Power Losses Control for Modular Multilevel Converters Under Capacitor Deterioration

Fujin Deng, Member, IEEE, Qian Heng, Chengkai Liu, Qingsong Wang, Senior Member, IEEE, Rongwu Zhu, Member, IEEE, Xu Cai, and Zhe Chen, Fellow, IEEE

Abstract—The modular multilevel converter (MMC) is attractive for medium/high-voltage and high-power applications because of the advantages of its high modularity, availability and high power quality. Due to chemical process, aging effect, etc., the capacitor in the submodule (SM) of the MMC would gradually deteriorate and the capacitance would drop, which would cause unbalanced SM power losses distribution in the same arm of the MMC and affect the reliability of the MMC. This paper proposed an equivalent-reference (ER) control method, which can effectively realize balanced SM power losses distribution in the same arm of the MMC through the voltage-balancing control for the virtual capacitor voltages in the MMC under the capacitor deterioration. The proposed ER control can effectively improve the reliability of the MMC with the balanced SM power losses distribution in the MMC under capacitor deterioration. The simulation studies with the time-domain professional tool PSCAD/EMTDC are conducted and a down-scale MMC prototype is also tested with the proposed control strategy. The study results confirm the effectiveness of the proposed control strategy.

Index Terms— Capacitor deterioration, control strategy, modular multilevel converter, power losses.

I. INTRODUCTION

MODULAR multilevel converters (MMCs) have become increasingly attractive for medium/high-voltage and high-power applications with the advantages such as the excellent output voltage waveforms and very high efficiency [1, 2]. A multilevel voltage can be produced with the flexible operation of the MMC while reducing average switching frequency without compromising the power quality [3, 4]. Recently, due to the easy construction, assembling, and flexibility in converter design, the MMC becomes promising for various applications such as machine drives [5], electric railway supplies [6] and microgrid [7].

Reliability is one of the most important issues for the MMC, because the MMC is composed of a large number of devices such as switch, diode and capacitor, where each device can be considered as a potential failure point [8], [9]. The electrolytic capacitor is widely considered for the MMC in some applications such as motor drive and microgrid [5], [7], [10-13] because of its feature such as high capacitance per unit volume. Due to the chemical process, aging effect, etc., the capacitor in the MMC would gradually deteriorate, which is normally expressed by the capacitance drop [14, 15]. Normally, the deteriorated capacitor needs to be replaced until its capacitance drops below the threshold value, such as 80% of the rated value [14].

Recently, several methods have been presented to monitor capacitance in the MMC. Reference [14] introduces a capacitor condition monitoring scheme for the MMC, where the capacitance in the MMC is estimated by a recursive least square algorithm based on the capacitor voltage, arm current and switching state. Reference [15] presents a capacitor condition monitoring scheme based on a Kalman filter algorithm, where the capacitance in the MMC is estimated based on the capacitor voltage and current. Reference [16] presents a simple capacitor monitoring algorithm based on the relationship between the reference SM capacitance and the monitoring SM capacitance. The above literature can effectively estimate the capacitance in the MMC with very high accuracy and the error is less than about 1%.

Owing to capacitor deterioration, the MMC would be operated with different capacitances in the different SMs. It would affect the performance of the MMC, especially the SM power losses in the arm of the MMC, which would affect aging of semiconductors and lifetime of SMs. Reference [17] presents an active power losses distribution method for the MMC based on circulating currents at fundamental frequency, second harmonic and dc voltage offset on the converter voltage waveform, which can change the balance of power losses between the top switch and bottom switch in each SM. However, it cannot balance the power losses distribution among the SMs in the arm under capacitor deterioration. Reference [18] presents an SM level power loss balancing control for the MMC based on switching loss model, unbalance degree extractor, power level balancing control regulator and enable module. However, it only reduces the imbalance of the SM switching losses distribution in the arm. It also only considers the whole SM switching loss and it does not consider the switching losses balancing distribution for each type semiconductor among the SMs in the arm. In addition, the real-time calculation of each semiconductor
switching losses and unbalance degree also increases the computation amount. Reference [19] presents the switching balancing (SB) algorithm and total losses balancing (TLB) algorithm to reduce the SM power losses imbalance in the arm. The SB algorithm reduces the SM switching power losses imbalance in the arm through equally distributing the number of transitions for the SMs in the arm, which can reduce the SM power losses imbalance in the arm. The TLB algorithm reduces the SM power losses imbalance in the arm based on the sum of the SM conduction losses deviation and switching losses deviation. However, the SB algorithm only considers the switching loss and omits the conducting loss. In addition, both SB and TLB algorithms only consider the power loss balancing for the whole SM, not for each type semiconductor, which can not realize power loss balancing for each type semiconductor among the SMs in the arm, which would result in different lifetimes for the same type of semiconductors in different SMs of the arm. In addition, the real-time monitoring of a large number of transitions for each SM and average number of transitions, real-time computation of conduction losses and switching losses of all semiconductors in each SM would increase the computation amount, which would require high processing capability for the controller.

In this paper, the power losses distribution of the MMC under capacitance deterioration is analyzed in detail, where the capacitor deterioration would cause different equivalent references (ERs) for the SMs in the same arm. It would result in unbalanced SM power losses distribution in the same arm of the MMC and cause different aging speed of semiconductors, and therefore affect the reliability of the MMC. In this paper, an ER control method is proposed for the MMC under capacitor deterioration, where the ERs for the SMs in the same arm can be kept close to each other through the voltage-balancing control for the virtual capacitor voltages. The proposed ER control method can effectively balance the SM power losses distribution in the same arm of the MMC based on the relationship between ER and semiconductor power losses in the arm. Therefore, the proposed power losses control strategy imposes the reliability of the MMC by improving the aging speed of the SMs. In comparison with [18] and [19], the primary contributions of this paper include: 1) this paper reveals the relationship between the capacitance and semiconductor power loss in the SM including conduction loss and switching loss; 2) this paper considers power loss balancing for both conduction loss and switching loss; 3) the proposed method not only can balance the power losses for the whole SM, but also can balance the power losses of the same type semiconductors in different SMs of the arm; 4) the proposed control algorithm is based on the SM capacitance, while the change of the SM capacitance is normally quite slow. It means that the capacitor value is not necessary to be updated in each control period, and accordingly simplifies the computation and reduces computation amount.

