Aim/Introduction: Assessment of cell behavior in vivo, such as distribution, retention to major organs, is important information for cell therapy. Radioisotope labeled cells and positron emission tomography (PET) are powerful tools to obtain quantitative information of cell trafficking. [^{89}Zr]Zr-DFO and [^{89}Zr]Zr-oxine are promising methods for cell labeling. We aim to optimize preparing condition of [^{89}Zr]Zr-complex and evaluate two labeling strategies with chimeric antigen receptor T (CAR-T) cell. **Materials and Methods:** [^{89}Zr]$ZrCl_4$ was prepared from [^{89}Zr]Zr-oxalate (Perkin Elmer) in the 1.0 M oxalic acid by trapping with QMA cartridge (Merck, Germany) and eluting with 1.0 N HCl. 0.7-7.0 nmol of DFO (DFO-Bz-NCS) and 0.02-2.0 μmol of oxine were used for preparation of [^{89}Zr]Zr-DFO and [^{89}Zr]Zr-oxine, respectively. CD19 CAR-Jurkat T cell was labeled with 0.08-0.24 kBq of each [^{89}Zr]Zr-complex. Labeling efficiency, cell viability, and production of cytokine IL-2 were assessed within 12 hr after cell labeling with [^{89}Zr]Zr-complex. Finally, we evaluated cell viability and cell proliferation rate of CAR-Jurkat T cell labeled with [^{89}Zr]Zr-DFO or [^{89}Zr]Zr-oxine up to 7 days. **Results:** Both 2.8 nmol of DFO and 2.0 μmol of oxine were shown 100% of chelation efficiency with 58.5±17.4 MBq of [^{89}Zr]$ZrCl_4$. CAR-Jurkat cell labeling efficiency with 0.08, 0.14, 0.19, 0.24 kBq of [^{89}Zr]Zr-DFO was 76.9±11.6%, 81.6±11.3%, 82.2±13.1% and 84.4±10.9%, respectively. And [^{89}Zr]Zr-Oxine showed labeling efficiency of 43.7±2.4%, 34.5±5.2%, 37.5±3.1% and 24.8±6.8% at the same dose points. Average cell viability after labeling with different dose of [^{89}Zr]Zr-DFO and [^{89}Zr]Zr-oxine was 93.5% and 91.6%, respectively. The [^{89}Zr]Zr-complex-labeled CAR-Jurkat cells similarly induced IL-2 release in positive target cell (Raji) at 70.7 ng/mL, compared to the unlabeled CAR-Jurkat cells (77.3 ng/mL). Up to day 7, the long term cell viability in the presence of 0.14 kBq [^{89}Zr]Zr-DFO and [^{89}Zr]Zr-oxine was around 88% and 20%, respectively. At the 0.08 kBq, the [^{89}Zr]Zr-DFO labeled cells were found to be more than 90% cell proliferative by day 3 and even more than 80% by day 7. [^{89}Zr]Zr-Oxine labeled cells showed only 56% capacity on day 1 and after day 3, the cell proliferation ability rapidly decreased in all doses. **Conclusion:** In this research, the preparation method of [^{89}Zr]Zr-DFO and [^{89}Zr]Zr-oxine with high chelation efficiency was optimized. Compared to CAR-Jurkat T cells labeled with [^{89}Zr]Zr-DFO and [^{89}Zr]Zr-oxine, [^{89}Zr]Zr-DFO labeled cells exhibited excellent cell viability and proliferation ability. **References:** None.

Aim/Introduction: Chimeric antigen receptor(CAR) T cell has been developed in recent years, producing impressive clinical reports in patients with hematologic malignancies. However, there is no standardized method available for cell trafficking and monitoring in vivo behavior of injected CAR T-cells. We assessed the feasibility of real-time in vivo ^{89}Zr-p-Isothiocyanatobenzyl-desferrioxamine B(Df-Bz-NCS, DFO) labeled CAR T-cell trafficking using PET. **Materials and Methods:** We constructed and produced CD19-targeting Jukat/CAR T-cells and T-cells obtained from human peripheral blood mononuclear cells(hPBMC). After synthesizing ^{89}Zr-DFO, cells were radiolabeled with 74~185 kBq in 5 × 10^6 cells/HBSS buffer at 37°C for 30 minutes. Then, we assessed the cell labeling efficiency, cell viability and function. For PET imaging of ^{89}Zr-DFO labeled CAR-T cells, we developed mouse xenograft models bearing both Raji(CD19 positive) and K562(CD19 negative) tumors in their bilateral franks. Serial images were acquired with PET/ magnetic resonance(MR) scanner from 1 hour to 7 days after injection of ^{89}Zr-DFO labeled cells. The biodistribution of CAR T-cells was also cross-confirmed by ex vivo tissue analysis with γ-counter, flow cytometry(FACS), Alu-PCR and immunohistochemistry(IHC), respectively. **Results:** The ^{89}Zr-DFO radiolabeling efficiency of Jurkat/CAR and hPBMC CAR T-cells was 70 ~ 79%, and radiolabeled activity was 98.1 ~ 103.6 kBq/10^6 cells. Cell viability after radiolabeling was > 95 %. There is no significant difference in function for IL-2 or IFN-γ secretion between unlabeled and labeled CAR T-cells. PET/MR images in xenograft models showed that most of the ^{89}Zr-labeled Jurkat/CAR T-cells were distributed in the lung(24.4 ± 3.4 %ID) and liver(22.9 ± 5.6 %ID) by 1 hour after injection. The cells gradually migrated to the spleen by day 1, where they remained stable until day 7(on day 7: lung 3.9 ± 0.3 %ID, liver 36.4 ± 2.7 %ID, spleen 1.4 ± 0.3 %ID). No significant accumulation of labeled cells was identified in tumors. A similar pattern was observed in ex vivo biodistributions on day 7(lung 3.0 ± 1.0%ID, liver 19.8 ± 2.2%ID, spleen 2.3 ± 1.7%ID). Similarly, the tracing of

^{89}Zr-labeled hPBMC CAR T-cells showed the same pattern. The distribution of CAR T-cells was also confirmed by FACS, Alu-PCR and IHC. **Conclusion:** We confirmed the feasibility of CAR T-cells trafficking in vivo using serial PET imaging after administration of ^{89}Zr-DFO labeling. Our results suggest that PET imaging of CAR T-cells, labeled with ^{89}Zr-DFO, can be used to investigate cellular kinetics, initial in vivo distribution, and safety profile of future CAR T-cell development. **References:** None.

In vivo Comparison Zr^{89} cell labelling techniques, internal Zr^{89}-Oxine labelling VS Zr^{89}-DFO-Bn-NCS cell surface labelling

S. J. Paisey, H. Almutairi, A. Dabkowski, C. Marshall, A. Ager; Cardiff University, Cardiff, UNITED KINGDOM.

Aim/Introduction: Two alternative strategies have been reported in the literature for the Zr^{89} labelling of cells. The most widely reported method involves the use of Zr^{89}-Oxine complexes to transport Zr^{89} across the cell membrane to internally label cells.[1] However, an alternative strategy has been published where a preformed Zr^{89}-Dfo-Bn-NCS complex is coupled to cell surface proteins.[2] Whilst both labelling methods have been used to good effect in specific cell types each method has the potential to adversely affect cells in different ways. Here we compare cell labelling and more importantly in vivo images of cells labelled via the 2 different methods in freshly extracted murine donor cells injected into wild type mice. **Materials and Methods:** Zr^{89} was produced and purified in house via adaptations of the methods of Walther et al[3],[4]. Murine cells extracted from the spleens of matched donor mice were split into 2 populations and simultaneously labelled with either Zr^{89}-Oxine via the methods of Ferris et. Al.[1] or Zr^{89}-Dfo-Bn-NCS via the methods of Bansal et. Al.[2]. Labelled the cells and immediately injected into wild type C57B/6 mice via tail vein (~5 x10^{6} cells, 0.8-2MBq). Mice were scanned for 1 hour under anaesthesia (isoflurane in O2, 1-2%) in a Mediso nanoscan PET/CT scanner up to 6 times post injection over a 15 day period. **Results:** Viable cell populations were obtained from both methods and showed similar biodistributions in vivo, however in our hands images of Zr^{89}-Dfo-Bn-NCS surface labelled cells contained anomalous concentrated hotspots of radioactive uptake randomly distributed throughout the body. **Conclusion:** More work is required to determine the exact cause of the anomalous hotspots of radioactivity derived from the Zr^{89}-Dfo-Bn-NCS surface labelled cells, however in the meantime caution should be exercised when imaging surface labelled cells particularly if the aim of the study is to show homing to metastases. **References:** 1) Ferris TJ, et al. Cancer diagnostic imaging using the novel T cell that specifically attracted a cancer cell

Y. Nakagami[1], *D. Kano*[2], *S. Hosokawa*[3], *Y. Kaji*[1]; [1]*Dokkyo Medical University, Tochigi, JAPAN,* [2]*National Cancer Center Hospital East, Kashiwa, JAPAN,* [3]*Hirosaki University, Hirosaki, JAPAN.*

Aim/Introduction: Our collaborator previously established a novel cell line, termed HOZOT, derived from umbilical cord blood mononuclear cells. HOZOT cells actively penetrate into a variety of human cancer cell lines, but not into normal cell lines, and form apparent cell-in-cell structures. We established In-111-labeled and Tc-99m hexamethylpropylene amine oxime (HMPAO)-labeled HOZOT cells for the investigation of cancer. This study describes radiolabeling of HOZOT cells for the evaluation of cell trafficking in a model of human breast cancer in mice. **Materials and Methods:** Different labeling buffers and incubation times were evaluated to optimize In-111-oxine labeling conditions. Therefore, incubation with 0.011 MBq of In-111-oxine per million HOZOT cells in PBS (pH 7.4) for 20 min is the best condition that provides optimum labeling efficiency without affecting cell viability and functionality. On the other hand, The Tc-99m of 500MBq was added to 1 mg of HMPAO solution. The million HOZOT cells were incubated with 500 MBq of Tc-99m HMPAO at 37 degrees C for 5 minutes. The radiolabeled HOZOT cells were administered to mice with MDA-MB-468 human breast cancer cells from their tail veins, and the mice were sacrificed after 6 hours from the injection. The biodistribution of the radioactivity in each organ and cancer cells was counted. **Results:** The labeling efficiency of In-111-oxine labeled HOZOT cells was 99%. The labeling efficiency of Tc-99m-HMPAO labeled HOZOT cells was 60%. The biological activity of the In-111-oxine labeled HOZOT cells and Tc-99m-HMPAO labeled HOZOT cells was maintained because the radiolabeled HOZOT cells were not stained with trypan blue. The radioactivity according to each organ was high in order of kidneys, liver, spleen, gallbladder, lungs, and cancer cells. There was a little radioactivity of other organs. **Conclusion:** We developed the novel cell labeling method for HOZOT cells. The main discharge route of In-111 and Tc-99m from a body is guessed as kidney urinary tract system and biliary tract system. The radioactivity of the cancer cells was caught enough. If the radioactivity is suitable for imaging, this radiolabeling method will become a novel cancer imaging method. **References:** Takeuchi M, et al. Cell-in-cell Structures Formed between Human Cancer Cell Lines and the Cytotoxic Regulatory T-cell Line HOZOT. Journal of Molecular Cell Biology (2010), 2, 139-151.

Toxicity, efficacy and tumour imaging of ^{195m}Pt-cisplatin in mice

E. A. Aalbersberg[1], *L. de Wit - van der Veen*[1], *K. Codée – van der Schilden*[2], *O. Zwaagstra*[2], *E. Vegt*[1], *W. Vogel*[1];
[1]*Netherlands Cancer Institute, Amsterdam, NETHERLANDS,*
[2]*Nuclear Research and consultancy Group, Petten, NETHERLANDS.*

Aim/Introduction: Cisplatin is used in first-line treatment of many cancer types, but not all patients show response while toxicity can be severe. Radiolabeled cisplatin could theoretically enhance the therapeutic effect, or it could be imaged to aid treatment choices by selecting patients with adequate tumour uptake of cisplatin. The aim of this study was to determine the toxicity and efficacy of ^{195m}Pt-cisplatin compared to normal cisplatin, and to investigate ^{195m}Pt-cisplatin tumour imaging in mice. **Materials and Methods:** ^{195m}Pt-cisplatin (CISSPECT®) was obtained from NRG. Toxicity was evaluated in 69 mice, which received 6 mg/kg cisplatin containing 0%, 25%, 50%, or 100% (~10MBq) of ^{195}Pt-cisplatin. Toxicity was quantified by loss of body weight measured 2-3x/week, renal function measured with ^{99m}Tc-MAG3 after 1 day, 1 week and 1 month, and histopathology after 1 day, 1 week and 1 month. Treatment efficacy of ^{195m}Pt-cisplatin was compared to standard cisplatin in 20 mice with a mammary gland tumour, and was measured as PFS and OS. SPECT/CT imaging of ^{195m}Pt-cisplatin was performed in 5 mice with a mammary gland tumour at 1 and 24 hours post-injection of 5-12 MBq ^{195m}Pt-cisplatin. **Results:** Specific activity at the end of irradiation was 91 MBq/g Pt. Radionuclide purity of ^{195m}Pt-cisplatin was 96.1% at start of experiments; ^{197}Pt-cisplatin was the main impurity (3.9% of the total radioactivity). ^{195m}Pt-cisplatin did not lead to weight loss >10% for any of the applied doses. Some animals in every ^{195m}Pt-cisplatin dose group had a delayed excretion of ^{99m}Tc-MAG3 one month after administration. Histopathology of the kidneys demonstrated a small number of mild lesions after one month, but this was comparable to animals receiving normal cisplatin only. No differences in PFS and OS were found between mice receiving ^{195m}Pt-cisplatin or normal cisplatin. Tumour uptake on SPECT/CT was mild to moderate, with diffuse background uptake in normal tissues due to the binding of cisplatin to plasma proteins. **Conclusion:** In the applied mouse model, ^{195m}Pt-cisplatin did not prove more toxic or effective than normal cisplatin for the treatment of cancer. SPECT imaging of ^{195m}Pt-cisplatin uptake in tumour is feasible with adequate image quality in mice. **References:** None.

99m-Tc dimercaptosuccinic acid renal scintigraphy is correlated to fibrosis in a model of Chronic Kidney Disease in rats

M. Bobot[1], *G. Hache*[1], *S. Fernandez*[2], *L. Balasse*[2], *A. Moyon*[1], *P. Garrigue*[1], *S. Burtey*[1], *B. Guillet*[1];
[1]*Aix Marseille Université - CERIMED - Assistance Publique Hôpitaux de Marseille, Marseille, FRANCE,* [2]*CERIMED, Marseille, FRANCE.*

Aim/Introduction: Chronic kidney disease (CKD) increases cardiovascular events risk and mortality. Fibrosis is the hallmark of CKD and the severity of CKD usually correlates with the magnitude of kidney cortical fibrosis. Evaluation of interstitial fibrosis is crucial in preclinical research focusing on CKD, however post mortem histological staining is currently the gold standard for assessing fibrosis in rodents' kidneys. Therefore, approaches that allow longitudinal assessment of kidney structure are required to refine studies involving rodents. Thus, we investigated dedicated small-animal SPECT/CT renal imaging to monitor renal damage in vivoduring the induction a chronic kidney disease in rats. **Materials and Methods:** We induced CKD in Sprague-Dawley rats, by feeding them a diet containing 0.25% or 0.5% adenine (ARD) during 4 weeks. Kidney function was assessed by serum creatinine and urea. [^{99m}Tc]--dimercaptosuccinic acid ([^{99m}Tc]-DMSA) scintigraphy was performed once a week. At the end of the protocol (Day 35), histology was performed in kidneys with hematoxylin and eosine to establish a score of tubular lesions and Sirius red to quantify deposition of collagen 1 and 3. **Results:** Compared to control rats, we showed an increase in serum creatinine, serum urea from Day 14to Day 35 in 0.5% ARD rats but not with 0.25%ARD. ARD significantly decreased ([^{99m}Tc]-DMSA uptake in kidneys from Day 14to Day 35, in both 0.25% and 0.5% ARD rats ($p<0.01$ and $p<0.001$, respectively). Compared to control group,we showed an increase in the score of tubular lesions (ctrl: 0.5±0.4; 0.25%ARD: 1.9±0.4, $p<0.001$; 0.5%ARD: 2.9±0.4, $p<0.001$), and an increase in interstitial collagen I and III accumulation in renal cortex(ctrl: 1.8±0.8%; 0.25%ARD: 7.7±1.9%, $p<0.001$; 0.5%ARD: 29.5±4.3%, $p<0.001$). Interestingly, [^{99m}Tc]-DMSA uptake at Day 28 is negatively correlated to Sirius red stainingat Day 35 ($r=0,89$, $p<0,0001$, $R^2 = 0,67$) **Conclusion:** [^{99m}Tc]-DMSA scintigraphy was representative of cortical fibrosis in ARD rats. This imaging strategy enabled, beyond scare formation, longitudinal monitoring of kidney fibrosis and could be used as a non invasive prognosis outcome to estimate kidney fibrosis. **References:** None.

EP-0636

Towards Imaging Cisplatin Resistance with ^{64}Cu PET

F. Al-salemee, *J. Bartnicka, T. H. Witney, P. J. Blower;*
King's College London, London, UNITED KINGDOM.

Aim/Introduction: Cisplatin has been for decades the backbone of several chemotherapeutic regimens used in the treatment of various cancer types, including ovarian, testicular, lung and bladder cancer. However, the efficacy of this drug is often practically abolished by the development of resistance early in the course of chemotherapy, especially in ovarian cancer. Consequently, many patients receive several cycles of cisplatin, and suffer its debilitating side effects, in vain. A correlation between cellular accumulation of cisplatin and copper transporters (CTR1, ATP7A, ATP7B) has been reported in the literature on numerous occasions. In this work, we are investigating the possibility of utilising copper accumulation

in tumours, detected by positron emission tomography (PET) imaging with unchelated ^{64}Cu(II), as an indicator of cisplatin accumulation and hence sensitivity/resistance. **Materials and Methods:** Two variants of the human ovarian carcinoma cell line A2780, wild type (WT) and cisplatin-resistant (CisR), were incubated at 37°C with [^{64}Cu]$CuCl_2$ in 24-well plates (10KBq/well) for 10, 30, 60 and 120 minutes (accumulation); or 120 minutes followed by supernatant removal and replacement with fresh medium and re-incubation for 10, 30, 60 and 120 minutes (retention). The cells and the supernatants were then counted for radioactivity and the cell-associated fraction of radioactivity was calculated and, in case of accumulation, related to cell number. Cisplatin resistance was compared between the two cell lines using a Sulforhodamine B assay allowing the determination of the half-maximal inhibitory concentration (IC50). **Results:** The cell-associated radioactivity for WT cells was 0.54(±0.03), 1.2(±0.2), 3.7(±0.3) and 5.6(±0.4)Bq/10^{3}cell after 10, 30, 60 and 120 minutes, respectively; while it was 0.31(±0.05), 0.57(±0.05), 0.99(±0.03) and 1.24(±0.06) Bq/10^{3}cell for CisR cells (n=4). Retention values at 10, 30, 60 and 120 minutes were 58.6(±2.5), 53.3(±1), 39.7(±2.4) and 28(±1.5) % for WT cells, respectively; and 51.8(±2.4), 47.8(±0.6), 35.6(±1.9) and 21.3(±5.2) % for CisR cells (n=4). The IC50 for WT cells was 2.2(±0.55) µM, compared to 10.3(±1.44) µM for CisR cells (n=3). **Conclusion:** In this cell line there is a clear negative relationship between copper accumulation and acquired cisplatin resistance in vitro. The modest dissimilarity in copper retention between the two cell lines suggests that the difference in accumulation is mainly due to a difference in uptake rather than efflux. The results justify experiments to confirm this finding in vivo in mice bearing these cell lines with a view to assessing the prospects for clinical evaluation of this novel application of PET for imaging cisplatin drug resistance. **References:** None.

In vivo monitoring of human lymphoma using ^{64}Cu-DOTA-rituximab PET in mouse xenograft model for alpha-particle radioimmunotherapy

C. Lee, K. Kim, S. Woo, C. Kang, C. Kang, K. Lee, Y. Lee, K. Song, S. Lim, I. Lim;
KIRAMS, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: PET radiopharmaceuticals using rituximab are required because it can be used for selecting proper patients for rituximab treatment through imaging and for monitoring advanced radioimmunotherapy such as alpha particle. The aim of this study is to evaluate the targeted imaging of ^{64}Cu-DOTA-rituximab PET in human lymphoma model. **Materials and Methods:** CD20 expression was evaluated in lymphoma cell lines (Jurkat and Raji cells). DOTA-rituximab was conjugated in optimized conditions. ^{64}Cu was chelated to DOTA-rituximab. The number of chelators on rituximab conjugates was verified using MALDI-TOF MS for comparison of rituximab and DOTA-rituximab. Immunoreactivity was performed and analyzed using GraphPad Prism software. Tumor xenograft models were established in balb/c-nu mice using CD20 positive cells. Animal PET/CT imaging was obtained by INVEON scanner (Siemens) after tail vein injection with or without pre-dose received 2 mg cold rituximab. Specific binding of tumor was evaluated by organ biodistribution assay and autoradiography. CD20 expression in tumor tissue was evaluated by immunohistochemistry. **Results:** CD20 protein was highly expressed in Raji cells. Radiochemical purity of ^{64}Cu-DOTA-rituximab was more than 95%. Binding to Jurkat cells was not specific, whereas Raji cells was blocked with an excess of cold rituximab, which evaluating the specificity of binding. Immunoreactivity was more 75%. In PET/CT imaging, binding of ^{64}Cu-DOTA-rituximab was shown in tumors without pre-dose injection group. On the other hand, there was no signal in tumors with pre-dose injection group. Radioactivity of tumor was much higher than other organs. Tumor specific uptake of ^{64}Cu-DOTA-rituximab was related to CD20 expression. **Conclusion:** We demonstrated that human lymphoma was specifically visualized by ^{64}Cu-DOTA-rituximab PET in xenograft model. This suggest that alpha particle immunotherapy using ^{225}Ac-DOTA-rituximab is applicable to human lymphoma. **References:** None.

Early prognostic value of 99mTc-3PRGD2 scintimammography in acute Radiation-induced lung injury

L. Shi, Q. Bai, W. Zhang, M. Yuan, L. Wei;
Tangdu Hospital, Xi'an, CHINA.

Aim/Introduction: Acute radiation pneumonitis (RP) and radiation pulmonary fibrosis (RPF) are the most common treatment-related toxicities induced by thoracic radiation therapy (RT), but not all the patients with RP deteriorate into RPF without intervention treatment (such as glucocorticoids treatment, may cause a series of side-effects). Evidences showed acute radiation-induced lung injury (RILI) was accompanied by high expression of Integrin αvβ3. In this study, ^{99m}Tc-3(poly-(ethylene glycol), PEG)4-RGD2 (^{99m}Tc-3PRGD2) was used as a radiolabeling probe which could combine with the over expressed Integrin αvβ3 in RILI rats' modals. Histopathological examinations, immunohistochemistry examinations and image analysis were used to evaluate if the ^{99m}Tc-3PRGD2 scintimammography have the early potential prognostic value on acute RILI. **Materials and Methods:** The stability and radiochemical purity of ^{99m}Tc-3PRGD2 radiation molecular probe was verified by TLC and UPLC methods. A total of 50 female rats (8 weeks) were randomly divided into the normal control group (NC, n=10), 15Gy pulmonary radiation-induced injury group (15GyPI, irradiation dose=15Gy, n=40). Each rat had its own markers. All rats' exposure pulmonary field was assessed and marked by CT. Static and dynamic ^{99m}Tc-3PRGD2-SPECT data were collected every 5 days since RT assessed. 90th day post-irradiation, the lung samples were collected for Histopathological and immunohistochemistry examinations. **Results:** Pathological results verified that 3/39(8%) rats in the

group 15GyPI showed Grade 0 RPF, 5/39(13%) rats showed grade I RPF, 14/39(36%) rats showed Grade II RPF and 17/39(43%) rats showed grade III RPF. Combination of pathological and immunohistochemical results, more accumulation and faster metabolic rate of ^{99m}Tc-3PRGD2(after 5~30 days RT assessed) indicated worse prognosis. Especially Grade III RPF showed significant more accumulate and faster ^{99m}Tc-3PRGD2 metabolic rate than Grade II RPF (P<0.01). **Conclusion:** Compared to CT images or clinical symptoms, significant different were found in ^{99m}Tc-3PRGD2-SPECT data 4-10 weeks earlier. ^{99m}Tc-3PRGD2 scintimammography have the potential early prognostic value on acute RILI and this will be guiding our further therapy. **References:** 1.Wu, J.G., et al., Biometabolic Distribution of 99mTc-3PRGD2 and Its Potential Value in Monitoring Chemotherapeutic Effects. Synthesis of ^{64}Cu-DOTA-T-DM1 and preliminary evaluation as a potential companion diagnostic agent for T-DM1

H. Kim, *I. Lee, E. Shin, E. Lee, R. Yoo, H. Chung, J. Shim;*
Korea Institute of Radiological & Medical Sciences, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Trastuzumab-DM1 (T-DM1) is an ADC composed of the humanized HER2 antibody trastuzumab covalently linked to the cytotoxic agent emtansine (DM1), a potent treatment of HER2-positive metastatic breast cancer (mBC). Radiolabeling an ADC with copper-64(^{64}Cu), combined with positron emission tomography (PET) imaging enables non-invasive and tracking of ADC biodistribution. This approach can directly evaluate in both preclinical models and patients whether an ADC retains its mAb selective tumor targeting capability. Our objective was to develop ^{64}Cu-labeled-antibody drug conjugates (ADC) as immuno-PET-based companion diagnostic agents for that of ADC. **Materials and Methods:** T-DM1 was conjugated with DOTA or NOTA bifunctional chelator at 25ºC for 2 h. The DOTA-ADC and NOTA-ADC were purified with acetate radiolabeling buffer (pH 5.5) via size exclusion chromatography using PD-10 column. The ratio of chelator per ADC was confirmed by MALDI-TOF. The chelator conjugated ADCs were radiolabeled with $^{64}CuCl_2$ and formulated for intravenous administration. **Results:** The number of DOTA and NOTA conjugated on T-DM1 were 3.5 and 3.7, respectively. The labeling efficiencies were no less than 95%. Specific activities ranged from 3 to 20 mCi/mg. The ^{64}Cu-DOTA-T-DM1 and ^{64}Cu-NOTA-T-DM1 were more than 95% stable after 48 hours in human serum. The ^{64}Cu-labeled ADCs showed similar distribution when compared to their parental mAbs, and retained the same selective tumor accumulation as their mAbs. **Conclusion:** These radiolabeled ADCs were synthesized and examined as potential companion diagnostic agents. ^{64}Cu-DOTA-T-DM1 and ^{64}Cu-NOTA-T-DM1 are a stable and effective immuno-PET tracer for HER2 positive tumor imaging in vivo. **References:** None.

Decreased Striatal VMAT2 Binding in Type 2 Diabetes Rat by ^{18}F-FP-(+)-DTBZ PET-CT

F. Xie, *D. Jiang, Q. Huang, S. Ren, F. Hua, F. Hua, Y. Guan;*
Huashan Hospital, Fudan university, Shanghai, CHINA.

Aim/Introduction: Diabetes is a risk factor for Parkinson's disease, and they share similar pathogenic pathways in mitochondrial dysfunction, endoplasmic reticulum stress, inflammation, and alterations in metabolism. Vesicular Monoamine Transporter type 2 (VMAT2) has proven as a useful imaging marker for quantificationof dopaminergic integrity in Parkinson's disease, ^{18}F-FP-(+)-DTBZis a VMAT2 ligand which could apply to measure it. The aim of this study was to examine the expression of VMAT2 in the striatal of type 2 diabetic rat model. **Materials and Methods: Materials and Methods:** of age) and age-matched lean controls (n = 6, 8 wk of age) were randomly assigned to be fed with high-sugar and high-fat diets to raise the fasting blood glucose, and develop of type 2 diabetes. At 3, 6 and 12 months of age, PET/CT scans were performed at 60 min post intravenous injection of ^{18}F-FP-(+)-DTBZ. Imaging data were analyzed using PMOD 3.4 software. The striatal specific uptake ratio (SUr) was calculated as [(uptake in striatum - uptake in cerebellum) /uptake in cerebellum]. **Results:** The body weight of the two groups was statistically different at 6 months (454.33 ± 55.88, 380.17 ± 18.84) (P< 0.05), but there was no significant difference at 3 months (267.20 ± 9.42,202.00 ± 5.70) and 12 months (402.33 ± 19.45,442.67 ± 87.52) (P> 0.05). The fasting blood glucose of the T2DM group at 6 months and 12 months (10.58 ± 3.00 mmol/L, 15.63 ± 5.85 mmol/ L) was significantly higher than the control group (5.95 ± 0.75 mmol/L, 5.40 ± 0.49 mmol/L) (P<0.05, P<0.0001). In the T2DM group, ^{18}F-FP-(+)-DTBZ uptake in the striatum was significantly lower at 12 months (2.68 ± 0.24) than in the control group (3.46 ± 0.23) (P= 0.0002). There was a significant negative correlation between ^{18}F-FP-(+)-DTBZ uptake and fasting blood glucose in the striatum of the two groups at 12 months (r^2= 0.753,P= 0.001). **Conclusion:** The increase of blood glucose could decrease the expression of VMAT2 in the dopaminergic pathway in the brain. The expression of VMAT2 in the striatum of T2DM rats is also negatively correlated with fasting blood glucose. **References:** 1. Pagano G, Polychronis S, Wilson H, et al. EP-0641

Synthesis And Pre-clinical Evaluation Of ^{124}Iodine-labeled Mucin1-folate Hybrid Peptide: Potential Theranostic Radiopharmaceuticals For Breast And Ovarian Cancers

I. Aljammaz, B. Alotaibi, F. AlRumayan, A. AlRabiah, S. Okarvi; King Faisal Spec. Hosp., Riyadh, SAUDI ARABIA.

Aim/Introduction: Epithelial mucin1 (MUC1) and folic acid (FA) are overexpressed by most epithelial cancers hence attracting increasing interest as potential targets for imaging and therapy. The high expression of MUC1 and FA on breast and ovarian cancers and low expression on normal tissues makes them potential targets for diagnosis and therapy of cancers. Different Ga-68 and F-18 labeled MUC1-FA-targeted PET tracers have been developed and demonstrated a high diagnostic efficacy. However, the short half-life of these radiotracers may limit distribution to distant imaging centers. Thus, as a part of our on-going research effort to develop theranostic radiopharmaceuticals, we here report the synthesis and preclinical evaluation of new $^{123/124/131}$I-MUC1-FA hybrid peptide conjugates. **Materials and Methods:** The synthetic approaches for the preparation of [$^{123/124/131}$I]-iodobenzene and pyridine MUC1-FA conjugates entailed sequence of reactions. The key precursors N-hydroxysuccinimide 3-tri-n-butylstannyl-benzoate and 3-tri-n-butylstannyl-pyridine carboxylate were radioiodinated using classical method involving 0.1% acetic acid/methanol, iodogen and NaI ($^{123/124/131}$I, 50 MBq) at room temperature. The N-succinimidyl-p-[I]-iodobenzoate ([$^{123/124/131}$I]-SIB) and N-succinimidyl-m-[I]-iodopyridine carboxylates ([$^{123/124/131}$I]-SIP) were purified using Sep-pak silica cartridge. MUC1-FA hybrid peptide was first reacted with [$^{123/124/131}$I]-SIB and [$^{123/124/131}$I]-SIP, followed by purification using C18 Sep-pak cartridge to furnish [$^{123/124/13}$I]-SIB- and [$^{123/124/131}$I]-SIP-MCU1-FA hybrid peptide conjugates. Radiochemical yields were >75% and synthesis times were ~45 min. **Results:** Radiochemical purity was always >98% without HPLC purification. The metabolic stability of [$^{123/124/131}$I]-SIB- and [$^{123/124/131}$I]-SIP-MUC1-FA peptide conjugates were determined in human plasma and revealed that these radioconjugates remained stable during incubation at 37ºC for at least 24 h. In vitro receptor binding tests on MCF7 as well as KB cell lines have shown that significant amount of the radioconjugates associated with cell fractions. In vivo characterization in normal mice revealed rapid blood clearance of these hybrid peptides with excretion by both urinary and hepatobiliary pathways. Initial in vivo biological characterizations in SCID and nude mice bearing MCF7 and KB cell line xenografts, respectively, demonstrated significant tumor uptake (>10%). The uptake in the tumors was blocked by excess injection of MUC1-FA hybrid peptide, suggesting a receptor-mediated process. **Conclusion:** These results demonstrate that these radioconjugates may be useful as precise theranostic radiopharmaceuticals for MUC1 and folate receptor-positive cancers and their metastasis. However, further evaluation is warranted. **References:** None.

In vivo longitudinal monitoring the permeability of the blood-spinal cord barrier in a dog hemisection spinal cord injury model using ^{13}N-NH_3 PET/CT

L. Zhang[1,2], Y. Jia[3], Y. Chen[1,2], X. Zhuang[3], H. Xia[1,2];
[1]Department of Neurosurgery, General Hospital of Ningxia Medical University, Yinchuan City, CHINA, [2]Ningxia Human Stem Cell Research Institute, General Hospital of Ningxia Medical University, Yinchuan City, CHINA, [3]Department of Nuclear Medicine, General Hospital of Ningxia Medical University, Yinchuan City, CHINA.

Aim/Introduction: Spinal cord injury is a devastating neurological disease that results in mechanical damage to the nervous and vascular structures, and thereafter the disruption of blood-spinal cord barrier (BSCB), which plays a protective and regulatory role for the spinal cord parenchymal [1]. And its disruption provides a unique opportunity for therapeutic intervention. A noninvasive and quantitative imaging method for evaluating the changes in BSCB permeability is crucial for the development of suitable therapeutic strategies for the treatment of SCI. **Materials and Methods:** Five male beagle dogs underwent a lateral hemisection on the tenth thoracic (T10) vertebra to build a hemisection SCI model. ^{13}N-NH_3 PET/CT was performed before SCI, and at 6 timepoints after SCI (1 day, 3 day, 7 day, 10 day, 14 day and 21 day). The uptake of ^{13}N-NH_3 in the spinal cord at T9-T10 was analyzed and quantitative assessed by maximum standardized uptake value (SUV_{max}) and mean standardized uptake value (SUV_{mean}). As an endogenous trigger of BSCB leakage[2], the expression level of monocyte chemoattractant protein-1 (MCP-1) in the serum at each timepoint was measured by canine cytokine antibody arrays. Correlation analysis was performed between the uptake of ^{13}N-NH_3 and MCP-1 levels. **Results:** Although BBB is permeable for ^{13}N-NH_3, ^{13}N-NH_3 could not across BSCB. Before SCI, the ^{13}N-NH_3 uptake in the spinal cord is at a very low level (SUV_{mean}=0.31 ± 0.18, SUV_{max}=0.36 ± 0.21). After SCI, the uptake gradually increased with time and peaked at 7 days (SUV_{mean}=0.97 ± 0.23, SUV_{max}=1.12 ± 0.28) after surgery, which showed the process of BSCB disruption. As the spinal cord self-healing, it showed a decrease in the uptake thereafter. But the uptake of ^{13}N-NH_3 in 21 days (SUV_{max}=0.67 ± 0.15, SUV_{mean}=0.79 ± 0.22) was still higher than the uptake before SCI ($P<0.05$). The SUV_{max} and SUV_{mean} value of ^{13}N-NH_3 were significantly correlated with MCP-1 (P=0.0073; P=0.0049). **Conclusion:** This study demonstrated that ^{13}N-NH_3 PET/CT is a feasible imaging method to assess the changes of BSCB permeability. Moreover, it possesses a wide prospect of clinical application for optimizing treatment protocols. **References:** 1. Bartanusz V, Jezova D, Alajajian B, Digicaylioglu M. Aim/Introduction: The study of human diseases and the initial development of new drugs and therapeutics is often done using animal models. Preclinical PET scanners dedicated to small animal imaging allow evaluating the total period of radiopharmaceutical biodistribution. The same animal can be studied along time, representing its own control (inter-subject variability eliminated). In this context, the main application is oncology: to determine if the subject is a candidate for the study and to assess the response to therapy in tumoural models. Since glucose has a high uptake in certain organs and in tumours, ^{18}F-FDG has been one of the most used radiotracers for cancer imaging. However, the access to preclinical PET scanners is usually a problem for research centres mainly due to the high cost of the equipment and infrastructural requirements, associated to limited research budgets. EasyPET technology (a patented axial microPET system) represents a solution, since it allows a significant reduction in the number of components and thus in the final equipment cost, while achieving good sensitivity and state of the art spatial resolution in all the FOV. In addition, easyPET is highly portable and compact, requiring minimal lab space. The purpose of this study was to assess the potentiality of easyPET system to image mouse solid tumours with ^{18}F-FDG. **Materials and Methods:** In total, 35 BALB/c-nu/nu mice were used for scanning: 21 males were inoculated (subcutaneously) on the right flank with WiDr cells (human colon cancer, 2-3-wks. inoculation) and 14 females with MCF-7 cells (human breast cancer, 4-7-wks. inoculation). ^{18}F-FDG (8-26MBq/0.2-0.5mL) was intraperitoneally (i.p.) administered. 40 min latter, the animals were anaesthetized (i.p.) with a mixture of ketamine/largactil (3:1) diluted in saline. A scan with 10^6 counts was performed approximately 60 min after ^{18}F-FDG injection. PET images were reconstructed with the 3D MLEM-OSEM algorithm. **Results:** EasyPET was able of detect and characterize tumours in a very early stage (1-1.5mm), as well as to monitor their size through time, with its anatomopathology confirmed by histological studies. **Conclusion:** EasyPET technology was for the first time applied for in-vivo preclinical studies and showed great potential for applications in oncology. This study showed that easyPET scans provided an early diagnosis of tumours originated by human colon and breast cancer cells, all confirmed by histology. By detecting tumours before any external signs, easyPET allows an earlier treatment. Furthermore, easyPET allows a direct molecular assessment of treatment effects by follow-up imaging. **References:** None.

Radiofluorinated gases as regional ventilation markers: Application to a rat model of acute lung inflammation

J. Llop Roig, *V. Gómez-Vallejo, U. Cossío, A. Lekuona;*
CIC biomaGUNE, San Sebastian, SPAIN.

Aim/Introduction: Imaging methods visualizing local areas of impaired ventilation may become a powerful tool in the early/differential diagnose of lung diseases, as well as for the development of new therapeutic approaches. Currently, ventilation studies in the clinical arena are performed with single photon emission computerized tomography (SPECT) using radiolabelled aerosols [1]. However, these show central airway deposition and peripheral "hotspot" formation in patients with obstructive lung diseases. Moreover, SPECT has limitations in terms of sensitivity, spatial resolution and image quantitation. Recently, we have developed a fast an efficient method for the production of the radiofluorinated gases [^{18}F]SF_6 and [^{18}F]CF_4, which proved efficient in the visualisation of lung ventilation in healthy rodents using Positron Emission Tomography (PET) [2]. Here, we describe the investigation of [^{18}F]CF_4 as a ventilation marker in an animal model of impaired lung ventilation and correlate the results with [^{18}F]FDG-PET. **Materials and Methods:** [^{18}F]CF_4 was produced by a double irradiation process as recently reported [2]. Ventilation studies were carried out in a rat model of lung inflammation induced by intratracheal administration of lipopolysaccharide (LPS). Dynamic 10-min [^{18}F]CF_4-PET images were obtained in list mode at t=4 hours after administration of LPS, during inhaled administration of the radiofluorinated gas. [^{18}F]FDG-PET static images were also obtained for each animal 30 minutes after the finalisation of the first imaging study. Ventilation images were reconstructed by OSEM-3D iterative algorithm and voxel-by-voxel analysis was carried out to determine the coefficient of variation as a surrogate indicator of non-uniformity of gas distribution. [^{18}F]FDG-PET images were analysed to determine Standard Uptake Values in the lungs. **Results:** Ventilation studies in control groups showed uniform distribution of the radiofluorinated gas and fast elimination of the radioactivity after discontinuation of the administration. For LPS rats, the coefficient of variation was significantly higher than that obtained in the control group. Compared to controls, the mean [^{18}F]FDG uptake in the lungs of LPS rats was almost 2-fold greater at 4h. **Conclusion:** Our results suggest that [^{18}F]

CF_4 is an appropriate marker of regional lung ventilation and may find application in the early diagnose of acute lung disease. **References:** [1] Burch WM, Sullivan PJ, McLaren CJ. Nucl. Med. A Computational Phantom of the Adult Labrador for Use in Preclinical Nuclear Medicine Dosimetry Studies

W. Bolch[1], *M. Sands*[1], *R. Milner*[1], *I. Dormehl*[2];
[1]*University of Florida, Gainesville, FL, UNITED STATES OF AMERICA,* [2]*University of Pretoria, Pretoria, SOUTH AFRICA.*

Aim/Introduction: With the completion of the canine genome project, dogs have been proven be an ideal species for pre-clinical investigations of both molecular imaging agents and therapy radiopharmaceuticals. There is thus an expressed need to establish computational anatomic models of dogs of different species to support the associated organ radiation dosimetry for these studies. In this work, we present a comprehensive hybrid computational anatomic and dosimetric model of the adult Labrador. This species is known to present with high incidence of osteosarcoma that is both genetically and phenotypically similar to human bone cancer. **Materials and Methods:** NURBS and polygon mesh models were constructed from high-resolution CT images of a 1.5-year Labrador imaged prior to euthanasia under an approved animal research protocol at the University of Florida. Bone samples from the skeleton were harvested and ex-vivo CT imaged at sub-millimeter resolution to obtain volume fractions of cortical bone, spongiosa, and medullary cavity space. Next, spongiosa bone cores were taken from 30 skeletal sites and subjected to microCT imaging at 30 micrometer resolution. The microCT images were segmented to assess volume fractions of trabecular bone and total marrow space of spongiosa. Voxel retagging procedures were applied to establish bone microstructures at varying marrow cellularities. Paired-image radiation transport was performed to assess values of monogenetic electron specific absorbed fractions across the canine skeletal sites. **Results:** A database of specific absorbed fractions (SAFs) has been assembled for both monoenergetic photons and electrons emitted within 32 different source tissues of the adult male Labrador phantom. Values of energy deposition to active marrow and skeletal endosteum were obtained via energy-dependent integration of the volumetric photon fluence in regions of trabecular spongiosa and newly developed canine-specific fluence-to-dose photon response functions. Canine-specific S values are presented for several key radionuclides used in diagnostic and therapeutic nuclear medicine. **Conclusion:** Dosimetric applications of the Labrador model are presented for model osteosarcoma tumors treated with ^{153}Sm-EDTMP or ^{153}Sm-PEI-MP. Based upon the ^{153}Sm S values established in this model, and a six-compartment biokinetic models of each agent (to include blood, urinary bladder content, kidneys, trabecular bone surfaces, cortical bone surfaces, and tumor), model tumor doses ranged from 16 to 50 Gy for ^{153}Sm-PEI-MP and from 8 to 25 Gy for ^{153}Sm-EDTMP. **References:** Biodistribution and pharmacokinetics of variously sized molecular radiolabelled polyethyleneiminomethyl phosphonic acid as a selective bone seeker for therapy in the normal primate model. In vivo imaging of ^{68}Ga-labelled NOTA-EGFRvIII aptamer

J. Park, *Y. Cho, J. Chae, W. Kang;*
Yonsei University College of Medicine, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Aptamers are synthetic single-stranded oligonucleotides that bind to a target molecule with high affinity and specificity. Glioblastoma is the most aggressive primary malignant brain tumors. Epidermal Growth Factor Receptor Variant III (EGFRvIII) is a most common extracellular EGFR mutation in glioblastoma. EGFRvIII has been considered as a promising target in cancer diagnosis and therapy because EGFRvIII is expressed only in tumor cells [1,2]. Herein, we investigate the biological characteristics of ^{68}Ga-NOTA- EGFRvIII aptamer as potential glioblastoma imaging agents. **Materials and Methods:** Ga-68 was concentrated using a NaCl-based ^{68}Ga eluate concentration method and labeled with NOTA conjugated EGFRvIII aptamers. Flow cytometry was performed on DKMG/EGFRvIII and U87-MG cell lines to confirm the expression of EGFRvIII. In vitro binding specificity of EGFRvIII aptamers was evaluated using confocal microscopy. In vivo PET/CT imaging of the ^{68}Ga-NOTA-EGFRvIII aptamer were determined in DKMG/EGFRvIII tumor-bearing nude mice. **Results:** ^{68}Ga- NOTA-EGFRvIII was prepared in 96-98% RCYs (decay-corrected, n = 10) with radiochemical purity above 98%. High levels of EGFRvIII expression was found in DKMG/EGFRvIII; however, EGFRvIII were not detectable in U87-MG cells. Confocal fluorescence microscopy images showed that Cy5-EGFRvIII aptamer bound specifically to EGFRvIII expressing DKMG/EGFRvIII cells, however, not bound to U87-MG cells. DKMG/EGFRvIII tumors were clearly visualized by microPET imaging in a tumor-bearing mouse at 60 after injection. **Conclusion:** NOTA EGFRvIII aptamer conjugate was successfully labeled with Ga-68. In vitro data showed that the EGFRvIII aptamer was selectively bound to target tumor cells. In addition, DKMG/EGFRvIII tumor xenografts in mice were clearly visualized on microPET imaging. Our study demonstrated that EGFRvIII may be a useful target molecule for the imaging of glioblastoma **References:** 1) Sampson JH, et al. Tumor-specific immunotherapy targeting the EGFRvIII mutation in patients with malignant glioma. Semin Immunol. 2008;20:267-275. 2) Bakas S, et al. EP-0647

Predictive and grading value of dynamic ^{99m}Tc-HYNIC-TPPTS-Tricine-3PRGD2 SPECT analysis on acute radiation-induced Pulmonary Fibrosis

L. Shi, Q. Bai, W. Zhang, M. Yuan, L. Wei;
Tangdu Hospital, Xi'an, CHINA.

Aim/Introduction: Acute radiation-induced pulmonary Fibrosis (RPF) is an important treatment-related toxicity after chest positioning radiotherapy. The evidence shows early stage RPF was accompanied by high expression of Integrin αvβ3. For these years, several researches set ^{99m}technetium-PEG4-E [PEG4-cyclo (arginine-glycine-aspartic acid)-D-phenylalanine-lysine)]$_2$ (^{99m}Tc-3PRGD$_2$) as a radiolabeling probe which could combine with the Integrin αvβ3. In this study, comprehensive analyses were used to evaluate if the ^{99m}Tc-3PRGD2 have the potential predictive and grading value on acute radiation-induced pulmonary Fibrosis. **Materials and Methods:** A total of 30 female rats (8 weeks) were randomly divided into the normal control group (NC, n=15) and the right lung radiation-induced injury group (RPI, irradiation dose=30Gy, n=15). HYNIC-TPPTS-Tricine-3PRGD$_2$ lyophilized kits were used for the preparation of ^{99m}Tc-HYNIC-3PRGD2 labeling. Immunohistochemistry methods were used to evaluate the expression of Integrin αvβ3. Histopathology examinations were performed after 60th days post radiation-treatment. computed tomography (CT) and Single photon emission computed tomography (SPECT) data were conducted post-radiation treatment. **Results:** The histopathology and immunohistochemistry results revealed that at the 60th day post-radiation treatment, the exposed right lung exhibited acute radiation-induced pulmonary fibrosis symptoms.Static whole-body SPECT scan showed significant differences in the ^{99m}Tc-HYNIC-3PRGD$_2$ accumulated between the exposed right lungs and normal left lungs 30min post-injection.In RPI, we also found that from the 9th day post-radiation treatment, the percentage clearance rate of ^{99m}Tc-HYNIC-3PRGD$_2$ in the right lung was significantly faster than that for the unexposed left lung. **Conclusion:** Overall, comparison of iconography (CT and SPECT) results, our data suggest that ^{99m}Tc-HYNIC-3PRGD$_2$ dynamic SPECT analysis have the potential predictive and grading value on acute radiation-induced pulmonary Fibrosis. **References:** 1.Trofimova, O.P., et al., [Radiation pneumonitis in the treatment of early-stage breast cancer]. easyPET-3D with ^{18}F-FDG: potentiality of quercetin in a cocaine exposure brain study in a mouse model

M. Pais[1,2,3], F. M. Ribeiro[4], C. Nicolucci[5], D. Priolli[5], C. Ramos[1], A. Parma[6], P. M. M. Correia[4], A. L. M. Silva[4], I. F. Castro[4], P. M. C. C. Encarnação[4], I. Mohammadi[4,7], J. F. C. A. Veloso[4], A. C. Santos[1,3,8];
[1]Institute for Clinical and Biomedical Research (iCBR), Coimbra, PORTUGAL, [2]Faculty of Sciences and Technology of University of Coimbra, Coimbra, PORTUGAL, [3]Institute of Biophysics of University of Coimbra, Coimbra, PORTUGAL, [4]University of Aveiro, Institute for Nanostructures, Nanomodelling and Nanofabrication (i3N) – Department of Physic, Aveiro, PORTUGAL, [5]Multidisciplinary Research Laboratory, São Francisco University, Bragança Paulista, BRAZIL, [6]Università degli Studi di Padova, Padova, ITALY, [7]Department of Basic Sciences, Faculty of Medicine, Sari Branch, Islamic Azad University, Sari, IRAN, ISLAMIC REPUBLIC OF, [8]Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL.

Aim/Introduction: Cocaine is one of the most commonly used drugs worldwide. In 2017, 3.5 million people in Europe, between the age of 15 and 64, used cocaine. Moreover, 17 million used cocaine at least once in their lifetime. During cocaine dependence, changes in brain's limbic system and in the central nervous system (CNS) occur, which may result in compulsive behaviour. The effects of this drug arise from the accumulation of dopamine in the synapses, resulting in euphoria that creates addiction. After opioids and cannabis, cocaine represents the most recurrent drug treatment. Flavonoids are a class of natural compounds with an increasing interest in the scientific and therapeutic fields. Quercetin is a flavonoid with a broad therapeutic action. The lack of specific treatment for chemical dependence brings up the need for alternatives to reduce cocaine addiction symptoms and quercetin can be the answer. Positron Emission Tomography (PET) images have a high sensitivity and can provide functional information at a molecular level. The acquisition of brain images using this technology and different radiopharmaceuticals, such as ^{18}F-fluorodesoxyglucose (^{18}F-FDG), allows the observation of brain regional changes. Animal models were proven to be an efficient way to predict drug addiction behaviour. Therefore, the present study intends to determine the influence of quercetin on cocaine exposure using a rodent's model. In this context, functional brain images using the easyPET system were acquired. **Materials and Methods:** 40 BALB/c mice were divided into 4 groups (control, cocaine, quercetin, cocaine+quercetin). ^{18}FDG (5.9-19.8 MBq in 0.2-0.5 mL) were intraperitoneally (i.p.) injected in the animals and 30 min after two stimuli (light and sound) were performed. 40 min after tracer administration, the animals were anesthetized (i.p.) with a mixture of ketamine/largactil (3:1) diluted in saline. Cocaine (0.5 mg/kg) and/or quercetin (50 mg/kg) were given also by i.p.. A scan with 10^6 counts was performed approximately 60 min after injection. **Results:** The analysis of cocaine exposure showed significant correspondence between the metabolically activated brain areas in mice and the ones mentioned for humans (striatum, thalamus, amygdala, brainstem and cerebellum). In mice it was also shown that quercetin triggered the same brain

areas. **Conclusion:** The easyPET system was able to identify the main brain areas in this animal model after cocaine exposure. In addition it was demonstrated that quercetin has potential to treat cocaine consumption. **References:** None.

99mTc-DTPA cerebral scintigraphy is associated with cognitive impairment in models of chronic kidney diseases in rats

L. Thomas[1], *M. Bobot*[2], *S. Fernandez*[3], *L. Balasse*[3], *A. Moyon*[2], *P. Garrigue*[2], *S. Burtey*[2], *G. Hache*[2], *B. Guillet*[2];
[1]*Aix Marseille Université - CERIMED, Marseille, FRANCE,* [2]*Aix Marseille Université - CERIMED - Assistance Publique Hôpitaux de Marseille, Marseille, FRANCE,* [3]*CERIMED, Marseille, FRANCE.*

Aim/Introduction: Recently, the importance of blood brain barrier (BBB) dysfunction has been highlighted as a key factor contributing to cognitive impairment in neurodegenerative disorders, and chronic kidney disease (CKD) patients have a higher risk of developing cognitive impairment. This risk is generally explained by the high prevalence of both symptomatic and subclinical ischemic cerebrovascular lesions. However, the influence of BBB dysfunction in this context has not been explorated so far. [99mTc]-diethylenetriaminepentaacetic acid ([99mTc]-DTPA) SPECT is a validated technique to assess BBB permeability. Thus, we conducted a preclinical study to determine whether quantitative evaluation of BBB permeability using the [99mTc]-DTPA SPECT can be associated with cognitive impairment. **Materials and Methods:** We induced CKD in male Sprague Dawley rats by Adenine rich diet (ARD) (0,5%) during 4 weeks or 5/6 nephrectomy, and evaluated BBB permeability by [99mTc]-DTPA SPECT/CT imaging during CKD and 2 months after cessation of ARD. CKD was assessed by biochemistry, indoxyl sulfate (IS) dosage in serum, and histology. We evaluated cognitive function by validated tests: working memory by the novel object recognition (NOR) test, spatial memory by the object location (OL) test, and social memory by the social interaction test (SI). **Results:** Compared to control, we described CKD in ARD rats throught i) an increase in creatininemia and urea in serum and an increased in fibrosis and tubuloinstestitial damage in kidneys. Interestingly, we demonstrated an increase in [99mTc]-DTPA uptake in brain (0.086±0.025%AI/g vs 0.003±0.010%AI/g; p<0.001; n=7), a decrease in the discrimination index in NOR (0.2±0.3 vs0.7±0.3; p<0.01; n=7), a decrease in the discrimination index in OL (0.02±0.09 vs0.39±0.07; p<0.01; n=11) and an increase in interaction time in SI (19.4±1.4s vs 7.6±1.6s, p<0.001, n= 12). [99mTc]-DTPA uptake in brain was correlated with and both the discrimination index in NOR (r=-0.86, p<0.01) and IS concentrations in serum (r=0.68, p<0.01). Similar results were observed in 5/6 nephrectomy rats (n=8). **Conclusion:** We report for the first time an increase in BBB permeability in two models of CKD in rats by [99mTc]-DTPA SPECT/CT imaging, which was correlated with cognitive impairment. This preliminary work highlights a potential involvement of CKD-induced BBB disruption in cognitive defect in CKD patients, as recently reported for chronic neurodegenerative diseases **References:** None.

MicroPET Imaging With [^{18}F]FP-(+)-DTBZ Reveals The Synergistic Neurotoxicity Of VMAT2 Inhibitor And MPTP To Dopaminergic Neurons

Y. Xu, *J. Tang*, *C. Liu*, *C. Zhao*, *H. Yu*, *Z. Chen*, *M. Xie*;
Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.

Aim/Introduction: Parkinson's disease is a common neurodegenerative disease characterized by progressive degeneration of dopaminergic pathways in nigrostriatal. Vesicular monoamine transporter 2 (VMAT2) is responsible for the storage and release of dopamine and alteration of its function is closely related to the viability of dopaminergic neurons and vulnerability to neurotoxins. In this study, using microPET imaging with 9-[^{18}F]fluoropropyl-(+)-dihydrotetrabenazine ([^{18}F]FP-(+)-DTBZ), the specific radioligand for VMAT2, we investigated the effects of inhibiting VMAT2 on 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP)-induced death of dopaminergic neurons in mice. **Materials and Methods:** C57BL/6 mice were randomly divided into 5 groups: vehicle, dihydrotetrabenazine (DTBZ, a specific inhibitor of VMAT2, 5 mg/kg), low dose MPTP (10 mg/kg), DTBZ (5 mg/kg) & MPTP (10 mg/kg) and high dose MPTP (30 mg/kg) group. Drug delivery lasted for 10 days except that the high dose MPTP was administered from the sixth day. MicroPET imaging with [^{18}F]FP-(+)-DTBZ was performed 1 week before or after the drug delivery. Finally, tissues were dissected for analyzing the contents of dopamine (DA) and its metabolite, the expression levels of VMAT2 and tyrosine hydroxylase (TH), as well as the degeneration level of dopaminergic neurons using HPLC, western blotting and immunohistochemistry. **Results:** In contrast to the control, DTBZ and low dose MPTP treated mice, DTBZ&MPTP and high dose MPTP treated mice displayed substantially declined uptake of [^{18}F]FP-(+)-DTBZ in the striatum. Quantitative data indicated that compared with the control group (1.54±0.25), there is no significant difference in the striatal SUV of DTBZ (1.34±0.24, p=0.375) and low dose MPTP (1.22±0.09, p=0.143) alone treated mice, while the dramatic decrease was discovered in the DTBZ&MPTP treated mice (0.95±0.14, p=0.037). Correlation analysis indicated that SUVs are highly positive-correlated to the contents of DA and its metabolite 3,4-Dihydroxyphenylacetic acid (DOPAC) (r=0.8467 and 0.9003; p=0.0005 and p<0.0001, respectively), and also showed good correlation with the expression levels of VMAT2 and TH (r=0.7675 and 0.7714; p=0.0158 and 0.0149, respectively). Immunohistochemical results further demonstrated that after inhibiting the activity of VMAT2, the number of dopaminergic neurons was dreadfully decreased by low dose of MPTP (38.1±2.8% of the control values). **Conclusion:** MicroPET brain imaging with [^{18}F]FP-(+)-DTBZ in mice revealed that DTBZ co-administration significantly aggravates the neurotoxicity of MPTP to dopaminergic neurons. **References:** None.

^{18}F-FDG-PET/CT to monitor combination therapy with Xc- inhibitor sulfasalazine and Vitamin C in prostate cancer

Z. Li, Z. Zheng, G. Luo, X. Shi, Y. Long, W. Shen, X. Zhang;
The First Affiliated Hospital of Sun Yat-Sen University, Guangzhou, CHINA.

Aim/Introduction: The anticancer potential of pharmacologic ascorbic acid (AA) has been detected in over 50 cancer cell lines.Former studies has reported that the cancer cell selective cytotoxity of VC is induced from steady-state H_2O_2 level, produced from autoxidation. SAS can induce cytotoxic effect by suppressing the system Xc--cystine/glutamate antiporter (xCT) in cancer cells, also relates to glutathione (GSH) biosynthesis, which is critical during intracellular antioxidation. We hypothesized that targeting Xc^--transporter by SAS could improve anti-cancer activity of VC through intermission of GSH biosynthesis which results in accumulation of reactive oxygen species (ROS). And ^{18}F-FDG PET/CT could monitor the therapeutic response of the prostate cancer in vivo. **Materials and Methods:** We employed two Castration-resistant prostate cancer (CRPC), without PSA express, prostate cancer cell lines PC3 and DU145 to set up our study. Anti-proliferation effect of VC and/or SAS on prostatic cancer cells was detected using WST-8 assay and colony formation. We used Annexin V-FITC/PI FACS to monitor cell apoptosis induced by different treatment protocols. Then changes of cellular ROS and GSH were detected to prove our hypothesis. In vivo, BALB/c nude mice bearing prostate cancer xenograft were carried out to assess anti-cancer effect of single or combined therapy of VC and SAS. Small animal FDG PET/CT was performed before, one week after and two weeks after therapy administrations to monitor therapeutic response of tumors. We investigated the expression change of apoptotic related proteins, including cleaved-caspase-3, HMGB1 and the pro BAX, BCL-2 using immunohistochemistry in response to the single or the combined treatments. **Results:** Our study revealed that SAS could improve cytotoxicity of VC in prostate cancer cells. The synergistic effect of SAS and VC leads to significant depletion of cellular GSH, leading to an clear accumulation of ROS and this synergistic effect can be reversed by antioxidant N-Acetyl-L-cysteine (NAC). Moreover, the synergistic effect of SAS and VC was also found to block Xenograft tumor growth because of apoptotic and necrotic cell death, as determined by Immunohistochemistry. FDG-PET/CT also showed a clearly more reduced uptake in combination therapy group than single therapy groups with VC or SAS. **Conclusion:** Our results demonstrate that SAS, as a relatively non-toxic drug can target cystine transporter to improve therapeutic effect of VC and induce better therapy outcome contrasted to single treatment in prostate cancer. ^{18}F-FDG PET/CT is highly correlate with different therapeutic methods and could predict the different response of prostate cancer in vivo. **References:** None.

Radiolabeling, selection and evaluation of indium-111 labeled anti-mesothelins in human mesothelin-expressing xenografts

W. Hsu[1], K. Cheng[1], Y. Chang[1], C. Ho[1], C. Yu[2], S. Yang[2], H. Hsu[2], C. Yang[2], C. Chang[1];
[1]*Institute of Nuclear Energy Research, Taoyuan, TAIWAN,*
[2]*Development Center for Biotechnology, Taipei, TAIWAN.*

Aim/Introduction: Mesothelin (MSLN) is a 40 kDa cell-surface glycoprotein which is highly expressed in a variety of human cancers, and has great value as a target for antibody-based therapies. The aim of this study was to develop an indium-111 labeled anti-mesothelin as a novel companion diagnostic agent to detect MSLN-expressing tumors in vivo. **Materials and Methods:** Full-length and minibody of anti-MSLN antibodies obtained from Development Center for Biotechnology in Taiwan were conjugated with p-SCN-Bn-DTPA. The Drug to antibody ratio (DAR) was determined by matrix-assisted laser desorption/ionization time-of-flight mass spectroscopy. After radiolabeling with indium-111, the radiochemical purity, stability and immunoreactivity of ^{111}In-DTPA-anti-MSLNs were qualified before in vitro and in vivo studies. Cellular uptake and internalization studies of indium-111 labeled full-length of anti-MSLN antibodies were performed using KLM-1, OVCAR-3 and NCI-H226 cell lines. Two forms of ^{111}In-DTPA-anti-MSLNs were selected by nanoSPECT/CT molecular imaging in KLM-1, OVCAR-3 and NCI-H226 tumor bearing mice. The pharmacokinetics and in vivo tissue distribution of full-length of ^{111}In-DTPA-anti-MSLN were evaluated in normal and KLM-1 tumor-bearing mice, respectively. The dosimetry of ^{111}In-DTPA-anti-MSLN was evaluated by OLINDA software. **Results:** The DAR of DTPA-anti-MSLNs was range 1-4. The labeling efficiency and immunoreactivity of ^{111}In-DTPA-anti-MSLNs were >90% and >40%, respectively. The stability of ^{111}In-DTPA-anti-MSLNs was greater than 90% after 24 h at room temperature. Full-length antibody has longer circulation time than minibody. NCI-H226 cell show the higher cellular uptake of ^{111}In-DTPA-anti-MSLN than KLM-1 and OVCAR-3 cell lines in vitro. KLM-1 xenograft has a higher in vivo tumor uptake of ^{111}In-DTPA-anti-MSLN than NCI-H226 and OVCAR-3 xenografts. Tumor/muscle ratio of ^{111}In-DTPA-anti-MSLN was >10 performed by biodistribution studies during 24-96 h drug distribution in KLM-1 xenograft. The AUC of ^{111}In-DTPA-anti-MSLN was 7742 %ID/gh. Radiation absorbed dose study show the safety of 5 mCi ^{111}In-DTPA-anti-MSLN treated in human. **Conclusion:** We established in vitro and in vivo platforms to evaluate the novel indium-111 labeled anti-mesothelin antibodies successfully. The full-length of ^{111}In-DTPA-anti-MSLN showed high specific targeting and long term circulation in MSLN-expressing xenografts. The ^{111}In-DTPA-anti-MSLN may be a potential companion diagnostic agent for patient selection or monitoring of MSLN expression during therapy. **References:** None.

EP-0653

Optimisation of Conjugation for Radioimmunoconjugate Based Imaging of Intranuclear Eptiopes

M. Veal, *B. Cornelissen;*
University of Oxford, Oxford, UNITED KINGDOM.

Aim/Introduction: Antibody based radioimmunoconjugates (RICs) have great potential for a broad range of applications in medical imaging, offering unparalleled versatility, selectivity and specificity. Conjugation with cell penetrating peptides such as Tat (GRKKRRQRRRPPQGYG), and radionuclides allows imaging of a large array of intra-nuclear targets by PET or SPECT imaging[1]. Here, we developed a simplified and more efficient methodology for conjugating functional groups to antibodies through the use of SPAAC based click chemistry. **Materials and Methods:** Selected antibodies (anti-γH2AX, anti-GFP, anti-pATM, and a non-specific rabbit polyclonal IgG) were modified using the amine-reactive reagent DBCO-STP, introducing multiple azide-reactive DBCO groups. After removal of non-reacted starting product, the extent of DBCO labelling is determined by absorbance (309 nm). The antibody-DBCO conjugate is then reacted simultaneously with an azide modified chelating agent (N_3-Bn-DTPA), and cell penetrating peptide (N_3-Tat). The yield of the click reaction was determined by the relative reduction in absorbance (309 nm). After addition of $^{111}InCl_3$, radionuclide incorporation yield was determined by instant thin-layer chromatography (ITLC). A549 cells were exposed to ^{111}In-IgG-Tat or ^{111}In-IgG (without TAT) for 2 hours, and the uptake of 111In into cells was measured. Furthermore, flow cytometry will be used to compare the affinity of antibodies conjugated using the new conjugation process against previously used method and an unmodified antibody. **Results:** We successfully synthesised ^{111}In-labelled Tat-conjugated versions of several antibodies, including both polyclonal and monoclonal antibodies derived from both mouse and rabbit hosts. Internalisation assays with non-specific rabbit polyclonal antibodies have shown a >50 fold increase in cell associated radioactivity in comparison to a non-Tat modified control group, demonstrating the capacity for the RIC to penetrate the cell (4.634 ± 0.061 % vs. 0.075 ± 0.024 %, respectively; P = 0.003). Furthermore, this capacity for internalisation was considerably greater than results obtained using the previous conjugation technique (0.113 ± 0.011% vs. 0.028 ± 0.001 %; P < 0.001). **Conclusion:** We developed a simple and robust method for modifying antibodies for imaging nuclear epitopes, with reduced purification steps, reduced risk of antibody-antibody cross-linking and increased cell internalisation. **References:** 1. Aim/Introduction: In modern radio-oncology, proper diagnostics and control of metastatic prostate cancer (mPC) and neuroendocrine tumours (mNET) cannot be imagined without application of Ga^{68}-PSMA and Ga^{68}-DOTATATE radionuclide-guided PET/CT. In world's leading clinics, Lu^{177}-PSMA and Lu^{177}-DOTATATE - the theranostic counterparts of the above mentioned radiopharmaceuticals (RP) - are currently used for treating mPC and mNET when other therapeutic approaches fail. Such therapy is capable of substantially improving the patients' quality of life and overall lifespan. This theranostic approach represents a substantial step towards personalized targeted diagnostics and therapy. In this study, we aimed to develop a simple, sensitive and accurate in vitro test system based on cancer cell lines that could be used as fast internal biological quality control for the synthesized RP binding capacity and for the studying the above mentioned RP-induced physiological effects in cancer cells. **Materials and Methods:** Radiolabeling of Ga^{68} and Lu^{177} RPs (PSMA-I&T and HA-DOTATATE) was done in TEMA isolator using Scintomics GRP automatic synthesis module. The labeling efficiency and radiochemical purity were determined using radio thin-layer and high-performance liquid chromatography. Processes were done in accordance with "68-Ga-PSMA PET/CT: Joint EANM and SNMMI procedure guideline for prostate cancer imaging: version 1.0". The test system was based on stable cancer cell lines: PC3 ($PSMA^{+/-}$), LNCaP ($PSMA^{++}$), NCI-H69 ($SSTR2^{+}$), AR42J ($SSTR2^{++}$), CorL23 ($SSTR2^{-}$); human dermal fibroblast cell line Hs68 was used as a non-malignant control. The cell lines were validated for the target receptor PSMA and SSTR2 expression levels by immunocytochemistry and fluorescence microscopy and used for RP binding assays in following experiments. The RP treatment-induced biomolecular profile changes in the cell lines were evaluated by FTIR spectroscopy. **Results:** As a result, an in vitro test system suitable for express biological quality control of in-house synthesized RPs for their binding to PSMA and SSTR2 receptors was developed. The binding assay results were comparable with the receptor expression levels in the corresponding cell lines. Preliminary results indicated that the RP treatment of cancer cells positive for target receptor expression is linked with the increase of total carbohydrate content, not seen in receptor-negative cells. **Conclusion:** This study showed that by means of Ga^{68} and Lu^{177}-RPs, it is possible to assess the binding capacity to live cells both qualitatively

and quantitatively. Further elaboration of the developed in vitro test system and protocols is planned to enable the prediction of the RP binding efficacy in individual patient-derived biopsy material. **References:** None.

Aim/Introduction: In the central nervous system, glutamate acts both as excitatory neurotransmitter and metabolic substrate channeled to the Krebs cycle after its conversion to alpha-ketoglutarate. Due to this double role, its extracellular concentration is tightly regulated. In particular, glutamate released by neurons in the synaptic cleft is removed by astrocytes and converted into glutamine to be transferred back to neurons for the conversion to glutamate configuring the so-called glutamate-glutamine cycle (GGC). Accordingly, the catalytic function of glutamine synthetase (GS) highly expressed in astrocytes plays a pivotal role in preventing glutamate toxicity. Although several studies reported an impaired GGC in amyotrophic lateral sclerosis (ALS), methods able to estimate glutamate processing rates by astrocytes are not available so far. Since the main fate of NH_3 taken up by cells is the production of glutamine by GS, we aimed to verify whether uptake kinetics of ^{13}N-NH_3 is altered in primary astrocytes harvested from SOD1^{G93A} mice as an experimental model of ALS. **Materials and Methods:** Astrocytes were isolated from brain harvested from neonatal (p2) wild-type (WT) and SOD1^{G93A} mice and cultured under standard conditions. Time-activity curves of cultured cells were defined using a dedicated instrument (LigandTracer, Ridgeview, SE) that consists of a beta-emission detector and a rotating platform harboring a Petri dish inclined at 30 degrees as to alternate cell position from nadir (for incubation) to zenith (for counting) every minute. For the experiments, astrocytes were incubated in saline enriched with 6 MBq/mL ^{13}N-NH_3 with or without glutamate 70 microM. Counting rate (counts per second, cps) of cultured cells was monitored for 30 minutes and normalized for both administered dose and cell number (C-Rate). **Results:** WT and SOD1^{G93A} astrocytes showed a similar ^{13}N-NH_3 uptake kinetics in the absence of glutamate and reached similar C-Rate values at 30 minutes (2.8±0.5 vs 2.9 ±0.6 cps, respectively, ns). By contrast, the presence of glutamate increased C-Rate to a greater degree in WT than in SOD1^{G93A} astrocytes (4.1±0.8 vs 2.7±0.8 cps, respectively, $p<0.01$). **Conclusion:** The present data suggest that monitoring NH_3 uptake might detect an abnormal GGC during the early disease stage of a mouse ALS model. This tool might complement the study of glutamate transporters and GS activity to clarify astrocyte role in ALS progression. **References:** None.

Biomarkers Exploration In a Small Animal Model of Cardiorenal Syndrome by 18FDG PET/MRI , Histology and Terahertz Imaging of the Kidney -Preliminary Results-

M. Furcea[1], *L. Agrigoroaie*[1], *C. Uritu*[2], *G. Stanciu*[2], *C. Mihai*[2], *I. Gardikiotis*[2], *R. Iliescu*[3], *C. Stefanescu*[3], *M. Gutu*[3];
[1]*University Hospital "Sf. Spiridon", Iasi, ROMANIA,* [2]*Advanced centre for research-development in experimental medicine - CEMEX, Iasi, ROMANIA,* [3]*University of Medicine and Pharmacy "Grigore T.Popa", Iasi, ROMANIA.*

Aim/Introduction: Cardiorenal syndrome is a clinical condition with a profound socio-economic burden, and elusive prognostic biomarkers. We present preliminary renal data of a rat model for the above pathology through multimodal imaging with 2-deoxy-2-[fluorine-18]fluoro-D-glucose (^{18}F-FDG) PET/MRI, histological analysis and terahertz (THz) spectrum reflectometry. **Materials and Methods:** We examined 24 male Wistar rats, divided into 3 lots: control (L1), heart failure (L2), cardiorenal group (L3). Heart failure was induced by intraperitoneal doxorubicin administration and renal failure by sub-total nephrectomy. ^{18}F-FDG PET/MRI scans were acquired at week 0 for L1, week 6 for L2 and week 18 for L3. Regions of interest were drawn on MRI images for kidneys and left ventricular cavity, which were used for volumetric assesment and VOI segmentation. PET derived GFR estimation was calculated based on the following formula: $GFR=Ki_{right}[min]*V_{right\ kidney}[ml]+Ki_{left}[min]*V_{left\ kidney}[ml]$. Ki is approximated as the slope of the linear regression of arterial tracer concentration by taking the renal activity as independent variable. A multi-flip spoiled GRE driven-equilibrium T1 relaxation time estimation sequence was employed for the study of ex vivo formalin-fixed rat kidneys. The histological assessment followed a standard hematoxilliyn-eozin protocol with 5 µm tissue slices, scoring the lesion progression on a visual scale from 0 to 4 (0-least affected, 4-severe disease). Paraffin-embedded renal tissue samples were further examined through THz pulsed-wave reflectometry, with resulting attenuation in the 0.2-3.3 THz range. **Results:** Through histological assessment, L1 was graded with a score of 0, L2 with a score of 1 (mild glomerular sclerosis, rare hyalinne cast-filled tubules, low inflammatory infiltration) and L3 with a score of 3 (moderate glomerular sclerosis, frequent hyalline casts, distorted tubular brush border and moderate inflammatory infiltration). The variation in arterial concentration explained by renal tracer dynamics for the 3 groups was $R^2_{L1}=0.97$, $R^2_{L2}=0.99$ and $R^2_{L3}=0.82$. Estimated GFR for

the L1, compared to literature (1.38 ± 0.1 ml/min), was within 1.26 ± 0.23 ml/min. L2 and L3 group deviated from L1 with values of 0.88 ± 0.14 ml/min, respectively of 0.52 ml/min. T1 renal parenchyma relaxation times were 403±42 ms for L1, 382±17 ms for L2 (suggested by increasead cellularity) and 301±22 ms for L3 group (expression of renal scarring) Study groups were differentiated by distinct patterns of the THz pulse attenuation. **Conclusion:** Our multimodal exploration of cardiorenal rat model was consistent in discriminating between study groups, hence confirming the hypothesis under study, with potential new non-invasive diagnostic avenues. **References:** None.

Radiobiological Evaluation of Copper-64 on Tumor Cells

D. Niculae, *R. Leonte, R. Serban, L. Chilug, D. Draganescu, M. Temelie, D. Savu;*
Horia Hulubei National Institute for Physics and Nuclear Engineering, Bucharest (Magurele), ROMANIA.

Aim/Introduction: Copper, as a natural bioelement in the human body, incorporated into a variety of proteins, is involved in key biological processes based on its redox properties. Its trafficking, accumulation and clearance are tightly controlled in normal health but often disturbed in disease states. These mechanisms can be exploited for both imaging and therapy, based on several radioisotopes of copper which are of certain medical interest. **Materials and Methods:** An automated process for the production and purification of copper radioisotopes produced by irradiating solid targets in a variable energy cyclotron has been developed, using an automated solid target system. To comparatively evaluate the biological effects we used a panel of tumor cell lines: U87MG (glioblastoma), AR2J (pancreatic cancer cells), HT29 (colon adenocarcinoma), A431 (epidermoid carcinoma) and DU-145 (prostate cancer cells) in comparison with non-tumoral, control cell lines (monocytes ATTC). We performed cytogenetic and radiocytotoxicity assays to evaluate the significant changes at cellular level induced by the exposure to 64CuCl2: cell viability by MTT/MTS, micronuclei testing genotoxicity and morphologic apoptosis and H2AX, when relevant. **Results:** A reliable process for production of ^{64}Cu by nuclear reaction ^{64}Ni(p,n), with low metallic impurities and of high specific activity, for biomedical application, is described. The process involves the plating of enriched ^{64}Ni (99.5%) on the target, pneumatic transfer to the irradiation station, mounted on a slope-down proton beam, irradiation at 14 MeV and uses automated module based on ion exchange chromatography to purify the resulted copper-64 chloride. Tumor cells were found to exhibit increased $^{64}CuCl_2$ comparing to normal cells; early DNA damage, higher cytotoxicity and genotoxicity were also observed in tumor cells, with different intensities for different cells tested. Double strain breakages were observed, which correlates with deficient DNA-damage repair capacity. The results contributes to elucidation of mechanisms involved, quantification of radiobiological effects and sustain the use of $^{64}CuCl_2$ for theranostic applications. **Conclusion:** The combination of positron, beta$^-$ and of high LET Auger electrons emissions imparts a high local radiation dose at the cellular level making it suitable for targeted radionuclide therapy, with high cytotoxic potency if the radionuclide is located within or close to cell nuclei. **References:** Qinghua Xie, Hua Zhu, Feng Wang, Establishing Reliable Cu-64 Production Process: From Target Plating to Molecular Specific Tumor Micro-PET Imaging, Molecules (2017); Avila-Rodriguez, M.A.; Nye, J.A. Radium-223 Inhibits Cancer Growth in Bone and Improves Survival in a Syngeneic Bladder Cancer Bone Metastasis Model

M. I. Suominen[1], *T. E. Kähkönen*[1], *J. H. E. Mäki-Jouppila*[1], *B. Sjöholm*[2], *I. Ahonen*[3], *D. Mumberg*[4], *K. Ziegelbauer*[4], *J. M. Halleen*[1], *S. Käkönen*[2], *A. Scholz*[4];
[1]*Pharmatest Services, Turku, FINLAND,* [2]*Aurexel Life Sciences Ltd., Askainen, FINLAND,* [3]*Vincit Oy, Turku, FINLAND,* [4]*Bayer AG, Berlin, GERMANY.*

Aim/Introduction: Radium-223 dichloride (Ra-223, Xofigo®) is a targeted alpha therapy which prolongs the survival of castration-resistant prostate cancer (CRPC) patients with symptomatic bone metastases. As a calcium-mimetic, Ra-223 selectively binds to hydroxyapatite and targets areas of high bone turnover such as bone metastases. The effects of Ra-223 on development and progression of osteolytic bone lesions and on survival in the syngeneic intratibial MBT-2 murine bladder cancer model in immunocompetent mice were investigated in this study. **Materials and Methods:** Female 5-7-week-old C3H/HeNHsd mice were inoculated intratibially with 5x10^5 MBT-2 cells on day 0. The mice were stratified based on body weight (n=40 per group) on day 5 and Ra-223 (300 kBq/kg, i.v.) or vehicle control was administered on days 5, 33, and 61. The tumor-induced osteolytic lesion area was imaged using radiography on days 10, 18, 25, 76, and at sacrifice. The mice were sacrificed when they met the predefined sacrifice criteria (> 20% body weight loss, palpable tumor outgrowth from the bone or general deterioration of health status). The study was terminated on day 158. **Results:** In this study, the first mice met the sacrifice criteria on study day 24 and the survival curves plateaued at 52% after 84 days in the control group and at 68% after 112 days in the Ra-223 treatment group. Survival on day 40 was significantly improved in the Ra223 treatment group compared to the vehicle control ($p< 0.001$), but the effect was not statistically significant at the end of the study. Based on X-ray imaging 25 days after cancer cell inoculation, Ra223 treatment also significantly decreased the bone lesion area compared to the vehicle treatment ($p=0.0041$). After initially sacrificing the mice with extensive bone lesions, tumor growth in bone was stabilized around day 25. The main reason for sacrifice at a later stage was breathing difficulties due to lung metastases, and in the Ra-223-treated mice only one mouse was sacrificed due to

bone metastases. Ra-223 treatment was well-tolerated; no body weight loss was observed. **Conclusion:** In summary, radium-223 dichloride (Xofigo®) demonstrates moderate single agent in vivo efficacy in the intratibial MBT-2 murine bladder cancer model of osteolytic bone metastasis. Retaining a functional immune system in syngeneic mouse models is particularly relevant for the characterization of potential immune-stimulatory effects of Ra-223. The promising results obtained in this model warrant further investigation of Ra223 in combination with immuno-oncological treatments like checkpoint inhibitors. **References:** None.

EP-0659

Imaging [^{18}F]olaparib in malignant glioma models

S. L. Hopkins, M. Mosley, P. Isenegger, J. Baguña Torres, F. Guibbal, A. Pacelli, R. Hueting, V. Gouverneur, B. Cornelissen;
University of Oxford, Oxford, UNITED KINGDOM.

Aim/Introduction: Imaging of the DNA damage repair enzymes, poly(ADP-ribose) polymerases (PARP), using a radiolabeled PARP inhibitor has been proposed for cancer patient selection, outcome prediction, dose optimisation, genotoxic therapy evaluation, and target engagement validation. We previously reported the synthesis of a radiolabelled structural equivalent of the FDA-approved PARP inhibitor, olaparib, to allow PET imaging in preclinical pancreatic tumour models.[1] Here, we have investigated the effect of administered dose on tumour uptake and target engagement of [^{18}F]olaparib in U87MG and U251MG malignant glioma models. **Materials and Methods:** The U87MG and U251MG cells and tumours were characterised for PARP1, PARP2, and PARP3 expression using Western blot and/or immunofluorescence. In vitro, specificity of [^{18}F]olaparib cell uptake was determined using an excess of unlabelled olaparib. In vivo, PET/CT images were acquired, 1 h after an intravenous bolus injection of 0.5, 1.0, 4.0, or 8.0 µg [^{18}F] olaparib and ex vivo biodistribution studies were subsequently performed. Separately, specificity of tumour uptake was evaluated by blocking of [^{18}F]olaparib using an excess of cold olaparib. **Results:** In vitro, [^{18}F]olaparib showed similar uptake across U87MG and U251MG cell lines. Cell uptake of 1 µM [^{18}F] olaparib could be blocked by more than 70% by addition of an excess of cold olaparib. In vivo, tumour uptake of [^{18}F]olaparib in both U87MG and U251MG mouse xenografts was higher for lower doses (0.5 and 1.0 µg) compared to higher doses (4.0 and 8.0 µg). Ex vivo biodistribution analysis showed U251MG and U87MG tumour uptake of 7.1 ± 1.5 and 6.5 ± 0.9 %ID/g, respectively for 1.0 µg dose vs. 3.3 ± 0.4 and 1.7 ± 0.2 %ID/g for 8 µg ($P < 0.001$). In a separate study, blocking decreased U251MG and U87MG tumour uptake from 6.1 ± 0.6 and 7.4 ± 0.9 %ID/g, respectively for 1.0 µg [^{18}F]olaparib to 1.2 ± 0.3 and 1.2 ± 0.2 %ID/g, respectively for 20 µg olaparib + 1 µg [^{18}F]olaparib ($P < 0.0001$). **Conclusion:** Taken together, we have demonstrated that [^{18}F]olaparib tumour uptake is dependent on administered dose, can measure PARP levels in glioma models, and is specific in vitro and in vivo. **References:** 1. Radiosynoviorthesis Using Sn-117m Colloid to Treat Canine Elbow Osteoarthritis Demonstrates Efficacy and Safety

C. A. Doerr[1], J. M. Donecker[1], N. R. Stevenson[1], G. R. Gonzales[1], J. C. Lattimer[2];
[1]*Serene, LLC, The Woodlands, TX, UNITED STATES OF AMERICA,*
[2]*University of Missouri, Columbia, MO, UNITED STATES OF AMERICA.*

Aim/Introduction: Homogeneous Sn-117m colloid (HTC) was studied in order to determine the safety and efficacy of radiosynoviorthesis (RSO) injections for the treatment of mild to moderate, and moderately severe canine osteoarthritis (OA). As a result of these trials, HTC is being commercialized in the US as a treatment for OA in dogs, and clinical trials in human arthritis using ascorbic homogeneous Sn-117m colloid (AHTC) will commence in Canada in 2019. **Materials and Methods:** Study 1 prospectively enrolled 44 dogs (45 elbows) with mild-moderate elbow OA into three randomized dosing arms, and Study 2 prospectively enrolled 15 dogs (27 elbows) with moderately severe elbow OA treated by a single dose. All dogs were followed up to 12 months. Therapeutic success by canine brief pain inventory (cBPI) was defined as either (1) improvement of >1 for pain severity score (PSS) AND >2 for pain interference score (PIS), or (2) improvement of >1 for PSS OR >2 for PIS. Therapeutic success by clinician's lameness examination (CLE) was defined as significantly improved p values between the two assessment time points. In Study 1 a force plate analysis was also evaluated with therapeutic success defined as improvement of >5% at any time point in the peak vertical force (PF) or the mean vertical impulse (IMP). Safety was assessed by analysis of CBC and blood chemistry, joint fluid, UA, and by owner and clinician assessment. **Results:** Study 1 (per protocol 34 elbows) demonstrated success in cBPI, CLE and force plate in the medium dose group which was selected as the only dose used for Study 2. Study 2 (per protocol 25 elbows) showed therapeutic improvement in cBPI and CLE. cBPI success using PSS AND PIS demonstrated improvement over baseline of up to 70.0%, over 12 months. cBPI success using PSS OR PIS demonstrated improvement over baseline of up to 81.8% over 12 months. CLE showed statistical improvement compared to baseline at day 90. Force plate evaluation demonstrated improvement in PF or IMP of up to 66.7% in either elbow over 180 days. No safety issues were noted. **Conclusion:** The therapeutic success and safety of HTC for OA in dogs supports the use of AHTC in upcoming human trials. **References:** None.

EP-0661

Validation of á2ä1 as cancer stem cell marker for molecular imaging using 1B50-1 mAb probes : A preliminary study on Hepatocellular Carcinoma

X. Guo, G. An, W. Zhao, Z. Zhang, H. Zhu, Z. Yang;
Peking University Cancer Hospital & Institute, Beijing, CHINA.

Aim/Introduction: In previous research, we identified a new antibody named 1B50-1 targeting α2δ1 which specifically expressed in cancer stem cells (CSCs). These α2δ1+ tumor-initiating cells (TICs) with stem cell-like properties, might be the cell of origin for HCC recurrence. Herein, we investigated whether near-infrared fluorescence (NIR) imaging Cy5.5-1B50-1 and positron emission tomography (PET) radiotracer ^{64}Cu-NOTA-1B50-1 were sensitive approaches for non-invasively detecting and quantitating of CSCs on hepatocellular carcinoma. **Materials and Methods:** 1B50-1 antibody was labeled with either an Cy5.5 or ^{64}Cu (using NOTA-NCS as bi-functional chelator).1B50-1+ Hep-12 cell lines and Huh7 cell lines culture and/or xenografted on NOD-SCID mice for ^{64}Cu-NOTA-1B50-1 evaluation. Binding affinity and binding specificity of ^{64}Cu-NOTA-1B50-1 were evaluated by various cellular researches. NIR imaging of Cy5.5-1B50-1 was performed in Hep-12 models at 4, 24, 48, 72 and 96 h post-injection. Micro-PET imaging of ^{64}Cu-NOTA-1B50-1 was performed in Hep-12 models or Huh7 models at 2h, 12h and 36h post-injection. Immunofluorescence (IF), immunohistochemistry (IHC) and autoradiography of tumor and main organ were carried out to confirm the expression of α2δ1. **Results:** The radiolabeling yield for 64Cu-NOTA-1B50-1 was 85±0.5 % (n = 5). The average specific activity was 8.2 GBq/μmol (n = 5). The mean radiochemical purity was 98.6 ± 0.6% (n = 5). In Hep-12 cellular uptakes studies, uptake of ^{64}Cu-NOTA-1B50-1 was significantly higher than that of Hep-11 ($P < 0.0001$); higher than the uptake of ^{64}Cu-NOTA-mIgG3 ($p < 0.0001$). The Bmax and Kd values of ^{64}Cu-NOTA-1B50-1 in Hep-12 cells were determined to be 0.9312 nM and 2.7 nM, respectively, showing high binding constant of the radiotracer in the cell line. In NIR images, higher tumor uptake of Cy5.5-1B50-1 could be visualized at all-time points measured (4-96 h) than that of Cy5.5-mIgG3. Furthermore, in micro-PET imaging studies, 64Cu-NOTA-1B50-1 showed a significant higher tumor uptake compared with 64Cu-NOTA-mIgG3 ($p<0.0001$, n=5),and the tumor uptake of ^{64}Cu-NOTA-1B50-1 decreased significantly with 0.5 mg cold 1B50-1 ($p < 0.0001$) further confirmed the specificity. The small lesions (0.3-0.4 cm) were successfully detected by ^{64}Cu-NOTA-1B50-1 PET imaging, and the tumor uptake of α2δ1+ low expression Huh7 models showed 9.90 ± 0.21ID%/g at 36 h. **Conclusion:** We successfully synthesized and evaluated ^{64}Cu-NOTA-1B50-1/Cy5.5-1B50-1 in α2δ1+ Hep12 models. And ^{64}Cu-NOTA-1B50-1/Cy5.5-1B50-1 had a great potential for non-invasive, real-time detection, staging, and follow-up supervision of the dynamic changes of α2δ1+ cells in vivo. It may be possible to early warning of recurrence of HCC at cellular level. **References:** None.

EP-0662

Using Radiolabelled APOMAB® For Non-Invasive ImmunoPET Imaging of Tumour Cell Death Following Chemotherapy

V. Liapis[1], W. Tieu[2], P. Takhar[2], A. Evdokiou[3], M. P. Brown[4], A. H. Staudacher[4];
[1]University of South Australia, Adelaide, AUSTRALIA, [2]Molecular Imaging and Therapy Research Unit, South Australian Health and Medical Research Institute, Adelaide, AUSTRALIA, [3]Discipline of Surgery, Breast Cancer Research Unit, Basil Hetzel Institute and Centre for Personalised Cancer Medicine, University of Adelaide, Adelaide, AUSTRALIA, [4]Translational Oncology Laboratory, Centre for Cancer Biology, SA Pathology and University of South Australia, Adelaide, AUSTRALIA.

Aim/Introduction: Early detection of tumour treatment responses represents an unmet clinical need with no approved non-invasive methods. APOMAB® is an antibody targeting Lupus associated antigen (La/SSB). La is over-expressed in malignancy and selectively targeted by APOMAB in cancer cells dying from DNA-damaging anti-cancer treatment. Therefore, APOMAB is a unique diagnostic tool that detects dead cancer cells in this clinical setting and thus could distinguish between treatment responsive and non-responsive patients.The aim of this study is To evaluate tumour and normal tissue uptake of Zirconium-89-labelled APOMAB in untreated and chemotherapy-treated tumour-bearing mice by whole body positron-emission tomography (PET) imaging. **Materials and Methods:** Mice bearing subcutaneous syngraft or human xenograft tumours were untreated or given cisplatin chemotherapy followed 24h later by intravenous injection of Zr89-APOMAB. Tumour treatment response was monitored using bioluminescence imaging and Zr89-APOMAB uptake was measured using an Albira SI PET imager. **Results:** Although tumour uptake of APOMAB was detected in untreated mice, uptake significantly increased in both syngeneic and human tumours of lung and ovarian cancers after chemotherapy but not in normal tissues. **Conclusion:** APOMAB® is a selective in vivo marker of chemotherapy-induced tumour cell death in both syngeneic and xenograft tumours. Given that tumour tissue, rather than normal tissues, was targeted after chemotherapy, these results support the clinical development potential of APOMAB® as both a predictive marker of treatment response and a theranostic imaging agent, which might guide delivery of APOMAB®-directed antibody radio or drug conjugate therapies. **References:** None.

"Theranostics" - Radioimmunodetection and Radioimmunotherapy for Metastatic Colorectal Cancer in Preclinical Cancer Models

T. Cuda[1], P. Thomas[2], S. Rose[3], S. Puttick[3], J. Hooper[1], Cancer Cell Biology Team, Mater Research Institute- The University of Queensland;
[1]The University of Queensland - Mater Research Institute, Brisbane, AUSTRALIA, [2]Royal Brisbane and Women's Hospital, Brisbane, AUSTRALIA, [3]CSIRO, Brisbane, AUSTRALIA.

Aim/Introduction: Worldwide, colorectal cancer is the third most common malignancy and forth leading cause of cancer-related death. The five-year survival for localised disease is 90%, but this plummets to 10% for metastatic disease[1]. The non-specific nature of current chemotherapeutic regimes results in varying degrees of systemic toxicity and myelosuppression, limiting disease control and survival[2]. Our laboratory has employed a monoclonal antibody (mAb) to a transmembrane glycoprotein, known to be overexpressed on the surface of colorectal cancer cells with minimal expression in normal tissue, in a theranostic approach for colorectal cancer. This project assessed the novel radiolabelled mAb as a cancer-specific PET imaging radioligand and a therapeutic radioligand for colorectal cancer in preclinical cancer models. **Materials and Methods:** As a diagnostic radioligand, we assessed the avidity during PET imaging of our Zirconium-89 (^{89}Zr)-mAb in detecting colorectal cancer in a range of mouse models. In a therapeutic phase, we performed tumour burden and survival experiments on mice carrying patient-derived colorectal cancers randomised into the following groups: 1) no treatment; 2) 5-fluorouracil (5FU) - a chemotherapy used as current standard of care; 3) a single dose of the therapeutic radioligand Lutetium-177 (^{177}Lu)-mAb; or 4) combination therapy of 5FU and a single dose of ^{177}Lu-mAb. **Results:** During the diagnostic PET imaging phase, we found that ^{89}Zr-mAb demonstrated significantly higher avidity than control radioligands for colorectal cancer. In the therapeutic phase of the study, a single dose of ^{177}Lu-mAb was significantly more effective than three doses of the chemotherapy regime 5FU at slowing tumour growth. ^{177}Lu-mAb improved the efficacy of chemotherapy thus opening the possibility of using the radioligand as a single agent or concurrently with chemotherapy. **Conclusion:** The current overall survival of patients with metastatic colorectal cancer is dismal. The emerging field of theranostics may offer a new therapy for patients with metastatic colorectal cancer. This study demonstrates proof of concept of a radiolabelled mAb specific to a transmembrane glycoprotein as both a radioimmunodetection and radioimmunotherapy agent for the prognostication and treatment of colorectal cancer in preclinical mouse models. Our future prospects will work towards eventual clinical trial. **References:** 1. Belov L, Zhou J, Christopherson RI. Cell surface markers in colorectal cancer prognosis. ^{68}Ga labeling, quality Control and preliminary Biological Evaluation of tumor PDL1 targeting Molecular NOTA-WL12

J. Jiang, *Z. Hua, Y. Zhi;*
Peking University, Beijing, CHINA.

Aim/Introduction: tumor immunotherapy is a new method of tumor treatment after surgery, radiotherapy and chemotherapy, but only some solid tumor patients can benefit from it. It is of great significance to screen the positive patients who have curative effect response to tumor immunotherapy. In this paper, a new polypeptide NOTA- WL12, with PD-L1 targeting was designed and synthesized, and the radioactivity labeling, quality control and preliminary biological evaluation of ^{68}Ga were carried out. It is expected that ^{68}Ga-NOTA- WL12 can be used to screen patients with tumor clinical immunotherapy as soon as possible **Materials and Methods:** in this project, 14 amino acid cyclic sequences WL12, were synthesized and obtained by peptide automatic synthesizer, and the target molecular probes which could be used for radiation labeling were obtained by means of amino coupling bifunctional chelating agent NOTA. NOTA-WL12, the peptide was confirmed by HPLC and MS. Then, the radionuclide ^{68}Ga was labeled and the ^{68}Ga -NOTA-WL12 PET molecular probe was obtained. The labeling efficiency was determined by Radio- HPL/TLC and the stability in vitro and in vivo was studied. The metabolism of HT29 and MDA-MB- 231mice in vivo was observed by Micro-PET equipment. **Results:** the NOTA-WL12 HPLC retention time 9.26 Min of 10mg grade, which can be used for radiochemical labeling, was synthesized in this project. Radio-HPLC analysis showed that the labeling rate was more than 95% and the radiochemical purity was more than 99%. The ^{68}Ga-NOTA-WL12 probe showed good radiochemical properties with a specific activity of 27.8-111.2 GBq/umol. In vitro stability studies showed that it remained 90% stable in 5% calf serum buffer for 4 h. Micro-PET imaging was performed at 1.0h after intravenous injection of 5.5 MBq . In the tumor lesions of mice with high expression of PD-L1, the radioactivity uptake was significantly increased, but no obvious radiation community was found in the tumor lesions of the negative control group. **Conclusion:** NOTA-WL12 peptide was designed and synthesized in this study. the PDL1 targeted NOTA-WL12 was radiolabeled by ^{68}Ga, and the ^{68}Ga-NOTA-WL12 molecular probe was obtained. The probe has good radiochemical properties, in vitro stability and good metabolic properties. The synthesis and preliminary biological evaluation of ^{68}Ga-NOTA- WL12 probe show that it is expected to be used in the screening of patients with tumor clinical immunotherapy. **References:** None.

Combined PET and MR imaging of HET-CAM xenografts for evaluation of targetspecific binding of radioligands

G. Winter[1], *A. B. F. Koch*[1], *J. Löffler*[1,2], *C. Solbach*[1], *G. Glatting*[3], *V. Rasche*[2], *A. J. Beer*[1];
[1]*Department of Nuclear Medicine, Ulm University, Ulm, GERMANY,* [2]*Center for Translational Imaging, Internal Medicine II, Ulm University, Ulm, GERMANY,* [3]*Medical Radiation Physics, Department of Nuclear Medicine, Ulm University, Ulm, GERMANY.*

Aim/Introduction: Specificity to the target structure is one of the main selection criteria in the development of new specific agents for oncological diagnosis and therapy. These data are obtained from tests in mice and an appropriate animal

experiment permit is required. The Hens egg test-chorioallantoic membrane (HET-CAM) model offers an excellent alternative in terms of animal welfare according to the 3R principles (Replacement, Reduction, Refinement) and does not require an animal experiment permit. An undeveloped immune response system allows the growth of vascularized tumor xenografts on the membrane surface and a determination of the target-specific accumulation of the drug of interest. [^{68}Ga]PSMA-11 was used to demonstrate the principle of the HET-CAM model for assessing specific radiotracer accumulation. **Materials and Methods:** Tumor xenografts were established by application of PSMA-positive cell line LNCaP C4-2 (1x10^6 cells) and the PSMA-negative control PC-3 (7.5x10^5 cells) in combination with matrix (40%, v/v) in silicon rings on the CAM on embryo development day (EDD)7. Between EDD12 to 14 MR and PET imaging was performed. Anatomical information was obtained by high-resolution imaging using a small animal MR (BioSpin 117/16, Bruker) [1]. For PET imaging 150µl [^{68}Ga]PSMA-11 solution was prepared and injected into a CAM vessel, followed by a dynamic 60-minute PET scan (Focus 120, Concorde Microsystems Inc.). Quantitative evaluation of tumor accumulation was achieved by gamma counter measurements (COBRA II, Perkin Elmer). Using reference point registration in 3D slicer software [2] MRI and PET data were superimposed. **Results:** Tumor growth could be successfully visualized by MRI. In PET, accumulation of [^{68}Ga]PSMA-11 was observed in the PSMA-positive tumor and in the chick embryo. According to the gamma counter measurements there was a significantly higher accumulation of [^{68}Ga]-PSMA-11 observed in LNCaP C4-2 tumors in comparison to PC-3: (0.26±0.71) %ID (LNCaP C4-2); (0.07±0.05) %ID (PC-3); (n=20). A ratio of (4.2±4.0) (PSMA-specific/non-specific) was calculated. Time-activity curves demonstrated an increasing tracer accumulation over time of (8.5±2.6) % in LNCaP C4-2. **Conclusion:** Quantitative evaluation of the specificity of radiotracer accumulation by PET using the HET-CAM model with xenografts was successfully demonstrated. Fusion of PET and MR images allowed for combined analysis of molecular PET data and high-resolution anatomical information. According to the 3R principle, the HET-CAM model could be used for the evaluation of new radiopharmaceuticals as an alternative for mouse experiments. **References:** [1] Zuo, Z. et al. 2017 and 2015. EP-0666

Radiobiological effect of in vitro ^{99m}Technetium labelling of red blood cells. Study with micronucleus assay in human peripheral blood lymphocytes

A. Abella Tarazona[1], *M. Asensio Ruiz*[1], *Á. García Aliaga*[1], *T. Chivato Martín-Falquina*[2], *M. Martínez Martínez*[1];
[1]*Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, SPAIN,* [2]*Hospital General Universitario Santa Lucía, Cartagena, SPAIN.*

Aim/Introduction: The purpose of this study is to evaluate by the cytokinesis-blocked micronucleus assay the degree of cytological radiation damage to lymphocytes occurring after in vitro Tc-99m labelling of red blood cells. **Materials and Methods:** The blood obtained from healthy voluntary donors (n=4) was processed and radiolabelled with different activities (3.7, 37, 185, 370 MBq and 740MBq) following the Procedure Guideline from the Royal Spanish Pharmacopea. After radiolabelling, 1ml of each sample, together with 1 ml of control sample and 1 ml of stannous control, were added respectively to 7 ml lymphocyte-selective medium and cultured at 37ºC for 72h. Cytochalasin B at a final concentration of 6 µg/ml was added 44h after the beginning of the culture to block cytokinesis. At the end of the incubation the cells were harvested, treated with a hypotonic solution containing 0.075 M KCl and fixed with a mixture of methanol:glacial acetic acid (3:1). Slides were stained with Giemsa at 5% and micronuclei were scored in 1000 binucleated cytokinesis-blocked cells. **Results:** Labelling efficiency was 92.7 ±2.6 (n= 20) The number of micronucleus scored in 1000 binucleated cells was 7±4 for control and 10±6 for stannous control. After incubation of isolated lymphocytes with 3.7, 37, 185 and 370 MBq, micronucleus scored in 1000 binucleated cells were 8±7, 19±4, 45±19, 102±25. Scoring of micronucleus was not posible in the labelling experiments with 740 MBq due to an almost complete impairment of the proliferation capacity of lymphocytes. **Conclusion:** The damage produced during the labelling of red blood cells with Tc-99m was slightly higher compared to the control and stannous control and it was proportional to radiolabelling activity.Compared with leukocyte labelling, the damage obtained in our results were much lower and agrees with the results of other authors in the evaluation of external leukocyte irradiation. It is an aspect to take into account in case of pediatric patients, with whom smaller activities are used and there is the possibility of injecting aberrant lymphocytes. **References:** Radiopharmaceutical Procedure Guideline Number 6. Preclinical evaluation of ^{68}Ga-DOTA-NT-20.3: A promising PET imaging probe to discriminate human pancreatic ductal adenocarcinoma from pancreatitis

A. Prignon;
Sorbonne Universite, Paris, FRANCE.

Aim/Introduction: Neurotensin receptor 1 (NTSR1) is overexpressed in human pancreatic ductal adenocarcinoma (PDAC). Specific non-invasive PET imaging probes may improve diagnostic accuracy and the monitoring of therapy for patients with PDAC. Here, we report the use of the ^{68}Ga-

labeled neurotensin (NTS) analogue DOTA-NT-20.3 to image human PDAC in animal models and to discriminate tumors from pancreatitis. **Materials and Methods:** PET imaging, biodistribution, blocking and histology studies were performed in subcutaneous AsPC-1 pancreatic tumor-bearing mice. In addition to the preclinical study, two tissue microarrays slides, constructed by small core biopsies (2 to 5) from standard paraffin-embedded tumor tissues were used to confirm the high (78%) positivity rate of NTSR1 expression in human PDAC. **Results:** ^{68}Ga-DOTA-NT-20.3 PET images showed rapid tumor uptake and high contrast between tumor and background with a fast blood clearance and a moderate accumulation in the kidneys. Ex vivo biodistribution showed low uptake in normal pancreas (0.22 %IA/g) and in remaining organs at 1 h post-injection, kidney retention (5.38 ± 0.54 %IA/g), fast clearance from blood and confirmed high uptake in tumors (5.28 ± 0.93 %IA/g) leading to a tumor-to-blood ratios values of 6 at 1 h post-injection. The significant decrease of tumor uptake in a blocking study demonstrated the specificity of ^{68}Ga-DOTA-NT20.3 to target NTSR1 in vivo.PET imaging was also conducted in an orthotopic xenograft model that allows tumors to grow in their native microenvironment and in an experimental pancreatitis model generated by caerulein injections. As opposed to ^{18}F-FDG, ^{68}Ga-DOTA-NT-20.3 distinguishes PDAC from pancreatitis. **Conclusion:** Thus, ^{68}Ga-DOTA-NT-20.3 is a promising PET imaging probe for imaging PDAC in humans. **References:** None.

Role of Syndecan Gene in the Pathogenesis of Liver Damage in Radioactive Iodine-131 Therapy

N. Yumusak[1], *A. Yigin*[2], *H. Atilgan*[3], *A. Kalayci Yigin*[4], *G. Koca*[5], *R. Yilmaz*[1], *M. Korkmaz*[5];
[1]*Department of Pathology, Harran University Faculty of Veterinary Medicine, Sanliurfa, TURKEY,* [2]*Department of Genetic, Harran University Faculty of Veterinary Medicine, Sanliurfa, TURKEY,* [3]*Department of Nuclear Medicine, Mustafa Kemal University, Hatay, TURKEY,* [4]*Cerrahpasa Medical Faculty, Istanbul University, Istanbul, TURKEY,* [5]*Department of Nuclear Medicine, Ankara Training and Research Hospital, Ankara, TURKEY.*

Aim/Introduction: The aim of this study was to investigate the presence of Syndecan gene in iodine-131(^{131}I) induced liver damage of rats after high-dose treatment. **Materials and Methods:** Fifty Wistar Albino rats were divided into five, as ten rats in each group. 111 Mbq/kg ^{131}I was administered to each rat in all experimental groups except the control. The control group consisted of rats with no intervention. 6th h, 24th h, 7th day and 30th days on the study the animals were sacrificed, and the evaluation of biodistribution and histopathological studies were performed on the livers removed. Western-blot, Real-time PCR and immunohistochemistry were carried out for Syndecan gene expression, and the differences between the groups were statistically evaluated. **Results:** Syndecan gene expression was observed to increase in the all ^{131}I-administered (6th h, 24th h, 7th day and 30th days) groups (P<0.01), whereas there was no expression in the control group. Immunohistochemical staining pattern in the extracellular source was observed in the overexpressed Syndecan groups (P<0.01). Histopathologically, there was difference for hyperemia, double nucleus, perivascular fibrosis, inflammatory cells and capsule thickening parameters in terms of incidence between the control and ^{131}I groups that shows the harmful effect of ^{131}I (P<0.01). **Conclusion:** The expression level of Syndecan gene was significantly upregulated in the ^{131}I administered groups. These results suggested that Syndecan genes might play a role in ^{131}I induced liver damage. **References:** None.

In-vivo ^{18}F-fluoro-thymidine Positron Emission Imaging For Disease Monitoring In A Mouse Model Of High-risk Myelodysplastic Syndrome

L. Sarda-Mantel[1], *F. Hontonnou*[2], *B. Hosten*[1], *N. Vignal*[1], *C. San*[1], *M. Pla*[3], *P. Fenaux*[4], *P. Kriet*[3], *C. Chomienne*[4], *R. Padua*[3];

Aim/Introduction: High-risk myelodyspastic syndrome (HR-MDS) is characterized by decreased apoptosis of bone marrow precursors which correlates with expression of BCL-2 protein , and is at risk of evolving to acute myeloid leukemia with increased bone marrow blasts. This disease occurs in elderly patients and has a poor prognosis in the absence of efficient treatment. The evaluation of new therapeutic agents in animal models of the disease is hampered by the absence of accurate in vivo biomarkers to follow the effect of the treatments, because bone marrow biopsy is not easy in mice. ^{18}F-fluoro-thymidine Positron Emission Tomography (FLT-PET) allows in vivo quantification of cell proliferation and has been suggested for the diagnosis and follow-up of myelodysplastic disorders in patients. Our aim was to evaluate the ability of FLT-PET to monitor bone marrow involvement in our triple transgenic MMTVtTA/TetoBCL-2/MRP8NRASD12 mouse model of HR-MDS. **Materials and Methods:** We investigated 3 groups of mice (FVB/N strain): normal controls (G1, n=7), 2-months old HR-MDS mice (G2, n=8), and 3 months-old HR-MDS mice (G3, n=8). All mice underwent FLT-PET/CT imaging (Inveon microPET/CT, Siemens), after intravenous injection of 7-10 Mbq of [^{18}F]FLT. Static acquisitions were acquired 1h15 after radiotracer injection. [^{18}F]FLT uptake in femoral bone marrow was quantified and normalized by the background blood pool activity, by using volumes of interest drawn on the femurs and the heart. Just before PET/CT, peripheral blood samples were taken for blood counts, and for BCL-2 and Mac-1hi/Gr1lo (blast cells) expression measurements. **Results:** Peripheral blood platelet counts were 1055±221, 895±118 and 823±181 x10^3/mm^3 in G1, G2 and G3

respectively (NS). BCL-2 expression was 1.2±1.1% in G1, 18±4% in G2 (vs G1: p<0.001) and 33±13% in G3 (vs G1: p<0.02, vs G2: p<0.05). Mac-1hi/Gr1lo expression was 1.3±1.8% in G1, 15±10% in G2 (vs G1: NS) and 24±2% in G3 (vs G1: p<0.002; vs G2: NS). [^{18}F]FLT-PET images of HR-MDS mice showed asymetric hot spots in femoral diaphyses, and sometimes in humerus. PET contrast in femoral bone marrow was 1.07±0.21 in G1, 1.62±0.67 in G2 (vs G1: p<0.03) and 2.07±1.08 in G3 (vs G1:p<0.02; vs G2:NS). **Conclusion:** [^{18}F]FLT-PET imaging shows femoral bone marrow abnormalities in HR-MDS mice, with intensity increasing with age, BCL-2 and Mac-1hi/Gr1lo blood expressions whereas platelets counts inversely decrease. These results suggest that [^{18}F]FLT-PET imaging is a surrogate non-invasive quantitative marker of HR-MDS bone marrow involvement and may be used for therapy monitoring in our mouse model. **References:** None.

Developing Peptide based Nanoconstructs as Potential Theranostic Agents

I. U. Khan[1], *E. Achilli*[2], *R. Zahoor*[1], *A. Fatima*[1], *M. Sohaib*[1], *A. Shahid*[1], *C. Flores*[2], *M. Grasselli*[2], *A. R. Jalilian*[3];
[1]*Institute of Nuclear Medicine and Oncology (INMOL), New Campus Road, Lahore, PAKISTAN,* [2]*Laboratorio de Materiales Biotecnológicos, Universidad Nacional de Quilmes-IMBICE (CONICET), Bernal, ARGENTINA,* [3]*Department of Nuclear Science and Applications, International Atomic Energy Agency (IAEA), Vienna, AUSTRIA.*

Aim/Introduction: The acronym THERANOSTICS epitomizes the inseparability of diagnosis and therapy, the pillars of medicine and takes into account personalized management of disease (usually based on nanomedicine) for a specific patient. Nanomedicines, especially in round shape particles or nanoparticles (NPs), are studied for application in the field of diagnosis and treatment of cancer. In this research work, we report on developing novel hybrid NPs (HNPs) prepared with a gold core and a multilayer coating of albumin (Alb) stabilised by a novel radiation-induced crosslinking method. The resultant bioconjugate thus possesses characteristics that make it highly biocompatible and a multifunctional platform for covalent immobilization of peptides. **Materials and Methods:** HNPs were decorated with a DOTA-Bombesin synthetic peptide in order to address cancer cells which overexpress GRP receptors. For fluorescence detection experiments, NPs were labeled with NHS ester BODIPY 630/650. Confocal microscope pictures were captured with Olympus FV300/BX61 microscope. Flow Cytometry analyses were performed with a BD FACSCalibur® cytometer. Briefly, cells were incubated for 1, 2 or 4 h with NPs diluted in the complete medium. Data acquisition and analyses were performed using the BD CellQuest Pro software package, recording 20,000 events. Radiolabeling was done with ^{177}Lu/^{68}Ga and tested the biological compatibility of novel radio-bioconjugate in rabbit animal models. **Results:** The conjugation of novel albumin-gold NPs with DOTA-BBN was characterized by the plamon peak and absorbance at 280 nm. The increment of absorbance at 280 nm shows the conjugation of peptide with albumin-gold nanoparticles. Flow cytometry analysis and confocal microscopy were applied to study the in-vitro specific interaction of these nanoconstructs to PC-3 and NCI-H460 cell lines. Furthermore, we tested the cytotoxicity of novel nano constructs by using 3T3 and Hela cells. The binding affinity of the decorated HNPs to gastrin-releasing peptide (GRP) receptor was tested by using PC-3; which was found in nanomolar range. The radiolabeling yield in most cases was >90%. The clinical potential of these radiolabeled nano bioconstructs was ultimately evaluated in tumor-bearing mice that showed siginificant uptake in tumor xenografts. **Conclusion:** Novel radiolabeled nanoconstructs based on gold NPs stabilized with many Alb layers may have great potential to be further evaluated as feasible tumor-seeking agents. This approach might be further extended to a tumor-specific targeting by using various neuropeptide derivatives as carrier of chemotherapeutic agents and should be tested in various malignancies beyond prostate cancer, thus ultimately, used as a future tool for Peptide Receptor Radionuclide Therapy. **References:** None.

Preclinical translational bridge studies supporting advancement of ^{111}In-Bn-DTPA-NLS-trastuzumab to Phase I clinical trial in patients with HER2-positive breast cancer

C. Chan[1], *Z. Cai*[1], *S. Done*[2,3], *R. Reilly*[1,4];
[1]*Departments of Pharmaceutical Sciences and Medical Imaging, University of Toronto, Toronto, ON, CANADA,* [2]*Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, CANADA,* [3]*Laboratory Medicine Program, University Health Network, Toronto, ON, CANADA,* [4]*Toronto General Research Institute, University Health Network, Toronto, ON, CANADA.*

Aim/Introduction: ^{111}In-Bn-DTPA-NLS-trastuzumab is a novel Auger electron-emitting RIT agent for HER2-positive breast cancer (BC). Our aim was to conduct preclinical translational bridge studies (pharmacokinetics (PK), radiation dosimetry, biodistribution and acute toxicity) to support the advancement of ^{111}In-Bn-DTPA-NLS-trastuzumab to Phase I clinical trial in patients with HER2-positive BC that will evaluate tumour and normal tissue uptake and dosimetry by SPECT imaging. **Materials and Methods:** Biodistribution studies were performed up to 144h p.i. in Balb/c mice injected i.v. with ^{111}In-Bn-DTPA-NLS-trastuzumab (60 µg; 6.1 MBq). Tissue uptake was expressed as %ID/g and converted to %ID/organ using organ weights. Cumulative radioactivity ($\tilde{A}_s$) in each source organ up to 144h p.i. was calculated by integrating the radioactivity vs. time curves. $\tilde{A}_s$ values were used to project radiation doses to target organs in humans using OLINDA/EXM. PK studies were performed after i.v. injection of ^{111}In-Bn-DTPA-NLS-trastuzumab (60 µg; 5.8 MBq). Blood samples were obtained up to 144h p.i. and ^{111}In concentration vs. time plotted and fitted to a 2-compartment PK model. Standard PK parameters were estimated. Acute toxicity studies were performed in Balb/c

mice injected i.v. with ^{111}In-Bn-DTPA-NLS-trastuzumab (60 μg; 0.9 MBq) which corresponded to 21-times and 30-times the planned radioactivity and mass doses, respectively for the Phase 1 trial on a MBq/kg and mg/kg basis. Toxicity was assessed by body weight, serum alanine aminotransferase (ALT) and creatinine (SCr), complete blood counts (CBC), hemoglobin (Hb), hematocrit (Hct) and histopathological examination of tissues at 14 days. **Results:** Organs with the highest uptake were blood, muscle and bone (21.1±2.1, 3.4±0.6 and 2.5±0.4 %ID/organ, respectively at 144h p.i.) The projected whole body dose to humans for ^{111}In-Bn-DTPA-NLS-trastuzumab was 0.052 mSv/MBq corresponding to 5.8 mSv for the Phase I dose (111 MBq; 5 mg). The highest normal organ doses were received by the bone, kidneys and liver (0.205, 0.08 and 0.07 mSv/Bq, respectively). ^{111}In-Bn-DTPA-NLS-trastuzumab exhibited biexponential elimination from blood with an α-phase half-life of 2.2h and β-phase half-life of 50.3h. There was no significant difference in body weight of mice receiving ^{111}In-Bn-DTPA-NLS-trastuzumab compared to mice treated with unlabeled Bn-DTPA-NLS-trastuzumab or normal saline. Similarly, there were no significant differences in CBC, Hb, Hct or serum ALT or SCr in mice treated with ^{111}In-Bn-DTPA-NLS-trastuzumab compared to control groups. No morphological changes in tissues were observed. **Conclusion:** Preclinical translational bridge studies indicate that ^{111}In-Bn-DTPA-NLS-trastuzumab will be safe to administer to patients with HER2-positive BC at an amount of 111 MBq (5 mg). **References:** None.

EP-0672

Evaluation specific infection in severe acute pancreatitiswith a novel probe ^{18}F-FDS

Z. Zhu[1,2], *Q. Peng*[3], *J. Li*[4], *Q. Wang*[5], *X. Zhang*[4], *X. Su*[5], *S. Hu*[1,2];
[1]*Department of PET Center, Xiangya Hospital, Central South University, Changsha, CHINA,* [2]*National Clinical Research Center for Geriatric Disorders (XIANGYA),* *Xiangya Hospital, Central South University, Changsha, CHINA,* [3]*Department of Pharmacy, Xiangya Hospital, Central South University, Changsha, CHINA,* [4]*School of Public Health, Xiamen University, Xiamen, CHINA,* [5]*Department of Nuclear Medicine,Zhongshan Hospital ,Xiamen University, Xiamen, CHINA.*

Aim/Introduction: Severe acute pancreatitis (SAP) is the most serious type of acute pancreatitis associated with high morbidity and mortality.Even more,when there is a secondary infection,it will be more dangerous.So it is very important to diagnose whether SAP is associated with secondary infection or not at an early stage. But so far there is no ideal method for initial clinical diagnosis.In this study, we utilize 2-^{18}F-fluorodeoxysorbitol (^{18}F-FDS) as a PET/CT tracer and try to identify SAP with kinds of infections on PET imaging at early stage. **Materials and Methods:** 36 male Sprague-Dawley rats were randomly divided into 3 groups and were injected with sodium tauronate firstly and then followed by 3 kinds of bacterias (Escherichia coli, Staphylococcus aureus and Inactivated Escherichia coli) respectively to induce SAP model with infections. Blood samples were collected at 3 time points for 0h,1h,3h after modeling to detect serum amylase and do blood routine analysis.Then the rats were performed with the PET/CT scan with ^{18}F-FDS and ^{18}F-FDG respectively at 3h and 6h(3 rats for ^{18}F-FDG or ^{18}F-FDS PET imaging each time point).After that,the animal welfare was executed, and the autoradiography, biodistribution were analyzed.HE staining and Graman staining were performed as well. **Results:** In the early 3h of PET/CT imaging after modeling, ^{18}F-FDS was observed to accumulate in the pancreatic site of E. coli-infected SAP model rats, and it was more evident at 6 h after modeling, and the diffusion range was greater.No significant was seen in the others. PET SUV values of ^{18}F-FDS in Escherichia coli, Staphylococcus aureus and inactivated Escherichia coli were 2.7±0.06, 1.03±0.19 and 0.67±0.18, respectively. There is a significant difference between the values of the E. coli group and the others (E.coli vs S.aureus, q=8.96, p<0.01; E.coli vs inactivated E.coli q=9.35, p<0.01). ^{18}F-FDG showed significant aggregation in each group (2.07±0.21 in the E.coli group, 2.30±0.53 in the S.aureus group, and 1.80±0.11 in the inactivated E.coli group).No significant differences were noted (F=1.69, p=0.26). Biodistribution results also showed that the ^{18}F-FDS of E. coli group had a pancreatic tissue distribution value of 1.25±0.17% ID/g;which is higher than the others(0.50±0.16% ID/g and 0.47±0.09%ID/g,F=28, P=0.0009).While the ^{18}F-FDG Biodistribution results showed no significant difference among these groups (1.34±0.11%ID/g,1.39±0.12%ID/g,1.21±0.12%ID/g;F=1.923, P=0.2263). **Conclusion:** ^{18}F-FDS PET imaging maybe is a promising method for evaluating of specific secondary infection in severe acute pancreatitis at an early stage.The imaging characteristics can be recognized as early as 3h after SAP onset. **References:** None.

RGDyc Peptide-modified Pamam Dendrimer Conjugates Labeled With Radionuclide ^{131}I For SPECT Imaging And Radiotherapy Of Lung Carcinoma

Z. Jinhe;
General Hospital of Southern Theater Command, PLA, Guangzhou, CHINA.

Aim/Introduction: Arginine-glycine-aspartic acid-tyrosine-cysteine (RGDyC)-modified PAMAM dendrimer labeled with radionuclide iodine-131 (^{131}I) was synthesized and utilized for targeted single photon emission computed tomography (SPECT) imaging and radiotherapy of cancer. **Materials and Methods:** In this study, amine-terminated poly(amidoamine) (PAMAM) dendrimer of fifth generation (G5) was used as a platform to conjugate with PEGylated arginine-glycine-aspartic acid-tyrosine-cysteine(RGDyC) peptide, followed by acetylation of the remaining terminal amines. Then the dendrimer was labeled with radioactive ^{131}I to form the targeted nanoplatform ^{131}I-RGDyC-PEG-PAMAM. The targeting and therapeutic effects were subsequently evaluated in vitro and in vivo. **Results:** We show that the PAMAM platform possesses approximately 33 PEG and 5.7 RGDyC moieties on each PAMAM. The dendrimer

platform can target human lung carcinoma A549 cells over expressing αvβ3 integrin due to the attached RGD. With the attached tyrosine moiety having the phenol group, the dendrimer platform can be effectively labeled with ^{131}I with high radiochemical purity and good stability. Importantly, the ^{131}I labeling renders the dendrimer platform with an ability to be used for targeted SPECT imaging and radiotherapy of an αvβ3 integrin-overexpressing lung carcinoma model in vivo. **Conclusion:** The developed targeted theranostic dendrimeric nanoplatform ^{131}I-RGDyC-PEG-PAMAM may hold promise to be used for targeted theranostics of human carcinoma. **References:** Shih YW, Chien ST, Chen PS, et al. α-Mangostin Suppresses Phorbol 12-myristate 13-acetate-Induced MMP-2/MMP-9 Expressions via αvβ3 Integrin/FAK/ERK and NF-κB Signaling Pathway in Human Lung Adenocarcinoma A549 Cells. On the reduction of uptake of radiolabeled DARPins in kidneys

A. Vorobyeva[1], *M. Altai*[1], *J. Garousi*[1], *S. S. Rinne*[1], *A. Schulga*[2], *S. Deyev*[2,3];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Shemyakin & Ovchinnikov Institute of Bioorganic Chemistry, Moscow, RUSSIAN FEDERATION,* [3]*National Research Nuclear University "MEPhI", Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: Designed ankyrin repeat proteins (DARPins) are small engineered scaffold proteins with molecular weight of 14-18 kDa. Radiolabeled DARPins 9_29 and G3 demonstrated high-contrast imaging of HER2 at the day of injection in preclinical studies. Their small size provides fast extravasation into tumors and efficient renal excretion enables rapid achievement of high tumor-to-organ ratios. However, high renal accumulation of activity for DARPins labeled with residualizing labels is a limitation for targeted radionuclide therapy. Better understanding of the mechanisms behind kidney uptake of DARPins could aid in the development of strategies to reduce it. In this study we have investigated whether the renal uptake of [^{99m}Tc]Tc(CO)$_3$-G3 could be reduced by administration of compounds that act on various parts of the reabsorption system in kidney. **Materials and Methods:** Biodistribution and renal uptake of [^{99m}Tc]Tc(CO)$_3$-G3 was measured ex vivo in healthy female NMRI mice 4 h after injection of the tracer. The effect of lysine and gelofusine (megalin ligands), colchicine (microtubule inhibitor), probenecid (organic anion transport inhibitor), mannitol (osmotic diuretic), furosemide (loop diuretic) as well as sodium maleate and fructose (decrease intracellular ATP) on renal uptake of [^{99m}Tc]Tc(CO)$_3$-G3 was investigated. The effect of maleate was additionally studied for another DARPin variant, [^{99m}Tc]Tc(CO)$_3$-9_29. Autoradiography of kidney sections was used to study the localization of activity in kidneys. **Results:** Co-injection of lysine or gelofusine was not effective for reduction of kidney uptake of [^{99m}Tc]Tc(CO)$_3$-G3. Administration of sodium maleate before the injection of [^{99m}Tc]Tc(CO)$_3$-G3 reduced its kidney-associated activity by 60.4 ± 10.3%, while administration of fructose reduced it by 46.9 ± 7.6% compared to the control. The decrease in kidney uptake provided by sodium maleate was also observed for [^{99m}Tc]Tc(CO)$_3$-9_29. Pre-injection of colchicine, probenecid, mannitol or furosemide had no effect on kidney uptake of [^{99m}Tc]Tc(CO)$_3$-G3. Kidney autoradiography showed mainly cortical accumulation of activity for all studied groups. **Conclusion:** The ineffectiveness of lysine to lower the kidney uptake of [^{99m}Tc]Tc(CO)$_3$-G3 suggests that its re-uptake is not driven by megalin receptor system. Both fructose and maleate lower the cellular ATP level in proximal tubule cells and their reduction of kidney re-uptake indicates the involvement of an ATP-driven mechanism of uptake. The decrease provided by maleate for both DARPins, G3 and 9_29, indicates that their uptake proceeds through a mechanism independently of DARPin scaffold composition. **References:** None

Application of ^{18}F-FMISO in Determination of Hypoxia Level in Murine CT26 Tumors During Various Stages of Development

L. Kiraga[1], *L. Cheda*[2], *B. Taciak*[1], *K. Różańska*[1], *K. Tonecka*[3], *A. Szulc*[3], *K. Kilian*[2], *E. Górka*[1], *Z. Rogulski*[2], *T. P. Rygiel*[3], *M. Król*[1];
[1]*Warsaw University of Life Sciences, Warsaw, POLAND,* [2]*University of Warsaw, Warsaw, POLAND,* [3]*Medical University of Warsaw, Warsaw, POLAND.*

Aim/Introduction: The aim of this research was to determine levels of hypoxia at various stages of tumor development using positron emission tomography (PET) and to compare

different methods of hypoxia evaluation in pre-clinical CT26 tumor model. **Materials and Methods:** For the experiments, BALB/c mice (females, 8-12 weeks old) were used. Each mouse was inoculated intramuscularly with CT26 cells (murine colonorectum carcinoma) in the right lower leg. Evaluation of hypoxia level was performed by intravenous administration of [^{18}F]fluoromisonidazole ([^{18}F]FMISO) followed by PET-CT imaging at the day 5, 7, 9, 12, 14, 16, and 18 after cancer cells transplantation. Tumor shapes on fused PET-CT images were contoured on each slide consisting part of tumor. Obtained VOI (volume of interest) was quantitatively analyzed using PBAS module of PMOD software. In each time-point images of 6-9 mice were analyzed. Intensity of hypoxia in tumor tissue was evaluated by counting SUV (standardized uptake value), and %ID/ml (per cent of injected dose per ml of VOI). The results were compared with two other methods of hypoxia determination: the molecular method based on the qPCR analysis of selected genes expression related to hypoxia and a fluorescence microscope imaging of pimonidazole (PIMO)-positive tumor areas. **Results:** Both PET and fluorescence microscopy methods showed that hypoxia increased till day 14 of tumor growth, whereas qPCR results showed that tumor hypoxia at molecular level was relatively high at early stage of tumor development. Additionally, necrotic regions dominated the tumor tissue at later stages of development, decreasing the number of hypoxic areas and completely eliminating normoxic regions (observed by PET). Comparing our results with available studies concerning tumor hypoxia we may conclude, that during tumor development the level of hypoxia fluctuates and two peaks of hypoxia occur. The first one is observed at the initial stage of tumor growth and the second one - in terminal stage, when chronically ischemic, hypoxic tissue starts to transform into necrosis. **Conclusion:** These results showed that molecular, gene expression-related methods of hypoxia determination are more accurate to prove changes undergoing at cellular level, however in order to visualize and count volumes of hypoxic regions in the investigated area, especially at further stages of tumor development, PET is the recommended tool. Furthermore, we noted interesting principle - during development of tumor, two peaks of hypoxia occur. **References:** None.

In vivo investigation of APN/CD13 inhibitors in tumor bearing animal models using 68Ga-NODAGA-cNGR radiotracer

A. Kis[1], *J. P. Szabó*[1], *T. Nagy*[1], *N. Dénes*[1], *I. Kertész*[1], *S. Lakatos*[2], *K. Halmi*[1], *E. Berényi*[1], *G. Trencsényi*[1];
[1]*Division of Nuclear Medicine and Translational Imaging, Department of Medical Imaging, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY,* [2]*Division of Radiology and Imaging Science, Department of Medical Imaging, Faculty of Medicine, University of Debrecen, Debrecen, HUNGARY.*

Aim/Introduction: Several malignant tumors, such as prostate, ovarium, pancreas carcinomas, melanomas and fibrosarcomas are positive for Aminopeptidase N (APN/CD13) receptor, which play an important role in neo-angiogenic process and metastatic tumor cell invasion. Our previous studies have already shown that ^{68}Ga-labeled NGR peptides bind specifically to APN/CD13 expressing tumor cells. ^{68}Ga labeled NGR peptides enable the investigation of the neo-angiogenic process with Positron Emission Tomography (PET). APN/CD13 inhibitors are potential chemotherapeutic agents in APN/CD13 positive tumors. The aim of this study was to investigate the effect of APN/CD13 inhibitors in subcutan and orthotopic HT1080 tumor bearing animal models using ^{68}Ga-NODAGA-cNGR. **Materials and Methods:** On day 0. CB17 SCID mice (n=30) were inoculated subcutan (n=15) with 1,5x10^6/animal/150 µl and orthotopically (n=15) with 1x10^6/animal/10 µl HT1080 (human fibrosarcoma) cells. Three days after inoculation the animals were randomly distributed into three groups (control, Bestatin [15 mg/kg] treated, Actinonin [5 mg/kg] treated). The daily intraperitoneal Actinonin or Bestatin treatments were administered for 7 days.^{18}FDG or ^{68}Ga-NODAGA-cNGR PET scans were taken on the 5th, 6th and 10th day to monitor tumor growth. On the 10th day 90 min after intravenous injection of 10±0,3 MBq ^{68}Ga-NODAGA-cNGR PET or PET/MRI scans and ex vivo biodistribution studies were made. Data were statistically analysed using unpaired Student's test. **Results:** On the 10th day PET scans were taken using ^{68}Ga-NODAGA-cNGR. In the case of subcutan HT1080 tumor bearing animals significant (p≤0,05) differences were observed in SUVmean values between Bestatin treated (SUVmean= 0,01±0,009) and control (SUVmean= 0,114±0,045) groups. Also singnificant (p≤0,05) heterogeneities were noticed among SUVmean values in orthotopically transplanted HT1080 tumor bearing animals, where SUVmean values were 0,009±0,006 in Actinonin treated groups and 0,026±0,013 in control groups. In subcutan tumors tumor/muscle (T/M) ratios - which were received from ex vivo biodistribution studies - are well correlated with in vivo T/M SUVmean ratios. However this kind of correlation was not observed during the investigation of orthotopically inoculated tumors. **Conclusion:** In the case of subcutan HT1080 tumor bearing animals' Bestatin treatment, while orthotopically inoculated HT1080 tumor bearing animals' Actinonin treatment reduced the ^{68}Ga-NODAGA-cNGR uptake in tumor in proportion to control group. This project was supported by the ÚNKP- 18-3-I-DE-32 new national excellence program of the ministry of human capacities. **References:** None.

EP-0677

Epigenetic Treatment with Histone Deacetylase Inhibitor Increases Uptake of [^{111}In]In-DOTA-TATE by Neuroendocrine Tumor Cells

I. Klomp*, S. U. Dalm, P. M. van Koetsveld, F. Dogan-Oruç, M. de Jong, L. J. Hofland;*
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: The somatostatin-2 receptor (SST2) is highly expressed on neuroendocrine tumor (NET) cells making it a suitable target for peptide receptor radionuclide therapy (PRRT)

using radiolabeled somatostatin analogues. Although PRRT has proven its value for treatment of NETs, treatment efficacy can be further improved by upregulating SST2. Epigenetic processes, such as histone acetylation, are highly involved in regulating gene transcription. Since histone acetylation is linked to transcriptional activation, histone deacetylase inhibitors (HDACis) may increase SST2 expression, and thus the efficacy of PRRT. We aimed to study the effect of the HDACi valproic acid (VPA) on SST2 expression and uptake of radiolabeled somatostatin analogues. **Materials and Methods:** Studies were performed in the human pancreatic NET cell line BON-1. Cell growth assays were performed to determine the EC_{50} of VPA after 7 day treatment. Subsequently, cells were treated for 7 days with the EC_{50} of VPA to study the effect on SST2 mRNA expression and uptake of [^{111}In]In-DOTA-TATE. Cells were trypsinized and cultured in 12-well plates on day 5. On day 7, different assays were performed: (1) RT-qPCR to determine the amount of SST2 mRNA expression and (2) uptake and internalization studies by incubating cells for 4h at 37ºC with 1nM [^{111}In]In-DOTA-TATE, +/- 1µM octreotide. The measured radioactivity was expressed as percentage added dose (%AD)/mg DNA. Additionally, reversibility of VPA treatment was determined. Cells were treated for 7 days with VPA, after which VPA-supplemented medium was replaced by medium without VPA to day 10. Samples for RT-qPCR were collected directly after treatment on day 7 (control + VPA-treated cells) and day 10 (only VPA-treated cells). **Results:** We found an EC_{50} value for VPA of 1mM. Seven day treatment with 1mM VPA resulted in both significant increased uptake and internalization of [^{111}In]In-DOTA-TATE compared to untreated BON-1 cells ($p<0.01$). In line with this, mRNA expression levels of VPA-treated cells were significantly upregulated after treatment ($p<0.05$). Moreover, reversibility of HDACi treatment was demonstrated by two-fold decreased SST2 mRNA expression levels 3 days after discontinuation of VPA when compared to SST expression directly after treatment ($p<0.05$). **Conclusion:** Results show that VPA is capable of inducing a reversible upregulation of SST2 expression and to enhance uptake of [^{111}In]In-DOTA-TATE. Therefore, the combination of VPA and PRRT potentially improves treatment efficacy. This combinational treatment will be evaluated further. **References:** None.

[1]*Department of Pediatrics and Children's Cancer Research Center, Kinderklinik München Schwabing, Klinikum rechts der Isar, Fakultät für Medizin, Technische Universität München, Munich, GERMANY,* [2]*Department of Nuclear Medicine, Klinikum rechts der Isar, Technische Universität München, Munich, GERMANY,* [3]*Institute of Pathology, Klinikum rechts der Isar, Fakultät für Medizin, Technische Universität München, Munich, GERMANY,* [4]*CCC München - Comprehensive Cancer Center, Munich, GERMANY,* [5]*Department of Orthopedic Surgery, Klinikum rechts der Isar, Fakultät für Medizin, Technische Universität München, Munich, GERMANY,* [6]*Department of Diagnostic and Interventional Radiology, Klinikum rechts der Isar, Fakultät für Medizin,Technische Universität München, Munich, GERMANY,* [7]*DKTK German Cancer Consortium Munich, Munich, GERMANY.*

Aim/Introduction: The radiogenomics methodology, which combines imaging data with omics data like transciptomics, was already applied to diverse adult cancer types, revealing correlations of molecular characteristics of the tumors based on features extracted from images. To the best of our knowledge pediatric cancer has not been assessed by functional radiogenomics so far, although the prognostic value of glucose uptake in PET in sarcoma has already been proven[1]. **Materials and Methods:** In our project we conduct a large-scale analysis of gene expression in Ewing sarcoma tumor tissue with respect to image features from 18F-FDG PET-CT or PET-MRI. We compare tumors with low glucose uptake (low SUVmax) to tumors with high glucose uptake (high SUVmax) in 11 Ewing sarcoma patients using differential expression analysis and machine learning. **Results:** Eight genes were significantly upregulated in tumors with low SUV compared to tumors with high SUV in Ewing sarcoma: ABCA5, ARHGAP18, GSTM3, KL, NAF1, NPY5R, PLSCR4 and SFMBT1. Some of these are already known predictive markers for survival in other cancer types, but not in Ewing sarcoma so far. Noteworthy, NPY and its receptors NPY1R and NPY5R are known targets of the fusion transcript EWS-FLI1 that is characteristic of Ewing sarcoma. It was shown before that NPY signaling via receptors 1/5 promotes cell death, whereas under hypoxic conditions signaling switches from 1/5 to 2/5, which rather promotes malignancy[2]. In our 11 patients NPY, NPY1R and NPY5R are all upregulated in tumors with low glucose uptake. Therefore, the mechanism of NPY signaling promoting cell death seems to be more active in tumors with low glucose uptake. **Conclusion:** We characterize Ewing tumors with respect to their glucose uptake on gene expression level, thereby contributing to a better understanding of tumor biology with regard to differentiation, inflammation and metabolism. As several studies state an association between lower SUVs and improved survival, the eight genes found to be differentially expressed may be predictive for outcome in Ewing sarcoma and provide potential targets for treatment, especially in tumors with high SUV having poor prognosis. By additional integration of more image features from first and second order in the future we aim to examine in more detail which molecular characteristics of Ewing tumors can be inferred from the imaging data. Furthermore, we want to improve prediction of outcome by combination of expression data and imaging data using machine learning methods like random forest. **References:** [1] Raciborska, ClinTranslOncol, 2016. EP-0679

GRPR mRNA Expression Levels to Select Patients Suited for GRPR-mediated Radionuclide Imaging and/or Therapy

S. Dalm, K. Ruigrok-Ritstier, C. M. Beaufort, J. W. M. Martens, C. H. M. van Deurzen, M. de Jong, A. M. Sieuwerts;
Erasmus MC, Rotterdam, NETHERLANDS.

Aim/Introduction: The gastrin releasing peptide receptor (GRPR) is overexpressed on estrogen receptor positive (ER+) breast cancers (BCs), making it a biomarker predictive for peptide receptor radionuclide imaging and therapy using GRPR radioligands. BCs can be diagnosed and characterized (e.g. hormone receptor expression) using histopathology and immunochemistry, respectively, on excised tumor material. Ideally this tumor material can also be used to characterize GRPR-expression on the cancer cells, and thus determine whether patients are suited for GRPR-directed interventions. However, a number of previous studies by ourselves and others using GRPR antibodies failed to correctly determine GRPR-expression, and standard immunohistochemistry staining protocols in our hospital using different GRPR antibodies produced debatable results. Therefore the aim of this study was to determine whether we can use GRPR mRNA expression to identify BCs suitable for GRPR-mediated interventions. Since the GRPR is also expressed on healthy breast tissue we aimed to determine a cut-off value for GRPR positivity. **Materials and Methods:** Tumor material and corresponding healthy tissue of 13 ER+ BCs were analyzed for GRPR-expression by RT-qPCR and in vitro autoradiography. For RT-qPCR, RNA was isolated and GRPR mRNA expression was evaluated and quantified relative to the average expression of 3 reference genes using the deltaCq method. For comparison in vitro autoradiography was performed. Tissue slices were incubated with 10^{-9}M of the GRPR radioligand ^{111}In-JMV4168, after which the percentage added dose (%AD) of the radioactivity bound to the tissue was quantified.Hematoxylin and eosin staining was performed to localize tumor cells and to determine the percentage of tumor cells present. **Results:** Both analyses were successfully performed in 11/13 cases. The %AD was significantly correlated with GRPR mRNA expression (Spearman's R=0.57, p=0.018). A cut-off was determined at 0.1 for relative GRPR mRNA expression (sensitivity:75%, specificity:82%) to detect GRPR transcripts selectively in tumor tissue. Eight cases had low (<0.1) expression in healthy tissue and high (≥0.1) expression in corresponding cancer lesions, however in 2/8 differences were small. In 1 case we found an inverse result and in 2 cases both tumor and normal were below cut-off. GRPR positive samples determined by RT-qPCR had a significantly higher %AD (p=0.005) and a higher percentage of tumor cells (p=0.02). **Conclusion:** With the help of the cut-off value determined in our study GRPR mRNA expression can potentially be used to screen ER+ BCs for GRPR-mediated nuclear imaging and/or therapy. More studies will be performed now to further validate these findings. **References:** None.

Loss of PSMA during neuroendocrine differentiation of prostate cancer is associated with elevation of metabotropic glutamate receptors as an alternative diagnostic target

M. K. Bakht[1,2,3], *K. F. Stringer*[4,1], *J. M. Lovnicki*[5], *A. Pillon*[1], *F. Shahbazi-Raz*[6], *J. J. Hayward*[6], *S. Oh*[2,3], *J. F. Trant*[6], *G. Cheon*[2,3], *C. Kwak*[7], *C. Jeong*[7], *K. Kang*[2,3], *Y. Wang*[5], *X. Dong*[5], *L. A. Porter*[1];

Aim/Introduction: Prostate-specific membrane antigen (PSMA) protein is encoded by the FOLH1 gene and is highly expressed in most of the prostate adenocarcinomas (AdPC). PSMA cleaves vitamin B9 to stimulate PI3K-Akt signaling through metabotropic glutamate receptors (mGluR) [1]. Its expression mostly correlates inversely with survival. However, the poor prognostic neuroendocrine (NE) prostate cancer (NEPC) lesions have suppression of the PSMA gene [2]. Treatment-induced NEPC (t-NEPC) is an emerging drug-resistant phenotype, and its visualization is a high priority. The possible alternative imaging options for NEPC has not been fully explored. In this work, we demonstrate that in PSMA-suppressed NEPC have elevated levels of most of mGLuR genes family members. **Materials and Methods:** We evaluated the transcript abundance for PSMA and mGluR family members including GRM1to 8 genes as well as SRRM4 (t-NEPC marker) across 909 tumors. We employed patient-derived xenograft (PDX) models to study the alterations of GRM1-8 in during NE-transdifferentiation of PSMA-positive AdPC. We also investigated changes of GRM genes in well-established prostate cancer cell lines including NCI-H660 as an NEPC model and LNCaP, DU145 and PC3 as AdPC models. **Results:** A significant elevation of GRM genes in NEPC patient samples and AdPC samples with high expression of NE marker genes was observed. There is a significant direct correlation between GRM1-6 and SRRM4 gene expression. Kaplan-Meier survival analysis of GRM genes showed high expressions of GRM1,3-4,5, and 8 genes are associated with poor outcome (log-rank p<0.05). PSMA-negative NCI-H600 as a model of NEPC has significantly higher levels of GRM1-4, 7, and 8 while NE-negative cell lines showed minimal expression of GRM genes. The PDX model of NE-transdifferentiation demonstrated a significant gradual elevation of GRM2-4 and 6 during the suppression of the PSMA gene. **Conclusion:** This work represents the loss of PSMA as an imaging target in NEPC is associated with an elevation in the expression of mGLuR genes family members.

The observed elevation of mGluR gene expression in NEPC demonstrates the possible ability of mGluR targeted imaging for follow-up imaging of low-PSMA patients and monitoring for NEPC development. **References:** [1] Kaittanis, Charalambos, et al. EP-0681

Metabolic changes of melanoma assessed by [^{18}F]FDG and [^{18}F]FLT PET during immune checkpoint inhibitor treatment: potential role as a predictive imaging biomarker

S. Oh, H. Youn, J. Paeng, Y. Kim, K. Kang, G. Cheon, J. Chung; Seoul National University, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: Immune checkpoint inhibitors (ICI) are immunotherapy agents that induce active inflammation against cancer cells, with target proteins like programmed cell death ligand-1 (PD-L1). While [^{18}F]FDG is widely used for cancer imaging by visualizing glucose metabolism, [^{18}F]FDG uptake of tumor may be variable in ICI treatment because both tumor and immune cells affect [^{18}F]FDG uptake. The aim of this study was to assess change of tumor glucose and nucleic acid metabolism using [^{18}F]FDG and [^{18}F]FLT PET during ICI treatment, to develop a potential imaging biomarker for monitoring and predicting response of tumor to ICI therapy. **Materials and Methods:** B16F10 murine melanoma cells (1×10^6) were inoculated to C57BL/6 mice and anti-PD-L1 antibody (10 mg/kg) was daily injected i.p. starting from day 5 after inoculation when tumor diameter was 2-3 mm. [^{18}F]FDG and [^{18}F]FLT PET scans were performed at day 6 and 7 (early phase), and also at day 13 and 14 (late phase). Tumor uptake of [^{18}F]FDG and [^{18}F]FLT was measured as target-to-background ratio on each images and compared between treated tumors (n = 26) and control tumors (n = 20). Tumor size was followed up and tissue was obtained at day 14. **Results:** Tumor growth was suppressed in the treatment group and tumor size was significantly different between the two groups on day 14 (463.77 ± 300 vs 181.52 ± 128.05 mm^3, p = 0.0049). At early phase, [^{18}F]FDG uptake of the treatment group was higher than that of control group (p = 0.0089), whereas [^{18}F]FLT showed insignificant difference between the two groups. However, at late phase, [^{18}F]FDG uptake presented similar uptake in both groups, whereas [^{18}F]FLT uptake of control group was markedly increased to a higher level than that of treatment group (p < 0.0001). When FDG-FLT uptake ratio was calculated, it was higher in treatment group than control group at early phase (p = 0.0035) as well as late phase (p < 0.0001). **Conclusion:** In ICI-treated group, [^{18}F]FDG and [^{18}F]FLT uptakes are varied at different phases. However, the FDG-FLT ratio (glucose metabolism-to-tumor proliferation ratio) is constantly higher in ICI-treated group, probably due to active inflammation. The results suggest that combination of [^{18}F]FDG and [^{18}F]FLT PET images can be a more effective imaging biomarker than [^{18}F]FDG and [^{18}F]FLT PET alone, in predicting and monitoring response to ICI. **References:** None.

SPECT Imaging of Endogenous Tumor Hypoxia Marker Carbonic Anhydrase IX with^{111}In-labeled VHH B9

S. A. M. van Lith[1], F. J. Huizing[1], B. A. W. Hoeben[1], S. Doulkeridou[2], M. Gotthardt[1], P. M. P. van Bergen en Henegouwen[2], J. Bussink[1], S. Heskamp[1];
[1]Radboudumc, Nijmegen, NETHERLANDS, [2]Utrecht University, Utrecht, NETHERLANDS.

Aim/Introduction: Hypoxia is present in the majority of solid tumors and is associated with poor outcome and radioresistance. Carbonic anhydrase IX (CAIX) is a transmembrane enzyme that is upregulated by cells under hypoxic conditions. Therefore, non-invasive imaging of CAIX could be of prognostic value and it may allow radiotherapy planning and treatment effect monitoring. The aim of this study was to validate and optimize SPECT imaging of CAIX expression in a head-and-neck squamous cell carcinoma model using an anti-CAIX variable domain of heavy chain antibody (VHH). **Materials and Methods:** VHH B9 was conjugated site-specifically with maleimide-DTPA and labeled with ^{111}In. The binding affinity and internalization of [^{111}In]In-DTPA-B9 was analyzed using SKRC-52 cells, which ubiquitously express CAIX. Subsequently, a dose-escalation study was performed in athymic nude mice with subcutaneous SCCNij153 head-and-neck cancer xenografts. Targeting specificity was determined by blocking specific uptake with unlabeled VHH B9, and by analyzing tumor uptake of an ^{111}In-labeled irrelevant VHH R2. A subgroup of mice was co-injected with plasma expander gelofusin, to reduce renal retention of [^{111}In]In-DTPA-B9. Tracer uptake at 4 hours after injection was determined by ex vivo radioactivity counting and SPECT/CT scans. Furthermore, spatial correlation between tracer uptake on autoradiography images and immunohistochemical staining of CAIX expression was analyzed. **Results:** DTPA-B9 was radiolabeled with ^{111}In at a specific activity of 4 MBq/µg. [^{111}In]In-DTPA-B9 bound to SKRC-52 cells with high affinity (IC_{50} = 11.3 nm, K_D = 27.2 nM) and the internalization rate of the tracer was relatively low (K_e = 0.01). A protein dose of 5 µg resulted in the highest uptake in SCCNij153 tumors in vivo (1.05±0.14%ID/g), with tumor-to-blood and tumor-to-muscle ratios of 11.5 and 24.7, respectively. Unlabeled B9 reduced tumor uptake to 0.30±0.03%ID/g and irrelevant [^{111}In]In-DTPA-R2 showed tumor uptake of 0.20±0.14%ID/g. Gelofusin did not significantly alter kidney uptake of [^{111}In]In-DTPA-B9. Immunohistochemistry and autoradiography images showed co-localization of [^{111}In]In-DTPA-B9 and expression of CAIX. **Conclusion:** [^{111}In]In-DTPA-B9 VHH shows specific targeting of CAIX expression in head-and-neck cancer xenografts. In ongoing studies we will determine if a fusion protein of B9 with an albumin binding domain shows improved tumor uptake compared to B9 alone. Furthermore

we will compare B9 to other CAIX imaging tracers and we will determine its potential for treatment selection and monitoring of hypoxia responses to therapy. **References:** None.

Aim/Introduction: The present study aims to verify whether the link between [^{18}F]-2-deoxy-glucose (FDG) uptake and activity of the reticular enzyme hexose-6P-dehydrogenase (H6PD) contributes to preserve PET/CT diagnostic power in experimental models of streptozotocin-induced diabetes mellitus (STZ-DM). **Materials and Methods:** The study included 72 Balb/c mice subcutaneously implanted with colon (CT26, n=36) or breast (4T1, n=36) cancer cells. Each cohort was subdivided into two clusters ("control" and "STZ-DM") that were further subdivided into three groups treated with saline or metformin (MTF) at low or high doses (10 or 750 mg/Kg daily, respectively). Two weeks after cancer cells inoculation, all mice were submitted to micro-PET imaging. After sacrifice, enzymatic pathways and response to oxidative stress were evaluated in harvested tumors. Finally, competition by 2-deoxy-glucose (2DG) on cell uptake of FDG and the fluorescent analogue 2-[N-(7-nitrobenz-2-oxa-1,3-diazol-4-yl)amino]-2-deoxyglucose (2NBDG) was studied in cultured cells. **Results:** At microPET imaging, 4T1 and CT26 cancer volumes and average metabolic rate of glucose (MRGlu) were superimposable in "control" mice and showed a similar reduction under MTF treatments. In STZ-DM group, both cancer volumes and MRGlu were slightly, yet significantly, lower than control ones, while MTF capability to decelerate lesion growth and MRGlu was virtually abolished. This metabolic reprogramming was not explained by any change in expression or activity of hexokinases, phosphofructokinase or glucose-6-phosphate-dehydrogenase while it closely agreed with the response of H6PD catalytic function. Differently from glucose, coincubation with 2DG virtually abolished FDG uptake in cultured cells and their capability to concentrate 2NBDG within the endoplasmic reticulum. **Conclusion:** These data challenge the current dogma linking 2DG/FDG uptake to the glycolytic rate and introduce a new model to explain the relation between glucose analogues uptake and hexoses reticular metabolism. This selective fate of FDG contributes to the high sensitivity of PET imaging despite moderate hyperglycemia. **References:** None.

