investigate interlineages during the progression from BE to EAC. Interlineages were investigated in fresh resected esophageal cancer specimens and in its non-malignant peritumoral tissue (n=11). During routine endoscopy samples from healthy volunteers were obtained and analysed by flow cytometry as controls (n=5).

Results: During progression from BE to EAC an increase of CD4+ cells was observed. The number of IL-22+ cells and IL-17A+ cells as well as the number of FOXP3+ cells/mg tissue increased in oesophageal cancer and in its peritumoral tissues as compared to healthy controls. The relative amounts of IL-22+ and IL-17A+ cells decreased while an increase of FOXP3+ cells was observed. Also more IL-10+ cells/mg tissue were observed in the tumours. In accordance to the latter finding high IL-10 mRNA expression levels were associated with poor survival in EAC patients. Interestingly, high IL-10 mRNA expression levels of IL-10 in the non-malignant peritumoral tissue also correlated with poor survival.

Conclusion: During progression from BE to EAC the infiltration of CD4+ immune cells increases. While the relative amount of pro-inflammatory cells is decreasing, the pro-tumorigenic cell population, represented by high IL-10 mRNA expression in EACs, demonstrates to suggest that especially regulatory T cells influence overall patient survival in EAC. Notably, high levels of IL-10 in the non-malignant peritumoral tissue also demonstrated to be unfavourable for patient survival. Thus, a pro-tumorigenic cell population might contribute to local recurrences despite radical endoscopic or surgical resection.

P0554 DIFFERENT GLAND PHENOTYPES ARE CLONALLY RELATED IN BARRETT’S ESOPHAGUS AND GLAND PHENOTYPIC DIVERSITY IS INCREASED IN PATIENTS WHO HAVE PROGRESSED TO DYSPLASIA

J. Evans1, E. Carlotti1, M. Rodriguez-Justo2, S. L. Preston1, N. Wright1, T. Graham1, M. Jansen4, S. A. McDonald1

Aims & Methods: Biopsies from patients with a new diagnosis or surveillance for BE were obtained at endoscopy and frozen. Immunohistochemistry was performed on frozen sections for proteins including MUC5AC, MUC2, MUC6 and p21. CD4+ and CD8+ T cells were detected in BE and CD8+ T cells were detected in the adenocarcinoma. A high proportion of CD4+ T cells were detected in BE and dysplasia, but not in the adenocarcinoma. A high proportion of CD8+ T cells were detected in the adenocarcinoma, but not in BE.

Conclusion: Our preliminary in vitro findings suggest there are differences in the epithelial and non-epithelial components of BE in the stroma. This is the first time that different gland phenotypes have been demonstrated to be clonal and suggests that Barrett’s displays phenotype as well
as genotypic evolution. Patients with dysplasia also show a significant increase in gland phenotype diversity (Shannon) per biopsy in adjacent to dysplasia glands compared with patients who do not have dysplasia.

Conclusion: BE is phenotypically diverse with a range of glandular phenotypes that are clonally related. An increase in phenotypic diversity may be a potential biomarker for progression which patients with BE are more likely to progress from BE to cancer with implications for diagnostic and surveillance policy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0556 ADHERENCE TO QUALITY INDICATORS AND SURVEILLANCE GUIDELINES IN THE MANAGEMENT OF BARRETT’S OESOPHAGUS: A RETROSPECTIVE ANALYSIS

D. Westerveld¹, V. Khullar², M. B. Rivera³, Y. Perbanti¹, M. Agarwal¹, J. J. Ford¹, J. Chakraborty¹, T. S. Brar¹, F. Ayoub¹, A. Gupta¹, C. E. Forsmark², P. V. Dragomir³, D. Yang²

Introduction: Adherence to quality indicators and surveillance guidelines in the management of Barrett’s oesophagus (BO) promotes high-quality cost-effective care.

Aims & Methods: The aims of this study were to evaluate (1) adherence to standardized classification (Prague Criteria) and a systematic four-quadrant biopsy protocol, (2) identify predictors of practice patterns, and (3) to assess adherence to surveillance guidelines for non-dysplastic BE (NDBE).

This was a Single-center retrospective study of endoscopies (EGDs) performed for BE between June 2008 to December 2015. Data on patient demographics, procedure characteristics and histology results were obtained from a prospectively collected electronic endoscopy database and chart review. Adherence to the use of Prague Criteria and systematic biopsy protocol were assessed based on operative report documentation. Guideline adherence surveillance EGD was defined as those performed within 6 months of the recommended 3–5 year interval. Uni- and multi- variate analysis were performed to identify predictors of practice patterns.

Results: A total of 397 patients (66.5% male; mean age 60.1 ± 12.5 years) had an index EGD during the study period. Adherence to the use Prague Criteria and systematic biopsies were 27.4% and 24.1%, respectively. Endoscopists who perform systematic interventions for BE were more likely to use the Prague Criteria (OR: 3.16; 95%C.I: 1.47–6.82) than those who do not. Longer time in practice (in years) was positively associated with adherence to Prague Criteria (OR 1.07; 95% CI: 1.02–1.12; p < 0.01) but with a lower likelihood of performing systematic biopsies (OR: 0.85; 95% C.I: 0.59–0.97; p = 0.01). Nearly 41% of patients with NDBE (11/27) underwent surveillance EGD sooner (range 1–24 months) than the recommended interval.

Conclusion: Adherence to quality indicators and surveillance guidelines in BE is low. Older age characteristics, including experience with endoscopic therapy for BE and time in practice predicted adherence to the use of Prague Criteria and systematic biopsies. Future efforts are needed to reduce variability in practice and promote high-value care.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0557 EXPRESSION OF TGF-B AND CD-44 IN AGE SPECIFIC SUBGROUP OF PATIENTS WITH ADENOCARCINOMA OF GASTRIC CARDIA

N. Lukavetsky, T. Fetyshy

Oncoology Department, Lviv Medical University, Lviv/Ukraine

Contact E-mail Address: lukavetsky@ukr.net

Introduction: Adenocarcinoma near the esophagogastric junction is one of the most lethal GI malignancies known. Surgical treatment of these cancers stays determinative factors of patient survival. Older persons often differ from the younger adult population in terms of biological and functional perspectives; as such, they may have particular needs which require an interdisciplinary approach and intervention, especially when faced with a cancer diagnosis. Additionally we analyzed control group of patients with non-cancer lesion or normal tissue of upper digestive tract (13 patients). We divided the patients into two groups. Group A consisted of 13 cancer patients and 7 control patients 65 years of age or older, while Group B consisted of 10 cancer and 6 control patients younger than 65 years of age. The two groups were comparable - there were no differences between the two groups regarding tumor stage.

Results: Elderly patients have statistically significant better survival (median 20.2 months) compared with younger patients (median 15.4 months) (p = 0.0045). The median survival rate of patients without TGF-B and/or CD-44 expression was significantly lower (7 m) than that of patients with positive expression (> 15 m) (p = 0.003). Regardless of patients age, CD-44 was significantly higher in the cancer tissue of elderly patients than in younger (p < 0.05). But no significant difference was observed in the TGF-B expression between group A and group B cancers tissue (p = 0.005).

Conclusion: The biology of tumors may be different in elderly patients, leading to a lower rate of tumor-related mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Barrett’s oesophagus (BO) is considered a premalignant condition for oesophageal adenocarcinoma (OAC). Once diagnosed, interval endoscopic surveillance is recommended to promote early detection of dysplasia and cancer. Occurrence and incidence of dysplasia and cancer among BO vary across populations. Recent studies show BO patients mortality is mainly related to non-oesophageal cancer and cardiovascular morbidity.

**Aims & Methods:** In this cross-sectional study, our aims were to describe the local BO clinical, endoscopic and histologic profile in our tertiary referral centre, and to compare the original histology from the endoscopic surveillance biopsy to the histology obtained from the EMR, to analyse any deviation and to demonstrate the importance of histological staging of the early neoplasia in BO. We also investigated the three-year survival in patients who had their EMR longer than 3 years ago, along with causes of death. We have conducted a retrospective analysis using our electronic database for endoscopic procedures for patients with BO, who underwent EMR from October 2010 to December 2016. We analysed the resection margins for both en bloc and piecemeal EMRs. We compared the original histology from the endoscopic surveillance biopsy to the histology obtained from the EMR, to analyse any deviation and to demonstrate the importance of histological staging of the early neoplasia in BO. We also investigated the three-year survival in patients who had their EMR longer than 3 years ago, along with causes of death.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Squamous cell carcinoma in the esophagus confined to the muscularis mucosae (MM) or submucosa up to 200 μm (SM1) has a risk of lymph node metastasis, it is defined as relative indication for endoscopic submu-

Results: 54 lesions in the ESD group and 51 lesions in the surgery group met the pathological criteria of relative indication for endoscopic resection. 10 patients underwent additional chemoradiation and were included in both groups. 8 patients underwent additional chemotherapy and 1 patient underwent additional chemoradiation in the surgery group. Lymphovascular invasion, submucosal invasion, and ASAP was significantly associated with mortality using Cox analysis. Adjusted for risk factor, and perioperative complication rate.

Conclusion: ESD does not compromise the long-term outcome compared to surgery. Further large number randomized controlled trials are necessary to confirm these results.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
treated by endoscopic resection were prospectively recruited from 16 hospitals throughout Japan. This cohort study was approved by the institutional review board at each hospital, and we obtained written informed consent from all patients. Using Lugol chromoendoscopy, we evaluated the dyslastic squamous epithelium in the esophagus. Lugol voiding lesion (LVL) was graded into 3 categories (A = no lesion; B = 1 to 9 lesions; C > 10 lesions per endoscopic view). Endoscopic images obtained from eligible patients at study entry were centrally reviewed in a blinded fashion by three endoscopists to determine the grade of LVL. ALDH2 status was determined by questionnaire facial flushing after alcohol drinking (present and past flushing inactive ALDH2, never flushing = active ALDH2). Lifestyle surveys were conducted using a self-assessment questionnaire. Data collected between July 2000 and Dec 2001 from a different cross-sectional cohort (n = 1042; M = 610/432) were used as an historical control.

Results: Between Sep 2005 and May 2010, 330 patients (M = 278/52) were registered. The proportions of the different grades of LVL were A = 50 (15.2%), B = 174 (52.7%), and C = 106 (32.1%). After adjusting for sex and age, controls and the LVL grade was associated with progressively higher proportions of heavy drinkers (8.4%, 24.8%, 26.2%, and 52.5%, respectively, p < 0.0001), frequently strong alcoholic beverages (2.3%, 7.2%, 11.8%, and 11.6%, respectively, p < 0.0001), heavy smokers (34.6%, 38.7%, 65.7%, and 70.8%, respectively, p < 0.0001), liking high-temperature food (46.6%, 19.6%, 20.8%, and 20.7%, respectively, p < 0.0001), not eating green-yellow vegetables almost every day (55.0%, 48.9%, 54.9%, and 71.1%, respectively, p < 0.0001), and not eating fruit almost every day (51.6%, 74.3%, 68.0%, and 75.3%, respectively, p < 0.0001). The risk of LVL grade B and C was strongly associated with the amount of alcohol consumption especially in inactive ALDH2. Odds ratio (OR) of LVL grade B associated with heavy drinking was significantly stronger in inactive ALDH2 (OR = 13.9; 95% CI 1.5-13.9) than non-temporaneous SCC in the controls (OR = 2.0; 95% CI 1.0-4.0). OR of LVL grade C associated with heavy drinking was significantly stronger in inactive ALDH2 (OR = 358) than active ALDH2 (OR = 138) (p < 0.05).

Conclusion: The development of dyslastic squamous epithelium in the esophagus was associated with the amount of alcohol consumption and genetic trait of inactive ALDH2.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0564 EVALUATION OF THE RISK OF METACHRONOUS SQUAMOUS CELL CARCINOMA OF THE OESOPHAGUS AND THE HEAD AND NECK AFTER ENDOSCOPIC RESECTION FOR SQUAMOUS CELL CARCINOMA OF THE ESOPHAGUS BASED ON THE GENETIC POLYMORPHISMS OF ADH1B AND ALDH2
Department Of Gastroenterology And Hepatology, Hokkaido University Graduate School of Medicine, sapporo/Japan
Contact E-mail Address: abiko1982@gmail.com

Introduction: Metachronous squamous cell carcinoma (SCC) of the oesophagus and the head and neck often occur in patients who previously underwent endoscopic resection (ER) for SCC of the oesophagus. This has become a problem regarding the curability of ER. Katada et al reported that alcohol abstinence significantly decreased the risk of developing a secondary SCC of the oesophagus, based on a prospective study of 330 patients from 16 hospitals1. However, there are few studies that have investigated the risk of developing a secondary SCC of the oesophagus and the head and neck based on the genetic polymorphisms of alcohol dehydrogenase-1B (ADH1B) and aldehyde dehydrogenase gene2 (ALDH2) which are closely associated with developing oesophageal SCC. No studies have evaluated the risk of developing a third (or more) SCC after ER for SCC of the oesophagus.

Aims & Methods: The study group included patients who underwent ER for SCC of the oesophagus at Hokkaido University Hospital. All patients were followed up by using endoscopic examination for ≥ 2 years. Overall, 126 patients were included in the study. The drinking and smoking histories before and after ER were carefully documented. To examine two single nucleotide polymorphisms (SNPs) on ADH1B and ALDH2 genotyping, we obtained approximately 1 ml of blood from the patients before the endoscopy. The subjects were classified as regular drinkers who consumed ≥ 1 units/week, current drinkers who consumed 1 to 8.9 units/week (light drinkers), 9 to 17.9 units/week (moderate drinkers), or ≥ 18 units/week (heavy drinkers); alcohol consumption (1 unit = 22 g, the ethanol content of one serving of sake). The physicians recommended all subjects to temperate in drinking and smoking. We retrospectively evaluated the risk of metachronous SCC of the oesophagus and the head and neck after ER for SCC of the oesophagus, based on the genetic polymorphisms for ADH1B and ALDH2 and the drinking and smoking histories.

Results: During a median follow-up period of 80 months (range, 24-228 months), a secondary SCC of the oesophagus and the head and neck was detected in 46 patients (36.5%). The high incidence groups had inactive heterozygous ALDH2 (rs671 GA, 36.3%; p < 0.05), moderate and heavy drinkers (42.9%; p < 0.01), continuous moderate and heavy drinkers after ER (21.5/35; p < 0.01). Multivariate analysis revealed that the inactive heterozygous ALDH2 (OR = 2.24; p < 0.05), moderate and heavy drinkers (OR = 3.4; p < 0.05) and continuous heavy drinkers after ER (OR = 2.7; p < 0.05) were independently associated with the risk of developing a secondary SCC after ER. A third SCC was detected in 19 patients (15.1%), and the high incidence groups had inactive heterozygous ALDH2 (17/83; p < 0.05), moderate and heavy drinkers (19/93; p < 0.05). A fourth SCC was detected in seven patients (5.6%), who were all cases of continuous moderate and heavy drinkers after ER. Six of the seven patients had an inactive heterozygous ALDH2. We analyzed the 63 patients with inactive heterozygous ALDH2 and moderate and heavy drinkers before ER based on their temperature history and found 38 patients in the temperature group (≤ light drinkers after ER) and 25 patients in the non-temperance group. The 5-year cumulative incidence rate of a secondary SCC was detected in the temperature group (20.5%) vs. non-temperature group (35.2%) (p < 0.05). The 5-year cumulative incidence rate of a third SCC revealed an incidence of 0% vs. 28.3% respectively (p < 0.01). The 7-year cumulative incidence rate of a fourth SCC revealed an incidence of 0% vs. 16.9% respectively (p < 0.05).

Conclusion: Among the patients who underwent ER for oesophageal SCC, an inactive heterozygous ALDH2 with a continue drinking habit were the significant risk factors of developing metachronous multiple SCC. These are the greater risk factors for developing a third (or more) SCC. Patients with inactive ALDH2 and a drinking habit should receive strict instruction for temperance.

Introduction: According to the Japanese guidelines for the treatment of esophageal cancer, T1a-EP or T1a-LPM squamous cell carcinoma (SCC) is definitive indication for endoscopic resection (ER) which is considered curable in them. T1a-MM or T1b-SM1 is a relative indication of ER, because 10-20% of the cases has metastasis in the previous analysis of operation cases. Recent advances in ER such as endoscopic submucosal dissection (ESD) and steroid injection for the prevention of stricture, provide us increasing opportunity to treat clinical MM/MM1 which means preoperative predicted invasion depth of MM/MM1. Recently we start to treat them because MM without lymphovascular invasion were reported to have very low risk of metastasis and occupy majority part of MM/MM1. There is no report about long term outcome of ER for clinical MM/MM1.

Aims & Methods: This study aimed to evaluate the clinical outcomes in patients having esophageal SCC with a predicted invasion depth of MM/MM1. We retrospectively reviewed 45 patients having esophageal SCC with a predicted invasion depth of MM/MM1. We predicted the invasion depth using conventional endoscopy, magnifying endoscopic classification of Japan esophageal society, and endoscopic ultrasonography (EUS). The patients were diagnosed and treated at our hospital from 2010 to 2013. All patients had T1a-MM/SM1 invasion in 28 patients, and SM2 invasion in 3 patients. The overall accuracy rate of diagnosing MM/MM1 invasion was 62% (28/45). Among patients with MM/MM1 invasion, 20 had no lymphovascular invasion, and
they were not recommended additional therapy. The remaining eight patients had tumors that were classified as deep invasive according to the Japan Esophageal Society (JES) guidelines. In total 33 cases were treated only by ER without additional therapy. In 24% of high risk case for metastasis were treated appropriately with additional therapy.

Conclusion: Our study suggests that ER is a valid treatment for superficial SCC with a preoperative predicted invasion depth of MM/MM/SM1. Disclosure of Interest: All authors have declared no conflicts of interest.

P0566 TRIAMCINOLONE INJECTION AND SHIELDING WITH POLYGLYCIC ACID SHEETS AND FIBRIN GLUE FOR THE PREVENTION OF POSTOPERATIVE STRICTURE AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD): A RETROSPECTIVE COMPARISON OF TWO PILOT STUDIES AND A HISTORICAL COHORT

Dept. Of Gastroenterology, University of Tokyo, Tokyo/Japan

Contact E-mail Address: sakaguchi-tky@umin.ac.jp

Introduction: Triamcinolone injection is an effective and widely used method for prevention of post-ESD deep infiltration. In our previous study, we had found that the combination of triamcinolone injection and the shielding with polyglycic acid sheets (PGA sheets) and fibrin glue is another novel and effective method for the prevention of postoperative stricture. Aims & Methods: 2 consecutive single-arm pilot studies were performed, and retrospectively compared with the results of a historical control group. After approval by the Institutional Review Board and trial registry, we enrolled patients with a diagnosis of superficial esophageal squamous cell carcinoma covering over half the circumference of the esophagus. In study group A (UMIN0031014462), performed October 2014 to 2015, immediately after the enucleated patients underwent endoscopic submucosal dissection (ESD), a total of 40 mg of triamcinolone acetonide was injected into the submucosal layer of the ESD defect, followed by adhesion of a PGA sheet to the post-ESD defect with fibrin glue. In study group B, performed July 2015 to 2016, a total of 40 mg of triamcinolone acetonide was injected into the submucosal layer of the ESD defect, followed by adhesion of a PGA sheet to the post-ESD defect with fibrin glue. As historical control group C, all patients at our institute who had undergone ESD for superficial esophageal squamous cell carcinoma covering over half the circumference of the esophagus during 2002 to June 2013 were enrolled. After exclusion of patients who did not undergo follow-up for at least 1 month, and patients who underwent salvage surgery after non-curable ESD, statistical analysis was performed on the incidence of postoperative stricture and required endoscopic balloon dilation (EBD) sessions in each of these 3 groups was performed.

Results: During the study period, 15 patients were enrolled in study A, 13 patients in study B, and 37 patients were enrolled as group C. After exclusion, 11 cases in group A (3 circumferential, 9 semi-circumferential), 11 cases in group B (11 semi-circumferential, and 30 cases in group C (3 circumferential, 27 semi-circumferential) were analyzed. Analysing postoperative stricture occurred in all circumferential cases in group A, it was successfully prevented in 1 case of circumferential ESD, 2 cases in semi-circumferential ESD. A sub-analysis comparing the semi-circumferential ESD cases was performed. There were no significant differences in tumor size (A: 34.9±8.1, B: 31.5±7.0, C: 34.8±13.8 mm) and operation times (A: 95.4±23.8, B: 108.2±31.1, C: 112.1±50.3 min) in the 3 groups. Group A demonstrated the most effective results in both the incidence of postoperative stricture (A: 11.1%, B: 6.3%, C: 55.6%), and the number of EBD sessions required (median A: 0, B: 0, C: 3).

Conclusion: The combination of triamcinolone injection and the shielding method with PGA sheets and fibrin glue is a promising method for preventing stricture after esophageal ESD. Prospective studies for confirmation of efficacy and safety are required.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0567 MULTICENTRIC ASSESSMENT OF THE ENDOSCOPIC MANAGEMENT OF SUPERFICIAL ESOPHAGEAL SQUAMOUS CELL CARCINOMA IN WESTERN POPULATION

Introduction: Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are the first line treatment for superficial esophageal squamous-cell carcinoma (SCC). Comparatively to surgery, endoscopic resection is minimally invasive and associated with a lower morbidity and mortality.

Aims & Methods: Evaluation of the endoscopic resection efficiency for superficial esophageal SCC and long-term outcome. Primary outcomes were cure rate after endoscopic resection defined as local recurrence or metastatic evolution. We conducted a retrospective multicenter study in 5 french tertiary care hospitals. All patients treated by EMR or ESD for histologically proven SCC were consecutively included. Esophageal SCC was defined as superficial after macroscopy evaluation including Lugol staining and endoscopic ultrasonography (EUS). Curative resection was defined as pT1a with free resection margins, without lympho-vascular embols.

Results: Between 1998 to 2016, 132 patients were enrolled and 148 tumors were resected (ER: 80, ESD: 68). The mean age was 63.9 [35.7–86.0] years-old and 108 (73%) patients were male. Mean tumor size was 15.0 mm in the EMR group and 35.0 mm in the ESD group (p < 0.001). The complete resection rate in the ESD group was 95.2% in ESD groups with respectively 30% (24/80) and 68.8% (p < 0.0001). The mean follow-up period was 22 months. The recurrence rate was 14.2% (9/60) in the EMR group and 2/68 in the ESD group (p = 0.001). At 12 months, recurrence-free survival rate was 84.4% and 74.6% at 24 months. Factors associated with recurrence in univariate analysis were: tumors size (p = 0.013), resection by ESD (p = 0.001), piecemeal resection (p = 0.016), and microscopic positive margins (p = 0.044). In multivariate analysis, risk factors for recurrence were: resection by EMR (OR = 7.315; IC [1.685–31.762]; p = 0.008) for additional therapy (OR = 2.635; IC [1.0–6.519]; p = 0.036). At 24 months, recurrence-free survival rate were 95.2% in ESD group, versus 59.8% in EMR group (p = 0.001). For infiltrating tumors ≥3 m3, metastasis free survival rate at 24 months was 100.0% after complementary treatment by radio-chemotherapy, and 62.2% without complementary treatment (p = 0.042).

Conclusion: Endoscopic resection of superficial esophageal SCC is safe and efficient. According to our results, ESD should be preferred to EMR because is associated with a higher cure rate and an increased recurrence free survival Rate.

Introduction: Oesophageal squamous cell carcinoma (ESCC) with invasion into muscularis mucosae (MM) or submucosa (SM1) (MM/MM1) has approximately 10% lymph node metastasis and is a relative indication for endoscopic resection (ER) as per the Japanese Esophageal Society (JES) guidelines. The consideration criteria for additional treatment of MM/MM1 ESCC are as follows: (1) lymph node invasion, (2) SM1, (3) positive vertical margins, and (4) diffuse pattern of infiltration (INF). However, the clinical validity of the JES guidelines has not been established. We evaluated the curative conditions after ER for MM/ MM1 ESCC based on long-term outcomes.

Results: We enrolled 98 consecutive MM/MM1 ESCC patients (88 males; mean age, 67 ± 9 years; e-curable group, 39 patients; non-e-curable group, 59 patients; mean follow-up period, 75 ± 44 months). There were no significant differences in the clinicopathological characteristics of the patients and lesions between the 2
groups. The proportion of patients with additional treatment after ER was signiﬁcantly lower in the e-curable group (9%, 39/397) than in the e-curable group (23%, 9/39, p < 0.05). Operation, radiotherapy, and chemoradiotherapy were administered to 3 (8%), 4 (10%), and 12 (5%) patients, respectively in the e-curable group and to 7 (12%), 22 (37%), and 10 (17%) patients, respectively in the non-e-curable group. The 5-year overall survival rates in the e-curable and non-e-curable groups were 97% and 75% (p < 0.05), respectively. The overall survival rate was significantly higher in the e-curable group. Three deaths (10%) occurred due to primary cancer. The other reasons were as follows: other organ cancer (35 cases), heart failure, 4 cases; pneumonia, 3 cases; and others, 11 cases. The 5-year disease-speciﬁc survival rates in the e-curable and non-e-curable groups were 100% and 98%, respectively. The lymph node recurrence rates in the e-curable and non-e-curable groups were 3% (1/39) and 7% (4/45), respectively. The local recurrence rates in the e-curable and non-e-curable groups were 0% (0/39) and 7% (4/45), respectively. The 5-year recurrence-free survival rates in the e-curable and non-e-curable groups were 100% and 98%, respectively. The 5-year recurrence-free survival rates in the group with INFa and no lymphovascular invasion and in the group with INFb, INFc, or lymphovascular invasion were 100% and 87%, respectively. The recurrence-free survival rate was signiﬁcantly higher in the group with INFa and no lymphovascular invasion than in the group with INFb, INFc or lymphovascular invasion.

Conclusion: Our study supports the clinical validity of the e-curable conditions after ER for MM/SM1 ESCC of the JES guidelines. However, MM/SM1 ESCC with INFa and no lymphovascular invasion may have more possible curative conditions after ER without additional treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Our prospective randomized study showed that patients treated by ESD had significantly lower complication rate and better perioperative outcomes when compared laparoscopic gastrectomy. ESD should be the first line treatment for intramucosal early gastric cancers.

(continued)
or those in which the biopsies were still taken from the different anatomical areas were not included.

Results: Only 148 patients were admitted to the study. The mean age was 49.7±
3 years, 60% were female (CE: 52-67, 95%). 264 via were sent with biopsies of the different areas of the stomach distributed as follows: 148 of antrum, 54 of atrophic gastritis, and 48 (32.4%) patients had biopsy of antrum, angle and body. From 148 patients, 116 (78.4%) had an endoscopic diagnosis of normal gastritis or mucosa and 32 (21.6%) had endoscopic diagnosis of PCLS. From 116 patients with endoscopic diagnosis of gastritis or normal mucosa, LCPM was identified in 46 patients (39.6%) (p < 0.001) and 1 of them were low-grade dysplasia. From 32 of patients with suspected endoscopic PCLS, the diagnosis was confirmed with histology in 26 patients (81.2%). A total of 72 patients had PCLS vs. 32 who were initially suspected (p < 0.01), with a total positive rate of 38.6%.

Conclusion: Pre-malignant conditions and lesions of the stomach (PCLS) can show as normal mucosa or gastritis during endoscopic procedure. 39.9% of patients who underwent endoscopic procedure with presumptive gastritis had PCLS. PCLS may be under-diagnosed if random biopsies are not taken. Therefore, taking biopsies from areas without suspected PCLS causes a change in the clinical management of patients, both for the initial diagnosis and for the staging according to OLGA and OLGUM systems.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Prognosis of GC has a noticeable relation with its clinical stage. Atrophic gastritis (AG), intestinal metaplasia (IM) and dysplasia are well-recognized risk factors for intestinal type GC (GC). A large cohort study has confirmed that the annual incidence of GC were approximately 0.1% for patients with AG, 0.25% for IM and 6% for high-grade dysplasia, which were much higher than those with normal mucosal. In addition, long-term follow-up studies have recognized risk factors for intestinal type GC (GC). A large cohort study demonstrated that the annual incidence of GC were approximately 0.1% for patients with AG, 0.25% for IM and 6% for high-grade dysplasia, which were much higher than those with normal mucosal. In addition, long-term follow-up studies have recognized risk factors for intestinal type GC (GC). Aims & Methods: We aimed to discuss the correlation between the combination of Helicobacter pylori antibody and pepipsonog and OLGA/OLGUM staging system in gastric precancerous lesions risk assessment. A total of 331 patients were enrolled after the examination of endoscopy at Endoscopy Center, the First Affiliated Hospital of Jiaxing Chinese Medical University from October 2014 to December 2015. According to the result of gastroscopy, gastric secretory and serum Helicobacter pylori antibody test, all patients were divided into four groups: Group A: Hp (+)PG (+), Group B: Hp (+)PG (-), Group C: Hp (-)PG (+), and Group D: Hp (-)PG (-). Positive definition was defined as PG1≥70 μL/g and PGR7.0. According to the range and degree of atrophy/intestinal metaplasia, patients were divided into five groups on the basis of OLGA staging system. The levels of Hp infection rate, PGI, PGI II and PGR were compared between different groups, and the correlation between ABC method and OLGA/OLGUM staging system were evaluated. Statistical analysis was accomplished by chi-square test and logistic regression modeling analysis.

Results: A total of 331 patients were enrolled. 214 patients were classified into group A, 106 patients into group B, 4 patients into group C and 7 patients into group D, respectively. According to the pathological results, 177 cases were non-advanced precancerous atrophic gastritis. 177 patients were divided into stage-0 group, 82 patients into stage-I group, 49 patients into stage-II group, 16 patients into stage-III group and 7 patients into stage-IV groups. The Hp infection rate was significant higher in patients with high-grade dysplasia, which was associated with a larger lesion size and the presence of high-grade dysplasia or adenocarcinoma. usual use of antiplatelet or anticoagulant did not increase the risk of bleeding after pre operative management. A prophylactic hemostasis was realized for 61.9% of the procedure, by clips alone or associated in 72.3% of the cases. Prophylactic clipping reduced significantly the risk of delayed bleeding. Perforation occurred in 3.7% of case. Median follow-up was of 31.2 months with a complete endoscopic resection rate of 96.2% which was associated in multivariate analysis with the lesion size and depressed expression. The en-bloc resection’s rate was of 44%. Vertical margins were negative in 91.8% of the cases. Negative lateral and vertical margins was associated in multivariate analysis with the lesion size and its en-bloc resection. Intraprocedural bleeding occurred in 5.9% of the case and was associated in multivariate analysis. Delayed bleeding occurred in 13.4% of the cases and was associated with a larger lesion size and the presence of high-grade dysplasia or adenocarcinoma. usual use of antiplatelet or anticoagulant did not increase the risk of bleeding after pre operative management. A prophylactic hemostasis was realized for 61.9% of the procedure, by clips alone or associated in 72.3% of the cases. Prophylactic clipping reduced significantly the risk of delayed bleeding. Perforation occurred in 3.7% of case. Median follow-up was of 31.2 months with at least one follow-up endoscopy (78.3%). Final success of endoscopic treatment occurred in 83.8% of the case. 30 patients had a recurrence (28.6%). 13 among them were successfully retreated with endoscopy, 12 still receiving endoscopic treatment with major complications (perforation 1–5% and delayed bleeding 10–15%). The aim of this study was to evaluate the safety and efficacy of the endoscopic treatment for non amplifiable sporadic adenomas (SDA) in two tertiary centers in a large series and to try to determine the predictive factors of outcomes with a long follow-up.

Aims & Methods: This retrospective study was conducted in two tertiary centers between 12/2003 to 03/2016. All the patients who underwent at least one endo-scopic treatment by EMR for SDA histologically proven were included. Patients with PAF and ampullary adenoma were excluded. All the following outcomes were systematically recorded in both centers: complete endoscopic resection, resection with negative lateral and vertical margins, recurrence, success of the congecurrent treatment and adverse events (Perforation, intra-procedural bleeding, delayed bleeding, others). There were analysed with multivariate analysis.

Results: 134 procedures were performed. The mean patient age was 65 years (33–
85), 50.7% were women. The mean SDA size was of 20.7mm (5-50 mm), mostly level 1. The second duodenal adenomas (PAF) and morphologically high-grade dysplasia gastric mucosal. While the gold standard for atrophy assessment is histology, the combination of serum pepipsonog and Helicobacter pylori antibiotic (Hp) antibody, known as the ABC method, has been suggested as a predictive marker for patients with GC.

Introduction: Additional surgery should be recommended in patients with non-curative endoscopic resection for early gastric cancer (EGC). However, this decision has often been hesitated according to patient condition such as advanced age or comorbidities. After the recognition of recurrence, the salvage surgery has been considered difficult. However, little has been reported on it.

Aims & Methods: The aim of this study was to clarify the results of salvage surgery for recurrence after non-curative ESD for EGC using data from a multi-center retrospective study (EAST study). Of 15,785 patients who underwent ESD for EGC at 19 participating institutions from January 2000 to August 2016, we only selected patients who met the current curative criteria for ESD who were retrospectively reviewed. Among 1969 patients enrolled into EAST study, 1064 patients underwent additional surgery, and 905 patients were observed without any additional treatment. We evaluated first site of recurrence, clinical course after salvage surgery, and long-term survival on the non-treatment group. Recurrence was classified regional LNM, and distant metastasis.

Results: Over a median follow-up period of 64 months, recurrence was detected in 27 patients. Among them, 2 patients were excluded from this study due to missing data. Of the 25 patients with recurrence, 8 patients were excluded due to local only site recurrence (inter-gastric recurrence and regional LNM 7), and distant metastasis 15 (60%). The first treatments for recurrence were endoscopic treatment 1, salvage surgery 7 (28%), chemotherapy 6, and best supportive care 11. Only one patient was alive without any recurrence for 31 months after salvage surgery. And one patient died of acute myocardial infarction just one month after salvage surgery. In the remaining 5 patients, recurrence was detected at 0, 2, 3, 5, 30 months after salvage surgery, and all of them died of gastric cancer. Median survival time of all 25 patients with recurrence was 6 months after salvage surgery. And median survival time of 7 patients who underwent salvage surgery was only 7 months from salvage surgery.

Conclusion: More than half of recurrence after non-curative ESD without additional surgery was distant metastasis, and the survival rate after salvage surgery was quite low.

Introduction: Due to the increase of elderly patients who are often receiving antithrombotic therapy for cardio- and cerebrovascular diseases, postprocedure bleeding after endoscopic treatments for early gastric lesions has become one of the major concerns of therapeutic endoscopists. The Japan Gastroenterological Endoscopy Society (JGES) and other related associations published the Guidelines for Gastroenterological Endoscopy in Patients Undergoing Antithrombotic Treatment in 2012. According to the guideline it is not necessary to suspend an antplatelet agent before endoscopic treatments including endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) if the agent is not combined with other antithrombotic drugs (monotherapy). On the other hand it is recommended that anticoagulants should be substituted with heparin before EMR/ESD. The aim of this study is to clarify the efficacy of the recommendations of the guideline.

Aims & Methods: In this study 888 early gastric lesions in 783 patients who underwent EMR/ESD at our hospital between January 2012 and March 2017 were retrospectively analysed. Postprocedure bleeding was defined as: (1) hematemesis or melena for which an emergency endoscopy was required and (2) bleeding which were confirmed with a repeat endoscopy after a drop ≥2 g/dL of haemoglobin level.

Results: The total number of patients undergoing antithrombotic therapy was 78, out of which 38 patients were taking anticoagulants only, 29 were taking antiplatelet agents only, 29 were taking anticoagulants and antiplatelet agents, and 11 were taking both. The antithrombotics were suspended in 22 cases (Group A), substituted with heparin in 18 (Group B), and kept continued in 38 (Group C). Postprocedure bleeding was encountered in 31 out of 783 cases (4.0%), 21 of which occurred in patients on antithrombotic therapy (21/78: 27%) whereas 10 of which occurred in those without (10/752: 1.3%). A univariate analysis between the patients with postprocedure bleeding and those without suggesting such variables age, gender, the diameter and number of the resected lesions, use of antithrombotics, and the expertise of the operating endoscopist revealed that only the use of antithrombotics was significant risk factor for the postprocedure bleeding (odds ratio = 15.926, 95% confidence interval: 7.415–34.288, p < 0.001). However, the rate of postprocedure bleeding was not significantly different among Group A, B and C. Among the 21 bleeding patients with antithrombotics, the agent had been suspended or substituted with heparin before EMR/ESD in 10 and had been continued without suspension in 11. There was no significant difference of bleeding rate between the two groups.

Conclusion: The use of antithrombotics was a significant risk factor for the postprocedure bleeding after EMR/ESD for early gastric lesions. The rate of bleeding was not significantly different regardless if the antithrombotics were suspended, substituted with heparin, or continued without suspension.

Aim: The aim of this study is to evaluate the usefulness of OLGA and OLGIM staging according to Lauren’s histological classification of GC in considering with other risk factors of gastric cancer. From January 2006 to December 2015, 607 GC patients and 677 control subjects were enrolled who underwent upper gastrointestinal endoscopy. Biopsies were taken from the greater curvature, antrum, and body for histological analysis. H. pylori infection was assessed by modified Giemsa stain, rapid urease test and culture. The OLGA stage (0–IV) was recorded by combining antral with body atrophy of antrum in case of diffuse type in which gastric cancer develops in case of intestinal type. The OLGIM staging systems have been suggested to provide risk estimation for GC.

Methods: Atrophic gastritis and intestinal metaplasia are the cancerization field in which gastric cancer (GC) develops. The OLGA and OLGIM staging systems have been suggested to provide risk estimation for GC. In the multivariate logistic analysis, age (odds ratios (ORs), 1.932; P < 0.001 for ages in the 40–59 and >60, respectively), family history of GC (OR, 2.119; P < 0.001), and H. pylori infection (OR, 1.963; P < 0.001) were independent risk factors for GC in the diffuse type as well as intestinal type (Table). High-risk OLGA stages were significantly associated with increased risk of GC in comparison to low-risk (OR, 3.778; P < 0.001): intestinal-type (OR, 4.318; P < 0.001) and diffuse-type (OR, 2.920; P < 0.001) (Table). High-risk OLGIM stages were significantly associated with increased risk of GC in comparison to low-risk (OR, 3.051; P < 0.001): intestinal-type GC (OR, 3.981; P < 0.001).  

Conclusion: High-risk OLGA and OLGIM stages were useful for intestinal type as well as diffuse type. This usefulness will be increased when combined with H. pylori status and family history of GC in regions with high prevalence of GC. Analysis regarding specific interaction among these three factors is undergoing.

Disclosure of Interest: All authors have declared no conflicts of interest.

4Division Of Gastroenterology And Hepatology, Department Of Internal Medicine, Korea University College of Medicine, Seoul/Korea, Republic of

Introduction: Gastrintestinal cancers are one of the most common malignancy worldwide. Especially endoscopic submucosal dissection (ESD) for early gastrointestinal cancers have been considered as the current standard cancer treatment. However, lack of counter traction during ESD is one of major difficulty. To overcome this problem, we developed new endoscopic technique using robotic manipulator and conducted study about efficacy and safety in vitro animal study.

Aims & Methods: A novel robotic suture manipulator is composed of control panel and a working arm, which grasp and move objects at the end of scope. A total of 10 porcine stomachs were used for the test. Porcine stomachs were assigned randomly to 2 groups and ESD was performed on mucosa of stomach using conventional technique and new endoscopic technique with robotic manipulator. Endoscopic experts and novice endoscopists performed ESD in 2 parts (antrum & body) of stomach. During procedure, robotic manipulator lifts up dissected tissue of stomach to make better visibility. Procedure time, complete resection rate, and complications such as perforation were recorded.

Results: The average procedure time for the robotic manipulator and conventional ESD was 42 minutes and 45.9 minutes. In novice endoscopists, the average procedure time using robotic manipulator is faster than conventional ESD group (p = 0.001, odds ratio 0.53, CI 0.32-0.83). Both endoscopic experts and novice endoscopists completed the ESD procedure for in bloc resection of target lesions using KUMC robotic manipulator. There was no difference in complete resection rates between two groups. No complication such as perforation was occurred in both groups during the procedures. There was no difference depending on resected location in stomach.

Conclusion: The robotic manipulator, which can perform ESD more easily showed feasible result comparing with conventional ESD. ESD using robotic manipulator could be helpful, especially in novice endoscopists. This research proposes a novel approach for safe and feasible method during ESD.

BMI, body mass index; CI, confidence interval; GB, gallbladder; HR, hazard ratio. *Hazard ratios were calculated using Cox proportional hazards models after adjustment for age at baseline (continuous variable), smoking status (current smoker, former smoker, never-smoker, and missing smoking status), alcohol consumption (frequency; five or more times/week, one to four times/week, less than one times/week, past drinker [no alcohol for a year], never-drinker, or missing information), monthly household income (Korean won [KRW], 1 United States dollar = 1170 KRW as of August 1, 2004; <500, 500, 000, 500-990, 000, 1, 000, 000-1, 490, 000, >1, 500, 000, missing information), and physical activity (yes, no). HRs were not presented for causes with less than 10 deaths.

P0580 DEVELOPMENT OF NOVEL ENDOCUTURAL IRREVERSIBLE ELECTROPORATION ABLATION DEVICE

1Division Of Gastroenterology And Hepatology, Department Of Internal Medicine, Korea University Anam Hospital, Seoul/Korea, Republic of
2Division Of Gastroenterology And Hepatology, Department Of Internal Medicine, Korea University College of Medicine, Seoul/Korea, Republic of

Introduction: Irreversible electroporation (IRE) is a promising novel technique for the ablation of tumors. An advantage of IRE is its mechanism to remove undesired cells by affecting the cell membrane without thermally destructing blood vessels, nerves and the surrounding tissues. Several clinical trials for applying IRE to human organs such as liver, pancreas, and kidney are conducted and studies about IRE ablation for gastrointestinal tumors also have been conducted recently. Here, we developed new endoscopic IRE device, and studied about its effectiveness and feasibility in animal model.

Aims & Methods: Newly developed endoscopic IRE ablative catheter works with single channel of endoscope. A pair of dipolar electrodes consist of pre-shaped 0.63 mm nitinol wire and the distance between each electrode is 10 mm. The electrodes are loaded within braided tube for stent delivery system then deployed when IRE catheter put in stomach through the endoscope. We performed endoscopy and IRE ablation was done on pig’s stomach mucosa by using endoscopy with newly developed IRE catheter. We divided pig’s stomach into 2 parts (antrum & body), and IRE ablation was applied on each part of the stomach. Pigs were sacrificed after 24 hours, and we collected their stomachs with surgical technique. Following fixation, tissues were stained with H&E.

Results: Ten male Yorkshire pigs and in vitro stomachs were used in this study. The tissue with H&E stain showed diffuse cell death 24 hr after IRE ablation.
Consistent with the mechanism of action of IRE on the cell membrane only, there was complete cell death within the IRE lesions without intervening live cells. But there was no difference in histology depending on gastric part in which ablation was applied. During the study, no complication was observed in pigs in 24 hours after ablation.

Conclusion: The new endoscopic IRE device, which can perform IRE ablation on gastrointestinal tract using endoscopy showed safe and feasible result.

P2052 ENDOSCOPIC SMALL CAPACITY FORCEPS INCREASE THE PATHOLOGICAL DIAGNOSIS OF GASTRIC INDEFINITE NEOPLASIA

1St. Marianna University School of Medicine, Kawasaki/Japan
2Gastroenterology And Hepatology, St. Marianna Medical University, Kawasaki/Japan
3Pathology, St. Marianna Medical University, Kawasaki/Japan

Contact E-mail Address: yasumasa_matsuo@marianna-u.ac.jp

Introduction: Endoscopic forceps biopsy (EFB) is the gold standard for gastric epithelial tumor diagnosis. However, definitive diagnosis is often difficult, and some cases are diagnosed as gastric indefinite neoplasia (GIN), which corresponds to category 2 in the revised Vienna classification. GIN lesions require short periods of follow-up. The most appropriate forceps size for gastric biopsy has yet to be determined. In the Japanese Classification of Gastric Cancer, diagnoses of GIN are attributed, at least partly, to the full size of biopsy specimens. Since specimens yielded by small biopsy forceps are small, the use of small biopsy forceps is expected to increase the rate of GIN diagnoses.

Aims & Methods: The relationship between forceps size and the frequency of GIN was investigated. The patients in this cohort were divided into two historical groups. The first group comprised patients evaluated during the period when standard biopsy forceps (SlF) were used (April 2010–March 2011), and the second comprised patients evaluated during the period when small biopsy forceps (SmF) were used (April 2011–March 2013). Standard caliber endoscopy was used for all esophagogastroduodenoscopy (EGD). We count the number of GIN and gastric carcinoma lesions. Patient characteristics, lesion characteristics (e.g., site, macroscopic appearance, and color tone), endoscopist experience level, biopsy specimen type, and groups diagnosed as GIN. The clinical courses of GIN cases were followed for 3 years, and the timing of EGD after the GIN diagnosis and the final pathological result were investigated.

Results: Among the 5420 patients who underwent EGD in the first period, 2, 584 (30.7%) underwent gastric biopsy with SlF. Among the 15,988 patients who underwent EGD in the second period, 4,204 (26.3%) underwent gastric biopsy with SmF. Gastric carcinoma was diagnosed in 7.93% (205/2584) and 7.54% (317/4204) of the SlF and SmF groups, respectively (P = 0.556). GIN was diagnosed in 0.73% (19/2583) and 1.25% (52/4204) of the SlF and SmF groups, respectively. The difference was significant (P = 0.048). The two groups diagnosed as GIN did not differ significantly in terms of the patient characteristics, the lesion characteristics, endoscopist experience level, biopsy specimen type, and groups diagnosed as GIN. The mean minor-axis lengths of the biopsy samples were 1.50 ± 0.50 mm and 1.38 ± 0.40 mm in the SlF and SmF groups, respectively. The SmF group samples tended to be shorter (P = 0.088). In both groups, 40% of the final diagnoses were epithelial neoplasias; no significant differences were observed.

Conclusion: SmF use may increase the rate of GIN. Thus, SmF use should be avoided with a standard caliber endoscopy.

P2053 THE ROLE OF STRESS AND NITROSAMINES IN THE DEVELOPMENT OF GASTRIC CANCER: A NEW MODEL OF ADENOCARCINOMA FORMATION WITH METASTASES IN RATS

Introduction: Stomach cancer is a leading cause of cancer-related deaths in the world. A lot of studies are carried out to find out the role of stress in cancer initiation is contradicted and debatable. Other natural factors such as nitrates, which are widely presented in daily food, are actively discussed as carcinogenic to humans. But, there is no clinical and epide- miological evidences that the nitrosamines itself can induce the stomach cancer.

Aims & Methods: For the better understanding of carcinogenic effects of daily stress and nitrates in development of stomach cancer, here we studied the role of these factors in adenocarcinoma in stomach of rats. The experiments were carried out in male adult rats (n = 200). To examine the role of stress and nitrosamines in gastric mucosal injuries we used: 1) the model of chronic social stress (over-population during 9 months); 2) the daily using of toluidine (2g/kg) in food and water with nitrates (2g/l); 3) the combined effects of stress + nitrosamines. The
upper endoscopy was performed using our in-house custom-made multichannel endoscopy system. Histological assay performed to analyze the changes in the gastric tissues.

Results: Using upper gastroscopy, we studied the stomach tissues during 9 months of lining of rats in chronic stress. There were no changes in the gastric mucosa during the first 2 months. In the third month 35% (7/20) of animals demonstrated multiple small peptic ulcer (n = 11). These changes progressed during other time of observation. 9 months of experiment. So, this time all rats showed peptic ulcers both types with significant increase in the number of ulcers (n = 21 and large, n = 9). Thus, this series of experiments clearly showed that chronic stress plays provoking role in the peptic ulcer formation in the stomach of rats. The deleterious effects of nitrosamines on the gastric mucosa observed 4 months after the beginning of daily using of toluidine and nitrites in 75% of gastric mucosa. These rats showed symptoms of atrophic gastritis. Other 25% (5 of 20) of animals did not demonstrate any changes in gastric mucosa. Thus, this series of experiments markedly showed that effect of long-term eating low-dose nitrosamines induced of atrophic gastritis in the stomach of majority of rats. In the same protocol of the first and second parts of experiments, we observed the changes in the stomach tissues during 9 months. The same scenarios of typical gastric injuries induced by stress and nitrosamines were observed in rats, i.e. they showed development of peptic ulcers and atrophic gastritis. But, 7 months after the start of experiment, these pathological changes of gastric tissues were associated with intestinal metaplasia of goblet cells, which is the pre-cancer symptom. In 9 months of study, symptoms of gastric adenocarcinoma were observed in 82% of rats (131 of 160). Tumor lesions was accompanied by the migration of metastatic tumor cells through the bloodstream in the liver. The number of metastatic nodes varied from 1 to 5.

Conclusion: Thus, in our research we clearly show that only combination of two provoking factors such as stress and nitrosamines cause development of gastric cancer with metastasis in the liver while the presence of these factors alone contribute mucosal injuries without oncolgical changes in the stomach.

Disclosure of Interest: All authors have declared no conflicts of interest.

6. A370 methionine, isoleucine, leucine, tyrosine, phenylalanine, lysine and arginine, patients, GC patients had higher levels of threonine, serine, alanine, valine, methionine, isoleucine, leucine, tyrosine, phenylalanine, l lysine, and arginine.
together with lower levels of phosphoserine, ethanolamine phosphate and urea (Table 1). The 14 GJFAAs revealed diagnostic values with AUC from 0.666 to 0.868, and the combined AUC of them reached to 0.902 (95% CI, 0.846–0.959) for the diagnosis of GC. Importantly, their AUCs were from 0.649 to 0.857, and the combined AUC reached to 0.880 (95% CI, 0.792–0.969) for the diagnosis of early GC. Particularly, leucine, threonine and serine are the most altered three GJFAAs between the two groups, whose fold change more than 2 and AUC value greater than 0.8. Moreover, the combined AUC of the 3 non-AAAs was 0.869 (95% CI, 0.805–0.934) for the diagnosis of GC. It was slightly higher than the combined 3 AAs 0.841 (95% CI, 0.773–0.908). Additionally, the pathway of aminoacyl-tRNA biosynthesis metabolism was excessively activated, which significantly responsible for the above alterations in early GC.

Conclusion: GJ_AA profiles may be helpful for improving GC diagnosis even in the early stage and for providing more information about its metabolism. Leucine, threonine and serine, three non-AAAs, warrant further validation as alternative metabolomic biomarkers for GC.

Disclosure of Interest: All authors have declared no conflicts of interest.

POS08 THE ASSOCIATION BETWEEN MMP-2/9 AND TYPE IV COLLAGEN AND THE LEVELS OF AROMATIC AMINO ACIDS IN GASTRIC JUICE OF GAstrIC CANCER PATIENTS

J. Lin, Y. L. Zhou, R. S. Lin, Z. Jin, J. Y. Han, Y. Xue, E. X. Yan, M. L. Meng Department Of Gastroenterology, Peking University Third Hospital, Beijing/China

Contact E-Mail Address: liujian-825@163.com

Introduction: It is reported that aromatic amino acids (AAAs) in gastric juice could be used as potential diagnostic biomarkers to screen gastric cancer (GC) [1–3]. However, the underlying mechanism remain elusive [4]. Our group had conducted a series of explorations on the reasons to cause such phenomenon before. The candidate molecules: 1) L-type amino-acid transporer 1 (LAT1), which is involved in the enhancement transport of amino acids and the accumulation of AAAs near cancer foci; 2) intracellular amino-acid-metabolizing enzymes, such as indoleamine 2,3-dioxygenase (IDO) and monoamine oxidase (MAO); 3) proteins involved in intracellular protein degradation or autophaugy, (e.g., SQSTM1/p62) had been examined [5]. However, because of the difference in the expression of the above proteins in different pathological classifications of GC issues, it is impossible to explain the phenomenon that the elevation of AAAs’ levels in gastric juice in almost all types of GC patients.

Aims & Methods: To investigate the role of proteolytic enzymes matrix metallo-proteinase-2/9 (MMP-2/9) in the abnormal elevation of AAAs’ concentrations in gastric juice of GC patients, gastric mucosal specimens and gastric juice samples were simultaneously collected from 29 GC patients, while MMP-9 was mainly and gender-matched non-neoplastic gastric disease (NGD) patients. The expression levels of MMP-2/9 and type IV collagen (Col IV) in gastric mucosal tissues were examined by immunohistochemical staining while the levels of AAAs in gastric juice of GC patients were measured by liquid chromatography-tandem mass spectrometry (LC/MS/MS). Furthermore, the association between them was evaluated by Spearman correlation analysis.

Results: On the one hand, the expression intensity of MMP-2/9 in GC group were significantly higher than those in NGD group, while MMP-9 was mainly lower than that in NGD group (P < 0.001 for all). Moreover, there was a positive correlation between the expression level of MMP-2 and MMP-9 (rho = 0.439, P < 0.01), but they were both negatively correlated with Col IV (rho = –0.454, P < 0.01; rho = –0.392, P < 0.01). On the other hand, significantly higher level of AAAs in gastric juice were observed in GC patients than those in NGD individuals (P < 0.001 for all). Ultimately, the expression levels of MMP-2/9 in gastric mucosal tissues were both positively correlated with the concentrations of AAAs in gastric juice (MMP-2: rho = 0.262, P < 0.05; MMP-9: rho = 0.297, P < 0.05). Furthermore, the levels of AAAs in gastric juice were positively correlated with the expression level of MMP-2/9 and Col IV (rho = 0.475, P < 0.01; rho = 0.457, P < 0.01, respectively).

Table 1: Relationship between the expression levels of MMP-2/9 and Col IV in gastric tissues and the levels of AAAs in gastric juice

**represents significant correlation using Spearman correlation analysis when the confidence level was 0.01; ***represents significant correlation using Spearman correlation analysis when the confidence level was 0.001.

Conclusion: The overexpression of MMP-2/9 resulting in the degradation of Col IV in basement membrane and extracellular matrix may lead to the variation of AAAs’ levels in gastric juice of GC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Several studies have demonstrated serum PGII level as a marker of the functional gastric mucosa, and a marker of some tumor including the gastric cancer. However, the modulation of the protein and its role in cancer is not fully understood. The aim of this study was to analyse the polymorphisms in the TATA BOX region, which provides a binding site for the transcription factor for the PG2 gene, in association with the PG2 circulating level and clinical parameters in population at risk for GC and in GC patients.

Aims & Methods: Gastric function of 180 patients (67 GC, 71 first-degree relatives of GC patients (FDR-GC) and 42 autoimmune chronic AG (ACAG)) was assessed by gastropanel test. We investigated the PG2 TATA BOX polymorphism frequencies in relation to serum PG2 (sPG2) expression level, HP positivity and risk for GC. TATA BOX DNA fragments were amplified by PCR and analyzed by the capillary-electrophoresis (GeneMapper software). Association among clinical data and PG2 polymorphisms were estimated by Receiver operating characteristic (ROC) curve and linear regression analyses.

Results: After ROC curve analysis, the sensitivity to discriminate GC at 15 ng/mL PG2 cut-off was 70.15% and 79.65% sensibility and sensitivity, respectively.

Conclusions: Accordantly to the literature, we confirm sPG2 level as a marker of some tumor including the gastric cancer. However, the modulation of the protein and its role in cancer is not fully understood. The aim of this study was to analyse the polymorphisms in the TATA BOX region, by interfering with the transcriptional factor and then with the transcription characteristic (ROC) curve and linear regression analyses.

P0590 HELICOBACTER PYLORI INFECTION ASSOCIATED WITH NONALCOHOLIC FATTY LIVER DISEASE: A LARGE-SCALE COHORT STUDY

T. Kim, T.J. Kim, H. Lee, J.J. Kim
Department Of Medicine, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: attack863@naver.com

Introduction: Previous studies suggested a link between Helicobacter pylori (H. pylori) infection and nonalcoholic fatty liver disease (NAFLD), yet large-scale longitudinal studies are lacking to elucidate this association.

Aims & Methods: A cohort study of 17,028 adults without NAFLD at baseline, who participated in a repeated health screening examination including an H. pylori-specific immunoglobulin G antibody test, was conducted to evaluate the association between H. pylori and NAFLD development. Fatty liver was diagnosed by ultrasonography.

Results: During the 83,130 person-years follow-up, participants with H. pylori infection had a higher rate of incident NAFLD than those who were uninfected. In a multivariable model adjusted for age, sex, body mass index, smoking status, alcohol intake, regular exercise, year of screening exam, and education level, the hazard ratio (HR) for NAFLD development in participants with H. pylori-infection compared to those without infection was 1.21 (95% confidence interval [CI], 1.10–1.34). The association persisted after further adjustment for metabolic variables, inflammatory marker, and liver enzymes. The association between H. pylori and NAFLD was still evident in an analysis using fatty liver index as a surrogate marker of NAFLD. In addition, the association between H. pylori infection and incident NAFLD did not differ across clinically relevant subgroups evaluated.

Conclusion: H. pylori infection was significantly associated with the development of NAFLD, independent of metabolic and inflammatory risk factors. H. pylori infection may play a pathophysiological role in NAFLD development, indicating that H. pylori eradication might play a role in reducing risk of NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0591 HELICOBACTER PYLORI INFECTION STATUS IN HUMAN IMMUNODEFICIENCY VIRUS-POSITIVE PATIENTS

Gastroenterology&hepatology, Osaka National Hospital, Osaka/Japan

Contact E-mail Address: seiya_weckle_0728@yahoo.co.jp

Introduction: Helicobacter pylori infects the gastric mucosa and causes chronic gastritis via the immunoreaction of the host. By contrast, the human immunodeficiency virus (HIV) infects CD4-positive T lymphocytes and destroys the immune system of the host. Some studies pointed out that the H. pylori infection rate is lower in HIV-positive patients. This is because in these patients, H. pylori is incidentally eradicated by the course of antibiotic therapy for HIV infection and because the supply of nutrients to H. pylori is prevented by the decrease in the number of CD4 lymphocytes.

Aims & Methods: We enrolled 290 HIV-positive patients who underwent esophagogastroduodenoscopy in our Hospital between January 2013 and September 2016. As end points of H. pylori infection examination, we retrospectively examined the presence of gastric mucosa atrophy, H. pylori infection, H. pylori eradication and comorbidity. As end points of HIV infection examination, we quantified the number of CD4 lymphocytes and the titer of HIV and investigated the presence of acquired immunodeficiency syndrome (AIDS). Based on these data, we examined the relationship between H. pylori and HIV infections.

Results: Of the 290 patients, 281 were men and 9 were women, whose median age was 46 years (range, 22–82 years). Ninety patients had atrophic gastritis or stomach or duodenal ulcer as end points of HIV infection examination, we retrospectively examined the presence of gastric mucosa atrophy, H. pylori infection, H. pylori eradication and comorbidity. As end points of HIV infection examination, we quantified the number of CD4 lymphocytes and the titer of HIV and investigated the presence of acquired immunodeficiency syndrome (AIDS). Based on these data, we examined the relationship between H. pylori and HIV infections.

Conclusion: In our study, the number of CD4 lymphocytes was higher in the HIV-positive patients with H. pylori infection, implying that the high CD4 count was suggested to be associated with persistent H. pylori infection. In addition, the success rate of H. pylori eradication was shown to be insufficient in HIV-positive patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0592 HELICOBACTER PYLORI INFECTION REDUCES THE RISK OF BARRETT’S OESOPHAGUS AND IG UNE INDEPENDENT FROM THE GEOGRAPHICAL LOCATION, A META-ANALYSIS

B. Eross1, N. Farkas2, K. Márta3, P. Hegy1
1Centre For Translational Medicine, University of Pecs, Pecs/Hungary
2Institute Of Biostatistical, University of Pecs, Pecs/Hungary
3Institute For Translational Medicine, University of Pecs, Pecs/Hungary

Contact E-mail Address: xeroba@yahoo.hu

Introduction: European and Northern American populations a decreasing prevalence of H. pylori infection has been observed, along with an increasing prevalence of Barrett’s oesophagus and an increasing incidence and prevalence of the adenocarcinoma of the oesophagus and gastro-oesophageal junction stenosis. H. pylori infection has been proven a protective factor against Barrett’s oesophagus, but some individual studies suggested the opposite.

Aims & Methods: Our aim was to scrutinise all data available on the relationship between H pylori infection and Barrett’s oesophagus prevalence, to see, if H pylori has a protective role for Barrett’s oesophagus and if it is dependent from the geographical location. A meta-analysis was performed using the preferred reporting items for systematic review and meta-analysis protocols (PRISMA-P). We conducted a systematic search in PUBMED, EMBASE and COCHRANE databases from inception to December 2016, for the keywords of Barrett’s, Barrett’s metaplasia, Barrett’s oesophagus, Barrett’s oesophagus, Barrett’s oesophagus, Helicobacter pylori, H pylori and Helicobacter. We also used information from the references of relevant publications to find further eligible studies. We have conducted a meta-analysis of the data from all studies included. We used the random effects model from DerSimonian and Laird.

Results: We have found 568 articles in PUBMED, 741 in EMBASE and 15 in COCHRANE databases. After exclusion of the articles without sufficient data on the prevalence of H pylori and Barrett’s oesophagus, we have identified 83 articles suitable for statistical analysis. This meta-analysis involved 98 665 patients with Barrett’s oesophagus and 720 800 patients without Barrett’s oesophagus. The statistical analysis from all 83 studies from five continents and 27 countries showed a protective effect of H pylori for Barrett’s oesophagus, except in Africa, overall Odds Ratio = 0.63 (95% CI:0.55, 0.71). The OR and 95% CI values were 0.34 (0.17, 0.67) for Asia, 0.71 (0.55, 0.91) for Europe, 3.05 (0.59, 15.73) for Africa, 0.60 (0.51, 0.71) for North-America, 0.95 (0.56, 1.64) for South-America and 0.56 (0.39, 0.82) for Australia. The OR and 95% CI values were 0.84 (0.43, 1.64) for Eastern Europe; 0.68 (0.52, 0.90) for Western Europe and 0.71 (0.55, 0.91) for all of Europe, suggesting that the protective role of H pylori infection is not different across Europe.

Conclusion: This large meta-analysis has given further evidence, that Helicobacter pylori infection has a protective role for Barrett’s oesophagus and this protective role is independent from the geographical location, apart from Africa. In view of the decreasing prevalence of H pylori in developed countries and the epidemiological rise of Barrett’s oesophagus and adenocarcinoma, it would be important to conduct further large, prospective, multinational studies on the effect of H. pylori infection on Barrett’s oesophagus.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: themaskroemer@gmail.com

Introduction: Helicobacter Pylori (H. Pylori) has been implicated in worsening outcomes in patients with hepatic encephalopathy. This is believed to be the result of its urease enzyme that increases the production of ammonia. Small studies so far have yielded contradictory results on whether the presence of H. pylori worsens treatment outcomes in hepatic encephalopathy. Therefore, the aim of this study was to assess the impact of H. pylori on mortality, morbidity and resource utilization among patients with hepatic encephalopathy using a national database.

Aims & Methods: This was a case-control study using the National Inpatient Sample 2013, the largest publicly available inpatient database in the United States. All patients with an ICD-9 CM code for a principal diagnosis of hepatic encephalopathy were included. There were no exclusion criteria. Patients positive for H. pylori were identified using the appropriate ICD-9CM codes. The primary outcome was all cause mortality. The secondary outcome was resource utilization as measure by use of abdominal imaging (CT scan and ultrasound of the abdo- men), length of hospital stay (LOS), total hospitalization charges and costs.

Multivariate regression analyses were used to adjust for the following confounders: Age, sex, race, income in patients’ zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

Results: A total of 55,560 patients with hepatic encephalopathy were included in the study, of which 20 had H. pylori infection. The mean patient age was 60 years and 42% were female. After adjusting for confounders using multivariate analy- sis, patients with and without H. pylori had similar adjusted odds of mortality (adjusted Odds Ratio (aOR): 1.71, 95% CI: 0.62-4.74, p = 0.30). As far as resource utilization, patients with and without H. pylori had similar adjusted odds ratios (aOR: 0.92, 95% CI: 0.88–10.40, p = 0.003), LOS (adjusted mean difference: 1.7 days, 95% CI: –0.02-3.42, p = 0.52), and total hospitalization charges (adjusted mean difference: $16588, 95% CI: $4499 - $37675, p=0.12). However, patients with H. pylori had higher adjusted total hospitalization charges compared to patients without H. pylori (adjusted mean difference: $6128, 95% CI: $1141 - $11115, p=0.01)

Conclusion: Presence of Helicobacter Pylori has no impact on inpatient mortality among patients with liver cirrhosis and hepatic encephalopathy. In addition, the presence of Helicobacter Pylori is not associated with any increase in resource utilization among this patient population, with the exception of total hospitalization costs. It is surprising to note that, although total hospitalization costs differ between the two groups, they received the same total hospitalization charges from admitting hospitals.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Helicobacter pylori infection has become more and more resistant to conventional first-line treatment regimens. So, there is a considerable interest in evaluating new antibiotic combinations and regimens. Nitazoxanide is an anti-infective drug with demonstrated activity against protozoa and anaerobic bacteria including Helicobacter pylori.

**Aims & Methods:** This work is designed to evaluate the efficacy and safety of a unique triple Nitazoxanide containing regimen as a treatment regimen in Egyptian patients with Helicobacter pylori infection.

**Methods:** Two hundred and twenty four patients with upper Gastro-intestinal tract (GIT) dyspeptic symptoms in whom Helicobacter pylori induced GIT disease were confirmed were included in the study. They have been randomized to receive either Nitazoxanide 500mg bid, Clarithromycin 500mg bid and Omeprazole 40mg twice daily for 14 days or Metronidazole 500mg bid, Clarithromycin 500mg bid and Omeprazole 40mg twice daily for 14 days. Laboratory evaluation for Helicobacter pylori antigen within the stool was done 6 weeks after cessation of Helicobacter pylori treatment regimens to assess the response.

**Results:** The response to treatment was significantly higher in group 1 of Nitazoxanide treatment regimen than group 2 of traditional treatment regimen. Group 1 (49.4%) of 114 patients who completed the study in group 1 showed complete cure while only 63 cases (60.6%) of 104 patients who completed the study in group 2 showed the same response according to per-protocol (PP) analysis (p < 0.001). The regimen was well tolerated by all the patients enrolled in the study.

**Conclusion:** Nitazoxanide-containing triple therapy is a promising therapy for the first-line eradication of Helicobacter pylori. (ClinicalTrials.gov Identifier: NCT02422706)

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Table 1:** H. pylori eradication rates in patients with and without previous intake of macrolides.

Contact E-mail Address: julio@psescam.jccm.es

**Introduction:** There is evidence that previous use of macrolides is a useful predictor of the likelihood of standard triple therapy failure in H. pylori eradication (Lim SG, et al. Dig Liver Dis 2016). The goal of this study is to evaluate whether previous intake of various macrolide antibiotics can predict failure to eradicate H. pylori using first-line clarithromycin-containing regimens.

**Aims & Methods:** Between February 2014 and June 2016 a total of 250 patients with H. pylori infection were prospectively included in a study whose goal was to assess the eradication rates obtained with first-line clarithromycin-containing regimens in our health area. Patients were randomly assigned to one of two regimens: A: Triple therapy (PPI, amoxicillin, clarithromycin, optimized with a double dose of PPI) for 10 days; and B: Concomitant therapy (PPI, amoxicillin, clarithromycin, and metronidazole administered concurrently) for 10 days. The eradication was evaluated by the Stool antigen test or with the Urease test in those patients with a gastroscopy performed after the treatment. A total of 113 patients in the group A (58 women; Median age: 54 years; Range: 21–79) and 106 patients in the group B (56 women; Median age: 49 years; Range: 18–81) completed the study protocol. The electronic medical records of the patients, which contained information regarding all the medication prescribed to the patient during the previous 12 years, were reviewed and the intake of macrolides (clarithromycin, azithromycin and erythromycin) was registered.