This paper is organized as follows. Section II presents the operation principle of the MMC. Section III analyses the relationship between the ER and the power losses of the MMC in detail under capacitor deterioration. Section IV proposes the ER control method for the MMC under capacitor deterioration.

The system simulation and experimental tests are presented in Sections V and VI, respectively, to show the effectiveness of the proposed power losses control strategy for the MMC. Finally, the conclusions are presented in Section VII.

II. OPERATION PRINCIPLE OF MMCs

A three-phase MMC is shown in Fig. 1(a), which has six arms. Each arm consists of n SMs and an arm inductor $L_a$. The upper arm and the lower arm in the same phase comprise a phase unit. Fig. 1(b) shows the i-th SM (i=1, 2, ……, n) in the upper arm of phase A, which contains the top switch/diode ($T_i/D_i$), the bottom switch/diode ($T_b/D_b$), the capacitor $C_{cui}$, and the bypass switch [20]. Normally, each SM is controlled with a switching function $S$ as

$$
S = \begin{cases} 
1, & T_i \text{ is on and } T_b \text{ is off} \\
0, & T_i \text{ is off and } T_b \text{ is on} 
\end{cases}
$$

Fig. 1. (a) Block diagram of a three-phase MMC. (b) SM unit.

Table I shows the two states of the SM. One is “On” state, when $S$ is 1. Here, the SM output voltage $u_{cai}$ equals the capacitor voltage $u_{cai}$. The other one is “Off” state and $u_{cai}$ equals 0, when $S$ is 0. In the “On” state, the charge and discharge of the capacitor $C_{cai}$ depends on the arm current flow direction. If the arm current $i_{cai}$ is positive, as shown in Fig. 1(a), the capacitor in On-state SM would be charged and $u_{cai}$ is increased. If $i_{cai}$ is negative, the capacitor in On-state SM would be discharged and $u_{cai}$ is decreased. In the “Off” state of the SM, the corresponding capacitor would be bypassed and $u_{cai}$ is unchanged, irrespective of the arm current flow direction [21].

In Fig. 1(a), suppose that the circulating current is suppressed with the method [22], the upper and lower arm current $i_{rui}$ and $i_{doi}$ in the phase A can be described as

\[
\begin{align*}
i_{rui} &= \frac{I_m}{2} \sin(\alpha t + \alpha) + \frac{i_{dc}}{3} \\
i_{doi} &= -\frac{I_m}{2} \sin(\alpha t + \alpha) + \frac{i_{dc}}{3}
\end{align*}
\]

(2)

where $I_m$ and $\alpha$ are the peak value and the phase angle of the phase current at the ac side of the MMC, respectively. $i_{dc}$ is the current at the dc side, as shown in Fig. 1(a).

According to [23] and [24], the voltage $u_{aui}$ in Fig. 1, which is the sum of the $n$ series-connected SMs’ output voltage, can be expressed as

\[
u_{aui} = \sum_{i=1}^{n} u_{rui}
\]

(3)

with

\[
u_{rui} = u_{aui} \frac{1 + x_{er-aui}}{2}
\]

(4)

\[
u_{aui} = \frac{1}{C_{aui}} \int i_{rui} dt = \frac{1}{C_{aui}} \int i_{aui} \frac{1 + x_{er-aui}}{2} dt
\]

(5)

where $x_{er-aui}$ is the ER for the $i$-th SM. $u_{aui}$, $u_{rui}$ and $i_{rui}$ are the SM output voltage, capacitor voltage and capacitor current of the $i$-th SM, respectively, as shown in Fig. 1(b).

III. ANALYSIS OF MMCs UNDER CAPACITOR DETERIORATION

A. Analysis of ERs

Normally, the chemical process, aging, etc. would cause capacitor deterioration, which would result in capacitance drop. Here, the deteriorated capacitor needs to be replaced until its capacitance drops below the threshold value, such as 80% of the rated value [14]. Consequently, the MMC would work with different capacitances in the different SMs.

Fig. 2 shows the upper arm of phase A, where the capacitance $C_{aui}$~$C_{cavi}$ are supposed to be uncertain. With the voltage-balancing control in [22], the capacitor voltages in the upper arm of phase A can be kept balanced as

\[
u_{aui1} = u_{aui2} = \cdots = u_{aui_n} = u_{aui}
\]

(6)

Under the modulation scheme in [22], the synthesized arm voltage $u_{aui}$ for the upper arm of phase A can be expressed as

\[
u_{aui} = n \cdot u_{aui} \frac{1 + x_{aui}}{2}
\]

(7)

with

\[x_{aui} = m \cdot \sin(\alpha t + \beta)
\]

(8)

where $x_{aui}$ is the reference for the upper arm of phase A. $m$ is modulation index. $\beta$ is the phase angle.

![Image of upper arm of phase A with notation](image-url)

Fig. 2. $n$ series-connected SMs in the upper arm of phase A.

Substituting (3), (4) and (6) into (7), the relationship between $x_{aui}$ and $x_{er-aui}$ can be obtained as

\[
x_{aui} = \frac{1}{n} \sum_{i=1}^{n} x_{er-aui}
\]

(9)

Combining (2), (5), (6) and (8), the (10) can be obtained as

\[
\frac{1 + x_{er-aui1}}{C_{aui1}} = \frac{1 + x_{er-aui2}}{C_{aui2}} = \cdots = \frac{1 + x_{er-aui_n}}{C_{aui_n}} = \frac{1 + x_{aui}}{C_{ave}}
\]

(10)

with

\[
C_{ave} = \frac{1}{n} \sum_{i=1}^{n} C_{aui}
\]

(11)

where $C_{ave}$ is the average capacitance in upper arm of phase A.