^{18}FDG-PET, MRI Relaxometry And Terahertz Reflectometry in a Multimodal Imaging Heart Study of a Cardiorenal Syndrome Small Animal Model

L. Agrigoroaie[1], *D. Furcea*[1], *C. Uritu*[2], *G. Stanciu*[2], *C. Mihai*[2], *I. Gardikiotis*[2], *R. Iliescu*[1], *C. Stefanescu*[1], *M. Gutu*[1];
[1]*University of Medicine and Pharmacy "Gr. T. Popa", Iasi, ROMANIA,* [2]*Advanced Center for Research and Development in Experimental Medicine CEMEX, Iasi, ROMANIA.*

Aim/Introduction: Cardiorenal syndrome is a intricate clinical condition, with reliable prognostic biomarkers still lacking. We present preliminary cardiac data of a cardiorenal syndrome rat model through 2-deoxy-2-[fluorine-18]fluoro-D-glucose (^{18}F-FDG) PET/MRI multimodal imaging, MRI relaxometry and terahertz (THz) spectrum reflectometry. **Materials and Methods:** We examined 24 male Wistar rats, partitioned into 3 lots: control (L1), heart failure (L2), cardiorenal group (L3). Heart failure was induced by intraperitoneal doxorubicin administration and renal failure by sub-total nephrectomy. ^{18}F-FDG PET/MRI scans were acquired at week 0 for L1, at week 6 for L2 and at week 18 for L3. Tracer kinetics were analysed by calculating standardized uptake values (SUV) and washout times at 50% (T50) and at 75% (T75) of peak SUV.The ex vivo formalin-fixed rat hearts were studied under a multi-flip spoiled GRE driven-equilibrium single pulse observation of T1 relaxation MRI sequence. For histological assessment, standard hematoxilyn-eosin staining of 5 µm tissue slices was used, scoring the progression of pathognomonic signs on a visual scale from 0 to 4 (0-no abnormality, 4-severe disease). Paraffin-embedded heart tissue samples were further examined through THz pulsed-wave reflectometry, with resulting attenuation in the 0.2-3.3 THz range. **Results:** Qualitative histological evaluation observed progression of heart disease from a score of 0 for L1 to a score of 2 for L2 (sparse areas of myocardial fibrosis, atherosclerosis, intracellular doxorubicin-induced vacuolisations) to a score of 4 in L3 group (extensive myocardial fibrosis, atherosclerosis, intra- and intercellular vacuolisations).In ^{18}F-FDG PET data, L1 and L2 displayed a statistically significant difference only in myocardial T75 (mean $T75_{L1}$=1.1 vs. $T75_{L2}$=1.9 min, $p<0.05$). In contrast, subjects from L3 vs. L1 exhibited prolonged myocardial washout times at T75 and at T50 (mean $T75_{L1}$=1.1 vs. $T75_{L3}$=40

min, p<0.001; mean $T50_{L1}$=3.5 vs. $T50_{L3}$=40 min, p<0.001); moreover, comparing L3 vs. L2 still yielded a significantly distinct temporal dynamics (mean $T75_{L2}$= 1.9 vs. $T75_{L3}$= 40 min, p<0.001; mean $T50_{L2}$=5.9 vs. $T50_{L3}$=40 min, p<0.05).T1 left ventricular muscle relaxation times were 374±23 ms for L1, 439±9 ms for L2 and 262±11 ms for L3 group, suggesting hypertrophic cardiomyopathy for L2 and dilatative cardiomyopathy for L3. Distinct patterns of the THz pulse attenuation were observed, differentiating the groups within the studied THz range. **Conclusion:** Our multimodal imaging investigations of a cardiorenal rat model were consistent in discriminating between study groups, confirming the hypothesis under study, and also suggests a potential for new diagnostic tools worth exploring. **References:** None.

[^{18}F]GE180-µPET Depicts Drug-induced Changes of Glial Activation by the TSPO-Agonist Etifoxine during Vestibular Compensation in the Rat

A. Krämer[1,2], *C. Branner*[1,2], *M. Lindner*[1,2], *M. Grosch*[1], *A. Gosewisch*[1,2], *R. Oos*[2], *P. Bartenstein*[2], *S. Ziegler*[2], *A. Zwergal*[1,3]; [1]*German Center for Vertigo and Balance disorders, DSGZ, University Hospital, LMU Munich, Munich, GERMANY,* [2]*Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY,* [3]*Department of Neurology, University Hospital, LMU Munich, Munich, GERMANY.*

Aim/Introduction: Initial symptoms after acute unilateral vestibular loss ameliorate over days to weeks due to central vestibular compensation (VC). Glial activation in the ipsilesional vestibular nerve and nucleus has been reported during VC, but its functional role for recovery remains unclear. The aim of the current study was to investigate, whether modulation of glial activation by the TSPO-agonist etifoxine (ETX) changes the course of behavioral recovery during VC in the rat model of unilateral labyrinthectomy (UL) and can be visualized by serial [^{18}F]GE180-µPET. **Materials and Methods:** 21 male SD rats underwent an irreversible chemical UL by transtympanic instillation of bupivacaine and p-arsanilic acid. 11 animals were treated with ETX (25 mg/kg body weight i.p. per day) for 7 days after UL, a control group (n=10) with saline injections. Behavioral symptoms of vestibular asymmetry were scored clinically (nystagmus, postural asymmetry) and by apparative testing in an open field (gait instability) on days 1,2,3,8,15,22,29 post UL. [^{18}F]GE180-µPET was recorded one week before and 1,8,15,22,29 days after surgery. The PET scans started 45 min after i.v. injection of 50 MBq [^{18}F]GE180 with a 15 min transmission, followed by a 30 min emission. Images were compared in a voxel-wise manner between time points and conditions using SPM8. **Results:** Nystagmus peaked on day 1 and ceased until day 8 post UL with no differences between groups. Postural asymmetry significantly ameliorated between days 5 and 15 in the ETX-group (p=0.008) and days 5 and 22 in the control group (p<0.001). Comparison of postural asymmetry scores between groups showed relatively lower values in the ETX-group on days 15 (p=0.032), 22 (p=0.002) and 29 (p=0.021). The ETX-treated group moved relatively more along the borders of the open field from day 8. In both groups, [^{18}F]GE180 uptake was increased from day 1 to 29 in the ipsilesional vestibular nucleus and bilateral hippocampus compared to baseline. ETX-treated rats showed a lower [^{18}F]GE180 uptake in the ipsilesional vestibular nucleus on days 8,15,22,29 and in the hippocampus after day 15 post UL compared to controls (p<0.005). **Conclusion:** Improvement of postural asymmetry by the TSPO agonist ETX is accompanied by a decreased glial activation in central vestibular networks during intermediate VC. This data suggest that the course of glial activation follows the recovery of vestibular function. [^{18}F]GE180-µPET is a feasible and sensitive method to depict and monitor drug-induced changes of glial reactions over time in vivo. **References:** None.

Cerebral Glucose Metabolism Differs According To Future Weight Change

K. Pak[1], *S. Kim*[2]; [1]*Pusan National University Hospital, Busan, KOREA, REPUBLIC OF,* [2]*Pusan National University Yangsan Hospital, Yangsan, KOREA, REPUBLIC OF.*

Aim/Introduction: The brain is known to play a central role in controlling the desire to eat. We aimed to evaluate the brain regions that might have a long-term effect on eating behavior and weight changes. Therefore, we utilized the data of cognitively normal subjects who are examined by several neurologic tests, and followed-up for 36 months from Alzheimer's Disease Neuroimaging Initiative (ADNI) database, and investigated to search the brain regions that are associated with future weight change. **Materials and Methods:** The weight of each subject was measured on each visit at baseline (W0), 36 (W36) months after brain ^{18}F-Fluorodeoxyglucose (FDG) positron emission tomography (PET). Percentage (%) change of weight was calculated as follows: [(W36-W0)/W0]*100. We classified each subject's change into one of three categories: weight loss, stable, and weight gain. Dynamic 3-dimensional scans of six 5-min frames were acquired 30 mins after injection of 185 MBq of FDG. Image analysis was done using Statistical Parametric Mapping 12 **Results:** Ninety-six subjects were included in this study (male 54, female 42). Subjects with future weight gain showed hypometabolism in left cerebellum compared with

those with future weight loss & stable. Percentage change of weight was positively associated with brain metabolism in right insula, and right caudate nucleus **Conclusion:** Subjects with future weight gain showed hypometabolism in left cerebellum, and the more cerebral Glucose Metabolism of right insula and right caudate nucleus the subjects have, the more weight will be gained in the future. This study raises the possibility that the brain glucose metabolism precedes the future weight change **References:** None.

A simultaneous FDG-PET/fMRI does not reveal neural plasticity following a working memory training

I. Ripp[1], *M. Emch*[2], *Q. Wu*[3], *J. Cabello*[1], *K. Koch*[2], *I. Yakushev*[1];
[1]*Department of Nuclear Medicine, Klinikum Rechts der Isar, Technical University Munich, Munich, GERMANY,* [2]*Department of Neuroradiology, Klinikum rechts der Isar, Technical University Munich, Munich, GERMANY,* [3]*Department of Neuroradiology, Klinikum rechts der Isar, Technical University Munich, Munich, Munich, GERMANY.*

Aim/Introduction: The concept of working memory (WM) training yielding improvements in even untrained cognitive domains is widely debated in the literature. These training effects have been ascribed a potential role delaying age- and disease-related cognitive decline. The relationship between these so called transfer effects and changes on the network level remain unclear. We studied the effects of an extensive 8 weeks long online supervised visual and verbal n-back WM training at the behavioral and neuroimaging level in 61 middle-aged healthy participants. **Materials and Methods:** To understand potential training induced neural plasticity, we acquired simultaneous 18F-fluorodeoxyglucose (FDG) PET and MRI data studying potential changes in metabolic and functional characteristics at a network and a single voxel level. Using a purely data driven approach, an independent component analysis (ICA), we extracted a number of neurocognitive networks (NCNs), as well as sensory networks as reference. Altered connectivity of NCN such as the default mode network (DMN) and central executive network (CEN), was hypothesized. Network integrity measurements were compared for each network of interest between pre- and post-training. At a single voxel level FDG-uptake was compared between pre- and post-training. **Results:** Based on both fMRI and FDG-PET imaging modality the anterior and posterior DMN, CEN and salience network were extracted. No difference in network integrity measures was found. Mass univariate analysis at the voxel level did not reveal significant training induced changes in FDG uptake. The evaluation of nine different neurospychological tests aqcuired before and after the training period revealed a significant practice effect, but no transfer effects, i.e. an improvement in tasks other than the trained tasks. **Conclusion:** In summary, our multimodal neuroimaging approach did not reveal WM induced changes. In accordance, our behavioural results reveal no transfer effects following a training suggesting to revise the concept of WM training. **References:** None.

Aim/Introduction: Repetitive transcranial magnetic stimulation (rTMS) is thought to exert its anti-depressant action through the serotonergic and dopaminergic system. Nonetheless, only the immediate effects on these systems have been thoroughly studied. Therefore, this study aimed to evaluate the effects - immediate and long-lasting - of an acute and chronic accelerated high frequency repetitive rTMS (aHF-rTMS) on serotonin transporter (SERT), dopamine and its metabolites in the cerebrospinal fluid (CSF) and serum of healthy beagle dogs. **Materials and Methods:** 22 dogs were randomly divided into 3 unequal groups: 5 active sessions (n=10), 20 active sessions (n=8), and 20 sham sessions (n=4). Each dog received an anatomical MRI, neuronavigation and a baseline [^{11}C]DASB PET scan, followed by an aHF-rTMS treatment over the left frontal cortex. 24 hours, 1 month and 3 months after the last stimulation session [^{11}C]DASB PET scans were acquired. After each scan, a CSF and serum tap was performed. The SERT binding index (BI) of 23 brain regions was calculated. The concentrations of dopamine (DA), homovanillic acid (HVA), 3,4-dihydroxyphenylacetic acid (DOPAC) in the CSF and serum were analysed on a reversed phase liquid chromatography system with electrochemical detection. Linear mixed models were used to analyse the data. **Results:** An acute (24 hours post) increase in SERT BI in the region containing the raphe nuclei (P-value = 0.04) was seen within the 20 active sessions group. In addition, the BI decreased in the subgenual cortex (P-value = 0.002), pre-subgenual cortex (P-value = 0.02) and left thalamic area (P-value = 0.04) one month after stimulation. Immediate (24 hours post) differences in SERT BI, were noticed between both active protocols in the left thalamic area (P-value = 0.04) and the pre-subgenual cortex (P-value = 0.01). Within the 5 active sessions group HVA was increased 24 hours (P-value = 0.02), 1 month (P-value = 0.04) and 3 months (P-value < 0.001) after the stimulation. A decrease in HVA was seen for the 20

sessions active group 1 month (P-value = 0.01) and 3 months (P-value = 0.04) after the stimulation. **Conclusion:** Both active protocols were able to modify the SERT BI, central DOPAC and HVA concentrations. Administering more sessions of an aHF-rTMS protocol induces changes in SERT BI in different brain regions other than when applying fewer sessions. The results imply that a single and four-day active HF-rTMS over the left frontal cortex provoke contrasting effects on the dopaminergic system. **References:** None.

Effects of Chronic Alcohol Self-Administration on Striatal Phosphodiesterase 10A Availability Are Associated with Poor Decision-Making

J. Ceccarini[1], *Y. E. Klingl*[2], *B. de Laat*[1], *G. Schroyen*[3], *M. Ooms*[4], *G. Bormans*[4], *K. Van Laere*[1];
[1]*Nuclear Medicine and Molecular Imaging, University Hospitals Leuven; Department of Imaging and Pathology, KU Leuven, Leuven, BELGIUM,* [2]*Department of Neurosciences, KU Leuven, Experimental Neurology and Leuven Brain Institute (LBI); Center for Brain & Disease Research, Laboratory of Neurobiology, VIB-KU Leuven, Leuven, BELGIUM,* [3]*Department of Imaging and Pathology, KU Leuven, Belgium, Leuven, BELGIUM,* [4]*Radiopharmaceutical Research Laboratory, KU Leuven, Leuven, BELGIUM.*

Aim/Introduction: Phosphodiesterase 10A (PDE10A) is a dual substrate enzyme highly enriched in dopaminoreceptive striatal medium spiny neurons, which are involved in psychiatric disorders such as addiction. Preclinical studies suggest a correlation of PDE10A in neuronal and behavioral responses to alcohol intake and preference[1,2]. However, little is known about the effects of alcohol exposure on PDE10A activity. We performed a longitudinal microPET [^{18}F]JNJ42259152 study to evaluate changes on PDE10A availability in rats subjected to different stages of alcoholization, in combination with behavioural assessments. **Materials and Methods:** Nine adult Wistar rats were monitored over a 10-week alcohol abuse reinstatement model[3], including 6 weeks of alcohol exposure, 2 weeks of withdrawal, followed by 1 week of relapse. Animals who reported an alcohol preference ≥30% during the first exposure phase were defined as alcohol-preferring rats. Decision-making and anxious behaviour were assessed with the rat Iowa Gambling Task and open field test over the 10-weeks´ time. Dynamic 60-min PDE10A [^{18}F]JNJ42259152 microPET scans were performed at alcohol exposure week 2, 4 and after relapse. In order to evaluate the effects of 6 weeks of alcohol exposure, a sham control group of 9 rats was added to the experiment. Parametric PDE10A BP_{ND} images were generated using a Logan reference tissue model with cerebellum as reference region[4], and were analyzed using VOI- and voxel-based approach. **Results:** Alcohol preference increased over time especially during week 3 and 6 of alcohol exposure, and during relapse (32±14%, 22±7%, 33±19%). Animals that showed poor decision making and higher anxiety levels displayed a greater alcohol preference. The first weeks of alcohol exposure resulted in an increased striatal PDE10A binding (12±16%), compared to controls. Comparing PDE10A BP_{ND} after 4- versus 2-weeks of exposure, showed a decreased PDE10A in the caudate-putamen and NuAc ($P_{FWE\text{-}corrected}$:0.02-0.003). This striatal PDE10A decrease was mostly present in alcohol-preferring rats (alcohol preference:30-70%), and was associated with impaired decision-making over the last exposure phase and abstinence (r_s>0.7). A similar regional decrease in PDE10A availability towards normalization was observed after one week of relapse ($P_{FWE\text{-}corrected}$:0.002-0.008). **Conclusion:** Chronic alcohol self-administration induces a reversible increased PDE10A enzymatic availability in the striatum that is related to higher alcohol preference and poor decision-making. These data implicate that PDE10A mediated signaling plays an important role in modulating the reinforcing effects of alcohol, suggesting that PDE10A inhibition may have beneficial behavioural effects on alcohol intake. **References:** 1.Logrip ML,Alcohol.2015;49:795-802. 2.Logrip ML.Front Integr Neurosci.2014;8:8-30. 3.Simms JA.Alcohol Clin Exp Res.2008;32:1816-1823. 4.Celen S.Neuroimage.2013;82:13-22.

F-18 labeled FAPI-74 in patients with lung cancer: biodistribution at 3 imaging time points

F. L. Giesel[1], *T. Lindner*[1], *S. Adeberg*[2], *F. Staudinger*[1], *P. Flechsig*[1], *H. Rathke*[1], *M. Röhrich*[1], *J. Debus*[2], *U. Haberkorn*[1], *C. Kratochwil*[1];
[1]*Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY,* [2]*RadioOncology, University Hospital Heidelberg, Heidelberg, GERMANY.*

Aim/Introduction: Recently, ^{68}Ga-labeled FAPI-04 was reported a promising tracer for imaging several tumor-entities (Ref-1). To overcome supply limitations of short-half-life (1h) generator nuclide ^{68}Ga with longer half-life (2h) cyclotron produced ^{18}F, the preclinically favorable ligand FAPI-74 was utilized as [^{18}F]AlF (Aluminium-Fluorid) complex. This retrospective analysis investigates the biodistribution and tumor-uptake of patients examined with clinical indication at different imaging time-points. **Materials and Methods:** FAPI-74 was successfully used for imaging of 5 patients (median age 52) with lung cancer undergoing to delineate target volume for planned external-beam radiotherapy. For all patients emission scans at 10 min, 1h and 3h after injection of mean 220 MBq ^{18}F-FAPI-74 were acquired. Normal organ distribution and tumor uptake (primary tumor, LN and distance Metastases, respectively) were evaluated

per SUV at each time-point. **Results:** In primary cancer average SUVmax was 12.5 at 10 min; 13.5 at 1h and 11.4 at 3h; in lymph node metastases it was 9.8, 12.1, and 11.4; in distant metastases 10.3, 10.9 and 11.8. So, for most lesions the uptake peaked later than 10 min. p.i. but there was already some wash-out between 1h and 3h p.i.. Biodistribution, pharmacokinetics and tumor-to-background ratios are comparable to the previous ^{68}Ga-labeled compound. **Conclusion:** The [^{18}F]AlF-labeled ligand FAPI-74 presented comparable tracer-characteristics to the recent published ^{68}Ga-FAPI-04. **References:** Giesel FL, Kratochwil C, Lindner T, Marschalek MM, Loktev A, Lehnert W, Debus J, Jäger D, Flechsig P, Altmann A, Mier W, Haberkorn U. ^{68}Ga-FAPI PET/CT: Biodistribution and Preliminary Dosimetry Estimate of 2 DOTA-Containing FAP-Targeting Agents in Patients with Various Cancers.J Nucl Med. 2019 Mar;60(3):386-392. doi: 10.2967/jnumed.118.215913. In-111 Labeled Cd166-targeted Peptide For Detecting Colorectal Cancer Stem-like Tumor In Vivo

S. Guan, T. Luo, C. Peng, T. Liao;
Institute of Nuclear Energy Research, Longtan District, Taoyuan, TAIWAN.

Aim/Introduction: Cancer stem cells (CSCs) involved in drug resistance, metastasis and relapse of cancers, which can significantly affect tumor therapy. Therefore, it is important to develop specific therapies targeted probe at CSCs for improvement of survival and quality of life of cancer patients. Studies have indicated that the CD166 protein has been considered as a specific marker for colorectal CSCs (CCSCs) detection. In this study, we attend to use polyethylene glycol (PEG) linked CD166-targeted peptides (CD166P-PEG) as a nuclear imaging agent probe for CD166 detection in CCSC xenograft animal model. **Materials and Methods:** The CD166+ HCT15 cells were obtained by Magnetic-activated cell sorting. The CD166 and stem cell markers expression were detected by using western blot. Tumor sphere assay was performed for stem cell characteristics assay. The CD166 anti-peptide (CD166ap) was discovered by using Phage display peptide library kit, Ph.D.™-12. The CD166ap was conjugated with PEG and DTPA (DTPA-PEG-CD166ap) for detecting the cell binding ability. The DTPA-PEG-CD166 and DTPA-PEG were labeled with In-111 (^{111}In-DTPA-PEG-CD166, ^{111}In-DTPA-PEG) for tumor detection in animal model. **Results:** In this study, CD166+ cells were successfully isolated from the HCT-15 CRC cell line using magnetic activated cell sorting (MACS) and presented CSC characteristics. Subsequently, we designed the CD166P-PEG which was comparable to CD166 antibody as a CCSC probe during cell binding assay and confirmed the CD166+ targeting ability. Finally, we further observed that the DTPA conjugated CD166P-PEG with indium-111 labeling (^{111}In-DTPA-PEG-CD166P) was significantly enhanced in tumors tissue site of CD166+ HCT-15 xenograft mice as compared with non-CD166P-PEG control. **Conclusion:** The radioisotope-labeled CD166-PEG may be useful to apply in CRC patients for CD166 nuclear medicine imaging. **References:** None.

Clinical translation of the PepProtect concept: Improved detection of cancer and metastases, applied in medullary thyroid cancer patients with [^{111}In]In-MG11 scanning during neprilysin inhibition

R. Valkema[1], *A. C. Froberg*[1], *T. Maina*[2], *B. A. Nock*[2], *E. de Blois*[1], *M. Melis*[1], *M. W. Konijnenberg*[1], *S. L. W. Koolen*[1], *R. P. Peeters*[1], *W. W. de Herder*[1], *M. de Jong*[1];
[1]*Erasmus Medical Center, Rotterdam, NETHERLANDS,* [2]*Molecular Radiopharmacy, INTRASTES, NCSR "Demokritos", Athens, GREECE.*

Aim/Introduction: Many tumour-targeted radioabelled peptides are (partially) instable in vivo, due to enzymatic degradation. It is known from preclinical studies that neprilysin (neutral endopeptidase, NEP) is a key enzyme in this process. In situ NEP inhibition by administration of a suitable inhibitor can stabilize circulating biodegradable radiopeptides, resulting in clearly enhanced tumour targeting [1]. The present ongoing first-in-human study investigates the effects of the oral NEP-inhibitor racecadotril (RAC) on the in-vivo stability of the CCK_2-receptor (CCK_2R) specific radiopeptide (([^{111}In]In-DOTA)D-Glu^{10})-gastrin(10-17), or [^{111}In]InMG11, and on the tumour uptake in patients with medullary thyroid carcinoma (MTC). [^{111}In]InMG11 has high affinity for CCK_2R-positive tumours, but it is instable in-vivo. RAC is a commercially available and safe NEP-inhibitor, registered as an anti-diarrhoea drug for adults and children. **Materials and Methods:** Until now, first 2 out of 12 planned MTC patients completed all 3 assessments: Base-1: RAC (only toxicity); Base-2: InMG11 scintigraphy and quantitative SPECT-CT (toxicity, [^{111}In]InMG11 stability, tumour uptake); Combination: RAC + [^{111}In]InMG11 scintigraphy and quantitative SPECT-CT (toxicity, stability, tumour uptake). A single dose of 400mg RAC was given orally 90 min before i.v. injection of [^{111}In]InMG11 (185 MBq/10 nmol peptide). **Results:** Patient 1 (female, 57y), 15 yr after neck surgery, serum calcitonin (Ct) 300 ng/L without known lesions: at Base-2, intact serum [^{111}In]InMG11 was 6% at 10 min after i.v. infusion, 1 neck lymph node (LN) was faintly visible on the planar 24h scan, with SUVmax 0.13 on quantitative SPECT-CT. Given in Combination, with RAC, intact serum [^{111}In]InMG11 impressively increased to 54% and the LN was clearly visible (SUVmax 0.40). Additional suspicious lesions were noted. Patient 2 (male, 48y), after recent irradical surgery for T4aN1bMx MTC, serum Ct 1188 ng/L: at Base-2, intact [^{111}In]InMG11 was 8%, with visible (index) tumour remnant (SUVmax 0.28); additional LNs and suspicious metastases were faintly seen. At Combination, intact [^{111}In]InMG11 was 73%, with much better visible tumour (SUVmax 1.29) and clearly visible LNs and metastases . Both patients had no grade-2/3/4 toxicity during the studies. **Conclusion:** We present first clinical proof of concept of the PepProtect concept in MTC patients in this preliminary study. Oral RAC effectively protected [^{111}In]InMG11 against enzymatic degradation, resulting in an impressive 3-4x

higher uptake in human MTC lesions. **References:** [1] J Nucl Med;55:121-7;2014.

EP-0693

[^{68}Ga]Ga-NODAGA-Il2 for imaging activated T-cells

I. Antunes[1], *E. L. van der Veen*[2], *F. V. Suurs*[2], *R. A. J. O. Dierckx*[1], *M. N. Lub-de Hooge*[3], *E. G. E. de Vries*[2], *E. F. J. de Vries*[1];
[1]*University of Groningen, University of Medical Center of Groningen, Dept. of Nuclear Medicine and Molecular Imaging, Groningen, NETHERLANDS,* [2]*University of Groningen, University of Medical Center of Groningen, Dept. of Medical Oncology, Groningen, NETHERLANDS,* [3]*University of Groningen, University of Medical Center of Groningen, Dept. of Hospital and Clinical Pharmacy, Groningen, NETHERLANDS.*

Aim/Introduction: Interleukin-2 (IL2) is a 15.5 kDa glycoprotein that binds with high affinity to IL2 receptors (IL2R) that are overexpressed on activated T-cells, which can play a major role in the tumor immune response. We have developed N-(4-[^{18}F]fluorobenzoyl)interlekin-2 ([^{18}F]FB-IL2) which has been successfully used for detecting activated T-cells in rodents[1] and currently in human studies. We now developed a simplified method to label IL2 with ^{68}Ga to allow usage in centers lacking a cyclotron. Here we present the synthesis of [^{68}Ga]Ga-NODAGA-IL2 and its in vitro and in vivo evaluation. **Materials and Methods:** NODAGA-NHS was conjugated with IL2 at pH 8.5 for 2 h at room temperature. The conjugate was purified and kept at -80^{0}C until the radiolabelling day. For the radiolabelling method, different parameters were tested in order to get the optimal synthesis method. The stability was tested (TCA precipitation) in human plasma. To evaluate the in vivo properties of the new PET tracer, an ex-vivo biodistribution of [^{68}Ga]Ga-NODAGA-IL2 (0.55±0.13 MBq) was performed in immunocompetent BALB/c mice (n=6). In addition, to evaluate its selectivity towards activated T-cells, a 60 min dynamic PET scan of [^{68}Ga]Ga-NODAGA-IL2 (0.44±0.18) followed by ex-vivo biodistribution was performed in severe combined immunodeficiency (SCID) mice inoculated with activated peripheral blood mononuclear cells (PBMCs). **Results:** When using small volumes of ^{68}Ga (20-50MBq-100 uL) in the presence of NaOAc (pH4.5) or HEPES (pH4.5), the [^{68}Ga]Ga-NODAGA-IL2 was obtained with 90% yield and radiochemical purity (>95%) within 30 min. However, with larger volumes of ^{68}Ga (600-300 MBq-1 mL) the yield of [^{68}Ga]Ga-NODAGA-IL2 was ≤ 10%. Nevertheless [^{68}Ga]Ga-NODAGA-IL2 could be obtained with high radiochemical purity (>95%) within 60 min. [^{68}Ga]Ga-NODAGA-IL2 showed high stability in human plasma with >90% of the tracer remaining intact after 60 min. Biodistribution of [^{68}Ga]Ga-NODAGA-IL2 in BALB/c mice showed high uptake in kidneys (162.8±18.9 %ID/g-60 min), spleen (19.8±3.5 %ID/g-60 min), liver (22.9±4.3%ID/g-60 min) and bone marrow (9.3±2.7 %ID/g-60 min). As for the PET study in SCID mice inoculated with activated PBMCs, the images clearly showed binding of the tracer to activated PBMCs. The [^{68}Ga]Ga-NODAGA-IL2 uptake was found to be higher in activated PBMCs (1.1±0.5 %ID/g) when compared with the uptake in the Matrigel itself (0.5±0.2 %ID/g). **Conclusion:** The new [^{68}Ga]Ga-NODAGA-IL2 showed increased binding towards activated T-cells, indicating that this tracer might be used to image activated T-cells in centres lacking a cyclotron. **References:** [1] Di Gialleonardo et al., J Nucl Med, **2012**, 53:679-86.

EP-0694

Imaging benign and malignant intracranial tumors with ^{18}F-fluoroglutamine PET

X. Xu[1], *H. Zhu*[1], *L. Zhu*[2], *H. Kung*[3], *Z. Yang*[1];
[1]*Beijing Cancer Hospital, Beijing, CHINA,* [2]*Beijing Normal University, Beijing, CHINA,* [3]*University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA.*

Aim/Introduction: To prospectively determine whether differences between benign and malignant intracranial tumors can be depicted with ^{18}F-(2S,4R) 4-fluoroglutamine (^{18}F-FGln) PET and compared with enhanced MRI. **Materials and Methods:** 33 patients (16 women, 17 men; age range, 26-79 years) with solitary intracranial tumors underwent dynamic or static whole-brain ^{18}F-FGln PET/CT after giving informed consent in this institutional review board-approved. Histopathologic diagnoses were made in all cases (15 high-grade gliomas, 9 metastases to the brain, 3 primary brain lymphoma and 6 benign lesions). In 6 benign lesions, 1 was cerebral infarction, 2 was chromophobe cell pituitary adenomas and last 3 were meningiomas. The maximum standardized uptake value (SUVmax) for lesion and peritumoral regions was measured on PET images was calculated. Differences were assessed with one-way analysis of variance, Fisher exact, and Student t tests. **Results:** Differences in SUVmax between high-grade gliomas (5.18±1.14), metastases (3.11±1.68), and primary brain lymphomas (7.01±1.39) were significant ($P < 0.05$). These differences were also significant at pairwise analysis. The time activity curve (TAC) of dynamic ^{18}F-FGln PET/CT in the three groups of malignant tumors show that lymphomas with a rapid increase in the early phase (0~5min. pi), and a consistent in the middle (5~15min.pi) and late phase (15~30min.pi); the high-grade gliomas with a low level in the initial phase, a slow increase in the middle and late phase; the metastases with a slow increase in the first and middle phase, and a consistent in late phase. In six benign lesions, there was high radioactive uptake in 3 meningiomas (SUVmax=5.32±1.34), moderate uptake in 2 pituitary adenoma (the SUVmax were 3.68±1.20) and mild radioactive uptake in the lesion edge of cerebral infarction (SUVmax=2.17). **Conclusion:** High-grade gliomas, metastases, and lymphomas may be distinguished on the basis of measured ^{18}F-FGln uptake and TAC. Higher uptake of ^{18}F-FGln is a significant feature of primary brain lymphomas. The uptake of ^{18}F-FGln in some benign tumors, such as the pituitary adenoma, and meningiomas requires special attention and further study. **References:** None.

EP-0695

Radiolabeling and biodistribution in the tumor xenograft

of ^{211}At-labeled anti-CXCR4 antibody for cancer stem cell targeted alpha-particle therapy

N. Oriuchi[1,2], S. Zhao[1], M. Aoki[1], C. Tan[1], S. Sugawara[1], K. Nishijima[1], S. Shimoyama[1], K. Washiyama[1], K. Takahashi[1], T. Ikezoe[3], H. Ito[1,4]; [1]Advanced Clinical Research Center, Fukushima Medical University, Fukushima, JAPAN, [2]Department of Nuclear Medicine, Fukushima Medical University, Fukushima, JAPAN, [3]Department of Hematology, Fukushima Medical University, Fukushima, JAPAN, [4]Department of Radiology, Fukushima Medical University, Fukushima, JAPAN.

Aim/Introduction: C-X-C chemokine receptor type 4 (CXCR4) is known to express in the various cancer stem cells. Aim of the study was to test the biokinetics of ^{211}At-labeled anti-CXCR4 antibody (^{211}At-CXCR4) in the tumor xenograft to see the possibility of cancer stem cell targeted radioimmunotherapy. **Materials and Methods:** Human acute leukemia cell line (U937) was maintained for in vivo examination. ^{211}At was produced via ^{209}Bi(α, 2n)^{211}At nuclear reaction using cyclotron MP-30 in our facility. Anti-CXCR4 monoclinal antibody was labeled with ^{125}I and ^{211}At. Radiochemical yield was evaluated by SE-HPLC and then purified with PD-10 column to secure radiochemical purity.Suspension of 1 x 10^7 cells in 100 µL PBS (-) were injected subcutaneously in the dorsal flank of the athymic Balb/c nude mice to prepare for in vivo biodistribution study. The animal studies were approved by the Local Animal Care Committee and were performed in accordance with our institutional guidelines. When the tumors were ~8-15 mm in diameter, ^{125}I, or ^{211}At-CXCR4 were injected intravenously into the animals. At 1 min, 1 hr, 6 hr, 24 hr, and 48 hr after injection, mice were euthanatized, and aliquots of blood were collected. Organs of interest were excised and weighed, and the radioactivity counts was measured to expressed as % injected dose/gram (%ID/g). **Results:** Blood clearance of ^{211}At-CXCR4 was slow; 66.9%ID/g at 1 min, 38.3%ID/g at 6 hr, and 20.4%ID/g at 24 hr in the serum, Biodistribution of ^{211}At-CXCR4 as well as tumor uptake was similar to that of ^{125}I-CXCR4. Radioactivity in the thyroid gland was slightly increased up to 24 hr. **Conclusion:** Although blood clearance of ^{211}At-CXCR4 was slow due to IgG nature compared with the physical half-life of ^{211}At, and the affinity of the antibody to tumors used in the present study was low, ^{211}At-labeled anti-CXCR4 antibody was stably radiolabeled and biodistribution including tumor uptake was similar to ^{125}I-labeled antibody, suggesting possibility of radioimmunotherapy targeting cancer stem cells. **References:** None.

EP-0696

Translational proof-of-concept with 68Ga-NeoBOMB1 in the Management of Gastrointestinal Stromal Tumor Liver Metastasis Treated with Interventional Radiology Methods

R. De Juan Rubio[1], M. Pretze[2], L. Reffert[2], F. Orlandi[3], J. Schmaljohann[1], S. Diehl[2], K. Büsing[2], N. Rathmann[2], S. Schönberg[2], C. Decristoforo[4], P. Hohenberger[2], B. Wängler[2]; [1]Universitätsklinikum, Mannheim, GERMANY, [2]Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY, [3]Advanced Accelerator Applications, Colleretto Giacosa, ITALY, [4]Medical University, Innsbruck, AUSTRIA.

Aim/Introduction: Ga^{68}-NeoBOMB1 is a novel DOTA-coupled gastrin-releasing peptide receptor (GRPR) high affinity antagonist with excellent in vivo stability. Our study aim was the translation of preclinical results and experience with the preparation of Ga68-NeoBOMB1 using a GMP kit approach and a licensed 68Ge / 68 Ga generator. Furthermore, we explored the application of ^{68}Ga-NeoBOMB1 in patients with gastrointestinal stromal tumors (GIST) before and/or after interventional treatment methods (selective internal radiotherapy (SIRT), electroporation, microwave) of liver metastases. **Materials and Methods:** Contrast-enhanced PET/CT studies were performed on a 40-slice PET/CT scanner with 80 ml arterial i.v. contrast. Images were obtained 45 minutes (early) and 120 minutes (delayed) following a ^{68}Ga-NeoBOMB1 injection of 1,5-2 MBq/kg (135-229 MBq) into the antecubital vein. We examined three patients (2f, 1 m; 51-77) with liver metastases prior to SIRT therapy. Image acquisition, attenuation correction, fusion, reconstruction and post-processing were performed on a dedicated workstation. SUVmax was determined both on the early and delayed imaging. Patients were followed clinically and with MR quarterly. **Results:** A validation of the production (radiosynthesis) and quality control were performed before starting the GMP production of ^{68}Ga-NeoBOMB1 for patient use. Six independent batches of ^{68}Ga-NeoBOMB1 were produced, all held the quality criteria with a radiochemical yield of >95% and radiochemical purity >95%. Patient one (f,77) (liver, peritoneum) had an isolated lesion in S8 (SUVmax early 11,2 delayed 16,6) and underwent electroporation with confirmed complete response after 11 month follow-up. Patient two (m, 57) (multiple liver) had a PET/CT before and after SIRT therapy , which showed response in S8 lesion (SUVmax 1,4 late 3,3) and persistence in S 2/3 (SUVmax 6,3 late 16,1). The patient underwent electroporation on the left lobe, and developed progressive disease at 3-month follow-up. Thus, PET-CT distinguished recurrence from response. Patient three (f, 51) (multiple liver) had SIRT and microwave therapy was followed by PET/CT 3 months with no residual uptake, however progressive disease was demonstrated at 3 months MR follow-up. **Conclusion:** We successfully introduced ^{68}Ga-NeoBOMB1 in our clinical environment and are now capable of routine production under GMP conditions for routine patient care of patients with GIST metastatic liver disease. The lesion-to-background contrast allowed staging and restaging of metastatic liver disease. PET/CT with ^{68}Ga-NeoBOMB1 seems to be useful in pre- and post-therapy assessment in GIST liver metastases which were treated by interventional treatment methods. **References:** None.

EP-0697

Comparison of ^{18}F-(2S, 4R) 4-fluoroglutamine imaging between healthy and tumor subjects

X. Xu[1], H. Zhu[1], L. Zhu[2], N. Li[1], H. Kung[3], Z. Yang[1]; [1]Beijing Cancer Hospital, Beijing, CHINA, [2]Beijing Normal

University, Beijing, CHINA, [3]University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA.

Aim/Introduction: The purpose of this study was to compare dynamic PET/CT imaging of ^{18}F-FGln between healthy and oncological subjects and explore the optimal imaging time in different cancer types. **Materials and Methods:** 13 healthy volunteers and 27 oncological patients underwent ^{18}F-FGln and ^{18}F-FDG PET/CT scans separately within one week. Distribution of ^{18}F-FGln in major organs of healthy and oncological subjects were analyzed and compared with those of ^{18}F-FDG. In addition, tumor ^{18}F-FGln avidity versus ^{18}F-FDG avidity in patients with paired PET scans (n=27) was evaluated. The SUVmax and SUR of tumors with ^{18}F-FGln were compared between two scan phases (early(10min), late(60min)) **Results:** ^{18}F-FGln activity (SUVmean) of most normal organs in cancer patients were lower than that of healthy subjects, especially in lung, muscle, spleen and heart ($p<0.05$). Additionally, FGln-avid tumors weren't uniformly with FDG-avid and vice versa. Overall, 24 of 27 pathological primary lesions suggestive of malignancy on both (early and late) ^{18}F-FGln PET/CT images, however, there was a significant decrease in SUVmax on late images in most cancer ($p=0.005$) while the SUR of lung cancers ($p=0.021$) and thyroid cancers ($p=0.386$) showed increase from the early to the late acquisition, but decrease was seen in breast lesions ($p=0.022$). **Conclusion:** Images provided by ^{18}F-FGln may further supplement the diagnosis of ^{18}F-FDG in cancer patients and detect the metabolic changes in different tumors. Furthermore, imaging time for ^{18}F-FGln PET/CT in different cancer types may need to be optimized to improve contrast resolution for visualization and quantification of tumors. **References:** Dunphy MPS, Harding JJ, Venneti S, Zhang H, Burnazi EM, Bromberg J, et al. EP-0698

PSMA expression a promising biomarker to predictdifferentiated thyroid cancer aggressiveness and outcome

M. Sollini[1], *L. Di Tommaso*[1], *M. Kirienko*[1], *C. Piombo*[2], *M. Erreni*[2], *A. G. Lania*[1], *L. Antunovic*[2], *A. Chiti*[1];
[1]*Humanitas University, Pieve Emanuele, ITALY,* [2]*Humanitas Clinical and Research Center, Rozzano, ITALY.*

Aim/Introduction: Prostate specific membrane antigen (PSMA), a type II integral membrane protein, is overexpressed in prostate cancer and on the endothelial cells of tumor neovessels of several solid malignancies, including differentiated thyroid cancer (DTC)[1].We aimed to test the potential role of PSMA as biomarker for DTC aggressiveness and outcome prediction, in terms of earlier recurrence/progression, iodine refractoriness, and presence of disease at last follow-up. **Materials and Methods:** We retrospectively screened all patients who underwent thyroidectomy between 01/01/2010 and 31/12/2017 in our institution. Applying the inclusion (a-histologically proved thyroid cancer, b- tissue availability) and exclusion criteria (a- no clinical or follow-up data, b- medullary thyroid cancer) a cohort of 59 patients (mean age 53.12±16.76 years) was selected. The monoclonal mouse anti-human PSMA antibody, that binds an epitope present on the extracellular portion of PSMA, was used to stain the tissue sections. The 3-points scale [2] was used to score PSMA positivity: 0-5% expression was considered as negative (score 0), 5-50% as moderately positive (score 1) and 50-100% as highly positive (score 2). A cumulative score (0-10%, 11-79% and 80-100%) was also explored. Univariate and multivariate logistic regression were performed to predict the presence of distant metastases, chosen as endpoint of aggressiveness. The area under the curve (AUC) was calculated. Cox models were built to predict patient outcome in terms of recurrence, iodine refractoriness, and status at last follow-up, calculated using the Kaplan-Meier failure function. **Results:** At immunostaining 12/59, 25/59 and 22/59 of patients had score 0, score 1 and score 2, respectively. According the cumulative score, PSMA expression was ≤10% in 17/59 cases, 11-79% in 31/59 cases and ≥80% in 11/59 cases. At multivariate analysis age, sex, histotype, vascular invasion, T and N parameters and PSMA positivity resulted significant predictors of distant metastases (AUC=0.92). Recurrence or progression occurred in 14/59 and 5/59 patients, respectively; median DFS was 23 months (range 3-82); 12 patients developed RAI refractoriness with a median time of 19.5 months (range 2-32); one patient died of DTC; 46 among the 58 patients alive at last follow-up were disease-free. The final multivariate model to predict RAI refractoriness included as covariates stage, high PSMA expression (≥80%), and the interaction between moderate PSMA expression (11%-79%) and stage. **Conclusion:** PSMA, a marker of neovasculature formation, expressed by DTC resulted to contribute to predict tumor aggressiveness and to be promising in outcome prediction. **References:** 1. Br J Pharmacol. 2016;3041-79.2. Sci Rep. 2017;7:5202.

EP-0699

Entresto®-treated mice show superior targeting of PC-3 xenografts vs. controls after injection of the SPECT tracer [^{99m}Tc]DB4

P. Kanellopoulos[1,2], *A. Kaloudi*[1], *M. de Jong*[3], *E. P. Krenning*[4], *T. Maina*[1], *B. A. Nock*[1];
[1]*Molecular Radiopharmacy, INRASTES, NCSR "Demokritos", Athens, GREECE,* [2]*Molecular Pharmacology, School of Medicine, University of Crete, Heraklion, GREECE,* [3]*Department of Radiology & Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS,* [4]*Cyclotron Rotterdam BV, Erasmus MC, Rotterdam, NETHERLANDS.*

Aim/Introduction: The gastrin-releasing peptide receptor (GRPR)-directed radiotracer [^{99m}Tc]DB4 (^{99m}Tc-[N_4^0,Pro[1],Tyr[4],Nle[14]] BBN, BBN: bombesin) has shown specific uptake in prostate cancer lesions in mice and in man. It is assumed that the tumor values achieved thus far may further improve by enhancing the metabolic stability of [^{99m}Tc]DB4. In situ metabolic stabilization

of [^{99m}Tc]DB4 may be achieved by co-injection of a suitable neprilysin (NEP) inhibitor, as previously shown for a series of BBN-like theranostic radioligands. In the present study, we compared the biological profile of [^{99m}Tc]DB4 in mice bearing PC-3 xenografts, treated or not with the FDA approved drug Entresto®, aiming to clinical translation of the NEP-inhibition concept. **Materials and Methods:** [^{99m}Tc]DB4 was injected in healthy Swiss albino mice without or with co-injection of the NEP-inhibitor sacubitrilat (0.3 mg sacubitrilat/kg body weight); a third mice group received a slurry of the FDA-approved drug Entresto® (containing 50 mg of the sacubitrilat-prodrug sacubitril/kg body weight) by oral gavage 30 min in advance. Blood samples collected 5 min postinjection (pi) were analyzed by RP-HPLC. Biodistribution was conducted in SCID mice bearing PC-3 xenografts in their flanks. [^{99m}Tc]DB4 was injected alone in mice 30 min after orally receiving Entresto®, or in untreated mice, or together with sacubitrilat; animals were sacrificed at 4 h pi and biodistribution was conducted. **Results:** While 26.3±2.9% (n=5) of [^{99m}Tc]DB4 were detected intact in peripheral mouse blood at 5 min pi, by Entresto® or sacubitrilat-treatment the percentage of intact radiotracer reached 71.5±1.8% (n=4) and 74.3±7.1% (n=4), respectively. A likewise impact of orally administered Entresto® or iv-injected sacubitrilat was observed on the uptake of [^{99m}Tc]DB4 in the PC-3 xenografts, which notably increased at 4 h pi from 6.5±1.2%ID/g (n=4) to 16.4±4.3%ID/g (n=3) and 16.2±0.7%ID/g (n=3), respectively. Uptake doubled in the GRPR-rich mouse pancreas, but intestinal and renal values were little affected by such treatment. **Conclusion:** This study has shown that oral administration of the FDA-approved drug Entresto® or iv-coinjection of the respective NEP-inhibitor sacubitrilat in mice substantially improved the stability of [^{99m}Tc]DB4 in peripheral mice blood. As a result, the uptake of [^{99m}Tc]DB4 in the implanted PC-3 tumors was favourably enhanced as well. The in-situ NEP-inhibition concept warrants translation in the clinic and is currently pursued. **References:** None.

Theranostic $^{64/67}$Cu SARTATE Clinical Trial - Imaging and PRRT of Patients with Meningioma:Preliminary safety data

G. P. Schembri, S. Dave, D. Chan, E. Hsiao;
Royal North Shore Hospital, St Leonards, AUSTRALIA.

Aim/Introduction: ^{67}Copper sartate is a novel agent with therapeutic applications across a number of somatostatin expressing tumours. We report preliminary safety findings in a first in human trial utilising 67Cu-Sartate. **Materials and Methods:** ^{67}Cu-SARTATE is being evaluated in a Phase I-IIa multidose trial with recurrent or progressive grade I-III meningioma (ACTRN12618000309280). Participants receive up to 4 therapy cycles (6-12 weeks apart) of approximately 5GBq of 67Cu-SARTATE, given concurrently with renoprotective amino acids. Safety visits occur between each cycle at fortnightly intervals. The last follow-up visit is planned for 12 weeks after administration of the last cycle. Adverse events were graded using CTCAE v4.03 criteria. **Results:** 11 cycles of therapy in 3 patients (4,4 and 3 cycles) have been completed at this time. All ^{67}Cu Sartate infusions were completed without incident. There were no reported clinical events related to blood pressure, heart rate, temperature or oxygen saturation. One patient developed sinus tachycardia attributed to thyroxine overdosage.There were no changes in renal function with stable creatinine and eGFR. Baseline eGFR 91 , post treatment 91. Total WCC were stable however reductions in lymphocytes counts were evident in all three patients though not with every cycle. PRRT has been noted to suppress B lymphocyte counts, though usually with ^{90}Yttrium. This typically resolves within 90 days. Dexamethasone (given as premedication) may be a contributing factor. The lowest value recorded was 0.4 X 10^9/L (grade 3 toxicity). This patient had a prexisting low platelet count suggesting underlying bone marrow dysfunction. The other two patients had grade 2 toxicity. No change in other FBC indices were evident. INR remained stable and urinalysis was unremarkable. Physical examination remained stable.Adverse effects (AE) were reported by all three patients. All the reported AEs were grade 1. Examples include minor rash and non trial related drug effects.Those potentially associated with therapy were metallic taste post treatment and transient blurred vison after 1 cycle. **Conclusion:** In this small phase 1 trial, initial results suggest therapy with ^{67}Cu Sartate is well tolerated with no directly related side effects requiring treatment. Minor grade 1 AE's, most not considered directly due to therapy. Grade 2/3 reduction in lymphocytes noted. Ongoing follow-up to trial endpoint required to confirm significance and resolution of this finding. **References:** 1. Sierra ML et al: Lymphocytic toxicity in patients after peptide-receptor radionuclide therapy (PRRT) with 177Lu-DOTATATE and 90Y-DOTATOC. Evaluation of Non-Small Cell Lung Cancer by PET/CT with $^{64}CuCl_2$: initial experience in humans

S. S. Medina[1,2], O. Garcia[1,3], S. Lopez[1];
[1]Instituto Nacional De Cancerologia, Mexico City, MEXICO, [2]Hospital Angeles Lindavista, Mexico City, MEXICO, [3]Hospital Médica Sur, Mexico City, MEXICO.

Aim/Introduction: Evaluate the diagnostic potential of the use of the PET/CT with $^{64}CuCl_2$ in patients with non-small cell lung cancer without mutations before to initiate therapy. **Materials and Methods:** Eleven patients with NSCLC without gene

mutations was included, baseline 18F-FDG-PET/CT and 64CuCl2 PET/CT imaging was performed. We calculate and compare the DRs of the $^{64}CuCl_2$ PET/CT with the standard imaging ^{18}F-FDG PET/CT. DRs were calculated as the ratio between the number of positive lesions visualized by $^{64}CuCl_2$ PET/CT and the total number of lesions visualized by ^{18}F-FDG PET/CT. **Results:** Overall, 8 out of 11 patients (73%) demonstrated high focal uptake of 64CuCl2 on PET/CT images. 36% patients showed higher uptake in the primary tumor. 27% patients showed tracer uptake in lymph nodes metastases, of which 18% patients do not demonstrated metastatic sites a when compared with previous 18F-FDG PET/CT. In 2 patients (18%) very low uptake was observed in the primary tumor in lung; and 3 patients (27%) very faint focal uptake was noted in previous non-pathologic bone fractures which was considered to be a nonspecific inflammatory process. To determine the DR of two radiotracers in detecting lesions, we performed a lesion-based analysis. A total 68 lesions were detected by 18F-FDG PET/CT, 24 of which were in the lung, 30 regional lymph-node metastases, 17 distant non-bone metastases (including non-regional lymph-node metastases) and 14 bone metastases. 64CuCl2 PET/CT showed significantly lower DRs than did18F-FDG PET/CT. A complete match was found with a previous 18F-FDG PET/CT study in 2 patients. No difference in bone metastases DR was observed between 18F-FDG PET/CT and 64CuCl2 PET/CT. The difference between the DR of 64CuCl2 PET/CT and that of 18F-FDG PET/CT was not statistically significant (P = 0.108). All patients was initially treated with therapy based in platinum agents, the four patients who showed the highest uptake in the primary tumor with 64CuCl2 PET/CT, presented partial metabolic response in the response evaluation (3-4 cycles, mean 3 cycles), and only one of them showed partial response by RECIST and PERCIST criteria visualized with 18F-FDG PET/CT. **Conclusion:** This study reports the first in-human application of a $^{64}CuCl_2$ PET/CT, in the primary staging of patient's with NSCLC chemo-naïve; these results may represent that $^{64}CuCl_2$ PET/CT uptake is based on the expression of CTR1 transporters seeking to differentiate between those patients who may benefit from platinum-based therapy. More studies are necessary for confirm these findings. **References:** None.

Metabolic Alternation in Liver Tumor and Parenchyma with ^{18}F-FDG PET and NMR Metabolomics in A Mouse Model

Y. S. Chung, G. Lin, T. Yen;
Chang Gung Memorial Hospital, Tao-Yuan, TAIWAN.

Aim/Introduction: Radiation induced liver disease (RILD) is thought as a limitation of radiation treating liver cancer. The mechanisms underlying the radiation response to the liver parenchyma and hepatocellular carcinoma (HCC) still remain the prosperous research subjects. The purpose of this study was to investigate the metabolites alternations of the liver parenchyma and tumor in a mouse model after receiving irradiation. **Materials and Methods:** The mice were implanted BNL liver tumor xenografted in right liver lobe, underwent 15 Gy irradiation. The ^{18}F-FDG PET images of liver parenchyma and tumor lesion were retrospectively evaluated in irradiated mice (RT, n=7) and non-irradiated mice (non-RT, n=6) served as a control at day 1 and day 3 after radiation. The independent metabolic study was carried out the tissues removing of the right liver parenchyma, left liver parenchyma and tumor after the mice with or without irradiation in 1 day (n=6, RT v.s.non-RT) and 3 days (n=6, RT v.s.non-RT). The metabolites of tissues and tumors were analyzed with nuclear magnetic resonance (NMR) techniques. **Results:** The SUVmax FDG uptake of the right liver parenchyma, left liver parenchyma and tumor regions were increased at day 1 and/or day 3 after receiving radiation. But, there is no statistical significant difference between RT and non-RT groups. The score plots from PCA metabolites analysis of right and left liver parenchyma and tumors revealed separate clusters of the RT and non-RT mice, indicating the differences on metabolites composition. In sophisticated metabolites analysis results, the glucose and acetate were significant elevated 12.3 ($p<0.001$) and 2.5 ($p<0.01$) folds of the right liver parenchyma in RT mice, respectively at day 1 after irradiation. The associated pathways induced by irradiation in right liver parenchyma were starch and sucrose metabolism ($p<0.027$), galactose metabolism ($p<0.036$), pyruvate metabolism ($p<0.032$) and glycolysis and gluconeogenesis ($p<0.036$) found significantly activated after irradiation in 1 day. **Conclusion:** The metabolites alternations of the liver parenchyma and tumor in a mouse model are found on as early as one day after receiving irradiation. The elevated glucose metabolism in liver parenchyma and tumor region after irradiation demonstrated with concurrently ^{18}F-FDG PET and metabolite analysis NMR techniques. **References:** None.

Use Of Whole Body SPECT/CT To Study Biodistribution Of [^{67}Cu]SARTATE In Subjects With Meningioma - Preliminary Results

D. L. Bailey[1], *K. P. Willowson*[1], *G. P. Schembri*[1], *A. Hedt*[2];
[1]*Royal North Shore Hospital, Sydney, AUSTRALIA,*
[2]*Clarity Pharmaceuticals, Sydney, AUSTRALIA.*

Aim/Introduction: Copper-67 SARTATE ([^{67}Cu]MeCOSAR-Tyr3-Octreotate, Clarity Pharmaceuticals, Sydney, Australia) is currently being trialled for treatment of somatostatin-expressing tumours. We have undertaken a first-in-human non-randomised, open label clinical trial in subjects with unresectable meningioma to study the biodistribution of the radiopharmaceutical in organs apart from brain, where there is no disease. **Materials and Methods:** To date, three subjects have had 11 cycles each of 5 GBq [^{67}Cu]SARTATE administered with simultaneous amino acid infusion. Imaging is performed using whole body SPECT/CT at time points 1, 4, 24 and 96 hrs after administration. All scans are performed on a dual-head gamma camera (Siemens Intevo.6) using an energy window on the 185 keV gamma photon of ^{67}Cu (Branching Ratio = 0.49). Organs of

interest were defined on the CT scan and from these the decay corrected percentage injected dose (%ID) in the target organs was measured at each time point. The remaining percentage in the rest of the body was also determined. The biological half-life ($t_{½(b)}$) of the radiopharmaceutical was determined by fitting exponential functions to the retention data. **Results:** Averaged over all cycles in the three subjects the peak %ID in the organs of interest, ranked in decreasing order, were: muscle - 13.3%, liver - 9.4%, kidneys - 4.1%, spleen - 3.4% and bone marrow - 1.6%. The effective half-lives measured were: blood pool - 22.5 hrs, muscle 22.6 hrs, bone marrow - 40.9 hrs, liver - 41.6 hrs, spleen - 43.1 hrs, kidneys - 48.5 hrs with the remainder clearing with a $t_{½(b)}$ = 47.1 hrs. **Conclusion:** Whole body SPECT/CT at multiple time points has allowed precise organ definition for evaluating biodistribution in multiple organs. These data will be used to assess whole body and organ dosimetry and can further be used to personalise the prospective individual dose of therapeutic radiopharmaceutical for the subject. **References:** None.

EP-0704

Feasibility and initial safety of $^{86/90}$Y-NM600 theranostics in a canine patient with metastatic osteosarcoma

R. Hernandez, I. Marsh, J. Grudzinski, E. Aluicio-Sarduy, M. Turek, J. Engle, Z. Morris, B. Bednarz, D. Vail, J. Weichert;
University of Wisconsin, Madison, WI, UNITED STATES OF AMERICA.

Aim/Introduction: Over the last three decades, survival for metastatic osteosarcoma (mOSA) patients has not improved substantially, thus novel combination therapies to treat mOSA are direly needed. Our study investigated the feasibility and toxicity profile of [^{90}Y]Y-NM600 for the treatment of mOSA in a translationally relevant companion canine model of mOSA. **Materials and Methods:** A 45 kg mastiff companion dog presented with wide-spread metastatic osteosarcoma (mOSA) was recruited through the UW-Madison veterinary clinic. Clinical examination, complete blood count (CBC), urinalysis, and comprehensive metabolic panel (CMP) were performed at entry. A [^{86}Y]Y-NM600 185 MBq (5 mCi) intravenous bolus was administered to the patient followed by the acquisition of serial PET/CT scans in a clinical PET/CT scanner at 2, 24, and 48h post-injection. Blood samples were collected prior each imaging timepoint to assess [^{86}Y]Y-NM600 blood clearance. Region-of interest analysis of the PET images was performed to determine [^{86}Y]Y-NM600 uptake -presented as standardized uptake value (SUV)- and clearance in the tumor and normal organs, and to estimate the dosimetry of therapeutic [^{90}Y]Y-NM600. A conservative 592 MBq (16 mCi) [^{90}Y]Y-NM600 activity was administered to investigate initial safety. Clinical examination, CBC, urinalysis, and CMP were performed regularly after the administration of both the imaging and TRT agents. **Results:** Selective uptake and prolonged retention of [^{86}Y]Y-NM600 in the primary and metastatic lesions was observed by PET/CT. Mean and maximum SUV in the tumor peaked at 4.6 and 7.6, respectively, at the 48 h post-injection timepoint. Blood circulation ($t_{1/2}$ = 9.3 hours) and hepatobiliary excretion of the radiotracer was evidenced by the initially elevated blood radioactivity and gradual distribution to the gallbladder and feces. Patient-specific dosimetry using a voxel-based dose calculation platform determined a tumor to bone marrow dose ratio greater than 2, for both the primary and the lung metastatic lesions. Administration of a [^{90}Y]Y-NM600 activity, delivering <1 Gy to the bone marrow, did not cause any acute and sub-acute adverse events (AEs). Serial CBC, CMP, urinalysis, and client-documented quality of life questionnaires documented no significant clinical or clinicopathologic AEs after [^{90}Y]Y-NM600 treatment. No clinically significant changes in serum biochemistry profile were noted and all hematologic cell lines remained constant or higher than baseline. **Conclusion:** Our data demonstrates the feasibility and safety of $^{86/90}$Y-NM600 theranostic approach in canines and provides guidance for further dose escalation studies in dogs and future Phase-1 human clinical trials. **References:** None.

Aim/Introduction: The glucagon receptor (GCGR) is a G protein-coupled receptor that is expressed primarily in the liver, where it plays a vital role in regulating glucose production and in maintaining glucose homeostasis. It has emerged as an interesting target in the development of pharmacological weight-loss therapies in recent years, particularly as part of poly-agonists that combine the benefits of GCGR agonism with agonism at the glucagon-like peptide-1 receptor. Determining in vivo target engagement of these dual-agonists has been a challenge. Here we describe the use of a novel GCGR targeting radiotracer [1] to visualise the interaction of glucagon receptor-targeting molecules with the glucagon receptor in a rodent

model. **Materials and Methods:** Healthy SD female rats were administered single i.v. bolus of [^{68}Ga]Ga-DO3A-S01-GCG over a range of different doses (n=39), with or without a prior s.c. or i.v. injected glucagon receptor binding compounds. Sixty minute dynamic PET scans were performed with a Siemens INVEON small animal PET/CT scanner. Uptake in tissues was calculated, and the volume of distribution (V_T) were estimated from a Logan plot using image-derived blood input function. **Results:** High specific accumulation was observed in the liver (1.49±0.17 %ID/g, < 0.25 µg/kg) compared to blood (0.19±0.04 %ID/g) at 60min after tracer injection. Liver uptake was shown to be dose dependent, with an in vivo K_d of 0.7 µg/kg and a mass effect of 0.15 µg/kg. The volume of distribution was significantly lower in rats dosed (s.c. 45min prior to tracer injection) with 0.75 mg/kg of a long-lasting glucagon-receptor agonist (2.75±1.47) compared to animals administered with tracer alone (7.25±2.49) (p=0.0488). Rats dosed (i.v. 15min prior) with 28 µg/kg of a murine acting dual-agonist showed significantly reduced V_T in the liver (2.66±0.24, p=0.0161). **Conclusion:** We show, for the first time, the ability to observe GCGR engagement of a GCGR agonist or dual GLP-1R/GCGR agonist in rodent liver in vivo. **References:** 1) Velikyan I, et al. First-in-class Positron Emission Tomography tracer for the Glucagon receptor. EJNMMI Res (2019) 9(1):17.

Preparation of I-125 labeled TAT peptide using stable iodination linker for White Blood Cell radiolabelling

T. Choi, B. Kim;
KIRAMS, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: HIV TAT-derived peptides as cell penetrating peptides(CPP) are promising tools for transducing therapeutic molecules which possess low membrane permeability. Radioiodine is commonly employed to prepare radiolabeled peptides. A major shortcoming of radioiodinated peptides prepared by direct labeling methods is their deiodination in vivo. For the preparation of more stable radioiodinated peptides, we introduced a new linker (3-ADIBO-3-oxopropyl-3'-[tributylstannyl]benzamide) to azido-TAT peptide. **Materials and Methods:** Bu_3Sn-TAT was synthesized with ADIBO-azide click chemistry in 50% acetonitrile and purified by prep-HPLC. I-125 was added to Bu_3Sn-TAT and followed by adding 10 µg of chloramine T. I-125 labeled TAT was purified by HPLC. Stability of reconstituted I-125 labeled TAT after nitrogen purged drying was evaluated in DMSO. THP-1, a monocytic leukemia cell line, was used to evaluate cell radiolabelling ability of I-125 labeled TAT peptide. **Results:** The radiolabelling yield was 93% at the maximum. I-125 labeled TAT was more stable at 4 ℃ than 40 ℃. For 14 days, approximately, 4% and 11% of I-125 labeled TAT was degraded at 4C and 40C, respectively. Cellular uptake was measured with carrier-free I-125 labeled TAT of carrier-added I-125 labeled TAT. Cellular uptake ratio of carrier-free I-125 labeled TAT was 1.4%.Cellular uptake ratios of carrier-added were 4.5%, 10.6%, 19.6%, 23.8%, and 19.8% at cold I-TAT 2.5, 5, 10, 25 and 50 µM concentrations, respectively. **Conclusion:** TAT peptides were successfully radioiodinated and penetrated into the cell. Intracellular uptake of HIV-derived TAT was thought to be influenced by cold I-TAT concentration to stimulate cell membrane endocytosis in order to intracellular intake via energy-dependent endocytosis. **References:** Enhanced tumor retention of radioiodinated anti-epidermal growth factor receptor antibody using novel bifunctional iodination linker for radioimmunotherapy, 2016. EP-0707

LDLR targeting for radiotheranostic drugs in glioblastoma

C. Malicet[1], *I. Tworowska*[2], *J. Nowak*[1], *P. Lécorché*[1], *L. G. Flores II*[2], *R. Zielinski*[3], *M. Khrestchatisky*[4], *J. Temsamani*[1], *E. Delpassand*[2];
[1]*Vect-Horus, Marseille, FRANCE,* [2]*RadioMedix Inc., Houston, TX, UNITED STATES OF AMERICA,* [3]*MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA,* [4]*Aix-Marseille Université, Centre National de la Recherche (CNRS), Institute of Neurophysiopathology (INP), Marseille, FRANCE.*

Aim/Introduction: The prognosis of patients with glioblastoma is poor with an average life expectancy of 12-15 months from diagnosis. Permeability of the blood-brain barrier (BBB) is one of the factors that limit efficacy of the drugs. The low-density lipoprotein receptor (LDLR) expressed at the BBB mediates the transport of endogenous ligands through the BBB. VECT-HORUS has identified and chemically optimized a family of peptide-vectors targeting the LDLR and able i) to cross the BBB and ii) to target tumors such as U87MG glioblastoma that express high levels of the human LDLR. The objective of this study was to determine the LDLR targeting properties of ^{68}Ga/^{177}Lu-radiolabeled peptide vectors using the U87MG glioblastoma model. **Materials and Methods:** The LDLR targeted DOTA-conjugates (VH-DO31, VH-DO33) and NODAGA conjugate (VH-NO31), (10-30ug, Vect-Horus, France) were labeled with 68Ga (1.5mCi) eluted from 68Ge/68Ga generator (ITG GmBH, Germany) or with 177Lu n.c.a (1mCi, ITG GmBH, Germany). The LDLR targeting properties of these conjugates were thus determined in vitro in U87MG cellular uptake studies, as well as in vivo in U87MG xenografted mice. The PET/CT images of U87MG xenografts generated in athymic nude mice (10 weeks, n=3) were acquired using G4 PET/Xray camera (Sofie Biosciences; 10min/scan) at 1h, 2h, 3h, and 4h post-injection. **Results:** All 68Ga/177Lu-labeled conjugates were synthesized with radiochemical purity higher than 91 % (radio-HPLC). Radiolytic stability was increased using C18 ethanol purification of the final products. 177Lu-VH-DO33 showed the highest retention of the agent in U87MG cell line at 1h (13.88± 1.6 %ID/mg) and 21h incubation time (8.7± 4 %ID/mg) compared to 177Lu-VH-DO31 (8.28 ±6.2 %ID/mg). The microPET imaging studies showed rapid accumulation and retention of all VH derivatives in the tumor as monitored up to 4h post-injection. All agents were eliminated through bladder and kidneys. There was no accumulation of agents in the bone marrow. The image-based biodistribution studies of 68Ga-VH-DO31, 68Ga-VH-DO33

and 68Ga-VH-NO31 showed that the tumor to muscle ratios (SUV ratio) after 30 min post-injection were 4.12, 5.07 and 3.88, respectively and remained at the same levels up to 3h post-injection. The SUV ratios of tumor to kidneys were as follows: 68Ga-VH-DO31 (0.46), 68Ga-VH-DO33 (0.84) and 68Ga-VH-NO31 (0.46) confirming renal elimination of the agents. **Conclusion:** VH derivatives showed favorable hLDLR targeting properties in vitro and in vivo in U87MG models. These preliminary results suggest that hLDLR may serve as a target for the development of radiotheranostic drugs for glioblastoma. **References:** None.

^{99m}Tc-labeled hydroxyapatite nanoparticles as potential tracers for solid tumors

Z. Novy[1], *V. Lobaz*[2], *M. Vlk*[3], *J. Kozempel*[3], *M. Hruby*[2], *M. Hajduch*[1], *J. Drymlova*[4], *R. Navratil*[4], *M. Petrik*[1];
[1]*Palacky University in Olomouc, Olomouc, CZECH REPUBLIC,* [2]*Institute of macromolecular chemistry, CAS, Prague, CZECH REPUBLIC,* [3]*Czech Technical University, Prague, CZECH REPUBLIC,* [4]*University Hospital Olomouc, Olomouc, CZECH REPUBLIC.*

Aim/Introduction: The aim of this work was to label newly prepared hydroxyapatite nanoparticles (HAP-NP) with 99mTc using clinically established radiotracer 99mTc-HDP, further verification of radiochemical stability of such labelled nanoparticles in vitro and mainly to describe their biodistribution in healthy and in tumor mice employing SPECT/CT as well as gold standard ex vivo biodistribution approach. Five different variants of nanoparticles were tested with specific biopolymer coating on the surface. **Materials and Methods:** Radiolabeling of nanoparticles was done under mild conditions, i.e. room temperature and pH 7.4, followed by quality control step represented by radiochemical purity check by iTLC in order to reveal labeling efficiency and in vitro stability of the tracer. Ex vivo studies were performed on healthy and tumor mice (1h, 6h, 24h p.i.). The biodistribution of labeled nanoparticles was also monitored by μSPECT/CT system 1h, 3h, 6h a 24h post injection for two different application approaches. First, in vitro prelabeled nanoparticles and second, 99mTc-HDP applied with various time intervals after unlabeled nanoparticles. We have studied influence of antiangiogenic therapy with bevacizumab to HAP-NP biodistribution in tumor-bearing mice too. **Results:** The HAP-NPs were labeled with high radiochemical purity and sufficient stability for their in vivo applications. Ex vivo biodistribution studies revealed dominant accumulation in the liver and spleen. The favorable tumor/blood ratio was determinated from tumor mouse study. In vivo imaging showed mainly the same organs as ex vivo study, i.e. liver and spleen. Ex vivo data from bevacizumab-treated tumor animals reported significant differences in HAP-NP accumulation in kidneys and heart, but not in the tumor. **Conclusion:** Tested HAP-NPs could be relatively easily labeled with 99mTc-HDP. Their in vitro stability is on satisfactory level. Biodistribution studies revealed high accumulation of NPs in liver and spleen. These findings were confirmed by SPECT/CT imaging in healthy and in tumor mice. In case of two-phase application approach, there were positive results for time intervals from three to six hours between injection of HAP-NP and 99mTc-HDP. But tumors were not visualized in SPECT scans. This project was supported by the Ministry of Health of the Czech Republic (grant No. 16-30544A). **References:** None.

In Vitro Evaluation of [^{18}F]FPA as a Fatty Acid Synthase-targeting Imaging Agent for Breast Cancer and its In Vivo Whole-Body Biodistribution in Normal Mice

Y. Huang[1], *C. Tsai*[1], *B. Ho*[2], *H. Ho*[2], *Y. Chang*[1], *C. Wu*[3], *R. Yen*[1,3], *C. Shiue*[1,3];
[1]*PET Center, Department of Nuclear Medicine, National Taiwan University Hospital, Taipei, TAIWAN,* [2]*Department of Anesthesiology, Wan Fang Hospital, Taipei Medical University, Taipei, TAIWAN,* [3]*Molecular Imaging Center, National Taiwan University, Taipei, TAIWAN.*

Aim/Introduction: Fatty acid synthase (FASN) is a key enzyme in fatty acid synthesis pathways and its expression has been known to be an indicator of poor prognosis in breast cancer (BC). Recently, a hypothetical model for FASN-regulated estrogen receptor(ER)-signaling in BC cells has been suggested. As one of the short fatty acids, [^{18}F]2-fluoropropionic acid ([^{18}F]FPA) has been proved as a promising oncological imaging agent. In order to clarify FASN-targeting uptake mechanism of [^{18}F]FPA in BC, we have studied its in vitro binding with ER$^+$ and ER$^-$ BC cells along with its whole-body biodistribution in normal mice using microPET imaging. **Materials and Methods:** [^{18}F]FPA was automatically synthesized based on reported methods with FLEXLAB module(iPhase). Briefly, fluorination of methyl 2-bromopropionatewith K[^{18}F]/$K_{2.2.2}$ in anhydrous MeCN at 110 ^{0}C for 10 min gave the radiofluorinated intermediate. After NaOH hydrolysis and H_2O dilution, the crude product was purified with a semi-preparative HPLC and the isolated [^{18}F]FPA solution was formulated and passed through a 0.22 μm sterile filter to give [^{18}F]FPA for QC, in vitro binding assay with ER$^+$ and ER$^-$ BC cells and in vivo uptake in normal mice. In vitro binding assays of [^{18}F]FPA with ER$^+$ and ER$^-$ BC cells were performed. MicroPET imaging were performed with normal ICR mice (20-30 g, n=3) using small-animal Argus PET/CT scanner. **Results:** The RCY of [^{18}F]FPA was 39.1±12.6 % (n=6, EOB after HPLC isolation) and the synthesis time without formulation was about 85 min at end of synthesis. The radiochemical purity was > 90 % as determined by analytical HPLC and TLC methods. Compare to previous results of FASN-targeting [^{11}C]Acetate, our results indicated that [^{18}F]FPA had significant uptake in both ER$^+$ and ER$^-$ BC cells at 15, 30 and 60 min. In addition, microPET images in normal mice showed that [^{18}F]FPA had significantly accumulation in bladder. **Conclusion:** [^{18}F]FPA has been automatically synthesized with Flexlab module. In vitro binding assay showed that [^{18}F]FPA had significant uptake in both ER$^+$ and ER$^-$ BC cells and its FASN-blocking studies are ongoing. MicroPET images in normal mice showed that [^{18}F]FPA had significantly accumulation in bladder

and its radiation dosimetry will be evaluated for incoming human studies. The evaluations of [^{18}F]FPA as potential imaging agent for BC and other diseases continue. **References:** None.

EP-0710

Structural Optimization of the Arecaidine Diphenylmethyl Ester Scaffold for Muscarinic Acetylcholine Receptor PET Tracer Development

M. Ozenil[1], *K. Pacher*[1], *C. Vraka*[1], *H. Spreitzer*[2], *M. Hacker*[1], *M. Mitterhauser*[1,3], *W. Wadsak*[1,4], *V. Pichler*[1];
[1]*Department of Biomedical Imaging and Image-guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Department of Pharmaceutical Chemistry, University of Vienna, Vienna, AUSTRIA,* [3]*Ludwig Boltzmann Institute Applied Diagnostics, Vienna, AUSTRIA,* [4]*CBmed GmbH - Center for Biomarker Research in Medicine, Graz, AUSTRIA.*

Aim/Introduction: Several neurodegenerative diseases are associated with altered functions of muscarinic acetylcholine receptors (mAChRs), which makes them an interesting target for neuroimaging. At EANM 2018, we reported on the tremendous gain in mAChR affinity of DPMARE (arecaidine diphenylmethyl ester) and FDPMARE (arecaidine bis(fluorphenyl)methyl ester) compared to arecoline itself. Regarding the affinity and subtype selectivity, these compounds feature promising characteristics for mAChR PET tracer development. Nevertheless, limited stability against human liver microsomes and pronounced nonspecific binding of [^{11}C]DPMARE and [^{11}C]FDPMARE observed in binding studies on living cells motivate us to further improve pharmacokinetic and accordingly physico-chemical properties prior to in vivo studies. **Materials and Methods:** Several new tracer candidates and their corresponding precursors based on the structure of DPMARE and FDPMARE were synthesized. Conjugates of arecaidine with the M1-prefering drug pirenzepine were prepared by nucleophilic substitution with a β-chloro amide (**1**, **2**). Compounds featuring different, generally more polar aryl substituents were synthesized by esterification of arecaidine with benzoin (**3**), (4-bromophenyl)(4-fluorophenyl) methanol (**4**), bis(6-fluoropyridin-3-yl)methanol (**5**), furan-2-yl(phenyl)methanol (**6**) and bis(4-methoxyphenyl)methanol (**7**). These novel potential mAChR ligands were characterized by 2D-NMR, ESI-MS, UV-HPLC and by X-ray crystallography if applicable. A competitive radioligand binding assay using [methyl-^{3}H]-N-methylscopolamine was performed to assess the in vitro binding affinity of the compounds. The most promising compounds were labelled with carbon-11 and were tested for their human liver microsome metabolism and plasma protein binding. **Results:** The K_i values of the newly synthesized compounds were in the order **1**, **2**, **7** > **3**, **6**, **5** > **4**, with the last compound offering a promising affinity in the low nanomolar range. The affinity was in close relation to the lipophilicity. LogP values were in the range of 0.57 up to 4.12 with the following trend: **1**, **2** < **5** < **3** < **7** < **6** < **4**. N-methylation of respective precursor molecules with [^{11}C]CH_3I as radiosynthon facilitated carbon-11 labelling in excellent yields. **Conclusion:** The major limitation of previously synthesized compounds was the high unspecific binding. For this set of compounds, we significantly reduced the lipophilicity. The most promising candidate for PET tracer development offers affinity in the low nanomolar range for M1 and M3-M5, with a 40-fold subtype selectivity of M1 over M2. The next step is to substitute arecaidine with 4-methylmorpholine-2-carboxylic acid, which allows to reduce lipophilicity on another part of the molecule and potentially reach further subtype selectivity. **References:** None.

EP-0711

Development of radiofluorinated CYP11B2-Inhibitors for the differential diagnosis of primary aldosteronism

A. Schirbel[1], *B. Heinze*[2], *P. Maier*[1], *M. Schneider*[1], *S. Samnick*[1], *A. K. Buck*[1], *B. Streile*[1], *K. Marienfeld*[2], *S. Hahner*[2];
[1]*University Hospital Würzburg, Department of Nuclear Medicine, Würzburg, GERMANY,* [2]*University Hospital Würzburg, Department of Endocrinology, Würzburg, GERMANY.*

Aim/Introduction: Primary aldosteronism is a frequent cause of secondary hypertension. It is associated with increased morbidity and mortality compared to hypertensive controls. The central diagnostic problem is the differentiation between bilateral and unilateral disease. This classification is crucial for further treatment as unilateral disease may be cured by surgery while patients with bilateral hyperaldosteronism receive lifelong medical treatment. The enzyme aldosterone-synthase (CYP11B2) is expressed exclusively in the adrenal cortex and is overexpressed in aldosterone producing adenomas. This enzyme should represent a highly suitable target for specific molecular imaging. A problem is the high expression of 11ß-hydroxylase (CYP11B1), which shows high homology to CYP11B2. Our aim was therefore to develop radiofluorinated inhibitors of CYP11B2 with high affinity and selectivity. **Materials and Methods:** Based on 3,5-disubstituted pyridines as known inhibitors we synthesized more than 100 compounds. In vitro analysis of the inhibitors was performed in the human adrenocortical carcinoma cell line NCI-H295 and in murine adrenocortical Y1 cells that were stably transfected with the respective human CYP11B enzymes. Suitable tracers were labelled with F-18 and evaluated in cell uptake experiments and frozen tissue imaging using slices of different human adrenal tumors. **Results:** 19 fluorinated inhibitors showed IC_{50}-values in the low nanomolar range for inhibition of CYP11B2 and selectivity factors up to 100. The corresponding radiofluorinated tracers were synthesized with high RCY and showed a variable cell uptake up to 30% in NCI-h295-cells. Frozen tissue imaging revealed a very high and selective uptake of six tracers in slices of aldosterone producing adenomas. **Conclusion:** For the differential diagnosis of primary aldosteronism we developed six suitable radiofluorinated tracers with high affinity and selectivity which will be evaluated in PET-studies using humanized mice. **References:** None.

EP-0712

1,5-Disubstituted 1,2,3-Triazole-based peptidomimetics: Synthesis and Application to Minigastrin

I. Valverde[1], *N. M. Grob*[2], *M. Béhé*[3], *T. L. Mindt*[4,5]; [1]*Institut de Chimie Moléculaire de l'Université de Bourgogne, Dijon, FRANCE,* [2]*Center for Radiopharmaceutical Sciences ETH-PSI-USZ, Institute of Pharmaceutical Sciences ETH, Zürich, SWITZERLAND,* [3]*Center for Radiopharmaceutical Sciences ETH-PSI-USZ, Paul Scherrer Institute, Villigen, SWITZERLAND,* [4]*Ludwig Boltzmann Institute of Applied Diagnostics, Vienna, AUSTRIA,* [5]*Medical University of Vienna, Department of Biomedical Imaging and Image Guided Therapy, Vienna, AUSTRIA.*

Aim/Introduction: Regulatory peptides have been shown to be suitable vectors for the specific delivery of radioactivity to tumors and metastasis for diagnostic and therapeutic applications in nuclear oncology. A potential drawback of such vectors is represented by their instability in vivo as the result of rapid degradation by intra- and extracellular peptidases. In the past, we have shown that the use of 1,4-disubstituted 1,2,3-triazoles as protease resistant trans-amide bond surrogates leads to an enhanced stability in radiolabeled bombesin and neurotensin derivatives and to an improved tumor uptake in vivo.[1] 1,5-disubstituted 1,2,3-triazoles have been considered as cis-amide bond and turn mimics. Moreover, structural studies support the evidence that some GPCR receptors prefer turn conformations in peptide/protein ligands.[2] One of these receptors is the CCK2 receptor (CCK2R), which is overexpressed in medullary thyroid carcinoma or small cell lung cancer. We herein wish to report the synthesis of analogs of a CCK2 receptor binding conjugate, [Nle[15]]MG11, containing a 1,5-disubstituted 1,2,3 triazole moiety in different backbone positions. **Materials and Methods:** Unlike previously described,[1a] the 1,5 disubstituted 1,2,3-triazole scaffold was introduced in the peptide sequence as a dipeptide mimic building block. This particular protease resistant moiety was synthesized by ruthenium-catalyzed azide-alkyne cycloaddition (click chemistry).[3] Triazole-substituted peptide conjugates were synthesized by classical solid phase synthesis methods. The optimization of the cycloaddition conditions and the synthesis of the building blocks used in the elaboration of the peptidomimetics will be discussed. **Results:** We have synthesized "clickable" azido acids and amino alkynes by straightforward procedures from commercial amino acids. These building blocks were successfully used for the synthesis of a series of analogs of the CCK2R-targeting [Nle[15]] MG11 conjugate. In vitro and in vivo studies to establish if the conjugates have retained biological activity are currently ongoing. **Conclusion:** Combination of solution and solid phase synthesis led to the synthesis of novel 1,5-disubstituted 1,2,3-triazoles-substituted MG11 analogs. To the best of our knowledge, this is the first report of the replacement of amide bonds with 1,5-disubstituted triazoles in a peptide-based conjugate for its use in radiopharmacy. **References:** 1) a) Valverde, I. EP-0713

Biological evaluation of radiolabelled peptides for oestrogen positive tumour theranostics

M. Gano, *F. Vultos, C. Fernandes, F. Silva, F. Mendes, J. D. G. Correia; Centro de Ciências e Tecnologias Nucleares, Instituto Superior Técnico, Universidade de Lisboa, Bobadela, PORTUGAL.*

Aim/Introduction: The oestrogen receptor (ER) is an important biomarker for prognosis and guiding treatment of breast cancers (BC). It has also been used as target for molecular imaging and therapeutics. Despite the enhancement in the BC survival rate due to new clinical strategies, there is still a need for more effective and personalized treatments. Theranostics is particularly suitable for that purpose. Radiolabelled peptides containing the LXXLL sequence have demonstrated high ER affinity and favourable behaviour in cellular and animal models. Thus, our aim was to compare the biological performance of two ^{111}In-LXXLL-peptide derivatives (single peptide and peptide coupled to an antitumoral agent, ER3AO) to assess their theranostic value in ER positive tumours. **Materials and Methods:** LXXLL-peptide derivatives were synthesized and conjugated to the bifunctional chelators by microwave-assisted solid phase synthesis. ^{111}In-complexes were obtained by reaction with $^{111}InCl_3$. Radiochemical purity and in vitro stability of ^{111}In-peptides were evaluated by HPLC. ER binding affinities were evaluated by a fluorescent polarization assay with the corresponding inactive In(III) complex peptide. Cellular uptake was assessed in MCF-7 (ER+) and MDA-MB-231 (ER-) human BC cells. The internalization rate of the ^{111}In-peptides into the cell nucleus was also evaluated. The ability to induce DNA damage in vitro was tested by incubation with double-stranded plasmid DNA for 140 hours. Biodistribution and in vivo stability was assessed in Balb/c mice with MCF-7 xenografts. **Results:** ^{111}In-peptides were obtained with high radiochemical yield and purity at high specific affinity. The ^{111}In-peptides demonstrated high in vitro stability. Both radiolabelled peptides have showed rapid and high uptake in MCF-7 cells (ER+). The ^{111}In-ER3AO, has had high nuclear internalization (higher than 50%) in MCF-7 cells and demonstrated ability to cause direct damage in DNA. Biodistribution studies of both ^{111}In-peptides in tumour-bearing mice indicated rapid clearance from blood and main organs, high kidney uptake and specific uptake in the ER-rich organs and tumours. Favourable target / non-target tissues radioactivity ratios were found. Differences in the biodistribution profiles of each ^{111}In-peptide derivative were mainly assigned with the involvement of each excretory pathway. High in vivo stability of the complexes was confirmed by HPLC analysis of urine and blood samples. **Conclusion:** Biological evaluation of both ^{111}In-peptide derivatives in cancer cells and tumour-bearing mice indicate promising features suggesting that is worthwhile to modify the peptidic derivative to improve the biodistribution/excretion profiles and further explore the potential for theranostic applications. **References:** None.

EP-0714

Development of O-[^{11}C]Methyl Ester Derivative of Sacubitril for PET Imaging of Neprilysin

V. Teyssier[1,2], *J. Simard*[2], *D. Petrenyov*[2], *F. Tournoux*[1,2], *J. N. DaSilva*[1,2];
[1]*Université de Montréal, Montréal, QC, CANADA,* [2]*Centre de recherche du centre hospitalier de l'Université de Montréal, Montréal, QC, CANADA.*

Aim/Introduction: Neprilysin (NEP), also known as CD10, is a cell surface membrane peptidase overexpressed in heart failure (HF) and in numerous malignant tumors. It is thus a target of choice for PET imaging. We have recently reported the radiosynthesis of the novel 11C-methylated derivative of LBQ657 (active metabolite of the antihypertensive drug sacubitril, an NEP inhibitor (NEPi) FDA approved in combinaison with valsartan to reduce the risk of cardiovascular death and hospitalization for HF in patients with chronic HF (NYHA Class II-IV) and reduced ejection fraction). Here, we present the development and initial autoradiographic evaluation of the novel [^{11}C]methylated derivative of Sacubitril, [^{11}C]SacOMe, for PET imaging of NEP. **Materials and Methods:** The O-[^{11}C]methyl ester analog was produced by O-[^{11}C]methylation of Sacubitril with [^{11}C]methyl triflate in the presence of K_{222} and potassium carbonate for 3 min at 50 °C using a Synthra® MeIplus Research platform. The reaction was then quenched and purified by semi-prep HPLC. [^{11}C]SacOMe was collected into MQ water, transferred through a light C18 Sep-pak, reformulated in<10 % EtOH/Saline and filtered. The identity of [^{11}C]SacOMe was confirmed by co-elution on analytical HPLC with unlabeled fully characterized standard SacOMe. In vitro autoradiography was performed on 20 µm-thick slices of rat kidney incubating [^{11}C]SacOMe (5nM) with or without NEPi (10 µM of thiorphan or Sacubitril) in a HEPES-buffered saline with BSA pH 7.4 for 20 min at 37 °C to discriminate total and non-specific binding, respectively. **Results:** [^{11}C]SacOMe was produced in 12±2 % radiochemical yield (32±3 % decay-corrected from [^{11}C]CO_2, n= 5) within 30 minutes. The radiochemical purity was >99% and molar activity was high at 407±92 GBq/µmol. The high signal observed in the renal NEP-rich outer medulla was completely blocked (>99.9%) in the presence of NEPi, demonstrating specific binding of [^{11}C]SacOMe to NEP. **Conclusion:** The one-step synthetic and purification automated process was optimized to produce the [^{11}C]SacOMe in high yields, purity and molar activity. High uptake and specific binding to NEP-rich areas of kidney slices suggest potential for PET imaging. Micro-PET, metabolism and selectivity binding studies are currently in progress. This innovative research is translatable to humans. **References:** None.

Design and validation of a 68Ga-radiolabelled PET imaging agent for in vivo evaluation of APJ expression

B. Louis[1], *A. Moyon*[2], *A. Bouhlel*[1], *L. Balasse*[1], *S. Fernandez*[3], *S. Simoncini*[4], *P. Brige*[5], *C. Souihi*[6], *G. Hache*[2], *F. Dignat-George*[7], *P. Garrigue*[2], *B. Guillet*[2];
[1]*C2VN INSERM 1263 INRA 1260 CERIMED Aix-Marseille Université, Marseille, FRANCE,* [2]*C2VN INSERM 1263 INRA 1260 CERIMED Aix-Marseille Université APHM, Marseille, FRANCE,* [3]*CERIMED Aix-Marseille Université, Marseille, FRANCE,* [4]*C2VN INSERM 1263 INRA 1260 Aix-Marseille Université, Marseille, FRANCE,* [5]*LIIE, CERIMED, Aix-Marseille Université, Marseille, FRANCE,* [6]*APHM, Marseille, FRANCE,* [7]*C2VN INSERM 1263 INRA 1260 Aix-Marseille Université APHM, Marseille, FRANCE.*

Aim/Introduction: This study aimed at developing a ^{68}Ga-radiolabelled PET imaging agent for assessing tissular APJ receptor expression. APJ has recently been reported to be overexpressed in various cancer types and especially during angiogenesis induction. To date, several APJ-targeted therapeutic strategies are explored. In this work, we designed AP747 as a potent specific ligand of APJ for PET/CT imaging of its expression in oncological applications. **Materials and Methods:** [^{68}Ga]gallium chloride solution was obtained from fractionated elutions of a Galliapharm generator (Eckert&Ziegler). AP747 was designed, produced, and radiolabelling was set up (pH5, 5min at room temperature). Radiochemical stability in NaCl0.9% and human serum was validated up to 2h after synthesis by radiochromatography on iTLC-SG and sodium citrate 0.1M pH5 (n=3). In vitro characterization of [^{68}Ga]Ga-AP747 specificity towards APJ was performed on APJ-overexpressing human colon carcinoma T84 cells, as verified by western-blot. Blocking was performed using a 50-fold excess of APJ ligand. Quantification of radioactivity was realized on background-corrected autoradiographs (n=3, Cyclone Perkin-Elmer). 4-month-old Swiss-nude mice were subcutaneously xenografted with 10^6 T84 cells (n=6) and rested for 4 weeks. 5.1±1.1MBq/50µL of [^{68}Ga]Ga-AP747 were IV injected (n=6), µPET/CT acquisitions performed 1h after radiotracer injection on a NanoScan PET/CT (Mediso). 24h later, in vivo blocking was realized by injecting 50µg of non-radioactive APJ ligand 30min before injecting [^{68}Ga]Ga-AP747 (n=6). Image analysis was performed using VivoQuant® software (InviCRO). Regions of interest were drawn over tumor and muscle for each animal quantified and corrected by the tissue volume (Mbq/mm3). Experiments were performed according to an Ethics Committee agreement by trained and qualified operators. **Results:** [^{68}Ga]Ga-AP747 was produced with a radiochemical purity of 96.7%±2.0 and stability in serum evaluated at 2h (95.0±1.5%). Autoradiographs showed APJ selective biding of [^{68}Ga]Ga-AP747 on T84 cells (16.64±10.98%) reversed by blocking (4,09±7.35%, *P=0.0183). Dynamic PET imaging showed favorable pharmacokinetic profiles with fast renal clearance and low background in liver, lungs, and digestive system. µPET/CT imaging of mice ectopic colon adenocarcinoma xenografts showed a high [^{68}Ga] Ga-AP747 tumor-to-muscle ratio (7.93±2.17) reversed after blocking in the same animals (1.03±0.31, *P=0.0235, n=6). Immunohistochemistry confirmed APJ expression in explanted tumor tissues. **Conclusion:** This proof of concept shows [^{68}Ga]Ga-AP747 might be a useful candidate for imaging APJ expression in tumors. [^{68}Ga]Ga-AP747 showed a specific and

strong uptake in colon adenocarcinoma tumor model in vitro and in vivo, and a low background in healthy organs. Upcoming studies will focus on the interest of this tracer for theranostic purposes. **References:** None.

EP-0716

Gallium-68 Labelled Radiotracer Based On Dota-curcumin For Imaging Of Colon-rectal Carcinoma

M. Asti[1], *G. Orteca*[2], *F. Pisaneschi*[3], *S. Rubagotti*[1], *T. W. Liu*[3], *G. Biagiotti*[4], *D. Piwnica-Worms*[3], *M. Iori*[1], *P. C. Capponi*[1], *E. Ferrari*[2];
[1]*AUSL-IRCCS Reggio Emilia, Reggio Emilia, ITALY,* [2]*University of Modena, Modena, ITALY,* [3]*MD Anderson Cancer Center, Houston, TX, UNITED STATES OF AMERICA,* [4]*University of Firenze, Firenze, ITALY.*

Aim/Introduction: Colorectal cancer is the third most commonly occurring cancer in men and the second most commonly occurring cancer in women worldwide. In the present study, we report a new gallium-68 labelled curcumin derivative (namely ^{68}Ga-DOTA-C21) and its initial validation as marker for early detection of colorectal cancer. **Materials and Methods:** The precursor and non-radioactive complexes were synthesized and deeply characterized by analytical methods then the curcuminoid was radiolabelled with gallium-68. The in vitro stability, cell uptake, internalization and efflux properties of the probe were studied in HT29 cells, and the in vivo targeting ability and biodistribution were investigated in mice bearing HT29 subcutaneous tumour model. **Results:** DOTA-C21 was synthesized with a 38% yield through a tree steps reaction and characterized by ESI-LC/MS and ^{1}H/^{13}C NMR spectroscopy. Post-processing of the generator elution was performed by cation exchange purification and $^{68}Ga^{3+}$ was incubated with 10 nmol of precursor in ammonium acetate buffer (pH 4). Kinetics were fast and the incorporation yield was 97±2 % after 5 min at 95 °C (n = 3). ^{68}Ga-DOTA-C21 exhibits decent stability (57±3 % after 120 min of incubation) in physiological media and a curcumin-mediated cellular accumulation in colorectal cancer cell line (121±4 KBq/mg of protein within 60 min). In HT29 tumour-bearing mice, the tumour uptake of ^{68}Ga-DOTA-C21 is 3.57±0.3 % of the injected dose per gram of tissue after 90 min post injection with a tumour to muscle ratio of 2.2±0.2. High amount of activity (12.73±1.9 % ID/g) is recorded in blood and significant uptake of the radiotracer also occurs in the intestine (13.56±3.3 % ID/g), lungs (8.42±0.8 % ID/g), liver (5.81±0.5 % ID/g) and heart (4.70±0.4 % ID/g). **Conclusion:** Further studies are needed to understand the mechanism of accumulation and clearance; however, ^{68}Ga-DOTA-C21 provides a productive base-structure to develop further radiotracers for imaging of colorectal cancer. **References:** None.

EP-0717

Development of a novel high affinity ^{89}Zr-Anticalin radiotracer directed against human CD98hc for diagnostic PET tumor imaging

V. Morath[1,2], *F. Deuschle*[1,3], *A. Schiefner*[1,3], *M. Heider*[1,4], *S. Ballke*[1,5], *C. Brandt*[1,3], *S. Reder*[1,2], *K. Steiger*[1,5], *F. Bassermann*[1,4], *M. Schwaiger*[1,2], *W. Weber*[1,2], *A. Skerra*[1,3];
[1]*Technische Universität München, München, GERMANY,* [2]*Department of Nuclear Medicine, München, GERMANY,* [3]*Lehrstuhl für Biologische Chemie, Weihenstephan, GERMANY,* [4]*Department of Medicine III, München, GERMANY,* [5]*Institute of Pathology, München, GERMANY.*

Aim/Introduction: Increased amino acid supply and dysregulated integrin signaling constitute two hallmarks of tumor biology and are pivotal for metastatic transformation of cells. In line with its involvement in both pathophysiological processes, overexpression of the cluster of differentiation 98 heavy chain (CD98hc) is clinically observed in various cancers, rendering it a promising tumor target. Hence, development of a ^{89}Zr-ImmunoPET radiotracer that targets corresponding heterodimeric amino acid transporters holds promise for deeper insight into tumor physiology and as a potential tool for in vivo diagnostics. **Materials and Methods:** An Anticalin (~20 kDa) with picomalor affinity (K_D = 50 pM) towards the human CD98hc ectodomain (hCD98hcED) and optimized plasma half-life using PASylation technology was labeled with $^{89}Zr^{IV}$ and subsequently used for preclinical PET imaging of xenograft tumor-bearing mice. **Results:** Our in vitro studies demonstrate specific binding of the radiolabeled Anticalin to several CD98hc-expressing human cancer cell lines, suggesting broader applicability in cancer research. Positron emission tomography (PET) imaging of mice bearing human prostate carcinoma, multiple myeloma or B-cell lymphoma using the ^{89}Zr-Anticalin radiotracer revealed strong and specific tracer accumulation in the xenograft tumors. For example, a biodistribution study with PC3 prostate carcinoma at t=24 h post injectionem revealed high accumulation of the radiotracer (8.6±1.1% ID/g) in the tumor, versus 5.4±1.1% ID/g in the cohort blocked with an excess of unlabeled Anticalin (p=0.0032), and a favorable tumor-to-muscle ratio of 11.8. **Conclusion:** So far, molecular imaging of amino acid transporter activity with ^{18}F-labeled amino acid mimetics such as FET or ACBC is an established diagnostic approach in clinical practice. The present study constitutes a first attempt to specifically target CD98hc for in vivo imaging in a preclinical setting. Our findings provide a proof of concept for the non-invasive diagnostic CD98hc-imaging. Consequently, the anti-CD98hc Anticalin radiotracer opens interesting biomedical applications in the area of cancer theranostics. **References:** None.

Bordeaux, FRANCE, [4]Institut für Biochemie, Universität Leipzig, Leipzig, GERMANY, [5]Institute of Chemistry & Biology of Membranes & Nanoobjects (UMR5248 CBMN) CNRS - Universite Bordeaux - Institut Polytechnique Bordeaux, Bordeaux, FRANCE, [6]Pôle d'Imagerie Electronique - Bordeaux Imaging Center UMS 3420 CNRS US4 INSERM, Bordeaux, FRANCE.

Aim/Introduction: Neuropeptide Y (NPY) receptor subtype-1 (Y_1) is known to be overexpressed in numerous tumors making radiolabelled NPY-analogues of interest for imaging and therapy [1].^{161}Tb is an interesting alternative to ^{177}Lu to deliver radiations, due to its emission spectrum rich in Auger electrons [2]. Here, we describe the combination of a receptor-targeting peptide with a releasable NLS-DOTA unit for the development of a subcellular active radiopharmaceutical. **Materials and Methods:** By solid phase peptide synthesis, the Y_1-preferring [F^7,P^{34}]-NPY was modified at Lys^4 with a fatty acid for stabilization, as well as a sequence consisting of an intracellularly cathepsin B-cleavable linker, a NLS and a DOTA chelator (pb12). The non-receptor binding control conjugate (pb13) was also synthetized. Following labelling with native terbium-159 (^{nat}Tb), plasmon waveguide resonance (PWR) was performed on MCF-7 cells. Receptor activation (IP_3 accumulation) and internalization were performed on COS7 cells stably co-expressing the Y_1 or Y_2 and the chimeric G-protein $G\alpha_{\Delta 6qi4myr}$ for pb12, pb13, ^{nat}Tb-pb12, and ^{nat}Tb-pb13 peptides. Furthermore, radiolabelling of the peptides with ^{111}In as surrogate for ^{161}Tb was conducted. Specific internalization and nuclear uptake of ^{111}In-pb12 into MCF-7 cells were determined. Finally, the ability of ^{nat}Tb-pb12 to convey terbium into MCF-7 cells was quantified using Particle-Induced X-rays Emission (PIXE). **Results:** pb12 and ^{nat}Tb-pb12 are full agonists at the Y_1 with an EC_{50} of 1.6 nM and 1.2 nM respectively while there were only able to activate the Y_2 at high concentration (10 µM). ^{nat}Tb-pb12 was able to stimulate internalization of the Y_1 whereas no internalization of the Y_2 was observed. Using PWR, binding affinities of pb12 and ^{nat}Tb-pb12 were 3.1±0.8 nM and 30.3±3.7nM respectively but pb13 and ^{nat}Tb-pb13 have no affinity regarding Y_1. On binding assays, affinities of ^{111}In-pb12 and ^{111}In-pb13 were 5.06 ± 3.52 nM and >1000 nM, respectively. Y_1-mediated internalization was 24.05 ± 8.15 % for ^{111}In-pb12 at 2h ($p = 0.006$). ^{111}In-nuclear fraction from ^{111}In-pb12 was 7.75 ± 2.44% and 4.60 ± 1.35 % of total binding at 2h without/with the cathepsin-B inhibitor CA-074Me ($p = 0.004$). Finally, PIXE experiments demonstrated the ability of ^{nat}Tb-pb12 to convey 2.27 fold more terbium into Y_1-expressing MCF-7 cells than non-exposed cells ($p = 0.041$). **Conclusion:** Our results demonstrate that the multivalent pb12 compound is a promising construct to deliver terbium in Y_1-expressing tumor cells. **References:** 1. Whole-body dynamic PET-MR imaging unveils the biodistribution and tissue kinetics of ^{11}C-buprenorphine in humans

A. Pinon[1], *C. Leroy*[1], *F. Caillé*[1], *P. Gervais*[1], *S. Jan*[1], *C. Comtat*[1], *Z. Chalampalakis*[1], *B. Fernandez*[2], *M. Bottlaender*[1], *N. Tournier*[1]; [1]*UMR 1023 IMIV, Service Hospitalier Frédéric Joliot, CEA, Inserm, CNRS, Université Paris Sud, Université Paris-Saclay, Orsay, FRANCE,* [2]*GE Healthcare, Applications & Workflow, Orsay, FRANCE.*

Aim/Introduction: Buprenorphine is a partial agonist of the µ-opioid receptors used for the management of severe pain or opioid-addiction maintenance therapy. PET imaging using radiolabeled buprenorphine offers a unique tool to non-invasively study the brain and tissue distribution in vivo and provide information regarding the clinical pharmacokinetics (PK) of this compound. We here report the first-in-human use of ^{11}C-buprenorphine obtained from a preliminary study in healthy subjects (EudraCT n°2017-001897-41). **Materials and Methods:** Buprenorphine was radiolabeled with carbon-11 at its O-methyl position to provide pharmaceutical grade ^{11}C-buprenorphine (9.7 GBq/µmol). Three healthy male volunteers (mean age 27 years) received an i.v. bolus of ^{11}C-buprenorphine (208.3±72.4MBq). Injection was immediately followed by repeated whole-body PET-MR scans acquired on a GE Signa PET-MR system during 90 min. PET images were reconstructed in order to provide whole-body dynamic PET images (with frames ranging from 2 to 16 min) automatically co-registered to MRI. Volumes of interests were drawn using Pmod software to yield decay-corrected time-activity curves in selected organs. Maximal uptake of the radioactivity in organs is expressed as the percentage of injected dose per volume (%ID.cm^{-3}±standard deviation). **Results:** In early and intermediate frames, prominent distribution sites were the liver (0.0108±0.0040%ID.cm^{-3}) and the gallbladder and bile ducts (0.1652±0.1873%ID.cm^{-3}), consistent with the known hepato-biliary clearance of buprenorphine. ^{11}C-buprenorphine was then secreted in the duodenum and progressively moved to the jejunum (0.0185±0.0162%ID.cm^{-3}) at the final frames. Accumulation of the radioactivity in the urinary bladder was relatively low (0.0353±0.0184%ID.cm^{-3} at final frame) suggesting a modest urinary excretion. The distribution of ^{11}C-buprenorphine to the brain cortex was obvious (0.0028±0.0002%ID.cm^{-3}) and consistent with the distribution of µ-opioid-receptors. A so far unreported uptake of ^{11}C-buprenorphine was observed in the myocardium

(0.0021±0.0002%ID.cm^{-3}). None of the 3 subjects experienced any adverse effects. **Conclusion:** This pilot clinical PET-MR study revealed the tissue kinetics ^{11}C-buprenorphine for the first time in humans. Imaging data are consistent with the known PK features of buprenorphine. This study confirmed the favorable safety profile of the procedure and the adequate brain uptake for opioid receptors imaging. The binding of ^{11}C-buprenorphine in the myocardium is consistent with the local expression of opioid receptors and the opioidergic regulation of cardiovascular function and myocardial stress resistance [1]. This may pave the way for the study of opioid-receptor systems in organs other than the central nervous system. **References:** [1] Headrick, J.P., See Hoe, L. E., Du Toit, E.F. and Peart,J.N. Preparation and Initial Evaluation of ^{18}F-labeled PSMA for Prostate Specific Membrane Antigen (PSMA) targeted PET imaging of Prostate Cancer

S. Okarvi, I. AlJammaz;
King Faisal Specilist Hospital and Research Centre, Riyadh, SAUDI ARABIA.

Aim/Introduction: Prostate specific membrane antigen (PSMA) expressed by most of the prostate cancers is a promising molecular target for prostate cancer diagnostic imaging and targeted radionuclide therapy. Although ^{68}Ga-PSMA-11 has been shown great potential for efficient targeting of prostate cancer in clinical settings. However, ^{68}Ga-PSMA-11 has some constraint due to its renal elimination, as radiotracer accumulation in the urinary tract may reduce the diagnostic confidence in the area of the ureter and effect the detection of local recurrence after radical prostatectomy. Additionally**,** half-life of ^{68}Ga (68 min) and limited amount of ^{68}Ga elution from the generator somewhat limited the doses for a larger group of patients. The purpose of this study was to develop a new generation PSMA ligand radiolabel with most clinically relevant and relatively longer half-life (110 min) PET radioisotope^{18}F. **Materials and Methods:** PSMA ligand, Glu-NH-CO-NH-Lys-pharmacophore was prepared by standard solid-phase peptide synthesis and linked to Ahx residue as spacer group. We have used 4-[^{18}F]fluorobenzaldehyde ([^{18}F]FB-CHO) as a synthon to prepare ^{18}F-PSMA. Aminooxy-functionalized PSMA was incubated with ([^{18}F]FB-CHO) in NH_4OAc buffer at pH 4 in the presence of MeOH at 90°C for 15 min. The resulting ^{18}F-labeled PSMA ligand was evaluated for its potential as a PET imaging probe in xenograft models expressing PSMA. Also, in vitro cell-binding was conducted on PSMA expressing LNCaP prostate cancer cell line. **Results:** The Aminooxy-functionalized PSMA was radiolabeled efficiently with ^{18}F in two-step and a high yield synthesis method to generate ^{18}F-labeled PSMA, which showed high metabolic stability in human plasma. Tumor cell binding indicated the high affinity and specificity of ^{18}F-PSMA towards PSMA-positive LNCaP prostate cancer cell line, with the binding affinity of 3.79±1.03 nM. In nude mice with LNCaP xenografts, ^{18}F-PSMA displayed efficient clearance from the blood and uptake and retention in all the major organs (excluding kidney) was found to be low to moderate (below 5%ID/g). The tumor uptake was 2.93% ID/g at 1 h p.i., with good tumor to blood and muscle ratios. **Conclusion:** Site-specific ^{18}F-labeled PSMA ligand against PSMA expression has been synthesized via chemoselective oxime formation between an aminooxy-functionalized PSMA and ^{18}F-FB-CHO moiety. Initial favorable in vitro and in vivo properties justify further preclinical studies of this PET radiotracer. **References:** None.

Aim/Introduction: Targeted delivery of cytotoxic small drug molecules using antibody-drug conjugates is a promising strategy for treatment of disseminated cancer. However, the large size of antibodies results in poor tumour penetration of the constructs. We have recently constructed a novel drug conjugate based on engineered scaffold-protein HER2-binding affibody molecule (7 kDa) fused with an albumin binding domain ABD_{035} for half-life extension. The construct was site-specifically coupled to the small drug molecule DM1. The affibody-drug conjugate (AffiDC) was designated as ($Z_{HER2:2891}$)-ABD-MC-DM1. Using radionuclide-based techniques it was possible to gather information about binding specificity, processing, in vivo kinetics and tumour targeting properties of our AffiDC. Treatment with the novel AffiDC was well tolerated and resulted in twice longer survival compared to control groups. Biodistribution studies revealed that AffiDC had high hepatic uptake. Hepatic toxicity is one of the major complications observed for many drug candidates in the clinic. We have therefore designed hydrophilized variants of our previously investigated AffiDC, containing polyglutamate spacers. The use of hydrophilic spacer for reduction of hepatic uptake was evaluated using radionuclide-based techniques. **Materials and Methods:** The three HER2-binding AffiDCs ($Z_{HER2:2891}$)-ABD-MC-DM1, ($Z_{HER2:2891}$)-ABD-E_3-MC-DM1 and ($Z_{HER2:2891}$)-ABD-E_6-MC-DM1 were site-specifically labelled with ^{99m}Tc using tricarbonyl chemistry. The binding specificity to and cellular processing by HER2-expressing cells was studied using SKOV-3 cell line. The influence of the presence or absence of glutamate spacer on the hepatic uptake was evaluated. In vivo tumour targeting properties was compared in mice bearing SKOV-3 xenografts injected with the respective radiolabelled AffiDCs and sacrificed at 4, 24 and 46 p.i. An additional group of mice bearing RAMOS xenografts (HER2-negative) was injected with the radiolabelled-AffiDCs

to confirm HER2 mediated uptake. **Results:** All three AffiDCs were efficiently labelled with ^{99m}Tc with preserved specificity of binding to HER2-expressing cells. The incorporation of the hydrophilic glutamate spacer reduced the liver uptake by 36% for both ($Z_{HER2:2891}$)-ABD-E_3-MC-DM1 and ($Z_{HER2:2891}$)-ABD-E_6-MC-DM1 compared to the parental ($Z_{HER2:2891}$)-ABD-MC-DM1 (8.7±0.2 and 8.6±0.9 vs. 13.4±0.8 %ID/g, 4 h p.i.). The newly designed hydrophilized AffiDCs targeted HER2-expressing xenografts in mice specifically. The tumour uptake was comparable to that of the parental AffiDC, ($Z_{HER2:2891}$)-ABD-MC-DM1, at all studied time points. **Conclusion:** The newly designed hydrophilized AffiDCs demonstrated reduced hepatic uptake, long residence in circulation and specific targeting of HER2-expressing xenografts. A particular advantage of radionuclide-based-techniques is that it enabled to compare the properties of several drug candidates in a quantitative manner. Thus, it represents a powerful tool for drug development. **References:** None.

Aim/Introduction: Autologous White Blood Cells (WBC) scintigraphy, the gold standard imaging procedure for diagnosis of infection, is characterized by an elaborate sequence of cell separation and radiolabelling. Besides in vivo imaging quality control, no molecular tool is available to evaluate WBC damage secondary to cell manipulation. High Mobility Group Box 1 (HMGB1) is a 30KDa protein of the alarmins family [1]. HMGB1 is secreted by activated monocytes and passively released from the nucleus of damaged cells following different types of injury [2, 3]. Aim of this study was to evaluate HMGB1 levels in plasma from patients with suspect of prosthetic joint infection (PJI), and in WBC cytosolic extracts (CE) before and after 99mTc-HMPAO labelling procedure, as a marker of induced WBC damage. **Materials and Methods:** Patients with suspect of PJI referred for WBC scintigraphy were prospectively enrolled. HMGB1 levels were evaluated in plasma at baseline (t_0), and in CE obtained from patients' leukocyte concentrate before (t_1) and after 99mTc-HMPAO labelling (t_2) by Immunoblotting analysis. In addition, blood samples from healthy donors without history or signs of acute/chronic illness were included as controls and evaluated under the same procedure. **Results:** Four patients and three healthy subjects were enrolled. Immunoblotting revealed that HMGB1 levels were significantly increased in plasma (t_0) from patients compared to healthy donors, due to the underlying disease (p=0.0028). Similar results were obtained in WBC-CE from patients (t_1) compared to healthy donors (p=0.0107). Moreover, HMGB1 levels in WBC-CE from 99mTc-HMPAO-labelled leukocyte concentrate (t_2) did not show significant changes compared to the cold cellular sample (t_1) (p=0.3369). **Conclusion:** These preliminary findings showed increased HMGB1 levels in plasma from patients with suspect of PJI. Furthermore, for each subject, HMGB1 levels evaluated in WBC-CE after radiolabelling with 99mTc-HMPAO did not show significant changes compared to those before 99mTc-HMPAO treatment. Prospective evaluation of a larger cohort of patients and controls is currently ongoing to test the results of this pilot study. **References:** 1. Goodwin GH, Sanders C, Johns EW. Molecular Mechanisms of Radium-223 Uptake in the Gastrointestinal Tract and Pharmacological Modulators to Improve Therapeutic Outcome

D. Abou[1], *N. Benabdallah*[1], *A. L. Villmer*[1], *M. Doucet*[2], *D. Chesner*[3], *N. C. Zachos*[2], *R. C. Riddle*[2], *D. L. J. Thorek*[1];
[1]*Washington University School of Medicine, Saint Louis, MO, UNITED STATES OF AMERICA,* [2]*Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA,* [3]*Johns Hopkins School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA.*

Aim/Introduction: Radium-223 dichloride is a first in class alpha particle emitting radionuclide formulation that targets sites of bone remodeling at bone metastases. It is approved for castrate resistant metastatic prostate cancer (mCRPC). An alkali earth metal series under Calcium, Radium-223 homes to the bone; however clinical experience has shown significant and rapid sequestration in the gut. Approximately 50% of the administered activity is concentrated in the duodenum several minutes after infusion. This leads to cases of gastrointestinal (GI) distress, drug cessation, and a reduction of the absorbed dose at sites of disease. We have investigated the distribution of Radium-223 in advanced small animal models of disease. Our work has shown that these model organisms recapitulate the clinical distribution of the radionuclide; and was used to elucidate mechanisms involved in uptake and transport of Radium-223. **Materials and Methods:** Radium-223 was produced using an in house microgenerator from radiochromatographic purification from source Actinium-227/Thorium-227. Naïve, male, skeletally mature, C57Bl/6 mice were administered 3.7kBq of Radium-223 dichloride in 30mM citrate for biodistribution at appropriate times after injection; excised organs were counted for activity; for autoradiographic localization in tissues; histological evaluation of radiotoxicity

in the GI was performed with immunofluorescence (IF) of TUNEL and gH2AX. Functional human gut epithelial organoids were used in a transwell assay of Radium-223 transport to evaluate a 75 compound library of ion channel modulators. Lead compounds that increased (positive control) or blocked Radium-223 transport were selected for in vivo testing of effect on distribution. **Results:** As with men, a significant proportion of administered Radium-223 was found in the intestinal tract of mice within 15min and excreted by 24h. DNA damage and cellular apoptotic cascades were observed in the duodenum and cecum at 24h in animals that had been exposed to the radionuclide therapy. Ex vivo testing of Radium-223 transport revealed an active process of transepithelial transport that could be inhibited with select pharmacophores. Lead ion-channel inhibitors were tested in vivo with coadministration of Radium-223. Biodistribution data demonstrated a decrease in early gut accumulation, renal excretion and a commensurate doubling of Radium-223 fixation in the bone. **Conclusion:** This work has detailed cellular transport processes in the intestinal epithelium that contributed to Radium-223 sequestration in this soft-tissue compartment. Pharmacological modulators from an in vitro organoid screen have in vivo efficacy. Several of these compounds are clinically approved and may contribute to improved patient management for mCRPC patients on Radium-223 dichloride. **References:** None.

Aim/Introduction: Parkinson's disease (PD) is a neuro-degenerative disorder characterized by the degeneration of dopaminergic nigrostriatal connections. The dopamine transporter (DAT) serves as a selective marker of dopamine terminal innervations in the striatum. DAT has been extensively studied through in vivo imaging by Single-Photon Emission Computed Tomography (SPECT) and Positron Emission Tomography (PET). Quantitative Structure-Activity Relationship (QSAR) analysis constitute a method for molecular design and screening of new chemical structures that has been shown to be highly effective in the prediction of physicochemical and/or pharmacological properties. In our case, we use the affinity constant to DAT binding as discriminant property. **Materials and Methods:** We have performed a QSAR analysis using a series of 65 drugs with different pharmacological properties, from which we have obtained the value of the affinity constant for DAT binding, from bibliographic reports. This property is an important requirement for the PET and SPECT radiotracers that are used to map DAT in the neuroimaging of PD. We have calculated a large number of molecular descriptors of these compounds using the DRAGON software and we have used the QSARINS software and genetic algorithm techniques to obtain the multiple linear regression (MLR) models. **Results:** The best results were obtained for the MLR model with four variables, among which are molecular descriptors related to the capacity of formation of hydrogen bonds and the lipophilic character. The values of R^2 (0.7554), Q^2 leave-one-out (0.6800) and external R^2 (0.7090) of the model, confirm its stability and robustness in predicting the value of the affinity constant DAT binding. **Conclusion:** The research for new compounds with the desired physicochemical properties requires enormous human resources and high economic cost. The proposed theoretical model can be a useful tool in predicting the binding affinity to DAT and therefore in the search for new PET and SPECT radiotracers used in the neuroimaging of PD. **References:** Brooks DJ, Pavese N. EP-0725

Theranostic Nanomedicine for Imaging and Treatment of Multiple Joints in Rheumatoid Arthritis

Z. Nosrati, *T. V. Esposito, M. Bergamo, C. Rodriguez-Rodriguez, K. Saatchi, U. O. Häfeli;*
Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, CANADA.

Aim/Introduction: Rheumatoid arthritis (RA) patients are frequently given anti-arthritic drugs including nonsteroidal anti-inflammatory drugs, glucocorticoids, disease-modifying anti-rheumatic drugs and biologics, or combinations thereof. Many patients fail to respond satisfactorily to these treatments or experience side effects. The main reason for non-ideal treatment is that insufficient drug doses reach the joints, therefore higher and more frequent doses needed.

To improve the drug pharmacological profile and direct the anti-inflammatory activity to the site of disease, i.e., the inflamed joints, we synthesized a pro-drug that increased circulation time resulting in sustained release when it reaches the microenvironment -of the inflamed joints. **Materials and Methods:** Our methods encompass the chemical syntheses of the polymeric prodrugs and the investigation of their stability and release kinetics. The pharmacokinetics of the prodrug was established after radiolabeling with In-111, and preclinical SPECT/CT imaging in an RA mouse model. The efficacy of the prodrugs is also established in the same RA model and compared to the free drug given in the same form/ timing as it is currently administered to patients. In vitro stability measurements of the prodrugs in human synovial fluid from rheumatoid arthritis patients is ongoing to better understand the impact of the local environment of an inflamed joint and how that influences drug release. **Results:** Results show that delivering methotrexate (MTX) bound to a carrier polymer produces a significant increase in drug uptake in the inflamed joints. When MTX was delivered as a prodrug, a 4x lower dose given every two weeks was just as effective as two standard dosages per week of free MTX. In addition, attaching folic acid (a targeting ligand that selectively binds to folate receptors) to the polymeric carrier helped to keep the active drug longer in the targeted lesion. **Conclusion:** In this study, using SPECT/CT we show our prodrug approach delivers higher concentrations of anti-arthritic drugs to inflamed joints than has previously been possible, despite lower and less frequent drug doses. Current studies include to utilize and test our novel pro-drug delivery system with other effective RA drugs to further improve their pharmacological profile in patients with RA. **References:** None.

Improvement and Comparison of Immobilized Artificial Membrane Chromatography (IAM) in Brain PET-Tracer Development: A Potential High Throughput Method to Predict Blood Brain Barrier Penetration?

C. Vraka[1], *S. Gloimueller*[1], *S. Mijailovic*[2], *L. Nics*[1], *M. Hacker*[1], *M. Mitterhauser*[2], *W. Wadsak*[1,3];
[1]*Radiology and Nuclear Medicine, Vienna, AUSTRIA,* [2]*Ludwig Boltzmann Institute Applied Diagnostics, Vienna, AUSTRIA,* [3]*CBmed, Graz, AUSTRIA.*

Aim/Introduction: In 2006 it was shown by Tavares et al. that permeability (Pm) measurements using immobilized artificial membrane chromatography (IAM) show a better correlation to the percent injected dose in brain than other in vitro parameters, e.g. logP [1]. Therefore, it was concluded that IAM measurements have a predictive value on blood brain barrier (BBB) penetration. In contrast, our group couldn't demonstrate any differences in Pm values between BBB penetrating and non-penetrating compounds using an extended dataset. Moreover, we found relatively high standard deviations (SD) of the Pm values caused by column batch differences and the calculation using an extrapolation to 100% aqueous phase [2]. Hence, the aim of this study is to evaluate the gradient IAM HPLC method described by Valko et al. [3] and the comparison with the described isocratic method [1,2] with regard to prediction of BBB penetration. **Materials and Methods:** For all measurements, an Agilent HPLC system (Series 1100/1200) was used. Injection volume was 5 µL of a 0.5 mg/mL reference standard solution, flow-rate was 1.0 mL/min and the linear gradient started from 0% acetonitrile (AcN) and 100% 50 mM ammonium acetate buffer (pH 7.4) to 100% AcN in 10.5 min, then keeping 100% AcN for 1 min and back to initial conditions within 0.5 min with an equilibration time of 5 min. The column (IAM P.C. DD2, 150x4.6mm) was calibrated with 8 reference compounds. Almost 100 compounds, categorized in BBB penetrating and non-penetrating drugs, will be tested. **Results:** So far, SD of the retention times are in the same range for all groups. The run time was reduced dramatically (one 15 min run in contrast to 4 different runs). However, K_{IAM} of the Tavares method show higher SD values for each compound caused by the extrapolation calculation. Additionally, no significant differences were found between the drug groups using the isocratic method. Preliminary data indicate also no significant differences between the drug groups using the gradient method. **Conclusion:** Preliminary data show a higher accuracy of the gradient method in comparison to the isocratic method. However, the results regarding the different drug groups should be compared and prediction of BBB penetration based on in-vitro IAM data has yet to be clarified. **References:** [1] Tavares AAS et al. EP-0727

Development of a potential theranostic candidate for PET imaging and Boron Neutron Capture Therapy

E. Jestin[1], *S. Bénard*[1], *V. Meneyrol*[1], *I. Ait-Arsa*[1], *J. Andries*[1], *F. Gimié*[1], *N. Goonoo*[2], *A. Bhaw-Luximon*[2];
[1]*GIP CYROI, Sainte Clotilde, FRANCE,* [2]*Biomaterials, Drug Delivery and Nanotechnology Unit, Center for Biomedical and Biomaterials Research (CBBR), University of Mauritius, Réduit, MAURITIUS.*

Aim/Introduction: Boron Neutron Capture Therapy (BNCT) is a promising radiotherapy for cancer treatment whose specificity is to deliver a precise and high dose of radiation while preserving the surrounding healthy tissue. We report here a boron containing tool that was also radiolabeled for PET imaging. **Materials and Methods:** Curcumin-BF_2 (CUR-BF_2) was synthetized. A new formulation process with copolymer PEG-b-PCL containing 1.1mg/ml of CUR-BF_2 was set up using an ethanolic formulation. No dialysis was needed to remove any organic solvent. The self-assembled polymeric micellar solution was then filtered at 0,22µm. Nanovectors size were determined with dynamic light scattering (DLS). Several in vitro IC_{50} were tested using MTT assay on MIA PACA tumor cells lines. CUR-BF2 was radiolabeled with a $^{18}F/^{19}F$ isotopic exchange method in a Tracerlab FX-FN module. The radioactive fluoride was eluted

from QMA cartridge with tetrabutylammonium bromide and dried by azeotropic distillation with acetonitrile to provide [^{18}F] TBAF. CUR-BF_2, triflic anhydride and tert-Butanol were added to the reaction vessel in acetonitrile and heated at 50°C for 15 min. The mixture was evaporated to dryness and dissolved in ethanol. Analytical HPLC measurements were performed to control the radiochemical purity, the specific activity and stabilities of the radiotracer. [^{18}F]CUR-BF_2 was formulated with copolymer PEG-b-PCL. Preliminary PET imaging studies were performed with control mice to visualize the biodistribution in organs. 7±5 MBq were injected intravenously. PET imaging acquisitions were performed during 60 min after injection. **Results:** Starting with 60GBq, [^{18}F]-CUR-BF_2 was obtained with an automation system with 97±0.5% radiochemical purities and up to 53 GBq/mg. Stabilities have shown no degradation, confirming their use for mice injection. The copolymer PEG-b-PCL allows the dissolution of up to 1.1 mg/ml of non-radioactive hydrophobic product for intravenous injection. Curcumin-loaded polymeric nanomicelles have a size distribution of 130±10 nm. PET imaging have shown accumulation in gallbladder, intestines, bladder and knee joint. **Conclusion:** A Boron-containing precursor was quantitatively radiolabeled on automated module through a ^{18}F/^{19}F isotopic exchange method with excellent RCP and SA. PET imaging are ongoing with several tumor models. **References:** None.

EP-0728

Compatibility of HYNIC-chelator with ^{99m}Tc-based Somatostatin Receptor Antagonists

R. H. Gaonkar[1], *F. Wiesmann*[1], *G. P. Nicolas*[2], *L. Del Pozzo*[1], *R. Mansi*[1], *M. Fani*[1];
[1]*Division of Radiopharmaceutical Chemistry, University Hospital Basel, Basel, SWITZERLAND,* [2]*Division of Nuclear Medicine, University Hospital Basel, Basel, SWITZERLAND.*

Aim/Introduction: PET imaging of somatostatin receptor (sstr)-expressing neuroendocrine tumors with ^{68}Ga-labeled sstr-antagonists showed improved sensitivity compared with^{68}Ga-labeled sstr-agonists[1]. Nevertheless, ^{99m}Tc remains the workhorse of diagnostic nuclear medicine. Therefore, the development of ^{99m}Tc-based sstr-antagonists is attractive and clinically relevant. Hydrazinonicotinamide (HYNIC) is a well-established chelator for ^{99m}Tc-labeling, performing excellently in combination with the sstr-agonist Tyr^3-octreotide (^{99m}Tc-HYNIC-TOC). Unexpectedly, when combined with the sstr2-antagonist SS01,^{99m}Tc-HYNIC-SS01 showed no uptake in sstr2-expressing cells[2], indicating loss of receptor recognition. The aim of this work was to determine whether HYNIC is a suitable chelator for the development of ^{99m}Tc-based sstr-antagonists. Herein we report the compatibility of HYNIC when employing spacers of different length. **Materials and Methods:** We coupled the peptide SS01, 4-Cl-Phe-cyclo(D-Cys-Tyr-D-Trp-Lys-Thr-Cys)D-Tyr-NH2,with the spacers β-Ala, Ahx (aminohexanoic), Aun (aminoundecanoic acid) or PEG4 and conjugated it with HYNIC at the N-terminus. We labeled all conjugates with 99mTc, using edda as co-ligand. We determined their hydrophilicity by partition coefficient experiments and checked their stability up to 4h on RP-HPLC. We determined in vitro cellular uptake, internalization and fate of the sstr2-surface bound radiopeptidefractionof each radio-conjugate using HEK-hsstr2cells. SPECT/CT imaging studies in HEK-hsstr2 bearing mice are in progress and will be reported. **Results:** The ^{99m}Tc-labeled conjugates formed single radioactive components with high radiochemical purity (~ 95%), which remained stable for at least 4h. The introduction of β-Ala, Ahx or PEG_4 did not significantly affect the hydrophilicity but resulted in a substantial improvement in receptor recognition, compared with^{99m}Tc-HYNIC-SS01. ^{99m}Tc-HYNIC-PEG_4-SS01 showed the highest hydrophilicity compared to ^{99m}Tc-HYNIC-Ahx-SS01 and ^{99m}Tc-HYNIC-β-Ala-SS01 (LogD= -2.03±0.13 versus -1.96±0.06 and -1.91±0.19, respectively). The introduction of Aun resulted in a very lipophilic conjugate, which was therefore excluded from further evaluation. The Ahx conjugate showed the highest uptake, with more than twice (36.60±0.19%) than that of β-Ala-(14.42±0.02%) and PEG_4- conjugates (14.77±1.93%) at 4h. Internalization rate was <14% for all conjugates, indicative of their antagonistic properties. Head-to-head SPECT/CT images of the β-Ala, Ahx and PEG_4 ^{99m}Tc-labeled conjugates will be presented. **Conclusion:** The chelator HYNIC can be considered for the development of ^{99m}Tc-based sstr2 antagonists when combined with appropriate spacers. Among the tested spacers, Ahx showed the best in vitro performance. Confirmatory studies with other analogs are on-going. **References:** 1. Nicolas G et al., J Nucl Med 2018;59:915 2. Abiraj K et al., EJNMMI Research 2018;8:75.

EP-0729

Differential ex vivo uptake analysis: an efficient method for tracer selection

M. Konrad, *M. Parzinger, A. Wurzer, R. Beck, H. Wester;*
Technical University of Munich, Garching, GERMANY.

Aim/Introduction: Typically the selection of promising candidates from a series of potential radiopharmaceuticals relies on the determination and comparative assessment of various parameters determined by in vitro and in vivo studies. A final decision is especially difficult if the candidates hardly or only marginally differ from each other, e.g. in the case of a series of peptide or peptidic diastereomers. Based on our experience that biodistribution studies even on large cohorts of animals often do not allow to accurately quantify small differences in the in vivo behavior of such compounds, we investigated whether the differential ex vivo radio-HPLC analysis of relevant tissue samples after coinjection of 4 diastereomeric ^{18}F-labeled PSMA tracers in a small cohort of mice could overcome this limitation. **Materials and Methods:** The 4 ^{18}F-PSMA inhibitors to be assessed were labeled as mixture, formulated and injected into LNCaP tumor bearing CB17-SCID mice (n=4). The relevant organs were dissected 0.5 h p.i. and homogenated using buffer with competitor (20 µM PMPA) and cell lysing components (HEPES, 1 M/NaCl, 1 M; 17:2) by means of a Potter-Elvehjem tissue grinder or a ball mill. The resulting extraction efficiencies were

calculated after centrifugation at 17,000 g and concentration of the supernatant over a StrataX SPE cartridge. The extracted solutions, containing the 4 diastereomers, were analyzed and relative percentage of each diastereomer quantified by radio-HPLC. Thereafter, the differential uptake of each diastereomer was calculated by comparison with the relative percentage of the diastereomers in the initially injected solution. **Results:** Deviating extraction efficiencies were observed for the relevant tissues and body fluids resulting in efficiencies of 90.5 ± 4.5% for blood, 48.0 ± 12.0% for kidney, and 44.0 ± 13.0% for tumor (all n=4). Quantification of radio-HPLC analyses revealed significantly different and reproducible uptake patterns for the 4 diastereomers and thus allowed for the selection of the candidate with the best tumor and lowest blood, and kidney uptake. **Conclusion:** A straight forward method was developed to identify a single peptide tracer in a mixture of 4 diastereomers as the one with the most favorable biodistribution by means of the analysis of their differential uptake patterns. This method not only delivers more accurate selection criteria of tracers with very similar in vivo behavior, but also helps to diminish the number of mice needed in preclinical evaluation. **References:** None.

EP-0731

Development of Dual sstr2- and sstr5-specific Radiolabelled Somatostatin Analogues

R. Mansi[1], *G. Nicolas*[2], *K. Abid*[3], *E. Grouzmann*[3], *A. Harris*[4], *M. Fani*[1]; [1]*Division of Radiopharmaceutical Chemistry, University Hospital Basel, Basel, SWITZERLAND,* [2]*Division of Nuclear Medicine, University Hospital Basel, Basel, SWITZERLAND,* [3]*Catecholamine and Peptides Laboratory, University Hospital of Lausanne, Lausanne, SWITZERLAND,* [4]*Somtheranostics SARL, Chemin du Midi 6, CH-1053 Cugy, SWITZERLAND.*

Aim/Introduction: Clinically approved radiolabelled somatostatin analogues show high affinity for the somatostatin receptor (sstr) subtype 2 (sstr2). Neuroendocrine tumours (NETs) mainly overexpress sstr2, however, co-expression of the subtype 5 (sstr5) has been reported in 20-50% of intestinal or bronchial NETs[1]. Therefore, dual sstr2- and sstr5-targeting has the potential of enhancing the radiotracer uptake on NET cells, the image contrast and the tumour absorbed dose. In this study, we report on the development of a new somatostatin analogue as a radio-theranostic agent for dual sstr2- and sstr5-targeting. **Materials and Methods:** We selected the 2-iodo-aminoacid analogue G02113 ((4-amino-3-iodo)-D-Phe-c[Cys-(3-iodo)-Tyr-D-Trp-Lys-Val-Cys]-Thr-NH_2)[2] with high sstr2 and 5 affinity, conjugated it with the chelator DOTA and labelled it with ^{68}Ga and ^{177}Lu. We characterized both radiotracers in vitro and in vivo using HEK cells with stably transfected human sstr2 (HEK-hsstr2) and sstr5 (HEK-hsstr5). We determined the affinity of ^{68}Ga-/^{177}Lu-DOTA-G02113 to each receptor subtype and studied their biodistribution, pharmacokinetics and imaging with dedicated micro PET/CT and SPECT/CT scanners. In our study, we used ^{68}Ga-/^{177}Lu-DOTA-NOC as reference. **Results:** ^{nat}Ga- and ^{nat}Lu-DOTA-G02113 have a similarly high affinity for sstr2 (IC_{50} = 0.32 and 0.35 nM, respectively), while the one for sstr5 is higher for ^{nat}Ga-DOTA-G02113 than for its ^{nat}Lu-counterpart (IC_{50}= 1.86 and 3.5 nM, respectively). Compared to ^{nat}Lu-DOTA-NOC, ^{nat}Lu-DOTA-G02113 has slightly better affinities for both receptor subtypes, however lower internalization rate (26.8±1.5% vs 18.1±0.7%, at 4h in HEK-hsstr2) with comparable externalization rate (40-50% within 4h). ^{68}Ga-DOTA-G02113 showed a high uptake in sstr2- and sstr5-expressing tumours (26.3±8.2 and 14.9±5.9 %IA/g, 1h p.i., respectively), similarly to ^{68}Ga-DOTA-NOC (30.1±8.2 and 11.6±5.0 %IA/g, respectively). There was a substantial kidney uptake (14.1±3.7 %IA/g at 1h p.i.), indicating renal excretion, and a noticeable liver uptake (6.4±1.9 %IA/g), possibly due to the lipophilicity of the radiotracer (log D = -0.95±0.1). ^{177}Lu-DOTA-G02113 reached its maximal uptake at 1h p.i. on sstr2- and sstr5-tumour (14.2±1.8 and 1.8±0.3 %IA/g, respectively), while about 60% remained in both tumours at 24h p.i. The mean time-integrated activity coefficient of ^{177}Lu-DOTA-G02113 was 8.6 h and 0.8 h in sstr2- and sstr5-expressing tumours, respectively. **Conclusion:** ^{68}Ga-DOTA-G02113 reveals its ability to target both receptor subtype sstr2 and sstr5 with high affinity, while in vivo results suggest suboptimal pharmacokinetic properties of ^{177}Lu-DOTA-G02113 for targeting sstr5. **References:** 1. Comparison of two potential ^{47}Ca/^{47}Sc radionuclide generator systems

D. Pawlak, W. Wojdowska, M. Żółtowska, I. Cieszykowska, J. L. Parus, P. Garnuszek, R. Mikołajczak;
Radioisotope Centre POLATOM, National Institute for Nuclear Research, Otwock, POLAND.

Aim/Introduction: Scandium-47 ($T_{1/2}$ = 3.35d, $E_{\beta max}$ = 600 keV), beta emitter with energy higher than that of ^{177}Lu ($T_{1/2}$ = 6.73d, $E_{\beta max}$ = 498 keV), is an attractive therapeutic radionuclide. It can be produced by irradiation of ^{46}Ca with thermal neutrons in ^{46}Ca(n,γ)^{47}Ca→^{47}Sc nuclear reaction or in cyclotrons via ^{48}Ca(p,2n)^{47}Sc channel. Due to the longer half-life of ^{47}Ca ($T_{1/2}$ = 4.54d) the ^{47}Ca/^{47}Sc system can serve as radionuclide generator. The aim of this work was to compare two methods of ^{47}Sc separation from ^{47}Ca allowing multiple separation of ^{47}Sc solution of high radionuclidic and chemical purity suitable for radiolabeling of DOTA-peptides. **Materials and Methods:**

$CaCO_3$ targets (40 mg, 5.0% enrichment in ^{46}Ca) were irradiated for 150 h in thermal neutron flux of 1.2 10^{14} $cm^{-2}s^{-1}$ in Maria reactor. Targets dissolved in HCl were loaded either on the extraction chromatography column with TBP (tributylphosphate) resin or the DGA (N,N,N′,N′-tetra-n-octyldiglycolamide) resin (Triskem Int). ^{47}Sc was eluted from DGA with 0.05 M HCl, and was used as such for radiolabelling of DOTATATE while ^{47}Sc was eluted from TBP with water and passed through the cation exchange column (AG50W-X8) to decrease its acidity. Subsequent separations of ^{47}Sc were carried out after about 4 days needed for ingrowth of ^{47}Sc. Target material was recovered via precipitation of calcium carbonate for repeated irradiation. **Results:** Irradiation of ^{46}Ca enriched targets resulted in radioactivity up to 400 and 300 MBq at EOB for ^{47}Ca and ^{47}Sc, respectively. Separation yields of ^{47}Sc in 4 consecutive separations were: about 80% for the TBP and about 90% for the DGA. The only measured radionuclidic impurity was ^{47}Ca with the concentration below 0.1% for both methods. DOTATATE labeling yields were above 90% and were comparable for both methods. **Conclusion:** Both tested extraction chromatography resins, DGA and TBP, allow to obtain ^{47}Sc with high yield and purity suitable for preparing radiopharmaceuticals. In addition, we demonstrated that ^{47}Sc can be effectively separated from ^{47}Ca up to 15 days after EOB. Acknowledgements: This project was supported with the funds awarded by the Ministry of Science and Higher Education in Poland within the agreement No. 3639/FAO/IAEA/16/2017/0, IAEA Research Contract No. 20496 and CERAD project, financed under Smart Growth Operational Programme 2014-2020, Priority IV, Measure 4.2. **References:** None.

EP-0733

SPE on tributyl phosphate resin as an alternative method of ^{47}Sc separation from ^{47}Ca

M. Zóltowska, D. Pawlak, W. Wojdowska, I. Cieszykowska, J. L. Parus, R. Mikołajczak;
Radioisotope Centre POLATOM, National Centre for Nuclear Research, Otwock, POLAND.

Aim/Introduction: ^{47}Sc ($T_{1/2}$ = 3.35d) is an attractive theranostic radionuclide due to its twin radionuclides emitting positrons ^{43}Sc and ^{44}Sc. It can be produced in $^{46}Ca(n,\gamma)^{47}Ca \rightarrow ^{47}Sc$ nuclear reaction with thermal neutrons. However, separation of ^{47}Sc from excess of Ca is a challenge, since the mass ratio of ^{47}Sc to Ca in the irradiated target ranges 1 to 10^6 - 10^8. In our experience, out of several methods investigated for separation of Sc from Ca, the extraction chromatography on tributyl phosphate (TBP) resin was found to be promising. Herein, in order to facilitate the separation process, we determined the separation coefficients (ion distribution between the resin and the solution in equilibrium, D_w) for Sc on TBP resin and HCl at various concentrations. **Materials and Methods:** Natural $CaCO_3$ (Sigma Aldrich), TBP resin (tributyl phosphate, TrisKem), 36% HCl, Fluka and ^{46}Sc ($T_{1/2}$ = 83.8 d) as a tracer were used. TBP distribution coefficients D_w were determined as described by Horwitz et al. [1]. In brief, three reference solutions of ^{46}Sc were prepared, against which the sorption efficiency of ^{46}Sc on TBP was investigated. Eppendorf vials with 50 mg TBP resin were weighed and 1 mL HCl of appropriate concentration was added. After soaking the resin, 40 µL (5ng) of ^{46}Sc solution was added, vials were shaken for 1 h and left for 10 minutes to stabilize the phases. Supernatant was separated by centrifugation and radioactivity of 100 µl aliquots was measured. **Results:** The calculated D_w values indicated that ^{47}Sc separation from Ca is most efficient in the HCl concentration range from 7.5 to 10 M. These findings were confirmed by separation of nuclear reactor produced ^{47}Sc on TBP resin from 9 M HCl solution with the 82% yield. The obtained ^{47}Sc was used to radiolabel DOTATATE with 95% radiochemical purity and specific activity 5.8 MBq/nmol. The influence of calcium excess on D_w values was also examined. **Conclusion:** Separation of Sc in HCl is most effective on TBP resin when using HCl in the concentration range 7.5-10 M. This was confirmed by ^{47}Sc separation with the yield higher than 80% when using 9 M HCl. Acknowledgements: This project was supported with the funds awarded by the Ministry of Science and Higher Education in Poland within the agreement Nr 3639/FAO/IAEA/16/2017/0 and CERAD project, financed under Smart Growth Operational Programme 2014-2020, Priority IV, Measure 4.2. **References:** [1] E.P. EP-0734

Development of a solid target system

D. Szikra[1], V. Forgács[1], G. Nagy[2], A. Vágner[2], A. Fekete[1], G. Trencsényi[1];
[1]University of Debrecen, Faculty of Medicine, Medical Imaging Department, Division of Nuclear Medicine, Debrecen, HUNGARY, [2]Scanomed Ltd., Debrecen, HUNGARY.

Aim/Introduction: Automatized production of radiometals for PET imaging is becoming more important, as the theragnostic concept gains broader application in the treatment of oncological patients. Working with cyclotron produced isotopes on a daily basis always calls for automatization of every possible process in order to decease personnel dose. Handling of the irradiated targets is causing the highest doses from the irradiated material and from the high backdround of the cyclotron bunker. Our aim was the development of a simple pneumatically actuated shuttle type solid target handling system for the production of 44Sc, 68Ga, 52Mn and other isotopes. **Materials and Methods:** A GE PETtrace 800 Cyclotron is used for daily production of 18F and 11C in our institute. The solid target system was designed not to disturb the routine isotope production The target system was constructed by using the beam entrance and foil holder parts of an old GE water target. Onto these parts a pneumatically actuated aluminum block was attached, that accepts the shuttle with the target material. When the shuttle is slided to the beam line by the metal block, it cooled from the back with a water cooling chamber. **Results:** Solid calcium pellet was pressed into the 8mm diameter cavity of the target shuttle and irradiated with beam currents up to 40 uA for 60-120 minutes without

any noticeable overheating or degradation. Irradiated calcium could be readily dissolved from the aluminum (AlMgSi1) shuttle with 4ml 3M HCl. Solid chromium, zinc powder or lead foil were also successfully applied for the production of ^{52}Mn, ^{68}Ga and $^{205/206}$Bi, respectively. **Conclusion:** The prepared target shuttles can be inserted into a shuttle port outside the cyclotron bunker, and transported through flexible tubing into the irradiation port. Irradiated shuttles can be transported back and dropped directly into a lead pot after irradiation, minimizing personnel dose. **References:** None.

[^{89}Zr]ZrOx/Cl preparation on commercial cassette base synthesis module

E. Cazzola[1], *J. Amico*[1], *A. Kotliarenko*[2], *D. Peruzzi*[1], *O. Azzolini*[2], *A. D'Angelo*[1], *M. Malachini*[1], *G. Keppel*[2], *G. Gorgoni*[1];
[1]*Ospedale Sacro Cuore, Negrar, ITALY,* [2]*National Institute of Nuclear Physics -INFN LNL, Legnaro, ITALY.*

Aim/Introduction: [^{89}Zr]Zirconium is one of the emergent isotope due to the favorable PET imaging characteristics (β+max 0.395 MeV; 22.7%) and halflife (T½78.4h) ideal to labeling Antibodies. Monoclonal antibodies (MAbs) are the most approved biopharmaceutical in the word with a multiple and selective targets.The immunoPET can facilitate the approval for new MAbs and can help on patient selection. Due of this needs a robust production, purification and labelling procedure should be optimized on automatic modules in order to minimize the operator dosimetry and increase the reproducibility.Aim of this work is based on easy modification of automatic, cassette base, commercial module in order to dissolve and purify the [89Zr]Zirconium in both formulation currently used from sputtered target. The single use cassette reducing the possibility to accumulate metal impurities in the purification step due to missing cleaning step mandatory on synthesis modules based on fixed tubes technology. **Materials and Methods:** A Eckert&Ziegler cassette base module were used to set up an automatic dissolution and purification procedure. The Sputtered [89Y]Yttrium targets were bombarded on TR-19 cyclotron at 12.5 MeV without degrader at different current 20-60 μA for a variable time 30-240 minutes. The coins were transferred on dedicated coated hotcell and finally insert on a EZAG module in order to dissolve and purify the [89Zr]/[89Y] material in a single use cassette. A 2 N HCl solution was used to dissolve the target material, the solution was transfer to ZR resin (Triskem) and recovered on vial in oxalate or chloride forms. **Results:** Ten sputtered target were processed after bombardment and final impurities profile were evaluated by γ-spettrometry and by ICP-MS. Molar Activity were calculated by tritation with DFO for booth chemical forms. **Conclusion:** What we described on this work is one of the possible way to optimize the [89Zr]Zirconium production starting from [89Y]Yttrium sputtered target, with a simple and single use cassette recovery process based on EZAG module to minimize the impurities. **References:** None.

US DOE Tri-Lab Research and Production Effort to Provide Accelerator-Produced ^{225}Ac for Radiotherapy: 2019 Update

K. John;
Los Alamos National Laboratory, Los Alamos, NM, UNITED STATES OF AMERICA.

Aim/Introduction: The current availability of accelerator produced ^{225}Ac from the US Department of Energy Isotope Program's Tri-Lab (ORNL, BNL, LANL) Research and Production Effort to Provide Accelerator-Produced ^{225}Ac for Radiotherapy will be presented. **Materials and Methods:** The Tri-Lab effort produces ^{225}Ac via the ^{232}Th(p,x)^{225}Ac nuclear reaction leveraging the US DOE high-energy accelerator facilities at Brookhaven National Laboratory (200 MeV at 165 μA) and Los Alamos National Laboratory (100 MeV at 275 μA). Targets are processed and final product is distributed from Oak Ridge National Laboratory. **Results:** To date, the Tri-Lab effort has produced and distributed over 250 mCi of accelerator-produced ^{225}Ac to end users for overall product evaluation including a variety of dosimetry, toxicity and biodistribution studies. Results of these studies suggest that the impact of the ^{227}Ac co-product on patient dosimetry will be minimal. Challenges remain with respect to the logistical considerations associated with the ^{227}Ac co-product including facility licensing and disposition of patient waste. **Conclusion:** The US DOE Tri-Lab effort is routinely distributing accelerator-produced ^{225}Ac for pre-clinical R&D with the aim of supporting clinical studies. Short term effort is focused on development of a Drug Master File with long term effort focused on development of processing capabilities aimed at supporting Ci-scale batches. **References:** (1) J.W. ^{68}Ga-Labeling of PSMA-11: Which Technique is the Best?

S. Pfaff[1,2], *V. Pichler*[1], *E. Schaier*[1,2], *F. Girschele*[1], *C. Philippe*[1], *M. Hacker*[1], *M. Mitterhauser*[1,3], *W. Wadsak*[1,4];

Applied Diagnostics, Vienna, AUSTRIA, [4]CBmed GmbH - Center for Biomarker Research in Medicine, Graz, AUSTRIA.

Aim/Introduction: ^{68}Ga-radiolabeling is probably one of the most interesting applications for radiopharmacy facilities, since this nuclide is easily available through ^{68}Ge/^{68}Ga-generators and the popularity of [^{68}Ga]Ga-PSMA-11 is flourishing. Besides conventional ^{68}Ga-complexations via synthesizing modules that are usually cassette-based or fixed-tubing-based, exotic techniques like microwave assisted- or microfluidic synthesis are available for radiolabeling. Recently, a KIT for ^{68}Ga-labeling of PSMA-11 was developed that does not need any synthesizers or energy supply. However, choosing the best approach among these possibilities is demanding and needs conscientious research. Consequently, this study aimed to compare a microfluidic-, microwave assisted-, KIT-, cassette-and fixed-tubing-based ^{68}Ga-labeling regarding their applicability and efficiency. **Materials and Methods:** PSMA-11 was purchased from ABX (Radeberg, Germany) and the KIT was provided by ANMI (Liege, Belgium). Gallium-68 was obtained from a ^{68}Ge/^{68}Ga-generator (GalliaPharm® from EZAG, Berlin, Germany or Galli Eo™/Ad from IRE Elit, Fleurus, Belgium). The applied synthesizers were SynChrom R&D (Elysia-raytest, Straubenhardt, Germany), GRP+ (Scintomics, Fürstenfeldbruck, Germany), PET-wave (CEM, Kamp-Lintfort, Germany) and NanoTek (Advion, Ithaca, USA) and the applied precursor concentrations were 2.5, 1.4, 0.42 and 0.5 µg/mL, respectively. The radiochemical conversion rate (RCR, determined by TLC and HPLC), radiochemical yield (RCY, content of product related to the starting activity, corrected for decay) or/and RCY not corrected for decay (RCY ncd) were determined. **Results:** ^{68}Ga-complexations of PSMA-11 using a microfluidic device resulted in a RCR of 93.3±7.5%. A RCR of 91.0±2.1% was achieved via microwave assisted synthesis in less than 1 min. The cassette-based-system resulted in a RCY ncd of 45.3±2.3% and shows overall synthesis time of more than 30 min. The fixed-tubing-based synthesizer achieved a RCY ncd of 73.7±6.2. KIT-based labeling gave a quantitative RCY ncd ≥ 90.3±2.6% within 5 min with minimal handling requirements. **Conclusion:** Microfluidic synthesis of [^{68}Ga]Ga-PSMA-11 was performed using low precursor amounts. Due to the ability of performing numerous syntheses consecutively, this approach could be feasible for a dose-on-demand approach using higher activities of cyclotron produced gallium-68. Microwave assisted synthesis achieved quantitative RCRs within <1 min using a remarkable low precursor amount. Hence, this approach is worth pursuing for clinical routine productions. The cassette-based-system achieved a good RCY, but the synthesis duration of >30 min reduces the activity yield. In contrast, the fixed-tubing-based system enabled high RCY in <20 min. The KIT needs a higher precursor amount, but enables a broad implementation of [^{68}Ga]Ga-PSMA-11 in radiopharmacy facilities due to its convenient applicability and low technical effort. **References:** None.

[^{18}F]FET production with a modified gallium-68 automated synthesizer in a Radiopharmacy without cyclotron facility

M. Riondato, *S. Pastorino, E. Giovannini, O. Ferrando, P. Lazzeri, V. Duce, A. Ciarmiello;*
Nuclear Medicine Department, La Spezia, ITALY.

Aim/Introduction: Among PET imaging applications, O-(2-[18F]fluoroethyl)-L-tyrosine ([^{18}F]FET) is gaining attention for the assessing brain tumors. [^{18}F]FET is an established radiopharmaceutical not commonly available in Italy, used by few hospital radiopharmacies with a cyclotron facility or purchased by other countries. The aim of this study is to demonstrate that a radiopharmacy without a cyclotron facility, but implemented with an automated synthesizer typically dedicated for 68Ga chemistry and a fully equipped Quality Controls (QCs) laboratory, can prepare [^{18}F]FET according to the European Pharmacopoeia(PhE) monograph starting from an external supply of [^{18}F]fluoride for radiolabeling. **Materials and Methods:** [^{18}F]FET radiosynthesis was carried out using a standard Modular-Lab PharmTracer (Eckert & Ziegler, EZ) in the typical setting for the production of gallium-68 peptides, implemented with a commercially available chemical vacuum pump (Laboport) and an external additional 3-way valve (Burkert). EZ disposable cassettes for 68Ga-peptide synthesis are reassembled and the reactor replaced with a glass MX-Tracerlab (GE). All reagents were purchased by ABX. All purifications were performed with on-line cartridges (QMA-Light, C18-Plus Long and Alumina N cartridges, Waters). [^{18}F]fluorine for radiolabeling (PhE grade), initially used to assess critical steps of radiosynthesis was 7.5-12 GBq. **Results:** [^{18}F]fluoride was automatically transferred (pneumatic system) from the shipped vial to an anionic exchange cartridge. After elution and azeotropic distillation, TET precursor (10 mg in 3.5 ml ACN) was added to the activated [18F]fluoride and the mixture heated at 100°C for 500 sec. Best hydrolysis condition was found in 1N HCl (3.5 ml) at 100°C for 15 min. Diluted and cooled reaction mixture was transferred on a C18-Plus Long cartridge and washed with water. Cartridge containing [^{18}F]FET was then eluted with 9 ml of ethanol/water (5:95 v/v). First 2 ml were discarted, while the rest collected after purification on Alumina N cartridge. The product was reformulated with saline to the standard final batch volume of 20 ml, and sterilized and collected. [^{18}F]FET was obtained during validation syntheses in a non-decay corrected yield of 24.1%±3.1% (n=8). After QCs all batches of [^{18}F]FET respected the monograph specifications. For the evaluation of enantiomeric purity, an easy, cheap and fast thin layer chromatography (TLC) method was proposed and successfully carried out. **Conclusion:** This work presents an initial experience of [^{18}F]FET production using an automated synthesis module, commonly applied for 68Ga-tracers. Synthetic strategy details and final purification without a HPLC are presented. **References:** None.

