Abstract: In this paper, we propose a secondary consensus-based control layer for current sharing and voltage balancing in DC microGrids (mGs). Differently from existing approaches based on droop control, we assume decentralized Plug-and-Play (PnP) regulators at the primary level, as they provide voltage stabilization and their design complexity is independent of the mG size. We analyze the behavior of the closed-loop mG by approximating local primary control loops with unitary gains. This analysis can be extended to the more complex case where primary control loops are abstracted into first-order transfer functions (Tucci et al., 2016a). Besides showing stability, current sharing, and voltage balancing in the asymptotic régime, we describe how to design secondary controllers in a PnP fashion when Distributed Generation Units (DGUs) are added or removed. Theoretical results are complemented by simulations using a 5-DGU mG implemented in Simulink/PLECS.

Keywords: Distributed control, voltage control, asymptotic stability, electrical networks, renewable energy systems.

1. INTRODUCTION

Power generation and distribution are rapidly changing due to the increasing diffusion of renewable energy sources, advances in energy storage, and active participation of consumers to the energy market (Ipakchi and Albuyeh, 2009). This shift of paradigm has motivated the development of microGrids (mGs), commonly recognized as small-scale power systems integrating Distributed Generation Units (DGUs), storage devices and loads. Since AC power generation is the standard for commercial, residential and industrial utilization, several studies focused on AC mGs (Guerrero et al., 2013; Riverso et al., 2015; Bolognani and Zampieri, 2013). However, nowadays, DC energy systems are gaining interest (Dragicevic et al., 2016) because of the increasing number of DC loads, the availability of efficient converters, and the need of interfacing DC energy sources and batteries with minimal power losses. The basic issues in control of DC mGs are voltage stabilization (Dragicevic et al., 2016; Tucci et al., 2016b) and current sharing, the latter meaning that DGUs must compensate constant load currents proportionally to given parameters (for example, the converter ratings) and independently of the mG topology and line impedances. Current sharing is crucial for preserving the safety of the system, as unregulated currents may overload generators and eventually lead failures or system blackout (Han et al., 2016). An additional desirable goal is voltage balancing, i.e. to keep the average output voltage of DGUs close to a prescribed level. Indeed, load devices are designed to be supplied by a nominal reference voltage: it is therefore important to ensure that the voltages at the load buses are spread around this value. To realize these objectives, hierarchical control structures have been proposed. In the primary layer, current sharing regulation is usually implemented through decentralized droop controllers. However, droop regulators alone induce steady-state voltage drifts and might fail to guarantee voltage stability. For solving this problem, in (Zhao and Dörfier, 2015; Meng et al., 2016; Andreasson et al., 2014) it has been proposed to complement them with a secondary distributed control layer based on consensus algorithms. The main drawback of these approaches is that voltage stability critically depends on the communication network, which can be compromised by faults, delays or cyber attacks. Moreover, in terms of control design, the tuning of stabilizing droop and consensus controllers is often done in a centralized fashion, i.e. exploiting knowledge about all DGUs and lines (Dragicevic et al., 2016). Synthesis algorithms of this kind become prohibitive for large mGs or networks with flexible structure. This motivated the development of scalable design procedures for local primary controllers as in (Tucci et al., 2016b) and (Zhao and Dörfier, 2015).
The aim is to stabilize the voltage only via primary decentralized controllers. These regulators, termed Plug-and-Play (PnP), have the following features: (i) the computation of the local controller for a DGU can be cast into a local optimization problem, (ii) each optimization problem exploits information about the DGU only and, at most, the power lines connected to it, and (iii) when a DGU is plugged-in, only neighboring DGUs must update their local controllers.

The goal of this paper is to enhance PnP controllers with secondary regulators in order to achieve current sharing and voltage balancing. Similarly to (Zhao and Dörfler, 2015), we exploit consensus algorithms requiring DGUs to communicate in real-time over a network with arbitrary, yet connected, topology. There are, however, several differences between the approach in (Zhao and Dörfler, 2015) and the present paper. First, as recalled above, in (Zhao and Dörfler, 2015) the networked secondary layer is necessary for voltage stability, as primary loops induce steady-state voltage drifts. In our case, secondary controllers can be turned off without compromising voltage stability. Second, in (Zhao and Dörfler, 2015) DGUs under the action of primary controllers are abstracted into ideal voltage regulators. We also use this simplification, but only for tutorial reasons. In fact, in (Tucci et al., 2016a) we show that our proof can be extended to the more realistic case where primary control loops are abstracted into first-order transfer functions.