**Results:** 89/219 patients (40.6%) had received at least one treatment with macrolides during the previous 12 years. H. pylori eradication rates with the two treatment regimens are shown in Table 1.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Background: Eradication of Helicobacter pylori (H. pylori) infection represents a clinical challenge. The current requirements demand eradication rates of ≥70%, which has made that the use of triple treatment including clarithromycin or metronidazole had been gave up on those countries, such as Spain, with high resistance rates. Quadruple therapy with a proton pump inhibitor (PPI) plus a single three-in-one capsule containing bismuth carbonate potassium, metronidazole, and tetracycline (BMT) have shown high eradication rates in clinical trials.
Aims & Methods: We aimed to evaluate the efficacy and safety of a PPI-bismuth based quadruple therapy in patients diagnosed of H pylori infection in a clinical setting of a Private Hospital, located at the North of Madrid (Spain). A prospective and real-life study was conducted, between March 2016 to February 2017, on consecutive patients with confirmed H pylori infection eradication indication. Patients were treated for ten days with a galenic preparation containing bismuth carbonate potassium 140mg, metronidazole 125mg, and tetracycline 125mg, three capsules four times daily, and esomeprazole 40 mg twice daily and probiotic during 30 days. The primary endpoint was H. pylori eradication rate. Ninty five percent of the area breath test performed, at least 28 days, after the end of treatment. Intent-to-treat (ITT) efficacy analyses included all patients who received study medication and took at least one dose of study medication; patients without an observed outcome were considered as treatment failures.
Results: Two hundred and forty-two patients, which excluded patients who did not complete the study or who had major protocol violations, were also included to conduct the ITT results.
Conclusion: A total of 100 patients, 60 (60.0%) women and 40 (40.0%) men, who fulfilled the respective demands of the inclusion and exclusion criteria, were enrolled consecutively. Five of these were lost to follow-up. Mean (standard deviation) [95% confidence interval] age was 47.1 (15.4) [40.0 to 52.0] years. Twenty-five (25.0%) patients had a prior history of using medications to treat H. pylori, most often clarithromycin, amoxicillin, and PPI. In the ITT population, the eradication rates were the 90.7 % (68/75) and the 80.0% (20/25) depending on whether the PPI-BMT treatment was administered as first-line or as rescue therapy, respectively. In the PP population, the eradication rates were the 98.6% (66/67) and 95.2% (20/21) in those patients treated with PPI-BMT as first-line or as rescue therapy, respectively. Eighteen (18.0%) patients reported at least one adverse event.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0599 COST EFFECTIVENESS OF HELICOBACTER PYLORI POPULATION SCREENING: ECONOMIC EVALUATION ALONGSIDE A RANDOMIZED CONTROLLED TRIAL WITH 13-YEARS FOLLOW-UP (THE HEF-PFY STUDY)
M. Bonme1, J. Hallas2, O.B. Schaffalitzky De Muckadell1
1A REAL-LIFE STUDY
H. pylori (Hp) infections are asymptomatic but 15% of those infected with Hp will eventually experience dyspepsia symptoms or ulcer.
Aims & Methods: We aimed to evaluate the cost effectiveness of population screening and eradication for Helicobacter pylori (Hp). This was a cost effectiveness analysis and cost utility analysis alongside randomized controlled trial with 13-years follow-up, with a random sample of the general population from the county of Funen, Denmark. 20,011 individuals aged 40–65 were randomized and invited in 1998–99; 12,530 were enrolled and of these 8658 individuals have been successfully followed up at 1, 5, and 13 years after intervention. Questionnaires included Gastrointestinal Symptom Rating Scale and the quality of life instrument SF-36. From SF-36 responses an SF-6D score was derived and used for calculation of quality adjusted life years (QALY). EQ-5D-5L was incorporated in the analysis. From SF-36 responses an SF-6D score was derived and used for calculation of quality adjusted life years (QALY) and Life-years gained. The evaluation has a National Health Sector perspective.
Results: There was no significant difference in index scores and in mean QALY between groups. Hp population screening and eradication with 13-years follow-up was not effective in regards to quality of life and the cost of screening was higher than not screening (14,372 DKK; 95% CI: 4,155−24,499). The probability of being cost-effective was 80% with a willingness to pay of 400,000 DKK per life-year gained. When including only peptic ulcer disease related costs the probability was 85% a willingness to pay of 100,000 DKK per life-year gained.
Conclusion: Hp population screening and eradication with 13-years follow-up was not effective in regards to quality of life and the cost of screening was higher than not screening.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0600 A SEVEN-DAY TRIPLE THERAPY CONTAINING A POTASSIUM-COMPETITIVE ACID BLOCKER COMPARED WITH PROTON PUMP INHIBITORS, AMOXICILLIN AND CLARITHROMYCIN FOR FIRST-LINE HELICOBACTER PYLORI ERADICATION IN JAPAN: A SINGLE-CLINIC RETROSPECTIVE STUDY
S. Yojiro
Sadamoto GI Clinic, Kitakushu/Japan
Contact E-mail Address: sadamotoy@yahoo.co.jp

Introduction: This study was evaluated the effectiveness and safety of Vonoprazan, a potassium-competitive acid blocker (P-CAB) compared with proton pump inhibitors (PPIs) for a first-line Helicobacter Pylori (H. pylori) eradication.
Aims & Methods: We retrospectively analyzed data from first-line H. pylori eradication treatment (vonoprazan or PPIs with 400 mg clarithromycin and amoxicillin) on consecutive patients (n = 348) between April 2008 and February 2017 at Sadamoto GI clinic, Japan. Patients who received 7-day P- CAB therapy (vonoprazan 20 mg twice daily; n = 498) were compared with those who received 7-day PPI therapy (lansoprazole 30 mg/day; n = 250). The eradication rates were calculated by intention-to-treat (ITT) and by per-protocol (PP). Compliance and adverse events were also assessed for each study group.
Results: ITT and PP analysis of the first-line H. pylori eradication for vonoprazan, lansoprazole, rabeprazole, and esomeprazole were 75.5%/86.8%, 63.9%/76.2%, 68.0%/79.5%, and 63.2/70.8%, respectively. The vonoprazan eradication rates were significantly higher than those of these PPIs (P < 0.05). There was no significant difference in the adverse events between the two therapies. Conclusion: Seven-day P-CAB triple therapy is more effective than 7-day PPI based triple therapy as a first-line H. pylori eradication without differences in tolerability.
Disclosure of Interest: All authors have declared no conflicts of interest.

P0601 AN OPEN-LABEL, RANDOMIZED CONTROLLED TRIAL OF VONOPRAZAN VERSUS ESOMEPRAZOLE AS PART OF FIRST-LINE TRIPLE THERAPY FOR HELICOBACTER PYLORI ERADICATION
Gastroenterology And Hepatology, Takamatsu Red Cross Hospital, Takamatsu/Japan
Contact E-mail Address: h-tama@gei.so-net.ne.jp

Introduction: Vonoprazan (VPZ) is a novel, orally bioavailable, potassium-competitive acid blocker for the treatment and prevention of acid-related gastrointestinal diseases. A phase III study revealed that VPZ is superior to lansoprazole as part of first-line therapy for Helicobacter pylori (HP) infection when combined with 400 or 800 mg/day clarithromycin (CAM).
Aims & Methods: The aim of the current study was to evaluate the efficacy and safety of VPZ. CAM (400 mg/day), and esomeprazole (ABPC; 1500 mg/day) triple therapy in post-marketing use in Japan. A randomized, open-label, single-center study was conducted to verify the superiority of VPZ to esomeprazole (EPZ) as part of first-line therapy in patients with HP infection. Three hundred and forty-nine Japanese patients with HP infection diagnosed using a rapid urease test were enrolled between June 2015 and October 2016. The patients were randomly allocated to VPZ group (VPZ 40 mg/day, ABPC 1500 mg/day, CAM 400 mg/day) or EPZ group (EPZ 40 mg/day, ABPC 1500 mg/day, CAM 400 mg/day) with stratification according to endoscopic findings of gastric/duodenal ulcer and H. pylori resistance determined via a microbial sensitivity test. The eradication rates were evaluated using the urea breath test 8 to 12 weeks after cessation of therapy.
Results: Three hundred and forty-five patients (177 men, 168 women; mean age 64.7 years [range 27–89 years]; VPZ group, 169; EPZ group, 176) completed the study. One patient in the VPZ group and three patients in the EPZ group discontinued the treatment because of adverse events. One patient in the VPZ group and three patients in the EPZ group were lost to follow-up. There was no significant difference in the overall first-line eradication rate between the two groups (81.7% [138/169] in the VPZ group vs. 74.4% [131/176] in the EPZ group [P = 0.10]). Furthermore, there was no significant difference in the first-line eradication rate in patients with CAM-sensitive HP (87.2% [82/92] versus 84.6% [77/91]) in the VPZ and EPZ groups, respectively, [P = 0.60]). The eradication rate was significantly higher among patients with CAM-resistant HP in the VPZ group than that in the EPZ group (73.6% [30/41] vs. 55.6% [35/63], [P = 0.044]). The first-line eradication rate in the patient with high estimated glomerular filtration rate (eGFR; > 60 ml/min/1.73 m²) was significantly lower than that in the patients with low eGFR (> < 60 ml/min/1.73 m²). 86.4% [32/37] in
the patients with low eGFR, 65.3% [34/53] in the patients with high eGFR [P = 0.034]. It was significantly higher in the VPZ group than that in the EPZ group (79.3% [23/29] versus 50% [11/13], respectively, [P = 0.023]). The first-line eradication rate in continuous smokers was significantly lower than that in non-smokers (81.0% [187/231] in non-smokers vs. 64.3% [27/42] in continuous smokers [P = 0.016]). However, there were no significant differences between the VPZ and EPZ groups in non-smokers (84.2% [96/114] versus 77.8% [91/117], respectively, [P = 0.21]) and in continuous smokers (84.2% [12/16] versus 57.7% [15/26], respectively, [P = 0.33]). Furthermore, the first-line eradication rates in both groups were not influenced by age, sex, body mass index, drinking habit, and the endoscopic findings of gastric/duodenal ulcers/scars. There were no significant differences with regard to adverse effects between the two groups.

Conclusion: In contrast to the previous reports, the first-line eradication rate of VPZ-based triple therapy with 400 mg/day CAM and 1500 mg/day ABPC was similar to that of EPZ-based triple therapy in all groups except in patients with CAM-resistant HP and high eGFR.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0602 THE IMPACT OF AMOXICILLIN RESISTANCE ON THE EFFICACY OF AMOXICILLIN-CONTAINING REGIMENS FOR HELICOBACTER PYLORI ERADICATION—A POST-HOC ANALYSIS OF FIVE RANDOMIZED TRIALS

J. Liou1, M. Chen1, J. Lin2, M. Wu1
1Dept. Of Internal Medicine, National Taiwan University Hospital Dept. of Internal Medicine Taiwan Helicobacter Consortium, Taipei/Taiwan
2College Of Medicine, Fu-Jen Catholic University, New Taipei City/Taiwan

Contact E-mail Address: dtm40646@pchome.com.tw

Introduction: The impact of amoxicillin resistance on the efficacy of regimens containing amoxicillin for Helicobacter pylori (H. pylori) eradication remains inconclusive. Therefore, we aimed to investigate whether the efficacy of amoxicillin-containing regimens is affected by amoxicillin resistance and to identify the optimal breakpoint of amoxicillin resistance.

Aims & Methods: This was a post-hoc analysis of five randomized trials conducted in Taiwan from 2007 to 2016. Patients who received amoxicillin-containing regimens were recruited. The minimum inhibitory concentrations (MICs) were determined by agar dilution test. Meta-analysis was performed to assess the risk ratio of eradication failure in amoxicillin resistant strains compared to susceptible strains of seven different regimens. We further performed pooled analysis and logistic regression in patients treated with clarithromycin triple therapy to identify the optimal breakpoint of amoxicillin resistance.

Results: A total of 2339 patients with available data of amoxicillin MICs were enrolled. Meta-analysis showed that the presence of amoxicillin resistance was an independent risk factor of treatment failure of H. pylori infection. However, GAFG is also found in adenocarcinoma with low-grade atypia occurring in the mucosa of the fundic gland type and H. pylori infection susceptibility. Atrophic gastritis (AG) or gastric cancer (GC) was observed. Furthermore, the first-line eradication rates in both groups were not influenced by age, sex, body mass index, drinking habit, and the endoscopic findings of gastric/duodenal ulcers/scars. There were no significant differences with regard to adverse effects between the two groups.

Conclusion: In contrast to the previous reports, the first-line eradication rate of VPZ-based triple therapy with 400 mg/day CAM and 1500 mg/day ABPC was similar to that of EPZ-based triple therapy in all groups except in patients with CAM-resistant HP and high eGFR.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0604 ASSOCIATION BETWEEN GASTRIC ADENOCARCINOMA OF THE FUNDIC GLAND TYPE AND H. PYLORI INFECTION

M. Matsuura, H. Kinugasa, K. Miyahara, M. Nakagawa
Internal Medicine, Hiroshima City Hiroshima Citizens Hospital, Hiroshima/Japan

Contact E-mail Address: maaaayay0917@gmail.com

Introduction: Gastric adenocarcinoma of the fundic gland type (GAFG) is gastric adenocarcinoma with low-grade atypia occurring in the mucosa of the fundic gland without atrophy, and is recognized that it is not related to H. pylori (Hp) infection. However, GAFG is also found in Hp-infected and past Hp-infected patients as well as in Hp-uninfected patients. It cannot deny the relationship between the progress of GAFG and Hp infection.

Aims & Methods: Ten lesions of GAFG resected endoscopically or surgically in our hospital from December 2010 to October 2016 were classified as Hp-uninfected (n = 5) and Hp-infected (n = 5). We analyzed both micromorphological and immunohistochemical features. The association with Hp infection was not clear. In immunohistochemical staining, MUC6 positive, MUC5AC positive, and MUC2 negative, CD 10 negative in all cases, whereas the ratio of MUC5AC/MUC2 positive was significantly higher in the Hp-infected group as 0.20 (P = 0.045). We reported that black pigmentation is recognized in GAFG (stomach and intestine 50:151–151, 2015), but no association between Hp infection and black pigmentation was observed. On the other hand, the rate of PPI administration divided pigmentation (n = 6) or no pigmentation (n = 4) are 50%, and it is suggested that the pigmentation in GAFG may relate with PPI (p = 0.091).

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Conclusion: Hp infection is suggested to be related to the invasion depth of CD. Hp prevalence was noted in 66.7% of cases. Specific management of hepatic cirrhosis has been established with ligation of esophageal varices in 2 patients after bleeding esophageal varices until eradication of varices. A treatment with β blockers was prescribed in primary prophylaxis of digestive bleeding by rupture of esophageal varices in 4 patients. Diuretic therapy and aspiration of the ascites fluid are performed in cirrhotic patients with ascites. A GFD is established in addition to the specific management of liver cirrhosis. Liver tests were standardized in 100% of patients with cryptogenic transaminasemia following GFD. The chronic liver disease was often decompensated and the hepatic signs for cirrhosis were in the foreground masking the response to GFD.

Conclusion: It is recommended to look for hepatic abnormalities during CD and even to think of the diagnosis of CD in front of liver cytolysis syndrome without obvious etiology and in the presence of a chronic cryptogenic or dysimmune liver diseases.

Introduction: Celiac disease (CD) is a life-long autoimmune disease affecting multiple organs of genetically susceptible individuals. One of the extra intestinal manifestations of the disease is thromboembolic events like strokes and veins' thrombosis.

Aims & Methods: The aim of this work is to determine the prevalence and clinical characteristics of the thrombosis observed during CD. Prospective multicenter work involving 154 adult celiac patients (42H, 112F), with an average age of 36.1 years ± 13.6, recruited between 01-01-2013 and 30-06-2014 with a minimum follow-up of 12 months. The diagnosis of CD was in all cases based on clinical, serological and histological arguments. Thrombotic complications were noted as well as their modalities of occurrence.

Results: Vascular thrombosis was diagnosed in 13 patients (8.4%), and occurred almost exclusively in women (84.6%) (11 F - 2 H). There are 6 cases of portal cavernoma, one associated with lower limb thrombosis, 4 cases of stroke and 3 cases of thrombosis of the lower limbs. The diagnosis of thrombosis revealed the diagnosis of MC in 8 patients (61.5%) with an average delay of 11.6 months and extreme delays of 1 to 43 months. These include 4 cases of a portal cavernoma, one associated with deep limb thrombosis, 3 cases of stroke, and one case of deep thrombosis of the lower limbs. The diagnosis of CD was made on average 72 months after that of thrombosis in 4 patients (30.8%). In one case, thrombosis was complicated 39 years after diagnosis of CD diagnosed in childhood at the age of 5 years without gluten-free diet. The thrombophilia assessment was carried out in all patients and. The thrombophilia assessment was was negative in 11 cases (84.6%). A S protein deficiency associated with the CD in one case and an antithrombin III deficiency in another case were detected. The use of oral contraceptives and in all cases a micro-dosed oestro-progestin was found in 7 women (63.6%). The treatment of women involved an anticoagulant and corticosteroids.

Conclusion: The diagnosis of CD must be evoked when there is a thrombotic disease without obvious cause, factors of thrombophilia may be present during the CD. Early CD diagnosis with respect to the gluten-free diet may prevent the development of this complication.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0608 DIFFERENT PROFILES OF TLR 2, 4, 7 AND 9 MRNA IN PBMC AND BIOPSY SPECIMENS OF PATIENTS WITH CELIAC DISEASE

Introduction: Celiac disease (CD) is an organ-specific autoimmune disease, and both adaptive and innate immunity are involved in its development. Recent studies suggest the dysregulation Toll-like receptors (TLRs) in innate immunity can confer risk to autoimmune diseases such as CD.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: In this study we investigated the TLRs 2, 4, 7, 9 genes expression in the ileum of patients with celiac disease compared with healthy control. Blood samples from 120 CD patients diagnosed according to the Iranian Society for Gastroenterology were collected and 120 healthy individuals were served as a control group during 2016. Also, among them, 20 duodenal biopsy specimens were collected randomly. Total RNA for both blood samples and biopsy specimens was isolated using a standard commercial kit. The mRNA expression of TLRs were quantified by relative qPCR with B2M as a reference gene.

Results: Significantly higher expression of TLR4 and TLR9 mRNA was observed in blood samples of CD patients compared to the healthy controls (P < 0.05), but there were no significant differences between expression of TLR2 and TLR7 mRNA compared to the controls. Furthermore, TLR4 and TLR2 expression level was increased in CD biopsy specimens compared to controls, whereas expression of TLR9 mRNA was decreased in CD patients. No significant differences in expression of TLR7 was observed in biopsy specimens.

Conclusion: The result of this study show that the alteration of TLR4 and TLR9 genes expression in intestinal mucosa of CD can be detected in PBMs in peripheral blood. This data supports the implication of innate immune system in the pathomechanism of celiac disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The mucus layer, covering the gastrointestinal mucosa, is considered as the first line of defence against mechanical, chemical, or microbiological aggressions arising from the luminal contents. Among all different cell types of the intestinal epithelium, the goblet cells are specialised in the secretion of mucus constituent. As an example of failing barrier function, patients with coeliac disease (CD) have been reported to have altered intestinal barrier. Human colonic mucus-secreting cells HT-29-16E are valuable tools to explore the effect of a specific treatment on permeability and mucus production by the human intestinal epithelium.

Aims & Methods: We investigated the new and innovative gluten detoxified bread (GFB; patent PCT/IB2013/007977) effects on mucus production by means of Alcian blue staining in comparison to the control bread (CB). In addition, MUC2 and MUC3 were quantified by ELISA and the permeability of the intestinal epithelium monolayer was evaluated by trans-epithelial resistance (TEER) measurement. The statistical analysis was conducted by one-way ANOVA followed by a Bonferroni post-hoc t-test.

Results: Mucin production by Alcian blue staining was expressed as % black pixels. As shown from Image J analysis, GFB increased the expression of MUC2 by % of 27.4 ± 1.82; P < 0.001, whereas CB did not (9.94 ± 0.67; P = 0.05). Higher MUC2 concentrations expressed as ng/ml were found on cells treated with GFB (10.82 ± 1.35; P = 0.01) compared to control. This result was not found for MUC3 (19.34 ± 0.18; P = 0.05). Alcian blue TEER values, expressed as a percentage of initial TEER, were observed after 24 hours of incubation with GFB in comparison to the control (163.2 ± 33.8; P = 0.01) which was not observed or CB (139.4 ± 28.8; P = 0.05).

Conclusion: It could be concluded that GFB has a potential of inducing MUC2 secretion by intestinal epithelial cells and improving intestinal epithelium permeability in vitro. Such observed potential may effectively contribute to consequent benefits such as higher gut barrier performance, decreased susceptibility to infections and better absorption regulation, thus ameliorating such alterations in colonic patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0612 FUNCTIONAL DYSPEPSIA SYMPTOMS ARE STRONGLY ASSOCIATED WITH COELIAC DISEASE: RESULTS FROM A POPULATION-BASED STUDY

M. Potter1, M. M. Walker2, M.P. P. Jones3, N. Koloski1, G. Brogan1, S. Keely1, N.J. Talley1
1Faculty Of Health And Medicine And Priority Research Center For Digestive Health And Nutrigenomics, The University of Newcastle, Callaghan/Australia/NSW
2Anatomical Pathology, University of Newcastle, Newcastle/Australia/NSW
3Psychology, Macquarie University Psychology, North Ryde/Australia

Introduction: Coeliac disease (CD) is estimated to affect up to 1 in 100 Australians (1). Although CD has a wide range of clinical manifestations, patients frequently present with gastrointestinal (GI) symptoms which overlap with functional GI disorders, particularly irritable bowel syndrome (IBS) and functional dyspepsia (FD); the prevalence of biopsy proven CD is higher in IBS (2) and in dyspepsia (3). Patients with CD have been shown to experience persistent GI symptoms despite long term treatment with a gluten-free diet (4).

Aims & Methods: The aim of this study was to define GI symptoms reported in an Australian cohort with a doctor diagnosis of CD and compare with those not reporting CD. A total of 3825 people (mean age 58.4 years, age range 18–100 years and 47.5% males) randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate =45%) which contained questions on whether the participant had ever been told by a physician that they had CD, and questions regarding GI symptoms to establish whether they had co-existent functional GI disorders. Adherence to a gluten-free diet was not assessed. Prevalence of CD, FD and IBS are reported with 95% exact confidence intervals. The difference between symptoms in those with CD compared with the unaffected population was tested for significance by Pearson chi-square test.

Results: The prevalence of doctor-diagnosed CD was 1.2% (95% CI 0.84–1.59) in this cohort. Subjects with CD reported significantly higher levels of GI symptoms than unaffected individuals, including abdominal pain associated with abnormal bowel habit, diarrhoea, bloating, distension, epigastric burning and early satiety (see Table). The prevalence of CD, FD and IBS are reported with 95% exact confidence intervals. The difference between symptoms in those with CD compared with the unaffected population was tested for significance by the Pearson chi-square test.

Table: Gastrointestinal symptoms reported by patients with and without self-reported coeliac disease (CD). Items reported as greater than once a day per week (*) or greater than or equal to “often” (**)

</tr>
</tbody>
</table>

Conclusion: The prevalence of gastrointestinal symptoms and in particular functional dyspepsia are significantly higher in patients with a doctor diagnosis of CD than those without such diagnosis. Studies of anti-CD biopsy proven coeliac disease in IBS is higher in IBS cohorts than healthy controls (2) and the value of screening with duodenal biopsy testing for CD in FD is concluded to be useful.

P0613 MALE GENDER AND UNDERWEIGHT ARE ASSOCIATED WITH OSTEOPOROSIS IN PATIENTS WITH NEW DIAGNOSIS OF COELIAC DISEASE

Department Of Medical-surgical Sciences And Translational Medicine, Sant’Aurea Hospital, University Sapientia, Rome, Italy

Contact E-mail Address: gloria.galli5@gmail.com

Introduction: Osteoporosis is a systemic skeletal disorder characterized by low bone density and micro-architectural deterioration with increase of bone fragility and consequent fracture risk. About 50–75% of patients (pts) with untreated coeliac disease (CD) suffer from bone mass loss (osteopenia or osteoporosis). Despite this strong correlation, guidelines do not express with certainty on the need to undergo a dual-energy X-ray absorptiometry (DEXA) scan in every patient with new diagnosis of CD. Recently, the DEXA screening was suggested for CD peri-post menopausal females, males over 55 years, pts with overt malabsorption or with a history of fragility fractures. Studies on bone mineral density (BMD) in CD pts led to disparate results, probably due to heterogeneous designs.

Aims & Methods: The aim of this study was to evaluate, in a cohort of consecutively newly diagnosed CD adults, the prevalence of BMD alterations at diagnosis and to evaluate associated clinical features. From January 2004 to December 2016, 258 consecutive pts (F = 72.4%) were diagnosed with CD. All pts were adults (median age 38, range 18–72 years), had atrophic disease and were invited to undergo a DEXA within 3 months from diagnosis to screen for osteoporosis (T-score < −2.5) or osteopenia (T-score < −1 and ≥−2.5). A total of 214 (82.9%) pts underwent the DEXA scan and were included in the study (F = 71.5%, median age 38, range 18–72 years). On the basis of DEXA results (codified according to WHO classification) pts were divided into 3 groups: pts with normal BMD, with osteopenia, and with osteoporosis. For each patient, reported risk factors for low BMD (underweight, alcohol intake, drugs, menopause, smoking) and serological PTH values were assessed. The signs/symptoms leading to CD and their duration before diagnosis, autoimmune/not-autoimmune comorbidities, familiarity for CD, previous fractures and serological assays (specific antibodies for CD, ferritin, cholesterol, triglycerides, and albumin) were also assessed. All the variables described were analyzed and compared between the 3 groups. Logistic regression was performed including into the model those independent variables which showed a significant difference at univariate analysis.

Results: At the DEXA scan, 85 (39.7%) and 129 (60.3%) pts had normal or low BMD, respectively. Among pts with low BMD, 91 (42.5%) had osteopenia and 38 (17.8%) osteoporosis. At logistic regression, clinical features significantly associated with osteoporosis were male gender (OR 4.7; 95% CI 1.3 to 17.4), underweight (OR 8.1; 95% CI 1.8 to 35.3) and increased PTH values (OR 5.1; 95% CI 1.4 to 18.8), while age >50 years and gastrointestinal symptoms at diagnosis time, menopause, alcohol intake and previous fractures were not associated. Clinical features significantly associated with osteopenia were male gender (OR 4.0, 95% CI 1.4 to 11.2) and increased PTH values (OR 2.6, 95% CI 1.1 to 6.4).

Conclusion: In newly diagnosed CD pts, the overall prevalence of BMD alterations was more than 60%, with osteoporosis in nearly 1/3. Osteoporosis was significantly associated with male gender, underweight and increased PTH. This study suggests that at CD diagnosis, DEXA scan might be of benefit, in particular in male underweight pts.

Introduction: Coeliac disease (CD) affects 0.6–1% of the population worldwide (1). Wheat avoidance in the absence of CD is common, and studies report a population prevalence of self-reported wheat or gluten sensitivity (SRWS) of...
up to 13% (2, 3). SRWS is defined as gastrointestinal (GI) or extra intestinal symptoms on ingestion of wheat or gluten-containing food (2, 3).

Aims & Methods: The aim of this study was to determine the prevalence of SRWS in an Australian population, define associated GI symptoms, and relate the diagnosis to demographic, lifestyle and medical factors. A total of 3825 people (mean age 58.4 years, age range 18–100 years and 47.5% males) randomly selected from the Australian population returned a mail survey (Digestive Health & Wellbeing Survey, response rate = 45%) which contained questions on wheat avoidance, GI symptoms, demographic, medical and lifestyle factors. We defined SRWS as people who reported gastrointestinal symptoms on ingestion of wheat based foods, but did not suffer from doctor diagnosed coeliac disease, inflammatory bowel disease or bowel cancer. Prevalence of SRWS is reported with 95% exact confidence intervals. The association between SRWS prevalence and potential risk factors was reported using unconditional logistic regression. The degree of differentiation of SRWS from health was evaluated through the area under the receiver-operator-characteristic curve.

Results: The prevalence of SRWS in this cohort was 13.5% (455/3331, 95% CI 12.5–14.5%). Only 11% (50/455) of these SRWS had received a doctor diagnosis of wheat or gluten intolerance. The most commonly reported GI symptoms (reported as more than weekly or often) associated with SRWS included abdominal pain relieved by bowel movements (54.5%), bloating (37.6%) and abdominal distension (30.8%). In a multivariate analysis, a diagnosis or SRWS was significantly associated with irritable bowel syndrome (IBS) and functional dyspepsia (FD) (Rome III criteria), female gender, and food allergy (see Table). Older age was negatively associated with SRWS. In this multivariate model, factors with no observed association included body mass index, depression, anxiety, sleep problems, proton pump inhibitor use, gastrointestinal infection, rheumatoid arthritis, scleroderma, migraine, Parkinson’s disease, asthma, pollen allergy, animal allergy, psychic stress and recent antibiotic use. The model provided useful although imperfect differentiation of SRWS from health (AUC = 0.76).

Table: Medical and demographic factors associated with a diagnosis of self-reported wheat sensitivity (SRWS).

Conclusion: SRWS has a prevalence of 13.5% in this Australian cohort. Those with SRWS are likely to report abdominal symptoms, including abdominal pain after a few hours or abdominal distension. SRWS is significantly associated with IBS and FD, younger age, female gender, and food allergy.

Insufficiency of functional bowel disease is usually associated with disorders of visceral sensitivity and intestinal motility, which result from a dysfunction of the central nervous system, intestinal microflora and immune system.

Aims & Methods: We aimed to highlight importance of intestinal enzymes (glucose, amylase, sucrase and lactase) in the etiology and pathogenesis of functional bowel disease. 74 patients with functional bowel diseases in age from 18 to 50 years (36 men and 38 women) were examined. According to Rome IV criteria (2016), 21 had irritable bowel syndrome (IBS) with predominant diarrhoea, 33 - functional diarrhoea, 6 - IBS with predominant constipation, 4 - functional constipation and 10 - mixed type of IBS. Activity of the mucosa enzymes of the small intestine was determined by Dahlquist-Trinder method in duodenal biopsies obtained during esophagogastrodudenoscopy.

Results: Lactase deficiency was identified in 87.8% of patients, maltase deficiency - in 48.6%, sucrase deficiency – in 51.3%, the glucoamylase deficiency – in 85.1%. The activity of all investigated enzymes was reduced in 23 (31.1%) patients with functional bowel diseases, failure of 1 to 3 enzymes detected in 47 (63.5%). Normal activity of enzymes was observed in 4 (5.4%) patients.

Conclusion: In 70 of 74 (94.5%) patients with functional bowel disease and a disorder of the stool, abdominal pain and flatulence, there was a decrease in the activity of intestinal enzymes, which may be a cause of intestinal symptoms.

Introduction: Epidemiological studies estimate a worldwide prevalence of CD of approximately 1:100 individuals, with a considerable proportion of patients remaining undiagnosed and untreated.

According to a study performed by the National Health and Nutrition Examination Survey in the United States, the prevalence of self-prescribed GFD in an unselected population of subjects aged 6 years or older was 0.5%. Epidemiological studies report a prevalence of WA in American population of around 0.4% until 0.6%.

The diagnosis of WA is basically based on skin prick tests (SPT), in vitro specific Immunoglobulin E (sIgE) assays and functional assays. SPTs and sIgE in vitro assays are the first-level diagnostics for WA. However, they are affected by a low predictive value. In particular, their low sensitivity can be explained by the fact that the commercial test reagents are mixtures of water/salt-soluble wheat proteins that lack allergens from the insoluble gluten fraction. The association between food allergy and celiac disease (CD) is still to be clarified.

Gluten-related disorders are an epidemiologically relevant phenomenon with a global prevalence that is estimated around 5%, drawing the attention of the scientific community.

Aims & Methods: We visited in our unit of celiac disease and gluten-related conditions during 2016 423 (F:312/111) new patients with clinical suspicion of CD. Of these 113 they were non celiac but were investigated for suspected non celiac gluten sensitivity. After in vitro tests for the exclusion of celiac disease, to verify the real prevalence of food allergy particularly to wheat protein, in non celiac patient referred our unit for symptoms after gluten ingestion, all these patients underwent allergicology study which consists on skin prick tests for food, including wheat (Alk-abello), LTP (lipid transfer protein) (peach Abello), alpha amylase, wheat flour, barley, corn, rice, grass pollen and histamine. Also all they performed patch tests for suspected allergy to nickel, if they reported sensitivity to nickel or allergy to local metal allergy (MA) diagnostics could overcome some limitations of sIgE in vitro assay using wheat flour extracts. We have used omega-5 gliadin (TRI 19) and mILP (TRI 14), glh admin, wheat, gluten that are available in the immunoCap assay, whereas the Afta – amylase/trypsin inhibitor in the microarray (TRI a A/TI) is available only in the ImmunoCAP, ISAC assay. The sIgE to omega-5 gliadin assay is highly reliable and now widely used to identify the patient with WDEIA.

Results: In our overall population, 113 (26.7%) non celiac patient had a history of immediate or not immediate reaction after ingesting gluten: the Allergologic tests found wheat protein sensitization in 14 patients of these (12.4%, 9 F). In addition we also found 5 (4.3%, 4F) patients with real allergy to wheat or wheat protein.

Conclusion: In our population 19/113 (16.8%) non celiac patient had real reaction after ingesting gluten: 14 (12.3%) had wheat protein sensitization and 5 (4.5%) had WA. These results are different and very high than that reported in the literature.

Reference
as colchicine. Short-term outcome of having BAD is well-described, but long-term effects remain unclear. The aim of the present study was to describe long-term symptoms, adherence to treatment and quality of life in a well-defined group of patients with BAD.

**Aims & Methods:** Between 2003 and 2016, 559 patients referred to our hospital for differently managed abdominal soft tissues were collected. The presence of clinically overt systemic disorders was excluded in all of them. After an overnight fast and at the same time in the morning, all the subjects underwent evaluation of post-prandial modifications of serum levels of pro-inflammatory cytokines (IL-1β, IL-6, TNFα), endogenous antioxidant system (uric acid), glucose, insulin and serum lipopolysaccharide (LPS), measured as putative factors responsible for inflammatory response. Serum samples were collected at fasting and every 30 minutes for a 4-hour period after an oral gluten load of 2 gr (in 10 HV) or 20 gr (in the other 10 HV). The presence and severity of symptoms such as epigastric pain, epigastric burning, fullness, early satiety, abdominal pain, abdominal distension, bloating, flatulence, nausea, vomiting, belching, heartburn, regurgitation, diarrhea, and headache, were evaluated by visuo-analog scale at fasting and every 30 minutes in the post-prandial period.

**Results:** In comparison with mean fasting values, none of the measured parameters showed a significant increase in the post-prandial period after the ingestion of 2 gr of gluten. On the contrary, after the ingestion of 20 gr of gluten mean post-prandial values of TNFα and IL-6 showed a significant increase (2.45 ± 1.75 pg/mL and 0.65 ± 0.31 pg/mL) as compared to mean fasting values (1.17 ± 1.49 pg/mL and 0.29 ± 0.15 pg/mL; p < 0.05). Mean post-prandial values of uric acid were also significantly lower (74.98 ± 5.02 mmol/L) than fasting values (45.34 ± 10.08 mmol/L; p < 0.05). No significant differences were detected in IL-6, glucose, insulin and LPS d after the ingestion of the 20 gr gluten oral load. Symptoms were absent after both oral loads.

**Conclusion:** The ingestion of gluten may not be a low, oral load of gluten induces a significant post-prandial inflammatory response causing the activation of the main endogenous anti-oxidant system. In HV, these activations are not accompanied by a symptomatic response. Further studies are needed to investigate the inflammatory and anti-oxidant post-prandial response in patients with gluten-related disorders.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Aims & Methods: All obese patients treated with IGB in a specialized obesity center, and that underwent balloon removal from June 2009 to June 2013 were analyzed and compared with logistic multivariate analysis. Patients that agreed to participate were interviewed by a trained investigator in person and answered a questionnaire survey and had their body weight measured. Interviews started on July 2015 and ended on July 2016. Medical records were reviewed on all patients that underwent balloon removal. This correlation was inverse (r = -0.20) and significant (p < 0.01). The correlation was stronger and more significant with patients who had withdrawn the balloon at two years (r = -0.585). In contrast, among non-insulin dependent patients, there was a non-significant decrease in HbA1C during the year post the device removal (6.5 ± 1.3 to 6.4 ± 0.8, p = 0.812). Ten patients (19.6%) of the initial 51 treated suffered from adverse events, 4(7.8%) of which were categorized as severe ones (two major bleedings and 2 hepatic abscesses).

Conclusion: IGB is an effective tool for weight reduction in obese patients with diabetes as it sustained metabolic achievements are preserved at least a year after device removal. Since DJBL bears a considerable amount of side effects, strategies to mitigate them are warranted.

Disclosure of Interest: All authors have declared no conflicts of interest.

% of weight regained * 2 years 3 years 4 years 5 years
<10% 20% (2) 15.6% (13) 18.5% (10) 33.3% (1)
Between 10 and 19% 70% (7) 62.7% (52) 59.3% (32) 66.7% (2)
Between 20 and 29% 10% (1) 14.5% (12) 14.8% (8) 0
Between 30 and 39% 0 2.4% (2) 1.9% (1) 0
Between 40 and 49% 0 1.2% (1) 5.6% (3) 0
Between 50 and 59% 0 2.4% (2) 0 0
Between 60 and 99% 0 1.2% (1) 0

Conclusion: IGB has a suboptimal long-term effect on body weight control after 2 to 5 years of balloon removal, with weight regain observed in up to two thirds of patients (66%). The following variables adversely affect long-term body weight control after IGB removal: lack of psychological support and nutritional counseling, sedentariness, and sedentary behavior. A multidisciplinary approach to assist obese patients treated with IGB in order to effectively maintain long-term body weight control.

Disclosure of Interest: All authors have declared no conflicts of interest.

8.66 ± 6.96 kg; 4 years [n = 54]; 9.9±± 3.44 kg and 5 years [n = 3]; 19, 96±± 12, 24; (p = 0, 51). The lower the HMI at the beginning of the treatment, the greater the weight regain after the IGB withdrawal. The mean weight regained increased during follow-up, but without significant difference among groups: 2 years [n = 10]: 4.66±± 4.91 kg; 3 years [n = 83]: 8.66±± 6.96 kg; 4 years [n = 54]; 9.9±± ±3.44 kg and 5 years [n = 3]; 19, 96±± 12, 24; (p = 0, 51). Conclusion: The results of this observational study show that re-implantation of the DJBL is viable and safe even only 4 months after explantation. After re-implantation, weight and HbA1c levels decreased one more time. Therefore, we have quite promising results that suggest re-implantation may be a viable option for a short-term BMI reduction, especially in obese, young patients.

P0626 THE COMPARATIVE EFFICACY OF OBESITY TREATMENTS IN YOUNG PEOPLE: A SYSTEMATIC REVIEW AND META ANALYSIS

S. S. Selvendran, N. Penney, N. Aggarwal, A. Darzi, S. Purkayastha
Surgery And Cancer, Imperial College London, London/United Kingdom

Contact E-mail Address: SS9612@ic.ac.uk

Introduction: Obesity in the young population is becoming increasingly prevalent. It is associated with short- and long-term consequences. Early and effective interventions are paramount. Current treatment options include: lifestyle modifications, pharmacological therapies, endoscopic treatments and bariatric surgery. However, the relative effectiveness of these treatments in this cohort remains unclear.

Aims & Methods: To systematically identify and meta-study the effects of obesity treatments that reduce body mass index (BMI) in overweight and obese young people. A systematic literature review of EMBASE and MEDLINE databases was conducted. Studies were included/excluded based on pre-specified eligibility criteria. Included patients were 21 years or younger. Lifestyle modification and pharmacological therapy searches were restricted to randomised control trials.

Results: 16,712 studies were identified with 80 studies complete with sufficient data for meta-analysis. Bariatric surgery caused the most weight loss in the short- and medium-term [pooled estimate of mean BMI loss: 13.77 kg/m²]. Lifestyle modifications and pharmacological therapy had a more moderate impact on weight [pooled estimate of mean BMI loss: 0.99 kg/m² and 0.94 kg/m² respectively]. Individual studies demonstrated that endoscopic treatment results in short-term BMI reduction, however insufficient data prevented meta-analysis.

Conclusion: This is the first systematic review and meta-analysis to comprehensively summarise and quantify the comparative efficacy of BMI reducing treatment options in the obese, young population. Currently, bariatric surgery is rarely considered in this young cohort. However, due to its high efficacy, physicians and patients should have a lower threshold for considering bariatric surgery when lifestyle and pharmacological interventions have failed. The present study demonstrates that surgical interventions provide smaller but statistically significant impacts on BMI reduction. There should be effective communication discussing the relative efficacy of all treatment options and their associated complications between those involved. This knowledge will assist clinicians in determining a holistic, patient-centred treatment programme for obese, young patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0627 FOOD-DERIVED MICRORNA AND INFLUENCE ON THE FECAL MICRORNA EXPRESSION

J. Link1, C. Langner1, A. Canbay1, P. Malfertheiner1, A. Link1
1 Department Of Gastroenterology, Hepatology And Infectious Diseases, Otto-von-Guericke University, Magdeburg/Germany

Contact E-mail Address: alinkmail@gmail.com

Introduction: Tumor development is a multistep process, which involves genetic and environmental factors. Diet is among the most important contributing factors and processed and red meat has been classified as carcinogenic for colorectal cancer. MicroRNAs (miRNAs) are functional, ubiquitously present molecules with great impact on tumor initiation and progression. Exogenous microRNA or xenomiRs have been identified in sera from different species suggesting an active transkingdom trespassing through biological barriers during digestive process.

Aims & Methods: In the present work, we evaluated whether miRNAs are present in various foods, and if miRNAs may be degraded through cooking and other forms of food processing. Furthermore, we tested if short-term vegetarian or meat-rich diet may influence human or plant-derived miRNA in feces and blood. For this purpose, six healthy subjects were asked to adhere to vegetarian or meat rich diet for 5 to 7 days and fecal and blood specimens were obtained at different time points. Plant-miRNAs were further investigated in gastric and colon mucosa. To evaluate the presence of miRNA in food, we selected several common foods prior and after cooking/processing. Quantitative real-time PCR was performed using TaqMan Assay.
Further intestinal [14C]-glucose uptake in isolated intestinal loops was assessed in presence or absence of NMU. During OGTT, blood was sampled to measure insulin secretion. [14C]-glucose uptake was assessed in isolated intestinal loops in presence or absence of NMU. A single intraperitoneal injection of NMU in C57Bl6 mice prevented the rise of glycemia following an oral but not an intraperitoneal load of glucose. Aims & Methods: The gut and brain peptide neuromedin U (NMU) is reported to stimulate gastric emptying and improves glucose tolerance. The gastric emptying blockade induced by NMU could also be indirectly via afferent vagal fiber activation. Through the blockade of gastric emptying, NMU reduces intestinal nutrient absorption and thus improves oral glucose tolerance. The gastric emptying blockade induced by NMU could also be through vagal-dependent mechanisms and improves oral glucose tolerance. A. Jarry1, N. Merah1, M. Fiamma2, L. Bodineau1, A. Bado1, J. Le Beye1, M. Le Gall1

1INSERM U1149, Paris/France
2INSERM U1158, Paris/France

Contact E-mail Address: annecharlotte.jarry@hotmail.fr

Introduction: The gut and brain peptide neuromedin U (NMU) is reported to decrease food intake and body weight, and to improve oral glucose tolerance suggesting that NMU may exert an incretin-like effect. NMU is thus considered as a promising candidate for the treatment of obesity and diabetes. However, and in contradiction with previous observations, NMU was recently presented as a “decretin” hormone able to decrease insulin secretion. The pathways through which NMU controls glycemia are thus uncertain and we sought to clarify some of NMU mechanisms of action on glucose homeostasis.

Aims & Methods: Oral (OGTT) and intraperitoneal (IPGTT) glucose tolerance tests were performed after an intraperitoneal injection of NMU or PBS in C57Bl6 mice that underwent a laparotomy or a troncular subdiaphragmatic vagotomy. During OGTT, blood was sampled to measure insulin secretion. [14C]-glucose uptake was assessed in isolated intestinal loops in presence or absence of NMU. Gastric retention of a phenol red gavage and total intestinal transit time were evaluated after an intraperitoneal injection of NMU or PBS. Activation of vagus nerve neurons by intraperitoneal injection of NMU was assessed by cFos immunostaining on brainstem slides going through the nucleus of the solitary tract (NTS) and the dorsal nucleus of the vagus (DMV). Direct impact of NMU on pyloric activity was assessed ex vivo in isolated cannulated chambers.

Results: A single intraperitoneal injection of NMU in C57Bl6 mice prevented the rise of glycemia following an oral but not an intraperitoneal load of glucose (OGTT versus IPGTT). Unexpectedly, during the OGTT, NMU injection prevented insulin secretion and only slightly improved peripheral insulin sensitivity. Furthermore intestinal [14C]-glucose uptake in isolated intestinal loops was barely reduced by NMU addition (~17% P < 0.05 vs PBS). Actually NMU injection blocked gastric emptying (gastric retention of a phenol red gavage at 30 min: +285% P < 0.001 vs PBS). This effect was partly prevented in vagotomized mice. In addition, injection of NMU induced c-fos expression in the nucleus of the solitary tract (NTS) of control but not vagotomized mice. In isometric chambers, NMU directly induced pyloric contraction in a dose dependent manner (basal contraction +21%, 7 kPa at 10-6 M).

Conclusion: These data demonstrate that a single intraperitoneal injection of NMU blocks gastric emptying directly by inducing pyloric contraction and indirectly via afferent vagal fiber activation. Through the blockade of gastric emptying, NMU reduces intestinal nutrient absorption and thus improves oral glucose tolerance. The gastric emptying blockade induced by NMU could also contribute to its anorexic effect.

P0629 LOW FODMAP DIET & PREBIOTIC GALACTOOLIGOSACCHARIDES IMPROVE IRRITABLE BOWEL SYNDROME SYMPTOMS AND RESPONSE TO LOW FODMAP DIET IS PREDICTED BY URINE METABOLOME, STOOL SHORT-CHAIN FATTY ACIDS AND VOLATILE ORGANIC COMPOUNDS: A RANDOMISED CONTROLLED TRIAL

Introduction: Dietary restriction of fermentable carbohydrates (low FODMAP diet, LFD) is effective at managing symptoms in 50-80 percent of patients with irritable bowel syndrome (IBS). Prebiotic B-galacto-oligosaccharide (B-GOS; HOST-G094) also reduce symptoms in IBS however the combination of the two therapies has not been investigated. This study investigated whether NMU affects the response to the LFD from those who do not is unclear.

Aims & Methods: This randomised controlled trial aimed to investigate whether 1) addition of prebiotic B-GOS could improve symptoms of IBS alongside the LFD and 2) if urinary metabolites, fecal short-chain fatty acids (SCFA) or volatile organic compounds (VOC) could identify factors at baseline that predict response. Sixty-nine adults fulfilling Rome criteria for IBS were recruited to a 3-arm RCT: control (sham diet/placebo), LFD (LFD/placebo) or LFD plus B-GOS (LFD/B-GOS) for four weeks. Validated questionnaires (Global symptom question and gastrointestinal symptom rating scale) assessed GI symptoms (response) and urine and stool samples were collected for analysis at baseline and week 4. To examine the relationship between responders and non-responders, urine metabolomics (700 MHz 1H-NMR), stool SCFA (gas liquid chromatography (GLC)) and stool VOC (GC-mass-spectrometry) were analysed on samples at baseline and 4-weeks. Urine metabolomics spectra and VOC profiles were analysed using unsupervised principal component analysis (PCA) and supervised pattern recognition methods (orthogonal partial least square discriminant analysis (OPLS-DA)) or PLS-DA respectively. Stool SCFA were compared using t-tests, models of prediction were tested using receiver operator characteristic (ROC) curves.

Results: There was a significant difference in response rates (adequate relief) between control (30%), LFD (50%) and LFD/B-GOS (67%) (p = 0.046), with post-hoc differences specifically between control and LFD/B-GOS (p = 0.015). Interestingly, B-GOS symptoms improved markedly in the placebo group compared to the LFD group only, there was a significant difference in the urine metabolome between responders and non-responders at both baseline (Q2 = 0.296 vs randomised –0.175) and at 4-weeks (Q2 = 0.485 vs randomised –0.203). At baseline, there were significant greater stool isobutyrate between responders (51.4 mg/100g) and non-responders (31.9 mg/100g; p = 0.04), with ROC curves supporting this as a predictor of response (AUC = 0.747, p = 0.063). Finally, there was a significant difference in VOC profiles between responders and non-responders to the LFD at baseline (p = 0.04). VOC profiles, modelled by PLS-DA, reveal significant separation of VOC profiles across the three treatment groups at 4-weeks (p = 0.02).

Conclusion: Addition of B-GOS to the LFD improves symptoms in IBS. Urine metabolomics, stool SCFA and VOC profiling are robust markers to stratify responders and non-responders to the LFD at baseline (p = 0.04). VOC profiles, modelled by PLS-DA, reveal significant separation of VOC profiles across the three treatment groups at 4-weeks (p = 0.02).

P0630 THE ANALYSIS OF PROTEIN CONSUMPTION PATTERNS IN PATIENTS WITH SIBO

V. Pilipenko, V. Isakov, A. Vlasova

Gastroenterology & Hepatology, Research Institute of Nutrition RAMS, Moscow/ Russian Federation

Contact E-mail Address: pilipenkowork@rambler.ru

Introduction: Small intestinal bacterial overgrowth (SIBO, a condition where bacteria (mostly) from animal source are essential for the production to consume more poultry than other groups. There were no different studies of nutrition in SIBO patients. Protein consumption is considered important for SIBO, as the proteins from animal source are essential for growth of CH4/H2-producing microorganisms. Aims & Methods: The aim of the study was to assess the protein consumption patterns in patients with different types of SIBO. Three-day food diary was modelled by PLS-DA, reveal significant separation of VOC profiles across the three treatment groups at 4-weeks.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: All types of SIBO patients consumed less meat than control (no signs of SIBO), however patients with hyperproduction of CH4 only demonstrated high consumption of fish, and it was a trend in patients with isolated H2-hyperproduction to consume meat more than other groups. There were no differences between groups in consumption of processed meat foods or eggs. Conclusion: There are specific animal protein consumption patterns related to the type of the SIBO, which can be used for the planning of dieietic interventions in patients for prevention of SIBO. All authors have declared no conflicts of interest.

INTRODUCTION: Patients suffering from chronic radiation-induced small bowel disease (RISBD) after cancer treatment have similar symptoms as patients with IBS (irritable bowel syndrome), despite dissimilar pathologic origin. RISBD is a common late effect after pelvic radiation therapy for gastrointestinal (GI), gynecological and urological cancer. The delayed development of ischemia, fibrosis, dysmotility and malabsorption in GI tissue, leads to IBS-like symptoms like abdominal pain, diarrhea, constipation and bloating. The low FODMAP diet seemed effective in alleviating IBS symptoms, but evidence is needed to investigate the effects of LFD on symptoms and health related quality of life (HRQOL) for patients with chronic RISBD.

AIMS & METHODS: In an open pilot study, 11 patients (mean age 46 years) with RISBD related IBS symptoms were instructed to follow LFD throughout a 4-week intervention period. A severity Scoring System (IBS-SSS) and IBS Symptom Questionnaire (IBS-Q) were used to assess symptoms. The Ad hoc questionnaire measured grade of tissue damage and typical RISBD complaints (focal incontinence, rectal mucus and rectal bleeding). Short Form Nepean Dyspepsia Index (SF-NDI) and 12-item Short Form Health Survey (SF-12) were used to evaluate HRQOL. A 3-day food record was used to estimate baseline intake of FODMAPs, to reveal dietary changes and to assess adherence to the diet. All schemes were completed at baseline and at 4 weeks. The study included no control group.

RESULTS: FODMAP intake was successfully reduced, and main additional changes in the diet were reduced intake of energy, carbohydrates and fiber. The adherence to the diet was high (mean 94.8%). IBS symptoms improved significantly based on mean total score of IBS-SSS and IBS-Q, which changed from 310.2 ± 0.08 to 274.4 ± 0.11 (p = 0.001). The severity of abdominal pain, abdominal distension, belching/flatus, constipation, diarrhea, early satiety, dissatisfaction with bowel habits and interference with daily life in general, improved significantly. Tendencies of improvement were also measured in comorbidity complaints (nausea, headache, backache, fatigue and muscle pain) and typical RISBD complaints. HRQOL improved based on SF-NF1 total score, which changed from 30.5 ± 9.4 to 18.3 ± 8.2 (p = 0.001) and based on mental (p = 0.047) and physical (p = 0.134) component summary score of SF-12.

CONCLUSION: The low FODMAP diet seems effective in alleviating IBS symptoms, and improving HRQOL in patients with RISBD. High compliance to LFD is possible with adequate diet counseling and continuous guidance. Further controlled studies with larger sample size should be conducted to verify our results and hopefully enable the implementation of LFD as a future management strategy for chronic RISBD.

</table>
is similar to the oral glucose-stimulated secretion of glucagon-like peptide 1 (GLP-1). GLP-1 is an incretin hormone secreted by endocrine L cells (ECC) from the distal gut. GLP-1 and glucagon, both originate from the same proglucagon precursor, differentially processed by prohormone convertase 2 (PC2) into glucagons in pancreatic α cells and by prohormone convertase 3 (PC3) into GLP-1 by enteroendocrine L cells (ECC) from the distal gut.

Aims & Methods: We hypothesized that, after pancreatectomy, proglucagon can also be processed into glucagon in EEC. We developed a 75% subtotal pancreatectomy model in C57Bl/6 mice. Control (Ct) mice underwent a laparotomy. Post-surgery, blood glucose levels were measured, and oral glucose tolerance tests (OGTT) were performed after 1 week. Insulinemia and glucagonemia were also measured in fed and fasted mice and during OGTT. After 2 weeks, animals were sacrificed and the remnant pancreas was sampled for glucagon and insulin immunohistochemistry. Proximal and distal intestinal segments were sampled for morphometric analyses as well as measurement of proconvertase and proglucagon mRNA levels. Colonic segments were incubated in a glucose-enriched medium for one hour and glucose-induced secretion of glucagon and GLP-1 were measured in the supernatant.

Results: As soon as one day post-surgery, pancreactectomized (Px) mice developed a hyperglycemia that maintained for over a week (351 mg/dl in Ptx mice vs 140 mg/dl in Ct mice, P < 0.05, 5 days post-surgery). This hyperglycemic state was accompanied by an oral glucose intolerance (area under the curve = 278% in Ptx mice, P < 0.01 vs Ct mice, 1 week post-surgery). During OGTT, intestinal glucose absorption increased (slope between 0 and 15 minutes = 69.9% in Ptx mice P < 0.01 vs Ct mice, 1 week post-surgery). Glucagonemia increased in fasted pancreactectomized mice (+146.6% in Ptx mice P < 0.01 vs Ct mice 1 week post-surgery). After sacrifice, alpha cell mass was decreased in the remaining pancreas (~79.2% in Ptx mice P < 0.05 vs Ct mice, 2 weeks post-surgery). Hypertrophy of the proximal colon to secrete glucagon was observed (~290.6% in Ptx mice P < 0.05 vs Ct mice, 2 weeks post-surgery). In pancreactectomized mice, an hypertrophy of the duodenum was associated with an increase in crypt depth (~77.7%, in Ptx mice P < 0.05 vs control mice, 2 weeks post-surgery) and villus height (~53.3% in Ptx mice P < 0.05 vs control mice, 2 weeks post-surgery).

Conclusion: These data establish an ability of the whole gut to adapt in response to pancreatectomy. The upper intestine (duodenum) become hyperplastic and may be used to improve glucose intolerance by to absorb glucose. The distal intestine (colon) is able to produce glucagon and may participate to the development of the reported hyperglucagonemia.

Introduction:

Endoscopic procedure was necessary in 9.7% of cases. The informed consent (36%) patients. The indications for PEG replacement were obstruction/mal- buried bumper syndrome (0.2%). PEG replacement was carried out in 330 more common modality for sedation (69.8%). The complication and mortality (63.2%) had antiplatelet and/or anticoagulant concomitant therapy.

Results:

Complications and early mortality in PEG were assessed.

References

3. Association of a safety report from the National Patient Safety Agency BMJ 2011;342:d2586
4. We aimed to prospectively evaluate the complication rates and mortality in patients after PEG placement or replacement. This is a multicenter prospective cohort study. Between 15th September 2015 and 15th September 2016, all patients that underwent PEG insertion or replacement, were included. Details about patient’s characteristics, ongoing therapies, comorbidities, indication for PEG placement/replacement, informed consent form signature were collected. Early and late (30 days) complications and mortality were assessed.

Results:

912 patients (426 [46.7%] male) were enrolled in 34 centers. Patients mean age was 72y (SD16.01, range 18-99). ASA status was 1 in 4.0%, 2 in 23.4%, 3 in 58.4%, 4 in 14.1%. PEG 1st placement was performed in 582 (64%) patients. Indications were: dysphagia for neurodegenerative diseases in 33.3%, degenerative neurologic illness in 21.3%, dementia in 14.6%, head and neck cancer in 14.4%, management of patient after the discharge from the hospital in 8.9%, nutritional support in oncological patients in 3.4%, medication administration in 1.5%, gastric decompression in 0.2%. The consent informed consent form was signed by a relative (without legal guardianship) in 49.6%, patient in 28.2%, legal guardian in 16%, medical director in 7% of patients. Thirty-days mortality was 2.4%.

Conclusion:

Our data confirm that PEG placement is a safe procedure with a mortality rate at 30 days of 8%. To our knowledge this is the largest prospective study on the use of PEG. Surprisingly in more than 50% of patients the consent form was not properly signed, leading to possible medicolegal consequences. Moreover, in 9% of the cases PEG was placed for an early discharge (more than for real clinical indication).

P0639 CLINICAL NUTRITION - ARE WE IGNORANT OR NEGLIGENT?
T.M.A. Gan, R. Asokumar, E. Salazar
Gastroenterology And Hepatology, Singapore General Hospital, Singapore
Singapore

Contact E-mail Address: aaron.gan2@mhoh.com.sg

Introduction: Early recognition and delivery of nutritional care by physicians has been shown to improve outcomes in malnourished hospitalized patients. However, physicians encounter multiple barriers in providing appropriate nutrition support. ESPEN guidelines on comprehensive hospital nutrition and nutritional training in medical education have been introduced to overcome these barriers, there appears to be a discrepancy in practice amongst physicians despite the availability of these resources.

Aims & Methods: We aim to assess the knowledge and attitudes of physicians towards clinical nutrition in a large tertiary teaching hospital in Singapore. An anonymous questionnaire comprising 15 multiple-choice questions from standard nutrition textbooks was administered. The questionnaire was designed to

assess (a) recognition of nutritional needs of hospitalized patients, (b) knowledge on the impact of clinical nutrition, and (c) application of nutritional intervention in common clinical practice. We included consultants, fellows and residents working in units where nutritional problems were common. Finally, we conducted a separate 5-question opinion survey to assess each participant’s nutritional training and exposure, based on a 5-point Likert scale ranging from “strongly agree” to “strongly disagree”.

Results: A total of 305 physicians volunteered to participate in this study. Forty (13%) did not reveal their specialty or staff grade and were excluded from analysis. The remaining 265 responders comprised 77 (29%) consultants, 58 (22%) fellows, and 130 (49%) residents. Amongst them, 232 (87%) were from medical disciplines and 33 (13%) from surgical disciplines. The median aggregate score (out of a maximum of score of 15) was obtained by consultants, fellows and residents was 6.0 ± 2.2 (range 2-12), 7.0 ± 1.8 (range 3-11), 7.0 ± 1.8 (range 1-10) respectively. All 3 grades of physicians achieved less than 50% of the maximum possible score. No significant difference in median aggregate score was observed between physicians from medical disciplines (6.5 ± 1.9) and those from surgical disciplines (7.0 ± 1.8). However, gastroenterologists performed significantly better than non-gastroenterologists (median aggregate score 9.0 ± 2.2 vs 6.0 ± 1.8, p < 0.001). In the opinion survey, a majority of physicians (63%) believed that nutrition-related teaching was inadequate during residency training and 44% felt that clinical nutrition was accorded insufficient attention during ward rounds. Only 33% of responders reported that they performed nutritional screening on admission, and a mere 10% were confident in providing nutrition counselling to malnourished patients. Interestingly, their overall performance was not different from that of other participants (see Table 1).

Introduction: Per-oral endoscopic myotomy (POEM) is a novel treatment modality for achalasia cardia (AC). The studies are limited in paediatric population.

Aims & Methods: In this study our aim was to analyse the feasibility, safety and efficacy of per-oral endoscopic myotomy in children We retrospectively evaluate the data of all children (<18 years) who underwent POEM at our institution from September 2013 to February 2017. All POEM procedures were performed under general anaesthesia in an endoscopy suit. Technical feasibility, safety and efficacy were analysed. Clinical success was defined as Eckardt score ≤ 3.

Objective: Paediatric intubating-tubed barium swallow and high resolution manometry were assessed and compared before and after POEM.

Results: Thirty children (15-boys, 15-girls) with mean age of 14.1 ± 3.32 (4–18) years, underwent POEM during the specified period. The sub-types of AC were type 1 (6), type 11 (9) and type III (11). Eight children had prior treatment with pneumatic balloon dilatation. POEM was successfully performed in all children. Anterior myotomy was performed in majority of children 23 (76%). Mean total length of myotomy was 10.9 ± 2.25 cm, with 7.9 ± 2.09 cm on esophageal and
GASTRODUODENAL DISEASE

RESISTANCE IN ARMENIAN CHILDREN WITH

Results:

Hp-associated GDD was diagnosed in 40 patients out of 47: 37 (92.5%) children were resistant to nifuratel. 34 (85%) children were resistant to triple therapy, of whom 25 (60.5%) were resistant to clarithromycin (25%), and 66.6% to doxycycline. All strains were susceptible to metronidazole. Significant improvement of epigastric symptoms and timed barium esophagogram (>50%) was documented in 94.4% of children. At median follow up of 504 days (30-1290) clinical success was noticed in 29 children (96.7%). Mean Eckardt score before and after POEM were 6.8±1.65 and 0.3±0.77, respectively (p<0.0001). Gastroscopy revealed erosive gastroduodenal and phlegal reflux in five children at 1 year (27.8%).

Conclusion:

Disclosure of Interest:

All authors have declared no conflicts of interest.

Introduction: Because of high prevalence of gastric malignancies in the adult population, high Helicobacter pylori (Hp) prevalence in Armenia is suspected. Risks of Hp infection in children and adults lead to decrease of effectiveness of standard eradication therapy [1, 2]. The aim of this study is to determine frequency of Hp antibiotic resistance in Armenian children.

Aims & Methods: 47 children with suspected gastroduodenal disease (GDD), hospitalized in Arabkir MC, were selected from April to December 2016 (23 boys and 24 girls, average age 8.98±4.40). Hp-associated GDD were diagnosed according to clinical, endoscopic and histological criteria.

Antral biopsy was cultured on 3% sheep blood Columbia agar and selective Hp media. Antibiotic susceptibility testing by disk diffusion method was conducted.

Results: Hp-associated GDD was diagnosed in 40 patients out of 47: 37 (92.5%) had gastritis and/or duodenitis, 3 (7.5%) had peptic ulcer disease (PUD). Seven out of 47 children were excluded from the study due to both histology and culture negative for Hp. Thirty-four (85%) were treatment-naïve patients and 6 (15%) had received eradication therapy previously. Main clinical symptoms were recurrent epigastric pain 34 (85%), nausea 28 (70%) and vomiting 13 (32.5%). By endoscopic criteria gastritis and/or duodenitis was seen in 18 (45%), non-erosive gastritis in 16 (40%), PUD in 3 (7.5%), normal mucosa in 3 (7.5%). Rapid urease test was positive in all antral biopsies (100%). Histology showed chronic gastritis and/or duodenitis in 2 (5%), gastric metaplasia of duodenal mucosa in 3 (7.5%), normal mucosa in 2 (5%). Hp was positive in 38 (95%) and negative in 2 (5%). Cultures were positive for Hp in 14 of 40 patients (35%). Susceptibility test was possible in 12 Hp strains from available14: all but 2 were resistant to metronidazole (83.3%), 4 to clarithromycin (33.3%), 3 double resistant to both metronidazole and clarithromycin (25%), and 66.6% to doxycycline. All strains were susceptible to amoxicillin and levofloxacin (100%), 6 strains were tested and found susceptible to rifabutin.

Conclusion: The data indicate a high rate of resistance to conventional triple therapy antibiotics: metronidazole (83.3%) and clarithromycin (33%). High resistance to doxycycline also was seen, despite limited use of this antibiotic in Armenian paediatric practice. High susceptibility to rifabutin might be useful for future treatment of specific eradication schemes for Armenia. High frequency of both erosive and non-erosive gastritis as well as high rate of gastric atrophy and dysplasia in these patients were noticed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0643 FEATURES OF CHRONIC GASTRITIS CAUSED BY CO-INFECTION OF HELICOBACTER PYLORI AND EBSTEIN-BARR VIRUS IN PEDIATRIC PATIENTS

E. Spivak, R. Levit

Pediatric, Medical State University, Yaroslavl/Russian Federation

Contact E-mail Address: spivak88@mail.ru

Introduction: It is known that co-infection of the gastric mucosa with highly pathogenic Hp strains and the Epstein-Barr virus is a risk factor for the development of severe gastritis and Helicobacter pylori–related peptic ulcer disease. However, the characteristics of such co-infection in children are not sufficiently studied.

Aims & Methods: The aim of this study is to estimate the role co-infection of highly pathogenic strains of Helicobacter pylori and Epstein-Barr virus in pediatric patients with chronic Hp-associated gastritis. Methods: 190 children aged 8–16 years were included in the study. All patients had chronic Hp-associated gastritis. All patients underwent clinical and laboratory examinations and endoscopy. Gastric biopsies were taken and inflammation graded according to the Sydney system. Polymerase chain reaction (PCR) was used to detect the presence of Epstein-Barr virus (EBV), Helicobacter pylori (Hp) and its highly pathogenic strains in the gastric mucosa of the patients.

Results: Persistent EBV infection was found in 83 children (43.7%) with chronic gastritis of the antral and (or) gastric body areas. Helicobacter pylori strains that possess the virulence factors (cytotoxin-associated gen A (CagA), vacuolating cytotoxin gen A (VacA), induced by contact with epithelium (IceA), and blood group antigen-binding adhesion (BabA)) were detected in 49 patients (25.8%). In most cases, the association of two or more virulence factors in one patient was observed. It was found that 39 pediatric patients had co-infection of the highly pathogenic strains of Hp and EBV. The study revealed no significant effect of the variant of the gastric mucosa infection on the clinical manifestations of gastritis - the nature of intoxication, abdominal and dyspeptic syndromes. At the same time, the endoscopic and morphological data analysis has revealed a severe gastritis with the development of paragastriatic and Signs of gastric mucosa atrophy observed mainly in the antral region, in patients with co-infection (highly pathogenic strains of Hp + VEBS). In addition, by correlation analysis, we found that the increase and development of the inflammatory process in the gastric mucosa was mostly influenced by the presence of CagA-positive strains of H. pylori in combination with EBV. We found that children infected by EBV without highly pathogenic Hp strains had mild mononuclear and polymorphonuclear cell infiltration without atrophy.