EP-0739

[^{131}I]ICF01012 automated radiosynthesis for first human targeted radiotherapy of metastatic melanoma

M. Cosson[1], *S. Levesque*[1], *M. Tempier*[1], *S. Tarrit*[2], *M. Galmier*[2], *J. Chezal*[2], *E. Miot-Noirault*[2], *F. Cachin*[1], *P. Auzeloux*[2];
[1]*Centre Jean Perrin - Service médecine nucléaire, Clermont Ferrand, FRANCE,* [2]*INSERM UMR1240 – Imagerie moléculaire et stratégies théranostiques (IMoST) – Université Clermont Auvergne (UCA), Clermont Ferrand, FRANCE.*

Aim/Introduction: [^{131}I]ICF01012 is a candidate for targeted radiotherapy of metastatic melanoma.[1-4] To complies with the current Good Radiopharmacy Practice, as well as for radiation protection, we developed a fully automated radiosynthesis on AllinOne tracer synthesizer (Trasis). We present here the main chemical and pharmaceutical data necessary for achieving the Investigational Medicinal Product Dossier (IMPD). **Materials and Methods:** Both radioactive precursor (Na^{131}I solution, Izotop) and chemical stannyl precursor (ERAS Labo) are GMP grade. The radiolabelling step is a nucleophilic substitution in acidic (HCl) conditions in presence of hydrogen peroxyde as oxydazer. Purification is achieved on a C18 cartridge. Finally, the product is eluted with an ethanol/water solution (15:85, v/v). Final sterilisation is conducted by filtration (0.22 µm filter). The synthesis module is located in a shielded hot cell that ensure a grade B environment in a grade C laboratory. The disposable cassette and program lines were specifically designed for this production. Eleven tests were checked on the final product: appearance, pH (paper), identification and radionucleidic purity (gamma spectrometer, Ortec), filter integrity (AiO, Trasis), endotoxin (Endosafe-PTS, Charles River). We use radio-HPLC (Shimadzu, Kinetex C18 column, Phenomenex) for identification, radiochemical and chemical purity of [^{131}I]ICF01012 solution. The only externalise tests are the determination of residual solvents and the sterility test. **Results:** Three consecutives synthesis of [^{131}I]ICF01012 were carried out for IMPD. The total radiosynthesis procedure time is less than 30 minutes. The mean radiochemical yield is 70% (64-76%). The HPLC method (12 min) is validated and allows to obtain identification of [^{131}I]ICF01012, chemical and radiochemical purity, and specific activity. The radiochemical purity is 97.7±0.5%, with an average specific activity of 31 GBq.µmol^{-1}. The chemical purity measurement showed that the residual amount of stannane chemical precursor is below the limit of quantification (50 ng.mL^{-1}). All intern release tests are carried out in less than 30 minutes after the end of production. Radiochemical stability was evaluated during the first 4 hours, without any de-iodation observed. **Conclusion:** Process validation was successfully performed by preparing and controlling three consecutive batches of [^{131}I] ICF01012. Our IMPD was validated in 2018 by the national French authority (ANSM). The clinical trial is active since January 2019. **References:** 1-Chezal JM et al., brevet PCT WO2008012782, 2008. 2-Chezal JM et al., J. Med. Chem., 2008, 51, 3133-3144. 3-Degoul F et al., Int. J. EP-0740

Radiolabeling of an anti-CD66 antibody with diagnostic and therapeutic radionuclides and biological evaluation

G. Fischer, *C. Hamp, J. Wenz, G. Winter, G. Glatting, A. J. Beer, C. Solbach;*
University Hospital, Ulm, GERMANY.

Aim/Introduction: Electron emitter-labeled anti-CD66 antibodies can be used for radioimmunotherapy within the concept of myeloablation prior to stem cell transplantation, with the aim of reducing side effects compared to conventional strategies. In addition to radiotherapy, radiolabeling with In-111 or Ga-68 enables diagnostic SPECT- or PET-imaging i.a. for dosimetry. Due to manufacturer-related antibody-modifications, the chelator conjugation procedure and the radiolabeling procedure needed to be re-established with respect to the radiometals Ga-68, In-111 and Y-90. Moreover, the biological evaluation of the antibody quality was extensively adapted. **Materials and Methods:** The conjugation chemistry of the antibody and the chelator DTPA (via p-SCN-Bn-CHX-A″-DTPA) was performed in 0.05 M HEPES buffer at pH 8.5 for 2 h at ambient temperature and was subsequently stored for 15 h at 4-8°C. SEC-LC followed by ultrafiltration was performed for antibody purification. An aliquot of the radionuclide (up to 788 MBq for Y-90 and up to 52 MBq for In-111 or Ga-68) in hydrochloric acid was adjusted with sodium-, ammonium-acetate or HEPES-buffer to a pH of 5 to 6, followed by the addition of 50-200 µg antibody in 15-214 µl of 0.9% NaCl-solution. Radiolabeling succeeded within a reaction time of 10 min at ambient temperature (Ga-68 and Y-90) or 1 h at 37°C (In-111). The chelator-to-antibody ratio (antibody/Arsenazo III competition test) and the antibody concentration were determined by spectrophotometric evaluation. The immunoreactivity of the antibody was determined by cell binding assay (granulocytes). Serum stability tests were performed by adding an aliquot of antibody to human serum at 37°C with subsequent analysis by radio-HPLC. **Results:** Chemical purities of the antibody conjugated with DTPA after purification were >95%. Radiolabeling yields were up to 96% for Y-90, 80% for Ga-68 and 74% in case of In-111. Ultrafiltration increased the radiochemical purities of In-111 and Y-90 labeled antibodies to >95%. The determined antibody-chelator-ratios were in the range of 4-6. Final antibody concentrations of 1-4 mg/ml were obtained by the purification procedure. Immunoreactivity tests showed that up to 90% of the Y-90 and 70% of In-111 labeled antibodies still bind to CD66 surface-proteins of granulocytes. In-111 labeled antibodies showed a high biological stability in human serum (88% intact after 24 h). **Conclusion:** The antibody-conjugation, the radiolabeling procedure and the biological tests were successfully re-established and transferred into a protocol-based, validated and GMP-compatible procedure. **References:** None.

EP-0741

High yield synthesis of [^{11}C]Methionine via [^{11}C] Methyltriflate by use of the Loop Method

C. Solbach, F. Arndt, R. Gratzl, A. J. Beer, G. Fischer, J. Wenz;
Clinic for Nuclear Medicine, University of Ulm, Ulm, GERMANY.

Aim/Introduction: [^{11}C]Methionine ([^{11}C]MET) is one of the most applied PET-radiopharmaceuticals. It is successfully used for the evaluation of brain tumors by PET. The corresponding radiosyntheses for the production of [^{11}C]MET use L-homocysteinethiolactone (HCTL) or L-homocysteine (HC) as precursors and [^{11}C]methyliodide ([^{11}C]MeI) as labelling precursor. Although these well-established production methods content a final chromatographic method as solid phase extraction or radio-HPLC for the separation of the product [^{11}C]MET from the reaction mixture, a clear contamination of the final radiopharmaceutical product solution with „cold" chemical impurities (e.g. HC, HCTL) may still occur. The application of the "loop-method" by use of the highly reactive C-11 labelling precursor [^{11}C]methyltrifluoromethylsulfonate ([^{11}C]MeOTf) for the production of [^{11}C]MET may reduce the content of cold impurities significantly due to a clearly reduced precursor amount. Moreover, the use of [^{11}C]MeOTf should lead to high radiochemical yields of [^{11}C]MET in a clearly shortened process time. **Materials and Methods:** $^{11}CO_2$ is produced by use of the ^{14}N(p,α)^{11}C-nuclear reaction (PETtrace 800 cyclotron, GE) followed by automated transformation into [^{11}C]MeI (MeI microlab, GE) and on-line conversion into [^{11}C]MeOTf by use of silvertriflate (on Graphpac GC) at 200 ° C. By passing the gaseous and highly reactive [^{11}C]MeOTf in a moderate inert gas flow (He 6.0, 50 ml/min) through the reaction loop (l: 700 mm, i.d.: 1mm, polyethylene; containing a solution of 375 µg (2.45 µmol) of L-HCTL and 1.8 mg (45 µmol) NaOH in 100 µl EtOH/H_2O 70/30 v/v) of a TRASIS All in one cassette module the desired product [^{11}C]MET is build. The labelling step is then followed by rinsing the reaction loop with 15 ml of PBS via 2 conditioned C-18 Sep Pak Plus SPE cartridges (Waters) and subsequently sterile filtration through a 0.22 µm sterile filter into a sterile septum sealed product container. **Results:** The loop method succeeds within 18 min after EOB (end of bombardment) and in excellent radiochemical yields of 37-50 % with respect to $^{11}CO_2$ allowing absolute yields of up to 35 GBq of [^{11}C]MET. The radiochemical purity of the final radiopharmaceutical solution was always >99%. The content of HCTL was always below the detection limit whereas the content of HC was always <22 µg/ml (<330 µg/batch). **Conclusion:** An effective and rapid method for the production of highly pure [^{11}C]MET allowing multi-patient application has been developed. Additionally, the reaction is characterized by the use of disposable products, whereby the reaction can be performed GMP compliant. **References:** None.

Investigation of automated radiofluorination methods for oxidatively sensitive aryl systems

A. McDonald[1,2,3], Y. W. Goh[1,2], J. M. White[3], A. Scott[1,2,4], U. Ackermann[1,2,4];
[1]Olivia Newton John Cancer Research Institute and La Trobe University, Heidelberg, AUSTRALIA, [2]Department of Molecular Imaging and Therapy, Austin Health, Heidelberg, AUSTRALIA, [3]School of Chemistry and Bio21 Institute, The University of Melbourne, Parkville, AUSTRALIA, [4]Department of Medicine, The University of Melbourne, Parkville, AUSTRALIA.

Aim/Introduction: Radio fluorination of aryl systems has been a significant challenge in the area of radiochemistry for some time. As more methods are developed, it is important to select the appropriate system for the target molecule at hand. A molecule of interest to our research group was the N-(4-chlorobenzyl)- indole-3-carbaldehyde, denoted Oncrasin-1, due to its potential as a radiotracer for oncology. Fluorination of this system was investigated, with radio fluorination of the benzyl ring at 3 different positions being to determine the optimal lead compound. This work investigates two precursor classes for radiolabelling; iodonium salts have been popular, with a variety of methods for forming them, compared with relatively new in boronic acid/ester precursor radiofluorination. **Materials and Methods:** Precursor synthesis was envisioned through coupling between an appropriate iodobenzyl halide and the indole-3-carbaldehyde, followed by oxidation to the iodonium salt. Successful synthesis of the iodobenzyl intermediate was followed by attempts to form a precursor utilizing multistep and one pot procedures were unsuccessful. Boronic acid pinacol ester precursors were synthesized through both a miyaura borylation with the iodine precursor previously synthesized as well as a sodium hydride coupling of the indole-3-carbaldehyde and the appropriate boronic ester benzyl bromide. Radiolabelling of this system was undertaken in an automated Flexlab module and utilized a custom potassium triflate eluent in combination with a copper triflate catalyst and pyridine co-solvent to produce radiofluorinated products. **Results:** Iodonium salt forming reactions were investigated using a benzyl iodide precursor. These reactions were unsuccessful however a multistep synthesis utilizing a diacetoxy-iodo intermediate produced a ring opened structure indicating that these conditions were preferentially oxidizing the indole structure over the desired benzyl iodide. Methods utilizing boronic acid pinacol ester precursors in combination with a copper triflate catalyst system initially produced no labelled products prior to fluoride elution optimization; standard bicarbonate and carbonate eluent systems result in alternative reactions. A potassium triflate eluent system was developed with a preconditioned carbonate QMA. Further optimization of the system was undertaken, with a preformed copper catalyst being less effective than the catalyst system formed in situ. Yields of 10-18% were obtained for the three precursors. **Conclusion:** Radiolabelling of aryl systems containing electron rich indole scaffolds should consider avoiding traditional iodonium salt forming reactions as oxidative

side reactions appear to be favoured over the iodonium salt forming reaction. Instead, boronic acid ester precursors offer an attractive alternative route for radiofluorination of these systems. **References:** None.

EP-0743

Synthesis and Complex Chemistry of the Bifunctional HBED-NN Chelator

A. Makarem, K. Klika, G. Litau, Y. Remde, K. Kopka;
German Cancer Research Center, Heidelberg, GERMANY.

Aim/Introduction: Radiometal-based radiopharmaceuticals bearing bifunctional HBED chelators are powerful tools for cancer diagnosis and therapy.[1] Bifunctional HBED chelators make strong complexes with trivalent gallium, and additionally, can be conjugated to bioactive molecules.[2] In this context, the copper(I)-catalyzed azide-alkyne cycloaddition (CuAAC) reaction is one of the popular conjugation methods for linking complexing agents to bioactive molecules.[3] We hereby introduce di-tert-butyl 2,2'-(ethane-1,2-diylbis{[5-(2-azidoethyl)-2-hydroxybenzyl]azanediyl})diacetate (in short: HBED-NN) as the first bifunctional HBED chelator with two terminal azide groups for direct "click" conjugation. We also studied this chelator for its potential use in gallium-based radiopharmaceuticals. Although the pharmaceutical profile of the hexadentate [Ga(HBED)] framework has been studied multiple times in other researches,[4] the exact structure of this complex has not been confirmed yet. For this reason, we investigated the complex chemistry of the [Ga(HBED)] coordination sphere and determined its structure geometry. **Materials and Methods:** The HBED-NN chelator entered into defined CuAAC reactions as well as complexation reactions under various conditions. In this context, we simulated the general synthetic route of HBED-based radiopharmaceuticals[5] for the preparation of the hexadentate [^{nat}Ga(HBED-NN)] complex. The structural features of this complex was studied by NMR techniques (1D, 2D, variable temperature). **Results:** The synthesis of HBED-NN (ester-protected) was accomplished in 5 steps. We next studied the click chemistry of this chelator using small terminal alkynes. For investigating the complex chemistry, we employed a representative vector model with an uncomplicated spectral pattern in the ^{1}H NMR spectrum especially in the upfield region where protons of the chelate cage appear. Phenyl acetylene met these requirements and therefore its "click" product was used as the overall complexing agent. Complete NMR characterization of [Ga(HBED-NN)] confirmed an octahedral structure with the carboxylate oxygens trans to each other and the phenolic oxygens cis to each other for this complex. **Conclusion:** We have introduced HBED-NN as a diazide variant of the bifunctional HBED chelator which enables "click" coupling without using linkers. Also, we determined the geometry of the [Ga(HBED)] chelate cage. This study shows that the HBED-NN chelator-type is potentially an excellent candidate for the development of new radiopharmaceuticals. **References:** (1) Afshar-Oromieh, A. et al. Eur. J. Nucl. Med. EP-0744

Robust cobalt cage assemblies as anionic radioisotope chelating agents: Efficient radiolabelling using the [^{99m}Tc]TcO_4^- anion and beyond

B. Burke[1], W. Grantham[2], V. Nail[1], I. Renard[1], D. Roberts[1], P. J. Lusby[2], S. J. Archibald[1];
[1]University of Hull, Hull, UNITED KINGDOM, [2]University of Edinburgh, Edinburgh, UNITED KINGDOM.

Aim/Introduction: Synthesis of ^{99m}Tc agents for SPECT imaging involves the chemical reduction of the [^{99m}Tc]TcO_4^- anion using methods which are often incompatible with chelator-biomolecule conjugates, limiting the potential applications. This reliance on redox reactions is a consequence of the assumption that the chemical reactivity of the pertechnetate anion is negligible; it does not bind to any ligand.[1] Here, we present the use of a robust self-assembled supramolecular cage structures for reduction-free encapsulation of [^{99m}Tc]TcO_4^-. Other anions also being assessed include [^{18}F]SO_3F^-, [^{18}F]BF_4^-, [^{123}I]I^-, [^{131}I]I^- and [^{188}Re]ReO_4^- for both nuclear imaging and radioisotope therapy applications. **Materials and Methods:** A supramolecular cage assembly terminating in amine groups was synthesised using a "assembly-followed-by-fixing" method which involves post-assembly oxidation of dynamic Co^{II} species to give a non-equilibrium Co^{III} analogue.[2] Radiolabelling was carried out using [^{99m}Tc]TcO_4^- directly from a ^{99}Mo/^{99m}Tc generator (Curium, UK) for 5 minutes at room temperature - extending the time does not improve radiochemical yield. Radiochemical stability measurements were carried out by adding individual competing anions, or serum, to pre-labelled cage for various times. SPECT imaging of the radiolabelled cage assembly was carried out in naïve mice and biodistribution compared to free [^{99m}Tc]TcO_4^-. **Results:** Radiolabelling with [^{99m}Tc]TcO_4^- was carried out to determine a radiolabelling EC_{95} value of 1.9 µM. Stability measurements demonstrated consistent equilibrium based anion competition and serum stability. When [^{99m}Tc]TcO_4^- labelled cage was imaged using SPECT in comparison with free [^{99m}Tc]TcO_4^-, a difference in biodistribution was observed, with significant uptake noted in the liver. These imaging results are consistent with the radiochemical stability data, in which the cage is reaching equilibrium with blood-based anions, releasing a small amount of free pertechnetate, causing some NIS mediated thyroid and stomach uptake. **Conclusion:** While the use of self-assembled carrier systems in nuclear medicine is still in its infancy, we have demonstrated a clear step forward, showing both the robustness of an amino terminating $Co^{III}_4L_6$ cage in vivo and that binding the [^{99m}Tc]TcO_4^- anion significantly affects its biodistribution.[3] This is the first step towards the development of reductant-free kit bioconjugates for targeted SPECT imaging. The approach is currently being translated to other anions for both PET imaging and radioisotope

therapy applications. **References:** [1] I Zolle. Technetium-99m Pharmaceuticals: Preparation and Quality Control in Nuclear Medicine; Springer: Berlin, Heidelberg, New York, 2007. [2] M.J. EP-0745

Critical impact of the conjugation strategy on the stability of ^{89}Zr-labeled immunoconjugates towards radiolysis

P. Adumeau, M. Moreau, L. Da Costa, C. Bernhard, A. Dubois, V. Goncalves, F. Denat;
Universite de Bourgogne, Dijon, FRANCE.

Aim/Introduction: For immunoPET imaging, zirconium-89 is very enticing for the radiolabeling of antibodies due to its radioactive half-life (3.3 days) matching the biological half-life of the protein. The radiolabeling of biomolecules with ^{89}Zr first implies the modification of the biomolecules to introduce a chelating agent, like desferrioxamine - DFO, the gold standard for ^{89}Zr radiolabeling.[1] Among the numerous bioconjugation strategies available, the most widely used is undoubtedly the random conjugation of lysine residues with isothiocyanate moieties, leading to the formation of a thiourea linker. The ionizing radiation generated by the radioelement can however degrade this linker, leading to its rupture and the release of the chelator/radiometal complex, and the thiourea linker has proven particularly sensitive to this phenomenon in the past.[2,3] Rudd et al. have proposed to use squaramate as an alternative to isothiocyanate, as it offers many advantages over the latter.[4] However, the behavior of the squaramide linker toward radiolysis has never been thoroughly investigated. **Materials and Methods:** In order to investigate the putative improved behaviour of the squaramide linker toward radiolysis, we have synthesized several trastuzumab-based conjugates bearing DFO derivatives via either a thiourea or a squaramide linker. These conjugates were then radiolabeled with ^{89}Zr using standard radiolabeling procedures, and the stability of the radioconjugates was investigated over the course of 7 days using size-exclusion chromatography. **Results:** The radiolabeling of the different conjugates yielded the radioconjugates with comparable yield (>95 %), radiochemical purity (>99 %) and specific activity (50 GBq/g). However, squaramide- and thiourea-based radioconjugates clearly showed different behaviours upon incubation at 37°C for 7 days, with the thiourea conjugates dropping to up to 60 % of integrity while the squaramide-based conjugates remained above 95 % of integrity. **Conclusion:** These preliminary results demonstrate that the squaramide linker is indeed more stable than the thiourea, and therefore the squaramate should replace advantageously the isothiocyanate moiety for the conjugation to lysine residues in the radiochemistry field. We are currently in the process of synthesizing more conjugates to confirm these results and extend these findings beyond trastuzumab-based conjugates. **References:** 1. Heskamp, S. et al. EP-0746

A Simple Azeotropic Drying Free Synthesis of [18F] FET Via Fluorination of Chiral NiII Complex Precursor In Conjunction With Tetrabutylammonium Tosylate

T. Skvortsova, O. Fedorova, R. Krasikova, V. Orlovskaya;
N. P. Bechtereva Institute of the Human Brain of Russian Academy of Sciences, Saint-Petersburg, RUSSIAN FEDERATION.

Aim/Introduction: [^{18}F]FET is an important and specific tracer for PET diagnostics of cerebral tumors. The number of [^{18}F]FET PET examinations is expected to increase in the next few years due to its logistical advantages over L-[^{11}C-methyl]methionine. We earlier developed a convenient synthesis of [^{18}F]FET via kryptofix mediated raduifluorination of a chiral Ni^{II} complex of an alkylated (S)-tyrosine Schiff base, Ni-(S)-BPB-(S)-Tyr-OCH_2-CH_2OTs (**I**). Radiochemical yield (RCY) of [^{18}F]FET was 26% (EOS) within 45 min synthesis time, using Scintomics Hotbox^{one} automated module. Here we optimize the ^{18}F-fluorination process via substituting kryptofix/carbonate with an inert phase transfer catalyst (PTC), tetrabutylammonium tosylate (TBAOTs). The novel protocol was adapted to GE TRACERlab FX N Pro, a commonly used ^{18}F-radiolabeling platform. **Materials and Methods:** [^{18}F]fluoride was eluted from QMA carb. cartridge with solution of 5 mg TBAOTs in 2 mL of ethanol. The solvent was evaporated; 2 mg of (**I**) in 0.9 mL of acetonitrile was added. Fluorination was performed at 100ºC for 5 min following removal of reaction solvent to dryness. After acidic hydrolysis (0.5M HCl/EtOH, 125ºC, 5 min) the pH of reaction mixture was adjusted to 9.0. Resulting turbid solution was passed through filtration column and three tC18 Light cartridges connected sequentially. [^{18}F]FET was eluted with 10 mL of sodium acetate (5 mM, pH 4) containing 3% of EtOH and further purified by passing through CM Plus cartridge to remove any residual nickel. **Results:** By using the chemically inert TBAOTs for radiofluorination of **I** a better RCY (40.6±3.4%, n=5, EOS) was achieved applying only 2 mg of precursor. [^{18}F]FET was obtained with radiochemical purity >99% and enantiomeric purity 95-96%. All results of the quality control were within the limits established by the European Pharmacopoeia. **Conclusion:** A simple, fast and azeotropic drying free automated synthesis procedure for [^{18}F] FET using **I** as a labeling precursor, was developed. The use of TBAOTs for elution of [^{18}F]fluoride and following fluorination resulted in over 40% practical yield of [^{18}F]FET within 35 min synthesis time. We believe that the benefits of this chemically inert PTC are worth evaluating in the preparation of other useful fluorine-18 labelled radiotracers. We acknowledge Russian Foundation of Basic Researches (RFBR, project N 18-29-01015) for financial support. **References:** None.

A Modified Procedure For The Synthesis Of A Potential Tau Imaging Agent [F18]-THK5351 Employing A Sumitomo Semi-automatic Chemical Synthesizer F121R

J. M. Cheung, *N. Ng, K. Liu, C. Ho;*
Hong Kong Sanatorium & Hospital, Hong Kong, HONG KONG.

Aim/Introduction: [^{18}F]-THK5351 is a promising tau tracer of arylquinoline derivative for PET imaging of neurofibrillary pathology in Alzheimer's disease (AD). It demonstrates high binding affinity for hippocampal homogenates of AD brains and less non-specific retention in white matter. However, repeated attempts to synthesize [^{18}F]-THK5351 following the literature procedure resulted in two inseparable products in HPLC purification with low yield. We, therefore, proposed a modified procedure that is more effective in the synthesis of this compound. **Materials and Methods:** With the Sumitomo F121R synthesizer, the protected precursor, (2S)-3-((2-(6-(methylamino) pyridin-3-yl)quinolin-6-yl)oxy)-2-((tetrahydro-2H-pyran-2-yl)oxy) propyl-4-methylbenzenesulfonate was fluorinated at various temperature settings (110-125ºC) to compare the product yields. The amount of precursor compound was systematically reduced to compare the yields under the same reaction conditions. To avoid forming two compounds and to keep the solvent homogeneity, a larger volume of potassium acetate with a higher concentration was used to neutralize the reaction mixture after acid hydrolysis, and the solid phase extraction solvent aqueous ethanol was diluted with HPLC mobile phase before proceeding to HPLC purification. **Results:** We were able to reduce the precursor compound proposed in the literature reference from 3 mg to 1 mg. The optimal temperature for the fluorination reaction was found to be 125ºC. After acid hydrolysis, the crude product mixture was neutralized with potassium acetate of a higher concentration (1.6M) in a larger volume (1.5 mL). Upon dilution of the aqueous ethanol eluent from the purification Sep-Pak light Oasis HLB with 0.6 mL HPLC mobile phase, the HPLC purified product [^{18}F]-THK5351 was eluted at 9 minutes as a single sharp peak. The radiochemical identity of the product was verified by spiked standard analysis, and the radiochemical purity was >99% by analytical HPLC with a reaction yield of 32.8±11.6%. The HPLC purified fraction was formulated into an injectable solution, which passed all quality control requirements, thus suitable for patient administration. **Conclusion:** The tau imaging agent [^{18}F]-THK5351 was successfully synthesized using a Sumitomo F121R synthesizer in our radiopharmacy laboratory at a yield of 32.8±11.6% (n=3) and >99% radiochemical purity though with less precursor (1 mg). These could be achieved by making modifications in the reaction temperature, adjustment on the pH of the crude reaction mixture followed by dilution with HPLC mobile phase before HPLC purification. **References:** None.

Study on Chelator-Free Zr-89 Labeling of PAMAM Dendrimers

G. Kim[1], *J. Lee*[1], *K. Yu*[2], *S. Kim*[1];
[1]*Dongguk Univ., Gyeongju, KOREA, REPUBLIC OF,*
[2]*Dongguk Univ., Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: The aim of the present study is to bind Zr-89 to oxygen sites of dendrimers without using a chelator in order to easily and stably coordinate Zr-89 to polyamidoamine (PAMAM) dendrimers 5G, which is widely studied as a drug delivery system. PAMAM dendrimers are promising nanomaterials because they are biocompatible and can carry drugs stably at the terminal amine sites. Zr-89 is a radioisotope that can be used as a diagnostic radionuclide using PET since it emits positron and has a relatively long half-life and is suitable for long-term study of drug delivery system. **Materials and Methods:** Polyamidoamine (PAMAM) dendrimers 5G and $ZrCl_4$ were purchased from Sigma-Aldrich and Zr-89 was supplied by Korea atomic energy research institute. A simple method is as follows: 1) Zirconium is introduced at room temperature using a chelator at the terminal amine sites of the dendrimer, and 2) zirconium is introduced into the dendrimer at room temperature without chelating, and confirming the yield and proceeding with biological evaluation. **Results:** The zirconium-bound dendrimers without chelator showed higher yields and showed a high label stability of ≥98% after the introduction of Zr-89. Cellular uptake of MDA-MB-231 cells was up to 40% ID. **Conclusion:** In conclusion, it has been confirmed that direct coordination of Zr-89 with dendrimer branches is effective in the study of diagnostic drug delivery using dendrimer, and thus it is possible to utilize more amine groups at the terminal of dendrimer when carrying the drug. **References:** Eszter Boros et al., Chelate-free radiolabeling of metal ion binding and heat-induced iron oxide nanoparticles, Chem. Sci., 2015, 6, 225.

EP-0749

Development of novel ^{68}Ga chelators for PET imaging

D. Sneddon[1], *W. T. Stuber*[2], *S. Faulkner*[2], *B. Cornelissen*[1];
[1]*Radiobiology Research Institute, University of Oxford, Oxford, UNITED KINGDOM,* [2]*Department of Chemistry, University of Oxford, Oxford, UNITED KINGDOM.*

Aim/Introduction: Gallium-68 (^{68}Ga, $t_{½}$ = 68 min) is a positron emitting radioisotope used clinically for positron emission tomography (PET) imaging. Typically, coordination of ^{68}Ga requires high temperatures and rigorous pH control, limiting its application, making it unsuitable for sensitive peptides and small molecules. Therefore, we have designed a series of novel macrocyclic and acyclic chelators and have investigated their coordination of ^{68}Ga. A panel of novel NOTA-based chelators, appended with mixed picolyl, nitrobenzene or longer chain carboxylic acid pendant arms were evaluated. **Materials and Methods:** Gallium-68 (220 MBq, 5.5 mL, 0.1 M HCl) was

eluted from an E&Z ^{68}Ge/^{68}Ga generator and the volume was reduced via a DGA resin. ^{68}Ga was eluted in H_2O (500 µL) and the pH adjusted to pH 4.5-5 using ammonium formate buffer (~100 µL, 5 M, pH 4.5-5). The chelator of interest (1 µmole) in H_2O or DMSO was added and the reaction mixture heated to 95°C for 10 min. Radiolabelling efficiency was measured by radio-iTLC and HPLC. After radiolabelling had been confirmed, the reaction conditions, including buffer, pH, temperature and time, were optimised. Competition studies were undertaken to assess relative complexation efficiencies of each chelator and compared to standard ^{68}Ga chelators, 1,4,7-triazacyclononane-1,4,7-triacetic acid (NOTA) and 1,4,7,10-tetraazacyclododecane-1,4,7,10-tetraacetic acid (DOTA). **Results:** Under standard labelling conditions (pH 4.5-5, 95°C), macrocyclic compounds were successfully radiolabelled, as determined by radio-iTLC and HPLC. Non-optimised yields varied but reached >80% for some compounds. Optimal radiolabelling conditions are being investigated to improve these yields. Stability assessments are currently underway. **Conclusion:** A series of novel chelators were successfully radiolabelled with ^{68}Ga. These results have allowed us to pinpoint necessary structural features for ^{68}Ga coordination, resulting in the design of a second generation of chelators for ^{68}Ga. **References:** None.

A simplified method for the radio-synthesis of [^{18}F]-flumazenil

P. Kumar, R. Joshi, N. Rao;
National Institute of Mental health and Neurosciences, Bengaluru, INDIA.

Aim/Introduction: [^{18}F]-flumazenil (FMZ) has been synthesized by various strategies involving complex purification by on-line high-performance liquid chromatography (HPLC) and also by solid phase cartridges. [^{18}F]-FMZ has been used for the assessment of the gamma amino butyric acid (GABA) receptors by positron emission tomography (PET). We have tried various solid phase extraction (SPE) cartridges combinations and calculated yields. Objective: To standardize and synthesize [^{18}F]-flumazenil using various combinations of the solid phase cartridges in order to minimize the loss of radiochemical yield during purification. **Materials and Methods:** [^{18}F] was produced by standard nuclear reaction using [H_2O^{18}] as a target material. The precursor nitormazenil was procured from ABX, Germany. The radio-fluorination was standardized for various parameters like temperature (130-160°C), precursor concentration (3-5 mg), various combination of SPE cartridges (HLB, tC18, C18 and alumina). the crude mixture was diluted with acidic water and passed through various combinations of the SPE cartridges (HLB + tC18, HLB + C18, C18 + Alumina) and final product eluted by using 2.0 mL of 20% ethanol/ phosphate buffer (pH-4.0). The mechanism of labeling is nucleophilic substitution and carried out in FX2N Tracerlab module. The combination of various cartridges and labeling parameters are established outside the module and then an automated protocol has been designed in FX2N module for clinical use. **Results:** The labeling was found to be maximum by using K^{18}F/kryptofix complex in the DMF at 160°C for 30 min. An equimolar concentration of [K/K2.2.2]$^+$18F$^-$/precursor was used and the incorporation of 18F in the flumazenil was found to be 19 ± 3%. The combination of C18 and alumina cartridges gave a better yield (5 ± 2 %) as compared to 1-2% by the other two combinations. The radiochemical purity was 95 ± 3 % as evaluated by Radio-HPLC with retention time at 15.4 ± 0.3 min (n = 10). This method was adopted for automation and a sequence (for FX2N) was created by us to run the protocol for clinical production of the [^{18}F]-flumazenil. **Conclusion:** [18F]-flumazenil was synthesized with higher radiochemical purity and a simple automated method has been developed for the clinical use. **References:** Vaulina D, Nasirzadeh M, Gomzina N. Upgrading a basic dose calibrator: development of an automatic decay-calculator

T. Chivato Martín-Falquina[1], *E. Miñana Olmo*[2], *M. Martínez Ramírez*[2];
[1]*Hospital General Universitario Santa Lucía, Cartagena, SPAIN,*
[2]*Hospital Universitario San Juan De Alicante, San Juan, SPAIN.*

Aim/Introduction: Dose calibrators are essential instruments in radiopharmaceutical practice. They allow for the accurate measurement of radioactivity required for radiopharmaceutical preparation and dispensing. Most modern devices include a decay function so the technician can easily prepare doses in advance. However, simpler or older dose calibrators may lack this feature, making the use of formulas or decay tables necessary in order to manually calculate the decay. We present a simple and affordable solution for those devices that feature a serial communication port, such as VDC-404 and VDC-603 (Veenstra Instruments, Netherlands), Atomlab 400 (Biodex Medical Systems, USA) or Curiementor 3 (PTW, Germany). **Materials and Methods:** Decay calculation was done with a Raspberry pi zero WH, a credit card size single board computer running Raspbian 9, connected to the dose calibrator (VDC-404, Veenstra Instruments, Netherlands) by a RS-232 DB9 to TTL adapter. We used a numeric keypad and a 16x2 I2C LCD display for input and output respectively. Software consists of a Python 3 script with the decay constants for ^{99m}Tc, ^{123}I, ^{131}I, ^{67}Ga, ^{90}Y, ^{51}Cr, ^{111}In and ^{18}F. To validate the device we prepared 30 doses set to different times and compared the decayed activity obtained via manual and automatic calculation. **Results:** The Raspberry receives the data about isotope, activity and measurement unit from the dose calibrator in real time, displaying it on the LCD. The operator can change the desired "use time" and the Raspberry will act as a decay calculator, showing in the display the resulting activity at

the new reference time. No difference was found in the decayed activity values regardless of the calculation method: manual or automatic. **Conclusion:** We have developed a modified dose calibrator that provides the operator with an instant and accurate value of the decayed activity, simplifying the task and reducing the risk of miscalculation that arises using calculators and decay tables. The device has minimal footprint, requires an investment of less than 40€ and compatibility with other dose calibrators models is possible with just slight changes to the script. All these characteristics make this device an interesting solution for Radiopharmacies still relying on manual decay calculations. **References:** Schematics, manual and code are available at https://github.com/tchivato/Decay_calculator

An Efficient Automated Radiosynthesis And Bioactivity Confirmation Of [^{18}F]FP-(+)-DTBZ As A VMAT2 Tracer

Z. Chen, *C. Zhao, C. Liu, J. Tang, Y. Xu, M. Xie;*
Key Laboratory of Nuclear Medicine, Ministry of Health, Jiangsu Key Laboratory of Molecular Nuclear Medicine, Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.

Aim/Introduction: PET imaging with [^{18}F]fluoropropyl-(+)-dihydrotetrabenazine ([^{18}F]FP-(+)-DTBZ) has shown its potential for tracing vesicular monoamine transporter type 2 (VMAT2) for related disorders such as Parkinson's disease. This study focused on the optimization of the radiolabeling method of [^{18}F]FP-(+)-DTBZ to fulfill the demands of pre-clinical and clinical application. **Materials and Methods:** Optimized labeling conditions were carried out through manual radiosynthesis of [^{18}F]FP-(+)-DTBZ by altering the molar ratio of the precursor to base (P/B), base species, solvents, reaction temperature, reaction time and precursor concentration. The method with highest radiochemical yield (RCY) were applied to automated radiosynthesis. Purification of the crude product was conducted with a Sep-Pak Plus C18 cartridge. Quality control and stability of [^{18}F]FP-(+)-DTBZ were carried out by HPLC. In vitro cellular uptake and blocking assays were performed in human neuroblastoma cell line SH-SY5Y. In vivo imaging with small animal positron emission tomography (microPET) was performed with normal Sprague-Dawley rats along with VMAT2 blocking test. **Results:** An RCY (as determined with HPLC) of 88.7 % was obtained with 1.0 mg precursor under the optimized condition (P/K_2CO_3 =1:8, heating at 120 °C for 3 min in dimethyl sulfoxide). This ^{18}F-labelling condition were successfully applied to an commercially available automated module and gave a high activity yield (AY) of 30-55 % (non-decay corrected) in ~40 min with a >99.0 % radiochemical purity (RCP) and a > 44.4 GBq/μmol molar activity (A_m). Stability test displayed that the RCP retained >98.0 % in 8 h both in saline and in phosphate buffer saline (PBS; pH 7.4). In vitro cellular uptake assay showed accumulation of [^{18}F]FP-(+)-DTBZ in SH-SY5Y cells, which could be significantly inhibited by VMAT2 inhibitor DTBZ. Rat brain microPET imaging displayed that the striatum has the highest uptake in brain with a standardized uptake value (SUV) of 2.74 ± 0.21 at ~70 min. Furthermore, the striatum SUV deceased 73% when [^{18}F]FP-(+)-DTBZ was co-injected with DTBZ (1.0 mg/kg), confirming the specificity of [^{18}F]FP-(+)-DTBZ to VMAT2. **Conclusion:** We optimized the radiolabeling method of [^{18}F]FP-(+)-DTBZ and successfully applied it to a commercial available module. The automated synthesis gave a high AY and high RCP of [^{18}F]FP-(+)-DTBZ. In vitro SH-SY5Y cell assay and in vivo rat microPET imaging confirmed its specific binding to VMAT2. Our optimized radiosynthesis of [^{18}F]FP-(+)-DTBZ facilitated its preclinical and clinical routine application for VMAT2 imaging. **References:** None.

AAZTA^5-squaramide ester: a promising tool for ^{177}Lu-labeling of monoclonal antibodies under mild conditions concerning immuno-based endoradiotherapeutic applications

B. Klasen, *E. Moon, F. Roesch;*
Institute of Nuclear Chemistry, Mainz, GERMANY.

Aim/Introduction: Combining the advantages of both cyclic and acyclic chelator systems, AAZTA is well suited for complexation of various diagnostic and therapeutic radiometals such as gallium-68, scandium-44 and lutetium-177 under mild conditions. Due to its specificity for primary amines and pH dependent binding properties, the squaric acid (SA) moiety represents an excellent tool for selective coupling of the appropriate chelator to different target vectors[1]. Therefore, the aim of this study was to evaluate radiolabeling properties of the novel bifunctional AAZTA^5-en-SA being coupled to a model antibody (bevacizumab) in comparison to DOTA-en-SA using the therapeutic nuclide lutetium-177. **Materials and Methods:** As proof-of-concept, bevacizumab was functionalized with a tenfold molar excess of either AAZTA^5-en-SA or DOTA-en-SA resulting in a ratio of 0.2-0.7 bound chelator moieties per protein. The corresponding immunoconjugates AAZTA^5-en-SA-mAb and DOTA-en-SA-mAb were purified twice via fractionated size exclusion chromatography (SEC) and subsequently radiolabeled with lutetium-177 at pH 7 and ambient temperature as well as 37° C. In vitro complex stability of [^{177}Lu]Lu-AAZTA^5-en-SA-mAb was investigated in human serum and PBS at 37 °C over a period of 15 days. **Results:** After 90 min, ^{177}Lu-labeling of AAZTA^5-en-SA-mAb resulted in almost quantitative radiochemical yields of > 98 % at ambient temperature and > 99 % at 37 °C, respectively. After purification via SEC, the radioconjugate [^{177}Lu]Lu-AAZTA^5-en-SA-mAb could be obtained with a purity of > 99 % and an apparent specific activity of 4.1 GBq/μmol. In contrast, ^{177}Lu-labeling of DOTA-en-SA-mAb showed negligible low radiochemical yields of < 2 % both at ambient temperature and 37 °C. Complex stability measurements of [^{177}Lu]Lu-AAZTA^5-en-SA-mAb in human serum indicated > 99 % protein bound activity within 15 days. In PBS, formation of a by-product led to slightly decreased stability of > 93 % intact conjugate over the same period. **Conclusion:** Coupling of AAZTA^5-en-SA to the monoclonal antibody bevacizumab could be confirmed via

successful ^{177}Lu-labeling with almost quantitative radiochemical yields both at ambient temperature and 37 °C. Within 15 days, the resulting radioconjugate indicated high in vitro stability of > 99 % in human serum and > 93 % in PBS, respectively. In contrast, no significant complexation of lutetium-177 via the DOTA functionalized analogue could be observed under identical conditions. Therefore, AAZTA^5-en-SA is a promising tool for ^{177}Lu-labeling of sensitive biomolecules such as antibodies for theranostic applications. **References:** [1] K.-H. Glüsenkamp, W. Drosdziok, G. Eberle, E. Jähde, M. F. Rajewsky, Zeitschrift für Naturforsch. C 1991, 46, 498-501.

Radiolabelled multifunctional hybrid magnetic nanoparticle probe for dual-modality (SPECT and MRI) medical in vivo imaging

G. Dodi[1], *C. M. Uritu*[1], *I. Gardikiotis*[1], *C. T. Mihai*[1], *L. Agrigoroaie*[2], *M. Furcea*[2], *B. I. Tamba*[1], *C. Stefanescu*[3];
[1]*Advanced Research and Development Center for Experimental Medicine, Grigore T. Popa University of Medicine and Pharmacy, Iasi, ROMANIA,* [2]*Department of Nuclear Medicine, University Emergency Hospital "Sf. Spiridon" Iasi, Iasi, ROMANIA,* [3]*Department of Biophysics and Medical Physics, Nuclear medicine, Faculty of Medicine, Grigore T. Popa University of Medicine and Pharmacy, Iasi, ROMANIA.*

Aim/Introduction: The development of non-invasive, high sensitive, high-resolution, and quantitative all-in-one multifunctional candidates that can be detected by multimodal techniques, namely single-photon emission computed tomography and magnetic resonance imaging (SPECT and MRI) represents a challenge in nanomedicine imaging. The main objective of this paper is to develop multifunctional hybrid magnetic- based nuclear imaging probes for evaluating their behaviour in biological systems in vitro and in vivo. **Materials and Methods:** An innovative strategy divided in several steps, was employed for achieving dual-modality candidate:- first, hybrid magnetic nanoparticles were synthesised using iron oxide core obtained by partial oxidation method and multifunctional silica shell chains; - then, cytotoxicity of the multifunctional hybrid magnetic tracer was investigated on normal V79 cell line; -further, the amine groups on the hybrid magnetic nanoparticles surface were radiolabelled with ^{99m}Tc, eluted from a ^{99}Mo/^{99m}Tc Drytec Generator system as $Na^{+99m}TcO_4^-$;- in vivo biodistribution of the obtained radiolabelled multifunctional hybrid magnetic nanoparticle probe was determined after intravenous administration on healthy experimental animals by in vivo SPECT imaging and ex vivo gamma counting of the excised tissues; - dual-modality imaging evaluation of the synthesised nanotracer was obtained by SPECT and MRI comparison studies. **Results:** The structure, external morphology, size distribution, colloidal and magnetic properties were characterised by FT-IR, TEM, XRD, DLS and VSM analyses. The characterization results confirmed the formation of well-defined crystalline magnetite conjugates with broad distribution, relatively high saturation magnetization and irregular smooth surface. In vitro cell viability assay displayed good biocompatibility of the conjugates with the percent of viable cells exceeding 80% after 48 h incubation for normal cell line. The magnetic amine functionalized Fe_3O_4 nanoparticles were successfully labeled with ^{99m}Tc using standard radiolabeling methods as reveled by the radiolabeling yield (≈ 90%) assessed using instant thin layer chromatography. Both the ex vivo biodistribution and in vivo SPECT imaging on healthy animals showed a similar pharmacokinetic biodistribution profile for ^{99m}Tc- amine Fe_3O_4 nanoparticles. **Conclusion:** In summary, we have developed new molecular imaging probes based on hybrid magnetic nanoparticles radiolabeled with the diagnostic radionuclide ^{99m}Tc for SPECT imaging and evaluated their biodistribution profiles in healthy animals.The obtained results opened opportunities to extend this new nanotracer for therapeutic use due to its versatile functions to link different molecules to the same core. **References:** Acknowledgement: This work was supported by a grant of Ministry of Research and Innovation, CNCS - UEFISCDI, project number PN-III-P1-1.1-PD-2016-1642, within PNCDI III.

Automated synthesis of [^{11}C]SC560 with Synthra® synthesis module

C. Kwizera, *I. F. Antunes, R. Zijlma, E. de Vries;*
Umcg, Groningen, NETHERLANDS.

Aim/Introduction: ^{11}C labeled 5-(4-chlorophenyl)-1-(4-methoxyphenyl)-3-(trifluoromethyl)-1H-pyrazole ([^{11}C]SC560) is a PET tracer that selectively binds to COX-1that is overexpressed in inflammatory conditions[1]. In order to potentially use this tracer in a clinical settings we developed an automated syntheses of the tracer. Therefore, this study aimed to describe the automated [^{11}C]SC560 production in a Synthra synthesis module and the evaluation of [^{11}C]SC560 selectivity towards a COX-1 expressing ovarian cancer cell line (OVCAR3)[2]. **Materials and Methods:** [^{11}C]SC560 was prepared by O-[^{11}C]methylation of the phenolic precursor with [^{11}C] methyl triflate in 0.25 ml dry acetone containing 5 µL of NaOH (1M). The reaction was performed in a Synthra synthesis module at room temperature for 3 min. Subsequently , the mixture was diluted with 1.3 ml of a solution containing HCL0.1M/ACN/WFI (9:1:1) and purified by High-performance-liquid-chromatography (HPLC, µBoundapak C18(5µm, 8x 300 mm)-mobile phase acetonitrile/ water (70:30 v/v), at flow rate of 3 ml/min). The radioactive product with a retention time of 14 min was collected and formulated in ethanol/WFI (containing 6µL of Tween20). The formulated tracer was submitted to quality control. For the in vitro studies, 0.1×10^6 OVCAR3 cells were plated in a 12 well plate 24 h before the experiment. SC560 (COX-1), Indomethacin (COX-1 and COX-2) and Celecoxib (COX-2) were added in triplicate to the cells. 30 min after the incubation with the inhibitors, [^{11}C]SC560 was added (<1MBq) and left to incubate at 37°C and 5% CO_2 for 30 min. Afterwards the cells were washed with cold PBS, trypsinazed, resuspended and transferred to tubes for the measurement of

radioactivity by gamma counter and cells counted by the trypan blue method. **Results:** The total automated synthesis time of [^{11}C] SC560 was 50 min with a radiochemical yield of 25%, a molar activity of ± 50000 GBq/µmol (n =3) and radiochemical purity was greater than 95%. The uptake of [^{11}C]SC560(6.15±0.69 %uptake/million cells) in OVCAR3 cells was significantly reduces in the presence of cold SC560 (4.47±0.22 %uptake/million cells, p=0.02) or Indomethacin (3.13±0.33 %uptake/million cells, p=0.015) but not with Celecoxib (5.31±0.88 %uptake/million cells, p=0.26). **Conclusion:** [^{11}C]SC560 can be produced reproducibly in an automated Synthra synthesis module. As a proof-of-principle we were able to demonstrate selectivity of of [^{11}C]SC560 in OVCAR3 cells. Further studies are ongoing to have a better understanding of this PET tracer for COX-1 expression. **References:** [1] Fujisaki et al., Ann. Nucl Med, 2005, 19:617-625. Initiation Of A Prospective Clinical Multicentre Trial With Local Production Of A Short-Lived PSMA-PET-Radiopharmaceutical In The D-A-CH-Region: Chances And Experiences

O. Neels[1,2], *C. Zippel*[1,2], *F. L. Giesel*[3,2,1], *K. Kopka*[1,2];
[1]*German Cancer Research Center, Heidelberg, GERMANY,*
[2]*German Cancer Consortium (DKTK), Heidelberg, GERMANY,*
[3]*University Hospital Heidelberg, Heidelberg, GERMANY.*

Aim/Introduction: The development of innovative radiotracers targeting PSMA for non-invasive imaging of prostate cancer and successive treatment results in an increasing number of multicentre clinical trials using the most promising PSMA ligand candidates. For prospective studies with short-lived radiopharmaceuticals like [^{68}Ga]Ga-PSMA-11, a regulatory and country-specific structure has to be established before recruitment of patients is possible. This structure allows the decentralized manufacturing of the investigational medicinal product (IMP) according to Good Manufacturing (GMP) and subsequent implementation of the respective tracer compliant with Good Clinical Practice (GCP). **Materials and Methods:** For the multicenter clinical trial (phases-I/-II) „Ga-68-PSMA-11 in high-risk prostate cancer" (NCT03362359) within DKTK a harmonized decentralized radiotracer production in multiple radiopharmacies has been set up for the very first time in the German speaking Radiopharmacy/Nuclear Medicine Community. In this prospective clinical study Nuclear Medicine physicians, radiopharmacists, urologists, pathologists and study related experts like lawyers and study nurses out of eleven study sites within the so-called D-A-CH region (Germany-Austria-Switzerland) have been involved. The basis for the accurately specified radioactive IMP manufacturing procedure was defined by EU-GMP requirements plus national standards (e.g. Medicinal Products Act and Radiation Protection Law). **Results:** For the recruiting study sites the required allowances, e.g. manufacturing authorization from local authorities as well as approval from ethics committees and national regulatory bodies such as BfS and BfArM in Germany, BASG in Austria as well as BAG and Swissmedic in Switzerland, have been obtained. The challenge of manufacturing a short-lived radiopharmaceutical at each of the participating geographically different sites with identical specification by adaption of production and quality control processes and parameters according to the IMP dossier (IMPD) during the starting phase of the clinical trial under a centralized quality assurance management has been achieved. **Conclusion:** The initiation and establishment of a multicentre clinical trial including the manufacturing of a short-lived radiopharmaceutical IMP across local study sites is very complex, but manageable. In view of the high European and national regulatory and legal burdens and the number of involved partners it is feasible in a defined time frame. Based on the achieved structures, the decentralized manufacture of novel short-lived radiopharmaceuticals can be established in the D-A-CH region and even on a European level for further investigator initiated multicentre clinical trials. We estimate our experiences important for the development of the field Nuclear Medicine at the national and international level taking into account the new EU regulation No 536/2014. **References:** None.

EP-0757

3D printing of SPECT phantoms using resin monomers radiolabeled in a one-pot process

L. Meier, *T. Läppchen, M. Fürstner, G. Prenosil, T. Krause, A. Rominger, B. Klaeser, M. Hentschel;*
Clinic of Nuclear Medicine, Inselspital, Bern University Hospital, University of Bern, Bern, SWITZERLAND.

Aim/Introduction: We aimed to develop a simple approach to 3D print radiolabeled phantoms. The clinical routine of PET and SPECT/CT is becoming increasingly important due to the possibility of determining tracer concentrations quantitatively. For multicenter clinical studies, scanners must be tested to allow comparability between diverse scanner types, or brands. Different phantom types are in use (Nema-, Jaszczak-, Derenzo-phantoms), requiring radioactive liquids filled into hollow phantoms. Recently, 3D printing technology has been introduced to print such phantom. An approach to use radiolabeled starting materials for 3D printers does not exist, yet [1]. Two general concepts of radiolabeling are applied to radiolabel molecules

either by covalently binding radioisotopes or using a chelator group to bind multivalent radioactive cations. Here, we followed a new one-pot approach of radiolabeling resin monomers in a phase transfer process: an aqueous solution of γ-emitter technecium-99m was mixed with hydrophobic 3D printer resin monomers, hydrophobic ligand additives were added and the water was chemically removed. Then, the phantom was printed with a standard SLA 3D printer. **Materials and Methods:** The following procedure was implemented: Pertechnetate solution was directly added to the resin monomer resulting a two-phase mixture. (A) A reducing agent also serving as a ligand was added to induce a phase transfer of the radiocation into the hydrophobic phase, (B) an anionic monomer amplified the phase transfer and (C) a chemical drying agent removed the residual aqueous phase. This radiolabeled starting material was directly used to print a radiolabeled phantom on a Projet1200 3D SLA printer. **Results:** A one-pot phase transfer procedure has been developed to radiolabel resin monomers by technecium-99m. A hydrophobic-hydrophilic balance of >100:1 was achieved as determined by a gamma counter (Wizard 2470). Radiolabeled 3D phantoms of different shapes (spheres, cylinders etc.) were printed. Homogenous distribution of the radioisotope in the polymer was confirmed by autoradiography and SPECT/CT of slices of a printed cylinder. Stable binding in the matrix was tested by washout cycles in ethanol at 50°C and in 0.1mol/l HCl overnight. No significant amount of radioactivity was washed out. **Conclusion:** 3D-printing of phantoms incorporating the radioisotope Tc-99m is feasible. When adapting the process to radiolabel longer living radioisotopes, the approach will enable reproducible quality control. **References:** [1] Filippou V. Med Phys 45, e740-760(2018).

EP-0758

Challenging The Validity Of Retrospective Sterility Testing

I. Koslowsky[1], *E. Schirrmacher*[2], *K. Logan Smith*[1];
[1]*Alberta Health Services, Calgary, AB, CANADA,*
[2]*University of Alberta, Edmonton, AB, CANADA.*

Aim/Introduction: Retrospective sterility testing has been part of the quality assurance program for radiopharmaceuticals for many years. The current approach is to let radiopharmaceuticals decay before sterility testing. Depending on the decay characteristics of the isotope, the sample may need to be retained for several months before it can be sent for testing: the applicability of the sterility test becomes questionable. The aim of this study was to determine whether microorganisms can sustain viability over time. **Materials and Methods:** The tests for sterility were performed using the &lt71&gt Sterility Tests methodology in the United States Pharmacopoeia. Growth promotion and method suitability studies were performed to confirm compatibility between the media, microbes, and products. Viability studies were performed using the following products: Tc99m-Medronate (MDP), FDG, and 10% Ethanol. Ethanol was selected, as it is a commonly used diluent in PET production; FDG and MDP are common imaging agents. Products were 'contaminated' with 30 or 90 cfus of 6 strains of organisms (3 aerobes, 1 anaerobe, 2 fungi). Aliquots were withdrawn at 30 hours, 4 days or 10 days for FDG and ethanol; and 4 days, 10 days, and 30 days for MDP. Fluid thioglycollate and tryptic soy broth media were inoculated, in triplicate, with the contaminated aliquots and incubated for 14 days at 30°C or at room temperature (20 to 25°C). Media were observed for growth at 5 days and 14 days. **Results:** Microorganisms were inconsistent in viability between products and time periods. Therefore microbes and replicates were pooled for each product (18 samples per time period per product). With FDG, 5 of 18 replicates exhibited growth at 30 hours with 3 of 18 replicates demonstrating growth at 10 days. Ethanol initially showed better sustainability (11 of 18 viable) at 30 hours; however only 1 replicate demonstrated growth at 4 days. MDP was more consistent in the type of microbes sustained and the length of time with 9 replicates growing at 4 days and 8 replicates sustained at 30 days. **Conclusion:** The current required method for testing sterility of radiopharmaceuticals is not sufficiently robust: there is reasonable risk in generating a false negative result. The number of false negative results in this study challenges the value retrospective sterility testing offers in a quality assurance program. Other techniques that establish and validate a sterile environment during production may bring more meaning to a quality assurance program. **References:** &lt71&gt Sterility Tests, USP41-NF36, 2018.

EP-0759

Time-lapse And Long-term Stability Of " RGD "lyophilized Kit

S. Lee, *S. Lo, S. Wang, S. Lo, S. Chen, M. Li;*
Institute of Nuclear Energy Research Atomic Energy Council, Taoyuan, TAIWAN.

Aim/Introduction: Integrin $\alpha_v\beta_3$ has been listed as an excellent candidate for cancer therapy, because of participate in tumor angiogenesis, and regulate the course and metastasis of cancer. Tripeptide RGD (Arg-Gly-Asp) is well known that can specific bind to integrin $\alpha_v\beta_3$, so many scientists have developed a cyclic pentapeptide (cRGDfK) for cancer drugs research. Previous study, we used this structure and combination with EB to develop a new tracer ^{111}In-DOTA-EB-cRGDfK with high affinity of albumin and $\alpha_v\beta_3$. NanoSPECT/CT image also confirmed that ^{111}In-DOTA-EB-cRGDfK had high accumulation amount at tumor site in MDA-MB-231 and 4T1 breast cancer animal model. Therefore, we development a DOTA-EB-cRGDfK lyophilized kit for ^{111}In labeled purpose. The aim of this study was to evaluate the time-lapse and long-term stability of lyophilized kit. **Materials and Methods:** The DOTA-EB-cRGDfK kit contents of the vial were lyophlized and sealed under nitrogen. This product is stored in the refrigerator at -20°C.Three batches of DOTA-EB-cRGDfK kit were inject 1~2mL of In-111 solution in 0.1N HCl (with 6~9 mCi). Shake vigorously, let the contents in the vial will be completely dissolved. Then, place the vial into a dry-heater for 15 minutes at 95°C.Let the vial stand for approximately 10

minutes, so it reaches room temperature. After preparation, the pH of the final products (^{111}In-DOTA-EB-cRGDfK injection) is 6~7. Final products are stand at room temperature for 0, 1, 2, 3, 4, 8, and 24 hours, the radiochemical purity of each time are analyzed by radio-high performance liquid chromatography. Three batches of DOTA-EB-cRGDfK lyophilized kit were taken out after 0, 1, 2, 3, 4, and 5 months after storage at -20°C. Then follow described above preparation methods to analyze the final products at that month. **Results:** The radiochemical purity of three batches of ^{111}In-DOTA-EB-cRGDfK radioactive products at the 0th, 1, 2, 3, 4, 8 and 24 hour was 97.9%±0.4, 98.0%±0.6, 98.0%±0.5, 97.8%±0.5, 97.7%±0.5, 97.6%±0.4 and 97.5%±0.5. The time-lapse stability results show that the ^{111}In-DOTA-EB-cRGDfK radioactive products had considerable stability within 24 hours. The radiochemical purity of ^{111}In-DOTA-EB-cRGDfK radioactive products that prepared from DOTA-EB-cRGDfK lyophilized kit can still >90% after 5 months. **Conclusion:** We demonstrated that the DOTA-EB-cRGDfK lyophilized kit have high degree of product stability, both in term of time-lapse and long-term analysis. The DOTA-EB-cRGDfK lyophilized kit can be more valuable in the marketing of breast cancer diagnostic drugs in the future. **References:** None.

EP-0760

Various Detection Techniques for ^{225}Ac

E. Arponen, T. Oikari, V. Haaslahti;
Hidex OY, Turku, FINLAND.

Aim/Introduction: Targeted alpha therapy (TAT) is a promising approach for treatment of cancer. The demand for suitable radioisotopes is strong. ^{225}Ac is an alpha particle emitting radionuclide with a 10 d half-life. ^{225}Ac yields several daughter radionuclides in its decay scheme and a net of four alpha particle emissions. The parent and the daughters are each individually lethal to cells. Recent studies of ^{225}Ac-PSMA617 for the therapy of metastatic castration-resistant prostate cancer have shown the clinical potential of targeted alpha therapy (1). The aim of this work is to study various detection techniques for quality control and radiation safety purposes of ^{225}Ac and its daughters. **Materials and Methods:** ^{225}Ac samples were measured with Hidex Triathler. Three different detection modes were applied in this study: liquid scintillation counting using alpha/beta separation electronics, high energy beta detection by solid plastic scintillator adapter and gamma detection by a well type NaI(Tl) crystal detector. In liquid scintillation counting, samples were mixed with AquaLight AB scintillation cocktail which provides optimal pulse length difference for separation of alpha emitters from beta emitters. With the plastic scintillator adapter and gamma detector samples were unharmed. **Results:** Triathler is a portable single-sample counter, which has a multichannel analyzer (MCA) and optional alpha/beta separation. The alpha decays can be clearly separated from the betas and yield a very low background as no natural alphas are present. Plastic scintillator adapter is sensitive to beta radiation and is only little affected by gamma background. The samples can be measured non-destructively in microtubes. The advantage of NaI(Tl) detector is that gamma spectrum shows also different gamma emitters. **Conclusion:** Triathler with alpha/beta separation and the plastic scintillator adapter is suitable for measuring ^{225}Ac and its daughters. Alpha/beta separation is however best suited to studying individual alpha and beta isotopes. The advantage of plastic scintillation adapter and gamma detector is that both liquid and solid samples such as TLC strips can be measured without the need for sample preparation. Further studies are planned for the development of detection methods for quality control purposes. Triathler can also be used as a wipe test counter to measure for possible radioactive contamination in laboratory areas. **References:** 1. Kratochwil C, Bruchertseifer F, Giesel F.L. et al. J Nucl Med 2016; 57:1941-1944.

EP-0761

Evaluation of ^{99m}Tc-tilmanocept retention in different syringes at different times

C. Franco Monterroso[1], B. Santos Montero[2], M. Hernández Fructuoso[2], E. Romero Herrera[1], S. Ruiz Llama[1], J. Castell Conesa[1];
[1]*University Hospital Vall d'Hebron, Barcelona, SPAIN,*
[2]*University Hospital Vall d'Hebron - IDI, Barcelona, SPAIN.*

Aim/Introduction: ^{99m}Tc-tilmanocept is a new radiopharmaceutical for imaging and intraoperative detection of sentinel lymph nodes. It has been widely reported that several radiopharmaceuticals are retained or adsorbed by plastic syringes to different extents. A high retention suggests a subsequent inadequate dosing (a lower administered dose) and can cause image quality problems (false negative) and even increase the cost. The aim of this study was to determine the ^{99m}Tc-tilmanocept retention percentage in the preparation vial after reconstitution and in different types of plastic syringes at different times. **Materials and Methods:** Six tilmanocept lyophilized vials (Lymphoseek®) were reconstituted with 222MBq of freshly eluted sodium pertechnetate in 0,7 ml sodium chloride 0,9%. 24 doses of 37MBq were dispensed: 12 doses in 1 ml Luer-Lock Chirana syringes (type A), and 12 in 1ml BD Plastipak™ syringe (type B). All dispensed doses were stored at room temperature (approximately 20-22 ºC).The activity in the syringes was measured immediately before and after simulated injections. The residual activity percentage in each syringe ((residual activity/initial activity) x100) was determined at t=0h, t=1h, t=2h and t=6h. The percentage of residual activity in labelled vials after dispensation was also evaluated ((residual activity/labelled activity) x100). A Capintec CRC-55tR dose calibrator was used to measure initial and residual activity. Results are reported as mean±SD for all samples. The level of significance was set at $P<0.05$ (Student's t-test). **Results:** The labelling efficiency of all vials used during this study were more than 98%.The percentage of residual activity in vials after doses dispensation was 8.40%± 2.56. The percentage of residual activity in type A syringes at t=0h, t=1h, t=2h and t=6h were 18.01% ±7.20, 19.71%±8.07, 22.32±4.08% and 39.95%±17.84 respectively.The percentage of residual activity in type B syringes

at t=0h, t=1h, t=2h and t=6h were 15.42%±8.59, 19.15%±9.64, 23.06%±10.65 and 31.91% ±12.25 respectively. There were not statistically significant differences between both types of syringes at all times: t=0h p=0.139, t=1h p=0.300, t=2h p=0.445, t=6h p=0.181. **Conclusion:** Both types of syringes show a high retention percentage, potentially causing underdosing and poor image quality. This retention is probably due to a mechanism of adsorption. We recommend the dispensation of 15-18% extra activity in every dose to compensate the retention and dispense doses immediately before injecting.The results show that measurement of retention in syringes should be regarded as an essential aspect of quality to assure the administered dose and avoid image quality problems. **References:** None.

EP-0762

Pharmacovigilance and Nuclear Medicine : French adverse event reports related to Radiopharmaceuticals

S. Langlet[1], *D. Pascal-Ortiz*[1], *D. Hillaire-Buys*[2], *I. Couret*[3]; [1]*Médecine nucléaire, Centre hospitalier, Perpignan, FRANCE,* [2]*Centre régional de pharmacovigilance, CHU Lapeyronie, Montpellier, FRANCE,* [3]*Médecine nucléaire, CHU Lapeyronie, Montpellier, FRANCE.*

Aim/Introduction: In nuclear medicine, the number of examinations is increasing (1.5 million in 2017 in France) and new radiopharmaceuticals (RP) become available. However, pharmacovigilance data remain scarce. The objective was to study RP-related adverse events (AE) reported in the French pharmacovigilance database since 1989. **Materials and Methods:** French pharmacovigilance reports involving the Anatomical Therapeutic Chemical classes V09 "Diagnostic RP" (DRP) and V10 "Therapeutic RP" (TRP) were screened from June 1989 to April 2018. 434 cases in which an RP was rated as unique "suspect" or "interaction" were identified and analysed. **Results:** Among the 434 cases, 150 (34%) were severe, including 13 deaths. DPRs were involved in 323 cases (74%), including (i) 264 cases (82%) of clinical and/or biological manifestations (CBM) among which 68 (25%) serious AE and 2 deaths, (ii) 43 cases (13%) of image alteration (IA), and (iii) 16 cases (5%) of medication errors (ME). Dermatologic (190, 41%) and general or injection-related (60, 13%) reactions were the most frequently reported CBM using DRPs, mainly ^{99m}Tc-HDP and ^{18}F-FDG. IA led to uninterpretable data in 34 cases (80%), mainly using ^{99m}Tc-DMSA, ^{18}F-FDG, and ^{99m}Tc-HDP. Several factors altering DRP biodistribution and responsible for IA were identified: (i) preparation (18/43, 42%), (ii) manufacture (7/43, 16%), (iii) injection (2/43, 5%), (iv) physiopathological factors (1/43, 2%), (v) prior treatment (1/43, 2%), and (vi) drug interactions (3/43, 7%). Concerning ME, a reversal of the DRP was identified in more than half of the cases. TRP were involved in 111 cases (26%) and concerned exclusively CBM, among which 68 (61%) serious AE and 10 deaths. ^{177}Lu-dotatate and ^{131}I-sodium iodide were the most frequently reported. CBM were mainly hematologic (64, 28%) (related to ^{177}Lu-dotatate), respiratory (40, 17%), and gastrointestinal (29, 13%). **Conclusion:** There is likely an important underreporting of RP-related AE given the low number of reports and the increasing number of examinations. CBM are less frequent but more serious in therapy than in functional imaging. Since preparation issues may impact RP biodistribution, pre-administration quality control should be performed as much as possible. Nuclear medicine teams need to be sensitized to RP-related AE notification, including IA and ME. **References:** None.

EP-0763

Patient-reported adverse events of diagnostic radiopharmaceuticals

N. Schreuder[1,2], *P. L. Jager*[3], *J. G. W. Kosterink*[1,4], *E. P. van Puijenbroek*[1,5]; [1]*University of Groningen, Groningen, NETHERLANDS,* [2]*GE Healthcare Radiopharmacy Zwolle, Zwolle, NETHERLANDS,* [3]*Isala Hospital, Zwolle, NETHERLANDS,* [4]*University Medical Center Groningen, Groningen, NETHERLANDS,* [5]*Netherlands Pharmacovigilance Centre Lareb, 's-Hertogenbosch, NETHERLANDS.*

Aim/Introduction: Adverse events (AEs) of radiopharmaceuticals can occur, but the reported frequency of 0.0023 - 0.011% is low [1,2]. However, this information originates from voluntary identification and reporting, which may decrease the rate. In addition, as there is usually no follow-up contact between the patient and the nuclear department, post-test adverse events may remain undetected. This study aims to investigate the type and frequency of adverse events of diagnostic radiopharmaceuticals as reported by patients within one week after administration. **Materials and Methods:** A validated questionnaire was used to collect data from patients undergoing a nuclear medicine procedure. We collected demographic data and analysed AEs occurring immediately after administration as well as those occurring later. Adverse events were analysed, coded and assessed for causality by two independent researchers. For the causality assessment, we used the Silberstein algorithm [2] that is specifically designed for AEs of radiopharmaceuticals. **Results:** In total, 1002 patients completed the questionnaire. A total of 186 patients (18.6%) reported a total of 379 AEs. Most reported AEs were general disorders, administration site conditions (42%), nervous system disorders (17%) and gastrointestinal disorders (9%). Most adverse events (80%) occurred shortly after administration of the radiopharmaceutical and 90% of those resolved without any sequelae within a median time of 15 minutes (IQR 2 - 120 min). However, 20% occurred later after the patient had left the nuclear medicine department. Of the reported AEs, 168 (99 patients) were determined to be possibly or probably related to the radiopharmaceutical. In the latter group, 113 AEs (68 patients) could probably also be attributed to the stress agent that is used with myocardial perfusion scans and were thus excluded from further calculations. AEs were mainly reported for most-used radiopharmaceuticals: Tc-99m oxidronic acid, F-18 fludeoxyglucose, and Tc-99m tetrofosmin. The overall frequency of patients experiencing adverse events

possibly or probably related to diagnostic radiopharmaceuticals was determined to be 2.72% (31/1002). **Conclusion:** Adverse reactions with diagnostic radiopharmaceuticals can occur, and the frequency as reported by patients was found to be 2.7% and higher than reported in the existing literature. **References:** (1) Hesslewood SR, Keeling DH. Frequency of adverse reactions to radiopharmaceuticals in Europe. Eur J Nucl Med 1997; 24:1179-1182. EP-0764

In vitro analysis of ^{99m}Tc-EDDA/HYNIC-TOC bonding to blood clots and comparison with other radiopharmaceuticals

***M. Valiente**, M. Villar, F. Cepa, S. Rubi, B. Luna, H. Navalon, C. Medina, F. Vega;*
Hospital Universitario Son Espases, Palma, SPAIN.

Aim/Introduction: Unexpected small hot spots were found in scintigraphic planar lung images with 99mTc-EDDA/HYNIC-TOC performed in our department in 9 neuroendocrine tumor studies, which could lead to diagnostic errors. Quality controls for testing radiochemical purity resulted normal, and a problem with injection technique was thus suspected. Several previous publications refer to formation of small thrombi that would embolize pulmonary arterioles when blood is aspired into the syringe during venous puncture. In order to determine if blood clot bonding exists, we have tested ^{99m}Tc-EDDA/HYNIC-TOC in coagulated and anticoagulated blood samples and also other radiopharmaceuticals under identical conditions as control experiments to support our in-vitro analysis. **Materials and Methods:** Tested radiopharmaceuticals were ^{99m}Tc-EDDA/HYNIC-TOC, ^{99m}Tc-MIBI and sodium pertechnetate (^{99m}TcO4$^-$) eluted from a ^{99}Mo/^{99m}Tc generator. All radiopharmaceuticals labelling and quality controls were developed according to summary of product characteristics. Whole blood samples were extracted from healthy adults. An heparinized tube was used as anticoagulant for half of the extracted blood and 1ml samples of both anticoagulated and non-anticoagulated blood were collected and incubated at room temperature with 200µl of radiopharmaceutical with an activity of 3'7-24MBq during 30min. Total activity was measured and non-bound activity was washed twice with 3ml of saline by removing supernatant after centrifugation at 1000g during 10min. Finally, bound activity was measured in sediment of both clotted samples and blood cells (mainly RBCs) of anticoagulated samples. Activity measurements, corrected by background and radioactivity decay were determined using a dose calibrator. **Results:** Results showed low activity fraction of ^{99m}Tc-EDDA/HYNIC-TOC bound to blood clots (9'4±2'6%; n=22) with no statistical significance in relation to activity retained in anticoagulated samples (p>0.05). MIBI (29'3±6'9%;n=15) and TcO4$^-$ (31'5±12'3%;n=8) showed higher fraction of activity bound to blood clots evidencing also a significant increase over fraction bound to RBCs in anticoagulated samples (12'4±2%,n=16, for MIBI and 10'6±2'5%,n=8, for TcO4$^-$). **Conclusion:** We found no evidence of ^{99m}Tc-EDDA/HYNIC-TOC bond to clots in our in-vitro experiment. Other radiopharmaceuticals as ^{99m}Tc-MIBI and TcO4$^-$ revealed increase of retention in contact with clots possibly explained by non-specific trapping and also, in case of ^{99m}Tc-MIBI, by interaction with hydrophobic fibrin involved in coagulation process. Our results are consistent with the fact that ^{99m}Tc-EDDA/HYNIC-TOC is a peptide which does not diffuse through cell membrane nor does it have a specific transporter. Further evaluation with larger sample size and considering other factors could be developed to characterize those increased uptake foci on scintigraphic images. **References:** None.

EP-0765

Development and validation of a HPLC method to determine chemical purity and radiochemical purity of [^{68}Ga]-DOTA-Pentixafor (PET) tracer

***S. Migliari**, A. Sammartano, M. Scarlattei, G. Baldari, G. Serreli, C. Ghetti, L. Ruffini;*
AZ. OSP. Universitaria Di Parma, Parma, ITALY.

Aim/Introduction: Due to its overexpression in a variety of tumor types, the chemokine receptor 4 (CXCR4) represents a highly relevant diagnostic and therapeutic target in nuclear oncology. Recently, [68Ga]-DOTA-Pentixafor has emerged as an excellent imaging agent for positron emission tomography (PET) of CXCR4 expression in vivo. Preparation conditions may influence the quality and in vivo behaviour of this tracer and no standard procedure for the quality controls (QCs) is available. Aim of this study was to develop a new rapid and simple HPLC method of analysis for the routine QCs of [68Ga]-DOTA-Pentixafor to guarantee the high quality of the finished product before release. **Materials and Methods:** A stepwise approach was used, based on the quality by design (QbD) concept of the ICH Q2 (R1) and Q8 (Pharmaceutical Development) guidelines in accordance with the regulations and requirements of EANM, SNM, IAEA and WHO. The developed analytical test method was validated because a specific monograph in the Pharmacopoeia is not available for [68Ga]-DOTA-Pentixafor. **Results:** The purity and quality of the radiopharmaceutical obtained according to the proposed method resulted high enough to safely administrate it to patients. Excellent linearity was found between 0.5 and 4 µg/ml, with a correlation coefficient (R2) for calibration curves equal to 0.9995, the average coefficient of variation (CV%) resulted <2% (0.14%) and the average bias% value was 100.21%. **Conclusion:** The developed method to assess the radiochemical and chemical purity of [68Ga]-DOTA-Pentixafor is rapid, accurate and reproducible allowing routinely use of this PET tracer as diagnostic tool for imaging CXCR4 expression in vivo, also assuring patient safety. **References:** Migliari S, Sammartano A, Scarlattei M, Serreli G, Ghetti C, Cidda C, Baldari G, Ortenzia O, Ruffini L. Risk management in a radiopharmacy: implementation of a microbiological contamination program based on a risk-assessment

M. Riondato, S. Pastorino, G. Giovacchini, E. Borsò, A. Ciarmiello; Nuclear Medicine Department, La Spezia, ITALY.

Aim/Introduction: One of the main risk in a radiopharmacy is the loss or reduction of sterility assurance and the subsequent microbiological contamination of injectable preparations. Clean-room and hot-cell environments must be periodically monitored and European Pharmacopoeia and Eu-GMP, which are the main guidelines in this context, have been recently implemented towards the determination of the acceptable levels of risk to ensure an appropriate radiopharmaceutical (RPh) quality. A Quality System driven by risks represents a crucial advance in legislation, now placing its emphasis on prevention of incidents rather than cure.The aim of the study is to develop an appropriated sampling layout for our radiopharmacy using risk analysis and experimental approaches. Results will be evaluated in order to implement the routinely inspections, to justify the microbiological monitoring frequencies and to propose risk-reducing measures. **Materials and Methods:** The number of monitoring points for a pharma-grade area depends on the size of each isolated environment (UNI EN ISO 14644-1), while their locations are driven by the risk level of contamination for the product quality. Sampling point risk levels were assessed using the failure mode and effect analysis (FMEA) approach. Room surfaces and gloved fingertip and workbench sampling were monthly monitored with TSA Petri dishes, two times per day (begin and the end as the worst case). After sampling dishes were incubated at 25°C/35°C and the number of colony forming units (cfu) counted. Criteria for evaluation of the results was based on current legislation. **Results:** A selection of representative points was identified for each environment. Kind of manipulation, infrastructure aspects, routinely practice and adequacy of cleaning specified in our procedures were considered in the assessment, as well as 4 years of historical data. Low, Mid and High risk level of contamination were addressed for 46 potential sampling points. 19 spots with significant severity were identified and the microbiological contamination tested at rest and in operation, both for bacteria and fungi growth. Clean-rooms respected the environmental requirements. Results for hot-cells were satisfactory, however 2 of the 5 isolators showed a slight deviation (gloved fingerprints at the end of the day) from the imposed criteria, probably due to the high frequency of entrance of disposable materials. **Conclusion:** The radiopharmacy has achieved compliance to guidelines implementing the microbiological contamination control program using a risk-assessment approach, confirming the 6 months monitoring frequency. Due to experimental evidence, the cleaning and disinfecting procedures applied to isolators have been implemented. **References:** None.

Application of production and quality control procedures of 18F-PSMA-1007: dominant in diagnosis of prostate cancer, through Synthera V2

***R. Shukurov**, M. Balashov, Z. Dadashov, M. Valiyev, E. Mehdi, F. Novruzov;*
Department of Nuclear Medicine, National Centre of Oncology, Baku, AZERBAIJAN.

Aim/Introduction: 68Ga-PSMA-11 is one of the tracer that successfully used in diagnosis of prostate cancer. However the limitation such as short half-life and radioactivity amount of 68Ga, getting from Ge-68\Ga-68 generators motivate scientist to develop new radiotracers for diagnosis of prostate cancer. 18F-PSMA-1007 is an attractive alternative to 68Ga-PSMA-11 and 18F-DCFPyL. Here in we presented synthesis of 18F-PSMA-1007 and quality control of this final product in vast quantities per batch, 18F-PSMA minimizes the need for daily multiple tracer syntheses and allows transfer to satellite centers. **Materials and Methods:** Fluorine produced in cyclotron was trapped in QMA cartridge (Synthera V2 module, IBA). Consequently, trapped 18F is eluted using TBA-HCO3. Drying was accomplished by azeotropic distillation using acetonitrile. After drying processes were over, labelling took place by adding precursor to the reaction vial. Solution were purified from chemical and radiochemical impurities by running through on C18 cartridge several times. The product was subsequently eluted with 30% EtOH, then passed through SCX cartridge. The main activity transferred to final product vial which obtained the phosphate buffered solution. 18F-PSMA radiochemical purity analyses are determined by HPLC and TLC methods. 18F-PSMA-1007 reference standard (ABX, Germany) was solved with 1ml ultra-pure water. The HPLC analyses were performed on C18 (4.6x250mm) column. The HPLC mobile phase was a mixture of acetonitrile/water/0.1% trifluoroacetic acid (TFA) (30:70:0.1) (Rf-7.5-8.0). Mobile phase for TLC analysis was acetonitrile/ water (60:40) mixture. **Results:** Yield of 18F-PSMA-1007 was 40%. Unlike HPLC analysis obtained by gradients for 18F-PSMA, in this HPLC analysis method suitable result was obtained by using isocratic solution. **Conclusion:** The radiochemical purity analysis with HPLC method has been improved and it makes possibility doing analysis without gradient pump. The chromatographic results which obtained from the standard and final product using isocratic buffer solution confirm reliability of this method. **References:** 1. EP-0768

Simultaneous production 18F-FDG and other 18F based (18F-NaF, 18F-FES, 18F-PSMA 1007, 18F-FET) radiopharmaceutical drug by a single run of medical cyclotron

Z. Dadashov, M. Valiyev, R. Shukurov, M. Balashov, F. Novruzov; Department of Nuclear Medicine, National Centre of Oncology, Baku, AZERBAIJAN.

Aim/Introduction: 18F-FDG is currently the most common used PET radiopharmaceutical in clinical oncology. Another Fluorine-18 based radiopharmaceuticals (NaF, FES, 18F-FET and F-PSMA) were popular for diagnostic methods using PET/CT in last few years. The objective of this study was to establish an easy, convenient and simultaneous production method for 18 Fluoride based molecules during routine synthesis of 18F-FDG production by using single run of cyclotron. **Materials and Methods:** The main core of this method to arrange level of F-18 input line into the V-vial. It can be clearly seen that, the amount of F-18 into V-vial. In general, 2.2 ml of transferred activity of radioactive fluorine from cyclotron collected inside V-vial.The first stage of production: 1.5 ml F-18 activity will be directly extract from the V-vial by the first synthesis module (SYNTHERA-A, IBA) for FDG synthesis; the second stage of production: 0.7 ml F-18 activity will be extract by second synthesis module (SYNTHERA-B, IBA) for NaF, FES or F-PSMA production. If there are several available synthesis modules in facility it should be possible to get several 18F-Fluorine based radiopharmaceuticals drug by single irradiation of enriched water by the cyclotron. The input line can be moved to any position in V-vial based on the required activity. The very important point of this procedure are to adjust the estimated bulk and properly arrange the F-18 input lines going to the different synthesis modules. **Results:** With this method, both synthesis processes can be performed simultaneously without any radiation exposure and it is possible to send the both product safely to the dispensing system. The process ends without any loss of activity. **Conclusion:** This is very appropriate and financially efficient method. To avoid cross contamination it should be better to make a separate dispensing system. In this method without using extra enriched water to get two radiopharmaceutical drugs and also saving production time. **References:** None.

^{89}Zr labelled nanoparticle coating with biotin inserted cell membrane as a biomaterial for enhancing long-term circulation and tumor targeting

***J. Lee**, P. Choi, M. Hur, S. Yang, Y. Kong, E. Lee, H. Song, J. Park; Korea Atomic Energy Research Institute, Jeollabuk-do Jeongeup-si, KOREA, REPUBLIC OF.*

Aim/Introduction: The final goal of nanomedicine is blood long-term circulation and effective drug delivery for diagnosis and treatment of various diseases. However, phagocytosis by macrophages is a critical issue indeed for delivering the drug to the target site. In order to solve this problem, camouflaged nanoparticles used with the natural erythrocyte membrane (Em). These cell membrane can overcome the immune barriers because CD47 proteins on Em are recognized by SIRP-alpha receptor of macrophage as a"Don't eat me" signal. In addition, biotin receptor s are overexpressed in many cancer cells, leukemia, ovarian, colon, mastocytoma, lung, renal and breast cancer cell lins[1]. Accordingly, we inserted biotin as the tumor active targeting ligands on Em surface. Their synergistic strategy is to enable long-term circulation and tumor targeting. **Materials and Methods:** Synthesized hollow mesoporous silica nanosphere (HMSN) was dispersed in a HEPES buffer (pH 7.5) at various concentrations. Zirconium-89 (^{89}Zr) has been incorporated with an advantageous half-life ($t_{1/2}$: 3.3 days) for long-term tracking of nanoparticles. The pH of ^{89}Zr-oxalate or chloride (~20 MBq) was adjusted to pH 7.5–8. After stirring with HMSN and ^{89}Zr at room-temperature for 24 hours, labeling efficiency was confirmed by radio-iTLC using 50 mM DTPA as the mobile phase. Em of the mice was isolated by a modified cell membrane extrusion method[2]. Biotin-DSPE-PEG was inserted on Em surface for tumor active targeting. Finally, Biotin-Em (BE) and ^{89}Zr labelled HMSN were co-extruded using mini-extruder. **Results:** BE camouflaged HMSN was successfully synthesized and characterized for in vivo long-term behavior and tumor active targeting. ^{89}Zr was incorporated under the mild condition with labeling efficiency of >96% on the silanol group of HMSNs by chelator free method[3]. After BE coating, the release of ^{89}Zr was decreased for long-term tracking. That means BE-^{89}Zr-HMSN can be used for the candidate of long-term tracking. Compared to the 89Zr-HMSN and Em-^{89}Zr-HMSN, BE-^{89}Zr-HMSN was accumulated effectively and rapidly in the tumor site. **Conclusion:** Having distinguished potentials viz. non-release of ^{89}Zr, long-term circulation and effective tumor targeting ability in biological systems this strategy can be applied extensively to identify the long-term in vivo behavior and tumor targeting of nanomedicine while enhancing their biocompatibility. **References:** [1] Russell-Jones G et al., Australia: Access Pharmaceuticals Australia Pty. Ltd; 2004. PCT WO2004/045647. [2] Xiaoqing R et al., Biomaterials; 2016, 92, 13-24. [3] Shreya G et al., Advanced science; 2016, 3, 1600122.

EP-0770

Fully Automated Radio Synthesis Of [18F]MK-6240 For Clinical Use

J. Toyohara[1], *T. Tago*[1], *K. Nishino*[1,2], *M. Sakai*[1,2], *K. Ishii*[1];
[1]*Tokyo Metropolitan Institute of Gerontology, Itabashi-ku, Tokyo, JAPAN,* [2]*SHI Accelerator Service, Shinagawa-ku, Tokyo, JAPAN.*

Aim/Introduction: Fluorine-18 labeled 6-(fluoro)-3-(1H-pyrrolo[2,3-c]pyridine-1-yl)isoquinolin-5-amine ([18F]MK-6240) is a second generation selective PET radiopharmaceuticals for detecting human neurofibrillary tangles, which are made up of aggregated tau protein. Herein, we report the fully automated two-step, one-pot radiosynthesis of [18F]MK-6240 using a commercially available radiosynthesis module, SHI CFN-MPS200 and its validation for clinical use. **Materials and Methods:** The cassette for [18F]MK-6240 synthesis was designed with compact and efficient routing, and the programs were developed to control the synthesis. Nucleophilic fluorination of the 5-di-Boc-6-Nitro precursor NGMA-239 with [18F]KF/K.222 complex was carried out using a stepped gradient temperature protocol [1], followed by acid deprotection, neutralization, SPE pre-purification [2] and semi-preparative HPLC (eluent: 425/20/500 ethanol/0.5M sodium phosphate corrective injection/water for injection). The radioactive fraction was collected, diluted with sterile saline and sterile filtered into a pyrogen-free collection vial as an ethanol containing saline solution. Three consecutive batches of [18F]MK-6240 were produced and all quality control tests were performed on the final product: appearance, radionuclide identity, radiochemical purity, chemical purity, molar activity, pH, shelf-life for 8 hours, residual solvents, filter integrity, sterility and bacterial endotoxins were analyzed. **Results:** The total synthesis time was within 90 min form the end of bombardment. Decay-corrected radiochemical yields were 7.5-14.1% based on formulated product (1750-3810 MBq). The radiochemical purity was ≥98% at end of synthesis and the product could be stored for 8 hours without too much radiolysis (radiochemical purity remained >97%). The use of SPE pre-purification and the preparative HPLC purification resulted in pure, sterile product with barely detectable levels of residual solvents, and extremely low levels of total chemical impurities (<0.3 µg/mL) and bacterial endotoxins (<0.1 EU/mL). Using the fluoride-free materials composed cassette such as silicon tube and polypropylene connectors, resulted in high molar activity (943-1541 GBq/µmol at the end of synthesis) of the product. Three consecutive productions of [18F]MK-6240 complied with the product specifications and process was confirmed to be appropriate for the production of [18F]MK-6240. Formulated [18F]MK-6240 maintained radiochemical purity, chemical purity, molar activity (≥37 GBq/µmol), as well as clarity and a pH over a period of 8 hours. **Conclusion:** [18F]MK-6240 was validated for clinical use with a SHI CFN-MPS200 radiosynthesis module. The methodology described herein can facilitate multi-center trials and widespread use of this radiopharmaceutical for imaging tau protein in vivo. **References:** [1] Collier TL, et al, J Label Compd Radiopharm 2017; 60:263-269. EP-0771

[18F]FPEB is a substrate for Pgp and Bcrp in the rodent brain

J. Choi, *K. Jung, S. Oh, K. Kang, S. Han, K. Nam, K. Lee, Y. Lee;*
Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: [18F]-3-fluoro-5-[(pyridin-3-yl)ethynyl] benzonitrile ([18F]FPEB) is a specific PET radiotracer for the metabotropic glutamate receptor 5 (mGluR5). Although its biological effectiveness were validated in the preclinical and clinical trials, the effect of efflux transporters on the brain uptakes of [18F]FPEB has not been reported. Therefore, the purpose of the present study is to determine whether the brain uptakes of [18F]FPEB is influenced by efflux transporters (i.e. P-gp and/or Bcrp) in the rodent **Materials and Methods:** Male Sprague-Dawley (260-300 g, n=5 for each group) rats were used. Male FVB (wild-type), Mdr1a/b$^{(-/-)}$, Bcrp1$^{(-/-)}$ and Mdr1a/b$^{(-/-)}$Bcrp1$^{(-/-)}$ genetic background were used (n=4 for each group). After animals were anesthetized, catheters were inserted into the tail veins. For mice, [18F]FPEB (7.4- 9.2 MBq) was injected to the tail vein. For rats, tariquidar (6 mg/kg) was bolusly injected to inhibit P-gp activity, followed by administration of [18F]FPEB (14.8-16.6 MBq). For attenuation correction, micro-CT imaging was conducted. Cortex, hippocampus, striatum and cerebellum were defined as volumes of interests. The obtained uptake value was represented as the standardized uptake value (SUV). **Results:** In the pharmacological inhibition model, P-gp blocked group with tariquidar showed 8 to 12% increase in the brain uptake compared with the control group. In the genetic ablation models, P-gp knockout mice such as Mdr1a/b(–/–) and Mdr1a/b(–/–)Bcrp1(–/–) there was a 8 ~ 53% increase in [18F]FPEB uptake compared with that in the wild-type mice. In contrast Bcrp knockout mice showed a decrement of 5 ~ 12% uptake and P-gp/Bcrp knockout group displayed an increment of 5 ~ 17% compared with wild-type. **Conclusion:** [18F]FPEB is a substrate of P-gp and Bcrp, where it is more affected by P-gp. **References:** 1. Non-invasive whole-body imaging of immune checkpoints using PET-labeled small molecules as predictive biomarker for response to therapy

M. Wazynska[1], *R. Butera*[2], *M. de Bruyn*[1], *A. S. S. Domling*[2], *P. H. Elsinga*[1], *H. W. Nijman*[1];
[1]*University of Groningen, University Medical Center Groningen,*

Groningen, NETHERLANDS, [2]University of Groningen, Faculty of Science and Engineering, Groningen, NETHERLANDS.

Aim/Introduction: PD1/PD-L1 blockade have transformed the landscape of oncology with unprecedented long term disease remission, and even cure in hard-to-treat cancers. Nevertheless, PD1/PD-L1 inhibitors are only effective in a subset of patients and predictive biomarkers for treatment efficacy are urgently needed. Positron-emission tomography (PET) is exquisitely suited as a biomarker as it offers an excellent sensitivity, high spatial resolution and can overcome the obstacles such as tumor heterogeneity, sampling errors and dynamic changes in checkpoint expression. Moreover, development of small molecule PD1/PD-L1 PET tracers would be highly beneficial, since available PD1/PD-L1 antibody based PET tracers are characterized by long biodistribution time, higher radioactivity burden, lower permeability and high production cost. **Materials and Methods:** We developed a potent class of small molecule PD-L1 antagonists based on PD1/PD-L1 blockade disruption bioassay, as well as NMR-based fragment screening approach to achieve high affinity, selectivity for PDL1, good stability and solubility. The lead compound was further modified to allow radiolabeling. Modifications included methylation and aromatic fluorine substitution. Synthesis of cold reference compounds and their precursors, PET-labelling, HPLC purification and formulation allowed to test selected tracer ([^{11}C]RB66, [^{18}F]RB67) in biological system. For binding experiments CHO.PD-L1, CHO.PD1, H292 and H358 cell lines were chosen. CHO cell lines were transfected with PD-L1 protein and PD1 (negative control). H292 and H358 were cancer cell lines with endogenous expression of PD-L1 (low and intermediate expression of PD-L1 respectively). H358 cell line was engineered into PD-L1 knock out using CRISPR/Cas9 technique. **Results:** Successfully synthesized PET-tracers did not exhibit significant binding towards CHO.PD1 and CHO.PD-L1. Testing [^{18}F]RB67 with H292 and H358 has shown no binding to negative control (H292) and a significant uptake in PD-L1 expressing cell line (H358). To further investigate the nature of this binding, [^{18}F]RB67 was tested on H358 PD-L1 knock out cell line and H358 PDL1 wild type cell line in condition allowing internalization (37 °C incubation) and other preventing it (4°C). Experiments has shown significant cell uptake at 37 °C, no binding to knock out cell line and cell line at 4°C. **Conclusion:** Results suggest that there is high binding of [^{18}F]RB67 to H358 PD-L1 expressing cells, no significant off-target binding and internalization is the main way for tracer uptake, however further investigation to fully confirm stated hypothesis is needed to be able to proceed with in vivo model. **References:** None.

EP-0773

Effective Surface Modification of the Zr-89 labeled Iron Oxide Nanocluster and tracking Biological Behavior for Tumor Xenograft Mouse Model

***P. Choi**, J. Lee, Y. Gong, E. Lee, S. Yang, H. Song, M. Hur, J. Park;*
Korea Atomic Energy Research Institute, Jeongeup, KOREA, REPUBLIC OF.

Aim/Introduction: Nanoparticles having the properties to target cancer cells by Enhanced Permeability and Retention (EPR) effect are used to study in vivo behavior and track their pharmacokinetics by zirconium-89 due to relatively long half-life. It is important to understand or to examine how surface properties of the nanoparticles affect the in vivo behavior. In this study, we select three of biocompatible coating materials which are easily coated on iron oxide nanoparticles and clearly unknown for its in vivo behavior such as polyethyleneimine (PEI), polyvinylpyrrolidone (PVP) and bovine serum albumin (BSA). After the surface modification, we could confirm what the coating materials are expected to help tumor target through measuring PET. **Materials and Methods:** Firstly, we synthesized the ^{89}Zr labelled iron oxide nanocluster (^{89}Zr-IONCs) by hydrothermal direct-labeling synthetic method. In order to change the surface properties of ^{89}Zr-IONCs for improvement of colloidal stability in biological environments and effective tumor target, the surface of ^{89}Zr-IONCs was coated by PEI, PVP and BSA through electrostatic interaction and hydrogen-bonding, respectably. Characterization for the surface coating was confirmed by DLS/Zeta-potential equipment. To examine biological behavior of each surface coated ^{89}Zr-IONCs, we performed colloidal stability experiment, cellular uptake and measurements of PET images for CT-26 tumor xenograft mouse. **Results:** The colloidal stability in biological medium such as PBS (pH 7.4), DMEM and serum was significantly high for 24 h after completion of all surface modification while non-coated ^{89}Zr-IONCs was shown to tend to aggregate in the solution (>600 nm). The surface charge of ^{89}Zr-IONCs was changed depend on the coating materials (^{89}Zr-IONCs@PEI : +18 mV, ^{89}Zr-IONCs@PVP : +0.12 mV, ^{89}Zr-IONCs@BSA : -32 mV) which affect for in vivo behavior after intravenous injection. Utilizing measurements of PET images, PVP and BSA coated ^{89}Zr-IONCs was rapidly reached in tumor site and continuously increased until 24 h. In contrast, no tumor uptake was shown for PEI coated ^{89}Zr-IONCs and bared ^{89}Zr-IONCs. Another one important thing is that liver uptake of ^{89}Zr-IONCs@PVP drastically decreased after 2 h of i.v. injection. **Conclusion:** Neutral or negative surface charge and higher colloidal stability of the nanoparticles was effective for tumor uptake rather than the other. Especially, PVP coating is expected to target cancer cells in the field of nanomedicine that was confirmed by PET images using Zr-89. **References:** None.

EP-0774

Development of novel ^{68}Ga-Labeledlong noncoding RNA MALAT1 probes for in vivo tumour imaging

***M. Dong**[1], Z. Liu[1], M. Yang[2], Y. Xu[2], D. Pan[2], G. Wang[1], T. Hu[1];*
[1]The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, CHINA, [2]Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.

Aim/Introduction: With the advent of next-generation sequencing technology, there is rapidly increasing interest in long noncoding RNAs (lncRNAs). The objectives of this study were to develop a novel ^{68}Ga-Labeled long noncoding RNA

MALAT1 probes to evaluate the characteristics of the imaging probe in vitro and to determine whether it can be used for imaging MALAT1 expression in malignant tumours. **Materials and Methods:** ^{68}Ga- MALAT1 ASO positron molecular probes were prepared in a one-step protocol starting from the precursor (NOTA-chelated oligonucleotides).The new ^{68}Ga- MALAT1 ASO binding to PBS solution and to human plasma proteins was examined by means of ultrafiltration. The biodistribution and biokinetics were evaluated in vivo in normal rats and athymic rat bearing HCC-LM3 tumor. Dynamic micro-PET imaging lasting up to 480min was performed immediately after intravenous injection of ^{68}Ga- MALAT1 ASO positron molecular probes. Blank studies were performed using ^{68}Ga-DOTA alone without oligonucleotide. The ^{68}Ga-antisense oligonucleotide uptake in tumors was also compared with ^{68}Ga-sense oligonucleotide uptakes. **Materials and Methods:** ^{68}Ga- MALAT1 ASO positron molecular probes were prepared in a one-step protocol starting from the precursor (NOTA-chelated oligonucleotides).The new ^{68}Ga- MALAT1 ASO binding to PBS solution and to human plasma proteins was examined by means of ultrafiltration. The biodistribution and biokinetics were evaluated in vivo in normal rats and athymic rat bearing HCC-LM3 tumor. Dynamic micro-PET imaging lasting up to 480min was performed immediately after intravenous injection of ^{68}Ga-MALAT1 ASO positron molecular probes. Blank studies were performed using ^{68}Ga-DOTA alone without oligonucleotide. The ^{68}Ga-antisense oligonucleotide uptake in tumors was also compared with ^{68}Ga-sense oligonucleotide uptakes. **Results:** The average radiochemical yields of ^{68}Ga- MALAT1 ASO was 50% (not corrected for radioactive decay) ranging 15 to 20min, and radiochemical purity was large than 98%. Intravenously injected ^{68}Ga- MALAT1 ASO positron molecular probes revealed high-quality PET images, allowing quantification of the biokinetics in major organs and in tumors. The biodistribution and biokinetics of intravenously administered ^{68}Ga- MALAT1 ASO positron molecular probes showed high uptake in the tumor tissues (3.04±0.11%ID/g, 2.04±0.04%ID/g at 30min, 60min respectively). Tumor/blood and tumor/muscle odds were 8.47±0.02, 8.1725±0.12 respectively at 60min after intravenously injected 100 uCi ^{68}Ga-MALAT1 ASO positron molecular probes. **Conclusion:** Our results provide evidence that ^{68}Ga-MALAT1 ASO is a convenient approach, and these novel probes can serve as novel specific molecular probes for in vivo imaging of tumour expressing MALAT1. **References:** None.

Development of novel [^{18}F]thiosemicarbazone metal fluoride complexes as potential neuroimaging agents

D. Stimson[1], *T. K. Venkatachalam*[1], *G. K. Pierens*[1], *P. V. Bernhardt*[2], *K. Mardon*[3], *D. C. Reutens*[1], *R. Bhalla*[1];
[1]*Centre for Advanced Imaging, University of Queensland, Brisbane, AUSTRALIA,* [2]*School of Chemistry and Molecular Biosciences, University of Queensland, Brisbane, AUSTRALIA,* [3]*National Imaging Facility, University of Queensland, Brisbane, AUSTRALIA.*

Aim/Introduction: The SPECT imaging agent [^{99m}Tc]HMPAO (Ceretec) is both neutral and lipophilic[1] (logP of 1.9) enabling blood brain barrier (BBB) permeability. Labelling strategies utilising stable metal-^{18}F bonds have been reported,[2,3] however these metal-^{18}F complexes are hydrophilic and will unlikely cross the BBB. Our interest is to develop ^{18}F-labelled agents with comparable properties to Ceretec as potential neuroimaging agents for PET. **Materials and Methods:** A series of structurally related indium chlorido complexes of bis-thiosemicarbazones were prepared, starting from the appropriately substituted bis-thiosemicarbazones[4]. Aliphatic groups were introduced into the structure to reduce the liphophilicity of the molecule. Fluoride was introduced into the coordination sphere using a halogen exchange strategy by replacement of chloride with nitrate (using $AgNO_3$) then treating the nitrato complex with potassium fluoride. Radiolabelling with fluorine-18 was achieved using a similar approach. Similarly, gallium chlorido complexes of bis-thiosemicarbazones were prepared and converted to their corresponding nitrate complexes before radiolabelling with fluorine-18. Complexes of both the indium and gallium compounds were characterised with NMR and X-ray crystallography[5,6]. Lipophilicity of gallium-fluoride complexes was assessed by measuring the octanol/water partition coefficient. Imaging studies of [^{18}F]diphenylthiosemicarbazone gallium fluoride in mice were performed using preclinical PET/CT. **Results:** The measured logP of [^{19}F]diphenylthiosemicarbazone gallium fluoride is 1. Imaging studies in mice with PET indicate that the [^{18}F]diphenylthiosemicarbazone gallium fluoride is stable in vivo and showed rapid uptake of the complex in the brain. **Conclusion:** To our knowledge, we have synthesised the first indium-^{18}F complex and report the first Ga-^{18}F complex studied in vivo. Our work highlights the potential of using ^{18}F-labelled indium and gallium fluoride compounds for neuroimaging with PET. **References:** 1. Establishing a GMP-compliant 89-Zirconium radiopharmaceutical production capability at the Royal Marsden Hospital Foundation Trust, UK

J. Tan[1], *C. Da Pieve*[2], *G. Smith*[2], *D. Turton*[2], *W. J. G. Oyen*[2];
[1]*Royal Marsden Hospital Foundation Trust (RMH), Sutton, UNITED KINGDOM,* [2]*Institute of Cancer Research (ICR), London, UNITED KINGDOM.*

Aim/Introduction: Owing to their high target affinity and specificity, radiolabelled antibodies have been extensively

investigated for the imaging of receptor expression in tumours. The long-lived positron emitter zirconium-89 has a half-life ($t_{1/2}$ = 78.4 hrs) compatible with the biological half-life of antibodies (mAbs). Positron Emission Tomography (PET) with zirconium-89-mAbs showed great potential to provide information about tumour targeting/target expression, and is a promising tool for personalized medicine and for accelerating/improving drug development. Although zirconium-89-mAbs have been prepared and clinically used for more than a decade in countries such as The Netherlands and USA, the stringent regulatory environment in the UK has delayed the GMP-compliant production of such radioimmunoconjugates. Herein we summarise the implementation of the general process described by Vosjan et al.[1] for the GMP-compliant preparation of mAb conjugates and their radiolabelling at the Royal Marsden Hospital (RMH) NHS Foundation Trust, UK. **Materials and Methods:** The production of a zirconium-89-mAb consists of two main phases: the preparation of the DFO-mAb conjugate and subsequent radiolabelling. Each phase, requiring extensive manual manipulations, was developed using the available infrastructure and services at RMH and the ICR, UK. Both processes were entirely carried out in a Grade A environment using commercially available mAbs. Risk assessments were produced when ready-to-use reagent or buffers were not available. Quality control, characterisation and quantification of the products were performed either at RMH Radiopharmacy and ICR expert laboratories, or external specialists. Zirconium-89 was purchased from BV Cyclotron VU, NL. **Results:** Although most of the processes followed standard radiopharmaceutical preparation techniques, some non-standard procedures required particular attention: PD10 desalting columns were tested to determine the removal of the storage germicide, and the content of oxalate/HEPES in the final product. UV-Vis measurements demonstrated germicidal removal according to manufacturer-suggested protocol. Ion-exchange HPLC was a reliable technique for the quantification of oxalate and HEPES levels. Facilities at the ICR were suitable for DFO-to-mAb ratio determination by ESI-MS, mAb quantification by UV, and Lindmo assay. RMH facilities were used for sterility and endotoxin determination, filter-integrity testing, and QC analysis by ITLC and SEC-HPLC. **Conclusion:** Our goal is to establish the RMH and ICR as a UK centre of excellence for the development and production of GMP-compliant zirconium-89-mAbs. The RMH-ICR team has already investigated the applicability of crucial steps with the objective of positive engagement with local regulators in the near future. **References:** 1. Vosjan MJWD et al. ^{18}F-Labeled PET Tracers Derived from Angiotensin II type 1 Receptor Antagonists

X. Chen[1], *M. Hoffmann*[2], *R. A. Werner*[1], *K. Arimitsu*[3], *H. Kimura*[3], *M. Decker*[2], *T. Higuchi*[1];
[1]*University Hospital of Würzburg, Würzburg, GERMANY,*
[2]*Julius Maximilian University Würzburg, Würzburg, GERMANY,*
[3]*Kyoto Pharmaceutical University, Kyoto, JAPAN.*

Aim/Introduction: Angiotensin II type 1 receptors (AT_1R) are involved in various diseases progress as well as the therapeutic applications, such as hypertension, heart failure, nephropathy and inflammation. ^{18}F&#8211labelled radiotracers derived from clinically used AT_1R antagonists using positron emission tomography (PET) technology can reflect the functionality of the renin&#8211angiotensin system by monitoring the pathophysiological distribution and alteration of AT_1R. **Materials and Methods:** By studying the structure&#8211activity relationship, fluorine was introduced to different positions of the aliphatic side chain of valsartan and irbesartan. Precursors and the corresponding cold references have been synthesized and evaluated in CHO&#8211K1 cell lines expressing human AT_1R. After successful radiolabeling, biodistribution and blocking studies were performed in rats and pigs. **Results:** The fluorine derivatives of valsartan and irbesartan showed almost identical IC_{50} values at AT_1R, 14.6 and 6.6 nM, respectively, as compared to their leads, 11.8 and 1.6 nM, respectively, as well as Angiotensin II 2.0 nM. Successful radiolabeling of both radiotracers in a one&#8211pot two steps procedure enabled in vivo PET imaging. Distinct kidney uptake could be observed using both radiotracers with specificity proved by blocking studies using either valsartan or irbesartan. **Conclusion:** The results demonstrated the strategy of deriving novel AT_1R PET tracers from clinically used AT_1R antagonists with the least structural modification. Both ^{18}F&#8211valsartan and ^{18}F&#8211irbesartan may serve as tracers for renal imaging, inflammatory assessment and cancer diagnosis by providing information regarding the distribution and alteration of AT_1R under pathophysiological conditions. **References:** 1. Aim/Introduction: Scandium (Sc) is a good candidate for theranostic applications, suitable for both imaging (Sc-43 and Sc-44) and therapy (Sc-47) [1]. A "proof-of-concept" study regarding first-in-human use of Sc-44 for imaging metastatic

neuroendocrine tumours was reported recently [2]. To date, quantitative Sc-44 PET imaging was not evaluated, however. The aim of this study was, therefore, to evaluate quantitative capabilities of Sc-44 PET in a commercial device. **Materials and Methods:** The NEMA/IEC body phantom was scanned using a Siemens mCT Biograph PET-CT. Sc-44 was produced at PSI's research cyclotron [2]. A single-bed list-mode (LM) acquisition (150s scan duration) was performed using the vendor-based Sc-44 setup and reconstructed according to the local clinical protocol used for whole-body oncologic [^{18}F]FDG PET examinations. In addition, we characterised the signal recovery according to the number of iterative updates (iterations from 1 to 10). For all reconstructions, pertinent image corrections (normalization, dead time, activity decay, random coincidence and attenuation) were applied. Presently, Sc-44 prompt-gamma and scatter corrections were not optimized and would potentially result in quantitative bias. To investigate this point, we reconstructed the acquired data with different scatter corrections available (no correction, relative correction and absolute corrections) [3].System cross-calibration with the local dose calibrator (BGcal) and image noise, expressed by the coefficient of variation (COV) were evaluated on the homogeneous background region (5kBq/mL) of the NEMA/IEC phantom. Maximum (RCmax) and 50% threshold corrected for background (RCA50) recovery coefficients were measured for all spherical inserts (25kBq/mL) present in the phantom. **Results:** Acceptable image noise (COV<15%) was achievable with low iteration numbers (it<3). System-to-dose calibrator differences were large, BGcal ranged from 66.3 to 68.1 % of the expected value, regardless of the scatter correction method applied. Despite the effect of over correction due to the applied scatter corrections, RC values measured in lesions exceeded the RC range recommended by the EARL/EANM for [^{18}F]FDG procedures [4]. For the tested range of iterations, RCA50 ranged from 29.9% to 59.9% for the smallest lesion (10 mm diameter), [45.5%:80.3%], [66.4%:75.6%], [71.7%:75.7%], [75.1%:78,6%] and [76.7%:80.9%], respectively, for the 13, 17, 22, 28 and 37 mm spherical inserts in the NEMA/IEC phantom. **Conclusion:** The results of this study show that clinical Sc-44 PET imaging has the potential to provide signal recovery in lesions of different sizes comparable with present F-18 PET standards. Nevertheless, the quantitative accuracy of Sc-44 PET still requires optimized scatter and prompt-gamma corrections. **References:** (Picture with references deleted)

New approach to production and quality control of 16α-[18F] fluoroestradiol ([18F] FES: The effective functional molecular imaging probe for positive estrogen receptors breast cancer

Z. Dadashov, *R. Shukurov, M. Valiyev, K. Eryilmaz, M. Balashov, F. Novruzov;*
Department of Nuclear Medicine, National Centre of Oncology, Baku, AZERBAIJAN.

Aim/Introduction: Hormonal therapy is one of the crucial methods in treatment of breast cancer with positive estrogen receptors. FES is an estrogen analogue and it is a radiopharmaceutical that enables detecting of estrogen receptor expression, also predicts response to hormonal therapy and manages to identify positive estrogen receptors with PET/CT imaging. Our aim was to develop a reliable, easy-to-use, remotely controlled synthesis for non-carrier added 16α -[18F]FES by nucleophilic substitution using a disposable FDG cassette for "Synthera V2". **Materials and Methods:** Production and purification processes executed using two FDG cassettes by changing their design and commands in sequences sections. FES reagent kit for "GE TRACERlab MX" (ABX®) was used during synthesis process. For purification process of final product usually HPLC system is required. Because not all production facilities are equipped with HPLC purification system we have solved this issue without HPLC using second synthera module. The purification process successfully executed by adjusting FDG cassettes' design and sequence commands in "Synthera V2" (IBA) synthesizer. Purification of the crude product accomplished using solid phase extraction cartridges (WAX, HLB Plus, Sep-Pak C18 and Light Alumina N). Formulation of the final product is implemented in the automatic synthesis. **Results:** TLC and HPLC were used to identify radiochemical purity of 18F-FES. Radiochemical and chemical purities were determined using the following HPLC conditions: Agilent 1200 HPLC, Kromasil 100-5- C18 column (4,6x250mm) eluted with 1 mL/min acetonitrile (50%) in water (50%) (Wavelength 254 nm, injection volume 20 mL). Reference standard (FES) has a Rf value of 7.58 and the Rf value of 18F-FES is 7.65 (Figure 1).Radio TLC was performed on F254 glass-backed silica plates (Merck), (eluent acetonitrile/H2O=95/5) and radioactivity was detected with a miniGita from Raytest. Rf value of 18[F] (0-0.1) and the Rf value of product is (0.7-0.8) (Figure 2). **Conclusion:** The purification of FES synthesis process is possible with 2 combined "Synthera V2" devices without HPLC. Production process took 60 minutes with 25% yield. Radiochemical purity of final product was 98% for both HPLC and TLC methods. **References:** 1.J Pharm Pharm Sci. 2007;10(2):256s-265s. In vivo visualisation of GLP-1 receptor expression with PET/CT in patients with morbid obesity undergoing bariatric surgery

L. Deden[1], *M. Boss*[2], *F. Berends*[3], *M. Brom*[2], *E. Hazebroek*[1], *M. Gotthardt*[2];
[1]*Rijnstate, Vitalys, Arnhem, NETHERLANDS,* [2]*RadboudUMC, Nijmegen, NETHERLANDS,* [3]*Rijnstate, Arnhem, NETHERLANDS.*

Aim/Introduction: An approach for in vivo beta cell imaging is targeting the glucagon-like peptide-1 receptor (GLP-1R) by radiolabeled exendin-4, a glucagon-like peptide-1 (GLP-1) analogue. However, the role of GLP-1 is wider than stimulating insulin secretion from the beta cells. For example: GLP-1 induces satiety and many effects of gastric bypass surgery are related to an increase in GLP-1 levels. Signaling mechanisms of GLP-1 in these effects are not completely understood yet, but involvement of GLP-1R is expected. Therefore, the aim of the study is to determine in vivo GLP-1R expression by assessing the distribution of ^{68}Ga-exendin-4 in human. **Materials and Methods:** Distribution of ^{68}Ga-exendin-4 uptake on PET/CT was analyzed in bariatric patients who underwent GLP-1R imaging between September 2015 and January 2019. PET/CT was performed one hour after injection of ^{68}Ga-exendin-4 (100±5 MBq). **Results:** In total 24 patients were included in this analysis, 10 patients prior to and 14 patients at least one year after Roux-en-Y gastric bypass surgery. Clear tracer uptake was observed in pancreas and duodenum in all patients. Most patients showed uptake in the salivary glands and pituitary (70-90%). In a part of the patients, tracer uptake was observed in breast tissue, small intestine, uterus and ovary and cardiac tissue (8-40%). **Conclusion:** GLP-1R expression was observed in several tissues in the human body in vivo. This biodistribution was not described before in human. GLP-1 is hypothesized to have an important role in many metabolic functions, however the exact mechanism of GLP-1R signalling is unknown. For example, GLP-1 may have an effect on hypothalamus-pituitary-adrenal axis via pituitary GLP-1 receptors. Effects of GLP-1 on cardiac function and blood pressure may be facilitated by GLP-1 receptors in cardiac tissue. Further research is needed to understand the role of GLP-1 and GLP-1R in these tissues and for this GLP-1R imaging may be a valuable tool. **References:** None.

Quantitative Clinical Imaging of ^{89}Zr: Developing the Patient Pathway

A. Fenwick[1,2], *L. Bartley*[2], *D. Deidda*[1], *W. Evans*[2], *K. M. Ferreira*[1], *S. Paisey*[2], *A. P. Robinson*[1], *C. Marshall*[2];
[1]*National Physical Laboratory, Teddington, UNITED KINGDOM,* [2]*Wales Research & Diagnostic Positron Emission Tomography (PET) Imaging Centre, School of Medicine, Cardiff University, Cardiff, UNITED KINGDOM.*

Aim/Introduction: The popularity of ^{89}Zr has increased in recent years, partly due to applications in the diagnosis and treatment of non-Hodgkin's lymphoma[1] and other immuno-PET studies[2]. This is of particular interest in patient treatment planning, where ^{89}Zr-labelled antibodies may be used as a dosimetry planning vector for ^{90}Y antibody therapies. Additionally, due to its relatively long half-life (78.42h), the tracking of tumour response to antibody therapy over several days is possible and shows future potential for this radionuclide. The successful implementation of these applications rely on the accuracy of the activity distribution determined using PET. This study investigated the quantitative accuracy of clinical PET systems for ^{89}Zr imaging. **Materials and Methods:** A 6L cylindrical phantom and a standard NEMA-IEC-PET body phantom were filled with solutions of ^{89}Zr with activities varying between 50 and 100MBq that were standardised by the National Physical Laboratory to determine the activity concentration. The phantoms were measured on a GE-690-PET/CT and a Mediso-Anyscan-Trio-PET/CT. Repeat measurements over 4 weeks were performed to confirm device stability. Different volumes of interest were manually drawn to assess partial volume effect and quantification accuracy. **Results:** Both systems demonstrated an ability to determine the activity within the selected regions to within 10% for large volumes, increasing to 20% for volumes down to 1mL when using an independent OSEM-based reconstruction method[3]. Manufacturer supplied software showed deviations of up to 20% on large volumes and up to 40% for volumes down to 1mL however these differences were dependent on the reconstruction. A major source of error was found to be the use of incorrect nuclear data within the manufacturer supplied software and therefore a simple post-processing correction method was developed. Standard uncertainties on the activity determination of 5-10% for the spheres in the NEMA phantom were calculated. **Conclusion:** The first traceable measurements of ^{89}Zr were performed on clinical PET/CT systems. Methods for calculating and propagating uncertainties are presented alongside protocols for creating suitable test phantoms in a traceable manner. The accuracy of two clinical imaging systems in the determination of activity uptake was assessed, and recommendations made for the verification of activity uptakes in different clinically relevant geometries aiding the use of this radionuclide in the clinical arena. **References:** [1] DOI:10.1007/s00259-006-0160-0. Instrumentation and Infrastructure for Setting up Advanced PET/CT Services beyond F18-FDG in a Developing Country

A. Fatima*, A. Parveen, I. Khan, A. Shahid;*
INMOL Cancer Hospital, Lahore, PAKISTAN.

Aim/Introduction: Our aim in this study is to share our experience in setting up advanced PET CT services beyond ^{18}FDG, including instrumentation and infrastructure. Our primary focus is to provide a cyclotron-independent solution, primarily ^{68}Ge/^{68}Ge generator as a one-stop shop comprehensive tool in an emerging economy. Due to resemblance of co-ordination chemistry of ^{68}Ga, ^{177}Lu and ^{90}Y, it is possible to use the same vector molecule for subsequent radionuclide therapy. **Materials and Methods:** ^{68}Ga is an easily-available generator-derived diagnostic trivalent radio metal with convenient labeling characteristics. Our center has launched a GMP compliant, fully automated click and start cassette-based synthesis system with easy handling (ITG, Germany) for the daily routine production of ^{68}Ga labeled radiopharmaceuticals. Since it was a new set-

up so all regulatory parameters, e.g., license commitments (including generator set-up, elution, drug preparation, ^{68}Ge breakthrough testing, final disposition), radiation protection program including development and implementation of written emergency procedures for leaking or damaged generators, have been well validated, documented and fully implemented. We have established the clinical practice by using DOTA-NOC for imaging of NETs and Prostate-Specific Membrane Antigen (PSMA) for imaging of prostate cancer, followed by treatment with ^{177}Lu-DOTATATE and ^{177}Lu-PSMA. Quality control parameters of ^{68}Ga/^{177}Lu-biomolecules were assured according to European pharmacopoeia. **Results:** We are able to establish a reliable, highly-efficient and medically approved high quality ^{68}Ge/^{68}Ge generator system with a shelf-life of at least 1 year, low ^{68}Ge breakthrough (not more than 0.005%), narrow elution profile and low metal-ion contamination. The elution efficacy of our ^{68}Ga/^{68}Ge generator is approximately 97±2.2%, while labeling efficacy of ^{177}Lu-biomolecules is 98±1.2%. One elution was able to provide doses for 3 to 4 patients. Unfortunately, the short half-life of ^{68}Ga limits the consumption duration. However, this drawback was compensated by the fact that the injected dose can be as low as 100 to 150 MBq still resulting in high quality images and the generator can be eluted repeatedly within 1-2 hour interval. **Conclusion:** ^{68}Ga appears to be a PET analogue of ^{99m}Tc with added value of better sensitivity, resolution, quantitation and personalized medicine. It is a cost-effective complement to cyclotron-based tracers. It can enable PET CT studies in remote hospitals without access to accelerators thereby promoting PET technique for earlier and better diagnostics. We have successfully validated and implemented a programme of advanced diagnostics and therapeutics using ^{68}Ga and ^{177}Lu ligands. This approach can be used in other developing countries." **References:** None. none

2-[^{18}F]FDG: The working horse trapped in the cell's metabolic network

E. Klebermass[1], *M. Mahmudi*[1], *V. Pichler*[1], *A. Miller*[2], *C. Vraka*[1], *T. Balber*[1], *A. Haschemi*[2], *W. Wadsak*[1,3], *M. Hacker*[1], *H. Viernstein*[4], *M. Mitterhauser*[1,5];

[1]*Department of Biomedical Imaging and Image-guided Therapy, Division of Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA,* [2]*Department of Laboratory Medicine, Medical University of Vienna, Vienna, AUSTRIA,* [3]*CBmed GmbH - Center for Biomarker Research in Medicine, Graz, AUSTRIA,* [4]*Department of Pharmaceutical Technology and Biopharmaceutics, University of Vienna, Vienna, AUSTRIA,* [5]*Ludwig Boltzmann Institute Applied Diagnostics, Vienna, AUSTRIA.*

Aim/Introduction: It is current knowledge that 2-[^{18}F]FDG is trapped in cells as 2-[^{18}F]FDG-6-phosphate. However, there is growing evidence that its accumulation in cells is not only a function of glucose transporter abundance and hexokinase activity, but the result of more complex cellular processes. Studies showed that metabolism of 2-[^{18}F]FDG can go way beyond the formation of its 6-phosphate derivative, suggesting glycogen metabolism and pentose phosphate pathway (PPP) to be involved (1). Additionally, Marini et al have proposed 2-[^{18}F]FDG accumulation to be strongly dependent on the endoplasmic PPP enzyme hexose-6-phosphate dehydrogenase (H6PD) (2). Therefore, this study aims at further elucidating the metabolic mechanisms and pathways involved to create a basis for a better understanding of 2-[^{18}F]FDG accumulation kinetics, 2-[^{18}F]FDG-negative tumours and efflux phenomena. **Materials and Methods:** The HPLC method by Rokka et al was modified, comprising all known and potential metabolites of 2-[^{18}F]FDG (3). Metabolism studies of 2-[^{18}F]FDG were performed with three different human cancer cell lines HT1080, Huh7 and HT29, using the PPP enzyme inhibitors dehydroepiandrosterone and carbenoxolone (CBX), or different starving times and cell culture media to influence metabolism. For each setting, 2 MBq/mL 2-[^{18}F]FDG were applied to the respective cells, which were then incubated for 1 h, lysed and analysed with radio-HPLC. Accumulation experiments were performed with similar conditions, where the overall retention of 2-[^{18}F]FDG in cells was determined. **Results:** 11 intracellular metabolites different from 2-[^{18}F]FDG-6-phosphate reached up to 95%, depending on the experimental setting. A shift in metabolism was particularly prominent under glucose withdrawal and pre-treatment with PPP inhibitors. In contrast to previous findings (2), the H6PD inhibitor CBX only significantly reduced 2-[^{18}F]FDG accumulation in Huh7 cells under starving conditions (-15 ± 2% compared to vehicle control, $p < 0.05$). Moreover, this was the only case where CBX pre-treatment lead to both a reduction of the H6PD metabolite 2-[^{18}F]FD-phosphogluconate and a lower intracellular 2-[^{18}F]FDG accumulation. **Conclusion:** 2-[^{18}F]FDG metabolism is extremely variant and strongly depends on internal and external influences. The interplay between 2-[^{18}F]FDG metabolism and PPP, as well as the potential impact of its metabolism need to be thoroughly investigated to get the whole picture of 2-[^{18}F]FDG retention. **References:** (1) Southworth R., Parry CR., Parkes HG., et al. EP-0784

Preparation and biological assessment of ^{64}Cu-NOTA-anti EGFR as a Radioimmunoconjugate for Diagnosis of EGFR^{+} ESCC by PET

B. Alirezapour, h. Yousefnia, A. Bahrami Samani;
Nuclear Science and Technology Research Institute, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: Immuno-PET provides valuable information about tumor location, phenotype, susceptibility to therapy, and treatment response, especially to targeted radioimmunotherapy. In this study, we prepared anti Epidermal Growth Factor Receptor (EGFR) antibody via identical chelator, NOTA (p-SCN-Bn-NOTA)

labeled with ^{64}Cu and performed preliminary biodistribution studies in mouse bearing ESCC to evaluate the EGFR expression levels using immuno-PET in an Esophageal Squamous Cell Carcinoma (ESCC) model. **Materials and Methods:** Cetuximab was conjugated with NOTA (Macrocyclics B-605), the average number of the chelator conjugated per mAb was calculated and total concentration was determined by spectrophotometrically. NOTA-Cetuximab was labeled with ^{64}Cu then Radiochemical purity and immunoreactivity by TE-8 cell line and serum stability of ^{64}Cu-NOTA- anti-EGFR were determined. The biodistribution studies and radioimmunoscintigraphy were performed in female BALB/c mouse bearing ESCC (^{64}Cu-NOTA- Anti-EGFR i.v., 100 µl, 20±5 µg mAb , 6, 12, 24 and 48 h). **Results:** ^{64}Cu-NOTA-anti-EGFR was prepared (RCP >98% ± 0.7, Specific activity 4.8 ± 0.7 µCi/µg). Conjugation reaction of chelator (50 molar excess ratio) to antibody resulted in a product with the average number of chelators attached to a mAb (c/a) of 3.4 ± 0.3. Labeling yield with ^{64}Cu in 400µg concentration of bioconjugate was 93.8% ± 1.1. Immunoreaction of ^{64}Cu-NOTA-anti-EGFR complex towards EGFR antigen was determined by RIA and the complex showed high immunoreactivity towards EGFR. In vitro and in vivo stability of radioimmunoconjugate was investigated respectively in PBS and blood serum by RTLC method. In vitro stability showed more than 91% ± 2.2 in the PBS and 79% ± 1.7 in the serum over 24 h. The Immunoreactivity of the radiolabeled anti-EGFR towards TE-8 cell line was done by using Lindmo assay protocol. Under these conditions, the immunoreactivity of the radioimmunoconjugate was found to be 0.78. The biodistribution of ^{64}Cu-NOTA- anti-EGFR complex in the mice with normal and ESCC at 6, 12, 24 and 48 h after intravenous administration, expressed as percentage of injected dose per gram of tissue (%ID/g). Biodistribution and imaging studies at 24 and 48 h post-injection revealed the specific localization of complex at the site of tumors. **Conclusion:** ^{64}Cu-NOTA- anti-EGFR is a potential compound for molecular imaging of PET for diagnosis and follow up of EGFR expression in oncology.Keywords— Anti- EGFR, Copper-64, Monoclonal Antibody, ESCC. **References:** None.

EP-0785

Radioimmunoimaging of EGFR with pretargeting Cetuximab in triple negative breast cancer

X. Lan, *L. Yuan, Y. Gai, R. An, Y. Zhang;*
Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, CHINA.

Aim/Introduction: Breast cancer is the second leading cause of morbidity and mortality in women. Triple negative breast cancer (TNBC) has special biological behavior and poor prognosis, and high expression of epidermal growth factor receptor (EGFR) plays an important role. Radioimmunoimaging (RII) is an important technique for tumor imaging. However, because of large molecular weight and long circulation time, monoclonal antibody (mAb) is not suitable for short half-life radionuclides. Pretargeting technique is a method of labeling mAb in vivo, which could increase the tumor/background ratio and make it possible for short half-life radionuclide. The objective was to explore the feasibility of ^{68}Ga PET imaging of EGFR with pretargeting Cetuximab in TNBC. **Materials and Methods:** Strained transcyclooctene (TCO) and electrond eficient tetrazine (Tz) have inverse electron-demand Diels-Alder reaction. Cetuximab-TCO was obtained by modifying Cetuximab with TCO-NHS. The radioligand ^{68}Ga-L-NETA-Tz was prepared by using L-NETA as a chelating agent. Human basal breast cancer cells MDA-MB-468 and MDA-MB-231 were cultured, and EGFR expression of the two cell lines were identified. Nude mice bearing xenografts of the two cell lines was established. 50 µg of Cetuximab-TCO was injected into the tumor-bearing mice in advance, and after different time (12, 24, 36 and 48 h), 150 µCi ^{68}Ga-L-NETA-Tz was injected. The "click chemistry" of TCO and Tz was realized in vivo. Small-animal PET imaging and biodistribution were performed to evaluate pharmacokinetic properties. Two control groups, MDA-MB-468 mice without injection of Cetuximab-TCO (C1) and MDA-MB-231 mice with negative expression of EGFR (C2), and one blocking group (MDA-MB-468 mice pretreated with 100 folds of excess Cetuximab) were also performed animal PET imaging for specificity study. **Results:** ^{68}Ga-L-NETA-Tz molecular probe was successfully prepared with high labeling yield of >95%. The expression of EGFR in MDA-MB-468 was much higher than that in MDA-MB-231. PET imaging and biodistribution results showed that the best imaging results were obtained at 36 h pre-injection of Cetuximab, in which the highest tumor uptake was achieved after 1 h injection of ^{68}Ga-L-NETA-Tz with optimal tumor/muscle ratio 4.67±0.46. However, there was no significant tumor uptake in the blocking group and two control groups. **Conclusion:** We successfully explored RII of monoclonal antibody with short half-life radionuclide. Pretargeting with Cetuximab-TCO for 36 h, ^{68}Ga-L-NETA-Tz could detect the high expression of EGFR in vivo, which provided a novel method for PET imaging of TNBC. Comparison of two HAES sedimantation agents for leukocyte separation in radiolabeling procedure

A. Socan, *T. Debelak, M. Kroselj, P. Kolenc Peitl;*
University Medical Centre Ljubljana, Ljubljana, SLOVENIA.

Aim/Introduction: HAES (2-hydroxyethyl starch), a plasma expander, in molecular weight 200/0.5 (mean molecular weight of 200kDa), has long been a sedimentation agent of choice for leukocyte radiolabeling in routine clinical practice. Due to serious side effects connected with HAES as plasma expander, today only HAES with lower molecular weight 130/0.4 (mean molecular weight of 130kDa) is available on the market and potential usage for radiolabeling of leukocytes. Our aim was to compare effectiveness in obtaining leukocytes for radiolabeling from blood using both types of HAES. **Materials and Methods:** 30 mL of venous blood from 18 individuals was withdrawn into 50 mL syringes containing 13 mL of sedimentation agent and 10 mL of anticoagulant (ACD-A) and allowed to sediment in the syringe for 60 min in accordance with EANM guidelines for leukocyte radiolabeling with ^{99m}Tc-HMPAO. 3 mL of venous blood was withdrawn into the vacutube with EDTA to gain erythrocyte, leukocyte and platelet numbers. After sedimentation LRP (leukocyte rich plasma) volume was assessed. During radiolabeling, samples (0.5 mL) of LRP and LPP (leukocyte poor plasma), after 10 min centrifugation of LRP at 150G, were collected. Number of different cell types present in each of the samples were measured by automatic haematology analyzer (Advia 120, Siemens), and leukocyte numbers available for radiolabeling and other cell types in cell sample were determined. **Results:** With usage of HAES 200/0.5 as sedimentation agent average volume of LRP for radiolabeling was 32.3±3 mL. Average number of leukocytes in cell sample available for radiolabeling was 4.2×10^9/L (54.8% of the average number of leukocytes in the whole blood - AWBL). The average number of erythrocytes in the sample used for radiolabelling was 2×10^{10}/L (0.5% of average erythrocyte number in the whole blood - AWBE), while average number of the platelets was 9×10^9/L (4% of average platelet number in the whole blood - AWBP) respectively. With HAES 130/0.4, the average volume of LRP was 20.2±6.1 mL, average number of leukocytes for radiolabeling was 4.8×10^9/L (66.5% AWBL), number of erytrocytes was 2×10^{10}/L (0.6% AWBE) and number of platelets was 5.5×10^{10}/L (24.8% AWBP). **Conclusion:** We can conclude that HAES 130/0.4 can be used as sedimentation agent for leukocyte radiolabeling instead of discontinued HAES 200/0.5. Sedimentation time of 60 min enables collection of leukocytes in numbers suitable for radiolabeling with erythrocytes and platelets numbers sufficiently low for good images to be acquired. **References:** None.

EP-0787

Contribution of 131-I NP-59 Planar and SPECT/CT Imaging in Patients with Hypersecretory Adrenal Syndromes and Incidentally Discovered Adrenal Masses

A. Sainz Esteban*, M. Ruiz Gómez, C. Gamazo Laherrán, J. Gómez Hidalgo, P. Turbay Eljach, N. Álvarez Mena, M. González Soto, B. Pérez López, M. Alonso Rodríguez, R. Ruano Pérez;*
Hospital Clinico Universitario, Valladolid, SPAIN.

Aim/Introduction: To assess the contribution of radioiodinated I-6-ßiodomethyl-19-norcholesterol (NP-59) imaging in hypersecretory adrenal syndromes and characterization of incidentally discovered adrenal masses in terms of diagnostic accuracy and anatomic localization. **Materials and Methods:** We include 37 patients (20 men, age: 60±11) investigated for adrenal hypersecretory syndromes, with or without adrenal nodules, (15 patients with ACTH-independent Cushing's disease, two hyperandrogenism and 18 hyperaldosteronism) and for characterization of incidentally discovered adrenal masses (two patients) using NP-59 scintigraphy with SPECT/CT imaging. Sequential anterior and posterior images of the upper abdomen were acquired between 2 and 7 days following intravenous injection of 37 MBq I-131 NP-59. Saturated solution of potassium iodide was given to block free radioiodine thyroid uptake. Twenty three patients with suspected hyperaldosteronism or ACTH-independent Cushing's disease received pharmacological adrenosuppressive preparation with dexamethasone. SPECT/CT imaging was performed on day 5 postinjection. Clinical and imaging data were reviewed to evaluate whether additional information derived from near-simultaneous anatomic localization aids study interpretation. The final diagnosis was obtained with clinical follow-up, other imaging tests and/or pathological studies when available. **Results:** Taking the final diagnosis as a final result, the NP-59 imaging produced 31 true-positives, one false-positive, three true-negatives, and two false-negatives (adenoma and bilateral adrenal hiperplasia). Sensitivity, specificity, positive predictive value, negative predictive value, and accuracy were 93.9, 75.0, 96.8, 60.0, and 91.9%, respectively. Of the 15 patients with suspected Cushing's disease, eight showed in the NP-59 scintigraphy hyperfunctional adrenal nodules, one nonfunctioning adrenal nodule, six bilateral adrenal hyperplasia and one normal scan. Of the two patients with suspected hyperandrogenism, one presented with a carcinoma and one with a hyperfunctional adrenal nodule. Of the 18 patients with suspected hyperaldosteronism four presented with hyperfunctional adrenal nodule, 10 with bilateral adrenal hyperplasia and four patients were normal. Of the two patients with incidentally discovered adrenal masses, one presented a bilateral adrenal hyperplasia and one with a hyperfunctional adrenal nodule. SPECT/CT assisted study interpretation by localizing focal uptake in small adrenal adenomas in two patients, by localizing focal uptake small bowel and gall bladder and distinguishing malignant radiological pattern on the CT in one patient. In the rest of the patients SPECT/CT confirmed adrenal origin of activity increasing reader confidence but did not change the planar interpretation of the study. **Conclusion:** NP-59 scintigraphy provides useful information on the functional status of hypersecretory adrenal syndromes. Besides, SPECT/CT imaging allows precise localization of the functional activity improving diagnostic interpretation. **References:** None.

The Possibility of ^{99m}Tc-1-thio-d-glucose Spect Using For Detection of Residual Tumor Tissue After Non-radical Surgical Treatment and Visualization Of Recurrence in Patients With a Brain Tumor

R. Zelchan[1], *A. Medvedeva*[1], *I. Sinilkin*[1], *O. Bragina*[1], *A. Ryabova*[1], *E. Stasyuk*[2], *A. Rogov*[2], *V. Skuridin*[2], *V. Chernov*[1], *E. Choynzonov*[1], *E. Mishina*[3];
[1]*Tomsk National Research Medical Center of the Russian Academy of Sciences includes the following Research Medical Institutes: Cancer Research Institute, Tomsk, RUSSIAN FEDERATION,* [2]*National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION,* [3]*Siberian State Medical University, Tomsk, RUSSIAN FEDERATION.*

Aim/Introduction: to study the possibility of ^{99m}Tc-1-thio-D-glucose (^{99m}Tc-TG) SPECT using for metabolic imaging of a residual tumor after non-radical surgical treatment and detection of recurrence in patients with a brain tumor. **Materials and Methods:** the study included 10 patients after non-radical surgery for a brain tumor and 9 people with a brain tumor recurrence. All patients underwent ^{99m}Tc-TG SPECT 2 hours after intravenous administration of the radiopharmaceutical at a dose of 500 MBq. The study was performed according to standard protocols; 32 projections were recorded in a matrix of 256x256 pixels without hardware magnification. During processing, the tumor/background index was calculated as the ratio of the intensity of radiopharmaceutical accumulation in the area of interest and the symmetric zone of the intact brain tissue. MRI with contrast and PET / CT were used as reference methods. **Results:** It was possible to visualize residual tumor tissue 14 days after surgery using ^{99m}Tc-TG SPECT in all 10 patients. The sensitivity of ^{99m}Tc-TG SPECT was 100%. The mean values of the tumor/background index were 1.55±0.27. Brain tumor recurrence was also detected in all patients (n = 9). In the group of patients with recurrent tumors, the values of the tumor/background index were 3.50 ± 0.43. The presence of residual tumor tissue after non-radical surgery, as well as the presence of recurrent brain tumor was confirmed by MRI and PET/CT data with ^{11}C-methionine. It should be noted, that in the study ^{99m}Tc-TG uptake only in tumor tissue were found. Also a physiological accumulation of the radiopharmaceutical in the projection of the soft tissues of the aponeurotic helmet, choroid, mucous membranes of the nasal and oral cavities was visualized. **Conclusion:** This study demonstrated that the ^{99m}Tc-TG selectively accumulates in a brain tumor. High values of the tumor/background index allow obtaining contrast images of the tumor tissue, which simplifies the diagnostic process. ^{99m}Tc-TG SPECT can be considered as a promising method of metabolic imaging of malignant brain tumors and their recurrences. It should be noted that with similar parameters of diagnostic efficacy with PET/CT, ^{99m}Tc-TG SPECT is advantageously characterized by simplicity of execution and low cost of the procedure itself. **References:** None.

EP-0789

^{99m}Tc-labelled ketal based nucleolipid nano assembly as SPECT-trackable Drug delivery system for CNS

S. Chaturvedi[1], *S. Swastika*[1,2], *A. Kaul*[1], *P. Panwar Hazari*[1], *S. Pal*[1], *B. Singh*[2], *P. Barthélémy*[3], *A. K Mishra*[1];
[1]*Institute of Nuclear Medicine and Allied Sciences (INMAS), Delhi, INDIA,* [2]*Department of Chemistry, Banaras Hindu University, Varanasi, INDIA,* [3]*ARNA laboratory, Univ. Bordeaux, INSERM U-1212, UMR CNRS 5320, F-33000, Bordeaux, FRANCE.*

Aim/Introduction: Nucleolipids are bioinspired hybrid molecules wherein nucleosides are modified using long lipidic chains. The result is an ampiphilic molecule bearing polar and non-polar heads capable of supramolecular association. The structural similarity of nucleolipids with cellular membranes, allow the nucleolipids to diffuse through the cells leading to enhanced cellular internalization. Extending the concept, we hypothesize that nucleolipid can be exploited as drug delivery systems for central nervous system (CNS). Design of drug delivery systems which can effectively cross the blood brain barrier for effective delivery of drugs remains a challenge. We aimed to explore the potential of nucleolipid nano-assemblies as a blood brain barrier permeable vehicle for the delivery of hydrophilic drugs and reactivators along with SPECT based tracking of the assemblies. **Materials and Methods:** The uridine based nucleolipid appended with two C_{15} lipid chains and bearing pH labile ketal linkage was synthesised using multi-step synthesis. Synthesis involved activation of 2′, 3′ hydroxyl followed by addition of palmitone. The 5′ position was tosylated and converted to amine for subsequent bioconjugation with chelator (diethylenetriaminepentacetic acid) for ^{99m}Technetium (^{99m}Tc) labelling. The compounds and intermediates were characterised using spectroscopic techniques. Nano-assemblies were formed through routine procedure and characterized for size along with physicochemical assessment through quenching and potentiometric studies. Various encapsulation parameters were evaluated. The nano-assemblies were ^{99m}Tc-radiolabelled. **Results:** After having encouraging results from our earlier work with standalone nucleolipids (brain uptake = 0.2 %ID/g, excellent radiolabelling, good biocompatibility), we have developed nucleolipid nano-assemblies with mean particle size distribution of 100-200 nm. Physicochemical characterization showed low non-specific protein binding and optimum stability. The encapsulation efficiency of hydrophilic drug, methotrexate, in nucleolipid nano-assemblies was found to be approximately 72%. Drug release kinetics was also assessed for a period of 24 h. Radiolabelling of nucleolipid nano-assemblies has been carried using ^{99m}Tc with more than 97 % specific activity. Animal biodistribution studies indicate stable formulation with predominantly hepatobiliary route of excretion. Encapsulation of hydrophilic reactivators oxime and release kinetics as function of time and pH is in process. Future studies will concentrate on real time tracking using SPECT imaging of drug loaded nucleolipids in mice models and subsequent assessment of brain uptake. **Conclusion:** If successful the nucleolipid nano-assemblies can be a novel drug delivery approach for delivery of drugs and reactivators in brain. **References:** None.

EP-0790

N-terminal position of histidine-glutamate-containing tag improves biodistribution of [^{99m}Tc]Tc-labeled DARPin G3

A. Vorobyeva[1], *A. Schulga*[2], *E. Konovalova*[2], *R. Güler*[3], *J. Löfblom*[3], *M. Sandström*[1], *J. Garousi*[1], *V. Chernov*[4], *O. Bragina*[4], *A. Orlova*[1], *V. Tolmachev*[1], *S. M. Deyev*[2,5];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Shemyakin & Ovchinnikov Institute of Bioorganic Chemistry, Moscow, RUSSIAN FEDERATION,* [3]*KTH Royal Institute of Technology, Stockholm, SWEDEN,* [4]*Cancer Research Institute, Tomsk National Research Medical Center Russian Academy of Sciences, Tomsk, RUSSIAN FEDERATION,* [5]*National Research Nuclear University "MEPhI", Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: Radionuclide molecular imaging of human epidermal growth factor receptor 2 (HER2) expression in disseminated cancer enables stratification of patients for HER2-targeted therapies. A small engineered scaffold protein DARPin G3 (molecular weight 14 kDa) is a possible agent for imaging of HER2. Based on experience with other scaffold protein, affibody molecules, we hypothesized that composition (hexahistidine H_6 or histidine-glutamate $(HE)_3$) and position (C- or N-terminus) of histidine-containing tags could influence the biodistribution of [^{99m}Tc]Tc$(CO)_3$-labeled DARPin G3 and might be used for optimization of its imaging properties. **Materials and Methods:** Four G3 variants containing a tag either at N-terminus (H_6-G3, $(HE)_3$-G3) or at C-terminus (G3-H_6, G3-$(HE)_3$) were recombinantly produced and labelled with [^{99m}Tc]Tc$(CO)_3$. Labelling yield, label stability, specificity and affinity of the binding to HER2-expressing cell lines, biodistribution and tumour targeting properties of these variants were compared. In vivo targeting was compared in BALB/C nu/nu mice bearing HER2-positive SKOV-3 xenografts at 4 and 24 h after injection. HER2-negative Ramos xenografts were used for specificity control. **Results:** All four G3 variants were labelled with an isolated yield of 50-70% and had radiochemical purity higher than 97%. All labels were stable under histidine challenge. Binding of all labelled variants to HER2-expressing cells in vitro was specific and dissociation equilibrium constants were similar, approximately 90 pM. The uptake in SKOV-3 xenografts was similar (7- 9 %ID/g at 4 h and 5-8 %ID/g at 24 h after injection) for all variants. The uptake in HER2-negative Ramos xenografts was significantly ($p<0.05$) lower than in SKOV-3 xenografts. Position and composition of histidine-containing tags had a strong influence on uptake in normal tissues. The tumour-to-liver ratio for [^{99m}Tc]Tc$(CO)_3$-$(HE)_3$-G3 (4.9 ± 0.3 at 4 after injection) was significantly ($p<0.05$) higher than tumour-to-liver ratios for [^{99m}Tc]Tc$(CO)_3$-H_6-G3, [^{99m}Tc]Tc$(CO)_3$-G3-H_6 and [^{99m}Tc]Tc$(CO)_3$-G3-$(HE)_3$ (1.6 ± 0.7, 1.8 ± 0.3, and 2.2 ± 0.3, respectively). [^{99m}Tc]Tc$(CO)_3$-$(HE)_3$-G3 provided also significantly higher tumour-to-lung, tumour-to-bone and tumour-to-muscle ratios. Better contrast of HER2 visualization using [^{99m}Tc]Tc$(CO)_3$-$(HE)_3$-G3 was confirmed by gamma-camera imaging. **Conclusion:** Position and composition of histidine-containing tags have a strong influence on biodistribution of [^{99m}Tc]Tc$(CO)_3$-labelled DARPins and can be used for optimization of their targeting properties. [^{99m}Tc]Tc$(CO)_3$-$(HE)_3$-G3 variant provided the highest tumour-to-tissue ratios, which should improve sensitivity of HER2 imaging in common metastatic sites. **References:** None.

EP-0791

Imaging of EpCAM expression in pancreatic cancer using radiolabelled DARPin Ec1

A. Vorobyeva[1], *A. Schulga*[2], *A. Abouzayed*[1], *E. Konovalova*[1], *T. Gunther*[1], *H. Ding*[3], *T. Graslund*[3], *A. Orlova*[1], *S. M. Deyev*[2,4], *V. Tolmachev*[1];
[1]*Uppsala University, Uppsala, SWEDEN,* [2]*Shemyakin & Ovchinnikov Institute of Bioorganic Chemistry, Moscow, RUSSIAN FEDERATION,* [3]*KTH, Stockholm, SWEDEN,* [4]*National Research Nuclear University "MEPhI", Moscow, RUSSIAN FEDERATION.*

Aim/Introduction: Efficient treatment of disseminated pancreatic cancer remains an unmet clinical need. One possible target for treatment is epithelial cell adhesion molecule (EpCAM). Intense EpCAM overexpression was found in 23-37% of pancreatic cancers. Several EpCAM-targeting therapeutics are currently in clinical trials. A precondition for their successful application is identification of patients having tumours with high EpCAM expression. Radionuclide molecular imaging offers a non-invasive approach for stratification of patients for EpCAM-targeting therapies. Designed ankyrin repeat proteins (DARPins) are promising candidates for targeting vectors for radionuclide imaging. Their small size (molecular weight of 14-18 kDa) creates potential for a high-contrast imaging at the day of injection. Particularly of interest is DARPin Ec1, which binds to EpCAM with affinity of 68 pM. The aim of the study was to evaluate the feasibility of imaging of EpCAM-expressing pancreatic cancer xenografts using radiolabelled Ec1. **Materials and Methods:** Ec1 was indirectly radioiodinated using N-succinimidyl-3-methylstannyl-benzoate to ensure rapid excretion of radiometabolites. EpCAM-expressing BxPC3 pancreatic cancer cell line was used for characterisation of [^{125}I]I-PIB-Ec1 in vitro and in vivo. Biodistribution of [125I]I-PIB-Ec1 was measured in BALB/C nu/nu mice bearing BxPC3 xenografts at 3 and 6 h after injection. EpCAM-negative Ramos xenografts were used as a negative control. MicroSPECT/CT imaging was used to confirm the biodistribution data. **Results:** EpCAM Ec1 was labelled with a radiochemical yield of 22±4%. The radiochemical purity was 99±0%. [^{125}I]I-PIB-Ec1 retained high specificity and picomolar affinity of binding to EpCAM expressing cells in vitro. The uptake of [^{125}I]I-PIB-Ec1 in BxPC3 xenografts was 66-fold higher ($p<0.0005$) than in EpCAM-negative Ramos xenografts, which demonstrated specificity of targeting. The [^{125}I]I-PIB-Ec1 cleared rapidly from blood and non-specific compartments. Already at 3 h p.i., the tumour uptake (3.8±0.9% ID/g) exceed by far the uptake in normal tissues (except kidneys), resulting in e.g. tumour to-blood ratio of 18±4 and tumour-to-pancreas ratio of 32±11. The tumour uptake did not decrease by 6 h, while there was an additional decrease of uptake in normal tissues. This resulted in a further increase of tumour-to-organ ratios. For example, the tumour-to-blood ratio increased to 43±12 and the tumor-to-pancreas ratio increased to 99±40. MicroSPECT/

CT imaging confirmed high-contrast visualization of BxPC3 xenografts. **Conclusion:** Indirectly radioiodinated DARPin Ec1 provided high-contrast imaging of EpCAM a few hours after injection. This can be utilized for imaging of EpCAM expression using SPECT (using iodine-123) and PET (using iodine-124). **References:** None.

EP-0792

Comparative Evaluation Of Tumour-targeting Properties Of An Antagonistic Bombesin Analogue Labelled With Residualizing (^{111}In-DOTA) And Non-residualizing (^{125}I-Tyr) Labels

M. Oroujeni, *A. Abouzayed, B. Mitran, V. Tolmachev, A. Orlova, U. Rosenström;*
Uppsala University, Uppsala, SWEDEN.

Aim/Introduction: Gastrin releasing peptide receptor (GRPR) is overexpressed in many cancers such as prostate, breast, pancreatic and lung. Bombesin analogues are short peptides with a high affinity to GRPR. Radiometal-labelled antagonistic bombesin analogues demonstrated good targeting of GRPR-expressing tumours. Internalization of bombesin antagonists by cancer cells was slow. We hypothesized that the residualizing properties of the label are not critical for a good tumour retention but a non-residualizing label would provide quicker clearance of activity from normal tissues. The aim of this study was to evaluate targeting properties of ^{125}I-Tyr-PEG2-RM26 and compare it directly with the properties of ^{111}In-DOTA-PEG2-RM26. **Materials and Methods:** The bombesin analogue Tyr-PEG2 [D-Phe^{6}, Sta^{13}, Leu^{14}] Bombesin[6-14] (denoted as Tyr-PEG2-RM26) was synthesized by standard manual solid-phase peptide synthesis. Tyr-PEG2-RM26 was labelled with ^{125}I using Iodogen at room temperature. In vitro stability of ^{125}I-Tyr-PEG2-RM26 in 1mM of NaI and half-maximal inhibitory concentration (IC50) were evaluated. In vitro binding specificity of ^{125}I-Tyr-PEG2-RM26 bound to two GRPR-expressing cell lines with a different level of expression, PC3 and DU-145 was tested by a saturation assay. The cellular processing of the labelled conjugate bound PC3 cell line was evaluated using an acid wash method. The biodistribution of ^{125}I-Tyr-PEG2-RM26 and ^{111}In-DOTA-PEG2-RM26) in Balb/c nu/nu mice bearing PC3 tumours was measured at three time points (0.5, 3 and 24 h). In vivo specificity of both radioconjugates was confirmed by saturation of GRP receptors with PEG4-RM26 as a blocking agent. **Results:** The labelling of Tyr-PEG2-RM26 with ^{125}I resulted in 75% radiochemical yield and 95% purity. ^{125}I-Tyr-PEG2-RM26 was stable in PBS and NaI. ^{125}I-Tyr-PEG2-RM26 retained binding specificity to GRPR expressing cell lines. The IC50 values of Tyr-PEG2-RM26 and DOTA-PEG2-RM26 were determined to be 1.5±0.6 nM and 3.1±1.1 nM, respectively. The cellular processing of ^{125}I-Tyr-PEG2-RM26 by PC3 cell line was characterized by fast internalization during the first hour of incubation followed by rapid leakage of radioactivity from cells. Biodistribution showed that the uptake in the pancreas and tumour was GRPR-specific for both radioconjugates. The blood clearance of ^{125}I-Tyr-PEG2-RM26 was appreciably slower and the activity accumulation in all organs was significantly higher than of ^{111}In-DOTA-PEG2-RM26. Tumour uptake of ^{111}In-DOTA-PEG2-RM26 was significantly higher than ^{125}I-Tyr-PEG2-RM26, resulting in significantly higher tumour-to-organ ratios at all studied time points. **Conclusion:** An introduction of a hydrophobic tyrosine moiety at N-terminus of RM26 could change cellular processing and biodistribution of antagonistic bombesin analogue in an unfavourable way. **References:** None.

Kit Based Re-188 Microspheres for Selective Intra-Arterial Radionuclide Therapy (SIRT) of Unresectable Liver Cancer

J. Shukla, *N. Kalra, A. Duseja, A. Chhabra, Y. Rathod, M. Parmar, R. Kumar, H. Singh, B. R. Mittal;*
Post Graduate Institute of Medical Education & Research, Chandigarh, INDIA.