Based on (10) and (11), it can be observed that the ER $x_{er-aui}$ for the $i$-th SM depends on the $C_{aui}$. Along with the drop of $C_{aui}$, the $x_{er-aui}$ will be reduced, as shown in Table II. On the other hand, according to (8) and (10), it can be seen that a dc component would be caused in $x_{er-aui}$, as shown in Table III, as follows.

1) Situation I: if $C_{aui} > C_{ave}$, $x_{er-aui}$ will be more than $x_{aui}$. Here, a positive dc component would be caused in $x_{er-aui}$. If $C_{aui}$ is far more than $C_{ave}$, the dc component in $x_{er-aui}$ would be big.

2) Situation II: if $C_{aui} = C_{ave}$ the $x_{er-aui}$ will be equal to $x_{aui}$ and there is no dc component in $x_{er-aui}$.

3) Situation III: if $C_{aui} < C_{ave}$, the $x_{er-aui}$ will be less than $x_{aui}$. Here, a negative dc component would be caused in $x_{er-aui}$. If $C_{aui}$ is far less than $C_{ave}$, the dc component in $x_{er-aui}$ would be small.

Fig. 3 shows the performance of the SMs with various capacitances in the arm, which is derived from the simulation in Section V. Fig. 3(a) shows the capacitances \( C_{\text{aux}} \)-\( C_{\text{aux}} \). The other capacitances are all 15 mF. The average capacitance \( C_{\text{ave}} \) in the arm is 14.775 mF. Among \( C_{\text{aux}} \)-\( C_{\text{aux}} \), only \( C_{\text{aux}} \) is more than \( C_{\text{ave}} \) and the others are less than \( C_{\text{ave}} \). Fig. 3(b) shows the dc component in \( x_{\text{er}_1} \)-\( x_{\text{er}_6} \), where only the dc component in \( x_{\text{er}_1} \) is positive and the dc components in \( x_{\text{er}_2} \)-\( x_{\text{er}_6} \) are all negative, which verifies the analysis in Table III. In addition, Fig. 3(c) shows the relationship among the fundamental components in \( x_{\text{er}_1} \)-\( x_{\text{er}_6} \), which almost meets the (10) and verify the analysis in Table II.

![Image](image_url)

Fig. 3. (a) SM capacitance. (b) DC component in \( x_{\text{er}_1} \). (c) Fundamental component in \( x_{\text{er}_1} \).

**B. SM Conduction Loss**

The conduction situation of the top and bottom switch/diode (\( T_1/D_1 \) and \( T_2/D_2 \)) in each SM, as shown in Fig. 1(b), is listed in Table IV. The conduction losses of the switch/diode are analyzed in detail as follows.

**TABLE IV**

<table>
<thead>
<tr>
<th>( i_{\text{ua}} )</th>
<th>( S )</th>
<th>( T_1 )</th>
<th>( D_1 )</th>
<th>( T_2 )</th>
<th>( D_2 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \geq 0 )</td>
<td>1</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>( i_{\text{ua}} )</td>
<td>0</td>

<td>0</td>
<td></td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>( i_{\text{ua}} )</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

1) **Conduction losses** \( P_{\text{ct}} \) of \( T_1 \): current \( i_{\text{ua}} \) flows through \( T_1 \) when \( i_{\text{ua}} \geq 0 \) and \( S_{\text{ua}} = 1 \). The \( P_{\text{ct}} \) can be expressed as [25]

\[
P_{\text{ct}, i} = -i_{\text{ua}} \cdot S_{\text{ua}} \cdot \left[ u_{\text{cco}} + r_c \cdot (-i_{\text{ua}}) \right] \cdot S_{\text{aux}}
\]

where \( u_{\text{cco}} \) and \( r_c \) are switch on-state zero-current collector-emitter voltage and collector-emitter on-state resistance, respectively. \( S_{\text{aux}} \) is the switching function for the \( i \)-th SM, which can be expressed with the Fourier series expansion as \((1+x_{\text{er}_i})/2\) [24], [26]. Therefore, (12) can be rewritten as

\[
P_{\text{ct}, i} = -i_{\text{ua}} \cdot \left[ u_{\text{cco}} + r_c \cdot (-i_{\text{ua}}) \right] \cdot \frac{1+x_{\text{er}_i}}{2}
\]

2) **Conduction losses** \( P_{\text{ct}, j} \) of \( D_1 \): \( i_{\text{ua}} \) flows through \( D_1 \) when \( i_{\text{ua}} \geq 0 \) and \( S_{\text{ua}} = 1 \). With the Fourier series expansion of \( S_{\text{aux}} \), the \( P_{\text{ct}, j} \) can be expressed as

\[
P_{\text{ct}, j} = i_{\text{ua}} \cdot \left[ u_{\text{cco}} + r_c \cdot i_{\text{ua}} \right] \cdot \frac{1+x_{\text{er}_i}}{2}
\]

3) **Conduction losses** \( P_{\text{cb}, j} \) of \( T_2 \): \( i_{\text{ua}} \) flows through \( T_2 \) when \( i_{\text{ua}} \geq 0 \) and \( S_{\text{ua}} = 0 \). With the Fourier series expansion of \( S_{\text{aux}} \), the \( P_{\text{cb}, j} \) can be expressed as

\[
P_{\text{cb}, j} = i_{\text{ua}} \cdot \left[ u_{\text{cco}} + r_c \cdot (-i_{\text{ua}}) \right] \cdot \frac{1+x_{\text{er}_i}}{2}
\]