At the mathematical level, in order to prove current sharing and voltage balancing, we characterize the eigenstructure of the product of three matrices (LDM), where L and M are the graph Laplacians associated to the electrical and the communication graphs, respectively, and D is a diagonal positive definite matrix defining the desired ratios between balanced currents. While several studies focused on the properties of the product of stochastic matrices (see e.g. (Jadbabaie et al., 2003)), which are central in discrete-time consensus, to our knowledge products of Laplacians received much less attention.

The paper is organized as follows. Section 2 summarizes the electrical model of DGUs and PnP controllers. The secondary control layer is developed and analyzed in Section 3 and 4. Section 5 demonstrates current sharing and voltage balancing through simulations in Simulink/PLECS (Allmeling and Hammer, 2013), where non-idealities of real converters and lines have been taken into account. Due to space limitations, we omit the proofs and refer to (Tucci et al., 2016a) for details.

1. INTRODUCTION

In (Tucci et al., 2016b), the aim is to stabilize the voltage only via primary decentralized controllers. These regulators, termed Plug-and-Play (PnP), have the following features: (i) the computation of the local controller for a DGU can be cast into a local optimization problem, (ii) each optimization problem exploits information about the DGU only and, at most, the power lines connected to it, and (iii) when a DGU is plugged-in, only neighboring DGUs must update their local controllers.

The goal of this paper is to enhance PnP controllers with secondary regulators in order to achieve current sharing and voltage balancing. Similarly to (Zhao and Dörfler, 2015), we exploit consensus algorithms requiring DGUs to communicate in real-time over a network with arbitrary, yet connected, topology. There are, however, several differences between the approach in (Zhao and Dörfler, 2015) and the present paper. First, as recalled above, in (Zhao and Dörfler, 2015) the networked secondary layer is necessary for voltage stability, as primary loops induce steady-state voltage drifts. In our case, secondary controllers can be turned off without compromising voltage stability. Second, in (Zhao and Dörfler, 2015) DGUs under the action of primary controllers are abstracted into ideal voltage regulators. We also use this simplification, but only for tutorial reasons. In fact, in (Tucci et al., 2016a) we show that our proof can be extended to the more realistic case where primary control loops are abstracted into first-order transfer functions.

At the mathematical level, in order to prove current sharing and voltage balancing, we characterize the eigenstructure of the product of three matrices (LDM), where L and M are the graph Laplacians associated to the electrical and the communication graphs, respectively, and D is a diagonal positive definite matrix defining the desired ratios between balanced currents. While several studies focused on the properties of the product of stochastic matrices (see e.g. (Jadbabaie et al., 2003)), which are central in discrete-time consensus, to our knowledge products of Laplacians received much less attention.

The paper is organized as follows. Section 2 summarizes the electrical model of DGUs and PnP controllers. The secondary control layer is developed and analyzed in Section 3 and 4. Section 5 demonstrates current sharing and voltage balancing through simulations in Simulink/PLECS (Allmeling and Hammer, 2013), where non-idealities of real converters and lines have been taken into account. Due to space limitations, we omit the proofs and refer to (Tucci et al., 2016a) for details.

2. PLUG-AND-PLAY PRIMARY VOLTAGE CONTROL

2.1 DGU electrical model

As in (Tucci et al., 2016b), we consider a DC mG composed of N DGUs, whose electrical scheme is shown in Figure 1. Each DGU, the generic renewable resource is modeled as a battery, and a Buck converter is used to supply a local load connected to the Point of Common Coupling (PCC) through an RLC filter. Furthermore, we assume that sources of current disturbances (Tucci et al., 2016b). The controlled variable is the voltage at each PCC. From Figure 1, by applying Kirchhoff's voltage and current laws and exploiting Quasi Stationary Line (QSL) approximation of power lines (Tucci et al., 2016b), we obtain the following model of DGU i