Conclusion: Co-infection with highly pathogenic Hp strains and the Epstein-Barr virus in pediatric patients is significantly associated with severe gastritis.

Disclosure of Interest: All authors have declared no conflicts of interest.
tion rates were significantly higher with sequential treatment (OR = 3.43; p = 0.06 for ITT analysis and OR = 5.30; 95% CI: 0.30–95% CI: 0.30; 95% CI: 0.12–0.77; p = 0.30–95% CI: 0.12–0.77; p = 0.03 for PP analysis). A second-line therapy was recommended in 26 of 134 cases (19.5%) for triple therapy based on MET; 80% (8/9 cases) for triple therapy based on quinolones and 80% (4/5 cases) for sequential therapy.

Conclusion: This endoscopic series reveals a high rate of H pylori infection (77.2%). The sequential therapy achieved a significantly higher rate of eradication than the standard empiric triple regimens regardless of using ITT (78.57% versus 61.53%) or PP (85.93% versus 65.30%) analysis. The eradication rates for the second-line therapy was significantly higher (87.5% for PP analysis) compared to the first-line standard therapy (76.99% for PP analysis).

Disclosure of Interest: All authors have declared no conflicts of interest.

P0645 GUT MICROBIOTA ALTERATIONS UNDER OLIGOFRUCTOSE-ENRICHED INULIN ADMINISTRATION IN PAEDIATRIC COELIAC DISEASE PATIENTS ON A GLUTEN-FREE DIET: RANDOMIZED CONTROLLED TRIAL

U. Krupa-Kozak1, N. Drabinska1, L. H. Markiewicz2, E. Jarocka-Cyrta3
1Department Of Gastroenterology And Nutritional Sciences, Medical University of Warsaw, Poland
2Department Of Internal Medicine, Medical University of Warsaw, Poland
3Department Of Internal Medicine, Medical University of Warsaw, Poland

Introduction: Imbalanced gut microbiota is suggested to be involved in the pathogenesis of coeliac disease (CD). In many CD patients, despite a long-term treatment with a gluten-free diet (GFD), the intestinal dysbiosis is not completely restored. Prebiotics, substances of the unique ability to shape intestinal microbiota, may be used as a non-invasive, low-risk GFD supplement to remedy the intestinal dysbiosis in CD patients.

Aims & Methods: The aim of the present study was to assess the effect of prebiotic oligofructose-enriched inulin (OEI) administration on the quantitative gut microbiota characteristics of CD children following a strict GFD for ≥1 year. A randomized, placebo-controlled 12-week dietary intervention was conducted on 34 CD children (62 % female, mean age 10 years) on GFD who were randomly assigned to prebiotic (OEI: 10 g/day) or placebo group (maltodextrin; 7 g/day). Before (baseline) and after the intervention, the anthropometric (weight, height) and biochemical blood parameters (C-reactive protein, creatinine, aspartate aminotransferase, alanine aminotransferase), quantitative gut microbiota characteristics (by real-time PCR) and concentration of short-chain fatty acids (by gas chromatography with a flame ionization detector) were assessed.

Results: Thirty CD patients completed the study. After 12-weeks intervention, the biochemical blood parameters remained normative in all CD patients, and the gut microbiota counts within each experimental group did not differ from their counts at baseline. However, in comparison with placebo group, Bifidobacterium counts was significantly (p < 0.01) higher in CD children consuming OEI-supplemented GFD. Moreover, the counts of Clostridium leptum group in children of prebiotic group did not show the decreasing tendency along with the time of GFD as observed in placebo group. The changes were reflected into bacterial number after the intervention that was constant in prebiotic group but tended to fall in placebo group. Microbiota counts corresponded well with microbial metabolic activity. In comparison with placebo group, the concentration of short-chain fatty acids was higher in OEI group (50.27 ± 69.95 mg/g, p < 0.05), mainly due to a significantly higher acetate formation (28.82 ± 44.06 mg/g, p < 0.05).

Conclusion: OEI administration significantly improved gut microbiota characteristics in CD patients.

P0646 EVALUATING GLUTEN IMMUNOREACTIVE PEPTIDES AS NON-INVASIVE MARKER OF GLUTEN-FREE DIET ADHERENCE IN PAEDIATRIC CELIAC DISEASE

A. Rodriguez-Herrera1, J. Comino1, V. Segura1, J. Diaz1, A. Muñoz-Suano2, A. Cebull1, C. Sousa2, The Delgado Group3

3Servicio De Analisis Clinicos., Hospital Universitario INGENSA de Ceuta, Ceuta/Spain
4Biomedal, Sevilla/Spain

Introduction: Treatment for celiac disease (CD) is a lifelong strict gluten-free diet (GFD). Patients should be followed-up with dietary interviews and serology as CD markers to ensure adherence to the diet. However, none of these methods
offer an accurate measure of dietary compliance. Presence of gluten related sub- stances in faeces after a gluten-free diet that transit through gastrointestinal tract happened and confirms gluten ingestion.

Aims & Methods: Detection of gluten immunogenic peptides (GIP) in stools as a marker of GFD adherence in CD paediatric patients was evaluated and compared against traditional methods of GFD monitoring. A prospective, non-randomized, multi-centre follow-up study, 2 years long, including 64 CD patients started on GFD when diagnosed (age range 0–18 years).

Fecal GIP was quantified by enzyme-linked immunosorbent assay (ELISA). Anti-tissue transglutaminase (anti-TTG) IgA and anti-deamidated gladin peptide (anti-DGP) IgA antibodies were measured simultaneously, during basal and follow-up visits at 6, 12, and 24 months. Correlations between fecal GIP and serum anti-gluten antibodies were established by Cochran’s and Friedman tests.

Results: 62 patients (97%) had detectable GIP levels in stools, during basal visit, before initiation of the GFD, whereas 20.3% of the patients were found to have positive GIP after treated with a GFD. Dietary transgressions were more frequent in 12% of patients; 3 years of age (p < 0.05).

Conclusion: The GIP ELISA enabled direct and quantitative assessment of gluten exposure early after ingestion. Detection of GIP in stools revealed lack of efficacy of traditional serological methods to verify GFD compliance in CD paediatric patients. The antibodies can be measured several times or even years to decrease after initiation of the GFD and reduction (but incomplete suppression) of gluten intake. The results are consistent with previous studies in sera. Faecal ELISA may be a useful tool: 1) on the diagnosis of CD, to ensure that a sufficient amount of gluten has been ingested to allow a correct CD diagnosis. 2) on treatment, for monitoring of short-term and long-term GFD compliance. 3) on the differential diagnosis of CD versus non-compliance.

Aims & Methods: The aim of this study was to evaluate hepatic FGFR21 and omentin-1 mRNA expression, and their serum levels as predictive markers of liver injury and insulin resistance in morbidly obese women with NAFLD. The study included 56 severely obese women who underwent intraoperative wedge liver biopsy during the bariatric surgery. Hepatic FGFR21 and omentin-1 mRNA was assessed by quantitative real-time PCR, while their serum concentration with commercially available enzyme-linked immunosorbent assays.

Results: FGFR21 serum level was significantly higher in patients with more extent steatosis (grade 2 and 3) compared to those without or with mild steatosis (grade 0 and 1) (p = 0.049). However, ROC analysis showed poor discriminatory power for FGFR21 serum level in differentiation between more and less extensive steatosis with AUC = 0.666. There was evident tendency to higher levels of hepatic FGFR21 mRNA in patients with lobular inflammation and fibrosis, and to lower levels in the case of ballooning degeneration and steatosis. There was positive mutual correlation between hepatic FGFR21 and omentin-1 mRNA levels (r = 0.73; p < 0.001). Fibrosis stage was associated with serum glucose and HOMA-IR (r = 0.03 and p = 0.02, respectively). Serum omentin was not associated with histopathological features. Hepatic omentin-1 mRNA levels exerted the tendency to be lower in patients with advanced steatosis and hepatocyte ballooning.

Conclusion: In conclusion our study, which focused on hepatic FGFR21 and omentin-1 mRNA expression, confirmed a marked expression of both molecules in the liver of morbidly obese patients with NAFLD. mRNA levels were affected by the extent of pathological abnormalities. In the case of maximal extent steatosis was associated with evident change in serum FGFR21 concentration in morbibly obese women with NAFLD. The vast amount of fat, both visceral and subcutaneous in severely obese patients may affect FGFR21 and omentin-1 serum levels. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: CUX1 (CUTL1) is a transcription factor belonging to homeobox proteins. It is responsible for driving the transcription of genes deemed to many cellular functions like proliferation, differentiation and cell death. It has been shown that its role can change and drive tumorigenesis. Up to now, its role is unknown in hepatic stellate cells. 

Aims & Methods: We focused on CUX1 activity in hepatic stellate cells undergoing hypoxic stress. LX-2 cells were treated with 100 ng/ml CoCl2 or kept at 37°C at low oxygen (<0.5%). Expression of CUX1 markers and activation markers was performed by RT-qPCR. Western blotting was performed to analyze the protein level of CUX1 and HIF-1alpha. Transfection with plasmid containing a promoter sequence for HIF-1alpha was performed simultaneously with CUX1 knock-down.

Results: LX-2 cells treated for 6 hours with CoCl2 or low oxygen showed an over-expression or a restoration of COL1A1 and ACTA2 after knock down of CUX1. Additionally, CDKN1A, CDKN1B, VEGFA and HIF1alpha were up-regulated in LX2 cells previously transfected with siCUX1. Protein level of CUX1 was significantly down-regulated, whereas HIF1alpha protein was strongly up-regulated by hypoxic condition. Transcriptional activity of HIF1alpha is not correlated with CUX1 expression.

Conclusion: CUX1 controls the activation of hepatic stellate cells. Its knock down promotes the hypoxia response. CUX1 could represent a key factor for controlling liver fibrogenesis. Its role in a liver fibrosis scenario needs to be further investigated.

P0657 HEPATIC FIBROBLAST GROWTH FACTOR-21 AND OMENTIN-1 mRNA LEVELS IN MORBIDLY OBESSE WOMEN WITH NON-ALCOHOLIC FATTY LIVER DISEASE

Contact E-mail Address: mwaluga@poczta.onet.pl

Introduction: Fibroblast growth factor-21 (FGFR21) and omentin-1 have been recognized as potent antidiabetic agents, with potential hepatoprotective activity. Aims & Methods: The aim of this study was to evaluate hepatic FGFR21 and omentin-1 mRNA expression, and their serum levels as predictive markers of liver injury and insulin resistance in morbidly obese women with NAFLD. The study included 56 severely obese women who underwent intraoperative wedge liver biopsy during the bariatric surgery. Hepatic FGFR21 and omentin-1 mRNA was assessed by quantitative real-time PCR, while their serum concentration with commercially available enzyme-linked immunosorbent assays.

Results: FGFR21 serum level was significantly higher in patients with more extent steatosis (grade 2 and 3) compared to those without or with mild steatosis (grade 0 and 1) (p = 0.049). However, ROC analysis showed poor discriminatory power for FGFR21 serum level in differentiation between more and less extensive steatosis with AUC = 0.666. There was evident tendency to higher levels of hepatic FGFR21 mRNA in patients with lobular inflammation and fibrosis, and to lower levels in the case of ballooning degeneration and steatosis. There was positive mutual correlation between hepatic FGFR21 and omentin-1 mRNA levels (r = 0.73; p < 0.001). Fibrosis stage was associated with serum glucose and HOMA-IR (r = 0.03 and p = 0.02, respectively). Serum omentin was not associated with histopathological features. Hepatic omentin-1 mRNA levels exerted the tendency to be lower in patients with advanced steatosis and hepatocyte ballooning.

Conclusion: In conclusion our study, which focused on hepatic FGFR21 and omentin-1 mRNA expression, confirmed a marked expression of both molecules in the liver of morbidly obese patients with NAFLD. mRNA levels were affected by the extent of pathological abnormalities. In the case of maximal extent steatosis was associated with evident change in serum FGFR21 concentration in morbibly obese women with NAFLD. Introduction: Macrophages play a pivotal role in the pathogenesis of non-alcoholic steatohepatitis (NASH) and are a major component of inflammatory cells infiltrated in NASH. However, the precise mechanism of how macrophages contribute to the pathogenesis of NASH remains unexplored.

Aims & Methods: We aimed to characterize the role and molecular regulators of macrophages in NASH and the therapeutic effects of macrophage depletion on NASH. C57BL/6 wildtype (WT) mice and transgenic LysM-Cre/DTR mice were fed with methionine-and-choline-deficient (MCD) diet for 5 weeks to induce steatohepatitis. Hepatic macrophages were depleted in WT mice by injecting liposomal clodronate (i.p. 50 mg/kg/week) and in LysM-Cre/DTR mice by injecting diptheria-toxin (DTox) (i.p. 100 mg/mice). Primary macrophages were isolated from bone marrow of WT mice. For the in vitro study, mouse immortalized hepatocytes AML-12 were cultured with primary macrophage conditioned medium and mouse primary macrophages were cultured with AML-12 hepatocytes conditioned medium to evaluate the interaction between macrophages and hepatocytes in steatohepatitis. A series of assays including cytokine profiling assay, DNA binding activity, flow cytometry and Western blot were performed.

Results: Hepatic macrophage marker CD68 expression was significantly higher in human NASH patients compared with normal controls (P < 0.001). Steatohepatitis was established in WT mice and LysM-Cre/DTR mice fed MCD diet, concomitant with significantly enhanced hepatic macrophage infiltration as indicated by F4/80 staining. Macrophage depletion by liposomal clodronate or DTox attenuated steatohepatitis in both animal models. This was also associated with reduced hepatic necroinflammation, oxidative stress, hepatic triglyceride accumulation, and secretion of pro-inflammatory cytokines in both liposomal clodronate-treated WT mice and DTox-treated LysM-Cre/DTR mice as compared to the corresponding control mice. Macrophage depletion was also accompanied by the reduction of neutrophils, which together can reduce inflammation. Upregulated macrophages were associated with the increased expression of hepatic pro-inflammatory cytokines including interleukin (IL)-1α, IL-1β, IL-12, IL-17, granulocyte-macrophage colony-stimulating factor, Monocyte chemotactant protein-1 (MCP-1) and macrophage inflammatory protein 1α (MIP-1α), and the activation of NF-κB and JNK signaling pathways in the liver. Macrophage-induced steatosis was mediated by increased hepatic lipogenesis and decreased hepatic lipolytic genes (P < 0.01), TGFβ (p < 0.05) secretion in the cultured HSCs' supernatant in different degree by the ELISA assay, and RT-PCR results revealed that Loureirin B down-regulated the expressions of F4/80 and α-SMA genes in the level of mRNA.

Conclusion: The Loureirin B mediated anti-hepatic fibrosis through repressing the Wnt signaling pathway. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is considered the hepatic manifestation of metabolic syndrome, with simple liver steatosis being capable of gradually progressing to inflammation, fibrosis, cirrhosis and even hepatocellular carcinoma. Still, disease pathogenesis is complex and no targeted therapies have yet been approved for NAFLD. Bile acids (BAs) constitute a wide class of steroid molecules with pleiotropic functions, contributing to the homeostasis of lipids and glucose. In the liver, they specifically modulate nuclear receptors from the NR1 subfamily, such as Farnesoid X Receptor (FXR) and Liver X Receptor (LXR), thus tightly regulating bile acid synthesis and oxidation and storage of triglycerides.

Aims & Methods: Our aim was to screen BA derivatives for their potential to selectively activate FXR, thus protecting liver cells against free fatty acid (FFA)-induced lipid accumulation and lipotoxicity. Nineteen novel BA derivatives were analyzed in a in silico molecular docking study for FXR and LXR activation, followed by evaluated in human cells using a FXR reporter assay. Assessment of FXR-dependent gene and protein expression was analyzed upon incubation of primary mouse hepatocytes and HepG2 cells with selected BA derivatives. In parallel, BA derivatives were co-incubated with oleic and palmitic acids (2:1) for assessment of cellular cytotoxicity and intracellular lipid accumulation.

Results: From the compound library, five BA derivatives showed stronger activation of FXR, comparing with their natural precursors. Incubation of HepG2 cells with FFAs led to a ~25% reduction in cell viability and ~55% increase in cell death, with a dose-dependent accumulation of lipid droplets. Pre-incubation of cells with selected derivatives efficiently prevented FFA-induced cell death and lipid accumulation. Finally, incubation of both HepG2 cells and primary mouse hepatocytes with BA derivatives strongly induced FXR, RXR, SHP, BSEP, FGFR19 and VLDLR mRNA levels, and repressed PARP1, LXR, SREBP-1c and CYP7a1 mRNA expression. Molecular docking studies and FXR reporter assays confirmed ligand affinity to FXR. Furthermore, chenodeoxycholic acid (CDCA) and related fatty alcohol-based derivatives were shown to be active activators of FXR at lower concentration compared with the parent molecule.

Conclusion: In conclusion, we identified novel BA derivatives that directly modulate liver nuclear receptors, such as FXR and LXR, thus protecting liver cells against lipotoxicity. New biomedical applications of these new molecules may be used as scaffolds for the development of targeted therapies for NAFLD.

Introduction: NAFLD is currently classified in non-alcoholic fatty liver (NAFL) and non-alcoholic steatohepatitis (NASH). It is a liver disease related to metabolic syndrome with rising socio-economic impact worldwide. NAFLD is defined by significant lipid deposition in hepatocytes that is unrelated to alcohol consumption. This high prevalence of liver disease occurs after a protracted inflammation, fibrosis and eventually cirrhosis. This disease is considered a manifestation of fructose-rich foods as shown by the multi-parallel hit theory. Autophagy is a self-digesting mechanism that helps the cells to overcome stress conditions derived by nutrient deprivation and massive storage, e.g. lipid and proteins. Autophagy dysfunction has been implicated in lipid accumulation related diseases. Up to now, it is yet fully understood the role exerted by autophagy in liver diseases not related to alcohol.

Aims & Methods: Here, autophagy has been analyzed in a mouse model of NAFL/NASH and in human in vitro model. Liver specimens were collected from 24 weeks old FLS and FLS-ob/ob mice. Liver tissue was snap frozen and kept at –80°C. RNA and proteins were isolated. RT-qPCR and western blotting was performed. HepG2 cells were incubated for 24h with 2mM oleic acid (OA) (HSCs), which were separated from Sprague-Dawley rat, were treated with different concentrations of Loureirin B. MTT assay was employed to determine HSCs proliferation, western blot was used to test the expressions of Frizzled-4 receptor protein and α-SMA. In addition, enzyme-linked immunosorbent assay (ELISA) was performed to measure the content of α-SMA, TGF-β1 and VEGF in the cultured HSCs' supernatant, and reverse-transcription PCR (RT-PCR) were utilized to detect the expressions of Frizzled-4 and α-SMA genes.

Results: MTT test showed that the proliferation of HSCs was inhibited significantly with a time and dose dependent relationship by the treatment of Loureirin B and liposomal clodronate, and dosedependent inhibition of Liposomal clodronate (IC_{50} = 0.1808g/L). Western blot analysis showed that the expressions of Wnt receptor protein and α-SMA were obviously lower in the group of Loureirin B treatment than that in the control group. Moreover, the Loureirin B and liposomal clodronate inhibited approximately 50% of p62/SQSTM1 (p < 0.05) secretion in the cultured HSCs' supernatant in different degree by the ELISA assay, and RT-PCR results revealed that Loureirin B down-regulated the expressions of Frizzled-4 and α-SMA genes in the level of mRNA.

Conclusion: The Loureirin B mediated anti-hepatic fibrosis through inhibiting the proliferation of HSCs through repressing the Wnt signaling pathway. Disclosure of Interest: All authors have declared no conflicts of interest.

Results: FLS-ob/ob mice, representing a NASH mouse model, showed an over-expression of markers BECN1, MAP1LC3B, SQSTM1, UVRAG, TFE2B, PRKAA_1_1 and PRKAA_2_2 in comparison with FLS mice that represent the NAFL model. Furthermore, the protein level of BECN1 and MAP1LC3B was down-regulated in FLS-ob/ob mice, whereas SQSTM1 and UVRAG were up-expressed. Interestingly, the phosphor forms of AMPKα2 was found up-regulated in FLS-ob/ob mice, while FLS mice did not show a quantifiable expression of P-AMPKα2. AMPKα2 was found stably expressed in both FLS-ob/ob and FLS mice. HepG2 cells treated with oleic acid showed a down-regulation of BECN1, MAP1LC3B, UVRAG and SQSTM1 proteins. AMPKα2 and its phosphorylated form resulted unvaried. Interestingly, Caffeine treatment caused a stronger reduction of autophagy markers, including the reduction of P-AMPKα2 also. The combination of Caffeine and OA had the most effect compared to single compounds by causing a stronger reduction of autophagy markers protein level. Baflomycin caused a reduction of MAP1LC3B and UVRAG only. Its combination with OA caused a stronger reduction of protein level. HepG2 MAP1LC3B-GFP-RFP showed an increase of red fluorescence after 48 h of treatment with 2 mM OA.

Conclusion: Autophagy mechanism is significantly activated in FLS-ob/ob mice, that lack of Leptin expression, and in HepG2 treated with OA, supporting that autophagy is strongly implicated in NASH. Targeting autophagy could represent a valid future therapeutic strategy for patients affected by NASH. Further studies are needed to better understand the role exerted by Leptin during autophagy in NASH.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Non-alcoholic fatty liver disease (NAFLD) pathogenesis associates with intracellular lipid accumulation in the liver. In addition, recent evidence supports a functional role for both mitochondrial dysfunction and microRNAs (miRNA/miRs) in NAFLD pathogenesis. In particular, deregulation of mitochondrial dynamics proteins, like mitofusin-2 (Mfn2) is frequently observed in obese and diabetic patients.

Aims & Methods: Our aims were to profile global liver miRNA expression changes during NAFLD progression and correlate them with the development of simple steatosis or NASH. mRNA quantification in both experimental and human NAFLD, C3Bl/B6 mice were fed either a standard or a fast food (FF) diet for 25 weeks; or a methionine- and choline-deficient (MCD) diet for 2 and 8 weeks. miRNA profiling was performed using liver RNA from 8 weeks MCD-fed mice, in TigaMan MicroRNA arrays. qPCR array data was analyzed using the HTqPCR package in Bioconductor. Liver biopsies were obtained from patients with simple steatosis or NASH. mRNA and protein expressions were analyzed by qRT-PCR and immunoblotting, respectively. miRNA targeting was evaluated by dual-luciferase reporter assays.

Results: Both FF- and MCD-fed mice developed NAFL-like features, including liver steatosis, inflammation and insulin resistance; as well as progressive steatohepatitis, severe liver damage and fibrosis. Strikingly, liver Mfn2 protein levels significantly decreased in both models (p < 0.05). Inversely, expression of Drp1, a mitochondrial fission protein, was found increased (p < 0.05). Other mitochondrial proteins, such as the voltage-dependent anion channel (VDAC), presented no expression changes. In human patients, Mfn2 protein levels decreased from no expression changes. In human patients, Mfn2 protein levels decreased from no expression changes. In human patients, Mfn2 protein levels decreased from no expression changes. mononuclear layer containing stem cells is a novel approach for regeneration of liver cells which can be a therapeutic option for those patients.

Aims & Methods: To determine the outcome after intrasplenic or intrahepatic injection of autologous bone marrow stem cells (ABMSC) transplantation in patients with liver cell failure secondary to chronic hepatitis C infection. Sixty chronic hepatitis C patients with liver cell failure were prospectively enrolled. They were classified into 3 groups; group I: 20 patients underwent (ABMSC) injection intrasplenic. Group II: consisted of 20 patients underwent (ABMSC) injection intrahepatic; after trans differentiation into hepatocytes with the double amount of growth factor. Group III: consisted of 20 patients underwent (ABMSC) injection intrahepatic and peritoneal after trans differentiation into hepatocytes with regular amount of growth factor. Group Ib: 10 patients underwent (ABMSC) injection intrahepatic after trans differentiation into hepatocytes with regular amount of growth factor. Group IIb: 10 patients underwent (ABMSC) injection intrahepatic after trans differentiation into hepatocytes with the double amount of growth factor. Group IIIb: (Control Group); consisted of 20 patients received treatment for chronic hepatitis C (MetS). The aim of this study was to determine how much impact the risk factors of metabolic syndrome has on ultrasonographic fatty liver, especially NAFLD.

Aims & Methods: A total of 41,258 adults who underwent routine comprehensive health checks, including abdominal ultrasonography, were selected. We calculated the adjusted prevalence ratios (PRs) for components of MetS (high blood pressure (BP), impaired fasting glucose, low-high density lipoprotein cholesterol (HDL-C), and high triglycerides) according to NAFLD.

Results: NAFLD was found in 13.8% of non-obese subjects and 52.3% of obese subjects. NAFLD was associated with most components of MetS in both obese and non-obese subjects. However, non-obese NAFLD patients had significantly higher PRs for certain components of MetS than did obese patients, especially among women. Body mass index, waist circumference, fasting blood glucose, triglyceride, HDL-C and aspartate aminotransferase, alanine aminotransferase, γ-glutamyl transpeptidase levels all affected NAFLD independently. The prevalence of metabolic syndrome was increased in mild (40.8%) and moderate (57.8%) NAFLD groups. When odd ratio (95% CI) for NAFLD group was compared to the contrast group, there was an increased risk of metabolic syndrome with odd ratio of 12.8 (95% CI, 9.1–17.0).

Conclusion: NAFLD and its components has a close association with MetS and also with each risk factors of MetS. Therefore, assessment for concurrent MetS among NAFLD patients is considered to be necessary.

P0667 LEAN-NAFLD IS THE STRONGEST PREDICTOR OF FUTURE OBESITY AMONG URBAN ADULT SRI LANKANS: RESULTS FROM A PROSPECTIVE, COMMUNITY COHORT FOLLOW-UP STUDY

Faculty of Medicine, University of Kelaniya, Ragama/Sri Lanka

National Center for Global Health and Medicine, Tokyo/Japan

Contact E-mail Address: maduniln@yahoo.co.uk

Introduction: Obesity is a global problem. Data from the South Asian region is limited.

Aims & Methods: In a cohort follow-up study we investigated obesity from urban, adult, Sri Lankans [selected by age-stratified random sampling from Ragama-MOH area, Gampaha District; initial screening 2007 (aged 35–64 years); re-evaluation 2014 (aged 42–71 years)]. On both occasions structured interview, anthropometry, liver ultrasound, biochemical and serological tests were performed. Total body fat (TFB) and visceral fat percentage (VFP) were assessed by impedance in 2014. General obesity (GO) was BMI >25 kg/m². Central-obesity (CO) was waist circumference (WC) >80 cm males and >90 cm females. Non-alcoholic fatty liver disease (NAFLD) was diagnosed on ultrasound criteria, safe alcohol consumption and absence of hepatitis B/C markers. Multinomial logistic regression was fitted to assess associations.

Results: In 2007 (n=2967), 614(20.7%) were overweight [51.9%-women] and 1584(53.4%) were obese [71%-women]. In a cohort follow-up study we investigated obesity among urban adult Sri Lankans: results from a prospective, community cohort follow-up study.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0668 THE USE OF THE FATTY LIVER INDEX TO DETERMINE THE PREVALENCE OF FATTY LIVER DISEASE (HEPATIC STEATOSIS) IN AN IRISH POPULATION

L. Reynolds, L. Rabbitt, C. Goulding
Acute Medical Unit, University Hospital Galway, Galway/Ireland
Contact E-mail Address: lauraj3reynolds@gmail.com

Introduction: Worldwide, the prevalence of fatty liver disease (FLD) is increasing, particularly in countries with rising obesity rates, such as Ireland. Studies suggest that up to 25% of those with FLD can progress to non alcoholic steatohepatitis (NASH) and be at risk of its sequelae, including cirrhosis and hepatocellular carcinoma. Indeed, NASH is now the second most common indication for liver transplantation in the US. Despite this alarming data, there is no prevalence data for Ireland in relation to FLD.

Aims & Methods: We aimed to use a simple screening tool, the Fatty Liver Index (FLI) to identify those at risk of having fatty liver disease (FLD) amongst all comers presenting to an Acute Medical Unit (AMU) and to use this data as an indicator of prevalence of FLD in Ireland.

Methods: In this prospective cohort study, all patients attending the Acute Medical Unit (AMU) were invited to take part. Their height, weight and waist circumference were measured, and triglycerides (TG) were added to their ‘routine AMU blood panel’, which also included measurement of gamma glutamyl transferase (GGT). Exclusion criteria were as follows: known liver disease, excess alcohol intake (>17 units per week for males, >11 units per week for females), age <18 years, pregnancy, active malignancy. The Fatty Liver Index (FLI), an algorithm based on Body Mass Index (BMI), waist circumference, TG and GGT was used to stratify patients into groups based on risk of having FLD. A FLI score of >60 is highly suggestive of having FLD, a score of 30-60 is indeterminate and a score of <30 is considered low risk for FLD. Ethical approval for this research was granted by the ethics committee of AMU.

Results: Data was completed on 316 participants; 58 were excluded, the majority due to either a history of alcohol excess or known liver disease. A total of 258 participants were therefore evaluated; 50% were male. One hundred and sixteen (45%) of participants were >60 on the FLI; 57.3% of which were male. Only 16% of males had a FLI <30, compared with 44% of females. Males had a significantly higher FLI than females; 60.9 vs. 43.12 (p = 0.0001). Those with a FLI >60 had a mean weight = 93.5 kg and BMI = 31.5, vs. 64.9 kg and 22.4 respectively for FLI <30 (p = 0.0001). There was a statistically significant difference in all parameters measured between all 3 groups (p < 0.0001), apart from height, although there was a trend toward lower height in the FLI <30 group, most likely due to the fact that it was 73% female. When overweight and obese were looked at, there was no height difference between the 3 groups. Those with a FLI >60 were older than those with FLI <30. 54.6 vs. 48 (p = 0.01).

Conclusion: In this study looking at prevalence of fatty liver in Ireland, 45% of participants were found to be at high risk, and 70% were at high or indeterminate risk. Worryingly, only 16% of males fell into the low-risk group. Apart from weight, GGT, TG and BMI this study also showed age and male sex to be significant risk factors for developing fatty liver. This group clearly needs follow up to further evaluate and manage their fatty liver.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0669 ROLE OF BISPHENOL A AS AN ENVIRONMENTAL FACTOR IN THE PROMOTION OF NON-ALCOHOLIC FATTY LIVER DISEASE (Hepatic Steatosis) in an Irish Population

C. Loguercio1, A. Federico1, A. G. Gravina1, M. Masarone2, S. Errico3, C. Nicolucci3, R. D. Introduction: Bisphenol A (BPA) is an endocrine disrupting chemical, a heterogenic group of chemicals usually found in food packaging or insecticide residues on vegetable crops, associated with type 2 diabetes mellitus (T2DM), cardiovascular disease and altered liver enzymes abnormalities, and in general with the whole blood glucose homeostasis.

Aims & Methods: We have evaluated BPA plasma and urine levels in non-alcoholic fatty liver disease (NAFLD) patients compared to healthy subjects and we evaluated the possibility to eliminate this environmental factor after a BPA-free diet regimen. Furthermore, we evaluated, in human HepG2 cells, the effects of exposure to different BPA concentrations on both oxidative stress induction and cell proliferation. We enrolled 60 patients with histologic diagnosis of NAFLD with or without T2DM, before a BPA-free diet, and healthy subjects, by subjecting them to evaluation of body composition using bioimpedance analysis. In vitro, the proliferation of BPA-exposed HepG2 cells at two different concentrations (0.025 and 0.05 mM) was evaluated, both at high (H-HepG2), in order to simulate human hyperglycemia, and at low (L-HepG2) glucose concentrations, for the potential hypoglycemic effect prescribed by T2DM patients.

Results: BPA levels were significantly higher in 60 NAFLD subjects, both in urine and in plasma (p < 0.0001) if compared to controls and, among this group, it appeared to be higher in 30 non-alcoholic steatohepatitis (NASH) patients compared to 30 simple steatosis (NAFL) ones (p < 0.05), independently from the presence of T2DM. After following a BPA-free diet for one month, NAFLD patients showed a significant reduction of BPA circulating levels (p < 0.05) without a significant reduction of urine levels, which represents the only way to eliminate BPA amount released into circulation by the food reservoir. In fact subjects with a higher fat percentage in body composition showed higher BPA levels in plasma and urine. In our population study, NASH patients showed a higher fat percentage in body composition in comparison with NAFL patients. BPA increased TBARS levels at 48 h in H-HepG2 cells versus controls.

Conclusion: Our study reveals a possible role of BPA as an environmental factor in the progression of NAFLD, particularly in obese and/or T2DM patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0670 ASSESSMENT OF FATTY PANCREAS IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE

Introduction: The clinical implications of non-alcoholic fatty pancreas disease (NAFPD) are still the topic of debate in human studies. It has been shown that fatty infiltration in pancreas correlates with metabolic risk factors and may represent significant manifestation of metabolic syndrome (MeS) in association with nonalcoholic fatty liver disease (NAFLD). The aim of our study was to determine the association of fatty pancreas (FP) in NAFLD patients with features of MeSand to determine a simple new noninvasive scoring system for FP prediction in NAFLD patients.

Aims & Methods: We conducted across-sectional study that included 143 subjects with NAFLD classified into two groups according to the severity grade of FP as follows: patients with non fatty pancreas and grade I light FP (n = 59) and patients with grade II severely and grade III highly FP (n = 84). Patients were analyzed for diagnostic criteria of MeS, underwent sonographic examination with adiposity measurements and liver biopsy. Liver fibrosis was evaluated semi-quantitative according to the META VIR scoring system and using non-invasive markers of hepatic fibrosis (NAFLD fibrosis score (NFS), BARD score, FIB4 score, NASH fibrosis score), for the prediction of MeS. In our study all patients were divided into two groups: 1. patients with NAFLD and NAFPD. Neither NAFLD non-invasive markers nor histological findings, NASH or MeS were significantly different between non fatty pancreas and grade I light FP patients. 2. patients with NAFL and NAFPD. Both groups were compared with grade I light FP patients. Only group with severely FP showed a higher fat percentage in body composition in comparison with non fatty pancreas in our study cohort. In multivariate analysis of FP predictors in our study cohort, logistic regression approach was used. Model of predicting occurrence of FP was designed from multivariate logistic regression analysis. The probability was estimated with the equation: 0.627 + 0.640 * 0.593 * glucose (fasting glucose level) – cholesterol level + 0.016 * triglycerides / cholesterol + 0.071 * serum lipase / triglycerides + 0.068 * serum glucose/insulin ratio + 0.015 * serum glucose/creatinine. In multivariate analysis of FP predictors in our study cohort, logistic regression approach was used. Model of predicting occurrence of FP was designed from multivariate logistic regression analysis. The probability was estimated with the equation: 0.627 + 0.640 * 0.593 * glucose (fasting glucose level) – cholesterol level + 0.016 * triglycerides / cholesterol + 0.071 * serum lipase / triglycerides + 0.068 * serum glucose/insulin ratio + 0.015 * serum glucose/creatinine.

Results of our study determined highly significant association of NAFLD and NAFPD. Neither NAFLD non-invasive markers nor histological reports of liver fibrosis showed significant association with presence of fatty pancreas. In multivariate analysis of FP predictors in our study cohort, logistic regression approach was used. Model of predicting occurrence of FP was designed from multivariate logistic regression analysis. The probability was estimated with the equation: 0.627 + 0.640 * 0.593 * glucose (fasting glucose level) – cholesterol level + 0.016 * triglycerides / cholesterol + 0.071 * serum lipase / triglycerides + 0.068 * serum glucose/insulin ratio + 0.015 * serum glucose/creatinine.
with use of antidiabetic agents and the absence of highly fatty pancreas, indicating its potential protective role. Simple noninvasive scoring system was designed from multivariate logistic regression analysis to estimate the occurrence of severely FP in NAFLD with best ability in the prediction in score values above 6.5.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a rapidly growing disease worldwide. The pathogenesis of NAFLD is not well recognized. Thyroid is totally involved in regulation of lipid and carbohydrate metabolism, body weight, and energy homeostasis. Therefore, the role of thyroid hormones in pathogenesis of hepatic steatosis is anticipated.

Aims & Methods: This study aimed to investigate thyroid hormone abnormalities in euthyroid subjects with hepatic steatosis. A cross sectional study was conducted between September 2012 and September 2015 at Namazi hospital, Shiraz, Iran. Study subjects were healthy individuals who had undergone liver biopsy in hospital liver histology. They were divided into two groups: 250 subjects of T and Q groups. After liver transplantation, Liver function tests, age, gender, weight, height, fasting plasma glucose, thyroid hormones, and lipid profile were recorded. Liver biopsy specimens were reviewed by an expert pathologist individually.

Results: A total of 210 individuals (130 women and 80 men) were included. Seventy six individuals (36.19 %) had hepatic steatosis and 19 individuals had steatohepatitis. Individuals with a history of chronic disease, hepatitis B or C infection, hepato-billiary cancers, those with > 20 grams/day alcohol consumption, and individuals receiving medications causing hepatic steatosis were excluded from the study.

Results: A total of 210 individuals (130 women and 80 men) were included. Seventy six individuals (36.19 %) had hepatic steatosis and 19 individuals had steatohepatitis (9.04 %) in liver histology. Mean age of individuals with and without hepatic steatosis were 32.9 ± 6.69 and 31.8 ± 6.72 years respectively (P < 0.05).

In univariate analysis higher weight, triglyceride, total cholesterol, alanine aminotransferase (ALT), alkaline phosphatase, fasting blood sugar (FBS) and thyroid stimulating hormone (TSH) were associated with hepatic steatosis (P < 0.05). In regression analysis, higher FBS, higher alkaline phosphatase, higher ALT and higher TSH (OR = 1.36; 95 % CI: 1.02–1.80, P < 0.03) were independent predictors of hepatic steatosis. In regression analysis, higher serum TSH was independently associated with steatohepatitis compared to those without steatohepatitis (6.83 ± 6.04 mIU/L and 2.10 ± 1.27 mIU/L) (OR = 2.11; 95 % CI: 1.45–3.07, P < 0.001). A cutoff value of 3.75 mIU/L for TSH was predictor of presence of steatohepatitis in liver biopsies (sensitivity = 73%; specificity = 89%; AUC = 0.754; P < 0.004).

Conclusion: Higher serum TSH is associated with hepatic steatosis and steatohepatitis in euthyroid subjects. Thyroid hormones may have crucial role in hepatic steatosis and may be targeted for treatment of NAFLD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Glucosidase II is part of the functional pathway of co-translational protein translocation and maturation in the endoplasmic reticulum. It is implicated in autosomal dominant polycystic liver disease (ADPLD) and autosomal dominant polycystic kidney disease (ADPKD). The β-subunit of glucosidase II, encoded by GANAB and PRKCSH, has been identified as one of the causative genes of ADPLD. Recent data suggest that the α-subunit of glucosidase II (Glua), encoded by GANAB, is associated with ADPKD and ADPLD. We aimed to identify GANAB mutations in an independent cohort of patients with the primary phenotype of polycystic liver disease (PLD) and to predict the influence of these mutations on glucosidase II function.

Aims & Methods: We identified genetic mutations in GANAB using molecular inversion probe (MIP) analysis in a cohort of PLD patients. Both patients with ADPKD and ADPLD were included for analysis. Mutations identified with MIP analysis were validated using Sanger sequencing. Bioinformatics prediction tools (PolyPhen-2, Align GVGD, SIFT, MutationTaster) were used to predict the functional significance of the mutations. YASARA&WHAT IF were used for analysis of the structural effects of the mutations. Primary cholangiocytes obtained from a patient with GANAB mutation (c.2515C > T) were used to study loss of heterozygosity.

Results: We identified and validated 6 new bona fide GANAB mutations in 7 different families. These are 2 frameshift (c.687delT and c.11_16delTACGGG), 1 splicing (c.2691-28C > G), 2 nonsense (c.250C > T and c.256C > T) and 1 missense (c.1835G > C). In silico analysis showed c.687delT and c.11_16delTACGGG are located in N-terminal domain of the protein. These mutations probably lead to a total defective protein. c.1835G > C is located in the active site of the protein. It is predicted to disrupt the composition of the active site and reduce enzymatic activity. The remaining mutations (c.2691-28C > G, c.250C > T and c.256C > T) are located in C-terminal domain, which interacts with PRKCSH. The mutations could result in early termination of this domain. It is speculated this disrupts the ability of the two subunits to interact. Western Blot showed no differences in Glucose expression in an ADPKD patient with GANAB mutation c.2515C > T compared to primary cholangiocytes obtained from a patient without PLD. This indicates in this patient no loss of heterozygosity occurs in cholangiocytes lining the hepatic cysts.

Conclusion: We describe six novel GANAB mutations that can cause PLD in a mixed population of ADPKD and ADPLD patients. These mutations are found in functionally important domains of α-subunit of glucosidase II, which may lead to impaired enzymatic activity of the complex. In contrast to other PLD related genes no loss of heterozygosity was found for GANAB in cyst epithelium.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In patients with morbid obesity, dietary treatment and physical activity are the first line of treatment, but if not responding, bariatric surgery is typically considered as the second line intervention. The main surgical procedures are the gastric bypass (G) and sleeve gastrectomy (SG) and gastric bypass (GBP), and they are choices in function of BMI, age and comorbidity. Both techniques have proven effective in weight loss. It is known that liver fibrosis evaluation with Point Shear Wave Elasticography (pSWE) is sufficient in these patients.

Aims & Methods: To study the difference between SG and GB and their impact on main clinical and laboratory hepatic metabolic indicators and scores 6 and 12 months after the intervention and pSWE at 12 months. We studied 68 obese subject candidate to bariatric surgery (45 female, 23 male). 28 underwent GBP and 40 SG. Blood tests, physical examination were assessed before surgery, after 6 months (68 patients) and after 12 months (51 patients) and pSWE after 12 months.

Results: In the comparison between GBP vs SG there was a statistically significant difference in the reduction in Fatty Liver Index (61% vs 37%, p = 0.015), waist circumference (26% vs 18%, p = 0.045), BMI (34% vs 28%, p = 0.016), total cholesterol (23% vs 0.05%, p = 0.001), ALT (increased by 15% in GBP, decreased by 27% in SG, p = 0.023) while no differences were observed in the other indicators considered. Ferritin level increased (52%) in SG and decreased (25%) in GBP (p = 0.02). No difference was observed for pSWE.

Conclusion: This study showed some significant differences in clinical and laboratory terms between the two types of intervention, in fact GBP seems to have a more powerful effect on weight loss and all related markers: all steatosis scores (FLI, HSI, LAP), BMI, waist circumference. This can be explained by better malabsorptive effect of this intervention and by a lower BMI starting point for reasons related to the intervention technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Polycystic liver disease (PLD) occurs in the setting of 2 different genetic disorders: autosomal polycystic liver disease (ADPLD) and autosomal polycystic kidney disease (ADPKD). These patients may develop hepaticomegaly as a result of multiple fluid-filled cysts. It is unclear whether PLD severity differs between ADPLD and ADPKD. Height adjusted liver volume (htTLV) reflects with symptomatic disease and diminished quality of life. We assessed hepaticomegaly with htTLV, as an objective parameter, in a large cohort of ADPKD and ADPLD patients

Aims & Methods: PLD patients, defined by >10 liver cysts on radiological imaging, were included in the international PLD registry. The cases were identified from clinical records at the University Leuven (Belgium), Seoul National University Hospital (South Korea) and Radboud University Hospital Nijmegen (the Netherlands). In a cross-sectional analysis, we selected patients for whom height adjusted total liver volume was measured prior to liver reducing therapy. We performed univariate and multivariate analyses to explore risk factors associated with severity of disease.

Results: Out of a total 1674 patients in the PLD registry, 1222 patients (1110 ADPKD, 112 ADPLD) could be selected. In the ADPKD > PLD group height adjusted liver volume is significantly lower compared with ADPLD patients (1050 ml/m vs 1922 ml/m; p = 0.000). Females have higher htTLV than men in both ADPLD and ADPKD. Severe height difference (htTLV > 3.200 ml/m) is more prevalent in ADPLD. Diagnosis, gender and age are independent predictors for severity of disease.

Conclusion: In this cohort more ADPLD patients had moderate to severe PLD compared to ADPKD patients. The severity of the disease is strongly associated with ADPLD and ADPKD patients and to identify new risk factors.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0675 CARDIOVASCULAR RISK DEVELOPMENT MODEL FOR THE (ATYPICAL) PATIENT WITH NON-ALCOHOLIC FATTY LIVER DISEASE

Introduction: Nonalcoholic fatty liver disease (NAFLD) affects about 1 billion people worldwide. Those with non-alcoholic steatohepatitis (NASH) among NAFLD patients have increased mortality rates compared to the general population, with cardiovascular diseases being the leading cause of death. Identifying patients at risk for developing cardiovascular events is of major importance, both in terms of prognosis, as in terms of the therapeutic attitude.

Aims & Methods: Our aim was to quantify the risk of developing atherosclerosis as a major cardiovascular risk factor, in NAFLD patients and to identify a screening strategy for those patients. We included patients with NAFLD and metabolic syndrome (MS) into 2 arms: with NAFLD and MS, and with NAFLD without MS. NAFLD diagnosis was based on clinical, biological and ultrasound determinations. We used FibroMax for evaluating the hepatic modifications (presence of steatosis and fibrosis). We have used the Collagen Proportion Area (CPA) computed by the software which was annotated manually using the NDP.view2 to facilitate machine learning. Each image was then analysed by the automated software, fat percentage (fat%) and Collagen Proportion Area (CPA) computed by the software were compared with the manual annotation. They were also correlated with LSM and CAP.

Results: There was an excellent concordance between manual and automatic measurements, with inter-class correlation coefficient, ICC = 0.98, (95%CI = 0.96-0.99, p = 0.0001). There was good correlation between fat% and steatosis grade, but with significant overlap between groups. Results were significantly higher CPA and fibrosis stage. LSM was significantly associated with CPA (Rho = 0.8, p = 0.001).CAP score correlated significantly with fat% (Rho = 0.45, p = 0.002) and effectively diagnosed steatosis > 5% (AUROC 0.82, 95% specificity, 60% specificity), but could not distinguish between grades.

Conclusion: We have developed and validated a system using automated software, using low-resolution images to provide a rapid, easily performed, objective assessment of steatosis and fibrosis in NAFLD, with excellent correlation with experts’ annotation. Objective measures would be helpful in the assessment of therapeutic response in clinical practice and in clinical trials for patients with non-alcoholic fatty liver disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0676 DEVELOPMENT AND VALIDATION OF AN AUTOMATED SYSTEM FOR ASSESSMENT OF LIVER STEATOSIS AND FIBROSIS IN ROUTINE HISTOLOGICAL IMAGES FROM PATIENTS WITH NAFLD

Introduction: Liver biopsy is the reference standard for diagnosing and staging non-alcoholic fatty liver disease (NAFLD). Steatosis grade and fibrosis stage are typically reported using semi-quantitative scores. Inter-and intra-observer variability in the current scoring systems may impact upon histological staging, and consequently upon the interpretation of responses to interventions in clinical trials.

Aims & Methods: We developed an automated method for steatosis and fibrosis quantitation using biopsies of NAFLD patients. We further validated Liver Stiffness Measurements (LSM) and controlled attenuation parameter (CAP) in this group, using quantitative assessment as reference. 246 consecutive patients with biopsy-confirmed NAFLD and transient elastography within 3 months of the biopsy were evaluated. Biopsies were independently scored by two histopathologists and digitalised at 2x magnification. Areas of steatosis and fibrosis were annotated manually using the NDP.view2 to facilitate machine learning. Each image was then analysed by the automated software. Steatosis grade and fibrosis stage have been compared with the manual annotation. They were also correlated with LSM and CAP.

Results: There was an excellent concordance between manual and automatic measurements, with inter-class correlation coefficient, ICC = 0.98, (95%CI = 0.96-0.99, p = 0.0001). There was good correlation between fat% and steatosis grade, but with significant overlap between groups. Results were significantly higher CPA and fibrosis stage. LSM was significantly associated with CPA (Rho = 0.8, p = 0.001).CAP score correlated significantly with fat% (Rho = 0.45, p = 0.002) and effectively diagnosed steatosis > 5% (AUROC 0.82, 95% sensitivity, 60% specificity), but could not distinguish between grades.

Conclusion: We have developed an automated software, using low-resolution images to provide a rapid, easily performed, objective assessment of steatosis and fibrosis in NAFLD, with excellent correlation with experts’ annotation. Objective measures would be helpful in the assessment of therapeutic response in clinical practice and in clinical trials for patients with non-alcoholic fatty liver disease.

Introduction: Today, nonalcoholic fatty liver disease (NAFLD) is the most prevalent form of liver disease and it is an increasingly frequent cause of cirrhosis. Although several factors have been associated with the disease, the biological basis of the histological diversity of severity of NAFLD remains unknown. Several relatively noninvasive parameters have been identified as predictive for advanced fibrosis stage in patients with NAFLD, but none of them has sufficient sensitivity or specificity to replace liver biopsy.

In all patients with NAFLD, there was a correlation between the presence of ats plaque and fibrosis, with the level of total cholesterol (p = 0.438), LDL cholesterol (p = 0.505), HDL-cholesterol (p = 0.438), and triglycerides (p = 0.911) were not correlated with the presence of ats plaque, nor on the entire group of patients or on each arm. In a univariate model of the risk of developing ats plaque, we included presence of NASI, the grade of steatosis, the stage of fibrosis, body mass index, abdominal circumference and creatinine clearance level. In this model, the stage of fibrosis has been shown to be a predictor with a positive effect on the presence of ats plaque (p = 0.004, adjusted OR = 7.19, CI[1.86,27.2]). This model correctly classified 90.9% of patients with ats plaque and 91.7% of patients without ats plaque.

Conclusion: NAFLD patients were found to be atypical for the development of cardiovascular risk. Staging of fibrosis has proved to be an important predictive factor. On the other hand, identifying NAFLD patients with ats plaques might select the patients in which liver biopsy might be indicated for better characterization of the liver disease. Screening and aggressive treatment of cardiovascular risk factors should be done in NAFLD patient.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: Aim of our study was to compare two non-invasive methods: fibrosis on serum markers and transient elastography (TE). We included 152 patients with NAFLD, 40 males (26.31%) and 112 females with age from 23 to 79 years.53 patients (23.02%) were overweight, 9 patients had normal weight and 24 (15.79%) had severe obesity. In all patients we calculated BARD, FIB-4 and NAFLD-FS fibrosis score (NAFLD-FS). Blood samples were collected to determine amionotransferases, glucose, albumin level, platelet count. The abdominal ultrasonography was performed by the same physician and steatosis was graded using a semi-quantitative scale of 1 (mild) to 3 (severe). TE was also performed by a single physician using a conventional M probe or XL probe, with 10 valid acquisitions. We considered significant fibrosis (F2) when estimated cutoff of F2 was 7.1 kPa, severe fibrosis (F3) when cutoff value was 9.5 kPa, and cirrhosis (F4) with cutoff value >12.5 kPa.

Results: 86.84% patients had metabolic syndrome and 51.31% had diabetes mellitus.40 patients had mild steatosis, 59 had moderate and 53 had severe steatosis. After we performed TE 69.07% of patients had no significant fibrosis, 14.47% had F2, 9.86% had F3 and 7.23% had F4. The area under the receiver-operating characteristic curve (AUROC) of TE was 0.823 (95%, 0.252–0.394) (p < 0.0001). Sensibility and specificity for cutoff 7.1 kPa was 0.74 respectively 0.79 to exclude significant fibrosis. NAFLD-FS correlated statistically significant with TE (p < 0.0001). BARD score did not correlate with TE and NAFLD-FS for significant fibrosis. FIB-4 correlated with TE for high degree of fibrosis (p = 0.004).

Conclusion: NAFLD-FS, FIB-4 and TE can be used together to evaluate the progression of fibrosis in NAFLD and to select the patients for liver biopsy. In our study BARD score was not useful in detection of high degree fibrosis.

P0678 EFFECTS OF UDCA AND STATIN COMBINATIONS ON LIPID PROFILE IN NAFLD PATIENTS
S. S. Vyalo
Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation

Contact E-mail Address: ssvalov@mail.ru

Introduction: Dyslipidemia has an important role in NAFLD and inflammation progress and insulin resistance development. The studies suggested the role of UDCA in lipid profile correction. UDCA replaced bile acid imbalance and improved triglyceride and cholesterol levels in NAFLD patients, has immunomodulatory action.

Aims & Methods: The aim of study was estimation of the efficacy of different dosage of ursodeoxycholic acid (UDCA) with statin combination treatment in patients with NASH and NAFLD. There are 180 patients with NAFLD. It was divided into two subgroups: fatty liver (90 subjects) – patients with normal level of ALT, and nonalcoholic steatohepatitis (NASH, 90 subjects) – patients with elevated level of ALT (the median is 78.5 U/l). All patients were divided in 3 groups. The blood test, liver enzymes, lipid profile, HOMA-IR, Fibroscan and stool test was checked every 2 weeks of treatment. First group was taken UDCA 10 mg/kg/day + simvastatin for 3 months. Second group was taken UDCA 15 mg/kg/day + simvastatin. Third group were fed the low-lipid and low-glyceric diet index only (900 kcal/day). After 3 months of treatment patients of third group (diet only) add UDCA 15 mg/kg/day to treatment for extra 3 months.

Results: The subgroups did not show any difference in terms of initial total cholesterol (TC), low-density lipoprotein cholesterol (LDL-C), and triglycerides (TG). After correction of the lipid spectrum showed a more intense dynamics in the group of patients taken UDCA combined with statin. After 3 months of follow-up there was a significant reduction in TC to 4.2 mmol/l, LDL-C to 1.8 mmol/l and TG to 1.2 mmol/l in the fatty liver subgroup, and TC to 4.1 mmol/l, LDL-C to 1.8 mmol/l and TG to 1.2 mmol/l in the NASH subgroup. Changes were similar in the subgroups. The level of total cholesterol, triglyceride and liver enzymes were decreased faster in group taken UDCA and statin independent from UDCA dosage. There is no side effects or liver enzyme elevation in group treated with UDCA and statins. In the NASH subgroup there was a significant decrease in ALT to 35 U/l. At the end of the first month of statin therapy combined with UDCA in the NASH subgroup a significant positive dynamics of ALT was found in patients with NASH (initially 78.5 U/l; after treatment decrease to 35 U/l). Stage of liver fibrosis was significant in patients taken UDCA and statin, as evidenced by the decrease in the index of fibrosis.

Conclusion: 3-month statin therapy in combination with UDCA showed significant lipid-lowering effects in patients with NASH, as well as normalization of A400

P0679 EFFECT OF GRANULOCYTE COLONY-STIMULATING FACTOR (G-CSF) ON MORTALITY AND COMPLICATIONS VIZ. SEPSIS, ENCEPHALOPATHY, HEPATORENAL SYNDROME, AND GASTROINTESTINAL BLEED IN SEVERE ALCOHOLIC HEPATITIS- A RANDOMIZED CONTROLLED STUDY
A. Sharma
Gastroenterology And Hepatology, Fortis Escorts Hospital Jaipur, Jaipur/India

Contact E-mail Address: abhinav_11005@yahoo.com

Introduction: Severe alcoholic hepatitis has very high short-term mortality. Compared to standard medical therapy (SMT), GCSF improves clinical and biochemical profiles, morbidity and mortality in these patients. We evaluated efficacy of G-CSF in modulating the disease course of severe alcoholic hepatitis over period of 3 months in terms of mortality, morbidity by Discriminant function (mDF), Child–Turcotte–Pugh (CTP) and Model for End-Stage Liver Disease (MELD) score in patients with severe alcoholic hepatitis. 50 patients with severe alcoholic hepatitis were randomly assigned to groups A and B (25 in each). Both groups were given SMT, while in addition, patients in group A were given 5 mg/kg GCSF subcutaneous (10 doses for 5 days). We assessed survival, changes in CTP, MELD and mDF scores and the development of complications.

Results: The baseline parameters in both groups were comparable. On day 6 group A had higher mean leukocyte and CD34 counts than group B (P < 0.05). The 90 days followed up 17 patients in group A (68%) and 9 in group B (36%) survived (P < 0.04). Mean changes for different scores were greater in group A then group B i.e. CTP (–41.97% vs –8.844%), MELD (–50.89% vs 10.09%) and mDF (–74% vs 18%) (P < 0.01). The percentages of patients who developed HRS, HL, or sepsis were lower in group A than in group B (28% vs 64%, 32% vs 64% and 28% vs 68%, respectively) (P < 0.01). There was no significant difference in GI bleed in both groups.

Conclusion: In severe alcoholic hepatitis, GCSF therapy significantly improves the survival. It also significantly reduces CTP, MELD and mDF scores and prevents the development of complications.

Introduction: Steatosis/steatohepatitis is one of the most common liver diseases with increasing prevalence and results from excessive alcohol consumption (alcoholic liver disease) or as nonalcoholic fatty liver disease (NAFLD). The differential diagnosis is of paramount importance as they have different management and therapeutic approaches, being liver biopsy the gold standard for establishing the diagnosis. The distinction between these two entities without biopsy is
difficult due to the unreliable history of alcohol consumption and lack of sensibility in the single angle. It is also important to overcome these difficulties. A non-invasive diagnostic and reliable tool that may be used to distinguish NAFLD from ALD, decreasing the need for live biopsy. GGT greater than 1.96 suggests the diagnosis of ALD and ANI lesser than −1.96 suggest NAFLD.

P0682 PROBIOTICS REDUCE ETHANOL-INDUCED HEPATIC INJURY BY MODULATING GUT MICROBIOTA AND INTESTINAL BARRIER INTEGRITY IN MICE

Y. Zhang, G. Chen, J. Sun
Gastroenterology, Zhongshan Hospital, Fudan University, Shanghai/China

Contact E-mail Address: xiaowan@163.com

Introduction: Gut-liver axis plays an important role in the pathogenesis of ALD. The probiotics of intestine enter the blood through the damaged intestinal mucosal barrier and cause liver damage. Nowadays, probiotics have been used in the prevention and treatment of a variety of diseases, including ALD. It has become a hot spot for the study of regulating intestinal micro ecological balance and enhancing intestinal barrier function, to prevent alcoholic liver injury. In this study, ALD mice were given probiotics to observe the protective effects on ALD and explore the possible mechanism.

Aims & Methods: Gut-liver axis plays an important role in the pathogenesis of ALD. The intestinal products of intestine enter the blood through the damaged intestinal mucosal barrier and cause liver function damage. Nowadays, probiotics have been used in the prevention and treatment of a variety of diseases, including ALD. It has become a hot spot for the study of regulating intestinal micro ecological balance and enhancing intestinal barrier function, to prevent alcoholic liver injury. In this study, ALD mice were given probiotics to observe the protective effects on ALD and explore the possible mechanism.

Results: HE and oil red O staining of liver tissues in alcohol group showed significant steatosis and inflammation response, and probiotics treatment can reduce liver injury. Compared with the control group, the LPS of alcohol group was significantly higher than that of the control group (62.36 ± 0.95 vs 12.23 ± 1.19 mg/ml, p < 0.05) and TNF-α (779.4 ± 1.01 vs 2724 ± 6.78 mg/ml, p < 0.05) was significantly increased. Probiotics can effectively cease endotoxemia (35.63 ± 1.84 vs 6 ± 2.36 ± 3.05 mg/ml, p < 0.05) and inflammatory factors TNF-α (526.6 ± 25.04 vs 779.4 ± 10.01 mg/ml, p < 0.05) induced by alcohol. RT-PCR results showed that probiotics increased the expression of Reg3b and Claudin-1 (P < 0.05). Compared with the alcohol group, the mRNA levels of intestinal tight junction protein Occludin and Claudin-1 were increased with probiotics treatment (P < 0.05). However, compared with the alcohol group, the mRNA level of ZO-1 showed no significant difference (P > 0.05). WB results showed the expression of Occludin and Claudin-1 increased in probiotic treatment group (P < 0.05).

Conclusion: Probiotics show protective effects on ALD by reducing alcohol-induced endotoxemia and liver inflammatory injury as well as improving the intestinal mucosal barrier and restoring the intestinal micro ecological imbalance. P0683 THE OVERWEIGHT ROLE IN THE OCCURRENCE OF HEPATOTOXIC REACTIONS DURING CHEMOTHERAPY OF ACUTE LEUKEMIA

I. Skrypnyuk, G. Maslova
Chemical Medicine #1, Ukrainian Medical Stomatological Academy, Poltava/Ukraine

Contact E-mail Address: scrin99@yandex.ru

Introduction: Chemotherapeutic drugs have a direct hepatotoxic effect, which leads to multiple increase in the risk of liver injury in patients with acute leukemias (AL). The development of hepatotoxicity limits the chemotherapy (CT) providing in full doses.

Aims & Methods: We aimed to assess the overweight role in an increase of risk level of hepatotoxic reactions in AL chemotherapy dynamics. The study involved 84 patients with newly diagnosed AL (64 – acute myeloid leukemia (AML), 20 – acute lymphoblastic leukemia (ALL)), ECOG II-II, aged 24-67 years, 41(48.8%) females, 43(51.2%) – men. The body mass index (BMI) and waist circumference (WC) function was assessed by the activity of alanine aminotransferase (ALT), aspartate (AST) aminotransferase, alkaline phosphatase (ALP), gamma-glutamyltranspeptidase (GGT), total bilirubin, total protein in the blood serum three times: at baseline and on the 28th and 56th day after starting induction of remission therapy, according to the ALL (prednisolone, doxorubicin, vincristin, asparagi nase, cyclophosphamide, cytarabine, mercaptopurine) and AML (cytarabine, doxorubicin) treatment protocols. To assess the severity of hepatotoxic reactions
lipid peroxidation, cytokines and mitochondrial dysfunction. Ferroptosis is an injury is not clear yet, and its pathogenesis is mainly related to oxidative stress, also increased year by year. However, the mechanism of alcohol-induced liver

P0864 RESEARCH ON FERROPTOSIS IN HEPATOCYTE INJURY INDUCED BY ALCOHOLIC

Y. Wu, T. Liu, G. Zhang; Xiangya Hospital, Central South University; Changsha/China

Contact E-mail Address: liuting818@126.com

Introduction: Alcohol abuse and alcohol dependence have become the world's greatest public health challenges. In 2016, the World Health Organization (WHO) estimated that 3.8% of the global population (approximately 265 million people) had alcohol use disorders. Use of hazardous amounts of alcohol results in more than 3 million deaths annually, and alcohol is also one of the major risk factors for the development of alcoholic liver disease (ALD), which occurs in the human population. Chronic consumption of alcohol in large quantities can cause serious damage not only to the liver but also to the heart, central nervous system, and other organs. The liver is especially vulnerable to damage from alcohol due to its extensive metabolic and synthetic functions. This paper presents the results of a retrospective study of 50 ALD patients who were treated at the Gastroenterology Department of the University of Rome, Italy.

Disclosure of Interest: All authors have declared no conflicts of interest.

4. Ganzert’s criteria and 40.7% (n = 9) met Escudier criteria. In the sub-group of patients who met criteria but were not transplanted (n = 6): in 66.7% (n = 4) the reason was absence of donor, in 16.7% (n = 1) there was liver function recovery and in 16.7% (n = 1) a contraindication was found (irreversible intestinal ischemia diagnosed intraoperatively). The mortality in this sub-group was 83.3%. The mortality rate in transplanted patients was 60%. All patients without emergent liver transplantation criteria survived.

Conclusion: Amanita phalloides poisoning has a severe and rapidly progressive presentation, often with indication for liver transplant. Patients are admitted late into ICU. Mortality rate is even higher in transplanted patients.

Introduction: Ingestion of amatoxin-containing mushrooms is a rare medical emergency. Amatoxin can cause massive hepatic necrosis and acute liver failure. Liver transplantation can be life saving but liver transplantation criteria are complex and not consensual. Mushrooms poisoning is associated with a high mortality rate.

Aims & Methods: We conducted a retrospective analysis of demographic, clinical, therapeutic and prognostic data of all patients with Amanita phalloides poisoning admitted to a Gastroenterology Intensive Care Unit (GIUC) of a tertiary hospital between 1997 and 2017.

Results: A total of 27 patients were included: 55.6% were male and the mean age was 53 ±15 years old (range, 18–75). The most frequent initial symptoms were vomiting (100%), diarrhea (93%), and abdominal pain (71%). The mean time between ingestion and onset of symptoms was 10.1 hours and GIUC admission was 50.9 hours. At admission 33.3% presented hepatic encephalopathy (25.9% grade 1; 3.7% grade 3 and 3.7% grade 4). Laboratory characterization at admission: mean INR was 4, total bilirubin 3.5 mg/dL, creatinine 1.9 mg/dL and factor V 25.8%. The different criteria for emergent liver transplantation were assessed: 37% (n = 10) met Clichy’s criteria, 59.3% (n = 16) met King’s College criteria, 35.3% (n = 9) met Ganzert criteria and 40.7% (n = 11) met Escudier criteria. In the sub-group of patients who met criteria but were not transplanted (n = 6): in 66.7% (n = 4) the reason was absence of donor, in 16.7% (n = 1) there was liver function recovery and in 16.7% (n = 1) a contraindication was found (irreversible intestinal ischemia diagnosed intraoperatively). The mortality in this sub-group was 83.3%. The mortality rate in transplanted patients was 60%. All patients without emergent liver transplantation criteria survived.

Conclusion: Amanita phalloides poisoning has a severe and rapidly progressive presentation, often with indication for liver transplant. Patients are admitted late into ICU. Mortality rate is even higher in transplanted patients.

Aims & Methods: This study was performed on 2704 subjects attending high school. Questionnaires regarding socio-demographic data, anthropometric characteristics, pattern and amount of alcohol intake, smoking habits, use of illicit drugs, and physical activity were administered to students. Moreover Italian versions of AUDIT, STAI-Y1, STAY-Y2 and ZUNG scale were administered.

Results: Alcohol intake was reported by 2126 students (79%); among them 1278 versions of AUDIT, STAI-Y1, STAI-Y2 and ZUNG scale were administered. Among students that reported binge drinking behavior than in those that did not report binge drinking (p < 0.0001).

Conclusion: Alcohol consumption and abuse among young students is alarming. Binge drinking behavior among young students seems to be very common and it seems a risk factor for the development of AUD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: This study aims to identify patients hospitalized for acute decompensation of cirrhosis with AKI, according to the ICA-AKI criteria, and to determine if its application leads to greater prognostic accuracy.

Methods: Retrospective analysis of hospitalized patients in a gastroenterology department for acute decompensation of cirrhosis, without acute-on-chronic liver failure, between January 2014 and December 2015. Identification of AKI according to the ICA-AKI criteria. The hospital length of stay of 11.6% of patients with AKI was longer hospitalizations (14.55 vs. 9.78 days, p < 0.05). There was a statistically significant association between the presence of infection and the development of AKI (p < 0.05). The ICA-AKI criteria were prospectively used in determining prognosis. Frontline Gastroenterol. 2013;4(3):191–197. doi:10.1136/igastro-2012-100291.

Conclusion: The ICA-AKI criteria allow the identification of decompensated cirrhotic patients in whom a worse prognosis is predicted. Thus, they constitute a useful tool in daily clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
predictors of in-hospital mortality. Patients with Sepsis-3 had higher incidence of ascites (36 vs 11%), palor (25 vs 17%), septic shock (15 vs 0%, p < 0.001) and transfer to the ICU (16 vs 2%; p = 0.001) than those without Sepsis-3. Similar findings were found for qSOFA.