Aim/Introduction: Unresectable primary and metastatic liver cancer have limited options for the treatment. Selective Intra-Arterial Radionuclide Therapy (SIRT) has been proved as a valuable option when the tumor is large, multinodular, portal vein is thrombosed, etc. SIRT may offer reduced toxicity profile, highly effective tumor responses, prolong survival and improved quality of life. **Materials and Methods:** Microsphere kit was developed and Re-188 microspheres have been prepared and underwent quality control procedures to qualify for human use. Clearance from Institutional ethics committee was obtained, and the patients (n=20) were assessed by hepatologist, interventional radiologist and nuclear medicine physician prior to the procedure. Pre-therapy assessment included clinical history, complete blood counts, LFT, serology for hepatitis B or C infection and triple phase CT/MRI/PET-CT for treatment planning. Child's score, alpha feto protein and portal vein status were documented. After informed written consent, a catheter was placed and a scout dose of 3-5 mCi Tc-99m / Re-188 microspheres was delivered. Whole body image was acquired under gamma camera. The ROI counts on anterior, posterior images were noted to calculate lung shunt fraction and tumour to normal liver ratio (TNR). The therapy dose (mCi) was calculated so that the maximum absorbed dose to lung, normal liver and bone marrow should not exceed 12 Gy, 30 Gy and 1.2 Gy respectively. For personalized dosimetry, whole body and SPECT/CT images were acquired

at 24 and/or 48 hours post therapy and the radiation absorb dose (Gy) to various organs was calculated by MIRD method. The response to SIRT was assessed on TPCT/PET-TPCT after 8-12 weeks post therapy by mRECIST. **Results:** Re-188 microspheres were easily administered; no gastroduodenal reflux and no procedure related complications/adverse events were noted. The localization of Re-188 microspheres in lesion was more than 75% of the administered dose. Out of 20 pts, 5 patients are surviving. Complete response was achieved in three patients, one patient underwent transplant surgery and doing well. The max survival was 30 months. 2 patients died before follow-up. The clinical condition of patients was improved on follow up.. **Conclusion:** Kit based Re-188 microspheres are cost-effective and convenient option for SIRT. **References:** 1. Shukla J et al. Two cases of Rhenium-188 microspheres for inoperable hepatocellular carcinoma. Clin Nucl Med. 2019;44: e93-e95. 2. Vadi SK,...Shukla J et al. Preparation and evaluation of biodegradable polymer micelle for brachytherapy

A. Makino, T. Mori, H. Okazawa, Y. Kiyono;
University of Fukui, Eiheiji-cho, Yoshida-gun, Fukui, JAPAN.

Aim/Introduction: Recently, injectable thermo-sensitive hydrogels have attracted increasing attention as carriers for tumor therapies (brachytherapy) since they are possible to retain therapeutic radionuclides at the injected site over a long period. In this study, a thermo-sensitive polymer micelle was newly designed as a carrier for brachytherapy. **Materials and Methods:** The thermo-sensitive micelle was prepared from the newly synthesized amphiphilic block polymer (PNnPG-b-PLLA), whose hydrophilic (thermosensitive) and hydrophobic units are consisted from poly(N-n-propyl glycine) and poly(L-lactic acid), respectively. PNnPG-b-PLLA was synthesized via N-carboxy anhydride (NCA) polymerization using PLLA as a macroinitiator and polymer length on hydrophilic and hydrophobic chains was determined by NMR. Micelle was prepared by injecting the polymer solution dissolved in acetone to the ice-cooled aqueous solution. Diameter of the micelle was determined by dynamic light scattering (DLS) method. The thermosensitive micelle encapsulating ^{64}Cu was co-incubated with LNCaP human prostate adenocarcinoma cell line, in vitro anti-tumor activity of the micelle was evaluated. **Results:** PNnPG and PLLA polymer unit lengths of the synthesized amphiphilic polymer (PNnPG-b-PLLA) were 70 mer and 30 mer, respectively. The micelle diameter at 15 degrees Celsius was 50-60 nm. The micelle showed thermosensitive behavior around 20-25 degrees Celsius, and character of the PNnPG unit was changed from hydrophilic to hydrophobic. Caused by the micelle surface hydrophobization, the micelles were quickly gathered by intermiceller hydrophobic interaction and formed submicron size aggregation. Importantly, the micelle directly injected to the transplanted tumor region of the model mouse showed effective retention behavior as expected, which was caused by the aggregation. To the hydrophobic core region of the micelle, beta-ray emitting ^{64}Cu could be encapsulated in high yield (>95%), and ^{64}Cu could be stably encapsulated into the micelle up to 96 h. In vitro study, cytotoxicity was observed depending on the dose of ^{64}Cu activity administrated. **Conclusion:** The newly prepared thermo-sensitive polymer micelle has basic characters as a carrier for brachytherapy. We are currently undergoing in vivo evaluation using tumor- bearing mice. **References:** None.

Magnetic properties of 2,3-dicarboxypropane-1,1-diphosphonic acid coated magnetite nanoparticles and radiolabeling with ^{99m}Tc and ^{90}Y for possible theranostic application

***A. A. Vukadinovic**, M. Peric, M. Radovic, M. Mirkovic, D. Jankovic, D. Petrovic, Z. Milanovic, S. Vranjes-Djuric;*
University of Belgrade, Vinca Institute of Nuclear Sciences, Belgrade, SERBIA.

Aim/Introduction: Combining the effects of hyperthermia and radiation therapy represents a new approach for possible application in cancer treatment. In this study, the heating efficiency of 2,3-dicarboxypropane-1,1-diphosphonic acid (DPD) coated magnetite nanoparticles in the presence of various ionic strengths has been explored. This allowed more profound understanding of magnetic behavior of Fe_3O_4-DPD MNPs. Radiolabelling method with γ emitter ^{99m}Tc and β emitter ^{90}Y was used as a reliable and powerful tool for determination of in vivo behavior. **Materials and Methods:** Fe_3O_4 MNPs were prepared by coprecipitation method, DPD water solution was added and the coating reaction was carried out overnight at room temperature. Radiolabeling of Fe_3O_4-DPD MNPs was performed with ^{99m}Tc using $SnCl_2$ as a reducing agent. ^{90}Y labeling of Fe_3O_4-DPD MNPs was performed using $^{90}YCl_3$ solution. The magnetic hyperthermia efficiency of Fe_3O_4-DPD MNPs was tested under alternating magnetic field (30 mT) and the resonant frequencies between 252-577 kHz. The in vitro stability of radiolabeled MNPs was tested in different solutions: saline (0.9 % NaCl), human serum and 0.01 mol/dm3 DTPA. Biodistribution studies were carried out in healthy male 4-week old Wistar rats. **Results:** In the magnetic hyperthermia studies, the temperature increase of Fe_3O_4-DPD MNPs (2 mg/ml) as a function of time was evaluated under different frequencies 252-577 kHz and magnetic field strength of 30mT. From the temperature curve it was observed that Fe_3O_4-DPD MNPs reach hyperthermia temperature even at lower frequencies. During in vitro stability studies, the radiochemical purity of ^{99m}Tc-Fe_3O_4-DPD MNPs determined after 24 h incubation in saline, human serum and DTPA was 92.9%, 84.2% and 91.5%, respectively, showing that ^{99m}Tc-Fe_3O_4-DPD MNPs exhibits excellent in vitro stability, regardless the incubation conditions. After 72h of incubation

in all tested media ^{90}Y-Fe_3O_4-DPD MNPs showed radiochemical purity of 87.6%, 79.4% and 91.3% for saline, human serum and DTPA, respectively. Biodistribution after i.v. injection showed a high accumulation of MNPs in the liver 1h after administration (16.03% ID/g for ^{99m}Tc-Fe_3O_4-DPD and 11.28% ID/g for ^{90}Y-Fe_3O_4-DPD MNPs) as well as the long-term retention in the same organ. Low accumulation of both radiolabeled nanoprobes in lungs was observed. **Conclusion:** Radiolabeling of Fe_3O_4-DPD MNPs with gamma emitter ^{99m}Tc, and beta emitter ^{90}Y, seems to hold great potential for future applications in different imaging techniques and radionuclide/hyperthermia therapy. Furthermore sufficiently high hyperthermia temperature even at lower frequencies, pave the way towards the possible theranostic application of Fe_3O_4-DPD MNPs. **References:** None.

EP-0796

Development of new radopharmaceutical based on ^{177}Lu-labeled HEDP, DPD and IDP for the potential palliative treatment of painful bone metastases

Z. Milanovic, *M. Radović, M. Mirković, D. Stanković, D. Janković, M. Perić, A. Vukadinović, D. Petrović, S. Vranješ Đurić;*
Vinca Institute of Nuclear Sciences, Belgrade, SERBIA.

Aim/Introduction: Aim/Introduction: Bone seeking radiopharmaceuticals are important option in the management of metastatic bone pain. Due to some negative characteristics of routinely applied therapeutic radiopharmaceuticals, there is still much potential for the improvement. The aim of the present study was to investigate ^{177}Lu-labeled ligands: 1-hydroxyethane 1,1-diphosphonic acid (HEDP), 2,3-dicarboxypropane-1,1-diphosphonic acid (DPD), and imidodiphospha tetetrasodium salt (IDP), as potential bone pain palliation agents. **Materials and Methods: Materials and Methods:** Complex formation between non-radioactive lutetium ($LuCl_3$) and tested ligands was examined, using conductance and cyclic voltammetry measurements. Labeling of ligands with ^{177}Lu was confirmed by three different methods ITLC, HPLC, and electrophoresis. Biodistribution and bone accumulation was determined by ex vivo measurement of radioactivity in organs followed by in vivo imaging studies in healthy Wistar rats. Radioactivity in organs was measured in a well counter and obtained results are expressed as a percentage of injected dose per gram (%ID/g). **Results: Results:** Results revealed that all three examined ligands are capable to form stable complexes with ^{177}Lu in high radiolabeling yield (> 90%) forming in vitro stable complexes. The most critical parameters, with highest influence on the radiolabeling were concentration of ligands and pH. Determined by electrophoresis, radiolabeled complexes were electronegative molecules. Bone accumulation and retention after 0.5, 2, 96, and 168 h for the ^{177}Lu-HEDP, ^{177}Lu-DPD, ^{177}Lu-IDP were: 1.13±0.22%, 2.18±0.23%, 3.62±0.55% and 6.3±0.01%, respectively. The highest selective bone accumulation with relatively low uptake in soft tissue (less than 1% at all 4-time points), was observed only for ^{177}Lu-HEDP. Unlike ^{177}Lu-HEDP, other two ^{177}Lu-labeled ligands showed insignificant bone (<1%) and high liver (>1.5%) and spleen (>2%) uptake. **Conclusion: Conclusion:** Obtained results suggest that different functional groups beside phosphonate/phosphate groups present in the HEDP, DPD and IDP significantly affect the bone accumulation of ^{177}Lu-labeled complexes. This implicates that among examined complexes, only^{177}Lu-HEDP is suitable for further preclinical investigations. **References:** None.

EP-0797

Radiolabeling of Gold Nanoparticles With Lu-177 as a Platform for Cancer Theranostics

N. Daems[1], *M. Ooms*[2], *T. Cardinaels*[2], *S. Baatout*[3], *C. Michiels*[4], *S. Lucas*[5], *V. Karen*[2], *A. Aerts*[3];
[1]*SCK-CEN/UNamur, Mol, BELGIUM,* [2]*Radiochemistry expert group, Nuclear Materials Science, SCK-CEN, Mol, BELGIUM,* [3]*Radiobiology Unit, Biosciences, Environment, Health and Safety, SCK-CEN, Mol, BELGIUM,* [4]*Unité de Recherche en Biologie Cellulaire-NARILIS, UNamur, Namur, BELGIUM,* [5]*Research Center for the Physics of Matter and Radiation-NARILIS, UNamur, Namur, BELGIUM.*

Aim/Introduction: In cancer radiotherapy, gold nanoparticles (AuNPs) have emerged as promising radiosensitizers, which accumulate in the tumor and increase the effectiveness of external beam radiotherapy by local production of reactive oxygen species (ROS) and secondary electrons upon irradiation. Five nm gold nanoparticles surrounded by an organic shell of polyallylamine (PAA) are produced by plasma vapor deposition and are conjugated to anti-EGFR-antibodies (Cetuximab-Ctxb) for active tumor targeting (AuNPs-PAA-Ctxb). In order to increase the therapeutic effect of the AuNPs-PAA-Ctxb, we aim to radiolabel the nanoparticles with ^{177}Lu. **Materials and Methods:** The labeling approach would be to first link Ctxb with bifunctional chelators (BFCs), DOTA or DTPA, followed by conjugation of Ctxb-BFC to AuNPs-PAA. The final step comprises the radiolabeling of the AuNPs-PAA-Ctxb-BFC complex with ^{177}Lu. **Results:** MALDI-ToF MS analysis indicated that a 20, 40 and 80 molar excess addition of BFCs to the labeling reaction, leads to an increasing BFC:antibody ratio of 2, 3 and 5, respectively. However, a 40 and 80 molar BFC excess profoundly reduced the binding capacity of Ctxb to EGFR-overexpressing A431 cells. A radiochemical purity of > 95% was achieved after 3h at 50°C for Ctxb-DOTA-^{177}Lu or instantly at room temperature for Ctxb-DTPA-^{177}Lu. Moreover, both radiolabeled immuno-complexes were stable for at least 3 days in serum at 37°C. In addition, we showed that Ctxb-BFCs retain their target binding capacity when conjugated to AuNPs-PAA. **Conclusion:** When successful radiolabeling of AuNPs-PAA-Ctxb with ^{177}Lu is achieved and the target binding capacity of the nanoconjugates is preserved, further experiments can be conducted to investigate the specificity of the enhanced cancer cell killing effect on EGFR-overexpressing A431 cells. Furthermore, the biodistribution and the therapeutic effect of the radiolabeled AuNPs-PAA-Ctxb-^{177}Lu could be assessed after injection in tumor-bearing mice. **References:** None.

Development of a bimodal (PET/NIR) tumor tracer for non-invasive staging and fluorescence guided surgery of prostate cancer

C. S. Kramer, T. Kanagasundaram, K. Kopka;
German Cancer Research Center (dkfz), Heidelberg, GERMANY.

Aim/Introduction: Prostate cancer is the second most common cancer type in men, thus modern treatment and diagnostic methods are needed especially for progressed stages. The detection of distant metastases and local lymph node metastases is not only important for oncological staging and therapeutic decision making, but also for oncological surgery. To provide a tracer that can be used for oncological staging in PET and for fluorescent light-guided surgery, we developed a PSMA-specific HBED-dye conjugate (1). To reduce the overall molecular weight we want to develop the next generation PSMA-specific tracer with a newly designed PET-activatable near-infrared (NIR) dye. While the PET-activated „hot" tracer enables oncological staging and preoperative planning, the NIR modality of the „cold" tracer can be used during surgery to detect more precisely lymph node metastases and enabling R0 resection while protecting healthy structures. **Materials and Methods:** Two different dye families (silicon rhodamines and silicon pyronines) were de-novo synthesized in high overall yields. Both classes of dyes are small molecules unifying the dye property and the radiolabel at an average MW of 500 g/mol. The silicon atom is not only crucial for the dye properties but fluorine can covalently bind to it, thus PET activation can proceed via a fluorine isotopic exchange. Therefore the silicon atoms needed to be decorated with a fluorinatable leaving group and a tert-butyl group that hampers hydrolysis. **Results:** The silicon pyronines possesses fluorescence properties in visible light with a high stokes shift from over 200 nm and can easily be radiolabeled via fluorine isotope exchange with up to 75% conversion. Initial stability experiments show water stability for at least 3.5 h. It is known that pyronines can be converted into NIR dyes in one step; experiments for this transformation are ongoing. The silicon rhodamines exhibit NIR properties (λ $_{abs}$ = 659 nm, λ $_{em}$ = 685 nm) with quantum yields up to 0.50 and initial experiments showed that PET nuclide labeling of this dye is possible. Furthermore, this dye class was also successfully coupled to a PSMA binding motif to enable first biochemical binding experiments. **Conclusion:** We could successfully synthesize de-novo two families of fluorescent dyes that can be "activated" for PET-imaging in an one step reaction whereby one dye class possesses NIR properties. The dye property and the radiolabel could so be reduced to an average molecular weight of 500 g/mol. **References:** (1) Kopka et al., J. Nucl. Med. 2018, 59, 639-645.

EP-0799
11ß-Ethylestradiol-PEG-DOTA: A novel highly affine estrogen a receptor ligand for radio-metalation

F. Braun[1], *S. Muñoz*[1], *V. Marmann*[1], *T. Fischer*[1], *H. Endepols*[1], *M. Pietsch*[2], *M. von Brandenstein*[3], *A. Drzezga*[1], *K. Schomäcker*[1];
[1]*University of Cologne, Clinic of Nuclear Medicine, Cologne, GERMANY,* [2]*University of Cologne, Institute of Pharmacology, Cologne, GERMANY,* [3]*University of Cologne, Clinic of Urology, Cologne, GERMANY.*

Aim/Introduction: Estrogen Alpha Receptors (ERα) are promising targets for radioactive estrogen-based vectors. After receptor binding, the radioactive estrogen is internalized and localized in the proximity of the DNA. This makes ERα an attractive target for use in the targeted radionuclide treatment. Up to this point, estrogens have mostly been labeled with radioactive halogens such as isotopes of iodine and fluorine. To overcome the obstacles of in vivo dehalogenation, 11ß-ethylestradiol (Ees), a much more affine ligand [1] than native Estradiol (Es), is labeled with radioactive metal ions such as ^{68}Ga and ^{177}Lu. **Materials and Methods:** Ees and Es were coupled to DOTA using a polyethylene glycol (PEG) linker and radiolabeled with ^{68}Ga and ^{177}Lu. The PEG-DOTA modified estrogens (EesPD and EsPD) were tested by a commercially available fluorescence polarization ligand binding assay in order to compare the affinity of the new compounds. The K_d-values of the corresponding radiolabeled compounds were determined by a newly developed binding assay basing on an ERα immobilisation on a high-adsorption plastic matrix (Brand). **Results:** The labeling of EsPD and EesPD yielded a radiochemical purity of >98% for ^{177}Lu and >96% for ^{68}Ga with a specific activity of 40 MBq/nmol. After 48h, stability of >89% in human serum was found in the case of [^{177}Lu] EsPD and -EesPD. The affinity experiments of non-radioactive precursor EsPD and EesPD revealed K_d-values of 70nM and 24nM. The binding assay with the corresponding radioactive estrogens labeled with ^{177}Lu resulted in K_d values of 610nM and 29nM. **Conclusion:** The modification with PEG-DOTA showed an obvious decrease in the receptor-affinity for both Ees and Es. However, EesPD also revealed that the presence of the ethyl group in the 11ß position of the steroid led to a higher affinity (factor 3). Labeling with radioactive lutetium resulted in a significant loss of affinity for EsPD (without ethyl group). In EesPD, this effect was not observed. The new compound EesPD appears to be an interesting precursor for use in targeting of BC with ERα overexpression. It shows potential for use in diagnosis as [^{68}Ga]EesPD as well as in therapy as [^{177}Lu]EesPD. **References:** Anstead GM, Carlson KE, Katzenellenbogen JA. Multimodal nanoparticles for integrated PET/MR imaging and therapeutic purposes

A. Deshotel[1,2], F. Bouraleh Hoch[1], V. Thakare[2], G. Laurent[1], C. Bernhard[2], A. Dubois[2], M. Moreau[2], A. Oudot[3], F. Brunotte[3], R. Bazzi[1], F. Denat[2], S. Roux[1];
[1]UTINAM, UMR 6213, CNRS, Université de Bourgogne Franche-Comté, 16 Route de Gray, 25030, Besançon, FRANCE, [2]Institut de Chimie Moléculaire de l'Université de Bourgogne, UMR 6302, CNRS, Université de Bourgogne Franche-Comté, 9 Avenue Alain Savary, 21000, Dijon, FRANCE, [3]Georges-François LECLERC Cancer Center - UNICANCER, 1 Rue Pr Marion, 21079, Dijon, FRANCE.

Aim/Introduction: In molecular imaging, overcoming limitations of some techniques by associating them with complementary advantages of others seems to be a promising strategy. Among the diverse options, allying the exceptional sensitivity of Positron Emitting Tomography (PET) with the high resolution of an anatomical modality like Magnetic Resonance Imaging (MRI) was the strategy chosen in this work. The development of imaging devices integrating those two modalities is in itself a major challenge as is the design and synthesis of multimodal probes. **Materials and Methods:** The synthesis of different theranostic nanoprobes for PET/MR imaging has been developed considering that the nanoparticles were to accumulate in unhealthy organs through EPR effect and to be eliminated by renal clearance. To get multimodal objects capable of immobilising different metal ions used in imaging (Gd^{3+} or ^{68}Ga) ultra-small gold nanoparticles were coated with different types of organic molecules. Macrocyclic chelators were coupled with a dithiolated anchoring part to get simple bifunctional ligands used to get a mixed layer on the surface of the nanoparticles. To overcome the complicated characterisation of these nanoparticles, three-way orthogonal platforms functionalised by two macrocyclic ligands and by a dithiolated grafting site were developed. To lessen the fast renal clearance of these objects, gold nanoparticles were grafted on biodegradable maghemite nanoflowers (negative contrast for MRI). The biodistribution of these nano-objects was studied in mice after radiolabelling using a preclinical PET/MR scanner. **Results:** The reduction of a gold salt in the presence of different dithiolated chelators provides ultra-small gold nanoparticles (core size: 2-3 nm, hydrodynamic diameter: 6-8 nm). After complexation of gadolinium, the nanoparticles were radiolabelled with ^{68}Ga. With a single intravenous injection, the biodistribution of these nanoparticles was followed simultaneously by T_1-weighted MRI (Gd^{3+}) and by PET (^{68}Ga) in mice with a PET/MR preclinical imaging device. Golden nanoflowers obtained by grafting gold nanoparticles on superparamagnetic iron oxide nanoflowers were followed in mice by T_2-weighted MRI (iron oxide) and PET (β^+ emitters) using the same imager as before. **Conclusion:** The different nanoprobes successfully behaved as imaging agents for integrated PET/MR imaging and were removed from the body through renal clearance in most cases. Owing to the therapeutic properties of the nanoparticles: radiosensitisation for the gold ones and magnetic hyperthermia for the iron oxide; the study of their biodistribution is a key step for their use as theranostics. **References:** Laurent et al. ^{99m}Tc-^{68}Ga-ICG MAA and Nano Colloid of human serum albumin: a tri-modal imaging agent

M. Marenco[1], M. G. Persico[1,2], G. Ferrarazzo[1], G. Cavenaghi[1], C. Aprile[3], L. Lodola[1];
[1]Fondazione IRCCS Policlinico San Matteo, Pavia, ITALY, [2]University School for Advanced Studies IUSS, Pavia, ITALY, [3]National Center for Oncological Hadrontherapy CNAO), Pavia, ITALY.

Aim/Introduction: Recent developments in sentinel lymph node (SLN) and in radio occult lesion localization (ROLL) suggest the need for a multi-modal contrast agent providing a better pre-surgical imaging via PET and an intra-operative mapping via fluorescence detection. For that reason, we have characterized a tri-modal SLN/ROLL targeting agent ^{99m}Tc-^{68}Ga-Indocyanine Green (ICG) with macroaggregated or nanocolloidal human albumin (^{68}Ga-^{99m}Tc-ICG-MAA/NC-HSA), based on SPET, PET and fluorescence imaging. **Materials and Methods:** Radiolabelling. Commercially available kits of MAA and NC-HSA particles are used for radiolabelling with ^{68}Ga and ^{99m}Tc. A buffered solution of ^{68}Ga-chloride is added to the MAA/NC kit previously dissolved in 2 mL saline. The ^{68}Ga-MAA/NC suspension is incubated in a heat block at 75 °C for 30 min. Then ^{99m}Tc Pertechnetate in saline is added to the labelling vial, incubated at room temperature for 20 min. Fluorescent tagging. A vial of ICG Pulsion® (25 mg) is dissolved in 5 mL water. 100 µL of this ICG solution is added to the ^{68}Ga-^{99m}Tc-ICG-MAA/NC-HSA vial (incubation at room temperature for 5 min). Quality control. The radiochemical purity (RP) after radiolabelling was assessed with ITLC, mobile phases MetOH:H_2O 85:15 and tribasic-citrate solution 0.1 M, pH 6 for ^{99m}Tc and ^{68}Ga respectively. Fluorescent purity was measured by the same iTLC method (MetOH:H_2O 85:15) scanned with a PDE (PhotoDynamicEye) probe. **Results:** The RP for the ^{68}Ga and ^{99m}Tc labelled MAA and NC was ≥ 97 %. without significant radioactivity at the solvent front (^{99m}Tc pertechnetate and free or hydroxylated ^{68}Ga) with the respective mobile phases. Fluorescent purity was affected by a variable amount (5-20%) of unbound dye. Additional in vitro stability tests of the hybrid imaging agent assessed with DTPA challenge, dilution test and incubation in human plasma confirmed the compound stability. Polycarbonate membrane (50-30 nm pore size, Nuclepore) filtration confirmed the absence of agglutination of NC after labelling procedure. **Conclusion:** This first attempt shows the possibility to obtain a SPET/PET/fluorescence imaging agent starting from commercially available kit, with a simple procedure and no additional pre- or post- purification steps. PET imaging with ^{68}Ga could provide a quantitative pre-operative map for surgical planning with a better spatial resolution and the possibility to predict signal intensity during surgery. The presence of Tc-99m could be useful to assess the validity of the

model proposed, in vitro at first and then in clinical practice. **References:** None.

^{68}Ga-DTPA-FITC-Silk Fibroin Nanoparticles, a Promising Agent for Positron Emission Tomography and Fluorescence Dual Modal Imaging

M. Asensio Ruiz[1], *A. Garcia Aliaga*[1], *A. Abella Tarazona*[1], *A. Lozano Pérez*[2], *J. Cenis*[2], *T. Martinez Martinez*[1];
[1]*Unidad de Radiofarmacia, Hospital Clínico Universitario Virgen de la Arrixaca, Murcia, SPAIN,* [2]*Departamento de Biotecnología, Instituto Murciano de Investigación y Desarrollo Agrario y Alimentario (IMIDA), Murcia, SPAIN.*

Aim/Introduction: In the last decades the Silk Fibroin Nanoparticles (SFNs) have received considerable attention not only for their ability to act as active vehicle for low bioavailability drugs and/or biomolecules, but also for their highly biocompatible and non-antigenic nature. On the other hand, ^{68}Ga has also attracted the attention though the increasing development of generator-based ^{68}Ga targeting vectors and their wide applications for diagnosis and treatment, especially, theragnosis. The purpose of this work is the dual labeling of SFN with fluorescein (FITC) and ^{68}Ga diethylene pentaacetic acid (DTPA), as a diagnostic agent with improved sensitivity and accuracy, and a new platform for future theragnostic applications. **Materials and Methods:** SFNs were prepared by nanoprecipitation in MeOH. The DTPA-functionalized silk fibroin nanoparticles (DTPA-SFNs) were prepared by amide coupling reaction using the EDC/NHS activating system. DTPA-FITC-SFNs were prepared by adding FITC in DMSO to DTPA-SFN in carbonate buffer. After the washing steps, DTPA-FITC-SFNs were dispersed in ultrapure water, autoclaved (121 ºC 30 min) and kept refrigerated and protected from light until use. For the optimization of radioisotope loading, aqueous suspensions of DTPA-FITC-SFNs from 1 to 10 mg/ml were incubated with up to 74 MBq of $^{68}GaCl_3$ in 0.1 M HCl from a ^{68}Ge/^{68}Ga generator. In order to improve the radiolabeling yield, different loading conditions (buffered aqueous loading media, incubation time and effect of temperature) were tested. Labeling yield was calculated as radioactivity in SFNs divided by total radioactivity. Stability of the labeling was tested by incubation in saline under stirring, at room temperature for 1 hour. The hydrodynamic characterization of the nanoparticles was performed by DLS technique and Zaverage (d.nm), PdI and Zpotential (ζ, mV) were determined before and after radiolabeling. **Results:** Radiolabeling yield was SFN concentration dependent, ranging from 16.31 ±1.38 % (n=6) to 58.00±2.63% (n=8), with a residual activity in supernatants after incubation from 2% to 12% (n=16). The radioactivity loading content varied from 11 MBq/mg SFNs to 4 MBq/mg SFNs (n=24). The size of the loaded nanoparticles slightly decreased after radiolabeling and the Z potential shifted to less negative values due the effect of positive charges contributed by the ^{68}Ga ions bounded to the DTPA in the nanoparticles. **Conclusion:** ^{68}Ga-DTPA-FITC-SFNs are a promising dual modal imaging agent. Further studies, including stability tests, cytotoxicity in cell cultures and in vivo distribution are needed in order to determine the actual performance and their effectiveness in nanomedicine. **References:** None.

EP-0803

Folate Receptor Targeted Dual-modality Imaging Agent For Molecular Imaging And Fluorescence-guided Surgery

D. Kim, M. Kim, S. Kim;
Wonkwang University School Of Medicine, Iksan, Jeollabuk-do, KOREA, REPUBLIC OF.

Aim/Introduction: Folate receptor (FR) is an ideal target for cancer imaging because it is frequently overexpressed in major types of human tumor, whereas its expression in normal organs is highly limited. Combining nuclear and fluorescence imaging techniques provides a novel approach for cancer imaging and monitoring surgery. In the present study, we developed Tc-99m Folate-Gly-His-Glu-Gly-Glu-Cys-Gly-Lys(-5-Carboxy-X-rhodamine)-NH_2 (Folate-ECG-ROX) as a dual modality imaging agent to target FR-positive tumor cells. Simultaneous labeling with Tc-99m and ROX could provide both nuclear and fluorescent imaging. The diagnostic performance and surgical usage of Tc-99m Folate-ECG-ROX as a dual-modality imaging agent for tumor was also evaluated in a murine model. **Materials and Methods:** Folate-ECG-ROX was synthesized using Fmoc solid-phase peptide synthesis. Radiolabeling of Folate-ECG-ROX with Tc-99m was done using ligand exchange via tartrate. Binding affinity and in vitro cellular uptake studies were performed. Gamma camera imaging, biodistribution and ex vivo imaging studies were performed using KB and HT-1080 tumor-bearing murine models. Tumor tissue slides were prepared and analyzed with immunohistochemistry staining and confocal microscopy. Surgical removal of tumor nodules in murine models with peritoneal carcinomatosis was performed under the fluorescence imaging system. **Results:** After radiolabeling procedures with Tc-99m, Tc-99m Folate-ECG-ROX complexes were prepared in high yield (> 97%). The K_d of Tc-99m Folate-ECG-ROX for KB cells was estimated to be 6.9 ± 0.9 nM. Gamma camera imaging revealed substantial uptake of Tc-99m Folate-ECG-ROX in KB tumors. Specific uptake of Tc-99m Folate-ECG-ROX was assessed by biodistribution, ex vivo imaging and immunohistochemistry staining studies. Under real-time optical imaging, the removal of visible nodules was successfully performed. **Conclusion:** We developed Tc-99m Folate-ECG-ROX as a dual modality imaging agent targeting FR of tumor. In vivo and in vitro studies demonstrated substantial and specific affinity of Tc-99m Folate-ECG-ROX for FR. Nuclear imaging using Tc-99m could allow quantitative assessment of organ distribution and tumor accumulation while fluorescent imaging using ROX could provide microscopic, ex vivo, and in vivo fluorescent imaging. Thus, Tc-99m Folate-ECG-ROX could provide both pre-operative molecular imaging and intra-operative guidance. Its feasibility was simulated in murine models. Taken together, results of the present study suggest that

Tc-99m Folate-ECG-ROX is a potential dual-modality imaging agent for diagnosis and surgical guidance of FR-positive tumor. **References:** None.

EP-0804

Prospective evaluation of a Novel Deep Learning Algorithm (PSMA-AI) in the assessment of 99mTc-MIP-1404 SPECT/CT in patients with low or intermediate risk prostate cancer

F. Pouliot[1], K. Sjöstrand[2], N. Stambler[3], J. Richter[2], K. Gjertsson[2], K. Johnsson[2], V. Wong[3], J. Jensen[3], L. Edenbrandt[2,4], A. Anand[2,5]; [1]Université Laval, Quebec City, QC, CANADA, [2]EXINI Diagnostics, Lund, SWEDEN, [3]Progenics Pharmaceuticals Inc, New York, NY, UNITED STATES OF AMERICA, [4]Gothenburg University, Gothenburg, SWEDEN, [5]Skane University Hospital, Lund, SWEDEN.

Aim/Introduction: ^{99m}Tc MIP-1404 (1404) is a PSMA targeted imaging agent for the detection and staging of clinically significant prostate cancer. Manual assessment of tracer uptake in SPECT/CT images introduces inherent limitations in inter- and intra-reader standardization. The study objective was to evaluate the performance of PSMA-AI assisted reads over manual assessment and known clinical predictors. **Materials and Methods:** The study analyzed 464 evaluable patients with very low-, low-, or intermediate- risk prostate cancer, whose diagnostic biopsy indicated a Gleason grade of ≤ 3+4 and/or who were candidates for active surveillance (1404-3301). All subjects received an IV injection of 1404 and SPECT/CT imaging was performed 3-6 hours post-dose. Three independent readers evaluated the images. All subjects underwent either voluntary RP (low- and intermediate-risk) or prostate biopsy (very low-risk) post dosing. Clinically significant disease was declared in subjects with Gleason grade 7 or higher. The PSMA-AI was developed and locked prior to the analysis. Three different independent readers used PSMA-AI to obtain quantitative expression of 1404 in the prostate against the background (PSMA-Index). PSMA-Index for all readers and subjects were compared to the histopathological reference, yielding 6 receiver operating characteristic (ROC) curves (3 manual reads + 3 PSMA-AI assisted reads). The clinical performance of the 1404 PSMA-AI assisted read was also evaluated by comparing the Area Under the ROC Curve (AUC), of a multivariate model (PSA, clinical staging and diagnostic Gleason score) with and without PSMA-Index. **Results:** The manual reads demonstrated AUCs of 0.62, 0.62 and 0.63. The reads with PSMA-AI demonstrated AUCs of 0.65, 0.66 and 0.66. The PSMA-AI performance in terms of AUC was higher than manual in all 3*3=9 pairwise comparisons between the two reader groups, with statistically significant improvement observed in five cases (nominal p<0.05), not accounting for multiple comparisons. The predictive ability of the baseline multivariate model, without PSMA-Index, was at AUC 0.74. Upon adding of PSMA-Index, the model predictive ability increased to AUC 0.77. The logistic regression model indicated that PSMA-Index (p=0.004), pre-surgery PSA (0.018) and % positive cores (p=<0.001) were significantly associated with clinically significant disease. When measuring reproducibility, log (PSMA-Index) correlation coefficients for pairs of PSMA-AI readers were 0.94, 0.97 and 0.98. **Conclusion:** The study demonstrated that PSMA-AI provides a standardized platform to generate reproducible quantitative assessment of 1404. The PSMA-AI assisted read demonstrated an additive improvement over manual assessment and other known predictors for identifying men with clinically significant disease. **References:** None.

EP-0805

18F-FDG PET/CT radiomic features for the prediction of clinical outcomes in locally advanced breast cancer (LABC)

A. Bettinelli[1], L. Evangelista[2], A. Zorz[1], L. Cuppari[2], M. Paiusco[1]; [1]Medical Physics Department, Veneto Institute of Oncology IOV - IRCCS, Padua, ITALY, [2]Nuclear Medicine Unit, Veneto Institute of Oncology IOV - IRCCS, Padua, ITALY.

Aim/Introduction: Current metabolic information, alongside immunohistochemical parameters, cannot accurately predict the clinical outcomes in LABC. Radiomic metabolic features extracted from 18F-FDG PET/CT may prove to be stronger predictive factors for determining neoadjuvant chemotherapy (NAC) outcomes, capturing the intratumoral heterogeneity which is considered to be strongly associated to treatment response. As a preliminary step, the relationship between tumor clusters, as defined by radiomic metabolic features, and histopathologic characteristics, tumor response to NAC, disease free survival (DFS) as well as overall survival (OS) in LABC patients has been investigated. Furthermore, we sought to identify an image-derived signature that can stratify patients into low/high survival groups. **Materials and Methods:** 18F-FDG PET/CT images of 72 LABC patients were retrospectively analyzed for metabolic radiomics. Immunohistochemical parameters included Ki67, ER, PR, and HER2. Primary tumors were delineated by a semi-automatic tool and checked by two expert nuclear medicine physicians. From PET images 168 features has been extracted in a 3D approach; IBEX software was employed for the task. Consensus clustering was used to group tumors that exhibit similar radiomic metabolic patterns. Chi-square test was applied in comparing the proportion of ER-positive (>10%), PR-positive (>10%), HER2-positive (+++), high Ki67 expression (>20%) and pathologic complete response (pCR) among clusters. Wilcoxon based, Fisher Score and Minimum-redundancy-maximum-relevance (mRMR) filter type methods were employed for feature selection. Four features were selected, for each method, as covariates for the COX proportional hazard

ratio model. Survival curves were obtained by Kaplan-Meier method. Patients were followed for at least 5 years. Analysis was performed by using Matlab and R-software. **Results:** Out of 72 patients, 40(55%) had a ER-positive LABC, 54(74%) showed a tumor proliferation index (Ki67)>20%, 19 (26%) were responders to NAC, 24 (33%) had a recurrence of disease and 18 (25%) died. A significant difference emerged for Ki67 expression among clusters, while any difference was found for other clinical data. The median value of each signature was able to stratify patient survival; in particular, according to the Fisher Score, patients with a value lower than the signature median threshold showed a better OS than the counterpart (p-value = 0.015). The stratification achieved with the identified signature outperform the one obtained with PR-positive status (p-value = 0.077), the most predictive immunohistochemical parameter. **Conclusion:** Radiomic features defining the signature, which capture metabolic phenotype, add valuable information for both LABC stratification and outcome prediction. Validation of the results is ongoing on a different sample. **References:** None.

Comparison of machine learning methods for automated [^{18}F]-FDG PET based hydrocephalus classification

M. Grosch[1], *L. Kaiser*[2], *S. A. Ahmadi*[1], *P. Bartenstein*[2], *A. Zwergal*[1,3], *S. Ziegler*[2];
[1]*German Center for Vertigo and Balance Disorders, University Hospital, LMU Munich, Munich, GERMANY,* [2]*Department of Nuclear Medicine, University Hospital, LMU Munich, Munich, GERMANY,* [3]*Department of Neurology, University Hospital, LMU Munich, Munich, GERMANY.*

Aim/Introduction: Machine learning methods aiming at enhanced medical image analysis are subject to ongoing research. In this study, [^{18}F]-FDG PET data from patients with normal pressure hydrocephalus (NPH) and healthy controls were processed to test the capability and accuracy of automated hydrocephalus classification. **Materials and Methods:** A total of 49 [^{18}F]-FDG PET datasets were included in the study, consisting of a study group with 25 NPH patients and a control group with 24 healthy subjects. Image data were normalized to percent injected dose per ml (%ID/ml) and average values in 83 brain regions were determined based on the Hammersmith atlas (n30r83; implemented in PMOD image analysis software). These were taken as input parameters for subsequent analysis. Univariate statistical analysis was performed using SPSS and multivariate analysis using scikit-learn software implemented in Python. Three different classification models (random forest (rf), logistic regression (lr), support vector machine (svm)) were implemented with 5-fold nested-cross-validation (nCV), feature reduction (FR) and principle components analysis (PCA) aiming to identify hydrocephalus patients. **Results:** Univariate SPSS analysis of input features in corresponding brain regions between groups yielded significant differences for 13 brain regions, which were exclusively located in the periventricular zones (e.g. caudate nucleus, thalamus, cingulate gyrus) ($p < 0.005$; Mann-Whitney-U-test). The classification accuracy averaged over 5 nCV folds was 0.87 (rf), 0.97 (lr), 0.95 (svm) without performing FR/PCA. FR to 10 features, based on an ANOVA calculation, without subsequent PCA resulted in an accuracy of 0.89 (rf), 0.83 (lr), 0.85 (svm) and with additional PCA to 5 components in an accuracy of 0.85 (rf), 0.91 (lr), 0.91 (svm). Extracting 5 components by applying PCA to all 83 features without FR provided a classification accuracy of 0.91 (rf), 0.93 (lr), 0.93 (svm). **Conclusion:** This pilot study indicates that advanced machine learning methods based on [^{18}F]-FDG PET features allow to classify NPH against healthy controls with high accuracy. Similar performance across applied classification models was found. Larger patient cohorts are needed to account for overfitting in training procedures. In addition, classification algorithms will be applied to patient groups with different cerebral pathologies in order to investigate them in clinically relevant questions. **References:** None.

EP-0807

A questionnaire-assist deep learning method to classify dementia diseases by using Tc-99m ECD SPECT image

F. Tseng[1], *Z. Lin*[1], *P. Chiu*[2], *G. Hung*[3], *Y. Ni*[1];
[1]*Institute of Nuclear Energy Research, Taoyuan City, TAIWAN,* [2]*Department of Neurology, Show Chwan Memorial Hospital, Changhua City, TAIWAN,* [3]*Chang Bing Show Chwan Memorial Hospital, Changhua City, TAIWAN.*

Aim/Introduction: Recently deep learning is a powerful tool in image classification. Tc-99m ECD single photon emission tomography (SPECT) images with a convolutional neural network can be applied to the classification of dementia diseases. However, it is not easy to acquire a large number of nuclear medicine images for training. In this study, we analyze the feature importance of dementia questionnaires with a deep neural network (DNN) and try to use the information to improve the convolutional neural network (CNN). **Materials and Methods:** For preparing materials of training data, data aggregation and data cleaning will be applied on seventy Tc-99m ECD SPECT images and five thousand questionnaires data from different sets of patients. After data pre-processing, we have trained five thousand questionnaires with DNN and seventy SPECT images with CNN. In the training process, transfer learning method was used in the CNN model such as ResNet50. Finally, we will concatenate feature vectors of DNN model into the flatten layer of CNN. **Results:** In the dementia questionnaires, the diseases divided into four cases: Alzheimer Disease (AD), Parkinson Disease (PD), Normal control (NC) and others. The preliminary predicted results of DNN model shown that the accuracy of AD, PD, and NC were 84%, 79% and 73% on the validation set of questionnaire. Since the number of Tc-99m ECD SPECT images was insufficient, we froze the weights of the CNN model for first several layers and fine-tune the neural network. We will adjust the parameters of the neural network and use cross-validation to obtain better predictive performance. **Conclusion:** Deep learning is a data-driven technology that

performs better as the number of training data increased. But medical nuclear images are expensive and difficult to obtain, especially in the normal database. The dementia questionnaires were expected to provide additional information to improve the training process. We believe that the method could increase the predictive performance of nuclear medicine images classification in the small-scale datasets. **References:** Yiming Ding, Jae Ho Sohn and Michael G. Reinforcement Learning for Automated PET Image Segmentation

R. L. Smith, *L. Bartley, S. Paisey, C. Marshall;*
Cardiff University, Cardiff, UNITED KINGDOM.

Aim/Introduction: To utilize quantitative information provided by PET it is necessary to differentiate abnormal tissue from surrounding areas; accurate image segmentation is therefore paramount. A popular image segmentation technique is thresholding which relies on the intensity of images and is suitable in PET due to the low resolution and high contrast. Large variability in intensities of pathologies and noise make defining a consensus on the optimal thresholding level difficult. To address these problems, we for the first time set PET image thresholding in a Reinforcement Learning (RL) paradigm. RL is inspired by behavioral psychology where an artificial agent makes actions (A_t) in an environment (E) described by its current state (S_t) seeking to maximize a reward (R) to perform a desired task. This sequential decision making is formulated as a Markov Decision Process (MDP). Q learning used in this work is a form of model free RL where the agent may select the best action based on values learned in a Q table during exploitation, or to explore the environment by taking random actions. With successive iterations the Q table is updated using the Bellman equation until optimal Q values and hence action selection policies are learned in the Markovian domain. **Materials and Methods:** RL for PET image segmentation of five spheres from the NEMA Image quality phantom was performed. 20MBq of Fluorine-18 was inserted into the background. Five spheres with varying inner diameter [37mm, 28mm, 22mm, 17mm, 13mm] were filled with 5MBq/ml of 18F. Image thresholding of PET images was framed as an MDP; S_t was defined as the thresholding value; A_t as increasing or decreasing the threshold value; R as the negative absolute difference between the ground truth volume and the segmented volume. Q learning was performed until the terminal state was reached. **Results:** The percentage difference between the ground truth volume and that calculated from the segmentation allows a measure of accuracy to be determined. This error value for the five spheres in descending volume was 1.3%, 0.8%, 0.01%, 1.6% and 2.0% respectively; exceeding performance of previous reported thresholding segmentation in the literature. **Conclusion:** The final paper will perform analysis of the method in-vivo using 18F studies where the ground truth will be obtained from organ dissection of the preclinical model. RL for PET thresholding provides an attractive option for image segmentation. **References:** None.

Low Dose CT to Assess Performance of Deep Learning Pre-Clinical Medical Image Segmentation for Automated Organ-wise Delineation of PET

R. L. Smith[1], *N. Evans*[1], *V. Florence*[2], *S. Paisey*[1], *E. Fittock*[1], *F. Siebzehnrubl*[1], *C. Marshall*[1];
[1]*Cardiff University, Cardiff, UNITED KINGDOM,*
[2]*Polytech Marseille, Marseille, FRANCE.*

Aim/Introduction: Micro-PET-CT allows non-invasive monitoring of biological processes, disease progression and therapy response. Morphological information provided by CT allows organ / tissue delineation for subsequent quantification of physiological information depicted by PET. Deep learning with convolutional neural networks (CNNs) has achieved state-of-the-art performance for automated medical image segmentation and utilized successfully by our group in Micro-PET-CT. The robustness of such approaches in the presence of noise addition / dose reduction of the CT data has not been explored. We thus simulate dose reduction of pre-clinical CT images using a Poisson noise model and evaluate the effect of segmentation performance with increasingly lower dose for 6 regions (skeleton, kidney, bladder, brain, lung, muscle and fat). **Materials and Methods:** Negating electronic noise and subject anatomy, variance in x-ray images may be asserted to quantum noise allowing a model for simulated image noise versus dose (mA) to be constructed. With a mono-energetic x-ray source the mean number of photons (N) incident on the detector is $N=N_o\exp^{(-projections)}$; N_o represents x-ray intensities. N is modelled as a Poisson process ($\lambda=N$) a term for the projection noise is thus $\log(N/N_o)$. Modulating N_o serves as a variable to control noise levels ($\sim 1/N_o$) in projections. A linear relationship between image variance in a central region of an example image and $1/N_o$ was found. As image variance ~ 1/mA, systematically reducing N_o has the effect of simulating a percentage dose reduction in mA. Simulated dose reduction of 5 test cases (50kVp, 300mA, 0.25x0.25x0.25mm) was performed in the sinogram domain allowing reconstruction of noisy simulated CT images. Dose reduction was performed from 10% - 100% in increments of 10%. Test images were segmented using our previously trained model for whole body pre-clinical image segmentation. The Dice coefficient of the six segmented regions for each test case and each dose reduction was assessed. **Results:** The percentage reduction in DICE from the ground truth serves as a measure of the reduction in performance of the segmentation with increasing noise. A 50% dose reduction was for all 5 test subjects resulted in a mean (across all 6 organs) percentage reduction in DICE <25%. **Conclusion:** The pattern in reduction in performance of segmentation as dose was reduced was

similar for each tissue. This may have implications for utilizing reduced dose CT coupled with a deep CNN for segmentation if the CT component is used to anatomically locate physiology on PET data. **References:** None.

Determining the influence of patient's positioning in prone/supine breast PET/CT examination on the selection of the contouring algorithm using radiomics features

D. Borys[1], *I. Gorczewska*[1], *K. Matusik*[2], *M. Jarzab*[3], *A. d'Amico*[1]; [1]*Department of PET Diagnostics, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice Branch, Gliwice, POLAND,* [2]*Silesian University of Technology, Gliwice, POLAND,* [3]*III Department of Radiotherapy and Chemotherapy, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice Branch, Gliwice, POLAND.*

Aim/Introduction: Any PET/CT study in standard clinical routine is performed in a supine position. Breast examination in MRI scan is executed in a prone position with a breast coil to improve the signal to noise ratio. This difference in patient position results in large deformation of the region of interest and impedes comparison of PET/CT study with MRI. We have compared the outcome of PET/CT scan in a supine and prone position. For both positions, a radiomic features of the lesion were determined using three contouring algorithms. Our question was how the selection of the algorithm influences the radiomic features and how the situation changes in both positions. **Materials and Methods:** 225 patients with lesions in breast were selected and double PET/CT series were performed in both positions: supine and additional prone. Mean age of patients was 46.2 years +/- 11 (range 21 to 72). Prone position was achieved using a homemade pad, with the shape of breast coil in MRI. Regions of interest including lesions were contoured using three segmentation methods: adaptive contouring, 41% maximum and 2.5 SUV implemented in Philips IntelliSpace station. Using pyRadiomics (v2.1.0), for the original image, 100 features were computed in groups: shape, first order and texture based (GLCM, GLRLM, GLSZM, GLDM). Data analysis was performed using python to compare above-mentioned parameters if they differ significantly regarding the algorithm used. Tests were performed for each position separately. Statistical significance was determined using Friedman's non-parametric test with p-value less than 0.05 considered as significant. **Results:** For both positions, we have observed significant differences for selected contouring algorithms in a various number of radiomic features. For supine, there were 63 parameters statistically different while in prone 64. 58 parameters were tatistically different in both positions, 32 had p-value above 0.05 meaning that there were no differences. In 10 parameters position of the patient during the study was crucial, because the statistical concluding was different - we have observed the change in p-value regarding the supine/prone position (varying from below to above-established level of statistical significance). **Conclusion:** Statistical significant differences were observed in more than half of analyzed radiomic features independently of the patient position. Based on the results we can conclude that the position of the patient during the PET/CT study in breast cancer imaging and the selection of the contouring algorithm may affect the variability of the determined radiomic features. **References:** Acknowledgment: Grant No. STRATEGMED2/267398/4/NCBR/2015.

EP-0811

Stability of PET Radiomic Features: A Preclinical Study

E. Alsyed[1], *R. Smith*[2], *C. Marshall*[2], *S. Paisey*[2], *E. Spezi*[1,3]; [1]*School of Engineering, Cardiff University, Cardiff, UNITED KINGDOM,* [2]*Wales Research & Diagnostic PET Imaging Centre, Cardiff, UNITED KINGDOM,* [3]*Velindre Cancer Centre, Cardiff, UNITED KINGDOM.*

Aim/Introduction: Extracting quantitative features from medical images is known as radiomics. Several studies support the claim of using radiomic features as biomarkers in cancer treatments. Defining the volume of tumour or region of interest (ROI) is one of the most critical steps in the radiomic process. Radiomic output may vary with different delineation size. The objective of this study is to evaluate the stability of PET image radiomic features with different tumour delineation volumes. **Materials and Methods:** Eight mice with 4T1 tumours injected with 10.0 ± 2.0 MBq of 18F-FDG, 50 minutes post injection they were imaged (by Mediso Nanoscan PET/CT) for 20 minutes. Four regions of interests (ROIs) were defined by four different systematic 3D-Contour sizes (4, 4.5, 5, 5.5 mm). Seventy-eight 3D-radiomic features were extracted using SPAARC (Spaarc Pipeline for Automated Analysis and Radiomic Computing an in-house developed tool built on Matlab) for each volume. The intra-class correlation coefficient (ICC) was calculated for each feature [2]. **Results:** Forty-two (54%) features show ICC ≤ 0.50. Only one feature (infoCorrelation1) of GLCM3D shows ICC ≥ 0.80. Thirty-five (45%) features exhibited 0.80 > ICC ≥ 0.50. **Conclusion:** Robustness and stability of PET image radiomics in tumour volume is feature-dependent. Different volumes of tumours affect the radiomic output. Further studies are needed to evaluate the influence of the partial volume effect on PET/CT image radiomic features. Radiomic features with high ICC can be safely used while features with low or medium ICC should be used with caution especially during patient management. **References:** 1. Cook, G. J. Precision and Accuracy of Radiomics Analysis at Poor Noise Conditions: a Phantom Study Using 3D Printed 'Tumor' Inserts

A. Somasundaram[1], *E. Pfaehler*[1], *J. van Sluis*[1], *D. Vállez García*[1], *E. G. E. de Vries*[1], *R. A. J. O. Dierckx*[1], *R. Boellaard*[1,2];

Aim/Introduction: ^{89}Zr-MAb PET, used in oncological studies to predict targeting of MAbs, suffers from poor signal-to-noise ratio, which affects quantitative radiomic metrics. In order to obtain an optimal ^{89}Zr PET radiomics analysis, it is important to identify those features least sensitive to noise. High versus low noise phantom studies were performed using 3D printed phantom inserts reflecting realistic tumor shapes and tracer uptake, to study radiomic feature accuracy and precision. **Materials and Methods:** A NEMA image quality phantom containing ^{18}F-FDG filled inserts was scanned for 30 minutes. From the list-mode scan, ten frames each for 5s and 120s frame durations were reconstructed. The noise conditions in 5s scan are comparable to those typically seen in ^{89}Zr PET. All images were reconstructed using three different reconstruction protocols with varying degrees (full width at half maximum in mm) of Gaussian smoothing: EARL1 (6.5 mm), EARL2 (5.0 mm), and clinical (2.0 mm). Volumes of interest (VOI) were manually defined on the low dose CT images. VOI perturbations of one voxel, including erosion, dilation, and translation, were applied to simulate segmentation errors. Intraclass correlation coefficients (ICC) were calculated between the ten frames for each frame duration. A similarity distance metric (SDM) measuring within-subject similarity was used to calculate the difference of the short frame duration feature as well as of the perturbed VOI feature from the original 30 minute scan feature. ICC and SDM above 0.75 were regarded as high. **Results:** For the different reconstructions, a high ICC was observed in 95-99% of features for the 120s frames, and in 84-90% of features for the 5s frames. In the 120s scan, 43%, 76%, and 86% of features yielded a high SDM for clinical, EARL2, and EARL1 reconstructions respectively. The percentages for the 5s scan dropped to 12%, 16%, and 21%, correspondingly. VOI translation yielded a high SDM for 87-99% of features for all reconstructions. VOI dilation or erosion by one voxel resulted in a high SDM for only 59-78% of features for EARL and 75-81% for clinical reconstructions. **Conclusion:** Although a majority of features from ^{89}Zr PET-like noisy images are similar between them, these features show a large bias compared with those from optimal noise conditions. VOI dilation and erosion have a larger impact on radiomic feature performance than VOI translation. Because increased smoothing results in lower noise, EARL reconstruction seems to result in a more favorable radiomic feature performance. **References:** None.

Image-based biomarkers for resectable NSCLC using F-18-FDG-PET/CT: evaluation of a novel Matlab based algorithm for better characterisation of radiomics features

K. Kneer[1], *J. Steinacker*[2], *N. Eberhardt*[1], *E. Yousefzadeh-Nowshahr*[1], *J. Raacke*[1], *S. Rüdiger*[3], *C. Kropf-Sanchen*[3], *M. Beer*[2], *V. Prasad*[1], *G. Glatting*[1], *A. Beer*[1];
[1]*University Hospital, Department of Nuclear Medicine, Ulm, GERMANY,* [2]*University Hospital, Department of Diagnostic and Interventional Radiology, Ulm, GERMANY,* [3]*University Hospital, Department of Internal Medicine II, Ulm, GERMANY.*

Aim/Introduction: Predictive and prognostic parameters from texture analyses (TA) of F-18-FDG-PET/CT in NSCLC are often calculated based on Cox proportional hazard method (CoxM). However, the value of some of the parameters in case of non proportional hazards can be challenging. In this work we evaluated a new Matlab based algorithm to determine the optimal prognostic threshold of these parameters. **Materials and Methods:** Pre-therapy PET/CT data of 81 patients (66a, f21, m60) with histologically confirmed NSCLC with a median follow-up of 4.6a were retrospectively analysed. A volume of interest defined for the primary tumor was analysed for PET and CT using MIPAV. We focused on the following imaging parameters: CT-volume and solidity, circularity, kurtosis, excentricity, SUVmax for PET. CoxM and our novel Matlab based methods were used to determine the prognostic values of aforementioned parameters. On Matlab, the optimal thresholds were determined as follows: 1.patient data were sorted in ascending order of the investigated parameter. Then different thresholds were defined using Matlab. Both groups as divided by the threshold were tested for significance (log-rank-test, $p<0.05$). 2.Best threshold was defined as the one with the lowest p-value. 3.We compared four groups by combining two parameters, e.g. SUVmax and CT-volume. P-value was calculated with the log-rank test. **Results:** None of the analysed image based parameters showed proportional hazard on CoxM. Poor negative prognostic value was observed for CT-volume >1434 mm³ (p=0.018). PET-parameters showed significant negative prognostic value for SUVmax >12.2 (p=0.003), solidity >0.9810 (p=0.004) or circularity >0.1966 (p=0.009). For small CT-volumes, prognosis was excellent independent of other PET/TA parameters. In larger tumors different subgroups could be defined by combining CT-volume and SUVmax/TA-parameters of PET. Tumors with larger volume and higher SUVmax showed significantly worse prognosis compared to tumors with smaller volume and lower SUVmax. Similar, tumors with larger CT-volume and higher PET-Solidity showed worse prognosis than those with higher volume and lower PET-Solidity (p=0.014). Poor prognosis was seen in patients with higher SUVmax and higher PET-Solidity compared to lower SUVmax and lower PET-Solidity (p=0.016). **Conclusion:** We successfully applied a novel algorithm for determination of optimal parameters and their prognostic threshold for TA data not showing proportional hazard as assumed in the Cox proportional hazard model. Powerful prognostic parameters could be defined for CT and

PET using TA of FDG PET/CT even for this homogenous low-risk NSCLC population. SUVmax, PET-solidity and CT tumor volume were found to be the best predictive factors. **References:** None.

EP-0814

The comparison of radiomics features on FDG PET/CT acquisition between supine and prone position

I. Gorczewska[1], *D. Borys*[2], *M. Jarzab*[3], *A. d'Amico*[1];
[1]*Department of PET Diagnostics, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice, POLAND,* [2]*Institute of Automatic Control, Silesian University of Technology, Gliwice, POLAND,* [3]*III Department of Radiotherapy and Chemotherapy, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice Branch, Gliwice, POLAND.*

Aim/Introduction: Combination of PET and CT allows the functional PET and anatomical CT images to be acquired under identical conditions. The standard study is performed in supine position. The major roles for PET/CT in breast cancer are detecting, localizing metastasis, monitoring the response to treatment and early detection of recurrence. Patient with breast cancer undergo the MRI study in a prone position. In this study we have compared 18F-FDG PET/CT scans performed in supine and additional prone position to verify if the radiomic features of lesion change significantly regarding to position of the patient. **Materials and Methods:** 225 patients with lesions in breasts were selected and two PET/CT series were performed in following positions: standard supine and additional prone. Mean age of analysed women was 46.2 years +/- 11 (range: 21 to 72 years). Prone position was achieved using a self-made pad, replicating the shape of breast coil in MRI. Regions of interest including lesions were contoured using three segmentation methods: adaptive contouring, 41% maximum value and 2.5 SUV implemented in Philips IntelliSpace station. Using pyRadiomics (v2.1.0), for the original image, 100 radiomic features were computed in groups: shape, first order and texture based (GLCM, GLRLM, GLSZM, GLDM). Data analysis was performed using python numpy, scipy and pandas modules to compare parameters if they differ significantly in both positions. Statistical significance was determined using Wilcoxon matched-pairs signed rank test. A p-value less than 0.05 was considered significant. **Results:** Each tested contouring method present significant differences in both positions (prone vs supine). For adaptive contouring there were 46 parameters statistically different. In the other 54 considered features the p-value was equal or greater than the assumed level of statistical significance. The method'41% of maximum level'had the following proportion of results with and without differences: 47 to 53 parameters. Evaluated proportion of results for 2.5 SUV method was 54 significant and 46 non-significant. From among 100 examined radiomic features, there were 25 with statistical differences with position as a differentiating variable in all algorithms at the same time. The common part in the insignificant parameters for all considered contouring methods were 20 parameters. **Conclusion:** Statistical significant differences were observed in almost half of analyzed radiomic features independently of the contouring method. Based on the results it is appropriate to conclude that the position of the patient during the PET/CT study in breast cancer imaging is very important. **References:** Acknowledgment: STRATEGMED2/267398/4/NCBR/2015.

Aim/Introduction: With increasing cancer incidences and treatment direction going towards personalised medicine, increasing research in the field, it is becoming increasingly important to capture maximum information related to disease processes, treatments, outcomes etc. All imaging reports are documented as free text discourse. Extraction of relevant information from free text biomedical reports is very cumbersome. Several open source NLP systems are available which make it less time consuming to extract information from radiology reports. In this study, we have validated a python script created in house for named entity recognition (NER) for specific disease identification phrases related to lung cancer diagnosis in a corpus of free text radiology reportsand compared it with an open source NLP system, cTAKES. **Materials and Methods:** This study has been approved by our institutional ethics committee. 100 expert-generated free text PET/CT and 100 CT scan reports from Tata Memorial Hospital performed on lung carcinoma patients were anonymized and cleaned to extract only the findings and impression using Python. Initially, we used cTAKES analysis engine AggregatePlainTextFastUMLS to extract around 12 disease identification phrases from the reports.An in house developed python script was simultaneously used for the same. We validated the output from both softwares against a gold standard of manual identification by a human reader. We specifically looked at recall (Sensitivity), specificity and accuracy of detecting reportsfor both the python script as well as cTAKES. **Results:** The overall recall, specificity and accuracy for NER by cTAKES for PET/CT reports were 0, 1 and 0.507 respectively and for CT scan reports was 0.069, 1 and 0.611. However, the same for our python script was 0.99, 0.99 and 0.99 respectively for PET/CT reports and 0.928, 1 and 0.970 respectively for CT scan reports. **Conclusion:** cTAKES recall and accuracy for NER for disease identification phrases lung cancer from PET/CT& CT scan reports is very poor due to the use of abbreviations and colloquial terminologies which are not mapped in dictionaries.

However the python script was more customized and hence worked very well for extracting these terms. These results may be used for modifying cTAKES script to ensure better performance. **References:** None.

Is there any correlation between the radiomic features extracted from CT and PET Images

A. K. Jha[1,2], *S. Mithun*[1,2], *U. B. Sherkhane*[1], *V. Jaiswar*[1], *N. C. Purandare*[1], *V. Rangarajan*[1], *A. Dekker*[2,3], *L. Wee*[2,3];
[1]*Tata Memorial Hospital, Mumbai, INDIA,* [2]*GROW-School for Oncology and Developmental Biology, Maastricht University Medical Center, Maastricht, NETHERLANDS,* [3]*Department of Radiation Oncology (MAASTRO Clinic), Maastricht, NETHERLANDS.*

Aim/Introduction: Use of visual interpretation of CT image and semi-quantitative parameters of PET image has been established in planning, interim evaluation and follow-up of patient in oncology. Although semi-quantitative parameters like SUVmax, TLG and MTV are used to prognosticate the disease as well as early treatment response.Radiomics analysis of PET and CT images suggest potentially informative features, which may be used for personalized treatment selection in oncology. The influence of CT image acquisition and reconstruction on radiomic features extraction requires investigation. The aim of this study was the correlation between radiomic features extracted from CT and PET images. **Materials and Methods:** 104 NSCLC patients with pre-treatment PET/CT scans were included in this study. The lung tumor in PET was delineated by SUV threshold (42%) and the same contour were copied to co-registered CT images. Subsequently, 1093 radiomic features were extracted from each tumor segment and for each image modality. The bin width for CT and PET radiomic analysis were 25 and 0.5 respectively. Correlation between the radiomic features extracted from CT and PET images was assessed by calculating the concordance correlation coefficient (CCC) between the two imaging modalities. **Results:** 54% of PET and CT radiomic features have mutually positive correlation and 46% have negative mutual correlation. 91(8.33%), 69(6.3%) and 51(4.67%) features, respectively, have CCC greater than 0.5, 0.7 and 0.9. only 32 (2.93) radiomic features had CCC equals to or more than 0.98. In top twenty features ten features are shape based features. Table one shows top ten radiomic features excluding shape based features with CCC values.Table 1: Top tan features having best correlation excluding shape based features **Conclusion:** Our study suggests that majority of PET and CT radiomic features are not correlated to each other. And majority of highly correlated features are shape based features. **References:** None.

Methionine PET Imaging For Differentiation Between Recurrent Brain Tumor And Radiation Necrosis: Radiomics Approach With Random Forest Classifier

M. Hotta[1], *R. Minamimoto*[1], *K. Miwa*[2];
[1]*National Center for Global Health and Medicine, Tokyo, JAPAN,* [2]*International University of Health and Welfare, Tochigi, JAPAN.*

Aim/Introduction: Distinguishing radiation necrosis from recurrent brain tumor is important for selecting an appropriate treatment strategy. However, an accurate diagnosis often remains challenging in conventional imaging. Although the lesion-to-background ratio (L/B ratio) using 11C-methionine (MET) PET provides good diagnostic performance in the diagnosis of recurrent brain tumor from radiation necrosis, this methodology still yields false-positive or -negative cases. The purpose of this study was to investigate the efficacy of MET PET using a radiomics approach with a random forest classifier for differential diagnosis between recurrent tumor and radiation necrosis. **Materials and Methods:** We enrolled 42 patients (age: 55.8±13.2 years) with glioma (n=21) and brain metastasis (n=21) who underwent MET PET between October 2014 and June 2016 due to suspected recurrence on MRI after radiation therapy. A total of 44 lesions showing abnormal MET uptake were used for analyses. Surgical histopathological analysis or more than 6 months of follow-up with MRI was the reference standard. For calculating the L/B ratio, the maximum standardized uptake value (SUV) of the lesion and the mean SUV of the normal brain cortex using 1.0 cm^3 sphere were measured. For radiomics analysis, the three-dimensional volume of interest was set to encompass the lesion, and the area with a SUV of more than 1.3 times of the normal brain cortex was automatically contoured; 42 textual features were extracted and used for machine learning. A random forest classifier was applied to separate the radiation necrosis from recurrent tumor after balancing the number of lesions in both radiation necrosis and recurrent tumor using the synthetic minority oversampling technique. Gini importance was used to identify relevant textual features for classification. **Results:** Thirty-three and 11 lesions were confirmed as recurrent tumor and radiation necrosis, respectively. For the differentiation between tumor recurrence and radiation necrosis, the L/B ratio evaluation and radiomic classifier demonstrated an area under the curve of 0.72 and 0.98, sensitivity of 66.7% and 90.1%, specificity of 63.6% and 93.9%, accuracy of 79.5% and 92.2%, positive predictive value of 84.6% and 95.2%, and negative predictive value of 38.9% and 88.6%, respectively. Gray level co-occurrence matrix (GLCM) dissimilarity was the most relevant textual feature for the diagnosis. **Conclusion:** A radiomics approach using MET PET yielded excellent results for differentiating radiation necrosis from recurrent tumor, which was superior to the L/B ratio evaluation. These findings should be validated on a larger scale using independent data for future clinical translation. **References:** None.

AI-based Tools for Automated Quantification of PET/CT Studies

L. Edenbrandt[1], *J. Ulen*[2], *O. Enqvist*[2,3], *E. Trägårdh*[4];
[1]*Sahlgrenska University Hospital, Gothenburg, SWEDEN,* [2]*Eigenvision, Malmö, SWEDEN,* [3]*Department of Electrical Engineering, Chalmers University of Technology, Gothenburg, SWEDEN,* [4]*Skane University Hospital, Malmö, SWEDEN.*

Aim/Introduction: Deep learning, a subfield of artificial intelligence, has become the method of choice for image analysis applications and therefore gained increased usage also in medical imaging. Automated deep learning-based quantification of PET/CT studies has the potential to improve or substitute current methods of assessing extent and activity of cancer in the human body. RECOMIA is a nonprofit organization with the objective of promoting research in this field by providing academic researchers with . **Materials and Methods:** The first step in automated quantification of PET/CT studies is usually to segment the organs of interest in CT. In this work two convolutional neural networks (CNN) were trained to segment 75 different organs. The networks were designed to handle the fact that the number of vertebrae and ribs can vary between different subjects.The organs included: 56 bones (skull, mandible, humeri, femuri, cervical vertebrae, thoracic vertebrae, lumbar vertebrae, sacrum, hip bones, ribs, scapulae, clavicles and the sternum) and 19 soft tissue organs (brain, lungs, heart, aorta, liver, gallbladder, ventricle, spleen, pancreas, adrenal glands, kidneys, urinary bladder, prostate, rectum and gluteus maximus muscles).A dataset of approximately 10,000 manual organ segmentations in 231 images were used to train the CNNs. Not all organs were annotated in all images, which had to be handled in the training process. The CT scans were split into training (80%) and validation (20%) groups. **Results:** The CNN-based segmentations were compared to the manual segmentations on the validation group. The overall recall was 93.4%, that is, there was agreement on 93.4% of the voxels that were manually labelled. Similarly, the overall precision was 95.3%. Another way to measure accuracy is by the per-organ Dice index. The average Dice index over the 75 organs was 0.91, (0.85 for the soft tissue organs and 0.93 for the bones).The run time of the CNNs was about 2 minutes on a desktop computer. **Conclusion:** AI-based tools can provide highly accurate and reproducible organ segmentations, similar to those obtained manually by radiologists, but much faster. We continue to train new CNNs to continuously improve performance. The tools developed in this project are available on request at www.recomia.org for research purposes. **References:** None.

EP-0819

Preliminary Results of Whole Liver Segmentation with Deep Learning for SIRT

X. Tang[1], *E. Jafargholi Rangraz*[1], *W. Coudyzer*[2], *J. Bertels*[1], *D. Robben*[1], *G. Schramm*[1], *W. Deckers*[2], *C. M. Deroose*[1,2], *K. Baete*[1,2], *M. J. Gooding*[3], *J. Nuyts*[1];
[1]*KU Leuven, Leuven, BELGIUM,* [2]*University Hospitals Leuven, Leuven, BELGIUM,* [3]*Mirada Medical Ltd, Oxford, UNITED KINGDOM.*

Aim/Introduction: For radiation dose calculation in selective internal radiation therapy (SIRT), an accurate liver segmentation is required. Our aim was to investigate the feasibility of using a convolutional neural network (CNN) for liver segmentation for SIRT patients. **Materials and Methods:** A multi-scale CNN [1] was modified for liver segmentation for SIRT patients. The CNN was trained on 230 datasets from three liver segmentation challenges, including Medical Segmentation Decathlon (MSD), LiTS17, and SLIVER07, and 12 SIRT patient datasets from UZ Leuven. Validation was performed on 12 datasets from LiTS17 and SLIVER07 challenges, and 13 SIRT patient datasets. The model was tested on 20 datasets from the MSD challenge and 32 datasets from 30 SIRT patients, which were not used in training and validation. The CTs from the three challenges are contrast-enhanced (CE) and some CTs from the SIRT patients are non-CE. The results are evaluated through the dice score (DSC) and the volume ratio (RV) of the CNN segmentation to manual delineation. **Results:** The trained model achieved a median DSC and RV of 0.97 and 0.99 on the challenge data for testing. This result was comparable to the highest DSC of 0.95 reported for the MSD challenge. A median DSC and RV of 0.94 and 0.93 were achieved on the 32 SIRT test datasets. CNN had poor performance for two SIRT test datasets, with DSC of 0.84 and 0.62. **Conclusion:** The CNN model trained on general data of liver cancer achieved good results on the SIRT data with relatively normal liver shapes and low disease burden, only slight adjustment may be needed for clinical use. However, the trained model failed on SIRT data with high tumor burden, diffuse tumor involvement, and low-dose CT, since these cases are not adequately represented in the training data. The lower performance on SIRT patients may result from a difference in manual delineation strategy between the clinical SIRT data and the challenge data. The experiments could also indicate some diversity between the SIRT data and the challenge data, resulting in worse segmentation of SIRT data using the model mainly trained on the challenge data. To solve the latter, collection of a larger (multi-institutional) datasets of representative SIRT work-up cases may be required. A more detailed analysis of the observed performance difference is ongoing. (This projected is funded by H2020-ITN project HYBRID.) **References:** [1] Kamnitsas et al., Medical Image Analysis 2017.

Med. Department, Cannizzaro Hospital, Catania, ITALY.*

Aim/Introduction: Radiomics on PET, including semiquantitative, first-order intensity, shape and textural features extracted from the tumors, provides information about tumor biology and behavior to get a better prognosis, and treatment response prediction in oncological patients. In this context, we present an innovative machine learning approach which purpose is to tackle the real-time, 3D tumor segmentation task in a nearly full automatized way. **Materials and Methods:** The proposed algorithm identifies a user-independent ROI around the tumor in the PET slice containing the SUVmax. The volume is then reconstructed using a slice-by-slice marching approach until a suitable automatic stop condition is met. The segmentation is performed using an enhanced local active contour based on the minimization of a novel energy functional which integrates the information provided by a machine learning component based on k-nearest neighbor classification method. As a result, the whole algorithm is automatic and the output segmentation is user independent. Five phantom experiments for a total of 30 radioactive spheres, and 41 clinical cases comprising 12 lung, and 29 head & neck cancers were used in our study. To train and validate the machine learning component, fixed ROIs were placed by three expert physicians in a subset of 3 phantom spheres and 6 patient lesions from the initial PET dataset with the purpose of identifying 3 different areas: tumor, background and border-line regions. The remaining data were used to assess the performances of the segmentation algorithm. The physicians performed manual segmentations around each lesion, and a ground truth estimation tool was employed to define a consolidated reference starting from different manual delineations. **Results:** Phantom performance results were divided considering small spheres with diameters < 22 mm and large spheres with diameter > 17 mm. In the smaller spheres, the mean dice similarity coefficient (DSC) was 78,84±6,18%. In the larger spheres, mean DSC increased to 90,36±2,75%. Clinical cases showed high agreement with the gold standard (R2 = 0.98). The mean DSC was 87,14±3,31% and 87,88±3,89%, in head & neck and in lung cancers. In order to confirm that the method was operator-independent, a sub-dataset of 5 head & neck, and 5 lung cancers was segmented by the three physicians. The result consisted of identical volumes. **Conclusion:** the proposed method can be efficiently applied in the clinical routine for tumor segmentation, and to extract radiomic features with potential benefit to improve tumor phenotyping, prognosis, and treatment response prediction, noninvasively. **References:** None.

EP-0821

AI-Based PET-to-PET Alignment Enabling Individual Tumour Tracking and Multi-Tracer Analysis

E. Tragardh[1], *J. Ulén*[2], *O. Enqvist*[2], *L. Edenbrandt*[3];
[1]*Skåne University Hospital, Malmo, SWEDEN,* [2]*Eigenvision, Malmo, SWEDEN,* [3]*Sahlgrenska University Hospital, Göteborg, SWEDEN.*

Aim/Introduction: In the clinic, multiple PET-CT scans from the same patient are often acquired and the value of these types of analyses has been illustrated in recent studies (1-2). However, tools for automatic analysis of dual PET/CT studies are lacking. For instance, tracking individual metastases in consecutive PET/CT studies is very time-consuming, making the evaluation of treatment response expensive. The aim of this study was to develop a method for automated comparison of PET tracer uptake in dual PET/CT studies. **Materials and Methods:** The CNN-based bone segmentation in (3) can be used to segment 56 individual bones from CT images. Given two PET/CT studies of the same patient, this method was applied to each CT image. Next, for each bone, a standard alignment software (Elastix) was used to estimate the (rigid) motion of that bone between the two studies. Using each motion on the corresponding voxels, allows us to align one PET image to the other with voxel precision. Using a fixed metastasis criterion, this allows tracking individual metastases between two different scans, speeding up the evaluation process. **Results:** We analyzed two cases to highlight the possibilities of the new technique. Patient A with prostate cancer and bone metastases underwent both an 18F-sodium fluoride (FLUR) and an 18F-fluorocholine (CHOL) PET/CT. The automated method detected 20 hotspots in the skeleton. Hotspots likely to represent metastases by visual analysis had SUVmax FLU/CHOL ratios less than 7 whereas most of those representing degenerative disease had higher ratios. Patient B with lymphoma underwent two 18F-FDG-PET/CT studies with 2 months interval. The automated method detected 19 hotspots in the skeleton. Four hotspots showed a decrease and 10 an increase of SUVmax of more than 10%. In five of the hotspots SUVmax differed less than 10% between the studies. **Conclusion:** We present a deep learning-based approach to segment the same object in two images and estimate a transformation between them. The method could be a tool to evaluate treatment response or for assessment of disease heterogeneity. The automated AI tool is available on request for research purposes at www.recomia.org. **References:** 1 Davis JC, et al. 18F-FDG Uptake During Early Adjuvant ... Evaluation of radiomics quantification using a multi-compartment multimodality imaging phantom

K. M. Meijer[1], *I. Hernández-Girón*[1], *W. M. Brink*[1], *A. Webb*[1], *C. H. Slump*[2], *L. F. de Geus-Oei*[1,2], *D. V. Kuznetsov*[3], *D. R. Schaart*[4,5], *F. H. P. van Velden*[1], *W. Grootjans*[1];
[1]*Leiden University Medical Center, Leiden, NETHERLANDS,* [2]*MIRA Institute for Biomedical Technology and Technical Medicine, University of Twente, Enschede, NETHERLANDS,* [3]*Electronic and mechanical support division, Delft University of Technology, Delft, NETHERLANDS,* [4]*Radiation Science and Technology, Delft University of Technology, Delft, NETHERLANDS,* [5]*Holland Proton Therapy Centre (HollandPTC), Delft, NETHERLANDS.*

Aim/Introduction: Accurate quantification of intratumor heterogeneity using radiomics features is becoming increasingly important for precise characterization of cancer lesions. In this study, the performance of PET, CT and MR imaging for depicting heterogeneous uptake and enhancement patterns was investigated. **Materials and Methods:** Multi-compartment 3D printed imaging phantoms, that can be inserted in the casing of the NEMA-NU2 PET image quality phantom, were used to simulate heterogeneous uptake and enhancement patterns in PET (Vereos digital PET scanner (Philips, Medical Systems)), CT (Aquilion One (Canon Medical Systems)), and MR (Philips Ingenia 1.5T (Philips Medical Systems)) imaging. Three different phantom inserts, consisting of cylindrical volumes containing different rectangular compartments (L-shape, stair-shape, and U-shape), were filled with different concentrations (ratios of 2:4:8:16 with respect to the background) of ^{18}F-fluorodeoxyglucose (FDG), iodinated contrast, and gadolinium contrast. The rectangular shapes were created at different scales, consisting of cubes with dimensions of 10×10×10 mm, 7.5×7.5×7.5 mm and 5×5×5 mm, respectively. Image acquisition was repeated 5 times (standard abdominal imaging protocols). Furthermore, high resolution CT imaging was performed for generating a ground-truth reference in order to determine the accuracy of radiomics quantification. A total of 54 radiomic features were extracted using PyRadiomics. **Results:** Regarding the test-retest analysis, features extracted from MR had the highest reproducibility (only 1 feature had more than 20% variation), followed by CT (17 features >20%) and PET (28 features >20%). The First-Order (FO), Gray Level Co-occurrence Matrix (GLCM), Gray Level Run Length Matrix (GLRLM), Neighboring Gray Tone Difference Matrix (NGTDM) features were reproducible on all imaging modalities, with variations below 20%. Furthermore, analysis showed that the scale of the heterogeneous structure significantly affected the absolute value of almost all radiomics features. PET was affected to a lesser extent by heterogeneity scale than CT and MR, with the GLCM feature group least affected. Finally, the absolute value of most FO, and GLCM features showed less than 20% deviation from the high-resolution ground-truth, whereas the GLRLM, Grey Level Size Zone Matrix (GLSZM) and NGTDM features showed significant deviations. **Conclusion:** This study showed that heterogeneous uptake and enhancement patterns can be simulated on PET, CT and MR imaging using a multi-compartment imaging phantom. The three imaging modalities showed different performances regarding test-retest reproducibility and accuracy of radiomic quantification. **References:** None.

EP-0823

A Novel Automated Deep Learning Algorithm for Segmentation of the Skeleton in Low-Dose CT for [(18)F] DCFPyL PET/CT Hybrid Imaging in Patients with Metastatic Prostate Cancer

K. Gjertsson, *K. Johnsson, J. Richter, K. Sjöstrand, L. Edenbrandt, A. Anand;*
EXINI Diagnostics AB, Lund, SWEDEN.

Aim/Introduction: [(18)F]DCFPyL (PyL-PSMA) PET/CT hybrid imaging is one of the most promising diagnostic assessments for prostate cancer patients. For accurate diagnosis and treatment planning the manual delineation of organs in three-dimensional hybrid imaging is essential but it is also a highly labor-intensive process. Our objective was to automate the process of accurate bone segmentation in whole body low-dose CT of PyL-PSMA PET/CT scans for subsequent automated detection of lesions in bone. **Materials and Methods:** We developed a deep learning algorithm based on cascaded deep convolutional neural networks for semantic segmentation of the 49 bones in 12 skeletal regions (thoracic- and lumbar vertebrae, sinister/dexter ribs, sternum, sinister/dexter clavicle, sinister/dexter scapula, sinister/dexter ilium, and sacrum). A training set (N=90) and validation set (N=22) of pairs of low-dose CT images and manually crafted segmentation maps were used to develop the deep learning algorithm. The algorithm's performance was further assessed on a test set (N=10) of low-dose CT drawn from a PyL-PSMA study with corresponding manual segmentations of five representatively chosen body parts (sinister ilium, lumbar vertebrae, sinister ribs, dexter scapula, and sternum) used as ground truth. The Sørensen-Dice score was used to evaluate the performance of the segmentation in PyL-PSMA PET/CT. **Results:** The segmentation algorithm required less than 120 seconds to generate a complete segmentation of a whole body low-dose CT of PyL-PSMA PET/CT scan and achieved a Sørensen-Dice score mean and standard deviation of 0.95 and 0.024 on the training set and 0.93 and 0.036 on the validation set. On the test set the algorithm achieved mean (and standard deviation) of 0.94 (0.016) for dexter clavicle, 0.91 (0.013) for sinister ribs, 0.92 (0.019) for sternum, 0.94 (0.033) for lumbar vertebrae and finally 0.97 (0.0033) for sinister ilium. Performance overall skeletal regions in the test set was 0.94 (0.027). **Conclusion:** The study has demonstrated the efficiency and effectiveness of our fully automated segmentation algorithm of the 49 bone in the 12 skeleton regions of whole body low-dose CT in PyL-PSMA PET/CT images. Future work includes automated lesion detection and categorization in PyL-PSMA/CT as well as further evaluation of the clinical utility. **References:** None.

Favorable Image Reconstruction for Adequate Myocardial Perfusion Imaging Using Rubidium-82 on a Digital PET System

S. S. Koenders[1,2], *J. D. van Dijk*[1], *P. L. Jager*[1], *H. Arkies*[1], *J. R. Timmer*[3], *M. Mouden*[3], *C. H. Slump*[2], *J. A. van Dalen*[4];
[1]*Isala hospital, Department of Nuclear Medicine, Zwolle, NETHERLANDS,* [2]*Technical Medicine Centre, University of Twente, Enschede, NETHERLANDS,* [3]*Isala hospital, Department of Cardiology, Zwolle, NETHERLANDS,* [4]*Isala hospital, Department of Medical Physics, Zwolle, NETHERLANDS.*

Aim/Introduction: The use of myocardial perfusion imaging (MPI) with Rubidium-82 (Rb-82) PET for the detection of coronary artery disease is increasing rapidly. Recently, PET systems with digital photon counting technology have become available. As these systems have an increased temporal and spatial resolution it is unknown which reconstruction settings are best to use for MPI assessment. Our aim was to determine an image reconstruction that provides sufficient defect visibility in MPI using a digital PET system. **Materials and Methods:** We retrospectively included 30 consecutive patients who underwent rest and regadenoson-induced stress Rb-82 PET/CT (Vereos, Philips Healthcare). PET data were reconstructed with a 3D ordered subset expectation maximization (OSEM) algorithm, using 4 combinations of iterations, subsets and Gaussian post-smoothing filters: 2 iterations, 15 subsets and filtering of 4 mm (2i15s4mm), 2i15s6mm, 3i15s8mm and 3i15s12mm. These settings were selected out of 15 settings that comprised a range of scan quality from excessively smooth to excessively noisy, where the extreme ones were rejected. For each patient, the four reconstructions were shown randomly and side-by-side to two expert teams consisting of a nuclear medicine physician and cardiologist. The readers ranked scan quality from best (score 1) to worst (score 4) and as adequate or inadequate. **Results:** The scan quality of the 2i15s6mm reconstruction was better than that of the reconstructions using 2i15s4mm or 3i15s12mm ($p \leq 0.001$). The mean scan quality was 2.4 ± 0.8, 1.7 ± 0.4, 2.1 ± 0.8 and 3.8 ± 0.4 for the reconstructions using 2i15s4mm, 2i15s6mm, 3i15s8mm and 3i15s12mm, respectively. All scans reconstructed with 2i15s6mm were scored as adequate. For the scans reconstructed with 2i15s4mm, 3i15s8mm and 3i15s12mm, 3% of the scans were scored as inadequate. **Conclusion:** Adequate scan quality can be obtained using the OSEM reconstruction algorithm in PET MPI using Rb-82 on a digital system. The combination of 2 iterations, 15 subsets and a Gaussian post-smoothing filter of 6 mm was preferred for defect visibility. **References:** None.

EP-0825
The Influence of Attenuation Artefacts Caused by Metallic Injection Ports in Breast Tissue Expanders on the Calculation of LVEF in MUGA Studies

A. Hughes;
Christie Medical Physics & Engineering, Royal Preston Hospital, Preston, UNITED KINGDOM.

Aim/Introduction: Breast cancer patients who have undergone mastectomy as part of their treatment are frequently fitted with tissue expanding implants to aid breast reconstruction. These devices have metallic injection ports which can cause attenuation artefacts in radiological images. Such patients may subsequently receive chemotherapy and undergo serial MUGA studies to detect changes in cardiac performance. The aim of this study was to investigate the impact of artefacts caused by breast tissue expanders on the calculation of left ventricular ejection fraction (LVEF). **Materials and Methods:** Through retrospective analysis of MUGA studies on patients fitted with tissue expanders a computer programme was written which could simulate the size and intensity of the observed attenuation artefacts and could be added to any location within an image. 20 MUGA studies of female patients without breast tissue expanders were then selected and the computer simulated artefact was added to one of five locations over the left ventricle: at the centre of the chamber and at the borders of the septal wall, lateral wall, valve plane and apex. For each patient, the original study and the five additional studies containing an artefact were processed using the EF Analysis software on a Xeleris 4.0 computer (GE Medical Systems), using automatic and manual edge detection methods. **Results:** The computed LVEF of the 20 patients in the original studies ranged from 44 to 75% (mean=59.5%). For those studies processed using automatic edge detection there was a general increase in calculated LVEF when the artefact was positioned over the centre of the chamber (mean=68.2%, range 37-79%). With the artefact over the boundary of the left ventricle the change in LVEF was much lower at all locations. With automatic processing the ventricular borders and identification of the end systolic frames were largely incorrect. In some patients the addition of the artefact caused the calculated LVEF to change by as much as ±25%. With manual edge detection the impact of artefacts located over the centre of the left ventricle were greatly reduced (mean LVEF=60.2%, range 46-75%). Furthermore, end systolic frames were correctly identified and the artefact caused individual discrepancies in LVEF of ±5%. **Conclusion:** Artefacts associated with breast tissue expanders can interfere with automatic edge detection routines leading to erroneous calculation of LVEF. However, with careful manual definition of the ventricular borders these errors can be avoided and reliable estimates of LVEF obtained, even in the presence of these artefacts. **References:** None.

EP-0826

Prevalence, Characteristic And Pronostic Value Of Extra-cardiac Uptake Of 99mtc-hydroxythylene Diphosphonate In Cardiac Amyloidosis

M. Abulizi[1], *N. Malka*[1], *M. Kharoubi*[2], *T. Damy*[3], *E. Itti*[1];
[1]*Hospital henri-mondor, medecine nuclear departement, Créteil, FRANCE,* [2]*Hospital henri-mondor, cardiologie departement, Créteil, FRANCE,* [3]*Hospital henri-mondor, cardiologie departement, Créteil, FRANCE.*

Aim/Introduction: Systemic amyloidosis is a serious disease resulting from extracellular deposition of amyloid fibrils within organs. The two main forms of cardiac amyloidosis (CA) are AL amyloidosis due to light chains, and transthyretin amyloidosis (TTR). Diphosphonate scintigraphy has demonstrated performance in assessing myocardial involvement in amyloidosis, particularly in TTR patients, with a worse prognostic in its presence. The prevalence, characteristics and prognostic value of extracardiac diphosphonate uptake have been poorly described. **Materials and Methods:** This retrospective study included all consecutive patients referred to the Amylose Mondor French reference center for suspicion of cardiac amyloidosis (CA) who underwent ^{99m}Tc-HMDP scintigraphy between October 2012 and December 2016. Whole-body images acquired at early phase (10 min post-injection) were analyzed for the presence of cardiac or extracardiac uptake and the patients were classified according to a new classification "MADI" (Methodological Amyloidosis Diagnosis Index), defined as follows: no uptake (MADI 0), exclusive extracardiac uptake (MADI 1), exclusive cardiac uptake (MADI 2) or both (MADI 3). Patient characteristics as well as their prognosis were compared according to their MADI classes. **Results:** 308 patients including 247 with CA, among whom 75 hTTR,107 wtTTR and 65 AL. 61 patients han no CA formes a control group. 187 patients (75.7%) with CA demonstrated significant myocardial uptake, including 182 TTR (100%) and 5 AL (7.7%). 72 patients (38.5%) with CA also demonstrated extracardiac uptake. The most common site of involvement was the pleuropulmonary field. Uptake in the digestive tract, kidneys, muscles and thyroid was described whereas spleen, liver and lymph nodes uptake was only observed in the AL group. 2 controls had pulmonary uptake. No TTR patients were found in the MADI 0 and MADI 1 classes. The MADI 1 class led to the conclusion of an AL form and the scintigraphic involvement (MADI 1 to 3) had a pejorative prognosis value ($p = 0.02$). In the TTRs, particularly the wtTTRs, the MADI 3 class had a pejorative prognosis value ($p < 0.0001$). **Conclusion:** Extracardiac uptake of^{99m}Tc-HMDP is quite common and seen in almost 30% of patients with CA. The MADI classification is likely to guide the clinician regarding the diagnosis, to guide the carrying out of complementary examinations and to stratify the prognosis according to the typing of amyloidosis. **References:** None.

EP-0827

Evaluation of washout rate with crosstalk correction between ^{123}I-BMIPP and ^{201}TlCl for triglyceride deposit cardiomyovasculopathy (TGCV)

T. Kamiya[1], *T. Watabe*[2], *K. Fujino*[1], *M. Chimura*[2], *K. Hirano*[2], *Y. Sakata*[2], *J. Hatazawa*[3];
[1]*Osaka University Hospital, Suita, JAPAN,* [2]*Osaka University Graduate School of Medicine, Suita, JAPAN,* [3]*Osaka University, Suita, JAPAN.*

Aim/Introduction: Triglyceride deposit cardiovasculomyopathy (TGCV) is aberrant TG accumulation in both coronary arteries and myocardium. In the diagnosis guide of TGCV, its criteria of washout rate (WOR) is less than 10% in ^{123}I-BMIPP scintigraphy. Because there is an interference between 159 keV gamma-lay emitted from ^{123}I and 167 keV gamma-lay emitted from ^{201}Tl in dual-isotope study with scintillation camera, WOR of ^{123}I-BMIPP includes error for their quantification. We evaluated the effect of crosstalk correction (CTC) between ^{123}I and ^{201}Tl in calculating WOR of ^{123}I-BMIPP for the diagnosis of TGCV. **Materials and Methods:** The cardio-hepatic phantom (Kyoto Kagaku Co.) was filled with ^{123}I and ^{201}Tl solution. For obtaining of CTC coefficient, which was defined the accurate or crosstalk detectability proposed by previous report[1), 2)], each single-isotope phantom study (^{123}I or ^{201}Tl) was acquired with dual energy window. After the calculation of the CTC coefficient, simultaneous dual-isotope phantom was scanned at early and delayed phase (20 hours). Radioactivity of ^{123}I and ^{201}Tl at early phase was each 100 kBq/mL and was left until delayed phase. The time-dependent count change with decay correction was defined in WOR. **Results:** CTC[^{123}I-^{123}I], CTC[^{123}I-^{201}Tl], CTC[^{201}Tl-^{123}I] and CTC[^{201}Tl-^{201}Tl] coefficients were 56.5, 22.3, 8.7 and 32.2 counts/MBq/sec, respectively. Compared to theoretical value (0.0%), the WOR without CTC was -21.0 ± 4.1%. On the other hands, the WOR corrected by CTC was 3.0 ± 0.6%. **Conclusion:** By applying CTC, WOR can be calculated more precisely in dual-isotope scintigraphy. **References:** 1) Jpn J Nucl Med Tech, 12. 8-14 (1992) 2) Radioisotopes, 43. 520-530 (1994).

EP-0828

Improved accuracy in diagnosing cardiac amyloidosis through increased myocardial 99mTc-DPD uptake associated with increased LV mass

L. Monaco[1], *A. Scarale*[2], *R. Sara*[2], *C. Popescu*[2], *M. Spallino*[2], *C. Dolci*[2], *M. Cuzzocrea*[1], *G. Cabrini*[2], *E. Gay*[2], *M. Milella*[2], *F. Musca*[2], *F. Caobelli*[3], *C. Rossetti*[2];
[1]*Università degli studi di Milano Bicocca, Milano, ITALY,* [2]*ASST Grande Ospedale Metropolitano Niguarda, Milano, ITALY,* [3]*Universitatsspital Basel, Basel, SWITZERLAND.*

Aim/Introduction: Cardiac involvement in systemic amyloidosis leads to progressive cardiomyopathy, therefore new therapeutic strategies are now available. ^{99m}Tc-DPD scintigraphy, based on Perugini qualitative-score, allows to identify

cardiac amyloidosis (CA) through a non-invasive procedure. However, a quantitative approach is desirable. Our purpose was to identify a semiquantitative parameter to improve the diagnostic accuracy in patients with suspected CA. **Materials and Methods:** We retrospectively evaluated 29 patients with suspected CA since January 2017 to September 2018. Each patient underwent comprehensive clinical evaluation, transthoracic echocardiography (TTE) and whole-body ^{99m}Tc-DPD scintigraphy. TTE estimated LV volumes, function and ventricular mass. In addition to Perugini' score visual interpretation, each scan was also semiquantitatively evaluated through cardiac uptake normalized to background activity (nCU), defined as [total counts (myocardial ROI) / total counts (right hemithorax background ROI)]. ROIs dimensions were identical in the same patient. Biopsy (7/29) or clinical follow-up determined CA final diagnosis. **Results:** A significant correlation between Perugini' score and nCU (r=0.89, p<0.001) was detected. nCU was unrelated to BMI (p=0.56). CA was confirmed histologically in 7/29 patients. A good diagnostic performance of nCU (AUC=0.675) was demonstrated by ROC curves, optimal threshold was 1.38 (sensitivity 85.7%, specificity 54.5%). An optimal threshold of 317.5 g/m2 was shown for LV mass (sensitivity 50.0%, specificity 78.6%). The simultaneous presence of nCU and LV mass above limits led to improve accuracy (global chi-square 15.75, p=0.03). **Conclusion:** In this small cohort semiquantitative nCU resulted at least non-inferior than the widely accepted Perugini visual score. Myocardial ^{99m}Tc-DPD uptake combined with LV mass improved diagnostic accuracy. **References:** None.

Assessment of three software packages in the estimation of left ventricular volumes and ejection fraction with resolution recovery algorithm in gated myocardial perfusion SPECT vs cMRI: preliminary results of a single centre

E. Calandri[1], *F. Guana*[2], *L. Conversano*[1], *S. Gallina*[1], *S. Leuzzi*[3], *E. Soligo*[4], *S. Debernardi*[4], *M. Liberatore*[5], *G. Chiorino*[2], *M. Pultrone*[1]; [1]*Department of Medicine and Urgency, Nuclear Medicine Unit, Ospedale degli Infermi, Ponderano, ITALY,* [2]*Laboratory of Cancer Genomics, Fondazione Edo ed Elvo Tempia, Biella, ITALY,* [3]*Department of Medicine and Urgency, Unit of Cardiology, Ospedale degli Infermi, Ponderano, ITALY,* [4]*Department of Medicine and Urgency, Radiology Unit, Ospedale degli Infermi, Ponderano, ITALY,* [5]*Department of Radiology, Oncology and Human Pathology, Nuclear Medicine Unit, "Sapienza" University, Rome, ITALY.*

Aim/Introduction: To evaluate the performance of three software in the quantification of left ventricular end-diastolic (EDV), end-systolic volume (ESV) and ejection fraction (LVEF) from ECG-gated perfusion SPECT applying a resolution recovery (RR) algorithm (GE Myovation Evolution), respect to cardiac MRI (cMRI) gold standard. **Materials and Methods:** We retrospectively analyzed 18 patients (13 men, 5 women; age range: 42-81), with suspected (12) or known (6) coronary artery disease. All patients underwent a dual-day gated-SPECT (8 gates/cardiac cycle) and cMRI (30 gates/cardiac cycle), with a mean interval of 10,5 months ± 8,4, without any health change or revascularization procedure between the two procedures, no arrhythmias or artifacts. Gated-SPECT was performed on a conventional γ-camera 60' after 99mTc-MIBI or 99mTc-tetrofosmin injection at rest (652 Mbq ± 81). Images were reconstructed by FBP and by RR protocol (OSEM, 12 iterations, 10 subsets, RR). EDV, ESV and LVEF were calculated employing Quantitative gated SPECT (QGS), Myometrix (MX) and Corridor 4DM (4DM). Statistical analysis was performed using R version 3.5.3. Mean values of EDV, ESV and LVEF were tested for significance using Wilcoxon or paired t-test (assumption of normality assessed using Shapiro-Wilk test). Agreement between imaging reconstruction algorithms and between gated-SPECT software packages and cMRI was studied with Pearson's (r) or Spearman's (R) correlation coefficients and Lin's concordance correlation coefficient (LCC). **Results:** Concerning EDV and ESV, a significant difference was noticed between imaging reconstruction algorithms for all parameters and between each software and cMRI (p<0,05), except for 4DM-FBP vs 4DM-RR(ESV) (p=0,074). Concerning LVEF, no significant difference was observed in QGS-FBP vs QGS-RR (p=0,086), 4DM-FBP vs 4DM-RR (p=0,269), MX-FBP vs cMRI (p=0,383). Concordance and correlation between imaging reconstruction algorithms were always >0,9; respect to cMRI, the concordance was always lower using RR compared to FBP. **Conclusion:** Despite of some limitations, such as the low number of patients and the retrospective approach, that do not allow to draw definite conclusions, our study suggests that 4DM-FBP vs 4DM-RR shows the best concordance for EDV and ESV, and QGS-FBP vs QGS-RR shows the best concordance for LVEF. Respect to cMRI, RR algorithm is always associated with a lower concordance if compared to FBP reconstruction. Significance tests suggest that no significant differences between imaging reconstruction algorithms for 4DM-FBP vs 4DM-RR in ESV evaluation, for QGS-FBP vs QGS-RR and for 4DM-FBP vs 4DM-RR in LVEF evaluation, occur. EF from MX-FBP is the only parameter that doesn't significantly differ from cMRI. **References:** None.

Noninvasive Tracer Kinetic Analysis of Brain ^{18}F-Florbetaben PET: a Comparison of Kinetic Models

S. Ferreira[1,2,3], *F. P. M. Oliveira*[1], *M. Silva*[1], *Â. Silva*[1], *C. Oliveira*[1], *J. C. Castanheira*[1], *S. C. Vaz*[1], *N. Matela*[3], *J. Sanchez-Gonzalez*[2], *D. C. Costa*[1]; [1]*Champalimaud Centre for the Unknown, Champalimaud Foundation, Lisboa, PORTUGAL,* [2]*Philips Healthcare Iberia, Madrid, SPAIN,* [3]*Institute of Biophysics and Biomedical Engineering, Faculty of Sciences of the University of Lisbon, Lisboa, PORTUGAL.*

Aim/Introduction: Currently, most of the brain ^{18}F-Florbetaben PET studies are only analyzed visually and/or using standardized uptake value ratios on late (90 minute post-injection) acquisitions. Although adequate for clinical practice, accurate amyloid PET burden cannot be quantified this way. Our aim was to compare four of the most popular reference region based kinetic methods on dynamic acquisitions. **Materials and Methods:** Twelve consecutive brain dynamic ^{18}F-Florbetaben PET studies acquired in the Philips Vereos Digital PET/CT were selected. Five had 60 minutes and seven 45 minutes duration starting immediately post-injection. Four patients had a clinical amyloid positive scan, while the remainders had a negative scan. Four kinetic methods were compared: simplified reference tissue method (SRTM2), modified reference tissue method (MRTM2), Logan plot and Patlak plot. Cerebellar grey matter was always the reference region. Comparison criteria were: (a) mean normalized residuals of the time activity curves fitting in 10 brain regions of interest (ROI) -mesial temporal cortex, prefrontal cortex, anterior cingulate, posterior cingulate, putamen, precuneus, caudate, occipital cortex, parietal superior cortex, parietal inferior cortex- (b) visual classification of the amyloid burden based on the parametric images generated by the methods and (c) visual evaluation of the parametric images noise level. **Results:** Very good fitting was achieved in all ROIs. Normalized mean residuals were approximately 2% for all methods, without statistical significance among them (Friedman ANOVA, $p = 0.212$). Visual evaluation of the amyloid burden based on the parametric images was concordant and identical to the clinical evaluation. Visually, the K parametric images from Patlak method displayed less noise compared to the distribution volume ratio (DVR) from Logan method, binding potential from MRTM2 (BP-MRTM2) and binding potential from SRTM2 (BP-SRTM2). In the 10 ROI considered, there were high to very high correlations among the DVR, BP-MRTM2 and BP-SRTM2 ($0.778 \leq r \leq 0.998$). The correlation between the K and the DVR, BP-MRTM2 and BP-SRTM2 varied between low and very high ($0.445 \leq r \leq 0.950$). The perfusion like parametric images V_0 (Patlak) and R_1 (MRTM2 and SRTM2) were of very good quality; with no visual differences among them. Very high correlation ($r>0.9$) was obtained in all 10 ROI considered. **Conclusion:** All four kinetic methods originated very good fitting and similar visual amyloid burden classification. Patlak K parametric images presented differences when compared to the DVR and BP images. Further studies are encouraged to tease out potential physiological or methodological reasons to explain these differences. **References:** None.

Standardization of PET MBF Quantification through Development of a One-for-all Software Tool

S. Nesterov[1,2], *R. Buechel*[3], *J. Dickson*[4], *V. Dilsizian*[5], *H. Gewirtz*[6], *A. Manrique*[7], *J. O. Prior*[8], *R. Sciagrà*[9], *M. Smith*[5], *A. Thomassen*[10], *J. Knuuti*[1];
[1]*Turku PET Centre, Turku, FINLAND,* [2]*IEPhB RAS, St.Petersburg, RUSSIAN FEDERATION,* [3]*Univ. of Zurich, UZH, Zurich, SWITZERLAND,* [4]*Univ. College London, Institute of Nuclear Medicine, London, UNITED KINGDOM,* [5]*Univ. of Maryland School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA,* [6]*Harvard Medical School, Boston, MA, UNITED STATES OF AMERICA,* [7]*Univ. Caen Normandie, CHU de Caen, GIP Cyceron, Caen, FRANCE,* [8]*Centre Hospitalier Univ. Vaudois, Lausanne, SWITZERLAND,* [9]*Careggi Univ. Hospital, Florence, ITALY,* [10]*Odense Univ. Hospital, Odense, DENMARK.*

Aim/Introduction: Reported stress MBF values for the healthy volunteers can be 1.50±0.74 mL/min/g (1) while patients with CAD can have 3.18±0.85 mL/min/g (2), the range of CFR normal cutoffs is from 1.44 (3) to 2.74 (4). The quantitative PET MBF analysis field is fragmented; the results cannot be safely pooled, and diagnostic cutoffs remain relatively institution-specific. One main reason of this variability—and the one we can affect—is that PET quantification is done with different software tools. We aim at building a free, open-source quantitative PET MBF image analysis software that can become a global standard. **Materials and Methods:** Experts from 11 centers worldwide were involved in the designing such a software. During the first iteration, they de novo generated product requirements and defined the currently problematic areas in MBF quantification. These items were compiled and fed back to the centers during the second iteration — to estimate the importance of each item—academic and practical—as well as evaluating the implementation priority of the features. A rating scale was used where 2 stood for extreme importance, 1 stood for moderate importance, and zero for no importance at all. **Results:** A list of 202 items in 19 categories was generated. Apart from certain obvious requirements, such as utilizing 17-segment LV polar plot, Q/R from PACS, DICOM read and write, etc., the majority of items had a greater variance in their ratings. For example, in tissue segmentation, the automatic one with manual adjustment scored 3.4 times higher the second most popular option of fully automatic segmentation. A human operator was preferred to start the segmentation process with manual definition of LV axes and the ability to correct and adjust contours for every single frame of the dynamic acquisition was required as well. The LV base was considered the best place for the blood pool ROI definition, followed by the left atrium and then the LV cavity. In the tool´s validation, the most important factors were evaluating operator and test-retest variability and standardization of acquisition and analysis protocols for tracers in current clinical use, followed by evaluating the tool´s prognostic value. **Conclusion:** The collective minds of experts in the field of quantitative PET MBF analysis are designing a software tool that can significantly advance knowledge in the field by becoming a global standard. **References:** (1) Krivokapich et al., 1989; (2) Zervos et al., 1999; (3) Morton et al., 2012; (4) Muzik et al., 1998.

Dependence of dead-time correction factors on attenuating conditions in the object

W. Zhao[1,2], *C. Caldwell*[3], *A. Celler*[2];
[1]*Department of Physics and Astronomy, University of British Columbia, Vancouver, BC, CANADA,* [2]*Medical Imaging Research Group, Department of Radiology, University of British Columbia, Vancouver, BC, CANADA,* [3]*Department of Medical Imaging, University of Saskatchewan, Saskatoon, SK, CANADA.*

Aim/Introduction: For post-injection SPECT scans of patients undergoing ^{177}Lu DOTATATE therapy, the high flux of photons may result in camera dead-time. In order to perform personalized dosimetry, quantitative measurement of activities in patients must be performed. Since images are reconstructed from primary photons (corrected for attenuation and scatter), dead-time correction must account for primary photon losses. However, for the same injected activity, these dead-time losses will be different for patients of different size, thus exhibiting different amounts of attenuation. The dead-time correction factor is usually determined using phantom experiments, where the photon attenuating conditions are obviously different from those in patients. Consequently, the correction factors obtained from these experiments may not accurately recover the dead-time count losses occurring in patient studies. Our aim was to propose a dead-time correction method that is less dependent on the photon attenuating conditions. **Materials and Methods:** Twelve planar scans (Siemens Symbia Intevo) were performed, using vials with ^{177}Lu activity and four different thicknesses of photon attenuating medium (0 to 20 cm thickness of solid water). The activities of sources ranged from 11 to 10585 MBq. Data were acquired into six energy windows: one photopeak, two scatter windows and additional three windows to cover the entire spectrum. The triple-energy-window method was used to remove scatter from and calculate the observed primary counts in the photopeak. The true primary counts for the scans with high activity were determined from the primary counts observed in scans with low activity (<1042 MBq), using linear extrapolation. For each attenuating condition, the primary photon count loss due to the dead-time, (defined as the percentage of true primary counts), was analyzed as functions of photon count-rates in A: the photopeak, B: the sum of the photopeak and scatter windows and C: the entire spectrum, as these three count-rates are easily obtained during patient scanning. **Results:** For the maximum investigated activity (~10.6 GBq), the difference between the primary photon dead-time count losses determined using the four photon attenuating slabs was the smallest when count-rates in the entire spectrum were considered. The values of these differences amounted to 9.4% for case A, 7.6% for case B and only 3.5% for case C. **Conclusion:** The dead-time correction factor for primary photons should be analyzed as a function of observed photon count-rate in the entire spectrum, as in this case its value is less dependent on the photon attenuating conditions in the object/patient. **References:** None.

EP-0833

Using phase space for SPECT Monte-Carlo simulation

D. Sarrut[1,2], *T. Baudier*[1], *J. Labour*[1,2], *J. Badel*[2];
[1]*CREATIS, Lyon, FRANCE,* [2]*Centre Léon Bérard, Lyon, FRANCE.*

Aim/Introduction: Detailed Monte-Carlo (MC) simulation of tomographic SPECT image acquisition remains a long process, in particular due to the very low sensitivity: only one gamma detected for about 1e5 emitted. Several Variance Reduction Techniques or fast GPU-based algorithms have been proposed [1-5]. However, the process still remains complex for large source activity distribution. Moreover, two specific issues remain. First, the tracking of the gammas inside the CT is performed for all acquisition angles. Secondly, the patient to detector distance is narrowed for each gantry angle and, during simulation, geometrical overlaps may arise between detector and CT volumes. **Materials and Methods:** Inspired from the Linac phase-space (PHSP) method and assuming that constant activity for all projection angles, we propose to perform the tracking of the gamma in the CT only once and to store the particles emerging the patient in a PHSP, avoiding to redo the tracking for all angles. With realistic activity, the PHSP size would be very large, around 100GB for 5e9 emitted gamma (about 150 MBq of In111). Instead, we proposed to exploit the ARF-nn method[2] to obtain similar image characteristic with about 10 times less particles. Moreover, a new tool that allows to store the gamma in PHSP when they just emerge from the patient skin, via a mask, was developed. From this PHSP, it is now possible to perform tomographic simulation varying the spect head distance without volume collision. **Results:** A complete detailed tomographic SPECT MC simulation have been performed using the two steps method described above. It allows to store a PHSP of 8 GB, from which all 30 angles projections can be simulated, avoiding to redo gamma patient tracking and allowing varying skin-to-detector distance without volume collision. All methods were implemented in GATE[5] and will be available to the community in the next version. **Conclusion:** We propose a two steps methods for detailed SPECT MC simulation based on adapted phase space and ARF-nn. **References:** [1] Ljungberg. EP-0834

Can SPECT Resolution Be Considered Invariant in Partial Volume Correction?

R. Gillen[1,2], *A. M. Denis-Bacelar*[2], *S. J. McQuaid*[1], *K. Erlandsson*[1], *K. Thielemans*[1], *B. F. Hutton*[1];
[1]*Institute of Nuclear Medicine, University College London, London, UNITED KINGDOM,* [2]*National Physical Laboratory, Teddington, UNITED KINGDOM.*

Aim/Introduction: Most partial volume correction (PVC) methods assume spatially invariant resolution. In SPECT imaging, however, the resolution may change under different imaging conditions: position in the field of view, acquisition and reconstruction parameters (application of resolution modelling (RM) and number of iterations), activity distribution and attenuation. This work aimed to investigate the bias introduced by PVC when assuming spatially invariant resolution. **Materials and Methods:** STIR [1] was used to generate digital phantoms, of varying complexity, with 'point sources' at four positions. STIR was then used to forward project (Technetium-99m SPECT with LEHR collimators) and reconstruct these data (using OSEM). 2D Gaussians were fitted to the Point Spread Function (PSF) of each reconstructed point source, giving Full Width at Half Maximum (FWHM) values in radial and tangential directions for different phantoms and conditions. A second set of phantoms, of the same shape and attenuation as above, were also generated with hot regions representing tumours of different sizes. These were convolved with two different kernels; one representing an appropriate PSF for the specific imaging conditions, and one representing a 'standard' PSF measured at the centre of a uniform cylinder. The bias introduced by applying PVC with an inappropriate PSF was estimated by comparing the Recovery Coefficients calculated from convolving the phantom with the standard kernel versus convolution with the specific kernel. **Results:** Resolution varied significantly depending on position within an object. For example, tangential resolution measured in an elliptical object was 13.4mm at the centre, and 7.7mm at a position 12cm from the centre. There were differences of up to 36% between radial and tangential resolution, depending on the shape and attenuation of the object, and position within the object. Resolution was also affected by the distribution of activity. Applying RM improved the resolution in most cases but introduced ringing artefacts and took longer to converge. Using a standard PSF for PVC introduced a bias which depended on lesion diameter and tumour to background ratio (TBR). For a TBR of 11, a bias of under 6% was measured for tumour diameters of 4cm or larger, but biases of 8-33% were demonstrated for smaller lesions (diameters between 3cm and 0.9cm). **Conclusion:** The common assumption of spatial invariance is inappropriate for PVC of SPECT imaging and may lead to inaccurate quantification. Measurement of the PSF, specific to patient and position, is required for accurate PVC. **References:** 1.Fuster et al 2013, https://doi.org/10.1118/1.4816676

Reproducibility Study of Lesion Features Extracted from ^{18}F-FDG PET Images of the Same Patients Acquired on Two Philips PET/CT Scanners: Digital VEREOS versus GEMINI TF

C. S. Constantino[1,2], *F. P. M. Oliveira*[1], *M. Silva*[1], *C. Oliveira*[1], *J. C. Castanheira*[1], *Â. Silva*[1], *S. C. Vaz*[1], *P. Vieira*[2], *D. C. Costa*[1];
[1]*Champalimaud Centre for the Unknown, Champalimaud Foundation, Lisbon, PORTUGAL,* [2]*Faculdade de Ciências e Tecnologia, Universidade Nova de Lisboa, Lisbon, PORTUGAL.*

Aim/Introduction: The recent addition of digital equipment to the clinical armamentarium of PET/CT leads to some concerns regarding inter-device data variability. Our aim was to compare the performance of two PET/CT devices (Philips Digital Vereos -VEREOS- and GEMINI TF -GEMINI-) on consecutive imaging data from the same subjects after a single administration of FDG. **Materials and Methods:** ^{18}F-fluorodeoxyglucose (FDG) PET images from 41 oncological patients (studied twice) were included (23 Females and 18 Males, with 65 ± 9 years old). Image acquisition was obtained with VEREOS and GEMINI scanners after a single radiotracer injection (246 ± 60 MBq). 22 subjects were examined first on the VEREOS, and 19 on the GEMINI. Immediately after the first examination, followed the second acquisition in the other scanner. Image reconstruction was applied with default clinical parameters (VEREOS: 4x4x4 mm³, OSEM 3 iterations and 15 subsets, relax factor 1.0; GEMINI: 4x4x4 mm³, OSEM 3 iterations and 33 subsets, relax factor 0.7). FDG avid lesions were identified by an experienced nuclear medicine physician first on the VEREOS data, unaware of the image source. Afterwards, all annotations were transposed to GEMINI data. An automatic segmentation algorithm, based on Bayesian classifier, was applied to all images. From the segmented lesions, first order statistics and geometric features were extracted [1]. The intraclass correlation coefficient (ICC) for absolute agreement between the correspondent features was assessed using IBM SPSS 20. **Results:** 164 FDG avid lesions were identified on VEREOS images. Of those, 161 lesions were confirmed and delineated on GEMINI images. The main anatomical localizations of the lesions included breast, liver, and lungs. A high agreement (ICC > 0.7) was demonstrated for most of the features, both in the first order statistics and those related to geometry. Energy, metabolic tumor volume, tumor lesion glycolysis, surface area, and SUVpeak revealed an excellent agreement (ICC > 0.9). SUVmax, a frequently used feature in the clinics, showed high agreement (ICC = 0.89). On average, this feature was statistically higher in VEREOS than in the GEMINI (95% confidence interval: 0.20-0.67). **Conclusion:** There is high agreement between most of the first order and geometric features extracted from both devices imaging data. Under controlled acquisition and reconstruction parameters, these features can be used in multi-scanner studies (including longitudinal patient evaluation), using VEREOS and GEMINI PET/CT devices. **References:** [1] H. Aerts et al., "Decoding tumour phenotype by noninvasive imaging using a quantitative radiomics approach," Nat. Commun., 5:4006, 2014.

EP-0836

Is it valid to simulate a decrease in the administered activity by a reduction in the acquisition time of a PET scan?

J. M. Martí-Climent[1], *E. Prieto*[1], *P. Aguilar*[1], *A. García*[1], *V. Morán*[2];
[1]*Clínica Universidad de Navarra, Pamplona, SPAIN,*
[2]*Clínica Universidad de Navarra, Madrid, SPAIN.*

Aim/Introduction: Short acquisition scan times are frequently used as a surrogate for the evaluation of low activity protocols in PET studies. The aim of this study was to evaluate the validity of this assumption. **Materials and Methods:** NEMA anthropomorphic image quality phantom with hot spheres (10, 13, 17, 22, 28, 37 mm) was scanned (192 s acquisition time) with a Biograph mCT TrueV PET/CT system with 3 sphere contrasts (8:1; 4:1 and 2:1) and decreasing background concentrations (Cn = 5.3/2^n kBq/mL, n: 0 to 6). The first acquisition (C0) was resampled to simulate acquisition times down to 3 s (Tn = 192/2^n s, n: 0 to 6). For each contrast and concentration-time combination, 3 consecutive scans were acquired. PET images were reconstructed with OSEM+TOF+PSF (3 iterations, 21 subsets, 2 mm Gaussian filter) and with a reconstruction fulfilling EARL criteria (OSEM+TOF with 3 iterations, 21 subsets, 5 mm Gaussian filter). A spherical volume of interest (VOI) with a diameter equal to the internal diameter of each sphere and centered on it was drawn on each sphere. For background, 9 circular regions of interest (ROI, 37 mm diameter) were drawn in the central plane of the spheres and in ± 2 and + 4 planes beyond. Images were analysed by means of background variability, and signal to noise ratio (SNR) and contrast recovery (CR) for each sphere. Person's correlation and Lin's concordance correlation coefficient (rho) were evaluated between pairs of acquisitions with equal concentration*time product (C0T1-C1T0, **…**, C0T6-C6T0). **Results:** CR values increased as the size of the spheres increased. SNR values increased when the size of the spheres increased, decreased when the contrast decreased and decreased when the acquisition time decreased. Analysis of the visible spheres showed rho values higher than 0.953 (CR) and 0.993 (SNR) for the 6 pairs of EARL reconstructions, and higher than 0.911 (CR) and 0.993 (SNR) for 5 pairs of OSEM+TOF+PSF reconstructions. **Conclusion:** Simulation of PET tracer activity reduction is possible with short acquisition protocols. The phantom study has shown the interchangeability of the images in terms of signal to noise ratio and contrast recovery, especially for the reconstruction meeting the EARL criteria. **References:** None.

Impact of the Bayesian Penalized Likelihood (BPL) algorithm on hypoxia PET/CT in patients with lung neoplasia

S. Hapdey[1], *E. Texte*[2], *P. Gouel*[2], *B. Barres*[3], *P. Bohn*[1], *S. Thureau*[4], *P. Vera*[1];
[1]*Nuclear Medicine dept, Centre Becquerel & QuantIF-LITIS EA 4108, Rouen Medical University, Rouen, FRANCE,*
[2]*Nuclear Medicine dept, Centre Becquerel, Rouen, FRANCE,*
[3]*Nuclear Medicine dept, Centre J. Perrin, Clermont-Ferrand, FRANCE,* [4]*Radiotherapy dept, Centre Becquerel & QuantIF-LITIS EA 4108, University of Rouen, Rouen, FRANCE.*

Aim/Introduction: To determine the impact of the Bayesian Penalized Likelihood (BPL) reconstruction algorithm in comparison to OSEM on hypoxia PET/CT images using ^{18}F-MIZO and ^{18}F-FAZA radiopharmaceuticals. **Materials and Methods:** First, a Jaszczak phantom with 6 fillable spheres (35-1000µL) with a low sphere-to-background radio (SBR=3) was scanned on a GE710 PET/CT and reconstructed with OSEM and BPL to determine the best BPL β parameter among 300, 350, 400, 500 and 600. Twenty patients with lung neoplasia suspicion were included. Each patient benefitted from ^{18}F-MISO and/or ^{18}F-FAZA PET/CT exams (i.e 38 lesions), reconstructed with OSEM and BPL (with β=300, 350 and 400). Lesion was considered as hypoxic if the lesion SUVmax ≥ 1.4. A blind evaluation of lesion detectability and image quality was performed on a set of 78 randomized BPL and OSEM images by 10 nuclear physicians. SUVmax, SUVmean and hypoxic tumor volumes (using three different segmentation methods: i/ fixed SUV≥1.4 thresholding (HTV1.4); 60% thresholding of SUVmax (HTV60%); 1.5*Mediastinum SUVmax thresholding (HTV1.5med)) were measured and compared for each reconstruction. **Results:** The phantom analysis showed a significant increase of quantitative parameters using BPL compared to OSEM (+37%, +28% and +22% with β=300, 350 and 400 resp.) but had no impact on sphere detectability. The optimal β determined by the phantom analysis was β350. Regarding patient data, as for phantom analysis, all quantitative parameters showed a significant increase with BPL compared to OSEM (+15% in SUVmax with β=350). However, BPL had no significant impact on lesion detectability (mean detectability score for the 10 observers of 32.9/38 and 32.2/38 for OSEM and BPL resp.) and the image quality analysis did not show a clear trend in favour of BPL or OSEM. There was no correlation between SUVmax increase with BPL and either SUV or hypoxic volume from the initial OSEM reconstruction. Only one lesion was additionally considered as hypoxic with BPL. HTV1.4 was not impacted by BPL reconstruction (whatever the beta parameter), while HTV60% and HTV1.5med were both smaller than the hypoxic volume measured with OSEM reconstruction. **Conclusion:** BPL allows a significant increase in quantitative parameters and contrast without significantly improving the lesion detectability or image quality. The variation in hypoxic volume by BPL depends on the method used but SUV≥1.4 thresholding seems to be the more robust method, not impacted by the reconstruction method (BPL or OSEM). This segmentation method must be preferred if hypoxia PET-guided radiotherapy boost are envisaged. **References:** None.

EP-0838

Constructing Bland-Altman plots in small to moderate sample sizes: use rather a factor between 2 and 2.4 than 1.96

O. Gerke, *Odense Agreement Working Group;*
Odense University Hospital, Odense C, DENMARK.

Aim/Introduction: Bland-Altman Limits of Agreement (BA LoA) are well known and widely applied in methods comparison and in observer variation studies on quantitative outcomes. Assuming normally distributed differences, usually the 97.5 percentile of the Standard Normal distribution (i.e. 1.96) is employed in their construction. Alternatively, the factor 2 was proposed earlier as appropriate approximation in practical applications, whereas the factor $t_{0.975,n-1}\sqrt{((n+1)/n)}$ was indicated to secure the property of BA LoA to represent a prediction interval with 95% coverage. The aim was to contrast the factors 1.96, 2, the respective t-quantile $t_{0.975,n-1}$, and the exact factor $t_{0.975,n-1}\sqrt{((n+1)/n)}$ in the construction of BA LoA with respect to their actual coverage probability in small to moderate sample sizes. **Materials and Methods:** In a simulation study, we investigated the probability of BA LoA constructed with abovementioned factors to cover the next observation when sampling from the Standard Normal distribution. Sample sizes were varied from n=10 to n=700, and we generated (n+1) observations from the Standard Normal distribution 10,000 times for each sample size. The first n observations of each fictive trial were used to derive BA LoA to which the last observation was compared to. The coverage probability was then the number of cases out of 10,000 fictive trials where the LoA comprised the last observation. **Results:** For the classical factor of 1.96, coverage probabilities circulated closely around the nominal level of 0.95 from n=400 onwards, whereas this was the case from n=70 on for both the approximate factor of 2 and the respective t-quantile $t_{0.975,n-1}$. The application of the approximate factor 2 kept, though, more conservatively the nominal coverage level than the respective t-quantile $t_{0.975,n-1}$ did as the empirical coverage exceeded the nominal level of 0.95 for all sample sizes n≥70 apart from n=160 for factor 2. Applying the exact factor of $t_{0.975,n-1}\sqrt{((n+1)/n)}$, the coverage probability varied only slightly around 0.95 for all sample sizes investigated. As $\sqrt{((n+1)/n)}$ converges to 1 with increasing sample size, $t_{0.975,n-1}$ and $t_{0.975,n-1}\sqrt{((n+1)/n)}$ implicated close to identical coverage probabilities for sample sizes of at least n=180. **Conclusion:** In order to retain prediction intervals with a coverage probability of at least 0.95, BA LoA should be constructed using rather $t_{0.975,n-1}\sqrt{((n+1)/n)}$ for n≤70 and 2 for n>70 than 1.96. Only if the sample size exceeds n=400 will the coverage probability of BA LoA employing the factor 1.96 be close to the nominal level of 0.95. **References:** None.

EP-0839

Nonparametric alternatives to Bland-Altman Limits of Agreement in case of non-normally distributed data

O. Gerke[1], *M. E. Frey*[2], *H. C. Petersen*[2], *Odense Agreement Working Group;*
[1]*Odense University Hospital, Odense C, DENMARK,*
[2]*University of Southern Denmark, Odense M, DENMARK.*

Aim/Introduction: The assessment of agreement in method comparison and observer variability analysis on quantitative measurements is usually done by means of Bland-Altman Limits of Agreement (LoA) for which the paired differences are implicitly assumed to follow a Normal distribution. Whenever this assumption does not hold, the respective 2.5% and 97.5% percentiles of the distribution of paired differences must be assessed by quantile estimation. In the literature, simple empirical quantiles have been used before. The aim of this project was to (a) compare 14 different quantile estimators as to which extent these successfully serve as prediction intervals for the next observation and (b) propose robust alternative quantile estimators to Bland-Altman LoA when the assumption of Normality does not hold. **Materials and Methods:** In a simulation study with 2,000 fictive trials per sample size and distributional assumption, both sample quantile estimators, subsampling quantile estimators, Kernel quantile estimators, and other methods for quantile estimation were applied. Sample sizes were n=30, 50, 80, 100, and 150, and six different distributions were used for the paired differences: Normal; Normal with 1%, 2%, and 5% outliers; Exponential; and Lognormal. The performance of the 14 estimators in generating prediction intervals was measured by their respective coverage probability for one newly generated observation. **Results:** For n=30, a sample quantile estimator based on one order statistics (namely using the smallest and largest observed difference as estimates for the 2.5% and 97.5% percentiles, respectively) outperformed all other estimators. Another sample quantile estimator that employed a weighted average of two order statistics around the respective target percentiles of 2.5% and 97.5% was the only estimator to achieve a coverage probability of at least 95% in all distributional scenarios for the remaining sample sizes. The Harrell-Davis subsampling estimator and estimators of Sfakianakis-Verginis type achieved the nominal level of at least 95% coverage for all investigated distributions for sample sizes of at least N=80, except for the Exponential distribution where the coverage probability was 94% instead. **Conclusion:** Simple sample quantile estimators based on one and two order statistics can be used when deriving nonparametric LoA for sample sizes of up to 50 and at least 50 observations, respectively. For sample sizes exceeding 80 observations, more advanced quantile estimators that make use of all observed differences are equally applicable, but may be considered intuitively more appealing than simple sample quantile estimators that are based on only a few observations from the sample. **References:** None.

What are the effects of respiratory gating method on measurement accuracy of SUVmax with respect to lesion size? An anthropomorphic phantom study

B. Serrano[1], *M. Salva*[1], *Y. Ben Ahmed*[1], *N. Garnier*[1], *R. Amblard*[1], *B. Paulmier*[2], *R. Villeneuve*[1], *F. Hugonnet*[2], *V. Nataf*[2], *M. Faraggi*[2];
[1]*Princess Grace Hospital Center, Medical Physics Department, Monaco, MONACO,* [2]*Princess Grace Hospital Center, Nuclear Medicine Department, Monaco, MONACO.*

Aim/Introduction: Standardized Uptake Value (SUV) measurement of lung lesions is impaired by both partial volume effect (PVE) and respiratory motion that induce lesion blurring. Those additional effects affect more the smallest lesions. We aimed to compare two methods of gating, an automatic amplitude-based gating (AABG) and a conventional 4 phase-based respiratory gating (PBRG), on SUVmax measurement on different sizes of lesions using an anthropomorphic phantom simulating breathing. **Materials and Methods:** This study was performed on a PET/CT (Siemens mCT), fitted with four rings and time of flight (TOF). We used an anthropomorphic TORSO phantom representing a patient. Ten spheres of various inner diameters (6 to 33mm) were introduced into the lungs (air density) with the possibility of adding an axial mechanical device simulating breathing movement with a frequency of 15 cycles/min. Concentration in the spheres was the same for all diameters. We varied the concentration between 5 to 100 kBq/ml. The background and liver activities were respectively (39±2) and (14±1) MBq. We studied 4 different PET acquisitions: a standard 2.5min acquisition without movement (SA) as our reference of "true SUVmax", a 2.5min acquisition with simulated breathing movement (BMSA) without any gating and a 10min BMSA with respectively PBRG and AABG correction. Gated acquisitions were monitored with a pressure sensor system (Anzai Medical Corporation). Parameters reconstructions were: 2 iterations, 21 subsets, gaussian filter (FWHM=2mm), matrix size 200x200 pixels, TrueX algorithm (OSEM+PSF) and TOF. The largest sphere (diameter 33mm) was considered as the reference for results normalization. **Results:** The reproducibility for each acquisition of SUVmax was high (r=0.96, p=0.0003). For all the acquisitions and all the tracer concentrations within the spheres, the smallest detectable sphere's diameter was 12mm indicating the effect of PVE. Compared to the reference SUVmax values obtained with SA, SUVmax decreased significantly in all spheres below 27mm diameter with non-gated BMSA acquisitions (Δ=-34±11%, $p<10^{-4}$), in all spheres below 18mm diameter with PBRG acquisitions (Δ=-13±7%, $p<10^{-3}$) while average loss on SUVmax was moderate with AABG in all spheres below 12mm (Δ=3±4%, $p<10^{-3}$). **Conclusion:** PVE mostly impaired detectability of spheres diameters below 12mm corresponding to 3 times the spatial resolution of our camera. SUVmax measurement accuracy was impaired for spheres below 18mm with PBRG and 12mm with AABG. Furthermore, this impairment was at least four times less marked with AABG compared to PBRG. **References:** None.

EP-0841

Software development and validation for Salivary Gland Scintigraphy using Gamma Camera

A. K. Jha, *S. Mithun, A. D. Puranik, S. Shah, A. Agrawal, N. C. Purandare, V. Rangarajan;*
Tata Memorial Hospital, Mumbai, INDIA.

Aim/Introduction: Radiation induced damage of salivary gland parenchyma leading to impairment of salivary function is known for years. Iodine-131 radionuclide therapy as well as external beam radio therapy (EBRT) leading to impairment of salivary functions and xerostomia has been reported in literature. Modalities such as CT, MRI and sonography provide morphological information, where as sialography and scintigraphy provide functional information of salivary glands. Since, radiation induces functional damage of salivary gland, hence functional assessment by sialography or scintigraphy becomes imperative to perform in this scenario. Salivary scintigraphy being a relatively non-invasive procedure is preferred widely. However, unavailability of standardized software makes salivary scintigraphy a cumbersome process. Aim of our study was to develop and validate software for salivary scintigraphy processing. **Materials and Methods:** Software was developed in Alladin Editor available on Xeleris 4.1 workstation, GE medical system. An anterior dynamic imaging was performed for 30 min (15 sec/frame; matrix: 128X128; zoom:2) after injection of 7 to 10 mCi of $^{99m}TcO_4^-$ intravenously. Sialagogue was administered orally 14 min after injection.Upon loading dynamic image in the software a composite image from 10 to 13 min displayed in view port. Software prompts to draw ROI over parotid and submandibular salivary gland as well as background on brain on composite image. Time activity curves are generated for all the salivary gland from the contour. Point of sialagogue administration and nadir is localised on the graph by the two localizers. Uptake as well as ejection fraction of salivary glands are calculated automatically by using standard formula. Software was validated on 30 patients' data by comparing uptake and ejection fraction calculated by salivary software with manual method on 30 patients. **Results:** Average uptake value for two parotid and two sub-mandibular glands were 0.41, 0.38, 0.28, 0.26 by software and 0.44, 0.36, 0.31, 0.29 were that of manual method. Likewise, average excretion fraction for two parotid and two sub-mandibular glands were 52%, 49%, 37%, 39% by software and 50%, 46%, 35%, 36% by manual method respectively. The overall percentage difference in estimation of salivary uptake and excretion fraction by two methods were 5% and 5.6% respectively. **Conclusion:** This software simplifies the salivary function estimation by scintigraphy method. This software also performs well on all the parameters and accurately calculates salivary uptake as well as salivary excretion function. **References:** None.

Evaluation of Atlas Based Attenuation Correction in Bone Scintigraphy

F. P. Oliveira[1], *Â. Silva*[1], *J. C. Castanheira*[1], *A. Canudo*[1], *S. Mairos*[1], *M. Silva*[1], *J. Cruz*[1], *A. Domingues*[2], *D. Veiga*[2], *M. Ferreira*[2], *D. C. Costa*[1];
[1]*Champalimaud Centre for the Unknown, Champalimaud Foundation, Lisboa, PORTUGAL,* [2]*Neadvance - Machine Vision, S.A, Braga, PORTUGAL.*

Aim/Introduction: Bone scintigraphy is widely used to map bone metabolism, in particular searching for osteoblastic bone lesions. In clinical practice, this is currently done qualitatively based

on visual inspection. Geometric mean of anterior and posterior projections is frequently computed for quantification purposes. However, this quantification method does not take into account real photon attenuation and sensitivity of gamma cameras. In this work, we propose an atlas based attenuation correction method to quantify radiopharmaceutical distribution. **Materials and Methods:** Whole-body CT acquisitions from 18 females referred for clinical reasons were used to build an attenuation atlas dataset. Another dataset was built with 10 minutes post-injection (610±56 MBq of ^{99m}Tc-Oxidronate) bone scintigraphy from 35 females. This dataset was used for validation. To create the attenuation atlas, the attenuation map on anterior-posterior direction was created from each whole-body CT, considering the photon energy of the ^{99m}Tc. Each 2D attenuation map was then geometrically aligned with a female bone scintigraphy atlas previously built. Then the attenuation atlas was obtained by averaging all 2D attenuation maps. The second step was the implementation of the attenuation correction and validation. The bone scintigraphy atlas was aligned with each patient's bone scintigraphy and then the geometric transformations found were applied to the attenuation atlas built. Since the attenuation profile of each patient depends on the anterior-posterior body thickness, before applying the attenuation map to the geometric mean of the anterior and posterior projections, a patient specific correction was performed. This was based on a linear regression model taking into account the patients' height and weight. Finally, the correction for the gamma camera sensitivity was applied. Validation was done by comparing the theoretical whole-body activity (injected activity corrected for the decay) with the estimated whole-body activity using the proposed methodology. **Results:** High agreement between the theoretical and estimated activities was achieved (intraclass correlation coefficient of 0.856, $p < 0.001$). Mean and median absolute deviations were 3.9% and 2.7%, respectively. There were four cases with a deviation equal or superior to 10%. **Conclusion:** The herein proposed methodology proved to have potential to be used in the estimation of the radiopharmaceutical body distribution. Further studies are imperative using late (more than 2 hours post-injection) acquisitions. Potential sources of error also need to be thoroughly investigated. **Financial support:** Project LISBOA/NORTE-01-0247-FEDER-017685 - BTSCAD (Bone Tumor Scan - CAD) under the PORTUGAL 2020 Partnership Agreement, through the European Regional Development Fund. **References:** None.

Outsourced Teleradiology in the swiss medical system: a financial analysis for a promising concept

F. Caobelli[1], *N. Schöni*[2];
[1]*Universitätsspital Basel, Basel, SWITZERLAND,*
[2]*University of Zürich, Zürich, SWITZERLAND.*

Aim/Introduction: Teleradiology is feasible and yields similar quality of traditional reporting. Only a few papers have investigated the financial impact of teleradiology, and only considering in-house systems for remote reporting, thus reporting high costs and limited impact on personal management. Conversely, an outsourced management of teleradiology is expected to provide major advantages in terms of organization of department workload, personnel management and cost optimization. We here report a financial analysis based on an innovative teleradiology model, wherein the reporting is outsourced to an external society. **Materials and Methods:** Costs were quantified using insurance reimbursements of swiss medical system as reference. A cost-minimization analysis was conducted considering a representative Institution performing among other investigations 50 FDG-PET/CT, 150 Thorax-Abdomen CT und 40 Thorax-Abdomen MR each week, employing 10 nuclear medicine physicians (2 engaged in PET) and 20 radiologists (2 engaged in CT, 2 in MR). The following aspects were considered: 1) the need of reassigning MD to different diagnostics in case of personnel shortage (PS) 2) the maximum number of scans that a MD can report in one day without loss of quality, with consequent need for reducing department's workflow 3) insurance reimbursement 4) the costs of outsourced teleradiology. Three scenarios of MD-PS (illness, congresses, vacations) were considered: 1=10%; 2=20% and 3=30%, **Results:** Total revenue per week in the representative Institution is 80,000 CHF for PET/CT, 72,990 CHF for CT and 43,830 CHF (=196,820 CHF/week). In Scenario 1, overall loss was 22,115 CHF/week. In Scenario 2, the loss increased to 39,364 CHF/week. Finally, in Scenario 3 the total loss reached 93,532/week. Assigning the canceled investigation to outsourced teleradiology allowed to limit money loss to 4,955 CHF in scenario 1 (-77%), 8,828 CHF in scenario 2 (-78%) und 21,022 CHF in scenario 3 (-79%). **Conclusion:** A flexible system for teleradiology accounting for fluctuating PS allowed to reduce the potential loss due to canceled scans. This is expected to financially impact even more those Institutions with less employees. It may be foreseen that a comparable increase in revenue can be obtained by optimizing the scanners utilized capacity without the need of increasing fix costs. **References:** None.

Study of different quantitative uptake metrics in F18-FDG PET/CT imaging in breast cancer: impact of workstation and segmentation method

M. Ibañez, *J. Navarro Fernández, L. Frutos Esteban, J. Contreras Gutiérrez, L. Mohamed Salem, F. Hernández Almagro, J. Villa Sánchez, I. Sime Loayza, M. Tomás Redondo, T. Rodríguez Locarno, T. Moreno Monsalve, R. Reyes Marlés, M. Castellón Sánchez, F. Nicolás Ruiz, E. Para Vergara, R. Mears Baño, M. Claver Valderas;*
Clinic Universitary Hospital Virgen de la Arrixaca, El Palmar, Murcia, SPAIN.

Aim/Introduction: There is increased interest in various new quantitative uptake metrics beyond standardized uptake value (SUV) in oncology PET/CT studies. The purpose of this study is to investigate the variability of several quantitative metrics

in breast cancer using F18-FDG PET/CT different workstation and segmentation methods focused on the breast lesion. **Materials and Methods:** Twenty patients with early to locally advanced breast cancer were studied. F18-FDG PET/CT were performed using a Philips Ingenuity TF64 (Cleveland, OH, USA). Two minutes/bed position and list-mode time of flight (TOF) adquisition were used. Image reconstruction was performed using 3 iterations and 33 subsets, 3D ordered subset expectation maximization (BLOB-OS-TF) being reconstructed in two types of matrices: 144x144 matrices with voxel size 4x4x4mm (standard voxels) and 288x288 matrices with voxel size 2x2x2mm (Small voxels) without PSF resolution recovery.The imagen analysis was reviewed using two worksations: IntelliSpace Portal 7.0 and Syngo.Via VB20A. Three automated segmentation methods were applied: adaptive thersholding method for IntelliSpace Portal 7.0 and 40% threshold of SUVmáx form IntelliSpace Portal and Syngo.Via.The quantitative metrics evaluated were SUVmax, SUVmean, SUVpeak, MTV and TLG by drawing region of interest (VOI) on the breast lesion. **Results:** For uptake metrics SUVmax, SUVmean, SUV peak, similar values for workstation as well as for 4mm and 2mm voxel size segmentation methods were obtained. SUVmax values were identical in all methods. While the MTV 4mm showed the greatest variability, MTV measured al 40% in IntelliSpace was 3-fold higher (15.2 CI95%:4.0-26.4) than in Syngo (5.8 CI95%: 4.4-7.2). A similar situation was observed for TLG 4mm data, since the IntelliSpace showed a 2-fold value than Syngo platform, although there were no statistically significant differences (p=0.126 for MTV and p=322 for TLG). SUVpeak was calculated only in 8 patients at 2mm by adaptive threshold and at 9 by threshold 40% used IntelliSpace Portal being limitation of this software. **Conclusion:** Although both workstation and segmentation methods render similar data for all variables, significant differences were obtained regarding MTV and TLG data. Therefore, in those studies in which these parameters are of interest, the software used must be taken into account since there is a possibility of unrealiability. **References:** None.

Comparison of different quantitative uptake metrics in ^{18}F-FDG PET/CT in breast cancer according to voxel size using different workstation and segmentation method

M. Ibañez, *J. Navarro Fernández, L. Frutos Esteban, J. Contreras Gutiérrez, L. Mohamed Salem, F. Hernández Almagro, J. Villa Sánchez, I. Sime Loayza, M. Tomás Redondo, T. Rodríguez Locarno, T. Moreno Monsalve, R. Reyes Marlés, M. Castellón Sánchez, F. Nicolás Ruiz, E. Para Vergara, R. Mears Baño, M. Claver Valderas; Clinic Universitary Hospital Virgen de la Arrixaca, El Palmar, Murcia, SPAIN.*

Aim/Introduction: There are several methods to quantify different uptake metrics to diagnose the tumor lesion severity. These values can be slightly modified attending to the segmentation methods, workstation employed, but specially to the voxel size. Therefore, the objective of the present study was to compare the similarity degree among the different uptake metrics according to the voxel size. **Materials and Methods:** Twenty patients with early to locally advanced breast cancer were studied. ^{18}F-FDG PET/CT were performed using a Philips Ingenuity TF 64 (Cleveland, OH, USA). Two minutes/bed position and list-mode time of flight (TOF) adquisition were used. Image reconstruction was performed using 3 iterations and 33 subsets, 3D ordered subset expectation maximization (BLOB-OS-TF) being reconstructed in two types of matrices: 144x144 matrices with voxel size 4x4x4mm (standard voxels) and 288x288 matrices with voxel size 2x2x2mm (small voxels) with out PSF resolution recovery. Two Workstation were used: IntelliSpace Portal 7.0 and Syngo.Via VB20A. Three automated segmentation methods were applied: adaptive thresholding method for IntelliSpace Portal 7.0 and 40% threshold of SUVmax for IntelliSpace Portal and Syngo via. Uptake metrics determined were SUVmax, SUVmean, SUVpeak, MTV and TLG for 4mm and 2mm voxel size. **Results:** Considering all methods as a whole, our data showed statistically significant differences for all parameters studied ($p<0.001$) excepting MTV and TLG. Specifically, the data obtain using 2mm voxel size were higher than 4mm voxel size for SUVmax, SUVmean, SUVpeak. Moreover, attending to the specific segmentation method, further differences were revealed. For instance, in the adaptive threshold method, MTV and TLG data were also significantly different depending on the voxel size. In addition, there were also statistically significant differences depending on the workstation used to determine the tumor lesion. In this regard, the IntelliSpace Portal 7.0 using 40% threshold of SUVmax showed no differences regarding MTV and TLG parameters and voxel size; however, the MTV data in the Syngo.Via was significantly higher at 4mm than 2mm ($p<0.001$). **Conclusion:** The voxel size modifies the quantitative uptake metrics in most parameters employed for tumor diagnosis. Therefore, data obtained by one or the other voxel size are not fully comparable. **References:** None.

EP-0846

Partial Volume Correction for Lymph Nodes in 18F-PSMA PET Images

J. Schaefferkoetter, *C. Ortega, P. Veit-Haibach, U. Metser; University Health Network, Toronto, ON, CANADA.*

Aim/Introduction: Partial volume effects in medical imaging result from limited scanner resolution and heterogenous tissue types within voxels. These effects degrade resolution and quantitative accuracy and are especially problematic for PET imaging. This is an important consideration for PSMA-PET as lymph node (LN) SUV measurements can be a key indicator for grading prostate disease. The work here investigates partial volume correction (PVC) for LNs in PET images. **Materials and Methods:** LN regions of interest (ROIs) were contoured on both CT and on PET volumes by a radiologist - these were used to generate mask volumes. The CT mask was the basis for the PVC and was transformed to the PET space by interpolation onto its corresponding voxel coordinate grid, accounting for any possible translational misregistration. Once transformed into

the PET space, each ROI in the mask was scaled to reflect its actual contrast, since this determines the local spill-over effect. Each contrast was found empirically, searching over a large range for the correct value. The ROI-scaled anatomical mask was then smoothed with a 3D kernel approximating the scanner response function - dividing the original anatomical volume by the smoothed data then yielded a map of PVC factors, which was applied directly to the PET volume. **Results:** The effects of the PVC were evaluated in a population of 74 patients and 241 LNs for both unsmoothed and 5mm Gaussian post-smoothed images. The PVC significantly affected region mean and max SUV measurements in the unsmoothed images. The trend showed good correlation between SUV increase and volume, generally following an exponential curve, with regions of 0.01 cm3 volume realizing an max SUV increase over 150% and those with 1 cm3 volume showing an increase around only 5%. The changes in corrected SUVs measured in the smoothed images were less pronounced. In fact, region mean was notably unchanged by the PVC for all LNs in the post-smoothed images. **Conclusion:** This work evaluated an approach to obtain partial volume effect-corrected SUVs for LNs, based on the volumes measured in their high resolution, anatomical images. However as expected, this work showed that any PVC for these small structures is less effective when when using image post-smoothing, which is often the case in clinical PET. As clinical guidelines focus on reference measurements for disease staging and grading, higher degrees of accuracy in image quantification may help to standardize patient management. **References:** Erlandsson, et al. 2012.

Aim/Introduction: Tektrotyde somatostatin receptor imaging is an essential step in neuroendocrine tumors (NETs) theragnostics, tailoring the eligibility for Peptide Receptor Radionuclide Therapy. This prospective PhD step NETs study aims to evaluate and compare the statistical differences of the pathological quantitative uptake radiolabeled somatostatin analogues (RSA) patterns between gastro-intestinal (GI-NETs) and pancreatic NETs (P-NETs). **Materials and Methods:** We studied, over a 12-month period, 53 patients, with a female/male ratio of 0.39:1, mean (±standard deviation (SD)) age 53.9-year-old (±10.3), histologically proven GI- and P-NETs, from 2 nuclear medicine centers. Study design: (gamma camera Siemens e cam Dual Head, LEAP collimator, appropriate software): dynamic scintigraphy (60 images, 1 image/second, 128x128 matrix), spot scintigraphy (10 minutes/image, 256x256 matrix), whole body scintigraphy (matrix 256x1024, 6cm/min bed movement) and SPECT (128x128 matrix, 132 images). Images were acquired at 10 minutes, 2-4 and 24 hours after i.v. administration of 10.57 MBq/kg bw ^{99m}Tc-Tektrotyd. Regions of interest (ROI$_s$) for each hot pathological area were defined. The uptake was quantified (counts/pixel) and the following indices were calculated: I_1=tumor/liver, I_2=tumor/spleen, I_3=tumor/lung, I_4=tumor/right thigh. Uptake kinetics graphs for all indices and the tumor heterogeneity graphs were compared. Statistical correlations were calculated to evaluate the pathological quantitative uptake indices differences between GI- and P-NETs. **Results:** Our data demonstrated the statistical correlations regarding the pathological quantitative uptake RSA patterns, with the next values: statistically significant negative correlation for I_4 (p=0.05, Pearson coefficient R -0.5, coefficient of determination R_2 0.24 and Spearman's coefficient R_s -0.47), with the mean I_4 GI-NETs 5.09, (2.88-8.80), variance (V) 3.25, SD 1.8, standard error of the mean SEM 0.31, respectively the mean I_4 P-NETs 4.6 (3.22 -5.94), V 0.94, SD 0.97, SEM 0.21. V 0.94, SD 0.97, SEM 0.21. For I_3 indice, was found a statistical positive correlation (R 0.32, R_2 0.104, Rs 0.25), with a mean I_3 GI-NETs 3.38, (1.12-5.73), V 1.60, SD 1.26, SEM 0.22, respectively a mean I3 P-NETs 2.15, (0.34-3.92), V 1.09, SD 1.04, SEM 0.23. For I_1 and I_2, the values were not statistically significant correlated (R 0.37, R_2 0.14, Rs 0.1053 for I_1, respectively R -0.02, R_2 0.15 and Rs 0.2). **Conclusion:** From our study, best indices to be calculated would be I_3 and I_4. Although, were not statistically significant correlations for all four indices the uptake kinetics analysis next to the tumor heterogeneity graphs represent important nuclear functional imaging features in NETs theragnostic approach. **References:** None.

Study of different quantitative uptake metrics in ^{18}F-FDG PET/CT imaging from malignant lymph node in breast cancer: impact of workstation and segmentation method

M. Ibañez*, J. Navarro Fernández, L. Frutos Esteban, J. Contreras Gutiérrez, L. Mohamed Salem, F. Hernández Almagro, J. Villa Sánchez, I. Sime Loayza, M. Tomás Redondo, T. Rodríguez Locarno, T. Moreno Monsalve, R. Reyes Marlés, M. Castellón Sánchez, F. Nicolás Ruiz, E. Para Vergara, R. Mears Baño, M. Claver Valderas; Clinic Universitary Hospital Virgen de la Arrixaca, El Palmar, Murcia, SPAIN.*

Aim/Introduction: The purpose of this study is to investigate the variability of several quantitative metrics in malignant lymph node breast cancer using ^{18}F-FDG PET/CT with different workstation and segmentation methods focused on the lymph nodes. **Materials and Methods:** Seventeen patients with locally advanced breast cancer (N1-N3) were studied. ^{18}F-FDG PET CT were performed using a Philips Ingenuity TF 64 (Cleveland, OH, USA). Two minutes/bed position and list-mode time of flight (TOF) adquisition were used. Image reconstruction was performed using 3 iterations and 33 subsets, 3D ordered subset expectation maximization (BLOB-OS-TF) being reconstructed in two types of matrices: 144x144 matrices with voxel size

4x4x4mm (standard voxels) and 288x288 matrices with voxel size 2x2x2mm (small voxels) without PSF resolution recovery. The image analysis was reviewed using two Workstation: IntelliSpace Portal 7.0 and Syngo.Via VB20A. Three automated segmentation methods were applied: umbral adaptative and 40% of the maximun tumor value as a thresthold with IntelliSpace Portal and segmentation 40% of the maximun tumor value by Syngo via. The quantitative uptake metrics evaluated were SUVmax, SUVmean, SUVpeak, MTV and TLG by drawing region of interest (VOI) on the breast lesion. **Results:** For uptake metrics SUVmax, SUVmean and SUVpeak, similar values for work stations as well as segmentation methods for both 4mm and 2mm voxel size were obtained. While the MTV 4mm showed the greatest variability, MTV measured at 40% in IntelliSpace was 4-fold higher (11.7 CI95%:1.7-21.7) than in Syngo (2.9 CI95%: 1.8-4). A similar situation was observed for TLG 4mm data since the IntelliSpace showed a 2-fold value than Syngo platform, although there were no statistically significant differences (p=0.05 for MTV and p=0.165 for TLG). SUV peak was calculated only in 4 patients at 2mm by adaptive threshold and at 3 by threshold 40% used intelliSpace Portal being limitation of this software. **Conclusion:** Although both workstation and segmentation methods render similar data for all variables, significant differences were obtained regarding MTV and TLG data. Therefore, in those studies in which these parameters are of interest, the software used must be taken into account, since there is a possibility of unreliability. **References:** None.

EP-0849

Quantitative assessment of joints affected by rheumatoid arthritis using [^{11}C]DPA713 PET

M. Yaqub[1], *N. Verweij*[2], *S. Pieplenbosch*[1], *R. Boellaard*[1], *C. van der Laken*[2], *A. A Lammertsma*[1];
[1]*Amsterdam UMC, Vrije Universiteit Amsterdam, department of radiology and nuclear medicine, Amsterdam, NETHERLANDS,* [2]*Amsterdam UMC, Vrije Universiteit Amsterdam, department of reumatology, Amsterdam, NETHERLANDS.*

Aim/Introduction: Rheumatoid arthritis (RA) is a systemic connective tissue disease that affects up to 2-4% of adults in developed countries. An accurate tool for both early diagnosis and monitoring of treatment could contribute to early instalment of effective therapy and reduction of permanent physical damage. The macrophage is an excellent imaging target for RA, because of its early infiltration in the synovium of RA patients and reflection of disease activity throughout the course of the disease. [^{11}C]DPA713 is a promising macrophage tracer for RA[1]. The aim of the present study was to develop an accurate plasma input kinetic model for quantification of [11C] DPA713 PET studies of arthritic joints in RA patients. A second aim was to use this model to assess the performance of various simplified quantitative approaches. **Materials and Methods:** Dynamic [^{11}C]DPA713 PET scans (60 min) were performed in 5 RA patients, including arterial and venous sampling. Using CT images, volumes of interest (VOIs) were drawn manually within the boundaries of RA active joints, healthy joints, and bone marrow regions. [^{11}C]DPA713 data were analysed using various plasma input models, i.e. single tissue (1T2k), and reversible (2T4k) and irreversible two tissue compartment models (2T3k), all including an additional fit parameter for blood volume. In addition, linearized/simplified methods were evaluated, i.e. Logan, Patlak, standardized uptake values (SUV) and target to blood ratios (TBR) averaged over various intervals, by comparing results with those of the optimal plasma input model. **Results:** Whole blood activity and plasma to whole blood activity ratios showed good agreement among patients and between arterial and venous samples. Visual assessment showed acceptable fits for all models in all segmented regions, except for the 1T2k model that didn't fit well in the bone marrow time activity curves. The Akaike goodness of fit criterion preferred the 2T3k model for all regions. Patlak K_i provided good agreement (R^2 = 0.83) with this non-linear 2T3k approach. SUV correlated highly with K_i (R^2=0.82) and showed a significant difference in uptake between unaffected vs affected RA regions (p=0.018). **Conclusion:** The optimal quantitative model for assessment of [^{11}C]DPA713 uptake in RA joints is 2T3k. K_i based on this 2T3k analysis showed good correlation with clinical levels of RA. Furthermore, SUV (at 30-60 min pi) is the preferred simplified quantitative method showing similar performance in identifying affected versus non-affected RA regions as K_i. **References:** [1] Gent Y et al, Arthritis Res Ther 2014 16:R70.