\[
\begin{align*}
\frac{dV_i}{dt} &= \frac{1}{C_{li}} I_{li} + \sum_{j \in N_i} \left( \frac{V_j}{C_{li} R_{ij}} - \frac{V_i}{C_{li} R_{ij}} \right) - \frac{1}{C_{li}} I_{li} \\
\frac{dI_{li}}{dt} &= -\frac{1}{L_{li}} V_i - \frac{R_{li}}{L_{li}} I_{li} + \frac{1}{L_{li}} v_i
\end{align*}
\]

where inputs \( V_{li} \) and \( I_{li} \) and states \( V_i \) and \( I_{li} \), and electrical parameters \( R_{li}, C_{li}, L_{li} \) and \( R_i \) are shown in Figure 1. In particular, \( V_i \) is the voltage at the PCC of each neighboring DGU \( j \in N_i \).
Toulouse, France, July 9-14, 2017
Proceedings of the 20th IFAC World Congress

Denied and no update of matrices if one of the LMIs is infeasible, the plug-in of DGU \( i \) in the whole mG after the addition of DGU \( j \). Then, each DGU in the set \( \{ 2 \} \). Next, we describe how to handle plugging-in/out of DGUs while preserving the stability of the mG. Whenever a DGU (say DGU \( i \)) wants to join the network (e.g. DGU 5 in Figure 2), it sends a plug-in request to its future neighbors, i.e. DGUs \( j \in \mathcal{N}_i \) (e.g. DGUs 2 and 4 in Figure 2). Then, each DGU in the set \( \{ i \} \cup \mathcal{N}_i \) solves the LMI problem (25) in (Tucci et al., 2016b) that, if feasible, gives a vector gain \( K_i \) guaranteeing voltage stability in the whole mG after the addition of DGU \( i \). Otherwise, if one of the LMIs is infeasible, the plug-in of DGU \( i \) is denied and no update of matrices \( K_j \), \( j \in \mathcal{N}_i \) is performed. We highlight that, upon the plugging-in of DGU \( i \), the update of gains \( K_j \), \( j \in \mathcal{N}_i \) is necessary as DGUs \( j \in \mathcal{N}_i \) will be affected by new lines \( ij \). Unplugging of a DGU (say DGU \( m \)) follows a similar procedure. Notably, as line \( mk \) will be disconnected, each DGU \( k \), \( k \in \mathcal{N}_m \) must successfully redesign its local controller before allowing the disconnection of DGU \( m \).

\(^2\) Line inductances \( L_{ij} \) are neglected as we assume QSL approximations (Tucci et al., 2016b).

3. SECONDARY CONTROL BASED ON CONSENSUS ALGORITHMS

PnP local controllers have the goal of turning DGUs into controlled voltage generators, i.e. to approximate, as well as possible, the identity \( V_i = V_{ref,i} \). As such, they do not ensure current sharing and voltage balancing, defined in the sequel.

Definition 1. For constant load currents \( I_{Li}, i = 1, \ldots, N \), current sharing is achieved if, at steady state, the overall load current is proportionally shared among DGUs, i.e. if

\[
\frac{I_{ti}}{I_{ij}} = \frac{I_{lj}}{I_{lj}} \quad \text{for all } i, j \in \mathcal{V}_{el},
\]

where \( I_{ti} > 0 \) are scaling factors.

A practical way to make DGUs share their load currents proportionally, for instance, to their generation capacity, is to measure the output currents in per-unit (p.u.), thus setting each scaling factor \( I_{ti} \) in (2) equal to the corresponding DGU rated current. On the other hand, if \( I_{ti} = I_{lj}, i = 1, \ldots, N \) (i.e. if the scaling factor is the same for all the DGUs), the current sharing condition becomes

\[
I_{ti} = (I_L)^T \quad i = 1, \ldots, N,
\]

where \( I_L = [I_{L1}, I_{L2}, \ldots, I_{LN}]^T \) is the vector of the local load currents.

Assumption 1. Voltage references are identical for all DGUs, i.e. \( V_{ref,i} = V_{ref}, \forall i \in \mathcal{V}_{el} \).

Definition 2. Under Assumption 1, voltage balancing is achieved if

\[
(V) = V_{ref},
\]

where vector \( V = [V_1, V_2, \ldots, V_N]^T \) collects the PCC voltages.