Conclusion: Sepsis-3 criteria are more accurate than SIRS criteria in predicting the severity of infections in patients with cirrhosis. qSOFA is a useful bedside tool to assess risk for worse outcomes in these patients. Patients with Sepsis-3 and positive qSOFA deserve more intensive management and strict surveillance.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0691 A SUBCLINICAL HIGH TRICUSPID REGURGITATION PRESSURE GRADIENT IS A RISK FACTOR FOR SURVIVAL AFTER LIVING DONOR LIVER TRANSPLANTATION
Gastroenterology And Hepatology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Japan/Japan
Contact E-mail Address: at841205@gmail.com

Introduction: Portopulmonary hypertension (POPH) is characterized by pulmon- ary vasoconstriction, while hepatopulmonary syndrome (HPS) is characterized by vasodilatation. Given that HPS could be resolved after orthotopic liver trans- plantation (OLT) even when hypoxemia were severe (PaO2 < 80 mmHg), impli- cations for OLT is accepted not only for deceased donor LT (DDLT), but also to living donor related LT (LDLT). However, the post-OLT course of POPH com- plicated patients are often unsatisfactory and severe (mPAP > 45 to > 50 mmHg) patients are considered as an absolute contraindication for OLT. The Japan Liver Transplant Society Practice Guidelines indicate that, unlike HPS, there are no data to support the concept that POPH (treated or untreated) should be an indication for OLT. Furthermore, the Practice Guidelines recommend that patients with mPAP < 35 mmHg be indicated for OLT, and PA-targeted therapy should be initiated in patients with mPAP > 35 mmHg. However, almost all of the patients in these articles had received DDLT, and no such analyses have been for LDLT patients. Given that left or right lobe LDLT grafts are smaller than DDLT grafts, PH-induced hepatic venous pressure may result in a strong congestive impact on the LDLT grafted liver. Although patients with confirmed POPH and HPS are rare, relatively pulmonary hypertensive patients and mild HPS patients may be more common.

Aims & Methods: The present objective is to investigate the clinical impact of subclinical PH on the inevitably small survival in grafted living donor OLT (LDLT). We recruited 84 OLT candidates for liver cirrhosis in a retrospective cohort study. Patients exhibiting a tricuspid regurgitation pressure gradient (TRPG) > 25 mmHg (median) on echocardiography were categorized as poten- tially having POPH (subclinical PH: n = 34). We evaluated pulmonary artery pressure (mPAP) measured after general anesthesia with FIO20.6 (mPAP-FIO20.6) was also also included as advisory data. Patients exhibiting PaO2 < 80 mmHg and an arterial-venous oxygen gradient (AaDO2) > 15 mmHg were categorized as potentially subclinical HPS. The clinical course after LDLT was investigated according to subclinical PH or HPS.

Results: Subclinical PH was correlated with a worse 1-year survival (p = 0.003). Subclinical PH (n = 1.021) and older donors (p = 0.008) were correlated with a poor 40-month survival. Although a higher mPAP-FIO20.6 was expected to correlate with a worse survival, a high mPAP-FIO20.6 was not a significant risk factor for the post-LDLT survival. When the post-LDLT survival was inves- tigated according to the TRPG and mPAP-FIO20.6 status, it was worst in patients who had a high TRPG and low mPAP-FIO20.6. The patients with a high mPAP-FIO20.6 had mPAP-FIO20.6 > 40 mmHg. When comparing the two-tailed p value < 0.05 was defined as indicating statistical significance.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The ALBI score was recently developed to assess the severity of liver dysfunction, taking into account albumin and bilirubin levels. We aimed to assess its prognostic performance in patients with liver cirrhosis complicated with upper gastrointestinal bleeding (UGIB) while comparing it with Child-Pugh (CP) and MELD scores.

Aims & Methods: Retrospective uncenter study, including consecutive adult patients with cirrhosis admitted for UGB between January 2011 and November 2015. Clinical, analytical and endoscopic variables were assessed and ALBI, CP and MELD scores at admission were calculated. Statistical ana- lysis was performed using SPSS v21.0 and MedCalc v.16.4.3, and a two-tailed p value < 0.05 was defined as indicating statistical significance.

Results: Included 111 patients with a mean age of 57.4 ± 12 years, 76.6% were males. Liver cirrhosis was most frequently alcoholic (89.2%) and the most common etiology for UGIB was variceal hemorrhage, in 75.5% of patients. During the first 30 days of follow-up another 10 patients died (1st year mortality of 18.8%). When comparing the three scores, regarding in-stay and 30 days mortality, only ALBI score showed statistical significant results, with an area under the curve (AUC) of 0.82 (p < 0.01) for both outcomes. Regarding 1st year mortality, AUC for ALBI, CP and MELD scores, were 0.71 (p < 0.01), 0.64 (p < 0.05) and 0.66 (p = 0.02), respectively, while for global mortality AUC were 0.75 (p < 0.01), 0.72 (p < 0.01) and 0.72 (p < 0.01), respectively. When comparing the AUC of the three scores, no significant differences were found regarding 1st year mortality and global mortality.

Conclusion: In our series, ALBI score accurately predicted both in-stay and 30 days mortality (0.82 (p < 0.01)), while CP and MELD scores weren’t able to predict these outcomes. All scores showed a fair prognostic prediction performance regarding 1 year global mortality. These results suggest that ALBI score is particularly helpful in the assessment of short term outcomes, with a better performance than the most commonly used scores, and may assist the clinician in the stratification of care at admission and maybe even in the referral to liver transplant.

P0693 CARVEDILOL VERSUS PROPRANOLOL EFFECT IN THE PRIMARY PROPHYLAXIS OF VARICEAL BLEEDING IN CIRRHOTIC PATIENTS WITH PORTAL VEIN THROMBOSIS

Introduction: Portal vein thrombosis (PVT) is recognized as an independent factor of variceal bleeding. Beta blockers are the mainstream treatment to prevent variceal bleeding in cirrhotic patients. Carvedilol has been shown to be equal to propra- nolol in preventing first bleeding in cirrhotic patients, however, the efficacy of this policy in patients with PVT is unknown.

Aims & Methods: The aim of this study was to evaluate the efficacy of carvedilol versus propranolol in the primary prophylaxis of variceal bleeding in cirrhotic patients with occlusive portal vein thrombosis. Between January 2014 and December 2015, cirrhotic patients with occlusive non-malignant PVT were enrolled in a tertiary center. PVT was suspected by Doppler ultrasound and computed tomography. Cirrhotic patients with esophageal varices and no previous variceal bleeding were randomized to carvedilol 6.125 mg daily or Propranolol 40 mg daily. End points were esophageal varical bleeding or death.

Results: During the study period forty eight patients were evaluated. Twenty one and twenty seven patients were randomized in carvedilol and propranolol arms respectively. Mean age was 49.2 ± 12.2 years. 33 (68.7%) were males; 60.4% had viral cirrhosis; mean Child-Pugh score was 7.2 ± 2.6 and mean follow up was 12.3 ± 9.1 months (range 1–29 months). All the patients had occlusive non-malignant PVT, most of them involving only the trunk, and grade 2 or 3 esophageal varices. Both carvedilol and propranolol groups had comparable variceal bleeding rates (14.2% vs. 14.8%, P = 0.002), bleed related mortality (9.5% vs. 11.1%, P = 0.027) and overall mortality (23.8% vs. 22.2%, P = 0.004) respectively. Adverse events in carvedilol group were hypotension (n = 2), requiring cessation of therapy, while and dyspnea (n = 3) resolved spontaneously. In the propranolol group there was 1 adverse event that required discontinuation of treatment (grade 2 atrio-ventricular block).

Conclusion: Our study suggests that carvedilol is probably not superior to propra- nolol in preventing first variceal bleeding in cirrhotic patients with occlusive PVT, and they both can be used as primary prophylaxis.

Introduction: Liver failure frequency (CFF: values $\leq 39$ Hz) identify cirrhotic patients with minimal hepatic encephalopathy (mHE) and predict their risk of developing overt hepatic encephalopathy (oHE). However, these results have been obtained in cirrhotics with advanced liver disease suffering a previous episode of liver decompensation (74% of patients) or oHE (14% of patients).

Aims & Methods: Herein, we evaluated the effectiveness of CFF in predicting the first episode of oHE in compensated outpatients undergoing a long-term follow-up. A total of 134 selected patients and 150 healthy subjects were evaluated using CFF. CFF was correlated with several non-invasive modalities, in an asymptomatic Fontan patient cohort may further elucidate this study.

Aims & Methods: Consecutive patients with a Fontan circulation are prospectively included for screening of liver fibrosis. This screening consists of a blood test for several non-invasive modalities, in an asymptomatic Fontan patient cohort may further elucidate this study.

randomized to placebo or LRGG treatment, for 2 months. In all intention to treat analysis, patients demographic characteristics, laboratory test, model for end-stage liver disease (MELD) score, and Child-Pugh class were evaluated.

**Results:** CFF value increased in both LRGG and placebo groups at the end of treatment. In subgroup analysis, the CFF value increased in LRGG group at the end of treatment compared to placebo (46.5 ± 5.7 vs. 41.1 ± 4.4 Hz, p = 0.015), thus indicating a better therapeutic outcome on mHE. Moreover, mHE reversal was achieved in 75.0% vs. 35.7% of the patients from LRGG and placebo groups, respectively (p = 0.047).

**Conclusion:** For the first time, we demonstrate that LRGG improves mHE (expressed by a significant CFF increase).

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0700 ASSOCIATIONS OF GENETIC POLYMORPHISM OF TOLL-LIKE RECEPTOR 3(TLR-3) AND SEX-LINKED TOLL-LIKE RECEPTOR 7 (TLR-7) ALLELES WITH THE HEPATITIS C VIRUS INFECTION OUTCOME IN EGYPTIAN POPULATION: A MULTICENTRE FAMILY-BASED STUDY**

**Aims & Methods:** The aim of this study was to assess the association between genetic polymorphism of TLR 3 and Sex-linked Toll-like receptor 7 alleles with HCV infection outcome in Egyptian families. A total of 135 Egyptian families (622 individuals) were recruited in this study from upper and lower Egypt (East and West delta). We compared the risk of allele carriage of selected markers in different groups. These groups included spontaneous clearance (SVC) (108 subject), chronic HCV (CHC) (patients 216), and negative control (298) individuals. The rs3775291 (C/T) was genotyped for TLR3. While the rs3853839 (C/G) was genotyped for TLR7 by real-time PCR using TaqMan® allele discrimination kit (Applied Biosystems) according to the manufacturer protocol. The distribution of the TLR7 rs3853839 (C/G) polymorphism was assessed separately in female and male subpopulations of the study due to the X-linked nature of the TLR7 gene.

**Results:** As regard TLR3 the frequency of the C allele was 88.5%, 83.4% and 71.06% for the SVC, control and CHC groups respectively. While the allele frequency of the T allele was found to be 11.5%, 16.5%, 30.9% in SVC, control and CHC groups respectively. When these alleles were compared between the 3 studied groups, The T allele of TLR3 rs3775291 was found to be significantly higher in both SVC spontaneous clearance (SVC) and control groups when compared to chronic HCV group [OR 0.42 (95% CI 0.21 to 0.82, Pc < 0.0372) and OR 0.40 (95% CI 0.23 to 0.71, Pc < 0.0054)] respectively. The same results was also reported in the male subpopulation as the same allele was found to be significantly higher in both HCV spontaneous clearance (SVC) and control groups when compared to chronic HCV group [OR 0.289 (95% CI 0.14 to 0.59, Pc < 0.0021) and OR 0.17 (95% CI 0.1009 to 0.28, Pc < 0.0001)] respectively.

**Table 1:** Association of the allele T of TLR3 rs3775291 polymorphism among the studied groups.

</tr>
</tbody>
</table>

**Conclusion:** The risk of development of chronic HCV infection was associated with T allele carriage of TLR3rs3775291 SNP. While the carriage of C allele of TLR7 rs3853839C allele was associated with spontaneous HCV clearance in both male and female subpopulations in Egyptian families.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

resulting in cirrhosis and graft failure within 5 years after transplant. Different studies are studying efficacy and safety of treatment with DAAs in the early post-transplant period in LDLT recipients with HCV genotype 4

Aims & Methods: This study aimed to identify which of the several treatment schemes for genotype 4 patients would constitute the best option. Twenty-four Italian centers were involved in this real-life study where HCV genotype 4 patients were treated with DAA drugs.

Results: Twenty-six patients completed the treatment course. Sustained virological response (SVR) at week 12 was achieved in 80.8% (21/26) of recipients, 100% (11/11) for Sofosbuvir-Daclatasvir and Sofosbuvir-Simeprevir group versus 66.7% (10/15) for Sofosbuvir-Ribavirin group (p < 0.05). No major side effects had been reported, anemia developed in patients received ribavirin respond to treatment with erythropoietin and reduction of the ribavirin dose.

Conclusion: Use of Daclatasvir/Sofosbuvir or Simeprevir/Sofosbuvir in early treatment of HCV genotype 4 post living donor liver transplant recipient achieved higher rates SVR than Sofosbuvir/Ribavirin.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0704 IMPROVEMENT OF LIVER STIFFNESS VALUES MEASURED BY TRANSITION ELASTOGRAPHY AFTER CHRONIC HEPATITIS C TREATMENT WITH DIRECT ACTION ANTIVIRALS AND EVOLUTIVE CORRELATION OF THROMBOCYTOPENIA AND PRESENCE OF ESOPHAGEAL VARICES

M. Perez Ferrer,1 I. Maestro Prada,1 A. Mcgee,2 J.L. Castro Urda,1 L.A. Castillo Hernandez,1 C. Garcia Ramos1

Introduction: An improvement in liver stiffness (LS) measured by transient elastography (TE) has been observed in patients with chronic hepatitis C treated with direct action antivirals (DAAs).1,2 The Baveno VI guidelines1,3 propose that patients with compensated advanced chronic liver disease (cACLD), LS measurement < 20kPa and a platelet count > 150000/μL can avoid screening endoscopy as their combination is highly specific for excluding clinically significant oesophageal varices (EV). These data need to be validated recently.1,4

Aims & Methods: The aim of this study was to quantify LS regression both (measured in Kilopascals) and qualitatively (Stages of F0-F4 fibrosis) in a stationary phase after the sustained virological response (SVR) in patients with cACLD (F4). The secondary objective was to assess whether this improvement in LF measurements has a clinical correlation with changes in platelet numbers and the presence of varices according to Baveno VI criteria.

Results: 94 patients (49 men and 35 women) with cACLD were included in the study. Median TE on baseline (BL) prior to DAA treatment was (mean range), 23.86 (12.5–75) kPa and decreased to [mean (range)] at SVR 24 and [mean range], 16.19 (3–62.7) kPa at SVR > 54. Both were statistically significant, showing a decrease in LS about 30% between BL and SVR > 54 and about 33% between BL and SVR > 54. We did not find statistically significant differences between SVR 24 and SVR > 54. Regarding the probability of qualitative improvement of the LS (from F4 to F3 or less) the AUC was 0.8 with 17.9 kPa as the cut-off point which has a Sensitivity of 0.76 and Specificity of 0.81. NPV = 78.12, PPV = 78.57. 32 patients with highly suggestive cACLD (LS > 15kPa) underwent upper endoscopy (UE): 10 (32%) had varices (5 small EV and 5 big EV).17 (53%) fulfilled the Baveno VI criteria (3 with small EV and 4 with big EV). There were only 3 cases of EV misdiagnosed by Baveno VI Criteria. We did not find any significant differences in platelet levels or in the regression of varices.

Conclusion: There is a significant improvement in LS data after treatment with DAAs both at SVR24 and SVR > 54. This improvement seems to be more likely to occur in patients with lower TE values in our study 17.9 kPa. We did not have enough available data in our study to support that this improvement in LS measured by TE has a relevant impact on the clinical management of the patient. The Baveno VI criteria are a useful tool in daily practice to avoid unnecessary UE. Further investigation with larger samples is needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0705 8 VERSUS 12 WEEKS OF LEDIPASVIR/SOFOSBUVIR REGIMEN IN PATIENTS WITH CHRONIC HEPATITIS C GENOTYPE 1 INFECTION

Department Of Gastroenterology And Hepatology, North Lisbon Hospital Center, University of Lisbon, Portugal, Lisbon/Portugal

Contact E-mail Address: joana.rita.carvalho@gmail.com

Introduction: The therapeutic regimens for chronic hepatitis C are now tending to be shorter and ribavirin free, more cost-effective and with fewer adverse effects.

Aims & Methods: We aimed at comparing the 8 weeks versus the 12 weeks regimens of ledipasvir plus sofosbuvir in patients with hepatitis C virus (HCV) genotype 1 infection without cirrhosis, treatment naïve, HCV RNA <6000000 UI/mL. We included 281 patients (pts) with genotype 1 and HCV RNA <6000000 UI/mL treated with ledipasvir plus sofosbuvir in the recommended dose: 120 pts - 8 weeks (group 1) and 161 pts - 12 weeks (group 2). The fibrosis stage was evaluated by transient elastography (Fibroscan®, Echosens, Paris) considering F4 >125 kPa. Patients with undetectable RNA after 12 weeks of treatment were considered cured – sustained virologic response (SVR).

Results: No significant demographic and clinical differences were found between the two groups with the exception of the fibrosis stage (table). Two hundred and forty-four patients concluded the treatment; the SVR was 99% in group 1 and 100% in group 2, without differences between the two groups (p = 0.275). Thirty three patients are still in follow up: group 1-15 pts and group 2-18pts. The reported adverse effects were mild in both groups (fatigue, insomnia, headache and pruritus) but more frequent in group 2 (p = 0.046).

Conclusion: Patients with chronic hepatitis C genotype 1 infection and RNA <6000000 UI/mL, the 8 weeks regimen of ledipasvir plus sofosbuvir without ribavirin has similar high cure rates with less adverse effects.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0706 CLINICAL FEATURES OF PATIENTS DEVELOPING HCC AFTER ACHIEVING SVR WITH DAA AGAINST CHRONIC HEPATITIS C

Gastroenterology, Nara Prefecture General Medical Center, Nara/Japan

Contact E-mail Address: k.ishida1549@yahoo.co.jp

Introduction: Although the conventional IFN-based therapy has made a significant achievement in treating patients with hepatitis C virus (HCV), the improving effects of hepatocarcinogenesis after achieving sustained virological response (SVR), patients intolerant of IFN, such as those with advanced age or liver cirrhosis (LC), could not save its privilege. The appearance of direct-acting antivirals (DAAs) has provided almost every patient with the chance to receive the treatment without any serious adverse effects (AEs). In addition, SVR could be highly expected in more than 95% of patients treated with DAAs. However, the preventive effects of the future hepatocarcinogenesis following eradication of HCV remains unknown. In our facility, the adoption of DAA to HCV infection management (P0707) and the achievement of SVR (P0707) in 157 of SVR, among which 5.9% (9/157) of patients developed hepatocellular carcinoma (HCC) within 2 years after achieving SVR.

Aims & Methods: We evaluated the clinical features of patients developing HCC after achieving SVR with DAAs against HCV. One hundred and fifty-three patients achieving SVR defined as negative HCV-RNA 12 weeks after cessation of DAA (oral combination therapy with Daslatavir/Asunaprevir, Ombitasvir/Paritaprevir/Ritonavir, Sofosbuvir/Ledipasvir, or Sofosbuvir/Ribavirin) were enrolled in this study (Age 69 ± 6.8, male/female 71/52, genotype1/2 122/31, chronic hepatitis/LC 124/29, PLT 15.3 ± 6.8/mL, Alb 3.8 ± 0.5 g/dL, WFA(þ)-M2BP, FIB-4 index 3.3 ± 0.5 COI, AFP 12.1 ± 2.4 ng/mL, PI(K)VA-I 2.8 ± 4.3 mAU/mL). All patients were divided into 2 groups (A: 9 patients with HCC developing after SVR achievement, B: 144 without HCC after SVR achievement). Serum parameters (PLT, WFA(þ)+M2BP, FIB-4 index, APRI, ALT, Alb, AFP, PI(K)VA-I) and age were evaluated between 2 groups.

Results: In group B, significant declining (pre-DAA treatment/the time of achieving SVR) was observed in ALT(A44.8 ± 3.6/19.5 ± 1.1 IU/L), AFP(11.9 ± 3.1/ 4.1 ± 0.3 nm/g/mL), WFA(þ)+M2BP(3.2 ± 0.5/1.9 ± 0.3 COI), FIB-4 index(3.7/2.0 ± 0.2) and APRI(1.2/1.0 ± 0.7 ± 0.5), and significant increase in Alb(4.1 ± 0.4/3.5 ± 0.4 g/dL) and PLT(15.3 ± 6.8/20.9 ± 13.2 mAU/mL). In group A, significant declining was observed only in ALT (45.1 ± 10.9/ 16.7 ± 2.2 IU/L). This result indicates that DAA treatment significantly ameliorates parameters related with hepatic fibrosis as well as hepatic inflammation in group B, however, it led to the significant amelioration only in the serum parameters and hepatic inflammation in group A. Next, focusing on parameters after achieving SVR, WFA(þ)+M2BP (A:3.4 ± 0.6/B:1.7 ± 0.2 COI) and FIB-4 index (5.7 ± 1.6/ 3.0 ± 0.2) were significantly higher and Alb(3.8 ± 0.2/3.4 ± 0.4 g/dL) was significantly lower in group A comparing with group B. When dividing group A into 2 groups (C: new occurrence/D: recurrence), AFP(3.0 ± 1.3/6.2 ± 1.8 mg/mL), WFA(þ)+M2BP (2.0 ± 0.8/3.8 ± 0.7 COI), FIB-4 index (3.6 ± 2.4/ 6.3 ± 2.0) and APRI (0.6 ± 0.1/1.0 ± 0.3) were higher and Alb(4.3 ± 0.1/ 3.6 ± 0.3 g/dL) and PLT (20.9 ± 13.2/13.4 ± 3.4 mAU/mL) were lower in group D than group C, although no significant difference was seen between 2 groups. This result suggests that there might be more patients with progressive hepatic fibrosis in group D comparing with group C. Finally, while univariate analysis showed WFA(þ)+M2BP, FIB-4 index and Alb were significantly associated with the development of HCC after achieving SVR with DAA against HCV, multivariate analysis revealed only Alb was the significantly independent factor contributing to HCC development after achieving SVR.

Conclusion: Low level of serum albumin as well as the progression of hepatic fibrosis could be associated with the development of HCC after achieving SVR with DAA to HCV. Disclosure of Interest: All authors have declared no conflicts of interest.

P0707 EARLY OCCURRENCE OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH HEPATITIS C VIRUS TREATED WITH DIRECT-ActING ANTIVIRALS

Department Of Surgery, Hyogo College of Medicine, Nishinomiya/Japan

Contact E-mail Address: shai1005@hoyo-med.ac.jp

Introduction: Direct-acting antivirals (DAAs) are novel antiviral drugs for hepatitis C virus (HCV) and have enabled the achievement of a high rate of sustained
virological response (SVR) [1]. However, the impact of DAAs on the occurrence of hepatocellular carcinoma (HCC) and HCC recurrence after curative hepatic resection of HCC has been recently discussed [2, 3], but remain unclear.

Aims & Methods: The clinical data of 97 patients who underwent curative hepatic resection for primary HCC with HCV at our department between January 2012 and January 31, 2017 was reviewed to check the impact of DAAs on HCC occurrence and recurrence. SVR was defined as no detection of HCV RNA in the serum at 24 weeks after the cessation of antiviral therapy.

Results: SVR was achieved in 21 patients treated with interferon (IFN)-based regimens, 16 patients with DAAs at hepatocytectomy. Between the two groups, there were no significant differences in the clinical characteristics, including the age, prevalence of diabetes mellitus, drinking history, preoperative liver function, operative procedures, tumor size and presence of liver cirrhosis, but the median duration from the date of SVR to the date of HCC incidence was significantly shorter in patients treated with DAAs (14 days, range: –123 to 235 days) than in those treated with IFN-based regimens (324 days, range: 33 to 4190 days). In particular, HCC was detected within 24 weeks after the cessation of antiviral therapy in 3 patients treated with DAAs. After hepatocytectomy, SVR was achieved in 21 (DAAs: 16 patients, IFN-based regimens: 5 patients) of the 67 patients without SVR when hepatocytectomy was performed, and the 1- and 3-year disease-free survival (DFS) rates were 93.3% and 83.0% in patients after SVR treated with DAAs (n = 25), 90.9% and 71.8% in patients with IFN-based regimens (n = 26) and 57.8% and 19.7% in patients without SVR (n = 46), respectively, regardless of the timing of hepatocytectomy, respectively. The DFS rate was significantly higher in patients with SVR than in those without SVR (p < 0.001), but was not markedly different according to the antiviral treatments (p = 0.594).

Conclusion: While DAAs were able to reduce the DFS rate, the early occurrence of HCC in patients after SVR treated with DAAs is more frequent than that among patients treated with IFN-based regimens. Therefore, careful follow-up with imaging series is needed even for patients with SVR treated with DAAs.

Introduction: Chronic hepatitis C infection is a systemic disease, one of the leading causes towards cirrhosis and hepatocellular cancer and it is to be considered nowadays a major health-related quality of life (HRQoL) burden.

Aims & Methods: The aim of this study was to assess HRQoL impairment of hepatitis C virus (HCV) infection among a broad sample of compensated HCV cirrhotic patients. We conducted a prospective study between January 1st 2016 to January 31, 2017, in a tertiary center, in which we included 110 patients with compensated HCV cirrhosis, aged between 50 and 75, with no history of neuropsychiatric illness but associated comorbidities (diabetes type 2, hypertension, dyslipidemia). The patients were completely evaluated according to the national protocol. Health status and fatigue of our patients were evaluated using the FACIT- F (version 4) and SF-36 survey. Respondents with HCV compensated cirrhosis were compared with a control group matched for age and sex with no prior history of HCV infection on the Mental (MCS) and Physical (PCS) Component Summary scores.

Results: Unadjusted comparisons between subjects infected with HCV (n = 110) and controls (n = 60) revealed that HCV patients had lower FACIT- F utility scores (43.2 ± 3.5 vs 49.5 ± 3.0, p < 0.05). Severe fatigue was present in 30% (33 patients) of the HCV group compared to 11.6% (7 patients) in controls. Subgroup analyses of respondents age 60 years and older revealed lower MCS score in HCV patients compared to controls (41.95 vs 49.72, p < 0.05). Control group registered higher PCS score (53.30 vs 45.2, P < 0.05) compared to the study group.

Conclusion: Although the results were obtained on a small group we observed that in untreated patients with chronic HCV infection, HRQoL is significantly impaired due to fatigue severity and age. Our result underline the need for effective antiviral treatment to decrease the burden of fatigue in this segment of population.

P0710 SOFOSBUVIR IN COMBINATION WITH RIBAVIRIN IN GENOTYPE 3 HEPATITIS C PATIENTS WITH CIRRHOSIS: AN EXPERIENCE FROM TERTIARY CARE HOSPITAL

A. A. Langhah
Gastroenterology Section, Medical Unit IV, Jinnah Postgraduate Medical Centre, Karachi Pakistan

Contact E-mail Address: draliakbar12@gmail.com

Introduction: Hepatitis C virus (HCV) is the most common cause of cirrhosis in this part of the world. Advent of Directly acting antivirals (DAAs) like Sofosbuvir (SOF) has dramatized the treatment and is the corner stone in treat- ing causes towards cirrhosis and hepatocellular cancer and it is to be considered nowadays a major health-related quality of life (HRQoL) burden.

Aims & Methods: We aimed to evaluate the safety and efficacy of SOF plus Ribavirin (RIB) in patients with compensated and decompensated cirrhosis. This is a prospective real-world cohort study of HCV with compensated or decompensated cirrhosis. Efficacy was assessed by Sustained Viral Response after 6 months of completion of treatment. Adverse events were recorded on designed proforma on serial follow-up visits.

Results: The cohort consisted of 9 1 consecutiive patients out of which 41 were compensated cirrhotics and 50 had decompensated cirrhosis. The mean age was 53.4 ± 11 years. Males were 47 (51.6%) and females were 44 (48.4%). Mean CTP and MELD score were 7.71 and 9.21 respectively. In compensated cirrhosis, SVR was achieved in 25 (84%) treatment naïve patients compared to treatment experi- enced patients where 5 (80%) achieved SVR. In decompensated cirrhosis SVR was achieved in 22 (77.3%) treatment naïve patients, whereas 13 (76.9%) patients achieved SVR in treatment experienced group. In 72% patients with cirrhosis, there were no side effects whereas most common adverse event was fatigue and drop of Hemoglobin by 1.0 g/dl. Furthermore, CTP and MELD scores decreased to 6.9 and 8.7 respectively after treatment.

Conclusion: Sofosbuvir in combination with Ribavirin in GT-3 HCV patients achieved good SVR in compensated cirrhosis than decompensated cirrhosis whereas fatigue and drop of Hb were the most common adverse effects.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0711 RECURRENTITY OF HEPATOCELLULAR CARCINOMA (HCC) FOLLOWING TREATMENT WITH PARITAPREIVIR/OMBITASVIR/RITONAVIR, DASABUVIR WITH RIBAVIRIN: A NATIONAL COHORT STUDY

D. Proca1, C.M. Preda1, C. Baicus2, C.P. Popescu2, M. Manuc3, C.S. Pop2, T. Voiosu2, E. Ceausu2, M. Diculescu2, A. Oproiu3

Contact E-mail Address: doina.proca@gmail.com

Introduction: New direct-acting antivirals (DAAs) have changed the management of HCV infection by being effective in more than 90% of cases [1, 2]. Unfortunately, it has been reported an unexpected high rate of HCC early recurrence following DAA treatment, but more data are needed [3–5].

Aims & Methods: From a national prospective cohort, enrolling 3717 Romanian patients with hepatitis C virus compensated liver cirrhosis who received reimbursement by Ombitasvir/Ribavirin, respectively, Dasabuvir and Ribavirin (OVB/PTV+ + DSV + RBV) for 12 weeks, from December 2015 to August 2016, we analyzed 21 patients with previous HCC. Most of them were treated through surgical resection (9/21), followed by radiofrequency ablation (RFA) 6/21, transarterial chemoembolisation (TACE) 5/21 and only one percutaneous ethanol injection (PEI). The patients received DAA treatment only if they had no cancer relapse 6 months after their last therapy session for HCC. All these patients were evaluated through CT scan or MRI 3 to 6 months after having finished their DAA therapy. The median follow-up is 6 months (3–12). Data were obtained from the Romanian National Health Agency.

Results: Two female patients decompensated and died because of acute liver failure following their having finished the 12 weeks therapy and the other one in week 7 of DAA therapy. This cohort was 52% females, median age 64 years (51–77), 76% IFN pre-treated, 50% associated NASH, 67% with severe necroinflammatory activity (severity score 3–Fibromax), 30% with co-morbidity 24% with Child Pugh A6. The median MELD score was 9 (6 + þ 3). SVR was reported in 19/21 as per protocol analysis (90.5%). Recurrence rate of HCC was 29%, higher in males (40%) than females (18%), higher in patients treated with TACE (40%) than in those with hepatic resection (33%), and the lowest risk of recurrence was observed in RFA (17%). These differences were not statistically significant because of the small sample size. The pattern of recurrence was: intrahepatic growth (1 patient), new intrahepatic lesion (1 nodule in 2 patients, up to 3 nodules less or equal to 3 cm in 1 case) and infiltrative ill-defined growth (1 case) in 1 patient. The conclusion was the presence of fibrosis, making CAUS a feasible tool for screening and evaluation of treatment efficacy in HCC patients not undergoing interferon-free therapy. The median follow-up is 6 months (3–12).

Disclosure of Interest: All authors have declared no conflicts of interest.

P0712 SHEAR WAVE ELASTOGRAPHY FOR THE DIAGNOSIS OF ESOPHAGOGRADIC VARIANCES

1Gastroenterology, Fundeni Clinica Institute, Bucharest/Romania
2Department of Hepato-biliary-pancreatic Surgery, Bucharest College of Medicine, Nishiguchi/Yapan

Contact E-mail Address: hiroko-i@hyo-med.ac.jp

Introduction: Shear wave elastography (SWE) has been used in clinical practice as a noninvasive method to diagnose liver fibrosis by measuring tissue stiffness.

Aims & Methods: The usefulness of SWE in the diagnosis of esophagogastric varices (EGV) associated with portal hypertension was evaluated. 550 patients who underwent measurements of liver stiffness (LS), spleen stiffness (SS) and EGV evaluation between January 2011 and July 2016 were included (no varices, n = 340; esophageal only, n = 107; stomach only, n = 14; esophagus and stomach, n = 89). Virtual Touch Quantification (VTQ) was used for measurements of LS and LS/SS. The spleen index was calculated as the sum of the echo levels (SI) (Linear regression analysis).

Results: LS, SS and SI showed significant increase in accordance with the severity of varices (p < 0.01). The area under the receiver operating characteristic curve (AUC) of LS, SS and SI for detecting varices was 0.8526, 0.9048, 0.8199, with the cut off values 1.67 m/s, 2.81 m/s, 18.5 cm2, respectively, and SS showed usefulness in detecting EGVs. When LS, SS and SI were compared for their ability to detect varices which were > F2 or with RC sign positive, LS, SS and SI were significantly higher for EGVs which require treatment (p < 0.001).

Conclusion: LS, SS and SI for detecting EGVs which require treatment were 0.8131, 0.8693, 0.8270, respectively. All modality showed good detecting ability, and SS particularly showed better performance. When each modality was compared in detection of gastric varices, LS and SS were significantly higher with the presence of gastric varices, but SI did not show a significant difference. The AUROC of LS, SS and SI for detecting gastric varices were 0.7359, 0.8611, 0.8470, and SS and SI showed a superior detecting ability while LS and SI showed decreased abilities.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0715 ATTENUATION COEFFICIENT MEASUREMENT (ACM) AS NOVEL REAL TIME ULTRASOUND ALTERNATIVE TO CAP (FIBROSCAN)
O. Dynyık1, N. Marunchyn2, N. Kolyviak2, O. Fedusenko3, V. Gurianov3
1Bogomolets Institute of physiology of the Ukrainian National Academy of Sciences, Kyiv/Ukraine
2Endocrinology, Bogomolets National Medical University, Kyiv/Ukraine
3Shupyk National Medical Academy of Postgraduate Education, Kyiv/Ukraine

Contact E-mail Address: nazariyobyliak@gmail.com

Introduction: The presence of fat droplets in the hepatocytes (micro- or macro-vesicular hepatic steatosis) under condition of chronic diffuse liver disease (CCDL) increases the attenuation of ultrasound (US). A group of Ukrainian scientists proposed an original algorithm for real-time US attenuation measurement (attenuation coefficient measurement – ACM = patent UA №2014 111234).

Aims & Methods: From total of 3274 patients who underwent abdominal US examination at our clinic: 90.0% were diagnosed with the CCDL; 9.0% were healthy according to Hamaguchi criteria. All these patient we provide ACM (dB/cm) measurement on SonoSite P7 device (Ultrasound, Ukraine), with a 1–6 MHz convex transducer in the right and left lobes. For diagnostic accuracy assessment (used ROC-analysis) we included 142 patients for subanalysis. Evaluation of diagnostic accuracy of ACM performed using ROC-analysis.

Results: Depending on the stage of steatosis according to B-mode median, 25 and 75% percentiles for ACM were as follows: control group 157 (1, 32–1, 53); 1, 86 (1, 78–2, 11); S2–2, 26 (2, 0–2, 49) and respectively for S3–2, 40 (2, 0–2, 82) dB/cm.

ACM value increase parallel the hepatic steatosis progression (p < 0.001), which was also accompanied with presence of very strong correlation between these parameters (r = 0.814, p < 0.001). In patient with NAFLD the association between maximum value of ACM and duration of T2DM and triglycerides (model 1, multiple correlation coefficient r = 0.55; R² = 0.26; p = 0.0044) and ALT (model 2, multiple correlation coefficient r = 0.55; R² = 0.25; p = 0.0005) were observed. After adjustment by the duration of T2DM the level of triglycerides (r = 0.44, p = 0.012) and activity of ALT (r = 0.44, p = 0.012) significantly correlated with ACM. The AUROC of ACM for steatosis diagnosis was 0.925 (95% CI 0.877–0.973). The optimal cutoff point was >2.27dB/cm, with sensitivity, specificity, PPV and NPV respectively 91.5, 77.3, 84.6 and 83.8%. ACM value significantly correlated with CAP (r = 0.630, p < 0.001). Conclusion: The ACM as novel real-time ultrasound approach can be used for noninvasive hepatic steatosis diagnosis, allows clinicians to monitor disease progression and response to treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: CUXI (CUTL1) is a transcription factor able to promote the expression of onco genes and survival factors, especially in stress condition, thus supporting tumorigenesis.

Aims & Methods: Here, we show CUXI activity during hypoxia in liver cancer cells. CUXI was knocked down and its targets were analysed by RT-qPCR in Hep3B cells under hypoxic and/or normal culture condition. The hypoxia condition was established by 24h treatment with 150 μM CoCl2 or with 0.5% O2 atmosphere. Hypoxia markers and CUXI were analysed by RT-qPCR. Transfection qith plasmid expressing a reporter sequence for HIF-1alpha was performed in combination with CUXI knock-down.

Results: Hypoxia determined the up-regulation of HIF1-alpha (Hypoxia inducible factor-1-alpha) and a stable or up-regulated expression of its inhibitor FH1 (SLC2A1) up to 24h prolonged hypoxia. VEGFA was significantly
overexpressed. Knock-down of CUX1 determined a significant down-regulation of HIF-1alpha, FHI-1 and VEGFA. Interestingly, the expression of CDKNA1 was only attenuated after CUX1 knock down and hypoxic stress. HIF1alpha transcriptional activity is dependent by CUX1 expression.

Conclusion: CUX1 exerts an oncogenic role in liver cancer by sustaining the survival mechanism and hypoxia. CUX1 silencing results in suppression of the hypoxia inducible factor and its target VEGFA causing a block of cell cycle in liver cancer cells modulated by the stable expression of CDKNA1.

Introduction: S-Adenosylmethionine (SAMe) is a kind of common liver-protecting medicine. Recent studies have shown that SAMe has the inhibitory effects on hepatocellular carcinoma (HCC). But the specific mechanism has not been elucidated.

Aims & Methods: Here, we examine the effects and relevant mechanism of SAMe on human hepatocellular carcinoma cell HepG2 and mouse hepatocyte AML12. RNA sequencing (RNA-Seq) was used to identify the differentially expressed genes between HepG2 cells which were treated with SAMe or not. And we used qRT-PCR to confirm expression of these genes. MTS and flow cytometry-based assays were carried out in response to SAMe treatment.

Results: A total of 472 SAMe-related genes were identified by RNA-Seq. We found that differentially expressed genes were enriched in cell cycle related signaling pathway significantly by the KEGG and GO Pathway enrichment analysis. Through the construction of protein-protein interaction network, we observed the module associated with cell cycle is in the middle of the whole network. All these results implied that cell cycle pathway may play a very important role in the regulation of SAMe effect on HepG2 cells. Then the RNA-Seq characterized genes involved in cell cycle (MCM3, MCM4, and E2F1) were confirmed by Western blot and qRT-PCR in HepG2 and AML12 cells. MTS analysis showed that SAMe could diminish cell proliferation. And flow cytometry-based assays indicated that treatment with SAMe altered cell cycle kinetics S phase cell cycle arrest.

Conclusion: Altogether, our data enforce the evidence of SAMe possessing of modulating CYCLINB, D, E and MATRIX subunit of the SWI/SNF complex, that is known to be mutated in hepatocellular carcinoma (HCC) remains unclear. The aim of this work is to investigate the role of BRG1 in human HCC cell lines by qRT-PCR and Western Blot. We used siRNA to down-regulate BRG1 in human HCC cell lines. Cell growth and cell invasion decreased in HuH7 and HepG2 cell lines. A positive modulating effect of BRG1 on cell cycle, cell invasion and its effect on the expression of target genes were observed.

Aims & Methods: We examined the expression of BRG1 in human tissue samples and HCC cell lines by qRT-PCR and Western Blot. We used siRNA to down-regulate BRG1 in human HCC cell lines. Cell growth and cell invasion of siRNA transfected cells were assessed by MTT assay and colony formation assay. The expression of target genes after BRG1 downregulation was investigated by qRT-PCR.

Results: BRG1 was found to be significantly increased in HCC samples compared to non-HCC samples. After BRG1 downregulation by siRNA, cell growth and cell invasion decreased in HuH7 and HepG2 cell lines. A positive modulating effect by BRG1 was shown for the expression of CyclinD1, D, E and MMP7 in either HepG2 or HuH7 cell lines.
Conclusion: Our results support the hypothesis that overexpression of BRG1 increases cell growth and cell invasion in HCC. Furthermore, the data highlight genes promoting proliferation and invasion that are being regulated by BRG1 during hepatocarcinogenesis. In particular, CyclinB, D, E and MMP7 appear to play a major role in this context and might be an important link between BRG1 expression and HCC development.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0720 PROGNOSTIC ROLE OF NEUTROPIL-TO-LYMPHOCYTE RATIO IN HEPATOCELLULAR CARCINOMA (HCC)

Aims & Methods: This study was aimed to investigate the prognostic value of NLR in patients with HCC. We performed a retrospective study including patients with hepatocellular carcinoma admitted in the hepatogastroenterology department of Sousse between January 2010 and December 2015.

Results: A total of 76 patients were included in this study. Mean age was 59.8 (33–87 years). The sex ratio was 3.22 (M/F (6/18)). Hepatocellular carcinoma occurred on a liver of cirrhosis in the majority of cases (90.7%). The main causes of cirrhosis were hepatitis B virus infection (11 patients-16%), non alcoholic steatohepatitis (6 patients-8.6%) and alcohol consumption (5 patients-7.2%). Our results showed that high NLR was associated with poor overall survival (OS) in HCC regardless of therapeutic choice (P < 0.05). Otherwise, high NLR was significantly correlated with the presence of vascular invasion (P = 0.002), lymph node metastasis (P = 0.04), tumor multifocality (P = 0.01) and higher incidence of AFP > 200 ng/ml (P = 0.04).

Conclusion: Elevated NLR indicates a poor prognosis for patients with HCC. The NLR is a readily available and inexpensive biomarker, and its addition to established prognostic scores for clinical decision making warrants further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0722 SURGICAL OUTCOME OF PATIENTS WITH FIBROLAMELLAR HEPATOCELLULAR CARCINOMA. DOES IT DIFFERS FROM COMMON HEPATOCELLULAR CARCINOMA?

E. El-Hanafy
Facultu Of Medicin, Mansoura University, Gastroenterology Surgical Center, Cairo/Egypt

Introduction: Fibrolamellar hepatocellular carcinoma (FL-HCC) has conventionally been considered to be a histologic variant of hepatocellular carcinoma (HCC), with distinct clinicopathologic features. It is a rare primary hepatic malignancy that was first described as a pathological variant of HCC by Edmondson in 1956 [1]. The etiology of FL-HCC remains unclear. It typically occurs in normal livers without underlying liver fibrosis or cirrhosis [2]. In contrast to HCC which usually found in the presence of cirrhosis or chronic hepatitis [3], FL-HCC has been reported to occur in association with focal nodular hyperplasia (FNH) a type of benign liver lesion. Many series have mentioned that FL-HCC is less aggressive than conventional HCC [4]. However, other studies have failed to confirm the observation of a better outcome in FL-HCC [5]. Other studies reported that the survival was similar between common HCC and FL-HCC, and that may be related to the higher resectability rate which improve the survival of patients with FL-HCC [6].

Aims & Methods: The aim of this study was to evaluate the clinicopathological features and the surgical outcomes of patients with FL-HCC who were referred to our tertiary referral center over a 15-year period. This is a retrospective study including 22 patients with a pathologic diagnosis of FL-HCC who underwent hepatectomy over a 15-year period. Tumor characteristics, survival and recurrence were evaluated.

Results: There were 11 male and 11 female with a median age of 29 years (range from 21 to 58 years). Two (9%) patients had hepatitis C viral infection and only 2 (9%) patients had alpha-fetoprotein level > 200 ng/ml. The median size of the tumors was 12 cm (range from 5–20 cm). Vascular invasion was detected in 5 (23%) patients. Four (18%) patients had lymph node metastases. The median follow up period was 42 mo and the 5-year survival was 65%. Five (23%) patients had a recurrent disease, 4 of them had a second surgery with 36 mo median time interval. Vascular invasion is the only significant negative prognostic factor.

Aims & Methods: To investigate the efficacy and safety of Microwave versus Radiofrequency Ablation in management of HCA. Out of 320 Patients presented with hepatic focal lesions over 1 year, data of 15 patients diagnosed to have HCA were collected retrospectively. The diagnosis of HCA in those patients was based on radiological findings using triphasic pelvi-abdominal CT, dynamic MRI or ultrasound. The diagnosis of HCA in those patients was based on radiological findings using triphasic pelvi-abdominal CT, dynamic MRI or ultrasound.

Results: Patients with single and multiple hepatocellular adenomas. Of note Microwave ablation is thermal Ablation is safe, feasible and able to eradicate the targeted hepatic focal lesion and prevent known complications of HCA.

Conclusion: Percutaneous ablation of HCA using Microwave or Radiofrequency thermal Ablation is safe, feasible and able to eradicate the targeted hepatic focal lesion and prevent known complications of HCA. Of note Microwave ablation is much more efficient in treating larger lesions through single puncture in contrast to Radiofrequency which needs more than one puncture.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Metabolic disorders, such as obesity and diabetes, are well known risk factors for hepatocellular carcinoma (HCC). Conversely, their impact on the natural history of HCC patients is not established.

Aims & Methods: This study aimed at evaluating the impact of metabolic disorders on clinical features, treatment and survival of HCC patients regardless of its etiology. We analyzed the Italian Liver Cancer (ITA.LI.CA) database regarding 839 HCC patients prospectively collected from 2009 to 2014. The following metabolic features were analyzed: BMI, diabetes, arterial hypertension, hypercholesterolemia and hypertriglyceridemia. According to these features, patients were divided into 3 groups: 0–1 metabolic features, 2 metabolic features, 3–5 metabolic features.

Results: As compared with patients with 0–1 metabolic features, patients with 3–5 features showed lower percentage of HCC diagnosis on surveillance (p 0.021), larger tumors (p 0.038), better liver function (higher percentage of patients with Child-Pugh A) [p 0.07] and MELD < 10 (p 0.003), higher percentage of metastases (p 0.024), and lower percentage of portal vein thrombosis (p 0.010). The BCLC stage and treatment options were similar among the 3 groups, with the exception of a less frequent access to locoregional therapies for BCLC stage B patients with 3–5 features (p 0.012). Overall survival and survival according to BCLC stage and/or treatment did not significantly differ among the 3 groups. Diabetic patients showed a lower survival (p 0.046). MELD score, HCC
motility, nodule size, BCLC stage, portal vein thrombosis and metastasis were independent predictors of lead-time adjusted survival.

Conclusion: Our “real-world” study suggests that motility disorders shape the clinical presentation of HCC but do not seem to play a major role in setting the patient survival, except for diabetes.

P0726 LIVER VOLUME AS A PREDICTOR OF RISK FOR HEPATOCELLULAR CARCINOMA IN CHRONIC HEPATITIS C PATIENTS

N. Kang, J.W. Chung, J. Kim
Internal Medicine, Seoul National University Bundang hospital, Seong-Nam city/ Korea, Republic of

Contact E-mail Address: namkyuny@gmail.com

Introduction: Chronic hepatitis C virus (HCV) infection pose risk for development of hepatocellular carcinoma (HCC), even after viral eradication with effective antiviral therapy. Therefore, risk prediction is clinically important for effective surveillance of chronic hepatitis C (CHC) patients, but this is not well established. Therefore, liver volume was measured on portal venous phase of CT image and correlated for body weight and height: liver volume index (LVI) = ratio of the expected standard volume to the measured liver volume. Kaplan–Meier analysis with the log-rank test used to compare HCC. Cox proportional hazard analysis was used to identify the independent predictors of HCC risk.

Results: The cumulative incidence of HCC was 2.1%, 16.2% and 46.1% at 1, 4 and 8 years, respectively. The risk of HCC was significantly higher in patients with liver cirrhosis compared with non-cirrhotic patients (P < 0.001). Presence of liver nodules was also associated with higher risk for HCC. (P < 0.001), whereas age, sex, alpha-fetoprotein and HCV RNA level were not significant predictors of HCC. Multivariate analysis show that LVI > 1 and presence of LC were independent predictors of HCC (HR: 63.53, CI: 1.24-124.28, P < 0.001/HR: 3.10, CI: 1.26-7.51, P = 0.012, respectively).

Conclusion: Decreased liver volume is an independent predictor of HCC in chronic hepatitis C. Liver volume index is useful in predicting risk of HCC in CHC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0727 HAND AND FOOT SYNDROME AS A PREDICTOR OF OUTCOME IN PATIENTS WITH HEPATOCELLULAR CARCINOMA TREATED WITH SORAFENIB

M. Ochi, A. Okawara, N. Kakinoki, T. Kamoshida, S. Hira
Department Of Gastroenterology, Hitachi General Hospital, Hitachi City/Japan

Contact E-mail Address: masaochips@hotmail.co.jp

Introduction: Sorafenib is a multi-thyrosine kinase inhibitor classified as a neo-vascularization inhibitor. A previous study indicated that the administration of sorafenib is a multi-thyrosine kinase inhibitor classified as a neo-vascularization inhibitor. The aim of this study was to assess the significance of liver volume in the prediction of HCC risk in CHC patients. A retrospective cohort of 101 CHC patients who received 4–phased dynamic CT imaging studies during sorafenib administration for liver volume and outcome of surveillance. Liver volumes were measured on portal venous phase of CT image and corrected for body weight and height: liver volume index (LVI) = ratio of the expected standard volume to the measured liver volume. Kaplan–Meier analysis with the log-rank test used to compare HCC. Cox proportional hazard analysis was used to identify the independent predictors of HCC risk.

Results: The cumulative incidence of HCC was 2.1%, 16.2% and 46.1% at 1, 4 and 8 years, respectively. The risk of HCC was significantly higher in patients with liver cirrhosis compared with non-cirrhotic patients (P < 0.001). Presence of liver nodules was also associated with higher risk for HCC. (P < 0.001), whereas age, sex, alpha-fetoprotein and HCV RNA level were not significant predictors of HCC. Multivariate analysis show that LVI > 1 and presence of LC were independent predictors of HCC (HR: 63.53, CI: 1.24-124.28, P < 0.001/HR: 3.10, CI: 1.26-7.51, P = 0.012, respectively).

Conclusion: Decreased liver volume is an independent predictor of HCC in chronic hepatitis C. Liver volume index is useful in predicting risk of HCC in CHC.

P0729 UNUSUAL METASTASIS OF HEPATOCELLULAR CARCINOMA

I. Nakhe1, I. Benelrbahadi2, F.Z. Ajana1
1Service Medecine C Rabat Maroc, Hospital Ibn Sina Rabat, Rabat/Morocco
2Rabat, Ibn Sina Hospital, Rabat/Morocco

Contact E-mail Address: ibissanamnakahe@gmail.com

Introduction: Hepatocellular carcinoma is the most common primary tumor of the liver and is estimated to cause more than a quarter of a million deaths each year throughout the world. Extrahepatic metastasis of HCC occurs in about 30–50% of patients, and it depends on HCC stages. I. The most frequent site is lung, followed by lymph node, bone, and adrenal gland. 2 Extrahepatic metastases to unusually sites from HCC have been reported in a few case reports. We report cases of patients with unusual extrahepatic metastatic sites from HCC.

Aims & Methods: We carried out a retrospective study of 16 patients with unusual extrahepatic metastasis of hepatocellular carcinoma out of 1047 cases of HCC treated at the hepatogastroenterology department "Medicine C" of the Ibn SINA University Hospital during the past 22 years. The diagnosis was suspected based on clinical signs and imaging data, and confirmed by histology when the biopsy of the metastasis was possible, were excluded from this study, patients with lung metastasis, lymph node and portal thrombosis.

Results: Our study included 16 patients, 10 men and 6 women with a mean age of 58.5 years ranging from 37 years to 75 years. 13 patients had cirrhosis due to hepatitis C virus, 1 patient had a cirrhosis due to viral B infection and 2 patients had HCC within anoncirrhotic liver. All patients had one or more HCC, ranging in size from 2 to 10 cm. The AFP was normal in 11 cases and elevated in 4 cases (> 200 ng/mL). We collected 4 cases of adrenal metastases, 3 costovertebral metastases, 2 gastric metastases, 2 brain metastases, 1 cranial metastasis, 1 caval metastasis, 1 ovarian metastases, 1 nasopharyngeal metastasis, and a case of metastasis in the path of percutaneous biopsy of HCC. In 4 cases the diagnosis of HCC and metastasis was synchronous while in 12 cases median time from diagnosis of hepatocellular carcinoma and extrahepatic HCC was 15.5 months. Therapeutic abstention was decided in 14 patients for the advanced stage of the disease. Cautious metastasis was resected surgically and HCC occurring in healthy liver was treated by laparotomy and upper pole gastrectomy in gastric metastasis. The average survival was estimated at 14 months with a decline of 17.3 months, 6 cases were lost to follow and 6 deaths occurred in our series.

Conclusion: The incidence of unusual and extrahepatic metastasis of HCC diagnosed during clinical course was not frequent. The diagnostic procedures for extrahepatic metastasis have been standardized, however considering the substantial advances in treatment of HCC, the detection of extrahepatic HCC is crucial for patients to receive appropriate therapy, which ultimately determines patient survival.

Introduction: Hepatocellular carcinoma is a rare primary hepatic tumor comprising features of both, cholangiocarcinoma and hepatocellular carcinoma (cHCC-ICC). Few data concerning the epidemiology of cHCC-ICC have been reported, mainly from surgically treated cases in Asian and American populations.

Aims & Methods: The main objective of this retrospective multicenter study was to evaluate epidemiological features and overall survival of histologically proven advanced CHCC patients in a French population. Data from patients treated for histologically proven cHCC-ICC in six French university hospitals between 2008 and February 2017, were retrospectively collected. The main clinical, biological, therapeutic features and OS were reported. Statistical analysis was performed using R software (R Foundation for Statistical Computing).

Results: Thirty patients were included (76.6% of men, median age 64 years [extreme 37–88]. Cirrhosis was associated in 33.3% of cases (Child-Pugh score A: 70%). Positive serology for hepatitis B virus and C was found in respectively.
Aims & Methods: The aim of this study was to evaluate the clinical manifesta-
tions, risk factors and prognosis of hepatocellular carcinomas with hepatic involvement. We conducted a retrospective study of patients diagnosed with hepatic hepatitis at our center between 2005 and 2016.

Results: During the 12 years, 36 hepatic lymphomas were identified, 27 primary hepatic lymphomas and 9 with secondary hepatic involvement. The mean age at diagnosis was 53.5±14.6 years and 50% were males. Only one patient had hepatitis B and none had hepatitis C. The majority (94.4%) had symptoms at the time of diagnosis, with fatigue (83.3%), night sweats (61.1%) and loss of weight (44.4%) being the most common. The imaging presentation was that of a single mass in 47.2% of cases, multiple masses in 30.6% and infiltrative mass in 22.2%. The most common lymphoma subtypes were diffuse large B-cell lymphoma (52.8%), MALT lymphoma (11.1%) and Hodgkin’s lymphoma (11.1%). Survival at the end of one year was 63.8% and 27.8% at 3 years. Age ≥ 60 years (p = 0.004) was the only factor that was significantly associated with higher mortality.

Conclusion: Hepatic lymphomas are rare entities that may occur in different ways, and diffuse large B-cell lymphoma being the most common subtype. They presented a 3-year survival of only 27.8% and the age over 60 years was the only factor significantly associated with mortality.

Aims & Methods: The aim of this study was to modify the Barcelona Clinic Liver Cancer (BCLC) staging system for hepatocellular carcinoma (HCC). This study aimed to modify BCLC system based on PS to derive more relevant modified BCLC system for HCC patients.

Results: This study aimed to modify BCLC system based on PS to derive more relevant modified BCLC system for HCC patients. The patients with PS 1 or 2 without VI or EHS were categorized to BCLC C regardless of tumor burden, VI or EHS. The C1-C4 sub-groups showed significant different OS distribution between groups (P = 0.001). The mBCLC#2 stage C was further sub-classified into C1, C2, C3 and C4 according to the variables which selected by statistical and clinical importance. The C1-C4 sub-groups showed significant different OS distribution between groups (P = 0.001). The conclusions of this study provide clinical data to improve the Barcelona Clinic Liver Cancer System.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Inhibition of microRNA-21 (miR-21) prevents necroptosis in the mouse pancreas. In turn, we recently showed that necroptosis contribute to hepatic necro-inflammation in the common bile duct ligation (BDL) murine model.

Aims & Methods: We aimed to evaluate the role of miR-21 in mediating deleterious processes associated with cholestasis. The functional crosstalk between miR-21 and necroptosis was investigated in vitro. miR-21 expression was evaluated in the liver of primary biliary cholangitis (PBC) patients. C57BL/6 wild-type (WT) or miR-21-deficient (miR-21−/−) mice were subjected to BDL or sham surgeries, with biochemical, molecular and histological analysis of hepatic damage, fibrosis, necroptosis and bile acid metabolism, after either acute (3 days) or chronic (14 days) injury.

Results: Studies in miR-21−/− primary mouse hepatocytes established a functional link between miR-21 and necroptosis through cyclin dependent kinase 2 mediating pro-fibrotic gene expression. Hallmarks of necroptosis were observed in the liver of BDL miR-21−/− mice, via relieved repression of cyclin dependent kinase 2. Further, miR-21−/− mice displayed improved adaptive response in the expression of bile acid homeostasis-associated genes.

Conclusion: miR-21 ablation ameliorates liver damage and necroptosis in BDL mice; as such, inhibition of miR-21 should arise as a promising approach to treat cholestatic liver diseases. Supported by FCT, Portugal through grants PTDC/IM-MEC/0895/2014 and UID/DTP/04138/2013, and fellowships SFHR/BD/9119/2012 (MBA), SFHR/BD/88212/2012 (PMR), and SFHR/BD/104160/201 (ALS).

P0735 IS COMPLETE STONE REMOVAL ALWAYS NECESSARY IN EXTREMELY ELDERLY PATIENTS?

Contact E-mail Address: n-okuda@ise.jrc.or.jp

Introduction: Endoscopic sphincterotomy, endoscopic papillary balloon dilation, and radial peripapillary incision are widely recognized as safe and effective treatments of choledocholithiasis. However, endoscopic stone removal does have some complications. Although the life expectancy of elderly patients has increased dramatically worldwide, little information is available on the necessity of complete endoscopic stone removal in extremely elderly patients.

Aims & Methods: The aim of this study was to evaluate the safety and efficacy of complete endoscopic stone removal in extremely elderly patients. We retrospectively evaluated all extremely elderly patients (older than 90 years) who had undergone complete stone removal for choledocholithiasis at Ise Red Cross Hospital between January 2012 and December 2016. Included patients were divided into complete stone removal and incomplete stone removal (failure to achieve complete stone removal and insertion of a plastic stent) groups. We compared the complication rate, overall survival (OS), and disease-specific survival (DSS) rate between the two groups.

Results: In total, 67 patients were included in this study; 36 (54%) had complete stone removal and 31 (46%) had incomplete stone removal. The median age of the patients was 92 years (range 90–100 years), median follow-up period was 462 days (range 6–1449 days) and the male-to-female ratio was 15:52. Baseline characteristics (age, body mass index, performance status, and comorbidities), rate of complications (perforation, bleeding, hypoxemia, or decreased blood pressure during the endoscopic procedure), and total number of endoscopic procedures did not significantly differ between the two groups. The median number of stones was one (range 0–5) and two (range 1–5) (P = 0.013), while the median diameter of the largest stones was 9 mm (range 0–27) and 14 mm (range 5–32) (P = 0.001) in the complete and incomplete stone removal groups, respectively. During the referral period, OS was 33.5% and 41.9% and DSS was 5.56% and 3.22% in the complete and incomplete stone removal groups, respectively. Kaplan-Meier analysis found no significant difference in OS and DSS between the two groups (P = 0.187 and P = 0.581, respectively).

Conclusion: Patients in the incomplete stone removal group tended to have more numerous and larger stones. This single-centre retrospective study revealed no significant difference in OS and DSS between the two groups. Complete stone removal might not be always necessary in extremely elderly patients aged 90 years and older.

P0736 THE EVALUATION OF TRANSPAPILLARY ENDOSCOPIC GALLBLADDER DRAINAGE WITH THE USE OF INTRADUCTAL ULTRASONOGRAPHY

Contact E-mail Address: dr200727@g.ks.so-net.ne.jp

Introduction: The number of indications for endoscopic transpapillary gallbladder drainage (ETGBD) to treat cholecystitis patients is increasing with the aging of the population and prescribing antithrombotic agents. ETGBD is one of the challenging procedure because it is difficult to identify the cystic duct (CD) orifice. From November 2015, we performed with ETGBD using intraductal ultrasonography (IDUS) complementarily. The CD orifice can be identified using IDUS, resulting in cannulation to the CD. We investigated the success rate and clinical outcomes of ETGBD in combination with using IDUS.

Aims & Methods: ERCP was performed in 1000 patients (1400 times) at New Tokyo Hospital between July 2015 and November 2016. Among them, 47 patients underwent ETGBD, 58 patients with IDUS and 39 without IDUS. In this study, we investigated the success rate of ETGBD retrospectively. The success of ETGBD was defined as cannulation into the gallbladder within two trials. Results: The mean age and male proportion of patients in the group with IDUS was similar to that in the group without IDUS (74.5±14.1 vs 73.3±11.3; P = 0.600 and 18/40 and 13/26; P = 0.828). The procedure success rate was 78.4% (76/97) in total; 86.2% (50/58) in the group with IDUS and 66.7% (26/39) in the group without IDUS (P = 0.026). Using IDUS under fluoroscope image all allowed patients in the group with IDUS to identify the CD orifice. ETGBD procedures in eight patients were unsuccessful because of a highly flexion of the CD in seven patients and an obstruction of the CD orifice caused by tumor invasion in one patient. Although both groups developed mild pancreatitis (one patient in the group with IDUS, and two patients in the group without IDUS), no significant difference was observed in the two groups (P = 0.563). All patients were successfully managed with conservative treatment. There were no any other complications in the two groups.

Conclusion: The success rate of ETGBD in the group with IDUS was significantly higher than that in the group without IDUS. IDUS may be useful as a complementary option of endoscopic gallbladder drainage.

P0737 THE RENDEZVOUS PROCEDURE FOR THE MANAGEMENT OF BILIARY DUCT INJURIES AFTER CHOLECYSTECTOMY: SHORT AND LONG-TERM OUTCOMES AND PREDICTORS FOR SUCCESS

1Department Of Surgery, Academic Medical Center, Amsterdam/Netherlands
2Interventional Radiology, Academic Medical Center, Amsterdam/Netherlands
3Gastroenterology, Academic Medical Center, Amsterdam/Netherlands
4Department Of Surgery, Academic Medical Center, Amsterdam/Netherlands

Contact E-mail Address: a.m.schreuder@amc.uva.nl

Introduction: Bile Duct Injury (BDI) following laparoscopic cholecystectomy is a persisting problem. The rendezvous procedure (RV) provides a combined endoscopic and percutaneous approach in order to re-establish bile duct continuity in complex BDI.

Aims & Methods: The aim of this study is to assess short-term and long-term outcomes of the RV. All consecutive patients with BDI referred to our tertiary center were analyzed retrospectively. RV procedure was performed when endoscopic stenting or PTC failed and when deemed feasible by a dedicated multidisciplinary team including a hepatopancreato-biliary surgeon, gastroenterologist and interventional radiologist. Classification of BDI, technical success of RV, procedure-related complications and outcomes were assessed.

Results: Among a total of 812 patients, RV was performed in 47 (5.8%) patients, of which 31 (66%) were diagnosed with complete transaction of the bile duct (type D3/Naraberg type E injury). Primary success rate of RV was 94% (44/47 patients). Reasons for failure (N = 3) were inability to pass a stricture and inability to make contact between the two wires. In 26/47 patients (55%) RV was the final successful treatment. In 17/47 patients (36%) RV acted as a bridge to
surgery; although the RV was initially successful, late complications (stenosis, stent dysfunction) required elective hepaticojejunostomy (HJ). Procedure-related adverse events occurred in 10 patients (18%) with cholangitis being the most frequent complication (N = 4.7%). No life-threatening adverse events and no 30-day mortality occurred.

Conclusion: In experienced hands, RV is safe with a final non-surgical success rate of 55%. When endoscopic stenting fails in patients with complex BDI, RV can be considered as a viable treatment option before surgical repair.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0739 TRANSGRECTAL GALLBLADDER PRESERVING CHOLECYSTOLITHOTOMY AND POLYPECTOMY BY PURE NOTES
B. Liu
Gastroenterology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou/China

Contact E-mail Address: 3217265338@yahoo.com

Introduction: Transcolonic and transrectal NOTES in human cases was greatly restricted by the fact of fecal contamination. We developed a detachable intracolonic balloon to help keep the colon sterile by blocking the colonic lumen. Although cholecystectomy is widely used for treating gallbladder polyps and gallstones, there is still a controversy about whether or not the gallbladder should be preserved. However, postcholecystectomy syndromes, such as bile duct injury and the correlation with colon cancer, remind us of the importance of gallbladder preservation.

Aims & Methods: Approved by the Independent Ethics Committee, we’ve completed 8 transrectal gallbladder preserving cholecystolithotomy (TRGCP) and 3 transrectal gallbladder preserving polypectomy (TRGPP) and 2 combined cases by pure NOTES. Moreover, 1 case of TRGCP was done by hybrid NOTES. As the figures show, the balloon was placed in the transverse colon to block the colonic lumen, and the distal colon cavity was disinfected with povidone-iodine solution. An incision was made on the anterior rectal wall 12–17 cm from the anus. The endoscope was advanced into the peritoneal cavity with liver and gallbladder identified. The bile was aspirated before an incision on the gallbladder wall was made. Stones and/or polyps were found inside of the gallbladder. Stone extractor and biopsy forceps were used to take out the stones. The polyps were coagulated and removed by electric biopsy forceps. The muscular layer and the adventitial layer were successively closed with endolips. Peritoneal cavity lavage was performed with sterile saline. The rectal incision was closed with endolips and endolamps tightly. At the end of the procedure, the balloon was pulled out after being deflated.

Results: The mean operation time (from incision making till the last clipping) was 180.5 min. (89–467 min.), 6 hours after anesthesia, the patients could drink water, and liquid diet was resumed 24 hours later. Postoperatively, 4 of the 14 patients felt mild abdominal distention which disappeared within 12 hours when they were able to get off the bed. For 1 patient with acute cholecystitis, a hybrid NOTES with laparoscopy was performed. Moreover, gallbladder drainage and peritoneal lavage were used, and the abdominal pain relieved soon. All the patients were discharged without any adverse events and all felt good during the follow-ups.

Conclusion: The usage of the detachable balloon can prevent the operative field from fecal contamination effectively. TRGCP and TRGPP by pure NOTES are suitable for both males and females. Transrectal route provides a novel alternative approach for the treatment of gallbladder polyps and gallstones. To our knowledge, this is the first human case series of transrectal gallbladder preserving cholecystolithotomy and polypectomy by pure NOTES. However, multietnereted, prospective, controlled researches with more cases are needed in the future.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0740 KML001, AN ORAL ARSENIC COMPOUND, AS PALLIATIVE CHEMOTHERAPY IN ADVANCED BILIARY TRACT CANCERS AFTER FAILURE OF GEMCITABINE BASED CHEMOTHERAPY
Department Of Internal Medicine And Institute Of Gastroenterology, Yonsei University Health System Dept. of Internal Medicine Dept. of Gastroenterology, Seoul/Korea, Republic of

Contact E-mail Address: woforce@naver.com

Introduction: Sodium metarsenite (NaAs2O3: code name KML001) is an orally bioavailable arsenic compound with potential anti-cancer activity. However, the effect of KML001 has not been evaluated in patient with biliary tract cancers. We investigated the potential of KML001 as palliative chemotherapy in patients with advanced biliary tract cancers who non-respond to gemcitabine-based chemotherapy.