4) **Conduction losses** \( P_{\text{cb}, i} \) of \( D_2 \): \( i_{\text{ua}} \) flows through \( D_2 \) when \( i_{\text{ua}} < 0 \) and \( S_{\text{ua}} = 0 \). With the Fourier series expansion of \( S_{\text{aux}} \), the \( P_{\text{cb}, i} \) can be expressed as

\[
P_{\text{cb}, i} = i_{\text{ua}} \cdot \left[ u_{\text{cco}} + r_c \cdot (-i_{\text{ua}}) \right] \cdot \frac{1+x_{\text{er}_i}}{2}
\]

From (13)–(16), it can be observed that the conduction loss of the \( T/D_1 \) and \( T_2/D_2 \) in the \( i \)-th SM is related to the ER \( x_{\text{er}_i} \), as shown in Table V. Combining (10) and (13)–(16), it can be seen that the capacitor \( C_{\text{aux}} \) drop causes reduced \( x_{\text{er}_i} \), which reduces \( P_{\text{ct}, j} \), \( P_{\text{cb}, j} \), and increases \( P_{\text{cb}, i} \), \( P_{\text{cb}, i} \) in the \( i \)-th SM.

**TABLE V**

**C. SM Switching Loss**

Based on above analysis, although all capacitor voltage in the arm are kept balanced with the voltage-balancing control, the drop of the capacitance \( C_{\text{aux}} \) reduces \( \text{ER} \) \( x_{\text{er}_i} \) for the SM, which would result in different switching frequencies and different switching losses for these SMs in the same arm. Under the voltage-balancing control method in [22], it is possibility that the SM with the dropped \( C_{\text{aux}} \) would reduce its switching time to reduce \( \text{ER} \) \( x_{\text{er}_i} \). Consequently, the capacitance drop would reduce SM switching frequency and decrease SM switching losses, as shown in Table VI.

**TABLE VI**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

Fig. 4 shows the SM losses with various capacitances in the same arm, which is derived from the simulation in Section V. The Infineon IGBT FZ1200R17HP4 is used in the MMC, where the losses are calculated based on the simulated current waveforms and the semiconductor specifications from the manufacturer. The junction temperature is considered to be 125°C. Along with the drop of the capacitance, as shown in Fig. 3(a), the conduction losses \( P_{\text{ct}, i} \), \( P_{\text{ct}, i} \) in \( T_1 \), \( D_1 \) is reduced and the conduction losses \( P_{\text{cb}, i} \), \( P_{\text{cb}, i} \) in \( T_2 \), \( D_2 \) is increased, as shown in Fig. 4(a), which verifies the conduction losses.
analysis in Table V. In addition, the drop of the capacitance causes the reduction of the SM switching frequency and the decrease of the switching losses $P_{stt}, P_{apd}, P_{apb}, P_{pstb}$ in $T_1, D_1, T_2, D_2$, respectively, as shown in Figs. 4(b) and (c), which verifies the switching losses analysis in Table VI. Fig. 4(d) shows the power losses of the top switch/diode $T_1/D_1$ and bottom switch/diode $T_2/D_2$. It can be seen that, along with the capacitance drop, the power losses of the top switch/diode $T_1/D_1$ is reduced and the power losses of the bottom switch/diode $T_2/D_2$ is increased, which results in that the error between the power losses of the top switch/diode $T_1/D_1$ and the power losses of the bottom switch/diode $T_2/D_2$ is increased along with the capacitance drop.

IV. PROPOSED POWER LOSSES CONTROL FOR MMCs UNDER CAPACITOR DETERIORATION

A. Proposed Control Strategy

Based on aforementioned analysis, although the capacitor voltages are kept balanced, the capacitance drop causes different ERs $x_{err,SM1}$-$x_{err,SM6}$ for the SMs in the same arm. The different ERs of the SMs would result in different SM losses in the same arm and affect the reliability of the MMC.

To improve the performance of the MMC, an ER control method is proposed for the MMC, as shown in Fig. 5, which can ensure that the ERs close to each other in the same arm. In Fig. 5, the capacitor voltage $u_{cau}$ in the upper arm of phase A is monitored, which can be expressed as

$$u_{cau} = u_{dom} + \Delta u_{cau}$$

where $u_{dom}$ is the dc component and $\Delta u_{cau}$ is the ripple component. In the steady state situation, the arm current does not affect the dc component $u_{dom}$ but the ripple component $\Delta u_{cau}$ [24]. In the proposed ER control, the virtual capacitor voltage (VCV) $u_{cau}$ is defined as

$$u_{cau} = u_{dom} + k_1 \cdot \Delta u_{cau}$$

where $k_1$ is the coefficient.

Based on the VCV $u_{cau}$, the voltage-balancing control [22] is implemented. The index list for the SMs in the arm is established through sorting VCV $u_{cau}$ in ascending order. The required on-state SM number $n_{on}$ is obtained by the arm reference $x_{arm}$, which is calculated not only based on the MMC control such as the active power control, reactive power control and dc-link voltage control but also the circulating current control. According to the index list, required on-state SM number $n_{on}$ and the arm current, appropriate SMs will be switched to the “On” state, and the ER $x_{err,SM1}$-$x_{err,SM6}$ for the SMs in the same arm will be generated, which can ensure the VCV balancing as

$$u_{cau} = u_{cau} = \cdots = u_{cau}$$

Combining (2), (5), (8), (17)-(19), (20) can be obtained as

$$k_1 \cdot \frac{1 + x_{err,SM1}}{C_{arm1}} = k_2 \cdot \frac{1 + x_{err,SM2}}{C_{arm2}} = \cdots = k_n \cdot \frac{1 + x_{err,SMn}}{C_{armn}}$$