In order to guarantee current sharing and voltage balancing, we use a consensus-based secondary control layer. Consensus filters are commonly employed for achieving global information sharing or coordination through distributed computations (Bullo, 2016). In our case, as shown in Figure 3, we adopt the following consensus scheme for adjusting the references of each PnP voltage regulator

\[
\Delta V_i(t) = k_I \sum_{j=1}^{N} a_{ij} \left( \frac{I_{ti}(t)}{I_{ij}} - \frac{I_{lj}(t)}{I_{lj}} \right),
\]

where \( a_{ij} > 0 \) if DGUs \( i \) and \( j \) are connected by a communication link (\( a_{ij} = 0 \), otherwise) and the coefficient \( k_I > 0 \) is common to all DGUs. The use of consensus protocols has been thoroughly studied for networks of agents with simple dynamics, e.g. simple integrators (Bullo, 2016), with the goal of proving convergence of individual states to a common value. In our case, however, (5) is interfaced with the mG dynamics and convergence of currents \( I_{ti} \) to the same value does not trivially follow from standard consensus theory. This property will be analyzed in Section 4.

In the sequel, we assume bidirectional communication, i.e. \( a_{ij} = a_{ji} \). The corresponding communication digraph is \( \mathcal{G}_c = (\mathcal{V}_c, \mathcal{E}_c, W_c) \) where \( (i, j) \in \mathcal{E}_c \iff a_{ij} > 0 \) and \( W_c = \text{diag}(a_{ij}) \). Note that the topology of \( \mathcal{G}_c \) and \( \mathcal{G}_{el} \) can be completely different. From now on, we will make the following standing assumption.

Assumption 2. The graphs \( \mathcal{G}_{el} \) and \( \mathcal{G}_c \) are weakly connected.
Proceedings of the 20th IFAC World Congress

If one of the LMIs is infeasible, the plug-in of DGU 2. Then, each DGU in the set \( \{m_k \} \) will be affected by new lines neighbors, i.e. DGUs 5 in Figure 2), it sends a plug-in request to its future a DGU (say DGU 1) wants to join the network (e.g. DGU 6). As such, they do not connected. Otherwise, \( \{m_k \} \) (see, the consensus theory. This property will be analyzed in Section 3.

For modeling the interaction of multiple DGUs, we represent disconnection of DGU \( i \) for positive currents, (iii) weights are line conductances \( R_{ij} \) and (ii) \( L_{ij} \) update of gains.

A practical way to make DGUs share their load currents is common to all DGUs. The use of consensus protocols has been thoroughly studied for networks of agents with distributed computations (Bullo, 2016). In our case, as shown for all the DGUs), the current sharing condition becomes where vector \( a \) where

\[ \dot{\Delta V} = -k \mathbf{L} \mathbf{D} \mathbf{I}, \]  

where \( \Delta V = [\Delta V_1, \ldots, \Delta V_N]^T = \mathbf{V} - \mathbf{V}_{\text{ref}} \). \( \mathbf{V}_{\text{ref}} = [V_{\text{ref},1}, V_{\text{ref},2}, \ldots, V_{\text{ref},N}]^T, \mathbf{I}_t = [I_{t1}, I_{t2}, \ldots, I_{tN}]^T, \mathbf{D} = \mathop{\text{diag}}(\frac{1}{r_{i1}}, \ldots, \frac{1}{r_{IN}}) \) and \( \mathbf{L} = \mathcal{L}(\mathcal{G}_c) \). Note that \( \mathbf{L} \) is the Laplacian matrix of \( \mathcal{G}_c \) with \( W_c \) replaced by \( k_1 W_c \).

4. MODELING AND ANALYSIS OF THE COMPLETE SYSTEM

The hierarchical control scheme of a DGU equipped with primary and secondary regulators is depicted in Figure 3. For studying the behavior of the closed-loop mG, we approximate PnP-controlled DGUs by unit gains and show that current sharing and voltage balancing are achieved in a stable way. For the more complex analysis where primary control loops are abstracted into first-order transfer functions, we defer the reader to (Tucci et al., 2016a).

4.1 Unit-gain approximation of PnP-controlled DGUs

By approximating primary PnP loops with ideal unit gains, we have the relations \( V_i = V_{\text{ref},i} + \Delta V_i, \forall i \in \mathcal{V}_c \).