Aims & Methods: The study was designed to evaluate safety, tolerability and effectiveness of KML001 as palliative chemotherapy in advanced biliary tract cancer. Inclusion criteria were 1) inoperable or metastatic cholangiocarcinoma and gallbladder cancer, and 2) previous history of failure to gemcitabine-based chemotherapy. Exclusion criteria were 1) naïve patient to chemotherapy, 2) ECOG PS > 3, and 3) history of decompensated congestive heart failure, uncontrolled arrhythmia, and QT prolongation (QTc > 480 ms). KML001 (Kominos, Konipharm International Co., Ltd.) was administrated as 7.5 mg daily to eligible subjects. Every two months, patient took response evaluation by biliary CT scan.

Results: A total of 44 patients (21 females and 23 males) were enrolled prospectively between November 2011 and October 2014. Mean age of the patients was 63±10.0 years, and mean performance status (ECOG PS) was 2.2±0.8. Among them, 18 patients were enrolled in the control arm and 44 patients were in the treatment arm. The median duration of follow-up was 7.3 months (range 0.01–24.8). The mean KML001 dose was 13.4±4.9 mg daily. The most common adverse events were grade 1–2 fatigue, nausea, and anorexia. No grade 3–4 adverse events were experienced. The median survival was 11.3 months (95% CI 5.6–17.0).

Disclosure of Interest: All authors have declared no conflicts of interest.
The number of liver segment drained with the number of liver segment. The drain was confirmed by removing the drains that had the segments resected in case of surgery, and/or the segments with invasion of more than 50% by tumor. The aim of the study was to evaluate the effect of the quality of the drainage on the patients survival. Quality of the drainage was defined by the percentage of liver segments drained. Results: 60 (38 men) patients were included from 01/2015 to 07/2016. Mean age = 69.84 years old. The classification of the stenosis was type II for 17 (29%) patients, type III for 20 patients (34%), type IV for 22 (37%). Histology corresponded to cholangiocarcinoma for 15 patients (25%) and others cancers for 19 (32%). Median follow-up was 8.5 months (5.5–16.5). The median of survival was 5 months (2.3–12.3). In unvaried and multi varied analysis there was a significant correlation between the percentage of segments drained > 50% (p < 0.05) and the survival. There was no impact on the survival according to the different techniques used to drain the bile ducts. To confirm the efficiency of the drainage, a ROC curve was performed establishing a correlation between patients receiving chemotherapy and percentage of liver drained (area curve = 0.7 (0.65–0.88). Conclusion: The survival of patient with a malignant stenosis of the biliary confluence is highly correlate with the rate of the liver segment drained. Disclosure of Interest: All authors have declared no conflicts of interest.

Table 1: Treatment outcomes

| Study period, mean, mo (range) | 1.5 (0.5–10.0) |
| Progression free survival, mo (IQR) | 1.7 (0.8–2.3) |
| Survival from study-enroll, mo (IQR) | 2.5 (1.4–4.9) |
| Best response, n (%) | 3 (6.5%) |
| SD | 23 (52.3%) |
| Not evaluated | 18 (40.9%) |
| ECOG, n (%) | 19 (43.2%) |
| Increased | 2 (4.5%) |
| Main | 8 (18.6%) |
| decreased | 31 (72.1%) |
| Adverse event, n (%) | 4 (9.3%) |
| Grade 1 | 16 (36.4%) |
| Grade 2 | 29 (65.9%) |
| Grade 3 | 12 (27.3%) |
| Grade 4 | 0 (0%) |
| Drop out cause, n (%) | 1 (2.3%) |
| - drug reaction | 4 (9.1%) |
| Patient’s death | 7 (15.9%) |
| - Disease progression | 22 (50.0%) |
| - Withdrawal consent | 5 (11.4%) |
| - Loss of follow-up | 2 (4.5%) |
| Poor general condition | 3 (6.8%) |

Conclusion: KML001 was safe and well tolerated in respects of adverse events. KML001 was also shown promising result in disease control and pain control. KML001 can be another palliative treatment option for patients with advanced biliary tract cancers who non-respond to gemcitabine based chemotherapy. Disclosure of Interest: All authors have declared no conflicts of interest.

P0742 SYSTEMATIC REVIEW AND META-ANALYSIS OF TRANSABDOMINAL AND ENDOSCOPIC ULTRASOUND FOR GALLBLADDER POLYPS

S. Z. Wemmaker1, M. P. Lamberts2, M. Di Martino3, J.P.h. Drenth4, K. S. Gurusamy2, C. J.h.m. Van Laarhoven1
1Dept. Of Surgery, Radboud University Medical Centre, Nijmegen/Netherlands
2Dept. Of Gastroenterology, Radboud Univers. Medisch Centrum, Nijmegen/Netherlands
3Surgery, Royal Free Campus, UCL Medical School, London/United Kingdom

Contact E-mail Address: sarah.wemmaker@radboudumc.nl

Introduction: Approximately 0.6% to 4% of cholecystectomies are for gallbladder polyps. The decision to perform cholecystectomy is based on presence of gallbladder polyp on transabdominal ultrasound (TAUS) or endoscopic ultrasound (EUS), or both. This decision is also influenced by whether the polyp is true or pseudo polyp. True polyps are neoplastic, either benign (adenoma) or (pre)malignant (dysplastic polyp/carcinoma). True polyps usually need surgery, as they are thought to have malignant potential through the adenoma-carcinoma sequence. (Pre)malignant lesions should be operated sooner than benign lesions. There has been no systematic review and meta-analysis on the accuracy of TAUS and EUS in the diagnosis of gallbladder polyps, true gallbladder polyps and (pre)malignant polyps.

Aims & Methods: The aim was to determine and compare the accuracy of TAUS and EUS for diagnosis of gallbladder polyps, differentiating between true and pseudo polyps and differentiating between (pre)malignant and benign polyps. Studies of TAUS and EUS were identified using the Cochrane Library and EMBASE. Search terms included: gallbladder polyps, benign polyps, malignant polyps, adenoma, dysplasia, dysplastic polyp, carcinoma, adenocarcinoma, true polyp, pseudo polyp, histology, accuracy, sensitivity, specificity, positive likelihood ratio, negative likelihood ratio, pooled estimates of sensitivity and specificity. Otherwise the principal of pretest probability were used to test whether TAUS or EUS was superior. Post-test probabilities were calculated using the median prevalence (as pre-test probabilities) and summary positive and negative likelihood ratios.

Results: A total of 17 studies were included in this review. For diagnosis of gallbladder polyps six studies on TAUS were included. The sensitivities and specificities of the studies ranged from 0.45 to 1.00, and 0.91 to 0.98 respectively. There were no studies on EUS for this topic. For differentiating between true and pseudo polyps, seven studies were included. All seven studies reported on TAUS, four studies also reported on EUS. The sensitivities and specificities of the studies ranged from 0.47 to 1.00 and 0.51 to 0.98 for TAUS, and from 0.63 to 1.00 and 0.84 to 0.96 for EUS. For differentiating between (pre)malignant and benign polyps, five studies were included. Four studies reported on TAUS and three studies on EUS. The sensitivities and specificities of the studies ranged from 0.91 to 1.00 and 0.46 and 1.00 for TAUS and from 0.69 and 0.92, and 0.87 to 0.95 for EUS.

No studies were of high methodological quality. The results of the pooled sensitivities, specificities and post-test probabilities are shown in Table 1. HRSOC analysis showed no significant difference between the diagnostic accuracy of TAUS and EUS for differentiating between true and pseudo polyps and for...
differing between (pre)malignant and benign polyps (p=0.174 and p=0.589 respectively).

**Conclusion:** Diagnostic accuracy of TAUS for diagnosis gallbladder polyps is moderate and decreases further when differentiating between polyp types. TAUS would regularly provide false positive results, leading to unnecessary surgery. There was no evidence that diagnostic test accuracy of EUS was better than TAUS. Further studies of high methodological quality are needed to determine diagnostic accuracy of EUS and TAUS for differentiating between polyp types.

This abstract is based on a pre-peer review draft of a Cochrane Review.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** miwa@yokohama-cu.ac.jp

**Introduction:** In its early stages, gallbladder cancer is an asymptomatic disease, and is associated with a poor prognosis if found in an inoperable condition. Several investigations have reported the utility of contrast-enhanced ultrasonography (CEUS) in low mechanical index (MI) contrast mode using a microbubble contrast agent for gallbladder lesions. However, CEUS images with low MI setting are influenced by the echogenicity of background B-mode and cannot depict precise vessel images, in contrast with high MI contrast mode.

**Aims & Methods:** The aim of this study was to assess the diagnostic value of CEUS in high MI contrast mode for characterizing polyloid lesions of the gallbladder (PLG). Thirty-six patients with PLG, including 17 with gallbladder cancer and 19 with benign polyps, who underwent CEUS were enrolled. The institutional review board approved this study and informed consent was obtained. Perfluorobutane-based contrast agent and high MI contrast mode was used for CEUS. Two blinded readers retrospectively evaluated images obtained in B-mode and CEUS. Kappa values, which reflect inter-observer agreement. Subsequently, patients were stratified according to lesion size at the largest diameter, and the diagnostic accuracy for gallbladder cancer in B-mode and CEUS were assessed.

**Results:** Two patients with malignant PLG could not be evaluated in B-mode due to sludge. Kappa values for CEUS were graded as good or excellent, and were better than in B-mode. Age and size of malignant PLGs were significantly larger than benign lesions. In B-mode, 80% (12/15) of malignant PLGs exhibited heterogeneity (p < 0.01). On CEUS, malignant PLGs exhibited sessile-shape (76% [13/17]), dilated vessels (71% [12/17]), irregular vessels (82% [14/17]), and heterogeneous enhancement (59% [10/17]) (p < 0.01). Except for heterogeneous enhancement, all features remained significantly different after stratification according to size of PLG between 11 mm and 20 mm on CEUS. The sensitivity, specificity, and accuracy for diagnosis of gallbladder cancer was 80% (12/15), 79% (13/19), and 73% (25/34) in B-mode, 94% (16/17), 89% (17/19), and 92% (25/28) in CEUS and 88% (7/8), 91% (10/11), and 89% (17/19) on CEUS after stratification according to size, respectively.

**Conclusion:** CEUS in high mechanical index contrast mode was a useful modality for differentiating gallbladder cancer and benign PLGs.

**ASSOCIATION OF CIRCULATING ADIPONECTIN LEVELS AND TUMOR STAGE IN CHOLANGIOCARCINOMA**

A. Saray, B. Gogov, N. Zubcevic, D. Probić, A. Mehmédović, A. Puhalović Department Of Gastroenterology And Hepatology, Clinical Center University of Sarajevo, Sarajevo/Bosnia And Herzegovina

**Contact E-mail Address:** sarayaida19@gmail.com

**Introduction:** Multiple recent studies have indicated that some of adipose tissue-derived hormones may significantly influence the growth and proliferation of GI tumors including liver cancer (1, 2). However, the role of adipokines such as adiponectin and leptin in biliary tract cancer have not been well studied before. The aim of the study was to analyze plasma concentrations of adiponectin and leptin in cholangiocarcinoma (CC) patients and to compare these concentrations to clinicopathological parameters.

**Aims & Methods:** Baseline levels of adiponectin and leptin were determined in 38 consecutive patients with newly diagnosed cholangiocarcinoma and 38 healthy control subjects. The association between adiponectin and leptin and tumor stage was evaluated using nonparametric Spearman’s correlation test. Control subjects were matched to case patients by age, sex and BMI. Survival analysis used the Kaplan-Meier curve and the Cox proportional hazards model.

**Results:** Overall median adiponectin concentrations were lower in CC patients versus control subjects (5.1 vs 9.3 mg/mL, P = 0.001). In CC patients with T stage 2–4 (n = 22) median adiponectin concentrations were significantly lower than in CC patients with T stage 1 (n = 16) (3.8 vs 6.6 mg/mL, P = 0.001). The mean leptin levels were not significantly decreased in CC patients (P = 0.45). Adiponectin concentrations were inversely correlated with tumor T stage (r = -0.811, P = 0.01) of CC patients. Higher adiponectin levels at baseline were associated with increased overall survival in T stage 2-4 patients (Cox F test = 2.139, P < 0.05).

**Conclusion:** This study identified an association between adiponectin levels and tumor stage suggesting a potential role for adiponectin in progression of cholangiocarcinoma. Furthermore these results suggest, for the first time, that serum adiponectin levels might represent a prognostic indicator in patients with CC. Our results support the hypothesis linking adipose tissue-derived hormones levels to growth of obesity-associated cancers (3). Adipokines appear to play an important role in risk prediction and management of cholangiocarcinoma patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**

Recent many studies have been conducted to investigate the association between obesity and cancer incidence. Most of the studies were on the relationship between obesity and cancer outcomes. There is evidence that obesity can affect the progression of cancer and influence on the nutrient status of patients and obesity can affect the pharmacokinetics of anticancer drugs. The impact of obesity on survival is known to vary in different cancers. Biliary tract cancer was less frequently analyzed and most of the studies were on the relationship between obesity and cancer incidence.

**Aims & Methods:** We performed this study to investigate the association between BMI and overall survival in advanced biliary tract cancer patients with chemotherapy. Between January 2005 and December 2015, two hundred and eighty-four patients who underwent chemotherapy for biliary tract cancer were retrospectively reviewed. The relationship between BMI (kg/m²) and overall survival (OS) was assessed. Based on World Health Organization BMI category and 2014 Clinical Practice Guidelines for Overweight and Obesity in Korea, BMI was classified as follows: underweight, <18.5 kg/m²; normal, 18.5-22.9 kg/m²; overweight, 23-24.9 kg/m²; obese, ≥25 kg/m².

**Results:** Median OS was 12.1 months for underweight patients, 10.5 months for normal weight patients (BMI 23–24.9 kg/m²) had a reduced risk of mortality in multivariate analysis (HR 0.491, CI 0.334–0.721; 95% p = 0.036). In the additional analysis for the effect of change in body weight and BMI to the overall survival, larger amount of change in body weight was associated with further decrease in overall survival.

**Conclusion:** Slightly overweight status and the maintenance of body weight during the initial period of chemotherapy is independent predictor of better overall survival in advanced biliary tract cancer patients with good performance status.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Conclusion:** PHC patients undergoing exploratory laparotomy have a high risk of an adverse outcome. A preoperative risk score for adverse outcome may help clinicians to inform patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Meier curves, and calibration curves revealed good predictive abilities. The risk score identified patients with a 1-year survival probability ranging from 15% to 73%.

Conclusion: We developed a prognostic score to predict overall survival for PHC patients using eight independent prognostic factors available at presentation. This score may help to inform patients and guide individualized treatment decision making.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Malignant biliary obstruction has a poor prognosis unless secondarily to a resectable primary cancer. Recent data on PTC for the relief of malignant obstruction in a palliative setting demonstrated a high early mortality. We have therefore examined outcomes of ERCP in inoperable malignant obstruction.

Aims & Methods: The Hospital Episode Statistics (HES) database contains diagnostic and procedural data for all hospital attendances in England. HES is linked to the Office for National Statistics (ONS) to provide mortality data. All subjects from April 2001 to April 2015 in England with an ICD10 code for cancer 2 years prior to ERCP or in the following 6 months were examined. Subjects undergoing a curative surgical procedure were excluded. Associations between demographics, co-morbidities, unit ERCP volume and mortality were examined by logistic regression.

Results: 49055 subjects were included in the study of whom 48.7% were male, median age 74.5 years (range 19–104). Pancreatic cancer was the most common aetiology (63.5%), followed by liver and intrahepatic bile duct malignancy (19.4%). Mortality was 4.16%, 10.9% and 19.6% for 7 days, in hospital and 30 day respectively. In multivariate analysis male gender (OR 1.14, (95% CI 1.08–1.20) p < 0.001); increasing by age quintile 64–71 (1.34, (1.23–1.47) p < 0.001), 72–77 (1.57, (1.44–1.72) p < 0.001); most deprived quintile (1.22, (1.12–1.33), p < 0.001); 11 to 15 (1.49, (1.33–1.66), p < 0.001) 16 to 20 (2.78, (2.55–3.03), p < 0.001); most deprived quintile (1.22, (1.12–1.33), p < 0.001); increasing co-morbidity score 1 to 5 (1.09, (1.02–1.16), p = 0.012), 6 to 10 (1.23, (1.12–1.35), p < 0.001) 11 to 15 (1.49, (1.33–1.66), p < 0.001) 16 to 20 (2.78, (2.55–3.03), p < 0.001); advancing year of ERCP 2013/14 (0.78, (0.74–0.80), p = 0.001), 2014/15 (0.85, (0.74–0.98) p = 0.028); and previous renal failure (1.92, (1.77–2.09), p < 0.001) were associated with increasing 30 day mortality. Asian ethnicity (0.82, (0.67–0.99), p = 0.036); Cancer of the extrahepatic and unpaired parts of biliary tree (0.60, (0.55–0.65), p < 0.001) and upper tertile of unit ERCP activity (>230) per annum (0.86, (0.80–0.93), p < 0.001) were negatively associated with 30 day mortality.

Conclusion: Short-term mortality in subjects with malignant biliary obstruction following ERCP was high. A better prognosis was observed in; high-volume ERCP units, Asian ethnicity and extrahepatic primary cancers. Male gender, advancing age, increasing co-morbidity score, greater deprivation and previous renal failure predicted death at 30 days.

P0750 EARLY DEVELOPMENT OF NONALCOHOLIC FATTY LIVER DISEASE IN GENETICALLY PREDISPOSED CHILDREN: WITH OVERWEIGHT AND OBESITY DOES NOT COINCIDE WITH METABOLIC DERANGEMENTS

K. Karnebeck1, J. Plat2, A. Vreugdenhil1

1Department Of Pediatrics, Maastricht University Medical Centre, Maastricht/Netherlands
2Department Of Human Biology, School Of Nutrition And Translational Research In Metabolism (nutrim), Maastricht University, Maastricht/Netherlands

Contact E-mail Address: kylie.karnebeck@umcn.nl

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a common chronic liver disease and in particular a health threat in obese children. Single nucleotide polymorphisms in genes encoding PNPLA3 (rs738409) and TM6SF2 (rs58542926) contribute to the development of NAFLD. It is however unknown whether liver pathological and cardiometabolic disturbances coincided in carriers and non-carriers of these risk alleles in an at-risk obese pediatric population. Therefore, we assessed cardiometabolic derangements, genetic predisposition for NAFLD and liver transaminase levels in children with overweight and obesity.

Aims & Methods: One hundred and seventy-four children (49% boys) from the Centre for Overweight Adolescent and Children’s Healthcare (COACH) at the Maastricht University Medical Centre were genotyped for PNPLA3 rs738409 and TM6SF2 rs651781. Anthropometric, cardiometabolic risk and liver-related parameters were determined.

Results: Anthropometric parameters did not differ significantly between carriers and non-carriers of the risk alleles. ALT and AST were significantly higher in PNPLA3 G allele carriers as compared to the C allele carriers (ALT; CC 21, (19–23); GG 26, (20–30), p = 0.034, (0.034, (0.034–0.034), GG 27, (21, (0.00–0.00), GG 30, (26, (0.06, (0.06), p = 0.048)). The odds ratio for having ALT levels above the cut-off values increased for every PNPLA3 G allele, with an OR of 2.51 (1.22;5.18; p = 0.004) for the PNPLA3 GG genotype, compared to the CC genotype. Carriers of the PNPLA3 risk allele did not show a deteriorated metabolic profile compared to non-carriers.

The TM6SF2 T allele carriers also showed a tendency increased transaminase levels, but a significantly healthier cardiometabolic profile compared to the GG genotype carriers. The metabolic syndrome was more prevalent in risk allele carriers. These results suggest that hepatic aberrations and metabolic disturbances apparently do not develop concurrently in this specific population. Furthermore, these children with a high liver health risk may not be identified by measuring cardiometabolic parameters.

P0752 PERCUTANEOUS EMBOLIZATION OF VISCERAL ARTERY PSEUDO-ANEURYSMS – A TERTIARY CENTER EXPERIENCE

R. Chavan1, J. Singh1, Z. Nabi1, R. Kalapala1, D.N. Reddy3

1Gastroenterology, Asian Institute of gastroenterology, Hyderabad, Hyderabad/India
2Gastroenterology And Hepatology, "Victor Babes" University of Medicine, Timisoara/Romania

Contact E-mail Address: drradhikachavan@gmail.com

Introduction: Visceral artery pseudo-aneurysms are rare, but potentially fatal if rupture. Pseudoaneurysm usually occurs most frequently after pancreatitis. Angiembolization with conventional trans-catheter approach is the standard treatment. Direct percutaneous embolization has been commonly used for treatment of peripheral artery pseudoaneurysm when trans-catheter approach is not feasible. However, very limited data is available regarding its safety and efficacy in visceral artery pseudoaneurysm.
Aims & Methods: We aimed to assess the technical feasibility, safety and effic-acy of percutaneous embolization as an alternative treatment option for visceral pseudo aneurysms. We retrospectively evaluated the data of patients who underwent percutaneous embolization at our institution from Feb 2007 to March 2017. All procedures were performed under ultrasound (US) guidance. Embolization materials, technical feasibility, safety and efficacy of percutaneous embolization were analysed. At 30 days follow up US with color Doppler/dual phase computed tomography was done to see for recurrence of pseudoaneurysm.

Results: 23 patients (18 male) with mean age of 34.4±4.21 (7–72) years, under- went direct percutaneous embo-lization for visceral pseudoaneurysm. Most common aetiology for pseudoaneurysm was pancreatitis (21), parac-terteny (3) and surgery (1). The site of pseudoaneurysm was splenic artery (23), left gastric artery (3), hepatic artery (3), inferior mesenteric artery (3) and gastroduodenal artery (1). Mean size of pseudoaneurysm was 1.8±0.6 (1–3.5) cm. Reasons for choosing percutaneous approach over trans-catheter embolization included - technical difficulties in 11 patients, excess collat-erals feeding artery in 5 patients, and recurrence after pre-evious embolization in 6 patients. Agents used for embo-lization- glue with lipiodol (21), coil (1) and coil with glue (1). Mean procedural time was 11.3±1.14 (6–16) minutes and fluoroscopy exposure time was 2.4±1.14 (1–6) minutes. Percutaneous embolization was successfully performed in all patients (technical success-100%). Mild adverse events included - local site pain in 19 (80%) patients. Moderate adverse event included - spleen infarct in 5 patients, all of which responded to conservative management. There were no major adverse events and no occurrence of distant embolization. At median follow up of 90 days (30–3186) there was no recurrence of pseudoaneurysm (clinical success-100%).

Conclusion: Percutaneous embo-lization is safe and effective for treatment of visceral artery pseudoaneurysm. Percutaneous technique may be considered as an alternative to trans-catheter embolization in cases of challenging anatomy, multiple collaterals and recurrence after previous embolization precluding trans-catheter approach.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0753 DEVELOPMENT OF AUTOIMMUNE PANCREATITIS IS INDEPENDENT FROM P21-MEDIATED PANCREATIC INFLAMMATION

Introduction: Chronic (CP) and autoimmune pancreatitis (AIP) are characterized by chronic and repetitive episodes of processes. Whether CP is pro-gressive for autoimmune is still unclear. AIP is considered mostly a T-cell mediated disease; how- ever, in induction of chronic pancreatitis macrophages play a pivotal role. Cyclin dependent kinase (cdk) inhibitors are critical regulators in inflammatory disease and proliferation, activation, differentiation, development and apo-tosis. In particular, p21 has been described as a mediator of inflammation and various autoimmune diseases by regulating T-cell activation and promoting macrophage development. We therefore examined the role of p21-mediated inflammation in AIP.

Aims & Methods: Human pancreas samples from CP and AIP patients were evaluated for p21 expression. To investigate the effects of p21 in pancreatitis, we intercrossed lympho-typox overexpressing mice (Tg(Elat1-LTa, b/h)) a model to study CP and AIP – with p21 deficient (p21-/−) mice. Infiltrating cells were visualized by immunohistochemistry, supported by gene expression analysis in an early and a progressive phase. Circulating autoantibodies and the presence of tertiary lymphoid organs (TLOs) were analysed to assess autoimmunity.

Results: p21 was upregulated in human CP patients but remained unchanged in AIP patients. p21 deficiency in LT mice (Lp21+/−) prevented early pancreatic injury. LTp21+/− mice had normal serum amylase, reduced inflammatory gene expression and cell influx. In acinar cells diminished proliferation and abrogated activation of non-canonical NF-κB pathway was observed. In contrast, 12 months old LT mice with and without p21 had similar inflammatory gene expres-sion and T & B cell infiltration. Interestingly, LT and LTp21−/− mice had compar-able tertiary lymphoid organs (TLOs), autoantibodies and elevated IgG levels. However, acinar cell proliferation, acinar-to-ductal metaplasia and acinar non-canonical NF-κB pathway activation remained impaired in LTp21+/− pancreata.

Conclusion: Our findings indicate that p21 is crucial for pancreatitis in LT-driven pancreatic injury. p21 is involved in early acinar secretion of inflammatory mediators that attract innate immune cells. However, p21 is not essential for humoral immune response, accountable for autoimmunity and lack of p21 does not rescue AIP. Importantly, p21 intercrossing in LT mice and protected acinar cells less susceptible to proliferation and transdifferentiation. We therefore suggest that chronic and autoimmune pancreatitis follow different inflammatory processes.

Alicante, Alicante/Spain

Introduction: Infectious complications are main causes of mortality in severe acute pancreatitis (AP). Most infections in AP are intestinal origin (2). The Nucleotide oligomerization domain 2 (NOD2) is a NOD-like receptor family member that senses and responds to bacterial wall peptides (3). Guenther et al. reported that p.R702W mutation was found to be associated with multiple organ failure and mortality in patients with AP (4). We aimed to investigate whether there is a correlation between NOD2 variants and AP severity in this study.

Aims & Methods: Group 1 (n = 27) was healthy. Group 2 (n = 36) and Group 3 (n = 32) were comprised of mild and severe pancreatitis patients according to the Atlanta 2012 classification (5). Four NOD2 variants and serum interleukin-6 (IL-6), Tumor Necrosis Factor-α (TNF-α) and lipopolysaccharide-binding protein (LBP) levels were studied.

Results: We detected p.R702W variant in 3 patients (3/32, 9.4%) in severe pancreatitis group, but this variant was not seen in the other two groups. 1007Ts variant was found in 3, 3 and 1 patient in mild (3/36, 8.3%) and severe pancreatitis (3/32, 9.4%) groups, and in healthy group (1/27, 3.7%), respectively. There was no significant difference in the frequencies of NOD2 variants between groups. Serum IL-6, TNF-α and LBP levels were significantly higher in the severe pancreatitis group than in the healthy group and mild pancreatitis group (all p < 0.001). However, there was no significant difference between these cytokine levels and NOD2 variants.

Conclusion: Our results suggest that there may be a relationship between the presence of p.R702W variant and severe pancreatitis.

Disclosures: All authors have declared no conflicts of interest.

P0757 A LUMEN AMPOUS METAL STENT WITH ANTI-REFUX VALVE FOR ENDSOCOPIC ULTRASOUND-GUIDED DRAINAGE OF PSEUDOCYST AND WALLED-OFF NECROSIS

Department Of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic of

Introduction: Pancreatic pseudocyst (PC) and walled-off necrosis (WON) are frequent complications of acute pancreatitis. Drainage procedure is required when complications and complications such as pain, biliary obstruction or infection occur. With technological advances, endoscopic ultrasound (EUS)-guided drainage replaced surgical treatment and has become the standard treatment. We developed a novel fully-covered lumen apposing metal stent (LAMS) with anti-reflux valve for the purpose of preventing complications such as stent migration or reflux of bowel contents while improving the stent patency. The aim of this study is to investigate the efficacy and the rate of complications of EUS-guided drainage using novel LAMS with anti-reflux valve for PC and WON.

Aims & Methods: We compared the treatment outcomes and the rate of complications of EUS-guided drainage using LAMS with endoscopic ultrasound drainage using plastic stents. Ten patients underwent EUS-guided drainage using the novel LAMS (LAMS group) and eighteen patients using conventional plastic stents (plastic stent group) from December 2013 to October 2016. A novel LAMS used in this study was designed to have bilateral flared ends, 4 anti-migration flaps (at each side) and a pair of 2 anti-reflux valves (inside the lumen). Technical success is defined as a successful placement of stent and clinical success is defined as a resolution of the PC/WON and disappearance of the symptoms.

Results: Among 10 patients treated with LAMS, 4 patients had complicated PC and 6 patients had WON. In plastic stent group, 15 patients had complicated PC and 3 patients had WON. The median size of fluid collection before treatment was 69.5 mm (range, 48–214 mm) in LAMS group and 92.0 mm (56–253 mm) in plastic stent group. Median duration of stent placement was 47 days (1–355 days) in LAMS group and 55 days (1–216 days) in plastic stent group. Treatment outcomes of the LAMS group were not inferior despite the significantly higher proportion of WON patients in the LAMS group compared to the plastic stent group. There were no statistically significant differences in the technical success rate (90% versus 94.4%; p = 0.095), clinical success rate (70% vs. 77.8%; p = 0.491), resolution rate (76.8% versus 80.7%; p = 0.705), complication rate (40% vs. 50%; p = 0.456). In LAMS group, 3 patients experienced mild fever and 1 patient showed peritonitis due to immediate stent migration. In plastic stent group, mild fever was developed in 4 patients, and 2 patients showed peritonitis due to immediate stent migration. In both stent groups, one patient in LAMS group and 3 patients in plastic stent group had active bleeding. Procedure time (30.7 minutes vs. 40.0 minutes; p = 0.106) and fasting period after treatment (3.1 days vs. 2.1 days; p = 0.344) were also not different between two groups.

Conclusion: For EUS-guided drainage, LAMS showed acceptable treatment outcomes and the rate of complications even in relatively more severe cases of pancreatic fluid collection. And no additional fasting period was required in the LAMS group compared to the plastic stent group. Further well-designed prospective studies are needed to validate these findings.

Disclosures: All authors have declared no conflicts of interest.
P0759  THE PREDICTORS OF STEP UP APPROACH USING ENDOSCOPIC ULTRASOUND-GUIDED TRANSMURAL DRAINAGE FOR WALLEDED-OFF NECROSIS

H. Shiomi1, A. Sakai1, T. Ezaki1, T. Nakagawa1, T. Kobayashi1, Y. Shiomi1, A. Masuda2, Y. Okabe1, T. Azuma1
1Gastroenterology, Kobe University Graduate School of Medicine, Kobe, Japan, 2Gastroenterology, Kagakawa Central City Hospital, Kagakawa/Japan

Contact E-mail Address: hshiomi@med.kobe-u.ac.jp

Introduction: Endoscopic ultrasound-guided transmural drainage (EUS-TD) has been shown to be a safe and effective minimally invasive treatment for walled-off necrosis (WON). However, in some cases, simple drainage is not sufficient to manage the symptoms of WON and step up approach such as direct endoscopic necrosectomy (DEN) and surgical necrosectomy may be required. The association with the outcome of endoscopic treatment for WON remain unclear.

Aims & Methods: This study aimed to retrospectively correlate the clinical characteristics and progression to chronic pancreatitis after the first episode of acute pancreatitis from September 2012 - September 2015. We collected relevant information of disease course and follow up until June 2016. We performed univariate and multivariate regression of the factors associated with the outcome of endoscopic treatment for WON.

Results: The mean size of WON was 126.63 ± 46.79 mm. EUS-TD was technically successful in 48/49 (97.9%) patients and 26 (54.2%) improved with EUS-TD alone while 14 patients were re-treated with step up approach. The mean size of WON in patients who needed step up approach had multi-locular (p = 0.05) and large size WON (p = 0.02) as compared to patients treated with EUS-TD alone. The extent of WON correlated significantly (p = 0.001) with the type of treatment. Gas bubbles sign within necrotic tissue on the abdominal CT imaging early after EUS-TD may help to perform necrocectomy during the treatment (p < 0.01). Bleeding as adverse events was observed in 3 patients (6.2%). Two patients improved with conservative therapy and 1 patient underwent transcutaneous arterial embolization.

Conclusion: The step up approach is safe and effective for the treatment of WON. Multi-locular, large size and extensive WON were important predictors for performing a step up approach. Gas bubbles sign within necrotic tissue after EUS-TD may help to perform necrocectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Clinical data has indicated that severe acute pancreatitis is a serious inflammatory disease with a systemic inflammatory response and multiple organ dysfunction. Acute renal injury caused by acute pancreatitis is a common complication that is associated with a high rate of mortality. Although the pathogenesis of acute necrotizing is not completely clear, the activation of inflammatory cytokines and coagulation are keys in the etiology.

Aims & Methods: We examined 155 patients with acute necrotizing pancreatitis. According to the international classification in 98 patients we diagnosed the moderate severe AP, and in 57 patients the severe AP. Disorders of kidney function were in 48 patients. We determined the creatinine level, indicators of hemostasis and inflammation.

Results: Analysis of the relationship of inflammation and hemostasis in patients with severe pancreatitis and renal dysfunction is accompanied by decreased of activated partial thrombin time (FVIIa = 25.227, p < 0.0001), increased of thrombin time (FVIIa = 19.428, p = 0.00004), fibrinogen concentration (FVIIa = 4.6046, p = 0.03568), D-dimers level (FVIIa = 28.456, p < 0.00001), and level of soluble fibrin-monomer complexes (FVIIa = 34.015, p < 0.00001), lack of activity of antithrombin III (FVIIa = 42.123, p < 0.00001), increased synthesis of C-reactive protein (FVIIa = 15.591, p = 0.00020), excessive production of proinflammatory cytokines (FVIIa = 19.997, p < 0.00001), IL-6 (FVIIa = 21.076, p = 0.00002), and TNF-a (FVIIa = 25.643, p < 0.00001). In acute pancreatitis patients with renal dysfunction was shown a direct correlation between severity of renal failure (SOFA score) and concentrations of IL-6 (R = 0.416484, p = 0.000504), CRP (R = 0.510742, p = 0.002376), D-dimers (R = 0.321619, p = 0.000856), soluble fibrin-monomer complexes (R = 0.290750, p = 0.017688), and duration of thrombin time (R = 0.296007, p = 0.015814).

Conclusion: The mechanism of the acute renal injury following acute necrotizing pancreatitis is complicated by the inflammatory cascades and hypercoagulable state is initiated this pathologic process.

Introduction: Acute pancreatitis (AP) may be severe in up to 20% of patients with substantial morbidity and mortality, which is related to a generalized inflammatory response. In some patients, this severe inflammatory response is down-regulated; in others it escapes control. Our group has previously described a TH1 profile associated with poor prognosis in AP, and a TH2 profile associated with a mild or moderate condition.

Aims & Methods: Our aim was the development of an index for an early assessment of prognosis in AP. We analyzed 12 cytokines in 117 patients, upon
admission to hospital. A receiver operating characteristic (ROC) analysis was built at day 0 for the prediction of severity. Later, a multiple discriminant analysis was performed, using the Wilks lambda test, to identify the variables that differ most between patients with mild AP and moderate/severe AP. A ratio calculated using the most discriminant cytokines was studied in relation to severity and mortality.

**Results:** ROC curves showed that TH1 cytokines IL6, IFNγ and TNF-α can be measured for the prediction of severe AP, while TH2 cytokines IL4, IL13, GMI-CSF, for the prediction of a mild or moderate condition. A stepwise analysis showed that IL13 and IFN-γ were the biomarkers which contributed most to the discrimination between mild and moderate/severe AP (Wilks' lambda = 0.855, p < 0.0001; Wilks' lambda = 0.747, p < 0.0001, respectively). The calculated IL13:IFNγ index. This ratio was significantly higher in patients with mild AP when compared between groups (p = 0.73–10–8). This difference was also observed between severe AP and the rest of the patients (p = 0.007). The ROC curve was also modified, increasing the area under the curve (AUC), the sensitivity and the specificity, in relation to AP severity.

Considering an IL13:IFNγ ratio that could be of great interest in the assessment of prognosis in AP. A high value of the IL13:IFNγ ratio at hospital admission is associated with a good prognosis of AP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** According to the diagnostic criteria by Cotton et al.1, post-ERCP acute pancreatitis is defined as the persistence of serum amylase levels three times or higher than the upper limit of the standard for 18 h. We investigated the cutoff serum amylase level that suggested ERCP-induced pancreatic inflammation in a prospective multicenter study.

**Aims & Methods:** Three high-volume centers, 2078 patients examined by ERCP between April 2015 and May 2016 were prospectively followed. CT was performed in patients whose serum amylase level exceeded the institutional upper limit on the day after ERCP (after 12–24 h) to investigate the presence or absence of a WON. Two expert radiologists diagnosed the images blinded and judged the presence or absence of pancreatitis based on the Balthazar grade. Patients with a preexisting high amylase level, clinically determined nosocomial infection had a difficult diagnosis due to the overlap of features of cancer before ERCP were excluded from analysis. Correlations of the serum amylase level after 2 h, that on the following day, abdominal pain under 4 h, and that persisting longer than 4 h with the presence or absence of pancreatitis were investigated using ROC analysis and the chi-square test.

**Results:** Amylase levels increased on the following day in 402 (21.5%) of the 1868 patients included, and 340 patients examined by CT were included in the analysis. ERCP-induced pancreatitis was diagnosed based on imaging in 204 patients (10.8%). The cutoff amylase level for judging the presence or absence of pancreatitis on the following day was 2.73 times higher than the institutional upper limit (sensitivity: 73.3%, specificity: 79.0%, positive likelihood ratio: 3.48, negative likelihood ratio: 0.34) with an AUC of 0.80. The cutoff level after 2 h was 2.73 times higher than the institutional upper limit (sensitivity: 45.6%, specificity: 79.7%, positive likelihood ratio: 2.24, negative likelihood ratio: 0.68) with an AUC of 0.63. Abdominal pain under 4 h was noted in 36 of the 204 patients in the pancreatitis group, and 12 of 136 patients in the non-pancreatitis group with a sensitivity of 17.7%, specificity: 91.1%, positive likelihood ratio 1.99, and negative likelihood ratio 0.90. Abdominal pain that persisted longer than 4 h occurred in 75 patients in the pancreatitis group and 12 in the non-pancreatitis group with a sensitivity of 36.7%, specificity: 91.1%, positive likelihood ratio, 4.12, and negative likelihood ratio, 0.69.

**Conclusion:** The appropriate cutoff serum amylase level for judging ERCP-induced pancreatitis on the day following ERCP is 2.73 times higher than the institutional upper limit. The diagnostic value of serum amylase levels 2 h after ERCP in predicting abdominal pain persisting for longer than 4 h, that specificity was high but the sensitivity was low. Therefore, setting a cutoff serum amylase level on the day after ERCP is very useful to diagnose ERCP-induced pancreatitis.

**P0764 CLINICAL EFFICACY AND SAFETY OF EUS-GUIDED LUMEN-APPOSING METAL STENT ASSISTED Pancreatic WALL-OFF NECROSIS DRAINAGE: A REAL-LIFE EXPERIENCE IN A TERTIARY HOSPITAL**

S.T. Law1, C. De La Serna Higuaera2, M. Perez-Miranda2, P. Gil2

2Gastroenterology And Hepatology, Rio Hortega, Valladolid/Spain

**Contact E-Mail Address:** stil68@hotmail.com

**Introduction:** Recently, lumen apposing metal stent (LAMS) has been developed and employed in abscess drainage. However, its use is limited by its cost [1] and its safety rises concerns as apparently associated with more adverse events [2]. The aim of this study was to investigate the efficacy and safety of LAMS in endoscopic ultrasound (EUS)-guided pancreatic wall-off necrosis (WON) drainage.

**Aims & Methods:** Patients All consecutive patients with necrotizing pancreateatitis with WON who underwent EUS-guided drainage using LAMS during the period of 1st Jan 2012 and 30th Jun 2016 were retrospectively retrieved from the institution database. Necrotizing pancreateatitis and WON were defined as according to the revised 2012 Atlanta classification. Those encapsulated fluid collection outside the pancreas were excluded from this study. The following data were collected: patient demographics, EUS and microbiologic features of the necrosis, procedural characteristics and their outcomes. Procedures All procedures were performed by 2 endosonographers. Once the WON was identified, a 19-gauge needle was inserted with 0.035-inch guidewire to allow for navigation of the AXIOS device, which was then advanced to create the fistula tract using the electrocautery tip. Once the delivery catheter was inside the WON, the distal and proximal flange of the stent were deployed subsequently under EUS and endoscopic guidance respectively. Outcome measures Primary outcome measures were: 1.technical success defined as stent deployment without any difficulty nor reposition; 2. clinical success defined as symptom resolution with the abscess size ≤2 cm on computed tomography (CT); Secondary measures are: 1. Stent revision due to its migration/dislodgment in case of unresolved abscess; 2. Adverse events; 3. WON recurrence Data analysis Continuous variables were expressed as median and IQR. Categorical data were expressed as absolute numbers and percentages.

**Results:** The clinical characteristics of the patients and their WONs are shown in Table 1. In the cohort, the deployment of LAMS (AXIOS: 15 ± 10 mm, n = 38; 10 ± 10 mm, n = 8) was technically success in 45 (97.8%, 3 cases required 2nd attempt for proper deployment) cases while one case required to switch over to a fully-covered metal stent due to the lengthy insertion tract. 26(60.9%) cases were managed with necrosectomy (median 1, IQR 2) in which 15(32.6%) of them had concurrent nasocystic drainage prior to each procedure. 43(93.5%) patients were treated successfully while two refractory cases required superin- posed insertion of a fully-covered metal stent coaxially to control the bleeding while the other five had bleeding stopped spontaneously. Delayed bleeding was reported in 4 cases;three were managed by local intervention such as administration dual antiplatelet and the bleeding site and one with uncontrolled bleeding due to disseminated intravascular coagulopathy and then died of multiple organ failure. Ten cases were reported to have stent migration during management in which two cases were dissolved during necrosectomy while the others were found during follow-up.

INTRODUCTION

Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) is a common and serious adverse event following ERCP, with a reported incidence of 9.7% in unselected patients [1]. Given huge economic and clinical burden, effective approaches for post-ERCP pancreatitis prophylaxis remains a major priority for research. Nonsteroidal anti-inflammatory drugs (NSAIDs) have also been shown the potential efficacy in prophylaxis PEP across high-risk patients, especially for diclofenac or indomethacin [3–5].

Recent, a prospective, double-blind, controlled trial conducted by Levenick [6] and colleagues in the USA showed that the reduction in PEP using indo-methacin was not as significant as previously reported. In fact, even in more cases of pancreatitis occurred in indomethacin group compared with placebo group. Subsequently, a high-quality meta-analysis also concluded that there is no prophylaxis for the prevention of PEP among average-risk patient(s) [7]. These findings raised the question that whether administration of rectal indomethacin should be recommended in average-risk patients.

Aims & Methods: We aimed to determine the beneficial effect of rectal indomethacin in the prevention of post-ERCP pancreatitis in average-risk of patients. We systematically searched Medline and EBMbase, Web of Science, and Cochrane library before October 2016. Studies that evaluated rectal administration of indomethacin in the prevention of post-ERCP pancreatitis were included in the analysis. We adopted a random-effects model to calculate overall relative risk (RR) and 95% confidence interval (CI).

RESULTS: We identified ten randomized clinical trials from initial search and finally included in the meta-analysis. Administration of rectal indomethacin significantly reduced the incidence of PEP in combined population (RR, 0.63; 95% CI, 0.50–0.77). There was no significant heterogeneity across included studies (I² = 14.2%, P = 0.31). In subgroup analysis, rectal indomethacin was effective in both high-risk (RR, 0.49; 95%CI, 0.35–0.71) and average-risk (RR, 0.69; 95%CI, 0.55–0.86) patients and reduced the risk of mild and moderate to severe pancreatitis. The overall results remained unchanged and robust in sensitivity analysis. There was no evidence of significant publication bias among this meta-analysis.

Conclusion: Rectal administration of indomethacin is an effective approach to prevent the incidence of post-ERCP pancreatitis both in high-risk and average-risk population undergoing ERCP. However, more high-quality randomized controlled trials are needed to further investigate the optimal timing for administration of indomethacin.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute pancreatitis (AP) is one of the most common gastrointestinal diseases requiring hospitalization with an annual incidence of 13–50 cases per 100,000 persons. It is a potentially fatal disease with an overall mortality ranging from 2 to 8%. Both epidemiology and outcomes are variable according to the different countries. Furthermore, few studies have considered the impact of hospital units on AP outcomes.

Aims & Methods: To evaluate both the trend and outcomes of acute pancreatitis according to the admitting hospital units: Surgery, Internal/General Medicine, Gastrointestinal (GI) Unit, Intensive Care Unit (ICU). This is a retrospective
cohort study based on the anonymous computerized database of hospital discharges in Veneto Region (North-East of Italy). The principal diagnosis of AP according to the International Classification of Diseases 9th revision, Clinical Modification (ICD 9-CM, code 577.0) of the hospital discharges was selected. The period from January 2001 to December 2015 was analysed. Veneto population was considered as the reference population (in the period, it varied from 4,529,823 to 4,927,527 inhabitants, with 51% females). Hospitalization, Length of stay (LOS), in-hospital mortality, need for surgery (according to the DRG 191–194, 199–201 which identified biliopancreatic surgery) were reported according to hospital Units. Statistics: Chi squared for trend and Odds Ratio (OR) were applied.

Results: During the analysised period, 23,389 overall hospitalizations for AP, annual hospitalizations of 32 patients/100,000 inhabitants and in-hospital mortality of 7.2% were observed. Characteristics of the patients were: mean age: 62.2 +/-19.3ys, 54% Males (M); Female (F) mean age: 65ys +/-19.3ys, male mean age: 59.4+/−19.3ys (p = 0.05). Hospitalizations was higher in males (M: 35.4, F: 28.4, OR 1.24 (95% CI: 1.20–1.27, p < 0.05) and it increased in a stepwise progression from youngest to oldest patients (from 4.4 to 44.1 to 51.2 to p < 0.05); a similar trend was observed when considering in-hospital mortality (from 0.5 to 10.3%, p < 0.05). From 2001 to 2015, hospitalization (32.4 to 29.5, p = 0.04), in-hospital mortality (1.41 to 0.79, p < 0.05) and need for surgery (NFS: 5.6% to 3.0%, p < 0.05) trends decreased. Conversely, admission trends increased during the analysed period both in General Medicine (from 34 to 63, p < 0.05) and Gastrointestinal (GI) units (from 14 to 29, p < 0.05). The Overall in-hospital mortality was the lowest in GI Units with a NFS of 3.6% (see Table). In comparison to General Medicine Units, GI units were associated with a low in-hospital mortality was the lowest in GI Units with a NFS of 3.6% (see Table). In comparison to General Medicine Units, GI units were associated with a low in-hospital mortality was the lowest in GI Units with a NFS of 3.6% (see Table).

Admitting Hospital Unit Number of Lengths of In-Hosp. Mortality NFS (%) (2001–2015) cases (%) stay (days) 

| General Medicine (Non GI) | 6,980 (30%) | 13.5 ± 10.7 | 4.3% | 88 (1.3%) |
| General Medicine (Non GI) | 3,797 (16%) | 12 ± 11.2 | 1.7% | 135 (3.6%) |
| Gastrointestinal (GI) Units | 12,112 (52%) | 13 ++ 13.6 | 2.7% | 443 (3.7%) |

Conclusion: During the last 15 years in the Veneto Region, hospitalization rate, in-hospital mortality rate and need for surgery of acute pancreatitis significantly decreased. Conversely, admissions in both General Medicine and GI units increased. Management of AP in GI units seems to be related with a better outcome: lower in-hospital mortality and probably, more eligible patients for surgical treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0767 COMPARISON OF CLINICAL COURSE AND OUTCOME OF ACUTE PANCREATITIS, RECURRENT ACUTE PANCREATITIS, ACUTE ON CHRONIC PANCREATITIS
N. Berry, D. Sharma, J. Samanta, N. Dhaka, S. K. Sinha, R. Kochhar, R. Paswan, S. Ghosh, V. Gupta, L. Yadav Gastroenterology, Postgraduate Institute of Medical Education and Research, Chandigarh/India
Contact E-mail Address: dibhya.sharma@yahoo.com

Introduction: Recurrent acute pancreatitis (RAP) and acute on chronic pancreatitis (ACP) are likely to have less severe disease and local complications in comparison to those with AP (possibly due to underlying chronic changes of fibrosis). However there is lack of literature regarding comparative studies between the natural course of disease and outcome of patients of AP vis-à-vis that of RAP and ACP.

Aims & Methods: This study was conducted to compare the clinical course and outcomes of patients with AP, RAP and ACP. 248 consecutive patients with diagnosis of AP, RAP or ACP were included during study period. Outcome measures studied were severity, organ failure (OF), persistent organ failure (POF), need for ICU stay, ventilator and renal support, hospital stay, need for percutaneous catheter drain (PCD), surgery and mortality.

Results: Out of 248,158 (64%) patients had AP, 45 (18%) patients had RAP and 43 (18%) patients had ACP. 86 (54%) of AP, 4 (9%) of ACP and none of patients in RAP group had severe AP according to revised Atlanta classification (p < 0.001). On comparison of OF, 101 (63%); of whom 54% had POF of AP, 6 (13%); of whom 9% had POF of ACP and none of RAP patients developed OF (p < 0.001). PCD and surgery requirement were seen in 89 (56%) & 9 (6%) of AP, 5 (11%) & 4 (9%) of ACP and none of RAP patients respectively (p < 0.001). AP as compared to RAP (18.80 ±14.58.82 ±11.2.36 ±4.4, p < 0.001) whereas ICU requirement was seen in significantly more patients in AP group (59.37%) than in ACP (5.11%) and RAP (0.6%) (p < 0.001). 41 (26%) of AP, 2 (4%) of ACP, but none of patient with RAP needed ventilatory support (p < 0.001), while 13 (8%) of AP patients, 1 (2.2%) of ACP and none with RAP required dialysis (p < 0.05). Mortality in AP, ACP and RAP was 29 (18%), 2 (4.4%), 0 (0%) respectively (p < 0.05). Patients with first attack of AP had more severe disease course as compared to those with ACP, while those with RAP had the least severe course.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0768 ACUTE PANCREATITIS IN PATIENTS WITH IPMNS: RETROSPECTIVE STUDY OF 346 PATIENTS OBSERVED FROM 2009 TO 2016
L. Brozzi1, A. Amadio2, F. De Marchi3, R. Teresa Marzilia1, I. Brecon4, P. Campanogola5, S.F. Crous1, A. Gabbrielli2, L. Frulloni6,1
1 Medicine, AOUI Verona-Pancreas Center, verona/Italy
2Gastroenterology, University of Verona, Verona/Italy
Contact E-mail Address: lorenzo.brozzi89@gmail.com

Introduction: In literature the frequency of acute pancreatitis (AP) in patients with IPMNs varies between 12 and 65%, but most of studies are from surgical series with often pancreatitis occurring before surgery was included. Furthermore, most of the studies include in the dictio of "symptomatic IPMNs" the presence of less severe disorders, such dyspeptic symptoms, making series unclear.

Aims & Methods: The aim of this study was to investigate the correlation between the severity of IPMN and acute pancreatitis to determine the frequency of AP, the severity of AP, the frequency of complications of AP, the mortality of AP, and the frequency of complications of AP. The apoB/A-I ratio positively correlated with Atlanta classification criteria (Atlanta 2012).

Conclusion: Almost all patients with IPMN had had symptoms. Although many indices have been developed to classify the severity of acute pancreatitis (AP), there is no ideal method for predicting SAP. The severity of AP, the frequency of complications of AP, the mortality of AP, and the frequency of complications of AP were significantly lower in patients with IPMN.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
28.4, OR 1.24 (95% CI: 1.20–1.27, p < 0.05). Trends decreased. Conversely, admission trends increased during the analysed period both in General Medicine (from 34 to 63, p < 0.05) and Gastrointestinal (GI) units (from 14 to 29, p < 0.05). The Overall in-hospital mortality was the lowest in GI Units with a NFS of 3.6% (see Table). In comparison to General Medicine Units, GI units were associated with a low in-hospital mortality was the lowest in GI Units with a NFS of 3.6% (see Table).

Admitting Hospital Unit Number of Lengths of In-Hosp. Mortality NFS (%) (2001–2015) cases (%) stay (days) 

| General Medicine (Non GI) | 6,980 (30%) | 13.5 ± 10.7 | 4.3% | 88 (1.3%) |
| General Medicine (Non GI) | 3,797 (16%) | 12 ± 11.2 | 1.7% | 135 (3.6%) |
| Gastrointestinal (GI) Units | 12,112 (52%) | 13 ++ 13.6 | 2.7% | 443 (3.7%) |

Conclusion: During the last 15 years in the Veneto Region, hospitalization rate, in-hospital mortality rate and need for surgery of acute pancreatitis significantly decreased. Conversely, admissions in both General Medicine and GI units increased. Management of AP in GI units seems to be related with a better outcome: lower in-hospital mortality and probably, more eligible patients for surgical treatment.

Introduction: The Scandinavian-Baltic Pancreas-Club database collects data from patients with chronic pancreatitis (CP) in Nordic countries. Grading of structural changes is important in the description of a CP cohort.

Aims & Methods: We aimed to characterise structural changes of the pancreas in patients with CP. Subjects with definitive or probable CP according to the M-ANNHEIM diagnostic-criteria were included. Structural changes were graded according to the M-ANNHEIM-classification. A subgroup was also scored by the modified Cambridge score. Clinical data on disease-duration, nutrition, exocrine function, pain, alcohol/smoking habits and frequencies of malnutrition and diabetes were collected. A grouping of the M-ANNHEIM score (A: Normal = 0, B: Minimal change = 1 to 2 and C: Moderate/marked = 3 to 4) was performed for correlation to the clinical data.

Results: The database contains 932 patients (623 men). The M-ANNHEIM-score was present from 446 subjects and both imaging scores from 93 subjects. The database contains 932 patients (623 men). The M-ANNHEIM-score correaltion to the clinical data.

P0771 OSTEOPATHY IS COMMON IN PATIENTS WITH CHRONIC PANCREATITIS, BUT IT IS NOT RELATED WITH VITAMIN D AND FECAL ELASTASE LEVELS (P-BONE STUDY)

Introduction: In patients with chronic pancreatitis (CP) malabsorption of vitamin D and K, alcoholism, smoking and inflammatory status contribute to low bone mineral density (BMD). A recent meta-analysis estimated the prevalence of osteoporosis (25%) and osteopenia (40%) in CP and highlighted limitations of the reviewed studies.

Aims & Methods: To evaluate the prevalence of osteoporosis and osteopenia in patients with CP and to investigate the correlation between BMD and CP features, and vitamin D and PEI. This is a multicentre cross-sectional study (P-BONE, a Pancreas 2000 project) on prevalent CP patients. The Diagnosis and severity of the disease was defined according to the M-ANNHEIM classification. Clinical information and biochemical variables were recorded; PEI was assessed by faecal elastase. Standardized osteodensitometry was performed by dual-energy x-ray absorptiometry (DEXA). Categorical variables were analysed by means of Fisher’s exact test, and continuous variables by t-test. A logistic regression analysis was performed to identify risk factors for osteoporosis or osteopenia. The relation between continuous variables was assessed with Pearson correlation coefficient.

Results: 211 consecutive CP patients were enrolled at 6 Centres (67% M; mean age 60 ±13 years). Osteopenia was diagnosed in 42% and osteoporosis in 22% of cases. Aetiology was alcoholic in 43%, and 18% had severe CP. 56% of patients had PEI. The mean value of vitamin D was 20 ng/ml and 56% of cases had vitamin D insufficiency. There was no correlation between vitamin D levels, or elastase levels and t-score at either spine or femur. Alcoholic aetiology was associated with higher risk of low levels of fecal elastase (p 0.02) and with lower level of vitamin D (p 0.001) but not with osteoporosis or osteopenia. Female sex and older age seems to be associated with a higher risk of developing osteoporosis (OR 4.5 95% CI 2–9.8 p 0.001; OR 1.09 95% CI 1–1.3 p 0.01) while a higher BMI is associated with a reduced risk of its occurrence (OR 0.89 95% CI 0.77–0.94 p 0.001).

Conclusion: The present data confirm a high rate of osteoporosis in CP patients. However, there was apparently no correlation between BMD, pancreatic exocrine function, severity of the disease or vitamin D levels. Other factors, such as vitamin K might deserve investigation for their possible relationship with bone mineral density in CP patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0772 NATURAL HISTORY OF PANCREATITIS ASSOCIATED WITH SPINK1 MUTATIONS
N. Muller1, O. Hentci1, F. Mair2, P. Ruszniewski3, P. Levy4, V. Rebours5
1Beaujon Hospital, Clichy/France
2Service De Gastroentérologie-pancréatologie, Universitè Denis Diderot Hospital Beaulieu, Service de Pancréatologie, Clichy Cedex/France

Contact E-mail Address: nelly.muller@aphp.fr

Introduction: SPINK1 is a gene coding for the inhibitor of the cationic trypsinogen. Heterozygous mutations prevalence is estimated at 2%. They are recognized as a risk factor for chronic pancreatitis. However few data are available regarding the natural history and the risk of complications in these patients.

Aims & Methods: A prospective monocentric study was carried out from 2000 to 2016 to describe the natural history of SPINK1 mutation related pancreatitis. All patients referred for idiopathic acute and/or chronic pancreatitis with a SPINK1 mutation, were included and followed annually. Epidemiological, genetic, clinical and morphological data were collected.

Results: We included 158 patients. Mutations of SPINK1 were: heterozygous (65%), homozygous (8%) N34S, others (27%). Median age at first symptoms was 41 years (26-70 years). Diagnosis was 20 [2–73] and 29 years [3–76]. During follow-up (median length:7.45 years), clinical manifestations were pancreatic pain (73%), pseudo-cyst (15%), acute pancreatitis (77%), cholestasis (6%), exocrine pancreatic insufficiency (EPI) (33%), diabetes (15%) and pancreatic adenocarcinoma (n = 6.4%). Calculations and duodenal abnormalities were found in 56% and 62%. Endoscopic treatment and surgery were performed for 16% and 14% of the patients. Four patients died including 3 due to pancreatic cancer). The risk of pancreatic cancer at 55, 60, 70 and 75 years was 9.4%, 14.7%, 28.9% and 46.7%. Risk factors of cancer were calculations (p = 0.03) and EPI (p = 0.04).

Conclusion: SPINK1 mutations should be searched for in young patients with idiopathic pancreatitis. Risk of pancreatic cancer is probably underestimated.
Cancer screening should be discussed especially in case of pancreaticitiss with calcification.

Introduction: The Scandinavian-Baltic-Pancreatic-club database collects patients with chronic pancreatitis (CP) from Nordic countries. Description of exocrine pancreatic insufficiency (EPI) and consequences is important in characterization of CP cohorts.

Aims & Methods: Characterise EPI from CP in a Northern European cohort. Patients with definitive or probable CP (M-ANNHEIM diagnostic criteria) were included from nine centres. Demographic data, body-mass index (BMI), faecal elastase (FE), enzyme-doses and lab-parameters were collected. Values: Mean (SD) unless otherwise stated. EPI-classification grouped patients as follows: A: Normal; B-Mild: EPI not requiring enzymes, C-Proven: EPI requiring enzymes.

Clinical parameter (A) Normal (B) Mild insufficiency (C) Proven insufficiency

Exocrine pancreatic function (%)
33 16 51

Faecal Elastase (μg/g) (mean (SD)) p < 0.001
368 (161) 128 (144) 51 (69)

Nutrition: BMI (kg/m²) (mean (SD)) p < 0.005
24.6(4.9) 23.7(4.3) 22.6(4.3)

Frequency BMI > 18.5 (%) p < 0.005
5 16

Vitamin D: Frequency <25μg/L (I) vs II) p < 0.005
7.4 23.7 17.6

Enzyme Treatment (lipase-units/day) (median [IQ range])
700–75000 120000

Hemoglobin: (median [IQ range]) p < 0.05
11.8(2.7–3.0) 10.7(2.8)

Faecal Elastase and disease duration (years)**
<10: 143(175) >10: 91(188)

*p < 0.001. 9% received <50000 lipase-units/day. 14 subjects having FE > 200 received enzymes, 48 subjects with FE < 100 received no enzymes.

**no age/sex differences in EPF

Conclusion: In our material frequency of EPI is higher than reported in the NAPS2 study (31%). Consequences of EPI were lower BMI, more frequent underweight, higher enzyme-doses and lower haemoglobin. Need for vitamin D supplements was highest in the group with mild EPI not receiving enzymes. Exocrine function was correlated with disease duration, but neither with age nor gender.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0774 FLUID AND HCO3-/C0- SECRETION AND CFTR ACTIVITY IS INHIBITED BY CIGARETTE SMOKE EXTRACT IN GUINEA PIG PANCREATIC DUCTAL CELLS

Introduction: Smoking represents an independent risk factor for the development of chronic pancreatitis (CP). It is well documented that secretion of pancreatic ductal alkaline fluid (which is regulated mostly by the anion exchanger and C0- secretion) is diminished in CP.

Aims & Methods: In this study we would like to understand whether smoking has any effects on pancreatic ductal fluid and HCO3-/C0- secretion. Guinea pigs were exposed to cigarette smoke four times a day for 30 min for 6 weeks. The CFTR expression was analysed by immunohistochemistry. Pancreatic ducts were isolated from guinea pig pancreas. Cigarette smoke extraction (CSE) was prepared by smoking of 15 cigarettes into 10 ml distilled water by a smoking machine. Intracellular Ca2+ concentration and pH were evaluated by microfluorometry. Fluid secretion was measured by video microscopy. CFTF currents were detected by whole cell configuration of patch clamp technique.

Results: Cigarette smoking significantly diminished the expression of CFTR and the fluid and HCO3-/C0- secretion in guinea pig pancreas. CSE dose dependently decreased fluid and HCO3-/C0- secretion in guinea pig pancreatic ducts via inhibition of anion exchanger, Na+/H+ exchanger and Na+/HCO3- cotransporter and also forskolin-stimulated Cl current of CFTR Cl- channel. CSE incubation altered the pattern of carbachol-induced Ca2+ signal in pancreatic ducts suggesting that smoking inhibitory effects may be regulated by calcium signalling.

Conclusion: Cigarette smoking and CSE inhibits pancreatic ductal fluid and HCO3-/C0- secretion and the activity of the CFTR which may play role in the smoke-induced pancreatic damage. This study was supported by OTKA, MTA, SZTA and UNKPs.

Introduction: Rapid on-site cytologic evaluation (ROSE) for determining the suitability of a specimen often provides high efficacy of endoscopic ultrasound-guided fine needle aspiration (EUS-FNA). In our center, we propose an additional role of ROSE in histological diagnosis aimed at improving diagnostic accuracy.

Aims & Methods: From January 2009 and December 2015, 215 patients were evaluated who underwent both EUS-FNA for pancreatic solid lesions and surgery. All adenocarcinomas suspected by ROSE were malignant tumors. It is suggested that ROSE may also have high agreement in final histological diagnosis. It is proposed that ROSE may also be useful for diagnosis of special type tumor.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic ductal adenocarcinoma (PDAC) has one of the most dismal prognoses of all cancer types. Diagnostic techniques for early malignan
t lesions are limited, which shows an evident need to understand the pathomechan-
ism leading to PDAC and find a suitable marker for early detection. Initial pro-
cesses in PDAC development involve acinar to ductal metaplasia (ADM) with further neoplastic progression into four pancreatic intraepithelial neoplastic (PanINs) stages. After accumulation of mutations, these lesions will further evolve into PDAC. Gastrokine 1 & 2 (GKN1 & GKN2) are secreted proteins
dominated in the stomach where they are involved in gastric epithelial homeostasis. While current research focuses on the exploration of tumor-suppressive properties of GKN1 in gastric tumors, nothing is known about GKN function in other organs. A whole genome microarray of KrasG12D Ptf1aCre (KC) mice, a mouse model with predisposition to pancreatic cancer, revealed strikingly high expression of GKNs in vivo. We will further analyze the involvement of GKNs in the development and progression of PDAC and explore the possibility to use them as biomarkers.

Aims & Methods: GKN1 & GKN2 expression was confirmed by qPCR in human and mouse pancreas samples. The expression of GKN1 was verified by western blot and immunohistochemistry (IHC) in mouse pancreas. Mouse pancreatic tissue and serum were analyzed by proteomic analysis. To investigate the role of GKNs in pancreatic carcinogenesis in vivo, we established mouse models by intercrossing KC mice with Gkn1−/− and Gkn2−/− mice respectively. The capability of acinar cells lacking Gkn1 and Gkn2 to transdifferentiate into ductal cells in vitro was tested.

Results: GKN1 was upregulated during early stages of pancreatic carcinogenesis in mouse and peri-tumoral human pancreas. GKNs were absent in healthy pan-
creas and tumor tissue. IHC showed specific GKN1 expression in premalignant PanIN lesions, while GKN2 positive cells were also localized in the stroma. ELISA and proteomic analysis in mice confirmed the secretion of GKNs into
cellular tissue. Preliminary results from the first time point of analysis showed accelerated tumor development in GKN1−/− mice. Wild type acinar cells transdifferentiated into ductal cells in vitro only in the presence of TGFA. On the contrary, Gkn1−/− and Gkn2−/− acinar cells transdifferentiated spontaneously, and resulted in GKNs in pancreatic ductal tissue.

Conclusion: We identified for the first time specific pancreatic carcinogenesis in pre-
neoplastic lesions in human and mouse pancreatic tissue. The secretion into
cellular tissue during carcinogenesis could make gastrokine a potential biomarker for the detection of early pancreatic premalignant lesions. With our mouse models we will provide in vivo evidence on the role of GKNs in pancreatic carcinogenesis in vivo, we established mouse models by intercrossing KC mice with Gkn1−/− and Gkn2−/−. Gastrokine 1 & 2 (GKN1 & GKN2) are secreted proteins
dominated in the stomach where they are involved in gastric epithelial homeostasis. Disclosure of Interest: The plasma levels of ezrin were analyzed using western blot. The t test was used to determine the difference between the two groups. No relationship between ezrin level and the patients age, sex or tumor size was noted. Patients with ezrin high expression had a shorter survival time than PDAC patients with ezrin low expression (Log-rank = 4.35, p = 0.03).

Conclusion: Activin pathway is related to cachexia and the local spread of PDAC, but not in metastasis or survival.

Introduction: Cell-free DNA (cfDNA) shed from tumors into the general circulation offers new opportunities to study genetic and epigenetic evolution of malignancies. Although ddPCR-based assays have rather high precision and sensitivity for detecting the rare fraction of circulating tumor-derived DNA (ctDNA) in patient plasma remains a technical challenge. Initial efforts have been made to quantify the ctDNA using conventional PCR, but the low sensitivity of this approach has limited its feasibility as a routine clinical test. New technologies for quantifying ctDNA are now sensitive enough for reliable application in the clinic (ref 1). Pancrætic ductal adenocarcinoma (PDAC) is among the most lethal human malignancies. Intraductal papillary mucinous neoplasias (IPMNs) are precursors of PDAC and provide models of neoplastic progression from a benign intraductal tumor through increasing grades of dysplasia to PDAC, and mutations in KRAS and/or GNAS mediate key signaling during early development of the tumors (ref 2). Better prediction of historical grades using non-invasive tools is urgently needed for IPMN patients to make appropriate management decisions.