Based on (20), in order to keep the ERs $x_{err,SM1}$-$x_{err,SMn}$ close to each other even if the capacitators $C_{arm1}$-$C_{armn}$ are not the same close in Fig. 5, the (21) should be satisfied.

$$k_1 \cdot \frac{1}{C_{arm1}} = k_2 \cdot \frac{1}{C_{arm2}} = \cdots = k_n \cdot \frac{1}{C_{armn}}$$

From (21), it can be seen that the coefficient $k_1$-$k_n$ in Fig. 5 can be decided based on the SM capacitances in the arm. The capacitance in the MMC can be calculated based on the relationship among the capacitor’s voltage, current and capacitance [14, 15], where the capacitor voltage is monitored and the capacitor current is obtained based on the monitored arm current and the switching function. The capacitance estimation can be achieved with high accuracy, where the error is less than about 1%. As a result, the proposed control in Fig. 5 can achieve that the ERs $x_{err,SM1}$-$x_{err,SMn}$ are close to each other in the same arm.

Fig. 4. Power losses of the SM1-SM6. (a) Conduction losses. (b) Switching frequency. (c) Switching losses. (d) Top and bottom switch/diode losses.

Based on above analysis, the different capacitance in the different SMs would cause different ERs for the SMs, which would cause different $T_1$ loss, $D_1$ loss, $T_2$ loss and $D_2$ loss in the different SMs, respectively. It would cause different aging speed of the $T_1$, $D_1$, $T_2$ and $D_2$ in the different SMs, respectively, which results in the different lifetime of the $T_1$, $D_1$, $T_2$ and $D_2$ in the different SMs, respectively, and therefore affects the reliability of the MMC.
With the proposed control strategy, the VCV \( u_{\text{can}1} - u_{\text{can}n} \) are kept balanced. According to (17) and (18), the dc components in \( u_{\text{can}1} - u_{\text{can}n} \) are kept the same. The only difference is the ripple amplitude in \( u_{\text{can}1} - u_{\text{can}n} \), which are with the relationship as

\[
k_1 \cdot \Delta u_{\text{can}1} = k_2 \cdot \Delta u_{\text{can}2} = \cdots = k_n \cdot \Delta u_{\text{can}n}
\]  

(22)

Suppose that the electrolytic capacitor is used in the MMC and the capacitor needs to be replaced when its capacitance drops to 80% of the rated value, according to (22), the capacitor voltage ripple amplitude would be increased by 0.25 p.u. at most. However, the capacitor voltage ripple amplitude is normally far less than the dc component \( u_{\text{dc}1} \) in the capacitor voltage [1-9]. Therefore, the impact of the different capacitor voltage ripple amplitudes on the MMC performance can be neglected, and the capacitor voltage \( u_{\text{can}1} - u_{\text{can}n} \) can be almost regarded as close to each other. As a result, the proposed control not only keeps the ERs \( x_{er,1} - x_{er,n} \) close to each other, but also almost keeps the capacitor voltage balancing, which would improve the losses distribution of the SMs in the same arm, as follows.

1) **Conduction losses**: according to (13)–(16), the same \( x_{er,1} - x_{er,n} \) ensures that the conduction losses \( P_{\text{can}}, P_{\text{ab}}, P_{\text{db}} \) and \( P_{\text{ad}} \) in the SMs of the same arm would be close to each other, respectively.

2) **Switching losses**: according to the voltage-balancing method [22], it is large possibility that the SMs in the same arm would work with the close switching frequency to produce the same ERs \( x_{er,1} - x_{er,n} \), which would improve the switching losses distribution of the SMs in comparison with that without the proposed control strategy.

Based on above analysis, it can be observed that the proposed control improves the conduction losses and switching losses of the semiconductors in the different SMs of the same arm, and therefore improves the reliability of the MMC. In comparison with [18] and [19], the proposed control considers both conduction losses balancing and switching losses balancing, where it not only can balance the power losses for the whole SM, but also can balance the power losses of the same type semiconductors in different SMs of the arm.

In addition, owing to that the change of capacitance is normally slow, the coefficients \( k_1 \)–\( k_n \) are not required to be updated in each control period, which simplifies the computation of virtual capacitor voltages and reduces the computation amount.

In the proposed control shown in Fig. 5, the coefficients \( k_1 \)–\( k_n \) corresponding to the \( n \) SM capacitances \( C_{\text{can}1} - C_{\text{can}n} \) are used to regulate the \( n \) SM capacitor voltage ripples to balance the power losses distribution in the arm. If the fault occurs to the \( i \)-th SM such as switch fault, diode fault, capacitor fault and the faulty SM is detected by the fault detection methods [16], [27-29], the \( i \)-th SM would be immediately bypassed from the arm by the SM bypass switch shown in Fig. 1(b). In this situation, the coefficients \( k_1 \)–\( k_{i-1} \) and \( k_{i+1} \)–\( k_n \) corresponding to the rest \( n-1 \) SM capacitances \( C_{\text{can}1} - C_{\text{can}(i-1)} \) and \( C_{\text{can}(i+1)} - C_{\text{can}n} \) are used to produce the \( n-1 \) virtual capacitor voltages \( u_{\text{can}1} - u_{\text{can}(i-1)} \) and \( u_{\text{can}(i+1)} - u_{\text{can}n} \) which are kept balanced by the voltage-balancing control and can ensure balancing SM power losses distribution for the rest \( n-1 \) SMs in the arm.
A. Enabling of Proposed Control

Figs. 7–10 shows the performance of the three-phase MMC, where the active power \( P \) and the reactive power \( Q \) is 100 MW and 0 MVar in the MMC system, respectively. Here, the capacitances \( C_{\text{cap}2} \sim C_{\text{cap}6} \), where \( C_{\text{cap}2} = 13.5 \) mF, \( C_{\text{cap}3} = 12 \) mF, \( C_{\text{cap}4} = 10.5 \) mF, \( C_{\text{cap}5} = 9 \) mF, \( C_{\text{cap}6} = 7.5 \) mF, respectively, as shown in Fig. 3(a).