Figure 4 shows the resulting control scheme, used for deriving the dynamics of the overall mG as a function of the inputs \( \mathbf{I}_L \) and \( \mathbf{V}_{\text{ref}} \). Starting from the left-hand side of Figure 4, we have, in order, (6) and (7)

\[ \mathbf{V} = \Delta \mathbf{V} + \mathbf{V}_{\text{ref}}. \]

Then, from basic circuit theory, we derive the relation between the vector of voltages \( \mathbf{V} \) and the vector of line currents \( \mathbf{I}_L = [I_{L1}, \ldots, I_{LM}]^T \) as

\[ \mathbf{I}_L = -\mathbf{W} \mathbf{B}^T \mathbf{V}, \]

where \( W \) is the weight matrix of \( \mathcal{G}_c \) and \( B = Q(\mathcal{G}_c) \) is the incidence matrix of the mG. Next, we get

\[ \mathbf{I}_t = \mathbf{I}_L - B \mathbf{I}_e \]

and, merging equations (6)-(9), we finally obtain

\[ \Sigma : \dot{\Delta \mathbf{V}} = -L D B W B^T \Delta \mathbf{V} - L D \mathbf{I} \mathbf{L} - L D B W B^T \mathbf{V}_{\text{ref}} \]

where \( M = \mathcal{L}(\mathcal{G}_c) = B W B^T \) is the Laplacian matrix of the electrical network and \( \mathbf{Q} = L D M \).

Obtained pre- and post- multiplying a diagonal matrix by a Laplacian \( (\mathbf{L} \) and \( \mathbf{M} \), respectively). It follows that \( \mathbf{Q} \) is not a Laplacian matrix itself because it might fail to be symmetric and have positive off-diagonal entries, even if weights of \( g_{el} \) and \( g_e \) are positive. Nevertheless, in the next Proposition, we show that \( \mathbf{Q} \) preserves some key features of Laplacian matrices.

\[ \mathbf{Q} \dot{\Delta \mathbf{V}} = \dot{\mathbf{V}} + \Delta \mathbf{V}. \]

Fig. 3. Complete hierarchical control scheme of DGU \( i \).

Fig. 4. Hierarchical control scheme with unit-gain approximation of PnP loops (dashed boxes).

**Proposition 2.** The matrix \( \mathbf{Q} = L D M \) has the following properties:

(i) \( \text{Ker}(\mathbf{Q}) = H_1 \); (ii) \( \text{Range}(\mathbf{Q}) = H_1 \); (iii) the linear transformation \( Q(H_1^1 H_1^1) \) is invertible; (iv) \( \mathbf{Q} \) has real nonnegative eigenvalues; (v) the zero eigenvalue of \( \mathbf{Q} \) has algebraic multiplicity equal to one.

**Analysis of equilibria** In order to evaluate the steady-state behavior of the electrical signals appearing in Figure 4, we study the equilibria of system (10). Hence, for given constant inputs \( (\mathbf{I}_L, \mathbf{V}_{\text{ref}}) \), we characterize the solutions \( \Delta \mathbf{V}^* \) of equation

\[ \mathbf{Q} \dot{\Delta \mathbf{V}} = -L D \mathbf{I}^*_L - \mathbf{Q} \mathbf{V}^*_{\text{ref}} \]

and characterize them through the following Proposition.

**Proposition 3.** For equation (11),

(i) there is only one solution \( \dot{\Delta \mathbf{V}}^* \in H_1^1 \); (ii) all solutions \( \Delta \mathbf{V}^* \in \mathbb{R}^N \) can be written as

\[ \Delta \mathbf{V}^* = \Delta \mathbf{V}^* + \alpha \mathbf{1}_N \quad \alpha \in \mathbb{R}. \]

Next, we establish relevant properties of the equilibria of (10).

**Proposition 4.** Consider system (10) with constant inputs \( (\mathbf{I}_L^*, \mathbf{V}^*_{\text{ref}}) \). Then, current sharing is achieved at steady state. Moreover, if \( \mathbf{V}^*_{\text{ref}} = V_{\text{ref}} \mathbf{1}_N \) (i.e. Assumption 1 holds) and \( \alpha \) in (12) is equal to zero, then the equilibrium \( \mathbf{V}^* \) verifies the voltage balancing condition (4).