Aims & Methods: In the current study, we sought to determine if quantification of major driver mutations such as KRAS and GNAS in the plasma cfDNA could serve as biomarkers for diagnosis of localized PDACs and risk stratification of IPMNs. We first established protocols for absolute quantification of the target mutant alleles using a Bio-Rad QX200 droplet digital PCR platform (ddPCR). Using this novel protocol, feasibility of the assay was tested. At present, 92 PDA and 145 IPMN patients with either benign or malignant disease have been recruited (UMIN00012810).

Results: Although ddPCR-based assays have rather high precision and sensitivity (0.01%), limited plasma cfDNA yields in patients with resectable PDAs (Stage 0-III) and IPMNs (Stage 0-II) in significant intrinsic errors due to “subtracted previous positive” that our approach allows the detection of localized early-stage disease and offers an alternative tool to monitor IPMN progression non-invasively.

Conclusion: By setting an appropriate protocol for ddPCR-based cfDNA assay, serial blood sampling allows physicians to conduct real-time detection and monitoring of tumor genomic alterations (ref 4). Although larger validation studies are required before introduction into the clinic, early results of the study indicate that our approach allows the detection of localized early-stage disease and offers an alternative tool to monitor IPMN progression non-invasively.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: The median follow-up period was 7.4 months (range 1.5–14.9 months); the overall response rate, severity grade and dose-intensity were analyzed. Treatment efficacy (overall survival (OS), progression-free survival (PFS), objective response rate) and treatment-related adverse events (AE) of patients (occurring during this period, 21 (31.8%) patients died. Median cumulative dose of gemcitabine (1000mg/m²) and nab-paclitaxel (125 mg/m²) regimen (on day 1, 8, 15 of a 28-day cycle) as the first line chemotherapy from February 2016 were administered. The incidence of neurotoxicity was 54.5% and 12 (18.2%) patients experienced grade ≥ 3 neurotoxicity. 30 (45.5%) patients showed grade ≥ 3 neutropenia and 10 (15.2%) patients had febrile neutropenia. Grade ≥ 3 gastrointestinal AE was observed in 11 (16.7%) patients and 26 (42.4%) patients experienced dermatologic AE such as alopecia and skin eruption. About 59% of patients experienced treatment delays due to adverse events. Dose reduction was performed in 39 (59.1%) patients and 14 patients experienced treatment cessation due to severe AE.

Conclusion: These results suggest that gemcitabine and nab-paclitaxel combination therapy is effective for metastatic pancreatic cancer treatment in East-Asian population group. Similar to previous studies, this combination therapy showed remarkable antitumor activity and myelosuppression. Careful monitoring and proper management during chemotherapy is required.

Introduction: Gemcitabine (Gem) therapy had been the standard treatment for advanced pancreatic ductal adenocarcinoma (PDAC) for long time. Even though FOLFIRINOX, a combination of fluorouracil, oxaliplatin and irinotecan, and gemcitabine-nab-paclitaxel (GnP) therapy are currently recommended as frontline drugs, Gem is still one of the important options. Efficient permeation of Gem into cells requires specialized integral membrane transporter proteins to cross plasma membranes. Among these transporters, the major mediators of Gem uptake into human cells are the human equilibrative nucleoside transporter 1 (hENT1). In the previous study started since 2005, we found hENT1 expression in endoscopic ultrasonography-guided fine-needle aspiration biopsy (EUS-FNAB) samples to be a useful prognostic marker of Gem-based chemoradiotherapy (Gem-CRT) for pancreatic ductal adenocarcinoma (PDAC) (Pancreas 2016). Since November 2011, our institution has replaced Gem + tegafur/gimeracil/oteracil (S-1) (GS-CRT) with Gem-CRT in an attempt to improve clinical response and prognosis. Aggregate median survival time (MST: months) of GS-CRT was compared with previous Gem-CRT result, and the superior efficacy of GS-CRT was observed (MST: 16 versus 20, respectively), particularly in hENT1-negative patients (MST: 9 versus 14, respectively). However, there were no differences in
hENT1-positive patients (MST: 25 versus 25, respectively). We suspect that gene expression could be related both to the rate of proliferation and to the rate of apoptosis.

Aims & Methods: In the present study, we evaluated hENT1 and dihydropyrimidine dehydrogenase (DPD: enzyme involved in the degradation of tegafur) expression in EUS-FNA samples for evaluating and predicting the clinical effect of endoscopic EGFR-TKI (n = 59) or chemotherapy (n = 10) with subsequent biopsy (n = 10) in order to have a valid indication for surgery. In the present study, we examined correlation between hENT1 and DPD expression in 38% of the cases and a plastic stent placement in 33%. There were 4 postoperative complications, which were 2 wound infections (20%), 1 bile duct stricture (10%), 1 recurrent acalculous cholecystitis (10%), and 1 pleural effusion requiring drainage (10%).

Results: Using the EUS-FNA specimens after diagnosis of PDAC, hENT1 and DPD expression could be successfully assessed in 79.2% (76/95) and 61.1% (58/95) of these cases, respectively. In those sufficient for hENT1 testing, 67.1% (51/76) were found to be positive. In those sufficient for DPD testing, 27.6% (16/58) were found to be positive. MST was significantly longer in hENT1-positive patients (MST: 30 versus 24, respectively; P = 0.0015). As for DPD, MST was significantly longer in DPD-negative patients (33 versus 14, positive; P = 0.001). In the multivariate model including pretreatment clinical factors (age, sex, tumor location, size, UICC-T classification, hENT1 expression, and DPD expression) and the clinical response after GS-CRT (response of GS-CRT, reduction rate in CA19-9 level, and distant metastasis after GS-CRT), only hENT1 expression (HR = 3.511; 1.545-7.981, P = 0.003) and DPD expression (HR = 0.232; 0.108-0.496, p < 0.001) were found to be significant independent prognostic factors.

Conclusion: hENT1 and DPD expression observed in EUS-FNA samples can be useful clinical predictors in PDAC cases treated with GS-CRT.

Introduction: Statins are widespread prescribed both for primary and secondary prevention of coronary artery disease and for the treatment of dyslipidemia. Several studies evaluated the association between statin use and the onset of pancreatic cancer (PDAC) in order to evaluate a possible chemopreventive effect, with controversial results. Systematic reviews and meta-analyses evaluating researches published up to 2012 did not find any association to the risk, but the lastest years new studies with interesting results have been published.

Aims & Methods: The aim of our study was to conduct a new systematic review and meta-analysis to clarify this association. A comprehensive literature search of PUBMED for articles published up to November 2016 and abstracts presented between 2012-2016 at the DDW and ASCO conventions was carried out. Eligible studies were case-control studies (CC), cohort studies (C) and randomized controlled trials (RCTs) assessing the effect of statin use on the risk of PDAC, compared with placebo or no treatment. Studies had to report Odds Ratio (OR), Relative Risk (RR), or Hazard Ratio (HR), estimates with 95% confidence interval (CI), or provide sufficient data for their calculation. Pooled adjusted ORs with corresponding 95% CIs were calculated using random effect model. Publication bias was assessed through Egger and Mazumdar test. Heterogeneity was assessed by means of the I² value.

Results: A total of 21 studies (12 CC, 6 C, 3 RCTs) contributed to the analysis. A total of 1383 PDAC patients and 299,304 controls were included. The pooled incidence of PDAC was 0.27% (3161/1167130) among statin users and 0.44% (8144/1835153) among the non-users. The overall pooled result for all studies evaluated a reduced risk of PDAC among statin users (OR 0.82; 95% CI 0.68–1.06; p = 0.019), compared to non–statin users. A 28% protective effect was limited to case-control studies (OR 0.72; 95% CI 0.56–0.93) and not to cohort (OR 0.93; 95% CI 0.73–1.19) nor RCTs (OR 1.04; 95% CI 0.70–1.58). No publication bias was found.

Conclusion: This is the first meta-analysis showing that statins exert a protective effect on the incidence of PDAC. Further studies taking into account statin dose, duration and subgroups of patients are needed in order to clarify the association.

Introduction: Genetic alterations responsible for the initiation of cancer may serve as immediate biomarkers for early diagnosis. Plasma levels of circulating cell-free DNA (cfDNA) were found to be higher than those of corresponding cancerous individuals; however, the major technical challenge for the widespread implementation of cfDNA genotyping as a diagnostic tool is the insufficient sensitivity and specificity of detecting early-stage tumors that shed low amounts of cfDNA. Droplet Digital PCR (ddPCR) has rather high precision and sensitivity for absolute quantification (0.01%). However, due to very low target concentrations of cfDNA in plasma, there may be an intrinsic error due to “subsampling” (Ref. 1). This is caused by limited cfDNA yield and missing targets at very low abundance during compartmentalization in ddPCR-based liquid biopsy assays. Such issues potentially result in large variations or errors in quantification, even when using highly accurate platform. Using ddPCR technology for early cancer diagnosis and risk stratification is still challenging.
Results: Limited cfDNA yields in patients with resectable colorectal and pancreatic cancers did not meet the requirement for efficient capture and quantification of rare tumor cell-derived mutant alleles within a limited cfDNA pool, two-step multiplex ddPCR targeting eight pre-amplification cycles followed by a second-run ddPCR were sufficient to approximate 5000–10,000 target alleles/ng cfDNA, resolving the subsampling issue; furthermore, the signal-to-noise ratio for rare mutant alleles against the massive background presented by the wild-type allele was significantly enhanced. The cut-off limit of reference intervals for mutant KRAS was determined to be approximately 50%.

Conclusion: The modification introduced in the ddPCR protocol facilitated the quantification of low-copy alleles carrying driver mutations, such as oncogenic KRAS, in localized and early-stage cancers using small blood volumes, thus offering a minimally invasive modality for timely diagnosis.

Introduction: Benefit of second line chemotherapy (SL) after failed first-line chemotherapy for advanced pancreatic cancer has not yet been established. We intend to identify prognostic factors and ultimately devise a model of clinical parameters for decision of SL versus basic supportive care (BSC) after failure of FL chemotherapy.

Aims & Methods: 408 patients who received gemcitabine-based first-line chemotherapy for advanced pancreatic adenocarcinoma at Yonsei University Hospital between January 2010 and December 2014 were retrospectively reviewed. Significant clinical parameters regarding second line related survival were chosen for predictive factor analysis.

Results: 161 of 408 (39.5%) received SL therapy. Median overall survival from the beginning of SL (OS2) was 20.0 weeks (14.0–28.0 weeks). In agreement with the reported evidence, ROSE along EUS-FNA was associated with a significantly improved survival (p = 0.001) and ECOG 0–1 (199 vs 109, p = 0.001), presence of peritoneal metastasis (p = 0.001) and duration of FL (p < 0.001). More patients with gemcitabine-based concurrent chemo-radiotherapy (CCRT) (p = 0.029) compared to FL only patients presented somatic mutations significant to OS2 were Braf at mutation (p = 0.019), HR = 0.870), duration of FL therapy (median duration 16 weeks (8.0–28.0 weeks) p = 0.004, HR = 0.986), presence of peritoneal metastasis (p = 0.002, HR1.732) at diagnosis, malignant thrombotic event during firstline chemotherapy (p = 0.001, HR > 0.428), Experience of CCRT was also a significant prognostic factor (p = 0.001, HR = 2.245); initial staging of the CCRT group was TNM stage3, which might be the ultimate factor impacting OS2.

Conclusion: Study suggests that SL chemotherapy may be beneficial for patients with longer duration of FL chemotherapy, higher BMI at diagnosis, patients without peritoneal metastasis at diagnosis, no malignant thrombotic event in chemotherapy and patient initially TNM stage3, who received Gemcitabine based CCRT.

Introduction: Rapid on site evaluation for endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) of the pancreas provides immediate information regarding cellular adequacy, avoiding repeated procedures.

Aims & Methods: The aim of this study was to evaluate the impact of ROSE in EUS-FNA of solid pancreatic lesions. Retrospective study of consecutive EUS-FNA of solid pancreatic lesions, in a tertiary center, between 2012 and 2016. A total of 259 EUS-FNA patients were included, 197 patients with EUS-FNA of solid pancreatic lesions with mean age of 63.4 (+/-12.8) years. The anatomical distribution of the lesions was: 56.4% in the head, 17% in the body, 10% in the uncinate process and 5.8% in the tail. The mean number of passes were 3.3 (+/-1.4) and the needle size was 25G in 60.8% and 22G in 33.8%, ROSE was performed 34.7% of the punctures (23.6% along with the initial EUS-FNA), with a mean number of passes 3.4 (+/-1.9). The diagnostic yield of initial EUS-FNA without ROSE was 44.8% vs 83.6% when ROSE was performed (p < 0.001). When not conclusive, there was no significant differences in the diagnostic yield of the repeated EUS-FNA with (and without ROSE). Beyond ROSE in the first puncture, higher levels of Ca 19.9 (199 vs 10g/mL, p = 0.001), size of the lesion (36.1 vs 29.8 mm, p < 0.001), invasion of adjacent structures (64.6% vs 43%) was noted, lymph node and malignancy (73.2% vs 25.4%, p < 0.001) was associated with EUS-FNA diagnostic accuracy. In multivariate analysis, ROSE (p = 0.001) and the size of the lesion (p = 0.023) were independent predictors of adequate diagnostic samples. In this study, ROSE allowed definitive diagnosis in 94.6% of the cases (ductal adenocarcinoma 54.7%), benign in 25.8% and indeterminate in 9.3%.

Conclusion: In agreement with the reported evidence, ROSE along EUS-FNA improved the diagnostic yield in solid pancreatic lesions and should be considered whenever possible in the first puncture, until an overall adequate diagnostic yield (>80%) is achieved.

Introduction: Postoperative digestive fistula remain a challenging condition associated with a high morb-mortality, unsatisfactory healing rates and high refractoriness. The limitation of current approaches highlights the need for a better therapeutic strategy in terms of both long-lasting efficacy and safety. Mesenchymal stem cell (MSCs) are strongly involved in tissue injury repair. MSCs feature an immune-privileged status while displaying pro-angiogenic,
and antiﬁbrotic properties. Increasing evidences point out MSC action via subcellular extracellular vesicles (EVs). MSC EVs recapitulate the therapeutic properties of their cellular counterparts while offering remarkable advantages in terms of safety (no proliferation, no differentiation, no vascular occlusion following administration) and shelf life stability. Herein, we evaluated, in a porcine model, the healing potential of EVs: MSC EVs delivered through a thermoresponsive gel (Pluronic F127) allowing the administration in a sol state through a catheter and gelation in situ at body temperature to retain EVs at ﬁstula site.

Aims & Methods: Seventeen esophageal ﬁstulas were surgically created by placing two plastic stents during 30 days into the neck of 9 pigs and randomized into control group (n = 6) and treated groups (gel alone n = 6 and gel-EVs n = 5). In the gel-EVs group, Pluronic F127 gel contained allogeneic EVs collected from the swine adipose stem cell conditioned medium. In the EVs group, radiological evaluation of ﬁstula healing was performed at day 30 and day 45, before histological assessment.

Results: All ﬁstulas were successfully induced at day 30. At day 45, the control group featured a large ﬁstula and perifistula inﬁltration in all pigs. For this group, radiological evaluation showed open ﬁstula tracts, which were conﬁrmed by histology. In the gel group and gel-EVs groups, radiological examination showed a complete ﬁstula closure in 66% (4/6) and 100% (5/5) of the animals, respectively. In the gel group, histological analysis conﬁrmed a complete ﬁstula closure for 3 from 6 cases while a partial closure was observed for 1 case from 6. In the gel-EVs group, histological complete ﬁstula closure was reported for 4 from 5 cases while a partial closure was evidenced in 1 from 5. In comparison with control group, treated ﬁstulas showed a reduced inﬂammatory inﬁltration and ﬁbrosis and an enhanced angiogenesis, especially in the gel-EVs group.

Conclusion: This study provides the ﬁrst evidence in the literature that MSC-EVs may provide a novel antiﬁbrotic effect in a pre-clinical esophageal model. EVs were fully administrated via a thermoresponsive Pluronic F127 hydrogel, gelling in situ to enable EV retention in the ﬁstula tract. Besides, the gel further provided a proangiogenic and an anti-inﬂammatory effect. The combined action of MSC EVs and the gel enhanced the healing associated pathways. This study demonstrates the feasibility to deliver EVs through a subcellular localized therapy.

Introduction: Limited data are available with regard to the prevalence of upper gastrointestinal endoscopic ﬁndings in asymptomatic healthy individuals as an endoscopy is an invasive and costly procedure.

Aims & Methods: Individuals were recruited from general population in Latvia as part of the GISTAR pilot study. The study group has been referred for an upper endoscopy and was tested for serum pepinosins and pepinosin I/II ratio <3

Introduction: Type 2 diabetes mellitus is characterized by a fatty liver disease which are highly prevalent, often overlapping metabolic disorders where upstream insulin resistance is thought to be a common pathogenic driver. Simultaneous treatment of both conditions has been reported with insulin sensitizing interventions including upregulation of the insulin receptor agonists, TGDs, and bariatric surgery. Duodenal Mucosal Resurfacing (DMR) is a minimally invasive endo-scopic procedure that has demonstrated glycemric eﬀect in patients with T2D seemingly via an insulin sensitizing mechanism.1 We report data supporting 12- mo durability of improved metabolic indices in patients with T2D after a single DMR procedure in a single-arm, open-label, multicenter study.

Aims & Methods: In this endoscopic DMR procedure, the duodenal mucosa was treated with hydrothermal ablation using a patented balloon catheter. Eﬃcacy was analyzed in a modified intent-to-treat cohort (mITT, patients who received ≥1 ablation) stratified into baseline alanine aminotransferase (ALT) level tertiles (- lower (ALT ≤ 28 U/L), middle (28 ≤ ALT ≤ 37 U/L), and upper (ALT ≥ 37 U/L)), and diﬀerences from baseline in glycemic and HOMA-IR were analyzed using repeated measures ANOVA. Data are reported as mean(sd).

Results: Baseline ALT and HbA1c in the mITT cohort (n = 27, age; 55(9) y; diabetes duration, 6(2.5) y; BMI, 32.5(4.2) kg/m2) were 37.0(20.6) U/L, and 6.0(1.3)% (P = 0.005), 37.0(20.6) U/L, and 6.0(1.3)% (P = 0.005), respectively. In the middle and lowest tertiles, 12-mo ALT reductions were 12(15) (P = 0.024), and 12(15) U/L (P = 0.72); respective body weight changes were −3.8(2.9) kg (P = 0.24), and −1.9(5.9) kg (P = 0.09). 12-mo reductions in AST, HbA1c and HOMA-IR were: −9.7(3.2)% (P = 0.13), −11.0(5.5)% (P = 0.002); and −4.7(5.2) (P = 0.048). In the lowest tertiles, 12-mo ALT reductions were −4(11) and −2(3) U/L.

Conclusion: A single DMR procedure in patients with T2D produced signiﬁcant reductions in HbA1c up to 12 months in the total cohort. In the highest baseline ALT group, ALT was signiﬁcantly lower at 1 month while remaining lower than baseline at 12 months accompanied by signiﬁcant lowering of hyperglycemia up to 12 months. Further studies are planned to quantify the eﬃcacy, safety and durability of the hepatic and glycemric effects associated with DMR.

In this group of asymptomatic healthy individuals, only 20% showed ulcer in HE stained sections under microscope. The width of the fibrosis was defined as the maximum diameter of SMA-positive area in the depth direction from the submucosa to the muscle layer at a site of ESD-induced ulceration or ulcer scarring. The safety and the treatment results of rebamipide at two sites (control group) and with base solution alone at the other two sites (rebamipide group) were assessed. The gastric ulcer stages were evaluated by endoscopy at four sites in the stomachs of three pigs. An endoscopy performed at an animal experimental laboratory in advance (13055 -(0)). ESDs of about 30 mm in diameter were performed at four sites in the stomachs of three pigs. The protocol was approved by the ethics review board of our institution. Four pigs were included in the study, and one was used as a control group for pathological evaluation of ESD-induced ulceration. All endoscopic procedures were performed between February 2014 and June 2016. The study was approved by local ethics committees and the Ethics Committee of the United Kingdom for Research on Cancer.

**Introduction:**

The shrinking rate of ESD-induced ulcer at 4 weeks after ESD were not significantly different from those at 1 week and 4 weeks, but not to a significant extent. The safety and the treatment results of rebamipide at two sites (control group) and with base solution alone at the other two sites (rebamipide group) were assessed. The gastric ulcer stages were evaluated by endoscopy at four sites in the stomachs of three pigs. An endoscopy performed at an animal experimental laboratory in advance (13055 -(0)). ESDs of about 30 mm in diameter were performed at four sites in the stomachs of three pigs. The protocol was approved by the ethics review board of our institution. Four pigs were included in the study, and one was used as a control group for pathological evaluation of ESD-induced ulceration. All endoscopic procedures were performed between February 2014 and June 2016. The study was approved by local ethics committees and the Ethics Committee of the United Kingdom for Research on Cancer.

**Results:**

The shrinking rate of ESD-induced ulcer at 4 weeks after ESD were not significantly different from those at 1 week and 4 weeks, but not to a significant extent. The safety and the treatment results of rebamipide at two sites (control group) and with base solution alone at the other two sites (rebamipide group) were assessed. The gastric ulcer stages were evaluated by endoscopy at four sites in the stomachs of three pigs. An endoscopy performed at an animal experimental laboratory in advance (13055 -(0)). Four pigs were included in the study, and one was used as a control group for pathological evaluation of ESD-induced ulceration. All endoscopic procedures were performed between February 2014 and June 2016. The study was approved by local ethics committees and the Ethics Committee of the United Kingdom for Research on Cancer.
Results: The delayed bleeding rate in the patients receiving antithrombotic therapy was 14.4% (22/153), which was significantly higher than that in the patients without antithrombotic therapy (5.7% (29/512)) (p = 0.0007). The median timing of delayed bleeding in patients receiving antithrombotic therapy and that in patients without antithrombotic therapy were 5.7 ± 4.6 days and 7.0 ± 6.8 days, respectively, without significant difference (p = 0.48). Of 153 patients taking antithrombotic agents, 126 continued antithrombotic agents (all of them were antiplatelet drugs) during ESD (continuation group), 38 discontinued antithrombotic therapy and resumed it after ESD (cessation group), and 30 switched to heparin therapy before ESD (heparin bridge group). One patient was excluded because of uncertain about the period of cessation. The delayed bleeding rate of continuation group, cessation group and heparin bridge group were 13.2% (5/38), 13.1% (11/84) and 20.0% (6/30), respectively, without significant difference (p = 0.63). The delayed bleeding rate of cessation group was 45.8% (5/11), which was not significantly different compared to that of heparin bridge group (p = 0.24). Deep vein thrombosis was observed in one patient in the cessation group.

Conclusion: Antithrombotic therapy increased the delayed bleeding rate. However, the delayed bleeding rate in the patients taking antithrombotic therapy during ESD was similar to that in the patients discontinuing antithrombotic therapy. Therefore, it is inappropriate that the patients with high risk of thrombosis continue antithrombotic therapy on gastric ESD, but the heparin bridge therapy requires a further examination.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0802 LOW-DOSE ASPRIN DELAYS THE ULcer HEALING AND INCREASES THE RISK OF POSTOPERAtoVE BLEEDING AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION THROUGH THE DUODENOGASTRIC REFLUX

N. Usuki1, S. Futagami1, T. Akimoto1, S. Agawa1, G. Ikeda1, H. Noda1, K. Haguchi1, Y. Maruki1, H. Yamawaki1, Y. Kodaka1, T. Kawagoe1, K. Miyake1, M. Kaise2, K. Iwakiri1

Introduction: Endoscopic submucosal dissection (ESD) permits en bloc resection for early lesions. The number of the patients taking anti-thrombotic agents including low-dose aspirin (LDA) has increased. The Japanese guidelines recommended endoscopic procedures without interruption of LDA therapy in patients at high risk of thrombotic events who use LDA alone. And, bile acid reflux is known to cause gastric mucosal damage though the exact mechanisms are still unclear.

Aims & Methods: In this study, we aimed to clarify whether LDA treatment and gastric bile acid contents synergistically affect on postoperative bleeding and healing of ulcer after ESD procedure. A total 224 patients with gastric neoplasms were treated with ESD at Nippon Medical Hospital, between January 2013 and June 2016. To investigate whether anti-thrombotic agents affect the ESD procedure-induced ulceration and ESD postoperative bleeding rate, we compared ulceration reduction rate (one month after ESD), postoperative bleeding rate and gastric bile acid contents among the patients treated with low dose aspirin, other anti-thrombotic agents and non-anti-thrombotic agents. On the day of ESD and one day after ESD, gastric juice was taken in endoscopy and total bile acids were measured spectrophotometrically after the enzyme reaction.

Results: Ulcer reduction rate in the patients treated with LDA was significantly higher (p = 0.0036) higher compared to that in the patients with non-anti-thrombotic agents. On the other hands, the number of patients taking antithrombotic agents are increasing because of evidence of antithrombotic therapy for prevention of thromboembolic events has been established and population aging advances, which is thought to be a serious problem related to increasing delayed bleeding after ESD.

Aims & Methods: To assess the influence of antithrombotic therapy on delayed bleeding after ESD, we retrospectively investigated the delayed bleeding rate after ESD among the continuation of antithrombotic agents, the cessation of antithrombotic agents and heparin bridge therapy. 735 lesions in 665 patients were treated with ESD from January 2006 to December 2016. We compared the delayed bleeding rate in 153 patients receiving antithrombotic therapy with 512 patients without that. Furthermore, we compared the delayed bleeding rate in the patients continuing antithrombotic therapy with that in the patients with the cessation of antithrombotic therapy or with heparin bridge therapy. The patients who were anti-thrombotic agents were treated with continuation aspirin or clopidogrel. The cessation period of antithrombotic therapy before ESD followed the guidelines for therapeutic endoscopy in antithrombotic agents-users from Japan Gastrointestitinal Endoscopy Society. We defined delayed bleeding as a hematoma, a melema, or a decrease of Hb > 2 g/dl.

Results: The delayed bleeding rate in the patients receiving antithrombotic therapy was 14.4% (22/153), which was significantly higher than that in the patients without antithrombotic therapy (5.7% (29/512)) (p = 0.0007). The median timing of delayed bleeding in patients receiving antithrombotic therapy and that in patients without antithrombotic therapy were 5.7 ± 4.6 days and 7.0 ± 6.8 days, respectively, without significant difference (p = 0.48). Of 153 patients taking antithrombotic agents, 126 continued antithrombotic agents (all of them were antiplatelet drugs) during ESD (continuation group), 38 discontinued antithrombotic therapy and resumed it after ESD (cessation group), and 30 switched to heparin therapy before ESD (heparin bridge group). One patient was excluded because of uncertain about the period of cessation. The delayed bleeding rate of continuation group, cessation group and heparin bridge group were 13.2% (5/38), 13.1% (11/84) and 20.0% (6/30), respectively, without significant difference (p = 0.63). The delayed bleeding rate of cessation group was 45.8% (5/11), which was not significantly different compared to that of heparin bridge group (p = 0.24). Deep vein thrombosis was observed in one patient in the cessation group.

Conclusion: Antithrombotic therapy increased the delayed bleeding rate. However, the delayed bleeding rate in the patients continuing antithrombotic therapy during ESD was similar to that in the patients discontinuing antithrombotic therapy. Therefore, it is inappropriate that the patients with high risk of thrombosis continue antithrombotic therapy on gastric ESD, but the heparin bridge therapy requires a further examination.

P0804 TRANSPANTATION OF AUTOLOGOUS ESOPHAGUS MUCOSA TO PREVENT STRICTURE AFTER CIRCUMFERENTIAL ENDOSCOPIC SUBMUCOSAL DISSECTION OF EARLY SQAMOUS CELL

L. Zhang1, F. Chai2, Z. Zeng, Y. Xin, P. Xue, Z. Xin, Y. Jin, X. Xia, B. Jia

1Gastroenterology, Xinqiao Hospital, Third Military Medical University, Chongqing, Qing/China

Contact E-mail Address: 18225537@163.com

Introduction: Esophageal endoscopic submucosal dissection (ESD) to remove superficial esophageal neoplasms is gradually becoming the standard treatment for superficial esophageal cancer, but is associated with esophageal stenosis, particularly when ESD involves the entire circumference of the luminal. Many methods to prevent post-ESD stricture, such as repeated Endoscopic balloon dilatation (EBD), temporary stent insertion, and oral steroid and intralesional steroid injection, have been used in different institutions. In recent years, new technologies such as autologous oral mucosal sheets or extracellular matrix scaffold material have also been suggested to manage esophageal strictures. There are no standard guidelines to prevent stricture in a patient with circumferential mucosal defect after ESD. In this study, we aimed to assess the effectiveness and safety of endoscopic transplantation of autologous esophagus mucosa in preventing formation of strictures after ESD.

Aims & Methods: We performed a single-arm, single-institute study. Nine patients who underwent wholly circumferential ESD for superficially extended
Patients with esophageal squamous cell carcinoma at the endoscopic center of Xinqiao Hospital, Third Military Medical University (Chongqing, China) from January 2015 to February 2017, were enrolled in this study. We collected specimens of autologous esophageal mucosal tissue from these patients. After undergone ESD, these mucosal pieces were affixed to the “ulcer surface” by hemoclips and then fixed by means of a covered metal mesh stent. The stent was removed on post-procedure day 7. All patients were monitored by endoscopy.

Results: In bloc ESD was safely achieved in all cases. The overall longitudinal diameter of resected specimens was 117.8 mm (range, 70 to 150 mm). Autologous esophageal mucosa was successfully transplanted to the “ulcer surface” using an endoscope. The number of mucosal patches ranged from 8 to 28. Complete re-epithelialization occurred within a median time of 8.6 days with a graft survival rate at 93.06%. Postprocedural stricture accompanied by dysphagia occurred in seven patients on post-procedure day 24.7 (range, 18–34 days). The median sessions of EBD and intralesional steroid injection was 3.3 (range 1–6). No other serious complications occurred in these patients, such as overall bleeding and perforation. Eight patients were still alive during the mean follow-up period of 11.6 months (range, 2.5 to 21 months). One patient developed lung metastasis and died of the disease 15 months after ESD.

Conclusion: Transplantation of autologous esophageal mucosa appears to be a safe means of relieving the severity of esophageal stenoses following circumferential ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Early neoplastic lesions in Barrett’s Esophagus (BE) can be effectively and safely removed by endoscopic resection (ER) using multi-band mucosectomy (MBM). Recently a new MBM device became available, designed for improved visualization, easier passage of accessories, and better suction power compared to other marketed MBM devices.

Aims & Methods: This study aims to document performance of the new MBM device for ER of early neoplastic lesions in BE.

This is a company sponsored, international, multicenter, single-arm, prospective registry study enrolling 300 subjects with early neoplasia in BE. Primary endpoint is successful ER defined as complete resection of the delineated target area in one procedure. Secondary outcomes: adverse events, procedure time.

Results: To date 259 subjects have been enrolled at 14 centers (Europe 10, US 3, Canada 1). Mean age was 67±9 years, with 87% males. In these 259 subjects, a total of 301 lesions were removed using the new MBM device, with a mean of 2.5±1.92 resections per procedure. Indication for ER was high-grade dysplasia (HGD) in 65%, early adenocarcinoma in 20%, visible lesion with low-grade dysplasia in 10%, and a visible lesion suspicious for neoplasia without pre-treatment histology in 5%. The primary endpoint of successful ER of a target lesion
was reached in 290/301 (96%) procedures. A perforation occurred in 3/301 ER procedures (1%, 95% CI 0.21%–3.88%). Two perforations were detected with the new MBM device in 1/301 (0.33%) procedures. Perforations were in 1% and significant post-procedural bleeding in 2%, complications were effectively managed endoscopically.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0807** COST-EFFECTIVE ANALYSIS COMPARING STANDARD BIOPSIES VS. DIGITAL BIOPSY BY CONFOCAL ENDOMICROSCOPY

Gastroenterology, Instituto Ecuatoriano de Enfermedades Digestivas, Guayaquil/Ecuador

Contact E-mail Address: carlosouamk@yahoo.es

Introduction: Endoscopy has greatly influenced gastroenterological diagnosis. However, most lesions can be suspected but not certainly diagnosed only on the basis of endoscopic findings and therefore, histology is needed. On the other hand the reliability of detecting lesions historically depends on the site, number, and size of biopsies (Bx) specimens with a 20–30% probability of sampling mistakes. Probe based Confocal Laser Endomicroscopy (p-CLE) allows endoscopist to perform intra-vivo mucosal cellular evaluation of the gastrointestinal (GI) tract with a high (90%) diagnostic accuracy. It allows to perform target Bx. Moreover, the NPV is >98%. There is no information in the literature regarding the economic impact of performing digital biopsies (DBx) by p-CLE.

Aims & Methods: The purpose of this study is to perform a cost-effectiveness analysis comparing the diagnosis of upper GI tract pathologies using only standard Bx following the literature recommendations (LR) vs. the diagnosis with DBx using p-CLE. This was a retrospective study with prospective collection data of patients included from Jan 2014 to Nov 2016. The pathologies included for p-CLE evaluation are summarized in Table 1. The diagnosis costs using standard Bx was calculated following the literature recommendations (Table 2). The standard Bx costs included the histological process and physician honoraria per Bx (USD 50.00), and one biopsy forceps per patient (USD 38.00). The DBx cost by p-CLE included the probe, the processor and the physician honoraria (USD 500.00). Baseline characteristics, p-CLE indications, the diagnostic accuracy of p-CLE and costs were described.

Results: 78 patients were included, 51.2% were female. The mean age was 50.18 years old. p-CLE indications distribution was: esophagus 29 (37.2%), stomach 46 (59%) and duodenum 3 (3.8%) subgroups. Biopsies were performed in 71/78 cases (91.0%). Table 1 shows the procedure cost reached with the different pathologies, by following the Bx LR for initial diagnosis and follow-up. The efficacy of p-CLE in our study was 91.7% sensitivity, 89.8% specificity, 64.7% PPV, 98.2% (59%) and duodenum 3 (3.8%) subgroups. Biopsies were performed in 71/78 and costs were described.

Table 1: Cost analysis following the Literature Recommendations (LR) for initial diagnosis and follow-up

Bx: biopsies; LR: Literature Recommendations. a. For initial diagnosis. b. For follow-up. c. Cost includes histological process and physician honoraria per biopsy (USD 50.00), and the Bx forceps per patient (USD 38.00).

Conclusion: In our population, the digital biopsy by p-CLE proved to be more cost-effective, when ≥10 biopsies were indicated, like in cases of a Barrett’s Esophagus ≥4 cm, a Gastric Tumor, or in the context of two or more suspected pathologies (e.g.: esophageal and gastric disease).

**P0808** GASTRIC PER-ORAL ENDOSCOPIC PYLOROMYOTOMY (G-POEM) IN THE TREATMENT OF REFRACTORY GASTROPARESIS: EXPERIENCE OF THE FIRST 9 CASES IN MEXICO

Endoscopy, IMSS, Mexico city/Mexico

Contact E-mail Address: mondragonmd@yahoo.co.uk

Introduction: Gastroparesis is a syndrome characterized by a delayed gastric emptying with absence of a mechanical obstruction. Reduction in QOL scores have been observed. Etiologies include: idiopathic, diabetic, post-surgical. Diagnosis is based on the combination of symptoms and a delayed gastric emptying scintigraphy(GES) of >10% after 240 min. Multiple treatments have been used but temporary results with morbidity, so no new treatment options have been explored. G-POEM is a new endoscopic treatment which is based in the POEM treatment for achalasic patients and consist in a creation of a submucosal tunnel in order to perform an endoscopic pyloromyotomy. Initial results have been promising.

Aims & Methods: The aim of this study was to evaluate the safety and efficacy of G-POEM in a group of Mexican patients with refractory gastroparesis. This prospective study was carried out in a tertiary care center in Mexico city, between December 2016 and April 2017. We included patients with refractory gastroparesis defined as presence of symptoms such as: nausea, vomiting, early satiety with inability to finish a normal meal, bloating and upper gastrointestinal pain. These patients were considered to be on medical treatment and did respond and have a positive gastroparesis cardinal symptom index (GCSI) score combined with a >10% of retention at 240 min in the GES study. Exclusion criteria were malignancy, peptic ulcer disease, normal GES and coagulation disorders. Procedure steps were performed in POEM procedure, beginning 5cms behind pyloric arch with an longitudinal incision, then submucosal tunnel creation, myotomy of the pyloric arch up to the serosa and 2cms before this point and finally closure with clips. Follow-up included GCSI, endoscopy and GES at 3 months after procedure.

Conclusion: Initial results have been promising.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P0809** ENDOSCOPIC MANAGEMENT OF FOREIGN BODIES IN THE UPPER GASTROINTESTINAL TRACT: A RETROSPECTIVE STUDY OF 1294 CASES

C. Geng, X. Li, X. Lei, C. Wang
Department Of Gastroenterology, West China Hospital of Sichuan University, Chengdu/China

Contact E-mail Address: genghong15scu@163.com

Introduction: Foreign body (FB) ingestion including food bolus impaction is frequently encountered in clinical practice. Few studies with large sample size...
towards endoscopic management of FBs had been reported. No direct evidence has demonstrated the relationship between duration of FB impaction and outcomes of endoscopic management. Moreover, it remains unclear whether endoscopic management of FBs under general anesthesia could improve endoscopic outcomes when compared with topical pharyngeal anesthesia.

**Aims & Methods:** The aim of the present retrospective study is to analyze our endoscopic outcome and explores the best timing and anesthesia methods of endoscopical intervention with FB ingestion. All consecutive patients suspected of FB ingestion were enrolled. The demographic, clinical and endoscopic data were collected and analyzed.

**Results:** Totally, 1294 cases were recruited in this retrospective research. The ages ranged from 7 months to 94 years, with a median age of 47.0 (31–63) years. The majority of patients (1191/1294 cases, 92.0%) presented with some symptoms after FB ingestion, in order of frequency odynophagia (415 cases, 32.1%), foreign body sensation (340 cases, 26.3%) and sore throat (267 cases, 20.1%). The most common underlying pathologies were oesophageal stricture (35 cases, 39.3%) and oesophageal cancer (11 cases, 12.5%). The procedure was performed under general anesthesia in 126 cases (9.8%) and under topical pharyngeal anesthesia in 1168 cases (89.2%). The mean time of FB impaction ranged from 4 hours to more than 2 years with a median time of 1 (0.63–3) days. Bony FBs, jujube pit, food bolus and dental prosthesis were the most frequent FBs in population. Anatomically, FBs were mostly impacted in the oesophagus (n = 1025, 86.9%), especially in the upper oesophagus (n = 702, 59.5%), followed by stomach (n = 95, 8.1%), duodenum (n = 36, 3.0%) and pharynx (n = 24, 2.0%). Nearly half of the patients (49.9%) developed FB-related complications, mainly including mucosal injuries (336 cases, 27.5%) and ulcers (210 cases, 16.2%). The most common underlying pathologies were oesophageal stricture (35 cases, 39.3%) and oesophageal cancer (11 cases, 15.5%). As the duration of FB impaction increased, positive finding and successful removal of FB by endoscopy significantly decreased (p = 0.001). Furthermore, complication rate significantly increased with time (p < 0.001). Age (OR = 1.15, 95%CI: 1.20–1.91, p < 0.001), type and location of FBs (OR = 4.51, 95%CI: 2.95–6.90, p < 0.001) and some symptoms (OR = 2.26, 95%CI: 1.48–3.46, p < 0.001), anesthesia methods (OR = 1.35, 95%CI: 1.05–1.75, p = 0.02) and duration of FB impaction (OR = 1.74, 95%CI: 1.50–2.00, p < 0.001) were verified as risk factors for development of FB-related complication by logistic regression analysis. General anesthesia could not improve positive FB detection (p = 0.181) or success rate of endoscopic management of FBs (p = 0.135), as well as decrease the complication rate when compared with topical pharyngeal anaesthesis (52.3% VS 47.5%, p = 0.033).

**Conclusion:** FB-related complication rate increased with time, endoscopic management under general anaesthesia could not improve therapeutic effects when compared with topical pharyngeal anaesthesia. Overall, Patients suspected of FB ingestion should receive endoscopic management as soon as possible.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0810 CLINICAL OUTCOMES AFTER ENDOCUTIVE RESECTION FOR ESOPHAGEAL SQUAMOUS CELL CARCINOMA COMPARING THE CASES WITH MM AND SM1 INVASION**

S. Yoshimizu1, T. Yoshih1, K. Namikawa2, A. Ishiyama2, T. Tsuchida1, J. Fujisaki2

1Cancer Institute Hospital, Tokyo/Japan
2Gastroenterology, Cancer Institute Hospital, Tokyo/Japan

Contact E-mail Address: yoshisukyo@shinjuku.affrc.or.jp

**Introduction:** Recent advances in endoscopic resection (ER) provide us increasing chances for resecting esophageal squamous cell carcinoma (ESCC) with muscularis mucosae (MM) and SM1 invasion as MM/SM1 invasive cancer is reported to have 8–20% of metastatic risks and is defined as relative indication for ER in guideline by Japan Esophageal Society. For them, we perform additional therapy such as chemo radiotherapy (CRT) or operation considering the risk of metastasis and patients’ condition.

**Aims & Methods:** To know the difference of metastatic risk and long time outcomes, retrospectively studied 121 cases of ESCC with pathological MM/SM1 invasion (MM/SM1:97/24) resected by ER from 2003 to 2013 in Cancer Institute Hospital. After pathological diagnosis of resected lesions, we performed additional therapy such as CRT, radiation therapy (RT) or operation, to the cases with lymphovascular invasion (LVI) or droplet infiltration (DI). Median observation period was 48 months.

**Results:** Enrolled cases included 112 males and 9 females and their median age was 66 (39–86). We resected ESCC by ESD in 71 cases and by EMR-C in 50 cases and their median size was 27 mm. Local recurrence was observed in 6 cases which were all after EMR (12%). As for local recurrence 5 cases were treated by re-EMR and 1 case by APC, resulted in no re-recurrence. Of 97 cases of MM, 15 cases (15.5%) had LVI, 10 cases (10.3%) had DI. We recommended additional therapy in 12 cases (10.5%). Additional therapy was performed in 15 cases (15.5%) (ope/CRT/RT/5/1). No case died of ESCC and 22 cases (22.7%) died of other diseases. Of 24 cases of SM1, 9 cases (37.5%) had LVI, 5 cases (20.8%) had DI. We recommended additional therapy in 25 cases (20.5%). Additional therapy was performed in 9 cases (37.5%) (ope/CRT/RT/chemotherapy: 3/4/1/1). Three cases died of ESCC and 5 cases (20.8%) died of other diseases. Comparing both groups, tumor size and local recurrence rate were not different each other. The frequency of LVI was significantly higher in SM1 than in MM (p < 0.05) and the frequency of DI was higher in SM1, although not significant (p = 0.161). The metastatic recurrence was observed significantly frequently in SM1 than MM (16.7% vs 2.1%; p < 0.01). The 5-year overall survival (OS) disease specific survival (DSS)/relapse free survival (RFS) were 81.7%/100%/94.1% for MM and 62.9%/87.9%/91.7% for SM1. OS and RFS were not different each other, however, CSS was superior in MM than in SM1 (p < 0.01).

**Conclusion:** ESCC with MM invasion was superior in metastatic recurrence and CSS than ESCC with SM1 invasion, although we treat MM/SM1 in the same way. Additional therapy should be considered more positively in cases of SM1 than in cases of MM, considering metastatic risk and patients’ conditions.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0811 GASTRIC ESD IN AN ANIMAL SURVIVAL MODEL USING THE ANUBIS-SYSTEM**

J. Bernhardt1, H. Steffen2, P. Kochler1, S. Schneider-Kortath2, K. Ludwig2

1Dept. Of Endoscopy, Klinikum Suedstadt Rostock, Rostock/Germany
2Dept. Of Surgery, Klinikum Suedstadt Rostock, Rostock/Germany

Contact E-mail Address: joern.bernhardt@kliniksued-rostock.de

**Introduction:** ESD in generally is still under evaluation. The one-piece resection of lesions larger than 2 cm has many advantages against piece meal resection. One advantage of flexible preparation in opposite position of the instruments in ESD. We used the ANUBIS-system for intragastric ESD.

**Aims & Methods:** The experimental study was conducted in a porcine model in general anesthesia. We started the study with 7 pigs in a survival model using the Anubiscope (Carl Storz, Germany). After insertion of the scope insufflations were done with the two arms of the scope using a grasper and a hook-knife. Also the grasper could use for coagulation. The specimen was removed with the scope after closing its valves.

**Results:** The procedure was successful in all animals with operation time ranging from 102 to 189 minutes with a learning curve. After weight gain in all cases, the animals were sacrificed after postoperative day 42 and the workup showed competent healing with a star-like scar.

**Conclusion:** The use of an operating platform like the Anubiscope has the advantage of flexible preparation in opposite position of the instruments in ESD. The disadvantages are the only two degrees of freedom of the flexible instruments and the rotation-like movements. Also, it is not possible to reach all regions of the stomach.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0812 USEFULNESS OF NARROW BAND IMAGING WITH MAGNIFYING ENDOSCOPY AS A SCREENING TEST FOR GASTRIC CANCER**

T. Morishita

Gastroenterology, Kameda Medical Center, Chiba/Japan

Contact E-mail Address: moristatu@yahoo.co.jp
ME-NBI is an important modality to diagnose early gastric cancer.

Introduction: Contact E-mail Address: ness of ME-NBI has been often reported\[2, 3\], some cases are difficult to diagnose

Results: The biopsy rate of NBI-ME and conventional endoscopy in Group M was 0 and 0.2%, respectively, while in Group S it was noted to be 4.2 and 1.8%, respectively. Thus, the detection rate of NBI-ME was significantly higher than that of conventional endoscopy in Group S (p < 0.01). The accuracy of biopsy with NBI-ME and conventional endoscopy in Group M was 0 and 3.2%, respectively, but in Group S it was noted to be 36.4 and 14.1%, respectively. Thus, the biopsy rate of biopsy using NBI-ME is significantly superior to conventional endoscopy in Group S (p < 0.01).

Conclusion: NBI-ME as a screening test for gastric cancer is useful for patients with severe atrophy of the background gastric mucosa because this technique has shown a higher detection rate of gastric neoplasms and better accuracy of biopsy.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0814 BEST PRACTICE IN PLACEMENT OF PERCUTANEOUS ENDOSCOPIC GASTROSTOMY WITH JEJUNAL EXTENSION TUBE FOR CONTINUOUS INFUSION OF LEVDOPA CARBIDOPA INTESTINAL GEL IN THE TREATMENT OF ADVANCED PARKINSON’S DISEASE: THE ROLE OF GASTROENTEROLOGIST A.G. Gravina, I. Apicella, V. M. Ormando, M.R. Amato, M. I. Russo, M. Romano, P. Esposito Medical And Surgical Department Of Clinical And Experimental Intrinsich “f Magnacca”, Hepatogastroenterology and Digestive Endoscopy Unit, University of Studies “L. Vanvitelli”, Napoli/Italy

Introduction: Levodopa is the gold standard in pharmaceutical treatment of the advanced Parkinson’s disease (APD) and its oral administration in advanced disease is associated with development of symptoms and motor and non-motor complications. Due to its short plasma half-life, Levodopa requires repeated dosing (1, 2). Impaired gastric emptying is common in APD and reduces the absorption of Levodopa, requiring progressively higher doses and more frequent administrations. Continuous duodenal administration of modulated Levodopa/ Carbipen gel by jejunal Extension Tube Placement through Percutaneous Endoscopic Gastrostomy (PEG-J), is a new therapeutic protocol in advanced APD (3).

Aims & Methods: Aim of this work is to verify efficacy and safety of intestinal gel (LCIG) delivered continuously through an Intrajejunal percutaneous tube (PEG-J). 24 adult (14 M, 10 F, median age 71 years) with APD and preserved sensitivity to L-Dopa were enrolled. 7 days before PEG-J placement, to evaluate the possible presence of mucosal or anatomical gastric anomalies, each patient underwent endoscopic esophagogastroduodenoscopy (EGD). Treatment with LCIG consists in a water-based suspension containing micronized levodopa (20 mg/mL) and carbidopa (5 mg/mL) in methylcellulose, administered by continuous jejunal infusion for 12h/day using a portable pump by PEG-J. Clinical evaluations were performed at baseline(T0), before LCIG initiation, and after 3 (T3) and 6 (T6) months of therapy. To evaluate efficacy and safety outcomes it has been used Unified Parkinson’s Disease Rating Scale (UPDRS) parts II, III and IV. For the analysis of the differences between the clinical variables and to exclude biases due to the small number of the sample in the question, the non-parametric Kruskal-Wallis H test was used for the comparison of three samples. A statistically significant value of p was less than 0.05. The analyses were carried out using SPSS version 13 (SPSS Inc., Chicago, IL, USA).

Results: 1) Success rate for PEG-J placement was 100%; 2) Eighty-four patients (33%) dropped-out LCIG at T3; 3) Sixty-six/16 patients (100%) showed statistically significant (p < 0.05) higher performances in daily common activities and statistically significant (p < 0.05) lower incidence and severity of motor fluctuations at T6 compared to their best oral therapy; 4) During observational period, 6 patients experienced adverse events.

Conclusion: 1) This study demonstrates that continuous intrajejunal LCIG’s infusion treatment is highly effective in decreasing motor fluctuations in advanced PD patients compared to oral administration of levodopa-carbidopa; 2) This therapeutic approach should be proposed in well selected APD patients with preserved sensitivity to L-Dopa.

Introduction: Post-endoscopic submucosal dissection (ESD) bleeding is the most common complication of ESD. In previous studies, the post-ESD bleeding occurred from 1.8% to 15.6% of total procedures [1–4]. Recently, many patients who underwent ESD, have been prescribed antiplatelets or anticoagu- lants, because of various underlying diseases such as cerebrovascular accidents or...
cardiovascular diseases [3]. Thus, the verified risk prediction model of post-ESD bleeding may help to determine preventive therapeutic options and restarting date of antiplatelet agents.

Aims & Methods: The aim of this study is to develop the predictive risk model of post-ESD bleeding. A total of 3574 patients, who were taken ESD from January 2007 to November 2016 in a Korean tertiary hospital, were included in this retrospective study. To avoid overfitting of the prediction model, we divided the patients randomly into two groups, either a derivation group or a validation group. Preoperative and procedural-related variables were selected via univariate and multivariate analysis. A risk score was calculated to assess the bleeding prediction model of a patient in the derivation group and was discriminated in the validation group.

Results: Post-ESD bleeding occurred in 248 patients (6.9%). In the derivation group, multivariate logistic regression revealed renal disease (odds ratio [OR], 3.90; 95% confidence interval [CI], 1.48–9.09; P = 0.0029), anti-platelet agent (OR, 3.07; 95% CI, 1.44–6.05; P = 0.002), and en-bloc resection (OR, 3.83; 95% CI, 1.34–10.34; P = 0.0059) as significant risk factors (C-statistic = 0.607; 95% CI, 0.552–0.661). In the validation model also showed discrimination power (C-statistic = 0.580; 95% CI, 0.533–0.627). Based on the scoring system of odds ratio, bleeding risk was 4.1% in the low risk set (score ≤ 4), 7.0% in the high risk set (score > 4, P = 0.003) (validation set).

Conclusion: Our study investigated a prediction scoring system of estimating the bleeding risk, including the patient, endoscopist factors. A risk score can be calculated before the procedure and the endoscopists can predict bleeding potency before the gastric ESD. Based on the scoring system, endoscopists may alter therapeutic plans such as prolongation of admission days or medication schedules.

The histological assessment and biopsy sampling protocol has been standardized among 595 patients with clinical suspicion of foreign body ingestion from 18 general hospitals in China. The patient data including age, gender, clinical features, and data about endoscopic management including types and locations of foreign bodies, retrieval devices, outcomes and complications were collected and analyzed.

Results: 1) The most common types of foreign bodies were fish bones (34.0%), chicken bones (22.1%), fruit nuclei (11.7%), and food bolus (14.6%). The majority of them were short objects (< 2.5 cm, 74.0%), subsequently followed by middle objects (2.5 – 6.0 cm, 24.5%) and long objects (> 6 cm, 1.5%). Most objects were lodged in the proximal esophagus (75.9%), followed by the middle segment (9.9%) and distal segment (8.9%) of esophagus. 2) 96.3% of all cases had obvious clinical symptoms. Clinical symptoms occurred more often in the proximal segment of the esophagus (98.1%) than any other segments of the upper gastrointestinal tract (92.6%) (P < 0.001). 3) The successful removal rate through endoscopy was 94.5%. It was even higher with general anesthesia (99.3%) than without it (92.7%) (P < 0.01). 4) Complication rate was as high as 34.0%, which was increased with long retention time and sharp objects (P < 0.001). The rate was increased by 2.2- and 6.1-folds after impacted for over 12 and over 24 hours respectively. Logistic regression analysis indicated that sharp objects had obviously more complications than non-sharp ones (OR 3.36, 95% CI: 1.97-5.74). In particular, the incidence of perforation was 5.6%, which was strongly related with long retention time and sharp objects (P < 0.03), but not with locations or lengths of the objects (P > 0.05).

Conclusion: General anesthesia could largely improve the retrieval rate through endoscopy. Foreign bodies, especially sharp shoulds, be removed as soon as possible within 24 hours, to further decrease severe complications.

Introduction: In gastrointestinal stromal tumors (GISTs) without a risk of metastasis to other organs, local resection is acceptable. In small GISTs, however, it is controversial whether surgical resection is necessary because a risk of recurrence/metastasis in these tumors including ulcerated GISTs as a minimally-invasive surgical option towards the inside of the stomach, endoscopic muco-submucosal incision and suture with the lesion inverted intraluminally-/intramurally-growing type. In the NEWS procedure, a lesion was resected in a resected in a following manner: endoscopic mucosal markings, laparoscopic serosal markings just behind the mucosal markings, endoscopic submucosal injection, laparoscopic sero-muscular incision and suturing with the lesion inverted toward the stomach, endoscopic submucosal dissection and laparoscopic retrieval. Short-term outcomes of NEWS and a potential risk of recurrence/metastasis in each tumor according the Fletcher’s classification were assessed. Some small GISTs which could be retrieved transorally had a high malignant potential. NEWS was feasible, safe and therefore recommended for these tumors including ulcerated GISTs as a minimally-invasive surgical option to resect these tumors without an extended surgical scar for the retrieval of the specimen and a risk of iatrogenic tumor cell seeding into the peritoneum during the procedure.

The incidence of oesophageal cancer has increased significantly over the past two decades. The majority of these cancers are incurable at diagnosis. Therefore, the management is aimed at maintaining quality of life by ensuring adequate nutrition and palliation of symptoms, mainly dysphagia. Self-expanding metallic stents (SEMS) have a well-recognised role in the palliative management of patients with oesophageal cancer. These stents are inserted endoscopically, under direct vision (EC) or with fluoroscopic assistance to endoscope (FAE). There is little evidence to compare outcomes between these approaches. Aims & Methods: The objective of this study was to compare the outcomes, using various performance indicators, in patients who underwent SEMS for palliation in oesophageal cancer via different approaches (EC or FAE) at the Royal Infirmary of Edinburgh (RIE). A retrospective observational study was conducted between May 2014 to April 2016; a total of 62 SEMS. The approach to stent insertion was subject to operator choice and availability of fluoroscopic guidance in palliative oesophageal stent placement. EC offers the advantage of stent placement with direct visualization, however a learning curve must be acknowledged. FAE insertion is a time-consuming procedure and exposes both patients and endoscopy staff to radiation. In conclusion, the approach used should be based on individual characteristics including operator experience, tumour characteristics and previous endoscopic interventions.

Introduction: Ingestion of caustic substances is relatively frequent and can cause severe oesophageal damage in the upper gastrointestinal tract, carrying important morbidity and even mortality.

Aims & Methods: We aimed to characterize the population assisted for caustic ingestion, the therapeutic approach, complications and risk factors for severe oesophageal lesions. Retrospective cohort of adults presenting due to caustic ingestion between 2000 and 2015. Demographic and clinical data were collected. The endoscopic Zargar classification was applied. We analysed risk factors for severe oesophageal lesions, defined as Zargar 2b-3. Statistical tests: Mann-Whitney, Spearman (significance level 5%).

Results: Overall 72 patients were included, with a mean age 53 ± 17 years, 65.3% female. Ingestion was voluntary in 49.3% of the cases, 33.3% had previous suicide attempts. Alkaline substance in 90.4%. Most common symptoms at admission: 60.3% odynophagia, 41.1% epigastic pain, 32.9% vomiting. Orophageal lesions in 41.1%. In 79.5% endoscopy was performed in the first 12 hours. Oesophageal lesions were present in 46.6% of patients (Zargar classification: 1-2.7%, Ha-23.3%, Hb-5.5%, Ilh-6.8%, Ihb-8.2%), gastric lesions in 58.9% and duodenal lesions in 13.7%, 53.4% were hospitalized, 51.3% in intensive/intermediate care units. The mean length of hospital stay was 14.9 days. Medical treatment prescribed: 76.7% proton pump inhibitors, 15.1% corticoids, 15.1% prophylactic antibiotics. Parenteral feeding was initiated in 28.8% of patients. Eight patients required invasive ventilation and two were tracheotomised. Early complications: infections in 12 patients (16.4%), perforations in 2 (2.7%); late complications: stenosis in 7 (9.6%); dilation in 6, surgery in 3. One patient died from gastric perforation after voluntary ingestion of acid. Severe oesophageal lesions were associated with increased inflammatory parameters, tachycardia and/or hypotension at admission and motivated longer hospital stays, requirement of intensive care and further complications (p<0.002). The ingestion of acidic substances (100% of voluntary intake) was associated with severe oesophageal damage in 3/7 (42.9%) patients, severe gastric lesion in 5/7 (71.4%), acidemia in 5/7 (71.4%), complications in 5/7 (71.4%) and 100% hospitalization.
Conclusion: Early changes in blood tests were seen in severe oesophageal lesions. Severe oesophageal lesions were associated with longer hospitalization and complications (infection/stenosis/perforation). Ingestion of acidic substances was a risk factor for severe digestive lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A value of the combination of magnifying endoscopy and of image enhancement endoscopy (IEE) technology (e.g. NBI, BLI) is reported in a diagnosis for the early gastric neoplasm. That method is useful, but in order to master it is necessary to learn and familiarize complex classifications. Therefore, this diagnostic method is still more difficult for general endoscopists. Linked Color Imaging (LCI) was recently developed using a laser endoscopic system (Fujifilm CF-180AI, Tokyo, Japan). LCI acquires images by simultaneously using narrow-band short wavelength light and white light in an appropriate balance. This combination of light provides more information about the vasculature and architecture on the mucosal surface than that obtained with typical white-light imaging. While we use acetic acid indigocarmine mixture (AIM) with LCI mode, we reported that the magnifying images of early gastric cancer are very clear, three-dimensional and near to real histology. So, we examined the examined the utility of this method.

Aims & Methods: This was a prospective observational study performed at a single tertiary referral center. The subjects are 120 lesions of 115 patients with gastric neoplasm. We are indicated the endoscopic submucosal dissection (ESD), and were given preoperative endoscopy in our hospital from September 2014 to February 2017. Firstly we observed the lesions by magnifying endoscopy with the LCI mode and diagnosed using VS classification system. Secondly we observed the lesions by magnifying endoscopy with LCI + AIM method and diagnosed using VS classification system. Furthermore, we classified tumor differentiation into high differentiation, moderately differentiated, and poorly differentiated by its surface pattern. Finally, we classified the visualization ability of the surface fine structure in Clear, Visible, and Invisible and evaluated it. We carried out ESD and compared the image with the histopathology.

Results: By the results, 92 lesions were gastric adenoma and 28 lesions were gastric adenoma. The differentiation ability of a cancer and the non-cancer (adenoma) did not have the significant difference between the LCI mode and the LCI + AIM methods. Diagnosis of differentiation of gastric cancer was correct in 87 of 92 cases (94.6%). In the classification of visualization ability, 32 lesions were Clear, 44 lesions were Visible, 11 lesions were Invisible and 44 lesions were Invisible by BLI mode, On the other hand, 45 lesions were Clear, 64 lesions were Visible, 11 lesions were Invisible and 44 lesions were Invisible by AIM mode. In the visualization ability of the surface fine structure, LCI + AIM method is significantly clearer than LCI mode (p < 0.001).

Discussion: When we use AIM, indigocarmine accumulates in pit of the duct, and duct structures become clear by the acetic acid. By LCI mode, we can observe the vascular pattern of the lesion clearly. So by the combination of AIM and LCI, we can observe the endoscopic images closer to actual histological images. By this combination of AIM and LCI, we can observe the endoscopic images closer to actual histological images. By this combination of AIM and LCI, we can observe the endoscopic images closer to actual histological images.

Introduction: Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early gastric neoplasms. The advantages of ESD include the ability to control the size and shape of the resection, permitting en bloc resection of large and ulcerated lesions. The frequency of gastric ESD for patients aged 85 years or older has increased along with increases in the average population age. However, few studies have reported the short-term and long-term outcomes of gastric ESD in elderly patients.

Aims & Methods: The aims of our study were to evaluate and compare the efficacy, safety, and clinical outcomes of gastric ESD in patients aged 85 years or older and in younger patients. The subjects were 705 patients who collectively presented with 876 gastric tumors (288 adenomas and 588 early gastric cancers). All patients underwent ESD at our hospital between June 2007 and December 2017. The patients were divided into two groups: elderly (≥85 years, consisting of 59 patients with a collective 71 lesions) and non-elderly (Group B; aged <85 years, consisting of 646 patients with a collective 805 lesions). We evaluated the clinical and pathological findings, resection rates, complications, and long-term outcomes, including the survival rate. The local and distant recurrence rates were analyzed in the cohort with curative resection and observationally managed with non-curative resection. The 3- and 5-year overall survival and tumor-specific survival rates were analyzed in the entire study cohort.

Results: The patients’ mean ages were 87 (Group A) and 71 years (Group B), and the male-to-female ratios were 30/29 (Group A) and 646/805 (Group B). No significant differences were found in the mean tumor size for Group A (15 mm) and Group B (20 mm). Regarding histopathological findings, the prevalence rates of tubular adenoma were 28.3% (21/71; Group A) and 33.8% (267/805; Group B); intramucosal carcinomas, 52.1% (37/71; Group A) and 53.8% (433/805; Group B); shallow submucosal invasive carcinomas (<500 μm), 7.0% (5/71; Group A) and 6.5% (52/805; Group B); and deep submucosal invasive carcinomas (>500 μm), 11.3% (8/71; Group A) and 6.6% (53/805; Group B). Once again, the groups showed no significant differences. The en bloc resection rates were 100% (71/71 lesions; Group A) and 97.1% (782/805 lesions; Group B); histological complete resection rates were 94.4% (67/71; Group A) and 92.9% (748/805; Group B), and the curative resection rates were 78.8% (56/71; Group A) and 86.3% (695/805; Group B). Among the non-curative cases, 13 (86.6%) of the 15 patients in Group A and 46.3% of the 35 patients in Group B received no additional treatment. These results were significantly higher for Group A than for Group B. Concerning complications, the postoperative hemorrhage rates were 2.8% (2/71 patients; Group A) and 2.6% (12/479 patients; Group B), and the perforation rates were 0% (0/71; Group A) and 0.5% (4/805; Group B). Regarding long-term outcomes, analysis of recurrence revealed the local and distant recurrence rates to be 0% for Group A and 0.9% (7/746; local) and 0.1% (1/746; distant) for Group B. Regarding survival analysis, the median survival period in Group A and Group B was 583 months and 1156 days, respectively.

Conclusion: Gastric ESD in patients aged 85 years or older can be effectively and safely performed. According to the long-term outcomes, gastric ESD performed as a local resection (total biopsy) in elderly patients may be acceptable, even in non-curative cases.

P0831 RESULTS FROM THE FIRST UK VIRTUAL COMPLEX POLYP MDM
A. Chatterjee, M. Rutter
Gastroenterology, University Hospital of North Tees, Stockton on Tees/United Kingdom

Contact E-mail Address: amitchattree@nhs.net

Introduction: Data from the UK Bowel Cancer Screening Programme (BCSP) has established that the assessment and management of large non pedunculated colorectal polyps (LNPCPs) varies markedly, leading to variable and often suboptimal outcomes, especially for the most complex lesions. A multicentre complex polyp multidisciplinary team meeting was created within the North East of England BCSP with the aim of ensuring more robust decision making and management of complex LNPCPs.

Aims & Methods: A virtual multidisciplinary MDM was conducted via audioconferencing within the North East of England between 2014-6 to discuss complex LNPCPs (LNPCPs with increased risk of malignancy or complexity associated with endotherapy, as defined in BSG/ACPGBI guidelines). Non-complex LNPCPs (LNPCPs with increased risk of malignancy or complexity associated with endotherapy, as defined in BSG/ACPGBI guidelines) were not discussed. Patient data was distributed securely via NHSmail. Outcomes were assessed prospectively using key performance indicators (KPIs) from the BSG/ACPGBI guidelines.2

Results: 63 complex LNPPC cases were managed via the MDM with 8 excluded from analysis (7: managed prior to MDM referral, 1: MDM advice not followed), 27 lesions were managed with primary endotherapy, 23 with primary surgery and 3 cases conservatively. Of the endoscopic cases, 2 required surgery due to failed endotherapy and went on to a finding of adenocarcinoma. The 22-month recurrence was 8.7% with no reported complications. The rate of surgical management using the BSG/ACPGBI KPI (including only surgically managed benign lesions or lesions subject to failed endotherapy) was 39.5%. The en-bloc resection

**Conclusion**

Endoscopists with higher ADR tend to detect significant more SSA and adenomas with 1–2 cm in size, but have lower proportions of pedunculated adenomas than those with a low ADR. In our study cohort no significant differences in flat shape or diminutive size was measurable.

Disclose of Interest: All authors have declared no conflicts of interest.

**P0832 DIFFERENCES IN DISTRIBUTION OF SIZE, SHAPE AND SERRATED HISTOLOGY OF COLORECTAL ADENOMAS BETWEEN ENDOSCOPISTS WITH LOW (<20%) AND HIGH (≥20%) ADENOMA DETECTION RATE**

**Aims & Methods:** Our study aim is to investigate the differences of size, shape and serrated histology of adenomas between low- and high-ADR group in our screening cohort. We analyzed 2354 screening colonoscopies performed by 26 endoscopists between 2007 and March 2017 within the austria certificate of screening colonoscopy. T-Test was used to assess differences.

**Results:** 39.1% of endoscopists were categorized in the ADR low- and 60.9% in the high-ADR group. Overall, mean ADR was 23.06% (SD 0.55) with a minimum of 0.3% and a maximum of 48.72%. In the low-ADR group mean ADR was 14.56 (SD 0.42) and 28.51 (SD 0.50) in the high-ADR group. Regarding to size, there was a significant difference (p = 0.029) in detection of adenomas of 1–2 cm in size with a mean of 8.44% (SD 6.02) in low- vs. 10.22% (SD 6.64) of all adenomas in high-ADR group but no differences between adenomas <0.5 cm, 0.5–1 cm and those bigger than 2 cm. Regarding shape, proportion of pedunculated adenomas in low-group-ADR differ significantly higher (p = 0.002), with a mean of 19.36% (SD 14.90) vs. 14.70% (SD 9.55) but there were no differences between flat and sessile adenomas. With a mean proportion of 4.43% (SD 5.61) vs. 6.64% (SD 5.97), the proportion of sessile serrated adenomas (SSA) differ significantly between low-ADR vs. high-ADR group (p < 0.01). There was no significant difference regarding traditional serrated adenomas (p = 0.800).