EP-0850

Development of PET in Europe

A. N. Stevens;
Medical Options, London, UNITED KINGDOM.

Aim/Introduction: To track the development and use of PET in Europe. The provision and level of scanning of PET (PET, PET/CT and PET/MR) in Europe varies widely both between and within countries where workload volume differs between providers. The large differences between facilities in terms of scan volumes and the range of tracers in use precluded a simple sampling approach and required identification of all European PET providers. **Materials and Methods:** Facilities with PET and or cyclotron(s) were identified from a number of sources primarily equipment manufacturers and sites providing PET. Sites were invited to describe their operation including their equipment profile, the number and types of patient studies performed and their use of radiotracers. We were able to identify over 95% of the PET cameras and cyclotrons operating in Europe. Over 50% of these sites provided workload numbers for 2018. To project total workload we employed a segmentation scheme for each country or region which identified ten types of facility allowing us to estimate more accurately patient numbers at sites who did not contribute workload data. **Results:** In 2018 there were 799 providers of PET and/or CT or MR in Europe of which 18 were mobile. PET/CT accounted for over 90% of the installed systems. PET cameras which comprised 2.2% of the total and PET/MR 5.3% were almost entirely operating in research

settings. FDG studies accounted for 88% of the total patient workload with oncology examinations accounting for 89% of FDG scans. Tracers other than FDG accounted for 12% of studies and of these Fluorine 58%, Gallium 27%, and Rubidium 9% were the significant nuclei in use. Characterising prostate disease accounted for 53% of the studies with F-Choline, 18F and 68Ga PSMA accounting for 96% of these investigations. Scan numbers rose by 9.0% from the 1.73m scans estimated for 2016 versus 7.8% between 2014 and 2016. There are wide variations across Europe both in terms of scans performed and patient throughput. In some cases this is due to reimbursement and in others working practices and patient catchment. **Conclusion:** Across Europe the number of FDG studies continues to grow as the proportion of patients in countries with low adoption levels chases that of the high adopters. In these countries oncology examinations are levelling off. Compounds other than FDG offer the major opportunity to expand the use of a PET. **References:** We thank the sites contributing to this study.

Multicenter study of rapid bone-SPECT/CT image acquisition

K. Miwa[1], *T. Murata*[2], *N. Miyaji*[3], *T. Kamiya*[4], *Y. Owaki*[5], *T. Okamoto*[6], *R. Emura*[7], *M. Takahashi*[8], *R. Kobayashi*[1], *T. Iimori*[2];
[1]*Department of Radiological Sciences, International University of Health and Welfare, Tochigi, JAPAN,* [2]*Department of Radiology, Chiba University Hospital, Chiba, JAPAN,* [3]*Department of Nuclear Medicine, Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo, JAPAN,* [4]*Department of Medical Technology, Osaka University Hospital, Osaka, JAPAN,* [5]*Office of Radiation Technology, Keio University Hospital, Tokyo, JAPAN,* [6]*Department of Radiology, Tsugaru General Hospital, Aomori, JAPAN,* [7]*Department of Radiology, Kimitsu Central Hospital, Chiba, JAPAN,* [8]*Department of Central Radiological Technology, Saitama Medical University Hospital, Saitama, JAPAN.*

Aim/Introduction: The addition of SPECT/CT to whole-body bone scintigraphy is time-consuming and can prolong the procedure by approximately 15 min per bed position. The duration of acquisition needs to be reduced without decreasing image quality and negatively affecting diagnostic confidence. This multicenter study aimed to determine the feasibility of rapid bone-SPECT/CT imaging for detecting bone metastases. **Materials and Methods:** We scanned NEMA body phantoms comprising six spheres (diameter: 10, 13, 17, 22, 28 and 37 mm) containing ^{99m}Tc solutions with a sphere-to-background ratio of 6 at seven institutions. We investigated image quality and the quantitative accuracy of GE Infinia Hawkeye4, GE Optima NM/CT640, GE Discovery NM/CT670, NM/CT670 CZT, Siemens Symbia T6, Intevo16 and Philips BrightViewX with XCT SPECT/CT systems. The duration of image acquisition varied from 1 to 30 (1, 2, 3, 4, 5, 10 and 30) minutes. Data were reconstructed using GE Evolution for bone, Siemens Flash 3D or xSPECT Quant and Philips Astonish, ten subsets, and a varying number of iterations. The smallest visually detectable sphere in reconstructed images acquired over different durations was identified. We then measured the %contrast and background variability of 17-mm spheres recommended by the Japanese Society of Nuclear Medicine Technology (JSNMT) bone-SPECT guidelines and standardized uptake values (SUV). **Results:** The 17-mm hot spheres were obvious on SPECT images acquired overa period of 3 min using all scanners. The %contrast increased with the number of iterations but became almost saturated starting from five iterations. The balance between %contrast and background variability differed among scanners. Three- and four-min SPECT image acquisitions were needed to optimize the number of iterations required to meet the JSNMT criteria. Smaller lesions were detected more effectively over longer acquisitions using the Discovery NM/CT670 CZT and Symbia Intevo16, although background noise was significantly higher than that of other scanners when acquisitions were ≤ 4 min. The SUV were relatively stable during 4-min acquisitions. **Conclusion:** Rapid bone SPECT/CT is technically feasible without loss of image quality and quantitative ability to detect potential bone metastases. **References:** None.

Added Value of Siemens xSPECT Bone Algorithm in Reading Musculoskeletal SPECT/CT

N. Gandy, *J. Phillips, K. Wallitt, Z. Win, M. Arshad, K. Ordidge, A. Gomes Moura, L. M. Perry, N. Soneji;
Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.*

Aim/Introduction: To determine whether use of the CT as frame-of-reference for image reconstruction (xSPECT bone) improves diagnostic confidence and detection of bone metastases or pain generators compared with iterative reconstruction with resolution recovery (Flash 3D) SPECT reconstruction when evaluating musculoskeletal SPECT/CT. **Materials and Methods:** 20 patients (30 more patients to be evaluated) referred for bone scans with musculoskeletal pain suspected to have bone metastases and/or degenerative pain generators were identified. Bone SPECT/CT scans were acquired using a Siemens Intevo Bold gamma camera at our centre. Data was reconstructed with both xSPECT (xSPECT/CT) and Flash 3D (F3D SPECT/CT) algorithms. Two consultant radionuclide radiologists performed a retrospective review of the reconstructions. The reviewers were blinded to the clinical indication and independently reviewed anonymised F3D SPECT/CT followed by xSPECT/CT datasets. Each case was given

a diagnostic confidence (1 to 3, low to high) and image quality (1 to 5, low to high) score. **Results:** The initial 20 cases included 8 cases for metastatic bone disease in known malignancy and 12 cases for pain generators. Inter-observer agreement for presence or absence of metastases and pain generators was 90% and 85% respectively. Average image quality score by both readers increased from 3.0 for F3D SPECT/CT to 4.7 for xSPECT/CT ($p<0.0001$). Diagnostic confidence for Reader 1 changed from 2.95 with F3D SPECT/CT to 2.98 with xSPECT/CT ($p=0.6663$), and from 2.77 to 2.95 for Reader 2 ($p = 0.0165$). Reader 2 identified an average of 2.3 more lesions on xSPECT/CT vs F3D SPECT/CT compared to Reader 1 with an average of 0.05 more lesions. xSPECT/CT helped identify low grade uptake within smaller joints compared to F3D SPECT/CT, although overall diagnosis was unchanged for the majority of cases. Only one discrepant metastasis case was identified demonstrating mottling of marrow uptake on xSPECT/CT due to tiny sclerotic metastases otherwise only visible on the CT component and not identifiable on F3D SPECT/CT images. **Conclusion:** The xSPECT/CT reconstruction provides potential scope to identify more subtle areas of radiopharmaceutical uptake with better anatomical localisation given the improved image quality. However, our findings demonstrate variable improvement of diagnostic confidence between readers and limited change in overall diagnosis. Further studies are needed to assess the improved clinical efficiency of xSPECT/CT reconstructions. **References:** None.

Optimized PET reconstructions: Can they be harmonized as well?

H. Vosoughi[1,2], *P. Geramifar*[3], *A. Rahmim*[4], *F. Emami*[2], *M. Hajizade*[1], *M. Momennezhad*[1];
[1]*Department of Medical Physics, Mashhad University of Medical Science, Mashhad, IRAN, ISLAMIC REPUBLIC OF,* [2]*Nuclear Medicine Department, Razavi Hospital, Imam Reza International University, Mashhad, IRAN, ISLAMIC REPUBLIC OF,* [3]*Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [4]*Departments of Radiology and Physics, University of British Columbia, Vancouver, BC, CANADA.*

Aim/Introduction: PET/CT images are extensively utilized for diagnosis, (re)staging and monitoring treatment response. Preferred protocols should have optimal image quality and detectability with accurate quantification, and as such reconstruction protocols should be optimized. There are significant variations in PET quantification due to differences in scanner hardware and reconstruction algorithms. To tackle the challenge of variability in quantitative values between PET images obtained using different scanners, determination of harmonized reconstruction is very important. **Materials and Methods:** Data acquisition of IQ-NEMA phantom with SBR 4:1, 6:1, 8:1 and 10:1 was performed on a SIEMENS Biograph6 TrueV PET/CT scanner. Raw PET data were reconstructed using 6 different iterations (x subsets) and Gaussian post-smoothing filters with FWHM 2, 4, 6, 8 and 10 mm. In addition, image reconstruction was performed with/without PSF modeling (HD and 3D mode). CNR, COV, percentage difference of CNR, RC_{max}, $RC_{A50\%}$ and RC_{peak} were evaluated for standardization, and were compared with EARL specification reference values. **Results:** CNR and COV improved using smoother filters and fewer iterations. COV was less than cutoff (15%) for all reconstructions of frames >3min. Percentage difference of CNR between FWHM 4 and 6mm for all reconstructions was more than other sequential filter pairs. Though in SBR4:1, the maximum value of CNR of the smallest sphere was 8, it was barely visible, but in SBR6:1, CNR increased to 15. Iterations 30-60 with suitable post-smoothing Gaussian filters harmonized quantitative PET data. There were no difference in RC curves between 3D and HD mode in SBR 4:1. In HD mode, RC_{max} and $RC_{A50\%}$ were overestimated in higher SBRs and higher iterations. Positive bias in RC_{max} and $RC_{A50\%}$ was observed for 13, 17, 22mm spheres caused by PSF-modeled reconstruction, creating edge artifact. However, applying 6mm Gaussian filter and/or using RC_{peak} reduced this bias. Furthermore using CNR as a surrogate for image quality demonstrated that 6 mm Gaussian filter can be appropriate towards optimized as well as harmonized imaging. **Conclusion:** Image quality and detectability in PET images strongly depends on activity to background ratios, reconstruction parameters and post-smoothing filter. The optimized post-reconstruction filter was found to minimize variations of RC in comparison to EARL references. In addition, accurate quantification is feasible utilizing PSF modeling when utilizing appropriate filters. **References:** None.

Regularized Reconstruction Improves Signal-to-noise and Quantification for ^{18}F- PSMA PET/CT Imaging

C. F. Uribe[1], *N. Colpo*[1], *E. Rousseau*[2], *F. Lacroix-Poisson*[2], *D. Wilson*[1], *A. Rahmim*[1,3], *F. Bénard*[1,3];
[1]*BC Cancer, Vancouver, BC, CANADA,* [2]*Universite de Sherbrooke, Sherbrooke, QC, CANADA,* [3]*University of British Columbia, Vancouver, BC, CANADA.*

Aim/Introduction: The popular ^{18}F-labeled PSMA-targeting PET tracer, ^{18}F-DCFPyL, has shown to be significantly superior in detecting metastatic prostate cancer than ^{18}F-FDG. Accurate quantification of ^{18}F-DCFPyL images can enable evaluation of therapeutic efficacy, comparison between centres, and the potential to build outcome predictive models. Ordered subsets expectation maximization (OSEM) is commonly used to generate PET images, but noise is amplified at high number of iterations. As such, limited iterations are used in practice to maintain adequate image quality; however, this may not be sufficient to achieve convergence and leads to lower standardized uptake values (SUV). The block sequential regularized expectation maximization (BSREM) algorithm, also called Q.Clear (GE Healthcare), allows convergence while avoiding noise amplification at higher number of iterations. In

this study, we perform quantitative comparison of OSEM and BSREM-based ^{18}F-DCPFyL images on a cohort of prostate cancer patients. **Materials and Methods:** Whole-body ^{18}F-DCFPyL PET/CT imaging was performed on 30 patients with biochemical recurrence following curative-intent therapy for prostate cancer. Images were reconstructed using OSEM (32 subsets, 2 iterations) and BSREM (32 subsets, 25 iterations, gamma=2, beta=400) including attenuation and scatter correction. Images were interpreted by experienced nuclear medicine physicians. Regions of interest (ROIs) for the 3 most active lesions were drawn using MIM (MIM Software) and fixed 40% threshold. Each ROI was cloned and shifted to a region in the vicinity of the lesion to determine the maximum, mean, and standard deviation (s.d.) of the background (bg) activity. SUVmax, SUVmean, signal-to-noise ratio (SNR, calculated as lesion_SUVmean/bg_s.d.), and contrast (calculated for both SUVmax and SUVmean w.r.t. bg_SUVmean) were compared between the two algorithms. As distributions were skewed, a $\log_{10}$ transformation was applied and the Shapiro-Wilk normality test suggested that the transformed data was normally distributed. A paired t-test was used to determine statistically significant differences. Values are reported as (mean, [95% confidence interval]). **Results:** Mean BSREM SUVmax=(17.4, [13.0-23.2]), SUVmean=(9.6, [7.5-12.2]), SNR=(53.7, [41.0-70.3]), contrast_max=(19.5,[13.2-28.7]), and contrast_mean=(10.0,[7.0-14.4]) were 28.9%, 15.7%, 34.9%, 17.5%, and 2.0% higher, respectively, than OSEM SUVmax=(13.5, [10.5-17.3]), SUVmean=(8.3, [6.6,10.4]), SNR=(39.8,[31.8-49.9]), contrast_max=(16.6,[11.9-23.1]), and contrast_mean=(9.8,[7.1-13.5]). Statistically significant differences between algorithms were observed for SUVmax ($p=8.0\times10^{-8}$), SUVmean ($p=7.8\times10^{-8}$), SNR ($p=3.9\times10^{-7}$), and contrast_max ($p=1.8\times10^{-2}$), but not for contrast_mean (p=0.7). **Conclusion:** Use of regularized reconstruction can achieve significantly higher lesion SUVmax, SUVmean, SNR, and contrast_max for prostate cancer imaging using an ^{18}F-labeled PSMA PET radiotracer. This may lead to improved image quantification and clinical task performance in prostate cancer patients imaged with ^{18}F-DCFPyL. **References:** None.

EP-0855

Does Bayesian penalized likelihood reconstruction (Q.Clear) for FDG-PET always outperform image quality of OSEM-based reconstruction?

J. M. M. Rogasch[1], *F. Hofheinz*[2], *S. Suleiman*[1], *M. Lukas*[1], *H. Amthauer*[1], *C. Furth*[1];
[1]*Charité-Universitätsmedizin Berlin, corporate member of Freie Universität Berlin, Humboldt-Universität zu Berlin, and Berlin Institute of Health, Department of Nuclear Medicine, Berlin, GERMANY,* [2]*Helmholtz-Zentrum Dresden-Rossendorf, Institute for Radiopharmaceutical Cancer Research, Dresden, GERMANY.*

Aim/Introduction: Bayesian penalized likelihood reconstruction for PET (e.g. GE Q.Clear) aims at improving convergence of lesion activity while ensuring sufficient signal-to-noise ratio (SNR). This study evaluated reconstructed spatial resolution, peak recovery (RCpeak) and SNR of Q.Clear compared to OSEM with time-of-flight (TOF) with and without point spread function (PSF). **Materials and Methods:** The NEMA IEC Body phantom was scanned for 3 min each (GE Discovery MI) for five times every 30 min (3.1, 2.6, 2.1, 1.8, and 1.5 kBq/ml F18) with spheres filled with 4- or 8-fold the background activity concentration (SBR 4:1, 8:1). Reconstruction with Q.Clear (beta, 150/300/450), "PSF+TOF 2.0" (in-plane filter, 2.0 mm; iterations, 2; subsets, 17), "OSEM+TOF 2.0" (identical), "PSF+TOF 6.4" (in-plane, 6.4 mm; 4/8) and "OSEM+TOF 6.4" (6.4 mm; 2/8) was performed. Spatial resolution was derived from 3D sphere activity profiles. RCpeak as ((sphere SUVpeak/background SUVmean) / true SBR). SNR as (background SUVmean/background SUVstddev). **Results:** Spatial resolution of Q.Clear 150/300/450 was each significantly higher than for all conventional algorithms (Wilcoxon, each $p<0.05$; except for Q.Clear 450 vs. OSEM+TOF 2.0 at SBR 4:1). Median spatial resolution at SBR 8:1 for Q.Clear 150, Q.Clear 300, PSF+TOF 2.0 and OSEM+TOF 2.0 was 3.6, 4.2, 5.0 and 5.1 mm compared to SBR 4:1 with 4.4, 4.9, 5.7 and 5.6 mm. SNR for Q.Clear 150 and OSEM+TOF 2.0 were similar at both SBR ($p>0.05$) but Q.Clear 150 showed higher RCpeak for the small spheres by +6.3 to 10.8% (diameter, 10 to 17 mm). SNR of Q.Clear 300 and PSF+TOF 2.0 were similar as were RCpeak (difference, +0.3 to 4.1%). Compared to PSF+TOF/OSEM+TOF 6.4, Q.Clear 150/300/450 each showed lower SNR (-79.7 to -35.9%) but higher RCpeak (+4.6 to 27.8%) at both SBR. **Conclusion:** Q.Clear improves reconstructed spatial resolution at high and low SBR compared to PSF+TOF and OSEM+TOF with both investigated iteration and filter settings. For specific conditions this resulted in higher RCpeak for small spheres at comparable SNR (Q.Clear 150 vs. OSEM+TOF 2.0). Highest RCpeak were achieved with PSF+TOF 2.0 and Q.Clear 150, but at the cost of lowest SNR. **References:** None.

EP-0856

Impact of Radiation Dose Reduction of CT component in Whole-Body PET/CT Protocols on CT Image quality

I. Ali[1], *Y. Mohamed*[2], *I. Naser*[1], *M. I. Amin*[1], *H. Abdel Gawad*[3], *M. Hamdy*[4];
[1]*Zagazeg university faculty of medicine, Zagazeg, EGYPT,* [2]*Cairo university faculty of medicine, Cairo, EGYPT,* [3]*Cairo university hospitals, Cairo, EGYPT,* [4]*Cairo university Hospitals, Cairo, EGYPT.*

Aim/Introduction: We aim to reduce radiation dose of CT component in the whole-body PET/CT protocols, without compromising the image quality, aided by advanced iterative reconstruction technique.Regarding the issue of radiation dose, it is worth noting the recent progress and further advancements that can reduce the dose to the patient from CT exams. Important dose reductions have already been obtained through the development of optimized imaging protocols, smarter and more efficient x-ray beam collimation, advanced reconstruction algorithms, and by control of the x-ray flux illuminating the object. **Materials and Methods:** Forty eight patients underwent CT imaging with two different doses

during Whole-body PET/CT exams. All patients were scanned using a similar technique except for the changes done for CT dose optimization. Effective dose (ED) from the CT component of the examination was estimated using dose-length product (DLP) values from reports generated by the scanner and the anatomy-specific conversion factor for the whole body (the K factor). Image processing of the low CT dose images was also done with advanced iterative reconstruction technique. The studies were randomized and blinded for experienced two CT readers who graded the imaging quality of anatomic structures. **Results:** CT protocol optimization resulted in reduction of the mean DLP, CTDI and ED from 1296.8±291.9, 13.6±2.6 and 19.45 to 796.5±165.3, 8.2±1.7 and 11.96 with 38.6% reduction of the mean CT radiation dose. The blinded analysis of image quality showed no clinically significant degradation of the lower-dose study that showed comparable means of image noise, contrast, edge detection and overall quality with the high dose study (3.0±0.42, 2.9±0.44, 2.96±0.31 and 2.98 ±0.5 versus 2.87±0.45, 2.83±0.35, 2.84±0.5 and 2.86±0.45 respectively). The lung parenchyma was better visualized on the higher-dose CT scans. **Conclusion:** We can significantly reduce the CT radiation dose in whole-body PET/CT protocols with maintenance of the image quality by using the advanced iterative reconstruction technique. **References:** None.

Dual Asymmetric Detection Heads Of A Novel Compact Molecular Breast Imaging System For Early Breast Cancer Diagnosis

G. Poma[1,2], *E. Cisbani*[3], *F. Garibaldi*[3], *F. Giuliani*[3], *T. Insero*[4], *M. Lucentini*[3], *A. Marcucci*[5], *P. Musico*[6], *J. Nuyts*[7], *F. Santavenere*[3], *C. Sutera*[1];
[1]*Istituto Nazionale di Fisica Nucleare, Catania, ITALY,* [2]*Dipartimento di Fisica ed Astronomia, Università degli Studi di Catania, Catania, ITALY,* [3]*Istituto Superiore di Sanità, Roma, ITALY,* [4]*Ospedale pediatrico "Bambin Gesù", Roma, ITALY,* [5]*Aernoautica Militare Italiana, Roma, ITALY,* [6]*Istituto Nazionale di Fisica Nucleare, Genova, ITALY,* [7]*KU Leuven, Leuven, BELGIUM.*

Aim/Introduction: Breast cancer is the most common cancer in women, and its early detection is a crucial aspect for an effective therapy. Mammography (MMG) is the most used technique for screening, able to identify small-size tumours; nevertheless MMG showed reduced performance in case of dense breast. MRI, US and Molecular Breast Imaging (MBI) techniques have been proposed as complementary to MMG. MBI, based on the use of radionuclides and gamma camera, provides functional, sensible and specific informations, appropriate to dense breast. It may represent a promising support to mammographic screening. **Materials and Methods:** In order to maximize the Signal-to-Noise Ratio (SNR) and spatial resolution in a MBI image, a new compact system, consisting of a two asymmetric (different geometries and collimations) detectors, has been developed. The two detector heads face each other in anti-parallel viewing direction, either mildly compressing the breast and allowing: spot-compression: a PMMA breast-phantom (with four spherical tumoral lesions inside, different sizes) is resting on the big detector (LH) and the small one points the lesion moving on the phantom; Limited-Angle Tomography (LAT): the LH and phantom are fixed and the SH rotates over an arc. A full scale prototype based on matrices of Position Sensitive PhotoMultiplier Tube (PS-PMT), coupled to segmented NaI(Tl) scintillators with parallel and pin holes optics has been constructed to evaluate the expected performances. Monte Carlo (MC) simulations using the GATE framework have been performed to evaluate the best detector configuration, in terms of sensitivity and spatial resolution, and data and image processing solutions; the detectors provide complementary planar images that shall be properly combined to get enhanced, diagnostic information with high specificity and sensitivity. **Results:** Preliminary lesion detectability outcomes show approximative 5 mm diameter as lower limit, confirmed by MC. Good correspondence of reconstructed and real tumor depth was found in LAT modality: trade-off between larger span and number of view, clinical session time and complexity need to be evaluated. The analysis of simulated and real data is ongoing to optimally exploit the MBI images in the different procedures and combine them to the mammographic/tomographic outcomes. **Conclusion:** After a description of the system, we will present the results of the performed measurements, in different modalities, including comparison with MC simulations and the LAT, at different lesions positions and with a diagnostic range of uptakes. Status of the analysis of the optimal MBI and mammographic image fusion will be also reported. **References:** None.

EP-0858

A preliminary assessment of metallic artefact reduction strategies for quantifying FDG activity around cardiac implantable electronic devices

M. Memmott[1], *I. S. Armstrong*[1], *J. Jones*[2], *V. J. Panin*[2];
[1]*Manchester University Hospitals NHS Foundation Trust, Manchester, UNITED KINGDOM,* [2]*Siemens Medical Solutions USA, Inc. Medical Imaging, Knoxville, TN, UNITED STATES OF AMERICA.*

Aim/Introduction: CT artefacts caused by high density objects in the field of view propagate through to attenuation-corrected PET reconstruction, causing significant positive and negative bias around the object, potentially leading to false positive or negative results. Two options for metallic artefact reduction (MAR) are available for the Siemens Biograph Vision; Cardiac MAR (CMAR) and iMAR. The former is a global attenuation correction (AC) map based algorithm derived to account for high-frequency metallic lead motion. The latter is a parameter-dependent iterative CT-sinogram based method. The iMAR algorithm has a preset available for cardiac implantable electronic devices (CIEDs) to improve CT quality but the impact of the algorithm on the accuracy of PET data around metallic devices has not been studied. This preliminary phantom work aimed to evaluate the accuracy of PET quantification around

CIEDs. **Materials and Methods:** A CIED was suspended in a water filled phantom containing ^{18}FDG and PET-CT data acquired using a standard clinical protocol. CT data were reconstructed with standard and iMAR algorithms, using all available presets. PET AC was performed using CMAR algorithm (standard CT) and iMAR CT. In addition, a method developed to better match AC and PET, based on time-of-flight consistency conditions, the maximum likelihood attenuation correction factor (TOF-MLACF) [1], was also investigated. The excellent time-of-flight performance of this system makes TOF-MLACF an interesting option to explore in this context. For each dataset, uniform PET slices were used to generate a statistical distribution of expected voxel values. The percentage of voxels outside the 95% confidence intervals of this distribution was calculated as a measure of artefact reduction. The first 10 focal hot-spots were also automatically identified using the maximal average of a 7-voxel regional cluster. **Results:** All reconstructions with the exception of $iMAR_{dental}$, TOF-MLACF and CMAR demonstrated one or more focal hot-spots adjacent to the device. The CMAR algorithm produced a global reduction in uptake in the presence of the device, with the greatest percentage of voxels (6.9%) outside the uniform distribution. The $iMAR_{dental}$ and TOF-MLACF reconstructions gave the lowest percentage of voxels outside the uniform distribution (6.2 % and 4.4%). **Conclusion:** This phantom study demonstrates that effective MAR in PET data could be achieved in the clinical setting using the $iMAR_{dental}$ preset, allowing interpretation of attenuation-corrected PET data. Results from the current TOF-MLACF prototype show promise, warranting further investigation. **References:** [1] Bal H et al. Phys Med Biol 2017; 62:2542-2558.

EP-0859

The Effect of Different Time Per Bed Position on Image Quality and Semi-Quantitative Measurements in ^{68}Ga-RM2 and ^{68}Ga-PSMA11 PET/MR Images

L. Baratto, H. Duan, H. Gandhi, M. Khalighi, A. Iagaru;
Stanford University, Palo Alto, CA, UNITED STATES OF AMERICA.

Aim/Introduction: PET/MR is used for assessment of prostate cancer because of its high soft tissue contrast recovery and high-quality PET images. Here, we evaluated the impact of different PET acquisition times (time per bed) on image quality, lesion detectability and quantification in a cohort of prostate cancer patients. **Materials and Methods:** We retrospectively analyzed data from 90 prostate cancer patients who underwent either ^{68}Ga-RM2 (n=45) or ^{68}Ga-PSMA-11 (n=45) PET/MR. The raw PET data were retrospectively reconstructed using different time per bed position (TpB): 30 seconds (s), 1minute (m), 2m, 3m and 4m. Each reconstruction was reviewed and qualitatively scored using a Likert scale (1 - poor, 5 - excellent quality). SUV_{max} values were measured from ^{68}Ga-RM2/PSMA PET/MR for up to 6 lesions compatible with prostate cancer. Uptake in gluteal muscles was also collected in all patients as a measure of image noise. **Results:** The mean±SD injected dose was 3.82±0.15 and 4.39±0.79 mCi for ^{68}Ga-RM2 and ^{68}Ga-PSMA11, respectively. The mean BMI was 26.49 and 27.71 for patients who underwent ^{68}Ga-RM2 and ^{68}Ga-PSMA11, respectively. The mean±SD scores for ^{68}Ga-RM2 PET images were 1.04±0.21 for TpB=30s reconstructions, 2±0.3 for TpB=1m, 3.07±0.45 for TpB=2m, 4.64±0.53 for TpB=3m and 4.78±0.42 for TpB=4m. The mean±SD scores for ^{68}Ga-PSMA11 PET images were 1.18±0.39 for TpB=30s reconstructions, 2.22±0.42 for TpB=1m, 3.40±0.58 for TpB=2m, 4.87±0.40 for TpB=3m and 4.91±0.36 for TpB=4m. A total of 129 lesions (66 on ^{68}Ga-RM2 and 63 on ^{68}Ga-PSMA11) were detected and the mean SUV_{max} measurements were: 11.07, 10.19, 9.57, 9.43 and 9.42 for the ^{68}Ga-RM2 TpB of 30s, 1m, 2m, 3m and 4m, respectively; 14.69, 12.82, 12.11, 11.72 and 11.52 for the ^{68}Ga-PSMA-11 TpB of 30s, 1m, 2m, 3m and 4m, respectively. The mean SUV measurements in gluteal muscles were: 0.32, 0.22, 0.19, 0.17 and 0.15 for the ^{68}Ga-RM2 TpB of 30s, 1m, 2m, 3m and 4m, respectively; 0.35, 0.27, 0.23,0.20 and 0.18 for the ^{68}Ga-PSMA-11 TpB of 30s, 1m, 2m, 3m and 4m, respectively. **Conclusion:** Here we shown that 3 or 4 minutes per bed position for both radiopharmaceuticals result in excellent image quality. Even data acquired at 2 minutes per bed resulted in diagnostic images (average score >3). **References:** None.

EP-0860

Optimisation of TOF and PSF PET Reconstruction for the Detection and Quantification of Metastatic Tumour Lesions in the Liver

Y. Bouchareb[1], N. Tag[2], H. Sulaiman[1], M. El-zain[1], A. Al-Jabri[2], Z. Jawa[2], H. Al-Dhuhli[2];
[1]Sultan Qaboos University, Muscat, OMAN, [2]Sultan Qaboos University Hospital, Muscat, OMAN.

Aim/Introduction: To optimise TOF and PSF-based PET reconstruction for an accurate estimation of F-18 FDG uptake within metastatic tumour lesions in the liver. **Materials and Methods:** Phantom PET/CT scans were performed on the mCT 128 slices Siemens scanner. The detection and quantification of metastatic tumour lesions in the liver requires the use of optimal number of iterations, number of subsets, filter size and matrix size in the iterative image reconstruction process. The NEMA image quality phantom was used; spheres 10, 13, 17, 22, 28 and 37 mm diameters and the background compartment were filed with F-18 activity. Spheres-to-background (2.1 kBq/mL) ratio was 4:1 (total activity was 29.8 MBq). Three types of reconstructions: OSEM-TOF-PSF (routine reconstruction), OSEM-PSF and OSEM-TOF were optimised by means of varying number of iterations (1 to 5 iterations), number of subsets (8 to 24 subsets), filter size (2 to 7mm) and matrix size (128x128 to 400x400 pixels). For each reconstruction, contrast recovery coefficients (CRC) were calculated for all spheres and compared to the expected EANM/EARL CRC values using the mean percentage difference (MPD) for all spheres. The resulting optimal reconstruction and the routine reconstruction (OSEM-TOF-PSF using 2 iterations, 21 subsets, 3mm filter size and 400x400 pixels) were also applied to 15 FDG PET/CT scans. SUVmax, SUVpeak and MTV (Metabolic Tumour Volume) were calculated for both reconstructions.

Results: From the CRC analysis, OSEM-TOF-PSF (2 iterations, 21 subsets, 3mm filter and 400x400 pixels), OSEM-PSF (2 iterations, 24 subsets, 3mm filter and 400x400 pixels) and OSEM-TOF (2 iterations, 12 subsets, 3mm filter and 256x256 pixels), found to be optimal in each type of reconstruction, provided an MPD of 13%, 7% and 4%, respectively. The latter was considered to be the optimal reconstruction. On patient data, the mean percentage differences, calculated within 24 lesions (15 patients), in SUVmax, SUVpeak and MTV between the routine reconstruction and OSEM-TOF (2 iterations, 12 subsets, 3mm filter and 256x256 pixels) were 8%, 7%, 30%, respectively. The visual assessment of reconstructed images by two NM physicians was in favour of OSEM-TOF-PSF (2 iterations, 21 subsets, 3mm filter and 400x400 pixels) in 80% of the lesions. **Conclusion:** The OSEM-TOF (2 iterations, 12 subsets, 3mm filter and 256x256 pixels) provides a better quantitative accuracy compared to routine reconstruction. However, for image quality purposes the OSEM-TOF-PSF (2 iterations, 21 subsets, 3mm filter and 400x400 pixels) offers better appearance of metastatic tumour lesions in the liver. **References:** None.

Comparison of two strategies for mitigation of gross misregistration of CT and PET in PET/CT imaging

T. Pan, B. Simon, R. Millican;
The University of Texas, Houston, TX, UNITED STATES OF AMERICA.

Aim/Introduction: Respiration induced gross misregistration between CT and PET can compromise the quality of PET/CT imaging. A solution to mitigate the issue is to perform repeat limited field-of-view PET/CT scan, which prolongs the scan time and incurs additional CT radiation exposure to the patient. The purpose of the study is to evaluate if average CT can achieve registration with the PET data, can avoid the repeat scan time, and can reduce CT radiation exposure to the patient. **Materials and Methods:** We reviewed 5 PET/CT studies with a repeat PET/CT scan due to gross misregistration between CT and PET at or near the diaphragm on a GE PET/CT scanner. Maximum misregistration was 4.75 cm. Both scan time and CT dosimetry of the PET/CT and repeat PET/CT were recorded. Extents of misregistration in the original and repeat PET/CT images were measured. Instead of repeat scan, we used an average CT scan of 5 sec to combat gross misregistration of CT and PET, and acquired 20 patient scans with the average CT. Comparison of average CT and repeat PET/CT on scan time, CT radiation dose, misregistration and impact to workflow was made. **Results:** For the 5 patients with a repeat PET/CT scan of 3 to 4 beds over the abdominal area, scan time was increased by 9 to 12 mins from PET, CT dose was increased by 3.4±1.7 mSv, and misregistration of 1.3 cm remained in 1 patient study, suggesting that it may not be reliable to remove misregistration with repeat scan. For the 20 patients with an average CT scan instead of repeat PET/CT, CT dose was increased by 2.1±1.5 mSv. Misregistration measured at the diaphragm was corrected on all 20 patients without additional PET data acquisition. The processing time of average CT was less than 2 min. **Conclusion:** Using average CT to combat misregistration between CT and PET of PET/CT imaging can save scan time by 9 to 12 mins, can reduce radiation exposure to the patient from 3.4±1.7 mSv of repeat CT to 2.1±1.5 mSv of average CT, and can be realized without any impact to patient throughput. Average CT was also more reliable than repeat CT to mitigate the gross misregistration problem between CT and PET. **References:** Pan et al, Attenuation correction of PET cardiac data with low-dose average CT, Medical Physics, 2006.

Taking Advantage of STIR Open Source Software in clinical PET Image Reconstruction Using the raw data obtained from a Commercial PET/CT Scanner

H. Jozi[1], P. Geramifar[2];
[1]Science and Research Branch, Islamic Azad University, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF.

Aim/Introduction: One of the most important components in Positron Emission Tomography (PET) imaging, is image reconstruction. At this point all raw data are converted into images that represent activity distribution in body using different iterative or analytical reconstruction methods. Modern imaging systems with their own commercial softwares and reconstruction algorithms, are alike a black box, which give no access to their users in modifying the parameters in reconstruction or correction algorithms. On the other hand, STIR[1] is an open source software that has never been used instead of commercial software in clinical routine. The aim of this study is to reconstruct PET raw data obtained from a Commercial PET/CT scanner using STIR. **Materials and Methods:** In this study, the header of PET scanner in the Siemens Biograph6 PET/CT imaging system was defined in accordance with existing parameters. In this modeling, parameters such as the number of segments, axial compression and maximum and minimum ring difference per segment ... were adjusted according to the michelogram of an actual scanner. Thereafter, the raw data of a patient's whole-body PET scan in the sinogram mode was extracted and reconstructed using STIR. The images were then compared with the ones reconstructed using commercial software of SIEMENS scanner (Syngo) as the gold standard. The algorithms used in image reconstruction were (1) FBP, (2) OSEM iterative algorithm with 2 iterations and 21 subsets and (3) iterative algorithm with 8 iterations and 21 subsets. The uptake difference was measured in various ROIs in normal tissues including the liver, lungs, heart as well as in pulmonary tumors. **Results:** The activity concentration obtained from the STIR reconstructed images in normal tissues of liver, lungs, heart and pulmonary tumors (after applying normalization), has a good conformity with those measured in clinical images reconstructed by the Syngo commercial software. **Conclusion:** The results shows the potential of using STIR open source software in the reconstruction of three-dimensional PET raw

data obtained from a commercial PET/CT system. Thus, STIR provides the possibility of improving different algorithms such as scatter correction, resolution recovery or motion correction in the commercial scanners. **References:** [1] Thielemans, Kris, et al. "STIR: software for tomographic image reconstruction release 2." Physics in Medicine & Biology 57.4 (2012): 867.

EP-0863

Quantitative Evaluation of TOF Benefits on the Simulated PET/CT Images Using Mont Carlo Study

H. Jozi[1], *P. Geramifar*[2];
[1]*Science and Research Branch, Islamic Azad University, Tehran, IRAN, ISLAMIC REPUBLIC OF,* [2]*Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Science, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: Time-of-flight (TOF) capability would improve the signal-to-noise ratio (SNR) and Noise Equivalent Counting Rate (NECR) of PET scanners. This improvement is mainly depend on the scintillator decay time, time response of coincidence circuits and front-end electronics. In this regard, we simulated a non-TOF clinical PET/CT scanner capable of TOF using GATE Monte Carlo simulation to quantitatively assess the possible advantageous of TOF in image SNR and improvement in counting performance of PET scanner. **Materials and Methods:** In this study, we simulated the Siemens Biograph6 true points PET/CT scanner (SIEMENS, Erlangen, Germany), using GATE Monte Carlo package with 500 ps timing resolution and 4.5 ns coincidence window. Simulated data were reconstructed in STIR, using both filtered back projection (FBP) and Iterative reconstruction (OSEM) methods. Attenuation correction was applied in both models (TOF and non-TOF) in the digital XCAT anthropomorphic phantom. Moreover, hyper-metabolic lesions were simulated. The images were compared in terms of contrast improvement (CNR), SNR, noise and coefficient of variations (CV) for TOF evaluation purpose. **Results:** It was shown that TOF information improves the image quality in terms of SNR and CNR, and it can significantly improve the fast convergence of the OSEM algorithms. Moreover, improved SNR in TOF reconstructed images demonstrate the benefit of TOF in high random fraction coincidences. Our simulated SNR_{gain} followed a recent model developed by Erikson, with a proportionality constant measured to be α^2=0.6. **Conclusion:** The results confirmed the advantages of TOF information in image reconstruction including better identification of image details, better contrast, and image noise reduction in terms of CV. Thus, the SNR_gain can be predicted for Iterative reconstruction methods, by means of a reliable Monte Carlo simulator. **References:** None.

Scan time optimisation of PET/CT examinations in case of patients in pain

A. Zagorska, *V. Kouykin*, *A. Tsonevska*;
Acibadem City Clinic Cancer Center, Sofia, BULGARIA.

Aim/Introduction: Cancer patients are staged or followed-up by PET/CT examinations. It is not uncommon to examine patients with pain that makes difficult the proper conduction of the study. The aim of this study is to investigate whether a reduced in comparison to the typically applied scanning time in a standard PET/CT protocol can be used in case of patients with difficulties to stay immobile during the examination. **Materials and Methods:** Two groups of 10 patients each referred for F-18 FDG scans on a Discovery™ IQ (GE Healthcare) PET/CT system were included in this study. The administered activity was 3 MBq kg-1. Patients were scanned in list mode at 2 minutes per bed position. Data were rebinned to simulate 1.75 min (retro reconstruction A), 1.5 min (retro reconstruction B) and 1 min (retro reconstruction C) per bed position acquisitions, without changing the other parameters. VPHD (iterative reconstruction algorithm) and Q.Clear (Bayesian penalized likelihood reconstruction algorithm) were applied. Subjective assessment of image quality for both groups was made by two experienced physicians using a three-point scale in the first stage of the study. In the second stage measurements of SUVmax in the liver, mediastinum, lung and a patient lesion were carried out. The differences between measured data for the primary examination and the retro reconstructions A and B were calculated. **Results:** Results from the first stage of the study showed that retro reconstructions A and B were with similar quality as the primary examination. The retro reconstruction C was not acceptable. Results presented as median, minimum and maximum in parenthesis and average of the differences for retro reconstruction A were as follows: SUV_{max}(mediastinum) 1% (-2%, 7%), 2%; SUV_{max}(liver) 1% (-2%, 7%), 2%; SUV_{max}(Lung) 2% (-2%, 6%), 2%. Results for retro reconstruction B were: SUV_{max}(mediastinum) 4% (0%, 12%), 5%; SUV_{max}(liver) 5% (-3%, 14%), 5%; SUV_{max}(Lung) 6% (-4%, 8%), 4%. Results for selected lesion were: VPHD, retro reconstruction A: SUV_{max} 0% (-3%, 3%), 0%; retro reconstruction B: SUV_{max} 2% (-2%, 4%), 2%. For Q.Clear, retro reconstruction A: SUV_{max} 1% (-3%, 5%), 1%; retro reconstruction B: SUV_{max} 0% (-3%, 8%), 2%. **Conclusion:** According to the present study, the time for patient examination can be reduced in case of severe disease to minimize the patient movement during the examination and/or interruption of the studies due to patients in pain. **References:** None.

Partial volume corrected image derived input functions for kinetic modelling of FDG PET brain studies

H. Keijzers, S. S. V. Golla, M. Yaqub, N. Scheltens, P. Scheltens, M. Hofman, R. Boellaard;
Amsterdam UMC, Amsterdam, NETHERLANDS.

Aim/Introduction: Cerebral metabolic rate of glucose (CMRglc) is an important biomarker in studies of Alzheimer's disease and can be obtained with FDG PET. By kinetic modelling the influx rate constant (Ki) of FDG can be determined, which is proportional to CMRglc. Kinetic modelling requires an arterial input function (AIF), normally derived by arterial blood sampling. Efforts have been made to omit arterial sampling by determining the input function directly from cerebral vasculature visible in PET images. However, partial volume effects caused by limited spatial resolution results in inaccurate image derived input functions (IDIFs). Partial volume correction (PVC) can improve the accuracy. This study assesses the accuracy of Ki determination with PVC IDIFs, by calculation of correlation and agreement between Ki derived using PVC IDIFs and Ki derived using AIFs. **Materials and Methods:** Forty-eight dynamic 18F-FDG PET scans with minimal patient motion, arterial blood sampling data and arterial manual samples, were selected from a group of 92 scans acquired in 46 patients in the NL-ENIGMA study (1). PVC was applied to the original PET images using Van Cittert iterative deconvolution combined with a highly constrained back-projection (HYPR) denoising method (2). Cerebral vasculature was segmented by threshold-based volume of interest (VOI). Using this VOI, IDIFs were extracted from the original PET images and the PVC PET images. All IDIFs were calibrated to the manual blood samples. Patlak analysis was performed to obtain Ki using AIFs and IDIFs. Correlation was assessed using linear regression, agreement was assessed with Bland-Altman plots. **Results:** Linear regression analysis shows very strong correlation between Ki derived using PVC IDIFs and AIFs ($r = 0.88$), and strong correlation when non-PVC IDIFs are used ($r = 0.63$). Bland-Altman analysis shows significant ($p<0.01$) bias in both cases (PVC; Ki mean difference = -0.0019 min^{-1}, non-PVC; Ki mean difference = -0.0043 min^{-1}), and limits of agreement (LOA) are smaller when PVC IDIFs are used (PVC; LOA = 0.0041 min^{-1}, and non-PVC, LOA = 0.0079 min^{-1}). **Conclusion:** Partial volume correction and calibration improves correlation and agreement between Ki derived using IDIFs and Ki derived using AIFs. It also reduces the bias, which remains significantly different from zero. The origin of the bias of Ki values by PVC IDIF is subject of further investigation. Other future directions include calibration of PVC IDIFs to venous manual samples.

Validation of reference regions for [^{18}F]Flortaucipir and [^{18}F]Florbetapir brain PET studies using non-invasive simplified metrics

S. S. V. Golla[1], B. M. de Vries[1], T. Timmers[1,2], E. E. Wolters[1,2], R. Ossenkoppele[1,2], S. Verfaillie[2], R. C. Schuit[1], P. Scheltens[2], W. M. van der Flier[2,3], A. D. Windhorst[1], B. N. van Berckel[1,2], R. Boellaard[1];
[1]Department of Radiology & Nuclear Medicine, Amsterdam UMC, Amsterdam, NETHERLANDS, [2]Alzheimer Center & Department of Neurology, Amsterdam UMC, Amsterdam, NETHERLANDS, [3]Department of Epidemiology & Biostatistics, Amsterdam UMC, Amsterdam, NETHERLANDS.

Aim/Introduction: Simplified reference tissue methods (SRTM) are applied for quantification of brain PET studies, particularly because they eliminate the need to perform arterial cannulation. SRTM requires a validated reference region. Ideally, a proper validation of a reference region would be to perform blocking or displacement studies along with histopathological assessments on post-mortem tissue samples usually resulting in complex study designs and cumbersome procedures. An alternative is to compare the distribution volume (V_T) of the reference region between patients and controls and/or before and after intervention/displacement. However, performing dynamic scans and arterial sampling is not always possible, specifically in elderly subjects and advanced disease stages. The aim of this study was therefore to determine if simplified non-invasive approaches could be used to verify if a previously validated reference region for [^{18}F]Flortaucipir and [^{18}F]Florbetapir PET imaging is still valid in subjects groups under conditions where verification using plasma input is not feasible. **Materials and Methods:** Dynamic 130 minutes [^{18}F]Flortaucipir PET scans, obtained from nineteen subjects (10 Alzheimer's disease(AD) patients and 9 controls(C)) and 90 minutes [^{18}F]Florbetapir dynamic scans obtained from fourteen subjects (8 AD patients and 6 C) were included in this study. Regional V_T's estimated from a reversible two tissue compartmental model (with V_B) for both tracers was considered as a standard for validating an optimal reference region. Semi-quantitative measures (standardised uptake value corrected for body weight(SUV_{BW}), lean body mass(SUL) and body surface area(SUV_{BSA})) were obtained by using part (early, middle, or late) of the dynamic scans. Simulations were also performed to evaluate the effect of flow and specific binding (BP_{ND}) on the semi-quantitative metrics. **Results:** Late uptake SUV_{BW}, SUL and SUV_{BSA} correlated well with V_T for [^{18}F]Flortaucipir and [^{18}F]Florbetapir. $SUL_{(80\text{-}100\ min)}$ (AD: r^2= 0.97; C: r^2=0.95) and $SUV_{BSA\ (50\text{-}70\ min)}$ (AD: r^2= 0.96; C: r^2=0.77) correlated best with V_T for [^{18}F]Flortaucipir and [^{18}F] Florbetapir respectively. A $SUL_{(80\text{-}100\ min)}$ less than 1 for [^{18}F] Flortaucipir and $SUV_{BSA(50\text{-}70\ min)}$ less than 0.03 for [^{18}F]Florbetapir suggests absence of specific binding. Simulations confirmed that SUL and SUV_{BSA} were only slightly (<5%) affected by 25%

changes in flow. Changes in SUL and SUV_{BSA} are predominantly related to the presence of specific binding. **Conclusion:** In situations where dynamic scanning and arterial sampling is not feasible $SUL_{(80\text{-}100\ min)}$ for [18F]Flortaucipir and $SUV_{BSA\ (50\text{-}70\ min)}$ for [18F]Florbetapir can be used to evaluate the use of a previously validated reference region. **References:** None.

A quantitative approach for the diagnosis of nonconvulsive status epilepticus from brain perfusion SPECT images

G. Reynés-Llompart[1,2], S. Jaraba Armas[3,4], J. Mora[2], J. Sala-Padró[3], L. Rodriguez-Bel[2], M. Veciana[5], J. Suils Ramón[2], M. Falip Centelles[3], C. Gámez-Cenzano[2];
[1]Medical Physics Department. Institut Català d'Oncologia, L'Hospitalet de Llobregat, SPAIN, [2]Nuclear Medicine-PET Department. Hospital Universitari de Bellvitge-IDIBELL., L'Hospitalet de Llobregat, SPAIN, [3]Neurology department, Epilepsy unit, Hospital Universitari de Bellvitge-IDIBELL. Universitat de Barcelona, L'Hospitalet de Llobregat, SPAIN, [4]Neurology department, Hospital de Viladecans, Viladecans, SPAIN, [5]Neurophysiology department, Hospital Universitari de Bellvitge-IDIBELL. Universitat de Barcelona, L'Hospitalet de Llobregat, SPAIN.

Aim/Introduction: Diagnosing status epilepticus (SE) is a challenging task, as EEG patterns can be difficult to interpret, and the absence of an EEG correlate does not rule out the definitive diagnosis. In this setting, the value of neuroimaging tools is crucial. The present work aims to develop a quantitative approach using 99mTc-HMPAO-SPECT in patients with clinical suspicion of SE. **Materials and Methods:** A total of 54 patients with clinical suspicion of SE were retrospectively included (39% women, median age 64.5 years). All of them underwent a perfusion HMPAO-SPECT. The final diagnosis of SE or no-SE (35 vs 19 patients), was based on clinical, therapeutical image and EEG results. Two experienced neurologists reviewed all the data. The radiopharmaceutical was administered during the clinical episode suspected to be a SE. SPECTs were acquired in a Philips Skylight and reconstructed in a dedicated station. Each reconstruction was normalized to the SPM SPECT template. We used in-house software to obtain a Z-score map comparing each individual SPECT to an external healthy normal database. Only the voxels inside a brain mask (excluding the sublobar area) were considered; all clusters of less than 100 pixels were also excluded. From the resulting map the maximum value (Z_{max}), the number of significant voxels with Z-score>2.5 (N), and the anatomical region with the maximum value were recorded. The latter was obtained using the AAL human brain atlas. The dataset was randomly split in a train (n=30) and test group (n=24). A univariate analysis of the train data was performed to find the relevant variables related to the final diagnosis of SE. Then, a logistic regression was fitted to predict SE. The model was validated using the training dataset by means of the receiver-operator characteristic curve (ROC) and its area under the curve (AUC). **Results:** The number of significant voxels N and the Z_{max} were highly correlated (r=0.89), thus only the latter was included in the logistic model as it was the one with the lower p-value (p=0.08, using a t-test). The anatomical region was statistically significant (p=0.01, using a Fisher exact test) as well as the patient age (p=0.01, using a t-test). For the logistic regression, the AUC for the train data was 0.88 and for the test data was 0.80, showing a good fit with the observed results. **Conclusion:** The proposed quantitative approach to diagnose SE using 99mTc-HMPAO-SPECT, shows a good correlation with the final diagnosis. **References:** None.

EP-0868

The Impact Of Reference Region Choice On The Apparent Ordering Of Amyloid Deposition

F. Heeman[1], M. Yaqub[1], L. Collij[1], S. Ingala[1], G. Salvadó[2], A. Wink[1], P. Visser[1], B. N. M. van Berckel[1], J. D. Gispert López[2], F. Barkhof[1,3], A. A. Lammertsma[1], I. Lopes Alves[1], o. the AMYPAD consortium.[1];
[1]Amsterdam UMC, Vrije Universiteit Amsterdam, Radiology and Nuclear Medicine, Amsterdam Neuroscience, Amsterdam, NETHERLANDS, [2]BarcelonaBeta Brain Research Center, Barcelona, SPAIN, [3]Institute of Neurology and Healthcare Engineering, University College London, London, UNITED KINGDOM.

Aim/Introduction: Capturing the initial stages of amyloid-beta accumulation is essential both for improving diagnosis of early Alzheimer's disease and selecting individuals for secondary prevention trials. To this end, several studies have attempted to identify the first regions that show amyloid pathology. Some of these developed staging frameworks, showing a temporal ordering of regions becoming amyloid positive[1]. Major differences in methodology between these studies exist, especially with respect to the reference region used for normalization. Therefore, the aim of this study was to assess the impact of different reference regions on the apparent ordering of regional amyloid pathology. Furthermore, since the standardized uptake value ratio (SUVr) may be biased by confounders, corresponding models were developed for the non-displaceable binding potential (BP_{ND}). **Materials and Methods:** Dual-time-window [18F]flutemetamol-PET scans and T1-weighted MR images (N=189, Table1) were included and preprocessed as described previously[2]. SUVr (90-110 minutes post injection) and parametric BP_{ND} images (obtained using receptor parametric mapping (RPM)[3]) were generated based on three reference regions ((RR), cerebellar grey matter (CBGM), whole cerebellum (WCB) and cerebral white matter (CRWM)). To this end, RPM's basis function (BF) settings were optimized, by correlating BP_{ND} obtained for all sets of BF settings, per RR, with regional BP_{ND} obtained using the simplified reference tissue model (SRTM) with CBGM as RR. Resulting images were warped into MNI space and global and regional values were extracted. For each set of global BP_{ND}+1 and SUVr values, Gaussian Mixture Modeling was used to define positivity cut-offs as the mean +2SD of the left (low amyloid) distribution. Next, these cut-offs were applied to all regions and those were ordered according to the frequency of positivity across the cohort. Finally, the

resulting ordering was compared between reference regions and metrics (SUVr vs BP_{ND}) using Spearman's rank correlation. **Results:** Orderings derived from BP_{ND} and SUVr images, using CBGM as RR, showed high correlation (ρ=0.93). Furthermore, this BP_{ND} derived ordering showed a high correlation with BP_{ND} derived orderings using WCB and CRWM as RR (ρ=0.97), the same was true for the SUVr derived ordering (CBGM) compared to SUVr derived orderings using WCB and CRWM as RR (range of ρ=0.98 and 0.99). **Conclusion:** The ordering of regional amyloid positivity appears to be robust against the choice of reference region. **References:** 1.Grothe et al.(2017)Neurology 89(20),2031-2038 2.Konijnenberg et al.(2018)Alzheimer's research therapy 10(1),75. 3.Gunn et al.(1997)Neuroimage 6(4),279-287.This work has received support from the EU-EFPIA Innovative Medicines Initiatives 2Joint Undertaking (grant No115952).

MR-guided partial volume correction of 3D PET images using a split Bregman optimized parallel level set framework

Y. Zhu[1,2], *A. Rahmim*[2,1];
[1]*Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA,* [2]*University of British Columbia, Vancouver, BC, CANADA.*

Aim/Introduction: Quantitative accuracy of PET images is influenced by the partial volume effect. In this work, we propose and evaluate a post-reconstruction partial volume correction (PVC) method with subtle MR-based guidance through parallel level set (PLS) regularization. The objective function is minimized with a non-smooth optimization technique, which avoids blurring of recovered images compared to smooth optimization. We compare performance against PLS solved with conventional smooth optimization and region-based voxel-wise (RBV) PVC. **Materials and Methods:** We utilized least-squares fidelity term (having knowledge of the blurring point spread function (PSF) kernel) along with MR-guided PLS regularization to formulate post-reconstruction PVC of PET images. To solve the minimization problem, we developed a non-smooth optimization technique based on the split Bregman method. An auxiliary variable was introduced to decouple the non-smooth part from the original problem. The non-smooth subproblem could then be efficiently solved with soft-thresholding. For the rest of the problem, we reached the approximate solution with a one-step steepest descent method to enable efficient 3D implementation. The proposed method was then assessed using the BrainWeb phantom and realistic PET simulations (n=20 noise realizations), followed by OSEM reconstruction (10 subsets, 24 iterations). Different PVC algorithms were assessed. Since RBV requires segmentation of MR images, we investigated both perfect segmentation and realistic segmentation obtained by segmenting BrainWeb MR images using SPM12. Mean percentage bias and coefficient of variability (COV) were computed. For comparison, regularization parameters in PLS methods were tuned to generate matched COV relative to RBV method. **Results:** For matched COV values (~18% for gray matter (GM) and ~42% for white matter (WM)), both RBV and PLS provided reduced bias compared to results obtained directly from pure OSEM reconstruction (27.5% for GM and 48.8% for WM). Among these methods, RBV with exact segmentation generated lowest bias (6.0% for GM and 7.4% for WM). The quantitative accuracy of non-smooth optimized PLS (bias: 11.9% for GM and 21.7% for WM) was significantly ($p<0.01$; paired t test) better relative to RBV with SPM12 segmented MR (13.8% for GM and 23.6% for WM) as well as smooth optimized PLS (18.0% for GM and 31.9% for WM). **Conclusion:** We propose a non-smooth optimized PLS method for post-reconstruction PVC of PET with subtle MR-guidance. The method shows better performance relative to smooth optimized PLS and RBV for realistic segmentations. **References:** None.

[18F]FDG PET/MR brain studies: Dependency of image-derived input function on the defined volume-of-interest and its radiotracer environment

Aim/Introduction: To show that accurate modelling of the tracer distribution in the volume-of-interest (VOI) and its corresponding background is necessary to perform an effective partial volume correction (PVC), for the purpose of calculating an accurate Image-derived input function (IDIF). **Materials and Methods:** Ten healthy controls underwent test-retest [18F] FDG brain PET/MRI examinations in a fully-integrated PET/MR (Siemens Biograph mMR). The imaging protocol consisted of a 60-min PET list-mode acquisition along with parallel MR acquisitions comprising of a 3D time-of-flight MR angiography (MRA), T1-MR and high-speed MR navigators for monitoring subject motion. Arterial blood samples (AIF) were collected as reference standard. A low-dose CT scan was performed for the purpose of attenuation correction. An automatic segmentation algorithm was used to segment three different regions (petrous, superior cervical and inferior cervical) of the internal carotid arteries from the MRA images. A brain mask was calculated from T1-w MR using SPM 12. This was done to correct for the spill-out from the brain to the artery. Motion vectors from MR navigators were used for motion correction. To recover the apparent tracer activity in the carotids, an iterative Mueller-Gartner PVC algorithm, which is aware of the spatial and temporal variability of the petrous background region was used. This bias was specifically introduced to identify the dependency of VOI and its radiotracer background on the calculated IDIF. Absolute percentage differences of the area-under-the-curve (AUC) between the IDIFs obtained from the different VOIs and AIF were calculated and reported. **Results:** Assessment of the percentage difference between AUC of IDIFs and AIF was

(1.5 ±1.0) % for petrous, (10 ±10) % for superior portion of the cervical and (30 ±20) % for the inferior portion of the cervical. **Conclusion:** The implemented PVC performed the best for petrous, with the IDIF deviating from AIF by less than 3%. Since the PVC was implemented only with the accurate modelling of the petrous region's tracer environment, the PVC performed better in the petrous region, in comparison to superior or inferior cervical. Based on our results, we have identified that, to obtain an accurate IDIF, a PVC with an accurate modelling of the VOI and its radiotracer environment is necessary. **References:** None.

MRI-guided Voxel-based Automatic Semi-quantification of Dopamine Transporter Imaging

J. Trnka, P. Dusek, D. Zogala, V. Ptacnik;
General University Hospital and Charles University, Prague, CZECH REPUBLIC.

Aim/Introduction: Functional imaging with ^{123}I-FP-CIT SPECT (DaTScan™) suffers from poor spatial resolution resulting in partial-volume effect in the striatal regions, which affects the subsequent semi-quantification. Definition of regions of interest for semi-quantification is further subject to user's experience and inter-observer variability. The aim of this work has been to develop an automatic method for definition of volumes of interest and partial-volume correction using patient-specific MRI and providing complete contrast recovery. **Materials and Methods:** The procedure consists of spatial pre-processing (MRI and SPECT/CT image registration and segmentation), partial-volume correction in SPECT images, and calculation of uptake indices in striatal regions. Spatial preprocessing was implemented in FMRIB software library. Partial-volume correction was performed by region-based voxel-wise (RBV) technique provided by PETPVC tool. Expected spatial resolution required by RBV method was estimated using anthropomorphic striatal phantom. Uptake indices were calculated for the whole striata, caudate nuclei, and putamina. Linearity and reproducibility were assessed. **Results:** It was possible to find a value of expected spatial resolution which provided complete contrast recovery in striatal phantom measurements for given acquisition and reconstruction conditions. Deviation of uptake indices from expected linear behavior was less than 0.15 in terms of RMSE. The reproducibility between repeated measurements was 3-7% depending on the simulated uptake ratio. Due to its nature, the method did not exhibit any inter/intra-observer variability. **Conclusion:** The proposed method provides complete recovery of striatal uptake. It can reduce inter/intra-observer variability, accurately define and localize volumes of interest, and effectively suppress partial-volume effect. Its results can be used for research purposes. The method can be reproduced using publicly available software. **References:** None.

Estimation of the spatial resolution of [^{18}F]-FDG brain PET(MR) scans using phantom measurements and human scan data

A. Marques da Silva[1], *G. Schramm*[2], *J. van Aalst*[2], *N. Mertens*[2], *K. Van Laere*[2], *M. Koole*[2];
[1]*PUCRS, Porto Alegre, BRAZIL,* [2]*KU Leuven, Leuven, BELGIUM.*

Aim/Introduction: Three practical approaches were compared to directly measure the spatial resolution of [^{18}F]-FDG brain PET(MR) using either the NEMA image quality (IQ) phantom, the Hoffman brain (HB) phantom or human PET/MR datasets. **Materials and Methods:** All scans were performed on a GE Signa PET/MR. IQ phantom data were obtained as part of NEMA acceptance procedures (10min acquisition, with 8:1 sphere to background ratio). HB phantom data were acquired using a 20min PET-only protocol. Five [^{18}F]-FDG human brain PET/MR datasets were obtained by the simultaneous acquisition of a 20min PET and anatomical MRI. For IQ and HB phantoms, attenuation correction (AC) was performed using a built-in template and a CT-based attenuation map, respectively. For human PET/MR data, a template-based MR-AC map was used. PET reconstructions were based on TOF information and OSEM (192x192x89 matrix, 1.6x1.6x2.8mm voxelsize), with 4 iterations, 28 subsets, and resolution modeling. An isotropic Gaussian postfilter with varying Full Width at Half Maximum (range: 3-8mm FWHM) was used to generate PET data with different spatial resolution. For IQ phantom, the reconstructed PET resolution was determined as the optimal Gaussian filter to match the measured radial profile through the different spheres, with the underlying theoretical profile modeling the sphere size, cold sphere edge and 8:1 sphere to background ratio. For the HB phantom, the compartments mimicking gray matter (GM), white matter (WM) and cerebrospinal fluid (CSF) were segmented using a CT scan and the PET resolution was determined as the optimal Gaussian filter for a partial volume correction using GM, WM and CSF maps to reconstruct the GM activity concentration [1]. For the human PET/MR data, an SPM12-based segmentation of the anatomical MR was performed, and the PET resolution was estimated as the optimal Gaussian filter for the segmented GM and WM tissue maps to reconstruct the PET data while assuming constant GM and WM activity concentrations. **Results:** For a clinically relevant Gaussian postfilter of 5mm FWHM, the estimated PET resolution was 5.7, 5.6 and 5.6 mm FWHM for the IQ phantom, HB phantom, and human PET/MR data, respectively. Additional values in the table included. **Conclusion:** Since all approaches provided very similar spatial resolution estimates, human PET/MR datasets can be considered to evaluate or monitor the spatial resolution of reconstructed [^{18}F]-FDG brain PET (MR) datasets and to align [^{18}F]-FDG brain PET(MR) imaging protocols in terms of resolution across centers and PET(MR) systems. **References:** [1] Muller-Gartner et al. JCBFM 1992.

Aim/Introduction: [18F]FPEB is a radioligand that affords high specific binding to metabotropic glutamate V receptors (mGluR5) in early clinical trials (1). We aim to evaluate the pharmacokinetics of [18F]FPEB and quantify regional brain distribution of mGluR5 in healthy Asian individuals. **Materials and Methods:** Five healthy volunteers (HVs) completed one or two [18F]FPEB dynamic 90 min PET scans. Arterial blood samples were collected for arterial input function and metabolite correction. Twelve cerebral region of interests (ROIs) were defined using magnetic resonance imaging (MRI) brain atlases and individual anatomical images, which included the neocortex (frontal, temporal, parietal and occipital cortices), subcortical regions (putamen, caudate) and limbic regions (amygdala, hippocampus, thalamus and the cingulate gyrus), the pons and cerebellum. One- and two-tissue compartment models (1TC, 2TC) and the Logan plot were applied to the regional time activity curves (TACs) to calculate regional distribution volumes (V_T) and binding potential (BP_{ND}). The simplified reference tissue model (SRTM2) was also used to estimate BP_{ND}. The pons was used as a reference region, as it showed low receptor expression. **Results:** The tissue TACs peaked within 5 minutes of tracer injection, with varying degrees of retention across regions. The highest uptake was seen in the putamen and insula, and lowest uptake in the pons. The 2TC and the reference tissue models showed a good fit to the data, but poor fitting was observed with the 1TC model. Good correlation between the V_T estimated by 2TC and the plasma reference graphical analysis (PRGA) was found. The PRGA showed the best fit for V_T across all regions, with standard errors <10% in > 75% of fits. The reference tissue models showed consistent estimates of $BP_{ND,}$ The BP_{ND} (SRTM2) of the basal ganglia, in the regions of the caudate nucleus and thalamus are 1.38 ±0.54 and 0.88±0.17 respectively, while the BP_{ND} of the insula and cortices, in the frontal, parietal and temporal lobes are 1.85±0.37, 1.55±0.32, 1.48±0.32, 1.54±0.31 respectively (2). **Conclusion:** We observed consistent values of V_T and BP_{ND} using PRGA and SRTM2 methods; these are appropriate models for analysing quantitative [18F]FPEB dynamic PET imaging of mGluR5 in the Asian population. **References:** 1. de Laat B, et al Preclinical Evaluation and Quantification of 18F-FPEB as a Radioligand for PET Imaging of the Metabotropic Glutamate Receptor 5. 2. Aim/Introduction: Quantitative assessment of the central nervous system metabolism with FDG-PET is usually calculated via standardized uptake values (SUV), and/or SUV ratios (SUVr). The choice of the denominator reference region influences data reliability within and between patients. As part of a larger project DistressBrain to examine associations between negative affect and brain regional metabolism in metastatic breast cancer (mBCa) patients, we investigated the optimal SUVr reference region in these patients. **Materials and Methods:** Forty-four female mBCa patients (60±11 y.o.) without brain metastases underwent two brain FDG-PET exams on the same day, 30-45 minutes and 3 hours post-injection (p.i.). A dataset of FDG-PET images acquired 30-60 minutes p.i. from a healthy group of twenty-eight female (76±5 y.o.) from the Alzheimer's Disease Neuroimaging Initiative was used as control group. All images were spatially registered to the Montreal Neurological Institute space. Voxel-wise statistical analysis was performed using the statistical parametric mapping (SPM12) toolbox. A paired t-test was used to search for SUV differences between 30-45 minutes and 3 hours p.i. Then, several reference regions were tested for intensity normalization: whole-brain, thalamus, striatum, pons and cerebellum. A two-sample t-test, with correction for age, was used to compare metabolic uptake patterns between the mBCa 30-45 min p.i. versus controls, per each reference region. A voxel-wise p-value of 0.05 with family-wise error correction for multiple comparisons was applied. **Results:** Overall brain SUVs were higher at 3 hours than 30-45 minutes p.i. with statistically significant differences only in the occipital cortex. Pons and cerebellum normalization originated significant higher SUVr values at 3 hours in all cortical and subcortical regions. mBCa patients showed insular, striatal and inferior frontal gyrus (BA 44, 45) hypometabolism compared to controls using the pons as reference region. Whole-brain and cerebellum normalization only depicted a small hypometabolic region in the insula. Normalization to the thalamus or striatum originated no significant differences between patients and controls. There was no area of significantly higher SUVr in the mBCa group in comparison with the controls whatever reference region used. **Conclusion:** mBCa patients showed higher occipital FDG uptake at 3 hours than 30-45 minutes p.i. Therefore, this brain region is not adequate for denominator reference to calculate SUVr.

Normalization by the pons appears more sensitive to distinguish brain metabolic pattern differences between mBCa and controls than other reference regions tested. This suggests no significant influence of mBCa patients' treatments in pons uptake. Financial support: FCT; PTDC/MHC-PSC/3897/2014. **References:** None.

EP-0875

Impact and correction of white matter spill-in counts on amyloid PET quantification

J. Silva-Rodríguez[1], *F. J. López-González*[2], *A. Moscoso*[1], *N. Efthimiou*[3], *P. Aguiar*[2];
[1]*Health Research Institute of Santiago de Compostela, Santiago de Compostela, SPAIN,* [2]*Universidade de Santiago de Compostela, Santiago de Compostela, SPAIN,* [3]*University of Hull, Hull, UNITED KINGDOM.*

Aim/Introduction: The partial volume effect (PVE) is one of the most prominent issues of amyloid(Aβ) PET quantification. PVE produces the spill-in of white matter (WM) counts into the gray matter (GM). This effect will be especially relevant in amyloid-negative images (low GM counts), such as those used for the estimation of SUVR thresholds, and highly dependent on WM uptake. In this work, we are aimed at providing a systematic study of the impact of WM spill-in counts on these cases and to evaluate the performance of different PVE correction methods. **Materials and Methods:** We examined 122 AV-45 PET images from cognitively normal patients recruited for ADNI2. Resolution standardization was carried out by smoothing to a resolution of 8-mm (ADNI) and by applying two PVE corrections: iterative Yang (iY) and regional voxel-based (RBV). SUVR values were normalized by using the cerebellum GM ($SUVR_{CGM}$) and the whole cerebellum ($SUVR_{WC}$) as reference regions. Amyloid-positive patients according to ADNI's $SUVR_{WC}$=1.11 were excluded. WM SUVR values were obtained for both the segmented and eroded WM ($SUVR_{WM}$ and $SUVR_{EWM}$). The variability of $SUVR_{WM}$ across the sample was studied. The correlations between SUVR and WM uptake were studied for all cases. We also tested a simple analytical correction based on the linear fitting of a subset of the data. **Results:** $SUVR_{WM}$ followed a Gaussian distribution with an average of 1.79 and a standard deviation of 0.24. Linear correlations were observed between $SUVR_{WM}$ and $SUVR_{CGM}$ (slope=0.28, Pearson's r=0.82) and $SUVR_{WC}$ (slope=0.13, r=0.64) for the smoothed data. These correlations were independent of using the whole WM or the eroded WM. When applying PVC, we observed a reduction on this effect (r=0.24 for iY, r=0.31 for RVB, both for $SUVR_{CGM}$). As a counterpart, PVC significantly biased SUVRs, which would invalidate the usage of SUVR thresholds calculated without PVC. The proposed analytical correction decreased the dependence of $SUVR_{CGM}$ (r=0.29) and $SUVR_{WC}$ (r=0.22) with $SUVR_{WM}$, while maintaining similar SUVR values, which makes it interesting to correct previously preprocessed data. **Conclusion:** We observed a significant variability of SUVR associated with the variations on WM uptake across patient samples and harmonization approaches. Resolution harmonization by image smoothing increased the effect significantly. These results can be helpful when designing new harmonization strategies, and might also explain some recent results showing that reference regions including WM (as in $SUVR_{WC}$) provide better quantification results, as the inclusion of WM will partially compensate the spill-in counts. **References:** None.

EP-0876

Feasibility of a Brainstem and Diencephalon Atlas in FDOPA PET / MRI Imaging

G. Demonceau[1,2], *Q. Demonceau*[1], *V. Lebon*[1,3];
[1]*CEA-SHFJ Orsay, Paris, FRANCE,* [2]*Bois de l'Abbaye, Liège, BELGIUM,* [3]*University Paris Sud, Paris, FRANCE.*

Aim/Introduction: to constitute an atlas of FDOPA uptake in the brainstem and diencephalon from images acquired in PET / MRI: the registration of the images on a reference model was carried out in MRI and then applied to PET images, the validation of the results taking place mainly in PET. **Materials and Methods:** we retrospectively selected 35 patients who underwent FDOPA PET / MRI: 15 considered as positive for dopaminergic denervation (visually decreased putaminal activity), 20 considered as normal (the control group). After reconstruction of the tomographic sections, the T1 images of each patient were registered on the T1 images of a reference model where several anatomical regions had been previously identified. The registration was carried out in a progressive way, in non-deformable and then deformable mode, after creation of a mask including the brainstem, the diencephalon and the striatum. The registration parameters were then applied to the FDOPA images acquired 90 min after injection. The choice of the optimal method of registration was based on the analysis of the dispersion of the activity in the summed image of the control group. A score was created, multiplying each SUV of each voxel of a predefined area by the spatially corresponding SUV in the model. Eight areas of the brainstem were used to create the final score. We finally investigated the correlation between the scores of 70 deformable registrations and the ability of specific brain regions to discriminate, using those registrations, the parkinsonian from the normal patients. **Results:** visually the images of the brainstem, diencephalon and striatum are correctly replaced after registration in all patients, without deformation. No manual correction was needed. A significant inverse correlation (Pearson's coefficient; p-values less than 0,0001) was found between the 70 scores and the corresponding p-values of a Student t-test comparing the control and patient groups in 5 non-striatal regions: the epiphysis, the hypothalamus, the pulvinar, the raphe nuclei and the substantia nigra. Furthermore, using the registration method with the highest score, two of those regions (the substantia nigra and the hypothalamus) exceeded the level of signification. Those statistical characters were also observed in well validated regions in Parkinson's disease, the caudate and the putamen. **Conclusion:** using the hybrid PET / MRI technique, it

is possible to reliably achieve an automatic analysis of FDOPA uptake in brainstem and diencephalon nuclei. The method is independent of the injected tracer, which broadens its scope. **References:** None.

EP-0877

Is I-123-MIBG cardiac SPECT-CT with attenuation and scatter correction a useful tool for the diagnosis of prodromal Lewy body disease compared to planar scintigraphy?

G. Roberts[1], *J. Lloyd*[2], *G. Petrides*[2], *K. Howe*[2], *T. Ali*[2], *R. Durcan*[1], *S. Lawley*[1], *H. Kain*[1], *P. Donaghy*[1], *J. O'Brien*[3], *A. Thomas*[1];
[1]*Newcastle University, Newcastle upon Tyne, UNITED KINGDOM,* [2]*Newcastle upon Tyne Hospitals, Newcastle upon Tyne, UNITED KINGDOM,* [3]*University of Cambridge, Cambridge, UNITED KINGDOM.*

Aim/Introduction: 123-I MIBG (meta-iodobenzylguanidine) cardiac imaging for sympathetic denervation is a validated diagnostic biomarker for dementia with Lewy bodies (DLB) and is listed as an indicative biomarker in the 2017 international consensus criteria for DLB diagnosis. There has been very little research in the diagnostic accuracy of cardiac MIBG in the prodromal stages of DLB or in the advantage of attenuation and scatter corrected SPECT-CT compared to planar imaging. We aimed to evaluate this in subjects with either MCI due to Lewy body disease (MCI-LB) or due to Alzheimer's disease (MCI-AD). **Materials and Methods:** An anthropomorphic chest phantom was filled with I-123 solution using activities typical of healthy subjects. The phantom was scanned on a Siemens Intevo with MELP collimators using both planar and SPECT-CT techniques. Further scans were acquired with a PMMA chest plate added, then breasts. The SPECT-CT images were reconstructed using OSEM with resolution recovery, attenuation and scatter correction (ACSC) applied.Twenty-nine healthy controls, 24 MCI-AD and 32 MCI-DLB subjects aged over 60 years were recruited and assessed clinically as part of a research study. Their diagnoses were confirmed by a panel of three expert old age psychiatrists. All were administered 111±10% MBq I-123-MIBG and imaged at 4 hours ±30 minutes using standard planar imaging, followed by SPECT-CT. SPECT images were reconstructed as above. The heart-to-mediastinum ratios on planar images (HMR_planar) were calculated using a circular cardiac region and rectangular mediastinum region, with corresponding spherical and cuboid regions for HMR_SPECT. **Results:** Phantom HMR_planar decreased by 20% with the PMMA plate added; 39% with plate and breasts. Cardiac counts with ACSC SPECT showed less dependence on phantom size than SPECT without ACSC (5% vs 33%). There was a significant linear relationship between HMR_planar and BMI ($p<0.01$, $R^2=0.44$) in healthy controls, but no significant relationship for HMR_SPECT ($p>0.1$, $R^2=0.03$). Healthy controls were used to provide reference ranges for HMR_planar and HMR_SPECT (mean±2SD). 20/24 MCI-AD cases had normal scans with planar and 21/24 with SPECT-CT. 17/32 MCI-LB cases were abnormal on both planar and SPECT-CT. The difference between mean HMR for normal and abnormal scans was much greater for SPECT-CT than planar. **Conclusion:** By reducing variation due to patient size, SPECT-CT improves separation between normal and abnormal cardiac MIBG scans, with a small improvement in MCI diagnostic accuracy. In clinical practice, SPECT-CT may be useful in borderline cases where the planar image result is unclear. **References:** None.

Aim/Introduction: Interictal ^{18}F-FDG PET has currently acknowledged the primary imaging modality for the presurgical metabolic assessment for focal epilepsy. Because of the localisation of the epileptic focus needs to be assessed at the individual patient level the Statistical Parametric Mapping (SPM) may be the best method for semi-quantitatively comparing a patient to a healthy database. Unfortunately, large datasets from healthy subjects are not yet available for ^{18}F-FDG PET/MRI, limiting the possibility of providing an accurate statistical evaluation of individual patient data. As an alternative, for quantifying the differences between hemispheres, the proposed application is the Asymmetry Index (AI) based seizure-zone localisation. The simultaneously measured functional and anatomical PET/MRI images and the availability of most advanced neuroimaging software allows the automatic evaluation of regional AI data in native space and MNI152 atlas space, as well. We aimed to compare the sensitivity of the native- and atlas space-based regional AI (rAI) calculation techniques with the SPM results in a selected temporal lobe epileptic patient's group. **Materials and Methods:** From our lab's FDG-PET/MRI Epilepsy Database we selected 36 patients (age ranges between 15 and 57, mean = 29.7 ± 10.1) whose large (> 3 cm^3) lateralised hypometabolic area was identified in the temporal lobe by SPM after the comparison with the control population of 19 subjects. In parallel with the SPM analysis, we generated Harvard-Oxford cortical atlas-based rAI data in MNI152 space (HO-rAI), and FreeSurefer segmentation (based on Desikan-Killiany Atlas) induced rAI in native-space (FS-rAI). We characterised the sensitivity of a rAI calculation methods by the maximal absolute value of rAI data measured in the temporal lobe regions. Because of the non-normality of data, we applied the paired Wilcoxon test to compare the rAI values, and Spearman's rank correlation coefficient to assesses the relationship between rAI and SPM's

t-max value. **Results:** We found that the rAI calculation in atlas space resulted in significantly (p = 0.0006) higher rAI values than the native-space parcellation technique. We also found a strong correlation between t-max and HO-rAI (rho= 0.547, p< 0.0001) and FS-rAI (rho= 0.603, p< 0.0001). **Conclusion:** Although we consider the cortical parcellation in native space as a subject-specific region delineation method, the usage of these regions for detecting asymmetry in FDG-PET images is not so sensitive than the rAI calculation in MNI152 space. (Acknowledgement: This research was granted by the EFOP-3.6.2-16-2017-00008 project.) **References:** None.

Correction of head motion and attenuation map realignment in PET/MR studies: comparison between PET-image based and EPI-image based methods

C. R. Brambilla[1,2,3], O. Zeusseu[1,4], J. Scheins[1], E. R. Kops[1], L. Tellmann[1], N. J. Shah[1,5,6], I. Neuner[1,7,6], C. Lerche[1];
[1]Institute of Neuroscience and Medicine 4, INM-4, Forschungszentrum, Jülich, GERMANY, [2]Department of Psychiatry, Psychotherapy and Psychosomatics, RWTH University, Aachen, GERMANY, [3]Faculty of Medicine – Faculty 10, RWTH University, Aachen, GERMANY, [4]Department of Medical Physics, HTW des Saarlandes, Saarbrücken, GERMANY, [5]Institute of Neuroscience and Medicine 11, INM-11, JARA, Forschungszentrum Jülich, Jülich, GERMANY, [6]JARA - BRAIN - Translational Medicine, Aachen, GERMANY, [7]Department of Psychiatry, Psychotherapy and Psychosomatics, RWTH Aachen University, Aachen, GERMANY.

Aim/Introduction: Dynamic PET is a method to analyze metabolic aspects of the brain using the time course of the activity distribution for deriving quantification parameters. In these studies, as data acquisition frequently lasts more than 1.0 h, head motion can degrade accuracy of the time activity curves (TACs), leading to erroneous quantification results. In addition, it also can lead to mismatches between the attenuation map and the subsequent PET frames affecting the final quantification. The aim of this work was to evaluate two head motion correction (MC) methods in a PET/MR study with [^{11}C]ABP688 bolus-infusion protocol. **Materials and Methods:** PET-image based method (M1): PET images were reconstructed according to a predefined framing scheme without attenuation and scatter corrections. For these dynamic images (non-MC), co-registration with respect to a reference image was done with PMOD [1] and the inverse rigid movement parameters were extracted and applied to each of the single attenuation maps. Subsequently, the Multiple Acquisition Frame (MAF) method [2] was used for image reconstruction using the matched attenuation maps. In a last step, the rigid transformation was applied to the attenuation corrected PET images generating the MC images. EPI-image based method (M2): EPI images (3 volumes) were repeatedly acquired during the dynamic PET study. They were acquired before and after the T1 anatomical acquisition (AC reference) at several timepoints before and after further MR sequences as part of an fMRI study during the last 30 minutes of the PET acquisition. For all EPI images, a realignment with respect to the very first EPI image was done with SPM12 [3] and inverse rigid movement parameters were extracted and applied to the static attenuation map. Subsequently, MAF was used for image reconstruction using the newly created dynamic and matched attenuation maps. Finally, rigid transformation was applied to the AC PET image frames of the entire dynamic acquisition. **Results:** We have evaluated the M1 method for a measurement using [^{11}C]ABP688 with 2.5 minutes frames during 65 minutes of PET acquisition [4]. After applying M1, visible misalignment between images disappeared and "jumps" in TACs were reduced. The M2 method is currently being analyzed. **Conclusion:** Both methods allows semi-automatic detection and compensation of inter-frame motion without additional tracking hardware. Both methods are expected to improve the accuracy of TACs in case of subject's motion in dynamic PET studies. **References:** [1] www.pmod.com/web/ [2] IEEE TMI, 16, 1997, 137-144. Acquisition period of amyloid PET imaging using [^{18}F]Florbetapir can be compressed without alteringstandardized uptake value ratios

K. Wgatsuma[1], M. Sakata[1], K. Ishibashi[1], K. Miwa[2], N. Kojima[1], Y. Osuka[1], H. Kim[1], K. Ishii[1];
[1]Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN, [2]International University of Health and Welfare, Otawara, JAPAN.

Aim/Introduction: The durations of uptake and acquisition time for the positron emission tomography (PET) image using [^{18}F]Florbetapir differ according to the purpose. The recommended uptake time ranges from 30 to 50 min post-injection, then image acquisition takes 10 - 20 min thereafter. Therefore, the duration of the entire procedure can range from 40 to 70 min. The present study aimed to evaluate the accuracy of quantitative PET measures acquired over a shorter scanning using [^{18}F]Florbetapir. **Materials and Methods:** Images were acquired from nine individuals (mean age, 84.4 y) using a Discovery MI PET/CT system (GE Healthcare). The mean injected dose of [^{18}F]Florbetapir was 352.1 MBq and two 20-min scans were performed starting at 30 and 50 min post-injection. The datasets were reprocessed to produce the following sets of sinograms: 30 - 35, 30 - 40 and 30 - 50 min and 50 - 55, 50 - 60, and 50 - 70 min after radiopharmaceutical administration, then the images were reconstructed under clinical conditions. All [^{18}F]Florbetapir images were separately normalized to a standard [^{18}F]Florbetapir template using Amygo neuro software (FUJIFILM Toyama Chemical Co. Ltd.). Anatomical volumes of interest (VOI) were automatically placed on seven regions. Mean cortical (cSUVR) and regional (rSUVR) SUVR were calculated with the cerebellar value as the reference. A cSUVR of > 1.10 was defined as amyloid positive. Significant differences among cSUVR and rSUVR were determined using repeated measures one-way analysis of variance and Friedman tests. Values with

P< 0.05 were considered significant. **Results:** The mean (± SD) cSUVR in nine individuals for 30 - 35, 30 - 40, 30 - 50, 50 - 55, 50 - 60, and 50 - 70 min procedural durations were 1.00 ± 0.11, 1.00 ± 0.11, 1.01 ± 0.12, 1.03 ± 0.13, 1.03 ± 0.13, and 1.03 ± 0.13. The SUVR in amyloid-positive patients increased slightly over time even after 30 min post-injection. The amyloid positivity of two individuals was inconsistent by uptake duration. The mean cSUVR and rSUVR did not significantly differ according to multiple comparisons except for those of the medial frontal regions. **Conclusion:** [^{18}F]Florbetapir imaging offers stable quantitative values even over durations as short as 5 min because the standard [^{18}F]Florbetapir protocol includes a larger dose and shorter uptake duration than PET imaging with other approved [^{18}F] labeled amyloid tracers. However, differences in uptake duration might affect the diagnostic outcomes of amyloid PET. **References:** Tiepolt S, et al. EJNMMI.2013;40:238-44.

EP-0881

Test-retest reliability of adenosine A_{2A} binding in the human brain with ^{11}C-preladenant-PET

M. Sakata[1], *K. Wagatsuma*[1], *T. Tago*[1], *K. Ishibashi*[1], *K. Ishii*[1], *K. Ishiwata*[1,2,3], *J. Toyohara*[1];
[1]*Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN,* [2]*Southern Tohoku Research Institute for Neuroscience, Koriyama, JAPAN,* [3]*Fukushima Medical University, Fukushima, JAPAN.*

Aim/Introduction: The aim of the present study was to evaluate the reproducibility of cerebral adenosine A_{2A} receptor (A2AR) quantification using ^{11}C-preladenant and PET in a test-retest study. **Materials and Methods:** Dynamic ^{11}C-preladenant PET scans (90-min) were performed twice for each subject in eight healthy male volunteers (26 ± 10 y.o.) using D710 PET/CT scanner (GE Healthcare). The subjects were asked to refrain from caffeine over half-day, and the time of the scans were roughly matched in each subject to avoid the effect of diurnal variation. The injected dose was 705 ± 46 MBq and the specific activity was 65 ± 19 MBq/nmol. During the scan, arterial blood was sampled at various time intervals, and the fraction of the parent compound in plasma was determined by HPLC analysis. ROIs were placed on the cerebellar cortices (as the reference region), putamen, and head of the caudate nucleus (as the target regions). According to the previous work[1], total distribution volume ratio (DVR) was estimated by Logan reference tissue method. Absolute test-retest variability (aTRV), and intra-class correlation coefficient (ICC)[2] were calculated as the index of repeatability. **Results:** The DVRs (mean ± SD (min - max), n = 8) were 5.6 ± 1.6 (2.4 - 6.9) at test scan and 5.3 ± 1.7 (1.8 - 6.9) at retest scan in putamen, and 4.4 ± 1.4 (1.8 - 6.2) at test scan and 4.1 ± 1.4 (1.4 - 5.3) at retest scan in caudate. The aTRVs of putamen and caudate were 18 ± 8 % and 18 ±9 %, respectively. The ICCs of putamen and caudate were 0.77 and 0.77, respectively. The smallest outlier of DVR was the result of the oldest (51 y.o.) subject. **Conclusion:** In this study, "moderate" test-retest reproducibility, and large inter-subject differences of ^{11}C-preladenant-PET were observed. These variances might be attributable to competition by endogenous A2AR binding ligands. The analysis of plasma caffeine concentration would be included in further studies. **References:** [1] Sakata, M, et al., JNM, 58:9, 2017. [2] Shoukri, MM, et al., BMC Med Res Methodol, 6:24, 2006.

EP-0882

Assessing regional FDG uptake in the brain in normal, low and high blood glucose levels

I. Sarikaya[1], *A. Albatineh*[1], *A. Sarikaya*[2];
[1]*Kuwait University Faculty of Medicine, Kuwait, KUWAIT,*
[2]*Trakya University Faculty of Medicine, Edirne, TURKEY.*

Aim/Introduction: Various studies have been performed to assess global or regional F-18 fluorodeoxyglucose (FDG) uptake in the brain, mainly in normo and hyperglycemia. In this study, using whole body F-18 FDG positron emission tomography/computed tomography (PET/CT) images, we assessed regional FDG uptake in multiple regions of the brain in normal, low and high blood glucose levels to understand if there are regional differences. **Materials and Methods:** In this retrospective study, whole body F-18 FDG PET/CT images were used to analyse the brain. Inclusion criteria included adult patients (age range 18-65 year-old) with no history of diseases or symptoms affecting the brain, no abnormal findings in the brain on both PET and low dose CT images, no image artefacts and no other factors affecting FDG uptake in the brain. Maximum standardized uptake values (SUVmax) were measured in lateral and medial frontal, temporal, parietal, and occipital cortices, lateral cerebellar cortex, posterior cingulate cortex, caudate nucleus, putamen, thalamus, brain stem, and scalp in patients with normal blood glucose (91-100 mg/dl), low blood glucose (61-70 mg/dl), and high blood glucose (171-200 mg/dl) levels. In each blood glucose range, fifteen (15) F-18 FDG PET images were analyzed (total 45 images). Mean ± SD of SUVmax of the brain regions for each blood glucose range was calculated and statistical analysis of the values were performed. **Results:** Mean **S**UVmax in all the assessed brain regions was significantly lower in hyperglycemia ($p<0.001$), and not different in hypoglycemia ($p> 0.05$) as compared to normoglycemia. In all blood glucose levels, FDG uptake is highest in lateral frontal cortex and lowest in medial temporal cortex and brain stem as compared to other regions of the brain. At blood glucose range of 171-200 mg/dl, hyperglycemia induced reduction in regional FDG uptake/SUVmax ranged from 55.9 % to 63.7 % (mean 60 ± 2.4) which was below 60% in medial temporal cortex, cerebellum and brain stem and above 60% in other brain regions. Mean scalp activity was lower in hyperglycemia ($p<0.001$), and not different in hypoglycemia ($p> 0.05$) as compared to normoglycemia. **Conclusion:** Gross assessment of regional glucose metabolism in the brain shows that hyperglycemia induced reduction of FDG uptake is approximately same in various regions of the brain which could be slightly less in medial temporal cortex, cerebellum and brain stem than other regions. Hypoglycemia does not seem a significant effect on regional or global FDG uptake in the brain. **References:** None.

EP-0883

Comparing Automated Regional Analysis Techniques of Neurologic ^{18}F-Fluoro-L-DOPA Images

D. Fajtai[1], *Z. Tóth*[1], *A. Fekésházy*[1], *Á. Csóka*[1,2], *A. Takács*[1], *I. Repa*[2], *M. Emri*[3];
[1]*Somogy County Moritz Kaposi Teaching Hospital, Medicopus Nonprofit Ltd., Kaposvár, HUNGARY,* [2]*Somogy County Moritz Kaposi Teaching Hospital, Dr. József Baka Diagnostic, Radiation Oncology, Research and Teaching Center, Kaposvár, HUNGARY,* [3]*University of Debrecen, Faculty of Medicine, Department of Medical Imaging, Division of Nuclear Medicine and Translational Imaging, Debrecen, HUNGARY.*

Aim/Introduction: PET imaging with ^{18}F-Fluoro-L-DOPA (F-DOPA) tracer provides a promising approach for examining various brain diseases, like Parkinson's disease (PD) which is a neurodegenerative disorder resulted as a progressive loss of dopaminergic neurons in the basal ganglia. In the case of PD, the neurons in the putamen were the most impaired compared to other segments of basal nuclei, and this can help to distinguish PD from other movement disorders. The decreased tracer intake in the putamen can be detected with proper segmentation and intensity normalisation, while the hemispherical differences can tell more about the severity of the PD. With the simultaneously acquired functional and anatomical PET/MRI images the problem of spatial registration of the MRI and PET images is theoretically solved, which simplifies the segmentation of basal ganglia, and so provides the automatization of the atlas-based regional analysis (AROI). For AROI calculation we implemented two techniques: a fast, less-accurate segmentation algorithm (F-AROI) and a slow, anatomically accurate method (S-AROI). We aimed to examine how the usage of the F-AROI and the S-AROI technique influence the calculated regional values. **Materials and Methods:** We used nine patient's T1 MR and F-DOPA PET image, examined with PET/MR in our facility. In both methods after the T1-based segmentation, we calculated the normalised ROI values using the mean F-DOPA uptake of the occipital fusiform gyrus as a normalisation factor. In the segmentation part of F-AROI we used the components of the FSL package, while in the S-AROI we applied the "recon-all" pipeline of FreeSurfer. Using these methods we evaluated the normalised ROI value of the dorsal and ventral putamen, caudate nucleus (CN), nucleus accumbens (NACC) and the CN+NACC region, in both hemispheres of all subjects. Because of the non-normality of data, we applied the paired Wilcoxon test with FDR correction to compare the normalised ROI values. **Results:** The statistical tests resulted that the choice of the algorithm has no significant effect ($p > 0.91$ in all cases) on the measured regional averages. **Conclusion:** The faster FSL based algorithm can reproduce the results of the FreeSurfer based slower method. On the other hand, we have found that the FreeSurfer segmentation process may tend to fail because of high volume structural abnormalities inside the brain, while the FSL based algorithm can serve useful results if the basal ganglia is not affected by the anomaly. EP-0884

Optimization of time acquisition of dopaminergic scan on a 360° CZT camera

P. Payoux[1], *E. Cassol*[1], *P. Blanc*[2], *N. Roth*[3], *A. Hitzel*[1], *P. Gantet*[1];
[1]*CHU Purpan, Toulouse, FRANCE,* [2]*CHG Albi, Albi, FRANCE,* [3]*Spectrum Dynamics Medical Ltd., Caesarea, ISRAEL.*

Aim/Introduction: The innovative 360-degree CZT detectors system (VERITON, Spectrum Dynamics system) proposes a higher photon sensitivity, allowing for decreased scan times and/or reduced doses. In dopaminergic assessment the minimal counts admitted for QC is up to 1.5 million. In this work, we have determined the mean time necessary to obtain this threshold. **Materials and Methods:** During March 2019, 68 subjects (38 males, 30 females) were addressed to our nuclear medicine department for dopaminergic scintigraphy. All underwent a DaTSCAN SPECT (185 MBq +/- 10%) on a Veriton system with a time acquision of 20 minutes (ref) in brain focus mode. Reconstruction parameters were following: OSEM3D 6 iterations 8 subsets; pre-iteration filter: convolution smoothing frequency 2, smoothing factor 0.125; post-filter: median filter, support 3. No correction of scatter and no correction of attenuation was applied. For each subject, an image corresponding to 1.5 million counts was extracted from the list-mode acquisition data and the time to obtain this image was calculated. Pre-time 20 minutes images and pre-counts 1.5 million counts images were analysed by 3 observers and binding potential (BP) was calculated by the DaTsoft3D quantification software. For all images, observers determine the final diagnosis, image quality and confidence. **Results:** Mean of total counts for 20 minutes acquisition was 2.4 M (>1.5 Mcounts). Pre-counts 1.5 M counts duration was 13.3 minutes on average (+33% time gain). Image analysis was similar for the original and the 1.5 Mcounts images and there was an excellent correlation of BP for the two sets of Data (0.970 for caudate nucleus, 0.988 for putamens). A small difference of the mean of binding potentials was observed: 0.12 ($p<0.0001$) for caudate nucleus and 0.06 ($p=0.0019$) for putamens. These differences are very small (in relative value 3% for caudate nucleus and 2% for putamens) and have no incidence on analysis. **Conclusion:** Based on brain focus, pre-counts 360° CZT acquisition should reduce the acquisition time of dopaminergic scan to 13.3 minutes on average with enough counts. With this acquisition mode, no modifications of diagnosis was observed compared to 20 minutes pre-time acquisitions. **References:** Assesment of a CZT camera (360°) 12 detectors for dopaminergic neurotransmission assesment. The Utility Of Technetium-99m ECD Brain Spect Using NeuroGam Software In Children With Autism Spectrum Disorder

P. Mohan[1], *G. Shroff*[2], *V. Mahajan*[3], *H. Mahajan*[3];
[1]*Mahajan Imaging Centre, New Delhi, INDIA,* [2]*NuTech Mediworld, New Delhi, INDIA,* [3]*CARING, Mahajan Imaging, New Delhi, INDIA.*

Aim/Introduction: Autism Spectrum Disorder (ASD) is one of the most prevalent disorders in child and adolescent psychiatry. The purpose of the study was to investigate perfusion patterns in children with ASD. In order to avoid missing brain lesions, we applied brain processing software NeuroGam with SPECT to evaluate and analyze the brain cerebral cortical blood flow. **Materials and Methods:** Forty children (36 boys, 4 girl; mean age: 6.9+/-1.7 years) with ASD disorder defined by DSM-III-R criteria were included in the study. Age- and sex-matched control group was also included in the study. Before arrival, patients were instructed to avoid caffeine, tea, or other drugs known to affect cerebral blood flow (CBF). To avoid head movement during scanning (20-30 min), the patient were made comfortable and relaxed. The uncooperative patients needed sedation. Tracer injection preceded sedation to avoid sedation-induced blood flow changes. Brain perfusion images were obtained 45 minutes after the intravenous injection of an adjusted dose of Tc-99m ECD to children. Visual and semiquantitative evaluations using NeuroGam software were performed. **Results:** NeuroGam software offers each corresponding region of interest expressed as a percentage of the mean pixel value in the entire volume, including the anterior cerebral, middle cerebral, and vertebral terrain. Significantly lower cortical activity was noted in the ASD group, particularly in the prefrontal regions, temporal and parietal lobes. **Conclusion:** NeuroGam software can help identify areas of cerebral cortex having significant hypoperfusion indicating decreased neuronal activity in children with ASD. Brain SPECT scan is simple, noninvasive, involves minimal radiation, and may serve as a cost-effective tool to identify children with ASD. **References:** None.

Determination of the activity of 99mTc-HMDP to be injected in adults to optimize the quality of the image

E. A. L. Bathily[1], *C. Meyer*[2], *O. Diop*[1], *F. Besson*[2], *B. Ndong*[1], *M. S. Djigo*[1], *A. Forbes*[2], *G. Grimon*[2], *K. Guèye*[1], *G. Thiaw*[1], *C. V. De Labriolle*[3], *M. Mbodj*[1], *E. Durand*[2];
[1]*Université Cheikh Anta Diop, Dakar, SENEGAL,* [2]*Biophysics and Nuclear Medicine Department, Kremlin Bicetre Hospital, Paris, FRANCE,* [3]*Nuclear Medicine Department, Armand Trousseau Hospital, Paris, FRANCE.*

Aim/Introduction: Our study is to review the habit that most often occurs to adapt the injected activity only to the patient "weight" (MBq/kg in adults), in an approach that aims to obtain a same image quality in all patients. Indeed, a large patient has a larger volume of distribution and a greater attenuation thickness; to detect the same flow of photons, it is necessary to inject more. General objective: propose an optimization of activity to be injected, by appreciation of the distribution volumes and attenuation thicknesses (AT). Specifically: - propose alternative formulas according weight, height and gender, allowing to homogenize the outgoing photon flux - compare these models to the recommendations and look at their dosimetric impact. **Materials and Methods:** The following data were recorded for130 patients who have done a 99mTc-HMDP scintigraphy at the Bicêtre hospital nuclear medicine department: gender, age, weight, height, injected activity, delay between injection and acquisition and image quality. We measured activities detected in counts/cm² at lumbar vertebra L3. Thanks to the CT, AT with regard to L3 were measured. Using linear regression analysis with R studio software, we were able to estimate the AT from the measured values. Extracellular volume (ECV) was calculated using the Christensen and Groth's formula:ECV=8117 ml / m2 x 0.00718 x (Weight) $^{0.425}$ x (Height) $^{0.725}$ - 28 ml **Results:** The measured activity in L3 was 806± 450 counts/cm². The Signal (counts / (min.cm)= surface concentration(counts/cm²) * scanning speed (cm / min). To have good image, the target signal (average) was 13140 and the target Theoretical Plasma Concentration (TCP) was 12.3 KBq / mL. The estimated AT was= 11,76905 + 0,079454* Weight - 5,133455* Height. The activity who must be injected to detect the same photon flux (Q_{target}) is thus calculated by the relation: $Q_{target} = 12.3* ECV *2^{3/6} *e^{(0,11 *AT estimated).}$ $Q_{target}= 12.3 * 8117* (0,00718 * (Weight)^{0,425} * (Height)^{0,725}) - 28 * 1,41 * e^{(0,11 * 11.76905 + 0.079454 * Weight - 5.133455 * Height).}$ Q_{target} ranged from 403 to 1400 MBq (40 to 140 kg) and between 9.2 to 11.2 MBq / kg for the weight Q_{target}. **Conclusion:** Our formulas are good alternatives in determining the activity who must be injected to minimize irradiation while optimizing image quality. Values are consistent with recommendations and diagnostic reference levels. **References:** None.

Comparison the ^{18}F-FDG regional size dependent PET segmentation method for texture analysis

S. Woo[1], *M. Cho*[1], *W. Kim*[1], *H. Sheen*[1], *K. Song*[2], *I. Lim*[1];
[1]*Division of applied RI, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Urology, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: Texture features are quantitative image

heterogeneity using ROI analysis. The regional segmentation method for ROI definition can affect the texture features. The aim of this study was to compare the PET image texture features depending on segmentation methods. **Materials and Methods:** NEMA IEC body phantom was used for PET image. ^{18}F-FDG were injected into the spheres with diameter of 22, 17, 13 and 10 mm. The ^{18}F-FDG PET image regional segment methods were used SUV 1.5, 2.0, 2.5 region growing, and edge detection. To optimize the reconstruction parameters were applied the 16, 21 subsets and TrueX with 2 iteration. Compare the calculated volume in each segment method with size of phantoms spheres. Texture features such as energy, kurtosis, and entropy were calculated using LIFEx software. To evaluate the difference of texture feature according to the segmentation method, reference segmentation method and relative change amount were calculated. **Results:** SUV 2.0 with 16 subsets and 2 iteration was no significantly difference between the actual size of phantom's spheres exclude 10 mm diameter sphere. Entropy PET images of SUV 2.0 segment methods with diameter of 22, 17 and 13 mm calculated as 0.96, 0.94 and 0.78 respectively. Energy of SUV 2.0 were calculated as 0.11, 0.12 and 0.18 respectively. Kurtosis of SUV 2.0 were obtained as 1.73, 1.89, 2.41 respectively. Entropy, energy, and kurtosis relative change with SUV 2.0 and edge detection was 0.53%, 0.85% and 2.97% change in 13 mm sphere of phantom. **Conclusion:** The result of this study was shown that optimized spheres segmentation method is SUV 2.0 in IEC phantom PET image with 16 subset and 2 iteration. The segmentation method should be considered for texture features analyzing. **References:** 1. Orlhac, Fanny, et al. "Tumor texture analysis in 18F-FDG PET: relationships between texture parameters, histogram indices, standardized uptake values, metabolic volumes, and total lesion glycolysis." EP-0888

The Prevelence of Severely Altered FDG Biodistribution - Addressing the Issue of Potentially Nondiagnostic FDG-PET/CT Scans

M. Weiler-Sagie[1], *S. Halperin*[2], *Z. Keidar*[1,2];
[1]*Rambam Health Care Campus, Haifa, ISRAEL,* [2]*Technion, Haifa, ISRAEL.*

Aim/Introduction: Changes in FDG biodistribution can reduce lesion detectability in FDG-PET/CT imaging. The prevelance of FDG PET/CT scans with severely altered biodistribution (SABD) is unclear. Insulin is known to alter FDG biodistribution and patients are therefore instructed to fast 4-6 hours prior to the scan. Hyperglycemia is known to alter FDG biodistribution and therefore SNMMI and EJNMMI guidelines recommend measurement of blood glucose level (BGL) before FDG injection and advise re-scheduling in patients with BGL > 200 gr/dL. The aim of the study was to assess the prevalence of scans with severely altered FDG biodistribution and test for correlation with BGL and other patient related and imaging related parameters. **Materials and Methods:** Two-hundred fifty-five consecutive skull-base to mid-thigh FDG-PET/CT scans from a single center were retrospectively re-reviewed. All patients are routinely instructed to fast 4-6 hours before the scan and the fasting status is re-confirmed before FDG injection. Scans were assessed by visual qualitative inspection of PET axial, coronal, sagital and MIP images for SABD. Severly altered biodistribution was defined as markedly increased diffuse muscular uptake that raises the reviewing physicians concern for a potentially non-diagnostic PET portion of the scan due to reduced lesion detectability and/or unreliable lesion standard uptake values (SUVs). Liver uptake was measured as SUVmean and SUVmax in a fixed volume of interest in the right lobe. Patients parameters including BGL measured immediately before FDG injection, age, gender, height, weight, and referral indication, were recorded. Correlation of SABD with BGL, body mass index (BMI) and liver SUVs was calculated. **Results:** Severly altered FDG biodistribution was present in 3% of scans (8 of 255). Referal indication was oncologic in 98% of the scans. The population consisted of patients 5-95 years of age. The male to female ratio was 1:1. BGL range was 68-290 mg/dL, with 151 patients (59%) with BGL >100 mg/dL, of them 8 (3%) with BGL >200 mg/dL. There was no correlation between SABD and BGL levels;(r=0.153), fasting hyperglicemia of BGL > 100 mg/dL (r=0.104), BGL > 200;(r=0.097), BMI (r=0.206), liver SUVmean (r=-0.040) or liver SUVmax (r=-0.011). **Conclusion:** The prevelance of severly altered FDG biodistribution was 3%. No correlation was found between SABD and BGL, BMI or liver SUV. Blood glucose level of > 200 gr/dL could not predict these potentially non-diagnostic scans, questioning the need for BGL measurement before FDG PET/CT scans in routine clinical practice. **References:** None.

Evaluation of SPECT Systems Performance using Carlson Phantom

R. Y. Aimazrou[1], *T. O. Aimutairi*[2], *A. K. Alosaimi*[3], *S. F. Aianazi*[4];
[1]*King Faisal Specialist Hospital and Research center, Riyadh, SAUDI ARABIA,* [2]*King Abdullah Hospital, Bisha, Bisha, SAUDI ARABIA,* [3]*King Faisal Medical city for Southern Region, Abha, SAUDI ARABIA,* [4]*Prince Mohammad Bin Abdulaziz Hospital, Riyadh, SAUDI ARABIA.*

Aim/Introduction: Evaluation of tomographic systems is essential procedure to obtain a reliable system with high-quality single photon emission computed tomography (SPECT) images. AAPM report numbers 52 recommend using Jaszczak phantom to evaluate the SPECT total performance. Whereas, many countries are using a Carlson phantom to evaluate their SPECT systems. This study is establishing reference values for the Integral uniformity (IU), root-mean-square noise (rms) and contrast measurement using a Carlson phantom as well as the number of resolved objects. **Materials and Methods:** In this study, measurement of the IU and rms of the uniform area and the contrast of the largest three spheres following the procedure described in AAPM report No.52. These measurements applied on twenty SPECT studies with and without using Chang and CT attenuation corrections. The phantom was injected with about

15-20mCi of Tc-99m activity. The phantom centered on the imaging bed. The LEHR collimators mounted on the camera. The acquisition parameters are; 140KeV peak, 20% energy window, 128x128 matrix, step and shoot mode, 128 views, 360º orbit, 400 K Counts/view, with non-circular orbit. Uniformity correction was applied to all the studies. Images were reconstructed by FBP algorithm with Butterworth filter, 0.5 cutoff frequency and order of 5. For each study, reconstructed images were evaluated visually looking for any distortion or ring artifact in the uniform area. The resolved spheres, cold and hot rods were counted, the straightness of the lines in the Mesh area were assessed. Three transverse slices were summed in the uniform region, and a 21X21 ROI pixel area used to calculate the IU and rms noise. The best slice of the spheres selected for the calculation of contrast. **Results:** Most of the studies in the uniform area showed uniform slices clear from any artifacts. The number of objects was increased when the attenuation correction was applied. Mesh squares showed straight lines in all the studies. IU and rms noise values showed a wide variation. Contrast decreased with decreasing sphere diameter. Contrast for the largest sphere was decreased when Chang AC applied while it was increased for the CT AC studies. For the smaller spheres, all the AC studies showed increased values. **Conclusion:** In this study, reference values for the evaluation of the SPECT systems were produced using Carlson phantom. This phantom has represented significant results to evaluate the performance of SPECT and SPECT/CT systems. **References:** AAPM report no. 52.

Thrombosis as incidental finding in ^{18}F-FDG PET/CT scan performed in oncologic patients: usefulness of intravenous contrast-enhanced CT

L. Garcia, C. G. Wakfie Corieh, E. Rodriguez Gallo, L. Landaeta Kancev, A. Blanes, R. Valhondo Rama, M. Garcia Garcia-Esquinas, M. J. Pérez Castejón, J. L. Carreras Delgado;
San Carlos Clinical Hospital, Madrid, SPAIN.

Aim/Introduction: The main indication for ^{18}F-FDG PET (Positron Emission Tomography) is the evaluation of cancer. Scientific evidence shows that oncologic patients have a hypercoagulable state due to malignant cells producing factors with procoagulant activity. Since at our institution we generally perform ^{18}F-FDG PET with intravenous (IV) contrast-enhanced computed tomography (CT), we aimed at evaluating the value of this combined technique in the detection of unknown thrombotic process. **Materials and Methods:** A retrospective study was carried out reviewing the medical records of patients who had undergone an IV contrast-enhanced ^{18}-FDG PET/CT scan from November 2014 to December 2017. A total of 120 patients diagnosed with thrombosis were included, what entailed an average of 4 patients/month with unknown thrombotic disease at the moment of undergoing the scan. Images were interpreted independently by two specialists with wide experience, a nuclear physician and a radiologist. **Results:** From the whole of patients, 57.5% were women and the average age was 59 years. The most frequent type of cancer was the colorectal one (23.3%), followed by lung and breast tumors, head and neck cancer and lymphoma. The 46.7% presented distant metastasis at the time of exploration, while the 13.3% had just regional lymph nodes involved. Out of the 120 patients, 71 (59.2%) presented pulmonary embolism (segmental pulmonary arteries were the most common location) and the remaining 49 (40.8%) were diagnosed from thrombotic disease in another location (jugular, cava or portal vein thrombosis were the most frequent findings). **Conclusion:** It is proved that oncologic patients have an increased risk of thrombosis and that treatment is different in cancer and non-cancer patients; therefore performing the ^{18}F-FDG PET/CT scan using IV enhanced-contrast could provide additional value for a correct diagnosis, ensuring that the optimal treatment is offered having a direct impact in the survival rate. However, further randomized controlled trials are required before firm conclusions can be made. **References:** None.

Imaging Protocol Optimisation for ^{223}Ra on Conventional Clinical Devices

T. Lima[1], R. F. P. Simões[2], L. Vasconcellos de Sá[3], B. Trimpin[1], E. Nitzsche[1];
[1]Aarau Cantonal Hospital, Aarau, SWITZERLAND, [2]National Cancer Institute - INCa, Rio de Janeiro, BRAZIL, [3]Institute of Radiation Protection and Dosimetry - IRD, Rio de Janeiro, BRAZIL.

Aim/Introduction: ^{223}Ra is used in the treatments of bone metastases (BM) from castration-resistant prostate cancer (CRPC). Attempts on extending the clinical indication have been proposed and evaluated, for example, in breast cancer patients presenting with metastatic bone lesions [1,2]. For CRPC, prescription and dosimetry are based on patient's weight [3], and research of the administration of a higher activity per weight has shown poor results [4]. The availability of imaging protocols would enable the evaluation of different treatment strategies in BM benefiting from individualised dosimetry. Different imaging protocols have been published [5,6,7,8] but the common energy window (EW) recommended includes a low EW which comprises of the emission from the ^{223}Ra and the lead characteristic X-Rays originated (RXC) from collimator. The aim of this work was to evaluate an optimized EW, to exclude contributions from RXC [9], in a conventional clinical device. **Materials and Methods:** For this work, a Siemens Symbia Gamma Camera was used. We evaluated the 4 proposed energy windows in 3 different planar acquisitions set-ups. First acquisition set-up consisted of three capillary tubes of 1 mm diameter and one with 6 mm diameter positioned directly in the patient bed. Subsequently set-ups consisted of two of the 1mm tubes and the 6 mm tube being placed in the PTW Head phantom with holders for capillary with an empty phantom and with water (mimicking scatter), respectively for the second and third set-up. For all acquisition the low energy all-purpose collimator was used and time was used as stopping condition. Profiles and signal to noise ratio

(SNR) were analysed for all evaluated energy windows. **Results:** The main difference between the energy windows evaluated was the energy peak used for the lower window either including or not including the RXC. For all set-ups noise was slightly lower at the proposed window (reduction of 12.5%, 12.3% and 14.9% for set-up one, two and three, respectively). The proposed energy window with 89keV also showed improvements in terms of SNR with gains ranging from 2 to 16% in the first set-up, 4 to 8% in the second and 5 to 30% in the third set-up. The lower the gains were found at more scatter conditions. **Conclusion:** The proposed energy window taking into account contributions from the lead collimator characteristic X-Rays has shown a potential to improve image quality in Ra-223 patient. Reduced improvements have been found on conditions with higher contributions from scatter. **References:** (Picture with references deleted)

Intercomparison of radionuclide calibrators used in the main Lithuanian hospitals with the secondary standard ionization chamber

K. Skovorodko[1], *A. Gudelis*[2];
[1]*Vilnius University Hospital Santaros Klinikos, Vilnius, LITHUANIA,* [2]*State research institute the Center for Physical Sciences and Technology (FTMC), Vilnius, LITHUANIA.*

Aim/Introduction: The accuracy of measuring radiopharmaceutical activity must comply with international standards and guidelines. The aim of this study was to assess the uncertainty of measured activities by radionuclide dose calibrators, which are used in Lithuanian hospitals for prescribed radiopharmaceutical dosage administration of commonly applied radionuclides for diagnostic and therapy procedures, with the help of the secondary standard radionuclide calibrator. **Materials and Methods:** Responses of twelve radionuclide calibrators that are used in three main hospitals' daily practice were compared with the readings of the secondary standard radionuclide calibrator Capintec CRC-15R (4π γ ionization chamber) brought to hospitals by the Ionizing Radiation Metrology Laboratory of the Center for Physical Sciences and Technology (FTMC) that is the National Metrology Institute (NMI) in Lithuania. Radionuclides ^{18}F, ^{99m}Tc, ^{131}I, ^{137}Cs, ^{57}Co and ^{223}Ra were selectively measured in two standard geometries: in 3 ml syringes and P6 vials. Ten readings of experimental values were taken with each instrument, corrections for the decay and for the background were applied. Then differences between experimental mean values and reference values were determined, the uncertainties were calculated. **Results:** The results of the intercomparison showed that the uncertainty for check sources was up to 8 % for ^{137}Cs and 2 % for ^{57}Co, uncertainties for diagnostic radionuclides ^{99m}Tc and ^{18}F in P6 vial geometry were found up to 13 % and 5 %, respectively; the uncertainty was within 15 % for ^{99m}Tc and 4 % for ^{18}F in syringe geometry, while uncertainties for therapy radionuclides ^{131}I and ^{223}Ra in P6 vial geometry were within 4 %, and within the tolerance of 5 % of the reference value in syringe geometry. **Conclusion:** The intercomparison measurements with secondary standard reference chamber and traceable radioactive sources could identify problems in accuracy of measurements done by radionuclide calibrators in hospitals, especially for different source geometry effects, at low energy or for lower activities. Hospital results revealed that regular check of radionuclide calibrators is necessary in order to meet the recommendations to be within 5 % (at k = 2 level) with the reference values for therapy radionuclides and within 10 % of the prescribed dosage for diagnostic procedures. **References:** None.

EP-0893

Acceptance and Quality Tests in Thyroid Uptake Systems

D. Verganelakis[1], *T. Makri*[1], *I. Sevaslidou*[1], *V. Lyra*[1], *M. Gavra*[2], *M. Chassiotou*[2];
[1]*Nuclear Medicine Department, Oncology Clinic 'Elpida', Children's Hospital "Aghia Sofia", Athens, GREECE,* [2]*CT & MRI Department, Children's Hospital "Aghia Sofia", Athens, GREECE.*

Aim/Introduction: The aim of this work is to suggest a protocol regarding acceptance and quality tests for all available types of thyroid uptake systems. Currently, there numerous types of thyroid uptake systems available in nuclear medicine departments worldwide dating back to 1980's until today's most recent models. Quality control (QC) tests vary amongst models with older systems to require more user involvement and time consuming processes. In recent uptake systems there are software embedded QCs that cover certain types of tests with variable ranges of errors, with minimum user involvement and minimum requirement of time. In order to achieve comparable results amongst different nuclear medicine facilities, further standardisation of QC tests is required. **Materials and Methods:** Three different types of thyroid uptake systems were used along with a set of test rods of Cs137 & Eu152. The uptake systems had different: i) number of channels, ii) software and algorithms, iii) maximum count rates, iv) differential and integral linearities, v) other hardware and physical characteristics. For all of them, Background, Contamination, Autocalibrate, System, Resolution, Constancy, Minimum Detectable Activity and Chi-Square tests were performed. **Results:** Each thyroid uptake system produced the same Background and Contamination result, but slightly different results in the Autocalibrate, System, Resolution, Constancy, Minimum Detectable Activity and Chi-Square test. The range of variation amongst results was between 0.5% to 6%. Varying certain parameters for each test, such as Counting time, Number of Repetitions, Duration of measurements, Precision factor, Correction factor, etc. produced statistically more convergent results amongst the various types of systems. **Conclusion:** There is a need for further standardisation and harmonisation of the Quality Acceptance and Control tests of the various thyroid uptake systems that are today available in order to reach comparable results of high accuracy and reliability amongst different nuclear medicine departments. **References:** None.

Development of Simulation Environment for bone SPECT imaging using SIMIND

H. Daisaki[1], *M. Shimizu*[2], *T. Iizuka*[2], *H. Shimada*[3], *T. Ino*[4], *T. Saito*[1], *I. Kuromori*[1], *H. Masuko*[1], *S. Fukai*[1,5], *K. Shimizu*[1], *T. Nakahara*[6], *K. Kashikura*[1];
[1]*Gunma Prefectural College of Health Sciences, Gunma, JAPAN,* [2]*Fujioka General Hospital, Gunma, JAPAN,* [3]*Gunma University Hospital, Gunma, JAPAN,* [4]*Gunma Cardiovascular Center, Gunma, JAPAN,* [5]*The Cancer Institute Hospital Of JFCR, Tokyo, JAPAN,* [6]*Keio University Hospital, Tokyo, JAPAN.*

Aim/Introduction: In Japan, the SPECT imaging guideline for bone scintigraphy was published in 2018, and the clinical use and image quality standardization of the SPECT imaging for bone scintigraphy are now spreading. Also, in recent years, quantitative evaluation using, for example, SUV using SPECT/CT camera has been used clinically. It may be useful to use simulation for standardization of image quality and evaluation of quantitative accuracy of the SPECT imaging. **Materials and Methods:** A digital phantom with Hot/BG ratio=6 was created by modifying QIBA-DRO (Washington University). And, a Monte Carlo simulation environment that simulates bone SPECT imaging was constructed using SIMIND[1)] (Ver 6.1.2) and the digital phantom. The simulation accuracy was verified in comparison with bone SPECT images acquired using NEMA body phantom filled with ^{99m}Tc solutions of BG=10.8kBq/ml and E-CAM (Siemens Healthcare) SPECT camera. The verification was physically performed using 17mm Hot sphere contrast ($Q_{H,17mm}$), background variability using 17mm ROI ($N_{B,17mm}$), and contrast noise ratio (QNR). **Results:** The bone SPECT image obtained by our constructed simulation had a difference of -1.9% at $N_{B,17mm}$, 5.2% at $Q_{H,17mm}$, and 7.6% at QNR, compared to the measured SPECT image. It was a relatively good agreement under conditions with sufficient statistics. However, in the conditions of acquisition duration with 10min/bed (20sec/step, 30 step) corresponding to a clinical situation, the image quality shows large variations among multiple simulations of 12.6% at $Q_{H,17\ mm}$, 12.7% at $N_{B,17mm}$, and 14.3% at QNR. **Conclusion:** The construction of a simulation environment simulating bone SPECT imaging was possible with relatively good accuracy. In the future, it may be applied to the evaluation of quantitative variability and the optimization of image quality. However, because physical indicators of image quality show variation depending on count statistics, it is necessary to pay attention to the variation in the case of imaging optimization. **References:**

EP-0895

Improving the Assessment of Dose Calibrator Linearity for the Clinical Activity Range

D. O'Keeffe;
Medical Physics and Bioengineering, Christchurch Hospital, Christchurch, NEW ZEALAND.

Aim/Introduction: Demonstration of the linearity of a radionuclide dose calibrator gives confidence that the accuracy of activity measurements can be maintained across the clinical range of activities typically used for imaging when only low or high activity calibration standards are available. Absolute activity accuracy is important for the control of patient dose, but the linearity is also important when performing relative measurements such as standardised uptake values (SUV) in PET and more recently in nuclear medicine imaging. Linearity as a performance measurement is well-known, but how to analyse the data when measuring it remains inconsistent across publications for the decaying source method, even in recent standards [1]. The aim of this investigation was to see if the decaying source method of linearity assessment could be improved for measurements in the clinical range of activities. This range was chosen because within this range the dose calibrator electrometer performance is more important than linearity changes due to saturation effects that are typically only observed when measuring high activities. **Materials and Methods:** Automated activity measurements were taken every 10 seconds for an 11 GBq Technetium-99m source decaying to 1 MBq in two models of dose calibrator that employed a microprocessor controlled multi-range electrometer. The activity variance versus mean activity was measured using a sliding analysis window of 10 readings (100 seconds). The linearity was measured using a linear fit to the logarithm of the activity readings versus time, and two models of decay were forced by performing the same fit for the decay fraction and by using the average decay corrected readings. **Results:** The variance measurements showed the range changes of the multi-range electrometers employed in the dose calibrators. These changes were subtle for high activities, but much clearer for low activity measurements. The fitting of the linearity measurement data varied depending on the degree of dose calibrator non-linearity, but the forced fit, using the decay fraction or decay corrected readings, gave consistent results. **Conclusion:** Multiple measurements of activity over the clinical range can provide useful information on the range changing of the dose calibrator electrometer. This can help with planning activity measurement points in other linearity assessment methods such as by dilution or attenuation sleeves. Combined with using fitting of activity data to the decay fraction or decay correction, the decaying source linearity assessment can be improved. **References:**

EP-0896

Proposal for National Quarterly Quality Control Tests for the SPECT/CT Systems

R. Y. Aimazrou[1], *S. F. Alanazi*[2], *T. O. Almutairi*[3], *A. K. Alosaimi*[4];
[1]*King Faisal Specialist Hospital and Research center, Riyadh, SAUDI ARABIA,* [2]*Prince Mohammad Bin Abdulaziz Hospital, Riyadh, SAUDI ARABIA,* [3]*King Abdullah Hospital, Bisha, SAUDI ARABIA,* [4]*King Faisal Medical city for Southern Region, Abha, SAUDI ARABIA.*

Aim/Introduction: Several international agencies have published numerous guidelines for QC tests for the SPECT and SPECT/CT systems. Most of third world countries lack any recommendations for routine testing of these systems. This study aims to propose a national quarterly QC (QQC) tests for the SPECT and SPECT/CT systems that guarantee the system reliability and optimized performance. **Materials and Methods:** Eight QQC tests were performed by a qualified medical physicist immediately after the PPM. The COR and intrinsic uniformity calibrations were acquired before conducting these tests. Up-to-date, more than 25 QQC tests have been conducted on five systems at King Faisal Specialist Hospital and Research Center. They include; intrinsic and extrinsic flood field uniformity, system spatial resolution and linearity, whole body system spatial resolution without scatter, total tomographic performance and SPECT/CT spatial registration tests. They are practical and consume about 3 hours. The required radionuclides and phantoms such as Carlson and two sizes quadrant bar phantoms were used. All these tests were evaluated visually and using the vendor software for the uniformity tests and COR calibrations. **Results:** These tests evaluate the performance of the system quantitatively and qualitatively using several performance indicators which demonstrates its suitability for clinical use. Several times it was found that the photopeaks needed to be adjusted. Uniformity tests showed consistent behavior of the systems with some abnormalities in some occasions. These were resolved by either acquire the uniformity calibration tables or retune the system. Consistently, 3-and-5 millimeters bars were determined for the system and whole-body spatial resolution tests, respectively and always the resolved bars were look linear. Most of the tests showed consistent behavior in resolving different objects of Carlson phantom. Three spheres, seven rods and four pairs of hot lesions inserts were usually resolved. Often, the uniform area looks uniform but with the occasional appearance of ring artifacts. Moreover, the linearity part shows straight lines in both directions. For SPECT/CT systems, the accuracy of image registration was evaluated visually by displaying the fused slices of SPECT and CT images of Carlson phantom. **Conclusion:** The proposed national QQC tests are suggested to be performed for the SPECT and SPECT/CT systems in order to offer a set of tests that have been constantly examined and could guarantee the system reliability. Tests results occasionally showed deficiencies in image quality or SPECT performance. Most of the issues were solved and modified by the user and/or service personnel. **References:** None.

EP-0897

Is there any ^{18}F-FDG PET/CT BAT pattern in oncological patients?

W. Jalloul[1], *E. Chifor*[1], *A. Tarca*[1], *M. Gutu*[1], *D. Chetan*[2], *C. Ștefănescu*[1], *A. Naum*[2];
[1]*Nuclear Medicine Laboratory, County Emergency Hospital „Sf. Spiridon", Iasi, ROMANIA,* [2]*Nuclear Medicine Laboratory, Regional Institute of Oncology, Iasi, ROMANIA.*

Aim/Introduction: Brown Adipose Tissue (BAT) represents an endocrine metabolic active tissue with complex pathological implications, demonstrating high uptake of ^{18}F-FDG. Consequently, ^{18}F-FDG PET/CT, highly used in cancer evolution assessment, proved to be an essential tool for its detection and quantification. The purpose of this study is to evaluate BAT ^{18}F-FDG PET/CT possible pattern characteristics in oncological patients as well as possible factors which can influence BAT activation. **Materials and Methods:** The BAT imaging pattern, with qualitative and quantitative statistical analysis, was realized in 48 ^{18}F-FDG PET/CT scans performed for 41 patients who were referred to our Nuclear Medicine Laboratory between July 2017 and April 2019, for different oncological diagnosis. **Results:** The median value (m_v) of patients age with ^{18}F-FDG BAT positive scans was 33.7 years. This tissue was active more often in female patients (58.5%), the m_v Body Mass Index (BMI) was 24.39, and the Blood Glucose (BG) level was normal (m_v = 90 mg/dl). In 58% of cases the initial diagnosis was Hodgkin's lymphoma and 51.2% of patients have received surgical treatment and chemotherapy. We noticed that 65.9% of cases were reported in cold seasons (autumn and winter), even if the scan room temperature was always the same. BAT was unilateral in 2.4% of cases, the rest being bilateral, with symmetric distribution in 68.3%, homogeneous in 43.9%. In 12.19% of cases the localization was unique, all the rest being multiple. We mention that the maximum value of SUV_{max} was calculated in paravertebral localization but supraclavicular SUV_{max} had the best Pearson correlation (ρ) with thoracic aorta SUV_{max} (used like reference). A statistical significant ρ (direct and low intensity, Sig<0.05) was found between BMI and BG level, and between latero-cervical SUV_{max} and SUV_{max} latero-thoracic. **Conclusion:** Complex BAT data can result from the ^{18}F-FDG PET/CT scans analysis, making evidence of multiple factors which could contribute to BAT activation. These data could be useful both for a correct image interpretation and for making new treatment strategies based on this type of tissue. **References:** None.

Variable Density 3D-grids for Non-uniform Activity Distributions in PET and SPECT Phantoms: a Proof of Concept

C. F. Uribe*, R. Ataya, R. Coope, A. Rahmim, F. Bénard;*
BC Cancer, Vancouver, BC, CANADA.

Aim/Introduction: Radiomics, extraction of extensive

quantitative features from radiological images, has generated recent interest promising improved assessment of disease and prediction of outcome. A challenge is that many radiomic features cannot be properly correlated to existing PET and SPECT phantoms which use compartments filled with uniform distributions of activity. This study presents a method to generate 3D-printed meshes of variable density, that, when immersed in a uniform tracer concentration, create predefined non-uniform activity distributions. The problem is to maximize the dynamic range between high and low activity concentrations, within the limitations of 3D-printing technology and system spatial resolution so gradients appear smooth. **Materials and Methods:** We developed MATLAB scripts that create 3D-meshes with two components: a 3D-grid of thin bars, and cubes centred at each node of the grid. The bars hold the cubes in position. Activity concentration (AC) is varied by cube size, specified by values in a three dimensional matrix with the elements representing concentration at each node. The symmetry of this geometry is exploited to minimize the number of stereolithography triangles and therefore its file size. Linear-gradients with grid spacing of 3, 4, 5, and 6mm were printed by Shapeways (Eindhoven Netherlands) using selective laser sintering (SLS). These phantoms were immersed in a solution with ^{18}F-FDG and scanned using a GE D690 PET scanner (GE Healthcare, USA). Imaging revealed a limit of ~.75mm between cube faces beyond which printer support material could not be removed. At 5mm grid spacing, the dynamic range varied from 1/2 to 1/8 of maximum activity. Spherical linear-gradients and uniform spheres were printed using 5 and 6mm grid spacings. **Results:** The optimal grid spacing was found to be 5mm, balancing image smoothing with the ability to create printable geometry. Initial measurements using a maximal AC of 125 kBq/mL on a linear-gradient phantom witha 5mm grid-spacing, showed decrease concentration of 1.1%/mm vs. a predicted 1%/mm. Gradient and uniform spheres ranging, for example, from 100% AC (at the centre) to 40% AC (periphery) likewise performed as expected. In this particular example, 44% AC was observed in the periphery relative to the maximum AC in the hot sphere. **Conclusion:** We have demonstrated a method for developing non-uniform distributions of activity with the potential to more realistically represent non-uniform features observed in patient images and for use towards radiomic feature applications. This approach can be used to create complex geometries with variable activity concentrations. **References:** PMID 28766726.

EP-0899

A web-based platform for collecting, researching and presenting molecular hybrid imaging artefacts

O. Roesner, M. Rullmann, B. Sattler, O. Sabri;
University Hospital Leipzig, Department for Nuclear Medicine, Leipzig, GERMANY.

Aim/Introduction: Imaging artefacts affect image quality and quantifiability and, thereby, may hamper the diagnostic interpretation. The possible reasons for and solutions to particular hybrid imaging artefacts should be made available to the users in the form of a representative collection of cases. Currently, this mainly exist as print media, coming with high logistic and temporal efforts in collecting and preparing, processing and provision of artefact cases. The instructive presentation of the cases is limited by inflexibility and impracticability due to the static nature of such media. These observations render the identification of a reason or adaptation of a solution strategy for an artefact based on print media almost impossible. **Materials and Methods:** A web-based platform was developed (http://www.ipet-science.de/artifacts/). An upload-mask has been implemented that captures artefact cases with all case-related data and images. Submitted cases will then be moderated by experts and scientifically processed. For cases with unknown reasons or solutions, a comment section where these aspects can be processed or discussed with other users is included. The user can search an increasing number of cases and adapt solution approaches for his own problem. A pilot-phase was performed. Invited users uploaded cases from the literature or their own clinical routine. Feedback was recorded in the form of an integrated questionnaire. **Results:** Over two months a total of 25 artefact cases were uploaded. The average time to upload was 13 min. The upload-mask reduces time needed to collect data and enables a sustainable and complete data collection. The database enables the structured collection of larger amount of data. The database and search-mask allow for a specific and faster research. 15 questionnaires could be evaluated. 80% rated the operability being very instructive, 75% the performance very practical and 85% the overall performance and necessity very interesting. **Conclusion:** The platform and the underlying software are stable. In terms of effort, completeness and sustainability, it shows clear advantages over the presentation in the form of print media. It will be a very useful toll in clinical practice to assist with artefacts in hybrid molecular imaging. The next steps include the ability to upload DICOM data. As the number of uploaded cases increases, an AI-based evaluation of the database is sought and then should assist the user in finding most reliable solution strategies for their own case very quickly. As legal data security issues are solved, the platform will enter wider test period. **References:** None.

[^{11}C]PBR28 and [^{11}C]UCB-J Blood Metabolite Analysis by Solid Phase Extraction

M. Huiban, S. Moz, M. A. Ali, G. Searle, R. Gunn, E. A. Rabiner, J. Passchier;
Invicro, A Konica Minolta Company, London, UNITED KINGDOM.

Aim/Introduction: Quantitative analysis of PET scans often requires the measurement of radioligand concentration in plasma over time. Chromatographic methods have been mainly used for this purpose in the past, in which blood samples may require pre-treatment or the use of online trapping column with column-switching HPLC methods to overcome plasma protein binding [1]. More recently, Solid Phase Extraction (SPE)

methods have been reported as an alternative [2], [3]. With these methods, typically plasma samples do not need to be pre-treated, as plasma proteins can be washed off the SPE cartridge using micellar solvents. Here we report our comparison of such SPE methods, using an automated sample processing system, against the gold standard HPLC methodology, for the analysis of [^{11}C]PBR28 and [^{11}C]UCB-J human plasma metabolites. **Materials and Methods:** Sample analysis was performed using the Biotage® Pressure+ 48 manifold system and Oasis® HLB 3cc 60mg flangeless cartridges. Plasma samples were diluted with micellar eluent consisting of a solution of 40mM SDS at pH 7.0 containing 5% of 1-BuOH. After loading of the samples, cartridges were rinsed with either water, or mixtures of water and methanol to wash away residual proteins and any polar radio-metabolites. Parent fraction of the radiotracer was left on the cartridges. Washed fractions and cartridges were measured for radioactivity content in well-counters, and parent fractions estimated as the ratio of these counts. Methods (e.g. volumes and composition of the rinsing solutions) were optimised for each tracer, comparing results with the parent fraction as determined by HPLC analysis (column switching method). **Results:** Average differences between HPLC and SPE for the parent fractions of [^{11}C]PBR28 and [^{11}C]UCB-J were 2.2% (n=5) and 1.9% (n=6) respectively. Highly reproducible results were obtained at each time-points, providing overall good agreement between radioligand parent curves. **Conclusion:** Excellent correlation was obtained for these two tracers between the HPLC and SPE methods. This methodology is currently being extended to [^{18}F] BCPP. The simplicity of these methods is very attractive, avoiding the need for complicated and expensive infrastructure, and opens up the use of these research tracers to a wider range of imaging facilities. **References:** [1] Hilton et al., Nucl. Med. Biol., 2000, 27, 627.[2] Katsifis et al., Nucl. Med. Biol., 2011, 38, 137.[3] Nakao et al., Nucl. Med. Biol., 2013, 40, 658.

EP-0901

Assessment of image quality comparing 2 acquisitions speeds in whole body bone scan with new generation of collimators and processing software

C. Garcia[1], *N. Gohimont*[2], *H. Sanon*[3], *R. Muteganya*[4], *M. Tondeur*[5]; [1]*CWaPi, Tournai, BELGIUM,* [2]*CHUB Hopital Erasme. Université Libre de Bruxelles, Bruxelles, BELGIUM,* [3]*Centre Hospitalier Universitaire Yalgado Ouédraogo, Ouagadougou, BURKINA FASO,* [4]*Clinique de l'Europe, Bruxelles, BELGIUM,* [5]*CHU Saint Pierre. Université Libre de Bruxelles, Bruxelles, BELGIUM.*

Aim/Introduction: Introduction: New generation of Cameras using LEHRS collimators and new processing image software C2D are reputed to enable decreasing scan times and/or administered activity without compromising image quality. C2D processing is applied to planar images with purpose to diminish statistical noise without degradation of image resolution and contrast. It combines a linear non-anisotropic edge preserving iterative filter with contrast enhancement procedure. The filtering procedure iteratively updates each pixel using signal strength and local variation in the pixel neighboring area. The contrast enhancement is done by deconvolution with empirical point spread function. At the last stage -the processed image is linearly blended with original image to preserve noise texture. **Materials and Methods:** Four nuclear medicine specialists independently and blinded concerning the acquisition characteristics, compared quality images of 38 patients using 2 speed acquisitions 15cm/min and 20cm/min. All examinations were scored with a 5 levels scale (1: poor/not clinically acceptable - 5: excellent quality). After this first analysis, the quality of the same WBS acquisitions were compared using 5 levels of C2D (no Clarity®, 20, 40, 60, 80 and 100% blending). All WBS were scored with the same scale and finally, a "best choice" concerning quality was made by each observer. **Results:** User preference between WBS at 15cm/min vs 20cm/min without any other intervention was 117 for slower speed and 44 for the quicker speed. The rate is 117/161 in favor of the slower one, (95% confidence interval: 65%-79%). Quality: only 30 examinations were scored non-diagnostic (poor quality). For the speed: no detectable difference was found (p=0.79), for both speeds the median C2D level preferred blending is 60%. Concerning the observer; we found statistically significant differences (p<0.0001). If we split the population following BMI: normal <=25 vs. overweighted > 25 patients, there is no detectable difference, (p=0.26). Multivariate analysis: The observer is the only factor impacting significantly on the choice of the blending parameter (p<0.0001). **Conclusion:** In our study, WBS at slower speed was preferred. There is a strong impact of the observer on the preferred blending value for choosing a parameter for the Clarity software. No obvious preferences for the level of blending of C2D were found, with a median "best choice" at 60% at both speeds. **References:** None.

Modern and Efficient Management in the Nuclear Medicine Departments: the Lean Approach

L. Metello[1], *P. Ratao*[2], *A. Roda*[3], *M. Capoulas*[4], *J. Nery*[5], *M. Nunes*[6], *A. S. Moreira*[7], *L. Cunha*[7]; [1]*ESS-IPP & IsoPor-Azores, Lda, Angra do Heroismo - Azores, PORTUGAL,* [2]*NM Dept, IPOFG-Lisboa & IsoPor-Azores, Lda, Angra do Heroismo - Azores, PORTUGAL,* [3]*Med Physics Dept, IPOFG-Coimbra & IsoPor-Azores, Lda, Angra do Heroismo - Azores, PORTUGAL,* [4]*Pharmacy Dept, HBA - Loures & IsoPor-Azores, Lda, Angra do Heroismo - Azores, PORTUGAL,* [5]*NM Dept, HGSA-Porto & IsoPor-Azores, Lda, Angra do Heroismo - Azores, PORTUGAL,* [6]*NM Dept, Unilabs-Porto & IsoPor-Azores, Lda, Angra do Heroismo - Azores, PORTUGAL,* [7]*IsoPor-Azores, Lda, Angra do Heroismo - Azores, PORTUGAL.*

Aim/Introduction: Healthcare Management is a highly challenging task, full of dilemmas regarding prioritization of investment and cost containment while always keeping the maximum quality of care. Therefore, tools are required to help managers to deal with such dynamic and complex challenges. "Lean Management" is one of them, proving its place by adding

value into a variety of industries over the last decades. In our specific case, starting a new NM Department was considered as the perfect opportunity to introduce Lean methods and technics and embedding them in our Quality Management System was considered a natural "step further", defining the Lean approach as a "quality improvement method that focuses on maximizing activities that are valued by the costumer and eliminating waste that hinders efficiency in the workplace". **Materials and Methods:** The first step was providing staff an overview about Lean methods and philosophy. Then, we went through the eight classical steps process for Lean implementation: 1) All staff levels were adequately involved; 2) Careful observation of the "gemba", with analysis of processes where they occur; 3) Efforts for elimination of all forms of waste (defined as "steps that do not add value in a process"); 4) Standardization of Practices: Standard Operating Procedures (SOPs) were adopted for every procedure (from patient reception to clinical reports release); 5) Flow improvement of all processes; 6) Use of visual cues for communication; 7) Add value to the customer; 8) Application of Lean tools for data collection and analysis, improving processes and sustaining change. Detailed practical specific examples of all and each of these steps will be given. **Results:** The seven categories of waste were analyzed and actions to minimize them were implemented, p.e.: optimizing the agenda (careful booking, patient instruction and follow-up about previous preparation for scans), close stock control, avoiding expired drugs and supplies, placing required supplies in each room at the right time and amount. Moreover, via adoption of the "5S Tool", we ended up by having a better organized and cleaner workplace, with "a place for everything, everything in its place". **Conclusion:** The implementation of Lean Management in Nuclear Medicine Departments shouldn´t be an end by itself: it is a continuous improvement process that seeks continuous attention, distinguishing Lean Management from conventional management systems by the involvement of every single collaborator, who is empowered to identify problems, propose and implement solutions, creating an overall culture for change (the kaizen principle). **References:** None.

EP-0903

Atomlab 100plus dose calibrator adjustment by 177Lu calibrated source in a phase I/II study for treatment of NH lymphoma with 177Lu-DOTA-HH1

P. Saletti[1], *S. Cardo*[2], *S. Raspanti*[2], *G. Belli*[1];
[1]*AOU Careggi, Florence, ITALY,* [2]*University of Florence, Florence, ITALY.*

Aim/Introduction: A radiopharmaceutical that will be soon used at Careggi University Hospital in a phase I/II study for NH lymphoma treatment is 177Lu-DOTA-HH1, even though 177Lu is not inserted in control unit of dose calibrators currently used at our Nuclear Medicine department in order to measure activity to be administered. The aim of present work is the determination of the specific calibration factor of 177Lu for an accurate activity measurement of radiopharmaceutical to be administered in current study. **Materials and Methods:** Biodex Atomlab 100plus is the dose calibrator involved in the present study together with a calibrated 177Lu source, a 20ml vial containing a 177Lu solution at 0.04M, that was sent to our department with a calibration certificate of National Physical Laboratory (Middlesex, UK). The activity was 214.3MBq (1% expanded uncertainty) at 12:00 of 31 july 2018 UTC. Measurements were performed in vial and calibration factor was adjusted until a difference of less than 2% was achieved. Later, 8 ml of solution were moved in a 10ml syringe and a similar procedure was repeated with the same requirement, i.e. a deviation of less 2%. **Results:** A deal setting value of 118 for the vial and of 116 for the syringe were found at the end of the whole procedure, both leading to a difference of less than 1% from activity expected values. Moreover, such values differ less than 1% from 117, the setting value suggested in operator manual of dose calibrator according to specific firmware in use. **Conclusion:** A simple procedure was actuated in order to adjust the calibration factor of Biodex Atomlab 100plus dose calibrator to be used in a phase I/II study for NH Lymphoma treatment. Obtained results are within 1% of expected activity values according to protocol procedure. This also confirm the worth of the dose calibrator in use because a deviation of less than 1% was highlighted with different investigated geomteries, 20ml vial and 10ml syringe and both in good agreement deal setting value in operator manual. **References:** Biodex - Atomlab 100 plus Operator Manual.

Freehand fluorescence tomography - Extending the hybrid image-guided surgery concept

M. N. van Oosterom[1,2], *P. Meershoek*[1,3], *M. M. Welling*[1], *F. Pinto*[4], *P. Matthies*[4], *H. Simon*[5], *T. Wendler*[6], *N. Navab*[7], *C. J. H. van de Velde*[2], *H. G. van der Poel*[3], *F. W. B. van Leeuwen*[1,3,8];
[1]*Interventional Molecular Imaging Laboratory, Department of Radiology, Leiden University Medical Center, Leiden, NETHERLANDS,* [2]*Department of Surgery, Leiden University Medical Center, Leiden, NETHERLANDS,* [3]*Department of Urology, Netherlands Cancer Institute-Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS,* [4]*SurgicEye, Munich, GERMANY,* [5]*Eurorad, Eckbolsheim, FRANCE,* [6]*Computer Aided Medical Procedures, Technical University Munich, Munich, GERMANY,* [7]*Computer Aided Medical Procedures, Johns Hopkins University, Baltimore, MD, UNITED STATES OF AMERICA,* [8]*ORSI Academy, Melle, BELGIUM.*

Aim/Introduction: Within the field of image-guided surgery,

hybrid- or dual-modality-based guidance technologies have been successfully applied to integrate the complementary qualities of radioactive guidance (i.e. in-depth localization) and fluorescence guidance (i.e. superficial and high-resolution localization). In this study, we investigate how the generation of a novel freehand fluorescence (fhFluo) imaging method can complement freehand SPECT (fhSPECT) in a hybrid setup, providing intraoperative augmented reality displays of the tracer distribution and virtual reality surgical navigation towards features defined in these images. **Materials and Methods:** An opto-nuclear detection probe (capable of gamma and fluorescence tracing) was integrated with a declipseSPECT surgical navigation platform. In this setup, near-infrared optical tracking was used to determine the position and orientation of the hybrid opto-nuclear probe, while recording its measurements at every location. Dedicated look-up table models were generated and used to reconstruct this information towards 3D fhSPECT and fhFluo reconstructions. Image resolution of both freehand imaging modalities was compared in a phantom setting, while in-tissue signal penetration was evaluated in flat-surfaced human skin explants. Finally, the combined potential of the fhSPECT and fhFluo technologies was evaluated in prostate and lymph node specimens obtained from five prostate cancer patients directly after sentinel lymph node dissection and prostatectomy. These patients received either separate injections of indocyanine green (ICG) and ^{99m}Tc-nanocolloid, or the hybrid tracer ICG-^{99m}Tc-nanocolloid. As reference, all conditions were also imaged with a handheld gamma camera and surgical fluorescence camera. **Results:** After hard- and software integration, the devised hybrid imaging and navigation setup was capable of creating 3D nuclear and fluorescence tomography scans. With a 1 mm imaging resolution, fhFluo was superior to fhSPECT (6 mm). However, the fluorescence modalities were restricted to a maximum tissue-depth of 0.5 cm, while the nuclear modalities were applicable at all evaluated depths (i.e. depths <2 cm). Both fhSPECT and fhFluo modalities enabled augmented- and virtual-reality navigation towards tracer hotspots. This also included relative hotspot quantification with an accuracy of 3.9% (fhSPECT) and 4.1% (fhFluo). Evaluation of prostate cancer specimens confirmed that fhSPECT provided in-depth detectability at low resolution, while fhFluo provided a superior resolution while being restricted to superficial detection. **Conclusion:** This study showed that when radioactive and fluorescent tracer features are combined, fhFluo provides complementary value to fhSPECT. By applying freehand technologies, a unique hybrid modality is created that supports intraoperative 3D imaging, augmented reality display and surgical navigation. **References:** None.

Simultaneous ^{125}I-seed and ^{99m}Tc guided breast cancer surgery : from probes characterization to clinical trial

C. Hoog, P. Koulibaly, J. Gal, T. Desdoits, C. Dejean, C. Chapellier, J. Haudebourg, J. Darcourt, E. Barranger;
Antoine Lacassagne Center, Nice, FRANCE.

Aim/Introduction: ^{125}I-seeds can be used as landmarks to localize non-palpable breast lesions instead of implanting metal wires (harpoons). This new technique is known to be more efficient and more comfortable for the patient, but requires a nuclear probe usually employed for ^{99m}Tc sentinel node detection. This study aimed to compare the performances of different probes to valid the feasibility of simultaneous ^{125}I and ^{99m}Tc detection and to present the preliminary results of the clinical trial "IODINE BREAST" comparing ^{125}I-seed and harpoon techniques. **Materials and Methods:** 3 probes were characterized according to the NEMA NU3-2004 standard (linearity, sensitivity, spatial resolution tests) for both ^{99m}Tc punctual sources and Ø 0.8 mm × 4.5 mm ^{125}I-seed (IsoSeed® - Eckert & Ziegler) emitting gamma emission of 140 and 27 keV respectively. Impact of ^{99m}Tc scatter (from injection point and sentinel node) on ^{125}I-seed detection was also assessed while performing in vitro simulations of clinical cases.The clinical trial comparing harpoon and ^{125}I-seed techniques is a prospective single-center, non-inferiority and randomized study with stratification according to histological status. The intermediary analyze concerned the first 116 patients. 60 harpoons and 56 ^{125}I-seeds (from 5 to 10 MBq) were implanted under imaging control (ultrasound or stereotactic mammography) within 24 hours (harpoon) or 10 days (seed) before surgery. ^{99m}Tc colloid areola injections for the sentinel node detection were scheduled the same day or the day before surgery. **Results:** The three probes presented heterogeneous performances but were all suitable for simultaneous ^{99m}Tc sentinel node and ^{125}I-seed detection. A ^{125}I-seed implanted just below an ^{99m}Tc injection point is the only case in wich ^{99m}Tc scatter may impact the seed localization.Intermediary results of the clinical trial confirmed the non-inferiority of the ^{125}I-seed technique compared to the gold standard harpoon technique and a gain of comfort (based on VAS scale) for the patient 3 to 24 hours after surgery ($p<0.003$) as well as a shortening of radiological and surgical durations ($p<0.03$). **Conclusion:** The non-significative impact of ^{99m}Tc scatter on ^{125}I-seed detection makes this relevant guided breast surgery possible with a single one nuclear probe. **References:** None.

EP-0906

Feasibility of PSMA-mediated fluorescence imaging at tracer dose

D. van Willigen[1], *A. W. Hensbergen*[1], *M. N. van Oosterom*[1], *F. A. van der Wijk*[1], *K. Bauwens*[2], *H. G. van der Poel*[3], *F. W. B. van Leeuwen*[1,2,3], *T. Buckle*[1,3];
[1]*LUMC, Leiden, NETHERLANDS,* [2]*ORSI Academy, Melle, BELGIUM,* [3]*NKI-AvL, Amsterdam, NETHERLANDS.*

Aim/Introduction: Fluorescence-guidance is an upcoming methodology to improve surgical accuracy. However, the ability to provide intraoperative fluorescence-guidance is 1) dependent on the amount/concentration of the fluorescent dye accumulated in the lesion(s) of interest and 2) hampered by tissue-dependent signal attenuation. This generally results

in application of relatively high doses, which can have negative impact on toxicity and costs. While tracer dose application (100 ug) is the mainstay in nuclear medicine, to date there is still controversy about the feasibility of receptor-mediated fluorescence imaging in vivo at tracer dose levels. Following validation of the performance of new bimodal tracer designs for PSMA in mouse tumor models we have set-out to validate the performance of fluorescence-guidance in a large animal (pig) model with increased translational character. Reasoning that basal PSMA levels in the prostate should already allow evaluation of the feasibility of PSMA-mediated fluorescence imaging in vivo, we evaluated the ability to identify the prostate in vivo after administration of a tracer dose PSMA-targeted tracer. **Materials and Methods:** A high affinity (19.2 ± 5.8 nM) Cy5-functionalized PSMA targeting tracer (EuK-(SO_3)Cy5-MAS_3; 100 ug) was administrated intravenously in five male and three female pigs (35-40kg). Blood and urine samples were obtained during 240 minutes. In vivo imaging and robot assisted prostatectomy were performed at four hours post injection in combination with Cy5 imaging using a clinical Cy5-modified laparoscopic system. Following in vivo imaging, tracer uptake in excised tissues (prostate, kidney, ureter, liver, abdominal fat, muscle, splenic tissue and salivary gland) was evaluated ex vivo using fluorescence confocal microscopy. **Results:** Presence of fluorescence in the blood was detected at early time points after tracer administration (t=5 - 20 minutes) with decreasing intensity over time. Urinary clearance was observed, with fluorescence still present in the urine at the time of imaging and subsequent prostatectomy (120 min). Robot-assisted prostatectomy could be aided by fluorescence imaging based on tracer uptake in the prostate. Confocal microscopy of excised tissues confirmed tracer uptake in the kidney and prostate and revealed a faint tracer-related fluorescence signal in the ureter. No fluorescence was detected in the liver, abdominal fat, muscle, splenic tissue or the salivary gland. **Conclusion:** Our findings indicate that intraoperative PSMA-mediated fluorescence imaging using a tracer dose regime is feasible. The applied approach in (non-tumor bearing) pigs widens translation opportunities from molecule to man and decreases the chance of applying non-successful image-guidance approaches in patients. **References:** None.