In the sequel, we show the convergence of \( \Delta \mathbf{V} \) in (10) to an equilibrium ensuring both current sharing and voltage balancing for constant \( \mathbf{I}_L^* \) and \( \mathbf{V}^*_{\text{ref}} = V_{\text{ref}} \mathbf{1}_N \).

**Stability analysis** We first analyze the dynamics of projections \( P_{H_1^1}(\Delta \mathbf{V}) = \Delta \mathbf{V} \) and \( P_{H_1^1}(\Delta \mathbf{V}) = \Delta \mathbf{V} \).

**Proposition 5.** If \( \Delta \mathbf{V} \) is given by system \( \Sigma \) in (10) for \( \Delta \mathbf{V}(0) = \Delta \mathbf{V}_0 \), then \( \dot{\Delta \mathbf{V}} = \Delta \mathbf{V} + \Delta \mathbf{V}, \) where \( \Delta \mathbf{V} \in H_1^1 \) and \( \Delta \mathbf{V} \in H_1^1 \) fulfill...
\[ \Sigma : \begin{cases} \dot{\Delta V} = 0_N \\ \Delta V(0) = (\Delta V_0)1_N \end{cases} \] (13)

and

\[ \hat{\Sigma} : \begin{cases} \dot{\Delta V} = -Q\Delta V - L_D I_L - Q V_{\text{ref}} \\ \Delta V(0) = \Delta V_0 - \Delta V_0. \end{cases} \] (14)

**Remark 1.** The splitting of \( \Sigma \) into systems \( \Sigma \) and \( \hat{\Sigma} \) implies that, if \( \Delta V_0 \) has zero average, then \( \Delta V(t) \) has the same property, \( \forall t \geq 0 \) and irrespectively of inputs \((I_L, V_{\text{ref}})\). This behavior can be realized by suitable initialization of the integrators appearing in Figure 4.

According to system \( \Sigma \), the value of \( P_{H_1}(\Delta V) = \Delta V \) remains constant over time and equal to \( \Delta V_0 \). Hence, in order to characterize the stability of equilibria (12), it is sufficient to study the dynamics (14). In an equivalent way, one can consider system (10) and the following definition of stability on a subspace.

**Definition 3.** Let \( \mathcal{V} \) be a subspace of \( \mathbb{R}^n \). The origin of \( \dot{x} = Ax, x(t) \in \mathbb{R}^n \) is Globally Exponentially Stable (GES) on \( \mathcal{V} \) if \( \exists \alpha, \eta > 0 : \|x(t)\| \leq \alpha e^{-\eta t}\|x(0)\| \). The parameter \( \eta \) is termed rate of convergence.

Note that \( \Sigma \) is a linear system and, for stability analysis, we can neglect inputs, hence obtaining

\[ \dot{\Delta V} = -Q\Delta V \\ \Delta V(0) = \Delta V_0. \] (15)

**Theorem 1.** The origin of (15) is GES on \( H^1 \). Moreover, the rate of convergence is the smallest strictly positive eigenvalue of \( Q \).

The above results reveal that, given an initial condition \( \Delta V(0) = \Delta V_0 \) for system (10) and constant inputs \( I_L \) and \( V_{\text{ref}} = V_{\text{ref}}1_N \), the state \( \Delta V \) converges to the equilibrium (12) with \( \alpha = (\Delta V_0) \).

Summarizing the main results of this Section, we have that the consensus scheme described by (5), Assumption 1 and

\[ (\Delta V_0) = 0 \] (16)

guarantee the asymptotic achievement of current sharing and voltage balancing in a GES fashion.

**4.2 PnP design of secondary control**

We now describe the procedure for designing secondary controllers in a PnP fashion. We will show that, as for the PnP design of primary regulators, when a DGU is added or removed, the secondary control layer can be updated only locally for preserving current sharing and voltage balancing. When a DGU (say DGU \( i \)) sends a plug-in request at a time \( t \), it chooses a set \( N_i^c \) of communication neighbors and fixes parameters \( a_{jj} > 0, \forall j \in N_i^c \) in order to design the local consensus filter (5). At the same time, each DGU \( i, j \in N_i^c \) updates its consensus filter by setting \( a_{jj} = a_{ji} \) in (5).