Disclose of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: daniela.pena@medizinuen.ac.at

Introduction: Patients of endoscopists with high (≥20%) adenoma detection rate (ADR) have less risk for interval cancer than those of low ADR (<20%). Lesion-related-factors, such as size, shape and histology influence the size, shape and histology of the lesions, and technical factors. Factors predicting technically difficult ESD when it is performed by non-Asian endoscopists should be clarified.

Aims & Methods: We aimed to identify the potential risk factors that are associated with a higher technical difficulty during ESD in a Western European setting where there are no available Asian experts. We prospectively recorded consecutive ESD cases performed by members of the ESD Working Group of the Spanish Society of Digestive Endoscopy. Demographic and clinical characteristics of the patients, location and morphology of the lesions, and technical factors were collected. We defined difficult ESD as those aborted procedures, time-consuming (duration > 180 min.) or when changing the technique to piecemeal resection was needed to remove the tumor. Analyses were carried out using IBM SPSS Software for Windows (IBM Corp., Armonk, NY, USA). Parametric continuous variables are reported as the mean ± standard deviation (SD). A Kolmogorov-Smirnov test was used to evaluate normal distribution. Categorical variables are reported as either frequencies or percentages. Statistical differences between the groups were analyzed using a chi-squared method for categorical data. The meaningful variables with a p value < 0.1 in the univariate analysis were included in the logistic regression model. Multivariate analysis was performed using binary logistic regression methods. Odds ratios (ORs) and 95% confidence intervals (CIs) were calculated to assess the strength of the influence of each individual variable.

**Results:** We included 265 lesions in 265 patients [mean age ± SD: 69 ± 10; 150 males (56.6%)]. They were recruited in 15 Spanish University Hospitals between January 2016 and March 2017. Location of the lesions were: esophagus (n = 7; 2.6%), cardia (n = 5; 1.8%); stomach (n = 48; 18.1%); duodenal bulb (n = 1; 0.3%); colon (n = 144; 54.3%) and rectum (n = 60; 22.6%). Mean lesion size was 38.6 ± 18.5 mm. Median duration of the procedure was 105 min. (8–375). In 73 cases (27.5%) criteria for difficult ESD were fulfilled. Endoscopic resection was aborted in 7 cases (2.6%). When endoscopic resection was achieved (n = 258; 97.3%) both situations, duration > 3 h and a piecemeal resection, were noted in 21 (8.1%) patients. Duration > 3 h in 25 cases (9.7%) and unsuccessful endoscopic resection was noted in 21 cases (8.1%).
resection in 20.7% were observed in isolation, respectively. Table 1 shows the univariate and multivariate analysis of factors regarding technically difficult ESD.

Table 1: Univariate and multivariate analysis of possible factors related to technically difficult ESD.

Complications

Intraprocedural bleeding 4.1 (1.9–8.7) 0.0003 |

Conclusion: The factors independently associated with technically difficult ESD were: procedure time-consuming or finished with a piecemeal resection; lesion size >30 mm; poor manoeuvrability, recurrent lesions and intraprocedural bleeding. Except for the last one, the remaining factors can be identified during the first diagnostic endoscopy. Endoscopists who will start performing ESD should try to avoid these difficult procedures in the early part of their learning curves.

Introduction: We established the Laparoscopic Endoscopic Cooperative Surgery (LECS) procedure to overcome the limitation of colorectal endoscopic submucosal dissection (ESD). This procedure is a local full-thickness resection of the combined procedure of laparoscopic assisted colectomy (LAC) and ESD procedure. Also, it is the method that is epoch-making for minimal invasive treatment that kept an intestinal function.

Aims & Methods: The aim of this study was to investigate the feasibility and safety of LECS procedure applied with endoscopic submucosal dissection (ESD) technique obtained adequate surgical margin. We performed ESD on 1341 patients (male: female = 1,131:210; mean age, 66.1 years). Among these cases, six cases had perforation (0.4%), and three of six cases required emergent surgery. We examined the cause of perforation and the limit of ESD from the view point of safety. We performed one-piece resection for 11 cases (male: female = 7:4; mean age, 63.5 years) of colorectal tumors using LECS procedure. In the first, the indication of LECS is at high risk of the perforation by the treatment of ESD and EMR and is the lesion that safety cannot secure. In addition, the indication is the lesion which is curable by the local excision without lymph node dissection. Therefore, submucosal invasive (T1) cancer with the risk of lymph node metastases does not become the indication for this full-thickness resection technique. From the above-mentioned basic concept, indications of the LECS procedure for colorectal tumors were thought to be as follows: 1) Intramucosal carcinoma (Tis) and adenoma with high-grade atypia (Vienna Classification:Category 3, 4) accompanied by wide and severe degree fibrosis in the submucosal layer (tumor recurrence after endoscopic and surgical resection); 2) submucosal tumors; 3) Intra-mucosal carcinoma (Tis) and adenoma with high-grade atypia involved appendix or diverticulum. We examined the clinical and pathological outcomes of the above-mentioned 11 cases.

Results: Four of six cases that caused perforation in ESD were cases with fibrosis in the submucosal layer. Three cases of those were moderate to severe degree fibrosis cases, and a limit of ESD seemed to exist in these lesions from the viewpoint of safety and curability. We accomplished full-thickness resection successfully for 11 cases using LECS procedure as follows: 5 cases of Tis cancer, 4 cases of adenoma, 1 case of schwannoma, and 1 case of GIST. The reasons we judged as the indication of LECS procedure were as follows: three cases accompanied by severe degree fibrosis, 2 cases involved diverticulum, 3 cases involved appendix, 2 cases of submucosal tumor, and 1 case of poor endoscopic operability. These cases were considered a limitation of ESD due to the high risk of perforation. An operative time was an average of 195.8 minutes (127 to 332), and the perioperative bleeding was an average of 8 g/dl (3 to 20). We experienced no complications, and average post-operative hospital stay was 7.7 (6 to 12) days. Histological examination of the resected specimens revealed negative lateral and deep margins. The postoperative follow-up was carried out first a half year later, and it was every one year subsequently. In the above-mentioned follow-up schedule, blood examination, colonoscopy, CT scan were performed for clinical evaluation. The residual/local recurrence case was absent for 31.6 months (range 10–60 months) for the mean follow-up period. Also, without complications such as postoperative anastomotic stricture or adhesive ileus, we followed favorable course.

Conclusion: We developed a LECS procedure to overcome the limit of ESD, and accomplished full-thickness one-piece resection of the tumors considered as high risk of perforation in the endoscopic treatment.

Aims & Methods:

The interviews provided an in-depth understanding of patient experience of GI procedures. 6 over-arching and inter-linking themes emerged across all procedures; anxiety, expectations, choice/control, communication/information, comfort and embarrassment/dignity. Relation of themes was seen e.g. if the procedure appointment was sooner than expected, patients were anxious about the potential outcome. Choice was important in terms of appointment, endoscopist and choice of pre-medication, however it was highly individualised. Communication prepared patients and managed expectations, with one patient describing poor endoscopist communication affecting the whole experience. Patients described embarrassment related to changing and waiting areas; sensitive nature of the test; exposure and physical reaction. Discomfort during the procedure was attributed to instrument and air insertion.

Conclusion: Despite heterogeneity between procedures consistent themes related to patient experience emerged. This work will be used to develop PREMs for patient experience. This work will be used to develop PREMs for patient experience.

Introduction: Patient experience is increasingly recognised as a key measure of quality of care. Ensuring positive experience is important to patients and fundamental in maximising participation in screening programmes and re-attendance for surveillance procedures. Current measures of patient experience of gastrointestinal (GI) endoscopy are clinician derived. Patient Reported Experience Measures (PREMs) should be patient derived and incorporate pre-and post-procedure experience. We aimed to identify themes considered as important to patients undergoing GI procedures as a basis for developing PREMs.

Aims & Methods: We aimed to identify themes important to patients undergoing GI investigations, to enable questionnaire development. Patients who had undergone upper or lower GI investigations (gastroscopy, colonoscopy and CT pneumocolon) were invited to attend for a semi-structured interview. 32 interviewees were purposefully sampled to ensure diversity. Interviews were conducted by a research fellow trained in qualitative methods and were audio recorded and transcribed verbatim. Recruitment continued until saturation was achieved. Analysis used qualitative thematic methods focusing on anticipated and emergent themes, using constant comparison to ensure that all perspectives were included in the explanation of the data.

Results: 168 patients were approached. 32 interviews were completed (12 gastroscopy, 10 colonoscopy and 10 CT pneumocolon), with a male/female ratio of 18:14. The time interval from examination to procedure ranged from 5 to 44 days. Mean age was 63.1 years (SD 11.5)

Introduction: Adequate bowel preparation is important to perform colonoscopy for accurate mucosa examination, lesion detection and treatment. Walking exercise is known to be effective for colon cleansing. However, it is difficult for patients with uncomfortable walking to improve the status of bowel cleansing.

Aims & Methods: Therefore, we prospectively evaluated the clinical feasibility and clinical validity of the abdominal vibration stimulation for bowel cleansing.
preparation. In this randomized, prospective, investigator-blind study and single center setting, 141 inpatients for elective colonoscopy were randomized to two groups. PEG solution was used for bowel cleaning in all patients. The one is walking over 3000 steps and the other is having abdominal vibrator more than 30 minutes before colonoscopy. After examination we recorded procedure results, sedation information, patient’s satisfaction and adequacy of bowel preparation by using the Boston Bowel Preparations Scale (BBPS).

Results: There were no significant differences between vibrator group (n = 75) and walking group (n = 66) in bowel preparation quality (Total BBPS 7.40 vs 7.23, p = 0.519), withdrawal time (30.40 vs 30.05 mins, p = 0.829), number of polyps (4.09 vs 3.17, p = 0.085), patient satisfaction (4.39 vs 4.12, p = 0.249) and number of diarrhea after taking PEG (11.49 vs 11.42, p = 0.903). Viscosity group was superior than walking group in time of first defection after taking PEG (112. 89 vs 123.42 mins, p = 0.005) andecal intubation time (6.23 vs 8.52 mins, p = 0.011).

Conclusion: Bowel preparation accompanied with abdominal vibration stimulation showed almost similar results to a walking group which was conventional methods for adequate bowel preparation. The patients who received the conditions which cause uncomfortable gait such as old age, CVA, Parkinsons, or joint disease, bowel preparation with abdominal vibrator is expected to help in proper bowel cleansing for therapeutic colonoscopy.

Disclosure of Interest: No conflicts of interest.

Introduction: Electrical and rheological properties of the submucosal cushion solutions are crucial to avoid complications secondary to endoscopic resections. Electrical resistance (R) of a substance is a feature of the difficulty to pass an electric current through that solution. The higher the R, the resection will be easier and safer, with less temperature increase.

Results: The solutions that showed the best basal R were: PL, HA, GS, TB and TB + PRP. At 60 minutes, the best R were: PRP, TB, PRP + TB, HA and GS. The best durability at 60 minutes was for TB, PRP, TB + PRP and PL that maintained the height at around 80% of its original in comparison to the other substances with were at around 60%. During the resection the solutions that underwent a lower temperature increase were: TB + PRP, PL, and TB.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0840 PATIENT SATISFACTION RELATED TO QUALITY OF INFORMATION GIVEN THROUGHOUT COLONOSCOPY
S. Sjöblom1, S. Jakobsson2, J. Ryhlander1, M. Simrén1, P. Stötzer1, G. Ringström1
1Department of Gastroenterology, Sahlgrenska University Hospital, Gothenburg/Sweden
2Centre For Person-centered Care, Institute of Health and Care Sciences, University of Gothenburg, Gothenburg/Sweden
3Institute Of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg/Sweden

Disclosure of Interest: No conflicts of interest.

Introduction: Patients with chronic diseases, such as inflammatory bowel disease, experience a lower degree of being involved in health care than others. Compared with other countries Swedish patients report lower possibility to be involved in their care and receive less information about care (1).

Aims & Methods: To investigate the perception of written and oral information given before and after a colonoscopy, the perceived knowledge of planned follow-up and preference to be more involved in decisions/participate in their care in different patient groups. Outpatients (>18 y) undergoing colonoscopy (all indications) were consecutively included (n = 862). Before the procedure patients completed questionnaires regarding sociodemographic data and the written information about bowel preparation and examination. After the procedure patients reported their perceptions about the information provided regarding the colonoscopy and the follow-up.

Results: Data from 862 patients were analyzed (447 females) (mean age 52; 18-90 y) A large number of patients (n = 740, 87%) rated the written information sent home before the colonoscopy as distinct, while a subset (n = 110, 13%) rated it as indistinct/very indistinct. When questions of importance were asked to the medical staff during the colonoscopy most patients were content with the answers from the physician or nurse. A small proportion of patients (n = 57, 7%) stated that they received too little information or that they did not understand the information about the colonoscopy results; these patients were mainly younger (<50 y) (p = 0.001). The majority of the patients (n = 602, 74%) reported thorough knowledge about the follow-up, while 26% (n = 207) lacked this knowledge. More than 1/3 (n = 275) of the patients wished to be more involved in decisions regarding their care and treatment. Desire for a higher degree of involvement were more pronounced in patients <40 y (p = 0.05) and in patients with IBD (p = 0.05) compared to patients with other indications for colonoscopy.

Patients referred from outpatient clinics in the hospital desires a higher degree of involvement than patients referred from primary care (p < 0.01).

Conclusion: The majority of the patients undergoing colonoscopy reported that they received satisfactory information about the procedure and preparation. However, there is room for improvement regarding follow-up information and patients’ involvement in their care and treatment. Specifically, improvements seem warranted for younger patients and patients with chronic diseases, such as IBD.

P0841 THE INCIDENCE OF SYNCHRONOUS ADVANCED NEOPLASIA OF RECTAL LATERALLY SPREADING TUMORS WITH A SKIRT

S. Osera, T. Shinoharah, A. Kudo, T. Yamada, T. Momoi, H. Fukushima, M. Furutakah, A. Tomorni, T. Hish Department Of Gastroenterology, Saku Central Hospital Advanced Care Center, Saku, Nagano Japan

Contact E-mail Address: shou@122@hotmail.com

Introduction: A “skirt” is a slightly elevated flat lesion with wide pits occasionally observed at the margin of laterally spreading tumors (LSTs), and rectal LSTs had significantly more skirt lesion in comparison to colonic LSTs. Although the clinicopathological, endoscopic, and molecular characteristics of LSTs with a skirt have been reported [1], there are no reports concerning the incidence of synchronous neoplastic lesions of rectal LSTs with a skirt.

Aims & Methods: The aim of this retrospective study was to clarify the incidence of synchronous advanced neoplasia (AN) of rectal LSTs with a skirt. A total of 13,116 cases underwent colonoscopy in our hospital between January 2012 and June 2016. Of these, 101 consecutive rectal LSTs were examined to assess the incidence of synchronous AN detection rate and the number of AN according to the location of AN lesion; divided into the right colon, left colon and rectum. A skirt was defined on the basis of the following endoscopic findings: spreading across the margins of the LST, consisting of a slightly elevated flat lesion, and containing wide pits. AN was defined as the presence of any of the following features: adenomas larger than 10 mm, adenomas with villous histology or high-grade dysplasia including intra-mucosal carcinoma and invasive cancer.

<table>

Results: A skirt was observed in 25 of 101 rectal LSTs (24.8%). Rectal LSTs with a skirt (median age 69 years, 52% female, mean size 51.7 ± 27.1 mm) had 22 high-grade dysplasia and 3 submucosal carcinomas, and rectal LSTs without a skirt (median age 72 years, 34% female, mean size 24.7 ± 16.0 mm) had 8 low-grade dysplasia, 45 high-grade dysplasia, and 23 submucosal carcinomas, respectively. The overall AN detection rate in rectal LSTs with a skirt (20.0%) was significantly lower compared with rectal LSTs without a skirt (46.8%, p = 0.02). As for the analysis of the AN detection rate according to the location, there were significant differences in the right colon (8.0% vs 29.9%, p = 0.03) and the left colon (4.0% vs 27.3%, p = 0.01) between LSTs with and without a skirt. In contrast, there was no significant difference with respect to the rectum (6.0% vs 6.5%, p = 0.41). The total number of AN in rectal LSTs with a skirt (n = 7; right colon: 2, left colon: 2 and rectum: 3) was significantly lower than in rectal LSTs without a skirt (n = 74; right colon: 35, left colon: 34 and rectum: 5). There were significant differences in the right colon (p = 0.03) and the left colon (p = 0.04), while, there was no significant difference between these groups with respect to the rectum.

Conclusion: The rectal LSTs with a skirt had significantly lower synchronous advanced neoplasia than rectal LSTs without a skirt, especially in the right and left colon. Our results may suggest that rectal LSTs with a skirt have different characteristics compared with rectal LSTs without a skirt in terms of the incidence of synchronous neoplastic lesion.

Introduction: Endoscopic resection of large lesions leads to extensive mucosal defects and submucosal exposure, with a substantial risk of adverse events. The prevention of these complications is inefficient with current methods. Endoscopic shielding, as a simple and safe technique, has been proposed to improve mucosal restoration, and therefore, the incidence of these events. Previous reports have confirmed the efficacy of the placement of hydrogels based on platelet-rich plasma (PRP) (1) or hialuronic acid with other substances (TriBio) (2), but never the combination of both hydrogels, in the prevention of delayed complications after mucosal damage.

Aims & Methods: To assess the efficacy of endoscopic shielding with the combination of PRP and TriBio in a rat model of thermal injury. Thermal injury was obtained according to our rat model (3). Lesions were performed in male Sprague-Dawley rats (400–450 g) under general anesthesia. Animals were randomized to receive one of the following shields onto the lesions: PRP + TriBio and PRP and TriBio. Rats underwent endoscopic follow-up at 7 days and 2 weeks. Afterwards, animals were sacrificed and ulcers sites were macroscopically and histopathologically evaluated.

Results: Animals treated with PRP + TriBio obtained the best results in comparison with other hydrogels (PRP and TriBio). Mucosal healing rate (percentage of mucosal restoration) at 14 days was significantly higher with PRP + TriBio (100% vs 82% and 90%; p < 0.05). Histological study confirmed these data, showing total restoration of mucosal layer with PRP + TriBio.

Conclusion: The use of a combination of two covering agents (TriBio and PRP) is the best approach to obtain mucosal healing in a rodent model of endoscopic thermal injury in colon.

Introduction: Colonicom procedures have become massive in the last years since colorectal cancer (CRC) is becoming a prevalent disorder. The next frontier of this technique will be to provide an active substance in a precise site of the colon (targeted therapy). This has many advantages (targeted therapy, dose adjustment, limiting side effects, assessment of mucosal healing, etc.); however, this selective and direct administration of drugs is not possible nowadays, but it is a true challenge. Following these evidences we have developed drug eluting platform to locally treat CRC lesions.

Aims & Methods: To evaluate the efficacy of intratumoral injection of our drug-eluting platform with different combinations of these anti-tumoral drugs (afibercept 2 mg/mL, cetuximab 16 mg/mL, panitumumab 6 mg/mL, irinotecan 3.5 mg/mL and bevacizumab 5 mg/mL) in a rat model of azoxymethane-induced colorectal cancer. Rats underwent endoscopic follow-up at 1 and 2 weeks after endoscopic therapy. Afterwards, animals were sacrificed and tumors were excised and macroscopically and histopathologically evaluated.
Results: Intratumoral injection was feasible in all animals with no adverse events. Biopsy size and size of tumors ranged from 6 to 8 mm. Approximately 1:1 anti-VEGF in comparison with Anti-EGF obtained the best results (significantly reduction in size and cell necrosis). However, only alfibrequin showed total acute tumoral necrosis.

Conclusion: Intratumoral injection of anti-VEGF in a drug-eluting platform is able to produce tumoral necrosis in an experimental model of CRC. This technique could open a new way to manage CRC.

P0844 A THREE-DIMENSIONAL IMAGING SYSTEM IMPROVES THE ENDOSCOPIC VISIBILITY OF NON-POLYPOID COLORECTAL NEOPLASMS

Department Of Gastroenterology, Graduate School of Medicine, Chiba University, Chiba City, Japan

Contact E-mail Address: matsumura919@yahoo.co.jp

Introduction: Three-dimensional (3D) imaging techniques have been developed in the medical field. Previous research reports that simulated 3D colonoscopy improves the detection of colonic lesions [1]. A novel 3D imaging system has been recently developed, which can create 3D virtual video images from conventional two-dimensional (2D) endoscopic images [2]. However, actual cases have not been studied.

Aims & Methods: This study aimed to investigate whether the 3D system can improve the visibility of colonic neoplasms compared with conventional 2D endoscopy. We studied non-polypoid colorectal neoplasms and recorded their videos using conventional 2D endoscopy and the 3D system. The movies were evaluated by 8 endoscopists (4 experts and 4 non-experts) and 4 medical students. Each neoplasm was assigned a visibility score between 4 (excellent visibility) and 1 (poor visibility).

Results: The mean visibility scores were 3.35±0.58 for 2D endoscopy and 3.75±0.44 for the 3D system. The score was significantly higher for the 3D system than for 2D endoscopy (p<0.01). When comparing the evaluations by the experts, non-experts, and medical students, the differences in the scores by the non-experts and medical students were noted to be higher (p<0.05). In contrast, the scores by the experts were also higher for the 3D system, but no statistical difference was observed (3.50±0.53 for 2D endoscopy and 3.87±0.35 for the 3D system, p=0.08). As a result, 10 out of 12 observers noted that the 3D system had better visibility than conventional 2D colonoscopy, and none of the observers noted deterioration in visibility with the 3D system.

Conclusion: The present findings suggest that the 3D imaging system improves the visibility of non-polypoid colorectal neoplasms, and this is more effective for non-experts. Our findings would contribute to improvement in the detection of these neoplasms.

Introduction: Pain is a subjective perception, which contributes to difficulties to provide adequate pain relief according to every patient’s needs. Colonoscopy is by many patients considered as a painful and strenuous procedure.

Aims & Methods: To investigate congruence and differences between patients’ and caregivers’ report of pain during colonoscopy. Patients (≥18 years) undergoing an outpatient colonoscopy (all indications) have consecutively been included (n=862). Before the procedure the patients completed questionnaires regarding sociodemographic information and anxiety. After the colonoscopy the patients registered their pain experience on a six-grade scale, ranging from “no pain” to “extremely severe pain”. Caregivers (physicians and endoscopy nurses) estimated patient’s pain using the same scale.

Results: Data from 785 patients has been collected, mean age 52 (18–90) years; 42% female. The patients’ report of severe, very severe or extremely severe pain (n=111), pain was underestimated by physicians and nurses in 58% of all assessments. This was most commonly seen among the youngest patients, 18–29 years (n=99), where pain was underestimated in 25.5% among the group. There was also a difference according to gender; physicians underestimated pain in 60% of men who reported “moderate pain” (n=66) while the nurses underestimated pain in 27% among the same group of men. Women’s pain was overestimated by caregivers in 26% (n=188) of all cases with mild pain. Patients undergoing colonoscopy for the first time (n=331), and reporting “moderate pain”, were underestimated by physicians in 58% and by nurses in 25%. 58% of the patient reports that they were anxious before the procedure. This group reported more pain than the group without anxiety (p<0.001). Presence of anxiety and a high level of anxiety among the group correlated negatively with the patient’s report. The agreement between pain reports from patients and caregivers were poor to fair, with slight differences between nurses (Kappa =0.37; p < 0.000) and physicians (Kappa =0.29; p < 0.000) in total, congruent pain reports between patients and caregivers were seen in 36% of all assessments.

Conclusion: Agreement between caregivers’ and patients’ pain reports is far from perfect, and the agreement is influenced by several factors such as the profession of the caregiver, as well as patient factors including pain severity, anxiety, age, gender and previous experience of colonoscopy. The goal for the future should be to individualize the use of analgesics based on every patient’s needs, which seems to be of special importance in specific groups of patients.

Introduction: The SCENIC consensus proposed recommendations for optimal detection and management of dysplasia during colonoscopic surveillance for IBD. Characterization of colonic lesions in IBD remains challenging even by using advanced endoscopic imaging modalities (high definition [HD], virtual chromoendoscopy [VCE] dye chromoendoscopy [DCE]).

Aims & Methods: We aimed to develop a unified endoscopic classification of advanced imaging to predict histology of colonic lesions, and to validated by international experts (Frankfurt Advanced Chromoendoscopy Ibd LSBims-FACILE Group). We developed an endoscopic classification of IBD lesions, based on morphology, colour, demarcation, surface pattern, vessel pattern, signs of inflammation (table). A library of 60 colonic lesions, including dysplasia, sessile serrated adenomas/polyps, invasive cancer and pseudopolyps collected at surveillance colonoscopy by using HD, DCE and VCE with i-scan or NBI were assessed. The diagnostic performance of the score was tested based on the final histopathology and the inter-observer variability of the eight examiners. The examiners have had to perform a pre-test (45 minutes) before analyzing the colonic lesions. Multivariate analysis with bootstrapping, of characteristics of the classification was performed to determine the strength of endoscopic predictors of dysplasia.

Results: Of the 60 IBD lesions, 33 (55%) were dysplasia, 6 (10%) cancer, 9 (15%) SSA/Ps and 12 (20%) pseudopolyps. Across the experienced academic raters sensitivity, specificity, PPV, NPV and accuracy in predicting histology, were 72%, 72%, 91%, 40%, 72%, 72% respectively. Individual rater accuracy ranged from 66% to 77% Sensitivity, specificity, PPV, NPV, accuracy, for predictions made with high confidence were 72%, 90%, 97%, 46%, 76%, which were significantly more accurate compared with a low confidence of diagnosis (76% vs 65%; p<0.001). Univariate analysis showed that the non polypoid lesions, irregular vessel architecture and signs of inflammation within the lesion were predictive of dysplasia. Subsequent multivariate analysis confirmed that of these endoscopic findings non polypoid lesion OR 11.6 (95% CI 6.71–20.2), surface pattern
OR 0.31 (95% CI:0.17–0.54), vessel architecture OR 5.1 (95% CI: 2.7–10.2), sign of dysplasia, with vessel architecture and morphology being the best predictors. The sensitivity, specificity, PPV, NPV and accuracy at the multivariate analysis stage were 94% (95% CI: 90–96%), 51% (95% CI: 43–58%), 88% (95% CI: 82–92%), 69% (95% CI:62–75%), 85% (95% CI: 79 –90%). Inter-observer agreement of the raters improved from the pre-test (Kappa = 0.27,95% CI: 0.19–0.38) to post test (Kappa = 0.34,95% CI: 0.23–0.45;P = 0.02) but was moderate.

Conclusion: We developed and validated the first endoscopic classification using all imaging modalities (HD, VCE, DCE) to characterize and differentiate dysplastic from non-dysplastic lesions in IBD. Non polypoid lesions, irregular surface and vascular pattern as well as inflammation within the lesions were predictive of dysplasia. The inter-observer variability of the score was moderate. The classification will be further refined based on the multivariate analysis and a prospective study is ongoing.

P0848 THE ROLE OF PROBE CONFOCAL LASER ENDOMICROSCOPY WITH ENHANCED ENDOCOSCOPY IN CHARACTERISATION AND ENDOSCOPIC RESECTION OF DYSPLASTIC LESIONS IN INFLAMMATORY BOWEL DISEASE PATIENTS

M. Iacucci1, X. Gui2, S. Ghosh3

Introduction: Detection, characterization and therapeutic management of flat dysplastic lesions during surveillance colonoscopy in inflammatory bowel disease (IBD) can be a challenge. The recent SCENIC consensus has introduced a new terminology and concept “endoscopically resectable” when the distinct margins of a detected lesion could be identified. New endoscopic techniques and skills are required to recognize the margins reliably and assess the surrounding mucosa to plan endoscopic removal successfully and organ sparing. We report our experience of the use of probe confocal endomicroscopy (pCLE) combined with selective electronic virtual (VCE) and dye chromoendoscopy (DCE) for management of challenging dysplastic lesions during surveillance in IBD.

Aims & Methods: IBD patients underwent surveillance colonoscopy using high-definition (HD)-iSCAN (Pentax EC-3940Fi; Japan) VCE and DCE in combination with pCLE (Cellvizio, Paris, France). pCLE was applied following IV injection of fluorescein 5% 10 ml to assess the histological features of the lesion, the margins and the mucosa surrounding the visible colonic lesion. Biopsies eventually proved dysplasia or SSA of the colonic lesions. The study was approved by the Calgary Conjoint Health Services Research Ethics Board of the University of Calgary. All patients gave informed consent.

Results: Seven patients with IBD and disease duration of ≥8 years and in clinical remission (Eaden, 2001 #2 (mean age 55 years; 6 male, UC = 4 CD = 3) were prospectively included. They underwent surveillance colonoscopy using HD-iSCAN (Pentax EC-3940Fi; Japan). When a colonic lesion was detected, selective iSCAN-VCE was performed with or without DCE (five out of seven had DCE)

(continued)
with methylene blue 1% to characterize the surface, vascular pit pattern and the margins of the lesion. Each of the 7 patients had non polypoid colonic lesions, 4 were sessile (Paris Is) and 3 flat (IIa/IIb). Four of them were amenable to endoscopic therapy and were successfully removed using endoscopic mucosal resection (EMR) en-block or piecemeal technique. Interestingly, one patient with multiple scattered ‘pseudopolyps’ had a 8 mm sessile pseudopolypoid lesion with a suspicious areas of SSA in the midst that was confirmed by real pCLE.

The endoscopic, endomicroscopic and histological findings of all the lesions were described in Table 1.

**Conclusion:** This case series highlights the first successful use of pCLE in combination with VCE and DCE to predict, characterise and treat colonic neoplasia in IBD. pCLE may be an additional tool to aid the endoscopist in therapeutic management by deciding endoscopic resectability versus colectomy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Serrated adenoma

Introduction: Endoscopic submucosal dissection (ESD) is one of the most useful methods for treating early colorectal neoplasms and conventionally utilizes an IT, hook, or needle knife. However, because these devices are used without fixation to target, it confers a potential risk of complications due to unexpected incision. To reduce the risk of complications from ESD performed using a conventional knife, we used a scissors-type knife (SB Knife Jr; Arita Sumitomo BAKEITE, Japan) that allows keeping an adequate dissection layer and preventing unexpected muscular layer injury. In the previous study, we reported that ESD performed using SB Knife Jr is a technically efficient and safe method for treating early colorectal neoplasms. However, the efficacy and safety of colorectal ESD using SB Knife Jr in elderly patients remain unclear.

Aims & Methods: The aims of our study were to evaluate the efficacy, safety, and clinical outcomes of colorectal ESD using SB Knife Jr in patients aged ≥75 years in comparison with those in younger patients. We evaluated 291 lesions in 271 patients (male-to-female ratio, 148:123; median age, 70 years) treated with ESD using SB Knife Jr between October 2010 to March 2017 at Kure Medical Center and Chugoku Cancer Center. The patients were divided into two groups, an elderly group (group A: age, ≥75 years; 95 patients, 97 lesions) and a non-elderly group (group B: age, <75 years; 176 patients, 194 lesions).

We evaluated the en bloc resection rate, complete resection rate, curative resection rate, en bloc resection rate, procedural time, complications, and long-term outcomes, including survival rate. The 3-year overall survival and tumor-specific survival rates were analyzed in the entire study cohort, and the local and distant recurrence rates were analyzed in the cohort with curative resection and observationally managed with non-curative resection.

Results: The mean age was 80.0 years in group A and 64.3 years in group B. The male-to-female ratios were 45:50 and 103:73 in groups A and B, respectively. Regarding histopathological findings, the prevalence rates of tubular adenoma were 37.1% (36/97) and 36.1% (70/194); T1a, 39.2% (38/97) and 44.8% (87/194); T1a, 10.3% (10/97) and 10.3% (20/194); and T1b, 13.4% (13/97) and 8.8% (17/194) in groups A and B, respectively, showing no significant difference. The mean resected tumor size was 33.9 ± 16.6 mm in group A and 34.7 ± 15.2 mm in group B, and the median procedural time was 75.6 minutes (range, 10-420 min) in group A and 75 min (range, 5-133 min) in group B, showing no significant difference. The en bloc resection rates were 96.9% (94/97) and 99.0% (192/194); the complete resection rates, 94.8% (92/97) and 94.8% (184/194); and the curative resection rates, 83.5% (81/97) and 88.1% (171/194) in groups A and B, respectively, showing no significant difference. Regarding complications, no perforation during the procedure occurred in any of the cases. The delayed bleeding rate was 1.0% (1/97) in group A and 2.6% (5/194) in group B. Delayed perforation and necrosis were observed in one patient each in group A and were treated conservatively. Regarding long-term outcomes, the local recurrence rate was 1.0% (1/97) in group A and 0.5% (1/194) in group B, and no distant recurrence was observed in the recurrence analysis cohort. Regarding survival analysis (mean follow-up period: group A, 523 ± 489 days; group B, 628 ± 582 days), the 3-year overall and disease-specific survival rates were 98.8% and 100% in group A, and 93.3% and 98.3% in group B. One patient (0.5%, 1/194) died of colorectal cancer and 9 patients (4.6%, 9/194) died of other diseases in group A, and 9 patients (4.6%, 9/194) died of other diseases in group B.

Conclusion: ESD performed with SB Knife Jr is a technically efficient and safe method associated with favorable long-term outcomes in cases of early colorectal neoplasms managed endoscopically.

**P0851 DETECTION AND CHARACTERIZATION OF SSA/PS DURING SURVEILLANCE COLONOSCOPY IN LONG STANDING USING ADVANCED ENDOCOSCOPY TECHNIQUES**

M. Iacucci1, O. Akinola2, R. Panaccione3, G.G. Kaplan2, X. Gui2, S. Urbanski2, S. Ghosh1

1University Of Birmingham, Institute of Translational Medicine, Birmingham, UK 2Department Of Pathology, University Of Calgary, Calgary, Canada 3Dept. Of Pathology, Alberta Health Services, Calgary, Canada

Introduction: Sessile Serrated polyps (SSA/Ps) are pre-malignant lesions that may lead to colorectal cancer in accelerated manner. These lesions are easily missed by endoscopists as these are difficult to detect in IBD patients. We aimed to assess the prevalence, detection rate and endoscopic findings of SSA/Ps in long standing IBD patients prospectively undergoing surveillance colonoscopy using dye (DCE) or virtual electronic chromoendoscopy (VCE) or high definition white light imaging (HD-WLE) colonoscopy.

Aims & Methods: A total of 270 randomized patients (55% men; age range 20–77 years, median age 49 years) with long-standing IBD (median duration of the disease 14 years) undergoing surveillance colonoscopy were assessed by HD-WLE (n=90), VCE (n=90) or DCE (n=90). Surveillance colonoscopy with High Definition (HD) alone, or with iSCAN VCE or DCE was performed. Endoscopic features were recorded in each group with regard to location, morphology (polyloid/non polyloid), size and mucosal pit pattern, and these were characterized using the Kudo modified classification and Paris classification. The histology was reported by modified Vienna classification.

Results: Thirty - three SSA/Ps were detected in 20 (11UC; 9 CD; 11 female, age range 34–72 y, median age 61 years) patients out of the 270 patients with IBD enrolled (12.2%). The endoscopic features of SSA/P lesions were: non-polyloid appearance (51.5%), predominant localization in the proximal colon (vs distal) (87%), ≤5 mm in size (48.4%). Kudo pit pattern modified type I0 (79%). Kudo pit pattern modified type I0 had a sensitivity of 79% and specificity of 82% for diagnosing SSA/Ps at surveillance colonoscopy in IBD patients. There was no difference in detection rates of SSA/P using HD-WLE, DCE or VCE.

Conclusion: SSA/Ps are not an infrequent finding at surveillance colonoscopy in IBD. There are prevalent in the right colon location and these generally have Kudo pit pattern of I0. SSA/Ps can be recognized endoscopically by Kudo pit...
PO852 IN VIVO HISTOLOGICAL PREDICTION OF COLORECTAL POLyps USING FICE TECHNOLOGY

J. Cortez-Pinto1, J. Moleiro1, L. Marques1, R. Barosa2, J. Castela1, J. Pereira Da Silva1, S. Faisas1, S. Mão De Ferro1, P. Lage1, A. Dias Pereira1
1Gastroenterology, IPOLFG, EPE, Lisboa/Portugal
2Gastroenterology, Hospital Garcia de Orta, Almada/Portugal

Introduction: The histological characterization of colorectal polyps using FICE (Fujinon Intelligent Color Enhancement) technology presents high diagnostic accuracy. However, the best results in histological prediction are a reflection of the clinical practice by trained endoscopists, and their application remains to be confirmed outside this context.

Aims & Methods: To evaluate the in vivo histological prediction accuracy of colorectal polyps (<10 mm) using WLE (White light endoscopy) and using FICE technology, by comparing both modalities. Prospective evaluation, using WLE and FICE, of colorectal polyps <10 mm in patients submitted to colonoscopy between 12/2016 and 02/2017 by four inexperienced endoscopists in FICE, except for a previous 20-minutes interactive session. Polyps were evaluated using the FICE classification (tubular or oval crypts (adenoma), round crypts or featureless appearance (hyperplastic polyps), indicating their confidence level (low <90% vs high >90%). Statistics: SPSS v23.

Results: 25 polyps were included, with a mean size of 4.5 mm, 14 adenomas, 10 hyperplastic and 1 serrated adenoma. From the global assessment of all polyps and observations, the use of the FICE classification for prediction of adenomatous polyps showed a high value of sensitivity, specificity, positive and negative predictive value identical to WLE (100%, 62.5%, 60% and 100%, respectively). The individual acuity of the endoscopists ranged from 66% to 95%, with a mean of 81.7%, and the overall histology obtained values of sensitivity, specificity, positive and negative predictive value identical to WLE (100%, 62.5%, 60% and 100%, respectively).

Discussion: The lack of recourse to magnification may have contributed to these results. The low confidence level of polyps smaller than 10 mm in FICE has been reported by other studies.

Conclusion: FICE technology may help inexperienced endoscopists in the histological prediction of polyps with a confidence level higher than observed in WLE, having both suboptimal acuities. The lack of recourse to magnification may have contributed to these results.

Disclosure of Interest: All authors have declared no conflicts of interest.

PO853 POLYP DETECTION RATES IN COLONOSCOPES PERFORMED UNDER GENERAL ANAESTHETIC COMPARED TO CONVENTIONAL SEDATION

B. Perren1, A. S. Bancel1, A. G. Lim1, P. Youd1, S. J. Moodie1, P. Patel1
1Medicine, Epsom and St Helier University Hospitals, London/United Kingdom

Contact E-mail Address: ben.perren@doctors.org.uk

Introduction: Colonoscopies are performed under general anaesthesia (GA) for various reasons but mainly due to previous experience being poorly tolerated with normal sedation. During the procedure, the endoscopist must be aware of the patient’s comfort levels and reactions to endoscopic manoeuvres. Polyp detection rate (PDR) was assessed in 404 colonoscopies, which were randomly selected to use for comparison. A significant increase in rate of polyp detection was found in GA studies (45% vs non-GA studies 30%, p = 0.05).

Aims & Methods: This study was undertaken retrospectively at a district general hospital. Results were analysed for all colonoscopies performed under GA between February 2016 and February 2017 to identify whether polyps had been detected, the number of polyps detected, and the site of polyp detection. Statistics: SPSS v23. A high PDR was significantly associated with a high PDR for colonoscopy. We propose to evaluate these factors in our daily practice, including all the endoscopists of our endoscopy unit.

Results: We evaluated 2719 Male patients (45.1%) and 3308 Female patients (54.9%). The median number of polyps per procedure was 140 (range: 10–720). 2054 colonoscopies detected 3914 lesions or polyps: 2914 tubular/villous adenomas, 496 serrated adenomas, 242 hyperplastic polyps (hyperplastic polyps located in the rectum and sigmoid colon were not considered as at risk for cancer and were excluded), 212 other histology leading to a total number of Polyps (MNPD) of 0.65 and a Polyp Detection Rate (PDR) of 34.1%. 1935 colonoscopies detected at least one adenoma (adenoma detection rate, 32.1%). Large Polyp Detection Rate was 7.9% with detection of 538 polyps (>1.37% of polyps), in 477 patients. Neoplasia Detection Rate was 3.6% (300 neoplasias in 220 patients). Among the endoscopists, the median PDR was 32.5% (range 14–62%). Among them, 4 had a PDR < 20%, 17 had a PDR between 20 and 39% and 9 had a PDR > 40%. Mean withdrawal time was 490 seconds (range 228–831). 10 physicians had a mean withdrawal time <420 seconds, 1 had a mean ADR < 55% and compared to 34% 5% for polyp detection and withdrawal time of more than 420 seconds (p > 0.05). In the univariate analysis, a high PDR was significantly associated with endoscopist-related factors: age, Male gender, a familial history of polyp/cancer, screening or positive faecal immunochemical test (FIT+) and quality of preparation. Regarding physician-related factors, a high PDR was significantly associated with Male gender, high volume (>140 colonoscopies per year) and withdrawal time. In the multivariable analysis, the only factor associated with a high PDR were: familial history of polyp/cancer, FIT+ and age of the patient.

Conclusion: In this large series of routine colonoscopies, we found medically-relevant polyps in more than one third of the patients, irrespectively of age and indications. In multivariate analysis, a high PDR was significantly associated with a familial history of polyp/cancer, FIT+ and age of the patient. This may suggest that the Male gender is no longer a risk factor for polyps. In addition, even if there are still discrepancies regarding PDR among physicians, we found that a high PDR was significantly associated with patient-dependant factors: age, Male gender, a familial history of polyp/cancer, screening or positive faecal immunochemical test (FIT+) and quality of preparation. Regarding physician-related factors, a high PDR was significantly associated with Male gender, high volume (>140 colonoscopies per year) and withdrawal time.

2IGR, Villejuif/Paris

Contact E-mail Address: mcavichi@wanadoo.fr

Introduction: Fecal immunochemical test (FIT) has progressively replaced the guaiac test for colorectal screening in average risk population in France since May 2015. With a high sensitivity and a good specificity, it is supposed to increase colorectal cancer-risk detection. However, its efficiency has not been described in routine colonoscopy.

Aims & Methods: Among 6027 colonoscopies performed between 01/2016 and 31/12/2016 in our endoscopy unit, 391 were performed for a positive FIT (FIT+).
Conclusion: for good Bowel preparation as compared to the traditional 4 L PEG. We PEG with bisacodyl does improve patient tolerability with a tendency to be better 22.5%) (p< 0.001). Nausea and vomiting were respectively (34% ¼
18.9% respectively compared to 1, 49.5% and 10% respectively in female 18 years of age, abdominal surgeries other than colonic, examinations done by residents in second and fifth year of training and specialists. Exclusion criteria: incomplete colonicoscopies or prior history of colonic surgery. Results: One hundred and eighty-eight colonoscopies (94 on each side) were included. There was no statistical difference in mean age (RLP:LLP = 61 Vs. 64 years; p > 0.05), gender (49 Vs. 52 males; p > 0.05), body mass index (27.4 Vs. 26.4; p > 0.05), previous history of abdominal surgery (44 Vs. 34; p > 0.05), surgical and overweight patients did not benefit from any of the positions (time to cecum: 650 Vs. 702 and 570 vs 657; p > 0.05), comfort: 4.2 Vs. 4.12 and 3.83 Vs. 3.96; p < 0.05, respectively).

Disclosure of Interest: All authors have declared no conflicts of interest.

P0858 COLONOSCOPY ON THE LEFT, RIGHT? I. Mocanu, A. Laranjo, S. Pires, N. Veloso, L. Gonçalves, R. Godinho, I. Medeiros 1 Gastroenterology, Hospital Espírito Santo de Évora, Évora/Portugal Contact Email Address: irma.mocanu.24@gmail.com

Introduction: With high variability of time spent to reach the cecum, depending on endoscopist experience, patient characteristics and type of colonoscope used. Recently, the ROLCOL study demonstrated an advantage in time and patient comfort during progression in right lateral position (RLP) when compared with traditional left lateral position (LLP).

Aims & Methods: To compare time to reach cecum, patient and endoscopist comfort (using a visual analogue scale (VAS) in colonoscopies with progression on RLP and LLP. Prospective study, between January and April 2017, of colonoscopies under conscious sedation, randomly assigned to RLP and LLP. Olympus 190 series and Fuji EC-530 W13 colonoscopes were used. Inclusion criteria: routine colonoscopies, patients > 18 years of age, abdominal surgeries other than colonic, examinations done by residents in second and fifth year of training and specialists. Exclusion criteria: incomplete colonoscopies or prior history of colonic surgery. Results: Conclusion: in our experience, progression in right lateral position did not show additional advantage over standard LLP in time to reach the cecum or patients comfort. We did not find any difference in time to progression or comfort between Olympus and Fuji colonoscopies. Disclosure of Interest: All authors have declared no conflicts of interest.

P0857 TWO LITERS OF POLYETHYLENE GLYCOL (PEG) WITH 15 MG OF BISACODYL VERSUS 4 LITERS OF PEG FOR BOWEL PREPARATION TO COLONOSCOPY, PROSPECTIVE RANDOMIZED STUDY, PRELIMINARY RESULTS. E.M. Amine1, Z. Abdelkrim1, E.M. Azira2, W. Khannous1, G. Kharrasse1, Z. Ismaili1 1Hepatogastroenterology, CHU Med VI Oujda, Oujda/Morocco 2Avicenne, Faculty of medicine Oujda, Oujda/Morocco

Contact Email Address: mekamine@hotmail.com

Introduction: Adequate bowel preparation is one of the most important quality factors of colonoscopy. Several formulations of bowel preparation have been evaluated with the ability to have a clean colon and be well tolerated by patients. Currently, PEG 4L solution is the preferred method of bowel preparation to colonoscopy. This preparation has the disadvantage of being poorly tolerated by patients. Furthermore, recent studies have shown that a low-volume PEG solution before colonoscopy with Bisacodyl for bowel cleansing is as effective and better tolerated as a large volume PEG (4L).

Aims & Methods: This study aims to study the efficacy and tolerance of the new regimen (2L of PEG associated with Bisacodyl) compared to the classical regimen (4L of PEG). Materials and methods: A prospective comparative random study comparing the tolerance, acceptability and efficacy of a protocol A based on 4L of PEG and a protocol B corresponding to 2L of PEG +15mg of Bisacodyl. Using the Boston Bowel Preparation Scale (BBPS) by endoscopists, who did not know bowel preparation type, to evaluate the quality of preparation.

Results: Sixty-six patients were included (35 in group A and 31 in group B), with a sex ratio = 1. The average age of patients was 52 ± 15 years (17–86 years) with a median of 51.5 years. Eight patients in the first group found the preparation difficult or moderately difficult vs 3 in group B (p = NS) with mild to severe side effects 54% of group A and 29% of group B (p = 0.03) and A mean side effect per patient was 2.26 vs. 1.89 (p = NS). Nausea and vomiting were respectively (34% and 19%) in group A and (23% vs 13%) (p = NS). However, 5 patients in group A had sleep disorders vs only one case in group B. Four patients who received 4L of PEG had expressed their refusal to resume the same preparation if necessary while 2 patients in group B had refused. A score greater than or equal to 7 was recorded for only 2 patients in group B (18.6% respectively). On the other hand, 6 out of 10 patients in group A were satisfied with the chosen procedure. The overall score obtained was 6.49 versus 7.32, respectively. This score (BBPS) tended to be better in protocol B than in protocol A in the right segment (2.55 vs 2.17), transverse colon (2.58 vs 2.43) and left colon (2.19 vs 1.94). This same trend was recorded in relation to the number of patients with hyperplastic polyps (9,9%) with 4 patients in group B and no patient in group A. Seven patients refused to repeat the test even if indicated. This refusal was secondary to the preparation in 4 cases (2 cases of each group). Abdominal pain and post-endoscopic distress; 66 patients scored with a maximum score of 10, 60% of patients rated this symptom in group B were respectively (62.8% and 65.7% vs 32% and 22.5%) (p = 0.016 and < p = 0.001).

Conclusion: Preliminary results from our study suggest that the low-volume 2 L PEG with bisacodyl does improve patient tolerability with a tendency to be better for Good Bowel preparation as compared to the traditional 4 L PEG. We continue our study to have a more significant number of patients view these new data with an associated confidence interval.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0859 NON-GRANULAR LATERALLY SPREADING COLONIC LESIONS >20MM (LSL) ARE SMALLER AND MORE COMMONLY MULTIPLE THAN GRANULAR LSL: IMPLICATIONS OF A ‘COLONIC MUCOSAL PHENOTYPE’ FOR PRACTITIONERS OF ENDOSCOPIC RESECTION D. J. Tate1, H. Awadie1, L. Desomer1, M. Sidhu1, K. Goodrick1, N. G. Burgess1, S. Whitaker2 1Department Of Gastroenterology And Hepatology, Westmead Hospital, Sydney/ Australia/NSW 2Westmead Clinical School, University of Sydney, Sydney/Australia/NSW

Contact Email Address: dtjate@gmail.com

Introduction: The surface morphology of laterally spreading colonic lesions >20mm (LSL) can be described as granular (G) or non-granular (NG). NG lesions are more difficult to detect, harder to resect endoscopically and harbour a higher risk of submucosal invasive cancer (SMIC) than G lesions.

Aims & Methods: We aimed to characterise the population of LSL in patients undergoing EMR within a local cohort. Between January 2008 and April 2010, LSL were identified within a prospective observational cohort of patients undergoing endoscopic mucosal resection at a single academic tertiary centre. LSL were interrogated using high-definition white light (HDWL) at the time of EMR and the morphology of LSL were described along with patient, lesion and procedural factors. All LSL detected during the study period were eligible. LSL with mixed or indeterminate morphology were excluded. Serrated LSL were excluded. Lesions not attempted for EMR were excluded. Patients with multiple LSL were categorised according to the largest (dominant).
Results: 1382 LSL in 1243 patients were analysed. 1155/1243 (92.9%) patients had a solitary LSL. The majority of patients with multiple LSL had two (77.3%) or three (15.9%) lesions. 889/1382 (64.3%) of LSL were G. G LSL were more likely to be solitary (87.0%) than NG LSL (77.5%, p < .001). G LSL were more commonly large (>40 mm in size) (49.3%) than NG LSL (26.0%, p < .001) and were more commonly found in the right colon (proximal to transverse colon) (54.2% versus 48.3%, p = .034). In 88 patients with multiple LSL the dominant LSL was G (49/88 [55.7%]). A dominant G LSL was associated with fewer other LSL than a dominant NG LSL, p = .029.

Table 1: The morphology of the dominant (largest) laterally spreading lesion (LSL) predicts the presence and number of synchronous LSL. Morphology of the dominant lesion did not predict the others would be of the same morphology (p = .697). The dominant LSL was large in 43.2% of cases. Size of the dominant LSL predicted size of the other LSL (p < .001). 58.0% of dominant LSL were located in the right colon. In 65.9% patients all LSL were in the same colonic segment; this was not predicted either by the location of the dominant LSL (p = .860) or its morphology (p = .228).

Conclusion: 7% of patients will have more than one LSL. In these patients the dominant lesion morphology predicts the presence and number of additional LSL. A dominant NG LSL was more commonly found in the right colon (proximal to transverse colon) (54.2% versus 48.3%, p = .034). In 88 patients with multiple LSL the dominant LSL was G (49/88 [55.7%]). A dominant G LSL was associated with fewer other LSL than a dominant NG LSL, p = .029.

P0860 WIDE-FIELD PIECEMEAL COLD SNARE POLYPECTOMY OF LARGE SESSILE SERRATED POLYPS WITHOUT A SUBMUCOSAL INJECTION IS SAFE

J. D. Tate, H. Awadie, F. Buhn, L. Desomer, R. Lee, S. Heitman, K. Goodrick, M. J. Bourke
Department Of Gastroenterology And Hepatology, Westmead Hospital, Sydney, Australia/NSW

Contact E-mail Address: dtate@gmail.com
Introduction: Large series suggest endoscopic mucosal resection is safe and effective for the removal of large sessile serrated polyps ≥10mm (large SSP) but it exposes the patient to the risks of electrocautery, principally delayed bleeding. Aims & Methods: We aimed to examine the feasibility and safety of piecemeal cold snare polypectomy (pCSP) for the resection of large SSP. Over 12 months sequential large SSP without endoscopic evidence of dysplasia referred to a tertiary endoscopy centre were considered for pCSP. The technique for pCSP was standardised. The lesion and its margins were assessed using high definition endoscopic imaging. Snare resection commenced at one margin including a 2–3 mm rim of normal tissue. A thin-wire snare was used in all cases. Firm downward pressure and suction of luminal gas aided tissue capture. Submucosal injection was not performed. High-definition imaging of the defect margin was used to ensure the absence of residual serrated tissue. Adverse events were assessed at 2 weeks and surveillance was planned between 6 and 12 months. Results: 41 SSP were completely removed by pCSP in 34 patients. 7 patients had two lesions removed. The median size of SSP was 15mm (IQR 14.5–20), range 10–35mm. The median duration of procedures was 4.5 minutes (IQR 1.4–6.3). There was no evidence of perforation or significant intra-procedural bleeding. There were no significant adverse events at 2 week follow up including delayed bleeding and post polypectomy syndrome. 8/41 lesions underwent first follow-up at median 6 months with no evidence of recurrence.

Conclusion: There is potential for pCSP to become the standard of care for non-dysplastic large SSP. This may reduce the burden on patients and healthcare systems of removing SSP, particularly by avoidance of delayed bleeding. Disclosure of Interest: All authors have declared no conflicts of interest.
in left colon and 6 (6%) in rectum. Pathological diagnosis was 22 (24%) hyperplastic polypl or SSA/P, 42 (46%) low grade dysplasia (LGD), 23 (26%) high grade dysplasia (HGD), and 11% submucosal invasive cancer. In the removal methods, HSP was 71 (77%) lesions and EMR was 21 (23%). The median procedure time of HSP and EMR was 37 seconds (range: 7–430) and 167 (range: 60–450) (p < 0.001). The median lesion size of was HSP and EMR was 12 mm (range: 10–30) and 20 (range: 10–26) (p < 0.001). The immediate bleeding of HSP and EMR occurred in 7 (10%) lesions and 6 (33%) (p = 0.009). The delayed bleeding of HSP and EMR occurred in 2 (3%) lesions and 0 (p < 0.001). Perforation was not occurred. No tumors were horizontal and vertical margin positive. In the pathological diagnosis, 86% of hyperplastic polypl or SSA/P, 86% of LGD, and 57% of HGD was resected by HSP, and submucosal invasive cancer was resected by EMR.

Conclusion: Of over 10mm colorectal lesions was resected by using bipolar snare, 77% were resected by HSP. The procedure time of HSP was significant shorter than EMR.

Introduction: The ‘SMSA’ polyp scoring system is an objective method of stratifying the difficulty of polypectomy based on expert consensus opinion. The score is simple, intuitive and has previously not been evaluated in a large multicentre setting.

Aims & Methods: We aimed to determine the ability of the SMSA polyp score to predict robust endpoints after endoscopic mucosal resection (EMR) of colorectal laterally spreading lesions (LSL). The SMSA polyp score was applied to a prospectively collected multicentre database of LSL resected by EMR over eight years. This score describes the complexity of polypectomy with respect to four major domains (table 2) and is subsequently divided into four levels. Standard inject and resect EMR procedures were performed with detailed patient, procedural and outcome data recorded prospectively over the study period including all features of the SMSA. In patients who had multiple lesions resected the largest lesion was retained for analysis. The primary endpoints were correlation of SMSA score with completion rate, adverse event rate and adenoma recurrence.

Results: 2305 lesions in 2305 patients (47.4% M, 45, 2% right colon) underwent EMR. The majority of lesions were SMSA 4 (50.2%) with a median lesion size of 30 mm (range 20–160 mm). Failed single session EMR occurred in 97 (4.2%) and this was predicted by increasing SMSA (SMSA p < 0.001). Intra-procedural bleeding was significantly more common with increasing SMSA (SMSA 2, 19/229 (8.3%) versus SMSA 4 291/1158 (25.1%), p < 0.001). Clinically significant post EMR bleeding (CSPEB) was more common as SMSA increased with 4 (1.7%) in the SMSA 2 group and 90 (7.6%) in the SMSA 4 group, p = 0.001. Intraprocedural perforation and delayed perforation were no different between the groups. After EMR surgery at two weeks was more common in the SMSA 4 group (p < 0.001). Of those patients that underwent their first surveillance colonoscopy (SCI), endoscopic recurrence (EDR) was more common in the SMSA 4 group than the SMSA 2 group, 206 (23.7%) as compared to 9 (5.4%), p < 0.001. This was also the case for histologic recurrence (p < 0.001). The difference in EDR persisted to the second surveillance colonoscopy (SCI2) with no recurrences in the SMSA 2 group versus 9.1% in the SMSA 4 group.

Table 1: Outcomes after endoscopic mucosal resection at the initial procedure, 2 weeks and subsequent surveillance procedures.

</table>

EMR – endoscopic mucosal resection, IPB – intra-procedural bleeding, IPP – intraprocedural perforation, CSPEB – clinically significant post endoscopic bleeding (bleeding after EMR requiring admission to hospital or re-intervention), 2w – two weeks, SCI1/2 – surveillance colonoscopy 1/2. * target sign or actual hole corresponding to DMI type III/IV - Sydney Classification (1)

Conclusion: SMSA is a simple readily applicable clinical score that identifies a subgroup of patients who are at increased risk of EMR related complications including CSPEB and recurrence. This information is useful for planning EMR lists with respect to time and resource allocation. Moreover SMSA could have a major impact on training, both in identifying appropriate training cases and providing an objective benchmark against which to assess the progress of trainees in EMR.

P0863 USE OF ACETIC ACID FOR EVALUATING SESSILE SERRATED ADENOMA/POLYP: A PILOT STUDY

S. Yamamoto, M. Shafazand
Gastroenterology, Sahlgrenska University Hospital Östra, Göteborg/Sweden

Contact E-mail Address: shuot515suke@gmail.com

Introduction: Sessile serrated adenoma/polyp (SSA/P) has been accumulated increasing attention since its risk for developing to cancer had been clarified. These polyps are difficult not only to detect but also to determine their precise margin after detection especially in right side colon. Such a difficulty leads high recurrence rate after endoscopic resection. Magnifying function and narrow band imaging (NBI) is reported to be useful for evaluation of SSA/P but it needs special equipment, extra time, and expertise. Easier, uncomplicated, and non time consuming method is desired. The use of acetic acid or acetic acid-indigo Carmine mixture have been introduced into endoscopic diagnosis in Barrett's esophagus, early gastric cancer, and colorectal early cancer. However, there have been no reports on using this agent as aid for the optimal diagnosis of the margin of SSA/P. If this rather cheap agent were helpful for realizing the precise margin of SSA/P, it could decrease insufficient removal of the polypl and recurrence after that.

Aims & Methods: The aim of this pilot study is to assess whether the acetic acid could facilitate the recognition of the margin of SSA/P. We used acetic acid as a mixture with indigo Carmine and compared it to conventional evaluating methods: narrow band imaging (NBI) and indigo Carmine. From December 2016 to February 2017, patients in whom SSA/P more than 10 mm were found in right side colon in daily practical colonoscopy by single endoscopist in our institute were included. We used the standard scope without magnifying function. First we observed lesions with conventional white light and NBI. Second, we recorded pictures with indigo Carmine (IC) spray alone on it. Finally, we sprayed the mixture of acetic acid and indigo Carmine mixture (AIC) directly through the endoscopic working channel without using catheter onto lesion. Using recorded pictures during these procedures, ability for recognizing the margin of polyps were compared between IC and AIC, or NBI and AIC by 3 endoscopists, and the concordance rate of diagnosis among these three were assessed as Kappa statistics.

Results: 9 SSA/P lesions in 7 patients were investigated. In all cases, AIC was helpful to recognize the margin of polyps without causing any obstructive effect. We also observed disappearance of mucous on the surface, dilated crypts caused by acid contact, and aceto-whithish reaction on the surfical glands in all lesions. In comparing the ability for recognizing the margin of the lesions, 6.3 in 9 lesions (mean among 3 practitioners) were thought to be as AIC better than IC, and
similarly 7.3 in 9 were better than NBI. Kappa value among participants was 4.8; moderate agreement (p = 0.0016). All polyps were removed endoscopically after evaluation. All lesions were histologically diagnosed as SSA/P without dysplasia. Conclusion: Acetic acid was useful and promising to facilitate the endoscopic recognition of the precise margin of SSA/P in right side colon. Strength of this method is that it is very simple and needs no special equipment nor skill.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Preoperative localization or tattooing is essential for minimally invasive surgery. Although preoperative endoscopic tattooing using India ink or indocyanine green is widely used, clinical evidence and safety profile supporting the use of these agents is lacking.

Aims & Methods: We assessed the efficacy and safety of preoperative endoscopic tattooing using autologous blood. A total of 80 patients who underwent endoscopic tattooing using India ink or autologous blood were included in this study. From February 2016, all patients who required localization of a target lesion before colorectal surgery underwent endoscopic tattooing using autologous blood at a single tertiary medical center, and the outcomes were collected prospectively. As a comparison, we retrospectively reviewed the medical records of a further 40 consecutive patients who underwent endoscopic tattooing using India ink before February 2016. The primary outcomes were the visibility of the tattooing in the peritoneal cavity and related adverse events.

Results: Endoscopic tattoos produced using India ink were visible in 38 (95%) patients, and tattoos created using autologous blood were visible in 36 (90%) patients. In the autologous blood group, the tattoo could not be identified in four patients due to excessive peritoneal fat, bleeding tendency, congenital anomaly, and tattooing in an inadequate depth. Eight (20%) patients in the India ink group and four patients (10%) in the autologous blood group experienced endoscopic tattooing-related adverse events.

Conclusion: Preoperative endoscopic tattooing using autologous blood is a feasible and safe modality for the preoperative localization of colorectal lesions.

Introduction: Lateral spreading tumors (LSTs) are defined as lesions > 10 mm with a low vertical axis and lateral extension. They are separated in 2 groups with 2 subclasses for each of them: granular LST (LST-G) with, or without large nodule; and non-granular LST (LST-NG). Confirmed into flat lesions (Ha) and depressed lesions (Ha+Hc). Every subclass has been associated with a prominent risk of cancer and submucosal invasion (T2m)3,2. Knowing this aspect could help for the decision of the resection technique (endoscopic mucosectomy EMR, endoscopic submucosal dissection ESD, or surgery). The aim of our study was to determine the risk of cancer (submucosal and mucosal adenocarcinoma) in a western series of LST treated by endoscopic resection, and to evaluate the ability of the endoscopist to predict the depth of cancer invasion.

Aims & Methods: The entire patients with a LST ≥ 20 mm treated between January 2012 and December 2016 in our single center were included. Endoscopic data were collected (size, location, LST classification, analysis of pit pattern, endoscopic suspicion of cancer). We also reported the resection technique, histological results, and the follow-up at 1 year.

Results: 377 LST were included in our study. The average age was 67.7 years old. The mean size of lesion was 40.6 mm. LST were located in the right colon, the rectum, the left colon and the transverse colon in 44.5%, 32.6%, 14.0% and 8.8%, respectively. The resection technique used was a monocle EMR in 15.4%, piecemeal EMR (pEMR) in 42.9%, ESD in 27.3% and assisted ESD in 14.5%. ESD was associated with a significant lower rate of recurrence after 1 year (4.9% against 18.1%). Considering the LST classification, there were 27.0% LST-G with large nodule, 28.4% LST-G with large nodule, 35.5% flat LST-NG Ha, and 9.0% LST-NG with depression Ha+Hc. The overall rate of adenocarcinoma was 19.7%, and 9.0% with submucosal invasion. The rates of adenocarcinoma and the rates of submucosal invasion in every subtype of LST are reported in table 1. They were higher for LST-G with large nodule (34.5% and 15.9% respectively) and for LST-NG with depression (35.3% and 20.6%). Regarding the prediction of submucosal cancer by the endoscopist, we report a low sensitivity, and positive predictive value (respectively 64.7% and 32.8%). However, we had a good specificity and negative predictive value (86.0% and 96.0%). Endoscopic predictors of submucosal cancer were invasive pit pattern (HR 33.0; p = 5.78e-07) and depression (HR = 11.86; p = 0.049).

Conclusion: Our western series confirm similar rates of submucosal adenocarcinoma according to the type of LST as compared to Asian series. LST-G with large nodule, and LST-NG with depression were associated with a higher risk of submucosal invasion and invasive pit pattern was the stronger predictor of malignancy. Endoscopic submucosal dissection should be systematically performed in these cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Evidence on an international variation of pathological types and anatomical distribution of colonic polyps is beneficial for early detection and management but limited.

Aims & Methods: To characterize differences in colonoscopy findings by ethnicity, a random sample of patients aged at least 50 years without colonic symptoms or history of colonic diseases who underwent colonoscopy were reviewed. Of 26,508 subjects, 2651 were randomly selected. Of 1300 subjects who met the inclusion criteria, abnormal findings were identified in 878 cases (67.54%), of which 452 cases had 940 polyps and 7 cancer lesions were found in 6 cases. Of 452 patients with polyps, half had only one polyp (53.76%) and were Asian (54.63%), followed by Caucasian (26.99%), Middle Eastern (15.71%), and other ethnic origins (2.65%) (Figure). Ethnicity-specific polyp prevalence were 36.26%, 38.05%, 27.24%, and 34.15%, respectively. Polyps of Caucasian subjects tended to be smaller (4.52 mm) and locate on the left side of the colon (38.05%), whereas 8.19% were large (> 10 mm) and 34.15% were large (> 10 mm). Hyperplastic polyp, tubular adenoma (TA), and tubulovillous (TVA) adenoma were identified in 43.19%, 53.83%, and 2.34%, respectively. Premalignant (TA + TVA) polyps were found in 56.08%, 50.19%, and 64.23% of the polyps of Asian, Caucasian, and Middle Eastern patients, respectively. Premalignant lesion were found in 52.91% of small polyps.

Conclusion: The findings suggested that number, size, distribution, and pathological type of colonic polyps vary across ethnic groups. As more than half of small polyps were a tubular adenoma, we propose that polyps of all sizes should be removed when feasible.

**Introduction:** Endoscopic submucosal dissection represents the standard of care for large superficial colo-rectal neoplasms in Japan. In Europe, only few studies referred to discussing results, essentially in the rectal location. Colonic ESD is more technically challenging because of the colonic loops, intestinal motility, the folded anatomy, problems caused by inconstant gravity, and submucosal fibrosis. Colonic ESD is also more risky because perforations are most often non-clinically significant in the rectal location (under peritoneal reflection) contrary to the colonic location. Here we reported our results of two years of colonic ESD performed by two French expert teams that began colonic ESD after a strong animal training and a strong experience in rectal and upper-digestive tract ESD.

**Conclusion:** Colonic ESD could be performed with similar results than rectal ESD in French expert teams with a strong experience in rectal ESD. Colonic ESD is more technically challenging because of the colonic loops, intestinal motility, the folded anatomy, problems caused by inconstant gravity, and submucosal fibrosis. Colonic ESD is more risky because perforations are most often non-clinically significant in the rectal location (under peritoneal reflection) contrary to the colonic location. Here we reported our results of two years of colonic ESD performed by two French expert teams that began colonic ESD after a strong animal training and a strong experience in rectal and upper-digestive tract ESD.

**Introduction:** It is well known that acromegalic have been at an increased risk of colorectal neoplasm. However, there has been few reports of them in Japanese patients with acromegaly. In this study, we attempted to elucidate the risk of colorectal neoplasm in Japanese patients with acromegaly comparing with healthy controlled patients.

**Aims & Methods:** Between April 2008 and September 2016, a total of 745 patients were underwent Hardy operation in our institute. Among them, a total of 178 patients were selected randomly from those who were performed colonoscopy in our medical check-up in the same period by means of being matched to cases of the age and gender. The incidence, size, location and histology of colorectal neoplasm were investigated.