Validation of NaI detector for whole body counting of thorium-227 / radium-223

I. Murray[1], *B. Rojas*[1], *R. Callister*[1], *A. Cleton*[2], *G. Flux*[1];

[1]*Royal Marsden NHSFT, Sutton, UNITED KINGDOM,*
[2]*Bayer AG, Clincial Pharmacology, Berlin, GERMANY.*

Aim/Introduction: Thorium-227 is an alpha emitting radioisotope with potential therapeutic applications in molecular radiotherapy. Thorium-227 decays to radium-223, which may have an independent biodistribution to that of the parent thorium-227 radiopharmaceutical. Pharmacokinetic measurements made with sodium iodide (NaI) detectors could introduce the potential for cross-talk between neighbouring gamma photopeaks as well as from scattered gamma photons due to their limited energy resolution. The aim of this work was to validate the use of a spectral analysis technique to distinguish the relative contribution of each isotope to a measured photon spectrum. **Materials and Methods:** A NaI detector was connected to a pulse height analyser positioned ~2 m above a phantom containing a mixture of thorium-227 and radium-223. Multiple energy spectra measurements were made over 14 days. Energy spectra per unit activity arising from unscattered thorium-227 photons and Ra-223 photons as well as from scattered photons were modelled. These spectra were scaled until the combination of these component spectra resulted in the closest match to the measured data. The scaling factors were assumed to be estimates of the activity in the phantom. **Results:** Measured estimates of activity followed the expected decay curves. The mean errors in estimating thorium-227 and radium-223 were -2.8% ± 6.6% and 2.5% ± 10.1% respectively. The differences between the integrals of the theoretical and estimated time activity curve were -2.3% and 1.6% for thorium-227 and radium-223 respectively. **Conclusion:** Whole body counting of thorium-227 / radium-223 can be achieved using a conventional sodium iodide detector. **References:** None.

Use of The Silicon Photomultiplier (SiPM)-based PET/CT Results in lower FDG Uptake in Mediastinal Blood Pool Compared to The Conventional PET/CT

Y. Toyama;
Tohoku university, Sendai city, JAPAN.

Aim/Introduction: The purpose of this study was to investigate whether FDG uptake of the liver and the mediastinal blood pool changes depending on the type of PET/CT. **Materials and Methods:** 177 patients, who underwent both conventional (no Time-of-Flight) and SiPM-based FDG-PET/CT (on another day) at our institution for the follow up after acute treatment were investigated. We excluded the cases with differences in patient's conditions between two scans. In SiPM-PET, respiratory gating was used around the diaphragm. We set VOIs (30mm in diameter) and measured the SUVmax / mean in the right hepatic lobe, further we set VOIs (10mm) and measured the SUVmax / mean in the blood pool of ascending aorta (at the height of sternum angle). Also, as a control, we set VOIs (10mm) and measured

the SUVmax in the aortic wall at the same level of blood pools. Furthermore, the contrast ratio (SUVmax in aortic wall/ SUVmean in blood pool) was measured to investigate the difference in contrast between aortic wall and blood pool. **Results:** Finally, 142 patients were investigated (72males. mean age at the time of SiPM-PET: 63.9 ± 13.6). There were no significant differences in the body mass index or blood glucose between two PET scans. The SUVmean (2.45 ± 0.34 vs 2.48 ± 0.40) and SUVmax (3.08 ± 0.44 vs 3.06 ± 0.49) of liver and the SUVmax of the ascending aortic wall (2.27 ± 0.29 vs 2.29 ± 0.34) were no significant difference between SiPM-PET/CT and conventional-PET/CT. However, in the blood pool of ascending aorta, SUVmean (1.60 ± 0.24 vs 1.76 ± 0.30, p<0.0001) and SUVmax (1.80 ± 0.27 vs 1.94 ± 0.32, p=0.0003) of SiPM-PET/CT were significantly lower than conventional. Therefore, the contrast ratio of SiPM-PET/CT was singnificantly higher than that of conventional (1.44 ± 0.23 vs 1.31 ± 0.15, p<0.0001). **Conclusion:** It is assumed that FDG accumulation of the ascending aorta became possible to separate into the wall and the true blood pool because of the improved resolution of the SiPM-PET camera, furthermore, the SiPM-PET/CT provided high contrast for aortic wall compared to the conventional PET/CT. However, there was no difference in liver accumulation between different resolutions. In conclusion, the present study has demonstrated that it is necessary to be careful to use blood pool as references for therapeutic response assessment or comparison of lesion between different PET/CTs. **References:** None.

Intraoperative real-time visualization of nerves using a novel nerve-specific tracer

T. Buckle[1], *A. W. Hensbergen*[1], *D. M. van Willigen*[1], *K. Bauwens*[2], *H. G. van der Poel*[3], *F. W. B. van Leeuwen*[1];
[1]*LUMC, Leiden, NETHERLANDS,* [2]*ORSI Academy, Melle, BELGIUM,* [3]*NKI-AvL, Amsterdam, NETHERLANDS.*

Aim/Introduction: Surgically induced nerve damage is common in oncological surgery, but can result in debilitating side-effects. Unfortunately, intraoperative nerve delineating techniques that provide real-time guidance are still unavailable. The anatomical variation between individual patients and what is presented in common anatomical atlases strengthens the demand for approaches that enable intraoperative nerve imaging. In an attempt to address this unmet clinical need, fluorescent tracers that specifically target myelin in the peripheral nervous system were developed, and their targeting- and nerve visualization ability was evaluated. **Materials and Methods:** Based on its (photo)physical- and targeting properties, the lead peptide sequence OP10' was selected from a matrix of different targeting peptides. OP10'was C-terminally functionalized using the visible dye Fluorescein or the far-red Cy5 dye, yielding OP10'-FITC and OP10'-Cy5. Myelin-related affinity was evaluated in vitro using myelinating Schwannoma cells (flow cytometry and confocal imaging). Specificity was confirmed through co-staining with a myelin-specific antibody. Binding was further evaluated in dorsal root ganglia (DRG) derived from THY-1 YFP mouse embryos. Microscopic and macroscopic nerve imaging was performed in THY-1 YFP mice following a local tracer administration. The intrinsic YFP signal expressed in axons of these mice was used as a control. The in vivo biodistribution of OP10' was evaluated after intravenous administration of a ^{111}In-radiolabeled version of the peptide (^{111}In-DTPA-OP10'). The ability of OP10'-FITC to visualize nerves in the hypogastric plexus surrounding the prostate was further evaluated in vivo in male pigs and ex vivo in human prostate tissue obtained after prostatectomy using a clinical imaging set-up. **Results:** OP10'-Cy5 displayed a nanomolar affinity for myelin (97±20 nM) and confocal microscopy indicated co-localization of peptide staining with myelin presence on the cell surface of myelinating Schwann cells. Binding to could further be confirmed on DRG's and ex vivo nerve tissue. Following local administration OP10'-Cy5 allowed for fluorescence imaging of the sciatic nerve in vivo (Figure 1), enabling clear discrimination from the background tissue. Biodistribution data revealed that OP10' does not enter the central nervous system (CNS) and as such has a minimal toxicity threat. Both in pigs and ex vivo human prostate tissue OP10'-FITC allowed of detection of the hypogastic plexus. **Conclusion:** OP10' has proven to be a potent nerve-specific tracer that is able to target myelin both under in vitro, ex vivo, and in vivo conditions. Biodistribution data further underlines that this particular nerve tracer does not pose a threat for the CNS. **References:** None.

Phantom-based image quality assessment of clinical ^{18}F-FDG protocols in digital PET/CT and comparison with conventional PMT-based PET/CT devices

S. Gnesin[1], *C. Kieffer*[1], *K. Zeimpekis*[2], *J. Papazyan*[3], *R. Guignard*[4], *J. O. Prior*[5], *F. R. Verdun*[1], *T. V. M. Lima*[6];
[1]*Institute of Radiation Physics, Lausanne University Hospital, Lausanne, SWITZERLAND,* [2]*Department of nuclear medicine, Zürich Universitätsspital, Zurich, SWITZERLAND,* [3]*Radiology and medicine nuclear department, Genolier Clinique, Genolier, SWITZERLAND,* [4]*Department of Nuclear medicine, La Tour Medical Group, Meyrin, SWITZERLAND,* [5]*Department of*

nuclear medicine and molecular imaging, Lausanne University Hospital, Lausanne, SWITZERLAND, [6]Department of nuclear medicine, Aarau Kantonsspital, Aarau, SWITZERLAND.

Aim/Introduction: We assessed and compared image quality obtained with clinical ^{18}F-FDG whole-body oncologic PET protocols used in three different, state-of-the-art digital PET/CT and two conventional PMT-based PET/CT devices. The goal was to evaluate improved trade-off between administered activity (patient dose exposure/signal-to-noise ratio) and acquisition time (patient comfort) while preserving diagnostic information achievable with the recently introduced digital compared to the previous analogue PET technology. **Materials and Methods:** We performed 300s list-mode (LM) PET acquisitions of a NEMA/IEC NU2 phantom, with activity concentrations of 5kBq/mL and 25kBq/mL for the background (9.5L) and sphere inserts respectively. Adopting the local clinical protocol setup, in each device, reconstructions were obtained varying the image statistics (10, 30, 60, 90, 120 and 180 s from LM data) and the number of iterations (range: 1 to 10). Quantitative cross-calibration, image noise on the uniform background assessed by the coefficient of variation (COV), recovery coefficients (RCs) evaluated in hot spheres and a cold contrast (in a lung insert) were measured per each reconstructed dataset. The characteristic time-activity-product (TAP), that is the scan time per bed position × mass-activity administered (in min.MBq/kg) was compared across datasets. **Results:** Good system cross-calibration was obtained for all tested datasets, <6% deviation from the expected value was observed. For all clinical protocol setups, image noise was compatible with clinical interpretation (COV<15%). Digital PET showed improved signal-to-noise compared to conventional PMT-based PET. RCs were comparable between digital and PMT-based PET datasets. Compared to PMT-based PET, digital systems provided comparable image quality with lower TAP (average ~40%, up to 70% less). **Conclusion:** This study compared the achievable clinical image quality in three state-of-the-art digital PET/CT devices (from all possible vendors [N=3]) as well as image quality obtained in two conventional PMT-based PET. Reported results show that a comparable image quality is achievable with a TAP reduction of ~40% in digital PET. This could lead to a significant reduction of the mass-activity administered and/or scan time with direct benefits in terms of dose exposure, image quality and patient comfort. **References:** None.

EP-0911

Monolithic PET detectors with sub-mm transverse and 6 layer DOI identification for next generation high resolution clinical PET scanners

***M. Stockhoff**, R. Van Holen, S. Vandenberghe;*
Ghent University, Gent, BELGIUM.

Aim/Introduction: Future high resolution PET systems are likely to depart from the pixelated detector design and move to monolithic scintillation crystals. This design allows high resolution 3D event positioning while maintaining high sensitivity, energy and timing resolution [1]. In a small market study, we found that the monolithic crystal is also more economical when compared to a pixelated detector design with < 2 mm pixel sizes (e.g. 0.5mm pixels > 3-4 times more expensive). Previously we demonstrated the 2D spatial resolution and the effect of sensor array related parameters [2]. The aim of this work is to use optical simulations to determine the depth resolution of a monolithic detector and explain the depth dependent resolution degradation. Furthermore, we demonstrate the uniformity over the whole detector and the spatial resolution when simulating a Derenzo-like collimator. **Materials and Methods:** In simulations, a 50x50x16mm^3 lutetium-yttrium oxyorthosilicate (LYSO) crystal is coupled to an SiPM array and calibrated in 1mm steps with a perfect 511keV pencil beam source. Per position the calibration data is organized in six depth-layers. Events are then positioned with a nearest neighbor algorithm. The ground truth DOI is extracted from the simulation data and compared to the determined depth layer. The hypothesis for depth dependent resolution degradation is varying amounts of statistical noise on the SiPM pixels. This is tested by simulating different scintillator light yields. The uniformity is evaluated with a flood source. The Derenzo-like phantom is simulated as pencil beams of 0.45-1.8mm diameter. **Results:** The layer classification accuracy is 72%. The mean depth positioning error is 1.6mm. The effect of depth-dependent resolution degradation clearly diminishes with increasing number of photons. Spatial resolution is generally improving with more light photons per scintillation event. In the Derenzo setup sources up to 0.6mm can be distinguished from one another. The flood source histogram shows artifacts in the form of hot spots and edge non-uniformities. **Conclusion:** This study demonstrates the 3D resolution that can be obtained with this detector without being constrained by practical limitations of experimental setups. In the future, these optical simulations may be used as a more precise (e.g. perfect calibration source) and fast method to obtain calibration data for real monolithic detectors. **References:** [1] Berg E et al. 2018 Semin. Nucl. Med. 48 311-31[2] Stockhoff M et al. submitted 03/2019 to PMB-108741 Advanced optical simulation study on the spatial resolution of a thick monolithic PET detector.

PET2020: Combination of clinical routine PET and molecular research in one compact and cost-efficient high resolution long axial FOV PET scanner

***S. Vandenberghe**[1], M. Stockhoff[1], C. Thyssen[1], N. Efthimiou[2], M. Akl[1], Y. D'Asseler[1], E. Achten[1], C. Vanhove[1], K. Muylle[3], E. Vansteenkiste[1], V. Keereman[1], J. Karp[4], R. Van Holen[1];*
[1]Universiteit Gent, Ghent, BELGIUM, [2]University of Hull, Hull, UNITED KINGDOM, [3]Vrije Universiteit Brussel, Brussel, BELGIUM, [4]University of Pennsylvania, Philadelphia, PA, UNITED STATES OF AMERICA.

Aim/Introduction: We describe a European long axial FOV

whole body PET imager using high-resolution, depth-encoding monolithic detectors. These detectors outperform current pixelated PET detector technology in clinical and Total Body PET. This detector technology has been used extensively in commercially available preclinical imaging systems. The combination of advanced positioning algorithms and fine SiPM sampling leads to high intrinsic spatial resolution (< 0.8 mm) and excellent DOI (6 layers). This was shown in the thin (8 mm) preclinical detectors and now translated into thicker (16 mm thick) clinical detectors with minimal degradation (still sub mm resolution and 6 DOI layers). Pixelated systems for clinical systems have in best case 2.8 mm x 2.8 mm pixels with no DOI information. **Materials and Methods:** For clinical routine FDG imaging, throughput and an acceptable system cost is important and therefore we present a simple compact and cost-efficient base system design of 70 cm bore (based on current clinical routine) and 70 cm axial length. The system consists of 14 rings with each ring composed of 40 blocks of 50x50x16 mm monolithic LYSO blocks coupled to analog SiPM. **Results:** By using an axial length of 70 cm the sensitivity increase (about a factor of 3) for single organ imaging is close to its maximum. This system will have a PET component cost that is 'only' a factor 2-2.5x higher than a current high-end state of the art clinical PET-CT (20 cm axial FOV) but will be 8 x more sensitive for clinical routine FDG body imaging. An isotropic spatial resolution of 2-2.5 mm is expected over the complete field-of-view based on the excellent spatial resolution of the detectors in combination with positron physics (mostly acolinearity). **Conclusion:** As the total component cost remains limited, the final price of this system will be comparable to that of current PET-MR systems. The first version of this system is funded by FWO Flanders and will be installed and used in a multidisciplinary environment (large and medium animals, human volunteers and plants). This combination of acceptable cost and superior performance can bridge the gap between clinical system and Full Total body PET systems. It can serve not only as a high-end imaging system for research but also as a general high throughput clinical imaging system, potentially gradually replacing current short axial FOV PET-CT, as it will be a more cost-efficient system over its full lifetime. **References:** None.

EP-0913

Physical Performance of a PET Scanner Prototype with Extended Axial Field of View using Sparse Detector Module Rings Configuration: A Monte Carlo simulation study

S. Zein, *N. A. Karakatsanis, A. Gupta, J. R. Osborne, S. A. Nehmeh;*
Weill Cornell Medical College, New York, NY, UNITED STATES OF AMERICA.

Aim/Introduction: To assess the physical performance of an extended axial field of view (AFOV) PET scanner prototype with sparse detector module rings configuration. **Materials and Methods:** The Siemens Biograph Vision (Bio-Vis) PET/CT scanner encompasses 8 rings of 38 LSO detector modules. Each module comprises 2 (axial) x 4 (transaxial) blocks. Each block includes 5x5 LSO crystals (3.2x3.2x20 mm^3) optically coupled to an array of 2x4 SiPMs. The axial length of each detector module ring is 32 mm, thus yielding a total AFOV of 256 mm. The Bio-Vis AFOV was extended to 480mm (Ex-PET) by interleaving the detector modules with 32mm physical gaps corresponding to the axial dimension of the Bio-Vis detector module. Lead shields of 3mm axial and 20mm radial dimensions were inserted in the gaps in between the detector module rings to reduce inter-crystal scattering. Monte Carlo models of the Bio-Vis (gold standard) and Ex-PET were developed using the Geant4 Application for Tomography Emission (GATE). Performance measurements of the two PET configurations were performed using GATE simulations and following the NEMA NU 2-2012 standards. The NEMA Image Quality (IQ) phantom was simulated using a target-to-background ratio of 4:1, and the corresponding images were reconstructed with a 3D-OSEM algorithm (3 iterations, 19 subsets, 431x431 matrix, and 1.6 mm slice thickness). For Ex-PET, a table flow motion approach, as per Bio-Vis option, was adopted to compensate for the count loss due to the gaps. **Results:** Reduction of less than 5% in the axial and transverse spatial resolutions were observed between Ex-PET and Bio-Vis. The Ex-PET model showed a system sensitivity of 19.37 cps/kBq, compared to 19.58 cps/kBq for Bio-Vis. No image artifacts were observed in the IQ phantom, and all spheres were detected. The contrast recovery of Ex-PET deviated by less than 4% from that of Bio-Vis for all spheres. The Ex-PET background variability was higher by ~30% for the 10mm sphere with the difference reduced to ~12% for the 22mm sphere. **Conclusion:** The proposed Ex-PET sparse module rings configuration allowed extending the PET AFOV from 256mm to 480mm without increasing the number of detector modules, while maintaining comparable contrast recovery and image quality to those of Bio-Vis. An increased, yet more uniform, background variability was observed with Ex-PET across the AFOV. **References:** None .

Aim/Introduction: ^{124}I is an increasingly used radionuclide in positron emission tomography (PET) imaging. The PET data are used, e.g., in pretherapy dosimetry, requiring (absolute) image quantification. However, ^{124}I PET quantification is impaired by the presence of prompt gamma coincidences. The objective

of this study was to assess the value of the prompt gamma correction (PGC) approach using phantom setups mimicking challenging conditions similar to what clinically observed in antibody and somatostatin receptor imaging. **Materials and Methods:** All measurements were performed on a Siemens Biograph mCT PET/CT system with ^{124}I (and ^{18}F for reference purposes). Three types of phantoms were used: (a) a soft-tissue tumor phantom (consisting of spheres of varying sizes mounted in an abdominal phantom) that mimics tumors embedded in a warm background, (b) a bone-lung tumor phantom that simulates tumors in cold lung and cortical bone tissues, where the activity was filled only in spheres and in the abdominal cavity, but not in the lung and cortical bone compartments, and (c) an organ phantom that simulates organs in a warm background with activity filled in spine, kidney and liver inserts as well as the abdominal cavity. A standard clinical acquisition protocol (low counting statistics) and a reference acquisition protocol (high counting statistics) were performed using an emission time of 240 s and 1 h, respectively. All ^{124}I data were reconstructed with (PGC_{on}) and without prompt gamma correction (PGC_{off}). The percentage differences between imaged and activity meter-based activity concentrations (ACs) were determined for PGC_{off} and PGC_{on} (and ^{18}F) images. **Results:** For all phantom setups, ^{124}I image quantification with PGC_{on} was close to the expected value (≤10%) and was comparable to that of ^{18}F images . AC deviations between PGC_{off} and PGC_{on} (ΔPGC) images were similar for both acquisition protocols. For phantom (a), the sphere (background) ΔPGC was, on average, -14% (-30%). For phantom (b), sphere in cortical bone inserts (lung insert) ΔPGC ranged from -90% to -60% (-1% to -4%). For phantom (c), ΔPGC for the spine, kidney, liver inserts were about -15%, -10%, -25%, respectively. The underestimation of the ACs in PGC_{off} images was a consequence of the scatter overcorrection when the prompt gammas are not modeled. **Conclusion:** PGC is effective and mandatory for reconstructing ^{124}I images to obtain higher quantitative accuracy, in particular for background, bone lesions and extended organs. The ACs (and thus the absorbed doses) are underestimated without applying a PGC. **References:** None.

Aim/Introduction: Most breast positron emission tomography (bPET) scanners consist of tightly packed discrete detector rings to improve scanner efficiency. In this study, we aimed to use new compressive sensing (CS) techniques and image inpainting in breast PET imaging to investigate the feasibility of decreasing the number of detectors while maintaining image quality. Conventional reconstruction methods generate severe artifacts in the reconstructed images. **Materials and Methods:** A dedicated breast PET scanner is based on LYSO crystals coupled with SiPM, and it consists of 14 compact modules with a transaxial field of view (FOV) of 180 mm in diameter and 50 mm axial FOV. Different methods for data recovery were investigated using simulated data in breast PET scanners with partial geometry (introducing gaps). A new CS technique was developed to recover missing observations in breast PET data acquisition. The methods used for filling the crack structure in sinogram PET data include partial differential equation based methods (PDE). A simulation experiment was performed to evaluate the proposed CS recovery algorithm. The simulation dataset consists of six disks of various sizes in a uniform background with an activity concentration of 5:1. Seven detector blocks (50%) turned off, and then the proposed CS algorithm was applied to recover the missing PET data. Also, different levels of noise were simulated to assess the performance of the proposed algorithm. The partially acquired sinograms were then retrieved using the proposed algorithm. For large gap structure, new CS produces better results. Comparisons were made by calculating the spatial resolution and contrast. **Results:** Both CS and image inpainting are skillful of recovering PET images with good quantitative accuracy from partially sampled data. So, an approach can be used to potentially reduce the cost of dedicated breast PET scanners while sustaining excellent image quality. The results of the Contrast Recovery (CR) for the recovered images was improved by more than 22%. The simulation results showed that the new CS algorithm could control gap artifacts, as well as Poisson random noise, and recovered spatial resolution. **Conclusion:** Our results showed that whether a large part of a whole of data is unknown, new CS techniques adjoined with the reconstruction in image space were the best strategy. Estimation of missing data in the inpainting method can improve the quality of recovered images, especially for small gap structures. **References:** None.

Quantitative gated PET and CT imaging of mice and rats using a fully integrated animal monitoring system

P. Mollet, *S. Neyt*, *B. Vandeghinste*;
Molecubes NV, Gent, BELGIUM.

Aim/Introduction: In cardiac research, non-invasive measurement of left ventricular end-systolic (ESV), end-diastolic volume (EDV) and left ventricular ejection fraction (LVEF) is a useful tool to evaluate and monitor cardiac function in health and disease. Respiratory gating techniques are useful to exclude

breathing artefacts which is beneficial for lung research. We evaluated the feasibility of cardiac, respiratory and dual gated PET and CT for mice and rats on the Molecubes B-CUBE PET and X-CUBE CT systems. **Materials and Methods:** In order to obtain physiological signals, Molecubes developed dedicated animal beds for mice and rats with fully integrated cardiac, respiratory and temperature monitoring capabilities. The electronics are equipped with a high precision clock to allow synchronisation of the monitoring signals with the PET and CT systems. For cardiac gated PET, a rat was injected with 14 MBq of 18F-FDG 60 min prior to scanning. A PET acquisition of 45 minutes was done. 3 ECG-leads connected to the rat front legs and left hind leg were used to obtain the cardiac signal. Additional the integrated pressure pad and carbon heat pad in the animal bed were used to capture the respiratory signal and maintain body temperature. A peak detection algorithm was implemented to identify the peak locations of the cardiac signal. For each cardiac cycle, 8 gates were defined and for each gate a PET image was reconstructed using the OSEM algorithm with default settings as provided by the Molecubes software. ESV, EDV and LVEF were calculated using PMOD PCARD v4.0. For respiratory gated CT imaging, the default respiratory gated CT protocol was used. The data was reconstructed using ISRA algorithm and a voxel size of 100 µm. End-inspiration and end-expiration aerated lung volumes were calculated with HU based segmentation with Horos. **Results:** For cardiac gated PET, a left ventricular ejection fraction of 58% was calculated based on EDV and ESV in a healthy rat. Respiratory gated CT imaging in mice showed that there was a 34% difference in aerated lung volume between end-expiration and end-inspiration phase of the respiratory cycle. **Conclusion:** Our results demonstrate the possibility of using the integrated monitoring system for both gated PET and CT imaging. Thanks to the high spatial resolution of the PET system, cardiac function can be visualised and quantified. µCT imaging has proven to be useful in determining the difference in aerated lung volume between end-expiration and end-inspiration phase of the respiratory cycle. **References:** None.

EP-0917

Metabolic Response Assessment Following Stereotactic Ablative Radiotherapy (SABR) in oligo lung metastases - How early we get to see!

A. Kasat, *S. Gawde, S. Parekh, A. Singal, S. Vangipuram; HCG Cancer Centre, Mumbai, INDIA.*

Aim/Introduction: FDG PET-CT is a well established cancer imaging tool for diagnosis, staging and response assessment. It is also well known that, post chemotherapy or radiotherapy, metabolic response precedes morphologic response which is based on size criteria. However, earliest time needed for the maximum metabolic response post radiosurgery has never been assessed. Present study evaluates the trend in metabolic regression post SABR with serial FDG PET-CT scans in patients with oligo lung or mediastinal metastases. **Materials and Methods:** 5 patients with oligometastatic lung tumors (Primaries: Colorectal cancer - 2, Breast - 2 and Head and neck cancer- 1) were planned for SABR by Deep inspiratory breath hold technique using Active breath controller & risk fractionated protocol. Doses delivered were in the range of 110-116gy biologic equivalent dose (BED). All patients underwent diagnostic pre- and post-treatment PET-CT scans. Post SABR PET-CT scans were timed serially at 48hrs, 7, 30, 60 and 90 days post treatment. PET-CT scans were reviewed in order to determine the pre- and post- treatment maximum standardized uptake value (max SUV) of the lesion, including "complete resolution" of FDG-avidity. Corresponding morphologic variations of the target lesions were studied on the corresponding CT images. **Results:** All the 5 patients showed serial regression in metabolic activity, with maximum regression in metabolic activity occurring at 1week post SABR. The observed metabolic regression was between 40-54% (median - 50%) at 48 hours and 67-82% (median 80%) at 1week post SABR. During the evaluation period, there was no significant change in size of the lesion. After 1 week of SABR, there was no further decrease in metabolic activity, most probably due to initiation of inflammation. **Conclusion:** In cases of recurrent solitary lung or mediastinal metastases, the metabolic response precedes morphologic response, with maximum response seen at 1 week post SABR. This is the first study reported in literature which looked into the trend of metabolic regression following SABR. **References:** None.

Systematic Error On The Displayed Delivered Activity Of The Medrad® Intego Pet Infusion System

A. Wenger, *C. Weyermann, M. Hofbauer, M. Christen, K. Zeimpekis; Universitätsspital Zürich, Zürich, SWITZERLAND.*

Aim/Introduction: The MEDRAD® INTEGO PET Infusion System is used worldwide in order to minimize the occupational dose of PET technologists. As of 2017, more than 400 units have been installed worldwide. This device prepares a ^{18}F-FDG solution and injects it to the patient, allowing the technologists to remain at distance during the injection, hence decreasing their occupational dose. The prescribed activity is based on a standardized protocol per kilogram of body weight. It is derived from an agreement between the PET/CT vendor and the local medical team, taking into consideration the sensitivity of the scanner, the minimum desired image quality and the desired acquisition time. Too low activity would result in noisy images and too high activity would result in unnecessary dose to the patient: a trade-off between both resulted in the aforementioned protocol. The accuracy of the activity preparation is therefore of high importance: a too low activity could result in a misdiagnosis due to a too low SNR. The aim of this work is to test the vendor's claim which guarantees a delivered activity within 10% error margin. **Materials and Methods:** We simulated patient injections of ^{18}F-FDG with three independent MEDRAD® INTEGO PET Infusion Systems, each of them used in our clinical routine. A wide range of activities

were ordered, from 100MBq to 300MBq, reflecting our clinical practices. The injected activities were collected in large vials. We withdrew samples from the vials and measured their activity in the activimeter of our local hotlabs. Several samples of different volumes and dilutions were prepared in order to exclude any volume effect or random errors from the activimeter measurements. After the initial study, we repeated a simpler version of the measurements for six months with a time interval of approximately 30 days. **Results:** We have found a systematic overestimation of the delivered activity displayed on the Intego system compared to the activity measured with our activimeters. This systematic deviation remains within the 10% margin and is linearly correlated with the prescribed activity. Hence, we could extract a correction factor, currently used in our clinical practice to correct for the device's activity overestimation. We have found that the correction factor is device dependent. **Conclusion:** We recommend every center currently using the MEDRAD® INTEGO PET Infusion System to introduce an analogous step in their QA protocol in order to correct for the device's systematic overestimation of the injected activity. **References:** None.

EP-0919

Phase Ia intra-individual comparison study of osteoblastic metastases using rapid high definition whole-body Na^{18}F digital photon counting PET/CT

C. L. Wright, K. Binzel, J. Zhang, E. Folefac, D. A. Diaz Pardo, D. G. Stover, J. P. Monk III, M. V. Knopp;
The Ohio State University, Columbus, OH, UNITED STATES OF AMERICA.

Aim/Introduction: Oncologic and non-oncologic bone imaging with sodium fluoride (Na^{18}F) PET/CT is used clinically for the detection and characterization of osteoblastic lesions. For those patients with symptomatic bony disease, standard Na^{18}F PET image acquisition times (60 - 120 s/bed) for whole-body assessment are longer than desired and new approaches to substantially reduce whole-body PET image acquisition time are needed. The recent introduction of clinical PET/CT systems equipped with digital photon counting PET (dPET) detectors enable new PET imaging approaches for reduced PET image acquisition times, PET imaging with reduced radiotracer doses and higher definition PET image reconstruction. The aim is to assess a substantially faster, whole-body, high-definition Na^{18}F PET imaging approach for the detection and characterization of osteoblastic lesions using dPET/CT technology. **Materials and Methods:** A Phase Ia intra-individual comparison of whole-body Na^{18}F dPET/CT imaging (Vereos, Philips) was performed using a target Na^{18}F dose of 185 MBq in 22 male oncologic patients. We performed investigational dPET acquisitions at a substantially faster 30 s/bed (at ~70 min post injection) and at the standard 90 s/bed (at ~85 min post injection). All image data sets were reconstruction using high-definition (voxel volume = 2x2x2 mm^3) and Time-of-Flight. All individual and matched data sets were reviewed using an Intellispace Portal workstation by a blinded reader panel to evaluate lesion detectability, overall image quality and background quality. **Results:** All patients had evaluable dPET images (n = 44) for qualitative assessment of ^{18}F biodistribution and osteoblastic lesions. ^{18}F-avidity within normal bone and osteoblastic lesions was visually comparable with faster 30 s/bed acquisitions to the standard 90 s/bed acquisitions. No discordant ^{18}F-avid osteoblastic lesions were identified between the 30 s/bed and 90 s/bed acquisitions. Quantitatively, the average SUVmean values were comparable for 30 s/bed and 90 s/bed acquisitions in terms of background skeletal muscle and normal vertebral bone. The average SUVmax of 39 osteoblastic lesions were also comparable for 30 s/bed and 90 s/bed acquisitions (30 ± 26 and 33 ± 28, respectively). **Conclusion:** Digital photon counting PET technology allow for 3x faster whole-body high-definition Na^{18}F PET imaging without loss of overall image quality, lesion conspicuity or quantitative accuracy. Faster PET image acquisition for patients with symptomatic bony disease remains an unmet clinical need and this Phase Ia study demonstrates rapid whole-body high-definition Na^{18}F PET imaging is readily achievable with dPET/CT technology. **References:** None.

Variability in NEMA NU 2-2012 Sensitivity Measurements of GE Discovery MI Digital Time-of-flight PET-CT Systems

A. Moreno, E. Ilan, M. Lubberink;
Uppsala University Hospital, Uppsala, SWEDEN.

Aim/Introduction: There is considerable variability in NEMA NU 2-2012 sensitivity values for identical scanners, which makes meaningful comparison difficult. For four identical Discovery MI PET-CT scanners recently installed at Uppsala University Hospital, variations in sensitivity during acceptance testing between scanners were > 10%. The aim of this work is to evaluate and compare the sensitivity according to the NEMA protocol in order to assess whether the variability in the results is due to experimental aspects or to actual differences in scanner performance. **Materials and Methods:** In order to isolate the source of variability, combinations of the NEMA sensitivity test were performed. Sensitivity was measured for all four scanners using a single phantom filling. The test was repeated in one of the scanners using a single filling while the phantom set-up was mounted and un-mounted completely in every measurement in order to assess the uncertainties introduced from it. Finally, sensitivity was measured repeatedly in a single scanner, with a single filling and a single set-up so random error could be evaluated. All tests were performed by the same medical physicist and the results were compared to those from the acceptance tests performed by the manufacturer´s specialist. **Results:** The mean sensitivity of the four scanners based on a single phantom preparation was 13.61 ± 0.14 cps/kBq, as compared to the 13.9 ± 0.71 cps/kBq in the acceptance tests. The sensitivity in one scanner using a single filling and introducing a set-up variation was 14.04 ± 0.15 cps/kBq. The sensitivity in that same scanner with a single set-up and a single filling was 13.58 ± 0.01 cps/kBq. **Conclusion:** Differences

in the NEMA sensitivity measurements between scanners was lower in our measurements using a single phantom filling as compared to the acceptance tests (coefficient of variation 1.0% versus 5.1%). According to the other tests, random errors between measurements are negligible (0.02%) while the set-up manipulation introduces an uncertainty (0.85%) which is comparable to the variability we measured between scanners. Differences in the acceptance tests arise therefore mainly from experimental errors and lack of reproducibility of setting up the experiment, and not from difference in actual scanner performance. **References:** None.

EP-0921

Accuracy of the Siemens Biograph Vision 600 for Radiotherapy planning; technical aspects and extra acceptance testing

E. Raaijmakers, S. Schip, van Het, E. Gerrits; Institute Verbeeten, Tilburg, NETHERLANDS.

Aim/Introduction: In 2018 Institute Verbeeten installed a new PET-CT scanner, the Biography Vision 600, for both Nuclear Medicine and Radiotherapy use. The RT scans are used for contouring and planning. It is therefore essential that volumes can be accurately outlined and can be translated to linac coordinates. During the acceptance testing we have paid special attention to the RT requirements. The aim of this study is to report on specific issues for this new scanner in relation to the Radiotherapy planning. **Materials and Methods:** Acceptance testing was done according to AAPM TG66. Table sag was measured with kettle belts placed on specific points on the RT bed. Sag was measured at different points on the table and compared to the zero position as well as the position in unloaded condition. This was done for weights up to 120 kg. Contouring accuracy was measured with the NEMA image quality phantom. The phantom was filled with different concentrations for the background. The known volumes of the bowls was compared to the different volumes acquired with the planning system Eclipse (Varian). Contouring was done on a percentage of SUV max. Also 4D CT and PET was tested using the Cirs thorax phantom with Na-22 sources as moving objects. **Results:** All table measurement were well within the AAPM standards. Table Sag, even with 130 kg, sag was less than 2 mm. For contouring the best value representing the volume was 30 % of SUV max. (older scanners typically use 42 %) 4D gating protocols were made clinically available. For that purpose timing between PET and CT was optimized. **Conclusion:** The scanner is well suited for RT applications. However, due to better resolution , contouring parameters of old- analogue- scanners cannot be used for the new scanners. Volumes will be underestimated if done so. **References:** Quality assurance for computed-tomography simulators and the computed tomography- simulation process: Report of the AAPM Radiation Therapy Committee Task Group No. 66. Mutic et al. Med Phys 2003;30:2762-2792.

Performance Evaluation of a Newly Designed SiPM-based Preclinical Scanner Based on NEMA-NU4 2008

M. Amirrashedi[1,2], S. Sarkar[1,2], P. Ghafarian[3,4], R. Hashemi Shahraki[1,2], P. Geramifar[5], H. Zaidi[6,7,8], M. Ay[1,2];
[1]Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]PET/CT and Cyclotron Center, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Chronic Respiratory Disease Research Center, NRITLD, Masih Daneshvari Hospital, Shahid Beheshti University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]Research Center for Nuclear Medicine, Shariati Hospital, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [6]Division of Nuclear Medicine and Molecular Imaging, Geneva University Hospital, Geneva, SWITZERLAND, [7]Geneva University Neurocenter, Geneva University, Geneva, SWITZERLAND, [8]Department of Nuclear Medicine and Molecular Imaging, University of Groningen, University Medical Center Groningen, Groningen, NETHERLANDS.

Aim/Introduction: Recent years have witnessed widespread interest and increased popularity in translational molecular imaging-based biomedical research stimulated largely by the availability of dedicated small-animal scanners. Among the promising animal imaging modalities, Positron Emission Tomography (PET), as a highly versatile research tool, has further enabled the quantitative assessment of disease progression and metabolic evaluation of cellular biology. Xtrim-PET is a newly designed Silicon Photomultipliers (SiPMs)-based prototype PET scanner dedicated for small laboratory animal imaging. Optimizing scanning protocols can be achieved through reliable system performance characterization and tuning. In this work, we present the performance evaluation of the Xtrim-PET according to the National Electrical Manufacturers Association (NEMA) NU-4 2008 standard. **Materials and Methods:** NEMA standard was used for measurement of spatial resolution, sensitivity, counting rate performance, scatter fraction and image quality. The in vivo imaging capability of the scanner is also showcased through scanning a normal mouse injected with ^{18}F-FDG. Furthermore, the performance characteristics of the developed scanner are compared with commercially available systems and current prototypes. **Results:** The volumetric spatial resolution at 5 mm radial offset from the central axis of the scanner is 6.81 µl whereas a peak absolute sensitivity of 2.99% was achieved using a 250-650 keV energy window and a 10 ns timing window. The peak noise-equivalent count rate (NECR) using a mouse-like phantom is 113.18 kcps at 0.34 KBq/cc with 12.5% scatter fraction, whereas the NECR peaked at 82.76 kcps for an activity concentration level of 0.048 KBq with a scatter fraction of 25.8% for the rat-like phantom. An excellent uniformity (3.8%) was obtained using NEMA image quality phantom. Recovery coefficients of 90%, 86%, 68%, 40% and 12% were calculated for rod diameters of 5, 4, 3, 2 and 1 mm, respectively. Spill-over ratios for air-filled and water-filled

chambers were 35% and 25% without applying any correction for attenuation and Compton scattering effects. **Conclusion:** The results demonstrated that the system has good spatial resolution and sensitivity, which makes it suitable for small animal studies. The quantitative capability of the system is being improved through the implementation of dedicated data correction techniques, including attenuation and scattering as well as statistical image reconstruction with accurate system modeling to further enhance overall image quality. Overall, our assessment proves practical and technical suitability of the Xtrim-PET for use in the preclinical imaging domain using molecular imaging probes. **References:** 1. National Electrical Manufacturers Association 2008 NEMA Standards Publication NU 4 - 2008.

EP-0923

Use of insulin to avoid false-negative for FDG-PET Imaging in cancer patients with high blood glucose level: a prospective cross-over study

H. Gauthier, E. Gobaert, N. Penel;
Centre Oscar Lambret, Lille Cedex, FRANCE.

Aim/Introduction: To determine whether insulin can improve the image quality and tumour uptake of 18-fluorodeoxyglucose (FDG) in patients with concurrent uncontrolled diabetes mellitus and cancer, and avoid false-negative results. **Materials and Methods:** Twenty-two patients with various malignancies (13 colon cancer patients, 7 lung cancer patients, 1 lung sarcoma patient, 1 unknown primary tumor patient) and high blood glucose level at the time of imaging (mean 14 +/- 3 mmol/L; mean glycosylated hemoglobin: 9,6%) were included. All patients underwent two PET studies (mean delay 12 ± 6 d). The first PET study was performed under fasting conditions for patients without known diabetes (n=3). Patients with known diabetes mellitus (n=19) continued to eat their standard meals and take their oral medication. The second PET study was performed under fasting conditions without diabetic medication for all patients. Patients received a sub-cutaneous insulin injection prior to the PET scan, and patient blood glucose levels were monitored until the levels were below 8.8 mmol/L. A visual assessment of the image quality of each PET scan (defined by the signal-to-background ratio) was performed by two independent observers who were blinded to the exam conditions. The mean peak of the standard uptake value (SUV) was measured at the tumor sites. **Results:** Blood glucose levels at the time of PET 2 after insulin therapy (mean: 7.2 mmol/L) were significantly lower ($p<10^{-4}$) than the blood glucose levels at either PET 1 (mean: 14 mmol/L) or PET 2 before insulin injection (mean: 12.7 mmol/L). The image quality of PET 2 scans was better than PET 1 scans in 14 cases, unchanged in 6 cases and worse in 2 cases. Patient tumors were visualized in 14 out of 21 patients. For these patients, the SUV of the tumor was significantly higher on PET 2 than on PET 1 ($p = 0.0001$). Only one false-negative result was observed (minimum follow-up of 6 months). For three patients, metastases that were not visualized on PET 1 appeared on PET 2. Improvement of the image quality was not influenced by body mass index, a decrease in the blood glucose level or the rate of glycosylated hemoglobin. **Conclusion:** This study confirmed that liver metastasis could be missed even if primary tumor or others metastatic sites are observed. Diabetic patients with hyperglycemia (≥ 160 mg/L) at the time of PET examination must beneficed of an insulin protocol. **References:** None.

EP-0924

Assessment of a Monte Carlo simulation of PET recordings from the fullly-digital Vereos camera

J. Salvadori[1], P. Marie[2,3], G. Karcher[3], L. Imbert[1,3];
[1]IADI UMR-1154, Nancy, FRANCE, [2]INSERM UMR-1116 DCAC, Nancy, FRANCE, [3]CHRU-Nancy, Nuclear Medicine, Nancy, FRANCE.

Aim/Introduction: Digital PET systems, involving solid-state silicon photomultipliers instead of conventional photomultipliers, allows improving time-of-flight capability and shortening dead time and piles-up effect. Furthermore, they were recently shown to enhance contrast-to-noise-ratio, lesion detectability and ultimately diagnostic confidence over a wide range of activity concentration. However, acquisition and reconstruction parameters need to be further optimized to fully benefit from this technology leap and Monte-Carlo simulations may constitute a useful tool for this purpose. The objectives of this study was to elaborate a Monte-Carlo modeling of the Vereos digital PET with the GATE platform and to assess this simulation by direct comparison between simulated and actual recorded data from the NEMA NU-2 2018 protocol. **Materials and Methods:** The Vereos system geometry was modeled together with its signal processing chain, according to the manufacturer's specifications and while taking into account background noise, energy blurring, temporal resolution, dead time and coincidence processing. The GATE simulation results were compared to actual recorded data obtained based on the NEMA NU-2 2018 protocol, with post-processing being provided by a homemade software. Simulated and actual data were both reconstructed with the open-source tomographic reconstruction software CASToR and identical parameters. **Results:** The simulated count-rate curves were fitted in order to match the actual ones using the dead-times and piles-up effects as adjustment parameters**.** Up to an activity concentration of 60 MBq/ml, a higher than 99 % agreement was obtained for single event rates, with maximal differences of 4 %, 6%, and 3 % for respectively total, random and true coincidence count-rates. This resulted in a lower than 10 % difference between the noise equivalent count rate (NECR) obtained from simulated (172 kcps at 49.7 MBq/ml) and actual (161 kcps at 55 MBq/ml) recordings. Lower than 5% differences were documented between simulated and actual recordings for axial sensitivity profile, as well as for timing and energy resolution over a wide range of activity concentration. The background relative noise and contrast recovery coefficients obtained from the spheres of an IEC phantom, were very close between simulated and actual

recordings, with maximum relative differences of 5% and 6%, respectively. **Conclusion:** PET recordings from the fully-digital Vereos camera can be simulated with the GATE software with high concordance relative to the actual physical properties of this camera. **References:** None.

EP-0925

Qualitative and Quantitative Assessment of Reducing the Scan Time for ^{18}F-flurodeoxyglucose (^{18}F-FDG) Wholebody PET/CT to 2 min/bed

A. McCann, D. Maguire, A. Dowling, L. Harris, R. P. Killeen, J. Lucey; UCD-SVUH PET CT Research Centre, St Vincent's University Hospital, Dublin, IRELAND.

Aim/Introduction: A pilot study of 20 ^{18}F-flurodeoxyglucose(^{18}F-FDG) patients was performed to investigate if quantitative PET/CT values in clinical images can be maintained with a reduced acquisition time (scan time reduced from 3min/bed to 2min/bed). The results of the pilot study confirmed that there was good correlation between the quantitative metrics associated with the mediastinal blood pool, cerebellum, bladder and metabolically active tumours for both scan times. However, a statistically significant difference was found in the quantitative metrics of the liver. This study expands the pilot study to a larger cohort of patients to investigate if the results found in the pilot study are representative of that of a larger population and determine if the reduced scan time is feasible without impacting quantitative metrics. **Materials and Methods:** Patients were administered 3 MBq/kg ^{18}F-FDG up to a maximum of 300MBq. Following a one hour uptake period, wholebody images were acquired on a Siemens Horizon PET/CT scanner. Listmode acquisition facilitated the reconstruction of 3min/bed and 2min/bed images. All images were iteratively reconstructed with time of flight. Images were analysed with Siemens Syngo. Via image software. Using well-defined regions of interests for both data sets, the SUVmax, SUVmean and metabolic volume of the primary tumour and the bladder were assessed. The liver signal-to-noise ratio (SNR) was calculated and the uptake in the cerebellum and mediastinal bloodpool compared. The clinical image quality was visually assessed by a board certified Nuclear Medicine Physician/Radiologist and rated using the Likert scale, with the observer blinded to the acquisition type. **Results:** A comparison of the quantitative metrics of both scan times in the pilot study found that the percentage difference in the SUVmax of the mediastinal blood pool, cerebellum and bladder were not statistically different with p-values > 0.05 (95% CI). However, the SNR of the liver and the liver SUVmax were found to be statistically different with p-value <0.05 (95%CI). The absolute value of the liver SNR for both scan times compare very well to those published in literature, which indicates that even with a reduced acquisition time the PET/CT is achieving acceptable image quality. Further results of the larger patient cohort will be presented and their clinical significance discussed. **Conclusion:** This study will determine, based on the results of the larger cohort of patients, whether a 33% reduction in scan time for ^{18}F-FDG whole body scans is feasible, without significantly impacting image quality. **References:** None.

EP-0926

In vitro detection limit of ^{89}Zr-labelled cells using a human PET system

L. Lechermann[1]*, R. Manavaki*[1]*, T. D. Fryer*[2]*, B. Attili*[1]*, D. Lau*[1]*, L. B. Jarvis*[3]*, L. Aloj*[1]*, B. Basu*[4]*, N. Patel*[5]*, M. Cleveland*[5]*, J. L. Jones*[3]*, F. I. Aigbirhio*[2]*, F. A. Gallagher*[1]*;*

Aim/Introduction: Imaging and in vivo tracking of cells can provide much needed information and help non-invasively to improve the accuracy, efficacy and safety of cell- and novel immune modulator therapies. Zirconium-89 ($t_{1/2}$=78.4 h) has been used recently to synthesize [^{89}Zr]Zr(oxinate)$_4$[1], a suitable radiotracer for cellular tracking and imaging using Positron Emission Tomography (PET)[2-4].This work presents an in vitro approach to quantify and determine the detection limit of T cells labelled with [^{89}Zr]Zr(oxinate)$_4$ utilizing a human PET system. **Materials and Methods:** [^{89}Zr]Zr(oxinate)$_4$ was synthesized according to published methods[4]. Jurkat cells were labelled with different amounts of [^{89}Zr]Zr(oxinate)$_4$ by a 30 min incubation in both PBS and complete RPMI 1640 medium at room temperature to generate different specific activities (SA) on cells (kBq/10^6). Labelled cell suspensions of 10^4, 10^5, 10^6 cells per well were seeded on 6-well plates. Plates were imaged on a GE Signa PET/MR and GE D690 PET/CT scanner for 30 min and reconstructed using parameters from a standard clinical protocol. The total activity in each well (n=34, 7 independent experiments) was determined by drawing regions of interests over each well on coronal images. Cell suspensions were transferred into 1.5 mL Eppendorf tubes after the scan, measured in a Triathler Gamma Counter (Hidex) and correlated with imaging data. In addition, cells were counted on a hemocytometer and checked for viability by trypan blue exclusion after each scan. **Results:** [^{89}Zr]Zr(oxinate)$_4$ was synthesized at a yield of >95% in an aqueous solution. The specific activity (SA) of labelled cells ranged from 0.4 kBq/10^6 cells to 41.2 kBq/10^6 cells. Cells could be visualized and quantified on PET images above a signal to background ratio of 20. Using this in vitro model, 5.20x10^5 cells with a SA of 2.18/10^6 cells could be visualized; in contrast, the lowest cell number that could be detected was 6.75x10^4 when the specific activity was 27.8 kBq/10^6 cells. **Conclusion:** The results show the feasibility of quantifying and detecting Jurkat T-cells labelled with [^{89}Zr]Zr(oxinate)$_4$. Cell detection using PET/CT or PET/MR depends on at least 3 factors: signal to background, cell number and specific activity per cell. This work has important

implications for human cell labelling procedures, particularly when using radiosensitive cells such as T-cells which require detection of low cell numbers while minimizing dose per cell. **References:** [1] Dalton Trans. 2014; 43(39): 14851-14857 [2] Clin Cancer Res. 2017; 23(11): 2759-2768 [3] Mol. Ther. 2018; doi:https://doi.org/10.1016/j.ymthe.2018.10.006 [4] J Nucl Med. 2018; 59(10): 1531-1537.

Optimization of CT acquisition protocol in brain 18F-FDG PET/CT

A. Loi[1,2], S. Zucca[3], P. Guglielmo[4], M. Bassu[2], M. Carta[2], N. Pisu[4], S. Sanna[4], S. Loi[3], F. Portesani[2], S. Aste[2], D. De Vittor[2], M. Boero[4];
[1]Centro PET, Cagliari, ITALY, [2]Alliance Medical, Cagliari, ITALY, [3]S.C. Fisica Sanitaria AOB, Cagliari, ITALY, [4]S.C. Medicina Nucleare AOB, Cagliari, ITALY.

Aim/Introduction: Optimize the CT acquisition parameters for brain PET/CT examination tailoring to to the specific diagnostic task: a low dose CT scan used for attenuation correction and anatomical alignment only and a medium dose CT scan with superior diagnostic imaging quality. **Materials and Methods:** Morphological imaging can provide guidance in the evaluation of the functional information related to the 18F-FDG uptake of the brain. A phantom study was carried on with a CATPHAN600 CT phan (CP). HU mean value and standard deviation, SNR and CNR were evaluated on the images of the uniform and low contrast test object were acquired with different $CTDI_{vol}$(1.1 mGy, 1.6 mGy, 3.3 mGy, 6.6 mGy, 13.1 mGy, 24 mGy, Body 32 cm phantom). In order to test the attenuation correction, PET/CT acquisition of a NEMA PET phantom (NU-94) was performed. The phantom was filled with a background solution with 8 kbq/ml18F-FDG while the two internal cylinders were filled with4 kbq/ml (Les1) and 16 kbq/ml (Les2). NU-94 acquisitions were performed varying $CTDI_{vol}$and using a list-mode PET acquisition time.The mean value and the standard deviation of the concentration were evaluated in the background region (ROI_b), and in the two cylinders ($ROI_1$and ROI_2). **Results:** As expected, the CT noise evaluated in the uniform section of CP decreased when $CTDI_{vol}$increased (std=24 HU @ 1.1 mGy and std=5.75 HU @ 24 mGy), leading to an increase of the SNR (from 0.5 to 2). CNR improved with the increase of CT dose. The modulation of CT tube current had no effect on the PET images of the NU-94 phantom. Concentration mean values were also not affected by the CT dose levels, giving similar image quality. Two CT acquisition protocols were defined. A CT acquisition with low dose level ($CTDI_{vol}$1.6 mGy) is performed for attenuation correction purpose only. The medium dose level CT protocol ($CTDI_{vol}$13.1 mGy) can be performed for better image quality. **Conclusion:** Two different CT acquisition protocols were defined for brain PET/CT. The CT low dose level protocol is judged adequate for attenuation correction purpose when a recent diagnostic or MR study is available and can be registered with the PET dataset supporting morphological evaluation. A medium dose level CT protocol is preferred when no complementary imaging is available as the improve image quality justifies the increase in patient dose. **References:** None.

Low Dose 68 Ga DOTA Zoledronate Bone PET/CT Scan on a High Definition Digital PET Scanner-First Technical Feasibility Study Done in Kuwait

B. M. Alenezi;
Jaber Alahmed For Molecular Imaging Center, Kuwait, KUWAIT.

Aim/Introduction: Gallium-68 zoledronate [^{68}Ga] Ga-DOTA^{ZOL} is a potent bisphosphonate PET tracer for evaluation of metastatic bone disease. We aim to assess the technical feasibility of doing a low dose 68Ga DOTA zoledronate bone PET/CT in a high definition digital PET/CT scanner and assess the image quality of the various image reconstructions parameters. **Materials and Methods:** Three patients who were referred for PET bone scan as a part of evaluation for metastatic bone disease were included in the study. All 3 patients were injected with 0.06mCi per kg of 68Ga zoledronate. The whole-body blood pool and delayed skeletal phase whole-body images were acquired using the advanced digital PET/CT system (GE Discovery MI). The acquisition time was 0.5 min/bed for whole body blood pool images and 3 min/bed for delayed whole-body images. Delayed whole body images were reconstructed at different time points (0.5 min/bed, 1 min/bed , 2min/bed and 3min/bed) and each data set was reconstructed with six different beta (β) values (150, 300, 450, 600, 800 and 1000) by using Bayesian penalized likelihood reconstruction (Q.Clear). The images were assessed by two different senior nuclear medicine physicians for the best image quality for the different reconstructions. **Results:** Whole body blood pool images showed high uptake in kidneys and urinary bladder as organs of excretion and faint uptake in heart blood pool and the vascular blood pool. The nuclear medicine physicians felt that the blood pool images are of high quality comparable to whole body blood pool of 99mTc MDP. After comparing all the reconstructed data sets using various bed positions and beta values the nuclear medicine physicians had a consensus opinion that one min per bed acquisition is as good as three minute per bed acquisition with respect to image quality for clinical reporting. Comparison of Beta values with Q.Clear revealed that 450 and less of beta values made the images noisy and more than 800 made it over smoothened. Hence a beta value of 600 to 800 gave the best images. **Conclusion:** Use of low dose of [^{68}Ga] Ga-DOTA^{ZOL} based bisphosphonates for metastatic bone scan imaging appears technically feasible. One min per bed position gave good quality images comparable to three min per bed on the high definition digital PET scanner. Best beta values for Q.Clear reconstruction appears to be between 600-800. **References:** None.

EasyPET-3D, a super high spatial resolution and cost-effective PET scanner for training and preclinical applications

F. Castro[1,2], *P. M. C. Correia*[1,2], *P. M. C. C. Encarnação*[1], *A. L. M. Silva*[1,2], *F. M. Ribeiro*[1], *I. Mohammad*[1], *A. I. Veloso*[3], *A. C. Santos*[4], *J. F. C. A. Veloso*[1,2];
[1]*Departamento de Fisica da Universidade de Aveiro & i3N, Aveiro, PORTUGAL,* [2]*RI-TE Radiation Imaging Technologies, Lda, Ílhavo, PORTUGAL,* [3]*DigiMedia, Universidade de Aveiro, Aveiro, PORTUGAL,* [4]*iCBR Coimbra Institute for Clinical and Biomedical Research, Coimbra, PORTUGAL.*

Aim/Introduction: EasyPET technology is an original concept for high-resolution 3D PET imaging that uses 2 opposite detector arrays rotating synchronously with 2 degrees of freedom and very high granularity, being capable to scan millions of lines of response (LORs) in minutes and perform full body mouse axial imaging with only a small number of detector cells. EasyPET achieves a great level of detail and spatial resolution that is very uniform in all the field of view (FoV) due to the intrinsic capacity to mitigate parallax errors, since its detector arrays are always collinear, unlike ring-based PET scanners. EasyPET-3D detector arrays can have different geometries and each scan can be performed with different parameters in order to achieve different sensitivity, level of desired detail/speed and image specific regions within the FoV, which is also a unique ability of this scanner when compared with existing systems. This study aims to characterize the performance of EasyPET-3D following NEMA NU 4-2008 standards. **Materials and Methods:** The tested EasyPET-3D system uses 2 arrays of 16x2 LYSO crystals of 2x2x30 mm^3 pixel size coupled to corresponding arrays of silicon photomultipliers with 1.3 mm^2 active area, covering an axial FoV of 35 mm length and maximum radial FoV of 50 mm diameter. A dedicated 3D reconstruction method was developed based in OSEM and MLEM algorithms, taking into account the original geometry of the scanner and the high number of possible LORs. **Results:** Based on NEMA standardized methods for performance evaluation of preclinical PET scanners, NEMA IQ and NEC phantoms filled with 18F-FDG and a point-like 22-Na source were imaged, in order to determine spatial resolution, sensitivity, uniformity and other NEMA parameters achieved by EasyPET-3D. Results and images will be presented. **Conclusion:** EasyPET-3D system results are very promising showing the high potential of this system for training and preclinical imaging research applications. EasyPET technology has the best cost/performance ever achieved in the history of PET imaging and thus systems based in this technology, such as the EasyPET-3D, have the potential to become the most affordable high-quality PET scanners in their class, which is not only limited to training and preclinical imaging applications but can also be upgraded to organ-specific clinical imaging such as positron emission mammography. Furthermore, EasyPET technology can be seamlessly integrated with CT or optical imaging to build hybrid scanners. **References:** Patent WO/2016/147130.

Aim/Introduction: Due to their size, nanoparticles can be easily labeled with several atoms bearing optical, radioactive and magnetic properties. MRI is sensitive to variations in T1 and T2* induced by nanoparticles and PET allows a highly sensitive and linear response to nanoparticles concentration. Therefore, PET/MRI is a technique of choice for the purposes of imaging and quantitating. This study aims at validating microPET/MR imaging both with phantoms and small animals for the study of nanoparticles. **Materials and Methods:** 7 mice were installed on a heated bed with respiratory gating before an intravenous injection of 5.2 ± 0.8 MBq of nanoparticules labelled by ^{68}Ga and gadolinium. Imaging was performed 15 min post-injection on a 7 T fully integrated PET/MR system with a helium-free magnet and SiPM-based PET insert. Fast spin echo images were acquired with TR of 1000 ms, TE of 11 ms, 4 averages, matrix of 256^2, and a field of view of 40 × 40 mm^2. List-mode PET data were acquired simultaneously during 30 min and then reconstructed using 3D-OSEM algorithm with the following corrections: random, scatter, dead time, normalization, and radioactive decay. Phantoms acquisitions were performed with ^{68}Ga. A homogeneous mouse-like cylinder was used to assess both signal to noise ratio (SNR) in MR imaging and PET count rate linearity. Image quality metrics were acquired with the NEMA-IQ phantom and spatial resolution was assessed using an ultra micro hot spot phantom. Just after imaging, the animals were sacrificed and ex vivo counting was then compared to in vivo PET quantification in four organs for each animal. **Results:** Phantom data showed that the count rate versus radioactive concentration relationship was linear up to 50 MBq. Qualitatively, a signal enhancement was visible on the liver and kidneys of mice. No significant differences were found between in vivo and ex vivo counting data. At high activities, the acquisition of PET data caused a detectable increase of the noise in simultaneously acquired spin echo images but did not affect the overall quality

of MR images. **Conclusion:** Using proper calibrations, PET/MR imaging of nanoparticles labelled with ^{68}Ga and gadolinium was performed easily with excellent spatial resolution and quantitative accuracy. **References:** None.

The effects of ^{18}F-FDG dose reductions on quantification and diagnosis in whole body PET/MRI

Y. Xu[1], *J. Guo*[2], *F. Li*[1], *C. Li*[1];
[1]*Hangzhou Universal Imaging Diagnostic Center, Hangzhou, CHINA,* [2]*GE Healthcare(CHINA), Shanghai, CHINA.*

Aim/Introduction: The study aims to investigate the effects of reduced tracer dose on the semi-quantification and clinical diagnosis in ^{18}F-FDG wholebody integrated PET/MR imaging. **Materials and Methods:** 20 patients (38.5±22y; BMI 20.13±3.84)with malignant tumors were performed 6min/bed whole body PET/MR(GE SIGNA)imagingwith respiratory gating at 45.29±9.22minafter injected standard dose (3.7MBq/kg). The imagingofreduced doses wassimulated byTOF and non TOF reconstruction with100%, 75%, 50% and 25% of the original data.The signal-to-noise ratio (SNR), SUVmax and SUVmean of liver background in each simulated dose were analyzed by paired t test while theSUVmax, SUVmean, metabolic tumor volume(MTV) and total lesion glycolysis(TLG) of the lesions by Wilcoxon test. Reconstructed images wererandomly assigned to four observation groups, with three observers in each group. χ^2 testwas used to do the statistical analysis forthediagnosis. **Results:** The image SNR decreases significantly ($P < 0.01$) with reduced dose. No significant difference was found both in SUVmeanof liverand 56 lesions(2-3 lesions/patient;D 22.88±15.09mm)at each dose,as well as in liver SUVmaxand lesions' SUVmax, MTV, TLG at 100%, 75%, and 50% simulated dose ($P > 0.05$). Yet SUVmax at 25% simulated dose was significantlyhigher than that of 100% ($P < 0.01$)..while MTV and TLG of lesions were lower ($P < 0.05$). Except 25% dose, the lesion detection rate from other doses and all the observers are consistent ($P > 0.05$).However, higher false positive rate of small lesions caused by increased noise at 25% doseresults in reading divergence among observers ($P < 0.05$, in comparison with 100% dose).In addition, the lesion detection rates of TOF images are higher than that of non-TOF images in each simulated dose($P < 0.05$). **Conclusion:** A 50% of standard dose can be feasible in ^{18}F-FDG PET/MR 6min/bed whole body examination. The lesion detection rate and the semi-quantitative are relativelyconsistentwith decreased SNR except at 25% dose. It's suggested to prolonge scan time when dose less than 50% in case of potential deviated SUVmax, MTV and TLG,degraded images quality and misdiagnosis of small lesions.Compared with non-TOFimages, TOFimages own improvedlesion detection rate,andgood consistency under various simulated doses. **References:** 1.Sah B R , Ghafoor S , Burger I A , et al. EP-0932

Feasibility of Ultra-Low Dose Ultra-High Definition PET/MR for Assessment of ACL Graft Healing

K. Binzel*, C. Kaeding, R. Magnussen, D. C. Flanigan, B. Sanders, M. V. Knopp;*
The Ohio State University Wexner Medical Center, Columbus, OH, UNITED STATES OF AMERICA.

Aim/Introduction: PET/MR for the assessment of ACL graft healing post-reconstruction surgery has been proven feasible. We have previously shown the ability to perform ultra-high definition (UHD) 1 mm isotropic voxel PET image reconstruction based upon the sensitivity and time of flight performance of next-generation digital photon counting systems. Here we aimed to simulate and test the feasibility of performing ultra-low dose imaging while maintaining the image quality and quantitative robustness previously experienced. **Materials and Methods:** 12 patients post-surgical ACL graft reconstruction had an MRI on a 3T Ingenia CX using the dedicated 16 channel knee coil, with both knees imaged sequentially. Dynamic PET/CT imaging was performed on a digital photon counting system (Philips Vereos) continuously for 75 minutes post-injection of 111 MBq ^{18}F-FDG. Listmode data were reconstructed using the 576x576 matrix 1mm^3 voxel volume protocol, with both PSF and Gaussian filter enabled. Default dynamic frame times of 5 minutes per frame were used, as well as 2.5 min/frame secondary reconstructions, simulating a 50% dose reduction by reducing the count data by the same fraction. Regions of interest were placed over the graft, bone tunnels, quadriceps muscle and PCL, as well as in the contralateral healthy knee, also imaged. **Results:** Excellent image quality and robust quantification resulted from the 2.5 min/frame, 50% dose reduction simulation reconstructions. SUVs measured on the low dose images were not significantly different ($p>0.25$) from full dose, 5 min/frame data in all regions except the muscle, where activity concentrations are extremely low and varied among patients. Since this evaluation, an additional 10 patients have now been imaged using an average dose of 48 MBq. Initial assessment shows that equivalent image quality can be produced, while still using the UHD reconstruction protocol. Quantification also appears robust and dynamic uptake curves from the graft signal appear similar to those seen in matched patients from the higher dose group. **Conclusion:** Next-generation digital PET/CT systems will allow for significant reductions in image acquisition time as well as injected radiotracer dose. Our already low-dose knee imaging has been further optimized to utilize an FDG injection below 50 MBq while maintaining visual and quantitative precision. The preserved ability to apply an ultra-high definition reconstruction protocol provides exceptionally detailed insight into the graft healing process post-reconstructive surgery, offering a non-invasive imaging methodology for sports medicine and other non-oncologic applications limited by concerns over patient

radiation exposure. **References:** None.

Aim/Introduction: To evaluate the impact of geometric distortions inherent to diffusion weighted imaging (DWI) in the field of PET-MRI lung oncology. **Materials and Methods:** 10 patients were prospectively recruited and underwent an 18F-FDG PET-MRI for lung oncology purpose. For all patients, the imaging protocol included several thoracic PET-MRI acquisitions: a PET acquisition performed one hour after the intra veinous injection of 18F-FDG; a set of DWI acquisitions with anterior-posterior phase encoding (b values of 0,500, 800 s/mm²) and reverse-phase encoding polarity (b value = 0 s/mm²); a high resolution post contrast-enhanced 3DT1-weighted FSPGR sequence. DWI data were corrected for geometric distortions using the reverse phase encoding method. All the DWI data (non corrected and corrected from the distortion) were warped to the same T1 weighted PET-MRI isotropic reference space before analyses. Quality of the co-registrations to the reference T1 PET-MRI was quantitatively assessed using mutual information metric. The percentage gain compared to non-warped DWI data was also computed. ADC feature maps of each lung lesion were computed from the DWI data non-corrected and corrected from the distortion, and voxel-wise percent differences together with paired t-test were computed. Finally, regional ADC-SUV monotonic correlations were explored from optimal realigned DWI-PET data. **Results:** Quality of the co-registration between DWI and T1 PET-MRI data was significantly improved by the reverse phase encoding method (relative gain on mutual information compared to non-warped DWI data : 4-46%, vs 0.4-27% for warped data without distortion correction, p inferior to 0.05). The between-ADC feature maps regional differences ranged from -100% to more than +150%. Regional correlations between ADC and SUV computed from optimal realigned DWI-PET data revealed only weak monotonic relationships between the two features at the voxel level (spearman coefficients inferior to 0.5 in all the cases). **Conclusion:** DWI-related distortions are significant in thoracic PET-MRI, and should be corrected for accurate DWI-PET multimodal analyses. ADC and SUV showed weak monotonic relationship at the voxel level, emphasizing their complementarity. **References:** Chang H, Fitzpatrick JM. [1]*Department of Nuclear Medicine Hopitaux Universitaires Paris Sud, APHP, Le Kremlin-Bicêtre, FRANCE,* [2]*IR4M unit UMR8081 Paris Sud-CNRS, Orsay, FRANCE,* [3]*GE Healthcare, Orsay, FRANCE,* [4]*Laboratoire de mathématiques Université Paris Sud-CNRS, Orsay, FRANCE,* [5]*CEA-Neurospin, Saclay, FRANCE,* [6]*Thoracic Oncology Institute, Université Paris-Sud, Hopital Marie Lannelongue, Le Plessis-Robinson, FRANCE,* [7]*Department of respiratory medicine, Hopitaux Universitaires Paris Sud, APHP, Le Kremlin-Bicêtre, FRANCE,* [8]*Service Hospitalier Frederic Joliot, Université Paris Sud, CEA, Orsay, FRANCE,* [9]*Thoracic Oncology Institute, Université Paris-Sud, Gustave Roussy, Villejuif, FRANCE.*

Aim/Introduction: To assess the T1/T2-mapping approach for PET-MRI multimodal tissular characterization in the field of lung oncology. **Materials and Methods:** Two phantom session including T1/T2-mapping methods (IR,VFA,SMART1 / MEFSE) were performed on the same PET-MRI. Accuracies of T1/T2 mapping methods were assessed by the error measures against the phantom ground truths. Reliabilities were assessed by computing the intraclass correlation coefficients estimates of the phantom measures (ICC, mixed effect model, absolute agreement). For clinical validation, 8 patients underwent a PET-MRI for suspected lung cancer, including PET, DWI and T1/T2-mapping acquisitions. For all lesions, images were warped into the same isotropic reference space before features maps computation. Voxel-wise spearman correlations were performed to explore monotonic relationships between T1, T2, ADC and SUV features. Considering the 4 features, the lesions were partitioned using an unsupervised gaussian mixture approach. Finally, features profiles were explored at the cluster level. **Results:** Based on phantom analyses, SMART1 was the most accurate T1-mapping method for T1 relaxation times above 500ms ($SMART1_{error}$ less than 10% for the two sessions, ranging from 11 to 103% for the others methods). IR

and SMART1 were the most reliable (ICC = 0.999;$_{95}$CI = 0.99-1 for both). MEFSE was highly accurate for T2 relaxation times ranging from 23 to 278ms, with high reliability (ICC = 0.986, 95CI = 0.86-1). The 8 clinical lung lesions all showed T1 and T2 relaxation times in the ranges 1090-2209.5ms and 57.1-99.8ms respectively. For all the lesions except 2, absolute r values were inferior to 0.5 for all the features pairs. Unsupervised clustering provided 2 components for 6 lesions, and 1 component for two highly homogeneous lesions. At the regional level, features profiles were significantly different, as well as their monotonic relationships. **Conclusion:** T1/T2-mapping is feasible for PET-MRI lung oncology purpose. The multimodal profiles of T1, T2, ADC and SUV features emphasized their potential respective contribution for the lesion characterization at the regional level. **References:** Damadian R. EP-0935

Cardiac Misalignment In PET/MR Attenuation Correction - A Frequent Artifact In Myocardial Perfusion Imaging, Which Is Enhanced By Adenosine-Stress

E. von Felten, G. Benetos, D. Patriki, D. Benz, A. Giannopoulos, G. P. Rampidis, A. Pazhenkottil, C. Gräni, T. Fuchs, P. Kaufmann, R. Buechel;
Department of Nuclear Medicine, Zürich, SWITZERLAND.

Aim/Introduction: Misalignment of positron emission tomography (PET) datasets and maps for attenuation correction (AC) is a well-known potential source of artifacts in myocardial perfusion imaging (MPI). A hybrid PET/MR scanner offers inherent spatial co-registration of the PET dataset an AC-maps from MRI (MRAC). Therefore, occurrence of misalignment may seem unlikely. We aimed to evaluate the prevalence and the impact of MRAC-misalignment during MPI with PET/MR using adenosine-stress. **Materials and Methods:** Twenty-eight patients underwent 13N-ammonia PET MPI during adenosine-stress and at rest. We acquired Dixon MR sequences for creation of MRAC-maps immediately prior to the stress and rest dynamic PET acquisition, respectively. Of note, the stress MRAC-map was therefore acquired during fully effective adenosine-stress. For both, stress and rest, we performed a 7-minute dynamic, followed by a 10-minute static PET acquisition. After reconstruction of PET data based on the original co-registration (non-shifted images), we examined cardiac contours from the summed static PET dataset and the MRAC-map for spatial misalignment. If necessary, we performed manual adjustment to assure optimal cardiac co-registration (shifted images). We calculated a shift-vector indicating the summed shift distance of PET against MRAC in x-, y- and z-axis. We assessed summed stress, rest and difference scores (SSS, SRS, SDS) in non-shifted and shifted datasets. Additionally, we assessed the difference in z-axis of the diaphragm's location between rest and stress MRAC-maps. **Results:** Manual correction of co-registration was necessary in 25 (89.3%) stress and in 12 (42.9%) rest PET datasets. Median shift-vector was significantly higher in stress than in rest datasets (14mm [IQR 11-19] vs. 0mm [IQR 0-8]). Median SSS, SRS and SDS were significantly higher in non-shifted than in shifted images (SSS: 12 [IQR 8-13] vs. 7 [IQR 5-9]; SRS: 7 [IQR 4-9] vs. 5 [IQR 4-6]; SDS: 5 [IQR 4-8] vs. 3 [IQR 1-5]; all p<0,01). The difference of the diaphragmatic position in the MRAC-map between rest and stress, indicating different breathing-levels during and after adenosine-stress, correlated with the difference of SSS between shifted and non-shifted images (r=0.405, p=0.012). **Conclusion:** Spatial misalignment between PET and MRAC datasets occurs frequently during MPI, even if performed on a hybrid PET/MR scanner. Our findings indicate that breathing levels differ depending on the presence or absence of adenosine-stress lead to MRAC-misalignment particularly due to the "upward creep" phenomenon. Systematic review for cardiac misalignment and its eventual correction by execution of a manual MRAC-shift should be implemented in every cardiac PET/MR protocol. **References:** None.

Ultra-fast Dynamic Perfusion ^{18}F-NaF PET in Prostate Cancer as Enabled by Digital Photon Counting PET/CT - A Feasibility Demonstration

K. Binzel, T. Porter, C. L. Wright, E. Folefac, J. P. Monk III, D. Diaz Pardo, D. G. Stover, I. Hsieh, J. Zhang, M. V. Knopp;
The Ohio State University Wexner Medical Center, Columbus, OH, UNITED STATES OF AMERICA.

Aim/Introduction: To assess the feasibility of ultra-fast frame rate dynamic perfusion of Na-^{18}F PET/CT for patients with advanced prostate cancer. **Materials and Methods:** Ten patients with suspicion of recurrent prostate cancer were imaged as part of this initial feasibility and methodology development study. Patients were imaged over one bed position at the site of suspected tumor for 15 minutes immediately following injection of 185 MBq Na-^{18}F. Imaging was performed on a digital photon counting system (Vereos Philips, dPET) with continuous listmode acquisition. The patients spent the remaining uptake period in the injection suite followed by whole body imaging at 75 minutes post-injection as per standard of care. Listmode data from the dynamic acquisition was clipped and reconstructed with various time frames from 1 second per dynamic frame to 15 seconds per frame. Regions of interest were placed over any present bone tumor as well as degenerative regions and a region of healthy bone within the dynamic field of view. **Results:** The ultra-short dynamic reconstructions produced evaluable data sets for all acquisitions. Using the longer acquisitions for reference, regions of interest were placed in a reliable manner.

Physiologic motion could readily be corrected for, however very little motion was observed. An adaptive reconstruction approach was utilized to minimize image noise which otherwise would have led to degradation of image quality due to the considerable reductions in count density. All this was accomplished while preserving quantitative accuracy due to the performance characteristics of the digital photon counting system, as validated by listmode data clipping simulations. The ultra-short 1 and 9 sec/frame dynamic curves gave exceptionally detailed views of the perfusion in both bone lesions and areas of degenerative changes. **Conclusion:** In this feasibility demonstration, we have demonstrated that one second per frame image reconstruction of dynamic perfusion Na-^{18}F PET/CT data is robustly achievable. By anatomic correlation to the CT, quantification of tumor features such as vascularity and perfusion appear to be robustly and accurately assessed. This methodology may be applied to assess perfusion characteristics of bone tumors where the PET based measurement of tumor microcirculation may help guide therapy planning. Additionally, response to therapy may potentially be assessed via follow up measurement of changes in rates of bone lesion perfusion. **References:** None.

Metal artifact reduction in ^{68}Ga-PSMA-11PET/MRI for prostate cancer patients with hip joint replacement using multiacquisition variable-resonance image combination

K. Kudura;
Nuclear Medicine Department, Zürich, SWITZERLAND.

Aim/Introduction: PET/MRI has a high potential in oncology imaging, especially for tumor indications where high soft tissue contrast is crucial such as genitourinary tumors. One of the challenges for PET/MRI acquisition is handling of metal artifacts. In addition to conventional methods more innovative techniques have been developed to reduce those artifacts such as the selective multi-acquisition variable-image combination (MAVRIC SL). The aim of this study is a quantitative and qualitative assessment of metal artifact reduction in ^{68}Ga-PSMA-11 PET/MRI for prostate cancer patients with hip joint replacement using a selective MAVRIC SL sequence for the whole pelvis. **Materials and Methods:** Retrospectively analyzed were data of 20 men with 37 metal hip implants diagnosed with PCA, staged or restaged by ^{68}Ga-PSMA-11 PET/MR from June 2016 to December 2017. Each signal cancellation per side or metal implant was analyzed in the LAVA-FLEX sequence, considered as the reference sequence, as well as T1-weighted FSE and MAVRIC-SL. Two reviewers reported independently on a four-point scale (0= not assessable, 1= only partially visible, 2= visible with substantial blurring, 3= good depiction of anatomical structures) whether abnormal pelvic ^{68}Ga-PSMA-11 uptake could be assigned to an anatomical structure in the tested sequences. **Results:** The smallest averaged signal void was observed on MAVRIC SL sequences with a mean artifact size of 26.17 cm2 (range 12.63 to 42.93 cm2, $p < 0.001$). The best image quality referring to anatomical assignment of pathological PSMA uptakes in the pelvis reported on a four-point scale by two independent readers was noted on MAVRIC SL sequences compared to T1-weighted FSE and LAVA-FLEX sequences with excellent interreader agreement. **Conclusion:** MAVRIC SL sequence allows better image quality in the surrounding of hip implants by reducing signal voids and increasing so the accuracy of anatomical assignment of pathological ^{68}Ga-PSMA-11 uptakes in prostate, pelvic lymph nodes and bones over LAVA-FLEX and T1-weighted FSE sequences. **References:** None.

EP-0938

Technical limitations of 18F-FDG PET/MR in pediatric oncology: Case-based review of false positive findings

K. Hawk, A. Muehe, F. Siedek, A. J. Theruvath, H. E. Daldrup-Link;
Stanford University, Palo Alto, CA, UNITED STATES OF AMERICA.

Aim/Introduction: 18F-FDG PET/MR has quickly become a powerful tool for staging, follow up and surveillance of pediatric cancer patients. The significantly reduced radiation exposure compared to 18F-FDG PET/CT and superior anatomic detail of the nervous system and soft tissues are among the many benefits of 18F-FDG PET/MR imaging in pediatric care. Nonetheless, 18F-FDG PET/CT has technical limitations. The nuclear medicine physician must have an intrinsic understanding of these limitations and be able to understand and recognize possible false positive findings. Inadvertent misclassification of normal or benign PET-avid findings as malignancy can have a great impact on further treatment and prognosis. This case-based work is designed to educate nuclear medicine physicians about the technical limitations of 18F-FDG PET/MR and potential false positive findings in pediatric cancer patients. **Materials and Methods:** Following a comprehensive literature search on current techniques in 18F-FDG PET/MR in pediatric oncology, we complied an extensive collection of most current evidence -based best practices in 18F-FDG PET/MR. This work presents our institutional approach and experience with performing more than 150 18F-FDG PET/MR scans of pediatric patients with a series of case examples detailing technical limitations and false positive findings. **Results:** The imaging protocol and reporting criteria for conducting 18F-FDG PET/MR imaging of pediatric oncology patients will be detailed. Classical technical limitations of the 18F-FDG PET/MR imaging technique are provided. Non-neoplastic etiologies including infection, inflammation, physiologic hypermetabolism and iatrogenic causes are detailed as potential false positive findings. Benefits and limitations of 18F-FDG PET/MR imaging when compared with 18F-FDG PET/CT will be detailed as we discuss research and clinical application directions of 18F-FDG PET/MR imaging. **Conclusion:** 18F-FDG PET/MR has emerged as a powerful tool in evaluation of pediatric oncology patients. This comprehensive case-based review details how 18F-FDG PET/MR can be used to evaluate the pediatric oncology patient. Through explanation of 18F-FDG PET/MR imaging techniques, reporting mechanisms,

technical limitations, and classic false positive findings, this exhibit provides the learner with detailed understanding of applying 18F-FDG PET/MR to evaluate pediatric tumors and how to accurately identify false positive findings in order to provide excellent patient care. **References:** None.

Validation Of Aseptic Filling Process Of A New Automated Dispenser, Karl 100

S. Emery, C. Rémy, M. Razzouk-Cadet, C. Grangeon-Chapon; CHUN, Nice, FRANCE.

Aim/Introduction: Positron-emission is a nuclear medicine functional imaging that needs sterile radiopharmaceutic injections. For radioprotection purposes, dose preparations are often performed by dispensing machines whose operation must ensure sterility of dispensed doses. The aim of this study was to test the aseptic filling process of a new automated dispenser used to prepare fluorinated tracers doses, Karl100. **Materials and Methods:** In order to validate Karl100 aseptic process, 12 media fill tests were performed replacing both radiopharmaceutical vials and sodium chloride 0.9% infusion bags by suitable TSB (Tryptic Soy Broth) packaging. All fluid handling operations were done by the automated dispenser in accordance with its usual operating procedure. 12 Rad-Inject syringes filled with TSB were obtained and were finally transferred in sterile vials as follow: -9 samples of 6 mL using only a needle for the transfer, -3 samples of 6 mL using the specific infusion set of the Rad-Inject which includes a 0.22 µm filter. Aninfusion bag of TSB was used for the 3 tests using an infusion set for transfer. In order to increase media fill tests sensitivity, the final samples were then filtered (0.45 µm) throught Steritest EZ system (Merck Millipore; Molsheim, France) and cultured for fourteen days in two different growth media, one for aerobic and fungal microorganisms (Bact/Alert SA 259789; Biomérieux, Craponne, France)at room temperatureand the other for anaerobic microorganisms (Bact/Alert SA 259790; Biomérieux, Craponne, France) at 35°C. **Results:** At the end of 14 days of incubation, all samples remained sterile without microbial growth: media fill tests were successful. **Conclusion:** Although preparation of the Rad-Inject syringe requires disassembly of the plunger under non-sterile conditions, thesesimulation tests validated the aseptic filing process of Karl100. The 0.22 µm filter on infusion set provides an additional protection against microbial contaminations even if radiopharmaceutical is already sterile in Rad-inject syringe. Futhermore this filter includes a mandatory bubble trap to remove the air of the Rad-Inject tubing. In conclusion, Karl100 and its disposable devices can be used safely for radiopharmaceuticals dispensing in nuclear medicine departments. **References:** None.

Simultaneous Ventilation/Perfusion SPECT Acquisition: Diagnostic Accuracy

N. Gandy, N. Soneji, J. Phillips, L. M. Perry, M. Woodward, K. Wallitt, H. Tam, D. Gopalan;
Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.

Aim/Introduction: To determine whether simultaneous acquisition of perfusion and ventilation components of VQ SPECT utilising Tc99m-MAA and Kr-81m-gas has equivalent image quality and diagnostic accuracy as sequentially acquired perfusion and ventilation studies. **Materials and Methods:** VQ SPECT studies were acquired on a Siemens Symbia T16 gamma camera. The original report was based on a sequential perfusion (10sec/view) followed by ventilation SPECT (20sec/view) (SVQ). A Tc99m window with lower and upper scatter was included during ventilation SPECT acquisition to acquire simultaneous perfusion data. The simultaneous perfusion SPECT was reconstructed with dual-energy (DEW) and triple-energy window (TEW) scatter correction. 10 anonymised studies (5 positive and 5 negative for pulmonary embolus (PE)) were retrospectively reviewed by three consultant radionuclide radiologists independently (40 more cases pending). The reviewers were blinded to acquisition and reconstruction methods for the perfusion study. Studies were scored for image quality (1-4) and perfusion defects were documented as matched, mismatched or reverse mismatched. Overall diagnosis was documented as positive for PE if at least one mismatched defect was identified. The original report for the SVQ acquisition of each study was taken as the gold standard. **Results:** A total of 90 reads were completed by the three reviewers. Average image quality score of perfusion images was 2.8 (SVQ), 2.9 (DEW) and 3.0 (TEW). Overall inter-observer agreement for presence of PE was 93.3% with two discordant readings for one case. This case was reviewed by a consultant cardiothoracic radiologist and diagnosed as positive on all three acquisitions. Intra-observer agreement for presence of PE between the three different acquisitions was 90% for Readers 1 and 2 and 100% for Reader 3 - total of 1 discordant reading by SVQ and 2 by TEW. The average sensitivity for positive PE diagnosis across all three readers was 86.7% for SVQ acquisition, 93.3% for DEW and 73.3% for TEW. Specificity for PE diagnosis was 100% for all three reconstructions. Accuracy for each type of reconstruction, SVQ, DEW and TEW was 93.3%, 96.7% and 86.7% respectively. There is no significant difference in sensitivity or accuracy between the different reconstructions. **Conclusion:** This study demonstrates equivalent diagnostic accuracy of simultaneous perfusion and

ventilation acquisitions in comparison to sequential acquisitions with preserved specificity and no significant change in image quality or sensitivity when scatter correction is applied. Implementation of simultaneous acquisition in daily practice will decrease acquisition time for VQ SPECT and improve departmental efficiency and patient comfort. **References:** None.

Phantom study for activity quantification of ^{177}Lu SPECT/CT imaging

O. Ferrando[1], *A. Chimenz*[1], *M. Riondato*[2], *G. Rambaldi*[1], *F. Foppiano*[1], *A. Ciarmiello*[2];
[1]*Department of Medical Physics - ASL5 Spezzino, La Spezia, ITALY,* [2]*Department of Nuclear Medicine - ASL5 Spezzino, La Spezia, ITALY.*

Aim/Introduction: To assess the of activity quantification with ^{177}Lu phantom studies on our SPECT/CT scanner (SYMBIA T2 - Siemens Healthcare). SPECT-based activity quantification is necessary for personalized image-based dosimetry in target radionuclide therapy as recommended by the EURATOM 2013/59 directive. **Materials and Methods:** Quantitative SPECT/CT studies with ^{177}Lu was performed using the methodology proposed in [1]. The scanner calibration factor and the recovery coefficients for different spherical objects in different radioactive backgrounds were evaluated. The used instrumentation consists of an uniform cylindrical phantom (5860 mL) and an IEC NEMA torso-phantom containing hot sphere inserts with volumes in the range (0.5 - 25) mL. The spheres were filled with a solution of ^{177}Lu with an activity concentration of 2.9 MBq/mL. Background activity concentrations were in the range (0.04 - 0.18) MBq/mL with the following sphere to background ratio: 67.1:1, 32.6:1, 19.4:1, 12.8:1. Images were reconstructed using the proprietary OSEM 3D algorithm (FLASH 3D, Siemens Healthcare), CT-based attenuation correction, energy window-based scatter correction and resolution recovery. **Results:** The scanner calibration factor was 5.1 cps/MBq. Mean recovery coefficients vary from 73% (for volumes of 25 mL) to 12% (for volumes of 0.5 mL) with variations in the range of 1% - 5%. The number of subsets and iterations and filtering applied to image reconstruction were chosen based on a previous study [2] and were set to 8iterations/8subset/no image filtering since these parameters seem to improve activity recovery and limiting the background variability. Background activity concentratrions were determined with errors between -3.5% and 4.2%. **Conclusion:** Following the indications of the EURATOM 2013/59 directive, concerning activity quantification for personalized dosimetry in radionuclide therapy, a scanner calibration factor and the activity recovery coefficients were found for ^{177}Lu applications. Our results show that activity in phantom can be determined with a difference less than 5% respect to the true activity. These results have to be validated in further studies with different object sizes and shapes and also with patient scans. **References:** [1] J. Zeintl et all. EP-0942

Sensitivity comparison between normal, fast and super-fast Low Dose SPECT/CT in order to localize and discriminate the nature of doubtful findings to complete whole-body bone scintigraphy in cancer patients

A. Farina[1], *R. Bonfiglioli*[1], *M. Maccagnani*[1], *S. Zoboli*[2], *S. Fanti*[1];
[1]*Nuclear Medicine Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY,* [2]*Nuclear Medicine Department, Maggiore Hospital, Bologna, ITALY.*

Aim/Introduction: The aim of this retrospective study was to assess the performance (sensibility) between different Low Dose SPECT/CT in a cohort of oncological patient who undergone to whole body bone scintigraphy in order to clarify doubtful findings. **Materials and Methods:** This is a single centre retrospective review on patients selected between subjects sent to our operating unit to be undergone to bone scintigraphy from September 2016 to March 2019 according to the following inclusion criteria: a) comprehensive clinical history and prior management data; b) observe of doubtful findings by nature or location during whole body bone scintigraphy; c) execution of segmental LD-SPECT/CT to complete the study; d) acquisition data of LD-SPECT/CT (normal: 3º every 15'; fast: 6º every 15'; super-fast: 9º every 5'); e) obtaining informed consent. All images were reviewed by two experienced nuclear medicine physicians. Technical data of LD-SPECT/CT acquisition were reviewed by one senior radiologic technologist. Overall, 169 patients were enrolled in our study (92 female, 77 male): 110 undergone to normal LD-SPECT/CT (Group A); 34 undergone to fast LD-SPECT/CT (Group B); 25 undergone to super-fast LD-SPECT/CT (Group C). The districts examined through LD-SPECT/CT were head and neck (16/169), chest (44/169), lumbar spine (36/169), pelvis (62/169) and legs (11/169). **Results:** In Group A we found 37 new findings of whom 22 confirmed by subsequent radiological investigations (59%). In Group B we found 12 new findings of whom 5 confirmed by subsequent radiological investigations (42%). In Group C we found 9 new findings of whom 7 confirmed by subsequent radiological investigations (78%). In every groups we were able to clarify the anatomic location of the doubtful finding and to provide bone structural information independently by subsequent radiological investigations. **Conclusion:** Fast and super-fast LD-SPECT/CT had a sensibility comparable to normal LD-SPECT/CT, but it permits to obtain the diagnostic information in shorter time (5-10 minutes vs 20 minutes). The mainly advantage is for frail patients who experience reduced discomfort due to a complex diagnostic investigation. **References:** None.

EP-0943

Comparative study of IQ-SPECT and conventional SPECTGated Myocardial Perfusion Imaging

D. Biao;
The Frist Affiliated Hospital of ZhengZhou University, Zhengzhou, CHINA.

Aim/Introduction: To compare the left ventricular semi-quantitative perfusion results and cardiac function parameters of IQ-SPECT equipped with SMARTZOOM collimator and conventional SPECT system equipped with low energy high resolution collimator (LEHR), and to explore the difference between the results of the two imaging methods. **Materials and Methods:** A total of 35 subjects with severe arrhythmia were excluded from November 2016 to April 2017. The resting-gated myocardial perfusion imaging (G-MPI) was performed by IQ-SPECT and conventional SPECT acquisition methods, respectively. A low dose CT scan was performed after the last acquisition for attenuation correction. Five-stage semi-quantitative visual analysis of images was performed by two senior nuclear medicine physicians using a double-blind method. Cardiac function parameters were obtained by the Cedars QGS software automated analysis software. Finally, the resting perfusion total score (SRS), ejection fraction (EF), end-diastolic volume (EDV), end-systolic volume (ESV), peak ejection rate (PER), and peak-time filling were obtained by the two acquisition methods. Rate (PFR). Analysis was performed using SPSS 22.0 software using paired sample t-test or paired sample rank sum test (Wilcoxon test). **Results:** The resting perfusion score of the IQ-SPECT system was higher than the conventional score [SRS: 4(6) and 3(6)]. The EF calculated by IQ-SPECT was reduced [EF: (58.14 ± 17.10)% and (62.66 ± 21.13)%]. IQ-SPECT calculated lower EDV [EDV: 73 (57) ml and 85 (46) ml]. The PER calculated by IQ-SPECT is low [(2.34±0.92) EDV/s and (3.15±1.15) EDV/s]. The PFR calculated by IQ-SPECT is low [(2.35±0.93) EDV/s and (2.58±1.15) EDV/s]. The difference in ESV between the two was not statistically significant [ESV: 30 (30) ml and 27 (41) ml]. **Conclusion:** Conclusion The new IQ-SPECT system can shorten the acquisition time and / or reduce the dose of radiopharmaceuticals injected into patients. When comparing the semi-quantitative perfusion results and functional parameters of the left ventricle obtained by IQ-SPECT with the conventional SPECT system, we found that Significantly, the SRS describing the myocardial perfusion index was higher in IQ-SPECT with lower EF values, EDV, PER, and PFR. **References:** None.

EP-0944

Performance characteristics of ^{225}Ac produced gamma and X-rays SPECT imaging with medium-energy collimator

S. Woo[1,2], *W. Kim*[1], *H. Sheen*[1], *C. Lee*[2], *K. Song*[3], *S. Lim*[2], *I. Lim*[2];
[1]*Division of applied RI, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Nuclear Medicine, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF,* [3]*Department of Urology, Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: Alpha emitted radioisotopes have a high radiation weighting factor. For this reason, the acquisition of acceptable quality of the alpha emitted radioisotope image has highly challenging. The aim of this study was the acquisition of ^{225}Ac produced gammas and X-rays for SPECT image with a medium-energy collimator. **Materials and Methods:** The National Electrical Manufacturers Association (NEMA) standard NU 4-2008 phantom filled with 115.7 μCi of a ^{225}Ac was scanned by Inveon multimodality scanner (Siemens Preclinical Solution, Knoxville, TN). The NEMA NU 4-2008 phantoms is a 50-mm-long, 30-mm-diameter cylinder and consist of different regions to analyze 3 distinct aspects of image quality. The first 20 mm of the phantom body are solid, with 5 fillable rods with diameters of 1, 2, 3, 4, and 5 mm. SPECT data acquired using 3 mm medium energy pinhole collimator. Two photopeak energy window setting was acquired as 86 (± 20% from ^{225}Ac, ^{213}Bi), 218 (± 20% from ^{221}Fr, ^{213}Bi), 440 (5% ^{213}Bi) keV. To correct the scatter and background, performed the triple-energy-window method. The acquired data were reconstructed by maximum a posteriori (MAP) 3D reconstruction (iteration 16 and subset 6) with point spread function (PSF) mode. The evaluation of images quality was performed by uniformity and full width half maximum (FWHM). In addition, we acquired ^{225}Ac SPECT mice image. **Results:** We are able to visualize the 2, 3, 4, and 5 mm diameter rods in the 86 keV X-ray image whereas 1, 2, 3, 4, and 5 mm diameter rods are visualized in gamma-ray image. The uniformity of 86, 218, and 440 keV with PSF were 0.50, 0.84, and 0.54, respectively. The FWHM of 86, 218, and 440 keV were 1.78 ± 0.12, 1.89 ± 0.07, and 1.50 ± 0.05 mm, respectively. The relative change of 86 keV compare to 440 keV uniformity and FWHM were 7.5 % increase and a 15 % decrease. According to the acquired ^{225}Ac SPECT of mice image, the radioisotope was highly uptake in liver area. **Conclusion:** X-ray image produced ^{225}Ac decay chain was similar uniformity as well as FWHM of its gamma-ray. The result of this study presented the importance of X-ray production of ^{225}Ac decay chain to improve the SPECT image quality with a medium-energy collimator. **References:** Robertson, A. K. H., et al. "Multi-isotope SPECT imaging of the 225Ac decay chain: feasibility studies." Physics in Medicine & Biology 62.11 (2017): 4406.

Beyond Nema For Modern Spect Cameras

A. Alosaimi[1,2], *S. Patford*[3], *J. Smith*[3];
[1]*King Fasial Medical City for Southern Region, Riyadh, SAUDI ARABIA,* [2]*Queensland University of Technology, Brisbane, AUSTRALIA,* [3]*Royal Brisbane and Women's Hospital, Brisbane, AUSTRALIA.*

Aim/Introduction: National Electrical Manufacturer Association (NEMA) published several standards to provide uniform

quality control (QC) tests for scintillation camera performance. Unfortunately, these guidelines do not include tests for the SPECT/CT systems, particularly the involvement of CT in the SPECT images. Therefore, this study aims to develop an extension to NEMA NU 1 standard to include additional QC specification. These are: (1) SPECT/CT Spatial registration, (2) CT attenuation correction accuracy and (3) whole-body SPECT/CT scan uniformity. **Materials and Methods:** Test (1) was performed by using either plastic IV tube filled with oral CT contrast solution mixed with ^{99m}Tc or 1 mm diameter metallic line sources filled with only ^{99m}Tc. The fusion registration misalignments were quantified with the scanner software in 6 degrees of freedom. Test (2) was accomplished by using a 20 cm diameter cylindrical phantom, which was filled with approximately 200 MBq of ^{99m}Tc. ROI of areas ranging from 0.7 cm^{2}to 13 cm^{2}centred on the trans-axial slices were used. Test (3) was performed by acquiring a SPECT of a line source over two contiguous bed positions. The uniformity line profile was obtained by taking the sum of the counts in each SPECT slice as a function of slice location. **Results:** It was found that the software needed adequate contrast for both SPECT and CT images to accurately detect the two line sources for fusion. The counts in a ROI on the non-CT attenuation corrected SPECT image was compared to the same ROI on the CT attenuation corrected SPECT image. The maximum deviation from the average counts and its slice location were reported as percentage non-uniformity. **Conclusion:** In order to achieve accurate registration result, the metallic line source phantom is recommended. The accuracy of attenuation coefficient for water applied can be imperially determined. The maximum non-uniformity artefact result was satisfied. **References:** 1.Chakraborty, D., Bhattacharya, A., Gupta, A. K., Panda, N. K., Das, A., & Mittal, B. R. (2013). Dual-Isotope Peptide Receptor Radionuclide Therapies with ^{177}Lu and ^{90}Y: Is Quantitative Imaging Possible?

C. Miller[1], *A. Rahmim*[1,2,3], *A. Celler*[2];
[1]*Department of Physics, University of British Columbia, Vancouver, BC, CANADA,* [2]*Department of Radiology, University of British Columbia, Vancouver, BC, CANADA,* [3]*Department of Integrative Oncology, BC Cancer Research Centre, Vancouver, BC, CANADA.*

Aim/Introduction: Peptide receptor radionuclide therapy using DOTATATE labeled with ^{177}Lu or ^{90}Y is a promising treatment for neuroendocrine tumours. However, Kunikowska et al. (2011) has shown that using these two isotopes simultaneously results in better patient outcomes. As ^{90}Y emits higher energy β- particles than ^{177}Lu, personalized dosimetry should be performed to not exceed dose limits to critical organs while optimizing tumour control. Kidneys are the critical organs in this therapy, and large variations in their doses have been observed. Assuming identical biodistributions of ^{177}Lu- and ^{90}Y-DOTATATE, dosimetry can be performed using ^{177}Lu SPECT imaging. Only ^{177}Lu emits suitable photons for imaging, while ^{90}Y is a pure β- emitter and cannot easily be imaged. Moreover, Bremsstrahlung photons created by ^{90}Y can cloud the ^{177}Lu spectrum, making activity quantification inaccurate. This work aims to determine if dosimetry based on quantitative imaging of ^{177}Lu in the presence of ^{90}Y is possible. **Materials and Methods:** Monte Carlo GATE simulations were performed of spheres containing ^{177}Lu, ^{90}Y, or both placed in a phantom filled with cold water, water with ^{90}Y, or water with ^{90}Y+^{177}Lu. Eighteen different concentrations of ^{177}Lu and/or ^{90}Y in the spheres and seven different background configurations were imaged with a simulated Siemens Symbia camera. Concentrations of each isotope were chosen based on injected activities which would not exceed dose limits to critical organs. The quantification accuracy and noise distribution were determined for every configuration. **Results:** With no background in the phantom, quantification error of ^{177}Lu remained below 12% for low concentrations of ^{177}Lu (0.3 MBq/ml) and 3% for high concentrations (2 MBq/ml) for all ^{177}Lu to ^{90}Y sphere ratios. With ^{90}Y+^{177}Lu background, the error ranged from 6% for low background ratios (1:10 background to ^{177}Lu-source) to 24% for high ratios (1:3 background to ^{177}Lu-source). The noise levels ranged from 20% for low concentrations of ^{177}Lu in the sphere to below 5% for high concentrations. **Conclusion:** Activity quantification of ^{177}Lu in the presence of ^{90}Y is achievable with an acceptable margin of error (< 15%) at low and high ratios of ^{177}Lu to ^{90}Y-sphere activity (maximum ratio 1:6) and moderate ratios of background to ^{177}Lu-source activity (maximum ratio 1:5). Errors are high (> 20%) with high background ratios (1:3) but this is rarely seen in patients. This suggests that quantitative dosimetry in dual isotope PRRT is possible. **References:** Kunikowska et al., Eur J Nucl Med Mol Imaging, 2011. 38(10):1788-97.

EP-0947

Shorter Dynamic Planar Scintigraphy to Estimate Myocardial [^{123}I]-MIBG Washout Rates

Y. Kumakura, Y. Shimizu, K. Ichikawa, N. Yoshida, K. Nomura; Saitama Medical Center, Saitama Medical University, Kawagoe, JAPAN.

Aim/Introduction: The heart-to-mediastinum ratio (HMR) and washout rate (WR) have served as simple semi-quantitative indices of myocardial [^{123}I]-MIBG scintigraphy for more than two decades. However, it is burdensome and inconvenient for patients with Parkinsonian symptoms to undergo the conventional scanning protocol, which demands two scans

approximately three hours apart. We introduced a short (30 min) dynamic planar imaging procedure, and have just completed scanning of approx. 240 patients suspected of Lewy body diseases. A pharmacokinetic model similar to a [^{18}F]-FDOPA inlet-and-outlet model (Kumakura et al., 2007) was applied to the TACs after correction for plasma and myocardium-specific counts. Then, we investigated the relationship between the semi-quantitative indices and the new kinetic indices indicative of [^{123}I]-MIBG loss from myocardium as well as unidirectional uptake to catecholamine storage vesicles. **Materials and Methods:** For now, a total of consecutive 130 patients suspected of LBDs were analyzed and reported here. We used a conventional two-detector SPECT camera (GE Discovery NM 630) equipped with ELEGP collimators. The dynamic imaging was started immediately after a bolus injection of 111 MBq of [^{123}I]-MIBG. To obtain TAC-based "input functions", we used mediastinum TACs after smoothing with a three-phase exponential decay function, a population-based blood-to-plasma ratio (BPR) curve, and a population-based metabolite correction (PBMC) curve. The two correction curves were published by another group. (Wu et al., 2016). We subtracted the smoothed mTACs from the hTACs to isolate myocardium-specific TACs. Then, we calculated magnitudes of three new indices representing unidirectional uptake (iUp), loss rate (iLoss), and non-specific distribution to myocardial interstitial space (iNs) for comparison with those of HMR and WR. **Results:** No patient failed. Linear regression analysis revealed that iUp/iLoss (an index of vesicular storage) was a significant predictor of delayed HMR (slope: 0.375, P< 0.0001, R2: 0.97) as well as early HMR (slope: 0.264, P< 0.0001, R2: 0.97). We found that 0.693/iLoss (min: pharmacological half life of [^{123}I]-MIBG trapped in myocardium) was a significant predictor of WR (slope: -0.0545, P< 0.0001, R2: 0.71). The mean of 0.693/iLoss was 15 min. **Conclusion:** In view of replacing the conventional 3h protocol, we confirmed that the HMRs and WR can be predicted from the new indices obtained from the 30 min planar dynamic procedure. It proved to be clinically feasible and well suited to quantitation of [^{123}I]-MIBG turnover and storage capacity in the sympathetic myocardial nerve terminals. **References:** Kumakura et al., PMID: 17652599; Wu et al., PMID:27081169.

"Fast" SPECT/CT, a new possibility for the assessment of bone metastasis as add-on to planar bone scintigraphy. Preliminary study in 31 patients

A. Baena[1], *M. Cruz-Montijano*[2], *S. García-Martínez*[2], *M. Pajares-Vinardell*[2], *J. Freire-Macias*[2], *M. De Bonilla*[2], *F. Partida-Palma*[2], *T. Gutierrez-Amares*[2];
[1]*Hospital Universitario Puerta del Mar, Cadiz, SPAIN,*
[2]*Hospital Universitario Puerta del Mar, Cádiz, SPAIN.*

Aim/Introduction: The aim of this study is to assess whether a "fast" acquisition SPECT/CT (SPECT-CT-F) can replace the standard SPECT/CT (SPECT/CT-S) study for the investigation of suspicious bone metastases after a whole-body bone scan (WB-BS). **Materials and Methods:** A total of 31 patients with a history of oncological disease and metastasis suspicion in a WB-BS that needed a SPECT/CT-standard and also underwent a SPECT-fast were included. Of the total number of patients, 60% were women. 38% had breast cancer, 29% prostate cancer, 16% other cancers and 16% suspected oncology. All studies were performed using a single low-dose CT scan, which was used for both rapid and standard SPECT. SPECT parameters were the following: a) SPECT-standard: 128x128 matrix, zoom factor 1, 20 s/view, 60 views; b) SPECT-fast: 128x128 matrix, zoom factor 1, 10s/view, 30 views. Obtaining total acquisition times of 14 min and 7s for the SPECT-standard and 3 min and 50 s for the SPECT-fast. The studies were independently evaluated by 3 nuclear medicine doctors with more than 20 years of experience, who independently judged each study (standard and fast SPECT). Findings were classified as metastatic, equivocal, benign or normal (negative for metastasis). The agreement between observers and intra-observer concordance between SPECT-standard and SPECT-fast was calculated. Statistical analysis of the results was performed using Cohen's Kappa. **Results:** Using SPECT/CT-S, 22 patients (71%) were classified as benign findings, 7 patients (22.6%) were classified as malignant findings and 2 patients were classified as equivocal findings (6.4%). There was a 80% (25/31) of agreement between the three evaluators (same diagnosis) in WB-BS and SPECT-standard. Of these 25 studies, 84% were benign findings and 16% were classified as malignant. A 100% of agreement was found between standard and fast SPECT for the same evaluator. **Conclusion:** This preliminary study can conclude that SPECT-fast may be useful in bone scintigraphy studies for discrimination between a benign and malignant finding in the context of oncological patients with suspicion of a single bone metastasis, making it possible notably reduce the SPECT acquisition time without compromise diagnostic value. **References:** Palmedo H, Marx C, Ebert A, Kreft B, Ko Y, Turler A, et al. Whole-body SPECT/CT for bone scintigraphy: diagnostic value and effect on patient management in oncological patients. Eur J Nucl Med Mol Imaging. 2014;41:59-67.

EP-0949

A rapid protocol to evaluate myocardial flow reserve with myocardial scintigraphy using CZT camera and Regadenoson

J. Pinaquy, *Q. Ceyrat*, *T. Couffinhal*, *H. Douard*, *F. Debordeaux*, *L. Bordenave*;
CHU, Bordeaux, FRANCE.

Aim/Introduction: Cardiac positron emission tomography (PET) is superior to single-photon emission computed tomography(SPECT) thanks to its quantitative analysis capabilities, especially for measuring myocardial blood flow (MBF) and myocardial flow reserve (MFR). The recent development of new cadmium zinc telluride (CZT) gamma cameras has enabled dynamic acquisition, allowing measurement of MBF and MFR.This prospective study

aimed to validate a rapid protocol, using Regadenoson, and to analyse the standard images from myocardial perfusion imaging (MPI) without any loss of information. **Materials and Methods:** From February to June 2018, 10 patients were prospectively enrolled in our study to evaluate the MBF and MFR. Patients were imaged using a solid-state dedicated cardiac camera (Discovery NM530c). All patients underwent a 1-day gated rest-stress protocol. Concomitant with the intravenous bolus administration of the resting ^{99m}Tc-tetrofosmin dose of 2.5 MBq/kg, a list-mode acquisition was started for 6 min immediately prior to the standard 10 min acquisition. On completion of the resting state images, pharmacological stress was induced using regadenoson. At the vasodilation peak , the second dose of ^{99m}Tc-tetrofosmin of 8 MBq/kg was injected, and 6 min of list-mode data was collected at the time of the injection, after which the standard acquisition of stress MPI over 5 min was realized. List-mode dynamic data were reformatted and reconstructed using Corridor4DM software(INVIA) into five different reconstruction models: three of 6 min (test 1: 21×3s, 1×9s, 1×15s, 1×21s, 1×27s, and 7×30s [32 frames]; test 2: 30×3s and 18×15s [48 frames]; and test 3: 60x 3s and 6x30s [66 frames]); and two of 4 and 3 min (20x3s and 6x30s [26 frames]; and 20x3s and 4x30s [24 frames], respectively). The primary endpoint was the difference between the five models, the secondary endpoint the image quality of the MPI. **Results:** The average age of the patients was 68.5 years and 40% were female. The study population had an average body mass index (BMI) of 28.4 kg/m²and all of the patients had at least one cardiovascular risk factor.The 6-min tests highlighted no significant difference in the flow measurement and MFR (p=0,15), and appears by decreasing acquisition time (<4 min). The image quality did not differ significantly (p=0.6) between dynamic acquisition and standard acquisition. **Conclusion:** We determined a fast (12 min), reliable and reproducible protocol with minimal mobilization of the patient, to flow measurements. This will enable reliable analysis MFR while maintaining both qualitative visual and functional data. **References:** None.

Evaluation of Veriton™ 360° CZT-camera performances for quantitative Dopamine Transporter (DaT) Imaging: a SPECT study based on quality and anthropomorphic phantoms

E. Cassol[1,1], *P. Gantet*[1], *P. Payoux*[1,2];
[1]*Department of Nuclear Medicine, University Hospital of Toulouse Purpan, Toulouse, FRANCE,* [2]*ToNIC Toulouse Neuroimaging Center, Toulouse University, Inserm, Toulouse, FRANCE.*

Aim/Introduction: Dopamine Transporter (DaT) imaging can be performed in SPECT on Anger-cameras either equipped with parallel (LEHR) or convergent collimators (Fan-Beam). Last year, a 3D Cadmium-Zinc-Telluride (CZT)-camera became commercially available. The VERITON™ system (Spectrum Dynamics Medical), uses 12 independent detector arms to provide 360° coverage. Our aim is to evaluate the performances of Veriton on Jaszczak phantom and to test acquisition modes and reconstruction parameters impact for binding potentials (BP) quantification in a striatal phantom. **Materials and Methods:** The Jaszczak Phantom™ containing the cold rods insert and 6 cold-spheres was filled with 267MBq of Iodine (^{123}I). Acquisitions were successively performed on Veriton and on DiscoveryNM/CT670 (General Electric Healthcare) with LEHR and Fan-Beam collimators. The striatal anthropomorphic phantom (Radiology Support Device, RSD) was filled with 28MBq of ^{123}I to achieve the following BP: 6.0 for right and left caudate nuclei, 6.0 for the right putamen and 2.4 for the left-one. On Veriton, acquisitions were performed in "non- brain- and striatum-focus modes" on Discovery670, with LEHR and Fan-Beam in 4 and 8 minutes. Iterative reconstructions were performed with different number of iterations. For each configuration, the number of counts was recorded. Image quantification was done with DaTsoft3D (Imsoft, Toulouse) to determine integral-non-uniformity percent, Contrast-to-Noise ratio (CNR) and BP. CNR variation was studied with sphere-diameter and number of iterations. The mean absolute error (MAE) was calculated between expected and measured BP values. **Results:** Image quality is improved with Veriton except for the spatial resolution observed to be more accurate on Fan-Beam images. The integral non-uniformity is lower and the volumetric sensitivity is 6.99×10^{6}cps/(MBq.ml^{-1}) versus 3.17×10^{6}cps/(MBq.ml^{-1}) for LEHR-Discovery. For all spheres, the CNR-value increases with the number of iterations (up to the 20th). Veriton-CNR is higher, from 1.5 to 2 times for spheres between 12 and 25mm diameter even though the small sphere remains difficult to detect due to its low CNR-value. In RSD, the relative pixel count-rate is 2.54; 1.93; 1.44; 1.71 for respectively striatum, brain, non "focus modes" and FB (1 is for LEHR). With "low" counts level, the MAE increases over 6 iterations but MAE is minimized with the "Brain-Focus" acquisition mode (under 0.2). **Conclusion:** For same acquisition-time, thanks to the focus mode, pixel-count is strongly increased when compared to LEHR-Discovery. ^{123}I-DaTscan image quality is not improved with Veriton when compared to Fan-Beam-Discovery. Binding potentials in brain compartments can be quantified with good accuracy if image-statistics are over 1.5Mcts. **References:** None.

Impact of acquisition and reconstruction parameters on cardiac perfusion imaging using the new 360° CZT VERITON camera

A. Manrique[1,2], *A. Bouthiba*[1], *B. Enilorac*[2], *P. Tager*[2], *C. N'Ganoa*[2], *N. Roth*[3], *D. Agostini*[1,2];
[1]*Normandie Université - EA 4650, Caen, FRANCE,* [2]*CHU de Caen, Caen, FRANCE,* [3]*Spectrum Dynamics, Caesarea, ISRAEL.*

Aim/Introduction: The Veriton camera (Spectrum Dynamics, Caesarea, Israel) is a multi-purpose SPECT scanner that uses 12 independent CZT detector arms to provide 360-degree coverage with minimal photon loss. The aim of this study was to assess the impact of a focus mode that allows a cardiocentric acquisition to increase sensitivity and resolution compared

to conventional circular orbit. **Materials and Methods:** We used the anthropomorphic torso phantom (Data Spectrum, Hillsborough, NC) with the cardiac insert filled with a solution of 99mTc (myocardium: 22 kBq/ml, liver: 35 kBq/ml, mediastinum: 1.2 kBq/ml). A defect (5,4 ml) filled with cold water was placed successively in inferolateral and anteroseptal positions. A series of 10 min list mode acquisitions was performed using successively automatic or manual body contour, with both circular orbit and cardiac focus. Acquisitions were reframed to 4 different acquisition durations (2.5, 5, 7.5 and 10 minutes) and processed using OSEM alone (40 iterations) or after applying a proprietary (Spectrum Dynamics) cardiac model (SD). Defect size and cardiac volume were measured using QPS and QGS. Resolution, assessed as the FWHM of the defect-free wall, and contrast-to-noise ratio (CNR) were calculated using ImageJ. Statistical analysis was performed using linear model (body contour, cardiac focus and acquisition duration were forced in the model). **Results:** Count statistics were increased by cardiac focus ($p<0.0001$), automated body contouring ($p<0.0001$) and acquisition duration ($p<0.0001$). FWHM was independently improved by using automated body contouring ($p<0.0001$) and SD reconstruction ($p<0.0001$). CNR was only increased by using SD reconstruction. The measurement of defect size was improved by cardiac focus ($p<0.001$), automated body contouring ($p<0.0001$) and increased acquisition duration ($p<0.05$). Finally, ventricular volume was overestimated by SD vs. OSEM (74±5.3 ml vs. 63±4.8 ml, $p<0.0001$) and to a lesser extent by automated vs. manual body contouring (70±7ml vs. 67±7 ml, $p<0.01$). **Conclusion:** When using the new 360° CZT Veriton camera, cardiac focus and automated body contouring improved both count statistics and resolution and resulted in an improved assessment of perfusion defects. Using a cardiac model in the reconstruction process improved contrast-to-noise ratio and resulted in an increased ventricular volume. **References:** None.

GATE-based simulations of the performance of the Symbia Intevo SPECT/CT system for evaluating novel image reconstruction algorithms

H. Kertesz[1], *N. Denisova*[2], *M. Ondar*[2,3], *J. Cal-Gonzalez*[1], *I. Rausch*[1], *P. Schaffarich*[1], *T. Beyer*[1];
[1]*QIMP Team, Center for Medical Physics and Biomedical Engineering, Vienna, AUSTRIA,* [2]*Khristianovich Institute of Theoretical and Applied Mechanics, Siberian Branch of Russian Academy of Sciences, Novosibirsk, RUSSIAN FEDERATION,* [3]*Novosibirsk State Technical University, Novosibirsk, RUSSIAN FEDERATION.*

Aim/Introduction: To model and evaluate the performance of a state-of-the-art SPECT/CT system (Siemens Symbia Intevo) using GATE simulations as part of an ongoing project for the validation of a novel image reconstruction algorithm using local regularization (MAP-L). **Materials and Methods:** The SPECT system is made of two NaI-based detector heads (59.1x44.5x0.95cm³). The useful field-of-view (UFOV) is 53.3x38.7cm.Low-energy high-resolution (LEHR) collimator was modelled, which is made of lead with hexagonal holes (diameter of 1.11mm, height 24.05mm, septal thickness 0.16mm).The SPECT model was evaluated following the NEMA NU1-2007 protocol for system planar sensitivity (SPS) and intrinsic spatial resolution (ISR). For the evaluation of the SPS a Petri dish (diameter 150mm, height 15mm) filled with 125MBq ^{99m}Tc was used. The evaluation of the ISR was done with the NEMA X-Y phantom made of a 3mm thick lead plate with 1mm slits positioned at a distance of 30mm. A point source (1GBq activity ^{99m}Tc) was placed in a lead shielded holder at a distance of 270 cm from the detector. The full-with half-maximum (FWHM) and full-width tenth-maximum (FWTM) were calculated for the UFOV and the central field-of-view (CFOV) corresponding to 75% of the UFOV. The simulated values were compared to the measured reference values that were obtained previously during the acceptance test of the system. The ISR in Y direction was not available in the acceptance test. **Results:** The simulated SPS with the LEHR collimator at 10cm distance was 92.8 (measured 88.7) cps/MBq and 93.8 (89.0) cps/MBq for detector 1 and 2, respectively. The ISR in X direction was 3.3mm (3.5mm) FWHM for both UFOV and CFOV, 6.3 (6.8mm) FWTM for UFOV and 6.4 (6.8mm) FWTM for CFOV. In Y direction the simulated ISR was 3.1mm FWHM and 6.1mm FWTM for both UFOV and CFOV. **Conclusion:** The proposed SPECT model showed good accuracy with less than 6% discrepancies in comparison to the measured reference values. The application of the model for the evaluation of novel image reconstruction algorithms in simulated numerical phantoms is work in progress. The model will be extended and validated with the high-energy collimator for ^{131}I simulations and will be available online. The financial support of the Austrian FWF Project I3451-N32 is gratefully acknowledged. **References:** None.

EP-0953

Head to head comparison of General Electric Swiftscan solution versus Siemens Symbia in bone scintigraphy on NaI-camera

M. Bailly, *F. Thibault*, *G. Le Rouzic*, *G. Metrard*;
CHR Orléans, Orleans, FRANCE.

Aim/Introduction: General Electric (GE) Swiftscan solution combines a new Low Energy High Resolution and Sensitivity collimator (LEHRS) with image processing (Clarity 2D) and tomographic step and shoot continuous mode. The aim of this study was to compare clinical and physical performances of this new technology in bone scintigraphy with Siemens Symbia. **Materials and Methods:** Physical phantom measurements were performed using GE pre-production LEHRS, GE Low Energy High Resolution (LEHR) and Siemens LEHR collimators, followed by a prospective clinical study approved by an ethic committee. 67 patients referred for bone scintigraphy were enrolled from February to July 2018. Whole-body, static acquisitions, and when needed SPECT were performed 2 hours after injection of 9.25

MBq/kg Tc-99m-methylene-diphosphonate (MDP). Each patient underwent two acquisitions consecutively on GE and Siemens gamma-camera, using respectively pre-production Swiftscan and LEHR collimator (order of passage was randomized). All the images were anonymized and blind-analyzed by 2 board certified nuclear medicine physicians. Image quality was visually scored and contrast over nose ratio was measured on whole-body scans. **Results:** Maximum sensitivity was 100 cts/MBq for Siemens LEHR on planar acquisitions. GE SwiftScan LEHRS and GE LEHR maximum sensitivity were respectively 9% and 22% lower. Using Clarity 2D, GE Swiftscan LEHRS spatial resolution was the best with 9.2 mm versus 10.1 mm and 10.6 mm for GE LEHR and Siemens LEHR collimators. In tomographic mode, the sensitivity of GE Swiftscan solution was superior to both LEHR systems (16% and 25% respectively for Siemens and GE). There was no significant difference in spatial resolution. In clinical use, signal was higher on Siemens system and noise was lower on GE Swiftscan solution. Contrast-to-noise ratios were not significantly different between the two systems. There was a significant image quality improvement with GE SwiftScan in planar images ($p<0.001$ for both observers) and in whole body scan ($p<0.05$ for one of the observers). No significant difference in image quality was observed on SPECT images. **Conclusion:** GE SwiftScan collimator design improved sensitivity compared to "classical" GE LEHR collimator without compromising resolution. Adding Clarity 2D, SwiftScan solution strongly enhances whole-body and planar image quality. In SPECT mode, it improves volumetric sensitivity without impacting image quality and can lead to time or dose reduction. **References:** None.

Effects of acquisition time, energy window width and matrix size on image quality in bone SPECT acquired using a general-purpose CZT gamma camera

S. Arvola[1], *M. Seppänen*[1,2], *T. Noponen*[1,3];
[1]*Department of Clinical Physiology and Nuclear Medicine, Turku University Hospital, Turku, FINLAND,* [2]*Turku PET Centre, Turku, FINLAND,* [3]*Department of Medical Physics, Turku University Hospital, Turku, FINLAND.*

Aim/Introduction: Cadmium zinc telluride (CZT) gamma camera has superior spatial resolution, energy resolution and sensitivity compared to conventional NaI(Tl) scintillator camera. The purpose of this study was to evaluate the effects of shorter acquisition time, narrower energy window and larger image matrix on the image quality of bone SPECT acquired using a CZT gamma camera. **Materials and Methods:** Ten prostate cancer patients at high risk of bone metastases underwent ^{99m}Tc-HMDP SPECT/CT examinations using Discovery NM/CT 670 CZT camera (GE Healthcare, Tirat Carmel, Israel). The data were acquired in list mode with three bed positions, 13 s/projection (about 48 min total acquisition time), ±7.5% energy window centered at 140 keV, and a 128 x 128 matrix. The SPECT data were reframed using Lister program of Xeleris 4.0 server (GE Healthcare, Tirat Carmel, Israel) to produce data sets with the total acquisition times of about 40, 30, 25, and 20 min, with the energy window widths of ±5, ±4, ±3, and ±2%, and with a 256 x 256 matrix size. From the reconstructed images, skeletal lesions were segmented using an SUV threshold which varied between different lesions but was constant for the same lesion in different images. Areas of normal appearing bone adjacent to the lesions were segmented to evaluate lesion contrast and background noise. Volumes and mean, peak and maximum SUVs of the lesions were also measured. **Results:** A total of 50 lesions were analyzed. Shorter acquisition time did not significantly affect lesion contrast. Narrower energy windows of ±5, ±4, ±3, and ±2% increased lesion contrast on average by 3, 7, 6, and 11%, respectively. Matrix size did not significantly affect lesion contrast. Noise was significantly higher in all reframed images. The mean SUVs, peak SUVs, and lesion volumes were significantly different only between the original images and the images corresponding to 256 x 256 matrix. Maximum SUVs were not significantly different between the original and any of the reframed images. **Conclusion:** Based on this study, shorter acquisition time and larger image matrix do not significantly affect lesion contrast, while narrower energy window slightly increases lesion contrast in bone SPECT acquired using a CZT camera. Lesion volumes and SUVs are only affected by larger image matrix. A more thorough analysis based on visual evaluation by experienced nuclear medicine physicians will reveal the optimal acquisition parameters, which provide images with sufficient contrast-to-noise ratio. **References:** None.

EP-0955

Monte Carlo simulations of pre-clinical SPECT systems with ^{99m}Tc and ^{188}Re sources

M. Beliš[1,2], *K. Van Hecke*[1], *T. Cardinaels*[1,3], *S. Vandenberghe*[2];
[1]*SCK•CEN, Mol, BELGIUM,* [2]*Ghent University, Ghent, BELGIUM,* [3]*KU Leuven, Leuven, BELGIUM.*

Aim/Introduction: Rhenium-188 (^{188}Re) is a β^-emitting radionuclide ($t_{1/2}$ = 17.0 h, E_{max} = 2.1 MeV), suitable for radiotherapeutic applications. In addition, it emits a 155 keV γray (15 %), which can be used for imaging with current SPECT (single-photon emission computed tomography) systems. However, several high-energy γrays in emission spectrum of ^{188}Re, together with radiation produced by β^-particles (Bremsstrahlung), may complicate quantitative imaging. The aim of our research is to simulate the spectra of detected events with ^{188}Re sources and compare with the SPECT gold standard, technetium-99m (^{99m}Tc). These simulations provide useful information about the amount of contamination, their origin, the scatter fraction and the detection efficiency with various parameters of a collimator. **Materials and Methods:** GATE software (Geant4 Application for Tomographic Emission) was used to execute Monte Carlo simulations. Point and volume sources of ^{99m}Tc and ^{188}Re were used in the simulations, either directly or wrapped in water-filled phantoms. Single-crystal NaI detectors (50×50×4 mm) were positioned at several distances from the center of the system. Various setups were simulated,

with no collimator present in the system, or using simplified tungsten collimator plates. The low-energy collimator plates had 1 or 20 lofthole openings (a gradual change from a circular aperture to a rectangular end). Novel high-energy collimator with loftholes was used for comparison as well. **Results:** Current results show an acceptable effect of the high-energy γ-rays from the ^{188}Re emission spectrum in the optimal energy window around 155 keV. However, a decrease of the spatial resolution in these small systems may be caused by penetration of high-energy photons or by the primary β$^-$particles reaching the detector. More than 60 % of the detected events in the energy window 155 ± 15 keV are primary events. On the other hand, scattering in the collimator is significantly low (4 % of the events). Most of the scattered photons are coming from the scattering in the phantom and the detector itself (crystal and backscatter from the electronics). These results will be confirmed by phantom studies with ^{188}Re and compared to experiments with ^{99m}Tc. **Conclusion:** Obtained results are promising for usage of ^{188}Re as a theranostic agent - both for the therapy and imaging - without the necessity of administration radiopharmaceuticals with pure diagnostic radionuclides. **References:** None.

EP-0956

Image quality and SUV accuracy evaluation of bone SPECT-CT images using new available techniques: xSPECT Bone® and xSPECT Quant®

V. Moran[1], *P. Aguilar*[2], *E. Prieto*[2], *E. Guillén*[1], *L. Sancho*[1], *J. Richter*[2], *J. Martí-Climent*[2];
[1]*Clinica Universidad De Navarra, Madrid, SPAIN,* [2]*Clinica Universidad De Navarra, Pamplona, SPAIN.*

Aim/Introduction: xSPECT-Bone® (xB) and xSPECT-Quant® (xQ) are new reconstructions that produce quantitative ^{99m}Tc-HDP-SPECT images. The aims of this study were to assess xB and xQ image quality in comparison to Flash-3D (F3D), and to compare SUV accuracy of SPECT images for both xB and xQ. **Materials and Methods:** A NEMA image quality phantom was scanned using a Symbia-Intevo SPECT-CT (Siemens). The phantom was filled with ^{99m}Tc, resulting in a sphere-to-background ratio of 5.3:1 and the spheres were also loaded with CT contrast to achieve around 350 HU in the CT image. SPECT-CT images were acquired with 1.5 and 4.5 million total counts for both 128 and 256 matrix size. Images were reconstructed with xB, xQ and F3D at 12, 24, 48 and 96 updates, 10mm postsmoothing, with attenuation and window based scatter corrections. A qualitative evaluation of image quality was performed with fixed reconstruction settings (48i, 1s, FWHM=10mm). Background variability (BV), hot-sphere-contrast (Q_H) and mean signal-to-noise ratio (SNR_{mean}) for each sphere, reconstruction and acquisition were measured. Mean recovery coefficient (RC_{mean}) was also measured for different diameters using xB and xQ. **Results:** xB reported better spatial resolution than xQ and F3D. Spheres with ø ≥ 22, 28 and 37 mm were detected in xQ, F3D and xB images (4.5-Mcounts). Spheres with ø≥28 mm were perceptible for both xQ and F3D and with ø≥37 mm for xB (1.5-Mcounts). BV was similar for xQ and xB, and higher than for F3D. For all spheres and updates, BV was within the range [6.4%-25.3%], [6.0%-26.6%] and [2.9%-10.2%] with xQ, xB and F3D (4.5-Mcounts); and [3.1%-37.6], [2.9%-39.4%] and [5.2%-20.9%] in 1.5-Mcounts images. Q_H was only above 70% for spheres with ø≥17 mm (xB) and ø≥37 mm (xQ). Q_H with F3D was below 70% regardless the updates for all spheres. SNR_{mean} was lower for xQ than for xB and F3D, regardless total counts. There was no substantial difference between SNR_{mean} for F3D and xB. SUV accuracy (RC_{mean}) was better for xB than for xQ. xB offered much higher recovery for the largest sphere (>85% for 1.5-Mcounts, >90% for 4.5-Mcounts) than xQ (>75% for both acquisitions). **Conclusion:** xB performance was better than xQ and F3D. Image quality did not differ significantly between xQ and F3D. SUV accuracy of bone SPECT images using xB is better than using xQ. Overall, xB did not only produces considerably better image quality, but also yield more accurate SUV value. **References:** None.

EP-0957

Synthetic planar bone scans reprojected from SPECT/CT data have better image quality than original planar bone scans

S. Arvola[1], *A. Sohlberg*[2], *M. Seppänen*[1,3], *T. Noponen*[1,4];
[1]*Department of Clinical Physiology and Nuclear Medicine, Turku University Hospital, Turku, FINLAND,* [2]*Laboratory of Clinical Physiology and Nuclear Medicine, Joint Authority for Päijät-Häme Social and Health Care, Lahti, FINLAND,* [3]*Turku PET Centre, Turku, FINLAND,* [4]*Department of Medical Physics, Turku University Hospital, Turku, FINLAND.*

Aim/Introduction: The purpose of this study was to evaluate the image quality of synthetic planar bone scans reprojected from SPECT/CT data. **Materials and Methods:** Fifteen prostate cancer patients at high risk of bone metastases underwent ^{99m}Tc-HMDP planar bone scintigraphy and SPECT/CT examinations using Discovery NM/CT 670 CZT camera (GE Healthcare, Tirat Carmel, Israel). SPECT/CT was performed immediately after bone scintigraphy. The SPECT data were acquired in list mode with three bed-positions, 120 projections, 13 s/projection, ±7.5% energy window centered at 140 keV, and a 128 x 128 matrix. The SPECT data were reframed using Lister program of Xeleris 4.0 server (GE Healthcare, Tirat Carmel, Israel) to reduce the time per projection into 5 s, which corresponds to a total acquisition time of about 25 min. The total acquisition time for planar bone scintigraphy was about 20 min. The SPECT data were reconstructed and reprojected into synthetic anterior and posterior planar images using HybridRecon-Oncology 3.0 software (HERMES Medical Solutions AB, Stockholm, Sweden). Benign and malignant skeletal lesions visible in both original and synthetic planar images were segmented using equally sized circular regions of interest (ROIs). Normal bone adjacent to lesion was sampled to calculate lesion to normal bone contrast-to-noise ratio (CNR). Circular ROIs were also placed on a normal rib and adjacent lung tissue to evaluate rib to lung CNR. **Results:** A total of 50 lesions and 15 normal ribs were analyzed.

The synthetic planar bone scans had significantly higher ($p < 0.001$) lesion to normal bone and rib to lung CNRs compared to the original planar bone scans. The median difference between synthetic and original planar bone scans was 205% for lesion to normal bone CNR and 244% for rib to lung CNR. **Conclusion:** Synthetic planar bone scans have better image quality than original bone scans. Therefore, it is possible to synthesize high-quality planar bone scans when only SPECT/CT is acquired decreasing the total acquisition time. Synthetic planar bone scans may also speed up the reading of whole-body SPECT/CT images significantly. **References:** None.

EP-0958

Effect of reconstruction iterations on the SUVs of ^{99m}Tc-HDP SPECT/CT

S. Arvola[1], *I. Jambor*[2], *M. Seppänen*[1,3], *T. Noponen*[1,4];
[1]*Department of Clinical Physiology and Nuclear Medicine, Turku University Hospital, Turku, FINLAND,* [2]*Department of Diagnostic Radiology, University of Turku, Turku, FINLAND,* [3]*Turku PET Centre, Turku, FINLAND,* [4]*Department of Medical Physics, Turku University Hospital, Turku, FINLAND.*

Aim/Introduction: The purpose of this study was to evaluate the effect of changing the number of iterations in ordered subsets expectation maximization (OSEM) reconstruction on the standardized uptake values (SUVs) of ^{99m}Tc-HDP SPECT/CT. **Materials and Methods:** SPECT data from three-bed ^{99m}Tc-HDP SPECT/CT examinations of nine patients acquired on Symbia T6, True Point SPECT/CT scanner (Siemens Healthineers, Erlangen, Germany) were reconstructed using HybridRecon-Oncology (version 2.1, Hermes Medical Solutions, Stockholm, Sweden) OSEM algorithm with 15 subsets and 1, 2, 3, 4, 5, 10 and 20 iterations. The reconstructions included corrections for photon attenuation, scatter and collimator detector response. Counts were converted into SUVs using the SUV SPECT package (Hermes Medical Solutions, Stockholm, Sweden). From the reconstructed images, a total of 52 skeletal lesions, including bone metastases and benign findings, were analyzed. A lesion was first segmented from the reconstructed image (iterations = 1) using a visually appropriate SUV threshold ranging from 5 to 12. Next, the resulting volume of interest (VOI) was copied into other differently reconstructed images of the same patient. Maximum, peak and mean SUVs (SUV_{max}, SUV_{peak} and SUV_{mean}) of the lesions were measured from the VOIs and compared between images reconstructed using different numbers of iterations. The patients also underwent ^{18}F-NaF PET/CT scans within two weeks of ^{99m}Tc-HDP SPECT/CT scans. The SUVs of same lesions were measured from the PET images and used as reference values. **Results:** The median $SUVs_{max}$ were 22.0, 26.6, 29.6, 29.9, 31.2, 34.5 and 36.5, the median $SUVs_{peak}$ were 18.7, 21.9, 23.4, 23.9, 24.4, 26.1 and 27.1, and the median $SUVs_{mean}$ were 14.5, 16.6, 17.3, 17.5, 17.7, 18.3 and 18.5 for SPECT with 1, 2, 3, 4, 5, 10 and 20 iterations and 39.0 ($SUVs_{max}$), 28.5 ($SUVs_{peak}$) and 23.1 ($SUVs_{mean}$) for PET, respectively. All three SUV measures were statistically different between differently reconstructed SPECT images and between SPECT and PET according to Wilcoxon matched-pairs signed rank test ($p < 0.001$). **Conclusion:** The SUVs of ^{99m}Tc-HDP SPECT/CT increase with the number of reconstruction iterations, and a very high number of effective iterations (subsets x iterations) is required to calculate SUVs that are completely converged and close to the corresponding SUVs of ^{18}F-NaF PET/CT. Increasing the number of iterations from 10 to 20 increased the SUVs of ^{99m}Tc-HDP SPECT/CT by less than 6%, suggesting that the SUVs are almost converged by 10 iterations and 15 subsets, with still clinically acceptable processing time of five minutes. **References:** None.

EP-0959

Feasibility and time reduction of I-123 MIBG planar imaging using a CZT-based whole-body camera: phantom study, and clinical study for patients with suspected or known Lewy body diseases

N. Okano[1], *I. Osawa*[1], *S. Tsuchihashi*[1], *K. Fukushima*[2], *I. Kuji*[2], *I. Matsunari*[3];
[1]*Department of Radiology, Saitama Medical University Hospital, Saitama, JAPAN,* [2]*Department of Nuclear Medicine, International Medical Center, Saitama Medical University, Saitama, JAPAN,* [3]*Division of Nuclear Medicine, Department of Radiology, Saitama Medical University Hospital, Saitama, JAPAN.*

Aim/Introduction: Myocardial sympathetic innervation imaging using 123I-metaiodobenzylguanidine (MIBG) has recently been used to diagnose Lewy body diseases (LBD). Using novel "whole-body" cadmium-zinc-telluride (CZT) camera (Discovery NM/CT 670 CZT), the heart-to-mediastinum uptake ratio (HMR) can be directly measured from planar imaging. However, evidence for the feasibility of high-speed cardiac SPECT imaging using CZT-based SPECT systems has been mostly limited to "cardiac-dedicated" CZT-cameras, such as D-SPECT and Discovery 530C. We aim to disclose properties of the novel whole-body CZT scanner in phantom study, and subsequently, explore feasibility and potential time reduction in clinical study. **Materials and Methods:** In phantom study, difference of HMRs according to types of scanners/collimators was evaluated. Images were acquired with referenced collection time/window width, and later, reframed to produce images with different collection times/window widths using Lister-tool to compare their HMRs.In clinical study, MIBG planar imaging was performed in 36 patients with suspected or known LBD. Images with a collection time of 300 seconds were obtained, followed by reframing to produce images with shortened collection times, and HMRs were compared to evaluate collection time-dependent difference. **Results:** In phantom study, the HMRs obtained from the CZT-based camera were lower than those obtained from the Anger camera with medium-energy general-all-purpose collimators, but were comparable to those obtained from the Anger camera with low-energy ultra-high-resolution collimators. The difference in HMRs between the normal and disease models were reduced as the window widths increased. The HMRs almost unchanged when the collection time was >

50 seconds. The HMRs for patients with clinically diagnosed LBD were significantly lower than those without (1.63 ± 0.08 versus 2.21 ± 0.08 at early phase ($p < 0.001$), and 1.54 ± 0.09 versus 2.08 ± 0.09 at delayed phase ($p < 0.001$)). There was good consistency in HMRs between the 300- second images (reference) and the 200-second (intra-class correlation (ICC) coefficients > 0.99), 100-second (ICC coefficients > 0.97) and 50-second (ICC coefficients > 0.89) images. **Conclusion:** In planar images with a whole-body CZT-based scanner, the HMRs of patients with LBD were significantly lower than those without. HMRs with the collection time > 50 seconds showed good consistency with those of 300 seconds (which was consistent with phantom study). Although, standardisation of the HMRs measured by whole-body CZT-based detectors may be required, these findings indicate a clinical utility and potential time reduction of this novel scanner for HMR measurements. **References:** None.

EP-0960

Comparison Of The Quality Of Brain Images Obtained With ^{99m}Tc-HMPAO Aquired Using Either The Veriton 360° CZT Camera Or A Conventional Anger Camera, And With An ^{18}F-FDG Analog PET System

M. Bordonne, *M. Chawki, T. Zaragori, V. Roch, R. Grignon, G. Karcher, P. Marie, L. Imbert, A. Verger;*
CHRU Nancy, Nuclear Medicine Department, Vandoeuvre les Nancy, FRANCE.

Aim/Introduction: The Veriton 360° CZT-camera (Spectrum Dynamics Medical) provides better performances in comparison to conventional gamma-cameras owing to CZT detectors features and also to an original 360° geometry of detection that allows acquisitions focused on the brain, which is particularly advantageous for brain SPECT imaging. This study aimed to assess the quality of the perfusion brain images provided by the 360° CZT-SPECT system, as compared with those provided by conventional Anger-SPECT and additionally, compared to analog PET recording of ^{18}F-FDG brain images. **Materials and Methods:** We retrospectively selected 3 groups of 21 patients matched for sex, age (±10 years) and who had undergone a brain ^{99m}Tc-HMPAO SPECT acquisition with either the 360° CZT-SPECT camera (Group 1) or a conventional Anger-SPECT system (Symbia T2, Siemens Healthineers, Group 2) or a brain ^{18}F-FDG recording with an analog PET camera (Biograph 6, Siemens Healthineers**,** Group 3). Images from each system were reconstructed with a similar level of convergence of the iterative reconstruction process, with corrections for attenuation and diffusion and with the recommended voxel sizes. Tomographic count sensitivity was measured from the projection SPECT images with the total recording counts corrected for the decay for each camera. Spatial resolution, assessed with a sharpness index in the frontal cortex; and grey (occipital)/white (semi-oval center)-matter contrast were obtained with an automatic algorithm. **Results:** Tomographic count sensitivity was 114% higher with 360° CZT acquisitions compared to those obtained with conventional SPECT camera (304±61 vs. 142±20 counts/MBq/s, $p<10^{-11}$). Image quality from the CZT-camera was: 1) much higher than that from conventional gamma-camera with, on average, a 30% higher sharpness index (10.5±2.4mm vs. 8.1±1.1mm, p=0.006) and a 40% higher contrast (1.23±0.47 vs. 0.88±0.36, p=0.005) and 2) close to that of FDG PET for which sharpness index was only 23% higher on average (13.0±2.7mm, p=0.01) and contrast was similar (1.03±0.27, p=NS). **Conclusion:** Image quality of perfusion brain SPECT images is markedly higher with the Veriton 360° CZT-camera, in comparison with that provided by Anger-SPECT camera, and it is even close to that observed for ^{18}F-FDG brain images from an analog PET camera. In addition, the high-count sensitivity of the 360° CZT-camera gives the possibility of significantly reducing acquisition time and / or injected activity. **References:** None.

EP-0961

Evaluation Of Early Vs. Standard Delayed Imaging Protocol In ^{99m}Tc- Sestamibimyocardial Perfusion Scintigraphy Using A Czt Based Gamma Camera

H. Sachani;
Narayana Hrudayalaya, Bangalore, INDIA.

Aim/Introduction: Myocardial perfusion scintigraphy has pivotal role in assessment of ischaemic state of the heart. It's an accurate, non-invasive imaging modality for assessment of significance of coronary artery stenosis and provides diagnostic & prognostic information in patients with suspected/ diagnosed coronary artery disease. Scans acquired on traditional dual detector have lengthy acquisition times (~15 minutes); ASNC imaging protocol prescribes minimum wait of 30 minutes between the exercise stress and stress imaging and 60 minutes between the rest injection and rest imaging reducing patient compliance because of lengthy acquisition time & long duration of entire examination (~4-5 hours). Early imaging could result in shorter waiting times for patients and be important in clinical situations like suspected ACS, where time is critical for therapeutic interventions. Aim of this study was to compare quality of early time point acquired ^{99m}Tc-Sestamibi MPI images with standard delayed acquisition protocol and to assess diagnostic performance on the basis of perfusion defects and quantitative parameters between two sets of images. **Materials and Methods:** 126 patients referred for clinically indicated myocardial perfusion imaging (MPI) study were enrolled. MPI was performed on CZT camera according to early imaging protocol (within 15 minutes of tracer injection) and repeat images were taken at 60 minutes post tracer injection. Image processing and reconstruction was done and quality was visually analysed by experienced NM physician. Summed stress score, summed rest score & summed difference score and quantitative MPI parameters like LVEF, ESV & EDV were compared between the two sets of images. Perfusion defects were assessed and compared between two sets of images taking coronary angiography findings as gold standard. **Results:** Early and delayed image sets compared for image quality showed moderate to substantial agreement. The

SSS, SDS, SRS and quantitative parameters had no statistical difference between two sets of images. Territory wise diagnostic accuracy of perfusion defects in two sets of images showed almost perfect agreement. **Conclusion:** Study concluded that images acquired at early time-point (under15 minutes post injection) are similar in terms of quality, quantitative data and territory wise diagnostic accuracy for detection of perfusion defects to images acquired at standard delayed time-point (~60 minutes post injection). Clinical information provided by early image is equivalent to that provided by standard delayed scan. Hence, adopting an early protocol can enhance patient compliance by reducing waiting time for imaging, overall length of examination and augment logistics of nuclear cardiology laboratories. **References:** None.

EP-0962

Comparing the use of IQ-SPECT versus LEHR-SPECT on the influence of abdominal radiotracer uptake in myocardial perfusion SPECT-CT

***A. de Vries**, J. van Rijs, J. E. Huijbregts;*
Gelre Hospitals, Apeldoorn, NETHERLANDS.

Aim/Introduction: IQ-SPECT (Siemens Medical Solutions) is a technology that allows short-time acquisition imaging of the heart by using a multi-focal collimator, a cardiocentric orbit, and advanced iterative reconstruction. The zoom effect of the so called SmartZoom collimators of IQ-SPECT may however also zoom in on unintended activity near the heart, e.g. radiotracer uptake in the gastric wall or biliary system[1], leading to an unreliable diagnostic value. The aim of this study is to investigate the use of IQ-SPECT versus LEHR-SPECT on the influence of abdominal radiotracer uptake in myocardial perfusion SPECT-CT. **Materials and Methods:** Unpaired data of 2 groups of patients (n=50 each) were compared in a retrospective study. The first group was scanned using conventional LEHR collimators on a Infinia Hawkeye SPECT-CT system (GE Healthcare) and reconstructed with filtered back projection. The second group was scanned with IQ-SPECT collimators on a Symbia Intevo 6+ and iteratively reconstructed. Only rest scans were compared, as those are more likely to be effected by nearby activity. Scans were scored by 2 observers on a 3-point Likert scale, 1) Good; 2) Average but reliable; 3) Unreliable. Statistical analyses was performed using the Mann-Whitney U-test for the non-attenuation-corrected (NAC) as well as the attenuation-corrected (AC) images. In addition to comparing patient data, a phantom study was designed. The Amsterdam gated (AGATE) dynamic cardiac phantom (Vanderwilt Techniques) was supplemented with a chamber representing the fundus of the stomach. ^{99m}Tc concentrations were 150 kBq/ml for the myocard compartment as well as the gastric wall compartment and 4.5 kBq/ml for the bloodpool. Scans were performed using IQ-SPECT (Symbia Intevo) and subsequently using LEHR-SPECT on the Infinia Hawkeye. Scans were scored on a 3-point Likert scale by 2 observers. **Results:** Mann-Whitney U-test resulted in no significant difference between IQ-SPECT and LEHR-SPECT with p-values of 0.055 for the NAC images and 0.716 for the AC images. No significant difference was observed (NAC p=0.402, AC p=0.656) when looking at the reliable scans (group 1 and 2) and unreliable scans (group 3). The phantom study confirmed the results of the patient study. **Conclusion:** No significant difference was observed between the assessability of the myocardial perfusion scans using IQ-SPECT or LEHR-SPECT. **References:** [1] Van Dongen A.J., Van Rijk P.P., J Nucl Med 2000; 41(8); 1315-7.

EP-0963

A whole-body bone SPECT of a high quality may be recorded in less than 20 minutes with the Veriton 360° CZT-camera

***L. Imbert**[1], M. Chawki[1], A. Bahloul[1], S. Melki[1], G. Karcher[1], A. Verger[1], F. Paycha[2], P. Marie[1];*
[1]CHU Nancy Hopital Brabois Adultes, Vandoeuvre les Nancy, FRANCE, [2]APHP, Hôpital Lariboisière, Paris, FRANCE.

Aim/Introduction: The Veriton™ 360° CZT-camera (Spectrum Dynamics Medical) is equipped with 12 swivelling high-resolution detectors covering an axial field-of view of 32 cm and assembled with a helicoidal CT in a hybrid system. The detectors may be positioned close to any part of the body and the overall detection system provides a much higher count sensitivity than current Anger-SPECT cameras. This study aimed to determine whether whole-body bone SPECT/CT acquisitions could be recorded using the Veriton camera: 1) with a comparable total recording-time to that of current whole-body bone planar scintigraphy (15 to 20 min) and 2) with a high enough image quality as compared with the bone SPECT currently obtained with 3.7 fold longer recording times on Anger cameras (10 vs. 3 min per bed position). **Materials and Methods:** Additional Veriton SPECT recordings of only 3-min per bed position were scheduled in 9 patients, who were initially referred to a conventional whole-body planar scintigraphy on an Anger camera equipped with parallel-hole collimators (Symbia, Siemens Medical Healthineers) and among whom, 6 had additionally undergone an 10-min Anger-SPECT recording centered on the pelvis. SPECT images were reconstructed for both cameras with dedicated iterative algorithms, corrections for diffusion and for attenuation with the CT map and additionally for the Veriton, with an original algorithm for partial volume correction (PVC). **Results:** Image quality, provided by the 3-min CZT-SPECT recordings centered on the pelvis, was comparable to that provided by the 10-min Anger-SPECT recordings with especially, equivalent image contrast (for lumbar vertebrae: 1.79±0.12 vs. 1.80±0.07, and for iliac crests: 1.83±0.20 vs. 1.76±0.11), and with equivalent spatial resolution assessed through a sharpness index (for lumbar vertebrae: 6.1±0.6% vs. 6.0±1.5% and for iliac crests: 9.9±2.3% vs. 9.1±1.0%). When reconstructed with the PVC algorithm, the sharpness index of the Veriton SPECT images was significantly enhanced (lumbar vertebrae: 8.5±0.7% and iliac crests: 11.4±2.0%; p = 0.001 and p = 0.002 for the comparisons vs. conventional SPECT

and vs. Veriton SPECT without PVC, respectively), whereas image contrast was not enhanced (for lumbar vertebrae: 1.75±0.13 and for iliac crests: 1.80±0.25). **Conclusion:** A whole-body bone SPECT recording, achieved with the Veriton 360° CZT-camera in no more than 20 min, could advantageously replace current bone scanning protocols associating planar whole-body and SPECT acquisition workflows. **References:** None.

EP-0964

Diagnostic performance of 360° CZT SPECT compared to a conventional camera in lung perfusion scintigraphy

K. Anindita[1,2], K. Delaunay[3,4], B. Mahida[4], K. Doyeux[4], F. Rouzet[4,3,1];
[1]Inserm 1148, Paris Diderot University, Paris, FRANCE, [2]ENSAM Paris Tech, Paris, FRANCE, [3]Paris Diderot University, Paris, FRANCE, [4]Department of Nuclear Medicine, Bichat Claude Bernard University Hospital, APHP, Paris, FRANCE.

Aim/Introduction: Lung perfusion scintigraphy is widely used in the diagnosis of pulmonary embolism (PE) and quantification of perfusion prior to lung surgery (Surg). Tomographic acquisitions have proved superior to planar ones but are time consuming. Cameras with CZT detectors constitute a technological leap forwards for SPECT imaging with greater sensitivity compared to conventional NaI cameras. The aim of this study was to assess whether the new generation Veriton CZT-camera (Spectrum Dynamics Medical) equipped with 12 detectors around 360° would allow acquisition time reduction without impairment of diagnostic and quantitative performances. **Materials and Methods:** 14 consecutive patients (age: 68 ± 15 years, males: 6, informed consent obtained) referred to our centre for lung scintigraphy were enrolled. After injection of 185 ± 19 MBq 99mTc-labelled macroaggregated human albumin, 10min SPECT (60 steps/detector, 10 sec/step) was acquired on a conventional camera Discovery NM/CT 670 (General Electric Healthcare). Immediately after completion of conventional imaging, patients were asked to move to Veriton for a 10min acquisition (list mode). Optimized clinical iterative reconstruction was performed with both systems and an additional reconstruction with acquisition duration reduced to 5 and 2.5 min on Veriton. The following parameters were recorded: 1/ Number of segmental perfusion defects (18 segments, PE group); 2/ Relative uptake quantification in each pulmonary lobe (5 lobes, Surg group) using the same CT-based segmentation. The outcome criteria were: 1/the reproducibility of the number of segmental perfusion defects (PE group, blinded readers, Intraclass Correlation Coefficient-ICC) and 2/the difference of relative quantification (Surg group, Bland-Altman plot). **Results:** In the PE group, the absolute agreement between conventional camera (CC) and Veriton CZT camera was excellent with ICC [95% CI] = 0.986 [0.746 - 0.999] for 10min acquisition duration on conventional camera and 2.5 min acquisition on Veriton (other results available in Table). In Surg group, the comparison lobe by lobe of relative perfusion showed no difference between acquisitions, with a mean difference [95% CI limits of agreement]: 0% [-3.8 ; +3.8] for 10min acquisition duration on CC and 2.5min on Veriton. **Conclusion:** Greater sensitivity of the Veriton compared to conventional camera offers the opportunity to decrease acquisition duration up to 75% without loss in diagnostic (PE) and quantitative (Surg) performances. **References:** None.

Dosimetric aspects with TL dosimetry in 99mTc-nanocoll lymphoscintigrafy in pregnant women

P. Saletti[1], M. Fedi[1], L. Ballati[2], A. Falivene[1], L. Vaggelli[1], G. Belli[1];
[1]AOU Careggi, Florence, ITALY, [2]University of Florence, Florence, ITALY.

Aim/Introduction: Lymphoscintigraphy in pregnant women requires a specific approach due to radioprotection constraints for the foetus. The aim of present work is to investigate if a reduced amount of radiopharmceutical could lead a good diagnostic result and verify, by TLD dosimetry, radioprotection compliance. **Materials and Methods:** A set of 6 pregnant women participated the study in the period 2015-2019 and a mean activity of 12MBq was administered (ranging from 6 to 20MBq) according to AIMN Guidelines. Before 99mTc-nanocoll injection, 3 stripes of 4 TLD each (12 in total) were placed in correspondance with womb; their removal was carried out before surgery. Lymphoscintigraphies were performed at Siemens e.cam gammacamera with LE-HR collimators and 15% energy window in orthogonal and oblique projection. TLD LiF100 were then read at Harshaw 6600 system and measured glow curves were lastly compared with 10 background TLD. **Results:** All obtained images were completely satisfactory from diagnostic point of view and an accurate indication of the sentinel lymphnode was always given for surgery. Mean TLD background resulted in 1.7nC (ranging from 0.7 to 3.0nC) while a mean of 1.6nC (ranging from 0.7 to 3.3nC) was measured in TLD placed on women. Taking into account related background of each TLD set, none among all TLD measured a real dose (i.e. no difference from background) proving that no radiological impact is connected with such modified approach to lymphoscintigraphy. **Conclusion:** The results pointed out with the present work have two main implications. First of all, absorbed dose by the foetus was completely irrelevant, as expected, due to reduced 99mTc-nanocoll administered activity even though scintigraphic images were absolutely adequate. Secondly, these evidences could be the starting point for a radioprotection programme involving all lymphoscintigraphic examination, even in non pregnant patients, if logistics such as scheduling time and hospital organisation could make it

possible. **References:** AIMN guidelines for Lymphoscintigraphy in Melanoma and Breast cancer.