**Theorem 1** ensures that the disagreement dynamics of the mG states is GES, independently of \( N_i^c \) . Let Assumption 1 hold for all the interconnected DGUs in the mG before \( t \) and let us denote the common reference voltage by \( V_{\text{ref}} \). If DGU \( i \) sets \( V_{\text{ref},i} = V_{\text{ref}} \) and if we choose \( \Delta V_i(\dot{i}) = 0 \) (thus having \( ([\Delta V_i(\dot{i})^T \Delta V_i(\dot{i})]^T) = 0 \), where \( \Delta V_i(\dot{i}) \) is the vector \( \Delta V \) prior the plugging-in of DGU \( i \), both current sharing and voltage balancing are preserved in the asymptotic régime (see Proposition 4). The procedure for handling unplugging operations while ensuring current sharing and voltage balancing is described in (Tucci et al., 2016a).

**5. SIMULATION RESULTS**

In this Section, we demonstrate the capability of the proposed control scheme to guarantee current sharing and voltage balancing when DGUs are added or load changes occur. Simulations have been performed in Simulink/PLECS. We consider an mG composed of 5 DGUs, arranged as in Figure 5, with non-identical electrical parameters and power lines. Notice that some DGUs have more than one neighbor, hence the impact of couplings on their dynamics will be larger. Moreover, we choose \( I_i^c = I_t, i = 1, \ldots, 5 \) (thus aiming to achieve the asymptotic current sharing condition (3)), and the voltage reference in Assumption 1 is \( V_{\text{ref}} = 48 \, \text{V} \). All the electrical and control parameters are collected in Appendix C of (Tucci et al., 2016a).

Simulations have been performed assuming all-to-all communication among DGUs. In the following, we describe Figure 6, which illustrates the evolution of the main electrical quantities (i.e. DGU measured output currents, PCC voltages and average PCCs voltage) during the consecutive simulation stages shown in Figure 5.

At time \( t_0 = 0 \), all the DGUs are assumed to be isolated and only the primary PnP voltage regulators are active. Therefore, as shown in stage 1, (i) each DGU supplies its local load while keeping the corresponding PCC voltage at 48 V, and (ii) the DGU output currents are different.

We further highlight that primary controllers have been designed assuming that all the switches in Figure 5 connecting DGUs 1-4 are closed. From (Tucci et al., 2016b), however, they also stabilize the mG when all switches are open.

At time \( t_1 = 5 \, \text{s} \), we connect together subsystems 1-4 and, according to the previous observation, no update of local controllers is required. At \( t_1 \) we also activate the secondary control layer for DGUs 1-4, thus ensuring asymptotic convergence of the output currents to the same value (see the plot of \( I_1 \), stage 2). This is achieved by adjusting the voltages at PCC (as shown in the plot of \( V_{\text{PCC}} \), stage 2).

Furthermore, by setting \( \Delta V_i(t_1) = 0, i = 1, \ldots, 4 \), as described in Section 4.2, condition (16) is verified and asymptotic voltage balancing is guaranteed (see \( V_{\text{av}} \) during stage 2).

For evaluating the PnP capabilities of our control scheme, at \( t_2 = 16 \, \text{s} \), DGU 5 sends a plug-in request to DGU 4. Previous PnP controllers of DGUs 4 and 5 still fulfill the plug-in conditions in (Tucci et al., 2016b): they are therefore maintained and the plug-in of DGU 5 is performed. At the same time, the secondary controller of DGU 5 is activated, and then the DGU contributes to current sharing (see the top plot in Figure 6, stage 3).

Furthermore, by setting \( \Delta V_i(t_2) = 0, i = 1, \ldots, 4 \), as described in Section 4.2, we can maintain the average PCCs voltage at 48 V (see \( V_{\text{av}} \), stage 3).

Finally, at \( t_3 = 30 \, \text{s} \) (stage 4), we halve the load of DGU 1, thus increasing the corresponding load current \( I_{11} \) and causing a peak in the corresponding output current. However, after few seconds, all the DGUs share again the total load current, while the averaged PCCs voltage converges to the reference value.
6. CONCLUSIONS

In this paper, a secondary consensus-based control layer for current sharing and voltage balancing in DC mGs has been proposed. Moreover, we presented a method for designing secondary controllers in a PnP fashion when new DGUs are added. As regards future developments, communication delays (Bliman and Ferrari-Trecate, 2008; Meng et al., 2014), will be included in the mathematical analysis.