In Fig. 7, the proposed control is enabled since 2 s. Fig. 7(a) shows the arm current \( i_{\text{ua}} \). Figs. 7(b) and (c) show the capacitor voltage \( u_{\text{cap}1} \sim u_{\text{cap}10} \), where the peak values of the \( u_{\text{cap}2} \sim u_{\text{cap}6} \) are increased to 1.08, 1.09, 1.1, 1.12 and 1.15 p.u., respectively, under the proposed control so as to improve the SM power losses distribution, which meets (21) and (22) in the proposed control. Suppose that the capacitor needs to be replaced when its capacitance is less than 80% of the rated value, it can be seen that the voltage peak value of the replaced capacitor is only 1.09 p.u., which is only increased by 1.8%. The ripple amplitudes in \( u_{\text{cap}1} \sim u_{\text{cap}6} \) under the proposed control are shown in Fig. 7(d), which are far less than the capacitor voltages, as shown in Fig. 7(b). In addition, the THD of the arm current \( i_{\text{ua}} \) without and with the proposed control is shown in Fig. 7(e), respectively. The THD of the MMC’s output voltage \( u_{\text{oa}} \) without and with the proposed control is shown in Fig. 7(f), respectively. The THD of the MMC’s output current \( i_{\text{a}} \) without and with the proposed control is shown in Fig. 7(g), respectively. The THD of the MMC’s output current \( i_{\text{a}} \) with the proposed control is almost the same to that without the proposed control, which shows that the proposed control has little impact on the performance of the MMC because the capacitor voltage ripple is quite small in comparison with the capacitor voltage.

Figs. 8 and 9 show the performance of the MMC under the proposed control. Fig. 8(a) shows the dc component in \( x_{\text{cap}1} \sim x_{\text{cap}6} \), which are quite small and can be negligible. Fig. 8(b) shows the amplitude of the fundamental component in \( x_{\text{cap}1} \sim x_{\text{cap}6} \), which are almost the same with each other and nearly equal to that in \( x_{\text{ua}} \). As a result, the proposed control effectively improves the equivalent references in the MMC. With the proposed control, the conduction losses, switching losses and switching frequency in SM1–SM6 are nearly close to each other, respectively, as shown in Figs. 9(a)–(c). The losses of the top switch/diode and the losses of the bottom switch/diode in SM1–SM6 are nearly close to each other, respectively, as shown in Fig. 9(d). Therefore, the losses difference between the top switch/diode and the bottom switch/diode in SM1–SM6 are nearly close to each other, as shown in Fig. 9(d), which improves the power losses distribution in the arm in comparison with that without the proposed control shown in Fig. 4.

This article has been accepted for publication in a future issue of this journal, but has not been fully edited. Content may change prior to final publication. Citation information: DOI 10.1109/JESTPE.2019.2922445, IEEE Journal of Emerging and Selected Topics in Power Electronics
In the proposed control, the different capacitor voltage ripples may be cause because of the different SM capacitances according to (21) and (22), where the SM capacitor voltage ripple would increase more if the SM capacitance drops more. Normally, the deteriorated capacitor needs be replaced until its capacitance drops below the threshold value, such as 80% of the rated value [14]. Fig. 11 shows the voltage ripple of the SM capacitor whose value drops to 80% of the rated value. In the MMC system, the rated SM capacitance is 15 mF and the corresponding equivalent capacity discharging time constant is 45 KJ/MVA, which is in the reasonable design range of the MMC [30]. From Fig. 11, it can be observed that the capacitor voltage ripple is increased along with the increase of the active power and reactive power. Even if the MMC works at the maximum power, the capacitor voltage ripple is still less than 20% and in the allowable range [18], [31].

B. Analysis of Capacitor Voltage Ripple

Fig. 10 shows the efficiencies of the MMC without and with proposed control, where the efficiency of the MMC without and with proposed control is quite close to each other.

![Efficiency](image3)

Fig. 11. Capacitor voltage ripple under various power.

C. Impact of Capacitor Monitoring Accuracy

The proposed control is based on the coefficients $k_1$-$k_n$, which are decided by the capacitor monitoring. As a result, the accuracy of the capacitor monitoring would affect the proposed control. Normally, the capacitance estimation can be achieved with high accuracy and the error is less than about 1%.

Figs. 12–15 show the semiconductor power loss errors $\Delta P_{stt}$, $\Delta P_{sdt}$, $\Delta P_{sdb}$, $\Delta P_{stt}$, $\Delta P_{sdb}$, $\Delta P_{stb}$, $\Delta P_{sdb}$ between SM 2 and SM 1, between SM 3 and SM 1, between SM 4 and SM 1, between SM 5 and SM 1, between SM 6 and SM 1, respectively. Fig. 12 shows the performance of the MMC without the proposed control. Figs. 13–15 show the performance of the MMC with the proposed control, where the different capacitor monitoring errors are considered for the MMC including 0, 0.5% and 1%. It can be observed that the semiconductor power loss errors would be increased along with the increase of the capacitor monitoring error. However, even the capacitor monitoring error reaches the maximum value, 1%, the semiconductor power loss errors are still quite smaller than those without proposed control. As a result, the proposed control effectively reduces the SM power losses imbalance in the arm of the MMC and improves the system reliability.
D. Change of Power