EP-0966

Development of I-131 Radionuclide Therapy Patient Monitor with Predictive Exposure Rate Capability

C. Munoz-Ferrada;
Gammasonics, Lane Cove, AUSTRALIA.

Aim/Introduction: Patients receiving large doses of radionuclides for therapy often require admission to a specialized ward of the hospital where they can be isolated from staff and the public until their external radiation exposure rates have decreased to acceptable levels. The development of a ceiling-mounted radiation monitors which connects to the hospital IT network and allows, the exposure rates to be monitored from any PC that can access the detector, either internally or externally. **Materials and Methods:** A radiation detector has been developed which is housing in a small case, it is activated by Power Over Ethernet (POE) and has an Ethernet network interface to connect to the hospital LAN. The software has been developed to address the output of the device on a COM channel of a PC. The system is located and calibrated at a given distance above the patient bed, but the detector adjusts at the "exposure rate of 1 m" and is calibrated independently. Multiple detectors in different rooms can be supported on one PC. The software performs real-time curve fitting (assumed monoexponentially) and extrapolation to estimate when the radiation exposure from the patient will be lower than the local regulatory limit. **Results:** In considering a typical patient trace over approx. 36 hours (not shown), abrupt drops in exposure rate are observed with voiding with a final drop to zero when the patient was discharged from the room. Extrapolation from the high initial levels of the decreasing exposure rate allows estimation of the earliest possible time for discharge, thus improving efficiency of room use and patient satisfaction whilst providing colour-coded feedback to local staff (nurses etc) about current exposure rates. **Conclusion:** This cost-effective device helps to optimally manage patients admitted after radionuclide therapy. It can be used for any radionuclide that emits photons where minimising exposure of the public must be ensured. **References:** None.

EP-0967

Uncertainty in Reference Phantom-Based Dosimetry Calculations: Impact of Number of Source Organs

A. Josefsson[1], *J. J. Siritantikorn*[1], *M. Tatit Sapienza*[2], *W. E. Bolch*[3], *G. Sgouros*[1];
[1]*Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES OF AMERICA,* [2]*São Paulo University, São Paulo, BRAZIL,* [3]*University of Florida, Gainesville, FL, UNITED STATES OF AMERICA.*

Aim/Introduction: Dosimetry for diagnostic agents is typically performed using the MIRD Committee, S-value method with a particular anatomical reference geometry. S-value based dosimetry methods provide the mean absorbed to a reference target geometry from a collection of source organs. The number of source organs considered, and their nature impacts the estimated effective dose value. In this work, we investigate how the number of source organs used impacts the effective dose for two different reference phantom geometries. **Materials and Methods:** Previously collected patient imaging data were used in the investigation. Two to four whole-body diagnostic PET/CT-images was acquired for 16 patients (5 male and 11 female) after administration of ^{68}Ga-DOTATATE. Volumes of interest (VOIs) were drawn for normal tissues on the PET/CT-images for the spleen, liver, kidneys, adrenal glands, brain, heart, lungs, thyroid gland, pituitary gland, salivary glands, testes, red marrow (L1-L5), muscle (right thigh) and whole-body. Dosimetric calculations were performed using the ICRP 110 voxelized phantoms, ICRP 133 specific absorbed fractions and ICRP 103 tissue weighting factors. Representing the Cristy-Eckerman (CE) stylized phantoms OLINDA/EXM version 1 using ICRP 60 tissue weighting factors was used. Three different approaches were used to evaluate the effect of what normal tissues where included in the dosimetric calculations: Based on 1) the organ weight (decreasing: muscle, liver etc.), 2) the tissue weighting factor (decreasing: lungs, red marrow etc.) and 3) the highest increase or impact on the effective dose coefficient. The whole-body activity was subtracted with the activity of the respective organs included and was used as the remainder-of-body activity in all calculations. **Results:** As the number of source organs included in the calculation was increased from 1 to 13, the effective dose coefficient, e, increased from 0.017 to 0.023 mSv/MBq for the ICRP phantom and the corresponding range for the CE phantom calculation increased from 0.012 to 0.027 mSv/MBq. The number of source organs required for e to converge to its final value was similar; 6 and 5 for ICRP and CE phantoms, respectively. **Conclusion:** Depending upon the reference phantom chosen and the number of source organs in included, effective dose estimates can vary by more than a factor of 2. Results obtained will also depend on the normal organ distribution of the imaging agent. **References:** None.

EP-0968

Establishment of National DRL for CT in Hybrid Imaging Studies "The First National NM CT (PET) Dose Audit for KW population"

M. Masoomi[1], *I. Al-Shammeri*[1], *J. Al-Shammeri*[2], *H. Elrahman*[1], *3 Farwaniya Hospital - Kuwait, 3 Mubarrak Al Kabeer Hospital -Kuwait, 3 Al-Jahra Hospital - Kuwait, 3 Chest Diseases Hospital - Kuwait, 3 Kuwait Cancer Control Center Hospital - Kuwait, 3 Jaber Al Ahmed MI - Kuwait;*
[1]*Nuclear Medicine Department, ADAN Hospital, Kuwait City, KUWAIT,* [2]*Nuclear Medicine Department, Faculty of Medicine, Kuwait University, Kuwait City, KUWAIT.*

Aim/Introduction: Diagnostic reference levels (DRLs), for CT part used in PET examinations are limited. Published DRLs from other countries may not be directly relevant to the state of Kuwait (KW). The aim was to propose a national DRL for CT part of PET imaging operating in KW, in support of optimization and dose reduction. **Materials and Methods:** The research was a multicentre collaborative study with participation of 7 PET-CT centres in KW. The data collection was restricted to adult oncology patients due to a limited number of the other studies. The study was based on the UK - IPEM methodology and the upper limit of entries for each centre was set to 30 with a total of 195 patients. The CTDIvol, DLP and scan length (SL) were recorded and Mean, Median, Standard Deviation, Minimum and Maximum values, 75th percentile as well as WB effective dose (ED) were calculated. All centres except one (Philips) accommodated GE PET/CT scanners with an integrated 64 slices CT, and applied AEC. **Results:** Dose and scan length statistics for the half body (HB) accounted for 51.5% of the total (195) and combined (WB +HB) examinations presented together with the Proposed local DRLs and Achievable doses. The CT data were used for AC and localization. Patient dose varied considerably, with a maximum of twofold variation in DLP. The ratio of maximum to minimum mean doses between different centers for HB and (WB+HB) for the same clinical studies varied between 1.1 - 3.7 for HB and 2.3 -6.2 for (WB+HB). There were variations of proposed and achievable local DRL in practice between 7 centers highlighting the need for national DRL. Third quartile DLP (mGy. cm) and CTDIvol (mGy) values (set for NDRL) for the HB PET/CT was (570, 5.2) which was higher than the current UK NDRL (400, 4.3) but lower than the Swiss National NDRL (620, 6). Comparatively, the Proposed NDRLs for (WB+HB) was (643, 4.6) which was lower than Swiss National Data (720, 5.0). The results were in reasonable agreement with the both centers, though, SWISS had entries of 5000 (HB), 706 (WB) and the UK had 370 (HB). Calculated ED varied from 5.4 to 13.4 mSv, with a mean value equal to 8.4 mSv. **Conclusion:** The study demonstrated the need for national CT DRLs for PET/CT and it has been proposed in KW for oncology examinations based on data collected from 7 centers. **References:** None.

Assessment the activity incorporated by the patient's caregivers after Iodine-131 thyroid therapy

M. J. Carapinha[1,2,3], *M. Reis*[4], *L. Silva*[4], *M. Santos*[4], *G. Costa*[5], *M. Silva*[5], *J. Isidoro*[5], *C. Nunes*[2,6], *A. Tavares*[2], *P. Teles*[4];
[1]*Escola Superior de Tecnologia da Saúde de Lisboa, Lisboa, PORTUGAL,* [2]*Escola Nacional de Saúde Publica, Universidade Nova de Lisboa, Lisboa, PORTUGAL,* [3]*H&TRC - Health & Technology Research Center, ESTeSL - Escola Superior de Tecnologia da Saúde, Instituto Politécnico de Lisboa, Lisboa, PORTUGAL,* [4]*Centro de Ciências e Tecnologias Nucleares, Instituto Superior Técnico Universidade de Lisboa, Lisboa, PORTUGAL,* [5]*Serviço de Medicina Nuclear, Centro Hospitalar e Universitário de Coimbra, EPE, Coimbra, PORTUGAL,* [6]*Centro de Investigação em Saúde Pública, Av. Padre Cruz, 1649-016, Lisboa, Lisboa, PORTUGAL.*

Aim/Introduction: Evaluate the activity incorporated by the caregivers of the patients undergoing thyroid cancer (TC) therapy with iodine-131 (131I), based on the amount of 131I excreted in the urine. **Materials and Methods:** An observational study was performed using a sampling of 22 patients and 34 caregivers. The patients, submitted to 131I treatments for TC, were discharged from hospital 48h after therapy. All caregivers received instructions on radiation protection, based on Euratom recommendations. A urine sample was collected from every caregiver, about 70h after dischargement of the patients. The samples of urine were analyzed by gamma spectrometry. A biokinetic model was used for the 131I according to the ICRP Publication 78 to quantify the activity incorporated by the caregivers, based on the concentrations of 131I present in the urine. All ethical principles of the investigation were respected. **Results:** The average activity of 131I given to the patients was 3207.3±1184.8 MBq. When the patients were discharged, the average effective dose rate measured at 1 meter distance was 8.2±6.1 μSv.hr-1 (1-25 μSv.hr-1). In the 34 caregivers with average of 48.1±18.6 years only in 3 caregivers wasn't detected 131I in the urine. The mean activity concentration of 131I founded in the urine samples has 97.4 Bq.L-1(range: 0.0-1146 Bq.L-1) and the mean H_T(thyroid) was 0.81±2.38 mSv, with a median of 0.03 mSv, a minimum of 0 mSv and a maximum of 9.46 mSv. The specific activity of 131I in urine: it is not the same among on the classes of the administered activity (p=0.019); it is not the same on the different classes of caregivers ages (p=0.470); it is not the same on the different degree of relationship (p=0.744). We observed a moderate correlation between the specific activity of 131I in the urine and the activity administered to the patients (ρ_{sp}=0.540; p=0.001); and a high correlation between the specific activity of 131I in the urine and the effective dose rate in the patients (ρ_{sp}=0.730; p<0.001). CI of 95%. **Conclusion:** The patients are a radioactive source that can increase the exposure of the caregivers to ionizing radiation. The specific activity of 131I in the urines of the caregivers is related to the activity administered to the patients. It is clear that caregivers of patients submitted to radioiodine therapy can be subject to internal contamination. The 131I concentration in the urine due to internal contamination do not represent a radiological hazard for the exposed individuals. **References:** None.

The Protective Effect of Vitamin D Against Radioiodine (RAI) Therapy Damage to Male Fertility

C. Cebi Sen[1], *A. Akbulut*[2], *G. Koca*[2], *A. Kirmit*[1], *H. Atilgan*[3], *B. Nacir*[2], *N. Yumusak*[1], *M. Korkmaz*[2];
[1]*Harran University, Sanliurfa, TURKEY,* [2]*Ankara Training*

and Research Hospital, Ankara, TURKEY, [3]Kahramanmaras Necip Fazil City Hospital, Kahramanmaraş, TURKEY.

Aim/Introduction: We evaluated evaluate antioxidant effects of active vitamin D (calcitriol) against high-dose radioiodine (RAI) therapy-associated damage of male fertility. **Materials and Methods:** Wistar albino rats were used and randomly into three groups (n=12). The first group was appointed as the negative control group and received no RAI or medication. The second group (RAI group) was administered only received 3 mCi/kg (111 MBq/kg) RAI by gastric gavage as the positive control group and the last group (RAI+calcitriol) was the treatment group that received 3 mCi/kg RAI by same method and calcitriol (200 ng/kg/day) by intraperitoneal route. Seven days after, intracardiac blood samples were taken for hormone analysis and testis samples were removed for the evaluations of histopathologic, total oxidant status (TOS), total antioxidant status (TAS), spermatological parameters. Caspase-8, and caspase-9 were used to show increased apoptosis resulting from testis damage and the terminal deoxynucleotidyl transferase mediated deoxyuridine triphosphate nick end labeling (TUNEL) assay was used to determine the frequency of possible DNA breaks because of treatment. **Results:** RAI led to significant increase in tissue TOS levels and significant decrease TAS levels ($p<0.05$ for each). It was demonstrated a significant decrease in epididymal spermatozoa viability and motility in all of the treatment groups, in comparison with the control group ($p <$ 001). A significant decrease was also detected in sperm DNA fragmentation, follicle-stimulating hormone (FSH) level in the RAI+calcitriol group when compared to the radioiodine group. The staining intensity of caspase-8,and caspase-9 antibodies was found to be statistically more significant in the RAI+calcitriol group than in the RAI group ($P <0.05$). The nuclear highlighting shown by the TUNEL was more increased in the RAI group than in the RAI+calcitriol group ($p <0.05$). **Conclusion:** Vitamin D demonstrated potent antioxidant and radioprotective effects on testis against RAI-induced oxidative damage. **References:** None.

The Evaluation of Bone Marrow Suppression and Secondary Malignancy Risk after Radioiodine Treatment in Patients with Thyroid Cancer after 10 Years Follow Up

***K. Toplutas**, S. Sager, R. Uslu Besli, S. Asa, S. Khosroshahi, H. Sayman, I. Uslu, K. Sonmezoglu;*
Istanbul University-Cerrahpasa,Cerrahpasa Medical Faculty Department of Nuclear Medicine, Istanbul, TURKEY.

Aim/Introduction: Radioiodine(I-131) treatment may have some adverse effects to non-thyroid tissue due to its energy and cumulative effect. Studies have shown a significant increase in the development of leukemia and salivary gland cancer after radioiodine treatment. The aim of our study was to examine the frequency of bone marrow suppression and secondary tumor growth in patients received high-dose radioiodine in our clinic before 2010 due to thyroid cancer. **Materials and Methods:** A total of 3000 patients with thyroid cancer were retrospectively reviewed. Patients were followed up for an average of ten years period in our department. The study included 74 patients(F=51,M=23) who received radioiodine ≥600 mCi. Patients were divided into two groups 600 mCi - 1000mCi(n=50), and ≥1000mCi(n=24). 71,6% of the patients were papillary thyroid carcinoma, 16.2% with follicular thyroid carcinoma, 5.4% had poorly differentiated thyroid carcinoma, 4% no detailed data was found on the pathology. **Results:** The mean age of the patients was 48.7 years. According to the first pathology reports, 10.8% (n = 8) of the patients had pT1, 8.2% (n = 6) pT2, and the remaining group of patients had pT3 and pT4 tumors.There were 44 patients with lymph node metastasis, 24 patients with lung metastasis and 14 patients with bone metastasis during diagnosis and treatment. Also brain metastasis was detected in 2 patients and liver metastasis in 2 patients. Among the group receiving 1000mCi or more(max 1700mci), 6 patients died and 8 patients were alive. For the group receiving 600-1000mCi, 8 of them died, 33 of them were alive. Only 3 out of our patients(700,750,1350mCi) developed bone marrow suppression. One patient had leukopenia. One patient had pancytopenia and another patient had bicytopenia. The patient with bistopenia had dysplastic changes in the peripheral smear. Treatment of 2 patients with bone marrow suppression was stopped accordingly. Four patients from all patients were recently diagnosed with a second primary malignancy including one patient with prostate cancer(1300mCi), one with larynx cancer(600mCi), one with lung cancer(1600 mCi), and the other patient received rectum cancer(850mCi) diagnoses. **Conclusion:** Although bone marrow suppression was seen in 6.1%(n=3) of the patients, secondary leukemia and treatment-related solid tumor development was not detected. The number of patients with solid tumors were not significantly different from the normal population. Complete blood count follow-up still useful test to prevent possible complications and side effects in patients receiving high iodine doses. **References:** None.

Evolution and evaluation of effective dose in the context of diagnostic nuclear medicine

***J. C. Ocampo Ramos**[1], E. Mora-Ramirez[2], M. Bardiès[1];*
[1]CRCT, UMR 1037, INSERM, Université Toulouse III Paul Sabatier, Toulouse, FRANCE, [2]Universidad de Costa Rica, Escuela de Fisica, CICANUM, San Jose, COSTA RICA.

Aim/Introduction: Small or medium differences are noted when the effective dose (ED) is calculated using different available software, tools, and methodologies. The calculation of the effective dose could be a little be tricky considering the different approaches, approximations and information available. A guideline about how to put a new diagnostic radiopharmaceutical into the market is missing, especially if it is a gender-specific drug. **Materials and Methods:** We used different inputs, available commercial, academic and in-house developed tools to test and evaluate the effective dose in an accurate way and being ICRP compliance. Biokinetics of several radiopharmaceutical were used and sex-specific inputs were considered when they were available. **Results:** The inappropriate input, use of software and the misinterpretation of the effective dose could yield to errors up to 10% in the ED assessment. The results in this work could be useful as a guideline of how to compute the effective dose properly in the context of diagnostic nuclear medicine for clinical and preclinical studies. **Conclusion:** Despite significant numeric differences in the organ absorbed dose, the effective dose is a robust quantity. Direct and wrong use of tools without the proper understanding and the definition of the ED is a major source of miscalculation. Care must be taken to ensure that the quantity calculated is clearly reproducible and in line with the ICRP recommendation. **References:** ICRP, 1991. 1990 Recommendations of the International Commission on Radiological Protection. Ultra-low Dose CT for PET Attenuation Correction

E. Prieto[1], *B. Aguilar*[1], *V. Morán*[1], *M. Pérez-Macho*[2], *C. Castellet-García*[3], *J. M. Martí-Climent*[1];
[1]*Clínica Universidad de Navarra, Pamplona, SPAIN,* [2]*Hospital Universitario Marqués de Valdecilla, Santander, SPAIN,* [3]*Consorcio Hospitalario Provincial de Castellón, Castellón, SPAIN.*

Aim/Introduction: Some clinical scenarios require several PET/CT studies in a short time interval (follow up, clinical trials, multi-tracer studies...). If CT image is redundant for localization/diagnosis, CT patient dose could be reduced substantially. The aim of this study is to explore the CT protocol for minimum patient dose without compromising accurate attenuation correction and PET image quality. **Materials and Methods:** Scans were acquired in Biograph mCT TrueV PET/CT and reconstructed with EARL parameters. A cylindrical uniform phantom (diameter 20 cm) was filled with 164 MBq of FDG and placed within a parallelepiped container (section 17x34 cm) filled with non-radioactive water. Twenty-one CT images were acquired (Tube potential: 80, 100, 120 kV; current-time product: 10, 20, 40, 60, 80, 100, 120 mAs, without AEC). A 300s PET image was reconstructed using each of the 21 mu-maps. CTs, mu-maps and PET images were visually inspected to identify and quantify potential artifacts. Additionally, a NEMA anthropomorphic phantom with 43 MBq in the background compartment containing two non-radioactive spheres and 4 hot spheres (contrast 8:1) was scanned with the clinical protocol for oncology (120s). PET images were corrected for attenuation using the clinical CT (120kV-80mAs-AEC) and the lowest achievable dose CT (according to the previous experiment). PET image quality was evaluated according to the NEMA NU-2 standard. **Results:** Cylindrical uniform phantom: CTDI ranged from 0.2 to 8.7 mGy. Only the two lowest CTDI conditions (80kV-20mAs and 80kV-10mAs) produced artifacts in CT images and mu-maps that caused a non-uniformity artifact in the PET Images. For all the rest PET images (CTDI ≥ 0.43 mGy), the mean uptake value in the most affected area varied less than 2% respect to the reference value. Noise level of CT images and mu-map was clearly dependent on CTDI, but noise in PET image did not vary significantly. NEMA anthropomorphic phantom: CTDI values were 5.57 mGy for the clinical CT (120kV-80mAs-AEC) and 0.82 mGy for the low dose CT (80kV-40mAs-noAEC). Contrast recovery coefficients for cold and hot spheres varied less than ±0.5%. The average lung residual varied from 9.98 % to 9.09% (increase of 1.2%). Background variability varied less than 2%. **Conclusion:** It has been demonstrated, with a wide phantom, that CTDI can be reduced to 0.43 mGy without any perceptible qualitative or quantitative degradation in corrected PET image. Using the NEMA phantom, a CTDI reduction of 85% did not degraded PET image quality. **References:** None.

EP-0974

Personal dose equivalent $H_p(10)$ in patient's family members after ^{131}I therapy in thyroid cancer and benign thyroid diseases

M. J. Carapinha[1,2,3], *T. C. Ferreira*[4], *M. T. Rézio*[4], *L. Salgado*[4], *S. Vaz*[4], *G. Costa*[5], *R. Ferreira*[5], *J. Isidoro*[5], *C. Nunes*[2,6], *A. Tavares*[2];
[1]*Escola Superior de Tecnologia da Saúde de Lisboa, Lisboa, PORTUGAL,* [2]*Escola Nacional de Saúde Publica, Universidade Nova de Lisboa, Lisboa, PORTUGAL,* [3]*H&TRC - Health & Technology Research Center, ESTeSL - Escola Superior de Tecnologia da Saúde, Instituto Politécnico de Lisboa, Lisboa, PORTUGAL,* [4]*Instituto Português de Oncologia de Lisboa, Francisco Gentil, EPE, Lisboa, PORTUGAL,* [5]*Centro Hospitalar e Universitário de Coimbra, EPE, Coimbra, PORTUGAL,* [6]*Centro de Investigação em Saúde Pública, Av. Padre Cruz 1649-016, Lisboa, PORTUGAL.*

Aim/Introduction: The aim is to quantify the personal equivalent dose $H_p(10)$ of the family members (FMs) of patients submitted to iodine-131 therapy (RAIT): thyroid cancer (TC) or benign thyroid diseases (BTD) and compare $H_p(10)$ values of children and adults. **Materials and Methods:** An observational study was performed in FMs of patients treated in two hospitals (83 FMs of 48 patients). After receiving instructions on radiation protection, based on Euratom recommendations, all FMs used a whole body thermoluminescent dosimeter (TLD) during 21 days. The FMs were divided in two groups: TC-Group, 65 FMs (5 children <10 y) of 37 patients treated for TC (average activity = 3369.6 MBq; range 1110-5920 MBq); BTD-Group, 18 adults FMs of 11 patients treated for BTD (average activity = 365.4 MBq; range 185-555 MBq). The TC patients were discharged 48h after therapy and BTD patients were treated as ambulatory patients. All ethical principles of the investigation were respected. **Results:** In the TC-Group, FMs had an Body Mass Index (BMI) of 26.1 ± 5.5 $Kg.m^{-2}$ and the mean of $H_p(10)$ was 0.14 mSv (range 0.00-3.37 mSv). At discharge, patients in this group had a mean effective dose rate measured at 1 meter distance of 10.4 $\mu Sv.h^{-1}$ (range 2-28 $\mu Sv.h^{-1}$). In the BTD-Group, FMs had a BMI of 26.8 ± 3.7 $Kg.m^{-2}$ and the mean of $H_p(10)$ was 0.37 mSv (range 0.01-2.40 mSv). The $H_p(10)$ value correlated with the degree of relationship and the age of the FMs. In both groups, the $H_p(10)$ of the FMs showed a moderate correlation to the RAIT activity (ρ_{sp}=-0.450; p=0.010) and no correlation with patients effective dose rate (ρ_{sp}=0.171; p=0.173) or BMI of FMs (ρ_{sp}=-0.074; p=0.585). In the TC-Group a moderate correlation was found between the effective dose rate and the RAIT activity administered (ρ_{sp}=0.342; p=0.009) and a non-statistically significant correlation between the effective dose rate and the BMI (ρ_{sp}=0.237; p=0.088). CI 95%. **Conclusion:** The FMs of the patients submitted to RAIT for BTD received higher doses when compared to FMs of TC patients. The $H_p(10)$ of the FMs was correlated to the degree of relationship and the age of the FMs. In the patients submitted to ^{131}I therapy for TC or BTD, the $H_p(10)$ of the FMs is associated to the ^{131}I administered activity. It is important to underline that the personal dose equivalent in these FMs does not reach the limits recommended by ICRP 97 and ICRP 94. **References:** None.

EP-0975

Radiation Exposure to Carers and Comforters from patients undergoing ^{18}F-FDG-PET/CT

E. Kalogianni, D. Levart, N. Heraghty, S. Soares, A. Cheetham, B. Corcoran, N. Mulholland, M. Vadrucci, G. Vivian;
King's College Hospital, London, UNITED KINGDOM.

Aim/Introduction: The UK legislative implementation of the new European Commission Basic Safety Standards (BSS) (Ionising Radiation (Medical Exposure) Regulations {IR(ME)R} 2017) were introduced to protect patients against the hazards associated with the use of ionising radiation in medical settings. The exposure of carers and comforters is now considered a medical exposure, falling within the scope of IRMER17. Under the regulation the employer is responsible to establish dose constraints with regard to the protection of carers and comforters and all exposures should be justified. The aim of this study was to estimate the in-hospital radiation exposure of carers and comforters accompanying patients undergoing PET-CT examinations and to establish guidance for radiation safety. **Materials and Methods:** 23 patients (13 females, median age was 62 years (30 - 93), median weight: 76 kg (48 - 130)) undergoing a FDG-PET/CT scan during a period of 4 weeks were randomly selected. Patients were injected with 4.5 MBq/kg of ^{18}F-FDG to a maximum of 400 MBq and rested in a quiet environment until scanning. All patients had equivalent dose rate measurements recorded at 1 m and 10 patients had additional equivalent dose rate measurements recorded at 0.5 m and 0.1 m from the mid abdomen.Measurements were performed using a Tracerco PED+ Personal Electronic Dosimeter, which records equivalent dose rate and cumulative dose, during the patients resting period and a series 900 Mini-Instruments survey meter. All measurements were corrected for background, measured in the same room without the patient. **Results:** The median injected activity was 342 MBq (224 - 425). The median resting period was 51 min (43 - 61). The median dose rates per unit of injected activity measured at 1m, 0.5 m and 0.1 m were 0.07 µSv/h/MBq (0.04 - 0.09), 0.20 µSv/h/MBq (0.11 - 0.50) and 0.75 µSv/h/MBq (0.40 - 0.89) respectively. The median cumulative dose received during resting period measured at 1m, 0.5 m and 0.1 m was 20 µSv (12-39), 76 µSv (34 - 201) and 234 µSv (167 - 301) respectively. The 95th percentile for these measurements were 33 µSv, 152 µSv and 286 µSv. **Conclusion:** Doses to comforters and carers were within the dose constraint recommended by the International Commission on Radiological Protection (Publication 103) of 5mSv per occurrence. This study confirms that comforter and carer radiation exposure levels from FDG PET-CT examinations practice are acceptably low. **References:** None.

EP-0976

Life quality improvement in Pediatric Patients submitted to Radioiodine Therapy for a return to daily life As Fast As Reasonably Achievable

M. Pizzoferro[1], *C. Polito*[2], *B. Cassano*[2], *M. F. Villani*[1], *M. Longo*[2], *E. Genovese*[2], *A. Castellano*[3], *A. Grossi*[4], *M. C. Garganese*[1];
[1]*Nuclear Medicine Unit, Bambino Gesù Children's Hospital-IRCCS, Rome, ITALY,* [2]*Medical Physics Unit, Bambino Gesù Children's Hospital-IRCCS, Rome, ITALY,* [3]*Oncology Unit, Bambino Gesù Children's Hospital -IRCCS, Rome, ITALY,* [4]*Endocrine Unit, Bambino Gesù Children's Hospital -IRCCS, Rome, ITALY.*

Aim/Introduction: Radioiodine (^{131}I) therapies on children with differentiated thyroid cancer and neuroblastoma can be a discouraging experience requiring an isolation period due to radiation safety concerns. Post-therapy radiation isolation depends on the value of dose-rate on the day of discharge (estabilished by Radiation protection97 and Italian regulation). Pediatric patients usually have dose-rate values on discharge involving a month of school absence and no contacts with other peers in order to avoid unduly irradiation. However, each patient

has an individual kinetic of radioactivity excretion depending on extension and uptake of disease, renal function and other individual parameters. The aim of our study is to improve patient quality of life reducing as much as possible the radiation isolation period after discharge by implementation of a specific patient radiometric protocol. **Materials and Methods:** Children affected by thyroid cancer or neuroblastoma are treated in our Istitution in a child-friendly therapy room, accompanied by their parents, for 3-4days. A well established dosimetric protocol is routinely applied including measurement of patient dose-rate at a distance of 1 meter by radiation detector up to 7days after radioiodine administration. All radiometric data are collected and analyzed to assess individual radiotracer excretion/retention time. For each patient radiation isolation period is calculated according to Italian regulation considering the dose rate on discharge. An update on 7thday after therapy administration (when ^{131}I-Whole Body Scan is scheduled) is also performed on the basis of relative emission rate value. **Results:** 69treatments were performed in our Istitution (2016-2018): 35 with high-administered activity of ^{131}I-MIBG and 34 ^{131}I-NaI administrations (13 thyroid remnant ablations, 21 metastatic treatments). Median age was 13years (range 3-20yrs); median weight was 47kg (range 12-123kg). Median administered activities were: 11GBq for ^{131}I-MIBG (range 3.1-18 GBq), 2GBq (range 1.11-2GBq) of ^{131}I-NaI for thyroid remnant ablation, 5.5GBq (range 2.2-10.8 GBq) of ^{131}I-NaI for metastatic treatments. Relative difference between dose rate measured on discharge vs updated value on 7thday led to a reduction of isolation period of: 24(range 6-34) days for ^{131}I-MIBG treatments, 10(range 0-26) days for thyroid remnant ablations; 18(range 2-32) days for metastatic thyroid treatments. **Conclusion:** Our protocol, routinely applied in clinical practice, makes the experience of the isolation period easier and positive for both patients and parents, from hospitalization in therapy room to a faster return to daily life. Radiometric data updated on 7th day safely allow reducing radiation isolation period, improving life quality in children submitted to radioiodine therapy. **References:** None.

EP-0977

Optimal shielding specification for ^{68}Gallium - validation by Monte Carlo Simulations and Empirical Measurements

A. McCann[1,2], *S. Cournane*[1], *A. Dowling*[1], *D. Maguire*[1], *R. P. Killeen*[1], *J. Lucey*[1], *L. L. Vintro*[2];
[1]*UCD-SVUH PET CT Research Centre, St Vincent's University Hospital, Dublin, IRELAND,* [2]*School of Physics, University College Dublin, Dublin, IRELAND.*

Aim/Introduction: Significant improvements in the design and availability of Gallium (^{68}Ge/^{68}Ga) generators has resulted in their increased presence in PET/CT facilities. Vial and syringe shields originally designed for ^{18}F are now routinely used with ^{68}Ga; however, ^{68}Ga has a more complex decay scheme than the pure positron(β+) emitter ^{18}F. Positrons from ^{68}Ga possess an energy (1899keV, 96.7%) significantly higher than those of ^{18}F (633keV, 96.8%). The ^{68}Ga positrons have a longer path length and result in more intense Bremsstrahlung radiation. In addition to the 511keV annihilation photons, ^{68}Ga also decays with gamma emissions of 1077keV(3.2%) and 1883keV(0.14%) which can further complicate the shielding requirements. The potential skin dose due to contact with an unshielded syringe has been reported to be approximately 11 times higher for ^{68}Ga than ^{18}F attributable to higher energy positrons[1]. Optimal shielding for ^{68}Ga should stop the positron emissions and significantly attenuate the gamma and Bremsstrahlung emissions. This study will compare simulated and measured transmission data for ^{18}F and ^{68}Ga and determine optimal shielding requirements for ^{68}Ga. **Materials and Methods:** Monte Carlo simulation (EGSnrc, Canada) and Radiological Toolbox V3.0(NRC, USA) will be used to generate radiation transmission data and model beta particle effective path length data for ^{68}Ga and ^{18}F through tungsten, lead, perspex and various combinations of these materials. Modelling will be complimented by empirical dose rate measurements performed with a variety of commercially available gamma and beta detectors, while energy spectra will be examined using the Ortec Digidart-LF portable MCA detector. **Results:** Commercially available PET syringe shields typically have a wall thickness of 7.5-9mm. PET Syringe shields are typically specified in terms of ^{18}F attenuation, with no specification given for ^{68}Ga. However, ^{68}Ga positrons are modelled to have a much longer effective path length in both tungsten and lead, compared to ^{18}F. Simulated results will characterize the gamma radiation of ^{68}Ga as it traverses through these materials, the interactions of its high energy positrons and their resulting bremsstrahlung radiation. Further theoretical and measured results will be presented in detail. **Conclusion:** This study compares simulated and measured transmission data for ^{18}F and ^{68}Ga for a range of commonly used vial and syringe shields towards presenting the optimum shielding requirements for ^{68}Ga. The accuracy of a range of commercially available dose rate meters for use with ^{68}Ga is also assessed. **References:** 1 Kemerink et al. Extremity doses of nuclear medicine personnel: a concern. EP-0978

External radiation exposure to the patient's environment after treatment with Cu-67 SARTATE

J. Preston[1], *E. Lengyelova*[1], *C. Biggin*[1], *M. Parker*[1], *M. Harris*[1], *E. van Dam*[1], *E. Bailey*[2], *D. Bailey*[2], *G. Schembri*[2];
[1]*Clarity Pharmaceuticals, Eveleigh, AUSTRALIA,* [2]*Royal North Shore Hospital, St Leonards, AUSTRALIA.*

Aim/Introduction: Cu-67 SARTATE, a beta and gamma-emitting therapeutic radiopharmaceutical is in clinical development as a potential treatment for a range of different SSTR-2 expressing cancers including meningioma, neuroblastoma and neuroendocrine tumours. Other Cu-67 based radiopharmaceuticals are also in development using different targeting moieties including GRPr (Bombesin) and PSMA analogues. An important component of radiopharmaceutical development is the assessment of radiation safety risks to the

patient's environment, including risk to the family, caregivers and the general public. This assessment also involves development of suitable radiation safety instructions, that balance the requirement of minimising radiation exposure to the family and carers without impacting on patient care and wellbeing; whilst also maintaining adherence and compliance to US radiation safety guidelines. **Materials and Methods:** Estimates of external radiation exposure from patients were obtained from predictive modelling using published dose coefficients for Cu-67 and preclinical estimates of effective half-life of Cu-67 SARTATE in the patient. According to these estimates, a series of radiation safety instructions were developed to ensure the radiation exposure to the patient's environment remains below acceptable radiation safety limits. The modelled estimates were subsequently compared to actual data utilising dose rate measurements acquired from the first-in-human clinical trial of Cu-67 SARTATE. **Results:** The radiation safety instructions developed applying the modelled estimates were shown to offer sufficient protection to the patient's family, caregivers and general public. The observed preliminary external dose rate measurements from an ongoing clinical trial with Cu-67 SARTATE verified that adherence to the radiation safety instructions ensure that radiation exposure to others remains below the acceptable limits. **Conclusion:** The radiation safety instructions following treatment with Cu-67 SARTATE in patients with meningioma have been shown to be sufficient, the external radiation exposure to family, caregivers and general public were below the generally accepted levels of 1mSv to children and pregnant/nursing mothers and the general public; and 5mSv for primary caregivers. Additionally, the preliminary dose exposure rates indicate that Cu-67 SARTATE can be given as an outpatient treatment, which is in line with NUREG 1556, Vol 9, Rev 2 (Table U.1). **References:** None.

EP-0979

Development of a quantitative annual risk assessment model for Nuclear Medicine: simulating radiation doses to hospital staff cohorts and members of the public

S. Cournane*, N. McArdle, J. McCavana;*
St Vincent's University Hospital, Dublin 4, IRELAND.

Aim/Introduction: Annual radiation risk assessments are performed to assess radiation doses that hospital staff, patients and members of the public are liable to receive. When radiation doses in excess of a 0.3mSv dose constraint from a single source are identified, practices are reviewed with the aim of reducing exposure and/or introducing additional dose monitoring where required. Nuclear medicine patients can be a source radiation exposure for their family, staff and members of the public within and outside of the hospital environment. Previous studies have calculated doses to different cohorts from patients based on proximity models and interaction patterns combined with dose rates and biokinetic models for single interactions; however, there is very little data or methodology available towards performing annual quantitative risk assessments. Accordingly, this study estimates, for a university teaching hospital and tertiary referral centre for breast and liver disease, the annual doses to the various staff groups and members of the public by examining the referral source frequency and pathways of patients attending for scans. **Materials and Methods:** Throughput, patient scanning frequency, injected activities, patient biokinetics, excreted activities, occupancy patterns, patient interaction patterns for various staff and patient cohorts, staff work rostering, workflow patterns and ward/clinical area design were examined to inform on parameter inputs to the quantitative risk assessment model. Information gained was through radiological information system, survey and interview techniques. **Results:** Modelled doses received and proximity models of staff from nuclear medicine patients will be compared to those presented in the literature, while estimated doses to family members will also be presented. Examples of annual modelled doses, per staff member, include those for ICU nurses (<15μSv), cancer day ward nurses, (<60μSv) and porters (<65μSv). In addition, theoretical scenarios simulated to examine the radiation exposures received from those staff members involved in, for example, pathological sampling from surgery (Sentinel node; <25μSv), nuclear medicine waste pipe leaking/bursting (<90μSv), and blood-sampling in phlebotomy (<10 μSv), will be presented, **Conclusion:** A risk assessment template quantifying risks as mentioned above has been developed, appropriate for current work practices. Annually, it can be populated with the breakdown of annual workload including referral sources to identify any groups at risk or workflows that require review. This tool has proved invaluable when educating staff cohorts throughout the hospital about the estimated typical doses that they receive in an environment, where sometimes the perceived risks are not commensurate with the real risks. **References:** None.

EP-0980

Comparison of correction factors for assessment of skin exposure of workers' hands in specific operations with selected radiopharmaceuticals

J. Hudzietzova[1]*, M. Fulop*[2]*, J. Sabol*[3]*, J. Doležal*[4]*, J. Kubinyi*[5]*, O. Kraft*[6]*, P. Povinec*[7]*, A. Vondrák*[8]*, L. Foltinová*[9]*;*
[1]*Czech Technical University in Prague, Kladno, CZECH REPUBLIC,* [2]*Slovak Medial University, Bratislava, SLOVAKIA,* [3]*Faculty of Security Management PACR, Prague, CZECH REPUBLIC,* [4]*Department of Nuclear Medicine, University Hospital Hradec Králové, Hradec Králové, CZECH REPUBLIC,* [5]*IZOTOPCENTRUM, s.r.o, Nitra, SLOVAKIA,* [6]*Department of Nuclear Medicine, University Hospital Ostrava, Ostrava, CZECH REPUBLIC,* [7]*PET centre BIONT, a.s., Bratislava, SLOVAKIA,* [8]*IZOTOPCENTRUM, s.r.o, Bratislava, SLOVAKIA,* [9]*UEBA, University of Economics in Bratislava, Bratislava, SLOVAKIA.*

Aim/Introduction: The correction factor, corresponding to the ratio of the skin exposure at the most exposed location and the exposure measured at the position of the finger dosimeter, may differ depending on working situations and conditions. The aim of the paper is to highlight possible differences in the

size of this factor during relevant specific procedures involving use of various radiopharmaceuticals and also to refer to the possible difference in its values in case of insufficient syringe shielding. **Materials and Methods:** The study included workers from selected nuclear medicine department engaged in using radiopharmaceuticals labelled with ^{18}F and ^{131}I (a total of 111 measurements). A similar pilot investigation was also carried out with ^{11}C and ^{68}Ga. Based on the monitoring using 12 TLDs fixed on workers' hands, the correction factor was calculated for workers handling the same radiopharmaceuticals. Its values referred to the position on the second index finger. In the case of ^{18}F measurements the effect of insufficient shielding was observed. **Results:** Following our present results, the correction factor referring to the index finger root was found to be significantly different for individual radionuclides. Based on our assessment, the correction factor involving ^{18}F and ^{131}I amounted to 3.5 and 1.9, respectively. From the pilot measurements involving ^{68}Ga, the correction factor was found to be 6.2 while in the case of ^{11}C its value was 2.8. In the specific case, when during the ^{18}F applications the insufficient shielding was used, the correction factor was up to three times higher than that under normal standard conditions. **Conclusion:** Preliminary results indicate that for different radiopharmaceuticals the correction factors may differ significantly. For this reason, it would be appropriate to verify the correction factors for each radiopharmaceutical and group of workers using the same radiopharmaceuticals. The correction factor assessed for standard situations should not be used in cases where the workers repeatedly use insufficient shielding. In such cases it is recommended to examine the values of the correction factors taking into account the influence of the insufficient shielding. Acknowledgments: The study has been partially supported by the project SGS18/100/OHK4/ IT/17 project. **References:** None.

EP-0981

Comparison of eye lens and hand skin exposures during handling ^{18}F, ^{11}C and ^{68}Ga radiopharmaceuticals

M. Fulop[1], *J. Hudzietzová*[2], *J. Sabol*[3], *P. Ragan*[1], *A. Vondrák*[4], *L. Foltínová*[5];
[1]*Slovak Medical University, Bratislava, SLOVAKIA,* [2]*Czech Technical University in Prague, Kladno, CZECH REPUBLIC,* [3]*Faculty of Security Management PACR, Prague, CZECH REPUBLIC,* [4]*IZOTOPCENTRUM, s.r.o, Nitra, SLOVAKIA,* [5]*UEBA, University of Economics in Bratislava, Bratislava, SLOVAKIA.*

Aim/Introduction: At present, in addition to ^{18}F-FDG radiopharmaceuticals, new PET radiopharmaceuticals labelled with ^{11}C and ^{68}Ga radionuclides are introduced in nuclear medicine. These radiopharmaceuticals emit the same penetrating gamma photons of 511 keV. Therefore, the optimized radiation protection for working with the ^{18}F labelled radiopharmaceutical is usually considered as sufficient approach also for these new radiopharmaceuticals. However, the ^{11}C and ^{68}Ga radionuclides emit positrons of higher energy than ^{18}F and the range in biological tissue of these positrons by several mm longer. The aim of the paper is to point out the importance of controlling the compliance with radiation protection requirements in PET workplaces for newly introduced positron radiopharmaceuticals where routine procedure applicable to handling of ^{18}F, ^{11}C and ^{68}Ga may result in higher skin and/or eye lens exposure. **Materials and Methods:** In nuclear medicine, a radiopharmaceutical is routinely administered to a patient via a cannula. The comparison of the exposure due to gamma photons and positrons of hand holding the infusion tube leading into the cannula with radiopharmaceutical solutions ^{18}F, ^{11}C and ^{68}Ga is simulated by the Monte Carlo code MCNP6 using a hand voxel phantom. In the same administration of the radiopharmaceutical, the administering person is inclined above the injection site and observes the infusion tube filling with the radiopharmaceutical while exposing the eyes to the gamma radiation and the positrons penetrating the infusion tube. The equivalent dose of the eye lens in the head voxel phantom is compared to the $H_p(3)$ calculations of the personal TLD dosimeter placed on the chest of the MIRD chest phantom for the same irradiation geometry. **Results:** Monte Carlo simulations with the phantom of the hand holding the infusion tube showed that when replacing the ^{18}F radiopharmaceutical with ^{11}C, the skin irradiation on the hands is increased by a factor of 2. The confusion of the ^{18}F radiopharmaceutical ^{68}Ga is more prominent, with a 4-fold increase in skin irradiation at the same actions hands. In the case of irradiation of the eye lens with an unshielded ^{68}Ga radiopharmaceutical at a distance of 50 cm, Monte Carlo simulations showed that the equivalent dose is a factor of 2 higher than the $H_p(3)$ value obtained by a personal chest dosimeter. **Conclusion:** The efficiency of radiation protection measures introduced when handling the ^{18}F radiopharmaceuticals should be carefully checked when introducing ^{11}C and ^{68}Ga labelled radiopharmaceuticals. Acknowledgements: Study has been supported - SGS18/100/OHK4/1T/17 project. **References:** None.

EP-0982

Incorporation Of ^{177}Lu During Care Of ^{177}Lu-PSMA And ^{177}Lu-DOTATATE Therapy Patients

C. Happel[1], *W. T. Kranert*[1], *B. Bockisch*[1], *U. Kratzel*[2], *J. Baumgarten*[1], *C. Nguyen Ngoc*[1], *E. Garayev*[1], *F. Grünwald*[1], *A. Sabet*[1];
[1]*University Medical Center Frankfurt / Department of Nuclear Medicine, Frankfurt, GERMANY,* [2]*Bavarian Environment Agency, Office Kulmbach, Kulmbach, GERMANY.*

Aim/Introduction: The determination of the annual effective ^{131}I dose of the nursing staff caused by incorporation on a nuclear medicine therapy ward is required in Germany. Since the establishment of ^{177}Lu-PSMA-617 for treatment of metastatic castration-resistant prostate cancer and ^{177}Lu-DOTATATE for neuroendocrine tumors the patient spectrum on nuclear medicine wards has changed, but currently routinely performed incorporation monitoring of ^{177}Lu is not prescribed. The reason is the absence of volatility of ^{177}Lu compared to ^{131}I. In a routinely performed incorporation analysis the 208keV

gamma-peak of ^{177}Lu was unexpectedly detected and a closer analysis was performed to estimate the effective dose for the employee concerned. Aim of this study is to present these data and to discuss the possibility of ^{177}Lu incorporation and potential reasons. **Materials and Methods:** Activity concentration in urine samples (collection for 24h) of the nursing staff of a nuclear medicine therapy ward was routinely examined fortnightly. During a week with two ^{177}Lu-PSMA patients (accumulated activity: 16.9GBq) and two ^{177}Lu-DOTATATE patients (accumulated activity: 10.9GBq) the 208keV gamma-peak of ^{177}Lu was detected in two 24h urine samples (0.88l and 3.5l respectively). ^{177}Lu is known to be not volatile, therefore the exact reason of the incorporation and the incorporation pathway remains unknown. Preparation was done in a flue and the direct contact of the nurses to the patients was restricted to a necessary Minimum. **Results:** For calculation of the dose a single ingestion with total resorption in the gastrointestinal tract and the biochemical behavior of ^{177}Lu-DOTATATE (which is previously described in several studies) was assumed. The calculated supply of activity using these presumptions corresponds to a proportion of 10^{6} of the administered activity. The detected ^{177}Lu activity in the urine samples was 70.9 and 14.4Bq leading to a concentration of 80.6 and 4.11Bq/l. The dose coefficient of ^{177}Lu-DOTATATE for the effective dose is $5.2*10^{-11}$Sv/Bq. The dosimetric evaluation of the measured values led to effective doses of $2.56*10^{-3}$mSv and $2.64*10^{-4}$mSv respectively. **Conclusion:** Due to biochemical behavior of ^{177}Lu and preparation in a flue, inhalation of the radiopharmaceutical is implausible. Incorporation by penetration due to unnoticed skin contamination is implausible as well because frequent contamination measurements were performed. In the follow-up samples of the employees concerned no ^{177}Lu was detected confirming the hypothesis of a unique incorporation by unnoticed ingestion. A systematic incorporation by inhalation can therefore be excluded. However, routine analysis of ^{177}Lu in incorporation monitoring might be reasonable. **References:** None.

EP-0983

Iodine 131 Excretion In Saliva And Bronchial Secretion In Differentiated Thyroid Carcinoma

B. Bockisch[1], *B. Sauter*[2], *M. Etzel*[3], *W. T. Kranert*[1], *S. Wagner*[1], *A. Sabet*[1], *F. Grünwald*[1], *C. Happel*[1];
[1]*University Hospital Frankfurt, Department of Nuclear Medicine, Frankfurt, GERMANY,* [2]*Kreiskliniken Darmstadt-Dieburg, Darmstadt, GERMANY,* [3]*Radiologie Darmstadt, Darmstadt, GERMANY.*

Aim/Introduction: Knowledge of radioiodine pharmacokinetics in ablative radioiodine-131 therapy of differentiated thyroid carcinoma (DTC) and its excretion is particularly important for the evaluation of potential contaminations and dosimetry. I-131 excretion of the salivary glands during radioiodine therapy of DTC is currently not adequately examined. Therefore, the aim of this study was a quantitative determination of this issue. **Materials and Methods:** A 68 year-old patient with DTC and tracheostoma was treated in our department with 3.45 GBq I-131 (i.v. administration). Suctioning of the bronchial secretion was necessary due to the tracheostoma. Bronchial secretion was highly contaminated with saliva because of esophagus obstruction with a esophago-bronchial fistula. Measurement of the remaining whole body I-131 activity was performed using a gamma probe calibrated for I-131. The complete saliva contaminated bronchial secretion was collected over 4 days, each suctioning separately, and measured in aliquots of 1 ml in a well counter (1,659 - 2,399 ml/fraction; saliva-contaminated bronchial secretion and lavage liquids). The resulting activity kinetics in saliva-contaminated bronchial secretion was compared to the I-131 whole body activity. **Results:** Measurements of the saliva-contaminated bronchial secretion showed a biexponential progression with effective half-life of 0.2 d (fast phase) and 1.16 d (slow phase). In parallel the activity kinetic of the whole body showed a biexponential progression as well with effective half-life of 0.28 d (fast phase) and 0.98 d (slow phase). ICRP calculated whole body dose amounted to 250 mSv. Assuming a continuous saliva excretion of 1.5 l/d, the activity concentration in saliva-contaminated bronchial secretion decreased from 2 MBq/ml on the first day to 30 kBq/ml on the fourth day after administration. The overall excreted I-131 activity in the cumulative saliva contaminated bronchial secretion was 2.1 GBq (60% of the administered activity). **Conclusion:** I-131 excretion in saliva contaminated bronchial secretion corresponds with whole body activity. I-131 activity excreted with the saliva is high due to almost absent remaining thyroid tissue (DTC: excretion 60%, uptake thyroid bed: ~1%). Especially during the first 24h after administration special radiation protection precautions are required in handling saliva, the resulting sewage water and waste as well. Saliva contaminated bronchial secretion leads to an increased radiation exposition of the respiratory tract. **References:** None.

EP-0984

CT optimisation and LDRLs for SPECT/CT in a Paediatric Hospital

E. Morris[1,2], *A. Rose*[1,2], *M. Easty*[2], *L. Biassoni*[2];
[1]*Barts Health NHS Trust, London, UNITED KINGDOM,* [2]*Great Ormond Street Hospital for Children NHS Foundation Trust, London, UNITED KINGDOM.*

Aim/Introduction: Diagnostic Reference Levels (DRLs) are required by European Council Directive 2013/59/EURATOM (1), to provide a benchmark for the radiation dose expected for typical examinations in typical patients. If a comparison of local patient's radiation doses to the DRLs shows the DRL to be consistently exceeded, an investigation and optimisation of the examination or corrective action to improve clinical practice can be implemented. Paediatric patients are especially sensitive to ionising radiations. In the last 15 years the radiology community have been trying hard to perform imaging tests of diagnostic quality with the minimum radiation exposure to the patient. After the installation of a new 16 slice SPECT/CT in our specialised

paediatric hospital, a project was initiated to optimise the CT protocols, both for attenuation correction and localisation of SPECT studies and use as a standalone CT scanner. The aim was to compare radiation dose and image quality with the standalone CT scanner in the hospital and national or international diagnostic reference levels, where available. **Materials and Methods:** The SPECT/CT scanner was initially set up using historical protocols. Image quality measurements were performed using a CATPHAN 500 and ATOM® Dosimetry Verification Phantoms in different paediatric sizes. Image noise measurements and contrast to noise ratios were compared against various scan parameters to identify the minimum required image quality at the lowest possible radiation dose. Radimetrics™ Radiation Dose Management software was used to record patient study parameters for setting LDRLs. Weight groups were used for all body examinations LDRLs, and age groups for head exam LDRLs. **Results:** Patient exposure parameters were gradually adjusted and image quality assessed by a Nuclear Medicine Physician and a Consultant Radiologist in an iterative process. The image quality and radiation dose received by the patients was comparable between the SPECT/CT and the standalone CT scanner. LDRLs have been set for selected examinations for some weight and age groups of patients. However, some weight and age categories are less well represented in the referred paediatric patient population and the threshold for sufficient patient numbers to set an LDRL in these categories has not yet been reached. **Conclusion:** LDRLs have been set for the most commonly used SPECT/CT examinations in the department with satisfactory image quality and low radiation exposure. **References:** European Commission. Council Directive 2013/59/EURATOM [internet]. [cited 18th April 2019] Available from https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=CELEX%3A32013L0059#ntr4-L_2014013EN.01000101-E0004

EP-0985

Challenging Radioiodine Therapies: The art of not tripping over your feet whilst looking up at the stars

***R. Fernandez**, A. Nunes, F. Hassan, V. Lewington, S. J. Allen;*
Guy's & St Thomas' Hospital, London, UNITED KINGDOM.

Aim/Introduction: Radioactive iodine (^{131}I) has been used to treat benign and malignant thyroid conditions for over sixty years. With advances in medicine, an increasing number of patients with complex co-morbidities are being referred for ^{131}I treatment. Treating this patient cohort brings challenges around minimisation of radiation dose to at-risk groups and management of radioactive waste generated during/after treatment. Patients in four different challenging situations were successfully treated after careful planning by multi-disciplinary teams experienced in delivery of radioiodine. **Materials and Methods:** Three patients with end-stage renal disease on dialysis were referred for radioiodine treatment (one patient treated with 3.7GBq following total thyroidectomy, two patients treated with 800MBq for benign thyroid disease). Of the latter group, one patient had significant mobility issues requiring assistance from a carer upon hospital discharge, whilst another was registered blind and dependant on her partner for home care. Another patient treated with ^{131}I for thyroid cancer developed chest pain shortly after hospital discharge and required care in the Emergency Department. A teenage patient with thyroid cancer who had swallowing difficulties and gastric motility complications required IV radioiodine administration and assistance from a carer during her inpatient stay. Another young patient with Graves' disease was referred for radioiodine treatment whilst an inpatient in a secure mental health unit (MHU). **Results:** Following each dialysis (with 2 day interval between dialysis sessions), decrease in residual ^{131}I activity varied between the malignant/benign patient groups [Range: 19-53%]. Instantaneous dose-rate, measured in rooms adjacent to treated patients was highest for the dialysis patient treated with 3.7GBq and was 11microSv/hour. Maximum occupational whole-body (WB) dose was 66microSv, recorded by a renal nurse attending to the patient during a 4 hour dialysis session. In the MHU an Occupational therapist received 42microSv WB dose during a group therapy session. Carers & Comforters wearing WB dosimeters for the contact period duration recorded minimal radiation dose [Maximum received was 1.8mSv by the blind patient's carer]. Maximum ^{131}I activity in generated solid radioactive waste (e.g. dialysis tubing) was 1MBq. This residual waste activity decreased by 50-60% with each subsequent dialysis. Solid radioactive waste retained from the MHU contained 0.2MBq ^{131}I. **Conclusion:** This study presents a number of very different, complex clinical scenarios, each involving patients requiring ^{131}I administration who presented with challenging comorbidities/complications. Careful planning of treatments by teams experienced in the delivery of radioiodine ensures that patients in these groups have equitable access to treatment. **References:** None.

EP-0986

Management Of Extravasation Of Lutetium 177 Dotatoc

***A. C. Bekker**, P. F. Staanum, H. Bluhme, A. K. Arveschoug;*
Department of Nuclear Medicine and PET, Aarhus University Hospital, Aarhus, DENMARK.

Aim/Introduction: In June 2018, a 68-year old woman with metastatic neuroendocrine tumor received the first out of four treatments with 7,5 GBq Lutetium-177-Dotatoc. The radioactive pharmaceutical was injected via intravenous catheter in cubital fossa in the left arm. Treatment was performed in a shielded room at The Department of Oncology, Aarhus University Hospital. Immediately after end of infusion, the nurse noticed a swelling in the upper left arm, proximal to the injection site. The patient confirmed having felt a slight discomfort during infusion. Action was now taken as to confirm an extravasal injection. **Materials and Methods:** A Rados RDS-120 surveymeter was used to measure radiation dose rate close to the injection site. A few minutes after end of injection, the dose rate was approximately 5000 microSv/hour. The patient was immediately transferred to

The Department of Nuclear Medicine and PET Centre in order to perform a wholebody-scan and a Spect-CT, including the upper left arm, using a Siemens Symbia T16 Spect-CT. The patient was transferred back to The Department of Oncology, a compression bandage was applied combined with bags with heated gel in order to stimulate the lymphatic drainage. Furthermore, the patient was instructed in elevating the arm while activating the venous pump by flexing and stretching the elbow, using an elastic cotton string tied to something stable. During the day the compression bandage was re-applied, as the swelling decreased. The patient continued exercising the left arm. **Results:** The post injection scans confirmed that the entire treatment dose was located in the patients upper left arm. Approximately 6 hours post injection, measurement of the radiation dose rate close to the injection site now showed a 5-fold decrease to 910 microSv/hour. 24 hours post injection the dose rate had decreased further to 104 microSv/hour, at day 4 to 49 microSv/hour and finally at day 7 to 29 microSv/hour. Wholebody and Spect-CT confirmed the decrease of activity in the arm and was now showing high uptake in the neuoendocrine tumour cells and uptake in the kidneys. **Conclusion:** With an immediate recognition and appropriate management it is possible to reverse an extravasal injection of Lu-177-Dotatoc by elevation, compression, heat and venous pump exercises. Thereby, it was possible to avoid any further discomfort to the patient including additional treatments. **References:** None.

EP-0987

I-RISK: A Mobile Application for Patient-Specific Instruction and Effective Dose Estimation for Family Members and Member of thePublic for Patients Receiving Iodine-131 Therapy

***K. Chuamsaamarkkee**, P. Charoenphun, M. Panawech, K. Thongklam, S. Vittayachokkitikhun, W. Chamroonrat;*
Division of Nuclear Medicine, Department of Diagnostic and Therapeutic Radiology, Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok, THAILAND.

Aim/Introduction: Radioiodine (^{131}I) therapy has been used for thyroid diseases for many decades and it is the most common therapeutic radioisotope. Following radioiodine therapy, several concerns regarding to radiation safety are rising, for instance; post-discharge patient instructions and the effective dose to family members and member of the public. Unfortunately, several concerns are not well managed due to lack of standard regulatory guidance. Therefore, I-Risk mobile application aims to provide the patient-specific instructions based on the ATA (American Thyroid Association) and IAEA (International Atomic Energy Agency) guidelines. I-Risk also provides the effective dose estimation for family members and public with user-defined scenario for duration and distance of ^{131}I treated patient contact. **Materials and Methods:** I-Risk classifies the users into two groups (a) the ^{131}I treated patients or their family members and (b) the healthcare practitioners. The ^{131}I treated patients or their family members are required to fill in the following parameters; type of disease (hyperthyroid or thyroid cancer), activity and date of treatment. For the healthcare practitioners, the radiation exposure of ^{131}I treated patient measuring by a survey meter is used as a primary input. The occupational factor and distance are also the crucial factors to estimate the effective dose. The thyroidal and extrathyroidal uptake fraction values are derived from the US NRC (United States Nuclear Regulatory Commission) recommendation. The effective half-life which depend on administration activity and time-point of measurement is taken from the published literatures based on Asian population data. **Results:** Patient-specific instruction based on the type of disease, administered activity and treatment date could be generated from I-Risk displaying in user-friendly interface. In addition, the total effective dose equivalent (TEDE) could be calculated using a dose rate data from survey meter fitted on the Asian population data. **Conclusion:** In conclusion, I-Risk can provide the individual specific instruction for ^{131}I treated patients. The healthcare practitioners can use I-Risk as a guidance to manage the radiation safety concerns. Subsequently, family members and public will get less unnecessary radiation exposure from the patients who received ^{131}I therapy. Additionally, I-Risk also provides the Q&A (question and answer) section which the users can directly enquire their questions to the experienced medical physicist. **References:** None.

EP-0988

Pattern Of Myocardial ^{18}F-FDG Uptake Related To Radiation Dose Before And After Radiotherapy In Patients With Esophageal Cancer

***X. Sha**[1], C. Han[2], G. Gong[1], Y. Yin[1];*
[1]Department of Radiation Oncology, Shandong Cancer Hospital Affiliated with Shandong University, Jinan, CHINA,
[2]Turku PET Centre, Turku University Hospital, Turku, FINLAND.

Aim/Introduction: With increased long-term survival in esophageal cancer patients with radiotherapy, radiation-induced cardiac toxicity happens more frequently. The purpose of this study was aiming to investigate change of myocardial [18F]FDG uptake before and after radiotherapy, and relationship between this change and radiation dose on myocardium during therapy. **Materials and Methods:** Ten patients with thoracic esophageal cancer with radiotherapy were enrolled in Shangdong Tumor Hospital, Jinan, China during 2016-2018. [18F]FDG PET imaging was performed 1-2 week before radiotherapy and 2-3 months after radiotherapy. Prior to PET imaging, patients were fasted over 12 hours.PET imaging data were analyzed using Carimas (developed in Turku PET Centre, Turku, Finland). Radiation dose data were outputted as Dicom image data format (each pixel represents radiation dose). Then it was fused with FDG PET imaging. Left ventricular myocardium (LV-VOI) was segmented based on FDG PET images. Using same LV-VOI, corresponding radiation dose was extracted from radiation dose image. Finally, the relationship between change of FDG PET uptake and radiation dose for left ventricular myocardium was calculated. **Results:** Three myocardial

accumulation patterns of FDG PET uptake related to radiation dose were categorized. Uptake of FDG was increased in high radiation dose in four patients, meanwhile, uptake of FDG was decreased in high radiation dose in another four patients. In last two patients, uptake of FDG was not significantly changed with radiation dose. Since without clinical data, it is not possible to correlate the FDG PET uptake pattern with cardiac toxicity in current study. **Conclusion:** In patients with esophageal cancer with radiotherapy, accumulation of FDG is complicated with increased, decreased or no-change modes related to radiation dose. **References:** [1] Evans J D, Gomez D R, Chang J Y, et al. A Significant Reduction Of The Radiation Exposure Of Medical Personnel In The Context Of Radioiodine Therapy By An Alternative Effective, Reliable And Accurate Method For Measuring The Pre-therapeutic Activity Of The [^{131}I]-iodine Capsule

***J. Ranjan**, U. Lützen, Y. Zhao, M. Jüptner, M. Marx, M. Zuhayra;*
Nuclear Medicine, UKSH, Kiel, GERMANY.

Aim/Introduction: The handling of the iodine-131 (I-131)-capsules in the context of the Radioiodine Therapy (RIT) leads to a significant radiation exposure of the medical personnel, especially their hands during the obligatory pre-therapeutic measurements. This study proves a significant reduction in the radiation exposure of medical personnel by determining the radioactivity of the I-131-capsules in an alternative measurement, which keeps the I-131-capsule itself in the shielded lead container during measurement. **Materials and Methods:** I-131-capsules are delivered in closed shielded lead containers. Hp(10) dose rates were measured on the surface of the lead container using a commercially available dose rate meter (Bertold Umo LB 123) and 4 mm steel fixation devices to ensure exact and reproducible measurement geometry on the surface of the lead container in two positions, the top and the side. The exact activity of the I-131-capsule was subsequently measured conventionally using a dose calibrator. Calibrating curves were created by linear correlation between the results obtained in [MBq vs. µSv/h]. The Hand Hp(0.07) and whole body doses were determined with thermo luminescent ring dose meters (TLD) and Optically stimulated luminescence dose meters (OLS) during measuring the activity of 115 I-131-capsules (cumulative activity 197 GBq) by using the two measurement methods within a period of 6 months. **Results:** The linear calibration curves show determination coefficients of R^2 0.999. The total relative measurement uncertainty of the method is ±6.1% and lies below the threshold limit for the maximum allowed uncertainty of ±10% for measuring radioactivity in radioactive drugs according to the European pharmaceutical regulations. The hand dose during the measuring period of 6 month was for the conventional measuring of the I-131-capsule in the dose calibrator 9.570 mSv (0.0486 mSv/GBq). Our new method for measuring the I-131-capsule using the fixing device and Bertold Umo LB 123 led only to 0.279 mSv (0.0014 mSv/GBq). This means a reduction of the hand dose by nearly 35 fold. The effective dose (whole body) for both measuring methods was under the detection limit of the dose meter. **Conclusion:** During the clinical routine the introduction of our new measuring method leads to a distinct reduction of the radiation exposure of the hands of the medical staff and allows an accurate determination of the activity of the [131I]-capsules prior to application. **References:** None.

Common Errors and Misconceptions in Radiation Protection

J. Cortese;
British Columbia Institute of Technology, Burnaby, BC, CANADA.

Aim/Introduction: There are many common misconceptions in the application of radiation safety principles and practices in Nuclear Medicine. Through a 20-year career in radiation safety training, auditing, inspecting and investigating, common errors have been observed in Nuclear Medicine departments across Canada. Discussing some of these errors and misunderstandings can be useful to promote best practice in Radiation Safety. **Materials and Methods:** Years of observations, inspections, investigations, interviews and audits have revealed common misconceptions among Nuclear Medicine practitioners. Through anecdotal evidence, explanation of the physical properties of radiation, physical measurements around radioactive sources, dose estimations and shielding calculations it can be demonstrated that some common practices in Nuclear Medicine are ineffective and some commonly neglected safety equipment can be very useful in the clinical setting. **Results:** Technologist explanations of dose and risk to patients are often incorrect. Lead aprons are often used when ineffective, and often the wrong type of lead aprons are purchased. Syringe shield use is often dismissed because of incorrect assumptions. Contamination monitoring programs are often set up improperly. **Conclusion:** Sharing expertise, physical measurements, scientific data and years of experience can prevent many common misconceptions in the application of radiation safety in Nuclear Medicine and promote best practice. Discussing the pros and cons of safety equipment and practice is an effective way to enhance the safety culture within the Nuclear Medicine community. **References:** None.

Absorbed Dose Estimation To Co-Habitants And Co-Travellers Of Patients Treated With Radioiodine For Differentiated Thyroid Carcinoma

I. Iakovou[1], *K. Hatziioannou*[2], *K. Badiavas*[2], *E. Papanastasiou*[3], *A. Zapros*[3], *G. Arsos*[1];
[1]*3rd Nuclear Medicine Laboratory, Aristotle University of Thessaloniki, Papageorgiou General Hospital, Thessaloniki, GREECE,* [2]*Medical Physics Department, Papageorgiou General Hospital, Thessaloniki, GREECE,* [3]*Medical Physics Laboratory, Aristotle University of Thessaloniki, AHEPA University Hospital, Thessaloniki, GREECE.*

Aim/Introduction: Thyroid remnant ablation with radioiodine is a well-established treatment for patients with Differentiated Thyroid Carcinoma (DTC) after thyroidectomy. After hospitalization of approximately 3-4 days these patients return to their homes presenting a possible radiation hazard to the people around them, such as co-travellers and co-habitants. This work aims to estimate the possible radiation burden to the people, both co-travellers and co-habitants, which came in contact with the patients after their release from the hospital, analyzing data obtained during their hospitalization. **Materials and Methods:** Over a period of 8.5 years data from 1066 patients were used to estimate the possible radiation burden to family members and people that came in contact with the patients, grouping them according to their age, type of contact with the patient (co-traveller, co-habitant) and patient family status, assuming different exposure scenarios for each group and based on the written precautions given to all patients before discharge. Possible correlations between the iodine effective half-life (Teff), estimated from patient dose rate measurements during hospitalization, patient age and the method used for thyroid preparation for ablation (Thyroid Hormone Withdrawal-THW or administration of recombinant human thyroid stimulating hormone-rhTSH) were also investigated. **Results:** Mean absorbed dose to adult cohabitants was estimated to be 15 μSv (range 0.1-117 μSv), to babies (0-5yr) and small children (5-10yr) 20 μSv (range 0.8-196 μSv), to children (10-18 yr) 15 μSv (range 0.5-117 μSv) and to co-travellers 9 μSv (range 0.2-115 μSv). The highest doses to co-habitants were estimated in the few cases where the patient was a single parent of one or more children (mean children dose 64 μSv, range 11-279 μSv). No statistically significant difference in Teff between THW (mean Teff: 16.0 hrs) and rhTSH (mean Teff: 15.5 hrs) groups was observed. **Conclusion:** Provided necessary precautions are followed, radiation burden to the family members and co-travellers of DTC patients treated with radioiodine following thyroidectomy can be kept well below the corresponding dose limits and constraints. **References:** None.

EP-0992

Radiation Exposure of Nurses Including Eye Lens in PET Facility in Association with Performance Status of Patients

M. Hosono, *N. Takahara*, *Y. Yakushiji*, *K. Sakaguchi*, *Y. Yamada*, *H. Kaida*, *K. Ishii*, *Y. Nishimura*;
Kinki University Faculty of Medicine, Osaka-Sayama, JAPAN.

Aim/Introduction: Radiation protection is an important issue for nurses who take care of patients in PET facilities, and equivalent dose to the lens of the eye should be assessed as well as effective dose. Radiation exposure of nurses may be increased when patients have problems in activities of daily living (ADL) and need intensive nursing care. We measured individual dose of nurses in consideration of performance status of patients. **Materials and Methods:** Individual dose of nurses was measured during PET practices through injection of FDG, nursing care, to patients' discharge from the facility. Each nurse wore 2 individual dosimeters (MYDOSE PDM-111, Hitachi Aloka Medical) on the chest and abdomen. Performance status of patients was recorded using Katz index of independence in ADL, which is a standard method to assess ADL by categorizing into 7 grades from Index 6 (good) to Index 0 (poor). Radiation doses and contact time were recorded and analyzed. Equivalent dose to the lens of the eye was measured using thermoluminescent dosimeter at the bilateral angles of the eye as Hp(3) for 5 nurses who cared totally 167 patients. **Results:** Nurses cared overall 902 consecutive patients, who were grouped into Index 6 of 825 patients (91.5%), Index 5 of 41 (4.5%), Index 4 of 13 (1.4%), Index 3 of 7 (0.8%), Index 2 of 6 (0.7%), Index 1 of 3 (0.3%), and Index 0 of 7 (0.8%). Mean contact time of nurses to patients was 1 min to 10 min for Indices 6 to 0. Radiation doses of nurses were correlated with ADL of patients. On the basis of these results, the weighted average of exposure of a nurse was 0.25 μSv/patient. The mean equivalent dose of the lens of the eye of the nurses was 1.7 and 2.2 μSv/patient on the right and left, respectively. **Conclusion:** This approach of considering ADL of patients for dose evaluation of nurses was useful to optimize radiation protection. In our facility, patients with poor ADL account for a small fraction of patients, then, how to reduce radiation exposure from good ADL patients is important for reducing overall radiation exposure. Equivalent dose of the lens of eye would be under the dose limit (20mSv/y) even if a nurse would care 5,000 patients/year. **References:** Katz S et al. N Engl J Med 1983;309:1218.Perez ME et al. Optimization of radiation doses received by personnel in PET uptake rooms. Health Phys 2014;107(5 Suppl 3):S198-201.

EP-0993

Radiation safety instructions given to all household contacts significantly reduce radiation exposure from illiterate patients treated with low dose radioactive iodine (I -131)

K. Salman[1], *S. Wagieh*[2], *A. Bakhsh*[1], *M. Al-Ezzi*[2], *T. Munshy*[1];
[1]*King Abdullah Medical City-Makkah, Makkah,*

SAUDI ARABIA, [2]King Abdullah Medical City-Makkah (Oncology Center), Jeddah, SAUDI ARABIA.

Aim/Introduction: Radiation safety instructions (RSI) represent a cornerstone in I-131 therapy. Illiteracy may be an obstacle in proper understanding of these instructions and may decrease ability of conveying these instructions accurately to family members and household contacts. **Aim**: To evaluate the significance of giving RSI to all household contacts of illiterate patients treated with low dose I-131 therapy **Materials and Methods:** 23 illiterate patients with thyroid cancer presented for post- operative ablation with 30 mCi (1110 MBq) I-131 were included. 11 patients received direct RSI from radiation safety officer (RSO) to convey them to their 51 household contacts .On the other hand, for the 54 household contacts of the remaining 12 patients an arrangement was done to meet all contacts by the RSO to give RSI directly. Thermoluminescent dosimeters (TLD's) were dispensed to all household contacts to measure radiation exposure. TLD's were collected on the fifth day and radiation exposure figures to household contacts were measured. **Results:** Radiation exposure figures to all household contacts were below 1 mSv, ranging from 143uSv to 535uSv. The first group of contacts had a mean exposure of 373± 139 (range: 218 to 535 uSv) .These figures for the second group of contacts , who received direct RSI from RSO were 193 uSv ± 91 (range :143-291 uSv) respectively, with a statistically significant difference between both figures (P<0.05) **Conclusion:** Radiation exposure to all contacts was below the radiation exposure constraint of 1mSv. Yet, radiation exposure figures were significantly less for household contacts who received direct RSI from RSO compared to those who received these instructions from the patient .Our results emphasize the value of giving direct radiation safety instructions to all household contacts of illiterate patients treated with I-131 to reduce radiation exposure figures and to achieve the ALARA principle. **References:** -Martin R., Silva F., Colon MA., Roman D., Gonzalez TB: Evaluation of Household Radiation Exposure and Safety after Ambulatory Radioiodine Ablation therapy. Iodine 131 In Ascites After Radioiodine Therapy (RIT)

B. Bockisch[1], *M. Etzel*[2], *B. Sauter*[3], *C. Happel*[1], *W. T. Kranert*[1], *N. Mader*[1], *A. Sabet*[1], *F. Grünwald*[1];
[1]*University Hospital Frankfurt, Department of Nuclear Medicine, Frankfurt, GERMANY,* [2]*Radiologie Darmstadt, Darmstadt, GERMANY,* [3]*Kreiskliniken Darmstadt-Dieburg, Darmstadt, GERMANY.*

Aim/Introduction: Pharmacokinetics of Iodine-131 and its excretion are important for dosimetry and to control possible contamination pathways. Biodistribution of Iodine-131 in patients with ascites has not been examined to date. Ascites occurs by pass over of fluids from blood vessels to the abdominal cavity and may therefore be contaminated with I-131. Concentration of I-131 in ascites was measured. **Materials and Methods:** A 57-years-old male patient with ascites suffering from Graves' disease received oral RIT (510 MBq, intratherapeutic thyroid uptake 83 %). Four days after administration scintigraphic imaging of the abdomen followed by a puncture of the ascites was done. 8 litre ascites of an estimated total volume of 20 l were removed and a sample of 1 ml analysed in a calibrated well counter. 15 days after administration, the puncture was repeated (8 l removed, estimated total volume of 14 l). **Results:** Activity concentration in punctured ascites 4 d and 15 d after administration was 0.165 kBq/ml (total of 1.32 MBq) and 0.35 kBq/ml (total of 2.8 MBq), respectively - corresponding to 1.5 % and 3.2 % of total extrathyroideal activity as measured by whole body and partial body (thyroid) activity with a calibrated gamma probe. An increased activity in ascites was not detectable in scintigraphic imaging compared to the surrounding tissue. **Conclusion:** Ascites is contaminated with I-131 in patients treated with RIT and may exceed the local contamination limits. Because most of the ascites of the first puncture was generated prior to radioiodine-131 administration, increased activity in the second puncture was detected. Activity concentration in ascites will depend on administered dose as well as individual bio-kinetics. Therefore, a puncture of ascites should be performed prior to RIT. If this is not possible it should be performed during inpatient treatment, as ascites has to be handled and disposed according to local radiation protection regulations. **References:** None.

EP-0995

Effective finger dose for the staff performing in house production of ^{68}Ga-PSMA and ^{68}Ga-DOTATOC

K. Dalianis[1], *K. Gogos*[1], *G. Kollias*[1], *E. Oikonomou*[2], *R. Efhtimiadou*[2], *V. Prasopoulos*[2];
[1]*Medical Physics Department, Hygeia SA, Athens, Marousi, GREECE,* [2]*PET/CT Department, Hygeia SA, Athens, Marousi, GREECE.*

Aim/Introduction: The PET/CT applications have been continuously increasing. Development and availability of radiopharmaceuticals is a key driving force of nuclear medicine establishment and expansion. New radiopharmaceuticals specific for particular diseases is one of the driving forces of the expansion of clinical PET. Although such an increase is a positive trend for the benefit of patients, the associated risk of radiation exposure of staff needs to be properly evaluated. The aims of this study were to estimate the effective finger dose for the staff involved in in house production of ^{68}Ga-PSMA and ^{68}Ga-DOTATOC. **Materials and Methods:** To estimate the effective dose from external exposure, all 5 members of the staff (2 nurses, 2 medical physicists, 1 radio pharmacist) worn ring thermoluminescence

dosimeters (TLDs). We use 1850 MBq Ge68/Ga68 generator which is eluted daily by the medical physicist. The synthesis is performed by the radio pharmacist. The doses were derived by the medical physicists. The injected activity per patient is 185-200 MBq . **Results:** A total of 22 examinations were performed . The collective finger doses received by all 5 members of the PET/CT staff were the following: Nurse 1 received 1.56 mSv as a finger dose and Nurse 2 received 2.25 mSv finger dose respectively. Medical Physicist 1 received 2.96 mSv finger dose and Medical Physicist received 2 3.12 mSv respectively. Radio pharmacist received 3.98 mSv finger doses. **Conclusion:** The personnel dose results are significantly lower than the recommended annual dose by International Commission for Radiological Protection. Ring dosimeters must be worn for the safety of the nuclear medicine personnel involved in synthesis and injection of Ga-68 peptides. **References:** [1] Dalianis K, Malamitsi J, Gogou L, Pagou M, Efthimiadou R, Andreou J, Louizï A, Georgiou E Dosimetric evaluation of the staff working in a PET/CT department, Nuclear Instruments and Methods in Physics Research A 569, 548 - 550. EP-0996

Dosimetric evaluation to medical workers operating in a PET/CT department after the use of in house production of Ga-68 peptides

K. Dalianis[1], *K. Gogos*[1], *E. Oikonomou*[2], *G. Kollias*[1], *R. Efhtimiadou*[2], *V. Prasopoulos*[2];
[1]*Medical Physics Department, Hygeia SA, Athens, Marousi, GREECE,* [2]*PET/CT Department, Hygeia SA, Athens, Marousi, GREECE.*

Aim/Introduction: Positron Emission Tomography is considered one of the most relevant diagnostic imaging techniques that provides both functional and morphological information for the patient. Due to the high-energy tracers emitting 511 KeV used in PET/CT departments and considering the risks associated to ionizing radiation that have been derived from previous studies, special attention is needed when dealing with radiation protection aspects in a PET/CT modality . Since the new era of in house production with synthesis modules new radiopharmaceuticals such us [68Ga]-PSMA and [68Ga]-DOTATOC new measurements concerning the doses to medical staff are needed. The aim of this study was to measure the effective wholebody dose of the personnel. **Materials and Methods:** The estimation of equivalent dose from external dosimetry for all three members of the staff was monitored with the use of TLDs badges and electronic dosimeters worn at the upper pocket of their overall (two medical physicists and one radiopharmacist). The average workload of the department is 3 patients per week. 19 patients were examined. Data were collected day-to-day concerning the interaction of the staff during synthesis procedures. **Results:** The elution of Ga-68 generator is done on daily bases by medical physicist and synthesis is performed by the radiopharmacist. The collective effective doses received by all 3 members of the staff were the following: Medical Physicist1 received 0.15 mSv whole body dose per month, Medical Physicist2 received 0.12 respectively. Radiopharmacist received 0.18 mSv whole body dose per month. **Conclusion:** Regulations exist to ensure safety of the medical workers according to ALARA principles. From our results we can observe that although there is an increase of the doses for technologists and nurses the numbers are significantly lower than the recommended annual dose limit. **References:** [1] D. EP-0997

Rotating duties among nurses to reduce occupational radiation exposure during PET/CT procedures

Y. Nishii, Y. Murata, N. Hayashi, N. Akagi, H. Iwasa, C. Komatsu, M. Hamada, T. Yamagami;
Kochi Medical School Hospital, Kochi, JAPAN.

Aim/Introduction: Reduction of radiation exposure and maintaining patient safety are important issues for nursing staff carrying out PET/CT examinations. The objective of this retrospective study was to evaluate the effect of nurses rotating their duties on exposure to occupational radiation during PET/CT procedures. **Materials and Methods:** Three nurses performing PET/CT procedures in our institution from January 2016 to December 2017 were included in this retrospective study. A total of 3,907 continuous PET/CT examinations were performed by the conventional duty method in 2016, while 3,598 examinations were performed using an improved duty method in 2017. The improved duties for PET/CT were divided into the following three roles of the examination procedure: A) precautions related to the examination and guidelines of the facilities; B) securing the route of the blood vessel; and C) measurement of blood sugar level, operation of the automated injector, and escort of the patient to the waiting room. The 3 nurses rotated each role one after another in succession,

resulting in each nurse carrying out all 3 roles, 4-6 times every day. The dose of radiation exposure of each nurse was measured every day using a pocket dosimeter. **Results:** There was a small difference in examination numbers in the years before and after the improvement in duties. However, the dose of radiation exposure of each nurse was reduced significantly following the improvement in duties (mean 3.19±0.56 μSv/day in 2016 vs. 2.21±0.33μSv/day in 2017, p<0.001). **Conclusion:** Rotating duties by sequential role sharing in nurses results in a reduction in occupational radiation exposure during PET/CT procedures. **References:** None.

EP-0998

Radiation exposure of staff from PET/CT performed with ^{18}F-FDG

M. Zdraveska Kochovska, S. Nikolovski, Z. Filipovski;
JZU UI PET, Skopje, NORTH MACEDONIA.

Aim/Introduction: The PET CT facility and cyclotron unit was established in Skopje at the end of 2016. The institution has own production unit with cyclotron manufactured by General Electric Medical Systems and three fully equipped radio pharmacy laboratories. The aim of this study is to present radiation doses to whole body and extremities received by technologists, physicists and radio pharmacists working in production unit during ^{18}F-FDG preparing and dispensing and also technologists working in diagnostic part during administration of the doses and positioning the patients for PET/CT scan. **Materials and Methods:** During this period about 1800 patients has been performed for PET/CT scan and number is increasing every year. TLD model Panasonic UD-802AS was used to measure Hp (10) the whole-body radiation doses and UD-807 calibrated to measure the personal dose equivalent Hp (0,07) for extremities. TLD reader is Panasonic UD-705, calibrated with source Cs-137 has gamma energy range of 33 keV to 1,3 MeV and dose display range from 85 μSv to 200 mSv. **Results:** The results show that all involved staff received about (1,98±0,05) mSv for whole body dose. For the extremity dose the difference was found between radio pharmacists working in QC laboratory and other staff. Maximum registered value of effective dose for one year was registered to one of the technologist working in a QC lab and it was 14,39 mSv. The results were compared with dose limits proposed by International Commission on Radiation Protection (ICRP, 2007) for whole body 20 mSv and maximum skin dose limit for extremities 500 mSv. **Conclusion: :** Following the basic rules of radiation protection and having on mind the inverse-square law with increasing the distance between radiation source and personnel and reducing the time of activity, absorbed dose decreases substantially. The results show that the staff is working in safety environment and follow the rules about radiation protection. **References:** 1. International Commission on Radiological Protection. EP-0999

Uptake of I-131 to the thyroid of infant mice administered to mothers and substances affecting the uptake

T. Hongyo, Y. Sawai, Y. Ueda;
Osaka Univercity, Suita, JAPAN.

Aim/Introduction: Large doses of radioactive iodine in the nuclear accident etc. may cause thyroid dysfunction and thyroid cancer in children due to internal exposure. This is because radioactive iodine is specifically incorporated into the thyroid and the younger the age, the more sensitive it is. Since infants absorb nutrients only through mother's milk, it is important to examine the degree of uptake of radioactive iodine taken into the infant thyroid and the substances that affect its uptake. **Materials and Methods:** Besides stable iodine tablet (potassium-iodide, 2μg/g BW), we used two different types of iodine inclusion to examine their suppression effect of the I-131 uptake: dried seaweed (50μg/g BW) and diluted iodine gargle (30 times diluted (3.3%); The iodine content was 2.33μg/g BW). Each iodine inclusion was given to the ICR mothers of the newborn baby mice, through a feeding tube, and I-131 (74kBq/mouse) was given 6 hours after the iodine inclusions, and the thyroid uptake suppression-effect of I-131 through breast milk was examined. The 0, 1, 3, 5, 7, and 10-day-old infants were euthanized 24 hours later, and the suppression effect of the I-131 uptake by iodine inclusions were examined with use of gamma scintillation-counter. The percentage of I-131 taken into the thyroid per body weight was evaluated. Moreover, we searched for materials without iodine which can possibly be a substitute for stable iodine tablet when iodine inclusions cannot be used. **Results:** The thyroid uptake rate per weight of I-131 was the highest at 0 day of age. When the mother was given the iodine inclusions, thyroid uptake of I-131 of the baby was significantly suppressed. However, the younger the baby was, the weaker the degree of suppression was. In 0-day-old infants, dried seaweed was more effective than potassium-iodide in suppressing thyroid uptake. As a substance that does not contain iodine, potassium perchlorate (22.3μg/g BW) was shown to suppress the uptake of I-131, and administration of cow milk to the mother significantly increased thyroid uptake rate per weight of I-131 in the infants. **Conclusion:** In the case of 0-day-old infants, the thyroid uptake rate per body weight of I-131 is the highest, so it is considered that it is necessary to pay attention to the protection of radioactive iodine internal exposure particularly immediately after delivery and under such circumstances, it is better to ingest dried seaweed rather than potassium-iodide and mothers should refrain from cow milk intake. **References:** None.

EP-1000

A Useful Pump To Inject Lutathera®

C. Rouet, M. Chassel, C. Blambert, R. Gaston, M. Coutier, A. François Joubert;
Centre Hospitalier Métropole Savoie, Chambery, FRANCE.

Aim/Introduction: Lutathera® (Lutetium [^{177}Lu]-oxodotreotide) must be administered by slow intravenous infusion over 30 minutes. The recommended administration method is the gravity method [1], which is not very intuitive and requires the staff to stay near the patient during the procedure in order to monitor the flow of Lutathera®. We provide a new method of administration by using the Plum 360™ (ICU Medical) [2], an active pump, able to infuse drugs from a glass vial kept straight. **Materials and Methods:** The pump, provided with two infusion lines, was first connected to 500 mL saline in bag. This tube connected the IV bag to the pump and the pump to an empty IV bag (to simulate the patient). The second line was connected from the pump to a glass vial (used to simulate Lutathera®). This vial was kept upright, in a shielded vial. Some medical devices were tested to provide the best infusion conditions. The system was approved by simulation of ^{99m}Tc (6 vials : 200-400 MBq / 22 mL in each, before assays) and ^{177}Lu (1 vial : 3000 MBq / 22 mL) infusion in the empty IV bag. Activities of the vials were measured before and after assay, with and without flushing the vials with saline. A study of costs was also carried out. **Results:** The pump was connected to the vial by adding a male-male connector with at its end, a long needle inserted into the vial cap. The vial had to be kept at an angle in order to keep the needle in the bottom of the vial. An air intake in the vial was required to replace the vacuum created (needle with a 0,22 µm filter). No radioactive leaks and contaminations were noticed. Without flushing the vial, the amount of residual activity was on average 2.8 % (+/- 0.7 %, n=3) with ^{99m}Tc and 2.6 % with ^{177}Lu (n=1). By flushing the vial, the residual activity was brought down to 0.6 % (+/- 0.5 %, n=3). The pump is also equipped with alarms in case of occlusion or presence of air in the system. The pump costs less than 1400 € and disposable materials are around 5 € per patient. **Conclusion:** The Plum 360™ is a useful and cost-effective pump to infuse radiopharmaceutical in vials, especially Lutathera®. **References:** 1. Lutathera® Summary of product characteristics. 2018 2. Plum 360™. ICU Medical. 2017.

EP-1001

Assessment of Occupational Radiation Doses in Different Diagnostic and Interventional Radiology and Molecular Imaging Services

Y. Bouchareb[1], I. Al-Maskery[1], H. Al-Zeheimi[1], A. Al-Rasbi[1], N. Al-Makhmari[2], A. Al-Haji[2], H. Al-Dhuhli[2];
[1]Sultan Qaboos University, Muscat, OMAN, [2]Sultan Qaboos University Hospital, Muscat, OMAN.

Aim/Introduction: Personal radiation dose monitoring, assessment and records keeping is a legal requirement in ionising radiation regulations for radiation workers in the different diagnostic imaging and therapeutic occupational groups. The purpose of this study was to assess occupational radiation doses in different diagnostic, interventional and therapeutic radiology and molecular imaging services, aiming to reduce personnel radiation doses further. **Materials and Methods:** Personal radiation doses recorded over the last three years were collected (n=104) from our TLD dosimetry service. Personal radiation doses were monitored on a monthly basis. Five different occupational groups were considered: diagnostic radiology (conventional x-rays and computed tomography), interventional radiology, nuclear medicine technologists and radiographers, medical physicists and nurses. For the sake of an objective assessment, only effective whole body doses measured using TLDs during the full 36 months in each speciality, were included in this study. Average mean doses, maximum and cumulative doses per year in each occupational group were estimated and compared against maximum permissible doses and the local dose investigation levels, which consists of 6 mSv per year for each occupational group. **Results:** Personal radiation analysis performed for the five occupational groups over three years resulted in an average personnel radiation doses of 1.23 mSv for nuclear medicine, 0.6 mSv for both diagnostic and interventional radiology, 0.45 mSv for medical physicists, 0.5 mSv for nurses. Over the three years, maximum whole body doses received by the nuclear medicine, diagnostic radiology, interventional radiology, medical physicists and nurses personnel were 7.4 mSv, 0.9 mSv, 0.5 mSv, 1.4 mSV and 2.1 mSv, respectively. Similar trends of average and maximum whole body doses were observed on a year-to-year basis. The higher maximum whole body dose in the nuclear medicine occupational group is believed to be due to the significant increase of the number radionuclide therapy sessions in the last two years (30% increase in number of patients). **Conclusion:** Personnel radiation doses for all occupational groups are well below maximum permissible doses setup in the ICRP and IAEA safety standards and the dose investigation levels currently applicable for radiation workers at our institution. These findings suggest, at the exception of nuclear medicine staff for whom the dose investigation level should be adjusted, lower dose investigation level for all other occupation groups without compromising the quality of service offered to patients. **References:** None.

EP-1002

The Quantitative Analysis of Uranium Isotopes in the Urine of an Ammunition Clean-up Worker deployed on Dutch North Sea Islands

F. Klimaschewski;
Uranium Medical Research Institute, London, UK, UNITED KINGDOM.

Aim/Introduction: Military target practice training sites on the Dutch Islands Vlieland and Terschelling in the North Sea include the use of uranium weapons. Civilians are employed

on those islands to collect projectiles, debris and remove tank wrecks. **Materials and Methods:** One subject involved in the clean-up reported severe multiple health problems (i.e. general weakness, problems with lung function and blood cells/leukemia) as a consequence of only two weeks of work on the testing sites. 24-hour urine analysis with ICP-MS was performed by Jülich laboratory four years after exposure to determine the concentration and precise isotopic composition of three uranium isotopes (^{234}U, ^{235}U, ^{238}U) in the urine specimen. **Results:** The analysis measured a ^{234}U concentration of 5.6E-04 ng/l (1.3E-4 Bq/l) and a ^{238}U concentration of 1.13E+01 ng/l (1.4E-4 Bq/l).) The ^{238}U/^{234}U ratio was 17 417, normally indicative of natural uranium. ^{235}U reported as non-detectable indicates a rather unusual result inconsistent with other population studies. **Conclusion:** The total uranium concentration measured in the urine of the subject years after exposure is below the mean concentration of uranium urine excretion in Germany (approx. 21.5 ng/d). However, this does not rule out the possibility of initial contamination of the lung with uranium from weapon systems at time zero that exceed permitted levels since uranium might have been metabolized several years after inhalation. Further research, especially into the environmental contamination, is warranted. **References:** None.

Development of a M4 PAM PET radioligand - [^{11}C]PF-06885190 - for a study in nonhuman primates

S. Nag[1], *R. Arakawa*[1], *K. Maresca*[2], *C. Butler*[2], *L. Chen*[2], *Z. Jia*[1], *E. Lachapelle*[2], *M. Jahan*[1], *T. McCarthy*[2], *L. Zhang*[2], *C. Halldin*[1]; [1]*Karolinska Institutet, Stockholm, SWEDEN,* [2]*Pfizer Inc, Cambridge, MA, UNITED STATES OF AMERICA.*

Aim/Introduction: Muscarinic acetylcholine M4 receptor functions as inhibitory auto-receptors for acetylcholine, and its activation inhibits acetylcholine release in the striatum. It is reported that within the striatum M4 receptor activation acts antagonistically with dopamine D_1-like receptors and indicate that M_4 receptors may be a potential target for the treatment of Parkinson's disease and other relevant central nervous system disorders. PF-06885190 has been identified and evaluated by Pfizer as a novel M4-selective PET ligand candidate with high affinity (human binding Ki = 0.16 nM, rat binding Ki = 7.15 nM) and selectivity. In this study, our aims were a) to radio-label PF06885190 with C-11 b) to evaluate the brain distribution of [^{11}C] PF06885190 as a PET radioligand for M4 in nonhuman primate (NHP) and assess whether the brain uptake of [^{11}C]PF06885190 can be blocked by a selective M4 PAM compound PF06852231 and c) to analyze radiometabolites in blood plasma of NHP. **Materials and Methods:** Precursor PF06898527 and reference standard PF-06885190, were synthesized in multi-step syntheses. Radiolabeling of [^{11}C]PF06885190 was performed in two steps via N-methylation of the precursor, PF06898527, followed by deprotection using HCl (0.5 N, 200 µL). Two PET measurements were performed using a male cynomolgus monkey, one at baseline and another after pretreatment with a selective M4 PAM compound PF06852231. The V_T of [^{11}C]PF06885190 was examined using Logan graphical analysis with arterial input function. Radiometabolites were analyzed in monkey blood plasma using gradient HPLC system. **Results:** Radiolabeling of [^{11}C]PF06885190 was accomplished successfully with moderate radiochemical yield and high radiochemical purity which was above 99%. Molar activity was 312 ± 128 GBq/µmol at the time of administration. The radioligand were found to be stable in the formulation with radiochemical purity exceeding 99% after 1h of end of the synthesis. In vivo, the whole brain uptake of [^{11}C] PF06885190 in NHPs was 4.1 SUV at the peak of the baseline condition. However, it showed fast wash-out as it dropped to half of the peak at around 10 minutes. The percent change of V_T from baseline was approximately -10% after pretreatment of a M4 PAM, PF06852231. Radiometabolite studies showed relatively fast metabolism, but still demonstrated that 17-20% of [^{11}C]PF06885190 remain unchanged in blood plasma at 90 min post-injection. **Conclusion:** Radiolabeling of [^{11}C]PF06885190 was performed successfully. Although sufficient brain uptake of [^{11}C]PF06885190 was observed, these data suggest that [^{11}C] PF06885190 might have low specific binding in the NHP brain. **References:** None.

TEPS-02

An efficient method for the labeling procedure of ^{68}Ga-PSMA and ^{68}Ga-DOTA-TATE

E. Poel, M. F. Lam, Y. Chahid;
Amsterdam UMC, location AMC, Amsterdam, NETHERLANDS.

Aim/Introduction: The increase in clinical use of ^{68}Ga-PSMA PET-CT and ^{68}Ga-DOTA-TATE PET-CT results in more commercially available labeling procedures of those peptides. The aim of this study was to obtain an easy method for ^{68}Ga-PSMA and ^{68}Ga-DOTA-TATE productions. Without the use of a labeling module and when commercial kits are not available. **Materials and Methods:** 1.1 ml ^{68}Ga solution in 0.1 M HCl was generated using a $Ti0_2$ based ^{68}Ge /^{68}Ga generator (Galli Eo, IRE ELit, Belgium). The sodium acetate buffer was made from European Pharmacopoeia (Ph. Eur.) sodium acetate buffer solution (Fischer Chemical, United Kingdom) and NaCl 0.9%. In case of ^{68}Ga-PSMA: 30 µg PSMA-11 (ABX, Germany) was solved in different buffer solutions, added to the 1.1 ml ^{68}Ga-solution and reacted for 5 minutes at room temperature. In case of ^{68}Ga- DOTA-TATE: 50 µg DOTA-TATE(ABX, Germany) was solved in different buffer solutions, added to the 1.1ml

^{68}Ga-solution and heated at 95°C for 7 minutes. Radiolabeling efficiency was obtained using a radio high-performance liquid chromatography (radio-HPLC) and thin-layer chromatography (TLC). **Results:** A radiolabeling efficiency >99% was obtained for both peptides using different dilutions of the Ph. Eur. buffer. In case of ^{68}Ga-DOTA-TATE the optimal buffer was obtained by diluting 5.0 ml of Ph. Eur. buffer with 95 ml NaCl 0.9%. The use of 3.0 ml of this buffer solution in the labeling procedure of ^{68}Ga-DOTA-TATE resulted in the highest radiolabeling efficiency (>99%). In case of ^{68}Ga-PSMA the optimal buffer was obtained by diluting 25 ml of Ph. Eur. buffer with 75 ml NaCl 0.9%. The use of 2.0 ml of this buffer in the labeling procedure of ^{68}Ga-PSMA resulted in the highest radiolabeling efficiency (>99%). **Conclusion:** An efficient method, without the use of a labeling module, for the labeling of ^{68}Ga-PSMA and ^{68}Ga-DOTA-TATE was obtained from the peptides and an easy made buffer solution. **References:** None.

TEPS-03

Quality assurance audit of in-house prepared 68Ga labelled radiopharmaceuticals: 5 years of institutional experience

***B. S. Shetye**, P. Monteiro, M. Pathan, S. Mithun, A. Jha, V. Rangarajan;*
Tata Memorial Hospital, Mumbai, INDIA.

Aim/Introduction: The progressive development of 68Ge/68Ga generator system, compatible gallium radiochemistry, ease of synthesis methods emerged with a new era of in-house labeled PET radiopharmaceuticals. The automated synthesis method is error free but expensive. Proper implementation of necessary measures before and during the procedure turns manual synthesis into reliable and cost-effective option. Hence, we assessed the performance of 68Ge/68Ga generators (n=9), labeling efficiency, quality control parameters of 68Ga-DOTANOC and 68Ga-PSMA prepared by manual synthesis. **Materials and Methods:** Total 1230 (DOTANOC n = 415, PSMA n= 815) synthesis were performed using nine ITG 68Ge/68Ga generators (30 mCi n= 7, 50 mCi n= 2). Rinsing was done using 5 ml of 0.05N HCl (n=100) 25µg of DOTANOC and 5µg of HBED-CC-PSMA in 0.025M sodium acetate buffer was used for labelling. It was done manually using IQs 68Ga fluidic module following standard procedure using 0.05N HCl as eluant. PSMA synthesis was done using GMP certified PSMA labelling kit. All reagents were prepared using Millipore water. Contamination of the stock solution was prevented by discarding leftover solutions. Cartridge and Millipore filter were conditioned just before the beginning of synthesis. The proper temperature was maintained throughout the synthesis. Delivery of 68Ga in a reaction vessel and loading of product over the cartridge were ensured by measuring the surface dose rate over a reactor and cartridge. RCP was measured by ITLC method using 0.1M sodium citrate. Labelling efficiency and stability of the product, radionuclidic purity were assessed. **Results:** Elution yield was 70 to 75%. Low yield between 25 to 56 % was reported for DOTANOC (n=75) and PSMA (n= 29). It got corrected by preparing reagents after every 15 days. Labelling efficiency for DOTANOC was 80 % (n= 350, STDEV = 0.004, pH= 5.5) and PSMA 84 % (n=786, STDEV=0.003, pH= 5.5). RCP of DOTANOC was > 97% and PSMA was > 99%. Radiochemical stability of product was studied up to 4 hrs. It was >94%. Product was measured after 36 hrs to rule out 68Ge breakthrough. No activity was observed in it. **Conclusion:** Our data showed reliable RCP results and consistent labeling efficiency by following proper measures as indicated above. Manual synthesis permits the use of a generator more cost-effectively and as per our own requirement. **References:** None.

TEPS-04

A High Yield Automated Synthesis Of ^{18}F-FLT On PET-MF-2V-IT-I Module With SPE Purification

***W. Hongyong**, P. Zou, M. Xie, Y. Liu, J. Wu, H. Wu;*
Jiangsu Institute of Nuclear Medicine, Wuxi, Jiangsu, CHINA.

Aim/Introduction: 3'-deoxy-3'-18F-fluorothymidine (^{18}F-FLT) is a thymine analog that is currently recognized as the best indicator of growth in assessing the proliferation of tumors and normal tissues. In one of these applications, this utility has been demonstrated in a variety of tumor models, such as lung cancer, colorectal cancer, and lymphoma. The synthesis of ^{18}F-FLT was automatically optimized by a solid phase extraction column (SPE) purification using a PET-MF-2V-IT-I synthesizer (PET-MODULE Technology Co., Ltd, Beijing). **Materials and Methods:** ^{18}F ion (352MBq) was adsorbed to the QMA column, and the K2.2.2/K_2CO_3 solution was rinsed. Under the nitrogen condition, the eluent was heated under acetonitrile at 120 ° C for 5 minutes, dried, and then 3-N-Boc-5'-O-dimethoxytrityl-3'-O-nosyl-thymidine(N-BOC-FLT) was dissolved. Acetonitrile was added to the reaction mixture, and heated at 100 ° C for 10 min; then hydrochloric acid (1 M) was added, and hydrolysis was carried out at 105 ° C for 5 minutes, the solution was neutralized with sodium hydroxide (1 M). Then, the resulting mixture removes excess fluoride ions through the aluminum column. The reaction mixture was washed with 20 ml of water and purified by C18 column, solid phase silica gel column, CM solid phase column or PS-2 solid phase column through ethanol. Finally, after aseptic filtration, ^{18}F-FLT was obtained. **Results:** The synthesized ^{18}F-FLT was purified by SPE using a domestic PET-MF-2V-IT-I synthera synthesizer. The precursor N-BOC-FLT requires 10 mg compared to other literature reports. In this reaction, although the precursor N-BOC-FLT used only 5 mg, ^{18}F-FLT was synthesized in a high yield, and the by-products were few. The synthesis method tested four SPE columns (C18, CM, Silica, PS-2) to purify ^{18}F-FLT. The yields of the automatically synthesized ^{18}F-FLT were 21%, 36%, 13% and 16% (EOS), respectively. Radiochemical purity ≥ 98%. The total reaction time using the SPE column is about 25 minutes and does not require HPLC for purification. From the results, the purification method using CM solid phase column is the most effective. **Conclusion:** We have developed a high-volume method for automated synthesis of ^{18}F-FLT. ^{18}F-FLT was synthesized automatically by means of a domestic PET-MF-

2V-IT-I module, a small number of precursors and SPE column purification method. **References:** None.

TEPS-05

Outstanding cleaning method for the reliability of the automated synthesis module with non-cassette type

H. Park, J. Kim, H. An, H. Lee, G. Lee, B. Lee, W. Lee, S. Kim;
Seoul National University Bundang hospital, Seongnam-si, Gyeonggi-do, KOREA, REPUBLIC OF.

Aim/Introduction: A commercialized available automated module (e.g., TracerLab FX_{FN} made by GE Healthcare) is used for easy and efficient production of ^{18}F-labeled radiopharmaceuticals. In case of non-cassette type module, the cleaning step is vitally required for maintaining yields of radiotracer after completing radiolabeling including acid or base treatment. Herein we present an efficient cleaning know-how acceptable in the TracerLab FX_{FN} platform to avoid unexpected production failures. **Materials and Methods:** After [^{18}F]FET production, the used 2N HCl and sodium acetate buffer in the deprotection occurred the serious contamination of parts in the module and then caused the decreasing the yield or generated the failure in the next production. The optimized cleaning procedure is performed as follows: i) All used reagent vials (No. 1-6) and reactor are rinsed by 2 mL distilled water (DW); ii) The reactor and O-ring are disassembled from the module, followed by sonication in acetone for 20 min; iii) After equipping to the module, the reactor except O-ring added 10 mL acetonitrile (ACN) and heated at 100 ºC for 5 min; iv) After cooling, the reactor including O-ring is heated at 100 ºC for 5 min again in the condition of lowered the reactor needle and opened two-way valve and reagent vials. At this time the distilled ACN efficiently cleanses all tubings as well as valves connected on the reactor; v) Finally, the reactor and reagent vials are rinsed with 2 mL ACN and 2 mL DW, respectively, followed by drying with the help of acetone and N_2 gas. Other formulation parts cleansed through the recommended method in the manual. **Results:** While the previous radiochemical yield (RCY) of [^{18}F] FET recorded in 20 ± 15% with a failure rate of 10% (n = 20), new cleaning method enhanced significantly RCY of [^{18}F]FET (35 ± 5%) with no production failure (n = 50). The prepared [^{18}F] FET satisfied all quality control test standards for clinical uses. **Conclusion:** The automated radiosynthesis equipped with new cleaning method provides high and reproducible yields of [^{18}F] FET suitable for routine clinical use. **References:** None.

TEPS-06

Determination of Aluminum in Pertechnetate and Perrhenate Solution in eluate of ^{99}Mo / ^{99m}Tc and ^{188}W/^{188}Re Generator

M. Karamivand[1], *F. Farajbakhshmamaghani*[2], *M. Davarpanah*[2];
[1]*Pars Isotope Co, Tehran, IRAN, ISLAMIC REPUBLIC OF,*
[2]*Pars Isotope, Tehran, IRAN, ISLAMIC REPUBLIC OF.*

Aim/Introduction: The ALUM-PARS kit provides a rapid, easy and inexpensive way to test aqueous solutions, particularly pertechnetate generator eluate, for trace quantities of aluminum. The United States Pharmacopeia 38-NF33 allows a concentration of aluminum ion in an injection ≤ 10 micrograms per milliliter (10 µg/ml) in technetium 99m eluate. **Materials and Methods:** This kit content chromazurol S, citric acid-sodium citrate buffer and saline 0.9% and was optimization parameters by spectrophotometry method. Freeze-dried ALUM-PARS kit by removing the water from the material and sealing it in a vial, the material can be easily stored, shipped, and later reconstituted to its original form for injection. Added 1 mL of pertechnetate eluate of ^{99}Mo / ^{99m}Tc or ^{188}W/^{188}Re generator to lyophilized ALUM-PARS kit and compared the intensity reference color. Also results of the analysis aluminum ion solution in eluate of ^{99}Mo / ^{99m}Tc and ^{188}W/^{188}Re generator by proposed procedure were found to be in excellent agreement with those obtained by atomic absorption spectrophotometric method. **Results:** Amount aluminum in pertechnetate solution eluate of ^{99}Mo / ^{99m}Tc and ^{188}W/^{188}Re generator determinate, hence was color change ALUM-PARS kit from yellow to violet (0 µg/ml to 40 µg/ml aluminum). **Conclusion:** Aluminum complex formation with ALUM-PARS kit, the intensity of the color is directly proportional to the amount of aluminum in the solution and this method is quick and easy application for Semi-quantitative determination of aluminum in Pertechnetate and Perrhenate Solution eluate of ^{99}Mo / ^{99m}Tc and ^{188}W/^{188}Re Generator. **References:** None.

TEPS-07

The "Radiopharmacy of errors": a serious game to strenghten quality

T. Martin, C. Maurel, N. Sapin, I. Benard-Thiery;
Radiopharmacy department, Centre Antoine Lacassagne, Nice, FRANCE.

Aim/Introduction: Manufacturing of radiopharmaceuticals must comply with certain quality standards and strict rules of radiation protection. Deviations from good practices and procedures are sometimes observed in current radiopharmacy practice. Therefore operator training has to be developed. Simulation is a source of innovative pedagogical developments in health care. The use of a "room of errors" constitutes a useful learning tool to reinforce the radiopharmacy technician skills and knowledge. **Materials and Methods:** Four radiopharmacy technicians took part in real-life situations characterized by a defined number of errors. Those were set up according to the internal procedures and the risk mapping of the radiopharmacy department. Two still scenes representing the daily work in a PET-lab and a SPECT-lab were created. In each scene, several mistakes could be found concerning hygiene, preparation and dispensation of the radiopharmaceuticals, quality control of the preparations, radiation protection, and transport of radioactive packages. In addition, a moving scene was played out, consisting in the preparation of a radiopharmaceutical in the SPECT-lab. In this scene, technicians had to find manipulation

errors. The radiopharmacy technicians had to report every error they could find. A debriefing was carried out to discuss and explain each situation afterwards. **Results:** In the PET-lab the radiopharmacy technicians found 58% (mean=7.5/13) of the errors. None of them detected the prescription error or knew the rules to indicate a radioactive contamination on the floor. 73% (mean=11/15) of the errors were discovered in the SPECT-lab. For example, technicians did not notice the low pressure of the shielded enclosure or the wrong batch number of an Iodine-131 capsule. During the moving scene 67% (mean=8.5/12) of the manipulation errors were detected. **Conclusion:** This work evaluated the potential benefits of creating a "room of errors" in a high risk process such as the radiopharmacy practice. This process represented an effective way to provide an update concerning good practices and a reminder concerning critical endpoints. The impact over the long term has yet to be evaluated. Nevertheless, direct purposeful experiences close to reality are the best way to learn and retain. The development of the "Radiopharmacy of errors" in other departments could be introduced to train technicians and evaluate practices. **References:** None.

TEPS-08

Quality Improvement of Patient Safety and Images through Analysis and Compliance with Standard Operating Procedures in ^{18}F-FDG PET/CT scan

S. Yoon, J. Ryu;
Asan Medical Center, Seoul, KOREA, REPUBLIC OF.

Aim/Introduction: This study aimed to improve patient safety culture and image quality through improvement activities such as analysis and compliance with standard operating procedures (SOPs). Asan Medical Center implemented standards of the international guidelines by establishing SOPs to ensure the accuracy and reliability of ^{18}F-FDG PET/CT scans. **Materials and Methods:** Patients who received ^{18}F-FDG PET/CT scan at Asan Medical Center from January 2014 to October 2015 before and after improvement activities were compared with respect to dose and uptake time of ^{18}F-FDG. Several causal factors, such as technologists, time zones, PET/CT equipment, and patient age and height were analyzed to find decisive fundamental factors to solve problems. Dose compliance rate and uptake time were measured. **Results:** Compliance rate for dose was 97.48%, an improvement of 7.31% compared to that before improvement activity. Deviation between actual and reference dose was 4.18%, 1.08% less than that before improvement activity. Over-dosing was 0.47%, 3.39% less than that before improvement activity. Average uptake time was 60 ± 2.10 min, 3.22 min less than that before improvement activity. **Conclusion:** The role and responsibility of the radiological technologist is to examine the proper dose and precise uptake time of ^{18}F-FDG in compliance with SOPs within the acceptable range and to constantly analyze performance to reduce deviations. This should be applied to quality management of the entire nuclear medicine examination and the PET/CT scan, and a series of efforts like this could eventually improve the patient safety culture and quality of examination. **References:** None.

TEPS-09

Appreciation of patients' feeling about the environment of a new digital PET-CT room

M. Pappon, P. Genoud, M. Meyer, J. Prior;
CHUV, Lausanne, SWITZERLAND.

Aim/Introduction: Since 20 years, advances in PET technology have been significant, with important benefits for the patients in term of diagnosis performances, but also patients' comfort. Many factors have been identified as affecting patients' experience of PET/CT: scan time, environmental temperature, discomfort in the waiting area, interactions with staff, pain and discomfort during the scan, symptoms of claustrophobia or duration of waiting time.The aim of our study was to compare patients' experience of PET/CT with our 2 PET/CT devices: a conventional PET/CT (GE Discovery 690, installed 2011), and a latest-generation digital PET/CT (Siemens Vision 600, installed 2018). **Materials and Methods:** Data were collected during 1 week in 51 consecutive patients for each PET/CT room. The patients filled one self-report questionnaire directly after the PET/CT imaging. The questionnaire comprised questions related to 5 different parts: room, table comfort, examination time, scanner and NM technologist help with 2-5 questions for each part. A four-point Likert scale was used for the response. **Results:** Concerning the PET/CT room, less patients were cold (score 1 or 2) with the water-cooled digital PET/CT as compared to conventional air-cooled PET/CT (19.6% vs 64.7%, p<0.001). Concerning the PET/CT comfort, more patients found the table comfortable (score 4) in digital PET/CT as compared conventional PET/CT (65% vs 43%, p=0.050). Moreover, contention material seemed better adapted (score 4) in digital PET/CT as compared conventional PET/CT (77% vs 61%, p=0.088).Concerning scanner duration time, there was no difference among group; however, more patients found that they did wait only shortly after the PET/CT acquisition (score 3 or 4) in the digital PET/CT as compared to conventional PET/CT, due to quicker image reconstruction time (86% vs 69%, p=0.034).Concerning the PET/CT camera, less patients found that ring diameter was too small (score 1) and so very stressful in the digital PET/CT as compared to conventional PET/CT (0% vs 10%, p=0.042).Concerning the technologists' help, there was no differences between scanners. **Conclusion:** Our study highlights that patient experience of PET/CT is heterogeneous, but in most cases, patients are satisfied or very satisfied. We found that room conditions, materials and organization of the examination of our latest-generation digital PET/CT are better adapted to optimize patient's comfort and reduce the examination stress. **References:** None.

TEPS-10

One instruction for all-managing pediatric protocols across departments

H. Søgaard, R. N. H. B. Christensen;
Aarhus University Hospital, Aarhus N, DENMARK.

Aim/Introduction: Children diagnosed with cancer are treated with chemotherapy. Due to the kidney toxicity of these drugs, they are examined with a GFR (glomerular filtration rate) test, as a part of their treatment protocol. The examination takes part at the Department of Pediatrics and Adolescent Medicine, and is performed as a collaboration between a nurse and a technologist from the Department of Nuclear Medicine. When attending these examinations, we observed that the procedure was different due to the individual nurse. The aim of this work is to provide the nurses with a valid protocol that is easily accessible and in detail describes how to perform the GFR test correctly. In addition, the protocol describes the procedures performed by the technologists. **Materials and Methods:** In 2018, 56 cancer diagnosed children were examined with a GFR test. A tracer of 20 MBq Tc99m-DTPA or 2 MBq Cr51-EDTA were injected and 5 blood samples were drawn at set times, within 2 hours from the injection. The children all had a central venous catheter (CVC), a central line catheter (PICC-line) or implantable port for tracer injection and blood sample drawing. The nurse handled the CVC. Tracer injection was always supervised by the technologist. The protocol was prepared in cooperation with a nurse specialist, and safe handling of the CVC, dead space and level of information, were all taken into consideration to obtain the right protocol beneficial for both the nurses and technologists. **Results:** Having one joint protocol we have observed that all the examinations are performed in a uniform way, regardless of which nurse is drawing the blood samples. The frequency of corrective actions and the risk of unsuccessful examinations are reduced. Due to the protocol there is no longer frustration or uncertainty in the team of nurses on how to perform the examination. Nor for the technologists, as the full procedure now is described in an approved document. **Conclusion:** It is now possible for nurses and technologists easily to find the applicable protocol in the hospital documentation files. Following this protocol, the examination is performed in a uniform way regardless of which nurse is performing the test. In the Department of Nuclear Medicine, we know with much more certainty that the blood samples received meets the requirements of the examination. **References:** None.

TEPS-11

Cost Saving of PET/CT and Contrast Enhanced CT in Lymphoma Patients

C. Vazzana, R. Sanco, M. Trevisan, F. Lincetto, A. Biscotto, L. Evangelista;
Istituto Oncologico Veneto IRCCS, Padova, ITALY.

Aim/Introduction: In modern oncology, combined imaging based on PET/CT plays a central role in the diagnosis, staging and post-treatment follow-up of patients with neoplastic disease. The possibility of performing TNM staging with a single examination PET/CT and contrast enhanced (ce)CT, provides a full diagnosis immediately and reduces the time required for the patient to undergo separate diagnostic examinations. The aim of our study was to analyse the impact of medical and nonmedical costs of PET/CT with simultaneous ceCT, in a cohort of patients with lymphoma. **Materials and Methods:** From October to November 2018, a total of 32 patients with Hodgkin and non-Hodgkin lymphoma referred to our institute was administered a questionnaire to evaluate the nonmedical costs of fluorodeoxyglucose (FDG) PET/CT. The questions elicited current working status at the time of the questionnaire, the type of work done, the distance from home to the institute, and the means of transport used. In the case of private transport, they were asked to provide the type of vehicle. Moreover, to evaluate the costs of informal care, they were asked to indicate whether someone accompanied them to the institute and the type of work done by the person. In addition, the medical costs related to PET/CT performed with ceCT, PET/CT with low-dose nonenhanced CT and separate ceCT were also recovered. The analysis of costs for PET/CT, and ceCT separately, and the hypothetical PET/ceCT costs were estimated. **Results:** The costs for ceCT, PET/CT, PET/ceCT in all patients, were 7767,68 euro, 21982,08 euro and 26177,92 euro, respectively. The expense for all 32 patients was 2387,62 comprising the working day, transport, and caregiver. The medical costs were 929,68 euro for PET/CT with separate ceCT, and 816,06 euro for PET/ceCT in a single session. Therefore, the economic recovery for each patient was equal to 12% . However, in our study population, the cost saving was equal to 17% , because the reduction of the number of hospital visits required by patients undergoing diagnostic imaging can improve the global costs. **Conclusion:** Our results show that FDG PET/CT performed with standard dose ceCT in a single session, in patients with lymphoma, provides benefits in terms of both medical and nonmedical costs **References:** Role and Cost Effectiveness of PET/CT in Management of Patients with Cancer Muhammad Wasif Saif,a,* Ifigenia Tzannou, Nektaria Makrilia, and Kostas Syrigosa.

TEPS-12

Managing patients and working spaces during facilities upgrade: a single-center experience

M. Maccagnani[1], D. Pedrini[2], A. Farina[1], A. Lambertini[1], S. Fanti[1], S. Barbieri[3];
[1]Nuclear Medicine Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, [2]Tecnical Department, Sant'Orsola-Malpighi Hospital, University of Bologna, Bologna, ITALY, [3]Department anesthesia Intensive Care, University of Padova, Padova, ITALY.

Aim/Introduction: Due to a recent structural upgrade to the working spaces of our PET-Centre within the department of Nuclear Medicine (Sant'Orsola-Malpighi-University-Hospital,

Bologna, Italy), we investigated potentially beneficial changes to patient management, clinical flow and radiotracer delivery, taking place in parallel with active renovation works. We aimed at drafting a set of guidelines to help managing future scenarios involving periodically occurring renovations in a setting of continued clinical activities. **Materials and Methods:** A preliminary inspection of the planned working sites within the ward was performed by the technologist team, in order to establish clear boundaries and border areas of the active renovation sites. The size of the patient population needing access to the ward (as well as that of the active medical and tech staff) within the planned time-frame of activities was estimated. All procedural alterations were discussed in a series of meeting with all the involved members of the medical management, medical physics and tech teams. Buffer and dedicated treatment zones were planned to guarantee proper care to patients with special needs, while capacity and location of public spaces were planned in accordance to current legislation (0.4pts/mt² within 40 meters of viable emergency exits). In addition, we also considered radiation exposure due to sharing waiting spaces with our conventional nuclear medicine ward (mixing of patients injected with different radionuclides). Temporary re-location of patients from the immediate vicinity of the active sites to our conventional nuclear medicine ward was initiated, without significantly modifying the timing of tracer delivery and image acquisition. The least flow-disruptive options were selected after a final consultation. Modifications to current hospital guidelines were drafted accordingly into a special directive. **Results:** Structural renovations within our PET-Centre took place between July 30th 2018 and progressed for the next 7 weeks. All changes to the usual clinical activities were implemented in accordance with the newly developed guidelines. No unexpected disruptions to the clinical flow occurred and no complaints were reported by either patients or health professionals up to the end of renovation works. **Conclusion:** Our single-centre study resulted in the drafting of a set of guidelines which allowed for a successful continuation of all clinical activities within our nuclear medicine department in parallel with major building renovations and tech upgrades. Those healthcare institutions facing periodical renovations, and especially high-volume imaging centers may also consider its adoption to minimize down-time and thus guaranteeing acceptable waiting times for patients. **References:** None.

TEPS-13

Discovery, A New Zealand Nuclear Medicine Department voyage that has made a real difference

P. E. Lamerton;
Hawkes Bay District Health Board, Hastings, NEW ZEALAND.

Aim/Introduction: This presentation will cover the change in work processes and management for staff and patients following the installation of the GE Discovery 650 NM/CT highlighting the benefits for a regional hospital. **Materials and Methods:** Hawkes Bay Memorial Fallen Soldiers Hospital is the only public hospital in Hawkes Bay region of New Zealand. Located on the east coast of the North Island it has a current population of 166,000. The radiology department has a main CT as well as the NM/CT providing a SPECT/CT service to this area with no PET/CT. The Nuclear Medicine department offers a wide range of scans maintaining considerable growth in numbers and variety of scans over the past 10 years. The business case for installation of the Discovery 650 NM/CT in late 2013 focused on having the CT as a backup CT scanner. It soon became apparent that this was only one of the many benefits following its installation such as helping the hospital to keep within the government fast track cancer targets. **Results:** Key changes were implemented which included NM technologists undertaking diagnostic CT training to extend their scope of practice, allocation of a dedicated CT session weekly, allocation of a CT member to work on the hybrid CT, modifying booking templates and creating an adaptive NM and CT team. **Conclusion:** In conclusion the results have been very positive for the management of the radiology department as a whole including NM and CT staff interaction and most beneficial for the patients as we now have one visit for the Nuclear Medicine scan and staging CT. For the patient this means one IV line for the visit and one point of contact which is less demanding and eases their journey through Nuclear Medicine. We have adapted our Nuclear Medicine service to meet growing demands in both modalities under severe economic restraints that control our NZ Public Health Hospitals. **References:** None.

Tracer extravasation in PET/CT: could we predict it?

M. Trevisan*, A. Biscotto, F. Lincetto, M. De Rossi, F. Ruffo, P. Reccia, A. Cervino, M. Burei, L. Cuppari, A. Carraro, L. Evangelista;*
Nuclear Medicine Unit, Veneto Institute of Oncology IOV - IRCCS, Padua, ITALY.

Aim/Introduction: Primary end-point of the present study was to evaluate the incidence of tracer extravasation in a large cohort of patients undergoing PET/CT or PET/contrast enhanced (ce) CT examinations for oncological requests. Secondary end-point was to assess if the correction of the routine procedures can reduce the tracer extravasation rate. **Materials and Methods:** Data from 1100 patients undergoing PET/CT exams were prospectivelycollected. Patients were affected by oncological disease (i.e. lymphoma in 19.3%, breast cancer in 15.5%, colon-rectal cancer in 5.3%, lung cancer in 14%, prostate cancer in 11.5% and other in 34.5% of cases).The majority of patients underwent 18F-FDG PET/CT or PET/ceCT (n=995; 86.8%). The following iinformation were recovered: age of patients, size of cannula (in gauge), injection site, the intensity of extravasation (low, moderate and severe), prediction of extravasation before PET/CT acquisition andeffects of extravasation on the semiquantitative evaluation in terms of standardized uptake value (SUV). **Results:** Median age was 67 years (range: 12-93 years). PET/CT was performed in 1075 patients (98%),while PET/ceCT in only 25 cases. The tracer extravasation was reported in

63 (5.7%) patients. It was defined as low in 25, moderate in 21 and intense in 17 subjects (39.7%, 33.3% and 30%, respectively). The presence of a tracer extravasation was predicted in 44.4% of cases; therefore 61% of patients performed a PET/CT examination with their arms raised above the head. SUV was considered as measurable in 64% of cases.Furthermore, a 25/27 gauge cannula and the antecubital venous access were correlated with tracer extravasation in 40% and 63% of patients, respectively. **Conclusion:** The rate of extravasation is low in a large cohort of patients, being inferior to 6%. However it can be further reduced by including specific procedures, in example the choice of cannula size and the injection site. **References:** None.

TEPS-15

Lutetium (177Lu) Oxodotreotide Therapy - Increasing Capacity and Demand

E. Seal;
University Hospital Birmingham, Birmingham, UNITED KINGDOM.

Aim/Introduction: On 29th August 2018 the National Institute for Health and Care Excellence (NICE) published guidance stating that Lutetium (177Lu) oxodotreotide (Lutathera) was now a recommended treatment option for neuroendocrine tumours. This meant that funding was now available to certain NHS patients which fitted the specific criteria set out in the NICE Guidelines. A departmental review of capacity and demand was carried out to determine the maximum number of patients that could be treated every year and what resources would be required to achieve maximum capacity. **Materials and Methods:** In previous years funding was limited to mainly private patients and patients taking part in clinical trials so the highest number of Lutathera treatments performed in one year was 37. Once the guidance from NICE had been issued and funding approved the Neuroendocrine Tumour team estimated there would be roughly 25 patients eligible every year for treatment, this would equate to 100 Lutathera treatments each year. With this being almost 3 times more Lutathera treatments than before several factors were taken into consideration to decide when the department would be able to manage with the demand: 1) There would be increased pressure on the gamma cameras due to more imaging slots being needed to image the patients after their treatment 2) Extra staff would need to be employed in order to run the service smoothly and efficiently 3) Staff doses have to be estimated to ensure suitable radiation protection could be provided and utilized 4) The rooms used for in-patient treatment are only free at certain times so calculations to work out how many nights are free a week would be done 5) Could Lutathera be administered as an out-patient, how would this work and what set-up costs would there be? 6) A national tariff had been applied to the procedure, was the funding enough to be able to supply the service to a standard the department were happy with? **Results:** All of these issues were discussed a plan was put into place. There were new staff hired, new protocols written and schedules created to allow for the 100 Lutathera treatments a year. **Conclusion:** This study aims to show how the service was changed in order to facilitate such an increase in demand for Lutathera treatment and what provisions were made to support the service. **References:** None.

TEPS-16

Estimate of thyroid volume aimed at radiometabolic treatment of hyperthyroidism

R. Russo, *L. Tommasi, E. Pomposelli, H. Rouhanifar, R. Piva, O. Gandini, M. Muratori, D. Maranzana, H. Belloni, G. Cuccu, D. Valentini, A. Muni;*
SS.Antonio Biagio e Cesare Arrigo hospital, Alessandria, ITALY.

Aim/Introduction: In the calculation of tailored dose for radiometabolic treatment of hyperthyroidism, an essential parameter is the estimate of the total thyroid volume or of the hyper-functioning nodule volume. In the daily routine the ultrasound (US) is the golden standard in the calculation of this crucial parameter. However evidences from the literature show that nuclear medicine techniques such as NaI-131 and ^{99m}Tc scintigraphy have the advantage of directly estimate the hyper-functioning glandular volume. Thus the aim of our study is to compare US, NaI-131 and ^{99m}Tc scintigraphy in the calculation of thyroid volume. **Materials and Methods:** We enrolled 10 patients with hyperthyroidism (8 patients with Basedow disease and 2 patients with Plummer disease) candidate to undergo radiometabolic treatment. For the analysis of scintigraphic data we used Siemens software "Esoft Thyroid Upatke Processing" that allows to estimate the percentage of thyroid tracer uptake, area, volume and weight of the gland. This software was previously set by performing measurements of images acquired on an antropomorphic thyroid-shape phantom containing ^{99m}Tc. From these measurements we found out 40% as the desaturation threshold that best reflects the real dimensions of the gland. Thus, after the application of this cutoff value on patients' scintigraphic images, we drawn minor and major axis on the corresponding isocontour. These values were imputed in the dedicated software in order to obtain the size of each lobe. **Results:** The thyroid volumetry data obtained with the different calculation methods underwent to statistical analysis by Excel and for each distribution the arithmetic average, median and standard deviation values were calculated. The inferential statistical analysis was then completed by obtaining the graphs of the distributions with the relative coefficients of determination R^2 and of correlation R. In particular the graphs were obtained by comparing the volume data between ultrasound and planar scintigraphy with ^{99m}Tc, planar scintigraphy with ^{99m}Tc and scintigraphy with NaI-131 and ultrasound with planar scintigraphy with NaI-131. The results show a strong correlation between the volume data of the three methods, as shown by the value of R which was always elevated and above 0,9. **Conclusion:** US, NaI-131 and ^{99m}Tc-scintigraphy can be used indifferently in the calculation of personalized radioiodine dose to be administered in hyperthyroidism treatment. However, in this scenario, ^{99m}Tc-scintigraphy demonstrated a higher

accuracy in the evaluation of thyroid volume respect to NaI-131 scintigraphy. ^{99m}Tc scintigraphy glandular volume showed a strong correlation with the values found with US. **References:** None.

TEPS-17

Biodistribution Mapping of ^{223}Radium Dichloride during the course of Treatments 2 to 6. A Patient Case Study

***J. Weekes**, I. Sayers, M. Foley;*
New Cross Hospital, Wolverhampton, UNITED KINGDOM.

Aim/Introduction: To evaluate the biodistrution of ^{223}Radium Dichloride (Xofigo) at 36 set anatomical sites (anterior and posterior) in Patient X over a period of at least 22 days post administration. This was performed for treatments 2 - 6 of Patient X's ^{223}Radium Dichloride therapy. The aim of this unique study was to look at the Effective and Biological half -life of ^{223}Radium Dichloride during the individual treatments and evaluate any changes in the half-life's that occur over the course of Patient DN's therapy. **Materials and Methods:** By using a scintillation counter, readings were acquired over set anatomical sites (anterior and posterior) for treatments 2-6. The readings were taken at the skin surface and the mean counts per second during a 20 second observation period were recorded for all sites. Background readings were also acquired and recorded. The data was recorded into identifiable Excel files eg.,treatment number etc., The whole analysis was done with R, a statistical programming language. Activity / time curves were plotted for each anatomical measurement site. **Results:** A Biphasic decay curve was observed in 98 % of sites on a $\log_{10}$ scale. Using all the data points over the treatments, it shows that the estimated gradients or effective half-life's increase with the number of treatments. **Conclusion:** Why would there appear to be a longer biological uptake of ^{223}Radium Dichloride at sites of disease as a result of increase treatments which naturally increases the effective half -life of ^{223}Radium Dichloride therapy. **References:** 1.CRUK website. Referral Rates and Overall Survival of Patients Receiving Ra223 Therapy for mCRCP at the Beatson West of Scotland Cancer Centre

***I. Kerr**, C. Brown, C. Findlay, G. Buchanan;*
Beatson West of Scotland Cancer Centre, Glasgow, UNITED KINGDOM.

Aim/Introduction: In May 2016, the Beatson Oncology Centre (BOC) opened a Ra223 therapy service treating mCRPC patients in the West of Scotland. This catchment area includes referrals from six Health boards, and a population of 2.8M. The aim of this work was to review the referral patterns and the outcome of patients in the three years since the service was established. **Materials and Methods:** The date of patient referrals to the service were audited to establish any trends in patient throughput. The Overall Survival (OS) of patients that completed all six cycles of Ra223 were compared with published data from the Alsympca trial. **Results:** A total of 178 patients were referred between May 2016 and April 2019. The audit of patient treatments revealed an initial referral rate in the first six months (8.4+/-6.2 per month) which was higher compared to the overall mean of the data (4.9+/-6.2 per month). This higher rate corresponds to a backlog of patients waiting for the service to open. As these patients were more likely to have progressed while waiting for treatment, they were more symptomatic and, therefore, less patients completed all six fractions (40% compared to 52%). Of note, following the Pharmacovigilance Risk Assessment Committee (PRAC) guidance which relegated Ra223 to third line treatment in July 2018, from September 2018 onwards, referrals have approximately halved. Of those patients completing all six fractions 51 out of 87 patients are now deceased, their OS was 9.7 months. This is not comparable with Alsmypca, which reported 14.9 months. This difference may be due to less stringent clinical criteria for treatment, a smaller sample size, and a proportion of patients treated with six fractions that are still alive. **Conclusion:** Deceased patients that completed all six cycles of treatment showed a lower OS than that found in the Alsympca trial. Additionally, the number of patients being referred to the service has been significantly impacted by the new PRAC guidance. The overall survival of this new cohort of patients has not yet been evaluated. **References:** None.

TEPS-19

Impact of TOF(Time of Flight) reconstructions on SUVmax(Standard uptake value) in AD(Alzheimer Disease)/PD(Parkinsonism Disease) patients:Using of ^{18}F-FDG,^{11}C-CFT and ^{11}C-PIB

***D. Wimalarathne**[1,2], X. Lan[1], Y. Zhang[1], W. Ruan[1], R. An[1], X. Sun[1], F. Hu[1];*
[1]Department of Nuclear Medicine,Union Hospital,Tongji Medical College,Huazhong University of Science and Technology, Wuhan, CHINA, [2]Department of Radiography and Radiotherapy,Faculty of Allied Health Sciences, General Sir John Kotelawala Defence University, SRI LANKA.

Aim/Introduction: This study evaluated the impact of TOF reconstruction on SUVmax among ^{18}F-FDG, ^{11}C-CFT and ^{11}-C-PIB suspected Alzheimer's patients. The use of SUVmax value plays an important role in neuro positron emission tomography magnetic resonance imaging (PET/MRI).TOF reconstructions have a significant impact on SUVmax, presenting a challenge for centres with well-defined protocols for diagnosis of Alzheimer's classifications based on SUVmax. This has led to the slow adoption of TOF reconstructions. **Materials and Methods:** Total

71 patients, the median age of 63±8.7 years old and median BMI (Body mass index) 23.91±3.34 (Kg/m2)) with suspected Alzheimer's disease underwent simultaneous PET/MR (SIGNA, GE Healthcare, USA) after injection of ^{18}F-FDG (2-deoxy-2-(^{18}F)fluoro-D-glucose), ^{11}C-CFT(Dopamine transporter/DAT) and ^{11}C-PIB(Pittsburgh compound). 22 ^{18}F-FDG, 24 ^{11}C-CFT and 25 ^{11}C-PIB patients' brain were scanned 15-20 min with arms down supine position. Each PET LIST mode data was reconstructed with and without TOF respectively using the system default three dimensional ordered subset expectation maximization iterative reconstruction algorithm (3D-OSEM). SUVmax of selected brain volume of interest (VOI) were measured using the PMOD 3.906 PNEURO module in both TOF and non-TOF images. T1 weighted MRI was employed for segmentation and brain was segmented to Frontal Lobe(FL), Temporal Lobe(TL), Parietal Lobe(PL), Occipital Lobe(OL), Caudate Nuclei(CN), Nucleus Accumbens(NA), Putamen(PU), Thalamus(Th), Pallidum(PA), Corpus Callosum(COC), Substantia Nigra(SN), Insula(IN), Anterior Cingulate Cortex(ACC), Posterior Cingulate Cortex(PCC), Cerebellum Cortex(CC), Cerebellum Medulla(CM), Brain Stem(BS) and White Matter(WM). TOF and non-TOF SUVmax values were assessed by paired t-test in SPSS 23.0. **Results:** SUVmax of each ^{18}F-FDG ^{11}C-CFT and ^{11}C-PIBs' selected brain volume in TOF images showed higher than those in non-TOF images. For all brain regions, the average SUVmax in ^{18}F-FDG ^{11}C-CFT and ^{11}C-PIB increased by 6.09%, 7.47% and 5.54% respectively in TOF reconstructions. The average SUVmax in ^{18}F-FDG TOF was significantly higher than in non-TOF images in all brain segments (i.e. $p<.05$). In ^{11}C-CFT, FL,TL,PL,OL,CN,NA,Th,PA,SN, ACC, PCC, CC, BS and WM showed significantly higher average SUVmax in TOF than in non-TOF (i.e. $p<.05$). The average SUVmax in ^{11}C-PIB TOF was significantly higher than in non-TOF in FL, TL, PL, OL, CN, NA, Th, IN, ACC, PCC and BS (i.e. $p<.05$). **Conclusion:** The quantitative differences of segmented brain volumes are apparent in TOF and non-TOF PET/MRI images. Depending on a greater quantitative effect from TOF reconstruction, simultaneously PET/MRI will positively impact the proper diagnosis of Alzheimer's disease. This study was supported by the Key Project of Hubei Province Technical Innovation (2017ACA182) **References:** None.

TEPS-20

Validation of Standardized Uptake Value about Hardware Components in Integrated PET/MRI

B. Kim[1], *M. Kim*[2], *I. Moon*[1], *H. Lee*[1], *G. Noh*[1];
[1]*Department of Nuclear Medicine, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Radiology, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: A cross calibration of PET is to identify discrepancies between PET scanner and dose calibrator to ensure the standardized uptake value (SUV). An MR based attenuation correction (MRAC) of PET/MRI needs to be considered in human body as well as in hardware components for MR imaging. However, the cross calibration of the integrated PET/MR has been only performed regardless of hardware components. The purpose of this study was to evaluate the SUV on the impact of hardware components in integrated PET/MRI. **Materials and Methods:** For performing the cross calibration between PET/MRI scanner and dose calibrator, we used a cylindrical water phantom, a Ge-68 cylindrical phantom, and a 3.0T integrated PET/MRI (Biograph mMR, Siemens, Germany). A cylindrical phantom of 9.52 L was filled with demineralised water, 59.2 MBq fluoride-18 solution, 0.2 mM Gadolinium-DTPA as a T1 relaxation modifier, and 150 mM NaCl as a conductivity to avoid artifacts from MR imaging. The cross calibration correction factor (CCCF) was produced by scanning the prepared phantoms regardless of the hardware components such as a patient table and RF body surface coils. After applying the CCCF, we obtained PET/MR images for the water phantom to check the accuracy of attenuation correction according to presence of the hardware components (hwc, non-hwc). DIXON sequences for MRAC were acquired simultaneously with PET. All PET images were reconstructed using 3D OSEM. A total of 103 regions of interest were drawn to measure mean SUVs (SUV_{hwc}, $SUV_{non\text{-}hwc}$) for the water phantom on each image. Statistical analyses were performed to compare SUV measurements on both images. **Results:** The CCCF obtained by the cross calibration using the water phantom and the Ge-68 phantom was 0.96. The SUV_{hwc} and $SUV_{non\text{-}hwc}$ which reflected the CCCF were measured as 0.922±0.016, and 0.998±0.010, respectively. SUV_{hwc} was identified as significantly smaller than $SUV_{non\text{-}hwc}$ ($P< 0.05$). The Difference between $SUV_{non\text{-}hwc}$ and SUV_{hwc} showed 0.076±0.018. **Conclusion:** The hardware components such as s patient table and RF body surface coils may have a considerable impact related to the underestimation of the SUV in integrated PET/MR imaging. The SUV validation which included the hardware components is able to ensure the accuracy of quantitative analysis. So, we suggest including hardware components when performing the cross calibration between PET/MRI scanner and dose calibrator. **References:** KELLER, Sune H., et al. Cross-calibration of the Siemens mMR: easily acquired accurate PET phantom measurements, long-term stability and reproducibility. EJNMMI physics, 2016, 3.1: 11.

TEPS-21

Optimization of Bayesian penalized likelihood reconstruction parameters for quantitative brain Positron Emission Tomography (PET) imaging

D. Ribeiro[1], *W. Hallett*[1], *O. Howes*[2,3,4], *R. McCutcheon*[2,3,4], *M. Nour*[2,3,4], *A. A. S. Tavares*[5];
[1]*Invicro, London, UNITED KINGDOM,* [2]*Institute of Psychiatry, Psychology & Neuroscience, London, UNITED KINGDOM,* [3]*Medical Research Council London, Institute of Medical Sciences, London, UNITED KINGDOM,* [4]*Institute of Clinical Sciences, Faculty of Medicine, Imperial College London, London, UNITED KINGDOM,* [5]*Edinburgh Imaging, The University of Edinburgh, Edinburgh, UNITED KINGDOM.*

Aim/Introduction: Nuclear medicine technologies have

recently seen advances in scanner hardware and reconstruction algorithms. Q.Clear is a Bayesian penalized likelihood reconstruction algorithm that presents improvements in the Positron Emission Tomography (PET) image signal-to-noise ratio (SNR)[1]. This study aims to evaluate the performance of Q.Clear against the ordered subset expectation maximization (OSEM) and filtered back-projection (FBP) algorithms, in dynamic brain PET images. **Materials and Methods:** Contrast recovery (CR) and background variability (BV) were investigated with the National Electrical Manufacturers Association (NEMA) Image Quality (IQ) phantom and resolution, axial uniformity and SNR were investigated with the Hoffman phantom, both filled with ^{11}C- or ^{18}F-labelled solutions. Data collection and reconstruction was performed using a Siemens Biograph 6 TruePoint PET-Computed Tomography (CT) and General Electric SIGNA PET-Magnetic Resonance (MR). The non-displaceable binding potentials (BP_{ND}) for the Substantia Nigra (SN), Striatum (St), Globus Pallidus (GP), Thalamus (Th), Caudate (Cd) and Putamen (Pt) from seven [^{11}C]PHNO PET-MR datasets were investigated. Intraclass correlation coefficients, repeatability coefficients (RC), coefficients of variation and bias from Bland-Altman plots were reported. Statistical analysis was conducted using a 2-way ANOVA model with correction for multiple comparisons. **Results:** For the Q.Clear reconstructions, as the β parameter increases, CR and BV decrease in the NEMA IQ phantom. The CR results are lower for FBP and OSEM versus Q.Clear. The BV results are higher for Q.Clear versus OSEM. For the Hoffman phantom, low β levels provide the best resolution and high β levels provide the best uniformity and SNR. When comparing a standard OSEM reconstruction of 6 iterations/16 subsets and 5mm filter with Q.Clear with different β values, the quantitative bias and RC were lower for Q.Clear with β=100 for the SN, Th and GP and with β=200 for the St, Cd and Pt. The Q.Clear with β=100, 200 and 400 are the only reconstructions across all structures that don't present statistically significant differences ($p<0.001$) when compared to the standard OSEM reconstruction. **Conclusion:** Q.Clear improves CR and provides better in plane, axial resolution and SNR in the PET-MR, in comparison to OSEM, and FBP in the PET-CT. Quantitative brain PET studies using [^{11}C]PHNO are more accurate when using Q.Clear with β<400 which is the value used for clinical ^{18}F-FDG whole-body studies. **References:** [1] Teoh EJ, McGowan DR, Macpherson RE, Bradley KM, Gleeson FV. Phantom and clinical evaluation of the Bayesian penalized likelihood reconstruction algorithm Q.Clear on an LYSO PET/CT system. J Nucl Med. 2015 Sep;56(9):1447-52.

Correlation of the Standardized Uptake Value(SUV) and the Apparent Diffusion Coefficient(ADC) Value in Breast Carcinoma with Simultaneous [18F]-FDG PET/MRI

M. Kim[1], *B. Kim*[2], *H. Jung*[1], *Y. Bang*[1];
[1]*Department of Radiology, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF,* [2]*Department of Nuclear Medicine, Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF.*

Aim/Introduction: Both the apparent diffusion coefficient (ADC) value and standardized uptake value (SUV) indirectly represent the biological characteristics of cancer. Our study attempt to evaluate the mutual association by comparing SUVs and mean and minimal ADC values at the same region in breast carcinoma. **Materials and Methods:** 40 patients (mean age: 41.64±7.95 years, range: 32-62 years) with breast cancers underwent F-18 FDG PET/MRI (Biograph mMR, Siemens, germany) examinations at our institute during a period from July in 2018 to March in 2019 were enrolled in this study. PET images were acquired 60 min after administration of F-18 FDG (5.18MBq/kg of body weight). We evaluated whether there was a correlation among the SUVs, ADC(b values; 0 and 1000 seconds/mm2)mean, and ADCmin values in the same region as maxSUV, peakSUV, and meanSUV. Pearson correlations were calculated to investigate the association between SUVs and mean and minimal ADC values. **Results:** 40 lesions were detected. The mean SUVmax, ADCmean and ADCmin were 8.53 ± 5.46 (range, 1.01-26.85), 956.20 ± 234.40 × 10−6 mm2/s (range, 425.70-1278.00 × 10−6), and 851.96 ± 222.32 × 10−6 mm2/s (range, 373.00-1211.00 × 10−6), respectively. We found a weak positive correlation between maxSUV and mean and minimal ADC values(correlation coefficient r=0.232, p=0.150 and r=0.302, p=0.059, respectively). **Conclusion:** Our study demonstrates a weak positive correlation between SUVs and mean and minimal ADC values at the same region of max, peak, and meanSUV in patients with breast cancer. we found that correlations could play an important role in assessing the tumor condition in a specific region of interest. **References:** Kitajima K, Yamano T, Fukushima K, Miyoshi Y, Hirota S, Kawanaka Y, Miya M, Doi H, Yamakado K, Hirota S. Case-by-case Evaluation of Clearance of Waste contaminated with Residues of the Radiopharmaceutical Xofigo

O. Nitzsche[1], *S. Thierfeldt*[1], *R. Kunz*[1], *K. Wittke*[2];
[1]*Brenk Systemplanung GmbH, Aachen, GERMANY,*
[2]*Bayer AG, Wuppertal, GERMANY.*

Aim/Introduction: Depending on the residual activity and the time it will take for decay of this activity below clearance levels, waste contaminated with radiopharmaceuticals can either be treated as radioactive waste or can be cleared and then disposed of as conventional waste (usually by incineration). Some radiopharmaceuticals contain radionuclides with half-lives that will not allow decay to activities below unconditional clearance levels within reasonable time. The radiopharmaceutical preparation Xofigo® with the active ingredient $^{223}RaCl_2$ is manufactured and marketed by Bayer AG (Bayer). The active ingredient of the preparation is Ra-223 with a half-life of 11.4 d. Xofigo® also contains Ac-227 with half-live of 21.8 a and its daughter nuclide with half-live of Th-227 18.7 d respectively, due to the manufacturing process. **Materials and Methods:** In this paper, a case-by-case analysis in accordance with German regulations is reported for waste contaminated with residues of Xofigo® with the aim of enabling the release of the waste without further restrictions. It is taken into account that the resulting waste have to be collected in a closed container and incinerated in waste incineration plants. The case-by-case assessment demonstrates that the potential exposure of persons of the general public will not exceed 10 µSv per calendar year. Especially for employees of waste incineration plants, it is further proven that the exposure to be expected for these persons is significantly below 1 µSv per calendar year. This ensures that no dose of more than 10 µSv/a can be obtained even in the case of superimpositions with exposures from releases for disposal from other sources. Exposure calculations were performed on the basis of the generic radiological model prepared for the deriving clearance levels for disposal of cleared wastes on landfill disposal sites or in incineration plants with appropriate adjustments to the model to account for the significantly lower quantities of Xofigo® waste and the special features of Rn-219 (daughter nuclide of Ra-223). The calculation is based conservatively on a substantial increase of the current annual applications in Germany. **Results:** The calculations of the potential exposure indicate that a decay time of 150 days should be observed. Also for the activity concentration of the long living mother nuclide Ac-227, the pharmaceutical release specification is used as a very conservative upper limit. **Conclusion:** Release of Xofigo® residues after decay of the short living nuclides Th-227 and Ra-223 towards the equilibrium with Ac-227 is possible without further requirements. **References:** None.

TEPS-24

A sensitive analytical method for the determination of the long-lived impurity ^{227}Ac in production batches of Xofigo® has been developed in order to allow for unconditional release of clinical waste after decay-in-storage

J. Gay[1], *I. Hunnes*[2], *A. K. Pearce*[3], *P. Ivanov*[3], *K. Wittke*[4];
[1]*Bayer AG, Berlin, GERMANY,* [2]*Bayer AS, Oslo, NORWAY,* [3]*National Physical Laboratory, Teddington, UNITED KINGDOM,* [4]*Bayer AG, Wuppertal, GERMANY.*

Aim/Introduction: Radiopharmaceuticals are produced according to high quality standards, however, the medical isotopes used, e.g. ^{68}Ga, ^{90}Y, ^{99m}Tc, ^{111}In, ^{123}I, ^{153}Sm, ^{177}Lu, ^{223}Ra or ^{225}Ac may be contaminated with long lived radionuclidic impurities. Although these contaminants typically account for less than 0.01% of the total radioactivity, they need to be considered for waste disposal and in many cases require setting up costly and tedious disposal concepts. In principle, the short half-lives of ^{223}Ra (11.4 days) and its daughter nuclides allow for decay-in-storage of Xofigo® related waste. However, traces of the long-lived mother nuclide ^{227}Ac of ^{223}Ra production potentially present in Xofigo® drug solution might require setting up a specific waste management pursuant to local regulations on waste disposal. Being able to determine ^{227}Ac as a weak ß-emitter next to a high excess of ^{223}Ra and its progeny (predominantly emitting α, but also β and γ) is analytically challenging. According to the current specification for drug release, the maximum content of ^{227}Ac is ≤0.004% relative to ^{223}Ra. A level that guarantees patient's safety related to exposure from ^{227}Ac being present only in traces, if at all. On the other hand it doesn't meet the requirements for unconditional release of Xofigo® related waste in some European countries due to very strict ^{227}Ac limits for waste disposal. Therefore, Bayer has developed a sensitive analytical method dedicated to waste management. **Materials and Methods:** The method consists of a radiochemical separation of potential traces of ^{227}Ac from ^{223}Ra with use of extraction columns following detection with liquid scintillation counting (LSC). **Results:** This method allows proof of ^{227}Ac levels below 0.000001% relative to ^{223}Ra, and thus unconditional release of Xofigo® related clinical waste. Results of ^{227}Ac measurements on Xofigo® production batches are provided to Xofigo® users on request. **Conclusion:** In summary, development of a sensitive analytical method to determine ^{227}Ac traces in Xofigo® production batches resulted in ecologically and economically improved waste management. **References:** None.

Differentiated thyroid cancer patiens treated with radioiodine-therapy and individualized recommendation of radioprotection

C. Moisescu-Goia, *A. Sabo, C. Pestean, I. Cecan, M. Crisan, E. Olariu, D. Piciu;*
Oncological Institute of Cluj-Napoca, Cluj-Napoca, ROMANIA.

Aim/Introduction: Patients with differentiated thyroid cancer who receive necessitate hospitalization. Radiological safety standards for nuclear medicine practice issued by CNCAN require that patients receive recommendations on radiation protection measures that have to be meet immediately after discharge. The purpose of the study is to highlight the importance of the individual recommendations that patients receive at discharge depending on the measured flow. **Materials and Methods:** The study was conducted on a sample of 11 patients with differentiated thyroid cancer admitted to the

Nuclear Medicine Laboratory of the Oncology Institute "Prof. Dr. Ion Chiricuta"Cluj-Napoca within one months. The subjects (two men and nine women) had T1b to T4c stage lymph node and lung metastases, aged between 23-80 years. I-131 activity was between 1.1GBq administrated and 3.7 GBq, with a mean of +/- SD +/- 2.78 GBq 0.96GBq. Measurements were performed on consecutive days (for 2 or 3 days) of patient flow, and on the day of discharge even the flow of personal lingerie used by patients during hospitalization was measured. **Results:** The 11 patients hospitalized were measured repeatedly, and the recorded flow at 1m distance was between 77.4 to 17 µSv/h on the first day post I-131administration therapy; to reach values between 10.4 and 1.8 µSv/h after 3 or 4 days of hospitalization. On discharge day of each patient the personal ligerie used during hospitalization was mesured. The recorded values were between 2.34 to 41.7 µSv/h, with a weight of 54.5% below 10 µSv/h. The results of the measurements revealed the lack of statistically significant correlations with the activity of I-131 administered, p = 0.736. **Conclusion:** The study highlighted the importance of the individualized recommendations on radiation protection based on measured flow values for discharged patients not the administered activity of I-131. **References:** None.