**Results:** As background, 84 patients (47.2%) were men and 94 patients were women, and the median age was 47.5 years old (18 to 75) in the case group. The median height/weight was 165.5 cm/65.1 kg in the case group and was significantly larger than the control group (163.4 cm/60.1 kg) (p = 0.038, p < 0.01 respectively). The median Body Mass Index (BMI) were 23.4 in the case group and 22.5 in the control group. There was a significant difference between two groups (p < 0.001). The frequency of colorectal neoplasm was 66.8% (119/178 patients) in the case group and was significantly higher than control group of 24.2% (86/356 patients) (p < 0.001). The average number of neoplasm in case group was 2.44 ± 1.74 mm in the case group and 1.77 ± 0.89 mm in the control group. There was a significant difference between two groups (p = 0.001). The distribution of neoplasm in the case group vs in the control group was shown 12.6% vs 12.8% in cecum, 30.3% vs 36% in ascending colon, 11.5% vs 12.8% in transverse colon, 15.1% vs 10.5% in descending colon, 66.4% vs 40.7% in sigmoid colon, and 31.9% vs 19.8% in rectum. The incidence of neoplasm in sigmoidal region had a significant difference in two groups (the case group 80.7% vs the control group 53.5%) (p < 0.001). In terms of neoplasm larger than 5 mm, the frequency was 34.5% (61/178 patients) in the case group and 7.6% (27/356 patients) in the control group (p < 0.001). In addition, as for neoplasm larger than 10 mm, that was 15.2% (27/178 patients) and 2.2% (8/356 patients) respectively (p < 0.001). The number of neoplasm resected by colonoscopy was 71 lesions (24.5% of all) in the case group and 5 lesion (16.4%) in the control group. The pathological examination in the case and control group showed eight and one had hyperplastic polyps, 2 and zero had sessile serrated adenoma/polyp, 3 and zero had inflammatory polyp, 48 and 19 had low to moderate grade adenomas, 4 and 3 had High grade adenomas, one and zero had carcinoid, and 5 and 2 had carcinoma respectively. There were no significant differences between two groups in the limited cases of high grade adenoma and carcinoma.

**Introduction:** Colonoscopy in ulcerative colitis (UC) is performed as first diagnosis and during screening for dysplasia and disease flares. It is an invasive procedure with a burden of discomfort and possible complications. To overcome discomfort and complications due to colonoscopy an Italian high-tech start-up (Endotics, Peccioli, Italy) developed a soft, self-propelled, disposable robotic colonoscope (R), approved with CE mark.

**Aims & Methods:** We wanted to compare diagnostic performance and tolerability of R with those of standard white light colonoscopy (S) in patients with ulcerative colitis. Consecutive patients referred for colonoscopy to our endoscopy department with clinically mild to moderate ulcerative colitis that signed the informed consent for both procedures were studied first with R and then with S (Olympus CF-145), by two different operators, blinded to previous observations. R had the following technical specifications: 17 mm outer diameter, rest position length probe 30 cm; maximum length of probe 54 cm; working length 210 cm; NTSC CMOS analog camera. Conscious sedation with midazolam was administered as
needed. We recorded endoscopic diagnostic activity according to Baron criteria, time to reach diagnostic, and patients pain/discomfort and operator’s difficulty.

Results: We studied 12 patients (7M:5F), mean age 41 yrs and disease duration 5.33 yrs. 53 colonic segments out of the 54 evaluated had the same assessment of disease activity (absent = 0 points, mild = 1 pt, moderate = 2 pts and severe = 3 pts) with a mean activity score with a mean difference of 0.33 pts (SD 0.60) with S, without significant difference. The caecum was reached in 11/12 cases by S in an average of 29.42 min (SD 28.94), and in 10/12 cases by R, in an average of 46.67 min (SD 24.98 min), with a mean difference of 17.25 min, not statistically significant. Incomplete colon explorations with R clustered in Milan, probably because of smaller experience. An average of 1.45 (SD 0.79) mg of midazolam were used during S while 0.41 (SD 0.38) mg during R. Mean pain/discomfort on a 0–10 scale was 2.08 (SD 1.67) for R and 4.17 (SD 1.74) for S, with a statistically significant difference (p = 0.06) favouring R. Mean perceived operator’s difficulty on a 0–10 scale was 4.44 (SD 1.78) for R, and 4.08 (SD 1.44) for S, with a mean difference of 0.42 pts favouring S, not statistically significant.

Conclusion: R appears to be a promising method for disease staging in patients with alternating colitis, because of comparable accuracy and reduction in pain and discomfort. A tool channel to obtain biopsies and perform therapeutic endoscopy, together with images of higher definition (CMOS digital Camera HD ready) and virtual chromo-endoscopy, useful for follow-up and screening for dysplasia in patients with long duration of disease are now available in the latest version of the R. “The column” connected to the latest version of the robot dysplasia in patients with long duration of disease are now available in the

Aims & Methods: A total of 40 endoscopic video clips depicting LSTs (10% randomly selected) were evaluated by 6 expert endoscopists; 3 from Japan and 3 from the West. Assessments included LST classification (LST-G homogeneous, LST-G mixed, LST-NG flat, LST-NG pseudodepressed), Paris classification, invasiveness, treatment suggestion and mean size of lesion. We calculated the interobserver agreement with weighted kappa and Chi square.

Results: Japanese endoscopists diagnosed more lesions as LST-G than Western (62.7 vs. 45.4%), Western diagnosed more LST-NG than Japanese (54.6 vs. 37.3%; p = 0.007). The interobserver agreement of the LST classification among the six experts was good (IC 0.93; 95% CI 0.85–0.97) for Japanese, and moderate at 0.45 (IC95% 0.27–0.64) for Western. Difference in concordance between the two cohorts was not statistically significant (p = 0.22). When only two categories were considered (LST-G vs NG), agreement was very good for Japanese (weighted Kappa of 0.81; 95% CI 0.65–0.97) and good for Western endoscopists (0.65; 95% CI 0.46–0.85). Again, difference in concordance was not statistically significant (p = 0.22).

Piecemal Endoscopic Resection was suggested in 34, 7% cases by Western, but never by Japanese endoscopists, whereas Endoscopic Submucosal Dissection was recommended in 54.6% and 16.1% cases by Japanese and Western experts respectively (p < 0.0001).

Conclusion: This study is the first to validate the LST classification system comparing East and West. There were significant differences in the types of LST diagnosed, and concordance was good in the Japanese cohort and moderate in the Western, but not significantly different. The recommendations for treatment were also different. We suggest a modification of the classification system to enable a more unanimous diagnosis and therapeutic strategy.

calculated the SMSSA score of difficulty and assessed the ability of SMSA to identify 5 outcomes: 3-months recurrence, 1-year recurrence, global recurrence (endoscopy not effective after 2 or more treatments), delayed bleeding and perforation. We compared results with those obtained using a subjective classification of difficulty: easy or medium vs difficult. Comparisons were conducted using clinical criteria and supplemented with logistic regression models.

**Results:** The SMSA scoring system classified 690 polyps (39%) as level 4 and 1098 (61%) as level 3, whereas the subjective classification system classified 399 (22%) as difficult and 1389 (78%) as easy or medium. The agreement between measures of difficulty was weak (κ = 0.33). 255 patients (19.9%) had recurrence 3 months after EMR, 84 (11.6%) had recurrence at 1 year, 78 (3.5%) suffered delayed bleeding and 35 (1.8%) perforation. The level 4 polyps had significantly higher rates of recurrence at 3 months and 1 year (p < 0.001 in both cases) and delayed bleeding too (p = 0.006), but not for perforation.

**Conclusion:** The SMSA grading tool is a predictor of outcomes or recurrences and bleeding following resection of LNPLC. However, in our multi-center sample, it does not appear to overcome the utility of a subjective indicator of difficulty made by the endoscopist during the EMR. It seems that this score can be used to facilitate planning, training or competency assessment, but efforts should be focused on validating the scoring system in a real situation, adjusting the score of variables or including new ones.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### Abstract: P0873. EFFICACY AND SAFETY OF ENDOCUTICAL RESECTION OF LARGE COLORECTAL ADENOMAS – CLINICAL EXPERIENCE OF A TERTIARY REFERRAL CENTER

**Introduction:** Colorectal cancer is a leading cause for cancer related mortality. Adenomatous polyp, the precursor, can usually be endoscopically resected to prevent cancer. Currently, there are no criteria for surgical vs. endoscopic resection and decision is individually made by the treating physician.

**Aims & Methods:** We aimed to evaluate factors associated with short-term efficacy and safety of endoscopic resection of large (>20 mm) and giant (>40 mm) adenomas. Consecutive cases that underwent endoscopic resection of adenomas larger than 20 mm were included. Endoscopic, clinical and histological details of polyps and of the endoscopic procedure were recorded as well as the need for further surgery.

**Results:** Total of 351 resections were included. Average diameter was 30.34 ± 10.66 mm. Surgery was indicated in 21 (5.98%) cases. In a multivariate analysis for efficacy, two variables were independent risk factors for surgery: adenoma size (OR 95%CI 1.08 (1.04–1.12)) and cecal location (OR 95%CI 0.59 (0.50–0.72)). Polyp size (OR 95%CI 3.20 (1.04–5.52)) and submucosal adrenaline injection (OR 95%CI 2.40 (1.11–5.19)) were independent risk factors for complications. In multivariate analysis for safety, independent risk factors for bleeding were: adenoma size (OR 95%CI 1.08 (1.04–1.12)), and cecal location (OR 95%CI 1.87 (1.11–3.11)).

**Conclusion:** Large and giant adenomas is generally a safe procedure when performed by an experienced endoscopist. Although adenoma size is the most significantly related to efficacy and safety, each case of giant adenoma should be evaluated in a referral center for feasibility of endoscopic resection.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0874 COLORECTAL MUCOSAL DEFECT CLOSURE FOLLOWING ENDOSCOPIC MUCOSAL RESECTION: A SYSTEMATIC REVIEW AND META-ANALYSIS**

C. Palmela1, P. Marques Da Costa2, A. O. Ferreira3
1Gastroenterology Department, Hospital Beatriz Angelou, Loures/Portugal
2Gastroenterology And Hepatology Department, Hospital de Santa Maria, Lisbon/Portugal

Contact E-mail Address: palmeira.carolina@gmail.com

Introduction: Clinical meaningful delayed bleeding is the most frequent adverse event following endoscopic colorectal mucosal resection. Observational and interventional studies on the efficacy of prophylactic closure (PC) following endoscopic mucosal resection (EMR) showed conflicting results.

**Aims & Methods:** The primary objective of this review is to evaluate the effectiveness in preventing bleeding and post-polypectomy syndrome (PPS) or perforation of PC of colorectal mucosal defects following endoscopic resection. We performed a systematic review and meta-analysis of randomized controlled trials (RCTs) from MEDLINE. We included studies with humans submitted to colonoscopy and in whom mucosal flat or sessile (Paris classification 0-II or Is) lesions with an estimated size ≥10mm were found and removed.

**Results:** 269 articles were initially screened. 5 were RCTs, 4 of them were pooled (RCTs) from MEDLINE. We included studies with humans submitted to colonoscopy and in whom mucosal flat or sessile (Paris classification 0-II or Is) lesions with an estimated size ≥10mm were found and removed.

**Secondary endpoints** were to compare these results with results of rectal ESD in very old people (≥80 years). Secondary endpoints were to compare these results with results of rectal ESD in very old people (≥80 years). A total of 344 patients were included, 53% were male, mean age of 81 ± 8 years. Bowel preparation: 66% SD and 34% PD. Overall, 72% of patients were included. There was an exploratory observational study of patients who underwent total colonoscopy between jun/2016-march/2017 with polyethylene glycol bowel preparation before and after SD protocol implementation. Bowel cleansing quality was assessed prospectively (using Boston Bowel Preparation Score) and compared between SD and PD groups.

**Conclusion:** ESD is feasible and efficient in very old patients. However, En bloc resection and R0 resection are less frequent than in younger patients probably due to more challenging lesions (more frequent cancer on the pathological analysis). ESD should be the treatment of choice for large rectal superficial neoplasms of the rectum in very old patients in view of its oncological efficiency and its safety in comparison to the surgical alternative.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic Submucosal Dissection has become the standard of care for large superficial rectal precancerous and cancerous lesions. It allows an en-bloc resection of large superficial lesions that increase the quality of pathological analysis and considerably decrease the risk of recurrence. Risk of having a delayed superficial lesions increase with age and no study have focused specifically on ESD in very old people (≥80 years). Indeed in this population alternative surgery had a high morbidity and is often refused or contraindicated for these patients.

**Aims & Methods:** Retrospective bientreus study of all cases of rectal ESDs performed between 06/2010 and 2016/2016 for superficial pre-cancerous or cancerous neoplasms in patients older than 80 years four French teams that performed more than 150 ESDs in the last 5 years. Primary Endpoint was to evaluate the En bloc, R0, curative resection rate and complications in patients older than 80 years. Secondary endpoints were to compare these results with rectal ESDs performed during the same period for patients younger than 80 years.

**Results:** 58 rectal ESDs were performed in four French centers between 06/2010 and 2016/2016 for superficial pre-cancerous or cancerous neoplasms in patients older than 80 years. Descriptive results: male 28 (48%), mean size of the specimen: 56.4 mm, mean duration of procedure 143.7 min, mean speed of ESD 19.8 mm/min, perforation rate: 3.6%, post-procedural bleeding: 7% (12%), second ary surgery 2% (4.3%) (All for pathological reason) Pathological analysis: low-grade dysplasia in 19%, high-grade dysplasia in 28%, intra-mucosal carcinoma in 5%, superficial submucosal carcinoma in 5%, deep submucosal carcinoma in 5%, villous adenoma in 3.4% and adenoma in 6.9%. Only 1 patients (1.7%) had a recurrent disease during endoscopic follow up. Primary Endpoint: En bloc resection: 86.2%, R0 resection: 62.5%, curative resection: 62.5%, Secondary Endpoint: Duration of procedure was longer in older people. Speed of ESD was lower. En bloc and R0 resection were lower in very old patients. Cancer was more frequent in very old patients (>80 years) and younger patients (<80 years) are resumed in table 1.

(continued)
Aims & Methods:

The primary objective was to determine the adenoma detection rate (ADR) in general, right and left hemicolectomy. Secondary objectives were polyp, advanced adenoma and carcinoma detection rates, size of adenomas and polyps in either localisation, intensity and effect of bowel preparation, rate of complete colono-scopy, need for re-endoscopy, duration of colono-scopy procedures, deepest point of insertion and complication rates. We reviewed retrospectively consecutive SCI patients who underwent colonoscopy from 2003 to 2017 and assigned an age-, gender- and year of performance-matched control group.

Results:

In 236 SCI, compared to 414 control patients, bowel preparation lasted longer (3.57 ± 1.0 vs. 3.09 ± 1.0 days, p = 0.001), achieved insufficient cleansing rate more often (23.7 ± 4.0% vs. 17.4 ± 3.7%), and caused more adverse events (30.9 ± 1.0% vs. 22.0 ± 3.3%). Colonoscopy needed longer time (36.9 ± 25.0 min, p = 0.001), remained incomplete more often (24.6 ± 4.6%, resulting in more re-colono-scopy (14.8 ± 4.3%). Endoscopy- and sedation-related adverse events were equal. However, neither overall nor rectal independent poly (30.9 ± 34.8%), adenoma (21.2 ± 21.0%), advanced adenoma (6.8% vs. 7.2%) or cancer (1.7% vs. 2.0%) detection rate overall nor size-dependent polyp (30.9 ± 34.8%), adenoma (21.2 ± 21.0%) and carcinoma (1.7% vs. 2.0%) were significantly differed. Results differed (p = 0.001) and length of colonoscopy was significantly longer (3.57 ± 2.0 vs. 3.07 ± 1.0 days, p = 0.001), remained incomplete more often (46.6% of patients diagnosed with malignant tumor pathology showed that 73.3% with conserved general status (n = 4) versus 46.7% of males (n = 2) with hematochezia versus 86.7% (n = 2) with constipation (p = 0.07) and 26.7% with conserved general status (n = 4) versus 75.4 years and a maximum age of 91 years. The prevalence of males was 51.0%, 10.5% of cases (n = 10) were diabetic, 12.6% (n = 12) hypertensive, 12.6% (n = 12) with ischemic heart disease. 8.4% (n = 8) had diabetes mellitus and 9% (n = 9) had a digestive neoplasia. Colonoscopy was indicated for hematochezia in 40% (n = 38), transit disorders in 33.6% (n = 32), abdominal pain in 14.7% (n = 14), IBS in 3.1% (N = 3), radiographic abnormalities in 13.6% (n = 13), iron deficiency anemia in 4.2%, and for patients with a family history of colorectal cancer in 1% of cases. Colonoscopy was abnormal in 83% (n = 93), with poly by 48.3% (n = 45), suspected lesions of malignancy in 16.1% (n = 15), Divarhia in 19.3% (n = 18), IBD in 3.1% (N = 3), arteriovenous communications in 12% (n = 11) and rectal erosions in 2.1% (n = 2). The rate of malignant lesions diagnosed by colonoscopy was 53.3% of females (n = 8) versus 46.7% of males (n = 7) (p = 0.26), 13.3% (N = 2) with hematochezia versus 86.7% (n = 13) with constipation (p = 0.07) and 26.7% with conserved general status (n = 4) versus 73.3% for ESD conversion regardless of size or location, particularly the duration of the dissection.

Disclosure of Interest: All authors have declared no conflicts of interest.

References:

4. Anha CR, Spungen AM, Bauman WA, Spungen AM, Bauman WA, Rosman AS, Shaw S, Hunt KK, Post JB, Galea M, Korsten MA. Clinical trial: the efficacy and safety of bowel cleansing or failure to reach the caecum could diminish adenoma detection rates (ADR) [6, 7], while complication rates could increase due to severe morbidity.

Results:

Despite intensified protocols, bowel preparation shows inferior results in SCI patients and colonoscopy needs more efforts to succeed, but pooled colonoscopy of patients with SCI was not associated to ESD conversion. R0 was achieved in 64.7% (n = 11/17) cases with en-bloc EMR resection and in 91% controls (p < 0.001). There were two recurrences (13.3%) at 3-months within the 15 cases with piecemeal resection. Procedures were noted in en-bloc (ESD or EMR) resection patients (p = 0.044). Three (7.7%) and one (1.3%) patients had an indication for surgery in case-control groups (p = 0.107).

Conclusion: The presence of certain factors should be assessed during the procedure to identify patients who need ESD conversion regardless of size or location, particularly the duration of the dissection.

Disclosure of Interest: All authors have declared no conflicts of interest.
burden of surgery, combined with the availability of various endoscopic closure devices.

Aims & Methods: To assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used. Also, to identify factors predicting surgery as a first line treatment, and failure of endoscopic treatment. Medical literature (Cochrane library, EMBASE, MEDLINE) from 1966 till September 2016 was searched. A systematic review and meta-analysis were performed on studies reporting technical and clinical success of endoscopic closure of acute iatrogenic perforations, according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines.

Results: 764 studies were identified. 28 studies, in human, met our inclusion criteria and were analysed. A total of 474 endoscopic closures were attempted in these studies. The overall technical success rate was 93.1% (n = 451/474, 95% CI: 90.6–95.4%), clinical success was 89.7% (n = 431/474, 95% CI: 85.5%–93.9%), and complication rate was 1.3% (n = 7/474, 95% CI: 0.3%–2.3%). Technical success for endoclip closure was 96.6% (95% CI: 94.2%–98.2%), and clinical success was 93% (95% CI: 87.1%–97.2%), and complications were 3% (95% CI: 69.9%–96.6%), clinical success was 77.9% (95% CI: 56.8%–93.3%), and complication rate was 4.1% (95% CI: 2.0%–6.8%). The technical success rate for Self-expanding metas-tem (SEMS) is 100% (95% CI: 71.5%–100%), clinical success is 91% (95% CI: 74.1%–108%), and complication rate of 9.1% (95% CI: 78.0%–112%). Only one study for endosuturing met our criteria, with technical and clinical success rate of 100%, and without any complication. Factors predicting failure of endoscopic treatment and need for early surgical intervention included large size, leucocytosis, fever, severe abdominal pain, large amount of peritoneal free air, necrotic or soft inflammatory margins, unfavourable anatomical site, stool contamina- tion, perforation, and failure of endoscopic closure.

Conclusion: Our study suggests that endoscopic closure is a suitable treatment option for acute iatrogenic gastrointestinal perforations. Several factors have been suggested as predictors of need for surgery as a first line treatment. The study is limited by the low methodological quality of most studies included, indicating the need for further research.

Disclosure of Interest: All authors have declared no conflicts of interest.

Dept. Of Gastroenterology, TF Clinic. Dept of Gastroenterology, Tokyo/Japan

Contact E-mail Address: tfclinie@hkhii.plala.or.jp

Introduction: In recent years, colorectal cancer (CRC) has become a focus of attention as likely representing “missed” or “rapidly-growing” lesions in colonoscopists screening for colorectal cancer (CRC). Currently, lesions thought responsible for CRC include sessile serrated adenomas/polyps or flat and depressed-type lesions occurring on the right side of the colon, and there is an increasing need for endoscopic modalities to prevent overlooking these lesions. Colonoscopic screening using narrow-band imaging (NBI) during colorectal withdrawal from the colon, which was started at our clinic since November 2008, suggested that the NBI colonoscopy was superior to white-light imaging (WLI) colonoscopy in detecting flat and depressed-type lesions (1). With NBI, the depressed area of a lesion is recognized as “whitish” and the surrounding ring-like mucosa as “brownish”, which constitutes the “O-ring sign”.

Aims & Methods: We aimed to evaluate the incidence and characteristics of the “O-ring sign” in depressed-type colorectal lesions. A total of 227 endoscopically resected and histologically confirmed depressed lesions (Ha + Ic, 156; Hc, 71) were included for analysis. The colonoscopic images of these lesions were retrospec- tively examined for “O-ring sign” positivity and intensity (grade 0, negative; grade 1, mildly to moderately positive; and grade 2, highly positive). Of these, 16 were excluded as unevaluable and a total of 211 evaluable lesions were analyzed. Results: Of the 211 lesions (Ha + Ic: 141; Hc: 70) analysed, 84 (Ha + Ic: 60; Hc: 24), 105 (Ha + Ic: 69; Hc: 36), and 22 (Ha + Ic: 12; Hc: 10) were found to be in grades 0, 1, and 2, respectively, with 60.2% of these shown to be “O-ring sign” positive. (p=0.044). In the 22 data subanalyses, NICE/WASP classification for adenoma showed sensitivity, specificity, positive predictive value and NPV of 82% (70–90%), 94% (80–99%), 96% (87–100%) and 72% (56–85%), respectively; for rectosigmoid polyps ≤5mm, with high confidence level (n=35), NPV for adenoma was 80% (59–93%).

Conclusion: The overall performance of endoscopists significantly improved with own hands of training, but did not meet the standards for the implementation of the "do not reset" strategy. However, the results may have been affected by the addition of an additional category (1s) to the NICE classification.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) has been acceptable as a minimally invasive therapy and providing en-bloc resection for early malignant and pre-malignant lesions of gastrointestinal cancer. Colorectal ESD has some difficulties such as a risk of perforation and its severity compare to gastric ESD. Hence, Colorectal ESD is more challenging than gastric ESD in endoscopic technique. In Japan, where has high incidence of gastric cancer, endoscopists
could have many experiences of gastric ESD that may be beneficial for the introduction of colorectal ESD. However, little is known about the learning curves of the young endoscopists who perform the colorectal ESD first.

**Aims & Methods:** We conducted multi-center retrospective observational study to elucidate the safety and learning curve of the trainee who perform the colorectal ESD first. A total of 1199 patients were consecutively treated between 2010 and August 2016. The endoscopists were classified as trainee (first ESD performed by endoscopist A) or as expert (endoscopist B). The reported complications and the learning curve of endoscopist B were compared with that of endoscopist A.

**Results:** A total of 1199 patients were consecutively treated between 2010 and August 2016. The endoscopists were classified as trainee (first ESD performed by endoscopist A) or as expert (endoscopist B). The reported complications and the learning curve of endoscopist B were compared with that of endoscopist A. The average operation time was 68.0 minutes, the median 80.1 (range 13-353) minutes. The complications were divided into 3 groups: 1. General complications: bleeding, pancreatitis, cholangitis, and perforation. 2. Treatment complications: removal of stone failed, bile duct injury. 3. Adverse events: sedation reaction, respiratory events, allergic reaction. The median age of the patients was 70 (range 26-91) years old, and genders were 158 males and 102 females. Results: The comparison of the average operation time between endoscopist A and B showed a statistically significant difference (P value 0.04). In addition, the learning curve of endoscopist B showed a statistically significant difference (P value 0.001).

**Conclusion:** The learning curve of endoscopist B was significantly shorter than that of endoscopist A. This result suggests that the introduction of colorectal ESD first was acceptable by the trainee endoscopist who had no experience of gastric ESD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0884 LARGE BALLOON DILATATION VERSUS MECHANICAL LITHOTRIPSY AFTER ENDOSCOPIC SPHINCTERO TOMY IN MANAGEMENT OF LARGE COMMON BILE DUCT STONES AMONG CIRRhotIC PATIENTS**

M. I. Radwan1, M. H. Elmaraz2, I. M. Ibrahim2, M. E. Morsy2

**Introduction:** Removal of large common bile duct (CBD) stones is one of the challenges during ERCP and it seems more difficult in cirrhotic patients due to severe liver function impairment, as well as to the risk of adverse events during ERCP such as bleeding, pancreatitis, and other complications that are associated with liver cirrhosis. It is very important to consider the surgical benefits and complications between mechanical lithotripsy and large balloon dilation after sphincterotomy in patients with liver cirrhosis. Ninety-eight cirrhotic patients with calcuric obstructive jaundice were included and randomly divided into two groups. Group A was treated by large balloon dilation (LBD), Group B: 49 patients treated by mechanical lithotripsy. All patients underwent sphincterotomy initially. Inclusion criteria for this study included: Age of 18-60 years, any sex, liver cirrhosis patients Child A or B with clinical and laboratory proved obstructive jaundice, presence of large bile duct stones and severe selective cannulation of the bile duct. Exclusion criteria included: Known allergy to the used contrast material, Child C cirrhosis, the Need for needle knife precutting in order to achieve bile duct cannulation, Selective bile duct cannulation achieved after moderate EUS and fluoroscopy guidance in Asa III, Asa IV, or both. All patients were subjected to thorough history taking, complete clinical examination. Enzymes concentrations were measured before and after the procedure, complete blood count and liver function tests were performed before and after the procedure.

Results: There were no dropouts and all subjects remained in the study till the end of the study. The reported complications were mainly bile leakage and biliary stricture. The difference was not statistically significant (P value 0.61). The rate of adverse events in this study was 10.2% (10/98) and bleeding was the commonest reported complication (50% [5/10]; group B that was treated by ML developed more (16.3%) adverse events than group A treated by LBD (4.1%) and the difference was statistically significant (P value 0.04).

**Conclusion:** In conclusion, endoscopic sphincterotomy plus LBD is a safe and effective treatment for endoscopic removal of large common bile duct stones in cirrhotic patients when compared with endoscopic sphincterotomy plus ML. LBD is the most common adverse event reported in cirrhotic patients undergoing these procedures.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P0885 SAFETY AND EFFICACY OF ENDOSCOPIST-DIRECTED BALANCED PROPOFOL SEDATION (BPS) DURING RETROGRADE CHOLANGIO-PANCREATOGRAPHY (ERCP)**

**Introduction:** Endoscopist-directed balanced Propofol sedation (BPS), defined as a fixed dose of an opioid and benzodiazepine combined with incremental doses of propofol, has been shown to be a safe and effective moderate sedation regimen for gastroscopy and colonoscopy. However, there are very limited data on the safety and efficacy of endoscopist-directed BPS in ERCP.

**Aims & Methods:** We aimed to evaluate the safety and efficacy of endoscopist-directed BPS during ERCP, as well as to compare patient outcomes with anesthesiologist-directed BPS, for both in-patients and out-patients undergoing ERCP. We performed a retrospective cohort study using prospectively collected endoscopy data from the gastroenterology and biliary and pancreatic unit of a tertiary care center where endoscopy-directed BPS during ERCP is routine practice amongst the ERCPists, all of whom have up-to-date advanced cardiac life support (ACLS) certification. ERCP nurses also maintain up-to-date certification in ACLS and cardiopulmonary resuscitation equipment and medications are available within the advanced endoscopy suite. During ERCP, the endoscopist and the endoscopy nurse as a team were responsible for monitoring patient vital signs (e.g., pulse, blood pressure, oxygen saturation levels). Each endoscopist was responsible for directing the provision and dosing of the BPS. Patient-level demographics and pre/post procedure vital signs were collected along with BPS drug dosages, American Society of Anesthesiologists score (ASA) and measured "hard endpoint" patient outcomes, including: need for bag-mask ventilation or endotracheal intubation, and need for ERCP due to sedation effects, need for hospital admission post-ERCP (out-patients only) or need for change in level of hospital care (in-patients only), and mortality within 24 hours of ERCP.

**Results:** Over the course of 17 months (October 2015 – March 2017), 501 patients underwent ERCP and received endoscopist-directed BPS (Cohort 1: 380 [76%] inpatient, mean age 64.1 years, 46% males, 24% ASA I, 65% ASA II, 11% ASA III). During this same time period, 424 patients received anesthesiologist-directed BPS (Cohort 2: 19 [79%] inpatient, mean age 65.0 years, 67% males, 48% ASA I, 29% ASA II, 25% ASA III). In Cohort 1, the indications for ERCP were: 231 (46%) suspected cholelithiasis, 68 (13%) stent replacement, 62 (12%) evaluation of known/suspected malignancy, 48 (10%) jaundice, 40 (8%) post-hepato-biliary intervention complications, 8 (2%) abdominal pain, and 44 (9%) other/unspecified. BPS dosages (mean ± SD; range) were: Fentanyl 0.06 mg±0.02 mg: 0.05–0.10 mg; Midazolam 1.7 mg±0.7 mg: 1.0–2.5 mg; and Propofol 178 mg±103 mg: 10–640 mg. Propofol dose was inversely correlated with patient age (r = −0.42, p < 0.001), ASA score (r = −0.19, p < 0.001) and Mallampati score (r = −0.24, p < 0.001). No clinically meaningful differences were found in patient vital signs pre and post ERCP. Moreover, no patient required bag-mask ventilation, endotracheal intubation nor hospital admission/ change in level of in-hospital care following ERCP. One patient in Cohort 2 who...
received anesthesiologist-directed BPS, required bag-mask ventilation and the ERCP was aborted due to sedation effects. There was no mortality from any cause within 24 hours of ERCP. All patients were discharged from the advanced endoscopy suite without adverse events.

Conclusion: Endoscopist-directed BPS appears feasible, safe and efficacious for ASA I-III patients undergoing inpatient or outpatient ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0887 DUODENOSCOPES AND LINEAR ECHOENDOSCOPES ARE NOT CONTAMINATED WITH ORGANISMS CAUSING NATIONWIDE PERSISTENT HIGH PREVALENCE IN THE NETHERLANDS

1Digestive Endoscopy & Hepatology, Erasmus MC University Medical Center, Rotterdam/Netherlands
2Medical Microbiology And Infectious Diseases, Erasmus MC University Medical Center, Rotterdam/Netherlands

Introduction: Recent studies describe multiple outbreaks of multi-drug resistant organisms caused by contaminated duodenoscopes, used for endoscopic retrograde cholangiopancreatography (ERCP) procedures. Contamination of duode- noscopes has been attributed to their complex design, which includes a number of flexible parts such as forceps elevator and elevator wire channel. Linear echoendoscopes (LEs), used for endoscopic ultrasound (EUS) procedures, have a similar design with an additional balloon channel. Previously, we found that contamination of duode- noscopes was widespread in the Netherlands. It is unclear if the increased awareness of contamination and associated outbreaks has improved reprocessing outcomes of duodenoscopes and linear echoendoscopes (DLEs).

Aims & Methods: This cross-sectional study was conducted to determine the prevalence of bacterial contamination of all reprocessed DLEs in The Netherlands. All 75 Dutch ERCP/EUS centres were invited to sample all DLEs using centrally distributed kits, according to uniform sampling methods described in our video instructions. Local staff sampled four to six sites per DLE depending on endoscope type, including swabs (protection cap, forceps elevator), flushed (biopsy, suction, air/water and forceps elevator channel) and brushes (biopsy, air/water and balloon channel). Samples were centrally cultured. Bacterial culture and culture interpretation were consistent with Dutch guidelines.

Disclosure of Interest: All other authors have declared no conflicts of interest.

*C Primary analysis: success defined as score of 1 or 2 (no assistance/minimal verbal cues). Acceptable failure rate - p0 = 0.1 and unacceptable failure rate - p1 = 0.3 **Sensitivity analysis: success defined as score of 1 (stringent definition of success)

tumor extent using SpyDS plus mapping biopsy was 92%. One patient developed mild cholangitis after the procedure. As for IPMN, pancreatocystoscopy using a SpyDS could visualize intraductal papillary tumors in all patients, and SpyDS guided biopsy/cytology was successfully performed. Diagnostic accuracy of malignancy was 100% without any adverse event after the procedure.

Conclusion: Preoperative evaluation using a SpyDS plus histological examination for pancreaticobiliary neoplasm was found to be useful and safety. Further study is needed to establish evidence about the usefulness of this technique.

Introduction: Endoscopic retrograde cholangiopancreatography (ERC) is one of the most technically complex procedures performed by gastroenterologists. After a significant increase in the indications for implementing ERCP, gastroenterologists began to pay greater attention to complications identification and prevention. Despite the widespread improvement of endoscopic techniques and endoscopic training composition and volumes ensure ERC competence in the US. Aims & Methods: (i) To define ERC learning curves, utilizing a centralized database, with a focus on cannulation rates using a large national sample of AET programs (AETPs). (ii) To critically examine the composition of current ERC training composition and volumes ensure ERC competence in the US. Aims & Methods: (i) To define ERC learning curves, utilizing a centralized database, with a focus on cannulation rates using a large national sample of AET programs (AETPs). *A Primary analysis: success defined as score of 1 or 2 (no assistance/minimal verbal cues). Acceptable failure rate - p0 = 0.1 and unacceptable failure rate - p1 = 0.3 **Sensitivity analysis: success defined as score of 1 (stringent definition of success)
**Abstract:**

The paper reports the feasibility of establishing competence and overall cognitive (100%) competence among AETs in ERCP validating the shift away from endoscopist- versus assistant-controlled wire-guided cannulation. The results confirm the substantial variability in learning curves and competence among AETs in ERCP validating the shift away from endoscopist- versus assistant-controlled wire-guided cannulation. The authors conclude that methods to improve native papilla cannulation are needed to clarify the safety profile of either technique.

**Introduction:**

A recent randomised study by Buxbaum et al. demonstrated a significantly lower rate of post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PERCPP) in endoscopist- versus assistant-controlled bile duct cannulation. The study set out to audit the rates of PERCPP at the end of training, with a focus on the impact of post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PERCPP) in endoscopist- versus assistant-controlled bile duct cannulation. The authors aimed to clarify the safety profile of either technique.

**Results:**

The authors report that 20 AETs participated, and 20 AETs were included in the final analysis. A total of 250 procedures were audited. E1 performed 132 procedures (54% female; median age 63) and A1 performed 118 procedures (67% female; median age 63). The rates of PERCPP in E1 and A1 were 2.3% (3 patients) and 1.7% (2 patients) respectively. One 84-year-old patient of E1 with a presumed malignant common bile duct (CBD) stricture had PERCPP and died 17 days after ERCP, having opted for palliation. The remaining 4 patients had uneventful conservative management of PERCPP. E1 had one patient with immediate bleeding post-sphincterotomy controlled with a CBD stent whilst A1 had 2 patients requiring adrenaline injection for haemostasis. In addition, E1 had one patient with retroduodenal perforation managed conservatively and A1 had one patient with CT evidence of intraduodenal haemorrhage which was uneventful. Both E1 and A1 had one case each of uncomplicated hyperamylasaemia. A summary of complications, with patient and procedural characteristics, is listed in Table 1.

**Conclusion:**

In our observational study, which was not intended or powered for statistical analysis, there was no overt difference in the rates of PERCPP when comparing between endoscopist- or assistant-controlled wire-guided CBD cannulation. The overall complication rate was similar and although there were some differences in procedural characteristics between the two endoscopists, there were no characteristics predisposing to PERCPP overtly skewed towards either endoscopist's case load. Further randomised trials, or a crossover study, provided the endoscopists and assistants were equally competent in both methods of wire cannulation, are needed to clarify the safety profile of either technique.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Aims & Methods: The aim of this study was to evaluate the impact of this protocol on the incidence and severity of PEP. Patients and methods Retrospective analysis of all patients submitted to ERCP in one center during 16 months, including patients hospitalized in the gastroenterology department who were managed according to the AHP and patients hospitalized in other departments who underwent standard hydration (SH). Patients who underwent AHP received intravenous sodium lactate solution (RL) at 200 mL/hour starting 1 hour before, during the procedure and the anesthetic recovery; in those who remained asymptomatic after the ERCP, the RL was maintained at 100 mL/hour for 8 hours and after it was changed to a balanced salt solution with glucose (PG) at 80 mL/hour; in those patients who had abdominal pain or amylase >3 times normal limit after ERCP, the RL was maintained at 100 mL/hour during 8 hours and after it was changed to PG at 120 mL/h. We evaluated the incidence and severity of PEP, the established point and procedure-related risk factors for PEP (except the difficulty of cannulation) and the occurrence of complications. Data were analyzed with SPSS statistical software.

Results: We analyzed 192 patients, 290 ERCP (AHP n= 168, SH n= 122). The incidence of PEP and procedure-related factors for PEP (except the difficulty of cannulation) and the occurrence of complications. Data were analyzed with SPSS statistical software.

Introduction: Pancreatitis is the leading complication of endoscopic retrograde cholangiopancreatography (ERCP). Some studies have shown that the use of vigorous hydration may reduce the incidence of this serious adverse event, the post-endoscopic retrograde cholangiopancreatography pancreatitis (PEP). In our department we implemented an aggressive hydration protocol for patients undergoing ERCP in order to prevent PEP.

Aims & Methods: The aim of this study was to evaluate the impact of this protocol on the incidence and severity of PEP. Patients and methods Retrospective analysis of all patients submitted to ERCP in one center during 16 months, including patients hospitalized in the gastroenterology department who were managed according to the AHP and patients hospitalized in other departments who underwent standard hydration (SH). **PROSPECTIVE STUDY OF EARLY PRECUT VS. UTMOST PRECUT WITH PANCREATIC STENT IN INITIAL PANCREATIC DUCT CANNULATION**

E.T. Park, B.C. Yun, S.U. Lee, B.H. Han
Internal Medicine, Kosin University, Gospel Hospital, Busan/Korea, Republic of

Contact E-mail Address: eunpark@hanmail.net

Introduction: In biliary access, repeated biliary cannulation attempts are a risk factor for post ERCP pancreatitis (PEP). Early precut is an effective technique for successful biliary cannulation and can significantly reduce the incidence of PEP. The aim of this study was prospectively to evaluate clinical efficacy the performance of utmost early precut with pancreatic stent in the patients whom pancreatic duct cannulation was performed initially.

Aims & Methods: When guidewire was placed in the pancreatic duct initially by chance, the patients were randomized into early precut (Group A) or utmost precut sphincterotomy with pancreatic stent (Group B). In Group A, pancreatic duct cannulation within 5 times and attempted precut papillotomy with or without early precut sphincterotomy. In Group B, the pancreatic stent was inserted and then precut with an incision over a pancreatic stent was done. Main outcome measurements were frequency of successful CBD cannulation and post-procedure related complications.

Results: From January 2015 to August 2016, the two groups were similar with regard to patient demographics. A total of 50 patients were enrolled. 26 patients were assigned to the Group A and 24 to the Group B. Successful CBD cannulation was achieved in 23 of 26 (88.5%) patients in the Group A and 23 of 24 (95.8%) patients in the Group B. The mean cannulation time was 16 minutes in the Group A and 14.8 minutes in the Group B. Post-procedure hyperamylasemia was significantly higher in Group A. The overall incidence of post-procedure pancreatitis was 11.5% (3/26) in the Group A and 4.2% (1/24) in the Group B (P < 0.001).

Conclusion: In patients with pancreatic duct cannulation initially by chance, compare to early precut group, utmost early precut with pancreatic stent over the guidewire initially facilitates biliary cannulation and the success rate is also high but also promise low incidence of post-ERCP pancreatitis. In experienced hands, utmost early precut technique can dramatically reduce the trauma of ampulla and risk of PEP compared with conventionally persistent cannulation attempts. Contact E-mail Address: ynnahh@schmc.ac.kr

Introduction: In a recent, a digital version of single-operator cholangioscope (SpyGlass DS) and direct POC (DPOC) using a multibending ultrasound endoscope were introduced as improved forms of each POC, especially in image quality and technical difficulty, respectively.

Aims & Methods: In this study, we prospectively compared the procedure success rate of SpyGlass DS and DPOC for diagnosis and treatment of BD lesions. A total of 15 patients with BD lesions (diameter of CBD ≥8mm) requiring evaluation or treatment using were enrolled prospectively. All patients received POCs using SpyGlass DS and multibending ultrasound endoscope for DPOC.

According to the presence of obstructive lesion, all patients were classified as obstructive type or non-obstructive type, respectively. Procedural success defined as an ability to advance the cholangioscope to the desired target and get adequate cholangioscopic visualization for the targeted lesion.

Results: The overall technical success rates of SpyGlass DS and DPOC were 100% and 93.3%, respectively (P = 0.5). In DPOC, 1 patient was failed to insert the endoscope into the CBD. In SpyGlass DS, 2 patients were failed to visualize the targeted lesion. The procedural success rates of SpyGlass DS and DPOC according to the type of lesion were not different in 9 obstructive type (100% vs. 88.9%, P = 0.5) and 6 non-obstructive type (66.7% vs. 100%, P = 0.227). The successful diagnostic and therapeutic procedures by DPOC and SpyGlass DS were observed in 8 of 8 patients (100%) and 7 of 9 patients (77.8%) (P = 0.265). respectively.

Conclusion: Both advanced image quality of SpyGlass DS and improved technical difficulty of DPOC by a multibending ultrasound endoscope showed comparable and high procedure success rates in patients with dilated BD. Future prospective studies focused on overall cost savings and long-term clinical outcomes are seems to be required for deciding adequate indications of each POC systems.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Management of common bile duct stones (CBDs) in patients with borderline CBD presents a surgical challenge. The aim of this study was to compare conservative treatment with endoscopic stone extraction for the treatment of borderline CBD with stones.

Aims & Methods: This prospective randomized controlled trial includes patients with CBDs in borderline CBD (CBD < 10mm) associated with gallbladder stones who were treated with conservative treatment or endoscopic stone extraction followed by laparoscopic cholecystectomy (LC) and intraoperative cholangiogram (IOC). The primary outcome, was successful CBD clearance. The secondary outcomes were the overall complications, cost, and hospital stay.

Results: LC and IOC revealed complete clearance of CBDs in 48 (96%) cases in the endoscopic retrograde cholangiopancreatography (ERCP) group (52% of patients by ERCP, and 44% of patient passed the stone spontaneously), and in the remaining two patients, the CBDs was removed by transcytosis exploration. In the conservative group, LC and IOC revealed complete clearance of CBDs in 90% of cases, and in the remaining 10% of patients, the CBDs was removed by post-ERCP papillotomy. Post-ERCP pancreatitis (PEP) is noticed significantly in the ERCP group (2% versus 8% [P = 0.04]). The average net cost was significantly higher in the ERCP group. Recurrent biliary symptoms developed significantly in the ERCP group after 1 year (10% versus 0%, P = 0.02) in the form of recurrent cholangitis and recurrent CBDs.

Conclusion: Management of CBDs in patients with borderline CBD represents a surgical challenge. Borderline CBD increases the technical difficulty of ERCP and increases the risk of PEP. Conservative management of CBDs in borderline CBD not only avoids the risks inherent in ERCP and unnecessary preoperative ERCP, but it is also effective in clearing CBDs. The hepatobiliary surgeon
During this 12-months period we have performed 1102 ERCPs, in 458 of them we had virgin papilla. All ERCPs had therapeutic intentions and all of the patients were followed up. In 13 patients papillary stenosis was observed due to duodenal stenosis (10/13) or postoperative situations (3/10). In two of them the indication was ceased (because the bile duct obstruction resolved spontaneously), 11 patients got percutaneous transhepatic drainage (PTD). The primary cannulation success rate of accessible papillae was 88.5% (394/445) while the overall cannulation success was 96.6% (430/445). 56.1% of primary successful cannulations were achieved by conventional method, in 14.2% we used pancreatic guidewire assisted technique, in 20.1% we used early precut sphincterotomy, and in the last 4.6% we used combined techniques. In 51 primary unsuccessful cases we repeated ERCP attempt 4 in 4 days on average and successfully cannulated 70.5% (36/51) of them at the second or third attempts. 27 of them were achieved by conventional method, 7 of them after extending the precut, one case was achieved by pancreatic guidewire technique, and we used profllaetic pancreatic stent in one patient, as well. Out of the 15 patients with finally unsuccessful cannulation, we performed precut without deep cannulation in 10 cases. 7 of them resolved after precut, 2 of the 10 patients got PTD and one patient required surgery. In 4 patients out of the 15 unsuccessful cannulations the obstruction resolved without any further intervention and one patient got PTD. We had in sum 3.4% (15/445) post-ERCP pancreatitis, 7 of them were mild, and 8 moderate, we had no severe one. We observed endoscopic signs of bleeding in 34 cases that required endoscopic therapeutic intervention (infiltration/coagulation/stenting), of them 7 of (6%) required blood transfusion. Three patients suffered perforation during ERCP. One of them got biliary stent and was discharged uneventfully on the 8th day. We had 2 sphincterotomy related perforations, 1 had early surgery – he died on the 14th day, another patient had delayed surgery, he recovered.

Conclusion: Quality assessment of ERCP performance is essential. Our overall cannulation rate was acceptable. We used pancreatic guidewire technique just after repeated, successful passage of pancreatic guidewire or just as part of the phase of process to avoid long lasting traumatising of the papilla. Our complication rate of post-ERCP pancreatitis was good while the post-sphincterotomy bleeding rate should be considered higher than in the literature, therefore we changed the settings of electrosurgical current.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: The aim of this study was to evaluate the accuracy of T1 stage subdivision of ESCC by higher frequency EUS probe prior to ESD treatment. From 2013 to 2016, there are 825 patients diagnosed with ESCC, further stage with 8% computed tomography and PET-CT. The EUS examination is performed with miniprobe (UM-2R, 12 MHz, UM-3R, 20 MHz; Olympus Optical Co. Ltd., Tokyo, Japan) and water immersion method. From 2013 to 2016, there are 825 patients diagnosed with ESCC, further stage with 8% computed tomography and PET-CT. The EUS examination is performed with miniprobe (UM-2R, 12 MHz, UM-3R, 20 MHz; Olympus Optical Co. Ltd., Tokyo, Japan) and water immersion method. The enrolled criteria of this study; 1; ESCC was proved by biopsy result. 2; T1a or T1b stage diagnosed by EUS. 3; No lymph nodes or distant metastasis. 4; Treatment with ESD. All EUS-T stage results were correlated with final pathological T stage, including T1a/T1b.

Results: Total 90 patients enrolled in this study and there were 83 patients with T1a and 7 were T1b stage of ESCC by EUS. After ESD treatment, all specimens were sent for histological examination and the final diagnosis was based on the cytology or histology results. The accuracy of the staging was obtained by the analysis of ROC curves. Results: Included 29 patients in a total of 30 lesions with conclusive histological/ cytologic diagnosis (8 inflammatory masses, 19 adenocarcinomas, 2 neuroendocrine tumors and 1 undifferentiated carcinoma). The mean SR value was significantly higher in the malignant tumors compared with the benign tumors (55.56 vs 23.93, p < 0.001). The sensitivity and specificity of SR for differentiation of pancreatic malignancy for a cut of 15.89 were, respectively, 95.45% and 87.5% (area under the curve of 0.89, 95% CI). The overall accuracy of the EUS elastography using the SR for the detection of pancreatic malignancy was 93%.

Conclusion: Quantitative EUS elastography presents good accuracy in the differentiation between malignant and benign pancreatic masses. It is a promising EUS technique in the diagnostic approach of solid pancreatic lesions, which may complement the study and characterization of the tumors, aiding in the diagnostic and follow-up of these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Quantitative second generation elastographic ultrasound (EUS) elastography allows the quantitative analysis of tissue stiffness and can be a useful auxiliary tool in the differential diagnosis of pancreatic solid tumors (1)(2).

Aims & Methods: The aim of this study was to evaluate the accuracy of the quantitative EUS elastography in the differential diagnosis of pancreatic solid masses, discriminating malignant from benign masses, using strain ratio (SR) analysis. A prospective study was performed for 15 months and included 29 consecutive patients who underwent EUS for the evaluation of solid pancreatic masses. EUS elastography was performed by 2 operators, using a linear echoendoscope. The mean of 3 measures was considered as the SR final result for each lesion. EUS-fine-needle aspiration of the lesion was performed after SR assessment and the final diagnosis was based on the cytology or histology results. The accuracy of the elastography was obtained by the analysis of ROC curves. Results: Included 29 patients in a total of 30 lesions with conclusive histological/ cytologic diagnosis (8 inflammatory masses, 19 adenocarcinomas, 2 neuroendocrine tumors and 1 undifferentiated carcinoma). The mean SR value was significantly higher in the malignant tumors compared with the benign tumors (55.56 vs 23.93, p < 0.001). The sensitivity and specificity of SR for differentiation of pancreatic malignancy for a cut of 15.89 were, respectively, 95.45% and 87.5% (area under the curve of 0.89, 95% CI). The overall accuracy of the EUS elastography using the SR for the detection of pancreatic malignancy was 93%.

Conclusion: Quantitative EUS elastography presents good accuracy in the differentiation between malignant and benign pancreatic masses. It is a promising EUS technique in the diagnostic approach of solid pancreatic lesions, which may complement the study and characterization of the tumors, aiding in the diagnostic and follow-up of these patients.

Introduction: Significant heterogeneity in geographic distribution in the prevalence of mediastinal lymphadenopathies have been documented in CT studies. Awareness of the geographic prevalence and characteristics of lymphadenopathies will be relevant when performing endoscopic ultrasound staging (EUS) in patients with malignant neoplasms.

Aims & Methods: 1. To document the prevalence and characteristics of mediastinal lymphadenopathies in patients submitted to EUS for non-malignant extra-thoracic disease. 2. To identify predictive factors for the presence of mediastinal lymphadenopathies. A prospective, unicentric study was performed between July and December 2016. Mediastinal stations 8, 9, 6, 7, 5, 4L and 2 were systematically evaluated using a linear echoendoscope in all patients undergoing EUS due to benign extra-thoracic pathology, without history of oncologic disease.

Demographic, clinical and EUS features were analysed, including location, number, shape, dimensions and echogenicity of the lymphadenopathies.

Results: We analysed 75 patients: M: F, 32:43; Mean age: 63.6 years. The majority (72%) of the patients presented lymphadenopathies in at least one mediastinal station, and 88% were found in stations 7 or 4L. Only 6% of these had short axis diameter > 10 mm, most were oval (59%) or triangular (37%) and 40% had a hyperechoic center. The prevalence of lymphadenopathies was higher in smoker patients (85% vs 64%, p = 0.024), with a higher average number of lymphadenopathies per patient in this group (2.1 vs 1.6; p = 0.017). Similar findings were documented in patients with relevant occupational or environmental respiratory exposure (prevalence 83% vs 71%; average number 3 vs 1.7). By logistic regression analysis, none of the variables assessed independently were associated with the presence of mediastinal lymphadenopathies.

Conclusion: This prospective Portuguese study documented a higher prevalence of mediastinal lymphadenopathies than previously reported in northern Europe, in particular due to the existence of oncologic disease. This higher prevalence, mostly in smokers or patients with relevant occupational exposure, may negatively influence the specificity and positive predictive value for malignancy of mediastinal lymph node (N) staging by EUS, with particular relevance in esophageal and pulmonary cancer staging.

Results: In our series, 16/22 females (73%), mean age 58 ± 13 years old (29–77). Most followed, 56 ± 34months (6–116). Cyst location: head/body/tail:11/8/3. Mean size in 1st EUS-FNA: 3 ± 1, 5cm (1, 2–7) cm vs 2nd EUS-FNA: 3, 1 ± 1, 9 cm, (1, 2–10) cm; with both EUS-FNAS with as 36% cysts > 3 cm. Mass/mural nodule present:7/22 vs 8/22 on 2nd EUS-FNA. Repetition of EUS-FNA does not引来 change or increase size. Mean interval between the two subsequent EUS-FNAS: 35 months (3–117). Cysts with CEA level > 192 g/mL (7 vs 10 patients) and acellular cystic fluid samples (62% vs 59%), between the 1st and the 2nd EUS-FNA, not statistically significant. There were 4 patients operated that had previously a repeated EUS-FNA (2nd EUS-FNA 3, 4, 7 and 10 months after the 1st EUS-FNA). Surgical pathology (respectively): Intraductal due to: nodule, imagiologic change or increasing size. Mean interval between the operated that had previously a repeated EUS-FNA (2nd EUS-FNA 3, 4, 7 and 10 months after the 1st EUS-FNA).

Aims & Methods: The aim of this study is to show the actual method of LBC and to evaluate the utility of LBC in EUS-FNA samples of the pancreatic lesions. 292 specimens obtained by EUS-FNA from patients with pancreatic disease were included in this study. Clinical history was punched on 210 cases, acinar cell carcinoma in three cases, adenosquamous cell carcinoma in one case, invasive ductal carcinoma derived from IPMN in three cases, metastatic pancreatic tumor in eight cases, pancreatic neuroendocrine tumor (PNET) in 20 cases, solid pseudopapillary neoplasm (SPN) in five cases, mass-forming pancreatitis in four cases, and autoimmune pancreatitis (AIP) in 40 cases. Just after EUS-FNA, tissue sample in the FNA needle was flushed out into petri dish with saline. The specimen was carefully examined to confirm the presence of intact cells and cytopreparation, formalin-fixed and processed for pathological evaluation. All residual liquid specimen in place was immediately immersed in liquid-based fixation medium (CytoRich™Red) at the bedside. The liquid was centrifuged and processed (1,000 X g for 5 min) on the wards. The preparation was reviewed by two experienced cytopathologists. The final diagnosis was reached relying on surgery in 9 patients (31%), on histology or mucin staining, a typical pattern of nCLE or by consensus (on EUS endo-scopy (nCLE) of the cyst wall and/or contrast-enhanced EUS was performed. Antigen 19-9 (CA 19-9), Carcinoembryonic Antigen (CEA) and glucose. When sent for cytology, mucin staining and determination of amylase, Carbohydrate Antigen 19-9 (CA 19-9), Carcinoembryonic Antigen (CEA) and glucose. When sent for cytology, mucin staining and determination of amylase, Carbohydrate Antigen 19-9 (CA 19-9), Carcinoembryonic Antigen (CEA) and glucose.

prophylaxis is mandatory during EUS-FNA of PCLs, since it does not seem to have a protective effect. Moreover, the rate in antibiotic resistance and possible adverse effects related to their use should be balanced against the very low infectious complication rate of EUS-FNA. One limitation of our study is its retrospective nature, with a significant delay between the EUS-FNA and the time to inquiry, which could have biased the patients answers.

Introduction: The endoscopic ultrasound (EUS) has proven useful in the study and evaluation of the adrenal gland (AG) by endoscopic ultrasound-guided fine needle aspiration (EUS-FNA), in both the left and right glands.

Aims & Methods: To analyze the diagnostic performance, safety, impact on clinical management, predictors of malignancy and cyto-pathological correlation of the EUS-FNA with adrenal gland.

Results: A review of 205 EUS-FNA of adrenal gland in 200 patients (154 males). Average age: 65.3 (DE 9.6). Primary tumor: lung 69%, unknown 10%, other 20%. Adrenal gland left (191); adrenal gland right (14). Main features: CT scan-positive 80%, CT scan-negative 20%, tumor diameter 5 cm (95%), tumor diameter ≤5 cm (5%), tumor diameter >5 cm (14%). Tumor pathology: benign (90%), malignant (10%). No deaths or serious adverse events were recorded. Agreement between EUS-FNB and surgical pathology was 100% with respect to diagnosis, despite significant advances over the past decade. Stereotactic body radiation therapy (SBRT) is able to deliver higher biological effective dose to the tumor over a shorter period of time with reduced local toxicity compared to conventional external beam radiation therapy. EUS-guided fiducial placement has shown to improve the accuracy and localization during SBRT.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Conventional EUS-guided fiducial placement requires back-loading each fiducial through the tip of the EUS needle. Thus, delivery of multiple fiducials can be cumbersome and time-consuming.

**Aims & Methods:** We aimed to evaluate the feasibility, safety, and performance characteristics of fiducial deployment in PC patients using a novel exchangeable FNA system with pre-loaded 22-gauge EUS fiducial needles. This was a single-center pilot study of 10 consecutive PC patients undergoing EUS-guided fiducial placement for SBRT. The fiducial delivery system contains a 22-gauge EUS needle pre-loaded with 2 gold markers with knurled design. After the 2 markers were deployed, the EUS fiducial needle insert was exchanged out for a second pre-loaded EUS fiducial needle insert through the exchangeable FNA system for total deployment of 4 markers in each patient. All patients underwent CT after fiducial placement as part of SBRT to evaluate successful deployment and complications. The primary endpoint was procedure success, defined as deployment of at least 3 fiducials into the desired target area. Secondary endpoints were total procedure time, fiducial delivery time, and safety.

**Results:** Fiducial placement was attempted in 10 consecutive patients with PC (mean age 61.7 years, males 60%). The tumor was located in the head (n = 6), neck (n = 2), and the body (n = 2) of the pancreas. Mean size of the tumor was 2.7 cm (range 1.6–5.3). Procedure success was achieved in all 10 (100%) patients. All 10 patients successfully received fiducials. Mean total procedure time was 12.2 minutes (range 5–18). By comparison, using historic controls of the first 10 patients who underwent conventional EUS-guided fiducial placement, the mean total procedure time was 26 minutes (range 16–44, p = 0.002). Mean fiducial delivery time was 4.2 minutes (range 1–8). There were no immediate or delayed (7 days) complications.

**Conclusion:** EUS-guided fiducial placement with a novel exchangeable FNA system with pre-loaded 22-gauge EUS fiducial needle is quick, technically feasible and safe. This system may theoretically decrease the risk to the clinical staff by eliminating the need for back-loading fiducials through exposed needle tip and handling of potentially dirty needles. Given the potential safety and time advantages, further prospective studies are warranted for validation.

**Introduction:** Bubbles can impair the visualization of the small bowel (SB) mucosa during capsule endoscopy (CE).

**Aims & Methods:** Our aim was to develop and to validate a computed algorithm, which would evaluate the abundance of bubbles in SB-CE. Two sets of 200 SB-CE normal still frames were extracted from 45 complete third-generation SB-CE videos. Two experienced SB-CE readers analyzed both sets of images twice, in a random order. Each still frame was categorized as "scarcely in" or "abundant in bubbles (<10% or >10% of bubbles covering the frame, respectively). Reproducibility (κ coefficient), sensitivity (Se), specificity (Sp), Receiver Operating Characteristic (ROC) curve, and calculation times were measured for different algorithms (Grey-level of co-occurrence matrix [GLCM], fractal dimension, Hough transform, and Speeded-Up Robust Features [SURF]) using the experts’ reading as reference. Algorithms with highest reproducibility, Se and Sp were then selected for a validation step on the second set of frames.

**P0918 AGE AND GASTRIC EMPTYING TIME ARE PREDICTIVE FACTORS FOR INCOMPLETE CAPSULE ENDSCOPY: RESULTS OF A MULTIVARIATE ANALYSIS IN A LARGE STUDY POPULATION**

**Introduction:** Capsule endoscopy has been demonstrated to be a first-line tool for small bowel visualization. However, it has some limitations such as incomplete examinations - i.e: the capsule does not reach the cecum - leading to missing lesions.

**Aims & Methods:** To evaluate those factors that can predict complete examinations, to identify those patients at risk for incomplete procedures and to define those approaches that may improve the efficiency of the examination reducing the time of the diagnostic process as well as the need to repeat procedures. A total of 1918 patients who underwent capsule enteroscopy at our center between 2008 and 2015 were retrospectively analyzed. We evaluated variables such as age, sex, anthropometric parameters, comorbidity, drugs, outpatient care, analytical parameters, indication of the test and transit times. Initially, a univariate analysis and then, a multivariate analysis using a logistic regression model were carried out.

**Results:** In the univariate analysis, the following variables showed a statistically significant association with the rate of incomplete examinations: age, gender, indication of procedure, outpatient care, history of abdominal surgery, heart disease, capsule ingestion posture, hemoglobin levels, renal failure and both gastric and small bowel transit times. These variables were included in the multivariate analysis were age > 65 years (OR = 1.99, 95% CI: 1.34–2.95), gastric transit time > 41 minutes (OR = 2.60, 95% CI: 1.72–3.93) and small bowel transit time > than 286 minutes (OR = 3.52 95% CI: 2.26–5.48) showed a statistically significant association with the risk of incomplete examination.

**Conclusion:** Incomplete capsule endoscopy is predictable. Patients older than 65 years and/or a gastric emptying greater than 42 minutes are independent predictive factors for incomplete procedures. In these clinical scenarios, pharmacological preventive measures or endoscopic introduction should be taken into account to avoid incomplete examinations.

Introduction: A variety many of pharmaceuticals for the treatment of colon disease can be more effective and have less side effects if targeted for precise delivery in the colon. Over the years, many types of delivery vehicles have been developed with the aim of targeting the colon, such as PB based delivery technologies, time dependent drug release mechanisms, pressure based mechanisms, flora sensitive mechanisms and others. These technologies have performed with variable degrees of success due to the wide distribution of motility and other physiological variability between patients. We describe a novel capsule technology which incorporates a diffused gas sensor that allows for an accurate sensing of colon entrance; as well as a 3D real time positioning system that allows for an accurate, programmable, localized, and in colon drug delivery system.

Aims & Methods: Data was collected from 14 patients that swallowed capsules in a multi-center clinical trial using an x-ray imaging capsule (GUT 2016). The patients were sent home to continue their normal life routine while the capsule naturally traveled in the gastrointestinal tract until excretion. (Subjects signed informed consent forms and the study was performed after local IRB approval). The capsules contained electronics and software that allowed for live communication between the capsule and a recording device that is placed directly on the patient’s back. This device tracks the position of the capsule and communicates with it, receiving diffused gas pressure from the capsule sensor and fusing this information with 3D position information from the capsule. The capsule system exhibited position accuracy of ±1 cm and the ability to detect movements in real time, as well as potential of ~1 ml of payload for drug containment.

Results: The average total transit time of the capsule was 43 hours (range: 15–68 hours). The average transit time to cecum was 13.8 hours, and the average time across the colon was 12.8 hours (range 6–25). The position tracking and the RF communication between the capsule and the recorder showed >90% coverage in all cases, even in obese patients. No adverse events were reported. Figure 1 illustrates the recorder placement on the patient back. Figure 2 is a typical averaged capsule position trace in the colon.

Conclusion: A capsule with accurate position tracking, 2-way communication, and on line algorithms can determine colonic entrance and identify exact locations in the colon. A wide variety of drugs can accurately be delivered to their exact target in the colon. It enables for a more effective (high dose) and less toxic (no systemic delivery) therapy for IBD and cancer.

Introduction: Colon Capsule Endoscopy (CCE) procedure requires a preparation regimen, which provides a clean colon, clear capsule images and promotes capsule propulsion through the entire colon. A four-point cleansing grading scale system (poor, fair, good and excellent) has been used to describe the quality of colon preparation. “Poor” and “fair” are considered inadequate cleansing, while “good” and “excellent” – adequate for polyp detection. Adequate cleansing has been associated with significantly higher diagnostic accuracy, when compared with inadequate cleansing (72% vs. 28% respectively; P-value < 0.007). When stratifying cases based on the colonoscopy miss rate of 2%, depending on polyp size and histology [1]. Colon Capsule Endoscopy (CCE) is a visualization diagnostic modality of the colon mucosa, which has demonstrated high sensitivity for polyps and adenomas [2]. Determining the nature of polyps detected by CCE but missed by the imperfect gold standard (colonoscopy), may facilitate both optimization of CCE application (potential CCE additive value) and increase colonoscopy polyp detection.

Aims & Methods: Characterize polyps detected by CCE, which were missed by colonoscopy. 695 screening population participants, from 17 sites in the United States and Israel, underwent CCE procedure followed by a blinded colonoscopy. The overall colonoscopy adenoma detection rate in this study was very high – 39% [2]. Following the blinded colonoscopy, the patient’s CCE report was assessed. Based on the findings in this report, the colonoscopy performing physician decided whether or not to immediately follow up with a second colonoscopy. 70 of the CCE findings were detected by the second colonoscopy. The 70 polyps were compared with 683 polyps detected by blinded colonoscopy, using logistic regression model. Adjusted Odds Ratios (Adj.OR) and corresponding Confidence Intervals (CI) were estimated.

Results: Of the 70 polyps missed by first colonoscopy and detected by second colonoscopy, 20 (29%) were ≤ 6 mm or larger (based on colonoscopy size classification), 19 (27%) were either adenomatous or sessile serrated lesions and 16 (23%) were described as either flat or sessile-flat by colonoscopy performing physician. Stratification of polyps based on location:

<table>
<thead>
<tr>
<th>Location</th>
<th>Detected by blinded colonoscopy (n=683)</th>
<th>Detected after CCE and unblinding (n=70)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cecum</td>
<td>64 (84%)</td>
<td>12 (16%)</td>
</tr>
<tr>

</tbody>
</table>

Abstract: P0920

Colon cleansing Sensitivity (≥6 mm); n = 272 Specificity (≥6 mm); n = 495

<table>
<thead>
<tr>
<th>Polyp Size</th>
<th>Adequate cleansing</th>
<th>Inadequate cleansing</th>
<th>P-value</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;6 mm</td>
<td>153/195 (78.5%)</td>
<td>54/77 (70.1%)</td>
<td>0.147</td>
</tr>
<tr>
<td>≥6 mm</td>
<td>308/350 (88.0%)</td>
<td>130/145 (89.7%)</td>
<td>0.600</td>
</tr>
</tbody>
</table>

Poor cases had significantly lower CCE sensitivity compared with fair, good and excellent cases, for 6 mm polyps (P-value = 0.007). When stratifying cases based on the current adequacy cutoff, sensitivity for 6mm polyps is similar in inadequate (“poor” + “fair”) cases compared to adequate (“good” + “excellent”) cases (70.1%, 78.5% respectively; P-value = 0.147).
Multivariate logistic regression revealed that after adjusting to polyp’s size, cecal and rectal segments were associated with increased chance of CCE additive value to colonooscopy (coccum vs. ascending or transverse colon: Adj.OR = 3.2 [95%CI: 1.3–7.6] and Adj.OR = 4.3 [95%CI: 1.4–14.6] respectively; rectum vs. ascending or transverse colon: Adj.OR = 2.6 [1.1–5.8] and Adj.OR = 3.6 [95%CI: 1.2–11.4] respectively). There were 59 patients (8.49% of study population), with at least one CCE additive value to colonooscopy event.

Conclusion: CCE has the ability to detect polyps missed by traditional colonooscopy, especially lesions in the cecum and rectum.