The dynamic performance of the MMC under the proposed control is shown in Fig. 16, where the reference of the active power is step changed from 90 MW to 50 MW. Figs. 16(a)–(c) show grid voltage $u_{dgs}$, grid current $i_{gs}$ and upper arm current $i_{ua}$ in phase A. Fig. 16(d) shows the upper arm capacitor voltage $u_{cap1}=u_{cap10}$ in phase A, where the ripple amplitudes of the $u_{cap1}=u_{cap10}$ are reduced along with the reduction of the active power. Figs. 16(e) and (f) show the conduction losses and switching losses of the semiconductors in SM 1–6, where the MMC works at 90 MW active power; Figs. 16(g) and (h) show the conduction losses and switching losses of the semiconductors in SM 1–6, where the MMC works at 50 MW active power. It can be observed that the conduction losses and switching losses of each type semiconductor in SM 1–6 are kept balanced, respectively, with the proposed control.
VI. EXPERIMENTAL STUDIES

A single-phase MMC with 7 SMs per arm, as shown in Fig. 17(a), is built in the laboratory. Fig. 17(b) shows the photo of the experimental circuit, where the IXFK48N60P is adopted as the switch/diode. An uncontrolled rectifier with electrolytic capacitors constitutes the dc bus voltage. The system control algorithm is implemented in the dSPACE1005 and the drive signals from the dSPACE1005 are sent to the driving panel in each SM by the optical fiber. The circulating current is suppressed with the method in [22]. The system parameters are shown in the Table VIII. To verify the proposed control, the small capacitance $C_{cap1} = 1.761$ mF and $C_{cap2} = 1.345$ are used in the experimental circuit, which are measured with the UNI-T UT612 LCR meter at 100 Hz and 25°C.

Fig. 18 shows the performance of the MMC, where the proposed control is enabled since 0.1 s. Fig. 18(a) shows the arm current $i_{an}$. Fig. 18(b) shows the capacitor voltage $u_{cap1}$, $u_{cap2}$ and $u_{cap3}$ in SM1, SM2 and SM3, respectively. Before 0.1 s, all capacitor voltages are kept balanced and the ripple amplitudes of all capacitor voltages are nearly the same with each other. After 0.1 s, the ripple amplitudes of the capacitor voltage $u_{cap1}$ and $u_{cap2}$ are increased under the proposed control so as to improve the SM power losses distribution, where the maximum peak value of the capacitor voltage is increased by 0.03 p.u. (1.7 V). Fig. 18(c) shows $u_{cap1}$, $u_{cap2}$ and $u_{cap3}$ under the proposed control, where the ripple amplitude of the $u_{cap1}$, $u_{cap2}$ and $u_{cap3}$ are 5.6 V, 7 V and 9.2 V, respectively, which meets the (21) and (22) in the proposed control. The ripple amplitudes of the capacitor voltages are far less than the capacitor voltages, as shown in Figs. 18(b) and (c). In addition, Fig. 18(d) shows that the THD of the upper arm current $i_{an}$ with the proposed control is almost the same to the THD of the $i_{an}$ without the proposed control, which shows that the proposed control has little impact on the performance of the MMC.

Fig. 18. Performance of MMCs. (a) $i_{\text{con}}$; (b) $u_{\text{con}1}$–$u_{\text{con}3}$; (c) $u_{\text{con}1}$–$u_{\text{con}3}$; (d) THD analysis of $i_{\text{con}}$.

Figs. 19 and 20 show the losses of the MMC with and without the proposed control, respectively, which includes the losses in SM1–SM7. The losses are calculated based on the experimental current and the semiconductor specifications from the manufacturer.

If the proposed control is not adopted, as shown in Fig. 19, along with the drop of the capacitance $C_{\text{cap1}}$ in SM2 and the capacitance $C_{\text{cap3}}$ in SM3, the conduction losses of $T_t$, $D_t$ are gradually reduced from SM2 to SM3, respectively; the conduction losses of $T_b$, $D_b$ are gradually increased from SM2 to SM3, respectively; the switching frequency is gradually reduced from SM2 to SM3; the switching losses are gradually reduced from SM2 to SM3. Consequently, the loss difference between the top switch/diode and the bottom switch/diode is gradually increased from SM2 to SM3, which would affect the reliability of the MMC. However, if the proposed control is used, as shown in Fig. 20, the conduction losses of $T_t$, $D_t$ are nearly kept the same in SM1–7, respectively; the conduction losses of $T_b$, $D_b$ are nearly kept the same in SM1–7, respectively; the difference of the switching frequency is reduced among SM1–7; the switching losses in SM1–7 are quite close to each other. As a result, the loss differences between the top switch/diode and the bottom switch/diode in SM1–7 are quite close to each other, which effectively improves the reliability of the MMC under capacitor deterioration.

(c) Switching losses of \( T_i \) and \( D_i \). (d) Switching losses of \( T_b \) and \( D_b \). (e) SM switching frequency. (f) Top and bottom switch/diode losses. (g) Loss difference.

Fig. 20. Performance of MMCs with proposed control including (a) Conduction losses of \( T_i \) and \( D_i \). (b) Conduction losses of \( T_b \) and \( D_b \). (c) Switching losses of \( T_i \) and \( D_i \). (d) Switching losses of \( T_b \) and \( D_b \). (e) SM switching frequency. (f) Top and bottom switch/diode losses. (g) Loss difference.

Fig. 21 shows the efficiency of the MMC without and with the proposed control. It can be observed that the efficiencies of the MMC without and with the proposed control are quite close to each other.

Fig. 22 shows the dynamic performance of the MMC with the proposed control, where the modulation index is reduced to half. Figs. 22(a) and (b) show that the arm current \( i_a \) and the ripples of capacitor voltages \( u_{cap1} \) and \( u_{cap3} \) are reduced. With the
proposed control, the conduction losses of $T_i$, $D_i$, $T_o$, $D_o$ and the switching losses of $T_i$, $D_i$, $T_o$, $D_o$ in different SMs of the arm are still kept balanced, respectively, when the modulation index is reduced to half, as shown in Figs. 22(c)–(f).