TEPS-26

A Phantom Study on Radiotracer Dose Reduction in Integrated PET/MR System

J. Zhuang, M. Bai;
Xuanwu Hospital, Capital Medical University, Beijing, CHINA.

Aim/Introduction: The purpose of the current study was to explore the feasibility of radiotracer dose reduction in the integrated PET/MR system achieved by the application of time-of-flight (TOF) method with phantom, while the image quality (IQ) was not inferior to its original level. **Materials and Methods:** Measurements were performed on GE SIGNA PET/MR following National Electrical Manufacturers Association (NEMA) NU 2-2007 protocol using IQ phantom. The hot-sphere-to-background activity concentration ratio was 4:1. All data were periodically acquired in list-mode format with an acquisition time of 11 minutes. The scans successively started at 0, 1/2, 1, 3/2, 2 half-lives of ^{18}F-FDG. The activity concentration of the hot spheres was 2.12×10^4 Bq/ml at the beginning of the scan. A CT-based attenuation map was used to carry out the attenuation correction. PET images were reconstructed using both TOF method and point spread function (PSF) correction, TOF method only, PSF correction only, neither TOF method nor PSF correction. The obtained PET images were quantitatively evaluated by contrast recovery, background variability, and signal-to-noise ratio (SNR) of hot spheres. A paired t-test was performed to assess the difference between the images acquired at lower radiotracer activity reconstructed with TOF method and those acquired at higher radiotracer activity reconstructed without TOF method. **Results:** The contrast recovery remained almost constant over the 2 half-life periods of ^{18}F-FDG, meanwhile the background variability displayed a rising tendency, and the SNR dropped as the radiotracer activity decreased. Using TOF to reconstruct could improve the contrast recovery ($p<0.05$) and SNR ($p<0.05$) significantly, and reduce the background variability ($p<0.05$). When the radiotracer activity decreased to 50%, background variability ($p>0.05$) and SNR ($p>0.05$) of the PET images reconstructed with TOF had no significant difference with the corresponding PET images acquired at 100% radiotracer activity reconstructed without TOF, while the PET images acquired at 50% radiotracer activity reconstructed with TOF had superior contrast recoveries to those acquired at 100% radiotracer activity reconstructed without TOF ($p>0.05$). **Conclusion:** The image quality of the PET images deteriorates with the radiotracer activity decaying. While the radiotracer activity decreasing to 50%, the decline of image quality can be compensated by using TOF method. Therefore, the application of TOF method can reduce at least half of the dose to patients from PET/MR examinations. **References:** 1. National Electrical Manufactures Association (NEMA). Standards Publication NU 2-2007. Performance Measurements of Positron Emission Tomographs. Rosslyn, VA: NEMA; 2007.

TEPS-27

Examination of the Correlation between patient-dependent parameters and radiation dose rates measured around patients undergoing PET/CT imaging using 18F-FDG

S. Alqahtani[1], *K. Soliman*[2], *A. Alenezi*[3];
[1]*PSMMC, Riyadh, SAUDI ARABIA,* [2]*Medical Physics Department, PSMMC, Riyadh, SAUDI ARABIA,* [3]*Faculty of Applied Medical Sciences, KSU, Riyadh, SAUDI ARABIA.*

Aim/Introduction: Patients undergoing 18F-FDG PETICT imaging are considered as external sources of radiation. Accurate dose rate estimation is important for conducting realistic risk assessments and performing dose reconstruction in cases of accidental exposures. The patient radiation self-attenuation factor is assumed to be a function of the patient's body size metrics; but can we use these metrics to predict the dose rate around the patients with accuracy in situation where direct dose rate measurements are not possible?. The objectives of this work were to measure the patient attenuation factor by performing direct dose rate measurements from patients, to study the possible correlation between the measured dose rate constant from the patients and their body size metrics and to measure the patients' voiding factor. Five different body size metrics were tested for correlation in this study **Materials and Methods:** We have measured the dose rate at one meter anterior to the patient body surface from 57 patients just before voiding and also immediately after voiding using a calibrated ionization chamber; the injected activity measured with a properly calibrated clinical dose calibrator used in the nuclear medicine department was corrected for decay and used to calculate the dose rate per unit activity **Results:** The measured average dose rate per unit activity was 92.2 14 $\mu Sv.hr^{-1}.GBq^{-1}$. This result is with close agreement with the value recommended by AAPM TG-

108. There was no statistically significant correlation between the dose rate constant per unit activity and the 5 patient body size metrics tested in the table below. The measured patient voiding factor was found to be equal to 0.89+0.06. **Conclusion:** Patient bladder voiding before scanning reduced the measured dose rate at one meter from the patient by about 11%. Patient body size metrics cannot be used solely to predict the dose rate levels expected from individual patient. The activity normalized dose rate constant of 92 (uSv/h/GBq) measured at one meter anterior to the patient can be used with confidence to estimate dose rates from patients undergoing PET/CT imaging using FDG because it includes patient body attenuation and scatter factor. The presented data can be used by medical physicist working in nuclear medicine for optimization of protection and justification of locally applied radiation safety measures. **References:** Madsen, M.T., Anderson, J.A., Halama, J.R., Kleck, J., Simpkin, D.J., Votaw, J.R., Wendt III, R.E., Williams, L.E. and Yester, M.V. TEPS-28

Typical patient doses from CT part of PET/CT examinations in Slovenia and comparison with other countries

J. Peric[1,2], *I. Zagar*[1], *D. Zontar*[3];
[1]*Institute of Oncology, Ljubljana, SLOVENIA,* [2]*Faculty of Health Sciences, University Ljubljana, Ljubljana, SLOVENIA,* [3]*Slovenian Radiation Protection Administration, Ljubljana, SLOVENIA.*

Aim/Introduction: In hybrid PET/CT imaging, the CT part (due to attenuation correction) allows for more precise determination of the activity in the selected volume and greater accuracy and reliability in lesion localization. Despite several important benefits, it should be noted that the addition of CT to the PET system increases radiation load in PET/CT imaging. Many previous studies emphasized a great need to optimize radiation exposure and radiation protection. However, the diagnostic reference level (DRL) for CT in hybrid systems in Slovenia has not yet been determined. **Materials and Methods:** The study involved 540 patients who had a PET/CT examination. We selected 180 patients per each nuclear unit in Slovenia. The first 60 patients had PET/CT from the top of the head to the middle of the thigh, the other 60 patients had a PET/CT from the base of the skull to the middle of the thigh and the last 60 patients had PET/CT of the entire body. The selected patient population had body weight 70 to 90 kg and average BMI 27.05 ± 2.8. The average value of Dose Length Product (DLP) was calculated for each individual protocol and compared between NM units in Slovenia and with already published diagnostic reference levels. **Results:** We found a statistically significant difference in the DLP between protocols carried out by different NM in Slovenia, taking into account the error possibility of 5%. The average DLP in the University Clinical Center Ljubljana was 20% lower than DLP at the Institute of Oncology Ljubljana and 40% lower at the University Clinical Center Maribor. On average NM units in Slovenia have lower (> 22%) DLP compared with DRL in Australia for all three protocols. The research also showed that height and gender had a statistically significant impact on the patient's dose. **Conclusion:** The results of the research will be a good basis for proposing the predicted diagnostic reference dose levels for hybrid PET/CT imaging in Slovenia, in order to optimize and improve work practice. **References:** None.

TEPS-29

CT Dose Optimization

B. Gillman;
British Columbia Institute of Technology, Vancouver, BC, CANADA.

Aim/Introduction: Computed tomography (CT) is not only ubiquitous in modern clinical environments but also a vital tool in obtaining diagnostic information. But rising concerns of CT radiation exposure have prompted many dose optimization and reduction strategies to be developed. Technologists should be aware of the techniques and technologies available to them to help reduce CT dose to patients. **Materials and Methods:** When investigating dose optimization, there are a number of essential aspects to consider. First, it is important to be familiar with how CT dose is measured and know the limitations involved these dose metric estimates. Second, learn what dose reduction strategies are available to you. These are a combination of actions the technologists can do (such as modifications of scanning parameters based on individual patient considerations), as well as built in features of the scanner itself (such as recent technological innovations such as Specific Organ Dose Adaption and Reduction protocol - SODAR) that can be taken advantage of. With these strategies in mind, the technologist can help optimize CT dose during three key phases of the scan: before, during, and after. During each of these phases, some of the most significant dose reduction techniques will be highlighted. Finally, it is equally important to look at methods for evaluating your departments current radiation usage and able to track changes (and hopefully improvements) over time. **Results:** Radiation dose metrics such as Dose-Length Product (DLP) should be monitored in clinical practice using Diagnostic Reference Levels (DRLs). DRLs are an established, effective technique to not only track changes, but also set guidelines for imaging radiation dose. **Conclusion:** It is important to know your scanner and understand the dose reduction technologies available to you as a technologist. Utilizing these strategies as they become standard of practice will reduce CT radiation exposure to your patients. **References:** None.

TEPS-30

Evaluation in animal imaging of the new generation of pre-clinical all-digital PET/CT

W. Xiao[1], *H. Yan*[1], *L. Wan*[2], *Q. Xie*[1];
[1]*Huazhong University of Science & Technology, Wuhan, CHINA,* [2]*Wuhan Raydata Technology Co., Ltd., Wuhan, CHINA.*

Aim/Introduction: It's well known that positron emission tomography(PET) has wildly extended its application area and proved more importance in both clinical diagnose and pre-clinical research. Here, in order to assess application of the new generation of all-digital animal PET/CT system - Trans-PET Discoverist 180, we performed a series of experiments to evaluate animal imaging performances. **Materials and Methods:** Materials: male wild type C57BL/6J mice, male myocardial infarction(MI) mice, male rats, rabbit 2-Deoxy-2-(^{18}F)fluoro-D-glucose (^{18}F-FDG) Trans-PET Discoverist 180 (Raycan Technology Co., Ltd, Suzhou, China) Methods: First, we performed scans for single wild type mouse and rat. Before experiment, animals were fasten overnight. For mice experiment, 200μCi of ^{18}F-FDG or ^{18}F-NaF was injected via tail vein. 60 minutes(min)(for FDG) or 120min(for NaF) after injection, the mice were placed on scan bed for 10min's PET static scan(10min/bed,inhaled anesthesia with 2~3% isoflurane) followed by normal mode CT scan. Rats experiments had the same protocol except the injected dose was 500μCi and the PET mode was set in whole body for 20min (10min/bed, 2 beds). We also performed scans for 4 mice or 2 rats in one scan. Next, MI mice without fasting were scanned and compared the data with wild type mice. We also performed dynamic scans for mouse and rat using ^{13}N-Ammonia to observe the blood flow in heart and brain. Last, we performed large animal scans on rabbits. 1mCi/kg ^{18}F-FDG was injected via ear vein. Rabbits were scanned 120min after ^{18}F-FDG injection for 20min in whole body mode(5min/bed, 4 beds). Data analysis: After PET scanning and image reconstruction, dicom data was processed with software Carimas(Turku PET center, Turku, Finland). **Results:** Trans-PET Discoverist 180 is a useful tool in pre-clinical research. PET image of single mouse is of high quality. The axial length of FOV is 10cm and enough for scanning of one whole mouse body. The large radial FOV enables 4 mice or 2 rats in one scan, that can be very helpful in short half-life radiotracer imaging. Mice heart imaging is clear and data can easily be processed and recognized by other software, such as Carimas. Dynamic scanning enables realtime and dynamic monitoring of pharmacokinetics in whole mice body or majority rat body. **Conclusion:** The large FOV of Trans-PET Discoverist 180 makes it a unique animal PET scanner for large animal, that has wildly extended its application area. And it's also able to do PET scan for monkey brain. **References:** None.

TEPS-31

Conventional vs. digital Philips PET/CT: evaluation of phantom data

A. Ebbens, T. Kuijer, E. Martens, B. J. de Wit-van der Veen; Netherlands Cancer Institute, Amsterdam, NETHERLANDS.

Aim/Introduction: A new digital PET/CT scanner was recently introduced at our department, enabling more detailed imaging and either dosage or acquisition time reduction. In a clinical setting, however, it is important that the quantitative performance of both our digital and conventional PET/CT scanners is comparable. Therefore, the aim of this study is 1. to compare reconstructions on both conventional and digital PET/CT and 2. to find optimal quantitative reconstruction parameters for the digital 2mm PET/CT. **Materials and Methods:** The NEMA NU2-2007 Image Quality phantom was filled with 3.9 Bq/mL ^{18}Fluorine (^{18}F)-FDG in the background and 18.1 Bq/mL ^{18}F-FDG in the six spheres (inner diameters between 10 to 37mm), to result in a 4.7:1 sphere-to-background ratio. A two bedposition (bp) scan of two and ten minutes per bed were performed on both conventional (Philips Gemini) and digital (Philips Vereos) PET/CT. Conventional scans were reconstructed according to standard 4mm-EARL (3 iterations (i) and 33 subsets (s)). Digital PET/CT reconstructions were the following: 4mm-EARL (3i15s and 3.0mm Gaussian), 2mm-3i7s, 2mm-3i11s and 2mm-3i17s, all without Gaussian or PSF. Recovery coefficients of the maximum voxel value (RC_{max}) were determined for each sphere using the EARL software tool. Accordingly, the RC_{max} was normalised to the largest sphere for all reconstructions. RC's were compared to the EARL-specifications. **Results:** The absolute RC_{max}-values of the EARL reconstructions at 10 minutes per bp of the conventional and digital PET/CT were within EARL-specifications, whereas all 10 minute 2mm recons were positioned above the maximal RC_{max}, especially for the two smallest spheres (10 and 13mm). The shape of the normalised curves for all reconstructions for the digital PET/CT were similar; the curve of the conventional scanner was generally lower for the two smallest spheres (10 and 13mm), and slightly higher for the 17mm sphere. **Conclusion:** In general, the digital PET/CT shows better recovery of the smallest spheres (<17mm), and remains within EARL specifications with the 4mm-EARL-recon. Quantification using the 2mm 3i7s reconstruction maintains a good recovery for small spheres, and corresponds best to conventional 4mm-EARL-PET/CT. Accordingly, quantitative comparison with the conventional PET is possible, however further optimization of the digital PET/CT protocols could be achieved using point spread function reconstruction and Gaussian filters. **References:** None.

TEPS-32

PET-CT acquisition protocol optimization with a new digital PET-CT

S. Cola[1], F. Fioroni[2], A. Palmieri[1]; [1]Nuclear Medicine S. Maria Nuova Hospital, Reggio Emilia, ITALY, [2]Physical Department S. Maria Nuova Hospital, Reggio Emilia, ITALY.

Aim/Introduction: In june 2018 a new G.E. Discovery MI has been installed in our departement.The aim of this study is to optimize the ratio between time acquisition and injected dose in relation with patient BMI index. **Materials and Methods:** In our institution the baseline protocol, for oncological PET-CT examination, consisted of the administration of 3.7 MBq/kg of FDG and an acquisition of 3.5 min/bed. In the new proposal WB FDG scan the activity was reduced to 3.0 MBq/kg and the acquisition time varies from 2 to 3 minutes depending on patient BMI index.The baseline perfusional brain protocol consisted of the administration of 2.8 MBq/kg FDG and 20

minutes acquisition. In the new proposal brain scan the activity was reduced to 2.5 MBq/kg and 15 minutes acquisition time in list mode method. We are going to reduce to 10 minutes the time of acquisition.The overall image quality was subjectively rating by the referring physician. **Results:** The examination were analized. In most cases the first data show that the examination quality was find good and has been scored as interpretable . We are going to analize all the data thorough way. **Conclusion:** The PET-CT high sensitivity allow to reduce PET doses and acquisition time without modify the image quality. It is important to pay attention to the BMI index of the patient **References:** None.

TEPS-33

Quantitative harmonization of Biograph mCT systems using post-reconstruction filter (EQ. Filter) and its validation in clinical studies for whole body ^{18}F-FDG

A. Hurtado de Mendoza, C. Soza, J. Flores, S. Lopez, J. Spuler, H. Amaral;
Center for Nuclear Medicine & PET/CT Positromed, Santiago, CHILE.

Aim/Introduction: To harmonize SUV metrics in different mCT systems including Time-of-Flight (TOF) and Point Spread-Function (PSF) technologies through the implementation of an EQ-filter tool to decrease intervariability across clinical protocols. **Materials and Methods:** To obtain a corrected ECF a uniformity phantom was used to cross calibrated two PET/CT Siemens systems: mCT FLOW (mCT1) and Biograph mCT 20 (mCT2). An image quality test with standard NEMA IQ phantom NU2-2007 according to EARL specifications was performed. An isocontour-VOI (41% and 50%, respectively) with unfiltered ultraHD (PSF + TOF) 2 iterations, 21 subsets, pixel size 4.07 mm² for mCT1 and unfiltered iterative + TOF 2 iterations, 21 subsets, pixel size 4.07 mm², for mCT2 was used to find the RCs for SUVs max and mean. To adjust RC curves an EQ-filter algorithm was applied smoothing the reconstructed images. Then a shorter scan was performed to find the minimal scan-time acquisition ensuring COV values (1) under 15% in the background of phantom. To correlate our results with the standard clinical whole-body 18F-FDG protocol for SUV max and peak in each scanner, we analyzed 10 lung and mediastinum lesions (< 3 cm of diameter) in four patients and tested using the Spearman´s rank test. **Results:** The harmonized parameters for mCT1 was ultraHD 2 iterations, 21 subsets, EQ.filter 7.6 mm, with an absolute error of 3.5% for RCs max and 1.4% for RC mean; for mCT2 was iterative + TOF 2 iterations, 21 subsets, EQ filter 5.6 mm, with an absolute error of 1.8% and 4.6% respectively. In both systems the absolute error for RCs max and mean for 17, 13 and 10 mm spheres was close to 2.4%. However, in the case of the RCs mean in mCT1, we obtained 0% of the of absolute error. The minimum time for mCT2 was 2 min for bed-acquisition providing 10% COV in the uniform background compartment and 0.7 mm/seg bed-velocity and 11.6% COV for mCT1. After harmonization we observed a consistent reduction in the values measured for SUV max and peak in comparison to the clinical protocol for each system, with a high correlation between them. **Conclusion:** EQ-filter harmonize the reconstructed parameters regardless the use of PSF and TOF capabilities decreasing the discrepancy and variability between SUV max, mean and peak quantifications in our intra-center context. **References:** 1. Koopman et al. EJNMMI Physics (2016) 3:22.

TEPS-34

Image quality of 18F-FDG for patients with a high body mass index examined on Si-photomultiplier based PET

B. Olsson[1], J. König[2], E. Trägårdh[1], J. Oddstig[3];
[1]Clinical Physiology and Nuclear Medicine, Skåne University Hospital and Lund University, Malmö-Lund, SWEDEN,
[2]Department of Radiology, Central Hospital, Kristianstad, SWEDEN, [3]3Radiation Physics, Skåne University Hospital and Lund University, Malmö-Lund, SWEDEN.

Aim/Introduction: Due to photon absorption and scatter the image quality for high body weight patients that undergoes ^{18}F-FDG PET examinations may be lower compared with normal-weight patients. In our clinical protocol, patients are administered an activity of 4 MBq/kg body weight, maximum 500 MBq, and for patients < 100 kg images are acquired for 1.5 min/bed position. To compensate for attenuation factors the acquisition time is prolonged for the overweight patients. The aim was to investigate if there is any difference in image quality for patients with a BMI above respectively below 30 kg/m² and if prolonging the acquisition time for patients with BMI ≥30 kg/m² would equalise the image quality for the high BMI patients. **Materials and Methods:** The study included 32 patients with a BMI ≥ 30 kg/m² and from a previous study we extracted 21 patients, referred to as the control group, who had a BMI < 30 kg/m² and a weight < 100 kg. The patients were injected with 4 MBq/kg, maximum 500 MBq, and imaged after 60 minutes on a Discovery MI (GE Healthcare, Milwaukee, WI, USA) PET-CT using a block-sequential regularization expectation maximization reconstruction algorithm (Q.Clear, GE Healthcare) with a beta-value of 550. The acquisition time for patients in the control group was 1.5 min/bed position. For patients with high BMI the acquisition time was 4 min/bed position, acquired in listmode, which allowed the studies to be truncated to six different acquisition times of 1.5 - 4 min/bed position with 30 sec intervals. Three regions-of-interest (ROIs) in the liver were drawn in each patient. Using the ROIs in the liver, the average signal-to-noise ratio (SNR) was calculated for each patient. **Results:** Patients with BMI ≥ 30 kg/m² had a mean BMI of 34.3 (30-49) kg/m² and for patients with BMI < 30 kg/m² was the mean BMI 23.6 (16-29) kg/m². For patients with a BMI ≥ 30 kg/m² SNR increased with increasing acquisition time, ranging from 10.4 to 16.8. An acquisition time of 1.5 min/bed position yielded a mean SNR of 10.3 for patients with BMI < 30 kg/m² and 10.4 for patients with BMI ≥ 30 kg/m². **Conclusion:** The quantitative analysis showed no significant difference in SNR between patients with BMI > 30 kg/m² and the control group for acquisition times of 1.5 min/bed position. The image quality should be confirmed by qualitative analysis of experienced nuclear medicine physicians. **References:** None.

Studies On Decision Of The Cut-off Standardized Uptake Values For Normal Bones In ^{18}F-fluoride Pet/ct And ^{18}F-fdg Pet/ct

R. Ono[1], *N. Fujita*[1,2], *C. Hasegawa*[1], *Y. Ito*[1], *T. Tada*[1], *R. Murayama*[1], *Y. Tsutsumi*[1,2], *T. Odagawa*[1], *M. Tamura*[1], *S. Abe*[2], *K. Kato*[1]; [1]*Departmemt of Radiological and Medical Laboratory Sciences, Nagoya University Graduate School of Medicine, Nagoya, JAPAN,* [2]*Department of Radiological Technology, Nagoya University Hospital, Nagoya, JAPAN.*

Aim/Introduction: For the detection of bone metastases, ^{18}F-fluoride (NaF) PET/CT and ^{18}F-FDG PET/CT are used as imaging modalities. If the standardized uptake values (SUVs) of normal bone are known, they can be used in differentiation of normal bones and bone metastases and have the potential to evaluate treatment response. To our knowledge, however, no reports have been published on the cut-off SUV to label a finding either normal or metastatic in ^{18}F-NaF PET/CT and ^{18}F-FDG PET/CT. The aim of this study is to determine SUVs from normal bones in ^{18}F-NaF PET/CT and ^{18}F-FDG PET/CT. **Materials and Methods:** Our study subjects were 7 patients who underwent ^{18}F-NaF PET/CT and ^{18}F-FDG PET/CT between April 2008 and July 2018 at our Hospital. In this study, normal bones were defined as those from which bone lesions such as cancer, fracture and metabolic bone diseases were excluded. We measured SUVmax and SUVpeak from the normal vertebral bodies of the cervical, thoracic, and lumbar vertebrae in 7 patients, and calculated mean SUVmax and SUVpeak, and coefficient of variation of each vertebral body. **Results:** The mean SUVmax and SUVpeak in ^{18}F-NaF PET/CT were 8.7 and 7.3 in the cervical vertebrae, 9.8 and 7.7 in the thoracic vertebrae, and 11.0 and 8.2 in the lumbar vertebrae, respectively. Those in ^{18}F-FDG PET/CT were 2.3 and 1.9 in the cervical vertebrae, 3.1 and 2.4 in the thoracic vertebrae, and 3.8 and 2.8 in the lumbar vertebrae, respectively. The coefficients of variation of SUVmax and SUVpeak in ^{18}F-NaF PET/CT were 0.27 and 0.24. Those in ^{18}F-FDG PET/CT were 0.28 and 0.27, respectively. **Conclusion:** Different normal vertebrae had different SUVs in ^{18}F-NaF PET/CT and ^{18}F-FDG PET/CT. The highest SUV was found in the lumbar vertebrae, followed in order by the thoracic and cervical vertebrae. It would be better to decide the cut-off values for each vertebral region. In order to decide the cut-off values to label a finding either normal or metastatic, both SUVmax and SUVpeak can be used. **References:** None.

TEPS-36

Verification of acquisition condition in dynamic imaging using continuous bed motion PET/CT

T. Umezawa, *T. Iimori, T. Murata, K. Sawada, Y. Masuda, T. Uno; Chiba University Hospital, Chiba, JAPAN.*

Aim/Introduction: PET/CT, which is capable of continuous bed motion (CBM) acquisition, can perform a wide range of dynamic acquisition, including Step & Shoot (SS). This method can be used with motion artifact of a patient or if the scan was aborted. If the scan suddenly stops, image noise increases due to the decrease in acquisition count. Thus, the use of normal reconstitution conditions could affect quantitative accuracy. In this study, we verified the optimal acquisition conditions in a dynamic collection using CBM. **Materials and Methods:** In this study, the PET/CT system used was the Biograph mCT Flow 20 R-4, manufactured by Siemens Healthineers (Erlangen, Germany). Physical evaluation of the dynamic acquisition was performed using the NEMA body phantom and image analysis software with the PET quality control tool, which was PET quact (Nihon Medi-Physics, Tokyo Japan). By reading several articles about dynamic acquisition methods, we determined that the dynamic acquisition pass number was seven. We calculated the contrast ratio (QNR_{10mm}) of the 10-mm hot sphere for the evaluation of both the Gaussian filter size and iteration and the subset number. Additionally, contrast ($Q_{H,10mm}$), background variability (N_{10mm}), contrast ratio (QNR_{10mm}), and Recovery Coefficient (RC) were calculated with and without image reconstruction at the time of flight and the point spread function. **Results:** Regardless of the Gaussian filter value, the noise tended to decrease gradually when greater than four sums, and the QNR_{10mm} exceeded the standard value when greater than four sums (the standard value of the Gaussian filter is less than 9 mm). In the evaluation of the recovery rate, four sums or greater showed a smaller value than did the standard. In the case of three sums or less, the 10-mm hot sphere could be identified by increasing the Gaussian filter value. However the 10-mm hot sphere could not be recognized at the Gaussian filter value of over 9 mm. **Conclusion:** By using the optimal acquisition conditions for each iteration number, we found that image quality that meets the criteria of image analysis values could be obtained even with passes of 4 sums or less. **References:** Yamamoto H, Takemoto S, Maebatake A, et al. Verification of image quality and quantification in whole-body positron emission tomography with continuous bed motion. Ann Nucl Med. 2019;33:288-294.

Evaluation of Respiratory Motion Correction on Liver Kinetic Analysis for Dynamic PET Imaging

Y. Shao[1], *J. Wang*[2], *X. Wang*[2], *J. Cui*[3], *N. Li*[3], *L. Huo*[2], *H. Zhang*[1]; [1]*Department of Biomedical Engineering, Tsinghua University, Beijing, CHINA,* [2]*Department of Nuclear Medicine, Peking Union Medical College (PUMC) Hospital, Chinese Academy of Medical Science and PUMC, Beijing, CHINA,* [3]*SinoUnion (Beijing) Healthcare Technologies Co., Ltd, Beijing, CHINA.*

Aim/Introduction: In PET imaging, respiratory motion is known to cause reduced accuracy in the localization as well as the quantitation of PET abnormalities. However, its impact on dynamic PET imaging has not been adequately investigated. This study aims to evaluate the effects of respiratory motion correction on the liver kinetic analysis. **Materials and Methods:** Two patients with hepatic cancer, and two patients

with cholangiocarcinoma (one with liver metastases) after interventional therapy underwent 60-minute dynamic ^{18}F-FDG PET imaging after low-dose CT scan. All the patients' respiratory motion was recorded simultaneously using the Anzai respiration gating system. For each PET scan, 23 frames (10×60s, 5×120s, and 8×300s) were reconstructed using time-of-flight (TOF) ordered subsets expectation maximization algorithm (OSEM) without motion correction (NMC). To correct for respiratory motion (MC), list-mode PET data were sorted into 6 respiratory phases, and for each phase, 23 frames were reconstructed in the same way as described above. Two spherical regions of interest (ROIs), with 20mm diameter each, were placed manually in the normal tissue at the apex of liver (UpNor) and in the middle of liver (MidNor). Time activity curves (TACs) of the maximum standardized uptake value (SUV_{max}) were extracted. TACs of the 6 gated phases were averaged to obtain a MC TAC. Kinetic analysis was performed with a 2-tissue-compartment model using PMOD (PMOD Technologies Ltd, Zürich, Switzerland) to obtain K_1, k_2, k_3, and K_i for the NMC and MC cases respectively. **Results:** Obvious liver motion could be observed for all the patients in the gated dynamic PET images. For the UpNor and MidNor ROI, comparing the MC case to the NMC case, K_1 increased by 20.95%±34.24% and 12.88%±35.27% respectively; and k_3 decreased by 39.47%±16.08% and 13.80%±6.43% respectively; and K_i, equaling $k_1 \times k_3/(k_2+k_3)$, decreased by 34.67%±13.91% and 17.34%±6.40% respectively. **Conclusion:** Respiratory motion can be clearly observed in dynamic PET imaging. With MC, the obtained kinetic parameters changed substantially compared with the NMC cases. Continued studies will be carried out in the future to include more clinical data. **References:** Choi Y, Hawkins R A, Huang S C, et al. Bayesian penalized-likelihood reconstruction algorithm in the advanced digital PET/CT system for 18F-NaF PET/CT in morbidly obese patients

M. Al-Daas[1], *L. Ali*[2], *A. Sasikumar*[3], *A. Esmail*[3], *F. Marafi*[3];
[1]*Jaber Al-Ahmad Center for Molecular Imaging, Shuwaikh, KUWAIT,* [2]*Kuwait universty, Jabriya, KUWAIT,* [3]*Jaber Al-Ahmad center for molecular imaging, Shuwaikh, KUWAIT.*

Aim/Introduction: Q.Clear, a Bayesian penalized-likelihood reconstruction algorithm for PET, was recently introduced by GE Healthcare on their PET scanners to improve clinical image quality and quantification. Our aim in this work is to determine the optimum penalization factor (beta) for clinical use of Q.Clear using advanced PET/CT system and compared it with the standard PET reconstructions. **Materials and Methods:** Ten morbidly obese patients (body mass index, 45.28 ± 4.45 kg/m2) referred for NaF PET-CT for evaluation of bone metastases were retrospectively analyzed. All the patients underwent a whole body 18F-NaF PET/CT scan using an advanced digital PET/CT system (GE Discovery MI) in JACMMI. All the patients were injected with 0.06 mCi/kg of 18F-NaF using a digital injector and imaged at 60 minutes post injection. Images were acquired for 2 minutes per bed and then reconstructed using Bayesian penalized likelihood reconstruction (Q.Clear) with different beta (β) value of 200, 400, 600, 800 and 1000. Signal-to-noise-ratio were measured in the third lumbar vertebra and in a representative lesion and were reviewed along with the visual quality of the images. The images were assessed by two different senior nuclear medicine physicians for the image quality for the different reconstructions. **Results:** All ten patients had interpretable 18F-NaF studies using conventional reconstruction. Both the nuclear medicine physicians had consensus opinion on the quality of the images obtained with the different beta values of reconstruction using Q.Clear reconstruction. All the Q.Clear reconstructions with various beta values had image quality comparable with conventional reconstructions. Reconstructions with beta values of 200, 400 and 600 gave noisier images. Images reconstructed with beta values of 1000 had excessively smooth images which the nuclear medicine physicians felt could affect the interpretability when compared with the conventional reconstruction. The SNR values progressively increased with increase in beta value. Q.Clear reconstructions with beta value of 800 gave the best image quality. **Conclusion:** Q.Clear reconstructions with beta value of 800 gives the best image quality while imaging morbidly obese patients using 18F-NaF. **References:** 1. TEPS-39

Influence of statistical fluctuation on the accuracy and stability of SUV and TBR - A phantom study

X. Xie*, M. Yun, H. Mi, X. Zhang;*
Department of Nuclear Medicine, Beijing Anzhen Hospital, Beijing, CHINA.

Aim/Introduction: The aim of this study was to evaluate the impact of statistical fluctuation on the accuracy and stability of SUV and TBR using phantom data. **Materials and Methods:** The image quality phantom with 4 hot spheres and 2 cold spheres in warm background was scanned. The activity ratio of the hot spheres to the background was 4:1. The PET data were acquired in list mode for 1800s, from which data were extracted to generate 10 images with different pixel sizes for each of the 60_s, 90_s, 120_s, 150_s, 180_s scanning times. Different scanning times correspond to different statistical fluctuation. SUVs (SUVmax and SUVpeak) and TBRs (TBRmax-max, TBRmax-avg, TBRpeak-peak and TBRmax-peak) of the three hot spheres

(diameter of 22 mm, 17 mm, 13 mm) were calculated. The relative differences (RD) between these quantitative values and their references were also calculated to evaluate the accuracy and reliability of these metrics under different noise levels. **Results:** The SUVs of the background were overestimated as the scan duration was shortened, especially for images with small pixel size. The RD of SUVmax with the pixel size of 2mm×2mm had the range of 87%-186% (corresponding scan duration of 180_s and 60_s). The SUVpeak was more stable than SUVmax, with the RD range of 30%-50%. For hot spheres, the SUVmax had similar but weaker trend as that of the background. The SUVmax of hot spheres had the RD range of 44-69%, 34-46% and 36-46% respectively. The SUVpeak of hot spheres had the RD range of 12-15%, -1-1% and -14--13%. As the TBRs, TBRmax-peak was the most accurate value under different statistic noise. The TBRmax-peak of 13-mm-diameter sphere which represents small lesions had the RD range of -2%-6%. TBRmax-max was generally underestimated and increased as the scan time and pixel size increased. TBRmax-max of 13-mm-diameter sphere had the RD ranged from -47% to -27%. TBRmax-avg was overestimated as the scan duration was shortened, which had the same tendency as the SUVmax. **Conclusion:** The SUVmax was overestimated as the scan time and pixel size decreased which gave rise to image noise. SUVpeak was less sensitive to image noise and had higher reproducibility and reliability under different statistical fluctuation. The TBRmax-peak is the most accurate and stable metric among a wide variety of TBR. **References:** None.

Optimization of image reconstruction for rapid image acquisition by ^{18}F-NaF bone PET: Comparison of OSEM and Bayesian penalized likelihood algorithms

T. Yoshii[1], *K. Miwa*[1], *K. Wagatsuma*[2], *M. Yamaguchi*[1], *M. Suga*[1], *Y. Kamitaka*[1], *T. Yamao*[1], *S. Hiratsuka*[1];
[1]*International University of Health and Welfare, Tochigi, JAPAN,* [2]*Tokyo Metropolitan Institute of Gerontology, Tokyo, JAPAN.*

Aim/Introduction: The Bayesian penalized likelihood reconstruction algorithm (BPL), commercially marketed as Q.Clear (GE Healthcare), is a reconstruction algorithm that allows for a full convergent iterative reconstruction leading to better image quality and quantitative accuracy while limiting noise. The BPL has been optimized as a reconstruction parameter for PET images with various tracers, but ^{18}F-NaF bone PET has not yet been evaluated. The present study aimed to determine the optimal image reconstruction of OSEM and BPL for rapid ^{18}F-NaF PET image acquisition. **Materials and Methods:** A custom-designed body phantom consisting of lung, soft tissue, normal spine, and a model metastatic bone tumor was scanned using a Discovery MI (GE Healthcare). The phantom allows optional adjustment of the activity distribution, tumor size and line attenuation coefficient. Bone PET images were reconstructed using OSEM + PSF + TOF (1 to 16 iterations, 17 subsets and a 4-mm Gaussian filter), BPL + TOF (β = 200 - 700) and scan durations of 30 to 120 (30, 45, 60, 90 and 120) seconds. We calculated signal to noise ratios (SNR) and contrast as indicators of image quality, recovery coefficients (RC) and count rate characteristics as indicators of quantitative accuracy. **Results:** At a scan duration of 120 sec, the optimal reconstruction parameters of OSEM + PSF + TOF and BPL+TOF were two iterations and β = 400, respectively. At 90 sec, SNR and contrast reconstructed using BPL + TOF increased by 24% and 18%, respectively, at the same noise level of OSEM + PSF + TOF applied to the optimal reconstruction. The BPL + TOF was superior to OSEM + PSF +TOF in terms of RC and count rate characteristics regardless of ^{18}F-NaF PET scan duration. The quantitative performance of BPL + TOF was better than OSEM + PSF + TOF because measured values of BPL + TOF were close to true values in terms of count rate characteristics. **Conclusion:** The present study determined the optimal reconstruction parameters for ^{18}F-NaF Bone PET at various acquisition durations. Our results suggested that BPL + TOF (β = 400) can maintain excellent image quality and quantitative accuracy over a shorter duration of acquisition. **References:** None.

TEPS-41

Development of a fully automatic analytical program for the ^{123}I- MIBG myocardial uptake measurement method

R. Sako[1], *Y. Uchiyama*[2], *Y. Kamiya*[3,1], *S. Ito*[2];
[1]*Graduate school of health sciences, Kumamoto University, Kumamoto, JAPAN,* [2]*Faculty of Life Sciences, Kumamoto University, Kumamoto, JAPAN,* [3]*Chibana Clinic, Okinawa, JAPAN.*

Aim/Introduction: Iodine-123 metaiodobenzylguanidine (^{123}I-MIBG) has been used to evaluate the cardiac sympathetic nerve in Lewy body diseases (LBDs) including Parkinson's and dementia with Lewy bodies. We recently developed a new method for ^{123}I-MIBG myocardial uptake measurements. However, this method is time-consuming because it uses several nuclear medical image analytical programs and requires manual operations. Therefore, a fully automatic analytical program is required to improve reproducibility, shorten operation time, and simplify analytical operations. The purpose of this study is to develop a fully automatic program for the ^{123}I- MIBG myocardial uptake measurement method. **Materials and Methods:** The ^{123}I-MIBG uptake index was calculated by dividing the output function by the input function. The input function was determined using the administered dose obtained by analyzing the count-time activity curve (TAC) of the pulmonary artery (PA) on dynamic chest images. The automatic region of interest (ROI) setting program for the PA was developed based on an image phase analysis of dynamic chest images. The integrated counts were obtained from the area under the curve (AUC) of the TAC on the PA-ROI, which was fitted using the gamma function. The gamma function fitting program based on mixed gamma distributions was developed using an expectation-maximization algorithm that analyzed the time activity curve of dynamic chest images. The output function was determined by the ^{123}I-MIBG single-photon computed-tomography counts on the polar map created by an automatic program that employs

circumferential analysis of short-axis images. To confirm the clinical usefulness of this program, 77 patients were examined using the automatic method and the results were compared with those obtained through the manual method. **Results:** The coincidence ratio between the location of the PA-ROI by the automatic program and that by manual methods was 90.4%. A good correlation was observed between the ^{123}I-MIBG myocardial uptake values obtained by the automatic and manual setting methods. The repeatability and reproducibility of the input function determination operations dramatically improved when using the automatic program. The time required for fitting analysis using the automatic method was 2-3 s as compared to 10 min for the current analytical method. **Conclusion:** We developed a fully automatic myocardial uptake quantification analytical program for the ^{123}I-MIBG myocardial uptake quantification method. This program contributes to improving reproducibility and reducing the time of analysis of the method. **References:** None.

TEPS-42

Accuracy of Planar Scan based and SPECT/CT based Quantification Methods in Bone Scintigraphy

D. Sercic[1,2], *A. Doma*[1], *I. Zagar*[1], *D. Skrk*[3];
[1]*Institute of Oncology Ljubljana, Ljubljana, SLOVENIA,* [2]*Faculty of Health Sciences, University of Ljubljana, Ljubljana, SLOVENIA,* [3]*Slovenian Radiation Protection Administration, Ljubljana, SLOVENIA.*

Aim/Introduction: Main purpose was to compare the results of the planar scan based and SPECT/CT based technique of activity quantifications and to determine the existence of possible correlations. In addition, to determine the potential impact of different patient based or acquisition dependent variables. **Materials and Methods:** The retrospective study included 90 osteoblastic skeletal lesions in 66 patients (30 males, 36 females) who had planar whole body bone scintigraphy and regional SPECT/CT performed at our institution between November 2017 and December 2018. Mean age of patients was 63 (17 - 89) years. Mean BMI was 28.7 (20.1 - 36.9) kg/m². The mean time between planar scan and SPECT/CT was 52 (22 - 166) min. The activity in lesions on planar images was calculated from measured activity in two opposite 2D projections against a known activity (standard source): $[ACTIVITY_{lesion}/((COUNTS_{lesionAP}-COUNTS_{bgdAP})+(COUNTS_{lesionPA}-COUNTS_{bgdPA}))/2=ACTIVITY_{std}/((COUNTS_{stdAP}-COUNTS_{bgdAP})+(COUNTS_{stdPA}-COUNTS_{bgdPA}))/2]$. Data was corrected for radioactive decay, absorbed and scattered counts accordingly. The commercially available SPECT/CT Q.Metrix quantification software (GE Healthcare inc.) was used to calculate quantification in SPECT/CT (3D) data. Several variables were analyzed: patient's gender, age, body mass index (BMI), measured activity in lesion (% of injected activity), time between application of radiopharmaceutical and the beginning of data acquisition, time between planar and SPECT data acquisition. Wilcoxon test of 2 samples was used for comparison of two methods of quantification. Depending on the data normality, independent samples T - test and Mann-Whitney U test were used to determine potential impact of different variables. **Results:** The difference between two quantification methods was statistically significant ($p \leq 0.001$). Difference in quantification between two methods (Mean ± STD) was 16.9% ± 28.2 (absolute difference 27.8 ± 17.3). There was a strong linear correlation between both quantification methods (the Pearson correlation value = 0,952). Based on linear regression analysis, the model was defined ($Q_{SPECT}=-0.032+1.536\times Q_{Planar}$; $R^2=0.91$) to predict the result of one method of quantification using the result of the second method. The level of measured activity in skeletal lesion affected the difference in results between both quantification methods ($p=0.008$). Other tested variables were not statistically significant. **Conclusion:** The difference between two methods of activity quantification was statistically significant. Quantifications based on planar scans and SPECT acquisition were in strong linear correlation. Quantification results are however unreliable in lesions with high osteoblastic activity on bone scans. Quantification of activity in skeletal osteoblastic lesions is independent of other tested variables. **References:** None.

TEPS-43

Evaluation of cingulate island sign ratios for the differentiation of dementia with Lewy bodies versus Alzheimer's disease using ^{123}I-IMP SPECT

N. Hayashi, *Y. Murata, A. Hirota, N. Akagi, H. Iwasa, K. Ito, H. Kazui, T. Yamagami;*
Kochi Medical School Hospital, Nankoku, JAPAN.

Aim/Introduction: Preserved activity in the posterior cingulate gyrus relative to the precuneus is called the cingulate island sign (CIS), which has been reported as a characteristic finding in dementia with Lewy bodies (DLB). Recently, the CIS ratio has been suggested to differentiate DLB from Alzheimer's disease (AD). The CIS ratio using ^{18}F-FDG PET or ^{99m}Tc-ECD SPECT, could be useful; however, that by ^{123}I-IMP SPECT has not been established. Therefore, the goals of this study were as follows: 1) to optimize image reconstruction and volume of interest (VOI) placement for calculating the CIS ratio, and 2) to determine the accuracy and cut-off value for ^{123}I-IMP SPECT. **Materials and Methods:** Seven patients with DLB and 17 patients with AD (including probable) underwent ^{123}I-IMP SPECT in this retrospective study. SPECT imaging was performed for 28 minutes after ^{123}I-IMP administration. Five images were generated using different image reconstruction methods (Flash 3D™ and FBP) and different correction methods (attenuation and scatter). Each image was evaluated by 3 VOIs. The CIS ratios were calculated as a ratio of posterior cingulate to occipital activity. The CIS ratio to distinguish DLB from AD was evaluated using the area under the curve (AUC) of the receiver operating characteristic (ROC). **Results:** The largest values for the AUC and accuracy were obtained from Flash 3D (CTAC+, SC+) and FBP (Chang+, SC+). The cut-off value, AUC, and accuracy were 0.901, 0.765, 83.3% and 0.936, 0.790, 79.2%, respectively. **Conclusion:**

Our results would provide a foundation for use of the CIS ratio on ^{123}I-IMP SPECT. The CIS ratio on ^{123}I-IMP SPECT could be useful with a cut-off value of 0.901 using Flash3D (CTAC+, SC+) in our institution. **References:** None.

TEPS-44

Introduction of a New 3D Analysis for the DATscan and the Realisation of a larger and more up to date Reference Set

A. Gelderblom[1], *P. Brinks*[2], *J. Habraken*[1], *J. Lavalaye*[1], *J. Salcedo*[1], *M. Vredenduin*[1];
[1]*St Antonius Hospital, Nieuwegein, NETHERLANDS,*
[2]*Diakonessenhuis, Utrecht, NETHERLANDS.*

Aim/Introduction: Dopamine transporter (DAT) scan analysis is now performed using a 2D software package with regions of interest in caudate nucleus and putamen. This requires several manual acts and is laborious and time-consuming. Manual processing may also cause differences in outcome due to inter-observer variance. A new software package - the BRASS analysis - can execute a fully automated 3D analysis. This project was set up to implement this new analysis. **Materials and Methods:** We selected a consecutive series of 149 patients with DAT scans between 2014 and 2016, allowing for at least two years of follow-up. The final diagnosis of the neurologist was used as a gold standard. 59 patients were clinically diagnosed with Parkinson's disease (PD), 65 were labelled normal. We excluded 25 patients, mostly because of a different diagnosis. The 124 patients were analysed with the BRASS programme. We related the resulting uptake values of the normal scans to the patient's age. With these results, we created four trend lines with a confidence interval of 2 SD. We then plotted the PD scans against these trend lines to assess how many would fall within the confidence interval. **Results: Conclusion:** The new BRASS method provides a semi-quantitative analyses that gives results matching clinical outcome but without the manual manipulations. This diminishes inter-observer variance and will therefore improve outcome reliability. **References:** None.

Cut-Off Frequency Optimization on Hot Bone Spine Lesions in 99mTc-HDP SPECT-CT

C. Ferreira, *C. Low*, *N. Rao*, *J. Cullis*;
University Hospital of Coventry and Warwickshire, Coventry, UNITED KINGDOM.

Aim/Introduction: Bone scans are the most commonly used imaging protocol in nuclear medicine. SPECT-CT is used to provide anatomic localisation of the detected lesions and has higher sensitivity than planar imaging alone. It also has a lower cost than PET-CT. When optimising SPECT-CT it is important to consider the reconstruction process because of the degrading imaging effects, like attenuation, scatter and depth-dependent resolution. The aim is to investigate the effects of varying cut-off frequencies on the contrast, signal-to-noise ratio and visual analysis whilst maintaining the order of the Butterworth filter constant. **Materials and Methods:** SPECT-CT bone scans are locally acquired on a GE Discovery 670 using a 20% energy window centred at 140 keV, LEHR collimators, 120 projections and 25 seconds per projection. These images are reconstructed using an iterative algorithm (2 iterations and 10 subsets) and filtered using a Butterworth filter (cut-off and order of 0.48 cycles.cm^{-1} and 10 respectively). The SPECT-CT images from 25 patients (12 males, 13 females, average age of 61.5±13.9 years) with spine lesions were reconstructed with different Butterworth frequency cut-offs (0.38, 0.48 and 0.68 cycles.cm^{-1}) and compared. Images were compared both subjectively by three consultants and quantitatively using contrast and signal-to-noise ratio. **Results:** The contrast increased significantly ($p<0.005$), but the signal-to-noise ratio decreased significantly ($p<0.005$) when the cut-off frequency was increased. Subjective assessment by three consultants inferred that the cut-off frequency of 0.68 cycles.cm^{-1} was considering optimal as this cut-off allowed for the detection of more lesions. The size of the lesions was also taken into consideration. Lesions with a larger size had increased contrast and a decreased signal-to-noise ratio, with the opposite being verified for small lesions. **Conclusion:** Before selecting the cut-off frequency it is important to take into account the size, intensity and localisation of the lesion. Image quality and clinical analysis of the images were found to be improved with a cut-off of 0.68 cycles.cm^{-1} in patients with spine lesions as it increased the number of detected lesions and the contrast of the images. **References:** Sayed, Inayatullah Shah & Syahirah Mohamed Nasrudin, Nor. (2016). Effect of Cut-Off Frequency of Butterworth Filter on Detectability and Contrast of Hot and Cold Regions in Tc-99m SPECT. TEPS-46

The Influence Of Attenution Correction On The Image Quality In Single Photon Emission Computed Tomography

S. Rep[1], *N. Frelih*[1], *L. Lezaic*[1], *J. Zibert*[2];
[1]*University Medical Centre Ljubljana, Ljubljana, SLOVENIA,* [2]*Faculty of Health Sciences, University of Ljubljana, Ljubljana, SLOVENIA.*

Aim/Introduction: Attenuation has a strong influence on the data and consequently on the quality of the image. Attenuation correction corrects the weakening of the rays in various depths. The non-diagnostic, low-dosage CT is usually used for the attenuation correction when the images are taken with the

SPECT/CT. The aim of this master's thesis is to find out how the attenuation correction in the case of the SPECT/CT influences the quality of the image. **Materials and Methods:** The Phantom NEMA IEC BodyPhantom was filled with the isotope technetium-99m. Eight images were captured, each with a different ratio of the specific activity between the phantom background and the spheres. The images were reconstructed in the program called Oasis by three different reconstructions: the filtered back projection, the non-corrected iterative reconstruction, and with the attenuation correction using the CT. The number of counts in the background and in all six spheres was measured. This was followed by the comparison of the contrast in images that were reconstructed using different methods. According to evaluated data, appropriate statistical analyses were performed: descriptive statistic, repeated measures ANOVA and Wilcoxon signed-rank test were conducted in Matlab. **Results:** On the images that were processed by the filtered back projection or the iterative reconstruction, the background is not homogeneous. On the images that were corrected using the CT, the number of counts is evenly spread across the entire background of the phantom, thus making the background homogeneous. The statistical analysis showed that contrast is typically significantly divergent among the different methods of reconstruction ($p < 0.005$). **Conclusion:** It was discovered that the increase in the number of counts, and consequently the image contrast, is proportional to the size of the sphere, and to the increased ratio of activity between the background and the sphere with all three types of reconstruction. The CT-AC images have the best contrast; images with iterative reconstruction are second best; images processed by the filtered back projection are third. Because the CT-AC images are of better quality than the non-corrected images, it is recommended that the CT-AC be used for all tests; however, due to the removal of artefacts caused by attenuation correction, it is also important to examine the non-corrected images every time. **References:** Grosser O S, Kupitz D, Ruf J et al. (2015). Optimization of SPECT-CT Hybrid Imaging Using Iterative Image Reconstruction for Low-Dose CT: A Phantom Study.

TEPS-47

Usefulness of partial volume effect correction in ^{201}Tl/^{123}I dual-isotope myocardial SPECT on CZT-SPECT camera

D. Ichioka[1], *S. Shiraishi*[2], *S. Tomiguchi*[3];
[1]*Graduate School of Health Science, Kumamoto, JAPAN,*
[2]*Kumamoto University Hospital, Kumamoto, JAPAN,*
[3]*Faculty of Life Sciences, Kumamoto, JAPAN.*

Aim/Introduction: A cadmium zinc telluride (CZT) detector single photon emission computed tomography (SPECT) device (CZT camera) has better energy resolution than a conventional NaI detector SPECT device, so it is reported its usefulness on dual-radionuclide imaging. However, affect of partial volume effect (PVE) to quantitative assessment of the myocardial radioactivity has not been evaluated enough. The aim of this study was to evaluate the usefulness of PVE correction for the estimation of ^{201}Tl and ^{123}I myocardial radioactivity in ^{201}Tl/^{123}I dual-isotope myocardial SPECT using CZT-SPECT camera by phantom study. **Materials and Methods:** ^{201}Tl, ^{123}I and ^{201}Tl+^{123}I water solutions were injected into the various sizes of rods in rod phantom and myocardial part of a chest myocardial phantom, respectively. SPECT data were acquired with list mode using a CZT-SPECT camera (Discovery NM 530c, GE). Each SPECT image was reconstructed with CT attenuation correction and scatter correction using triple energy window (TEW) method. Recovery coefficient (RC) curve for full width at half maximum (FWHM) was obtained from rod phantom images, and PVE correction was performed using RC corresponding to FWHM of the myocardial wall thickness using myocardial part in the chest phantom. The relative error was calculated by using the estimated value of myocardial radioactivity concentration and the measured true value. **Results:** Underestimation of myocardial radioactivity concentration was observed in under 20mm diameter of ^{201}Tl and ^{123}I rods. Relative error after PVE was within 10% between the estimated and true value of each rod size. **Conclusion:** PVE correction using RC in addition to attenuation and scatter correction was suggested to be useful for quantitative estimation of myocardial radioactivity in ^{201}Tl/^{123}I dual-isotope myocardial SPECT. **References:** None.

TEPS-48

The Evaluation of the impact of ^{99m}Tc gamma rays on x-ray detectors during a CT low dose acquisition

A. Resende Geao, *A. Santos;*
Hospital CUF Descobertas, Lisboa, PORTUGAL.

Aim/Introduction: The objective of this study was to study the potential impact of gamma photons with energy of 140Kev from ^{99m}Tc decay in ^{99}Tc, in CT for anatomical reference or for attenuation correction, considered low dose CT. Both x-ray and gamma ray are electromagnetic radiation and both have similar chemical and physical characteristics. With the newest SPECT/CT equipment installed on our Nuclear Medicine department we wanted to evaluate the impact of gamma rays on x-ray detectors during SPECT/CT and the possibility of gamma-generated noise on CT images. **Materials and Methods:** To evaluate the contribution of photons from technetium, gamma photons with an energy of 140 kV, in low dose CT, when a SPECT / CT is performed. Acquisitions were made in every combinations possible of mA and kV for the new GE 850. First with the phantom filled with water and then 740MBq (20mCi) of ^{99m}Tc were added and the same acquisitions were performed. The study was performed on our Gamma Camera (SPECT/CT) with the Jaszczak Phantom. **Results:** After reviewing the images for each acquisition parameter of low dose CT, with and without ^{99m}Tc activity, no significant different values were found in any of these images. These results suggest that any scattered radiation emitted from the phantom was eliminated and excluded by CT detectors. **Conclusion:** Although theoretically unlikely for gamma rays to affect CT acquisition, this study was performed to test the possibility that gamma rays can cause increased noise on CT images. After reviewing the images and comparing

hounsfield units and the standard deviation of the ROI values, no obvious noise was found. The number of x-ray photons is very high compared with gamma photons even for the low dose CT aqqisition and a high ^{99m}Tc activity. **References:** None.

The effect of metal artifact reduction on quantitative SPECT/CT imaging

T. Konishi[1], *T. Shibutani*[2], *K. Okuda*[3], *H. Yoneyama*[1], *R. Moribe*[1], *M. Onoguchi*[2], *K. Nakajima*[4], *S. Kinuya*[5];
[1]*Department of Radiological Technology, Kanazawa University Hospital, Kanazawa City, JAPAN,* [2]*Department of Quantum Medical Technology, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa City, JAPAN,* [3]*Department of Physics, Kanazawa Medical University, Kahoku-gun, JAPAN,* [4]*Department of Functional Imaging and Artificial Intelligence, Kanazawa University, Kanazawa City, JAPAN,* [5]*Department of Nuclear Medicine, Kanazawa University Hospital, Kanazawa City, JAPAN.*

Aim/Introduction: Metal implants have been proven to cause severe artifacts on computed tomography (CT) images, which can affect CT attenuation correction (CTAC) for quantitative single-photon emission computed tomography (SPECT)/CT. Several studies have reported that metal artifact reduction (MAR) technology has improved image quality of CT and the quantitative accuracy of the standardized uptake values (SUVs) of positron emission tomography /CT. Recently, MAR technology has been introduced for SPECT/CT and may prove to be useful. This study aimed to evaluate the effect of MAR on quantitative SPECT/CT. **Materials and Methods:** We used an elliptic cylinder phantom filled with Tc-99m uniform solutions in which two artificial hip prostheses were set to acquire SPECT/CT images. Radiotracer concentration was 64.7 kBq/ml. The artificial joints comprised femoral stem, femoral head, and acetabular components, which were made of metal alloy. SPECT/CT images were reconstructed using CT data processed with and without MAR for CTAC. Quantitative SPECT/CT images with and without MAR were created and compared. Total 44 circular regions of interest (ROIs) were set on the CT and SPECT/CT images with a diameter of 13.5 mm (5.0 pixels). Fourteen ROIs were placed in the dark streak areas in which Hounsfield units (HUs) could be underestimated, 19 in the white streak areas in which HUs could be overestimated, and 11 in the non-artifact areas. We compared mean SUVs (SUV_{means}) obtained from quantitative SPECT/CT images with and without MAR to evaluate the effect of MAR on quantitative SPECT/CT. **Results:** There was a remarkable reduction in metal artifacts on CT images processed with MAR. For ROIs in the dark streak areas, the use of MAR increased SUV_{mean} from 0.91 ± 0.15 to 1.03 ± 0.06 ($P < 0.001$), whereas for ROIs in the white streak areas, the use of MAR decreased SUV_{mean} from 1.07 ± 0.05 to 1.04 ± 0.05 ($P < 0.001$). There was no significant difference in SUV_{mean} with and without MAR in the non-artifact areas. We observed errors in SPECT/CT quantification from −29.1% to +16.7% without MAR, depending on the ROI localization. When MAR was used, these errors were reduced to a range between −7.45% and +13.1%. **Conclusion:** Results of this study indicated that MAR could improve the quantitative accuracy of SPECT/CT. MAR can serve as a practicable technique for quantitative SPECT/CT in patients with metal implants. **References:** None.

Performance Evaluation of a New Collimator Optimized for ^{177}Lu Preclinical SPECT Imaging

N. Colpo[1], *C. Uribe*[1], *J. Rousseau*[1], *C. Kamphuis*[2], *F. Beekman*[2,3], *F. Bénard*[1,4];
[1]*BC Cancer, Vancouver, BC, CANADA,* [2]*MILabs B.V., Utrecht, NETHERLANDS,* [3]*Delft University of Technology, Delft, NETHERLANDS,* [4]*University of British Columbia, Vancouver, BC, CANADA.*

Aim/Introduction: There is growing interest in radiopharmaceutical development for radioligand therapy; ^{177}Lu is a popular radioisotope for this purpose. This study aims to design and evaluate a new collimator optimized for ^{177}Lu imaging. Performance was also evaluated for other isotopes. **Materials and Methods:** We designed a collimator (XUHS-BM) for the MILabs U-SPECT^{+}/CT with a larger bore to accommodate bigger/mature mice with subcutaneous xenografts. An increased bore thickness was used to reduce penetration from higher energy gammas. Qualitative Jaszczak hot rod phantom and quantitative line sources (0.38mm diameter) with ^{99m}Tc, ^{177}Lu, ^{111}In and ^{67}Ga were scanned for 1h using a rat/mouse collimator (UHR-RM, previously used to image larger mice) and the new XUHS-BM. Images were reconstructed (20% wide photopeak windows: ^{99m}Tc (140kev), ^{177}Lu (208keV), ^{111}In (173 and 247keV), ^{67}Ga (93, 184 and 300keV) using the similarity regulated ordered subset expectation maximization algorithm (64 subsets, 3 iterations) with scatter correction and 0.4mm voxel size. Spatial resolution was determined by visually inspecting the rods in the Jaszczak image (0.85, 0.95, 1.1, 1.3, 1.5, 1.7mm) and by calculating the full width half maximum (FWHM) of the line sources. The energy spectra of different bed positions from uniform cylinder scans were added to determine the total detected events for each photopeak. The total events, measured activity, and scan time provided the sensitivity in cps/MBq. The system energy resolution of each photopeak in the energy spectrum was determined by calculating the FWHM. **Results:** The spatial resolutions of XUHS-BM were 0.7mm (^{99m}Tc), 0.8mm (^{67}Ga) and 0.9mm (^{177}Lu, ^{111}In). Rods in the Jaszczak were better visualized with XUHS-BM than UHR-RM images, due to improved count statistics. The sensitivity of XUHS-BM was 3.6 times greater for ^{99m}Tc, ^{111}In and ^{177}Lu and 2.1 times greater for ^{67}Ga compared with UHR-RM. System energy resolutions for each photopeak/isotope slightly improved with the XUHS-BM compared to the UHR-RM (from 10.3% to 9.8% for ^{177}Lu, 208keV). Significant improvements in image quality were seen including ^{177}Lu at low activity levels. **Conclusion:** A custom-designed collimator showed higher sensitivity and excellent qualitative

spatial resolution compared to a rat/mouse collimator, resulting in superior image quality for a variety of radiopharmaceuticals. Improved system energy resolution could be due to lower septal penetration. Our results suggest that the new XUHS-BM collimator is an interesting alternative to image larger mice with SPECT radioisotopes using low levels of injected activity. **References:** None.

TEPS-51

Repeatability and stability evaluation of ^{177}Lutetium quantification

***M. C. Dekker**, D. M. V. Huizing, B. J. de Wit - van der Veen;*
Antoni van Leeuwenhoek, Amsterdam, NETHERLANDS.

Aim/Introduction: The aim of this study is to evaluate the repeatability and stability of ^{177}Lutetium (^{177}Lu) quantification on our Siemens Symbia TruePoint SPECT-CT. **Materials and Methods:** A vial (~20 ml) with a known amount of ^{177}Lu was positioned next to the patient during post-therapy planar gamma and SPECT-CT acquisitions, after intravenous injection of 7400 MBq ^{177}Lu-DOTATATE. Planar gamma images acquired 0.5, 4, 24 and 72 hours post-injection were used for repeatability evaluation. A ROI with a diameter of 5 cm was drawn in the middle of the vial on both posterior and anterior view to determine the sum of the counts. Accordingly, the geometric mean was calculated to correct for different detector distances. The geometric mean was correlated to the activity in the vial at the time of the acquisition. SPECT-CT scans performed 24 hours after injection were used to evaluate quantification stability over time. A cylindrical VOI with a diameter of 4cm radius was drawn around the vial and the sum of counts in the VOI was compared with the activity in the vial at the time of acquisition. All analysis was performed using PLANET Onco (DOSIsoft, Cachan, France). **Results:** Planar imaging series of 9 patients were used to assess quantification repeatability, with a mean activity of 94.1 MBq (range 39.4-141.6) in the vials. The first scan at 0.5h post-injection was used as the reference time point. A mean difference of 13.7% between the first and all other scans was observed, with differences ranging from 0.4% to 51.4%. A total number of 36 SPECT-CT scans (of which 24 were usable) performed between March 2016 and January 2019, were used to evaluate quantification stability. The mean activity in the vials was 72.4 MBq (range 30.0-122.0). The quantification stability assessment shows a steady line between the know amount of radioactivity and measured sum of counts over time, with a coefficient of variation of 6.8%. Two vials with high amounts of radioactivity (122.0 and 104.4 MBq) both underestimated the mean ratio between count and activity in de vial. **Conclusion:** Vial measurements on planar and SPECT-CT imaging showed repeatable and stable quantification for ^{177}Lu during three years. These results indicate that quantification with our Siemens Symbia TruePoint SPECT-CT is suitable for potential dosimetric analysis. This method is a reliable way to determine the stability of the camera. **References:** None.

Agreement between functional parameters of myocardial perfusion assessed with gated IQ-SPECT and conventional SPECT/CT

***W. Martínez**, V. Poblete García, E. Noriega Álvarez, E. Casillas Sagrado, A. García Vicente, Á. Soriano;*
Servicio de Medicina Nuclear. Hospital General Universitario de Ciudad Real, Ciudad Real, SPAIN.

Aim/Introduction: Aim: to compare values obtained with gated IQ-SPECT system with those obtained with a conventional device with low-energy high-resolution (LEHR) collimators. **Materials and Methods:** Methods: we prospectively evaluated 28 patients [mean age= 52.8-year-old (18-80), 27 men], with suspected coronary artery disease. All patients underwent a myocardial perfusion study (only stress for 24 patients and stress+rest for 4 patients) using both gamma-cameras consecutively. Each patient underwent a single injection of 20mCi of ^{99m}Tc-tetrofosmin. IQ-SPECT was equipped with Smartzoom collimators and images were acquired over 208º cardio-centric orbit with 17 views per detector and 9 seconds/view, zoom of 1, matrix of 128x128 and tolerance window of 40%.The conventional gamma-camera equipped with LEHR collimators was considered as the reference method. Gated-SPECT images were acquired over 180º thoraco-centric orbit, with 60 views of 35 seconds, matrix of 64x64, zoom of 1.3 and tolerance window of 40%. Uncorrected images and corrected (by CT) images were obtained.Mean and SD values of left ventricular ejection fraction (LVEF), end-systolic (ESV) and end-diastolic volumes (EDV) and SDs were calculated for each method. Mann-Whitney was performed to compare the values obtained with both techniques. p-values <0.05 were considered statistically significant. **Results:** Results: the total acquisition time was around 5 minutes using the IQ-SPECT, being shorter than 20 minutes used with conventional technique. The perfusion images were normal in all patients and they were similar with both techniques.The mean of LVEF, ESV and EDV obtained with conventional technique and IQ-SPECT were respectively: LVEF = 52.9% (49.2-56.6) and 48.1% (43.8-52.4); EDV = 114.8ml (100.9-128.7) and 108.4ml (94.6-122.2); and ESV = 56.8 ml (45.8-67.8) and 58.6ml (47.9-69.2). Not significant differences were found between these values (LVEF p = 0.08, EDV p = 0.50, ESV p = 0.81). Agreement degree on the functional parameters between both systems was 0.648 for the LVEF, 0.873 for the ESV and 0.934 for the EDV. **Conclusion:** Conclusions: our findings suggest a tendency of IQ-SPECT to produce smaller LVEF than conventional LEHR myocardial perfusion imaging. These findings are consistent with previous studies. **References:** None.

TEPS-53

Development of cardiac phantom for evaluation of fusion image of Myocardial perfusion imaging and CT-A

***A. Kikuchi**[1], Y. Honma[1], H. Honma[2], A. Andou[2], M. Kitama[1], G. Okuyama[1];*
[1]Department of Radiological Technology Faculty

of Health Sciences, Sapporo, JAPAN, [2]Ono Memorial Hospital, Sapporo, JAPAN.

Aim/Introduction: The usefulness of fusion images of CT angiography (CT-A) and Myocardial perfusion imaging (MPI) has been reported. However, MPI and CT-A fusion image accuracy has not yet been reported when creating fused images. That is because there was no phantom for CT-A, MPI image evaluation corresponding to both devices. Therefore, we developed a CT and MPI compatible hybrid phantom. **Materials and Methods:** The heart and trunk created a phantom using acrylic considering radiation absorption.In the lung part, a phenol resin was used in consideration of absorption.For the blood vessel model of the heart, the material of EPDM in consideration of the CT value at the time of imaging was used.Three 10 mm diameter acrylic markers are placed in the myocardium to verify the alignment accuracy of MPI and CT-A.We have verified marker detectability due to differences in imaging conditions such as pixel size, CT-A detectability has due to differences in CT imaging conditions, and verification of fusion image accuracy using images.As for the difference in detectability, MPI performed visual evaluation for circumferential-curve by axial image and verification of fusion image accuracy of processor.. **Results:** In the case of the pixel size of 3 mm, MPI was able to draw all the markers when the pixel size was 3 mm, but partially not able to be drawn when the pixel size was 6 mm. The CT-A model was able to be drawn regardless of the difference in imaging conditions. Fusion image accuracy was performed on CT-A and MPI, which differ in image conditions, but there was no discrepancy between CT-A and MPI in visual evaluation. From this, we were able to verify the Fusion image accuracy of the processor used this time. **Conclusion:** It has been confirmed that the CT-MPI hybrid phantom we developed are phantoms that did not use contrast agents and that could be used to verify the accuracy of fusion images. This said that to be because the installation position and size of the myocardial marker were appropriate in consideration of the resolution of the myocardial image. In the future, I would like to proceed with verification under more imaging conditions. **References:** Piccinelli M, Santana C, Sirineni GKR, et al. Diagnostic performance of the quantification of myocardium at risk from MPI SPECT/CTA 2G fusion for detecting obstructive coronary disease: A multicenter trial. Examination of myocardial extraction using Semantic Segmentation by Deep learning

K. Okada[1], *A. Kikuchi*[1], *T. Kawakami*[1], *Y. Honma*[1], *K. Nakajima*[2], *H. Yoneyama*[3];
[1]*Hokkaido University of Science, Sapporo, JAPAN,* [2]*Kanazawa University, Kanazawa, JAPAN,* [3]*Kanazawa University Hospital, Kanazawa, JAPAN.*

Aim/Introduction: In the examination using 99mTc preparation in cardiac nuclear medicine, extra-cardiac activity often affects myocardial image, and various measures have been reported. We apply the image processing technology using artificial intelligence, and report as we developed a method to extract only the myocardial region necessary for diagnosis at the image level. **Materials and Methods:** As myocardial extraction program, Semantic Segmentation 1) by Deep Learning model U-Net 2) was used. The data we used was an axial image, and pixels in images were manually labeled the myocardium, liver, small intestine, and BG. Accuracy and loss were examined using 1920 images as training data and 480 images as test data and 360 images as data for verification. Furthermore, since the pixels in images of BG was very large among the data as the number of training data, compared Dice coefficients with and without Class Weight. **Results:** In the result of the learning model which does not consider the difference in the number of learning, accuracy was close to 1 at around 100 epoch, but validation accuracy converged at around 0.9 Although loss decreased to near 0, validation loss increased and finally divergence at around 1.5. The same tendency was confirmed in any learning model. On the other hand, in the examination of the presence or absence of Class Weight which consider the difference in the number of learning, It was shown that there was almost no difference in Dice coefficients and it was found that it was not necessary to consider Class Weight. **Conclusion:** In this result, all learning models used this time, the accuracy and loss both show the same tendency, and it was found that which largely depends on the data used this time. In the future, it will be necessary to create a learning model using multicenter clinical data. **References:** [1] Jonathan Long, Evan Shelhamer, Trevor Darrell, "Fully Convolutional Networks for Semantic Segmentation", 2014.[2] Olaf Ronneberger, Philipp Fischer, Thomas Brox, "U-Net: Convolutional Networks for Biomedical Image Segmentation", 2015.

mcARM An Automated Motion Correction Algorithm For MPI Spect

A. Szucs[1,2], *Z. Fegyvári*[2], *B. Kári*[3,4,2], *O. Pártos*[4];
[1]*Eotvos Lorand University, Budapest, HUNGARY,* [2]*Mediso Medical Imaging Systems, Budapest, HUNGARY,* [3]*Semmelweis University, Department of Radiology, Budapest, HUNGARY,* [4]*Semmelweis University, Nuclear Medical Center, Budapest, HUNGARY.*

Aim/Introduction: In myocardial perfusion imaging patient motion can introduce hazardous effects in the reconstructed image volumes. The change in reconstructed left ventricle (LV) values can alleviate or increase total perfusion deficit (TPD) scores in patients, leading to repeated acquisition or misdiagnosis of patient data. A fully automatic image space method working in complete field-of-view (FOV) is created applying image analysis on the projection frames and the reconstructed volume as well. The combined techniques (image space and reconstructed volume space) are designed to increase accuracy of the detected motion vectors. **Materials and Methods:** We

propose an image based automatic method that estimates motion vectors based on a multi-stage pipeline. As a first step, a sub-pixel accurate registration method is applied in an inter frame manner to detect larger (>= 2 pixels) movements on complete FOV projection images. In the second step, the motion corrected frames are reconstructed and we apply an automatic LV segmentation algorithm (ARM) on the reconstructed volume. The segmented LV mask is reprojected on each frame. As the third step, we run local Lucas-Kanade Optical Flow in a small neighborhood of the reprojected LV mask to capture smaller (<2 pixels) movements in the projection images. To handle sub-pixel accuracy motion correction, bilinear interpolation scheme is applied on the projection frames. The mcARM method was validated using physical phantom and patient studies as well using 99mTc MIBI, 99mTc Tetrofosmin radiotracers. Thirty-seven patients were evaluated following tracer injection on Mediso AnyScan systems. The performance of mcARM was compared against Cedars-Sinai MoCo method using OSEM reconstruction method. The detectability of perfusion defects caused by motion artifacts were evaluated quantitatively calculating the TPD scores, aided by visual interpretation of the sinogram and linogram of the corrected studies. **Results:** The proposed method (mcARM) showed significant improvement over MoCo based on our findings on both phantom and patient studies calculating the TPD scores and by visual interpretation. With a median age of 53.95 years and body weight of 81 kgs, the method was evaluated on 37 patients, 17 male and 20 female. The algorithm showed an improvement of 20% in the calculated TPD scores compared to MoCo and relative error of 10% compared to manually corrected images. **Conclusion:** A fully automatic complete FOV motion correction algorithm is introduced, with fast running times (2-4 seconds). Evaluation on patient and phantom studies showed promising results for future developments in automatic SPECT motion correction. **References:** None.

The use of effervescent granules in myocardial perfusion imaging; the full secret to a man's heart

J. Goh[1], *M. Ng*[1], *M. Chang*[1], *K. Tan*[1], *Y. Wong*[1], *Z. Huang*[2], *J. Tan*[2], *K. Tong*[3];
[1]*Sengkang General Hospital, Singapore, SINGAPORE,*
[2]*National Heart Centre, Singapore, SINGAPORE,*
[3]*Singapore General Hospital, Singapore, SINGAPORE.*

Aim/Introduction: Myocardial perfusion imaging (MPI) plays an integral role in diagnosing, managing and long-term follow up of patients with coronary artery disease (CAD). Radiopharmeceutical ^{99m}Technetium-sestamibi, is administered intravenously to depict the distribution of blood in the myocardium in MPI studies. Increased activity in subdiaphragmatic organs adjacent to the heart, especially bowel uptake, often interferes with the evaluation of the inferior myocardial wall. It results in either an underestimation or overestimation of the uptake in the inferior myocardial wall. Hence, a revised MPI technique with introduction of a sufficient quantity of not highly attenuating gas (4g EZ-GAS granules) into the stomach of patients to distend the stomach and consequently displace the organs adjacent to the heart was investigated. The aim of this study is to investigate if a distended stomach will aid in removing the gastrointestinal (GI) attenuation artefact and consequently, eliminate the false positive inferior wall defect seen in MPI. **Materials and Methods:** A prospective study of 120 patients undergoing either dipyridamole myocardial perfusion or RAMP exercise protocol or myocardial perfusion rest was conducted. Patients were allowed 100ml of water and 100ml of choice beverage with creamer prior to the SPECT scan. They were scanned at 30 - 60 minutes post ^{99m}Technetium-sestamibi injection. 4g of sodium bicarbonate-citric acid-simethicone effervescent granules (EZ-GAS) with 30ml of water was given to each patient after the first scan and a repeat scan was performed immediately. The presence of activity in the liver, bowel and stomach were determined visually on reconstructed images. A reduction by 3 or more reconstructed image slices with visible GI activity between the initial and repeated scan was assumed as bowel displacement by distension of stomach. Image interpretation was conducted by 2 independent nuclear physicians. **Results:** 25 of the patients (approximately 20%) showed negligible to no change in the GI activity seen on the initial and repeated scan images. 58 patients (approx. 50%) demonstrated slight to moderate changes in the GI activity seen between the initial and repeated scan images. The remaining 37 patients (approx. 30%) were reported with noticeable changes in the GI activity between the initial and repeated scan images. **Conclusion:** A distended stomach does reduce the frequency of "hot" GI activity seen on the reconstructed images slices, thereby improving the activity counts of the inferior myocardial wall. **References:** Van Dongen, A. J., & Van Rijk, P. P. (2000). Minimizing liver, bowel, and gastric activity in myocardial perfusion SPECT.

Diagnostic utility of 99mTc-DPD scintigraphy in patients with suspected cardiac amyloidosis

E. N. Andersen[1], *A. Hodt*[1], *E. Gude*[2], *T. Bach-Gansmo*[1];
[1]*Oslo University Hospital Ullevål, Departement of Radiology and Nuclear Medicine, Oslo, NORWAY,* [2]*Oslo University Hospital Rikshospitalet, Departement of Cardiology, Oslo, NORWAY.*

Aim/Introduction: The aim of this prospective investigation was to determine the diagnostic utility of ^{99}mTc-3,3-diphosphono-1,2-propanodicarboxylic- acid (DPD) scintigraphy in patients referred with echocardiographic signs of myocardial hypertrophy potentially related to amyloidosis. **Materials and Methods:** The study was performed at Oslo University Hospital and was performed on all patients who underwent evaluation for suspected cardiac amyloidosis in the period of November 2018 and April 2019. Of approximately 50 planned patients, 11 patients (8 males, and 3 females, median age 71) have so far been included with written consent. At the time of writing

cardiac biopsy has been performed in 6 patients. Patients were scanned using one Siemens hybrid SPECT/CT (Symbia Intevo Bold) with a low-energy high-resolution (LEHR) collimator after intravenous injection of 700 MBq of 99mTc-DPD. Whole body (WB) scintigraphy was performed approximately 3 hours post-injection. SPECT/CT was performed in patients with visually detectable uptake in the myocardium. The whole body scans was visually scored with the grading devised by Perugini et al.[1] **Results:** Of the 11 99mTc-DPD patients, the WB were clearly negative in 8 patients, slightly positive in 1 patient (Perugini grade 1), positive in 1 (Perugini grade 2), and strongly positive in 1 patient (Perugini grade 3). Cardiac biopsy was positive for transthyretrin (TTR) in the Perugini grade 3 case, and Perugini Grade 1 patient had light chain (AL) amyloid deposits. For the patients with negative DPD scintigraphy, 1 was positive for light chain amyloidosis, and 3 patients had negative biopsies with regards to amyloidosis. **Conclusion:** The incidence of TTR is low in our population of patients with hypertrophic cardiomyopathy, and some uptake of DPD can be visualized in patients with light chain amyloidosis. **References:** Perugini, E., Guidalotti, P. L., Salvi, F., Cooke, R. M., Pettinato, C., Riva, L., ... & Fallani, F. (2005). Noninvasive etiologic diagnosis of cardiac amyloidosis using 99mTc-3, 3-diphosphono-1, 2-propanodicarboxylic acid scintigraphy. Journal of the American College of Cardiology, 46(6), 1076-1084.

Analysis Of Influence Factors And Correlation For Quality Of Wholebody Bone Scan Imaging

T. Lu, G. Yang;
Shandong Cancer Hospital affiliated to Shandong University, JInan In ShanDong province, CHINA.

Aim/Introduction: Whole-body bone is the most common examination in nuclear medicine. It can clearly show the bone morphology and reflect bone metabolism; good image quality is critical to clinical diagnosis. This paper aims to analyze the influencing factors and correlation of the quality of whole-body bone imaging, and propose improvement measures to improve image quality. **Materials and Methods:** A retrospective study was selected on 1524 patients who received whole-body bone scan in nuclear medicine department from Apr 1 2018 to Aug 30 2018 in Shan Dong Tumor Hospital; The image quality was classified into A(good quality), B(normal quality) and C(poor quality) according to the clinical evaluation index of SPECT/CT instrument; Summarizing gender, age, blood calcium, urea nitrogen, creatinine, body mass index (BMI), injection to imaging interval, nuclide abnormal concentration at the injection site, treatment measures, bladder filling status, soft tissue intake, foreign bodies and nuclide contamination, etc; measurement data who have influence on image quality are further grouped and compared between groups; using variance analysis and graded logistic regression analysis to analyze influencing factors and correlation for quality of whole-body bone scan imaging, and proposing improvement methods. **Results:** In this study, 40% patients had good imaging quality, 50.3% patients with general imaging quality and 9.7% patients with poor imaging quality. The quality of the whole-body bone scan was correlated with gender(X^2=65.642,p=0.010), age (X^2=9.227,p=0.002), blood calcium(X^2=4.615,p=0.032), BMI(X^2=8.975, p=0.003), injection to imaging interval(X^2=20.890, p=0.001), nuclide abnormal concentration at the injection site(X^2=9.227. p=0.002), radiotherapy(X^2=3.115, p=0.003), bladder filling state(X^2=15.644, p=0.001) and soft tissue uptake(X^2=35.642, p=0.001); urea nitrogen, creatinine, foreign body and nuclide contamination were not statistical correlation with image quality. The first influencing factor was injection technique, accounting for 10.8%, followed by high soft tissue intake and bladder filling, accounting for 7.4% and 6.6%, respectively. Comparison between BMI and serum calcium showed that patients with ages less than 45 years and BMI less than 23.9 had better imaging quality, and there was no statistical difference between blood calcium groups. **Conclusion:** There are many factors affecting the quality of whole-body bone scan images in clinical work; the main factors are injection site and technique, soft tissue intake, bladder filling state, injection to imaging interval; followed by gender, age, BMI and blood calcium. Improving injection techniques, reducing soft tissue intake and emptying the bladder before examination can significantly improve the quality of imaging. **References:** None.

Performance And Analysis Of Vertebral $^{99}Tc^{M}$-mdp Uptake After Chest Tumor Radiotherapy

T. Lu, G. Yang;
Shandong Cancer Hospital affiliated to Shandong University, JInan In ShanDong province, CHINA.

Aim/Introduction: To analyze the changes in vertebral 99Tcm-MDP uptake and the correlation with clinical radiotherapy parameters in chest tumor patients. **Materials and Methods:** A retrospective study was conducted in 110 patients who underwent chest tumor radiotherapy in our hospital from April 20, 2014 to October 31, 2018; and performed whole-body bone scan before and after radiotherapy. The clinical information, tumor factors and radiotherapy plan were analyzed by semi-quantitative analysis. We divided the results of bone scan into normal vertebral uptake group and abnormal vertebral uptake group, meanwhile analyzed the change in vertebral body 99Tcm-MDP uptake and the correlation with clinical radiotherapy parameters. Calculated (T/N前) - (T/N后)/(T/N前), draw ROC curve, and found the best diagnosis threshold of vertebral 99Tcm-MDP uptake abnormality. **Results:** In 110 patients, 48(43.6%) patients had local poor vertebral radioactivity uptake, with minimum vertebral exposure dose 1039.5cGy, maximum dose 4480cGy, and average dose 2139.5cGy; the shortest imaging interval was 61 days; and the remaining 62(56.4%) patients had no obvious abnormal radioactive uptake. The degree of vertebral body uptake was correlated with radiotherapy dose(X2=4.401,p=0.036),

radiotherapy frequency(X2=2.241,p=0.027), vertebral body irradiation dose(X2=5.913,p=0.015) and the imaging interval before and after radiotherapy(X2=12.542,p=0.013); and was no statistical correlation with age, gender, BMI, single radiotherapy dose, PTV, PTV dose, vertebral irradiation volume and the distance from radiotherapy target center to vertebral center. Grouped imaging intervals and compared between groups, we found that there was a difference between 3-6 months and 7-12 months in vertebral body uptake, abnormal vertebral 99Tcm-MDP uptake at intervals less than 6 months accounted for 2/3. The sensitivity and specificity of evaluating the 99Tcm-MDP uptake abnormality were 74.6% and 82.9% respectively. The area under the curve was 0.934 by ROC curve, indicating that (T/N前) - (T/N后)/(T/N前) was better for evaluating change rate of 99Tcm-MDP uptake in vertebral body, and the optimal diagnostic threshold for 99Tcm-MDP uptake abnormality in vertebral body was 0.161. **Conclusion:** 99Tcm-MDP uptake in vertebral after radiotherapy with chest tumor is closely related to radiotherapy dose, radiotherapy frequency, vertebral irradiation dose and imaging interval. With radiotherapy dose, radiotherapy frequency and vertebral body irradiation dose increased, the probability of abnormality of 99Tcm-MDP uptake is greater; and the earlier imaging time after radiotherapy, the higher detection rate of vertebral injury. The change of vertebral body 99Tcm-MDP uptake can reflect the degree of radioactive vertebarl damage to some extent. **References:** None.

TEPS-60

Quantitative accuracy of standardized uptake value (SUV) for xSPECT Bone technology using new supine phantom

T. Shibutani[1], *M. Onoguchi*[1], *T. Konishi*[2], *H. Yoneyama*[2], *H. Ichikawa*[3], *K. Okuda*[4], *K. Nakajima*[5];
[1]*Department of Quantum Medical Technology, Institute of Medical, Pharmaceutical and Health Sciences, Kanazawa University, Kanazawa city, JAPAN,* [2]*Department of Radiological Technology, Kanazawa University Hospital, Kanazawa city, JAPAN,* [3]*Department of Radiological Technology, Toyohashi Municipal Hospital, Toyohashi city, JAPAN,* [4]*Department of Physics, Kanazawa Medical University, Kanazawa city, JAPAN,* [5]*Department of Functional Imaging and Artificial Intelligence, Kanazawa University, Kanazawa city, JAPAN.*

Aim/Introduction: Standardized uptake value (SUV) of bone SPECT using xSPECT Bone technology has clinically been used as a quantitative index. Although some fundamental research of xSPECT Bone technology has been reported, the phantom study simulated human body has not been performed. We demonstrated the quantitative accuracy of SUV for xSPECT Bone algorithm using the phantom simulated human body. **Materials and Methods:** Phantom was used as a Sim² bone phantom (Kyoto Kagaku, Co., Ltd., Japan), which simulated the thorax portion including spine and lung. The supine is composed different 5 tumor regions (the diameter of the sphere: 13, 17, 22 and 28mm, and whole vertebral body: diameter of 36mm and length of 35mm) in the vertebral body. We prepared K_2HPO_4 solution of cortical and soft bone regions (CT value: 1000 and 300 HU) for the phantom. Tumor and normal bone parts were filled with a mixed solution of ^{99m}Tc and K_2HPO_4 of 300 and 50 kBq/mL, respectively. The body part was also filled with a ^{99m}Tc solution of 8 kBq/mL as background (BG). Radioactive concentration ratio of tumor, normal and B.G were 6:1:0.16. SPECT/CT scanner used a dual-head Symbia Intevo BOLD (Siemens, Erlangen, Germany) equipped with a low-energy high resolution (LEHR) collimator. SPECT data were acquired with 256×256 matrices, 2.4 mm of pixel size, the circular orbit of 360° in 3° increments. SPECT images were reconstructed using ordered subset conjugate gradient minimization method incorporating xSPECT Bone algorithm. The volume of interests(VOI) were drawn on tumor parts and normal bone using GI-Bone software, and mean SUV was calculated. We calculated the recovery coefficient (RC) of other tumor region as a reference of the tumor region of the whole vertebral body. Mean SUV ratio (SUVR) of the tumor and normal bone parts was used to evaluate the contrast. **Results:** The SUV_{mean} for tumor region of the whole vertebral body and normal bone were 5.78 and 1.03 for soft bone, and 5.77 and 1.08 for cortical bone, respectively, and relative error was within 3-8%. The RCs of 13, 17, 22 and 28mm tumor regions were 33.7, 44.5, 58.9 and 77.2 for soft bone, and 32.9, 47.7, 62.3 and 82.8 for cortical bone, respectively. The SUVR of each tumor region was 1.9-5.6 for soft bone and 1.8-5.4 for cortical bone. **Conclusion:** The SUV calculated by xSPECT Bone algorithm showed high quantitative accuracy and could be a good basis for further clinical application. **References:** None.

TEPS-61

Creation Of A Labeled Technetium-99m Colloid Drug For The Detection Of Guarding Lymph Nodes

A. Rogov, *E. Stasyuk, E. Nesterov, V. Sadkin, E. Shelikhova;*
National Research Tomsk Polytechnic University, Tomsk, RUSSIAN FEDERATION.

Aim/Introduction: Lately the interest to use of radioactive colloidal nanomaterials in medicine has been grown. They found their application for labeling autoleucocytes, to carry out lymphoscintigraphy and to identify "sentinel" lymph nodes. The most suitable radionuclide for labeling nanoparticles is short-lived technetium-99m, which is today used for diagnosis in almost all areas of medicine. Preliminary studies have shown that stable colloidal compounds can be obtained by a simple way by means of adsorption of reduced technetium-99m on gamma-aluminum oxide. Selection for the use of aluminum oxide as a carrier of technetium-99m is its low toxicity and good adsorptive properties, availability, and low cost. At the same time, a crucial factor for success is not their chemical composition, but the size of nanoparticles.Aim:Obtaining suitable for tagging with technetium-99m aluminum nanopowder with particle size in the range of 50-100 nm. **Materials and Methods:** As the object of study the was used nanopowder gamma-oxide Al_2O_3. It prepared from nanopowder of aluminum hydroxide by its was gradually heating to 400°C for 2 hours. The particle

size was determined using electron microscope Philips SEM515. The average particle size is in the range of 100-200nm. Before the adsorption technetium-99m on oxide Al_2O_3 it was carried out acidizing. In this regard, were found the optimal conditions of oxides acidizing which maximum adsorption of ^{99m}Tc. The maximum of radionuclide adsorption is observed on oxide treated with HCl in an amount of $2 \cdot 10^{-4}$ mol/g. Technetium-99m presenting in the original eluate in the highest degree of oxidation (+7) and does not have a sorption capacity. **Results:** Therefore, research was made to of reduced technetium-99m in lower degrees of oxidation (+5) and it is more chemically active. To of reduced technetium-99m we used Tin(II) chloride dihydrate ($SnCl_2 \cdot 2H_2O$). When carrying out the synthesis of the drug used ultrasonic and vial with preparation was heated in a water bath (70-80°C) for 30min. In a finished pharmaceutical the particle size was determined by photons cross-correlation spectroscopy using analyzer of particle size Nanophox produced by company «Sympatec GmbH» **Conclusion:** The measurement showed that 85% of the particles are in the range of 95-150nm. These figures confirm suitability of the drug and the feasibility of conducting trials of the drug on laboratory animals in accordance with the European Convention for the Protection of Vertebrate Animals used for Experimental and other Scientific Purposes (Strasbourg, 1986). **References:** None.

Lymphoscintigraphy and sentinel node localization in gynaecological cancers into practice: a UK single-centre protocol

L. Pereira, K. Brooks, T. Barnden, O. Devaja, A. Corrigan;
Maidstone and Tunbridge Wells NHS Trust, Maidstone, UNITED KINGDOM.

Aim/Introduction: In the ESMO 2017 guideline on cervical cancer, the sentinel node (SLN) dissection is pointed as standard in the treatment of vulvar cancer. It also mentions that there is increasing evidence suggesting an important role in cervical cancer. Finally, it emphasises that the nuclear procedure for the detection of SLN (in addition to the blue dye) should only be done in centres with enough expertise and training. Despite this relevant reference, gynaecological SLN is not performed routinely in most European centres. Aim: To share this centre's experience in setting up and performing lymphoscintigraphy and sentinel node location in gynaecological cancer patients. **Materials and Methods:** A total of 381 female patients have undergone one of the procedures (vulvar or cervical SLN scintigraphies) between January 2011 and April 2019. While the protocol has been updated in line with the 2014 EANM guideline, the department developed it in a way that would meet the service needs and reflect a personalised approach. **Results:** This presentation will entail two parts: a brief clinical overview, which will include common indications and examples of imaging results; and a technical description and explanation of the protocol, which will comprise: delivery of a patient-centred service through liaison with oncology specialist nurses, surgeon and the patient and its relatives; the detailed preparation of the facilities, exemplified and illustrated with pictures; radiopharmaceutical proprieties, biodistribution and handling; dose preparation and types of administration; hybrid imaging acquisition parameters and radiation protection considerations. **Conclusion:** This work presents our current gynaecological protocol, which has been adapted over the years in in view of the department's experience and the guidance and literature available on this matter. Furthermore, it clarifies the technologist's role in this process and highlights the importance of a multidisciplinary team effort when dealing with this particularly sensitive pathology. **References:** Marth, C. Landoni, F. Colombo, N. Mahner, S. McCormack, M. Gonzalez-Martin, A. 2017. "Cervical Cancer: ESMO Clinical Practice Guidelines for Diagnosis, Treatment and Follow-Up." TEPS-63

Net Administered Activity As A Surrogate Quality Control Indicator For Non-Imaging Breast SLNB Procedures

L. Wason, A. Nicol, J. Dennis, C. Flynn;
NHS Greater Glasgow And Clyde, Glasgow, UNITED KINGDOM.

Aim/Introduction: Many centres perform non-imaging sentinel lymph node biopsy (SLNB) to accurately stage axillary lymph node involvement in breast cancer. The aim is to administer adequate activity of radiopharmaceutical to ensure the sentinel nodes can be detected in theatre using a gamma probe. These intradermal administrations can be challenging - small volume, high concentration radiopharmaceutical, dead space in syringe, high pressure and respiratory movement could all be significant factors in determining if the target net activity is administered. As imaging is not used to confirm tracking of the radioisotope from the injection site to the axilla, an alternative method of confirming administration of the appropriate activity to each patient is sought. Anecdotal communication from theatre indicates it is possible to have a situation of no radiopharmaceutical detected in the axillary nodes. In the absence of imaging to directly check radiopharmaceutical tracking to the lymphatic system we propose the net administered activity as an alternative quality control indicator of satisfactory radiopharmaceutical administration. **Materials and Methods:** Consecutive patients undergoing breast SLNB over a period of seven months were reviewed. The dispensed and residual activity was collected for 58 patients and the net activity administered calculated. The administered activities and percentage residuals were compared to the DRL for both same day (20MBq) and next day (40MBq) procedures. The maximum and minimum values for each were also obtained. The residual was converted into a percentage of the net administered activity. Mean, median and standard deviations were obtained for the percentage residuals for all administrations. **Results:** The mean±stdev administered activity for same day and next day procedures was 20.8MBq ± 2.0 and 38.7MBq ± 3.3 respectively. The results show that 69% of administrations were within 10% and 95% within 20% of the

DRL. All administrations were within 25% of the DRL. The mean residual activity as a percentage of administered activity was 12.5±9.0%, with a maximum of 48.5% and a minimum of 2.8%. **Conclusion:** This investigation demonstrates that there are technical challenges associated with breast SLNB intradermal injections and there may be a role for a check on administered activity by measuring residuals. This must be balanced against the potential safety risk associated with measuring residual activities. Further work will include inter-operator assessment and raising operator awareness. **References:** None.

Clinical Effectiveness Of Sentinel Node Biopsy In Early Oral Cavity Carcinoma

Y. Herrera-Martinez, Á. Bonilla De Damiá, V. Pachón Garrudo, D. Tamayo Carabaño, R. Álvarez Pérez, J. Jiménez-Hoyuela García; Hospital Universitario Virgen del Rocío, Seville, SPAIN.

Aim/Introduction: This study investigates the effectiveness of sentinel lymph node biopsy (SNLB) in patients with oral carcinoma without clinically and radiographically cervical lymph nodes involvement. **Materials and Methods:** Prospective study in 34 patients with T1-T2N0M0 squamous cell carcinoma of the oral cavity. Lymphoscintigraphy was performed after the administration of four peritumoral injections of 3 mCi of ^{99m}Tc-nanocolloid. The sentinel lymph node (SNB) was detected by the acquisition of dynamic, early, delayed, SPECT/CT images. The day after the SLN detection, its intra-operative recognition was carried out using a Navigator GPS® scintigraphic probe. The first sentinel node was excised, and subsequently elective deferred lymphadenectomy was performed if tumor infiltration of the SNB was observed. Follow-up was performed on average 9 months (range 2-21 months). **Results:** Thirty-four patients (16 men and 18 women) were included in the study with an average age of 59,2 years. Lesions were localized in the tongue in 22 cases (64,7%), 10 (29%) in the floor of the mouth and 2 (5%) in the gum. A mean of 2,29 SLN was excised per patient. The bilateral drainage of the radiotracer was observed in 7 patients (20,5%). The SLN was localized in all patients (100%). Metastases were found in 9 of the 34 patients (26%); in those patients with initial negative SLN, recurrence was observed in only one case during the follow-up. Cervical lymphadenectomy was avoided in 74% of the patients. **Conclusion:** SLNB allows a correct cervical staging of oral cavity carcinomas, avoiding unnecessary cervical lymphadenectomy. **References:** None.

Quantitative estimation of the renal tubular function with ^{99m}Tc- MAG3: comparative software approach using two methods in a pediatric population

M. J. Carapinha[1,2,3], R. Silva[1], F. Silva[1], S. Figueiredo[1,3], L. Vieira[1,3]; [1]Escola Superior de Tecnologia da Saúde de Lisboa, Lisboa, PORTUGAL, [2]Escola Nacional de Saúde Publica, Universidade Nova de Lisboa, Lisboa, PORTUGAL, [3]H&TRC - Health & Technology Research Center, ESTeSL - Escola Superior de Tecnologia da Saúde, Instituto Politécnico de Lisboa, Lisboa, PORTUGAL.

Aim/Introduction: The ability to quantify function by Effective Renal Plasma Flow (ERPF) using camera based Technetium-99m mercaptoacetyltriglycine (^{99m}Tc-MAG3) clearance methods is an accurate and time-saving technique as compared with the standard laboratory tests. Often providing information not possible with the conventional radiological modalities, this quantitative assessment can be determined by a linear formula - Modified Gates Method (MGat) - or a quadratic approach - Modified Schlegel Method (MSch). The aim of this work was to evaluate the effect of the MGat and MSch methods on the absolute value of ERPF in ^{99m}Tc-MAG3 dynamic renography. **Materials and Methods:** A retrospective study with a non-probabilistic sample of twenty one children (9.5 ±3.1 years; 32.1±10.7 kg) referred for diuretic (12.8 ± 4.8 mg of furosemide) ^{99m}Tc-MAG3 (120.0 ± 27.5 MBq) renogram was used. Data were available in Xeleris GE™ workstation database at Lisbon School of Health Technology (ESTeSL) and were processed using Renal Analysis application. To obtain the ERPF (mL/min) parameter by the MSch and MGat methods, all the studies were manually processed by the same operator considering the following regions of interest (ROI): left kidney (LK), right kidney (RK), peri-renal background (BKG), aorta artery (AA) and injection site (IS). Additionally, right and left kidney Area (A), uptake (Up) and $T_{1/2}$ quantitative parameters were assessed for each method. To evaluate the significance and association between the variables, the Shapiro-Wilk, Wilcoxon and Spearman correlation tests were used, considering α=0.05. **Results:** Paired samples Wilcoxon test found significant differences in ERPF MGat and MSch ($p<0.01$); RKA MGat and MSch ($p<0.05$); LKA MGat and MSch ($p<0.05$). Contrarily, there were not significant differences for Uptake ($p>0.05$) and for $T_{1/2}$ parameter ($p>0.05$), considering L and R kidneys, when MGat and MSch methods were applied, though higher significance values were found in Up parameter. **Conclusion:** Results suggest that the applied method may possibly influence the obtained ERPF absolute value. MGat and MSch methods originate different ERPF and A values, despite similar metrics for the Up and $T_{1/2}$ parameters. The effect of location of the kidneys (L-R) seems to slightly affect method association criteria for all the parameters with more impact in the LK values. **References:** None.

TEPS-66

Comparison of Single and Dual Isotope Imaging for 3D Lung Lobar Quantification with SPECT-CT

T. Sousa, S. Gregg, K. Wechalekar; Royal Brompton and Harefield Foundation Trust Hospital, London, UNITED KINGDOM.

Aim/Introduction: Chronic obstructive pulmonary disease affects 400 million individuals worldwide and is predicted to be the third leading cause of death by 2020. Lung volume reduction

surgery (LVRS) is an established means of targeting hyperinflation in patients with severe emphysema. Preoperative evaluation of regional lung function is essential to planning and predicting the outcomes of surgery. Our previous work [1] established the ability to perform 3D lung lobar quantification (3DLLQ) using hybrid CT + sequential lung perfusion and ventilation (VQ) SPECT offering accurate quantitation at lobar level. The purpose of this study is to compare 3DLLQ analysis between sequential and simultaneous dual isotope VQ SPECT-CT. **Materials and Methods:** 20 patients (14 Male, 6 Female, mean age 65, range: 39-79 years) referred for lung lobar quantification were included. Initially, perfusion (^{99m}Tc) and Ventilation (^{81m}Kr) SPECT-CT scans were acquired sequentially followed by simultaneous dual isotope VQ SPECT-CT acquisition. Scans were performed using a general purpose dual head gamma camera (GE Infinia Hawkeye). Hybrid Recon for Lung and 3DLLQ applications (Hermes Medical Solutions) were used to reconstruct the attenuation-corrected SPECT images and to calculate the percentage contribution of each lobe to total lung function for each technique as demonstrated previously [1]. **Results:** Bland-Altman plots for the assessment of right and left lung function demonstrate excellent agreement between single isotope and dual isotope imaging techniques (+3.1 and -3.2 for Q and +3.9 and -3.9 for V) In lobes, the limits of agreement were very good for both Q and V quantification (+4.4 and -4.7 for Q and +3.4 and -3.5 for V). There was an excellent correlation between the two imaging techniques for the assessment of differential lung function ($r>0.98$, $P<0.001$ for both V and Q) with a mean ±SD difference of 0.05±1.6 for Q and 0.0±2.0 for V. Also, correlation between the techniques for lobar contribution was very good ($r > 0.97$, $P< 0.001$ for both V and Q). The mean ±SD difference between techniques for all the lobes was 0.14±2.3 (Q) and 0.02±1.8 (V). **Conclusion:** Our investigation demonstrates that simultaneous dual isotope VQ SPECT-CT acquisition is feasible in 3DLLQ. This reduces the acquisition time considerably, resulting in increased patient comfort. In addition, image quality is improved due to reduction in motion artefacts and mis-registration between perfusion, ventilation and CT. **References:** [1] Thillainathan AV,2013, EANM, SPRINGER, Pages: S292-S293, ISSN:1619-707.

Assessment of 2-hour Images for ^{99m}Tc-HYNIC-TOC Studies Using Image Interpretation and Image Analysis

S. Tavares[1], *M. Jessop*[1], *D. Pencharz*[1], *E. Manca*[1], *N. Singh*[1], *S. Figueiredo*[2];
[1]*Royal Sussex County Hospital, Brighton, UNITED KINGDOM,*
[2]*Lisbon School of Health Technology, Lisbon, PORTUGAL.*

Aim/Introduction: Scintigraphy with ^{99m}Tc-HYNIC-TOC (Tektrotyd®) is valuable for the diagnosis of neuroendocrine tumours (NETs), particularly those expressing a high density of somatostatin receptors. The aim of this retrospective study was to examine our current local Tektrotyd® imaging protocol, assessing the usefulness of 2-hour whole body imaging. **Materials and Methods:** Whole body scintigraphy was performed in seventeen patients at 2 and 4 hours after intravenous administration of 740MBq ^{99m}Tc-Tektrotyd®. SPECT-CT was performed in all cases at 4 hours. 10/17 patients had positive findings. The whole-body images were independently assessed by two experienced Nuclear Medicine Physicians and judgement was made in each case on whether the 2-hour imaging was felt necessary for accurate diagnostic interpretation. In addition, Image Quality Metrics (IQM) were used to evaluate target-to-background-ratio (TBR) (right dome of liver/ right calf) on the Xeleris™ v.3.0 workstation, and image texture analysis i.e. contrast, energy (uniformity), correlation, entropy and homogeneity, was performed using LIFEx software with a region of interest (ROI) over the right dome of liver. **Results:** To standardize image comparison, the liver was chosen as the image feature for analysis. Image texture analysis showed very little difference between the 2 and 4-hour images for homogeneity (average of 2%), uniformity (average of 1%) and correlation (average of 2%). Entropy decreased (average of 23%) by the 4-hour image as biodistribution stabilized, and contrast was far more variable depending on the individual patient. TBR increased from 2 to 4-hour by an average of 19%. Both Nuclear Medicine Physicians agreed that for 16/17 patients the 2-hour image was not necessary for accurate diagnostic interpretation. **Conclusion:** Following assessment of the usefulness of 2-hour images in ^{99m}Tc-Tektrotyd® studies, as part of the imaging protocol for diagnosis and staging of patients with NETs, it can be concluded that the 2-hour imaging adds little additional diagnostic information, and is less useful than 4-hour imaging where pathological areas become more prominent. In addition, if SPECT-CT is available for further clarification of lesions, the 2-hour images could safely be omitted, resulting in more streamlined imaging, reducing patient inconvenience and improving scanner and staff efficiency. **References:** 1. TEPS-68

Quantification Of Technetium-99m Sestamibi Thyroid Scintigraphy In Ait Type I And Ii

E. Kranenborg, *M. v Rutte, J. Lavalaye, J. Habraken;*
St. Antonius Hospital, Nieuwegein, NETHERLANDS.

Aim/Introduction: Amiodarone induced thyrotoxicosis

(AIT) is a thyroid disease, caused by the use of amiodarone. Amiodarone is medication against cardiac arrhythmias. AIT can be divided into 3 types. Type I is an excessive production of the thyroid hormone. Type II is a destructive thyroiditis. Type III is a combination of type I and II. The treatment of AIT is difficult and not always successful. Distinguishing between type I and II is important to optimize the treatment. Currently there is no gold standard to diagnose AIT. Technetium-99m sestamibi thyroid scintigraphy (^{99m}Tc-STS) is regularly applied to differentiate between the different types of AIT. However, these images are only assessed visually. It may be of added value to quantify these images, to give more specific determination between type I en II. **Materials and Methods:** ^{99m}Tc-STS was performed with 185 MBq sestamibi and acquisition of static images 2, 10, 15 and 60 min after injection. 18 AIT patients who underwent ^{99m}Tc-STS, were retrospectively assessed. For every patient a fixed ROI was placed in the middle of one thyroid lobe. For every single patient the same ROI location was used on all planar images. A background ROI was drawn to correct for background radiation. The average number of counts in every image was plotted in a graph. **Results:** 14 Patients were diagnosed as type II and 2 patients as type I. 2 patients were visually indistinguishable (type III). All type I en II patients corresponded with the follow up diagnosis. The type III patients were after follow up diagnosed as type I (1 patient) and type II (1 patient). The quantification results were plotted against the diagnosed type of AIT. The graphs show a clear difference between type I and II, especially at 15 min. The results at 15 min images are between 0.91 - 2.3 cts/pixel (type I) and 0.24 - 0.62 cts/pixel (type II). The results of type III who turned out to be type II was 0.57 and type I was 0.94. The results at 15 min are always above 0,8 cts/pixel for type I and always below 0,8 cts/pixel for type II. **Conclusion:** This study has shown that ^{99m}Tc-MIBI quantification is a reliable and easy method for diagnosis and classification of AIT. It is possible to define a clear cut-off between type I and II. The quantification method for these patients is in full correspondence with the clinical follow-up. **References:** None.

TEPS-69

Serum creatinine measurement as a predictor for single sample GFR using 99mTc-DTPA

***G. Hilland**, A. Matos, C. Findlay;*
NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM.

Aim/Introduction: Radionuclide measured Glomerular Filtration Rate (mGFR) assessment using 99mTc-DTPA (Diethylenetriamine Pentaacetic Acid) is widely used in Nuclear Medicine for patients pre-nephrotoxic chemotherapy or assessment of potential live kidney donors (PLKD). British Nuclear Medicine Society (BNMS) guidelines published in 2004 recommended using a 4-sample slope intercept GFR protocol (SI-GFR). However updated BNMS guidelines published in 2018 recommend a single sample GFR measurement (SS-GFR) for patients without ascites, oedema or other expanded body space. The recommended single sample time should be based on the best available estimate of body surface area normalised GFR. One such measurement is the estimated GFR (eGFR) based on serum creatinine concentration. The purpose of this audit was to compare SI-GFR and the SS-GFR measurements to aid confidence in transitioning to a SS-GFR method. We also wished to look at the validity of using eGFR as a single sample time predictor. **Materials and Methods:** Using 4-sample SI-GFR measurements, the equivalent SS-GFR was calculated using the single sample time point identified in the guidelines. The patient's most recent eGFR measurement was used to identify which of the 4 blood samples would be the SS equivalent. **Results:** Thirty 99mTc-DTPA SI-GFR patients were retrospectively reviewed. The thirty patients comprised 21 pre-chemotherapy assessment and 9 PLKD patients with an average eGFRs of 84.9 ± 61.8 mL/min/1.73m². The average SI-GFR and SS-GFRs were 84.2 ± 50.4 and 83.9 ± 53.5 mL/min/1.73m² respectively. Time between eGFR and mGFR was 23 ± 83 days. Comparison of eGFR measurements with SI-GFR and SS-GFR were statistically different. Recommended single sample times for eGFRs > 50 mL/min/1.73m2 demonstrated no clinical significance between SI-GFR and SS-GFR (p>0.05) however SS-GFRs for patients with eGFRs of 25-50 mL/min/1.73m2 were consistently higher than SI-GFRs. Average time between eGFR and mGFR for all patients was 11.7 ± 4.4 days. **Conclusion:** Preliminary findings using eGFR to determine single sample times for 99mTc-DTPA mGFRs gave mixed results. As anticipated eGFR is not a good predictor of SS-GFR or SI-GFR measurements. With regard to mGFR methods, SS-GFRs at 2, 3 and 4 hours do correlate with SI-GFRs. However low GFRs estimated at 25-50 mL/min/1.73m2 (6 hour SS-GFR) give significantly different results from SI-GFRs. It may be that using the 6 hour single sample improves accuracy for lower GFRs. **References:** None.

TEPS-70

End of Chromium-51 availability: Setting-up of a new protocol, validation and impact analysis

***S. A. Figueiredo**, G. Allenbach, J. O. Prior, J. Delage, J. Costes;*
CHUV, Lausanne, SWITZERLAND.

Aim/Introduction: Chromium-51 (^{51}Cr) was used for red blood cells (RBC) volume determination until December 2018, when its production stopped. Re-infusion of RBC labeled in vitro with technetium-99m (^{99m}Tc) followed by dilution measurement is also a documented alternative method. The aim of this work is to compare these two techniques in terms of labelling efficiency, accuracy and impact in our daily practice. **Materials and Methods:** Simulation tests were performed to validate the alternative calculation method. Blood samples were collected from healthy volunteers and RBC labeled with ^{99m}Tc reduced by PYP. Then, labeled cells were injected in a two-liter flask of water. Flask samples were withdrawn at three time points (20, 30 and 40 minutes) and measured by gamma counter to calculate the flask volume. Results were compared with the theoretical two-liter flask volume. ^{99m}Tc method was compared to ^{51}Cr method regarding to: labelling efficiency, processing time, supplies costs

(PYP kits vs. ^{51}Cr) and wastes management. **Results:** After two washing steps, the labelling efficiency of RBC with ^{99m}Tc (n=4) was significantly superior than the labelling with ^{51}Cr (98.9 ± 0.47%, vs 87.5 ± 2.5[1], p>0.0005). Flask volume estimation with ^{99m}Tc labelled RBC (n=3) was 2,112 ± 15 mL for a theoretical volume of 2000 mL (+5.6%). ^{99m}Tc leakage from cells was not measured during this study, but will be measured in the first patient for improving calculation accuracy. ^{99m}Tc procedure for RBC volume calculation is longer than ^{51}Cr procedure (3.5 hours vs 2.5 hours) due to the ^{99m}Tc PYP reduction step and the multiple washing steps to remove extracellular PYP. ^{99m}Tc procedure is more economical compared to ^{51}Cr, even if processing time is longer. Moreover, ^{99m}Tc generator allows a much easier ^{99m}Tc supply than ^{51}Cr. Finally, the ^{99m}Tc half-life (6.02h) makes the wastes management much easier in comparison to ^{51}Cr (27.8d). **Conclusion:** This study validates ^{99m}Tc RBC labeling in vitro as an alternative method to ^{51}Cr for RBC volume determination with high reproducibility. Volume measurement accuracy will be further improved by correcting for the bias introduced by ^{99m}Tc RBC leakage. **References:** 1: Richard J. Kowalsky, Steven W. TEPS-72

Glomerular filtration rate: Comparison of two tracers

L. Janus, T. Andersen, K. Thilsing-Hansen, D. Roholdt, C. Led, P. Andersen, H. Thomsen, O. Gerke, P. Høilund-Carlsen, J. Simonsen; Odense University Hospital, Odense C, DENMARK.

Aim/Introduction: At our department, we used to measure glomerular filtration rate, GFR, with Cr-51-labelled ethylenediaminetetraacetate (Cr-51-EDTA). Since the supplier at short notice closed down the production of this tracer, we were forced to replace it. The choice fell on Tc-99m-labelled diethylenetriaminepentaacetate (Tc-99m-DTPA) which is also a well-established GFR tracer. However, no direct comparison between the two seemed to exist. We therefore made a head-to-head comparison in patients referred to us for a medical indication. **Materials and Methods:** During the last four weeks with Cr-51-EDTA available we administered both Cr-51-EDTA (GE Healthcare) and Tc-99m-DTPA (Mallinckrodt Pharmaceuticals) to most of our patients. Injections were consecutive (3.7 MBq of Cr-51-EDTA, 8 MBq of Tc-99m-DTPA) and the standard number of blood samples were drawn. A well counter (2470 Wallac Wizard 2™, Perkin Elmer) registered energy peaks for both Cr-51 and Tc-99m, and the two were counted simultaneously. **Results:** A total of 54 patients were examined with this dual-isotope method; 51 of them with single-sample GFR measurement (blood samples 3 h p.i.) and three of them with the multiple-sample method (blood samples 3h, 4h, and 5h p.i.). Results for the 51 single-sample measurements are presented. Mean GFR measured with DTPA (GFR_{DTPA}) did not differ from that determined with EDTA (GFR_{EDTA}); the mean [95% CI] difference was 0.40 [-0.40;1.19] mL/min. The difference ranged from -7.30 to 7.31 mL/min; 95% Limits of Agreement according to Bland & Altman were [-5.12;5.92]. However, a regression line revealed that GFR_{DTPA} exceeded GFR_{EDTA} at high GFR values (difference<0 at GFR_{EDTA}>80 mL/min) and vice versa (difference>0 at GFR_{EDTA}<80 mL/min). **Conclusion:** GFR_{DTPA} can replace GFR_{EDTA} since the difference between the two lies within few GFR units that most often will have no clinical consequence. However, data indicated that the two tracers are not handled completely similarly in the body and that differences become more marked at the extremities of the GFR spectrum. Hence, a more detailed comparison between the two tracers, especially at poorer renal function, is warranted. **References:** None.

TEPS-73

Association between TNM staging and primary tumor parameters assessed in ^{18}F-FDG-PET/CT study in NSCLC patients

K. Pietrasz[1], P. Cegla[1], K. Witkowska[2], R. Czepczynski[3], M. Bryl[4], W. Cholewinski[5,1];
[1]Nuclear Medicine Department, Greater Poland Cancer Centre, Poznan, POLAND, [2]Affidea Medical Center, Poznan, POLAND, [3]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Science, Poznan, POLAND, [4]Oncology Department at Regional Centre of Lung Diseases in Poznan and Department of Thoracic Surgery, Poznan University of Medical Sciences, Poznan, POLAND, [5]Chair and Department of Electroradiology, Poznan University of Medical Science, Poznan, POLAND.

Aim/Introduction: Lung cancer is the leading cause of death in Poland and worldwide in both sexes and around three million new cases are diagnosed worldwide. The aim of the study was to compare the TNM stage of the cancer with biological parameters of primary tumor as SUV_{max}, MTV and TLG in patients with NSCLC. **Materials and Methods:** Retrospective analysis was performed on a group of 79 newly diagnosed lung cancer patients. PET scans were acquired on Gemini TF PET/CT scanner between 60-90min after injection of ^{18}F-FDG with the mean activity of 364±75 MBq, with the area being examined from calvaria to half way down the thigh. The reconstructed PET images were evaluated using MIM 6 Software for SUV_{max}, MTV and TLG values. For MTV calculation a 3D lung phantom study was performed for simulation of the variety of activity and volume. **Results:** In the whole analyzed group, 31 patients were women, while 48 patients were men. In 38 patients NSCLC were diagnosed in the left lung, while in 41 patients in right lung. The analysis of the cancer stage showed stage IA2 in 8 patients, stage IA3-6 pts, stage IB-4pts, IIA-3 pts, 15 patients with stage IIB, stage IIIA-17 pts, IIIB-5, IIIC-5, IVA in 7 patients and stage IVB in 9 patients. The lowest TLG values were observed in stage IA2 (11.31±15.27) and the highest in stage IIIC (1003.20±953,59). The lowest value of SUV_{max} and MTV were found in stage IA2 (6.8±3.8 and 1.37±0.42 respectively). The highest value of SUV_{max} was found in stage IIA (13.4±11.4) and MTV in stage IIIC (108.15±127.24). **Conclusion:** Metabolic parameters of the tumor and proliferative process expressed with MTV and TLG represent different from TNM

staging system biological description of lung cancer, which may be important for the treatment and prognosis. **References:** None.

Assessment of ^{18}F-FDG PET/CT texture analysis to discriminate NSCLC from radiation pneumonitis after CIRT

M. Suga[1,2], *R. Nishii*[3], *K. Yamazaki*[3], *Y. Kamitaka*[1,2], *K. Miwa*[2], *R. Kohno*[4], *K. Tanimoto*[1], *T. Higashi*[3], *H. Tsuji*[1];
[1]*QST hospital, National Institute of Quantum and Radiological Science and Technology, Chiba, JAPAN,* [2]*Department of Radiological Sciences, International University of Health and Welfare, Tochigi, JAPAN,* [3]*Department of Molecular Imaging and Theranostics, National Institute of Radiological Sciences, QST, Chiba, JAPAN,* [4]*Department of Accelerator and Medical Physics Therapy Systems Section, National Institute of Radiological Sciences, QST, Chiba, JAPAN.*

Aim/Introduction: The differentiation of local recurrence from a primary tumor and radiation pneumonitis (RP) is critically important for selecting optimal clinical therapeutic strategies to manage post carbon-ion radiotherapy (CIRT) in patients with non-small cell lung cancer (NSCLC). Although 18F-FDG PET/CT (FDG-PET/CT) plays a key role in the metabolic imaging of patients with NSCLC who require CIRT management, PET/CT diagnosis based on SUVmax cannot always distinguish between NSCLC and RP. The present study aimed to determine whether FDG-PET/CT texture parameters can differentiate NSCLC from RP after CIRT. **Materials and Methods:** We retrospectively analyzed FDG-PET/CT image data from 32 patients with histopathologically proven NSCLC who were scheduled to undergo CIRT, and 31 patients who were diagnosed with RP after CIRT (50.0 Gy (RBE) in single fraction). Radiation pneumonitis was diagnosed by biopsy or at clinical follow-up > 1 year after CIRT. Volumes of interest (VOI) on tumors were delineated using a threshold of 40% of the maximum standard uptake value (SUVmax) in each lesion. The SUV parameters of SUVmax, SUVpeak, SUVmean, metabolic tumor volume (MTV), total lesion glycolysis (TLG) and seven typical texture parameters of FDG-PET/CT were determined using PETSTAT image-analysis software. Data were statistically compared between NSCLC and RP using nonparametric Wilcoxon rank sum tests. Diagnostic accuracy was assessed using ROC curves. **Results:** Among SUV parameters, MTV ($p < 0.0001$) and TLG ($p = 0.001$) significantly differed between NSCLC and RP. The feature quantities of texture parameters, namely, GLRLM, GLSZM, NGLCM3D, NGLCM and NGTDM significantly differed between NSCLC and RP. The areas under the receiver operating characteristics (ROC) curves (AUC) were as follows: SUVmax 0.64, MTV 0.86, TLG 0.75, GLRLM 0.83, GLSZM 0.76, NGLCM3D 0.71, NGLCM 0.72 and NGTDM 0.82. Diagnostic accuracy was better using GLRLRM or NGTDM than SUVmax ($p < 0.01$). **Conclusion:** The texture parameters of FDG-PET/CT were useful to differentiate NSCLC from radiation pneumonitis after CIRT, and GLRLM and NGTDM in particular would be promising parameters with excellent diagnostic accuracy. **References:** None.

TEPS-75

Impact of respiratory and ECG gated ^{18}F-FDG PET/CT for cardiac sarcoidosis

K. Hanaoka, *S. Watanabe*, *Y. Shibata*, *H. Kaida*, *K. Ishii*;
Institute of Advanced Clinical Medicine, KINDAI University, Osaka-sayama, JAPAN.

Aim/Introduction: Myocardial accumulation of ^{18}F-FDG is affected by respiratory and cardiac motion. The aim of this study was to estimate the impact of respiratory and ECG gated ^{18}F-FDG PET/CT on the diagnosis of cardiac sarcoidosis. **Materials and Methods:** Eighteen patients were acquired on a GE Discovery 710 PET/CT equipped with a Varian RPM respiratory gating system and ECG system. Non-gated PET images and two kinds of gated PET/CT images, Respiratory-gated PET (PET events during inhalation were reduced and reconstructed with conventional helical CT) and ECG-gated PET (16 bin ECG gated PET reconstructed with conventional helical CT) were created from list-mode clinical 18F-FDG PET/CT data. These data were analyzed using a polar map divided according to the 17-segment model of the American Heart Association. The SUVmax of cardiac volume data, accumulation pattern on polar map, and wall motion on ECG-gated PET were measured and compared. **Results:** The average rate of SUVmax improvement from nongated PET on respiratory-gated PET and ECG-gated PET at ES and ED showed 4.0, 28.7 and 3.8%, respectively. Compared with non-gated PET, accumulation in respiratory-gated PET was more localized and shifted to the center of the polar map. Three patients with the high accumulation showed regional wall motion abnormalities in same segment. **Conclusion:** For a ^{18}F-FDG PET/CT scan for cardiac sarcoidosis, both respiratory-gated and ECG-gated PET/CT scans are recommend to localize regions of accumulation in the polar map and to detect the myocardial wall motion abnormalities. **References:** 1) Advanced imaging of cardiac sarcoidosis. TEPS-76

Correlation of HPV status and biological parameters assessed in ^{18}F-FDG-PET/CT study in head and neck cancer patients

P. Cegla[1], *E. Majchrzak*[2], *R. Czepczynski*[3], *K. Pietrasz*[1], *A. Kaczmarek*[1], *W. Golusinski*[2];
[1]*Nuclear Medicine Department, Greater Poland Cancer Centre, Poznan, POLAND,* [2]*Department of Otolaryngology, Head and Neck Surgery and Oncology,Greater Poland Cancer Centre, Poznan, POLAND,* [3]*Department of Endocrinology, Metabolism and internal Medicine, Poznan University of Medical Science, Poznan, POLAND.*

Aim/Introduction: Head and neck cancer still remain a significant public health problem taking sixth place in the frequency of morbidity and mortality and they are a serious diagnostic problem both in Poland and worldwide. Despite

the newer treating methods many patients die because of the primary tumor resistance to treatment. PET/CT is a modern method of functional imaging, which enables the assessment of a variety of biological processes. HPV positive cancer are epidemiologically distinct from HPV negative. The aim of the study was to assess the influence of HPV infection on biological parameters obtained in ^{18}F-FDG-PET/CT study in patients with head and neck cancer. **Materials and Methods:** Retrospective analysis was performed on a group of 55 patients with newly diagnosed head and neck cancer. PET scans were acquired on Gemini TF PET/CT scanner 60min after IV injection of ^{18}F-FDG with the mean activity of 364±75 MBq, with the area being examined from calvaria to half way down the thigh. Several PET biological parameters in primary tumor include SUV_{max}, SUV_{mean}, TotalSUV, TLG and MTV were assessed and the correlation between HPV$^+$ and HPV$^-$ patients was checked. For statistical analysis T-test and Mann-Whitney test were used and the materiality level $p<0.05$ were considered significant. ROC curves were used to obtain best cut-off point between HVP$^+$ and HPV$^-$ patients in all assessed parameters. **Results:** HPV$^-$ patients showed higher values for all assessed parameters compared to HPV$^+$ group but without any statistically significant differences: for SUV_{max} 9.3±3.7 vs 8.5±3.3 (p=0.52), for SUV_{mean} 5.2±2.0 vs 4.8 vs 2.2 (p=0.47); for TotalSUV 1694.0±1948.7 vs 1141.5±1251.7 (p=0.36); for TLG 108.34±124.69 vs 73.06±80.11 (p=0.36); for MTV 20.30±25.86 vs 14.04±12.62 (p=0.42). The best cut-off value determining HPV$^+$ and HPV$^-$ patients for SUV_{max} was 9.7, for SUV_{mean} 4.4, for TotalSUV 3921.9, for TLG 251.00 and for MTV was 34.52. **Conclusion:** In this limited study we did not observe any statistically significant differences between HPV$^+$ and HPV$^-$ patients, however HPV$^-$ patients tend to show higher values for all assessed parameters which may be helpful in differentiation and diagnosis of patients with head and neck cancer. The best cut-off level was found and might be helpful to differentiate the high-risk HPV negativity subtypes from positivity. **References:** None.

TEPS-77

Parametric Whole Body FDG PET Scan: Just Do It!

H. Danielsen, *M. F. Pedersen, L. C. Gormsen, O. L. Munk;*
Aarhus University Hospital, Aarhus, DENMARK.

Aim/Introduction: Whole-body ^{18}FDG PET imaging (WB-PET) is routinely used for the assessment of malignant diseases based on standard uptake values (SUV) and requires that the patient lies still for 10-15 minutes. FlowMotion Multiparametric PET is a new dynamic WB-PET (DWB-PET) protocol introduced by Siemens that allows imaging of the rate of tracer uptake and apparent distribution volume, which are more quantitative measures than SUV. However, DWB-PET requires that the patient is injected in the scanner and remains still up to 70 minutes. This is a review of our experiences and recommendations for patient handling during DWB-PET. **Materials and Methods:** 35 patients were scanned in the Siemens Vision 600 PET/CT scanner. Patients with clear signs of tremors, pains, claustrophobia or nervous bladder were excluded. On arrival, we informed the patient about the entire procedure and stressed the importance of lying still during the extended scan. Patients were placed head first supine with arms along the body, a peripheral venous catheter (PVC) was placed and blood-glucose was measured. Positioning aids were carefully placed to make patients feel comfortable. The patient line (PAS) from the automated FDG-injector was coupled with the PVC. The examination involved a topogram, AC-CT, 6-minutes scan of the chest region started at tracer injection, and a series (9-12) WB-PET where the last WB-PET scan correspond to clinical routine WB-PET at 60 min p.i. **Results:** We found that image artifact could be reduced by optimizing the patient handling: 1) Hand movements led to pelvis artifacts, which could be minimized by instructing the patient to hold two small wedges; 2) Head movements were reduced with a special head-holder, a pillow and wedges on the side; 3) Effect of residual FDG in PAS was avoided by moving the PVC from the antecubital fossa to the dorsal side of the hand and by removing the PAS right after injection. For all scans, the AC-CT and DWB-PET were visually inspected for movement, and divided into two groups; Acceptable movement and non-acceptable movement for both head and hand. When comparing groups of patients with antecubital PVCs (N=17) with hand PVCs (N=18), we found a reduction in hand-movements from 29.4% to 17.6% resulting in less image artifacts. **Conclusion:** For extended-acquisition DWB-PET examinations, it is essential to allocate time to inform and position the patient and to use positioning aids to reduce movements and thus artifacts in the parametric image. **References:** None.

TEPS-78

18F-FDG PET/CT prone vs. supine

D. Boon, *C. de Haan;*
Dijklander ziekenhuis, Hoorn, NETHERLANDS.

Aim/Introduction: The aim of this study is to compare prone (hanging breasts) and supine acquired 18F-FDG PET/CT for visualisation of primary tumours and regional lymph nodes in breast cancer patients. The patients did not have prior surgery or any other treatment. **Materials and Methods:** Twenty-six patients were included from September 2018 to April 2019. All patiënts signed an informed consent form. One hour after injection of 150-250 MBq (depending on the bodyweight) 18F-FDG PET/CT was performed, primarily PET/CT images from orbitae to sinus pleurae were acquired in prone position, with the help of a breast-support board. Subsequently, a standard PET/CT in supine position from skull to knees was acquired. The scan time per bed position was three and a half minutes for both procedures. A nuclear medicine physician compared both scans to assess diagnostic differences. **Results:** Generally there is no difference in diagnosis between prone and supine, however some cases in prone position shows a better lesion detection because there is less compression of breast tissue. In 46,2% (n = 12) there is no difference between prone and supine. In 23% (n = 6) there is a improved view of the primary tumour, 15,4%

(n = 4) shows a better view of the lymph nodes and 7,7% (n = 2) a better view of the primary tumour and the lymph nodes. However, in 7,7% (n = 2) the nuclear medicine physician assesses the supine position as superior in lesion detection. **Conclusion:** Prone position PET/CT improves the visualization of the primary tumour and the number of detected axillary lymph nodes. Therefore, it is a valuable addition to standard supine PET/CT for locoregional assessment of breast cancer patients. **References:** S.C. Teixeira et all, Additional prone 18f-fdg pet/ct acquisition to improve the visualization of the primary tumour and regional lymph node metastases in stage ii /iii breast cancer. In: S.C. Teixeira; Breast cancer tailored staging using molecular imaging. University of Amsterdam; 2016: p. 43-59.

TEPS-79

The effect of image based motion correction on the HRRT scanner

R. B. Bertelsen, M. L. F. Schwartz;
Nuclear Medicine and PET, Skejby, DENMARK.

Aim/Introduction: The aim of this study is to uncover for how many patients it is necessary to use HRRT_users_software_1.2 for image based motion correction on the HRRT. The scanner has a high resolubility of 2.5 mm which can cause the smallest movement to affect the image quality. Most of the patients scanned on the HRRT are diagnosed with either Parkinson's disease (PD) or Alzheimer's disease (AD). Because of the side effects from those diseases it is difficult for the patients to lie completely still during the scan. **Materials and Methods:** To narrow down the data we have chosen to focus on patients from three different projects: Project1 involving PD patients and healthy individuals all experiencing REMsleep behavior disorder (RBD). The patients where scanned with ^{18}F-Dopafor 20 minutes. Project2 involving PD patients with or without RBD scanned for 90 minutesusing ^{11}C-Mener. Project3 wanted to exam the effect of ketones in the brain. The patientswhere scanned for 120 minutes using ^{18}F-FDGfor the last 60 minutes. The data was collected during the period May 2014 to March 2019. To map the movement of the patients we analyze the data with a Motion QC program, which is a part of HRRT_users_software_1.2. To determine if the images should be motion corrected we calculate the RMS displacement and maximum displacement. If the results exceed the determined references, we will make an image based motion correction using the Motion Correct program from the HRRT_users_software_1.2. **Results:** Project 1 showed that none of the patients had moved so much that an image based motion correction was necessary. Project 2 showed the need for motion correction in close to 18 % of the scanned patients. In project 3 we saw an even higher range of movement during the scans. It showed that 41 % of the scans needed to be motion corrected. **Conclusion:** The longer the patients has to lie in the scanner the harder it gets to stay completely still. Therefore the use of image based motion correction is justified for the long scans. Because the image based motion correction is a further image processing and it puts the results further from the original raw data, we recommend making the scans as short as possible. **References:** None.

Aim/Introduction: PET/MR imaging provides a unique opportunity to acquire structural, metabolic and functional data simultaneously. The purpose of this study was to assess the predictive value of multiparametric PET/MR imaging data in head and neck cancer patients treated with radiotherapy. **Materials and Methods:** Twenty patients with histopathologically proven head and neck squamous cell carcinoma (HNSCC) treated with modern 3D based radiotherapy in our institutions were enrolled in this retrospective survey. FDG PET/MR imaging was performed before and after the therapy for all the subjects. Pretreatment tumor SUVmax, SUL_{peak}, total lesion glycolysis (TLG), and metabolic tumor volume (MTV) PET parameters and diffusion-weighted MR based ADC_{mean} parameters were measured. According to the result of post-therapy imaging 2 patient subgroups were created: 1.: patients achieving complete response (CR) and 2: subjects with post-treatment viable tumor tissue (Non-CR). Pretreatment imaging parameters were correlated with therapy response. Statistics included Spearman's correlation and Mann-Whitney U test using SPSS 25 software. **Results:** After completion of radiotherapy, imaging showed complete response for 8 patients while metabolically active tumor tissue was observed in 12 cases. We were unable to find statistically significant difference between the pretreatment SUV_{max} (p=0,135), SUL_{peak} (p=0,343), TLG (p=0,135) and ADC_{mean} (p=0,734) values of CR and Non-CR patient groups, although pre-therapy MTV parameter proved to be significantly higher in Non-CR group (p=0,007). Between the evaluated pretreatment PET and MR parameters, a weak correlation was only observed for PET SUVmax and MR ADC_{mean} values (r= -0,346 p= 0,135). **Conclusion:** According to our preliminary results pretreatment PET SUV_{max}, SUL_{peak}, TLG and MR ADC_{mean} parameters were unable to predict therapeutic response, while MTV seems to be more

accurate for this purpose. Further examination with involving more patients to the study could be essential to validate these preliminary results. **References:** Wang, K., Mullins, B. TEPS-81

Comparison And Evaluation Of The Effectiveness Between Respiratory Gating Method Applying The Flow Mode And Additional Gated Method In PET/CT Scanning

D. Jang, *Y. Park, G. Lee, H. Cho;*
Seoul national university bundang hospital, Bundang-Gu, Seongnam-Si, Gyeonggi-Do, KOREA, REPUBLIC OF.

Aim/Introduction: The present study aimed at assessing the effectiveness of the respiratory gating method used in the flow mode and additional localized respiratory-gated imaging, which differ from the step and go method. **Materials and Methods:** Respiratory gated-imaging was performed in the flow mode for twenty patients with lung cancer (10 patients with stable signals and 10 patients with unstable signals), who underwent PET/CT scanning of the torso using Biograph mCT Flow PET/CT (Siemens, Germany) at Bundang Seoul University Hospital between June 2018 and September 2018. Additional images of the lungs were obtained by using the respiratory gating method. SUVmax, SUVmean, and Tumor Volume (cm^3) of non-gating images, gating images, and additional lung gating images were found with Syngo,bia (Siemens, Germany). A paired t-test was performed with GraphPad Prism6, and changes in the width of the amplitude range were compared between the two types of gating images. **Results:** The following results were obtained for all patients when the respiratory gating method was applied: $SUV_{max} = 9.43 \pm 3.93$, $SUV_{mean} = 1.77 \pm 0.89$, and Tumor Volume $= 4.17 \pm 2.41$ for the non-gating images, $SUV_{max} = 10.08 \pm 4.07$, $SUV_{mean} = 1.75 \pm 0.81$, and Tumor Volume $= 3.56 \pm 2.11$ for the gating images, and $SUV_{max} = 10.86 \pm 4.36$, $SUV_{mean} = 1.77 \pm 0.85$, Tumor Volume $= 3.36 \pm 1.98$ for the additional lung gating images. No statistically significant difference in the values of SUV_{mean} was found between the non-gating and gating images, and between the gating and lung gating images ($P>0.05$). A significant difference in the values of SUV_{max} and Tumor Volume were found between the aforementioned groups ($P<0.05$). The width of the amplitude range was smaller for lung gating images than gating images for 12 out of 20 patients (3 patients with stable signals, 9 patients with unstable signals). **Conclusion:** In PET/CT scanning using the respiratory gating method in the flow mode, any lesion movements caused by respiration are adjusted. In addition, the width of the amplitude range decreased according to the stability of respiration to a more significant degree in the additional lung gating images than the gating images. We found that gating images provide information that is more useful for diagnosis than the one provided by non-gating images. For patients with irregular signals, it may be helpful to perform localized scanning additionally if time allows. **References:** None.

TEPS-82

Technical acquisition modality of cerebral PET/CT images in patients with memory disorders

L. Pavanello, *F. Sciume, M. Cucca, D. Grigolato, M. Zuffante, E. Biggi, M. Ferdeghini;*
Azienda Ospedaliera Universitaria Integrata di Verona, Verona, ITALY.

Aim/Introduction: This study wants to evaluate the importance of acquisition modality images in patients with memory disorders using a method with dynamic frames imaging. **Materials and Methods:** 26 adults patients (14 men, 12 women, range: 55-72 years) were studied between February 2018 to March 2019. All the patients were administered with the same 18F-amyloid tracer and PET/CT Philips Gemini TF Big Bore was used for acquisition images. Head scan was performed at 90 minutes post-injection of 300 MBq 18F-amyloid tracer. Patients have been positioned supine with the head and neck relaxed in the special support, the scanner laser aligneed to the orbital-meatal and median sagittal planes, arms along the body and support under the knees to maintain greater stability and comfort. Brainstem and cerebellum must be understood in the fiel of view. The CT parameters were: 120 KV, 70 mAs pitch 0.813, 16x1.5mm collimation, thickness 5, FOV 600, the acquisition field from vertex to the base of the skull, rotation time 0.5 sec. PET images were acquired with 4 dynamic bed position, each acquisition was of 5 min/bed, start delay from bed of 5 sec, FOV 256 mm. **Results:** 3/26 patients were necessary to interrupt the examination due to patients limited collaboration. 1/3 patients repeat all the images scan because he moves during the first frame and 2/3 patients were possible elaborate images by removing final frames in which the patients had moved. In all other cases it was possible to merge the 4 frames and obtain a single 20 minute image. **Conclusion:** Dynamic acquisition technique with 4 frames makes it possible to reduce repeating the exam because images elaboration allows to exclude the final frames in cases patient may have moved the head. **References:** None.

Caloric Restriction improves Established Proteinuria in Adriamycin-Induced Nephropathy:A N^{13}-ammonia PET study

J. W. A. Sijbesma[1], *A. van Waarde*[1], *A. Klooster*[2], *R. H. J. A. Slart*[1], *H. H. Boersma*[1], *R. A. J. O. Dierckx*[1], *H. van Goor*[3], *S. J. L. Bakker*[4];

[3]*Pathology and Medical Biology, Groningen, NETHERLANDS,*
[4]*Nephrology, Groningen, NETHERLANDS.*

Aim/Introduction: Reduction of proteinuria is an important strategy to prevent loss of kidney function. Preclinical studies suggest that caloric restriction (CR), induced at a young age, protects against age-related proteinuria. We hypothesized that CR in established proteinuria reduces urinary protein excretion (UPE). The current study investigated the effect of CR in established renal disease using N^{13}-ammonia PET for kidney perfusion assessment. **Materials and Methods:** Male Wistar rats (n= 56; age 12± 2 week) were intravenously injected with 2.1mg/kg Adriamycin (doxorubicin) as a model with induced renal dysfunction. At 6 weeks after injection, baseline UPE was measured. Mean arterial blood pressure was determined followed by a 10 minute positron emission tomography (PET) scan with N^{13}-ammonia (45.3± 5.6MBq). At 7 weeks after Adriamycin injection rats were randomly assigned to 4 groups: An ad libitum (AL) and a CR group (60% of ad libitum food intake) fed with a 12% protein diet (12%AL, 12%CR) and an ad libitum and a CR group fed with a 20% protein diet (20%AL, 20%CR). All groups were treated for 12 weeks. UPE was measured at week 9 and 12. The blood pressure measurement and PET scan were repeated at the end of the study. PET scan was used to determine the mean standard uptake value (SUVmean) of N^{13}-ammonia in the cortical and medullar region. **Results:** At baseline UPE was similar in all groups ($p>0.20$) with a median value of 495 and an interquartile range of 127mg/24h. After 12 weeks of diet, all animals exposed to CR had a 20.3% lower UPE ($p=0.003$) compared to ad libitum fed animals. At week 9 this effect was only seen in the 12%CR group. SUVmean was significantly higher in the 12%CR group compared to the 12%AL group for the cortical ($p<0.001$) and medullar region ($p<0.05$) at the end of the study. Compared to baseline SUVmean was significantly increased in the 12%CR group in both regions ($p=0.001$). The opposite effect was seen in the 12%AL group where SUVmean was decreased. ($p<0.05$). Blood pressure in animals exposed to caloric restriction was 21.2% lower ($p<0.0001$) compared to AL fed animals. **Conclusion:** CR lowers UPE and blood pressure in rats with established proteinuria. Increasing SUV in the 12%CR group indicates improved kidney function on PET imaging. CR was most effective if applied in combination with protein restriction. These results may guide future intervention studies in patients with proteinuric and obesity-related nephropathy. **References:** None.

Influence of intravenous diuretics on the detectability of local prostate cancer recurrence in ^{68}Ga-PSMA-11 PET/CT

L. Dijkstra, *I. Alberts, G. Prenosil, A. Rominger, A. Afshar-Oromieh;*
Nuclear Medicine Inselspital, Bern, SWITZERLAND.

Aim/Introduction: Generally, 68Ga-PSMA-PET/CT is performed at 1h post injection of radiotracer (p.i.). While numerous studies show that delayed imaging increases tumour detectability, increased bladder activity can make the detection of locally recurrent lesions more difficult. In this study, we investigate the effect of an examination protocol including oral hydration and diuretics, and determine the effect on tumour detection. **Materials and Methods:** This retrospective study evaluated 76 patients referred to our centre for 68Ga-PSMA-11 PET/CT. Our protocol was as follows: 30 min p.i. patients were given oral hydration with 1L of water, and at 1h p.i. 20mg of Furosemide was administered intravenously. Additional late imaging without further hydration or diuresis was performed at 2.5h p.i. Two physicians read the standard and late datasets in a blinded and un-blinded read to determine the detectability of locally recurrent lesions. **Results:** At standard imaging 40 lesions of locally recurrent PC were identified in 35 patients. At late imaging, 44 lesions were identified in 37 patients. In later imaging, the bladder activity (standardised uptake value) SUV was observed to increase. In four cases, the activity in the bladder at later imaging was seen to mask the PC lesions. Although these lesions also showed higher SUV at late imaging, the increase was seen to overlap with the bladder, explaining the reduced detectability. **Conclusion:** The addition of oral hydration and furosemide to our examination protocol resulted in increased detectability of PC lesions at standard imaging. In the late imaging, however the detectability decreases when no second injection of furosemide and water is given. Further studies are required to optimise the examination protocol of such patients. **References:** None.

Tracer Uptake Of Hepatocellular Carcinoma In Psma Pet Is Associated With Arterial Phase Hyperenhancement In Mri

A. Kanzog, *L. Stegger, M. Schaefers, B. Noto;*
Department of Nuclear Medicine, Münster, GERMANY.

Aim/Introduction: To investigate if tracer uptake of hepatocellular carincoma lesions in PSMA-PET is associated with arterial phase hyperenhancement in MRI. **Materials and Methods:** 11 patients with proven hepatocellular carcinoma which underwent 68Ga-PSMA-PET/MRI from 06/2018 to 11/2019 in preparation for selective internal radiation therapy were enrolled. 2 MBq Ga-68-PSMA-11per kg body weight were injected. PET images were acquired over 40 minutes in one bed position of the upper abdomen beginning with injection. MRI sequences were acquired concurrently including multiphase contrast enhanced MRI. All liver lesions discernible on MRI with a

LI-RADS score ≥ 4 were considered HCC lesions and noted. HCC lesions were categorized as showing tracer uptake in PSMA-PET if they visually showed a focal tracer uptake unequivocally above background. HCC lesions were categorized as showing arterial phase hyperenhancement in MRI if they showed increased intensitiy in arterial phase images compared to native images and were unequivocally more intense than surrounding liver parenchyma in arterial phase images. Statistical analyses were performed using IBM® SPSS®, Version 24. Fisher's exact test was used to assess association of tracer uptake of lesions in PET and arterial phase hyperenhancement in MRI. **Results:** 25 lesions with a LI-RADS score ≥ 4 were detected and considered to represent HCC lesions. Of those 19 showed tracer uptake in PSMA-PET of which all also presented with arterial phase hyperenhancement in MRI. 6 lesions showed no tracer uptake in PSMA-PET of which only one presented with arterial phase hyperenhancement in MRI. Fisher's exact test showed a strong association of tracer uptake in PSMA-PET and arterial phase hyperenhancement in MRI ($p < 0.001$). **Conclusion:** Tracer uptake of hepatocellular carincoma lesions in PSMA-PET is strongly associated with arterial phase hyperenhancement in MRI. **References:** None.

SUVmax in Organ Confined Prostate Cancer and Its Correlation with PSA level and Gleason Score. A Single Center Study

M. Khaskhali;
Sindh Institute of Urology and Transplantation, Karachi, PAKISTAN.

Aim/Introduction: The early management of Prostate Cancer is a challenging issue, for the appropriate tumor staging in newly diagnosed Prostate Cancer (PC). Prostate Specific Antigen and Gleason Score are considered to be major parameters for treatment planning. The novel radio tracer Ga-68 Prostate Specific Membrane Antigen (PSMA)-11 PET-CT shows increased metabolic activity in PC and provides reliable information about tumor grading. The increased metabolic activity of Ga-68 PSMA-11 is defined as Standardized Uptake Value (SUV)max. **Materials and Methods:** The retrospective analysis of 77 patients who were referred to department of Nuclear Medicine and Molecular Imaging for Ga-68 PSMA-11 PET-CT from September 2017 to February 2019. All of them had biopsy proven organ confined adenocarcinoma and their PSA level were obtained 4-5 weeks prior to Ga-68 PSMA PET-CT scan. **Results:** There were total 77 patients included in our study with mean age of 66.33 years having histologically proven Prostate cancer. The GS of all patients ranges from 6 to 10. The mean PSA for all patients was 37.24 ng/ml ranging from 1.2 to 239 ng/ml with a median value of 22 ng/ml. Mean SUVmax of all patients was 17.33±14.59 with a median of 14.03 ranging from 2.03 to 81.35. SUVmax in PC was higher in patients having PSA level more than 10 than those whose PSA level is <10. Correlation of SUVmax with PSA and GS showed significant correlation (rSpearman 0.306 & 0.367) having p-value 0.01. **Conclusion:** The SUVmax of organ confined tumor correlates well with PSA level and Gleason Score. The intensity of focal radiotracer activity clearly differentiates disease site from healthy part of organ and can be a reliable guide for needle biopsy. We also found that median SUVmax and median PSA values increase with increasing GS. So we recommend that PSMA PET-CT can be performed in cases of organ confined tumors with GS of 6 and PSA level of <10 also as they show significant radiotracer uptake in tumor. **References:** None.

The addition of late PSMA-ligand PET/CT imaging for the differentiation between benign and malignant PSMA uptake

L. Dijkstra*, I. Alberts, G. Prenosil, A. Rominger, A. Afshar-Oromieh;*
Nuclear Medicine Inselspital, Bern, SWITZERLAND.

Aim/Introduction: PSMA ligand PET/CT has commonly been performed at 1h post injection of radiotracer. However, additional late imaging has been shown to be a powerful method for the discrimination between lesions of prostate cancer (PC) and non-PC lesions, such as nerve ganglia. Nevertheless, there are no pre-existing studies which show the pattern of tracer uptake at late imaging, which this present study aims to address. **Materials and Methods:** 50 patients were retrospectively analysed who underwent standard (1.5h) and late (2.5h p.i.) ^{68}Ga-PSMA-11-PET/CT. Lesions with tracer uptake greater than background as well as PC-lesions were identified by two physicians in an unblinded consensus read of both sets of imaging. The localisation and standardised uptake values (SUV) for the lesions was noted. A thin-slice CT enabled the morphological characterisation of the lesions as ganglia, bone metastases, locally recurrent PC lesions or lymph node metastases. **Results:** We identified 82 PSMA-positive ganglia at standard imaging (1.5h p.i.) in 70% of our patients with an additional four ganglia being revealed at late imaging only (total 86). We identified 66 PC lesions in 44 patients (88%). Of these, we identified 45% (n=30) as lymph nodes. At late scanning, 73% of the LN exhibited an increase in SUVmax, whereas only 65% of the ganglia exhibited a decreasing or stable SUVmax. **Conclusion:** We noted that at late imaging, increasing tracer uptake provides additional diagnostic information aboutn the likelihood of malignancy. However, increasing SUVmax alone cannot reliably differentiate between LN and ganglia, since 35% of ganglia also exhibited increasing SUVmax. Reliance on these values alone therefore is a potential diagnostic pitfall, and we draw attention to our thin slice CT protocol which allowed for better morphological characterisation of ganglia. **References:** None.

Correlative assessment of lumbar intervertebral disc degeneration in alkaptonuria patients using quantitative analysis in 18F-NaF PET/CT and MRI grading systems

E. H. Alawadhi[1]*, A. Mistry*[2]*, S. Vinjamuri*[3]*, J. Gallagher*[1]*, R.*

Lakshminarayan[4], *J. Dillon*[1];
[1]*Institute of Ageing & Chronic Disease, University of Liverpool, Liverpool, UNITED KINGDOM,* [2]*Department of Radiology, Royal Liverpool and Broadgreen University Hospitals, Liverpool, UNITED KINGDOM,* [3]*Department of Nuclear Medicine Royal Liverpool University Hospital, Liverpool, UNITED KINGDOM,* [4]*Liverpool Clinical Laboratories, Royal Liverpool & Broadgreen University Hospitals Trust, Liverpool, UNITED KINGDOM.*

Aim/Introduction: Alkaptonuria (AKU) is a metabolic bone disease characterised by elevated homogentisic acid (HGA). Over time HGA deposits in connective tissue forming cartilage pigmentation leading to advanced premature arthritis. Quantitative and qualitative assessment from 18F-NaF-PET/CT and MRI can be used to evaluate lumbar intervertebral disc degeneration in AKU patients. The aim of this study was to evaluate the relationships between the 18F-fluoride uptake from PET/CT and morphological MRI data by measuring maximum standardised uptake value (SUV_{max}) and Pfirrmann grading systems at lumbar intervertebral discs and assess the effect of gender and age on these values. **Materials and Methods:** A total of 203 lumbar discovertebral units (DVUs) from 34 AKU patients (19 men,15 female) who underwent whole body 18F-NaF PET/CT and MRI were analysed. Mean age of subjects was 48.38 ± 10.04 years, with no age difference between genders. Subjects were separated into four groups stratified by decade of life. Image viewing and analysis software HOROS was used. The ROI were drawn over the lumbar DVUs on three sagittal CT slices covering the disc plus endplate of the two adjacent vertebrae, from segment T12/L1 to segment L5/S1, then correlated to PET images in order to measure the SUV_{max}. Lumbar disc degeneration was assessed from MRI using 8 level validated modified Pfirrmann grading system. The measured values were compared with each other. The effect of gender and age for SUV_{max} and Pfirrmann score was tested. **Results:** Lumbar disc spaces were more likely to be degenerative when SUVmax and Pfirrmann score for DVU were higher. There was a correlation between SUVmax and Pfirrmann scores at all lumbar DVU levels ($p < 0.05$) except at L2/L3. However several cases showed that despite an advanced grade 8 Pfirrman score there was decreased 18F-NaF uptake. Female subjects had lower SUV_{max} values and Pfirrmann scores than male subjects. Although SUV_{max} for all DVU showed no correlation with age ($p > 0.1$), there were significant correlations between Pfirrmann score and age ($p < 0.0001$). **Conclusion:** Lumbar intervertebral disc degeneration of patients with ochronotic arthropathy was associated with increased 18F-fluoride uptake on PET and high Pfirrmann score on MRI. Several advanced grade 8 Pfirrman score discs showed little corresponding SUV_{max} on PET/CT. These cases were more likely to have fusion at the interbody level with inactive calcification. This study demonstrates the correlation between functional PET and anatomical MRI findings until intervertebral disc fusion occurs in ochronotic patients. **References:** None.

TEPS-89

Relationship between standardised uptake values, Hounsfield Units and bone density value of vertebral body in the lumbar spine: a study in alkaptonuria subjects using 18 F-NaF PET/CT and DEXA scan

E. H. Alawadhi[1], *S. Vinjamuri*[2], *J. Gallagher*[1], *R. Lakshminarayan*[3], *J. Dillon*[1];
[1]*Institute of Ageing & Chronic Disease, University of Liverpool, Liverpool, UNITED KINGDOM,* [2]*Department of Nuclear Medicine Royal Liverpool University Hospital, Liverpool, UNITED KINGDOM,* [3]*Liverpool Clinical Laboratories, Royal Liverpool & Broadgreen University Hospitals Trust, Liverpool, UNITED KINGDOM.*

Aim/Introduction: Alkaptonuria (AKU) or black bone disease is a metabolic bone disease characterised by elevated homogentisic acid (HGA), which causes severe osteoarthropathy. An abnormal active bone lesion in the spine can be evaluated by 18F-NaF PET/CT. This study aimed to clarify the differences in 18F-NaF uptake and bone attenuation coefficients according to the bone densitometry reports at the lumbar spine levels (L1-L4) using semi-quantitative maximum standardised uptake values (SUVmax) and Hounsfield Units (HU) from PET/CT images. **Materials and Methods:** We analysed the data of 38 patients with alkaptonuria (mean age ± SD, 50.3 ± 10.9) who underwent 18FNaF PET/CT and DEXA scans. To evaluate the relationship between the distribution of sodium fluoride (18F-NaF) uptake and bone density values, SUVmax from PET, mean HU from CT and T-score from DEXA of lumbar vertebrae body were compared. In order to determine HU for each lumbar vertebra body (L1-L4), ROI was drawn covering the trabecular bone region in the sagittal slice section at three different anatomical locations. The exact ROI was copied to PET images to measure the SUVmax. The average HU and SUVmax for each lumbar level were generated. **Results:** According to the DEXA report, thirty-one patients (75.6%) of the 38 AKU patients had a normal bone mineral density at the average lumbar vertebral body (L1-L4), noting that mean SUVmax value measured from PET was 12.22 ± 38.9 and mean HU measured from CT was 159.1 ± 82.7. Five patients (12.2%) had osteopenia, with measured SUVmax of 11.54 ± 3.9 and mean HU of 99.6 ± 38.9. Only one patient (2.4%) had osteoporosis at lumbar spine with SUVmax 9.99 and mean HU 18.2. There was a moderate correlation between SUVmax and T-score at upper lumbar vertebral bodies (L1 and L2) $p < 0.05$, and no clear correlation at L3 and L4 ($p = 0.67$ and 0.63). A strong relationship was noted between HU and T-score at all lumbar vertebral bodies ($p < 0.001$). SUVmax at lumbar vertebral bodies proportionally increases at the higher values of vertebral HU. These observations were more significant in L1 and L2 and less so at L3 and L4. **Conclusion:** Lower bone mineral density at the lumbar spine was associated with decreased 18F-NaF uptake in PET imags and less bone attenuation coefficients in CT images. Radiographic quantitative methods from 18F-NaF PET/CT can highlight areas of higher bone metabolism and give structural information in AKU patients. **References:** None