VII. CONCLUSIONS

In this paper, the SM power losses distribution in the arm of the MMC under capacitor deterioration is analyzed in detail. The capacitor drop results in the different ERs for the SMs in the same arm and causes unbalanced SM power losses distribution in the same arm, where the losses of the switch $T_i$, diode $D_i$, switch $T_o$ and diode $D_o$ would be different in the SMs with different capacitances, respectively, and therefore affects the MMC reliability. An ER control method is proposed for improving the reliability of the MMC under capacitor deterioration. Through the voltage-balancing control for the virtual capacitor voltages, the ERs for the SMs in the same arm can be kept close to each other. It improves the unbalanced SM power losses distribution in the same arm, where the losses of the switch $T_i$, diode $D_i$, switch $T_o$ and diode $D_o$ would be close to each other in the SMs with different capacitances, respectively, and therefore improves the reliability of the MMC under capacitor deterioration. The simulation and experiment results show the effectiveness of the proposed control strategy.

Fujin Deng (S’10-M’13) received the B.Eng. degree in electrical engineering from China University of Mining and Technology, Jiangsu, China, in 2005, the M.Sc. degree in electrical engineering from Shanghai Jiao Tong University, Shanghai, China, in 2008, and the Ph.D. degree in energy technology from the Department of Energy Technology, Aalborg University, Aalborg, Denmark, in 2012.

He joined the Southeast University in 2017 and is currently a Professor in the School of Electrical Engineering, Southeast University, Nanjing, China. From 2013 to 2015 and

from 2015 to 2017, he was a Postdoctoral Researcher and an Assistant Professor, respectively, in the Department of Energy Technology, Aalborg University, Aalborg, Denmark. His main research interests include wind power generation, multilevel converters, high-voltage direct-current technology, DC grid and offshore wind farm-power systems dynamics.

Qian Heng received the B.Sc. from Nanjing University of Aeronautics and Astronautics, Jiangsu, China, in 2017. Currently, she is working towards the M.Sc. degrees in the School of Electrical Engineering, Southeast University, Nanjing, China. Her main research interests include multilevel converters and high-voltage direct-current technology.

Chengkai Liu received the B.Eng. degree in electrical engineering from Southeast University, Nanjing, China, in 2018. He is currently working toward the Ph.D. degree in the School of Electrical Engineering, Southeast University, Nanjing, China. His main research interests include multilevel converters and dc grid.

Qingsong Wang (S’14-M’17) received the B.Sc. and M.Sc. degrees from the Department of Electrical Engineering, Zhejiang University, Hangzhou, China, in 2004 and 2007, respectively, and the Ph.D. degree from the School of Electrical Engineering, Southeast University, Nanjing, China, in 2016. From November 2015 to November 2016, he was a joint Ph.D student with the Department of Energy Technology, Aalborg University, Aalborg, Denmark, where he focused on electric springs.

From July 2004 to July 2005, he was an engineer in Shihlin Electronic & Engineering Co., Ltd, Suzhou, China. From July 2007 to August 2011, he was an engineer in Global Development Center of Philips Lighting Electronics, Shanghai, China. In October 2010, he was promoted to be a Senior Engineer. From August 2011 to September 2013, he was a Lecturer in PLA University of Science and Technology, Nanjing, China. Since 2017, he has been with Southeast University, where he is currently a Lecturer in the School of Electrical Engineering.

Dr. Wang’s research interests are focused in the areas of control and applications of power electronics to power systems, smart grid, and lighting drivers.

Rongwu Zhu (S’2-M’5) received the B.Eng. in Electrical Engineering from Nanjing Normal University, Nanjing, China, in 2007 and Ph.D. degree in energy technology from Department of Energy Technology, Aalborg University, Aalborg, Denmark, in 2015. From 2011-2012, he was a guest researcher with Aalborg University. He is currently a Senior Researcher with Chair of power electronics, at Christian-Albrechts-University of Kiel (Germany). He has published over 60 technical papers (over 20 of them in international peer-review). His research interests include high-power multilevel modular converters, DC-grid and wind-farm power systems, smart transformer-fed distribution system, reliability and lifetime of power converters, modelling and stability of the power electronics-based electric grid.
Xu Cai received the B.Eng. degree from Southeast University, Nanjing, China, in 1983, and the M.Eng. and Ph.D. degrees from China University of Mining and Technology, Jiangsu, China, in 1988 and 2000, respectively, all in electrical engineering.

He was with the Department of Electrical Engineering, China University of Mining and Technology, as an Associate Professor from 1989 to 2001. Since 2002, he has been a Professor with Shanghai Jiao Tong University, Shanghai, where he has also been the Director of the Wind Power Research Center since 2008. He was the Vice Director of the State Energy Smart Grid R&D Center, Shanghai, China, from 2010 to 2013. His current research interests include power electronics and renewable energy exploitation and utilization, including wind power converters, wind turbine control system, large power battery storage systems, clustering of wind farms and its control system, and grid integration.

Zhe Chen (M’95–SM’98–F’18) received the B.Eng. and M.Sc. degrees all in Electrical Engineering from Northeast China Institute of Electric Power Engineering, Jilin City, China, MPhil in Power Electronics, from Staffordshire University, England and the Ph.D. degree in Power and Control, from University of Durham, England.

Dr Chen is a full Professor with the Department of Energy Technology, Aalborg University, Denmark. He is the leader of Wind Power System Research program at the Department of Energy Technology, Aalborg University and the Danish Principle Investigator for Wind Energy of Sino-Danish Centre for Education and Research.

His research areas are power systems, power electronics and electric machines; and his main current research interests are wind energy and modern power systems. He has led many research projects and has more than 400 technical publications with more than 10000 citations and h-index of 44 (Google Scholar).

Dr Chen is an Associate Editor of the IEEE Transactions on Power Electronics, a Fellow of the Institution of Engineering and Technology (London, U.K.), and a Chartered Engineer in the U.K.
